New Features for Release 11.1.1.6 lxiii

Part I Introduction

1 Developer's Quick Start Guide

1.1 WebCenter Portal Developer's FAQ 1-1
1.2 Installing Required Software 1-3
1.3 Preparing for Team Development 1-3
1.4 Creating a New Framework Application 1-3
1.5 Preparing for Iterative Development 1-4
1.5.1 What Is Iterative Development? 1-4
1.5.2 How Does Iterative Development Work? 1-4
1.5.3 Enabling Iterative Development 1-6
1.5.4 Turning Off Iterative Development 1-6
1.6 Creating Application Resource Connections 1-7
1.6.1 Where Are Connections Located? 1-7
1.6.2 How Do I Access the Connection Wizards? 1-7
1.6.3 Where Can I Learn More About Connections? 1-8
1.7 Planning the Portal Layout 1-8
1.8 Working with Skins 1-8
1.9 Preparing for Round-Trip Development 1-8
1.10 What Configuration Files Should I Know About? 1-9
1.10.1 The Framework Application Template Default web.xml File 1-9
1.10.2 The Framework Application Template Default faces-config.xml File 1-10
1.10.3 The Framework Application Template Default trinidad-config.xml File 1-11
1.10.4 The Framework Application Template Default adfc-config.xml File 1-12
1.11 Installing Database Schemas 1-12

2 Understanding Oracle WebCenter Portal

2.1 What Is Oracle WebCenter Portal? ... 2-1
2.2 Introducing the WebCenter Portal: Framework ... 2-2
2.3 What Are the Main WebCenter Portal: Framework Features? ... 2-2
2.3.1 Portlets and Pagelets for Accessing Remote Applications and Services ... 2-2
2.3.1.1 What Are Portlets? ... 2-3
2.3.1.2 What Are Pagelets? ... 2-3
2.3.1.3 What is the Difference Between Portlets and Task Flows? ... 2-3
2.3.2 Oracle WebCenter Portal's Composer Allows User Customization ... 2-4
2.3.3 Content Integration with Supported Content Repositories ... 2-4
2.3.4 Search Framework ... 2-5
2.3.5 Resource Catalogs Help Organize the Development Experience ... 2-5
2.3.6 Application Security ... 2-6
2.4 Introducing Oracle WebCenter Portal: Services ... 2-7
2.4.1 WebCenter Portal: Services and the REST APIs ... 2-9
2.5 Introducing Oracle Application Development Framework (Oracle ADF) ... 2-10
2.5.1 What Is Oracle ADF? ... 2-10
2.5.2 Why Is Oracle ADF Important for WebCenter Portal Developers? ... 2-10
2.5.3 What Does Oracle ADF Technology Include? ... 2-10
2.6 Introducing Oracle JDeveloper and the WebCenter Portal Extension ... 2-10
2.7 Understanding the Application Life Cycle ... 2-12
2.8 Design Questions to Consider Before You Start ... 2-12
2.8.1 User Considerations ... 2-12
2.8.2 Site Administrator Considerations ... 2-14
2.8.3 Developer Considerations ... 2-14
2.9 Overview of WebCenter Accessibility Features ... 2-16
2.9.1 Generating Accessible HTML ... 2-16
2.9.2 Accessibility Features at Runtime ... 2-17
2.9.3 Accessibility Considerations for Portlets ... 2-17

3 Preparing Your Development Environment

3.1 Installing Oracle JDeveloper ... 3-1
3.2 Installing WebCenter Portal's Extension for Oracle JDeveloper ... 3-1
3.3 Setting the User Home Directory Environment Variable ... 3-2
3.4 Working with the Integrated WebLogic Server ... 3-2
3.4.1 How to Start and Stop Integrated WLS ... 3-2
3.4.2 What You May Need to Know About Integrated WLS ... 3-3
3.4.3 The WebCenter Preconfigured Server Readme File ... 3-3
3.4.4 What You May Need to Know About Preconfigured Portlet Producers ... 3-4
3.4.4.1 OmniPortlet and Web Clipping ... 3-4
3.4.4.2 The WSRP Sample Portlet Producers and Portlets ... 3-5
3.4.4.3 The PDK-Java Sample Portlet Producer and Portlets ... 3-6
3.5 Installing Database Schemas ... 3-6
3.5.1 Installing Schemas With RCU ... 3-7
3.5.2 Installing WebCenter Portal's Schema with a SQL Script ... 3-7
3.6 Installing the Oracle WebCenter Adapter for SharePoint ... 3-7

4 Working Productively in Teams

4.1 Enabling Source Control on Framework Applications 4-1
4.1.1 Creating a Subversion Repository 4-2
4.1.2 Understanding Oracle Team Productivity Center 4-3
4.2 Understanding Framework Application Files Affected by Developers 4-4
4.2.1 Files Associated With Common Objects 4-4
4.2.2 Developer Actions Affecting Metadata Files 4-4
4.3 Implementing Common Requirements One Time 4-12
4.4 Portlet Producer Considerations 4-13
4.4.1 Portlet Producer Connections 4-13
4.4.2 Portlet Producer Name Clashes 4-13
4.4.3 Combining Portlets from Different Portlet Producers 4-13

5 Creating Framework and Portlet Producer Applications

5.1 What Are Application Templates? 5-1
5.2 Creating a Framework Application 5-2
5.2.1 How to Create a Framework Application 5-3
5.3 Adding Pages to a Portal 5-8
5.4 Understanding the PortalWebAssets Project 5-9
5.4.1 Introduction 5-9
5.4.2 Decoupling the Static Application Resources Project 5-9
5.4.3 Deployment Options 5-11
5.4.4 Using EL to Manage Static Resources 5-11
5.4.4.1 Defining a Base URL Preference 5-11
5.4.4.2 Mapping URLs Dynamically 5-11
5.5 Creating a Portlet Producer Application 5-12
5.5.1 How to Create a Portlet Application Using a Template 5-13
5.5.2 What Happens When You Use a Portlet Producer Application Template 5-13
5.6 How Is a Framework application Security Configured by Default? 5-14

6 Advanced Configuration Options

6.1 Manually Configuring a Framework Application With Technology Scopes 6-1
6.1.1 What are Technology Scopes? 6-1
6.1.2 Adding and Removing Technology Scopes 6-2
6.1.3 What Are the Default Technology Scopes for a Framework Application? 6-4
6.1.4 Which Technology Scopes Are WebCenter Portal: Framework Application-Specific? ... 6-5
6.1.5 Can I Create a WebCenter Portal: Framework Application by Adding the Oracle WebCenter Portal: Framework Technology Scope Later? 6-5
6.1.6 Migrating a WebCenter PS2 or Earlier Application to a WebCenter Portal: Framework Application 6-5
6.2 Extending Non-WebCenter Portal: Framework Applications to Include WebCenter Capabilities 6-5
6.3 Creating a Project by Importing a WAR File 6-6

7 Preparing Your Application for WebCenter Portal Services

7.1 Understanding WebCenter Portal Services Technologies 7-1
7.1.1 Understanding WebCenter Portal Horizontal Services 7-1
7.1.2 Understanding WebCenter Portal APIs 7-2
7.1.3 Using WebCenter Portal Data Controls 7-5
7.2 Preparing Your Framework Application to Consume Services 7-6
7.2.1 How to Prepare Your Application to Consume Services 7-6
7.2.1.1 Implementing Security for Services 7-7
7.2.1.2 Setting Up SSL-Protected Connections for Services 7-8
7.2.2 Setting Up a Database Connection 7-9
7.2.2.1 Associating Existing Database Connections 7-12
7.2.3 Setting Up an External Application Connection 7-12
7.3 Extending Your Framework Application with Custom Components 7-13
7.3.1 Introducing the Resource Action Handling Framework 7-13
7.3.2 Registering a Resource Viewer 7-14
7.3.3 Creating a Resource Authorizer Class 7-18
7.3.4 Specifying the View Handler and Navigation Behavior 7-19
7.4 Configuring General Settings for Your Services 7-21
7.4.1 Building a Preferences User Interface 7-23
7.4.2 Using General Settings to Specify the User's Locale 7-24

8 Introducing the AviTrust Portal Framework Sample Application

8.1 About the AviTrust Portal Framework Application for WebCenter 8-1
8.2 Downloading the AviTrust Portal Framework Application 8-2
8.3 Browsing Portal Framework Features at Runtime 8-2
8.3.1 Exploring the AviTrust Sample Portal Home Page 8-3
8.3.2 Navigating the Site Using Tabs 8-6
8.4 Accessing and Using the Resource Manager 8-11
8.5 In-Context Editing of Web Content at Runtime 8-15
8.6 Exposing Social Computing Services 8-19
8.6.1 Adding a Discussion Forum 8-20
8.7 WebCenter Framework Components in the AviTrust Portal Demo 8-21

Part II Setting Up Your Portal Structure

9 Understanding Framework Applications

9.1 What is a Framework Application? 9-1
9.2 What is Oracle WebCenter Portal: Framework? 9-3
9.2.1 How Do I Add Oracle WebCenter Portal: Framework to a Project? 9-3
9.2.2 What Features Does the Oracle WebCenter Portal: Framework Provide? 9-3
9.3 What is the Portal Life Cycle? 9-4
9.4 Creating a WebCenter Portal: Framework Application 9-4
9.5 Understanding the Features of a WebCenter Portal: Framework Application 9-5
9.5.1 Understanding Pages, Page Templates, and the Portal Page Hierarchy 9-5
9.5.2 Securing Your Portal Pages 9-9
9.5.3 Understanding the Navigation Model and the Navigation Registry 9-11

9.5.4 Understanding Resource Catalogs and the Catalog Registry 9-13
9.5.5 Other Design Time Folders 9-15
9.5.6 Tips for More Advanced Development Use Cases 9-15
9.6 Developing Your Portal's Look and Feel 9-16
9.7 Changing Default Portal Preferences 9-16
9.7.1 What Are the Default Portal Preferences? 9-16
9.7.2 How to Change the Default Preferences at Design Time 9-17
9.8 Using Iterative and Round-Trip Development Techniques 9-17
9.9 What is the Application Sources Folder? 9-18
9.10 Running and Testing a Portal 9-18
9.11 WebCenter Portals at Runtime 9-19
9.11.1 Preserving Runtime Customizations on the Integrated WebLogic Server 9-19
9.11.2 Runtime WebCenter Portal Administration Console 9-20
9.11.3 How Security Settings Affect the Runtime Portal? 9-21
9.11.4 Runtime Editing of Portal Resources 9-21
9.12 How are WebCenter Portal Files Organized? 9-22
9.12.1 Understanding the Organization of a WebCenter Portal: Framework Application . 9-23
9.12.1.1 How is a WebCenter Portal: Framework Application Organized? 9-23
9.12.1.2 Why Is a WebCenter Portal: Framework Application Organized the Way It Is? 9-24
9.12.2 Viewing Your Portal Project on the Filesystem 9-24
9.12.3 Viewing Your Portal Project in JDeveloper 9-25
9.13 Changing the Default Home Page and Login/Logout Target Pages 9-26
9.13.1 Understanding How the Home Page is Specified 9-26
9.13.2 How to Change the Default Home Page 9-27
9.13.3 How is the Default Index Page Specified? 9-28
9.13.4 Specifying the Target Page After a Login or Logout 9-29
9.14 Basic Portal Development Tasks 9-30

10 Understanding the WebCenter Portal Life Cycle

10.1 What is the WebCenter Portal Life Cycle? 10-1
10.2 What Are the Major Life Cycle Tasks? 10-3
10.2.1 One-Time Setup Tasks 10-4
10.2.2 Development Environment Tasks 10-4
10.2.3 Nightly Build Environment Tasks 10-5
10.2.4 Testing Environment Tasks 10-5
10.2.5 Stage Environment Tasks 10-5
10.2.6 Production Environment Tasks 10-5
10.3 Who Participates in the Portal Life Cycle? 10-6
10.4 Understanding the Build and Test Environments 10-6
10.5 Understanding the Staging and Production Environments 10-8
10.5.1 Provisioning the Staging Environment 10-9
10.5.2 Adding Content to the Staging Environment 10-9
10.5.3 Moving the Portal from Staging to Production 10-9
10.6 Tools for Managing the Life Cycle 10-10
10.7 Configuring a Nightly Build Script 10-10
10.8 Setting Up a Staging or Production Environment for the First Time 10-11

10.9 Moving a WebCenter Portal: Framework Application to an Existing Environment 10-11
10.10 Deploying to Managed Servers 10-12
10.11 Deploying and Configuring the Application on Targeted Servers 10-12
10.11.1 Introduction 10-12
10.11.2 Using the Deploy and Configure Script 10-12
10.11.3 Managing Post-Deployment Changes 10-15
10.12 Building and Deploying Personalization for WebCenter Portal Files 10-15
10.12.1 Building the WCPS MAR File 10-15
10.12.2 Deploying WCPS Files to a Server 10-17
10.12.3 Deploying WCPS Files to an Archive File 10-17
10.12.4 Importing and Exporting MAR Files 10-18
10.13 Using the Propagation Tool to Propagate From Staging to Production 10-18
10.13.1 Introduction to the Propagation Tool 10-19
10.13.2 Configuring the Propagation Tool 10-20
10.13.2.1 Configuring the URL Connection With Oracle Enterprise Manager Fusion Middleware Control Console 10-20
10.13.2.2 Configuring the URL Connection with WLST 10-21
10.13.3 Propagating Portal Metadata 10-22
10.13.4 Propagating WCPS Files 10-22
10.14 Propagating Content From Oracle WebCenter Content 10-23
10.15 Managing Security Through the Life Cycle 10-23
10.15.1 Migrating Security Policies for First-Time Deployment 10-23
10.15.2 Migrating Security Policies On Redeployment 10-24
10.15.3 Migrating Credentials for First-Time Deployment 10-24
10.15.4 Migrating Credentials On Redeployment 10-24
10.16 Migrating Portlet Preferences 10-25
10.17 Rolling Back Production Site Changes 10-25

11 Building a Navigation Model for Your Portal

11.1 Introduction to Navigation Models 11-1
11.2 Creating a Navigation Model 11-2
11.3 Adding Resources to a Navigation Model 11-4
11.3.1 How to Drag and Drop a Resource onto a Navigation Model 11-5
11.3.2 How to Add a Content Item to a Navigation Model 11-5
11.3.3 How to Add Content Based on the Results of a Query to a Navigation Model 11-7
11.3.4 How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model 11-9
11.3.5 How to Add a Page Hierarchy to a Navigation Model 11-13
11.3.6 How to Embed Another Navigation Model Within a Navigation Model 11-15
11.3.7 How to Extend Navigation Model Data 11-16
11.3.7.1 How to Add a Link to a Custom Resource 11-17
11.3.7.2 How to Add a Component to a Navigation Model 11-18
11.3.7.3 How to Add a Custom Folder to a Navigation Model 11-20
11.3.7.4 How to Add a Custom Content Provider to a Navigation Model 11-21
11.3.8 How to Organize Resources in a Navigation Model 11-23
11.3.9 How to Set Display Options for a Resource 11-23
11.4 Selecting the Default Navigation Model 11-25

11.5 Editing the Navigation Renderer 11-26
11.6 Setting the REDIRECT_OPTIONS Context Parameter 11-27
11.7 Enabling Runtime Administration of Navigation Models 11-27
11.7.1 How to Edit the Navigation Registry File 11-28
11.7.2 How to Enable Further Development of Deployed Navigation Models 11-29
11.7.2.1 Importing a Navigation Model 11-29
11.7.2.2 Exporting a Navigation Model 11-29
11.8 Working with WebCenter Portal: Spaces Navigation Models 11-29

12 Designing the Look and Feel of Your Portal

12.1 Introduction to Page Templates and Styles 12-1
12.1.1 Page Templates 12-2
12.1.2 Page Styles 12-4
12.1.3 Mashup Styles 12-6
12.1.4 Content Presenter Display Templates 12-7
12.2 Working with Page Templates 12-7
12.2.1 Introduction to the WebCenter Portal Application Seeded Page Templates 12-8
12.2.2 How to Create a Page Template 12-9
12.2.3 What You Should Know About Creating Page Templates for WebCenter Portal Applications 12-14
12.2.4 Enabling Runtime Switching of Page Templates 12-15
12.2.5 How to Edit a Page Template 12-17
12.2.6 How to Delete a Page Template 12-17
12.2.7 How to Enable Runtime Administration of a Page Template 12-17
12.2.8 How to Enable Further Development of Deployed Page Templates 12-18
12.2.8.1 Importing a Page Template 12-18
12.2.8.2 Exporting a Page Template 12-18
12.2.9 How to Create and Manage WebCenter Portal: Spaces Page Templates 12-19
12.3 Working with Page Styles 12-19
12.3.1 How to Create a Page Style 12-19
12.3.2 How to Enable Runtime Administration of a Page Style 12-22
12.3.3 How to Enable Further Development of Deployed Page Styles 12-23
12.3.3.1 Importing a Page Style 12-23
12.3.3.2 Exporting a Page Style 12-24
12.3.4 How to Create and Manage Page Styles for Spaces 12-24
12.4 Working with Mashup Styles 12-25
12.4.1 How to Create a Mashup Style 12-26
12.4.2 How to Enable Runtime Administration of Mashup Styles 12-28
12.4.3 How to Enable Further Development of Mashup Styles in a Deployed Application 12-29
12.4.3.1 Importing Mashup Styles 12-29
12.4.3.2 Exporting Mashup Styles 12-30
12.4.4 How to Create and Manage Mashup Styles for Spaces 12-30

13 Adding Resources to Your Portal

13.1 Adding Pages to Your Portal 13-1

13.2 Adding Service Task Flows to Your Portal 13-2
13.3 Adding Custom Task Flows to Your Portal 13-3
13.4 Adding Content from Content Server to Your Portal 13-3
13.5 Adding Portlets to Your Portal 13-4
13.6 Adding Pagelets to Your Portal 13-4
13.7 Adding External Applications to Your Portal 13-5
13.8 Adding Data Controls to Your Portal 13-5

14 Visualizing Your Portal Navigation

14.1 Introduction to Navigation Visualization 14-1
14.2 Adding Built-in Navigation Task Flows to a Page Template 14-2
14.2.1 How to Add a Navigation Task Flow to a Page Template 14-3
14.2.2 Navigation Task Flow Parameters 14-4
14.2.3 What You May Need to Know About Navigation Task Flow Style Classes 14-9
14.3 Programmatically Adding Navigation to a Page Template 14-10
14.3.1 Using the Navigation Expression Language APIs 14-10
14.3.1.1 Introduction to the Navigation Context 14-11
14.3.1.2 Introduction to the Navigation Runtime Model 14-12
14.3.1.3 Introduction to the Navigation Resource 14-14
14.3.1.4 How to Render the Navigation Model as a List of Links 14-16
14.3.1.5 How to Render the Navigation Model as a Tree 14-17
14.3.1.6 How to Render the Navigation Model as a Three-Level Menu 14-17
14.3.1.7 How to Render the Navigation Model as Breadcrumbs 14-18
14.3.1.8 How to Render Master-Detail Navigation 14-19
14.3.2 Using the Navigation REST APIs 14-21
14.4 Using Portal Navigation to Create a Sitemap 14-22

15 Creating and Managing Skins

15.1 Overview of Skins 15-1
15.2 Creating a Skin in JDeveloper 15-2
15.2.1 What You Should Know About Skin Creation 15-2
15.2.2 How to Create a CSS File 15-3
15.2.3 How to Define Skin Selectors 15-4
15.3 Editing portal-skin.css 15-4
15.3.1 What You Should Know About portal-skin.css 15-4
15.3.2 How to Edit portal-skin.css 15-5
15.4 Enabling Runtime Administration of Skins 15-6
15.4.1 What You Should Know About Enabling Runtime Administration of Skins 15-6
15.4.2 How to Enable Runtime Administration of a Skin 15-8
15.4.3 How to Enable Further Development of Deployed Skins 15-8
15.4.3.1 Importing a Skin 15-9
15.4.3.2 Exporting a Skin 15-10
15.4.4 Creating a Skin in JDeveloper and Making it Available at Runtime 15-10
15.4.5 How to Create and Manage Skins at Runtime 15-11
15.5 Applying Skins to WebCenter Portal: Framework Applications 15-11
15.5.1 Applying a Skin at Design Time 15-11
15.5.2 Applying a Skin at Runtime 15-12

15.6 How to Create and Manage Spaces Skins 15-12
15.7 Deploying a Skin as a Separate Shared Library 15-13
15.7.1 About Skin Sharing 15-13
15.7.2 How to Deploy a Skin as a Separate Shared Library 15-14
15.8 Conditionally Changing Skins for Users 15-15
15.9 Troubleshooting Problems with Skins 15-16
15.10 Files Relates to Skins 15-17
15.10.1 adf-config.xml 15-17
15.10.2 trinidad-config.xml 15-18
15.10.3 trinidad-skins.xml 15-18

16 Creating and Managing Resource Catalogs

16.1 Overview of Resource Catalog 16-1
16.2 Creating a Custom Resource Catalog 16-4
16.2.1 How to Create a Custom Resource Catalog 16-4
16.2.2 How to Define Connections to Resources 16-6
16.2.3 How to Manage Content in the Resource Catalog 16-6
16.2.3.1 Adding a Folder 16-8
16.2.3.2 Adding a Link 16-8
16.2.3.3 Adding a Resource Catalog 16-11
16.2.3.4 Adding a Component 16-11
16.2.3.5 Adding a Custom Folder 16-13
16.2.3.6 Adding a Custom Content Provider 16-13
16.2.3.7 Dragging and Dropping a Resource into the Catalog 16-14
16.2.3.8 Editing a Resource 16-15
16.2.3.9 Deleting a Resource 16-15
16.2.3.10 Rearranging Resources in the Catalog 16-15
16.2.4 How to Expose Data Controls Created at Design Time 16-16
16.2.5 How to Expose Data Controls Created at Runtime 16-18
16.2.6 How to Control Visibility of Portlets in the Resource Catalog 16-18
16.2.7 How to Configure the Default Resource Catalog for an Application or Page 16-20
16.2.8 What You May Need to Know When Defining a Resource Catalog 16-20
16.2.9 How to Define Task Flow Parameters and Attributes of the Enclosing Show Detail Frames for Task Flows 16-21
16.3 Managing a Resource Catalog and Enabling Runtime Administration 16-22
16.3.1 Managing Resource Manager Entries 16-22
16.3.2 Enabling Further Development of Deployed Resource Catalogs 16-22
16.3.2.1 Exporting a Resource Catalog 16-23
16.3.2.2 Importing a Resource Catalog 16-23
16.3.3 Working with Spaces Resource Catalogs 16-24
16.4 Filtering Items in the Resource Catalog 16-24
16.4.1 Resource-Level Filtering 16-24
16.4.2 Catalog-Level Filtering 16-24
16.5 Configuring Multiple Resource Catalogs 16-26
16.5.1 How to Configure Multiple Resource Catalogs 16-26
16.5.2 What Happens at Runtime 16-28
16.6 Troubleshooting Problems with the Resource Catalog 16-29

17 Adding and Using the Resource Manager

17.1 Introduction to Runtime Resource Management 17-1
17.2 Working with Portal Resources in JDeveloper 17-3
17.2.1 How to Add a Resource to the Resource Manager 17-3
17.2.2 What You May Need to Know About the Content Directory 17-5
17.2.3 How to Update Portal Resource Properties 17-5
17.2.4 How to Remove a Resource from the Resource Manager 17-6
17.3 Enabling Runtime Administration of Your Portal 17-6
17.3.1 How to Add the Resource Manager Task Flow 17-6
17.3.2 How to Use the Resource Manager at Runtime 17-7
17.3.2.1 Accessing the Resource Manager 17-8
17.3.2.2 Creating a Resource 17-8
17.3.2.3 Uploading and Downloading a Resource 17-10
17.3.2.4 Editing a Resource 17-10
17.3.2.5 Copying a Resource 17-10
17.3.2.6 Setting Security for a Resource 17-11
17.3.2.7 Deleting a Resource 17-11
17.3.2.8 Showing or Hiding a Resource 17-11
17.3.2.9 Editing the Source Code of a Resource 17-12
17.3.2.10 Setting Properties on a Resource 17-13
17.3.2.11 Previewing a Resource 17-13
17.4 Enabling Round-Trip Development of Resources 17-13
17.4.1 How to Download a Resource Using the Resource Manager 17-16
17.4.2 How to Import a Portal Resource into JDeveloper 17-16
17.4.3 How to Export a Portal Resource from JDeveloper 17-17
17.4.4 How to Upload a Resource Using the Resource Manager 17-19

Part III Customizing Your Application and Extending Customization Options

18 Introduction to Composer

18.1 Application and User Customizations 18-2
18.2 View and Edit Modes of a Page 18-2
18.3 Customizing Capabilities in Page View Mode 18-3
18.3.1 Rearrange Components 18-3
18.3.2 Change the Layout 18-4
18.3.3 Expand and Collapse Components 18-5
18.4 Editing Capabilities in Design View in Page Edit Mode 18-6
18.4.1 Add Content 18-8
18.4.1.1 Add a Tab Set or a Tab to a Box Component 18-12
18.4.1.2 Add Box Components Adjacent to Existing Ones 18-13
18.4.1.2.1 Add Box Above 18-13
18.4.1.2.2 Add Box Below 18-14
18.4.1.2.3 Add Box Left 18-15
18.4.1.2.4 Add Box Right 18-15
18.4.2 Rearrange Page Content 18-16
18.4.3 Edit Component Properties and Parameters 18-17

18.4.4 Reset and Override Component Properties in the Current Layer 18-20
18.4.5 Edit Resource Strings 18-21
18.4.6 Show or Hide Components 18-27
18.4.7 Delete Components 18-28
18.4.8 Change the Layout 18-28
18.4.9 Edit Page Properties 18-29
18.4.10 Wire Components to Page Parameters 18-30
18.4.11 Reset Page 18-30
18.4.12 Reset Application Customizations on Detecting Errors 18-32
18.4.13 Create Labels On Saving Application Customizations 18-32
18.4.14 Manage Application Customizations 18-33
18.5 Editing Capabilities in Source View in Page Edit Mode 18-37
18.5.1 Rearrange Page Content Using Cut and Paste Options 18-40
18.5.2 Edit Content Inside a Task Flow 18-41
18.5.2.1 Reset Task Flow 18-43
18.5.3 Edit Content Inside a Declarative Component 18-44
18.5.4 Show or Hide Components 18-45
18.6 Composer Components 18-46
18.6.1 Page Customizable 18-47
18.6.2 Change Mode Link and Change Mode Button 18-48
18.6.3 Panel Customizable 18-48
18.6.4 Show Detail Frame 18-49
18.6.5 Layout Customizable 18-49
18.7 Security and Composer 18-50
18.7.1 Page and Task Flow Security 18-51
18.7.1.1 Task Flow Security 18-53
18.7.2 MDS Customization Restrictions 18-54
18.7.3 Component Action-Level Security 18-54

19 Enabling Runtime Creation and Management of Pages

19.1 Introduction to Page Creation and Management 19-1
19.2 Creating Pages and Task Flows 19-2
19.2.1 How to Create Pages 19-3
19.2.1.1 How to Add the Page - Create New Task Flow 19-4
19.2.1.2 Setting Security for the Page Service 19-4
19.2.1.3 How to Create Pages at Runtime 19-6
19.2.1.4 Structure of Pages Created at Runtime 19-6
19.2.1.5 How to Access Pages Created at Runtime 19-8
19.3 Defining Values for the Page - Create New Task Flow Parameters 19-8
19.3.1 How to Access Page - Create New Task Flow Parameters 19-8
19.3.2 Setting Scope in a Page - Create New Task Flow 19-10
19.3.3 Setting an Outcome Parameter 19-11
19.3.4 Specifying Styles 19-12
19.3.4.1 Out-of-the-Box Styles 19-12
19.3.4.2 Custom Styles 19-14
19.3.5 Specify an ADF Template 19-15
19.3.6 Showing a Command Link 19-15

19.3.7 Displaying an Image 19-16
19.3.8 Customizing the Label 19-16
19.4 How to Create Task Flow View Pages 19-17
19.5 Managing Pages 19-18
19.5.1 Using the Page Service Data Control to Manage Pages 19-18
19.5.2 Using the Page Service APIs to Manage Pages and Task Flows 19-18
19.6 Introduction to Custom Styles and Templates 19-19
19.6.1 How to Create Templates for Pages Created at Runtime 19-19
19.6.1.1 How to Create a Page or Page Fragment Style 19-19
19.6.1.2 How to Edit Create Page Dialog Styles 19-24
19.6.2 Using ADF Templates 19-25
19.6.2.1 How to Specify the ADF Template Name Using the Task Flow Parameter 19-25
19.6.2.2 How to Specify the ADF Template Name Using API Parameters 19-26
19.6.3 Creating Styles for the Create Page Dialog 19-26
19.6.3.1 How to Create a Style for the Create Page Dialog 19-26
19.6.3.2 How to Reference a New Style from the Page - Create New Task Flow 19-27
19.7 Customizing Page Service Views 19-28
19.7.1 Rendering Pages with ADF Faces Components 19-29
19.7.1.1 Rendering Pages as Tabs Using ADF Faces Components 19-29
19.7.1.1.1 Rendering Pages as Tabs Using af:navigationPane 19-29
19.7.1.1.2 Rendering Pages as Tabs Using af:panelTabbed 19-29
19.7.1.2 Rendering Pages as Links Using ADF Faces Components 19-30
19.7.1.2.1 Rendering Pages as Links Using af:commandLink 19-30
19.7.1.2.2 Rendering Pages as Links Using af:goLink 19-30
19.7.1.3 Rendering Pages as Image Links Using ADF Faces Components 19-31
19.7.2 Managing User Security on Pages and Task Flows 19-32
19.8 Advanced Information for the Page Service 19-32
19.8.1 Using the Page Service Java APIs 19-32
19.8.1.1 Configuration Settings Required for Using Page Service APIs 19-33
19.8.1.2 Introduction to the Page Service APIs 19-33
19.8.1.3 How to Set up Your Application to Use the Page Service APIs 19-35
19.8.1.4 Example: How to Create a Page 19-37
19.8.2 Using the Page Service Data Control 19-38
19.8.2.1 How to Add the Page Service Data Control 19-39
19.8.2.2 How to View, Edit, and Delete Pages at Runtime 19-42
19.9 Page Service Samples 19-42

20 Enabling Runtime Editing of Pages Using Composer

20.1 Designing Editable Pages Using Composer Components 20-1
20.1.1 How to Create a Customizable Page 20-2
20.1.2 How to Enable Runtime Customization Using a Page Customizable 20-3
20.1.3 How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button 20-4
20.1.4 How to Define Editable Areas of a Page Using Panel Customizable Components 20-6
20.1.5 How to Enable Layout Customization for a Page Using a Layout Customizable 20-7
20.1.6 How to Enable Component Customization Using Show Detail Frame Components 20-9

20.1.7 How to Create a Page Template for Creating Customizable Pages 20-10
20.1.8 How to Enable Customization in a Populated Page 20-11
20.1.9 What Happens When You Add Composer Components 20-12
20.1.10 What Happens at Runtime 20-13
20.1.11 What You May Need to Know When Designing Editable Pages 20-13
20.2 Designing Editable Pages Using Composer Components: Example 20-14
20.3 Populating Pages with Content 20-17
20.3.1 What You May Need to Know When Adding Content to the Page 20-18
20.3.1.1 Considerations for Adding Task Flows 20-18
20.4 Troubleshooting Composer Problems 20-18

21 Extending Runtime Editing Capabilities Using Composer

21.1 Overview of Extensibility Options 21-1
21.1.1 Composer Add-Ons 21-2
21.1.2 Composer Custom Property Panels 21-2
21.1.3 Composer Events Handlers 21-2
21.1.4 Drop Handlers 21-3
21.1.5 Component Property Filters 21-3
21.1.6 Customization Manager 21-3
21.1.7 Composer Toolbar Customization 21-3
21.1.8 Configuration Files 21-4
21.2 Creating Composer Add-Ons 21-4
21.2.1 How to Create and Register Add-Ons 21-5
21.2.1.1 Creating an Add-On Task Flow 21-5
21.2.1.2 Registering Add-Ons with Composer 21-7
21.2.1.3 Registering Add-Ons in adf-config.xml 21-8
21.2.2 What Happens at Runtime 21-9
21.2.3 How to Exclude Composer Default Add-Ons 21-9
21.2.4 How to Display the Customization Manager Add-On 21-10
21.2.5 How to Selectively Display Add-Ons 21-10
21.3 Creating Custom Property Panels 21-11
21.3.1 How to Create and Register Custom Property Panels 21-11
21.3.1.1 Creating a Custom Property Panel 21-12
21.3.1.2 Registering a Custom Property Panel for a Component 21-12
21.3.1.3 Registering a Custom Property Panel for a Task Flow 21-13
21.3.2 What Happens at Runtime 21-15
21.3.3 How to Override Default Property Panels 21-15
21.3.4 How to Exclude Default Property Panels 21-16
21.3.5 How to Selectively Render Property Panels 21-16
21.3.6 How to Display Properties and Parameters in a Custom Property Panel 21-16
21.4 Extending the Expression Builder 21-20
21.4.1 How to Extend the Expression Builder 21-21
21.4.2 How to Protect Expression Language 21-22
21.4.3 What Happens at Runtime 21-22
21.5 Configuring Custom LOVs or Pickers for Task Flow Parameters 21-23
21.5.1 How to Configure an LOV 21-28
21.5.1.1 Configuring a Static LOV 21-28

21.5.1.2 Configuring a Dynamic LOV 21-29
21.5.1.3 Configuring a Picker 21-30
21.5.1.3.1 Creating the Picker Task Flow 21-30
21.5.1.3.2 Registering the Picker for a Task Flow Parameter 21-34
21.5.1.4 Configuring an LOV from a Global List 21-35
21.5.2 What Happens at Runtime 21-36
21.6 Configuring Event Handlers for Composer UI Events 21-38
21.6.1 How to Create and Register Handlers for Composer UI Events 21-38
21.6.1.1 UI Events that Support Event Handler Registration 21-39
21.6.1.2 Creating a Save Event Handler: Example 21-40
21.6.1.3 Registering an Event Handler with Composer 21-41
21.6.2 What Happens When You Create and Register Event Handlers 21-41
21.6.3 Performing Additional Composer Event Handler Configurations 21-41
21.7 Configuring Drop Handlers in the Resource Catalog 21-43
21.7.1 How to Create and Register Java Drop Handlers 21-43
21.7.1.1 Creating a Drop Handler 21-43
21.7.1.2 Registering a Drop Handler with Composer 21-47
21.7.1.3 Adding an XML Component to the Resource Catalog 21-47
21.7.2 What Happens at Runtime 21-48
21.8 Defining Property Filters 21-49
21.8.1 How to Define Property Filters 21-50
21.8.2 What Happens at Runtime 21-50
21.8.3 How to Remove Property Filters 21-51
21.9 Enabling Parameter Support on the Customization Manager Task Flow 21-51
21.9.1 How to Set the Customization Manager Task Flow Parameters 21-53
21.9.2 What Happens When You Enable Parameter Support 21-54
21.10 Customizing the Composer Toolbar 21-54
21.10.1 How to Rearrange or Hide Toolbar Elements 21-56
21.10.2 What Happens at Runtime 21-56
21.10.3 How to Add New Sections to the Toolbar 21-57
21.10.4 How to Override a Toolbar Section to Display Custom Content 21-58
21.11 Enabling Direct Select in Design View 21-58
21.11.1 How to Enable and Configure Direct Select 21-59
21.11.2 What Happens at Runtime 21-61
21.12 Troubleshooting Problems with Composer Extensibility Features 21-62

22 Performing Advanced Composer Configurations

22.1 Enabling Custom Actions on a Show Detail Frame Component by Using Facets 22-1
22.2 Enabling Custom Actions on a Show Detail Frame Component By Using Facets: Example . 22-2
22.2.1 How to Create an ADF Task Flow 22-2
22.2.2 How to Include an Additional Actions Facet 22-4
22.2.3 How to Create a Redirection Page 22-4
22.2.4 How to Create Navigation Rules Between Pages 22-5
22.2.5 What Happens at Runtime 22-6
22.3 Enabling Custom Actions on a Task Flow 22-7
22.3.1 How to Enable Custom Actions Directly on a Task Flow 22-7

22.3.2 How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow ... 22-9
22.3.2.1 Defining Custom Actions at the Instance Level ... 22-9
22.3.2.2 Defining Custom Actions at the Global Level ... 22-10
22.3.2.3 Configuring Custom Actions that Display Task Flow Views in a Separate Browser Window ... 22-12
22.3.3 What Happens at Runtime ... 22-14
22.3.4 How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example ... 22-14
22.4 Enabling Custom Actions that Display on Task Flows in the Component Navigator ... 22-16
22.4.1 How to Configure Custom Actions in the Component Navigator ... 22-17
22.4.1.1 Defining the Logic for the Custom Action ... 22-17
22.4.1.2 Creating a JSPX Page Containing the Custom Action ... 22-18
22.4.1.3 Calling the JSPX Page from the Application Page Containing the Task Flow ... 22-19
22.4.2 What Happens at Runtime ... 22-20
22.5 Configuring a Keyboard Shortcut to Access Composer ... 22-21
22.5.1 How to Enable Linkless Entry Into Edit Mode ... 22-21
22.5.2 How to Configure an Event Handler for the Shortcut Key ... 22-22
22.5.3 What Happens at Runtime ... 22-22
22.6 Creating Event-Enabled Task Flows ... 22-22
22.7 Configuring an Application Page to Display in Source View by Default ... 22-22
22.7.1 How to Configure an Application Page to Display in Source View by Default ... 22-23
22.7.2 What Happens at Runtime ... 22-23
22.8 Disabling the Source View Menu for an Application ... 22-23
22.8.1 How to Disable the Source View Menu ... 22-23
22.8.2 What Happens at Runtime ... 22-24
22.9 Disabling Task Flow Zoom Capability ... 22-24
22.10 Applying Styles to Components ... 22-25
22.11 Configuring the Persistence Change Manager ... 22-27
22.11.1 Overview of the Default Change Manager Configuration ... 22-27
22.11.2 How to Configure ComposerChangeManager in Existing 11.1.1.1 Applications ... 22-29
22.11.2.1 Updating CHANGE_PERSISTENCE Context Parameter in the web.xml File ... 22-29
22.11.2.2 Adding Relevant Entries to the adf-config.xml File ... 22-29
22.12 Configuring Runtime Resource String Editing ... 22-30
22.12.1 Overview of the Resource String Editor ... 22-31
22.12.2 How to Enable the Resource String Editor in Your Application ... 22-32
22.12.3 How to Configure the Override Bundle ... 22-32
22.12.4 What Happens at Runtime ... 22-34
22.13 Troubleshooting Problems with Advanced Composer Configurations ... 22-34

23 Performing Composer-Specific MDS Configurations

23.1 Introduction to MDS ... 23-1
23.2 Using Composer Sandbox ... 23-2
23.2.1 How to Enable Composer Sandbox Creation ... 23-3
23.2.1.1 Updating Your Application's adf-config.xml File ... 23-3
23.2.1.2 Updating Your Application's web.xml File ... 23-4
23.2.1.3 Selecting a Database Store for Your Application ... 23-5
23.2.1.4 Enabling a Full Page Refresh at Runtime ... 23-5

23.2.2 What Happens at Runtime 23-5
23.2.3 How to Disable Sandbox for an Application 23-7
23.2.4 How to Destroy Stale Sandboxes 23-7
23.2.5 How to Enable Application Sandbox Creation 23-8
23.2.6 What Happens When You Enable Application Sandbox Creation 23-8
23.3 Adding Customization Layers to View and Edit Modes: Example 23-8
23.3.1 How to Add Composer to a JSF Page 23-9
23.3.2 How to Create a Custom SiteCC Tip Layer 23-10
23.3.3 How to Create a Custom UserCC Tip Layer 23-11
23.3.4 How to Implement the ComposerSessionOptionsFactory Class 23-13
23.3.5 How to Register the Implementation with Composer 23-14
23.3.6 How to Configure WebCenterComposerFilter 23-14
23.3.7 How to Redirect the Servlet to Enable Switch Between MDS Customization Layers 23-15
23.3.7.1 How to Create the AppNavigationUtils Class 23-16
23.3.7.2 How to Create AppCloseHandler 23-16
23.3.7.3 How to Register the AppCloseHandler 23-17
23.3.7.4 How to Create AppModeBean 23-17
23.3.8 What Happens at Runtime 23-18
23.4 Troubleshooting MDS-Related Problems with Composer 23-18

24 Modifying Default Security Behavior of Composer Components

24.1 Applying Component-Level Restrictions by Defining Customization Policies 24-1
24.1.1 How to Define Type-Level Customization Policies 24-2
24.1.2 How to Define Instance-Level Customization Policies 24-3
24.2 Applying a Component Instance-Level Customization Restriction By Using Security Roles: Example 24-4
24.2.1 How to Configure ADF Security 24-5
24.2.2 How to Define Roles and Grant Privileges in the jazn-data.xml File 24-5
24.2.3 How to Customize the SessionOptions Object to Include Customization Policy 24-8
24.2.4 How to Register the Implementation with Composer 24-10
24.2.5 How to Configure WebCenterComposerFilter 24-10
24.2.6 How to Apply an Instance-Level Customization Restriction 24-10
24.2.7 What Happens at Runtime 24-11
24.3 Applying Tag-Level Security Using the customizationAllowed Attribute 24-13
24.3.1 How to Enable Application Customization on an Image Component 24-14
24.3.2 How to Restrict Customization on an Image Component 24-14
24.4 Applying Attribute-Level Security 24-14
24.4.1 How to Define Change Persistence at the Component Level 24-15
24.4.2 What Happens at Runtime 24-15
24.5 Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions 24-16
24.5.1 How to Add an enableSecurity Section to adf-config.xml 24-16
24.5.2 Defining Security at the Actions Category Level 24-17
24.5.3 Defining Security at the Actions Level 24-19
24.6 Implementing Task Flow Security 24-21
24.6.1 Granting Permissions on Task Flows 24-21

24.6.2 Enabling Task Flow Permission Check 24-23
24.7 Overriding Composer's Default Security Policies 24-23
24.7.1 How to Create a Custom Security Policy 24-24
24.7.2 How to Register a Custom Policy with Composer 24-25
24.7.3 What Happens at Runtime 24-25
24.8 Troubleshooting Problems with Composer Components Security 24-25

25 Customizing Task Flows

25.1 Preparing for Task Flow Customization 25-2
25.1.1 WebCenter Portal: Spaces: Create a New Task Flow Customization Application ... 25-2
25.1.2 WebCenter Portal: Framework Application: Enable Customization 25-2
25.2 Configuring the JDeveloper Customization Developer Role 25-3
25.3 Customizing Oracle WebCenter Portal Task Flows 25-5
25.3.1 Examples: Customizing Task Flows for WebCenter Portal: Spaces 25-5
25.3.1.1 Example: Customizing the Worklist Task Flow 25-5
25.3.1.2 Example: Customizing the Discussion Forums Task Flow 25-8
25.3.2 Examples: Customizing Task Flows for Custom Framework Applications 25-10
25.3.2.1 Example: Customizing the Document Library - List View Task Flow 25-11
25.4 Applying Task Flow Customizations to Deployed WebCenter Portal Applications 25-11
25.4.1 Creating a Metadata Deployment Profile for Custom WebCenter Portal Applications .. 25-12
25.4.2 Deploying Task Flow Customizations Directly from JDeveloper 25-13
25.4.3 Deploying Task Flow Customizations Using WLST 25-16
25.5 Removing Customizations from Deployed WebCenter Portal Applications 25-17
25.6 Catalog of WebCenter Portal Task Flows 25-17

Part IV Integrating and Publishing Content

26 Introduction to Integrating and Publishing Content

27 Managing Content Repository Connections

27.1 Overview of Content Adapters 27-1
27.2 Configuring Content Repository Connections 27-2
27.2.1 How to Create a Content Repository Connection Based on the Oracle Content Server Adapter 27-2
27.2.2 How to Create a Content Repository Connection Based on the Oracle Portal Adapter .. 27-8
27.2.3 How to Create a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint 27-11
27.2.3.1 Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint 27-11
27.2.3.2 Mapping Microsoft SharePoint Content and Services 27-13
27.2.4 How to Create a Content Repository Connection Based on the File System Adapter 27-15
27.2.5 What Happens When You Create a Repository Connection 27-16
27.2.6 What You May Need to Know When Creating a Repository Connection 27-17

27.2.6.1 What You Should Know About Using Identity Propagation and External Application Authentication Methods ... 27-17
27.2.6.2 What You Should Know About Oracle Portal ... 27-18
27.2.6.3 What You Should Know About Oracle WebCenter Adapter for SharePoint ... 27-19
27.3 Editing Content Repository Connections ... 27-21
27.3.1 How to Edit a Common Repository Connection ... 27-21
27.3.2 How to Edit a WebCenter Portal: Framework Application-Specific Content Repository Connection ... 27-23
27.4 Using an Existing Repository Connection for a New WebCenter Portal: Framework Application ... 27-23

28 Working with Content Data Controls

28.1 Overview of Content Data Controls ... 28-1
28.1.1 The getItems Method ... 28-2
28.1.2 The search Method ... 28-2
28.1.3 The advancedSearch Method ... 28-3
28.1.4 The getURI Method ... 28-4
28.1.5 The getAttributes Method ... 28-4
28.2 Configuring Content Data Controls for JCR Adapters ... 28-4
28.2.1 How to Configure a Content Repository Data Control ... 28-5
28.2.2 What Happens When You Configure a Content Repository Data Control ... 28-6
28.3 Editing Content Repository Data Controls ... 28-8
28.4 Securing a Content Repository Data Control ... 28-9
28.5 Integrating Content Using Content Data Controls ... 28-9
28.5.1 How to Publish Content As Links ... 28-10
28.5.1.1 Publishing Content As a Textual Link ... 28-11
28.5.1.2 Creating a Clickable Image to Link to a Document ... 28-15
28.5.2 What Happens at Runtime ... 28-16
28.5.3 How to Publish Content in a Table ... 28-17
28.5.3.1 Displaying Files and Folders in Read-Only Format ... 28-17
28.5.3.2 Displaying the Name Attribute As a Go Link ... 28-21
28.5.3.3 Configuring a Table to Show Only Files ... 28-24
28.5.4 What Happens at Runtime ... 28-26
28.5.5 How to Publish Folder Content in a Tree ... 28-27
28.5.5.1 Displaying Files and Folders in Read-Only Format ... 28-27
28.5.5.2 Displaying File Names As Hyperlinks ... 28-30
28.5.6 What Happens at Runtime ... 28-32
28.5.7 How to Add Search Capabilities to Content Repositories ... 28-33
28.5.7.1 Adding Simple Search Capabilities ... 28-33
28.5.7.2 Adding Advanced Search Capabilities ... 28-34
28.5.8 What Happens at Runtime ... 28-37
28.5.9 What You May Need to Know When Using Search Capabilities ... 28-38

29 Creating Content Presenter Display Templates

29.1 Adding Content Presenter to an Application ... 29-1
29.2 What Is a Content Presenter Display Template? ... 29-2
29.3 Using the Out-of-the-Box Display Templates ... 29-2

29.4 Creating Content Presenter Display Templates 29-3
29.4.1 Overview 29-4
29.4.2 Defining Single-Item Display Templates 29-4
29.4.3 Defining Multiple-Item Display Templates 29-8
29.4.4 Using EL Expressions to Retrieve Content Item Information 29-10
29.4.4.1 Retrieving Basic Information About a Content Item 29-10
29.4.4.2 Working with Content Item Properties and Values 29-11
29.4.4.3 Working with Content Item Icons and URLs 29-14
29.4.5 Discovering Content Type Property Names 29-14
29.4.6 Referencing External Files in Display Templates 29-16
29.4.7 Referencing Site Studio Region Elements in a Custom View 29-16
29.4.8 Using the Content Presenter Display Template 29-17
29.5 Using Content Presenter Display Templates in a Framework Application 29-18
29.5.1 Export a Content Presenter Display Template as a Portal Resource 29-18
29.5.2 Upload the New Content Presenter Display Template 29-21
29.5.3 Test the New Content Presenter Display Template 29-22
29.6 What Happens at Runtime? 29-24
29.6.1 Runtime Overview 29-24
29.6.2 Identifying Display Templates for Selected Content Items 29-24
29.7 Performance Considerations for Content Presenter Display Templates 29-25

30 Integrating the Documents Service

30.1 Introduction to the Documents Service 30-1
30.2 Setting Up Connections 30-2
30.3 Setting Security for the Documents Service 30-2
30.4 Using the Documents Service with Other WebCenter Services 30-4
30.5 Setting Parameters to Upload Files to Content Repositories 30-4
30.6 Using Adapters with the Documents Service 30-5

31 Adding Content Task Flows and Document Components to a Portal Page

31.1 Understanding the Content Presenter Task Flow 31-1
31.2 Understanding the Documents Service Task Flows 31-2
31.3 Understanding Document Components 31-10
31.4 Adding a Selected Folder or File to a Page 31-12
31.5 Adding a Content Task Flow to a Page 31-16
31.6 Modifying Content Task Flow Parameters 31-18
31.7 Content Task Flow Parameters 31-20
31.7.1 Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates 31-20
31.7.2 Document Explorer Task Flow Parameters 31-25
31.7.3 Document List Viewer Task Flow Parameters 31-27
31.7.4 Document Manager Task Flow Parameters 31-29
31.7.5 Document Navigator Task Flow Parameters 31-31
31.7.6 Folder Viewer Task Flow Parameters 31-33
31.7.7 Recent Documents Task Flow Parameters 31-35
31.7.8 Document Viewer Task Flow Parameters 31-36
31.7.9 Document Mini Properties Task Flow Parameters 31-38

31.7.10 Document Properties Task Flow Parameters 31-38
31.7.11 Rich Text Editor Task Flow Parameters 31-38
31.7.12 Document Upload Task Flow Parameters 31-40
31.7.13 Document Version History Task Flow Parameters 31-40
31.7.14 AutoVue Task Flow Parameters 31-41

32 Integrating Wikis and Blogs

32.1 Introduction to Wikis and Blogs 32-1
32.2 Requirements for Wikis and Blogs 32-1
32.3 Integrating Wikis 32-2
32.3.1 What You Should Know About the Document Explorer Task Flow 32-2
32.3.2 Adding the Document Explorer Task Flow to Provide the Wiki Functionality 32-2
32.3.3 Modifying Document Explorer Task Flow Parameters 32-3
32.3.4 What Happens at Runtime 32-3
32.3.5 Displaying Wiki Page Links Within Content Presenter 32-5
32.4 Integrating Blogs 32-5
32.4.1 Understanding the Blog Task Flows 32-5
32.4.2 Adding a Blog to a Page 32-7
32.4.2.1 Establishing a Selected Folder as a Blog Folder 32-8
32.4.2.2 Adding a Custom Blog to a Page Using the Blog Task Flows 32-9
32.4.3 What Happens at Runtime 32-10
32.4.4 Modifying Blog Task Flow Parameters 32-11
32.4.5 Blog Task Flow Parameters 32-12
32.4.5.1 Blog Archives Task Flow Parameters 32-12
32.4.5.2 Blog Banner Task Flow Parameters 32-12
32.4.5.3 Blog Digest Task Flow Parameters 32-12
32.4.5.4 Blog Recent Posts Task Flow Parameters 32-13
32.4.5.5 Blogs Task Flow Parameters 32-13

Part V Enabling Communication and Collaboration

33 Integrating the Announcements Service

33.1 Introduction to Announcements 33-1
33.1.1 Understanding the Announcements Service 33-1
33.1.2 Requirements for Announcements 33-2
33.1.3 What Happens at Runtime 33-2
33.2 Basic Configuration for the Announcements Service 33-3
33.2.1 Setting Up a Connection for Announcements 33-3
33.2.1.1 Announcements Connections 33-3
33.2.1.2 How to Set Up Connections for Announcements 33-4
33.2.2 Adding the Announcements Service at Design Time 33-7
33.2.2.1 Announcements Service Task Flows 33-7
33.2.2.2 How to Add Announcements to Your Page 33-8
33.2.2.3 How to Modify Announcements Service Task Flow Parameters 33-8
33.2.3 Setting Security for Announcements 33-11
33.3 Advanced Information for the Announcements Service 33-12

33.3.1 How to Add the Announcements - Quick View Task Flow 33-12
33.3.2 Customizing Announcements Views 33-13
33.3.3 Obtaining Space RSS News Feed URL for the Announcements Service 33-14

34 Integrating the Discussions Service

34.1 Introduction to Discussions 34-1
34.1.1 Understanding the Discussions Service 34-1
34.1.2 Requirements for Discussions 34-2
34.1.3 What Happens at Runtime 34-2
34.2 Basic Configuration for the Discussions Service 34-3
34.2.1 Setting up Connections for Discussions 34-3
34.2.1.1 Discussions Connections 34-3
34.2.1.2 How to Set Up Connections for Discussions 34-3
34.2.2 Adding the Discussions Service at Design Time 34-6
34.2.2.1 Discussions Task Flows 34-6
34.2.2.2 How to Add Discussions to a Page 34-7
34.2.2.3 How to Modify the Discussions Service Task Flow Parameters 34-8
34.2.3 Setting Security for Discussions 34-11
34.3 Advanced Information for the Discussions Service 34-12
34.3.1 Adding the Discussions - Popular Topics Task Flow 34-12
34.3.2 Adding the Discussions - Recent Topics Task Flow 34-13
34.3.3 Adding the Discussions - Watched Forums Task Flow 34-13
34.3.4 Adding the Discussions - Watched Topics Task Flow 34-14
34.3.5 Adding the Discussions - Quick View Task Flow 34-14
34.3.6 Obtaining Space RSS News Feed URL for the Discussions Service 34-15
34.3.7 Using Custom Discussions APIs 34-15
34.3.8 Using the Discussions Service REST APIs 34-15
34.3.8.1 Discussions Entry Point 34-16
34.3.8.2 Discussions Resource Type Taxonomy 34-16
34.3.8.3 Security Considerations 34-16
34.3.8.4 Discussions Resource Types 34-16
34.3.8.4.1 urn:oracle:webcenter:discussions:forums 34-17
34.3.8.4.2 urn:oracle:webcenter:discussions:forum 34-17
34.3.8.4.3 urn:oracle:webcenter:discussions:forum:topics 34-19
34.3.8.4.4 urn:oracle:webcenter:discussions:forum:topic 34-20
34.3.8.4.5 urn:oracle:webcenter:discussions:forum:topic:messages 34-22
34.3.8.4.6 urn:oracle:webcenter:discussions:forum:topic:message 34-23
34.3.9 Troubleshooting the Discussions Service 34-24

35 Integrating the Instant Messaging and Presence Service

35.1 Introduction to the IMP Service 35-1
35.1.1 Understanding the IMP Service 35-1
35.1.2 Requirements for IMP 35-2
35.2 Basic Configuration for the IMP Service 35-2
35.2.1 Setting up Connections for the IMP Service 35-3
35.2.1.1 IMP Service Connections 35-3

35.2.1.1.1 Mapping User Names to IM Addresses 35-3
35.2.1.2 How to Set Up Microsoft LCS Connections for the IMP Service 35-4
35.2.1.3 How to Set Up Microsoft OCS and Microsoft Lync Connections for the IMP Service 35-7
35.2.2 Adding the IMP Service at Design Time 35-10
35.2.2.1 IMP Service Task Flows 35-10
35.2.2.2 How to Add the IMP Service to your Application 35-11
35.2.3 Setting Security for the IMP Service 35-12
35.3 Advanced Information for the IMP Service 35-15
35.3.1 Enabling Network Presence 35-15
35.3.1.1 Setting Up Yahoo! Messenger Presence 35-15
35.3.1.2 Setting Up Other Network Presence Providers 35-17
35.3.2 Customizing IMP Views 35-19
35.3.3 Troubleshooting the IMP Service 35-20

36 Integrating the Mail Service

36.1 Introduction to the Mail Service 36-1
36.1.1 Understanding the Mail Service 36-1
36.1.2 Requirements for the Mail Service 36-3
36.2 Basic Configuration for the Mail Service 36-3
36.2.1 Configuration Roadmap - Mail Service 36-4
36.2.2 Setting up Connections for the Mail Service 36-5
36.2.3 Adding the Mail Service at Design Time 36-11
36.2.3.1 Mail Service Task Flows 36-11
36.2.3.2 How to Add the Mail Service to your Application 36-11
36.2.3.3 How to Modify the Mail Service Task Flow Parameters 36-12
36.2.4 Setting Security for the Mail Service 36-13
36.3 Advanced Information for the Mail Service 36-14
36.3.1 Invoking the Mail Compose Page 36-14
36.3.2 Configuring the Number of Mails Displayed 36-15
36.3.3 Troubleshooting the Mail Service 36-16

37 Integrating the Polls Service

37.1 Introduction to Polls 37-1
37.1.1 Understanding the Polls Service 37-1
37.1.2 Requirements for Polls 37-2
37.1.3 What Happens at Runtime 37-2
37.2 Basic Configuration for the Polls Service 37-2
37.2.1 Setting up Connections for the Polls Service 37-3
37.2.2 Adding the Polls Service at Design Time 37-3
37.2.2.1 Polls Task Flows 37-3
37.2.2.2 How to Add the Quick Poll Task Flow to Your Page 37-3
37.2.2.3 How to Modify the Polls Service Task Flow Parameters 37-3
37.2.3 Setting Security for Polls 37-5
37.3 Advanced Information for the Polls Service 37-5
37.3.1 How to Add the Polls Manager Task Flow 37-5
37.3.2 How to Add the Take Polls Task Flow 37-6

37.3.3 How to Add the View Poll Results Task Flow 37-6
37.3.4 Using the Polls Service Data Controls 37-6
37.3.4.1 Take Poll Data Control 37-6
37.3.4.1.1 createResponse 37-6
37.3.4.1.2 createResponseForLatestAvailablePoll 37-6
37.3.4.1.3 getPublishedPolls 37-7
37.3.4.1.4 getResults 37-7
37.3.4.1.5 saveResponse 37-7
37.3.4.2 Polls Manager Data Control 37-7
37.3.4.2.1 addQuestion 37-8
37.3.4.2.2 addQuestion 37-8
37.3.4.2.3 closePoll 37-8
37.3.4.2.4 closePollAfterDate 37-8
37.3.4.2.5 closePollAfterDays 37-9
37.3.4.2.6 closePollAfterResponses 37-9
37.3.4.2.7 createPoll 37-9
37.3.4.2.8 deletePoll 37-9
37.3.4.2.9 editPoll 37-9
37.3.4.2.10 editPoll 37-10
37.3.4.2.11 findPoll 37-10
37.3.4.2.12 getPolls 37-10
37.3.4.2.13 getPollsByUser 37-10
37.3.4.2.14 getPollsByUserCount 37-10
37.3.4.2.15 publishPoll 37-10
37.3.4.2.16 publishPollOnDate 37-11

Part VI Working with the People Connections Service

38 Introducing the People Connections Service

38.1 Overview of the People Connections Service 38-1
38.1.1 People Connections Service Task Flows 38-2
38.1.1.1 Activity Stream 38-2
38.1.1.2 Connections 38-5
38.1.1.3 Feedback 38-6
38.1.1.4 Message Board 38-7
38.1.1.5 Profile 38-9
38.1.1.6 The Publisher Task Flow 38-11
38.1.2 People Connections Service Requirements 38-12
38.2 Troubleshooting the People Connections Service 38-12

39 Basic Configuration for the People Connections Service

39.1 How to Set Up a Database Connection for the People Connections Service 39-1
39.2 How to Add People Connections Task Flows to a Page 39-1
39.3 Setting Security for the People Connections Service 39-2
39.4 Establishing Site-Level Settings for People Connections Features 39-3
39.4.1 Understanding the People Connections Site-Level Setting Scripts 39-3

39.4.1.1 Preparing and Running settings-insert.sql 39-3
39.4.1.2 Preparing and Running settings-update.sql 39-4
39.4.2 Supported Site-Level Settings for People Connections Features 39-5
39.4.2.1 Activity Stream Site-Level Settings 39-5
39.4.2.2 Connections Site-Level Settings 39-6
39.4.2.3 Feedback Site-Level Settings 39-7
39.4.2.4 Message Board Site-Level Settings 39-8
39.4.2.5 Profile Site-Level Settings 39-9
39.4.3 Example: Configuring Connections to Accept Invitations Automatically 39-11

40 People Connections Task Flow Binding Parameters

40.1 How to Revise People Connections Task Flow Binding Parameters 40-1
40.2 People Connections Task Flow Binding Parameters 40-3
40.3 What You Should Know About the Activity Stream Advanced Query Option 40-12

41 Using People Connections Data Controls and Java APIs

41.1 Using People Connections Data Controls 41-1
41.1.1 Adding a Data Control to Your Project 41-1
41.1.2 Working with People Connections Management Data Control 41-3
41.1.2.1 connectionLists 41-4
41.1.2.2 groupedPeopleCounts 41-4
41.1.2.3 receivedInvitations 41-4
41.1.2.4 sentInvitations 41-5
41.1.2.5 acceptInvitation(String invitationId) 41-5
41.1.2.6 addConnectionsToList(List userids, String listName) 41-5
41.1.2.7 createConnectionList(String listName) 41-5
41.1.2.8 declineInvitation(String invitationId) 41-6
41.1.2.9 dropConnectionList(String listName) 41-6
41.1.2.10 getConnectionList(String connectionListName) 41-6
41.1.2.11 getConnections(String userid, String connectionListName, String filterPattern, String sortBy, int startIndex, int fetchSize) 41-7
41.1.2.12 getNumberOfConnections(String userid, String connectionListName, String filterPattern) 41-7
41.1.2.13 ignoreInvitation(String invitationId) 41-8
41.1.2.14 inviteUserForConnection(String userid, String invitationMessage, Collection connectionListNames) 41-8
41.1.2.15 isConnectionListModifiable(String listName) 41-8
41.1.2.16 isConnectionPartOfUnmodifiableList(String connecteeGuid) 41-8
41.1.2.17 removeConnection(String userid, boolean fromListOnly, String listName) 41-9
41.1.2.18 searchUsers(String filterPattern, int startIndex, int fetchSize) 41-9
41.1.2.19 updateConnectionListsMembership(String member, Collection addListIds, Collection removeListIds) 41-9
41.1.3 Working with Profile Data Control 41-10
41.1.3.1 Method: getProfile(String userId) 41-10
41.1.3.2 Method: getProfileForUpdate(String userId) 41-10
41.2 People Connections Service Java APIs 41-10

42 People Connections Service REST APIs

42.1 Activity Stream REST APIs 42-1
42.1.1 Activity Stream Entry Point 42-2
42.1.2 Activity Stream Resource Type Taxonomy 42-2
42.1.3 Activity Stream Security Considerations 42-2
42.1.4 Activity Stream Resource Types 42-2
42.2 Connections and Profile REST APIs 42-10
42.2.1 Connections and Profile Entry Point 42-10
42.2.2 Connections and Profile Resource Type Taxonomy 42-11
42.2.3 Connections and Profile Security Considerations 42-11
42.2.4 Connections and Profile Resource Types 42-11
42.3 Feedback REST APIs 42-23
42.3.1 Feedback Entry Point 42-23
42.3.2 Feedback Resource Type Taxonomy 42-24
42.3.3 Feedback Security Considerations 42-24
42.3.4 Feedback Resource Types 42-24
42.4 Message Board REST APIs 42-26
42.4.1 Message Board Entry Point 42-26
42.4.2 Message Board Resource Type Taxonomy 42-27
42.4.3 Message Board Security Considerations 42-27
42.4.4 Message Board Resource Types 42-27
42.5 Creating an Invitation 42-30
42.5.1 Creating an Invitation 42-30
42.5.2 Deleting an Invitation 42-32

Part VII Helping Users Find Content

43 Integrating the Links Service

43.1 Introduction to the Links Service 43-1
43.1.1 Understanding the Links Service 43-1
43.1.2 Requirements for the Links Service 43-3
43.1.3 What Happens at Runtime 43-3
43.2 Basic Configuration for the Links Service 43-4
43.2.1 Setting up Connections for the Links Service 43-4
43.2.2 Adding the Links Service at Design Time 43-4
43.2.2.1 Links Service Task Flows 43-4
43.2.2.2 How to Add the Links Service to your Application 43-4
43.2.3 Setting Security for the Links Service 43-6
43.2.4 Troubleshooting the Links Service 43-6
43.3 Advanced Information for the Links Service 43-6
43.3.1 Using the Links Service REST APIs 43-6
43.3.1.1 Links Entry Point 43-7
43.3.1.2 Links Resource Type Taxonomy 43-7
43.3.1.3 Security Considerations 43-7
43.3.1.4 Links Resource Types 43-7
43.3.1.4.1 urn:oracle:webcenter:links:results 43-7

44 Integrating the Tags Service

44.1 Introduction to the Tags Service 44-1
44.1.1 Understanding the Tags Service 44-2
44.1.2 Requirements for the Tags Service 44-2
44.1.3 What Happens at Runtime 44-3
44.2 Basic Configuration for the Tags Service 44-3
44.2.1 Setting up Connections for the Tags Service 44-3
44.2.2 Adding the Tags Service at Design Time 44-3
44.2.2.1 Tags Service Components 44-4
44.2.2.2 Tags Service Task Flows 44-4
44.2.2.3 How to Add the Tags Service to your Page 44-5
44.2.2.4 How to Modify the Tags Service Task Flow Parameters 44-7
44.2.3 Setting Security for the Tags Service 44-8
44.3 Advanced Information for the Tags Service 44-9
44.3.1 Using the Tags Service Java APIs 44-9
44.3.2 Using the Tags Service REST APIs 44-9
44.3.2.1 Tags Entry Point 44-10
44.3.2.2 Tags Resource Type Taxonomy 44-10
44.3.2.3 Security Considerations 44-10
44.3.2.4 Tags Resource Types 44-11
44.3.2.4.1 urn:oracle:webcenter:tagging:tags 44-11
44.3.2.4.2 urn:oracle:webcenter:tagging:tag 44-12
44.3.2.4.3 urn:oracle:webcenter:tagging:taggedItems 44-13
44.3.2.4.4 urn:oracle:webcenter:tagging:taggedItem 44-14
44.3.2.4.5 urn:oracle:webcenter:tagging:users 44-15
44.3.3 Optional Way to Show Tags on Pages 44-16
44.3.4 Using the Resource Action Handling Framework to Tag Custom Objects 44-20
44.3.5 Troubleshooting the Tags Service 44-21
44.3.5.1 Tag Center Results Do Not Appear When Tag Is Clicked 44-21
44.3.5.2 The Tag Center Does Not Display Tagged Documents 44-21
44.3.5.3 The Tagging Button Does Not Display On Page 44-21
44.3.5.4 Clicking a Tagged Resource Does Not Go To The Correct Page 44-22

45 Integrating the Search Service

45.1 Introduction to Search 45-1
45.1.1 Understanding the Search Service 45-1
45.1.1.1 Understanding Search with the Oracle SES Adapter 45-2
45.1.1.2 Understanding Search with WebCenter Portal's Search Adapters 45-2
45.1.1.3 Click Actions on Search Results 45-2
45.1.2 What Happens at Runtime 45-2
45.2 Basic Configuration for the Search Service 45-3
45.2.1 Configuration Roadmap - Oracle SES 45-3
45.2.2 Setting up Connections for Oracle SES 45-5
45.2.3 Adding the Search Service at Design Time 45-9
45.2.3.1 Search Service Task Flows 45-9
45.2.3.2 How to Add the Search Service to Your Page 45-9
45.2.3.3 How to Modify the Search Service Task Flow Parameters 45-10

45.2.4 Setting Security for the Search Service 45-13
45.3 Advanced Information for the Search Service 45-13
45.3.1 Adding the Search Task Flow 45-14
45.3.2 Adding the Search - Saved Searches Task Flow 45-14
45.3.3 Adding the Search Preferences Task Flow 45-14
45.3.4 Configuring Search with the Oracle SES Adapter 45-14
45.3.5 Configuring Search with WebCenter Portal's Search Adapters 45-16
45.3.6 Using the Search Service Java APIs 45-17
45.3.7 Using the Search Service REST APIs 45-17
45.3.7.1 Search Entry Point 45-18
45.3.7.2 Search Resource Type Taxonomy 45-18
45.3.7.3 Security Considerations 45-18
45.3.7.4 Search Resource Types 45-18
45.3.7.4.1 urn:oracle:webcenter:search:results 45-18
45.3.8 Using the Search Service Data Control 45-21
45.3.8.1 Search Data Control Methods, Attributes, and Classes 45-21
45.3.8.1.1 SearchServiceDCRows 45-21
45.3.8.1.2 SearchServiceDCRefiner 45-22
45.3.8.1.3 SearchServiceDCRefinement 45-22
45.3.8.2 Integrating the Search Data Control 45-22
45.3.9 Building Adapters for the Search Service 45-22
45.3.9.1 How to Add a Search Source 45-23
45.3.9.2 How to Register a Custom Adapter 45-28
45.3.9.3 Search Adapter Attributes 45-28
45.3.9.3.1 Searchable Attributes 45-28
45.3.9.3.2 Keywords 45-28
45.3.9.3.3 Date Condition 45-29
45.3.9.3.4 Complex Date Condition 45-29
45.3.9.3.5 Person Condition 45-29
45.3.9.3.6 Complex Person Condition 45-29
45.3.9.3.7 Access 45-30
45.3.9.3.8 Selectable Attributes 45-30
45.3.9.4 What Happens at Runtime 45-31
45.3.10 Customizing the Search UI Without WebCenter Portal's Search Service APIs 45-31
45.3.11 Troubleshooting the Search Service 45-33

46 Integrating the Activity Graph Service

46.1 Introduction to the Activity Graph Service 46-1
46.1.1 Understanding the Activity Graph Service 46-1
46.1.2 Requirements for the Activity Graph Service 46-7
46.1.3 What Happens at Runtime 46-8
46.2 Basic Configuration for the Activity Graph Service 46-8
46.2.1 Configuration Roadmap for the Activity Graph Service 46-8
46.2.2 Setting Up Connections for the Activity Graph Service 46-10
46.2.3 Adding the Activity Graph Service at Design Time 46-11
46.2.3.1 Activity Graph Service Task Flows 46-11
46.2.3.1.1 The Recommended Connections Task Flow 46-11

46.2.3.1.2 The Similar Spaces Task Flow 46-12
46.2.3.1.3 The Similar Items Task Flow 46-13
46.2.3.2 How to Add Activity Graph Service Task Flows to a Page 46-14
46.2.3.3 How to Modify Activity Graph Service Task Flow Parameters 46-15
46.2.3.4 Activity Graph Service Task Flows and Task Flow Parameters 46-16
46.3 Advanced Information for the Activity Graph Service 46-17
46.3.1 Using the Activity Graph Data Control 46-18
46.3.2 Using the Activity Graph Service REST APIs 46-19
46.3.2.1 Activity Graph Entry Point 46-19
46.3.2.2 Activity Graph Resource Type Taxonomy 46-19
46.3.2.3 Security Considerations 46-20
46.3.2.4 Activity Graph Resource Types 46-20
46.3.2.4.1 urn:oracle:webcenter:activitygraph:recommendations 46-20
46.3.2.4.2 urn:oracle:webcenter:activitygraph:recommendations:recommendation . 46-22
46.3.2.4.3 urn:oracle:webcenter:activitygraph:items 46-22
46.3.2.4.4 urn:oracle:webcenter:activitygraph:items:item 46-23
46.4 Extending the Activity Graph Service 46-24
46.4.1 Defining Custom Node Classes 46-25
46.4.2 Defining Custom Actions 46-26
46.4.3 Defining Custom Similarity Calculations 46-28
46.4.4 Defining Custom Rank Calculations 46-29
46.4.5 Registering Custom Activity Providers 46-31
46.4.6 Registering Custom QRPPs 46-32
46.5 Troubleshooting the Activity Graph Service 46-33
46.5.1 Troubleshooting the Activity Graph Service Task Flows (All Task Flows) 46-33
46.5.2 Troubleshooting the Recommended Connections Task Flow 46-34
46.5.3 Troubleshooting the Similar Spaces Task Flow 46-34
46.5.4 Troubleshooting the Similar Items Task Flow 46-34

Part VIII Helping Users Keep Track

47 Integrating the Analytics Service

47.1 Introduction to the Analytics Service 47-1
47.1.1 Understanding the Analytics Service 47-1
47.1.2 Requirements for the Analytics Service 47-2
47.1.3 What Happens at Runtime 47-2
47.2 Basic Configuration for the Analytics Service 47-3
47.2.1 Configuration Roadmap for the Analytics Service 47-3
47.2.2 Setting up Connections for the Analytics Service 47-5
47.2.2.1 How to Set Up a Connection to the Analytics Database 47-6
47.2.2.2 How to Set Analytics Collector Properties 47-6
47.2.2.3 How to Set Up a Connection to the Analytics Collector 47-7
47.2.3 Adding Analytics Event Code to Your Application 47-8
47.2.3.1 Including Event Code for Page Views 47-8
47.2.4 Configuring a Namespace for Analytics Customizations in MDS 47-9
47.2.5 Adding Analytics Task Flows at Design Time 47-9
47.2.5.1 Analytics Task Flows 47-10

47.2.5.2 How to Add Analytics Task Flows to a Page 47-10
47.2.5.3 How to Modify Analytics Task Flow Parameters 47-12
47.2.5.4 How to Allow End Users to Customize Analytics Task Flows at Runtime 47-13
47.2.5.5 Analytics Task Flows and Task Flow Parameters 47-14
47.2.6 Setting up Security for Analytics Task Flows and Usage Data 47-15
47.3 Building Analytics Reports 47-16
47.3.1 Using SQL Data Controls 47-16
47.3.2 SQL Statements for Out-of-the-Box Analytics Reports 47-18
47.3.2.1 Analytics SQL: WebCenter Portal Traffic 47-19
47.3.2.2 Analytics SQL: Page Traffic 47-20
47.3.2.3 Analytics SQL: Login Metrics 47-20
47.3.2.4 Analytics SQL: Space Traffic 47-20
47.3.2.5 Analytics SQL: Space Response Time 47-21
47.3.2.6 Analytics SQL: Portlet Traffic 47-21
47.3.2.7 Analytics SQL: Portlet Instance Traffic 47-21
47.3.2.8 Analytics SQL: Portlet Response Time 47-22
47.3.2.9 Analytics SQL: Portlet Instance Response Time 47-22
47.3.2.10 Analytics SQL: Search Metrics 47-22
47.3.2.11 Analytics SQL: Document Metrics 47-23
47.3.2.12 Analytics SQL: Wiki Metrics 47-23
47.3.2.13 Analytics SQL: Blog Metrics 47-23
47.3.2.14 Analytics SQL: Discussion Metrics 47-23
47.3.3 Sample Queries for User Metrics 47-24
47.3.3.1 Sample SQL: Filter by User Property 47-24
47.3.3.2 Sample SQL: Group by User Property 47-24
47.3.4 Sample Analytics Database Queries for Specific Metrics 47-24
47.3.4.1 Sample SQL: User Activities 47-25
47.3.4.2 Sample SQL: Space Activities 47-25
47.3.4.3 Sample SQL: Space Activities for a Specific Time Period 47-26
47.3.4.4 Sample SQL: Activity for a Service During a Specific Time Period 47-27
47.3.4.5 Sample SQL: Search Phrases 47-28
47.3.4.6 Sample SQL: Page Views 47-28

48 Integrating the Lists Service

48.1 Introduction to the Lists Service 48-1
48.1.1 Understanding the Lists Service 48-1
48.1.2 What Happens to the Lists Service at Runtime 48-1
48.2 Basic Configuration for the Lists Service 48-2
48.2.1 Setting Up Connections for the Lists Service 48-2
48.2.2 Adding the Lists Service at Design Time 48-2
48.2.2.1 Lists Service Task Flows 48-2
48.2.2.2 How to Add the Lists Service to your Application 48-3
48.2.3 Enabling Users to Work with Lists at Runtime 48-3
48.3 Adding Lists to a Resource Catalog 48-4
48.4 Using the Lists Service REST APIs 48-4
48.4.1 Entry Point for Lists 48-5
48.4.2 Lists Resource Type Taxonomy 48-5

48.4.3 Lists Security Considerations 48-5
48.4.4 Lists Resource Types 48-5
48.4.4.1 urn:oracle:webcenter:space:lists 48-6
48.4.4.1.1 Navigation Paths to lists 48-6
48.4.4.1.2 Supported Methods for lists 48-6
48.4.4.1.3 Resource Types Linked to from lists 48-11
48.4.4.2 urn:oracle:webcenter:space:list 48-11
48.4.4.2.1 Navigation Paths to list 48-12
48.4.4.2.2 Supported Methods for list 48-12
48.4.4.2.3 Resource Types Linked to from list 48-16
48.4.4.3 urn:oracle:webcenter:space:list:rows 48-16
48.4.4.3.1 Navigation Paths to rows 48-16
48.4.4.3.2 Supported Methods for rows 48-16
48.4.4.3.3 Resource Types Linked to from rows 48-22
48.4.4.4 urn:oracle:webcenter:space:list:row 48-22
48.4.4.4.1 Navigation Paths to row 48-22
48.4.4.4.2 Supported Methods for row 48-22
48.4.4.4.3 Resource Types Linked to from row 48-26
48.4.4.5 urn:oracle:webcenter:space:list:columns 48-26
48.4.4.5.1 Navigation Paths to columns 48-26
48.4.4.5.2 Supported Methods for columns 48-26
48.4.4.5.3 Resource Types Linked to from columns 48-30
48.4.4.6 urn:oracle:webcenter:space:list:column 48-30
48.4.4.6.1 Navigation Paths to column 48-30
48.4.4.6.2 Supported Methods for column 48-31
48.4.4.6.3 Resource Types Linked to from column 48-34
48.5 Troubleshooting the Lists Service 48-34

49 Integrating Notifications

49.1 Introduction to Notifications 49-1
49.1.1 Understanding Notifications 49-1
49.1.2 Requirements for Notifications 49-2
49.1.3 What Happens with Notifications at Runtime? 49-3
49.2 Basic Configuration for Notifications 49-4
49.2.1 Adding the Notifications Namespace 49-4
49.2.2 Creating a Notifications Connection to a Mail Server 49-5
49.2.3 Creating a Notifications Connection to a BPEL Server 49-6
49.2.4 Setting Application Defaults for Notifications 49-7
49.2.4.1 What You Should Know About Subscription Defaults 49-7
49.2.4.2 Setting Notifications Subscription Defaults 49-9
49.2.5 Adding Notifications Task Flows to Your Application 49-11
49.2.5.1 Notifications Task flows 49-11
49.2.5.2 How to Add a Notifications Task Flow to a Page 49-12
49.2.5.3 Subscription Preferences Task Flow Input Parameters 49-13
49.2.6 Setting Security for Notifications 49-13
49.3 Advanced Information for Notifications 49-14
49.3.1 Using Notifications Java APIs 49-14

49.3.1.1 Configuration Settings Required to Use Notifications Java APIs 49-14
49.3.1.2 Introduction to Notifications Java APIs 49-14
49.3.1.3 How to Set up Your Application to Use Notifications Java APIs 49-15
49.3.2 Using Notifications Data Controls 49-16
49.3.2.1 Adding a Data Control to Your Project 49-16
49.3.2.2 Understanding the Notification Subscription Data Control 49-17
49.3.2.3 Notification Subscription Data Control Methods and Attributes 49-17
49.3.2.3.1 Method: getUserSubscriptionPreferences 49-17
49.3.2.3.2 Method: getScopeSubscriptionPreferences 49-17
49.3.2.3.3 Method: saveUserSubscriptionPreferences 49-18
49.3.2.3.4 Method: saveScopeSubscriptionPreferences 49-18
49.3.2.3.5 Method: getSubscriptions 49-18
49.3.2.3.6 Method: unsubscribe 49-19
49.3.2.4 Notification Subscription Data Control Classes 49-19
49.3.2.4.1 SubscriptionPreference 49-19
49.3.2.4.2 Subscription 49-20

50 Integrating the Recent Activities Service

50.1 Introduction to the Recent Activities Service 50-1
50.1.1 Understanding the Recent Activities Service 50-2
50.1.2 What Happens at Runtime 50-2
50.2 Basic Configuration for the Recent Activities Service 50-3
50.2.1 Setting up Connections for the Recent Activities Service 50-3
50.2.2 Adding the Recent Activities Service at Design Time 50-3
50.2.3 Modifying Recent Activities Service Task Flow Parameters 50-7
50.2.4 Setting Security for the Recent Activities Service 50-7
50.3 Advanced Information for the Recent Activities Service 50-7
50.3.1 Refining the Behavior of the Recent Activities Service 50-7
50.3.2 Obtaining RSS News Feed URL for the Recent Activities Service 50-8

51 Integrating the Worklist Service

51.1 Introduction to the Worklist Service 51-1
51.1.1 Understanding Worklists 51-1
51.1.2 Requirements for the Worklist Service 51-2
51.1.3 What Happens at Runtime 51-2
51.2 Roadmap - Configuring the Worklist Service for WebCenter Portal: Framework Applications 51-3
51.3 Basic Configuration for the Worklist Service 51-5
51.3.1 Setting up Connections for the Worklist Service 51-5
51.3.1.1 Worklist Service Connections 51-6
51.3.1.2 How to Set Up Connections for the Worklist Service 51-6
51.3.2 Adding the Worklist Service at Design Time 51-8
51.3.2.1 Worklist Service Task Flows 51-8
51.3.2.2 How to Add the Worklist Service to your Application 51-8
51.3.3 Setting Security for the Worklist Service 51-8
51.4 Advanced Information for the Worklist Service 51-9

52 Integrating the Events Service

52.1 Introduction to the Events Service 52-1
52.1.1 Understanding the Events Service 52-1
52.1.2 Requirements for the Events Service 52-2
52.1.3 What Happens at Runtime 52-2
52.2 Basic Configuration for the Events Service 52-2
52.2.1 Configuration Roadmap for the Events Service 52-3
52.2.2 Setting Up a Connection for the Events Service 52-4
52.2.3 Adding the Events Service at Design Time 52-6
52.2.3.1 Events Task Flows 52-6
52.2.3.2 How to Add the Events Service to Your Application 52-7
52.2.4 Setting Security for the Events Service 52-8
52.3 Using the Events Service REST APIs 52-8
52.3.1 Events Entry Point 52-9
52.3.2 Events Resource Type Taxonomy 52-9
52.3.3 Security Considerations 52-9
52.3.4 Events Resource Types 52-9
52.3.4.1 urn:oracle:webcenter:events:gsEvents 52-9
52.3.4.2 urn:oracle:webcenter:events:gsEvent 52-10
52.3.4.3 urn:oracle:webcenter:events:gsCategories 52-12
52.3.4.4 urn:oracle:webcenter:events:gsCategory 52-13
52.4 Troubleshooting the Events Service 52-14

53 Integrating the RSS Service

53.1 Introduction to the RSS Service 53-1
53.1.1 Understanding the RSS Service 53-1
53.1.2 Requirements for the RSS Service 53-2
53.1.3 What Happens at Runtime 53-2
53.2 Basic Configuration for the RSS Service 53-3
53.2.1 Setting Up a Proxy Server for the RSS Service 53-3
53.2.2 Adding the RSS Service at Design Time 53-3
53.2.2.1 About RSS Viewer Task Flow 53-4
53.2.2.2 How to Add the RSS Viewer Task Flow to Your Application 53-4
53.2.2.3 How to Modify RSS Viewer Task Flow Parameters 53-5
53.2.3 Setting Security for the RSS Viewer Service 53-6

Part IX Extending Your WebCenter Portal Application

54 Using Oracle WebCenter Portal REST APIs

54.1 Introduction to REST 54-1
54.2 Understanding the Username-Based Security Token Encryption 54-2
54.3 Benefits of Using REST 54-2
54.4 Introduction to WebCenter Portal's REST APIs 54-3
54.5 Understanding the Link Model 54-4
54.5.1 The Resource Index 54-5
54.5.2 The Anatomy of a Link 54-7

54.5.2.1 Resource Type 54-8
54.5.2.2 Relationship 54-8
54.5.2.3 Capabilities 54-8
54.5.2.4 Media Type 54-9
54.5.2.5 Templates 54-9
54.6 Understanding Items Hypermedia 54-11
54.7 Navigating Hypermedia Using HTTP 54-11
54.8 Security Considerations for WebCenter Portal REST APIs 54-13
54.9 Security Considerations for CMIS REST APIs 54-13
54.10 Understanding Common Types 54-14
54.10.1 Common Types 54-14
54.10.1.1 personReference 54-14
54.10.1.2 groupSpaceReference 54-14
54.10.2 Portable Contact Types 54-15
54.10.2.1 name Portable Contact Type 54-15
54.10.2.2 address Portable Contact Type 54-15
54.10.2.3 organization Portable Contact Type 54-16
54.10.2.4 value Portable Contact Type 54-16
54.11 Managing Caches 54-16
54.12 Configuring a Proxy Server 54-16
54.13 WebCenter Portal's REST API Examples 54-17
54.13.1 Navigating the Message Board Hypermedia 54-17
54.13.1.1 Accessing the Resource Index 54-17
54.13.1.2 Reading Messages 54-18
54.13.1.3 Creating a New Message 54-19
54.13.1.4 Updating a Message 54-21
54.13.1.5 Deleting a Message 54-21
54.13.2 Displaying Activity Stream Data 54-22
54.13.3 Using the WebCenter People Connections Service REST APIs with Ext 54-24
54.13.3.1 Creating the HTML Page 54-24
54.13.3.2 Creating the JavaScript File 54-24
54.13.3.3 The Result 54-27
54.13.4 Updating User Status 54-27

55 Integrating Other Oracle Applications

55.1 Integrating Oracle and Other Applications in WebCenter Portal 55-1
55.2 Integrating Siebel Applications 55-2
55.2.1 Integrating Siebel Applications as Web Services 55-2
55.2.1.1 Preparing the Siebel Application 55-3
55.2.1.1.1 Creating an Inbound Web Service 55-3
55.2.1.1.2 Creating Operations for the Inbound Web Service 55-4
55.2.1.2 Consuming a Siebel Web Service in a Framework Application 55-5
55.2.1.2.1 Creating a Data Control Based on a Siebel Web Service 55-5
55.2.1.2.2 Creating a Page Flow Diagram 55-6
55.2.1.2.3 Adding Pages and Navigation to the Page Flow Diagram 55-6
55.2.1.2.4 Creating the Query Page 55-7
55.2.1.2.5 Creating the Results Page 55-8

55.2.1.2.6 Testing the Application 55-8
55.2.2 Integrating Siebel Applications Using the Siebel Web Engine 55-9
55.3 Integrating E-Business Suite Applications 55-9
55.3.1 Introduction to Integrating EBS Applications 55-10
55.3.1.1 Understanding EBS Integration 55-10
55.3.1.2 Requirements for Integrating EBS Applications 55-10
55.3.2 Integrating EBS Applications in a Framework Application 55-10
55.3.2.1 Preparing the EBS Application for Remote Access 55-11
55.3.2.2 Registering the EBS WSRP Producer in the Framework Application 55-11
55.3.2.3 Creating a JSF Page to Consume the Remote Producer 55-12
55.3.2.4 Testing the Framework Application 55-12
55.3.3 Integrating EBS Applications in Spaces 55-12
55.3.3.1 Preparing the EBS Portlet for Remote Access 55-13
55.3.3.2 Registering the EBS WSRP Producer in Spaces 55-13
55.3.3.3 Adding the EBS Portlet to a Spaces Page 55-13
55.3.3.4 Testing the Spaces Portlet Connection 55-14
55.4 Integrating JD Edwards Applications 55-14
55.4.1 Integrating JD Edwards Applications in a Framework Application 55-14
55.4.1.1 Preparing the JD Edwards Application for Remote Access 55-14
55.4.1.2 Registering the JD Edwards WSRP Producer in the Framework Application . 55-15
55.4.1.3 Creating the JSF Page to Consume the Remote Producer 55-15
55.4.1.4 Testing the Framework Application 55-16
55.4.2 Integrating JD Edwards Applications in Spaces 55-16
55.4.2.1 Registering the Producer 55-16
55.4.2.2 Adding the JD Edwards Portlet to a Spaces Page 55-16
55.4.2.3 Testing the Spaces Portlet Connection 55-17
55.5 Integrating PeopleSoft Applications 55-17
55.5.1 Introduction to Integrating PeopleSoft Applications 55-17
55.5.1.1 Understanding PeopleSoft Integration 55-17
55.5.1.2 Requirements for Integrating PeopleSoft Applications 55-18
55.5.2 Integrating PeopleSoft Applications in a Framework Application 55-18
55.5.2.1 Preparing the PeopleSoft Application for Remote Access 55-18
55.5.2.2 Registering the PeopleSoft WSRP Producer in the Framework Application ... 55-19
55.5.2.3 Creating the JSF Page to Consume the Remote (WSRP) Producer 55-20
55.5.2.4 Setting up WS-Security for PeopleTools 55-21
55.5.2.4.1 Configuring WS-Security for WSS10 SAML Token with Message Integrity 55-21
55.5.2.4.2 Configuring WS-Security for WSS10 SAML Token with Message Protection ... 55-21
55.5.2.4.3 Configuring WS-Security for WSS10 Username Token with Password 55-22
55.5.2.5 Testing the Framework Application 55-23
55.5.3 Integrating PeopleSoft Applications in Spaces 55-23
55.5.3.1 Registering the Producer 55-23
55.5.3.2 Adding the PeopleSoft Portlet to a Spaces Page 55-24
55.5.3.3 Testing the Spaces Portlet Connection 55-24
55.6 Integrating Oracle Business Intelligence Presentation Services 55-24
55.6.1 Introduction to Integrating Oracle Business Intelligence Presentation Services 55-25

55.6.1.1 Understanding Oracle Business Intelligence Presentation Services Integration 55-25
55.6.1.2 Requirements for Integrating Oracle Business Intelligence Presentation Services ... 55-25
55.6.2 Configuring Credentials for Connecting to the Oracle BI Presentation Catalog 55-26
55.6.2.1 Creating the BIImpersonateUser 55-26
55.6.2.2 Granting Permissions to BIImpersonateUser 55-26
55.6.3 Integrating Oracle Business Intelligence Presentation Services in Framework Applications 55-27
55.6.3.1 Installing the Required Business Intelligence Extensions 55-27
55.6.3.2 Creating a Framework Application that Integrates with Oracle BI Presentation Services 55-28
55.6.3.2.1 Creating the Framework Application and JSF Page 55-28
55.6.3.2.2 Configuring the Application to Display the Oracle BI EE Presentation Catalog 55-29
55.6.3.2.3 Enabling the BI ADF Task Flow Permission 55-30
55.6.3.3 Testing the Framework Application 55-31
55.6.3.3.1 Adding Oracle BI Objects to the Resource Catalog 55-31
55.6.3.3.2 Adding Business Intelligence Content at Runtime 55-32
55.6.3.3.3 Modifying a Business Intelligence Object's Prompt Values 55-32
55.6.3.3.4 Modifying a Business Intelligence Task Flow's Initialization Parameters . 55-32
55.6.3.4 Post-Deployment Connection Configuration 55-33
55.6.3.5 Securing Oracle BI EE Objects Included in a Framework Application 55-33
55.6.4 Integrating Oracle Business Intelligence Objects in WebCenter Portal: Spaces 55-33
55.6.4.1 Adding or Modifying a Presentation Services Connection After Deployment 55-33
55.6.4.2 Adding Oracle BI Objects to the Spaces Resource Catalog 55-35
55.6.4.3 Adding Oracle BI Content at Runtime 55-35
55.6.4.4 Modifying a Business Intelligence Object's Prompt Values 55-36
55.6.4.5 Modifying a Business Intelligence Task Flow's Initialization Parameters 55-36

56 Extending the Spaces Application Using JDeveloper

56.1 Downloading a Workspace for Spaces Development 56-1
56.2 Including Additional Shared Libraries in Spaces 56-3
56.2.1 What You Should Know About Shared Library Deployment for Spaces 56-4
56.2.2 Deploying Your Own Custom Code and Task Flows in Shared Libraries 56-5
56.2.3 Rebuilding the Spaces Shared Library List 56-6
56.2.3.1 Editing the Shared Library List 56-6
56.2.3.2 Setting Build and Deployment Options (config.properties) 56-8
56.2.3.3 Building and Deploying the Shared Library List (extend.spaces.webapp.war) 56-9
56.2.3.4 Reverting to a Previous Shared Library List 56-10
56.2.3.5 Troubleshooting Shared Library Deployment 56-11
56.3 Developing Resources for the Spaces Application 56-12
56.3.1 Using the WebCenterSpacesResources Project for Round-Trip Development 56-12
56.3.2 Opening and Exploring the WebCenterSpacesResources Project 56-14
56.3.3 Enabling Direct Uploads to the Spaces Application 56-16
56.3.4 Editing Spaces Resources in JDeveloper 56-17
56.3.4.1 Downloading a Spaces Resource Directly into JDeveloper 56-19

56.3.4.2 Importing a Spaces Resource into JDeveloper 56-20
56.3.4.3 How to Build Spaces Resources 56-22
56.3.5 Uploading Resources Directly to the Spaces Application 56-23
56.3.6 Exporting Spaces Resources to an Archive 56-25
56.3.7 Troubleshooting Resource Round-Trip Development 56-26

57 Integrating with Oracle WebCenter Portal: Spaces

57.1 Introduction to WebCenter Portal: Spaces 57-1
57.2 Exposing Spaces in WebCenter Portal Applications Using APIs 57-4
57.2.1 Introduction to Spaces APIs 57-4
57.2.2 Case Study 1: Purchasing Application Uses a Space to Evaluate Suppliers 57-5
57.2.3 Case Study 2: Customer Support Center Application Uses a Space to Discuss Customer Escalations 57-7
57.2.4 How to Set Up Your WebCenter Portal Application to Use the Spaces APIs 57-8
57.2.4.1 Verifying That the Spaces Application Is Up and Running 57-8
57.2.4.2 Setting Up the WebCenter Portal Application to Use Spaces APIs 57-9
57.2.4.3 Securing the Connection Between the Application and Spaces 57-11
57.2.4.4 Setting Up the Spaces Client Context 57-11
57.2.5 How to Provide Spaces Functionality in WebCenter Portal Applications 57-12
57.2.5.1 Managing Spaces and Space Template 57-13
57.2.5.1.1 Creating a Space 57-14
57.2.5.1.2 Creating a Custom Attribute 57-14
57.2.5.1.3 Creating a Space Template 57-15
57.2.5.1.4 Deleting a Space 57-15
57.2.5.2 Managing Space Membership 57-15
57.2.5.2.1 Adding Members to a Space 57-16
57.2.5.2.2 Inviting Users to Join a Space 57-17
57.2.5.2.3 Removing Members from a Space 57-17
57.2.5.2.4 Retrieving Role Information 57-18
57.2.5.3 Retrieving Information for Spaces and Space Templates 57-18
57.2.5.3.1 Retrieving a List of Spaces 57-19
57.2.5.3.2 Retrieving a List of Public Spaces 57-19
57.2.5.3.3 Retrieving a List of Discoverable Spaces 57-19
57.2.5.3.4 Retrieving Space Metadata 57-20
57.2.5.3.5 Retrieving a List of Space Templates 57-22
57.2.5.3.6 Retrieving Space Template Metadata 57-22
57.2.5.3.7 Retrieving the Spaces URL 57-23
57.2.5.3.8 Retrieving a Space URL 57-23
57.2.5.3.9 Retrieving RSS Feed URLs for Space Services 57-24
57.2.6 How to Handle Exceptions Raised by Spaces APIs 57-25
57.2.6.1 Providing Localized Error Messages 57-26
57.2.6.2 Listing the Error Stack 57-26
57.2.7 Finding More Information on Spaces APIs 57-27
57.2.8 Troubleshooting Issues with Spaces APIs 57-27
57.3 Using the WebCenter Portal: Spaces REST APIs 57-28
57.3.1 WebCenter Portal: Spaces Entry Point 57-28
57.3.2 WebCenter Portal: Spaces Resource Type Taxonomy 57-29

57.3.3 WebCenter Portal: Spaces Security Considerations 57-29
57.3.4 WebCenter Portal: Spaces Resource Types 57-29
57.3.4.1 urn:oracle:webcenter:spaces 57-30
57.3.4.2 urn:oracle:webcenter:siteresources 57-31
57.3.4.3 urn:oracle:webcenter:spaces:resource:templates 57-35
57.3.4.4 urn:oracle:webcenter:space 57-35
57.3.4.5 urn:oracle:webcenter:space:resourceindex 57-38
57.3.4.6 urn:oracle:webcenter:space:roles 57-39
57.3.4.7 urn:oracle:webcenter:space:role 57-39
57.3.4.8 urn:oracle:webcenter:space:icon 57-40
57.3.4.9 urn:oracle:webcenter:space:attributes 57-41
57.3.4.10 urn:oracle:webcenter:space:attribute 57-42
57.3.4.11 urn:oracle:webcenter:space:members 57-42
57.3.4.12 urn:oracle:webcenter:space:member 57-44
57.3.4.13 urn:oracle:webcenter:space:lists 57-44
57.3.4.14 urn:oracle:webcenter:space:list 57-46
57.3.4.15 urn:oracle:webcenter:space:list:rows 57-47
57.3.4.16 urn:oracle:webcenter:space:list:row 57-48
57.3.4.17 urn:oracle:webcenter:space:list:columns 57-50
57.3.4.18 urn:oracle:webcenter:space:list:column 57-51
57.4 Exposing Enterprise Applications in Spaces 57-52
57.4.1 Exposing WebCenter Portal Applications in Spaces 57-53
57.4.2 Exposing Oracle Applications in Spaces 57-53
57.4.3 Exposing Non-Oracle Applications in Spaces 57-53

Part X Working with Portlets and Portals

58 Overview of Portlets

58.1 Introduction to Portlets 58-1
58.1.1 Portlet Anatomy 58-2
58.1.2 Portlet Resources 58-4
58.1.2.1 JSF Portlets 58-4
58.1.2.2 Prebuilt Portlets 58-5
58.1.2.3 Parameter Form and Parameter Display Portlets 58-6
58.1.2.4 Web Clipping 58-7
58.1.2.5 OmniPortlet 58-8
58.1.2.6 Programmatic Portlets 58-9
58.1.2.7 Deciding Which Tool to Use 58-10
58.1.3 Portlet Modes 58-11
58.1.3.1 View Mode 58-11
58.1.3.2 Edit Mode 58-11
58.1.3.3 Edit Defaults Mode 58-12
58.1.3.4 Help Mode 58-12
58.1.3.5 About Mode 58-12
58.2 Portlet Technologies Matrix 58-12
58.2.1 General Suitability 58-15

58.2.2 Expertise Required ... 58-17
58.2.3 Deployment Type ... 58-18
58.2.3.1 PDK-Java Producers ... 58-18
58.2.3.2 WSRP Producers ... 58-19
58.2.3.3 Producer Architecture ... 58-20
58.2.4 Caching Style ... 58-21
58.2.5 Development Tool ... 58-22
58.2.6 Portlet Creation Style ... 58-22
58.2.7 User Interface Flexibility ... 58-24
58.2.8 Ability to Capture Content from Web Sites ... 58-24
58.2.9 Ability to Render Content Inline ... 58-25
58.2.10 Charting Capability ... 58-26
58.2.11 Public Portlet Parameter Support ... 58-26
58.2.12 Private Portlet Parameter Support ... 58-27
58.2.13 Ability to Hide and Show Portlets Based on User Privileges ... 58-27
58.2.14 Multilingual Support ... 58-28
58.2.15 Pagination Support ... 58-28
58.2.16 Authenticating to External Applications ... 58-28

59 Creating Portlets with the Oracle JSF Portlet Bridge

59.1 Introduction to the Oracle JSF Portlet Bridge ... 59-1
59.2 Creating a Portlet from a JSF Application ... 59-2
59.2.1 How to Create a JSF Portlet Based on a Page ... 59-2
59.2.2 How to Create a JSF Portlet Based on a Task Flow ... 59-5
59.2.2.1 Creating a Portlet From a Task Flow Using the Create Portlet Entry Dialog ... 59-5
59.2.2.2 Creating a Portlet From a Task Flow Using the Manage Portlet Entries of Task Flows Dialog ... 59-7
59.2.3 How to Test a JSF Portlet Using the Integrated WebLogic Server ... 59-8
59.2.4 What Happens at Runtime ... 59-9
59.3 What You May Need to Know When Creating a JSF Portlet ... 59-9
59.3.1 General Guidelines ... 59-10
59.3.2 Portlet Guidelines ... 59-11
59.3.3 Security Guidelines ... 59-12
59.3.4 JSF Guidelines ... 59-13
59.3.5 Oracle ADF Guidelines ... 59-13
59.4 Copying a Runtime-Created Skin to a JSF Portlet Producer Application ... 59-16

60 Creating Portlets with the Portlet Wizard

60.1 Introduction to Java Portlets ... 60-1
60.1.1 Introduction to Standards-Based Java Portlets ... 60-1
60.1.2 Introduction to PDK-Java Portlets ... 60-3
60.2 Creating Java Portlets ... 60-4
60.2.1 How to Create a JSR 286 Java Portlet ... 60-5
60.2.2 What Happens When You Create a JSR 286 Java Portlet Using the JDeveloper Wizard 60-13
60.2.3 After You Create a JSR 286 Java Portlet Using the JDeveloper Wizard ... 60-14
60.2.4 How to Create a PDK-Java Portlet ... 60-14

60.2.5 What Happens When You Create a PDK-Java Portlet 60-20
60.2.6 After You Create an Oracle PDK-Java Portlet Using the JDeveloper Wizard 60-21
60.3 Troubleshooting Java Portlets 60-21
60.3.1 Cannot Access the Create Portlet Wizard 60-21
60.3.2 Cannot Add the Portlet Functionality that I Want to the Portlet 60-22

61 Coding Portlets

61.1 General Guidelines for Coding Java Portlets 61-1
61.1.1 Guidelines for Portlet Modes 61-1
61.1.1.1 Guidelines for View Mode 61-2
61.1.1.1.1 HTML Guidelines for Rendering Portlets 61-2
61.1.1.1.2 Cascading Style Sheet Guidelines for Rendering Portlets 61-3
61.1.1.2 Guidelines for Edit Mode 61-4
61.1.1.2.1 Guidelines for Edit Mode Operations 61-4
61.1.1.2.2 Guidelines for Buttons in Edit Mode 61-4
61.1.1.2.3 Guidelines for Rendering Personalization Values 61-4
61.1.1.3 Guidelines for Edit Defaults Mode 61-4
61.1.1.3.1 Guideline for Edit Default Mode Options 61-5
61.1.1.3.2 Guidelines for Buttons in Edit Defaults Mode 61-5
61.1.1.3.3 Guidelines for Rendering Personalization Values 61-5
61.1.1.4 Guidelines for Help Mode 61-5
61.1.1.5 Guidelines for About Mode 61-5
61.1.1.6 Guidelines for Preview Mode 61-5
61.1.1.7 Guidelines for Full Screen Mode (PDK-Java Only) 61-6
61.1.2 Guidelines for Navigation within a Portlet 61-6
61.1.2.1 Intraportlet Links 61-7
61.1.2.2 Application Links 61-8
61.1.2.3 External Links 61-8
61.1.2.4 Internal/Resource Links 61-8
61.1.3 Guidelines for JavaScript 61-9
61.2 Enhancing JSR 286 Java Portlets 61-9
61.2.1 How to Edit the Portlet Deployment Descriptor File 61-9
61.2.2 How to Add Custom Portlet Modes 61-10
61.2.3 How to Access User Information 61-11
61.2.4 How to Customize the Runtime Environment 61-12
61.2.4.1 Supported Container Runtime Options 61-12
61.2.4.2 Setting Container Runtime Options for All Portlets in an Application 61-19
61.2.4.3 Setting Container Runtime Options for Individual Portlets 61-20
61.2.5 How to Use Portlet Events 61-21
61.2.5.1 Defining a Portlet Event at the Application Level 61-21
61.2.5.2 Adding a Processing Event to a Portlet 61-22
61.2.5.3 Adding a Publishing Event to a Portlet 61-23
61.2.6 How to Use Public Render Parameters 61-23
61.2.6.1 Defining a Public Render Parameter at the Application Level 61-24
61.2.6.2 Adding a Public Render Parameter to a Portlet 61-25
61.2.7 How to Add Personalization 61-26
61.2.7.1 Adding a Portlet Preference to a Portlet 61-26

61.2.7.2 Simple Portlet Personalization Example 61-27
61.2.8 How to Use Portlet Filters 61-29
61.2.8.1 Adding a Portlet Filter to an Application 61-29
61.2.8.2 Applying a Portlet Filter to a Portlet 61-30
61.2.9 How to Implement Portlet Caching 61-31
61.2.9.1 Implementing Expiry-Based Caching 61-32
61.2.9.2 Implementing Validation-Based Caching 61-33
61.2.10 How to Implement Export of Customizations (WSRP 2.0) 61-34
61.2.11 How to Implement Rewritten URLs for Resource Proxy 61-35
61.2.12 How to Implement Stateless Resource Proxying 61-35
61.2.13 How to Enable Java Object Cache for Preference Store Access 61-36
61.2.14 How to Implement Security for JSR 286 Portlets 61-36
61.3 Enhancing PDK-Java Portlets 61-36
61.3.1 Guidelines for PDK-Java Portlets 61-37
61.3.2 How to Add Portlet Modes 61-37
61.3.3 How to Implement Public Parameters 61-38
61.3.4 How to Implement Private Parameters 61-43
61.3.4.1 About Private Parameters 61-43
61.3.4.2 About Portlet URL Types 61-44
61.3.4.3 Building Links with the Portlet URL Types 61-45
61.3.4.4 Building Forms with the Portlet URL Types 61-46
61.3.4.5 Implementing Navigation within a Portlet 61-48
61.3.4.6 Restricting Navigation to Resources 61-51
61.3.5 How to Use JNDI Variables 61-51
61.3.5.1 Declaring JNDI Variables 61-52
61.3.5.1.1 Variable Types 61-52
61.3.5.1.2 Variable Naming Conventions 61-52
61.3.5.1.3 Examples 61-53
61.3.5.2 Setting JNDI Variable Values 61-53
61.3.5.3 Retrieving JNDI Variables 61-54
61.3.6 How to Access Session Information 61-55
61.3.7 How to Enhance Portlet Performance with Caching 61-58
61.3.7.1 Activating Caching 61-60
61.3.7.2 Adding Expiry-Based Caching 61-60
61.3.7.3 Adding Validation-Based Caching 61-61
61.4 Testing Portlet Personalization 61-61
61.5 Creating a Struts Portlet 61-61
61.5.1 How to Create a New Flow and View to Host the Portlet Actions 61-63
61.5.2 How to Create the New JSPs 61-64
61.5.3 How to Create a Portlet 61-64
61.5.4 How to Extend the Portlet to Add Business Logic 61-65
61.5.5 How to Register the Producer 61-65

62 Testing and Deploying Your Portlets

62.1 Introduction to Portlet Deployment Testing in a Development Environment 62-1
62.2 Testing a Portlet Producer Application on Integrated WebLogic Server 62-2
62.2.1 How to Test JSR 286 Portlets on Integrated WebLogic Server 62-3

62.2.2 What Happens When You Test JSR 286 Portlets on Integrated WebLogic Server ... 62-4
62.2.3 How to Test PDK-Java Portlet Producer Applications on Integrated WebLogic Server . 62-5
62.2.4 What Happens When You Test PDK-Java Portlet Producer Applications on Integrated WebLogic Server ... 62-7
62.3 Deploying a Portlet Producer Application to an Oracle WebLogic Managed Server Instance ... 62-7
62.3.1 How to Create Deployment Profiles ... 62-8
62.3.1.1 Creating a WAR Deployment Profile ... 62-8
62.3.1.2 Creating a Deployment Descriptor ... 62-10
62.3.2 How to Create and Provision a WebLogic Managed Server Instance ... 62-10
62.3.3 How to Create and Register the Metadata Service Repository ... 62-10
62.3.4 How to Create a WebLogic Managed Server Connection ... 62-10
62.3.5 How to Deploy a Portlet Producer Application to an Oracle WebLogic Managed Server Instance ... 62-11
62.3.6 What Happens When You Deploy a Portlet Producer Application to an Oracle WebLogic-Managed Portlet Server ... 62-12
62.4 Registering and Viewing Your Portlet ... 62-13

63 Creating Pagelets with Oracle WebCenter Portal's Pagelet Producer

63.1 About Server Communication and the Proxy ... 63-2
63.1.1 The Pagelet Producer Proxy ... 63-2
63.1.1.1 About Pagelets and the Proxy ... 63-3
63.1.2 About HTTP and CSP ... 63-4
63.1.2.1 HTTP ... 63-4
63.1.2.2 CSP ... 63-5
63.2 Using Pagelets in Web Applications ... 63-5
63.2.1 Adding a Pagelet to a JSF Page in Oracle JDeveloper ... 63-6
63.2.1.1 Registering the Pagelet Producer with a WebCenter Portal: Framework Application ... 63-6
63.2.1.2 Adding a Pagelet to a JSF Page ... 63-7
63.2.1.3 Securing a Pagelet ... 63-8
63.2.2 Adding a Pagelet to a Web Page ... 63-8
63.2.2.1 Inserting Pagelets Using Javascript ... 63-8
63.2.2.1.1 Adding a Preference Editor Using Javascript ... 63-9
63.2.2.2 Accessing Pagelets Using REST ... 63-10
63.2.2.2.1 Pagelet Inject API ... 63-11
63.2.2.2.2 Data Retrieval APIs ... 63-13
63.2.2.3 Using Automatic Resizing with IFrames ... 63-14
63.2.3 Adding a Pagelet to a Page in WebCenter Portal: Spaces ... 63-15
63.3 Building Pagelets Using the Pagelet Producer ... 63-16
63.3.1 Using the Adaptive Pagelet Scripting Framework ... 63-16
63.3.1.1 Handling Structured HTTP Responses ... 63-17
63.3.1.2 Using Event Notification ... 63-19
63.3.1.2.1 Page-Level Events for Use with the Scripting Framework ... 63-23
63.3.1.3 Using In-Place Refresh ... 63-24
63.3.1.4 Using Session Preferences ... 63-25

63.3.1.5 Adaptive Pagelet Development Tips 63-27
63.3.2 Using Pagelet Producer Credential Mapping 63-28
63.3.3 Modifying Pagelet Functionality at Runtime 63-31
63.3.3.1 Creating Web Injectors 63-31
63.3.3.2 Creating Custom Parsers 63-33
63.3.4 Debugging Pagelets 63-34
63.3.4.1 HTTP Tracing 63-34
63.3.4.2 Transformation Tracing 63-36
63.4 Working with WSRP and Oracle JPDK Portlets 63-37
63.4.1 Using Pagelet Chrome 63-37
63.5 Working with OpenSocial Gadgets 63-38
63.5.1 Configuring Authentication 63-39
63.5.2 Storing User Preferences 63-39
63.5.3 Accessing WebCenter Portal Profile Information 63-39
63.5.4 Accessing a User's Activity Stream 63-40
63.5.5 Using Gadget Eventing 63-41
63.5.6 Example: Consuming an External OpenSocial Gadget 63-41
63.5.7 Example: Consuming a Local OpenSocial Gadget 63-41

64 Consuming Portlets

64.1 Introduction to Consuming Portlets 64-1
64.2 Registering Portlet Producers with a WebCenter Portal: Framework Application 64-2
64.2.1 How to Register a WSRP Portlet Producer 64-3
64.2.2 How to Map a Producer's Declared User Categories to an Application's Defined Java EE Security Roles 64-10
64.2.3 How to Register an Oracle PDK-Java Portlet Producer 64-11
64.2.4 How to Edit Portlet Producer Registration Settings 64-15
64.2.5 How to Test a Portlet Producer Connection 64-16
64.2.6 How to Refresh a Portlet Producer 64-16
64.2.7 How to Delete a Portlet Producer 64-16
64.3 Adding Portlets to a Page 64-17
64.3.1 How to Add a Portlet to a Page 64-17
64.3.2 What Happens When You Add a Portlet to a Page 64-18
64.3.3 What Happens at Runtime 64-20
64.4 Setting Attribute Values for the Portlet Tag 64-21
64.4.1 How to Set Attribute Values for the Portlet Tag Using the Property Inspector 64-22
64.4.2 How to Set Attribute Values for the Portlet Tag in Source Code 64-22
64.4.3 Common Attributes of the Portlet Tag 64-23
64.4.4 Appearance Attributes of the Portlet Tag 64-25
64.4.5 Behavior Attributes of the Portlet Tag 64-28
64.4.6 Portlet Modes Attributes of the Portlet Tag 64-29
64.4.7 Style Attributes of the Portlet Tag 64-30
64.4.8 Binding Attributes of the Portlet Tag 64-31
64.4.9 Customization Attributes of the Portlet Tag 64-31
64.4.10 Other Attributes of the Portlet Tag 64-31
64.4.11 What You May Need to Know About Maximize, Minimize, Restore, and Move 64-32
64.4.12 What You May Need to Know About IFRAMEs 64-33

64.5 Copying Portlets 64-34
64.5.1 How to Copy a Portlet and Place it on the Same Page 64-34
64.5.2 How to Copy a Portlet from One Application Page to Another 64-36
64.6 Deleting Portlets from Application Pages 64-38
64.7 Consuming WebCenter Services Portlets 64-39
64.7.1 Consuming WebCenter Services Portlets in Oracle Portal 64-40
64.7.2 Consuming WebCenter Services Portlets in Oracle WebLogic Portal 64-40
64.7.3 Consuming WebCenter Services Portlets in Oracle WebCenter Interaction 64-40
64.7.4 Setting WebCenter Services Portlets Parameters 64-41
64.7.4.1 Common WebCenter Services Portlets Parameters 64-42
64.7.4.2 Document Manager Portlet Parameters 64-42
64.7.4.3 Discussion Forums Portlet Parameters 64-43
64.7.4.4 Blogs Portlet Parameters 64-44
64.7.4.5 Lists Portlet Parameters 64-44
64.7.4.6 Polls Manager Portlet Parameters 64-44
64.7.4.7 Take Polls Portlet Parameters 64-45
64.7.4.8 Worklist Portlet Parameters 64-45
64.7.4.9 Announcements Portlet Parameters 64-45
64.7.4.10 Mail Portlet Parameters 64-45
64.7.4.11 Activity Stream Portlet Parameters 64-45
64.7.4.12 Tag Cloud Portlet Parameters 64-47
64.8 Adding the Portlet Producer Task Flow 64-47
64.9 Troubleshooting Portlets 64-48
64.9.1 Diagnostic Tools for Troubleshooting Portlets 64-48
64.9.1.1 Identify the Portlet Instance 64-49
64.9.1.2 Examine the Portlet Consumer Test Page 64-50
64.9.1.2.1 Access the Portlet Consumer Test Page 64-51
64.9.1.2.2 Locate the Portlet Producer 64-52
64.9.1.2.3 Locate and Run the Portlet Instance 64-52
64.9.1.2.4 Perform Sanity Checks 64-53
64.9.1.2.5 Check Consumer Configuration Entries 64-54
64.9.1.3 Examine the Producer Test Page 64-54
64.9.1.3.1 Access the Producer Test Page 64-56
64.9.1.3.2 Run the JSF Portlet as a Servlet 64-56
64.9.1.3.3 Examine the SOAP Monitor 64-56
64.9.2 Configuring the Portlet Logging File 64-57
64.9.3 Portlet Displays a Portlet Consumer Error 64-59
64.9.4 Portlet Displays a Portlet Timeout 64-59
64.9.5 Portlet Displays a Remote Portlet Communication Error 64-61
64.9.6 Portlet Displays a Remote Portlet Error 64-62

65 Creating Portlets with OmniPortlet

65.1 Introduction to OmniPortlet 65-1
65.2 Adding OmniPortlet to Your Application 65-2
65.3 Customizing OmniPortlet 65-3
65.4 Troubleshooting OmniPortlet Problems 65-4

66 Creating Content-Based Portlets with Web Clipping

66.1 Introduction to Web Clipping 66-1
66.2 Adding Web Clipping to Your Application 66-3
66.3 Integrating Authenticated Web Content Using Single Sign-On 66-4
66.4 Advanced Features of Web Clipping 66-6
66.4.1 Using the Web Clipping Transport API 66-7
66.4.1.1 Implementing the Web Clipping Transport API 66-7
66.4.1.2 Deploying the Web Clipping Transport API 66-7
66.4.2 Rewriting Image Links to Use a Resource Proxy 66-8
66.5 Current Limitations of Web Clipping 66-8
66.6 Troubleshooting Web Clipping 66-9

Part XI Delivering Personalized Content

67 Personalizing WebCenter Portal Applications

67.1 Introduction to Personalization 67-1
67.1.1 Personalization Architecture 67-2
67.1.2 Personalization Conductor 67-2
67.1.2.1 Personalized Scenarios 67-2
67.1.2.2 Personalized Application Flow 67-3
67.1.2.3 Property Set Integration 67-3
67.1.2.4 Provider Integration 67-3
67.1.3 Personalization Property Service 67-3
67.1.3.1 Property Service Architecture 67-3
67.1.3.2 Property Sets 67-4
67.1.3.3 Property Locators 67-4
67.1.4 Personalization Providers 67-4
67.1.4.1 Out-of-the-Box Providers 67-5
67.1.4.1.1 Property Service Provider 67-5
67.1.4.1.2 CMIS Provider 67-5
67.1.4.1.3 Activity Graph Provider 67-5
67.1.4.1.4 People Connections Locator 67-6
67.1.4.2 Custom Data Providers 67-6
67.1.4.3 Function Providers 67-6
67.2 Integrating Personalization in Your Application 67-6
67.2.1 Personalization Requirements 67-7
67.2.2 Authoring Personalized Scenarios in JDeveloper 67-7
67.2.2.1 Creating a Properties Namespace 67-8
67.2.2.2 Creating Property Sets and Property Definitions 67-9
67.2.2.3 Creating a New Scenario in the Scenario Editor 67-10
67.2.2.4 Specifying Scenario Flow Using Node Types 67-12
67.2.2.5 Defining Property Sets and Property Locators 67-13
67.2.2.6 Implementing and Calling Function Providers 67-13
67.2.2.7 Implementing and Calling Data Providers 67-14
67.2.2.8 Using the Out-of-the-Box Providers 67-16
67.2.2.8.1 Using the Property Service Provider 67-16

67.2.2.8.2 Using the CMIS Provider 67-16
67.2.2.8.3 Using the Activity Graph Provider 67-19
67.2.3 Creating File-Based Scenarios 67-23
67.2.4 Displaying Targeted Content at Runtime 67-27
67.2.4.1 Presenting Content with Content Presenter 67-27
67.2.4.2 Presenting Content with a Custom User Interface 67-27
67.3 Tutorial: Creating, Testing and Deploying a Simple Application 67-27
67.4 Extending Personalization 67-38
67.4.1 Adding Custom Providers 67-39
67.4.1.1 Extending the AnnotatedConfiguration Class 67-39
67.4.1.2 Implementing the Required Interfaces 67-39
67.4.1.3 Creating the Resource Files 67-47
67.4.1.4 Wiring the Data Provider to the Conductor 67-47
67.4.1.5 Invoking your Data Provider in a Scenario 67-47
67.4.2 Adding Custom Locators 67-48
67.4.2.1 Understanding Property Locators 67-48
67.4.2.2 Implementing the Required Interfaces 67-48
67.4.2.3 Implementing Security 67-49
67.4.2.4 Creating a Property Set Definition 67-49
67.4.2.5 Putting It All Together 67-49
67.4.2.6 Invoking the Property Locator 67-53

68 Using Personalization APIs Externally

68.1 Using Java APIs 68-1
68.2 Using the Property Service REST APIs 68-1
68.2.1 Accessing the Property Service's Resource Index 68-2
68.2.2 Creating a Namespace Using the Property Service 68-2
68.2.3 Viewing Property Set Definitions Within a Namespace Using the Property Service 68-3
68.2.4 Creating a Property Definition Within a Namespace Using the Property Service ... 68-3
68.2.5 Viewing Property Definitions Within a Namespace Using the Property Service 68-3
68.2.6 Creating a Property Set Definition Within a Namespace Using the Property Service 68-3
68.2.7 Creating a Property Set Within a Namespace Using the Property Service 68-3
68.2.8 Viewing a Property Set Within a Namespace Using the Property Service 68-3
68.2.9 Accessing the Conductor ResourceIndex 68-3
68.2.10 Accessing Namespaces Using the Conductor 68-4
68.2.11 Creating a Scenario Within a Namespace Using the Conductor 68-6
68.2.12 Viewing Scenarios Within a Namespace Using the Conductor 68-7
68.2.13 Executing a Scenario Using the Conductor 68-8
68.2.14 Viewing Data Providers Within a Namespace Using the Conductor 68-8
68.2.15 Viewing Detailed Data Provider Properties Within a Namespace Using the Conductor 68-10
68.2.16 Viewing Data Provider Connections Within a Namespace Using the Conductor . 68-12
68.2.17 Viewing Data Provider Connection Resources Within a Namespace Using the Conductor 68-14

68.2.18 Viewing Data Provider Connection Resources Method Within a Namespace Using the Conductor 68-19
68.2.19 Viewing Function Providers Within a Namespace Using the Conductor 68-20
68.3 Property Service REST APIs 68-24
68.3.1 Property Service Resource Index 68-24
68.3.1.1 ResourceIndex 68-24
68.3.2 Namespace CRUD 68-28
68.3.2.1 Create Namespace 68-28
68.3.2.2 Retrieve Namespace 68-30
68.3.2.3 Update Namespace 68-32
68.3.2.4 Delete Namespace 68-34
68.3.2.5 Retrieve all Namespaces 68-34
68.3.2.6 Delete all Namespaces 68-48
68.3.3 Property Definition CRUD 68-49
68.3.3.1 Create Property Definition - Create Integer Property Definition 68-49
68.3.3.2 Create Property Definition - Create Integer Array Property Definition 68-51
68.3.3.3 Retrieve Property Definition 68-54
68.3.3.4 Update Property Definition 68-56
68.3.3.5 Delete Property Definition 68-57
68.3.3.6 Retrieve all Property Definitions 68-58
68.3.3.7 Delete all Property Definitions 68-61
68.3.4 Property Set Definition CRUD 68-61
68.3.4.1 Create Property Set Definition 68-62
68.3.4.2 Retrieve Property Set Definition 68-66
68.3.4.3 Retrieve All Property Set Definitions 68-67
68.3.4.4 Delete all Property Set Definitions 68-68
68.3.5 Property Set CRUD 68-69
68.3.5.1 Create Property Set 68-69
68.3.5.2 Retrieve Property Set 68-75
68.3.5.3 Update Property Set 68-80
68.3.5.4 Delete Property Set 68-83
68.3.5.5 Retrieve all Property Sets 68-84
68.3.5.6 Delete all Property Sets 68-85
68.3.6 Property CRUD 68-86
68.3.6.1 Create Property 68-86
68.3.6.2 Retrieve Property 68-88
68.3.6.3 Update Property 68-90
68.3.6.4 Delete Property 68-91
68.3.6.5 Delete all Properties 68-92
68.3.7 JSON Payload 68-93
68.3.8 Exceptions 68-93
68.3.9 Query Parameters 68-93
68.3.10 Search Expressions 68-94
68.3.10.1 Format 68-94
68.3.10.2 Supported Operators 68-94
68.3.10.3 Supported Attribute Names 68-94
68.4 Using the Conductor REST APIs 68-96
68.4.1 Using the Data Provider Management APIs 68-96

68.4.1.1 Getting a Collection of Data Providers (GET) 68-97
68.4.1.2 Getting a Single Data Provider's Metadata (GET) 68-101
68.4.1.3 Getting Information About a Data Provider Connection (GET) 68-112
68.4.1.4 Getting Information about an Executable Resource for a Data Provider and Connection (GET) 68-115
68.4.1.5 Getting Method Information for an Executable Resource for a Data Provider and Connection (GET) 68-124
68.4.1.6 Getting Entire Data Provider Information with Details Projection (GET) 68-127
68.4.2 Using the Function Provider Management APIs 68-145
68.4.2.1 Getting a Collection of Function Providers (GET) 68-145
68.4.2.2 Getting Metadata for a Single Function Provider (GET) 68-171
68.4.3 Using the Namespace Management APIs 68-173
68.4.3.1 Getting a Collection of Namespaces (GET) 68-173
68.4.3.2 Retrieving a Single Namespace (GET) 68-177
68.4.3.3 Creating a Namespace (POST) 68-179
68.4.3.4 Deleting a Namespace (DELETE) 68-181
68.4.4 Using the Scenario Management APIs 68-182
68.4.4.1 Getting a Collection of Scenarios (GET) 68-182
68.4.4.2 Retrieving a Single Scenario (GET) 68-184
68.4.4.3 Creating a Scenario (POST) 68-187
68.4.4.4 Updating a Scenario (PUT) 68-190
68.4.4.5 Deleting a Scenario (DELETE) 68-193
68.4.4.6 Execute a Scenario (POST) 68-194
68.5 Calling Personalization Client Services Using ELs 68-195
68.5.1 Calling Personalization Client Services from JSF Pages 68-195
68.5.2 Calling Personalization Client Services from JSP Pages 68-196
68.5.3 Personalization Context Object Method Reference 68-196
68.5.4 Enabling Single Sign-on 68-198

Part XII Completing Your WebCenter Portal Application

69 Securing Your WebCenter Portal: Framework Application

69.1 Introduction to WebCenter Portal: Framework Application Security 69-2
69.2 Creating an Application Role 69-2
69.3 Configuring ADF Security 69-3
69.3.1 Configuring ADF Security Settings 69-3
69.3.2 Automated Security Grants for WebCenter Portal Services 69-8
69.4 Using the Role Manager Task Flow 69-16
69.5 Using the Enterprise Role Member Task Flows 69-17
69.6 Using the Page Hierarchy Security Editor 69-17
69.6.1 Introduction to Page Hierarchy Security 69-17
69.6.1.1 Page Hierarchy Model 69-18
69.6.1.2 Page-level and Page Hierarchy Security 69-19
69.6.1.3 Inherited and Delegated Security 69-19
69.6.2 Building a Page Hierarchy 69-20
69.6.2.1 Adding a Page Hierarchy to a Navigation 69-20
69.6.2.2 Adding Pages to a Page Hierarchy 69-20

69.6.2.3 Delegating Security 69-21
69.7 Creating Login Pages and a Login Component 69-22
69.8 Creating a Login Portlet 69-23
69.9 Adding Portlets to a Login Page 69-23
69.10 Creating a Self-Registration Page 69-24
69.10.1 Integrating the Spaces Self-Registration Task Flow 69-24
69.10.2 Building a Custom Self-Registration Page 69-25
69.10.3 Creating a Self-Registration Invitation Page 69-25
69.11 Creating a Reset Password Page 69-26
69.12 Configuring Basic Authentication for Testing Portlet Personalization 69-26
69.13 Working with External Applications 69-27
69.13.1 Using External Applications 69-28
69.13.1.1 Secured Service Connections 69-28
69.13.1.2 Automated Single Sign-On 69-30
69.13.2 Supplying User Credentials 69-31
69.13.3 Managing External Applications 69-31
69.13.3.1 Adding External Application Task Flows 69-32
69.13.3.2 Working with External Applications in Oracle JDeveloper 69-33
69.13.3.2.1 Registering an External Application in Oracle JDeveloper 69-33
69.13.3.2.2 Editing External Application Registration Details in Oracle JDeveloper .. 69-35
69.13.3.2.3 Deleting External Application Registration Details in Oracle JDeveloper 69-36
69.13.3.3 Working with External Applications in Enterprise Manager 69-36
69.13.3.4 Working with External Applications Using WLST 69-36
69.14 Registering Custom Certificates with the Keystore 69-36
69.15 Overriding Inherited Security on Portlets and Customizable Components 69-39
69.15.1 Portlets Security 69-41
69.15.1.1 Defining Security at the Actions Category Level 69-41
69.15.1.2 Defining Security at the Actions Level 69-42
69.16 Identity Propagation Mechanisms 69-44
69.17 Securing Identity Propagation Through WSRP Producers with WS-Security 69-45
69.17.1 Identity Propagation Without WS-Security 69-46
69.17.2 Identity Propagation with WS-Security 69-46
69.17.3 Configuring Security for WSRP Portlets 69-48
69.18 Implementing PDK-Java Portlet Security 69-49
69.18.1 Assumptions 69-49
69.18.2 Introduction to PDK-Java Portlet Security Features 69-49
69.18.2.1 Identity Propagation 69-49
69.18.2.2 Authorization 69-49
69.18.2.3 Message-level Security 69-49
69.18.3 Single Sign-On 69-50
69.18.3.1 External Application 69-50
69.18.3.2 No Application Authentication 69-51
69.18.4 Portlet Security Managers 69-51
69.18.4.1 Implementing Your Own Security Manager 69-52
69.18.5 Message Authentication 69-52
69.18.6 User Input Escape 69-53
69.18.6.1 Default Container Encoding 69-53

69.18.6.2 Escape Methods 69-53
69.19 Troubleshooting Security Issues 69-54
69.19.1 Error Message Appears When Running a Page with a Content Repository Data Control Method Being Consumed 69-54

70 Deploying and Testing Your WebCenter Portal: Framework Application

70.1 Introduction to Oracle WebLogic Servers 70-1
70.2 Deploying a Framework Application to the Integrated WebLogic Server 70-2
70.2.1 Running a Framework Application in the Integrated WebLogic Server 70-3
70.2.2 Deploying a Framework Application to the Integrated WebLogic Server 70-4
70.3 Deploying a Framework Application to a WebLogic Managed Server 70-4
70.3.1 Deployment Roadmap 70-5
70.3.2 Packaging a Framework Application 70-6
70.3.2.1 Packaging Database Connections and Application Security 70-7
70.3.2.1.1 Packaging the Database Connections 70-7
70.3.2.1.2 Packaging Application Security Data 70-9
70.3.2.2 Creating Deployment Profiles 70-10
70.3.3 Preparing the Target Environment for Deployment 70-12
70.3.3.1 Creating and Provisioning an Oracle WebLogic Managed Server Instance 70-12
70.3.3.2 Creating and Registering the Metadata Service Repository 70-12
70.3.3.3 Configuring the Target Environment 70-12
70.3.3.4 Creating a WebLogic Managed Server Connection 70-13
70.3.4 Deploying a Framework application to a Managed Server 70-13
70.3.4.1 Deploying to a Managed Server Using Local Data Sources 70-14
70.3.4.2 Deploying to a Managed Server Using Global Data Sources 70-20
70.4 Transporting Customizations Between Environments 70-24

71 Building Multilanguage Portals

71.1 Language Support in ADF Faces Components 71-2
71.2 Using Resource Bundles to Support Multiple Languages 71-2

Part XIII Appendixes

A Files for WebCenter Portal: Framework Applications

A.1 About Files A-1
A.2 Files Overview A-2
A.3 Files Related to WebCenter Portal: Framework Applications A-2
A.3.1 catalog-registry.xml A-2
A.3.2 default-catalog.xml A-3
A.3.3 default-navigation-model.xml A-3
A.3.4 index.html A-3
A.3.5 navigation-registry.xml A-3
A.3.6 pages.xml A-3
A.3.7 error.jspx A-3
A.3.8 home.jspx A-3
A.3.9 login.jspx A-3

A.3.10 navigation-renderer.jspx A-4
A.3.11 pageTemplate_globe.jspx A-4
A.3.12 pageTemplate_swooshy.jspx A-4
A.4 Files Related to JSR 286 Portlets A-4
A.4.1 portlet.xml A-4
A.4.2 oracle-portlet-tags.jar A-6
A.4.3 portlet_mode.jsp A-6
A.4.4 portlet_name.java A-7
A.4.5 portlet_nameBundle.jar A-7
A.4.6 web.xml A-7
A.5 Files Related to PDK-Java Portlets A-7
A.5.1 producer_name.properties A-7
A.5.2 _default.properties A-8
A.5.3 index.jsp A-8
A.5.4 portlet_name_modePage.jsp A-8
A.5.5 provider.xml A-8
A.5.5.1 provider.xml Syntax A-9
A.5.5.2 provider.xml Sample A-9
A.5.6 web.xml A-9
A.6 System Files A-10
A.6.1 adf-config.xml A-10
A.6.2 DataBindings.cpx A-13
A.6.3 faces-config.xml A-13
A.6.4 page_name.jspx A-13
A.6.5 PageDef.xml A-13
A.6.6 trinidad-config.xml A-15
A.6.7 web.xml A-15
A.6.8 weblogic-application.xml A-15
A.6.9 mds Subdirectory A-15
A.6.10 wsdl Subdirectory A-15
A.7 Files Related to Security A-16
A.7.1 connections.xml A-16
A.7.2 jazn-data.xml A-20
A.7.3 cwallet.sso A-22
A.7.4 jps-config.xml A-22
A.7.5 adf-config.xml A-22
A.8 Oracle JDeveloper Files A-23
A.8.1 pagetemplate-metadata.xml A-23
A.9 Files Related to Oracle WebCenter Portal Services A-23

B Composer Component Properties and Files

B.1 Composer Component Properties B-1
B.1.1 Page Customizable B-2
B.1.2 Change Mode Link and Change Mode Button B-5
B.1.3 Layout Customizable Component B-7
B.1.4 Panel Customizable Component B-11
B.1.5 Show Detail Frame Component B-17

B.1.6 Custom Action B-24
B.1.7 Show Property B-27
B.2 Composer-Specific Files and Configurations B-30

D Guidelines for Creating Task Flows to Be Used in Composer-Enabled Pages

D.1 Guidelines for Effective Geometry Management and Pagination D-1
D.1.1 Guideline 1: Create Task Flows that Flow D-2
D.1.1.1 Example 1: Oracle ADF Faces Table Component with Its autoHeightRows Attribute Set to a Specific Value D-2
D.1.1.2 Example 2: Oracle ADF Faces Iterator Component Inside a Panel Group Layout with a Scrolling Layout D-3
D.1.2 Guideline 2: Limit the Number of Records Displayed in a Task Flow D-3
D.1.3 Guideline 3: Specify a Minimum Height for the Task Flow D-5
D.1.4 Guideline 4: Include UI for Accessing Data Beyond the Display Limit D-5
D.2 Guidelines for Efficient Use of Task Flow Parameters and Customization and Personalization Options D-7
D.2.1 Guidelines for Implementing Task Flow Parameters D-10

D.2.2 Guidelines for Implementing Customization D-10
D.2.3 Guidelines for Implementing Personalization D-11
D.2.4 Guidelines for Implementing Implicit Personalization D-11
D.3 Example of a Framework Application Containing a Task Flow Created By Following the Guidelines D-12

Glossary

Index

Preface

This guide explains how to build portal applications using WebCenter Portal: Framework and provides in-depth information for all of the following tasks:

- How to set up and prepare your development environment for portal development, including iterative and round-trip development.
- How to plan, build, deploy, and manage a Framework application.
- How to secure, administer, monitor, and maintain a Framework application and all of its associated components.
- How to develop custom navigation user interfaces for a portal.
- How to prepare an application for, configure, and integrate Oracle WebCenter Portal services.
- How to integrate content into a Framework application.
- How to deliver personalized content to a Framework application.
- How to plan, build, deploy, and manage portlets for a Framework application.

> **Note:** For the portable document format (PDF) version of this manual, when a URL breaks onto two lines, the full URL data is not sent to the browser when you click it. To get to the correct target of any URL included in the PDF, copy and paste the URL into your browser's address field. In the HTML version of this manual, you can click a link to directly display its target in your browser.

Audience

This guide assumes the audience has already read and performed the steps in the Oracle Fusion Middleware Tutorial for Oracle WebCenter Portal Developers.

This manual is written for all of the following developers:

- The developer who wants to build a WebCenter Portal: Framework application or integrate Oracle WebCenter Portal functionality to their application.
- The component developer, who wants to build portlets from Oracle WebCenter Portal services.

This guide also assumes that the audience has already read the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* and is familiar with the following technologies:

- Java

- Oracle JDeveloper
- JavaServer Faces
- Oracle Application Development Framework (Oracle ADF) (purpose, basic architecture, basic development skills)
- Oracle ADF Faces components
- Oracle WebLogic Server

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

Related Documents

For more information, see the following documents in the Oracle Fusion Middleware 11*g* Release 1 (11.1.1.6.2) documentation set or on Oracle Technology Network (OTN) at http://www.oracle.com/technology/index.html.

- *Oracle Fusion Middleware Tutorial for Oracle WebCenter Portal Developers*
- *Oracle Fusion Middleware Tutorial for Oracle WebCenter Portal: Spaces*
- *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- *Oracle Fusion Middleware Error Messages Reference*
- *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*

Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
`monospace`	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

What's New

What's new in Release 11.1.1.6? Faster performance, simplified connection interfaces, and enhanced design-time experience to name a few. Read this quick-reference page for a concise summary of what's new in this release and for pointers to more detailed information.

Note: Release 11.1.1.6.0 is part of a *patch set*. A patch set is a single-installation collection of patches that are designed to be applied together. Patching involves copying a small collection of files over an existing installation.

A patch is normally associated with a particular version of an Oracle product and involves updating from one minor version of the product to a newer minor version of the same product (for example, from Release 11.1.1.5.0 to Release 11.1.1.6.0).

All users must install the Release 11.1.1.6.0 patch set for continued support.

New Features for Release 11.1.1.6

The following table lists and describes new features in this release and provides links to more detailed information in our guides.

Feature	Description	For More Information, See…
Blogs	More special characters allowed in blog names: ■ When you create a blog, you can now use the following special characters in blog names in addition to letters and numbers: ? \ / : [ ] * ' " | Enhanced commenting: ■ Commenting is now available when you view the list of blog entries and not on just the entry itself.	■ "Working with Blogs," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

Feature	Description	For More Information, See…
Certification	More technologies certified against the WebCenter Portal application platform: ▪ Microsoft Lync 2010 for IMP ▪ WebSphere Application Server V7 ▪ Internet Explorer 9 Browser ▪ Chrome Browser 10 and chrome support ▪ Microsoft Office 2010 on Windows XP (32-bit and 64 bit)	▪ "Microsoft Lync Prerequisites," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* ▪ Oracle Fusion Middleware Supported System Configurations page at `http://www.oracle.com/technology/software/products/ias/files/fusion_certification.html`. ▪ "Working with Microsoft Office and Explorer Integration," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Discussions service	▪ Discussions task flows are streamlined for greater ease of use.	▪ "Working with the Discussions Service," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Documents service	▪ Follow a clearer set of steps to connect to the Oracle WebCenter Content repository. ▪ Upload multiple files from your desktop by drag and drop. ▪ Select and upload multiple files from the Document Explorer in one step. ▪ View file upload progress. ▪ Share documents more easily. ▪ Perform in-context workflow approval. Approver can view and approve or reject unreleased content from the contribution mode without needing to enter edit mode. ▪ Enter contribution approval mode on a page with content (either HTML or Site Studio) in a workflow. View and approve or reject unreleased content from contribution approval mode without entering edit mode.	▪ "Managing Content Repositories," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* ▪ "Configuring the Documents Service Content Repository Connection," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* ▪ "Uploading New Files," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ "Working with the Documents Service Task Flows and Document Components," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ "Publishing Content Using Content Presenter," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ "Approving or Rejecting a File in a Workflow," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Events service	▪ Task flows are streamlined to enhance usability. For example, users can now view links to events from both calendar and list views.	▪ "Working with the Events Service," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

Feature	Description	For More Information, See…
Notifications	▪ Subscription messages now use IMIP rather than iCal for notifications about events. Consequently, event notifications are added automatically to your Outlook Calendar, without your having to open the notification attachment and add it yourself.	▪ "Subscribing to Events," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Pagelet Producer	More robust Pagelet Producer: ▪ Use SharePoint web parts, including those requiring Kerberos authentication. ▪ Includes support for logging of HTTP traffic between a proxy and a resource. ▪ Added detailed pagelet debug logging. ▪ Available as a unified producer for non-standards-compliant web applications. ▪ Enables consumption of gadgets from other OpenSocial containers, such as iGoogle, and exposure of them as pagelets that can be consumed by WebCenter Portal sites, other Oracle portals, or Oracle Web Content Management for WebCenter sites. ▪ Enables production of OpenSocial gadgets and exposure of all existing pagelets as gadgets.	▪ Chapter 63, "Creating Pagelets with Oracle WebCenter Portal's Pagelet Producer" ▪ "Managing the Oracle WebCenter Portal's Pagelet Producer," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
Pages	▪ New Administrator-level **Delete Personalization** option enables removal of all users' customizations from business role pages or personal pages in one step. ▪ New system pages are available to support viewing and managing application metrics, space memberships, spaces, and space templates. ▪ The **Subscribe** system page is now named **Self-Service Membership** to more-closely reflect its use case.	▪ "Removing All User Customizations from a Business Role Page," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ "Removing All User Customizations from a Personal Page," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ "Working with System Pages," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Performance	Accelerated performance at design time and runtime: ▪ Experience faster initial page downloads. ▪ Forgo session creation for unauthenticated users. ▪ Realize faster creation times for WebCenter Portal: Framework applications.	—

Feature	Description	For More Information, See…
Portlet producers	▪ New Enterprise 2.0 portlet producer is available for exposing task flows from WebCenter Portal services as portlets. Integrate portlets with WebCenter Portal applications, Oracle WebLogic Portal, and Oracle WebCenter Interaction. The new Enterprise 2.0 portlet producer is certified with WebSphere, MySQL, Internet Explorer 9, and Chrome 10.	▪ Chapter 58, "Overview of Portlets" ▪ Section 64.7, "Consuming WebCenter Services Portlets" ▪ "Configuring the E2.0 Portlet Producer," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
Publisher	▪ Upload multiple files at once through the Publisher task flow.	▪ "Sharing Files Through the Publisher Task Flow," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Search service	▪ There are more task flow parameters to limit the scope of searches. Administrators can narrow the scope of searches to specific spaces, services, and document types. They also can add attributes to the list of standard attributes returned with each search result item, and they can hide standard refiners available to users with search results. ▪ You can now build portals using a navigation model that enables SES and public search engines, such as Google and Bing, to crawl and index the full text content of pages.	▪ "Working with the Search Service," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ▪ Chapter 11, "Building a Navigation Model for Your Portal" ▪ Chapter 45, "Integrating the Search Service" ▪ "Managing Oracle SES Search in WebCenter Portal," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
Security	▪ Support is available for an OAuth2 Provider in an OAuth client. ▪ Support is available for dynamically determining group membership via integration with Oracle Entitlements Server.	▪ Chapter 69, "Securing Your WebCenter Portal: Framework Application" ▪ "Managing WebCenter Portal Application Security," in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* ▪ "Understanding Security," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

Feature	Description	For More Information, See…
Tags service	■ We have updated the edit tags user interface in the Document Explorer task flow. ■ The Tags button component and the Edit Tags task flow have a new parameter that enables developers to disable the Shared control. ■ The previously-named "Tag Cloud" task flow is now called the "Tag Selection" task flow; and a new standalone Tag Cloud task flow is available in the design-time catalog.	■ "Working with the Tags Service," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* ■ Chapter 44, "Integrating the Tags Service"
Wikis	■ Access wiki creation features with greater ease: Use a **New Wiki Document** button in a Documents service task flow or in the wiki itself. ■ Experience improved performance in loading wikis, launching the wiki editor, and saving changes to your wiki.	■ "Creating a Wiki Document Using the New Wiki Document Action," in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

Part I

Introduction

Part I contains the following chapters:

- Chapter 1, "Developer's Quick Start Guide"
- Chapter 2, "Understanding Oracle WebCenter Portal"
- Chapter 3, "Preparing Your Development Environment"
- Chapter 4, "Working Productively in Teams"
- Chapter 5, "Creating Framework and Portlet Producer Applications"
- Chapter 6, "Advanced Configuration Options"
- Chapter 7, "Preparing Your Application for WebCenter Portal Services"
- Chapter 8, "Introducing the AviTrust Portal Framework Sample Application"

1 Developer's Quick Start Guide

As a developer, if you are preparing to build a WebCenter Portal: Framework application for the first time, you need a good roadmap that shows you where to start and helps guide your initial experience. This chapter provides guidance, best practices, and tips for Framework application developers setting up their development environment for the first time.

> **Tip:** If you are just getting started, we recommend that you look at Section 1.1, "WebCenter Portal Developer's FAQ" first.

This chapter includes the following sections:

- Section 1.1, "WebCenter Portal Developer's FAQ"
- Section 1.2, "Installing Required Software"
- Section 1.3, "Preparing for Team Development"
- Section 1.4, "Creating a New Framework Application"
- Section 1.5, "Preparing for Iterative Development"
- Section 1.6, "Creating Application Resource Connections"
- Section 1.7, "Planning the Portal Layout"
- Section 1.8, "Working with Skins"
- Section 1.9, "Preparing for Round-Trip Development"
- Section 1.10, "What Configuration Files Should I Know About?"
- Section 1.11, "Installing Database Schemas"

1.1 WebCenter Portal Developer's FAQ

Table 1–1 addresses basic questions to help you get started with Framework application development.

> **Tip:** Before you begin to design and build a Framework application, we recommend that you read Chapter 9, "Understanding Framework Applications." This chapter presents an overview of Oracle WebCenter Portal: Framework, and provides tips and links to more detailed information.

Table 1–1 WebCenter Portal Developer's FAQ

Question	Answer
What software do I need to install before getting started?	At a minimum, you need Oracle JDeveloper and the WebCenter Portal extension for Oracle JDeveloper (a JDeveloper add-in that includes WebCenter Portal functionality). Typical portal environments also include database, content repository, and search engine installations. See Section 1.2, "Installing Required Software."
How do I set up source control for my team?	JDeveloper can integrate with a variety of source control systems. See Section 1.3, "Preparing for Team Development."
What can I do to increase my team's productivity?	The best way to improve your team's productivity is by enabling **iterative development**. With iterative development enabled, you can see portal file changes updated in runtime by simply refreshing the browser. See Section 1.5, "Preparing for Iterative Development."
How do I create a new Framework application?	WebCenter Portal provides an out-of-the-box template that creates a pre-configured Framework application for you. This basic portal application includes all of the features you need to get started including a default set of pages, out-of-the-box page templates, and navigation. See Section 1.4, "Creating a New Framework Application."
The default Framework application includes files and features I do not intend to use. Can I remove them?	Yes, you can add and remove Framework application components. For more information, see Section 6.1, "Manually Configuring a Framework Application With Technology Scopes."
How do I make database and content repository connections?	JDeveloper provides a connection wizard that lets you create these kinds of connections. These connections seamlessly integrate with certain components that you may use in a portal, like the Content Presenter task flow. See Chapter 27, "Managing Content Repository Connections."
I'd like to create a highly customized navigation UI for my portal. Is that possible?	Yes, you can control all aspects of how the navigation UI is rendered using the APIs provided by WebCenter Portal: Framework. A popular technique is to use EL to customize how the navigation UI is rendered. For example, you can hide certain links based on the user's role or change the look and feel of a link based on specified criteria. For more information, see Chapter 14, "Visualizing Your Portal Navigation."
How is portal security configured by default?	By default, a Framework application is configured with ADF security. A default username and password (weblogic/weblogic1) are created automatically for you, and you can use this username/password combination for testing purposes immediately. See also Chapter 69, "Securing Your WebCenter Portal: Framework Application."
How do I customize the way content is displayed in my portal?	One common technique is to use the Content Presenter task flow. Content Presenter lets you add content to a page and customize the way the content is displayed using templates. For more information, see Chapter 26, "Introduction to Integrating and Publishing Content."
How do I create a consistent layout for the pages in my portal?	The page template feature allows you to create a layout that any page in your portal can share. In addition to the basic page layout, you can also add features like navigation user interfaces to the template. See Section 1.7, "Planning the Portal Layout."
There are so many ADF components. How do I figure out which ones to use?	WebCenter Portal: Framework provides the WebCenter Portal – Framework Catalog. This catalog includes a collection of components commonly used for building portals. For more information, see Chapter 16, "Creating and Managing Resource Catalogs."
I'd like to change the default skin. How do I do that?	A skin is a style sheet that defines the look of your portal. WebCenter Portal: Framework provides a portal skin that you can conveniently edit in JDeveloper. For more information, see Section 1.8, "Working with Skins."

Table 1–1 (Cont.) WebCenter Portal Developer's FAQ

Question	Answer
Can developers modify or add new portal features that have been deployed into production?	WebCenter Portal provides a solution for round-trip development. See Section 1.9, "Preparing for Round-Trip Development."
What do I need to know about moving the portal from the development environment to the testing, staging, and production environments?	The portal life cycle describes the path a portal takes from development and testing environments to a staging environment and, ultimately, a production environment. For detailed information on managing the life cycle, see Chapter 10, "Understanding the WebCenter Portal Life Cycle."
Where can I get more background information on developing Framework application?	We recommend that you review Chapter 9, "Understanding Framework Applications." This chapter presents an overview of Oracle WebCenter Portal: Framework, and provides tips and links to more detailed information.

1.2 Installing Required Software

A typical development environment includes these components:

- **JDeveloper** – See Section 3.1, "Installing Oracle JDeveloper."
- **WebCenter Portal's Extension for Oracle JDeveloper** – See Section 3.2, "Installing WebCenter Portal's Extension for Oracle JDeveloper."
- **Supported Database** – (Optional) For example Oracle Database 11g.
- **Supported Content Repository** – (Optional) For example, Oracle WebCenter Content 11g.
- **Search Engine** – (Optional) For example, Oracle Secure Enterprise Search (SES).

See also the *Oracle Fusion Middleware Installation Guide for Oracle WebCenter Portal*.

1.3 Preparing for Team Development

It's important to consider the overall **team development environment**. To be useful, a team development environment must be configured to allow developers to share common resources, like databases, content repositories, and source code. A well-planned team environment allows you to quickly and consistently develop, build, and update your WebCenter Portal: Framework applications.

> **Tip:** Typically, one member of the development team creates a new Framework application and checks it in to the source code repository. You can create any required database or content repository connections and check those in as well.

For more detailed information on team development topics like source control and file sharing, see Chapter 4, "Working Productively in Teams."

1.4 Creating a New Framework Application

WebCenter Portal: Framework provides a wizard for creating new portal applications. The wizard uses an out-of-the-box **WebCenter Portal – Framework Application** template that ensures the appropriate application components are included.

After the Framework application is created, you can then configure database and content repository connections and check those in to the source control system as well.

If you wish, you can manually configure the Framework application. For example, you might decide to remove some components from the framework application if you know you will never need them.

For detailed information on creating, extending, and modifying Framework applications, see Chapter 5, "Creating Framework and Portlet Producer Applications." For more information on managing connections, see Section 1.6, "Creating Application Resource Connections."

1.5 Preparing for Iterative Development

This section discusses WebCenter's iterative development feature.

- Section 1.5.1, "What Is Iterative Development?"
- Section 1.5.3, "Enabling Iterative Development"
- Section 1.5.4, "Turning Off Iterative Development"

1.5.1 What Is Iterative Development?

Iterative development lets you make changes to your Framework application while it is running on the Integrated WebLogic Server and immediately see the effect of those changes simply by refreshing the current page in your browser. The iterative development feature works by disabling certain optimization features. Iterative development allows developers to work more quickly and efficiently when building a Framework application.

For example, iterative development lets you see changes to these components almost instantly upon a browser refresh:

- page definitions
- navigation model
- page hierarchy
- existing JSPX files
- page templates
- resource catalog
- addition of task flows to pages
- addition of portlets to pages

The following kinds of operations are not supported by iterative development. These operations require you to re-run the application:

- creating any *new* file explicitly (JSPX, page definition, page hierarchy, and so on)
- creating a new file implicitly. For instance, when you add a sub-page to a node in the page hierarchy, a new `*pages.xml` file is created.
- editing any configuration file, like `web.xml` or `adfc-config.xml`.

1.5.2 How Does Iterative Development Work?

Iterative development works by turning off certain MDS and runtime layer caches. Because these performance optimization features are disabled, you might notice some slower performance when running your application in a development environment.

Note: When an application is deployed to the Integrated WebLogic Server, the `org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION` flag is automatically set to `true` in the `web.xml` file on the server. This setting causes the server to automatically check the modification time of your JSP and skinning CSS files, and discard saved state when they change. This configuration occurs whether or not the iterative development feature is enabled.

When iterative development is enabled, the following changes to application configuration occur:

- The MDS Cache size is set to `0`. This setting causes all metadata files to be re-loaded on each request.
- The Navigation Model cache is invalidated on each request.

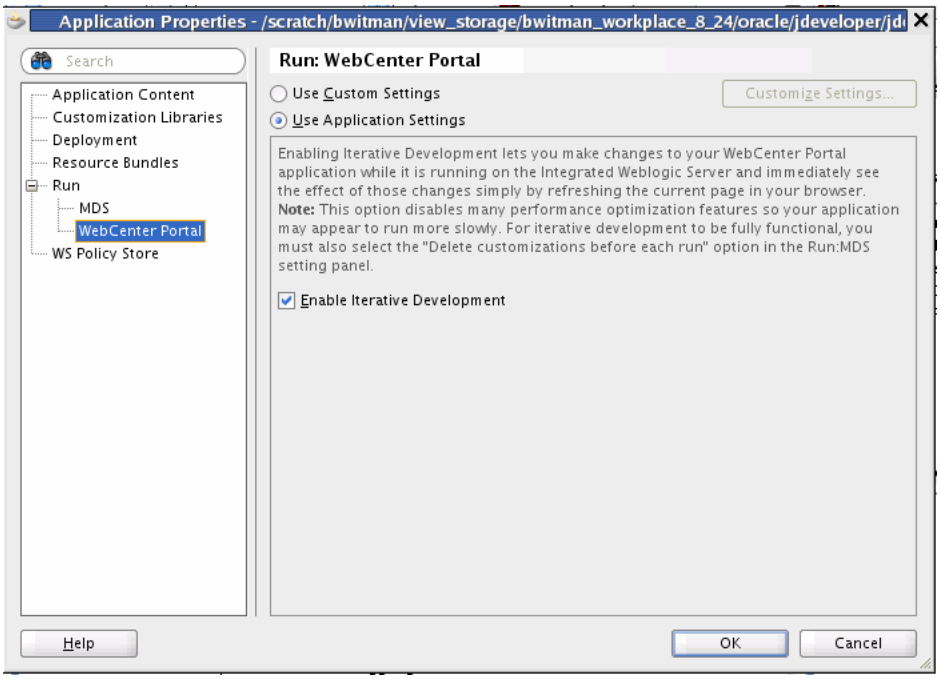
For skin development, you can set the application to use uncompressed skins. This setting is not the default and should only be used in a development environment. You can update `web.xml` to enable this functionality with the following context parameter:

```
<context-param>
    <param-name>org.apache.myfaces.trinidadinternal.DISABLE_CONTENT_COMPRESSION</param-name>
    <param-value>true</param-value>
</context-param>
```

Note: When consuming Oracle JSF Portlet Bridge Portlets in your application, ADF attempts to share the skin between the consumer and producer. Therefore, if you are disabling compression on the consumer, you should also do that on the producer. Otherwise, the producer will not generate the correct code to match the uncompressed IDs generated by the consumer. See also Chapter 59, "Creating Portlets with the Oracle JSF Portlet Bridge."

Note that if you edit the base definition (source) of a resource at runtime while the portal is running in the Integrated WebLogic Server, iterative development will not work as expected: if you edit the resource file in JDeveloper and save, you will not see the change when the running page is refreshed. The reason is because when a resource is edited at runtime at the base document level in the Integrated WebLogic Server, a *copy* of the resource's base document is created in the MDS write directory. From that point forward, this copied version will be used, and the version of the base document in JDeveloper will be ignored. If you run into this issue and want to pick up changes made to the file in JDeveloper, you will need to re-run the application after taking the following steps:

1. In the Application Navigator, click the **Application Menu** icon next to your application's name and choose **Application Properties**.
2. In the Application Properties dialog, expand the **Run** node in the left pane, then select **MDS**.
3. In the right pane, select **Delete customizations before each run**. Doing so clears the MDS of any runtime customizations every time the application is run.
4. Click **OK**.



1.5.3 Enabling Iterative Development

This section explains how to enable iterative development, if it has been disabled.

> **Note:** The iterative development feature is enabled by default when you create a new Framework application.

1. Select **Application Properties** from the Application menu.
2. Along the left side of the Application Properties dialog, expand the **Run** node.
3. Select **WebCenter Portal**.
4. Select **Enable Iterative Development**, as shown in Figure 1–1.

Figure 1–1 Enabling Iterative Development

5. Click **OK**.

1.5.4 Turning Off Iterative Development

This section explains how to turn off iterative development. Iterative development is enabled by default; however, it's a good practice to turn off iterative development for testing purposes before you deploy your application to a production server.

1. Select **Application Properties** from the Application menu.
2. Along the left side of the Application Properties dialog, expand the **Run** node.
3. Select **WebCenter Portal**.
4. Unselect **Enable Iterative Development**.
5. Click **OK**.

1.6 Creating Application Resource Connections

Connections allow the Framework application to access external data and services. For example, if you wish to use the Content Presenter task flow to display content from an Oracle WebCenter Content Server repository, you need to configure a connection to the repository. If you intend to consume portlets from a portlet producer, you need to configure the producer connection.

> **Tip:** A good practice is to create and test your connections once and check them into your source control system. Then, other developers on your team can check out the connections and use them. This technique also allows your team to keep in sync whenever a connection changes.

This section describes the different ways to access the wizards for creating new connections. See also Section 1.6.3, "Where Can I Learn More About Connections?."

1.6.1 Where Are Connections Located?

Depending on how you invoke a wizard to create a connection, connections are placed in one of the following locations:

- Under Application Resources in the Application Navigator

  Connections created here can be used in the current application only. This is the most common way to create a repository connection.

  For certain services, you can drag and drop a connection from Application Resources onto a page to create different types of task flow regions. To learn more, refer to the individual WebCenter Portal: Services chapters.

- Under IDE Connections in the Resource Palette

  Connections created here can be reused across Framework applications. To use these connections in an application, you just have to drag and drop the connection from the Resource Palette onto the Connections node in that application.

1.6.2 How Do I Access the Connection Wizards?

To access a connection wizard from the New Gallery:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **Connections**, select the type of connection you want to create, and click **OK**.

   Depending on your selection, the **Create <*Connection_Type*> Connection** dialog opens.
3. The **Create Connection in** option is set to **Application Resources** by default.

   You can select **IDE Connections** to create a connection in the Resource Palette.

To access a connection wizard from the Application Navigator:

1. Right-click the **Connections** node under Application Resources and select **New Connection**, then select the connection type from the context menu.
2. Depending on your selection, the **Create <*Connection_Type*> Connection** dialog or wizard opens.

   The **Create Connection in** option is set to **Application Resources** by default.

To access a connection wizard from the Resource Palette:

1. Click the **New** icon in the Resource Palette, select **New Connection**, then select the connection type from the context menu.
2. Depending on your selection, the **Create <*Connection_Type*> Connection** dialog or wizard opens.

   The **Create Connection in** option is set to **IDE Connections** by default.

1.6.3 Where Can I Learn More About Connections?

For information about creating and consuming connections, see:

- Chapter 27, "Managing Content Repository Connections"
- Chapter 64, "Consuming Portlets"
- Part IV, "Integrating and Publishing Content"
- Chapter 70, "Deploying and Testing Your WebCenter Portal: Framework Application"

1.7 Planning the Portal Layout

You can use **page templates** to control the layout of your portal. A page template is a JSPX file that specifies the look and feel of your portal's pages. The template defines header, footer, content, and navigation regions within the page. You can apply the template to any number of pages, resulting in a consistent look and feel.

WebCenter Portal: Framework provides several default page templates to help you get started. For more information, see Chapter 9.5.1, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."

1.8 Working with Skins

A **skin** is a CSS file that defines the overall look of a portal, including color schemes, fonts, and the display characteristics of ADF Faces components. WebCenter Portal: Framework also provides a portal skin file that you can conveniently edit in JDeveloper. This file lets you override settings in the default skin. Just open the file, uncomment any components you wish to modify, and save the file when you are finished making changes. For details, see Chapter 15, "Creating and Managing Skins."

1.9 Preparing for Round-Trip Development

Round-trip development refers to features and techniques that allow you to retrieve resources from a deployed, runtime portal back to JDeveloper for maintenance or enhancement. After modifying a resource in JDeveloper, you can use the Resource Manager to upload the resource back to the deployed portal. WebCenter Portal's round-trip development features provide a simple, convenient way to modify portal resources without redeploying the entire application.

For more information on round-trip development, see Section 17.3, "Enabling Runtime Administration of Your Portal" and Section 17.4, "Enabling Round-Trip Development of Resources."

1.10 What Configuration Files Should I Know About?

A number of automatically generated configuration files are placed under the `WEB-INF` and `Page Flows` folders of a portal project when you create a Framework application.

> **Tip:** For a complete listing of portal configuration files, see Appendix H, "Manually Migrating a Framework Application."

This section briefly describes these file:

- Section 1.10.1, "The Framework Application Template Default web.xml File"
- Section 1.10.2, "The Framework Application Template Default faces-config.xml File"
- Section 1.10.3, "The Framework Application Template Default trinidad-config.xml File"
- Section 1.10.4, "The Framework Application Template Default adfc-config.xml File"

1.10.1 The Framework Application Template Default web.xml File

Part of Framework application configuration is determined by the content of its J2EE application deployment descriptor file: `web.xml`. The `web.xml` file defines many application settings that are required by the application server.

> **Note:** Rather than being specified in `web.xml`, the context root path is assigned when the application is deployed.

Typical runtime settings include initialization parameters, custom tag library location, and security settings. Depending on the technology you use, other settings may be added to `web.xml` as appropriate.

> **Note:** For standard Java EE files like `web.xml`, there is usually a counterpart Oracle-specific file with additional Oracle-specific options, for example, `weblogic.xml`.

The `web.xml` file is located in the `/public_html/WEB-INF` directory relative to the project in your Framework application.

When you first create your Framework application, configuration settings for JSF servlet and mapping and for resource servlet and mapping are automatically added to the starter `web.xml` file.

The `Faces Servlet` entry inside `<servlet></servlet>` tags provides information about the JSF servlet, `javax.faces.webapp.FacesServlet`. This servlet manages the request processing life cycle for web applications that use JSF to construct the user interface. The configuration setting maps the JSF servlet to a symbolic name, *Faces Servlet*.

The `resources` entry inside `<servlet></servlet>` tags provides information about the ADF resource servlet used to serve up web application resources (images, style sheets, JavaScript libraries) by delegating to a `ResourceLoader`.

The <servlet-mapping></servlet-mapping> tags map the URL pattern to a servlet's symbolic name. You can use either a path prefix or an extension suffix pattern.

By default, JDeveloper uses the path prefix /faces/*. That is, when a URL, for example, http://localhost:8080/SRDemo/faces/index.jsp, is issued, the URL activates the JSF servlet, which strips off the faces prefix and loads the file /SRDemo/index.jsp.

Note: If you prefer to use the extension jsf for web pages instead of jsp or jspx, then you must set the javax.faces.DEFAULT_SUFFIX context parameter to jsf, for example:

```
<context-param>
   <param-name>javax.faces.DEFAULT_SUFFIX</param-name>
   <param-value>.jsf</param-value>
</context-param>
```

Then add a servlet mapping in web.xml that invokes the JSP servlet for files with the extension jsf.

To edit web.xml in Oracle JDeveloper, right-click web.xml in the Application Navigator and choose **Open** from the context menu. This opens web.xml in the Web Application Deployment Descriptor editor, in Overview mode. If you are familiar with configuration element names, then you can also use the XML editor to modify web.xml.

For information about the configuration elements you can use in the web.xml file, see "Oracle ADF XML Files" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

1.10.2 The Framework Application Template Default faces-config.xml File

Use the faces-config.xml file to register a Framework application's resources, such as custom validators and managed beans, and to define all page-to-page navigation rules. The default name of this file is faces-config.xml, though this naming convention is not required.

Depending on how resources are packaged, an application can have one or multiple faces-config.xml files. For example, you can create individual JSF configuration files for:

- Different areas of your application
- Each library containing custom components or renderers

For more information about creating multiple faces-config.xml files, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

Example 1–1 illustrates the default faces-config.xml file provided through the WebCenter Portal: Framework Application template. This file is located in the /public_html/WEB-INF directory relative to the project in your Framework application.

Example 1–1 Default faces-config.xml File Provided Through the Framework Application Template

```
<?xml version="1.0" encoding="US-ASCII"?>
<faces-config version="1.2" xmlns="http://java.sun.com/xml/ns/javaee">
  <application>
```

```
    <default-render-kit-id>oracle.adf.rich</default-render-kit-id>
    <view-handler>oracle.webcenter.portalframework.sitestructure.handler.CustomViewHandler
    </view-handler>
  </application>
  <managed-bean>
    <managed-bean-name>preferenceBean</managed-bean-name>
    <managed-bean-class>oracle.webcenter.portalframework.sitestructure.PreferencesBean
    </managed-bean-class>
    <managed-bean-scope>application</managed-bean-scope>
  </managed-bean>
</faces-config>
```

To edit the `faces-config.xml` file, double-click it in the Application Navigator. By default, the file is opened in the Editor window in *Diagram* mode, as indicated by the active **Diagram** tab at the bottom of the Editor window. When creating or modifying JSF navigation rules, Diagram mode enables you to visually create and manage page flows. For more information, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

To create or modify configuration elements other than navigation rules, use the Editor's Overview mode. Enter this mode by clicking the **Overview** tab at the bottom of the Editor window.

JSF allows multiple `<application>` elements in a single `faces-config.xml` file. When you use the JSF Configuration Editor, you can edit only the first instance. For any other `<application>` elements, you must edit the file directly using the XML editor. To use the XML editor, open the `faces-config.xml` file and go to the **Source** tab in the Editor window.

For reference information about the configuration elements you can use in the `faces-config.xml` file, see "ADF Faces Configuration" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

1.10.3 The Framework Application Template Default trinidad-config.xml File

The default `trinidad-config.xml` file, available when you create a Framework application, contains information about the application skin family. Additionally, it can contain information about the level of page accessibility support, page animation, time zone, enhanced debugging output, and the URL for Oracle Help for the Web (OHW). Like `faces-config.xml`, the `trinidad-config.xml` file has a simple XML structure that enables you to define element properties using JSF Expression Language (EL) or static values.

Example 1–2 illustrates the default `trinidad-config.xml` file provided through the WebCenter Portal: Framework Application template. This file is located in the `/public_html/WEB-INF` directory relative to the project in your Framework application.

Example 1–2 Default trinidad-config.xml File Provided Through the Framework Application Template

```
<?xml version="1.0" encoding="US-ASCII"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">

  <skin-family>fusion</skin-family>

</trinidad-config>
```

In addition to the skin family, you can define the following application values in the `trinidad-config.xml` file:

- Page animation
- Level of page accessibility support
- Time zone
- Enhanced debugging output
- Oracle Help for the Web (OHW) URL

For reference information about the `trinidad-config.xml` file, see "ADF Faces Configuration" in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

1.10.4 The Framework Application Template Default adfc-config.xml File

The `adfc-config.xml` file is the configuration file for an ADF unbounded task flow. This file contains metadata about the activities and control flows contained in the unbounded task flow. The default name for this file is `adfc-config.xml`, though this naming convention is not required.

If **ADF Page Flow** is specified as a Selected Technology on the Technology Scope page of the Project Properties dialog, a new `adfc-config.xml` source file is automatically created within the project. The `adfc-config.xml` file is the main source file for an unbounded task flow.

The `adfc-config.xml` file is located in the `/public_html/WEB-INF` directory relative to the project in your Framework application.

Note: If you do not plan to use task flows in your Framework application, you can delete the `adfc-config.xml` file.

For more information about task flows and the `adfc-config.xml` file, see "Oracle ADF XML Files" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

1.11 Installing Database Schemas

Certain Oracle WebCenter Portal components require schemas that must be installed in a supported database. For details, see Section 3.5, "Installing Database Schemas."

2

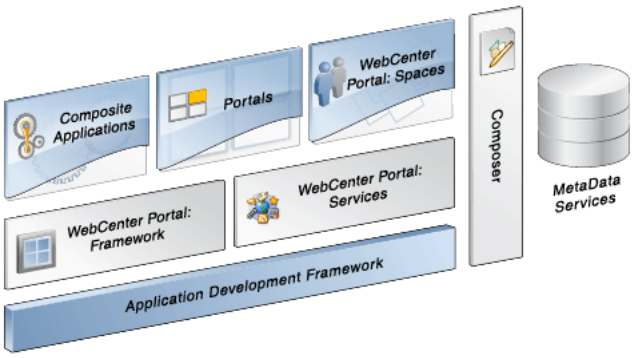
Understanding Oracle WebCenter Portal

This chapter introduces you to Oracle WebCenter Portal and helps you understand what you must consider when using WebCenter technology to build an application.

This chapter includes the following sections:

- Section 2.1, "What Is Oracle WebCenter Portal?"
- Section 2.2, "Introducing the WebCenter Portal: Framework"
- Section 2.3, "What Are the Main WebCenter Portal: Framework Features?"
- Section 2.4, "Introducing Oracle WebCenter Portal: Services"
- Section 2.5, "Introducing Oracle Application Development Framework (Oracle ADF)"
- Section 2.6, "Introducing Oracle JDeveloper and the WebCenter Portal Extension"
- Section 2.7, "Understanding the Application Life Cycle"
- Section 2.8, "Design Questions to Consider Before You Start"
- Section 2.9, "Overview of WebCenter Accessibility Features"

Audience



This chapter is intended for developers of Framework applications. Developers should review this chapter carefully to determine what options are available to them.

2.1 What Is Oracle WebCenter Portal?

Oracle WebCenter Portal provides design time and runtime tools for building enterprise portals, transactional web sites, and social networking sites. Typical WebCenter use cases include employee intranets, customer extranets, dashboards, blogs and wikis, community discussion forums, online stores, and many others. WebCenter provides the tools you'll need to create these kinds of applications.

Figure 2–1 provides an overview of the Oracle WebCenter Portal architecture, showing the major components that comprise the product.

Figure 2–1 Overview of Oracle WebCenter Portal Architecture

2.2 Introducing the WebCenter Portal: Framework

The Oracle WebCenter Portal: Framework provides portal-specific features to a Framework application. These features include page hierarchies, navigation models, delegated security, customization, and others. Portals can also include features like portlets, content management system integration, personalization, social computing services, search, analytics, and more.

From the perspective of an end user, a portal is a web site with pages that are organized by tabs or some other form of navigation. Each page can contain portlets, static content, dynamic content, and task flows. Authorized users can also customize their view of a portal by adding their own pages, adding portlets of their choosing, and changing the Look And Feel of the interface.

For a complete overview of the Oracle WebCenter Portal: Framework, Chapter 9, "Understanding Framework Applications."

2.3 What Are the Main WebCenter Portal: Framework Features?

This section discusses a few of the major features that can be used in a Framework application. These features support integration of remote applications, page customization, content integration, personalization, security, and others.

- Section 2.3.1, "Portlets and Pagelets for Accessing Remote Applications and Services"
- Section 2.3.2, "Oracle WebCenter Portal's Composer Allows User Customization"
- Section 2.3.3, "Content Integration with Supported Content Repositories"
- Section 2.3.4, "Search Framework"
- Section 2.3.5, "Resource Catalogs Help Organize the Development Experience"
- Section 2.3.6, "Application Security"

2.3.1 Portlets and Pagelets for Accessing Remote Applications and Services

This section discusses two technologies–portlets and pagelets–that let you integrate remote applications into your portal pages.

- Section 2.3.1.1, "What Are Portlets?"
- Section 2.3.1.2, "What Are Pagelets?"

2.3.1.1 What Are Portlets?

A portlet is a reusable Web component that can draw content from many different sources. Portlets provide a means of presenting data from multiple sources in a meaningful and related way. Portlets can display excerpts of other web sites, generate summaries of key information, perform searches, and access assembled collections of information from a variety of data sources. Because different portlets can be placed on a common page, the user receives a single-source experience. In reality, the content may be derived from multiple sources.

For information about the different ways you might create portlets and how you might use portlets, including the pre-built portlets available with WebCenter Portal, see Chapter 58, "Overview of Portlets." For information about consuming portlets on pages and linking them, see Chapter 64, "Consuming Portlets."

2.3.1.2 What Are Pagelets?

A pagelet is a reusable user interface component similar to a portlet, but while portlets were designed specifically for portals, pagelets can be run on any web page, including within a portal or other web application. Pagelets can be used to expose platform-specific portlets in other web environments.Any HTML fragment can be a pagelet, but pagelet developers can also take advantage of many of the features available to portlet developers to write pagelets that are parameterized and configurable, to dynamically interact with other pagelets, and respond to user input using Ajax patterns.

Oracle WebCenter Portal's Pagelet Producer provides a collection of useful tools and features that facilitate dynamic pagelet development. For detailed information about pagelet development and configuration using the Pagelet Producer, see Chapter 63, "Creating Pagelets with Oracle WebCenter Portal's Pagelet Producer."

2.3.1.3 What is the Difference Between Portlets and Task Flows?

As explained in Section 2.3.1.1, "What Are Portlets?," portlets are reusable Web components that can draw content from many different sources. Portlets can manage and display anything from static HTML to Java controls to complex web services and process-heavy applications.

A single portlet can also have multiple instances—in other words, it can appear on a variety of different pages within a single portal, or even across multiple portals if the portlet is enabled for Web Services for Remote Portlets (WSRP). You can customize portlets to meet the needs of specific users or groups.

Task flows let you build customizable applications with reusable units of business logic. They represent a modular approach for defining control flow in an application. Each task flow represents a reusable piece of business logic. With isolated memory and transaction scopes, task flows are decoupled from the surrounding application. This decoupling allows task flows to be included in Oracle WebCenter Portal's Composer, for instance.

A task flow encapsulates control flow rules, activities, and managed beans to implement business modules. Task flows are easily reusable within WebCenter Portal applications. You can drag and drop task flows onto any customizable WebLogic Portal application page. In this sense, you can think of a task flow as a "local portlet" that can be reused and dropped into any ADF application.

While task flows are high-level implementations of business processes, they do not host data-access or business logic. Task flows must interact with data controls and declarative bindings for these purposes. These data controls and bindings in turn interact with the ADF Business Components framework.

Following the Oracle-submitted standard JSR 329, you can expose your task flows as standards based portlets. In this way, one application encompasses both the base application functionality and the portlets to be consumed for integration. When you revise your application, the portlets are naturally and automatically updated right along with it, rather than requiring a separate development project. To support JSR 329, the Oracle WebCenter Portal: Framework provides the Oracle JSF Portlet Bridge. For more information about the Oracle JSF Portlet Bridge, see Chapter 59, "Creating Portlets with the Oracle JSF Portlet Bridge."

In addition to consuming task flows as portlets, you can consume task flows as shared libraries in a JSF application to enable you to embed these JSF fragments directly. You can wrap the transactions around the task flows along with the other functionality in their application. For more information, see Chapter 14, Getting Started with ADF Task Flows" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework.*

2.3.2 Oracle WebCenter Portal's Composer Allows User Customization

Composer is an easy, browser-based environment that you can add to existing JSF applications. End users can then use Composer to edit the page at runtime to create their own mashups. To make pages editable at runtime in this way, you simply add Composer design time components to a page in JDeveloper. If you create a blank page in JDeveloper with just Composer components, users have the ability to redesign the page while in Edit mode using Composer. Some of the tasks they can perform include:

- Editing page settings and parameters
- Adding content to the page
- Editing component properties and parameters
- Wiring components to page parameters
- Arranging content on the page
- Changing the layout for components on the page
- Removing components from the page

The Composer tag library provides the components that you can add to make a page editable at runtime and define the behavior of content on the page (for example, move, sequence, or hide components).

In Composer, the Component Catalog dialog box, which is displayed by clicking the Add button on the page, displays the default runtime Resource Catalog Viewer. Users can browse the components in the viewer and then add them to the page. By default, the viewer displays the default Resource Catalog, which contains all of the Oracle ADF components and portlets available to the application. To control what components are visible to users in the viewer, you can modify the default Resource Catalog, or create one or more of your own Resource Catalogs. Resource Catalogs can contain items such as portlets, layout components, task flows, documents, and Oracle ADF Faces components.

For more information about implementing Composer components in your application, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."

2.3.3 Content Integration with Supported Content Repositories

JCR (Java Content Repository API, also known as JSR 170) adapters enable you to make data stored in content management systems, such as Oracle WebCenter Content, Oracle Portal, or even your file system, available to your application.

Using JDeveloper, you can use the prebuilt JCR data control to grab the content and drop it onto your page. You can leverage the provided prebuilt user interface to display the content in your Framework application. This architecture enables you to build your user interface once and then at deployment time or during runtime, switch to whatever back end is required without having to recompile or rebuild the application. In addition, you do not need to learn the intricacies of each content management system's custom APIs. For example, you could create a data control that selects content from any JCR 1.0 compliant repository or file system. When the data control is created, you can drop it onto a JSP document as a table.

If you retrieve data from a content repository other than Oracle Portal, Oracle WebCenter Content, or the file system, then you can create your own JCR adapter. From the Content Repository Configuration page of the Create Data Control wizard, you can choose the content repository from which you want to retrieve data.

The Content Presenter task flow lets you conveniently add content to your application. Content Presenter allows you to select a single item of content, multiple content items, or query for content, and then select a template to render the content on a page in a Framework application. In addition, you can design custom display templates for Content Presenter. See Chapter 29, "Creating Content Presenter Display Templates." For more information, see also "Adding Content Using Content Presenter" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* and Chapter 27, "Managing Content Repository Connections."

2.3.4 Search Framework

Search is one of the most common and useful features of any web application. Oracle WebCenter Portal: Framework has a unified, extensible Search framework that enables the discovery of information and people through an intuitive user interface. The powerful Search framework enables you to seamlessly include enterprise-wide search capabilities into your application. With all relevant and secure information easily navigable, users do not need to switch between applications performing multiple searches. See Chapter 45, "Integrating the Search Service."

2.3.5 Resource Catalogs Help Organize the Development Experience

The Resource Catalog provides a federated view of the contents of one or more otherwise unrelated repositories within a unified search and browse user interface. Resources are created and published in their source repository, then exposed to the developer through the JDeveloper Resource Palette and to the end user through the Resource Catalog Viewer. The Resource Palette contains the WebCenter Portal Catalog, which includes elements that are commonly used in portal development.

Resource Catalogs can contain the following components:

- **Layout components.** The primary layout component is a `Box`, which is a container that can hold all other types of components. At runtime, you must have a `Box` into which you can drag and drop components. You can also add and arrange child components and delete components from a `Box`. See the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.
- **Oracle ADF Faces components.** You can add `Text`, `Image`, `Page Link`, `Web Page`, and `Website Link` components to your page. These are analogous to the JDeveloper design time components `Rich Text Editor`, `Image`, `Command Link`, `Web Page`, and `Go Link`, respectively.

The `Text` component enables you to add rich text on the page. Adding this component invokes a text editor that can be resized and is similar to an HTML editor. You can add text and format it using the options available in the editor. See the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

- **Portlets.** You can add WSRP, JSF Portlet Bridge Portlets, or PDK-Java portlets from any producer that was registered in JDeveloper. For more information about registering portlet producers and adding portlets to a page, see Chapter 64, "Consuming Portlets."
- **Pagelets.** Oracle WebCenter Portal's Pagelet Producer provides a collection of useful tools and features that facilitate dynamic pagelet development. For detailed information about pagelet development and configuration using the Pagelet Producer, see Chapter 63, "Creating Pagelets with Oracle WebCenter Portal's Pagelet Producer."
- **Task Flows.** If you have created task flows in JDeveloper, you can add these task flows from JAR files onto your page at runtime. For more information about ADF task flows, see the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.
- **Documents.** If you have configured the Documents service in your application, you can add documents from this service. For more information about the Documents service, see Chapter 30, "Integrating the Documents Service."
- **Data Controls.** Several WebCenter Portal services provide data controls for building a customized user interface with a Framework application or task flow. The documentation for each service includes more information about that service's data control. See the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

2.3.6 Application Security

With the Oracle ADF extensions provided in Oracle WebCenter Portal, you can define security for an entire application, a page hierarchy, part of a page hierarchy, navigational components, or a single page. You can define security for individual actions provided by customizable components. In addition, for Oracle WebCenter Portal: Services that connect to back-end servers using web services, you can provide secure identity propagation with WS-Security.

Because Oracle WebCenter Portal security is based on the JAAS and J2EE standards, enterprise roles defined in the existing identity management store can be leveraged directly when securing a Framework application. You need not synchronize roles within the application being built. It just references and uses the defined users and roles directly. Note also that you can use file-based security for the development phase of the application and then easily switch over to enterprise identity management at deployment time.

Oracle WebCenter Portal also provides application roles that you can use to represent the policy of an application. By associating permissions with an application role defined within the policy store, you can keep them self contained within the application. On deployment, you can then associate users and enterprise roles with the application roles to grant those permissions to end users.

In some cases, it is desirable to leverage existing applications that have their own authentication mechanism, such as email. The email system is often on a different authentication system (with different user names and passwords) than the new application. The application must map the email user to the application user such that

end users do not have to enter their user names and passwords each time they need information. Oracle WebCenter Portal: Framework provides the means to securely manage these user names and passwords with the External Application functionality.

For more information about options for securing your Framework application, see Chapter 69, "Securing Your WebCenter Portal: Framework Application."

2.4 Introducing Oracle WebCenter Portal: Services

Oracle WebCenter Portal: Services expose social networking and personal productivity features through services, which, in turn, expose subsets of their features and functionality through task flows.

Table 2–1 describes each of the available services.

Table 2–1 Oracle WebCenter Portal: Services

Service	Description	Chapter
Activity Graph	Leverages collective intelligence to benefit search and social applications.	Chapter 46, "Integrating the Activity Graph Service"
Analytics	Enables you to display usage and performance metrics for your Framework application.	Chapter 47, "Integrating the Analytics Service"
Announcements	Provides the ability to post announcements about important activities and events to all authenticated users.	Chapter 33, "Integrating the Announcements Service"
Blog	Provides easy integration of a blog application within the context of your application.	Chapter 32, "Integrating Wikis and Blogs"
Discussions	Provides the ability to create threaded discussions, posing and responding to questions and searching for answers. Also provides an effective group communication mechanism for important activities and events.	Chapter 34, "Integrating the Discussions Service"
Documents	Provides content management and storage capabilities, including content upload, file and folder creation and management, file check out, versioning, and so on.	Chapter 30, "Integrating the Documents Service"
Events	Provides the ability to create and maintain a schedule of events relevant to a wider group of users. Events are published to all authenticated users.	"Working with the Events Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* Chapter 52, "Integrating the Events Service"
Instant Messaging and Presence (IMP)	Provides the ability to observe the status of other authenticated users (whether online, offline, busy, or away) and to contact them instantly.	Chapter 35, "Integrating the Instant Messaging and Presence Service"
Links	Provides the ability to view, access, and associate related information; for example you can link to a solution document from a discussion thread.	Chapter 43, "Integrating the Links Service"

Table 2–1 (Cont.) Oracle WebCenter Portal: Services

Service	Description	Chapter
Lists	Provides the ability to create, publish, and manage lists. Users can create lists from prebuilt structures or create their own custom lists.	"Working with the Lists Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* Chapter 48, "Integrating the Lists Service"
Mail	Provides easy integration with IMAP and SMTP mail servers to enable users to perform simple mail functions such as reading messages, creating messages with attachments, replying to or forwarding existing messages, and deleting messages.	Chapter 36, "Integrating the Mail Service"
Notes	Provides the ability to "jot down" and retain quick bits of personally relevant information. **Note:** This service is available only in Oracle WebCenter Portal: Spaces.	"Working with the Notes Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
Notifications	Provides a means of subscribing to services and application objects and, when those objects change, receiving notification across one or more selected messaging channels.	Chapter 49, "Integrating Notifications"
People Connections	Provides social networking capabilities, such as creating a personal profile, displaying current status, and viewing other users' recent activities.	Chapter 38, "Introducing the People Connections Service"
Polls	Enables you to survey your audience (such as their opinions and their experience level), check whether they can recall important information, and gather feedback.	Chapter 37, "Integrating the Polls Service"
Personalization	Enables you to deliver content within your application to targeted application users based on selected criteria.	Chapter 67, "Personalizing WebCenter Portal Applications"
Recent Activities	Provides a summary view of recent changes to documents, discussions, and announcements.	Chapter 50, "Integrating the Recent Activities Service"
RSS	Provides the ability to access the content of many different web sites from a single location—a news reader.	Chapter 53, "Integrating the RSS Service"
Search	Provides the ability to search services, the application, or an entire site. (This includes integrating Oracle Secure Enterprise Search for WebCenter Portal searches.)	Chapter 45, "Integrating the Search Service"
Tags	Provides the ability to assign one or more personally relevant keywords to a given page or document.	Chapter 44, "Integrating the Tags Service"

Table 2–1 (Cont.) Oracle WebCenter Portal: Services

Service	Description	Chapter
Wiki	Provides the ability for geographically diverse teams to originate and collaborate on web documents.	Chapter 32, "Integrating Wikis and Blogs"
Worklists	Provides a personal, at-a-glance view of business processes that require attention (including a request for document review, and other types of business process that come directly from enterprise applications).	Chapter 51, "Integrating the Worklist Service"

WebCenter provides task flows for these services through the Oracle WebCenter Portal: Services Catalog. For information about how to prepare your application to consume these task flows, see Chapter 7, "Preparing Your Application for WebCenter Portal Services."

How Oracle WebCenter Portal: Services Integrate with Each Other

WebCenter Portal: Services are designed to be integrated with each other. Here are some examples of the ways WebCenter Portal: Services work together:

- The Search service is designed to search any WebCenter Portal service in your application. For example, if you have the Documents service in your application, then the search operation looks for terms in document names and in the documents themselves. The results include tag hits, so any matching tags on your documents and pages are also returned, with relevance based on the quality and frequency of tags.
- The Links service lets you view, access, and associate related information across services. For example, in a discussion forum, you can link to a related discussion forum, document, URL, or event. The Links service also supports bidirectional links between objects, such as a link from a discussion topic to a document and back to the discussion topic.
- The Presence icon can appear in any WebCenter Portal service where a user is indicated. For example, click the author's name on a document to invoke a context menu and send an instant message or mail to that person.
- The Recent Activities service lets you view the most recent additions or changes to the announcements, documents, discussions, and pages in your application.

2.4.1 WebCenter Portal: Services and the REST APIs

You can access many of the WebCenter Portal services through their REST APIs. REST APIs allow you to create rich, interactive client-side applications. REST commands use standard HTTP methods as requests to point to the resource being used. Every request returns a response, indicating the status of the operation. If the request results in an object being retrieved, created, or updated, the response includes a standard representation of that object.

For more information and a complete list of the services that include REST APIs, see Chapter 54, "Using Oracle WebCenter Portal REST APIs."

2.5 Introducing Oracle Application Development Framework (Oracle ADF)

This section briefly introduces Oracle ADF and discusses how WebCenter Portal benefits from Oracle ADF technology.

2.5.1 What Is Oracle ADF?

The Oracle Application Development Framework (Oracle ADF) is an end-to-end application framework that builds on Java Platform, Enterprise Edition (Java EE) standards and open-source technologies to simplify and accelerate implementing service-oriented applications. Used in tandem, Oracle JDeveloper and Oracle ADF give you an environment that covers the full development life cycle from design to deployment, with drag-and-drop data binding, visual UI design, and team development features built in.

2.5.2 Why Is Oracle ADF Important for WebCenter Portal Developers?

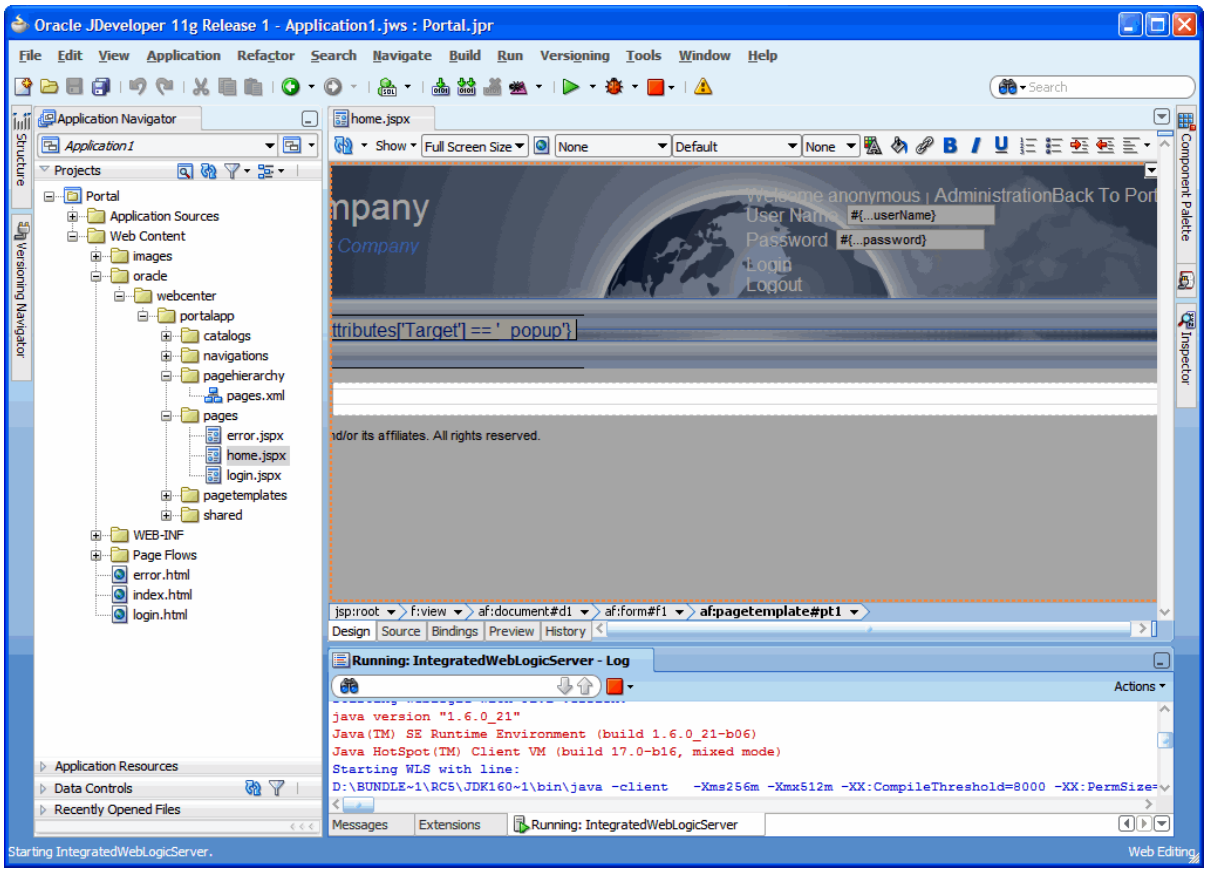
You can build portals using a variety of different technologies and approaches, and WebCenter supports a variety of open industry standards for portal-building. Oracle ADF provides a solid foundation for WebCenter Portal development, which allows integration with the entire Oracle Fusion Middleware stack. Oracle WebCenter Portal lets you build portals that plug into this overall architecture, leveraging features provided by the rest of the stack.

2.5.3 What Does Oracle ADF Technology Include?

Oracle ADF uses a set of standard JSF components that include built-in Ajax functionality. Ajax is a combination of asynchronous JavaScript, dynamic HTML (DHTML), and XML. This combination allows requests to be made to the server without fully re-rendering the page. While Ajax allows rich client-like applications to use standard Internet technologies, JSF provides server-side control.

Oracle ADF provides over 150 rich components, including hierarchical data tables, tree menus, in-page dialogs, accordions, dividers, and sortable tables. Oracle ADF also provides data visualization components, which are Flash and SVG-enabled and capable of rendering dynamic charts, graphs, gauges, and other graphics that can provide a real-time view of underlying data. Each component also supports skinning, along with internationalization and accessibility.

ADF task flows represent a critical component for you to understand and use in your application development. They provide a modular approach for defining control flow in an application. Instead of representing an application as a single large JSF page flow, you can break it up into a collection of reusable task flows. In each task flow, you identify application activities, the work units that must be performed in order for the application to be complete. An activity represents a piece of work that can be performed when running the task flow. Task flows also have the advantage of being able to be packaged and deployed with the application, rather than requiring a separate deployment like remote portlets. For more information about task flows, see the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.



2.6 Introducing Oracle JDeveloper and the WebCenter Portal Extension

Oracle JDeveloper is an integrated development environment (IDE) for building service oriented applications using the latest industry standards for Java, XML, web services, portlets, and SQL. JDeveloper supports the complete software development

life cycle, with integrated features for modeling, coding, debugging, testing, profiling, tuning, and deploying applications. JDeveloper's visual and declarative approach and Oracle ADF work to simplify application development and to reduce mundane coding tasks. For example, code for many standard user interface widgets, such as buttons, lists of values, and navigation bars, are prepackaged for you. All you need to do is select the appropriate widget from the Component Palette and drop it into your application.

WebCenter Portal's extension for Oracle JDeveloper includes all the development functionality you need for building Framework applications. Oracle WebCenter Portal components are readily accessible from a catalog of resources.

Figure 2–2 Oracle JDeveloper and the WebCenter Portal Extension

The WebCenter Portal extension also provides several wizards to help you with essential development tasks such as building portlets, consuming an existing portlet, creating a data control to a content repository, and securing your application. By significantly reducing the amount of coding you do, JDeveloper and the WebCenter Portal extension dramatically increase your productivity as a developer.

In JDeveloper, the easiest way to ensure that you properly define an application and its projects with the appropriate technology scope is to apply an application template. An application template automatically partitions the application into projects that reflect a logical separation of the overall work. The WebCenter Portal extension provides two templates optimally configured for building Framework applications:

- **WebCenter Portal – Framework Application** template. Prepopulates the application with a project and libraries optimally scaled for the creation of data controls and consumption of portlets and Web 2.0 services. Includes Oracle

WebCenter Portal: Framework features like site navigation, page hierarchies, delegated administration, and page templates.

- **WebCenter Portal – Portlet Producer Application template.** Prepopulates the application with a project and libraries scoped for the creation of portlets.

It is not required that you use these templates. If you prefer, you can create your own Framework applications and portlet applications by manually scoping the application technologies and creating the relevant projects. For more information, see Chapter 3, "Preparing Your Development Environment."

For more information about JDeveloper, access the many educational aids from the JDeveloper Start Page, accessible from JDeveloper's Help menu.

2.7 Understanding the Application Life Cycle

The portal life cycle describes the path a portal takes from development through production. Phases of the life cycle include development, testing, staging, and production. For detailed information on the life cycle, see Chapter 10, "Understanding the WebCenter Portal Life Cycle."

2.8 Design Questions to Consider Before You Start

When you design your Framework application, you must consider the needs of your audience. In particular, it is important to think about what features and capabilities your Framework application end users, administrators, and developers need. Before you begin to actually build a Framework application, take a look through the questions listed below and use the answers to help plan your application.

This section includes the following subsections:

- Section 2.8.1, "User Considerations"
- Section 2.8.2, "Site Administrator Considerations"
- Section 2.8.3, "Developer Considerations"

2.8.1 User Considerations

The following list suggests questions you should ask about the end users of your Framework application:

- **How many users are there?** If your Framework application must serve a large number of users, then you must take that into account when you define your deployment environment.That is, you must choose a topology that can support the number of users you expect to access your Framework application and set the configuration parameters of the different services accordingly.

  To help you decide which Oracle Application Server configuration best supports your Framework application, see the *Oracle Fusion Middleware Enterprise Deployment Guide for Oracle WebCenter Portal*.

- **Do users need to edit pages and create enterprise mashups by adding resources?** If you plan to let users edit pages, you must add Oracle WebCenter Portal's Composer components to your application. You should also consider questions such as which areas you want to make editable and what resources to make available to users.

  When you design your application, you must choose where to insert the Composer components to make those areas of the page editable. Components that

allow users to add to the page must appear in a Resource Catalog at runtime. You can also choose to have different catalogs available depending upon the context of the application or the user's privileges.

If you choose to allow page editing, the application must be able to associate the customizations with particular users, which means some form of authentication is required for users of the application. Furthermore, since the user's customizations are stored in Metadata Storage (MDS), you must ensure that your deployment system has access to MDS for the storage and retrieval of customizations.

For more information about the Composer and exposing resource catalogs, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."

- **Do users need to customize their portlets?** Portlets can optionally include a customization mode (Edit mode) that enables an authenticated user to customize the portlet at runtime. The Edit mode might allow the user to enter things such as the portlet's title or a parameter that affects the content of the portlet. For example, you could implement an Edit mode that enables the user to enter ticker symbols for a stock portlet. When the user's changes are applied, the portlet displays the prices for their chosen ticker symbols.

  If you choose to implement customization, then you must also implement some form of security for the application consuming the portlet. Only authenticated and authorized users can customize an application.

  In considering portlet customization, you should also consider whether the portlets are load balanced. If they are load balanced, then you must use database backed customization to ensure that all of your middle tiers can access to the user's customization data. Otherwise, the user has to personalize the same portlet multiple times.

  For more information, see Chapter 58, "Overview of Portlets."

- **Which services do your users need to access?** WebCenter provides a variety of services, such as Documents, Discussions, Search, People Connections, and Instant Messaging and Presence. You must decide which of these services your users need and then configure those services. When the desired services are installed and configured, you can add task flows to your application pages that access those services. The services that you choose to implement can also impact the topology you choose. For example, you might choose to have WebCenter Portal's discussion server and content repositories reside on different systems, which must both be accessible to your application.

  For more information, see Table 2–1, " Oracle WebCenter Portal: Services" and Chapter 7, "Preparing Your Application for WebCenter Portal Services."

- **Will there be both authenticated and unauthenticated (public) users?** Several of the WebCenter Portal services offer limited functionality for unauthenticated users. For example, unauthenticated users can view but not contribute to discussions, and the REST services (most of them) are only available to authenticated users. Due to this loss of functionality, it sometimes works better to create special public pages designed just for unauthenticated users.

  Use the portal page hierarchy editor to set delegated administration security policies on individual pages or on multiple pages. For more information, see Section 9.5.2, "Securing Your Portal Pages."

2.8.2 Site Administrator Considerations

The following list suggests questions you should ask about the administrators of your application:

> **Note:** It is critical that the Framework application administrator and the developers communicate when the application is under construction. At design time, developers must make many choices that determine what the administrator can do to the application at runtime. For example, if the developers choose not to implement skins, then the administrator has no control over the look and feel of the application. Hence, the administrator and the developers should ensure that they consult over these decisions at design time.

- **Do administrators need to customize pages and portlets for users or user groups?** You may want to enable your Framework application administrator to customize pages and portlets to provide default views of the Framework application for users.
  - **Framework application look and feel.** By implementing skins for your Framework application, you enable administrators to choose the look of the pages in the application.

    For information about how to implement skins, see Chapter 19 "Customizing the Appearance Using Styles and Skins" in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework* and Chapter 15, "Creating and Managing Skins."
  - **Customizable Pages.** The administrator can customize the layout of the page.

    For information about customizable components, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."
  - **Portlets.** Portlets can optionally include a customization mode (Edit Defaults mode) that enables the administrator to customize the portlet. The administrator's customization is treated as the default view of the portlet for all other users.

    For more information about portlets, see Chapter 58, "Overview of Portlets."

2.8.3 Developer Considerations

The following list suggests questions you should ask about the developers who will contribute to your application:

- **Do developers and administrators want to use the Oracle WebCenter Portal: Framework features in their application?** Generally, developers should consider using the Framework application template to create framework applications. The template ensures that a new application is provisioned properly with the correct framework technology scopes and features. These portal-specific features include page hierarchies, delegated administration, navigation models, and page templates. In addition, runtime administration tools allow authorized users to modify and change these portal features. For more information Chapter 9, "Understanding Framework Applications."
- **Should developers build task flows or portlets as reusable components?** Thanks to the Oracle JSF Portlet Bridge, developers can make their task flows into JSR 286 portlets. Hence, they have the option of creating reusable components either as

task flows, which can potentially be made into JSR 286 portlets through the bridge, or directly as JSR 286 portlets. If the primary purpose of the component is inclusion in one or more portals, then developers may prefer to build it directly as a JSR 286 portlet, without going through the bridge. If the primary purpose of the component is local execution in a JSF application, then the developer may prefer to create it as a task flow first and then, optionally, use the bridge to run it as a JSR 286 portlet. Building task flows means that the components can be used in other ADF applications without having to repackage them as portlets first.

- **Do developers need to integrate content from content repositories (for example, Content Server, file system, or Oracle Portal)?** If you have content located in content repositories to expose in the Framework application, then you must use JCR adapters and data controls to make that content available.

  For information about including content through JCR data controls and adapters, see Chapter 27, "Managing Content Repository Connections."

- **Will the visible/editable content of the WebCenter Portal: Framework application vary depending upon the identity of the user?** If you plan to have content in your Framework application that is not for everyone, then you must set up a security model with login and user roles that enable you to control access. Components, portlets, and pages can display or not display, depending upon a user's identity. If the content is open to everyone (for example, a Human Resources Framework application with content for all employees), then you might not need to implement access control. The Oracle WebCenter Portal: Framework page hierarchy feature allows you to set security policies on individual or multiple pages in the page hierarchy. For more information, see Section 9.5.2, "Securing Your Portal Pages."

  Furthermore, with Composer, you can allow users to edit the content within the application. Again, you must consider whether you want to restrict that capability to certain users and, if so, you must factor that into your security model.

  For more information about implementing a security model for your Framework application, see Chapter 69, "Securing Your WebCenter Portal: Framework Application."

- **Does your WebCenter Portal: Framework application need to provide access to external applications?** In many cases, you might have external applications to surface in your Framework application. For example, you might have email, Human Resources, or financial applications that you would like users to be able to view from within the application. To provide seamless interaction for the user, you must employ an external application credential store of some kind.

  For more information about accessing external applications from your Framework application, see Chapter 69, "Securing Your WebCenter Portal: Framework Application."

  If you have legacy external application portlets that were built for Oracle Portal, then you can reuse those portlets in a Framework application. This feature allows users to view these portlets from their Framework application rather than having to open each application separately or go back to Oracle Portal. When building such portlets, though, you must remember that they typically must authenticate themselves to the external application before retrieving and displaying any data. As previously mentioned, such authentication requires a credential vault, where the Framework application can store the credentials necessary for logging into the external application. Oracle WebCenter Portal: Framework provides choices in Oracle JDeveloper for incorporating portlets based on external applications.

For more information about external application portlets, see Section 69.13.3, "Managing External Applications."

- **Will the WebCenter Portal: Framework application be developed by a team of developers?** If your Framework application is being developed by a team, then you must think about some additional design considerations. For example, when doing team development, you must be much more aware of which files various JDeveloper actions touch, and may want to take advantage of JDeveloper's ability to integrate code management systems.

  For more information about team development, see Chapter 4, "Working Productively in Teams." See also Chapter 1, "Developer's Quick Start Guide."

2.9 Overview of WebCenter Accessibility Features

Accessibility involves making your application usable by persons with disabilities such as low vision or blindness, deafness, or other physical limitations. In the simplest of terms, this means creating applications that can be used without a mouse (keyboard only), used with a screen reader for blind or low-vision users, and used without reliance on sound, color, or animation and timing.

Oracle software implements the standards of Section 508 and WCAG 1.0 AA using an interpretation of the standards at `http://www.oracle.com/accessibility/standards.html`.

This section describes accessibility features that are specific to WebCenter Portal. For general information about creating accessible ADF Faces pages, see the Developing Accessible ADF Faces Components and Pages section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. For information about accessibility features in JDeveloper, see the help topics available by selecting the JDeveloper Accessibility node under JDeveloper Basics in the online help table of contents.

2.9.1 Generating Accessible HTML

WebCenter Portal provides several Composer components that you can add to your application pages to make them editable at runtime. These components provide attributes that are used to generate accessible HTML. To ensure that the pages you create are accessible, you must set these attributes, listed in Table 2–2.

Table 2–2 Accessibility Attributes for WebCenter Portal's Composer Components

Component	Accessibility Attributes
`pe:changeModeButton`	No accessibility attributes.
`pe:changeModeLink`	No accessibility attributes.
`pe:imageLink`	`shortDesc`—Mandatory. This attribute transforms into an HTML `alt` attribute. `accessKey`—Optional. This attribute sets the mnemonic character used to gain quick access to the component.
`pe:pageCustomizable`	No accessibility attributes
`pe:layoutCustomizable`	`shortDesc`—Mandatory. This attribute transforms into an HTML `alt` attribute. `accessKey`—Optional. This attribute sets the mnemonic character used to gain quick access to the component.
`cust:panelCustomizable`	No accessibility attributes

Table 2–2 (Cont.) Accessibility Attributes for WebCenter Portal's Composer

Component	Accessibility Attributes
`cust:showDetailFrame`	`shortDesc`—Mandatory. This attribute transforms into an HTML `alt` attribute.

2.9.2 Accessibility Features at Runtime

When you enable users to customize a page at runtime, you must ensure that any customizations are also accessible to all users. For all components that users can create at runtime, all accessibility-related attributes are shown in the Property Inspector where users can set them appropriately.

For a list of accessibility-related attributes for WebCenter Portal-specific components, see Table 2–2. For a list of accessibility-related attributes for other components, see the Developing Accessible ADF Faces Components and Pages section in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

2.9.3 Accessibility Considerations for Portlets

IFrames are not very well accommodated by today's screen readers and so are not permitted by some accessibility standards.

> **Note:** Portlets created using the Oracle JSF Portlet Bridge have the `requireIFrame` container runtime option set to `true` as these portlets are too complex to render directly on Oracle ADF pages due to JavaScript issues.

WebCenter Portal provides an optional attribute in the `adf:portlet` tag called `renderPortletInIFrame`. You can set this attribute to false to avoid ever using IFrames. For detailed information, see Section 64.4.12, "What You May Need to Know About IFRAMEs."

3

Preparing Your Development Environment

This chapter discusses tasks you may need to perform to set up your development environment.

> **Tip:** If you are just getting started, we recommend that you look at Section 1.1, "WebCenter Portal Developer's FAQ" first.

This chapter includes the following sections:

- Section 3.1, "Installing Oracle JDeveloper"
- Section 3.2, "Installing WebCenter Portal's Extension for Oracle JDeveloper"
- Section 3.3, "Setting the User Home Directory Environment Variable"
- Section 3.4, "Working with the Integrated WebLogic Server"
- Section 3.5, "Installing Database Schemas"
- Section 3.6, "Installing the Oracle WebCenter Adapter for SharePoint"

3.1 Installing Oracle JDeveloper

Oracle JDeveloper provides an integrated development environment for developing WebCenter Portal: Framework applications. For information on obtaining and installing Oracle JDeveloper, see the Oracle JDeveloper page on OTN at:

`http://www.oracle.com/technetwork/developer-tools/jdev/overview/index.html`

3.2 Installing WebCenter Portal's Extension for Oracle JDeveloper

Before you can begin to develop Framework applications, you need to install the WebCenter Portal's extension for Oracle JDeveloper. The WebCenter Portal extension is a JDeveloper add-in that provides the complete set of WebCenter capabilities and features to the JDeveloper Studio Edition.

To install the WebCenter Portal extension:

1. Start Oracle JDeveloper.
2. If the Select Default Roles dialog displays, select **Default Role** to enable all technologies, and click **OK**.
3. If a dialog opens asking if you want to migrate settings from an earlier version, click **No**.
4. From the **Help** menu, select **Check for Updates**.

5. Click **Next** in the Welcome page of the Check for Updates wizard.
6. On the Source page, under Search Update Centers, search for the **WebCenter Portal extension**, select it, then click **Finish**.
7. When prompted, restart JDeveloper.

JDeveloper is now configured to create WebCenter Portal: Framework and Portlet Producer applications.

For more information on obtaining and installing Oracle WebCenter Portal: Framework, see the Oracle WebCenter Portal page on OTN at:

`http://webcenter.oracle.com`

3.3 Setting the User Home Directory Environment Variable

Oracle strongly recommends that you set an environment variable for the user home directory that is referenced by JDeveloper. By setting this variable, you can avoid receiving long pathname errors that are known to occur in some circumstances.

For detailed instructions on setting this variable on Windows, Linux, UNIX, and Mac OS X operating systems, see "Setting the User Home Directory" in the *Oracle Fusion Middleware Installation Guide for Oracle JDeveloper*.

3.4 Working with the Integrated WebLogic Server

Installation of Oracle WebCenter Portal: Framework reconfigures the Integrated WebLogic Server (WLS) domain in JDeveloper to include additional libraries and several prebuilt portlets. This section discusses the Integrated WLS, including how to start and stop it, and describes some of the preconfigured portlet producers and prebuilt portlets it provides. It contains the following subsections:

- Section 3.4.1, "How to Start and Stop Integrated WLS"
- Section 3.4.2, "What You May Need to Know About Integrated WLS"
- Section 3.4.3, "The WebCenter Preconfigured Server Readme File"
- Section 3.4.4, "What You May Need to Know About Preconfigured Portlet Producers"

3.4.1 How to Start and Stop Integrated WLS

Options for starting Integrated WLS are available in the **Run** menu in Oracle JDeveloper.

- To start Integrated WLS in debug mode, select **Debug Server Instance** from the **Run** menu.

  Running the service in debug mode helps in debugging the service.

- To start Integrated WLS in the regular mode, select **Start Server Instance** from the **Run** menu.

There are a couple of ways to determine if Integrated WLS is running and to stop it.

- The Terminate menu shows you a list of running server(s) and the deployed application(s), if any. (Figure 3–1). To stop a server (or to undeploy an application) select it from this menu.

Figure 3–1 The Terminate Menu Shows What Is Running

- Select **Terminate** from the Run menu, and select the server to stop it.
- Access the Integrated WLS console from a browser:

  `http://localhost:7101/console`

> **Note:** Sometimes WebLogic Server is not accessible (for example, if a user tries to restart WebLogic Server too quickly, before it has successfully shut down). In this case, you may have to manually shut down or stop the Java process.

3.4.2 What You May Need to Know About Integrated WLS

Integrated WebLogic Server (Integrated WLS) is a preconfigured WebLogic Server that provides a complete Java 2 Enterprise Edition (Java EE) 1.4-compliant environment. It is written entirely in Java and executes on the Java Virtual Machine (JVM) of the standard Java Development Kit (JDK). You can run WebLogic Server on the standard JDK provided with your operating system or the one provided with Oracle JDeveloper.

You can use Integrated WLS as a platform for pretesting Framework application deployments on your local computer by establishing an application server connection to it from Oracle JDeveloper. When you run the application in Integrated WLS, it is actually deployed as if you were deploying it to a WebLogic Server instance in an application server. For more information about Integrated WLS, see Section 70.3, "Deploying a Framework Application to a WebLogic Managed Server."

> **Note:** You can specify the Java Virtual Machine (JVM) settings for a Framework application running on the Integrated WLS in the `setDomainEnv.sh` script located here:
>
> *JDEV_SYSTEM_DIRECTORY*`/DefaultDomain/bin/`
>
> The default memory values are:
>
> `-Xmx512m -XX:PermSize=128m -XX:MaxPermSize=512m`
>
> When creating or referring to the `JDEV_SYSTEM_DIRECTORY`, keep in mind that, on a Windows platform, a WebCenter domain name cannot contain spaces, and the domain cannot be created in a folder that has a space in its path. Also, pages in Framework application are not rendered if there is a space in the path to the system directory in Oracle JDeveloper. Therefore, ensure that `DOMAIN_HOME` and `JDEV_SYSTEM_DIRECTORY` paths do not contain spaces.

3.4.3 The WebCenter Preconfigured Server Readme File

The WebCenter Preconfigured Server Read Me file contains valuable information about how to use Integrated WLS. Additionally, it contains links to the preconfigured

portlet producers. You can access the Preconfigured Server Read Me file by selecting **WebCenter Preconfigured Server Readme** from the Oracle JDeveloper Help menu.

3.4.4 What You May Need to Know About Preconfigured Portlet Producers

The WebCenter preconfigured server provides a variety of ready-to-use portlets that you can add to your application pages. Simply register the producers contained in the default server with your Framework application, and then select the producers' portlets from Oracle JDeveloper's Application Resources panel.

This section provides a brief description of the preconfigured producers and some of the portlets they provide. It contains the following subsections:

- Section 3.4.4.1, "OmniPortlet and Web Clipping"
- Section 3.4.4.2, "The WSRP Sample Portlet Producers and Portlets"
- Section 3.4.4.3, "The PDK-Java Sample Portlet Producer and Portlets"

For information about registering portlet producers, see Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application." For information about adding portlets to pages, see Section 64.3, "Adding Portlets to a Page."

3.4.4.1 OmniPortlet and Web Clipping

The Integrated WLS contains PortalTools, which provides access to the *design time at runtime* OmniPortlet and Web Clipping portlet. Design time at runtime means that users define portlet content after the portlet is placed on an application page and the page is run. This concept is explained more fully in Section 58.2.6, "Portlet Creation Style."

To access OmniPortlet and Web Clipping portlet producers:

1. Start the Integrated WLS (see Section 3.4.1).
2. From the **Help** menu, select **WebCenter Preconfigured Server Readme**.
3. In the Readme file, go to the heading **Preconfigured Portlet Producers**, and click the **PortalTools Welcome Page** link under **PortalTools Portlet Producers**.

   This opens the PortalTools Welcome page.
4. On the PortalTools Welcome page, copy the URL of the Web Clipping Producer link, the OmniPortlet Producer link, or the Sample Portlet Producer link, and use it as the producer URL in the Oracle PDK-Java Portlet Producer Registration Wizard.

> **Note:** For information about registering a portlet producer, see Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application."

Once you have registered a producer, its portlets become available on Oracle JDeveloper's Application Resources panel. In the Application Resources panel, under the Connections node, select a producer name to list its portlets, then drag a portlet onto a Framework application page. (For information about adding portlets to pages, see Section 64.3, "Adding Portlets to a Page.".)

The PortalTools Welcome page contains producer URLs for three producers:

- The **Web Clipping producer** provides the Web Clipping portlet, which is a browser-based declarative tool that enables dynamic reuse of content from another web source. When the source changes, the content in the Web Clipping portlet also

changes. With the Web Clipping portlet, you use a web browser to navigate to the web page that contains the desired content. Using Web Clipping Studio, which is accessed through the portlet, drill down through a visual rendering of the target page to choose the desired content. For detailed information about the Web Clipping portlet, see Chapter 66, "Creating Content-Based Portlets with Web Clipping."

- The **OmniPortlet producer** provides OmniPortlet, which is a declarative portlet-building tool that enables you to build portlets against a variety of data sources, including XML files, character-separated value files (for example, spreadsheets), web services, databases, web pages, and SAP data sources. OmniPortlet users can also choose a prebuilt layout for the data. Prebuilt layouts include tabular, news, bullet, form, chart, or HTML. For information about OmniPortlet, see Chapter 65, "Creating Portlets with OmniPortlet."
- The **Sample Portlet Producer** is useful for illustrating the potential of an OmniPortlet. The sample producer is for demonstration and should not be used to create real-use portlet instances.

3.4.4.2 The WSRP Sample Portlet Producers and Portlets

The Integrated WLS includes sample WSRP portlet producers and portlets you can use with your application. For more information on WSRP portlet producers, see Section 58.2.3.2, "WSRP Producers."

Note: You can find the source code for the sample portlets is in the following EAR file:

JDEV_HOME`/jdeveloper/webcenter/modules/oracle.portlet.server_11.1.1/wsrp-samples.ear`

where *JDEV_HOME* is the location where JDeveloper is installed on your machine.

To access WSRP sample portlet producers:

1. Start Integrated WLS (see Section 3.4.1).
2. From the **Help** menu, select **WebCenter Preconfigured Server Readme**.
3. In the Readme file, go to the heading **Preconfigured Portlet Producers**, and click the link for the **WSRP Tools Portlet Producer** or **Sample Portlet Producer** under **WSRP Portlet Producers**.

   Both links open different WSRP Producer Test Pages—one that has Parameter Form and Parameter Display portlets, the other for different WSRP producer versions of sample portlets.
4. Copy the Web Services Description Language (WSDL) URL for a WSRP producer—either WSRP v1 WSDL or WSRP v2 WSDL.

   Use the copied link as the producer URL in the WSRP Producer Registration Wizard.

Note: For information about registering a portlet producer, see Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application."

Depending on where the portlet producer connection was registered, its portlets appear either under Application Resources or in the Resource Palette. From here, you can drag and drop a variety of sample portlets onto your Framework application pages.

3.4.4.3 The PDK-Java Sample Portlet Producer and Portlets

The Integrated WLS includes sample PDK-Java portlet producers and portlets you can use with your application. Use the PDK-Java sample portlets to familiarize yourself with the types of functionality that are available through PDK-Java portlets.

To access PDK-Java sample portlet producers:

1. Start Integrated WLS (see Section 3.4.1).
2. From the **Help** menu, select **WebCenter Preconfigured Server Readme**.
3. In the Readme file, go to the heading **Preconfigured Portlet Producers**, and copy the link location for the **PDK-Java Sample Producer** or **PDK-Java Struts Sample Producer** link under **PDK-Java Portlet producers**.

   Use the copied link as the producer URL in the Oracle PDK-Java Portlet Producer Registration Wizard.

> **Note:** For information about registering a portlet producer, see Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application".

Depending on where the portlet producer connection was registered, its portlets appear either under Application Resources or in the Resource Palette. From here, you can drag and drop a variety of sample portlets onto your Framework application pages.

3.5 Installing Database Schemas

To use certain Oracle WebCenter Portal components, you must install schemas into a supported database. This section discusses the schema installation for Oracle, SQL Server, and DB2 databases.

For information on which databases that WebCenter supports, see the document "Oracle Fusion Middleware Supported System Configurations" on OTN.

Table 3–1 lists the schemas that are used with WebCenter and the methods by which you can install them. The Repository Creation Utility (RCU) is the recommended approach for all the schemas. However, for WebCenter Portal's schema, you have the option of installing with a SQL script, as explained below.

Table 3–1 Database Schema Summary

Schema	Description	Installation Method
WebCenter	To use the Tag, Links, Lists, Polls, and People Connections services, you must have WebCenter Portal's schema installed in your database.	▪ RCU (preferred) ▪ SQL script (On Oracle databases only. See below for details.)
Portlets	For storing customizations in portlet producers.	RCU only

Table 3–1 (Cont.) Database Schema Summary

Schema	Description	Installation Method
Activities	For Activity Graph and Analytics products.	RCU only
Discussions/WebCenter Portal Discussions Crawler	Used as the back end for the Discussions and Announcements services.	RCU only

3.5.1 Installing Schemas With RCU

Oracle recommends that you use RCU to install all WebCenter database schemas. For detailed information, see "Creating Schemas" in the *Oracle Fusion Middleware Repository Creation Utility User's Guide*.

3.5.2 Installing WebCenter Portal's Schema with a SQL Script

To use the Tag, Links, and People Connections services, you must have the WebCenter Portal schema installed in your database. You can do this by using the built-in SQL Worksheet utility that you used in the previous step.

To install the WebCenter Portal schema:

1. From the **Tools** menu, select **SQL Worksheet**.
2. In the Select Connection dialog, click the pencil icon to edit the connection.
3. Modify the connection to use an administrator username and password, such as `SYS` (using the `SYSDBA` role) then click **OK**.
4. Click **OK** to close the Select Connection dialog.
5. From the Tools menu, choose **SQL Worksheet**.
6. Enter the following SQL statement in the SQL Worksheet panel:

   ```
   @@JDEV_HOME/jdeveloper/jdev/extensions/oracle.webcenter.install/sql/oracle/wc_schema.sql
   ```

   where `JDEV_HOME` is the location where JDeveloper is installed on your machine.
7. Click the **Execute Statement** icon, or press **F9**, to run the script.
8. At the prompt, enter `webcenter` as the name for the schema and a password for the schema, such as `welcome1`. The name of the schema *must* be `webcenter`.
9. If prompted for the Default Tablespace and Temporary Tablespaces, re-enter the default values `users` and `temp`, then accept them.

3.6 Installing the Oracle WebCenter Adapter for SharePoint

Before you configure the Oracle WebCenter Portal adapter for SharePoint as described in Section 27.2.3, "How to Create a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint," you must install it in JDeveloper.

The adapter files are located in the **Oracle WebCenter Portal Companion DVD** in the `ofm_wc_generic_jcr_sharepoint_adapter_11.1.1.4.0.zip` file. When you extract this ZIP file to a temporary location, you will find the adapter files in the *TEMP_LOCATION*`/WebCenter/services/content/adapters` directory.

To install the adapter:

1. Start Oracle JDeveloper, if it is not already running.
2. From the **Help** menu, select **Check for Updates**.
3. Click **Next** in the Welcome page of the Check for Updates wizard.
4. On the Source page, select **Install From Local File**, then select `oracle.webcenter.content.jcr.sharepoint.ear` from the *`TEMP_LOCATION`*`/WebCenter/services/content/adapters` directory. This is the temporary directory in which you extracted the contents of the `ofm_wc_generic_jcr_sharepoint_adapter_11.1.1.4.0.zip` file from Oracle WebCenter Portal Companion DVD.
5. Click **Finish**. When prompted, restart JDeveloper.

4

Working Productively in Teams

This chapter contains information for a team development environment, where developers are sharing files in Oracle JDeveloper. It includes information about source (or version) control systems, namely Subversion.

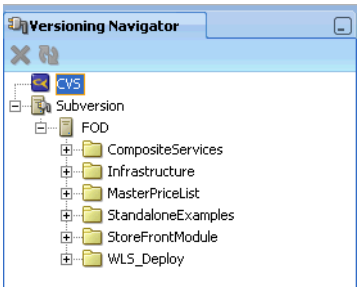
> **Tip:** Typically, one member of the development team creates a new portal application and checks it in to the source code repository. You can create any required connections and check those in as well.

This chapter includes the following sections:

- Section 4.1, "Enabling Source Control on Framework Applications"
- Section 4.2, "Understanding Framework Application Files Affected by Developers"
- Section 4.3, "Implementing Common Requirements One Time"
- Section 4.4, "Portlet Producer Considerations"

4.1 Enabling Source Control on Framework Applications

You can use source control in a Framework application similar to the way you would use source control in any other development environment.



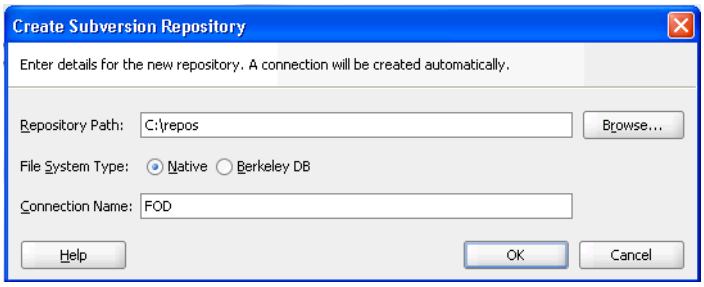
JDeveloper includes Subversion for source control. Oracle also provides free extensions to other source support systems, such as Concurrent Versions System (CVS), Dimensions, and ClearCase. You can install these extensions directly from inside JDeveloper through the **Help - Check for Updates** menu option, which is the recommended way install extensions. If you cannot connect to the internet from your JDeveloper instance, then download the extension from Oracle Technology Network (OTN) at `http://www.oracle.com/technetwork/index.html`. Point the **Check for Updates** wizard to the local file you download.

Note: You may need to configure a proxy server to access the extensions. To set up a proxy server:

1. In Oracle JDeveloper, choose the **Tools** menu option, then select **Preferences**.
2. In the Preferences dialog, scroll down the list and select **Web Browser and Proxy**.
3. In the right pane, under Web Browser and Proxy, select **Use HTTP Proxy Server** and enter the host name and port number of your proxy server, and note any exceptions. Click **OK**.

There are two ways to use Subversion, or any other installed source control system: In JDeveloper, either click the **Versioning** menu or use the Versioning Navigator (click **View - Team - Versioning Navigator**). The Versioning Navigator is shown in Figure 4–1.

Figure 4–1 Versioning Navigator



For detailed information about Subversion, see the Oracle JDeveloper online help system and the "Using a Source Control System" section in the *Oracle Application Development Framework Developer's Guide*.

4.1.1 Creating a Subversion Repository

To create a Subversion repository:

1. From the **Versioning** menu, choose Subversion, and then **Create Local Repository**. The Create Subversion Repository dialog displays (Figure 4–2).

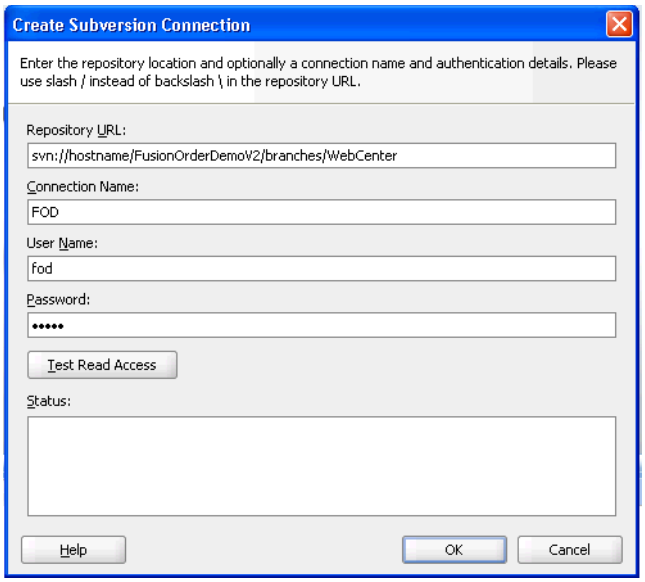


Figure 4–2 Create Subversion Repository

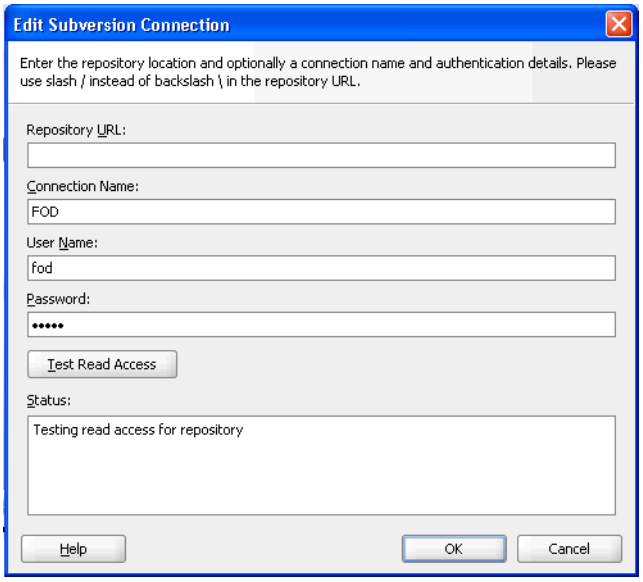
2. In the **Create Subversion Connection** dialog, enter connection details, and then click **OK**. (Figure 4–3)



Note: An alternative way to create a connection is to right-click **Subversion** in the Versioning Navigator and select **New Repository Connection**.

Figure 4–3 Create Subversion Connection

3. Later you can edit these pages on the Edit Subversion Connection page (Figure 4–4).

Figure 4–4 Edit Subversion Connection

4.1.2 Understanding Oracle Team Productivity Center

Oracle Team Productivity Center is an Application Lifecycle Management tool that enables software development teams to collaborate and work productively when developing applications using JDeveloper. This also is a free extension to JDeveloper.

Oracle Team Productivity Center integrates task, bug, and defect repositories, such as JIRA, Bugzilla, and its own built-in task repository into the IDE. It provides a chat interface inside JDeveloper and other team working benefits, such as recording details of files checked into the source control system against tasks and developer productivity aids, such as saving the context of your IDE.

For more information, or to download Oracle Team Productivity Center, go to Oracle Technology Network (OTN) at
http://www.oracle.com/technetwork/index.html.

4.2 Understanding Framework Application Files Affected by Developers

An important aspect of working with any source control system is understanding which files are affected by any particular action. Without this knowledge, you may inadvertently corrupt the source by checking in or checking out either too few or too many files given the actions you are performing on the project. This section helps you understand what files are needed for the main actions you may perform while building a WebCenter Portal: Framework application.

This section contains the following subsections:

- Section 4.2.1, "Files Associated With Common Objects"
- Section 4.2.2, "Developer Actions Affecting Metadata Files"

4.2.1 Files Associated With Common Objects

The main objects with which you work in a Framework application are as follows:

- Pages
- Portlets
- Task flows
- Data controls

Each of these are fairly complex objects, made up of several different metadata files.

For information about page metadata files, see the "Introduction to the ADF Metadata Files" section in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*. For information about portlet and producer metadata files, see Appendix A, "Files for WebCenter Portal: Framework Applications."

4.2.2 Developer Actions Affecting Metadata Files

Table 4–1 lists developer actions and the files that are affected by these actions. Take this information into account while managing your files.

Table 4–1 Developer Actions Affecting Metadata Files

Action	Files Affected
Creating or editing the following connection: ■ BPEL ■ Content Repository; for example, Oracle Content Server, Oracle Portal, file system ■ Database ■ Discussions ■ External Application ■ Instant Messaging and Presence ■ Mail ■ Oracle Secure Enterprise Search ■ Oracle PDK-Java Producer ■ WSRP Producer	Adds or updates: ■ *app-root*/.adf/META-INF/connections.xml with the connection ■ *app-root/projectname/projectname*.jpr with connection libraries ■ *app-root*/.adf/META-INF/adf-config.xml with service-level configuration, including the default connection An external application connection, and all connections that require an external application connection (including Mail, Content Repository, and Instant Messaging and Presence) also add or update the following files: ■ *app-root*/src/META-INF/jps-config.xml with the credential store provider ■ *app-root*/src/META-INF/cwallet.sso with the user name and password **Note**: All secure data specified for connections is stored in cwallet.sso, referenced in jps-config.xml. For example, the password for a database connection is stored in cwallet.sso.
Creating a WebCenter Portal data control	Adds or updates following data control files under *app-root/projectname*/adfmsrc: ■ *projectpackage*/DataControls.dcx with the data control definition ■ *projectpackage/dcname*.xml with the data control structure ■ *projectpackage/dcname*/*.xml with data structure definitions used by the data control ■ *app-root/projectname*/adfmsrc/META-INF/adfm.xml with a pointer to the DCX file ■ *app-root/projectname*/adfmsrc/return.xml with the definition for default operations used on collections Updates *app-root/projectname/projectname*.jpr with content repository libraries
Adding or updating pages in a page hierarchy	■ Adds or updates the parent page's page hierarchy file (/oracle/webenter/portalapp/pagehierarchy/*Pages.xml), and updates pages.xml when the parent is the root page of the hierarchy ■ Updates the original parent pages's page hierarchy file when a page is detached from the parent page (for example, when it is removed from the page hierarchy or when it is reparented) ■ Adds or updates the page definition file (*PageDef.xml) for the pages involved (adding a new pagedef file updates *app-root/projectname*/adfmsrc/*projectpackagename*/DataBindings.cpx to add the pagedef and its mapping to the JPSX page)
Adding or updating or removing resources in site resources	Updates mds/oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/generic-site-resources.xml

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Registering an Oracle PDK-Java or WSRP portlet producer	Adds or updates *app-root*/src/META-INF/jps-config.xml with the credential store provider Adds: ■ Tag library ■ *app-root*/mds/producer.pxml (pertaining to the registered producer) ■ A number of files pertaining to the registered producer to *app-root*/mds/directory: producer Adds or updates *app-root/projectname*/adfmsrc/*projectpackagename*/DataBindings.cpx with factory classes to data bindings Updates: ■ *app-root*/.adf/META-INF/connections.xml with a connection to the producer and the URL connection associated with it ■ *app-root*/.adf/META-INF/adf-config.xml with configuration for the metadata repository and the credential store ■ *app-root/projectname*/src/META-INF/orion-application.xml with the WebCenter Portal shared libraries ■ *app-root/projectname/projectname*.jpr with the libraries needed for any Framework application including external application libraries ■ *app-root/projectname*/public_html/WEB-INF/web.xml with the portlet servlets and filters and also external application automated login entries Copies the keystore file to *app-root*/.adf/META-INF if the producer is WSRP and supports WS-Security
De-registering an Oracle PDK-Java or WSRP portlet producer	Updates *app-root*/.adf/META-INF/connections.xml to remove the producer and URL connection Removes producer-related files from *app-root*/mds/ **Note**: Although the producer is removed from the application, you may need to manually remove the metadata files, portlet view tag, and portlet bindings from the application. Everything else should be left alone in case other producers rely on *app-root/projectname*/public_html/WEB-INF/web.xml or *app-root*/.adf/META-INF/adf-config.xml. The metadata files are removed by the deregister operation; however, any customizations on the producer side might need to be manually removed if the producer was not available during deregistration.

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Adding or removing a portlet from a page Adding or removing a portlet on a page from a portlet producer connection in the Resource Palette	When adding a portlet from a portlet producer in the Resource Palette, WebCenter Portal first registers the producer with the application (if it is not registered). See the "De-registering an Oracle PDK-Java or WSRP portlet producer" row for files affected. It then adds or removes the portlet from the page, affecting the files described in this row. Adds or updates: ■ *app-root/projectname*/adfmsrc/*projectpackagename*/DataBindings.cpx with a new PageDef mapping (if it does not exist) ■ *app-root/projectname*/public_html/WEB-INF/faces-config.xml (This happens whenever you add an Oracle ADF component, such as a portlet, to a page.) ■ adf-faces-config.xml (This happens whenever you add an Oracle ADF component to a page.) ■ *app-root/projectname*/public_html/WEB-INF/oracle-webservices.xml if the portlet is WSRP Adds: ■ A number of files pertaining to the newly cloned portlet instance to *app-root*/mds/ ■ A number of WSDL and XML files to *app-root/projectname*/public_html/WEB-INF/wsdl if the portlet is WSRP Updates: ■ *app-root/projectname*/public_html/*pagename*.jspx with the <adfp:portlet> tag (JSF faces tags are replaced with Oracle ADF faces tags.) ■ *app-root/projectname*/adfmsrc/*projectpackagename*/pageDefs/*pagename*PageDef.xml with the region binding and page variable definitions ■ *app-root/projectname*/public_html/WEB-INF/web.xml with secure-ref entries if the portlet is WSRP

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Dragging a file or folder from a content repository connection to a page Dragging a content repository data control on a page	Updates: ■ *app-root/projectname*/public_html/*pagename*.jspx with appropriate ADF faces tags ■ *app-root/projectname*/adfmsrc/*projectpackagename*/pageDefs/*pagename*PageDef.xml with the region binding ■ *app-root/projectname*/adfmsrc/*projectpackagename*/DataBindings.cpx with a listing of the page definitions ■ *app-root/projectname*/adfmsrc/META-INF/adfm.xml with a pointer to the data bindings file ■ *app-root*/.adf/META-INF/adf-config.xml with MDS configuration entries ■ *app-root/projectname/projectname*.jpr with service libraries, dependent libraries, and JSP tag libraries ■ *app-root/projectname*/public_html/WEB-INF/web.xml with ADF library, external application, and MDS configuration entries Adds or updates all connection-related files for any service that requires connections Copies over any required connection that was not present in the application, which updates *app-root*/.adf/META-INF/connections.xml and *app-root/projectname/projectname*.jpr **Note**: The Recent Activities, Search, and Tags services add the search extension to adf-config.xml and create the sample service-definition.xml file (if it does not exist). The service-definition.xml file lets developers define QueryManager implementations for their service.
Creating a JSR 286 portlet application or adding a portlet to an existing application that uses JSP file	Adds or updates: ■ *app-root/projectname*/public_html/WEB-INF/portlet.xml ■ *app-root/projectname*/public_html/WEB-INF/oracle-portlet.xml ■ *app-root/projectname*/public_html/WEB-INF/web.xml Adds Java and JSP source files for the portlet

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Creating a JSR 286 portlet application or adding a portlet to an existing application that uses the ADF/JSPX option	A portlet application generated with this option uses the Oracle Portlet Bridge to access a Faces application. Adds or updates: ■ *app-root/projectname*/public_html/WEB-INF/portlet.xml with configuration information for the portlet bridge ■ *app-root/projectname*/public_html/WEB-INF/oracle-portlet.xml with configuration information for the portlet bridge ■ *app-root/projectname*/public_html/WEB-INF/web.xml with configuration information for a Faces servlet ■ *app-root*/src/META-INF/orion-application.xml with shared library import statements for adf.oracle.domain and oracle.webcenter.skin Adds: ■ Java and JSPX source files for the portlet ■ *app-root/projectname*/public_html/WEB-INF/faces-config.xml
Creating a PDK portlet producer application	Adds or updates: ■ *app-root/projectname*/public_html/WEB-INF/web.xml with producer servlet definitions and producer deployment details ■ service_id.properties with producer configuration attributes ■ *app-root*/src/META-INF/orion-application.xml with shared library import statements for oracle.portal Adds Java and JSP files for the portlet
Registering a secure WSRP producer (WS-Security)	Updates *app-root*/.adf/META-INF/connections.xml with the secure producer connection definition **Notes**: The connections.xml entry for a secure producer looks different in terms of how the security policy is stored. Instead of the whole security policy description, the security policy is just a URI (that is, a "pointer" to the policy in the policy repository). The secure ref attributes in connections.xml are stored in the credential store (as defined by *app-root*/src/META-INF/jps-config.xml). The credential store configuration information (as defined by jps-config.xml) is stored in *app-root*/.adf/META-INF/adf-config.xml. At design time, the credential store is stored in an Oracle Wallet by default; that is, META-INF/cwallet.sso.

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Configuring ADF Security for a project	Adds or updates: ■ *app-root/projectname/*public_html/WEB-INF/web.xml with login configuration, ADF authentication servlet, security constraints, logical roles and mappings ■ *app-root*/src/META-INF/jps-config.xml with identity store, credential store, policy store, anonymous provider, and login modules ■ *app-root/*.adf/META-INF/adf-config.xml with ADF identity store and credential store configuration ■ *app-root*/src/META-INF/jazn-data.xml with an XML identity store ■ *app-root*/src/META-INF/jazn-data.xml with application permissions
Adding a component or service on a page	Updates: ■ app-root/projectname/public_html/WEB-INF/weblogic.xml with data source (WebCenterDS, ActivitiesDS) configuration and WebCenter Portal shared libraries ■ app-root/src/META-INF/weblogic-application.xml with WebCenter Portal shared libraries and XML parser configuration ■ *app-root/projectname/*public_html/WEB-INF/web.xml with data source configuration, context parameters and listeners, JSP servlet, resource servlet, adfBindings filter, and photo servlet entries ■ *app-root/*.adf/META-INF/adf-config.xml with MDS configuration mappings ■ *app-root/projectname/projectname*.jpr with service-specific libraries ■ app-root/projectname/src/META-INF/jazn-data.xml with task flow security grants (if the application has been configured with ADF security) ■ *app-root/projectname/*adfmsrc/*projectpackagename/*pageDefs/*pagename*PageDef.xml with the region binding ■ *app-root/projectname/*adfmsrc/META-INF/adfm.xml with a pointer to the data bindings file ■ *app-root/projectname/*adfmsrc/*projectpackagename/*DataBindings.cpx with the task flow binding definition factory and pageDef entries ■ *app-root/projectname/*public_html/*pagename*.jspx with appropriate ADF faces tags **Notes**: Some services also affect additional files or have a design time dependency on other services. These services are listed in the following rows. The *projectname*.jpr and web.xml files are updated with service libraries and dependent libraries.
Activity Streaming	Dependent Services: External Application, IMP

Table 4–1 (Cont.) Developer Actions Affecting Metadata Files

Action	Files Affected
Announcements	Updates: ■ `weblogic-application.xml` with the discussions shared library ■ *`app-root/`*`.adf/META-INF/adf-config.xml` with MDS mappings and service-specific configuration entries Dependent Services: External Application, IMP, Links, Search
Composer	Updates: ■ *`app-root/projectname/`*`public_html/WEB-INF/web.xml` with context parameters ■ *`app-root/`*`.adf/META-INF/adf-config.xml` with MDS mappings and ADF faces, resource bundle, and catalog configuration entries Adds `$PROJECT_DIR/src/<projectpackagename>/default-catalog.xml`
Discussions	Updates: ■ `app-root/src/META-INF/weblogic-application.xml` with the discussions shared library ■ *`app-root/`*`.adf/META-INF/adf-config.xml` with MDS mappings and service-specific configuration entry Dependent Services: External Application, IMP, Links, Search

4.3 Implementing Common Requirements One Time

It is good practice for the project administrator to implement any common developer requirements one time and then check in that version for all to use. By planning ahead and having the administrator take care of these common requirements up front, you can reduce redundancy and error.

For example, suppose two developers must add OmniPortlet on different pages of an application. If the project administrator has registered the OmniPortlet producer, then it is available for both of them to use. If not, then each developer likely registers the OmniPortlet producer separately, leading to unnecessary duplication and confusion.

Another example: suppose many developers need content from the same content repository. One person should set up and check in the needed connection first. Other developers then can simply reuse the same data control.

4.4 Portlet Producer Considerations

When working in a team environment, bear in mind the following considerations pertaining to portlet producers:

- Section 4.4.1, "Portlet Producer Connections"
- Section 4.4.2, "Portlet Producer Name Clashes"
- Section 4.4.3, "Combining Portlets from Different Portlet Producers"

4.4.1 Portlet Producer Connections

When building an EAR file for your project, connections are loaded for the entire application rather than individual projects. For example, suppose you have an application with two projects: P1 and P2. P1 has 100 registered producers and P2 has no producers. When you build an EAR file for either project, all 100 of P1's producer connections are loaded into `connections.xml`. Note, though, that you can also edit `connections.xml` manually.

When you run the predeployment tool to create a targeted EAR file, all of the connections in `connections.xml` must be accessible. Hence, in our example, the generation of a targeted EAR file for either project would fail if any of the 100 portlet producer connections for P1 are unavailable for some reason. Given this behavior, you must carefully consider how you plan to subdivide your overall development effort into applications and projects.

4.4.2 Portlet Producer Name Clashes

While Oracle WebCenter Framework lets you register two portlet producers under the same name, it generally is better to avoid this situation. For example, if two developers working on the same application inadvertently register a portlet producer with the same name, then usually it is best to change one name to be unique. If you have two portlet producers registered under the same name, then it becomes very difficult to distinguish between them when debugging errors or performing administrative tasks on the portlet producers.

4.4.3 Combining Portlets from Different Portlet Producers

In some cases, you might have multiple developers building portlets and ultimately you want those portlets to be combined under a single portlet producer. The developers must be conscious of some potential issues.

- Portlet names and JSP paths could clash. Portlet developers should use prearranged class package names and JSP paths to avoid naming clashes when portlets are combined within one portlet producer in one application.
- When you create a JPS portlet in the Portlet wizard, the directory for the portlet modes defaults to `portlet`*`n`*`\html\`*`mode_name`*, where *n* is a number that increments for each portlet you create. To avoid directory and file name clashes, portlet developers should change the directory name on the Content Type and Portlet Modes page of the Portlet wizard. Select the portlet mode and then change the directory name in the corresponding field to something unique.
- When you combine portlets into one portlet producer, you must manually merge the portlet descriptor files, avoiding identifier clashes as you do so as follows:
  - JPS portlet identifiers in the `portlet.xml` and `oracle-portlet.xml` files are generated automatically starting from `portlet1`. When you manually

merge multiple portlet descriptor files into one, you must change any portlet identifiers that clash with one another.

  - Similarly, the PDK-Java portlet identifiers in `provider.xml` are automatically generated starting from `1`. When you manually merge multiple `provider.xml` files, you must change any portlet identifiers that clash with one another.

- You must manually merge any web descriptor (`web.xml`) changes; for example, security role information.
- For PDK-Java portlets, you also might need to manually merge `.properties` files.
- When using many different portlets, parts of files might not be checked in properly because they are overwritten by someone else or because JDeveloper does not pick up the changed files correctly. For example, you might deploy an application with many types of portlets and see the following error in two of the three OmniPortlets:

  ```
  mdsId
  oracle/adf/portlet/OmniPortlet_1172537210873/ap/Portlet100_0b4156e9_0111_1000_
  8001_82235f273a39.pxml not found

  mdsId
  oracle/adf/portlet/OmniPortlet_1172537210873/ap/Portlet100_250498fc_0111_1000_
  8002_a9fe7286a54e.pxml not found
  ```

  If you receive error messages like these, then ensure that all `*.pxml` files from the development environment are copied over to the deployed environment.
- Your portlet customizations might not appear in your deployed environment. Make sure that the content of the `oracle\adf\portlet\<`*`portletInstanceName`*`>.pxml` file is correct and that it refers to the proper *`*.pxml`* files.

5

Creating Framework and Portlet Producer Applications

WebCenter Portal provides templates for creating two kinds of applications: Framework applications and Portlet Producer applications. A Framework application is an ADF web application that is configured for building portal Web applications that include navigations, social computing services, and runtime customization. A Portlet Producer application is configured for building and deploying standards-based portlets.

This chapter includes these topics:

- Section 5.1, "What Are Application Templates?"
- Section 5.2, "Creating a Framework Application"
- Section 5.3, "Adding Pages to a Portal"
- Section 5.4, "Understanding the PortalWebAssets Project"
- Section 5.5, "Creating a Portlet Producer Application"
- Section 5.6, "How Is a Framework application Security Configured by Default?"

5.1 What Are Application Templates?

To readily find and use the appropriate components in your Framework or Portlet Producer application, you must ensure that the right technology scopes are set, tag libraries added, and required Java classes are added to the class path. Once you do this, relevant components are included in the Component Palette and relevant context menus become available in JDeveloper.

Fortunately, Oracle provides out-of-the-box application templates to ensure that scopes are set properly and the right tag and Java libraries are added to create Framework or Portlet Producer applications.

Using the **WebCenter Portal – Framework Application** template generates default WebCenter Portal: Framework projects with unique technology scopes, libraries, and default files. Additionally, the template limits the types of options that are exposed in the JDeveloper user interface to those appropriate for Framework projects.

> **Note:** In addition to populating the application with default files and folders, the template populates the Resource Palette with the WebCenter Portal – Framework Catalog and the WebCenter Portal – Services Catalog. The Services Catalog contains data controls and task flows that you can use to integrate WebCenter Portal services in your application. The WebCenter Portal – Framework Catalog contains a collection of components that are most commonly used for building portals. For more information see Chapter 16, "Creating and Managing Resource Catalogs."

Application templates provide a means of easily creating an application with a pre-defined set of projects and technology scopes. Templates also provide a means of partitioning an application into projects that reflect a logical separation of the overall work.

The application templates include:

- **WebCenter Portal – Framework Application**: Populates the application with a *portal project* and a *static application resources* project. The portal project includes features like site navigation, page hierarchies, delegated administration, security, page templates, and runtime customization. A Framework application can consume portlets, incorporate content management services, and include WebCenter social computing services. The static application resources project includes static application resources like HTML and image files. By default, this project is called PortalWebAssets. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. See Section 5.2, "Creating a Framework Application" and Section 5.4, "Understanding the PortalWebAssets Project."
- **WebCenter Portal – Portlet Producer Application**: Populates the application with a project scoped for creation of JSR 286 (standards-based) and Oracle PDK-Java portlets. See Section 60.1.2, "Introduction to PDK-Java Portlets."

It is not required that you use these templates. If you prefer, you can create your own Framework or Portlet Producer applications by manually scoping the application technologies and creating the relevant projects. For more information, see Section 6.1, "Manually Configuring a Framework Application With Technology Scopes."

If you are working with an existing application that was created with some other template, you can also extend it with WebCenter Portal components. To do this, you must manually add any required projects, technology scopes, and tag libraries. For information about extending existing applications, see Section 6.2, "Extending Non-WebCenter Portal: Framework Applications to Include WebCenter Capabilities."

This section describes how to create an application using the WebCenter Portal – Framework Application template.

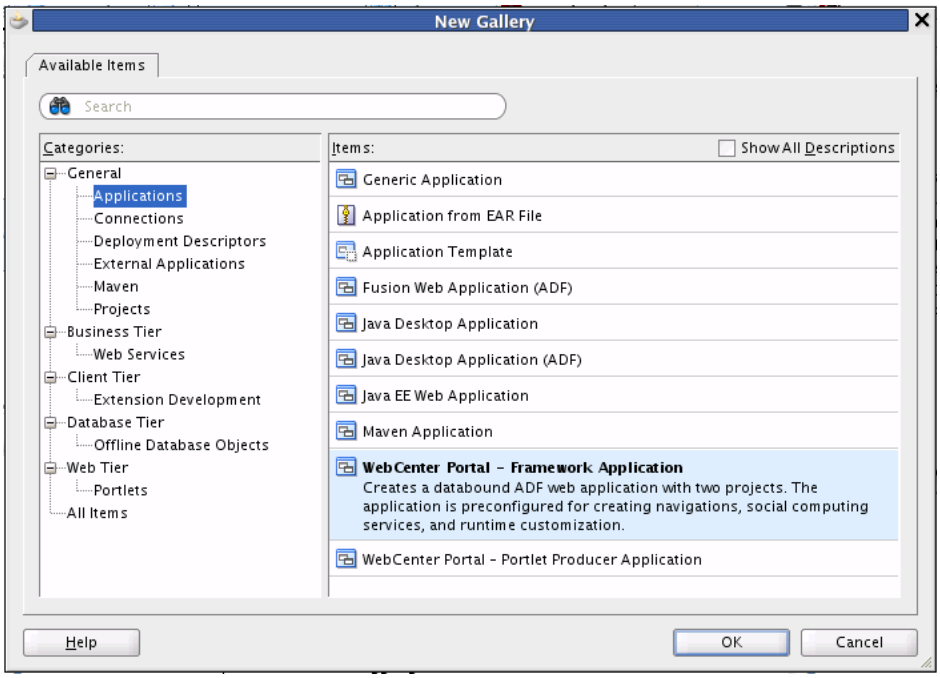
> **Note:** Technology scopes control the options that appear by default in the New Gallery dialog. They can also be used to control the context menus that appear in JDeveloper and to add tag libraries to the project so that tags appear in the Component Palette.

5.2 Creating a Framework Application

This section explains how to create a WebCenter Portal: Framework application. A Framework application is a portal created with a special template called the

WebCenter Portal – Framework Application template. For more information about portals, see Chapter 9, "Understanding Framework Applications."

- Section 5.2.1, "How to Create a Framework Application"



> **Tip:** The **WebCenter Portal – Framework Application** template prepopulates the Framework application with a single portal project that includes features like site navigation, page hierarchies, delegated administration, security, page templates, and runtime customization. For more information, see Section 9.12, "How are WebCenter Portal Files Organized?."

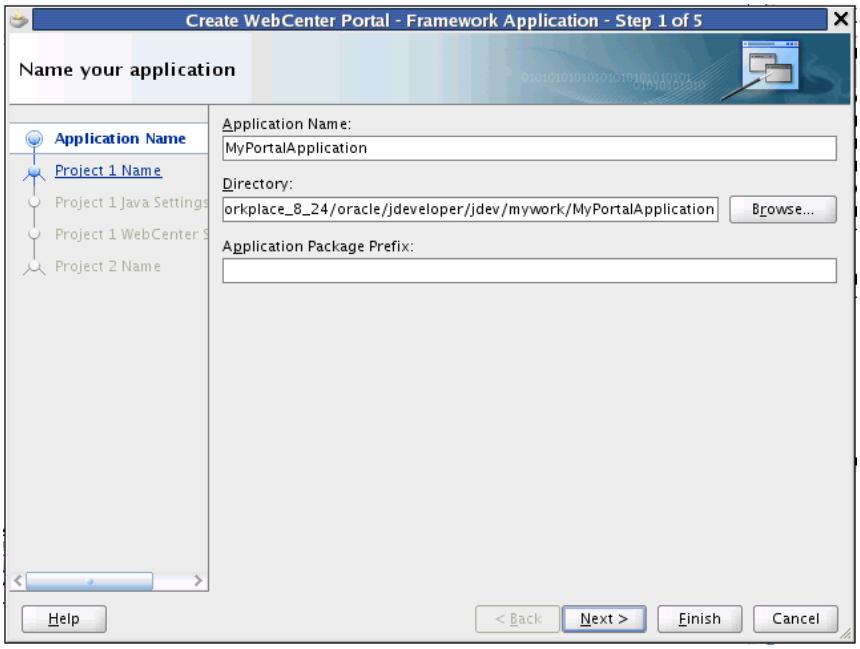
5.2.1 How to Create a Framework Application

A Framework application is a portal you create using the WebCenter Portal – Framework Application template. To create a portal with this template:

1. Access the application creation wizard. JDeveloper provides several ways for you to access this wizard. For example:
   - From the **File** menu, choose **New**. In the New Gallery dialog, expand **Applications**, select **WebCenter Portal – Framework Application**, and click **OK**. For example, see Figure 5–1.

Figure 5–1 New Gallery Dialog

   - From the Application menu, select **New**. In the dialog select **WebCenter Portal – Framework Application**.
   - If you have an existing application that is open, in the Application Navigator, right-click **<*Application-Name*>** and choose **New**. In the New Gallery dialog, expand **Applications**, select **WebCenter Portal – Framework Application**, and click **OK**.
   - If you have an existing application that is open, in the Application Navigator, from the **<*Application-Name*>** drop down menu, select **New**. In the New



Gallery dialog, expand **Applications**, select **WebCenter Portal – Framework Application**, and click **OK**.

Note: At this point, you are on the first page of the Create WebCenter Portal – Framework Application wizard. The wizard includes four pages, which are explained in the following steps.

---

2. Enter a name for the application in the **Application Name** field, as shown in Figure 5–2.

Figure 5–2 Create WebCenter Portal – Framework Application Wizard Step 1 of 5

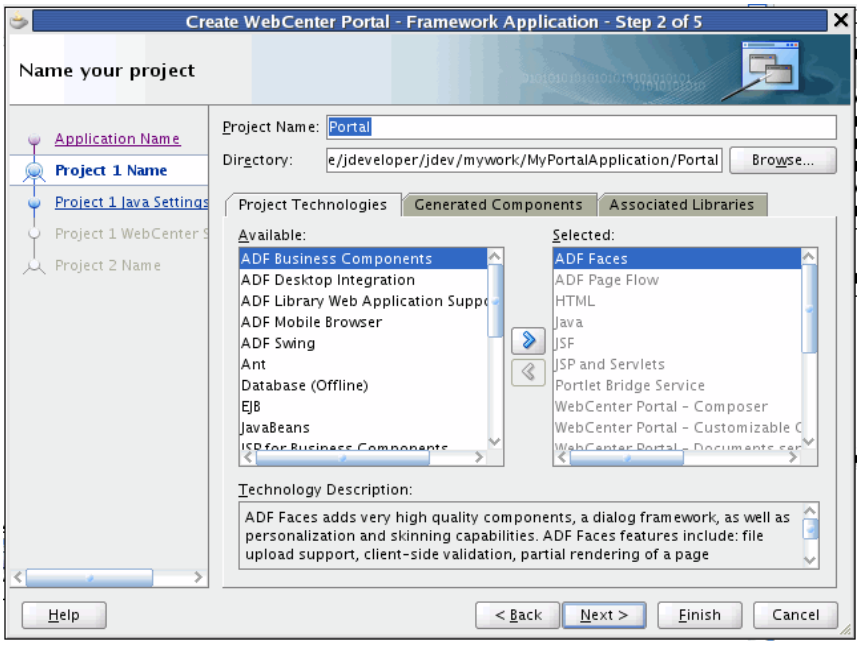
3. In the **Directory** field, enter a path to the directory where you wish to store the application, or accept the default path.

   For example:

   ```
   C:\JDeveloper\mywork\Application1
   ```

   Optionally, click the **Browse** button to navigate to the desired directory.

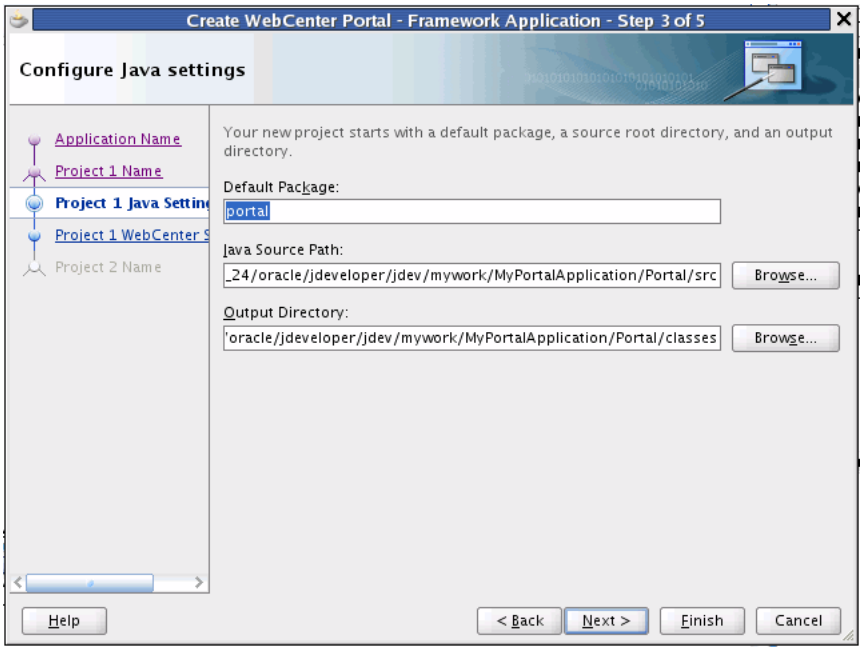
4. If required, in the **Application Package Prefix** field, enter a prefix to use for packages created within this application.



Note: Depending on how you launched the wizard, you might see an Application Template list. If you do see this list, make sure **WebCenter Portal – Framework Application** is selected.

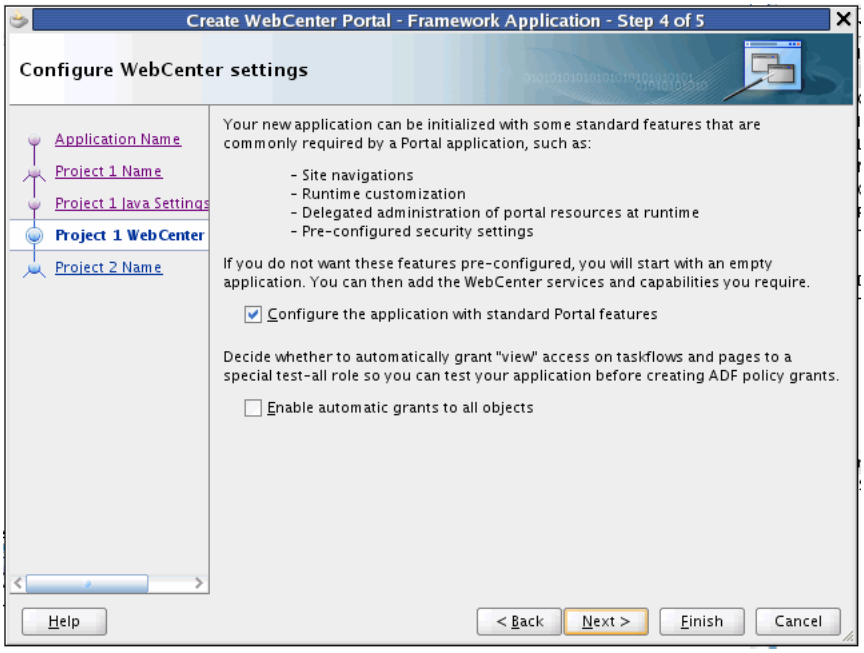
Tip: At this point, you could click **Finish** to create a project with default Framework features, including page hierarchies and navigations. We'll continue and review the rest of the wizard pages.

5. Click **Next**.



6. Enter a project name, as shown in Figure 5–3.

Figure 5–3 Create WebCenter Portal – Framework Application Wizard Step 2 of 5

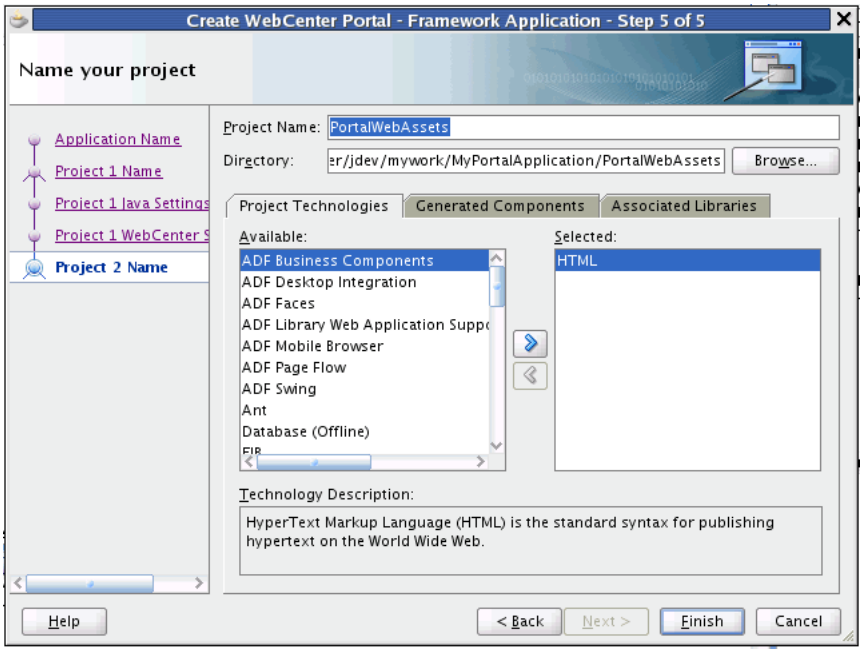


7. Enter a directory in which to place the project, or use the **Browse** button to select a directory.
8. Optionally add or remove **Project Technologies**. For more information, see Section 6.1.3, "What Are the Default Technology Scopes for a Framework Application?."
9. If you wish, select the **Generated Components** and **Associated Libraries** tabs to view additional configuration files and libraries that will be added to the project. For more information, see Section 1.10, "What Configuration Files Should I Know About?."
10. Click **Next**.
11. If you wish, enter a Default Package name and directories for the default Java source files and output class files, as shown in Figure 5–4.

Figure 5–4 Create WebCenter Portal – Framework Application Wizard Step 3 of 5

12. In the next wizard page, two check boxes appear, as shown in Figure 5–5. Generally, the default settings are recommended; however, see the following note for more information on this wizard page.

Figure 5–5 Create WebCenter Portal – Portal Framework Wizard Step 4 of 5



Note: If you want your application to include the features of Oracle WebCenter Portal: Framework, like page hierarchies and navigations, leave the first box checked (**Configure the application with standard Portal features**). If you uncheck this box, the result is that you will create a traditional Oracle Fusion Web Application that does not contain Framework features. For detailed information on the effect of checking or unchecking this box, see Section 6.1, "Manually Configuring a Framework Application With Technology Scopes."

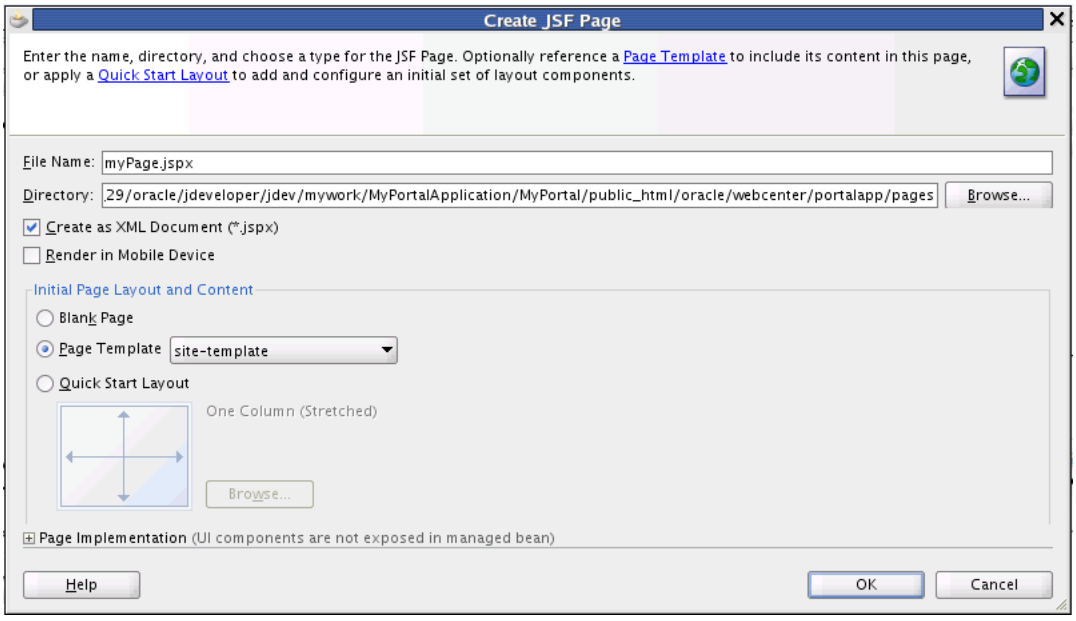
Oracle recommends that you leave the first checkbox selected, unless you know for sure that you do not want to use the Oracle WebCenter Portal: Framework features.

The second checkbox, **Enable automatic grants to all objects**, allows you to create a special role called test-all with View access on all taskflows and pages. This option is primarily added to make testing the application easier. It is unchecked by default.

13. Click **Next**.
14. In the final wizard page you are given a chance to configure the static application resources project. By default, this project is called PortalWebAssets. The project includes static application resources like HTML and image files. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. See For more information, see Section 5.4, "Understanding the PortalWebAssets Project.".

Figure 5–6 Create WebCenter Portal: Framework Application Wizard Step 5 of 5

15. Click **Finish** to create the Framework application.



5.3 Adding Pages to a Portal

The WebCenter Portal – Framework Application template populates a new portal application with several pages. This section explains how to add new pages to your portal application. See also Section 9.5.1, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."

> **Note:** Always create portal pages in JDeveloper as JSP *documents* (`.jspx`) rather than JSP *pages* (`.jsp`). For page customizations to be stored, the page must be represented in XML. By choosing to create an XML representation of the JSP document (`.jspx`), you ensure that customizations are always possible for the Framework application page.

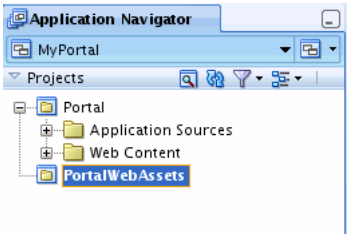
1. Start JDeveloper.
2. In the Application Navigator, right-click the `pages` folder (`Web Content/oracle/webcenter/portalapp/pages`) in your portal project and select **New**.
3. In the New Gallery, expand **Web Tier,** select **JSF** and then **JSF Page,** and click **OK.**
4. In the Create JSF Page dialog (Figure 5–7), enter a file name for the page.

Figure 5–7 The Create JSF Page Dialog

5. Select **Create as XML Document (*.jspx).**
6. Select a page template. For more information on page templates, see Section 9.5.1, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."
7. Click **OK**.

For information about the other settings in this dialog that are not specific to Framework application pages, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

5.4 Understanding the PortalWebAssets Project



This section discusses the PortalWebAssets project. If you wish, you can place static resources like HTML files and images in this project. The PortalWebAssets project is created, by default, in new Framework applications.

- Section 5.4.1, "Introduction"
- Section 5.4.2, "Decoupling the Static Application Resources Project"
- Section 5.4.3, "Deployment Options"
- Section 5.4.4, "Using EL to Manage Static Resources"

5.4.1 Introduction

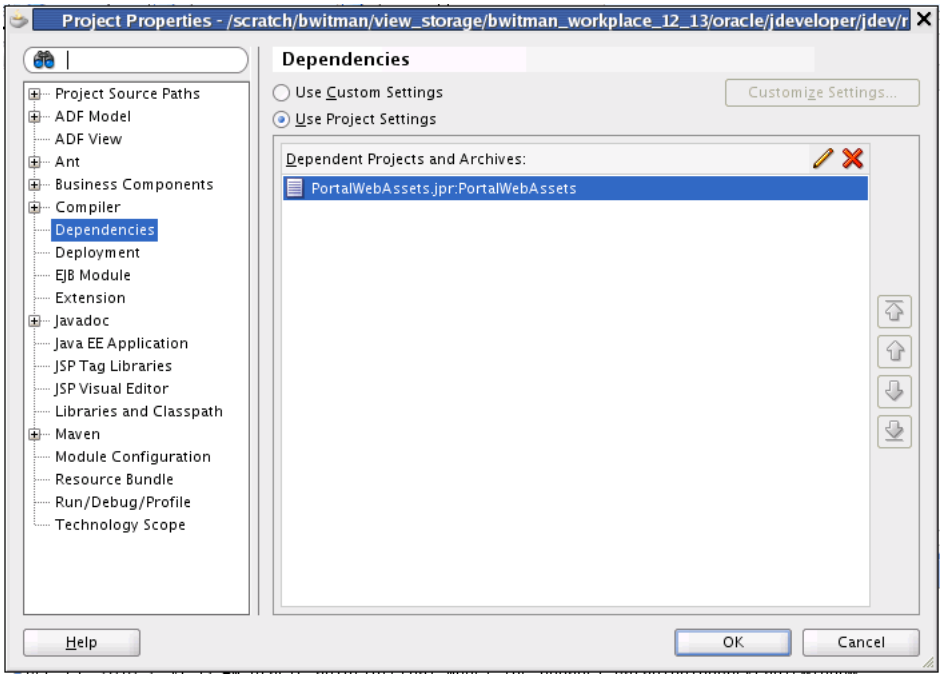
Static resources for a web application, like HTML and image files, are typically bundled and deployed with the application. Requests for both dynamic and static resources are generally handled by the host application server. One way to optimize server performance is to separate the static resources from the application and deploy them on a different (possibly less expensive and more scalable) server. Framework applications support this scenario with a static application resources project, which can include static resources like HTML and images. By default, this project is called PortalWebAssets, but you can rename the project if you wish. See Figure 5–8.

Figure 5–8 The PortalWebAssets Folder

To use the static resources project, simply add content (like HTML or image files) to the project. You can do this directly from the file system, by adding files under the `../PortalWebAssets/public_html` directory, or by adding in JDeveloper. For instance, to add an HTML file, select **New** from the File menu, and use the New Gallery wizard to create the resource.

> **Note:** CSS files used for skins must remain in the Framework application project. Do not attempt to place skin CSS files in the static application resources project.

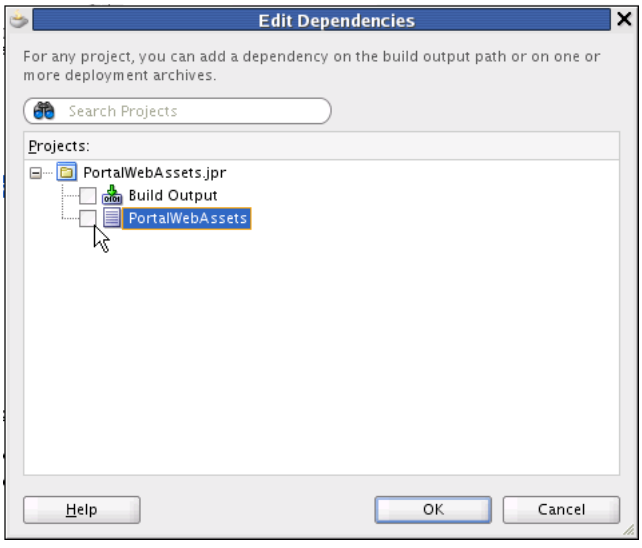
5.4.2 Decoupling the Static Application Resources Project



By default, a portal project includes the static application resources project (PortalWebAssets) as a dependency. This means they are built together and deployed to the same server. If you do not wish to deploy static resources to another server, then you do not need to take any action with respect to the static resources project.

If you wish to decouple the PortalWebAssets project from the Portal project, do the following:

1. Right-click the Portal project and select **Project Properties**.



2. In the Project Properties dialog, select the **Dependencies** node, as shown in Figure 5–9.

Figure 5–9 Project Dependencies Dialog

3. To remove the dependency, click the **Delete** button, or select the **Edit** button and deselect the project in the Edit Dependencies dialog, as shown in Figure 5–10.

Figure 5–10 The Edit Dependencies Dialog

4. Generate two distinct archives (`Portal.ear` and `PortalWebAssets.jar`), and deploy them to separate servers. See Section 5.4.3, "Deployment Options."

5.4.3 Deployment Options

The `Portal.ear` file is typically deployed to the application's managed server. The `PortalWebAssets.jar` file can be deployed to any J2EE compliant server container, usually by creating a WAR deployment profile in the PortalWebAssets project and including it in an EAR deployment profile. Another, simpler, option is to unzip the JAR file into an Apache web server. See also Chapter 70, "Deploying and Testing Your WebCenter Portal: Framework Application."

5.4.4 Using EL to Manage Static Resources

Developers can use EL expressions to dynamically generate the target URL for static resources. You have two options for using EL. With the first option, you need to define a base URL preference. The second allows you to map URLs dynamically.

5.4.4.1 Defining a Base URL Preference

This solution provides a single preference that uses a "base" URL to redirect resources to a desired server. With this option, EL expressions take a format that is illustrated by the following sample:

```
<af:image source="#{preferenceBean.baseResourceURL}/images/globe.png"/>
```

To configure this option, add a preference to the `adf-config.xml` file as follows:

```
<portal:preferences>
...
    <portal:preference id="oracle.webcenter.portalapp.baseresourceurl"
        desc="Default Base Resource URL EL"
        value=
       "#{request.scheme}://#{request.serverName}:#{request.serverPort}#{request.contextPath}"
       resourceType="BaseResourceURL" display="true"
    />
...
</portal:preferences>
```

The only limitation of this technique is that you can only map values to one server. There is only one preference value that can be returned. If you want to dynamically configure URLs, choose the technique described in the next section, Section 5.4.4.2, "Mapping URLs Dynamically."

5.4.4.2 Mapping URLs Dynamically

This solution lets you construct URLs dynamically through the ability to specify multiple namespaces. With this option, resources become a parameter to the preference, allowing the resources to be mapped to the correct namespace.

This solution supports two ADF component categories:

The first category includes static resources referenced by ADF Faces components. This type of call is illustrated by the following sample:

```
<af:image
source="#{preferenceBean.staticResourceURL['/oracle/webcenter/portalapp/static/ima
ges/globe.png']}"/>
```

The second category includes static resources referenced through the `inlineStyle` of ADF Faces components. This type of call is illustrated by the following sample:

```
<af:panelBorderLayout id="pt_pgl1"
inlineStyle='background-image:url(#{preferenceBean.staticResourceURL["/oracle/webc
```

```
enter/portalapp/static/images/globe.png"]});'>
```

The EL expression:

```
#{preferenceBean.staticResourceURL['<resource path>']}
```

performs a resource namespace lookup to derive the resource URL prefix. The input to the lookup is the path of the resource (for example: `/oracle/webcenter/portalapp/static/images/globe.png`). To establish the mappings between resource namespaces and URLs, edit the `<portal:resource-mappings>` section of the `adf-config.xml` file.

To configure this option, add a preference to the `adf-config.xml` file as follows:

```
<portal:adf-portal-config>
    <portal:preferences>
    ...
    </portal:preferences>
    <portal:resource-mappings>
        <portal:resource-mapping path="/"
 url-prefix="#{request.scheme}://#{request.serverName}:#{request.serverPort}#{request.contextPath}"
       />
    </portal:resource-mappings>
</portal:adf-portal-config>
```

The lookup yields the prefix of the resource URL. The final value of the resource URL is derived by concatenating the URL prefix with the path to the resource. For example,

```
/oracle/webcenter/portalapp/static/images/globe.png
```

yields:

```
http://myserver/static_resources/oracle/webcenter/portalapp/static/images/globe.png
```

At development time, the url-prefix lookup always resolves to the application's context URL, for example: `http://<server>:<port>/<context root>`.

Example 5–1 shows a sample mapping configuration in `adf-config.xml`:

Example 5–1 Sample Namespace Lookup Mapping

```
<portal:adf-portal-config>
    <portal:preferences>
    ...
    </portal:preferences>
    <portal:resource-mappings>
        <portal:resource-mapping path="/oracle/webcenter/portalapp/static"
            url-prefix="http://myserver/static_resources"/>
        <portal:resource-mapping path="/mycompany/static/images"
            url-prefix="http://myserver/static_resources"/>
        <portal:resource-mapping path="/mycompany/myapp/static/images"
            url-prefix="http://myserver/static_resources/myapp2"/>
    </portal:resource-mappings>
</portal:adf-portal-config>
```

5.5 Creating a Portlet Producer Application

A portlet producer application is configured to build standards-based (JSR286) and Oracle PDK-Java portlets. This section explains how to create a portlet application

using the Portlet Producer Application template. See also Chapter 58, "Overview of Portlets."

For information about extending an existing application to enable portlet creation, see Section 6.2, "Extending Non-WebCenter Portal: Framework Applications to Include WebCenter Capabilities."

This section includes these topics:

- Section 5.5.1, "How to Create a Portlet Application Using a Template"
- Section 5.5.2, "What Happens When You Use a Portlet Producer Application Template"

5.5.1 How to Create a Portlet Application Using a Template

The Portlet Producer Application template consists of a single project, *Portlets*. Use the Portlets project to create JSR 286 (standards-based) and Oracle PDK-Java portlets.

To create an application using the Portlet Producer Application template:

1. Access the application creation wizard in any of the following ways:
   - From the **File** menu, choose **New**. In the New Gallery dialog, expand **Applications**, select **Portlet Producer Application**, and click **OK**.
   - From the Application Navigator, select **New Application**.
   - If you have an application open, then in the Application Navigator open the application name drop down menu and select **New Application**.
   - In the Application Navigator, right-click the application name and choose **New**. In the New Gallery dialog, expand **Applications**, select **Portlet Producer Application**, and click **OK**.
2. In the Name your application page of the creation wizard, enter a name for the application in the **Application Name** field.
3. In the **Directory** field, accept the default path or enter a path to the directory where the application should be stored.

   For example:

   ```
   C:\JDeveloper\mywork\Application1
   ```

   Optionally, click the **Browse** button to navigate to the desired directory.
4. If required, in the **Application Package Prefix** field, enter a prefix to use for packages to be created within this application.
5. From the **Application Template** list, select **Portlet Producer Application**.

   Note: The Application Template list appears only when you invoke the wizard by clicking **New Application** in the Application Navigator as described in step 1.
6. Click **Finish** to create the portlet application with default project configurations.

5.5.2 What Happens When You Use a Portlet Producer Application Template

Using the Portlet Producer Application template generates the default *Portlets* project with the Java, JSP and Servlets, and Portlet technology scopes. It limits the types of

options that are exposed in the JDeveloper user interface to those appropriate for creating portlets.

When you right-click this new project, options to create JSR 286 and Oracle PDK-Java portlets are provided.

5.6 How Is a Framework application Security Configured by Default?

By default, a WebCenter Portal: Framework application is configured with ADF security. A default username and password (weblogic/weblogic1) are created automatically for you, and you can use this username/password combination for testing purposes immediately.

Default login and logout pages are also provided with the WebCenter Portal: Framework Application template.

For more information on ADF security, see Chapter 69, "Securing Your WebCenter Portal: Framework Application." See also the section on *Enforcing ADF Security in a Fusion Web Application* in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

6 Advanced Configuration Options

This chapter discusses techniques for manually configuring and extending a WebCenter Portal: Framework application. This chapter includes the following sections:

- Section 6.1, "Manually Configuring a Framework Application With Technology Scopes"
- Section 6.2, "Extending Non-WebCenter Portal: Framework Applications to Include WebCenter Capabilities"
- Section 6.3, "Creating a Project by Importing a WAR File"

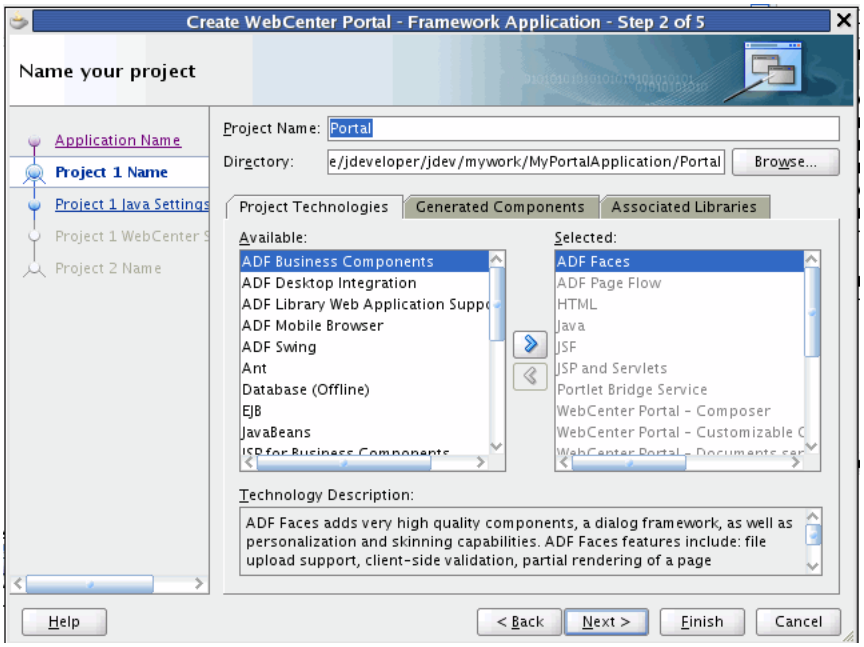
6.1 Manually Configuring a Framework Application With Technology Scopes

This section discusses how to manually configure a WebCenter Portal: Framework application by adding or removing technology scopes.

- Section 6.1.1, "What are Technology Scopes?"

  Section 6.1.2, "Adding and Removing Technology Scopes"
- Section 6.1.3, "What Are the Default Technology Scopes for a Framework Application?"
- Section 6.1.4, "Which Technology Scopes Are WebCenter Portal: Framework Application-Specific?"
- Section 6.1.5, "Can I Create a WebCenter Portal: Framework Application by Adding the Oracle WebCenter Portal: Framework Technology Scope Later?"
- Section 6.1.6, "Migrating a WebCenter PS2 or Earlier Application to a WebCenter Portal: Framework Application"

6.1.1 What are Technology Scopes?



Framework applications are comprised of a collection of project technologies and features or *technology scopes*. Each scope has associated libraries that provide specific features to the application. You can manually add or remove technology scopes to manually configure your application. For example, you may wish to remove some components from your Framework application that you know you will never use.

6.1.2 Adding and Removing Technology Scopes

You can add or remove technology scopes (and their associated libraries) in the following ways.

First, you can modify the defaults when you create a new application. Figure 6–1 shows the list of available and selected technology scopes presented in the Create WebCenter Portal – Framework Application wizard. The scopes in the Selected column indicate the default set of technology scopes that comprise a framework application. For more information on this wizard, see Section 5.2, "Creating a Framework Application."

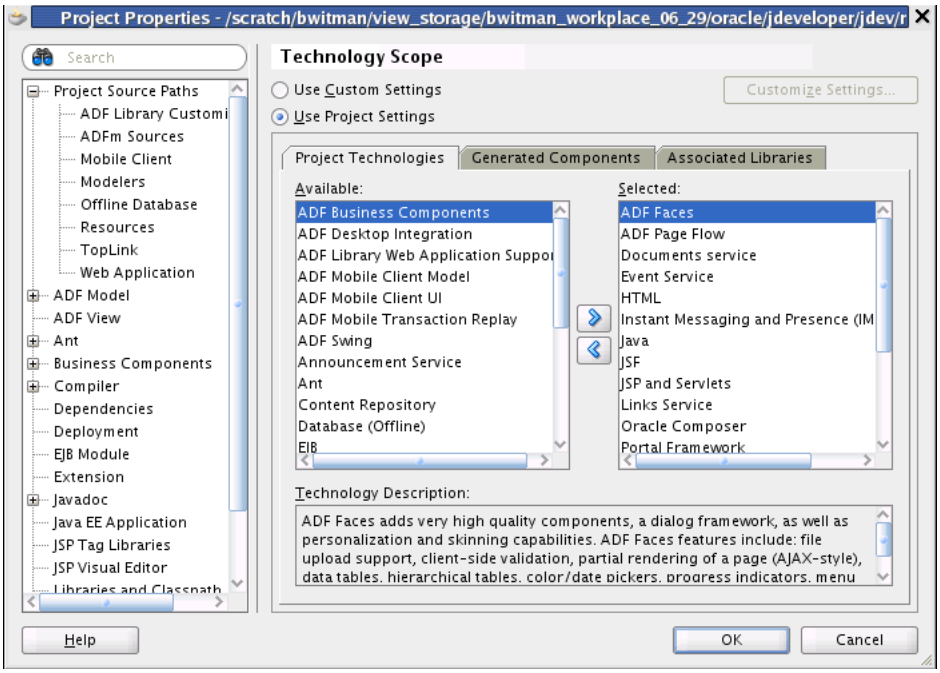


Figure 6–1 Create WebCenter Portal: Framework Application Wizard Step 2 of 5

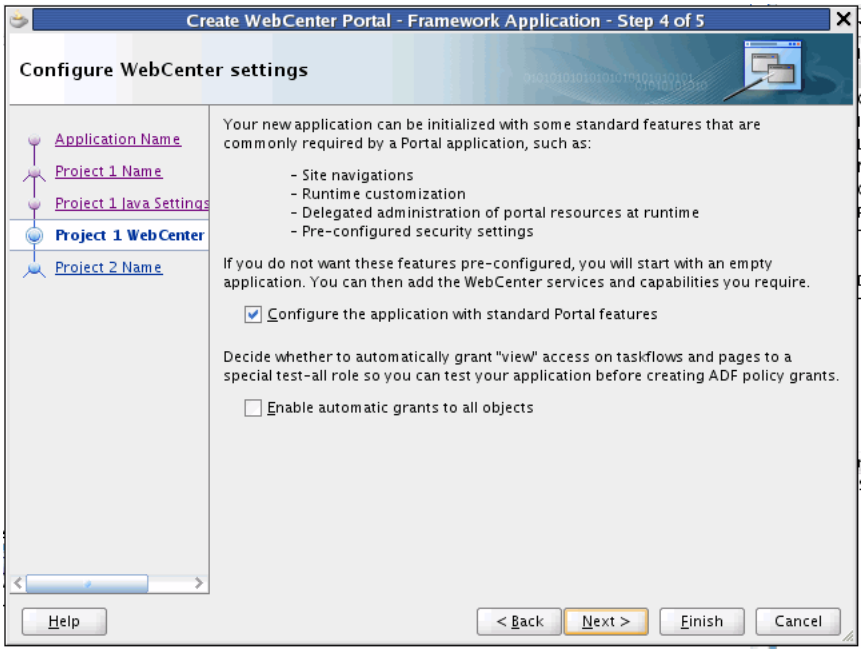
You can also adjust technology scopes in the Project Properties dialog. Select **Project Properties** from the Application menu. Then, select **Technology Scope** from the tree. The dialog lets you move project technologies in and out of the project, as shown in Figure 6–2.



> **Tip:** Click on a scope in the dialog to display a short description at the bottom of the dialog.

Figure 6–2 The Technology Scope Dialog

When you create a Framework application using the Create WebCenter Portal – Framework Application wizard, you have one other opportunity to determine the default configuration of the application that is created, and its technology scopes. The final screen of the wizard includes a checkbox labeled **Configure the application with standard Portal features**, shown in Figure 6–3.

Figure 6–3 Create WebCenter Portal: Framework Application Wizard Step 4 of 5

Checked by default, this option tells the wizard to add the Oracle WebCenter Portal: Framework features, like navigations, page hierarchies, delegated administration, and so on, to the application. If you uncheck this box, your application will not include

these features. Essentially, you will create an application that is functionally equivalent to a WebCenter PS2 (WebCenter 11g Release 1 11.1.1.2.0) application.

6.1.3 What Are the Default Technology Scopes for a Framework Application?

Table 6–1 lists the *default* technology scopes and libraries that are included with applications created with the WebCenter Portal – Framework Application template. The **Oracle WebCenter Portal: Framework** technology scope is the only scope that is portal-application specific. This scope provides navigations, page hierarchies, delegated administration, and the rest of the portal features described in Chapter 9, "Understanding Framework Applications."

> **Note:** The Oracle WebCenter Portal: Framework technology scope is added by default to an application created with the Framework application template. The Framework application creation wizard gives you a chance to omit this technology scope if you unselect the **Configure the application with standard Portal features** checkbox in the Framework application creation wizard (Figure 6–3). In this case, you will create an application that is functionally equivalent to a WebCenter PS2 (WebCenter 11g Release 1 11.1.1.2.0) application.

Table 6–1 Default Technology Scopes and Associated Libraries

Default Technology Scopes	Associated Libraries
ADF Faces	JSF Core
ADF Page Flow	JSF HTML
Documents Service	ADF Faces Runtime 11
Events Service	ADF Common Runtime
HTML	ADF Web Runtime
Instant Messaging and Presence (IMP) Service	MDS Runtime
Java	MDS Runtime Dependencies
JSF	Commons Beanutils 1.6.1
JSP and Servlets	Commons Logging 1.0.3
Links Service	Commons Collections 2.1
Oracle WebCenter Portal's Composer	ADF Page Flow Runtime
WebCenter Portal – Framework	ADF Controller Runtime
Portlet Bridge Service	JSP Runtime
Portlet View	
Smart Tag	
Tags Service	
WebCenter Portal's Customizable Components	
WebCenter Portal: Services	
XML	

6.1.4 Which Technology Scopes Are WebCenter Portal: Framework Application-Specific?

When the Configure the application with standard Portal features checkbox is selected in the Framework application creation wizard (Figure 6–3), the Oracle WebCenter Portal: Framework technology scope is added to the application in addition to the rest of the application technology scopes. If you were to unselect this checkbox, the Oracle WebCenter Portal: Framework technology scope would not be added.

6.1.5 Can I Create a WebCenter Portal: Framework Application by Adding the Oracle WebCenter Portal: Framework Technology Scope Later?

This case is not supported. If you want to create a Framework application, you must start with the WebCenter Portal: Framework Application template. For details, see Section 5, "Creating Framework and Portlet Producer Applications."

One possible solution is to create a new Framework application, then turn your existing Framework application into an ADF Library. Then, include the ADF Library in the WebCenter Portal: Framework Application.

6.1.6 Migrating a WebCenter PS2 or Earlier Application to a WebCenter Portal: Framework Application

The recommended best practice for migration is to create a new (PS3) Framework application using the WebCenter Portal: Framework Application template and then manually migrate the content, configurations, and logic from your old PS2 application to the new framework application. If it is not possible to follow this recommended practice, then follow the procedures described in Appendix H, "Manually Migrating a Framework Application."

> **Tip:** Another possible solution is to create a new Framework application, and then turn your existing Framework application into an ADF Library. Then, include the ADF Library in the Framework application.

6.2 Extending Non-WebCenter Portal: Framework Applications to Include WebCenter Capabilities

If your business requirement is to create a non-Framework application, say a Fusion web application, but you want to also include WebCenter capabilities in that application, you can do so by adding the required technology scopes and libraries. For example, you could add features like web services, task flows, and search to the application.

> **Note:** You cannot create a Framework application simply by adding the Oracle WebCenter Portal: Framework technology scope to a non-portal application. This use case is not supported, as explained in Section 6.1.5, "Can I Create a WebCenter Portal: Framework Application by Adding the Oracle WebCenter Portal: Framework Technology Scope Later?."

The technology scopes limit user interface options to those appropriate to the type of application project you are building. The libraries provide the components and elements useful in constructing application content. You can extend an existing

application to integrate content from various repositories, create portlets, or consume portlets and WebCenter Portal services. You can extend ADF applications from the current release or from a 10.1.x.x release.

While extending your application, you may decide to create projects that are optimized for specific WebCenter capabilities. This section steps you through the process of manually creating projects like those provided with the WebCenter templates and adding the required technology scopes and libraries to projects.

To enable WebCenter capabilities in an application:

1. Open your application.

   Click **Yes** if you are prompted to migrate your application settings.

   > **Note:** If you migrated a 10.1.3.x Framework application, then the application continues to have the Model, ViewController, and Portlets projects.

2. Optionally, create new projects for defining the application data model, consuming content, or creating portlets:
   a. In the Application Navigator, right-click the application and select **New Project** from the context menu.
   b. In the New Gallery, expand **General**, select **Projects**, then **Generic Project**, and click **OK**.
   c. In the Create Generic Project wizard, in the **Project Name** field, enter a name for the project.

      For example `View`.

   d. In the **Directory** field, specify the directory path for storing the project or accept the default path.
   e. Click **Finish** to create the new project.
3. Right-click a project and select **Project Properties**.
4. In the left side of the dialog, select **Technology Scope**.
5. In the Project Technologies part of the dialog, add the required technologies and libraries depending on which WebCenter-related capabilities you want to enable in the selected project. See Table 6–1 for a complete list.
6. Save your work.

6.3 Creating a Project by Importing a WAR File

Follow this procedure if you have an existing WAR file you want to import into your application environment through JDeveloper. Once the project is imported, you can configure it with WebCenter Portal features manually, as described in Section 6.1, "Manually Configuring a Framework Application With Technology Scopes."

> **Note:** Connection information is stored in the application-level EAR file and is not automatically imported with a project-level WAR file. Therefore, when you import a project-level WAR file, you must reconfigure any connections upon which the application relies.

To import a WAR file into JDeveloper:

1. Right-click your application in the Application Navigator, and choose **New Project** from the context menu.
2. In the New Gallery, expand **General**, select **Projects**, then **Project from War File**, and click **OK**.
3. Follow the wizard instructions to complete creating the project.
4. Right-click the newly created project in the Application Navigator, and select **Project Properties** from the context menu.
5. Add the required technology scopes and libraries depending on which WebCenter-related capabilities you want to enable in the selected project. For more information, see Section 6.1, "Manually Configuring a Framework Application With Technology Scopes."
6. Click **OK** to close the Project Properties dialog.

7

Preparing Your Application for WebCenter Portal Services

This chapter describes how to prepare your application to consume services in Oracle WebCenter Portal.

This chapter includes the following sections:

- Section 7.1, "Understanding WebCenter Portal Services Technologies"
- Section 7.2, "Preparing Your Framework Application to Consume Services"
- Section 7.3, "Extending Your Framework Application with Custom Components"
- Section 7.4, "Configuring General Settings for Your Services"

7.1 Understanding WebCenter Portal Services Technologies

Oracle WebCenter Portal Services enrich existing portals and Web sites with enterprise 2.0 capabilities, including social computing services, personal productivity services, online awareness and communications, content integration, and Web analytics.

See Also:

- Section 2.4, "Introducing Oracle WebCenter Portal: Services" for conceptual information about services
- Chapter 3, "Preparing Your Development Environment" for fundamental information about Framework applications, such as how to create an application

This section summarizes the key technologies available in services. This can help you determine which services to implement and the best way to customize your user interface.

This section includes the following subsections:

- Section 7.1.1, "Understanding WebCenter Portal Horizontal Services"
- Section 7.1.2, "Understanding WebCenter Portal APIs"
- Section 7.1.3, "Using WebCenter Portal Data Controls"

7.1.1 Understanding WebCenter Portal Horizontal Services

Some services in WebCenter Portal are considered *horizontal* services in that they interact with other services across an application.

Table 7–1 lists service integration in Oracle WebCenter Portal: Framework.

Table 7–1 Service Integration in WebCenter Portal

WebCenter Portal Services	RSS	Search	Tags	Links	Comments and Likes	Activity Stream	Activity Graph	Notifications	Analytics
Activity Graph						X	n/a		X
Announcements	X	X		X		X		X	
Blogs		X	X	X	X	X	X	X	X
Discussions	X	X	X	X	X (replies on topics)	X	X (replies)	X	
Documents, including wikis		X	X	X	X	X	X	X	X
Events		X partial		X		X		X	
Instant Messaging and Presence (IMP)								X	
Lists	X	X	X	X		X		X	
Mail								X	
Notes		X		X					
People Connections		X partial	X partial		X (Activity Stream, Message Board)	X (Message Board, Profiles, Feedback	X (Message Board)	X	X
Polls									
Recent Activities	X								
Search		n/a	X			X partial			X
Tags		X	n/a			X			

Notes: Notes, space Events and Favorites are available *only* in WebCenter Portal: Spaces applications.

The Search service (listed in the table) uses WebCenter Portal search adapters to search each available service. However, large-scale implementations should be configured to use Oracle SES search for best performance. Oracle SES searches applications for the following resources:

- Documents, including wikis and blogs
- Announcements and Discussions
- WebCenter Portal: Spaces applications only: spaces, lists, pages, and people resources in Spaces

For more information, see Chapter 45, "Integrating the Search Service."

7.1.2 Understanding WebCenter Portal APIs

This section describes the APIs available for WebCenter Portal services.

Note the following considerations when multiple customization options are available:

- Use REST APIs to build a custom client for accessing WebCenter Portal: Spaces; for example, an iPhone application that interacts with Spaces.
- REST APIs may provide the fastest and easiest way to customize the user interface and develop custom components. Consider using data controls or native APIs to build a custom user interface for accessing Spaces.
- Use data controls or native APIs to build a custom portal or composite Framework application.
- Use data controls or native APIs if you are proficient with Java, JDeveloper, and ADF. To use other languages, especially JavaScript, use REST APIs.

Table 7–2 lists services with available APIs. For services that use a 3rd-party back end, it includes available back end APIs.

Table 7–2 Supported Technologies for Services

WebCenter Portal Service	Data Controls	Java APIs	REST APIs	Back End APIs
Activity Graph	Section 46.3.1, "Using the Activity Graph Data Control"	*Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*	Section 46.3.2, "Using the Activity Graph Service REST APIs"	
Analytics	Section 47.3.1, "Using SQL Data Controls"	*Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*		
Announcements				Web Services with Oracle WebCenter Portal's Discussions Server (requires configuration, because WebCenter Portal is set up with custom authentication) See the Jive Forums documentation on the Oracle Fusion Middleware documentation library (in the WebCenter Portal product area)

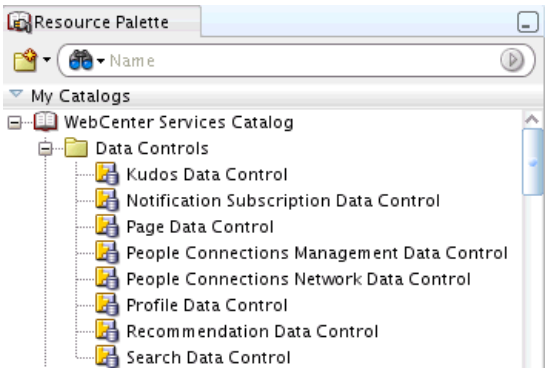
See Also: *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal* for more information about Expression Language APIs

7.1.3 Using WebCenter Portal Data Controls

Several services provide data controls for building a customized user interface with a Framework application or task flow. Deploying this task flow into an ADF library allows for a portable consumption of the task flow; for example, you could add it to a Spaces application Resource Catalog (Composer) to build site templates.

You do not need to integrate a service before you can use its data control to edit the user interface. An application is configured for the respective service when one of its data controls or task flows is used.



Note: Oracle ADF architecture provides data controls for the user interface to understand the structure of your data. Metadata describes data collections, properties, methods, and types. When you drag and drop attributes, collections, and methods onto a page, JDeveloper automatically creates the bindings from the page to the associated services.

See *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* for detailed information about data controls.

To use a built-in data control:

1. In JDeveloper, create a WebCenter Portal Framework application with any connections required for the services.
2. In the Resource Palette, expand My Catalogs, WebCenter Portal - Services Catalog, and Data Controls.
3. Right-click the data control and choose **Add to Project**.

Figure 7–1 Data Controls in the Resource Palette

4. Drag and drop methods and properties from the data control to a ADF JSF page.

Note: There are two other ways to add data controls to your application:

- From the Resource Palette, choose IDE connections, and navigate to the data control. Right-click the data control, and select **Add to Project**.
- From Project Properties, choose Libraries and Classpath, and click the **Add Library** button. With this approach, you must know the JDeveloper library that contains the data control you want.

7.2 Preparing Your Framework Application to Consume Services

This section describes the steps you must take to prepare your application to use WebCenter Portal Web services. It includes the following subsections:

- Section 7.2.1, "How to Prepare Your Application to Consume Services"
- Section 7.2.2, "Setting Up a Database Connection"
- Section 7.2.3, "Setting Up an External Application Connection"

7.2.1 How to Prepare Your Application to Consume Services

You can configure any application to include a service. When you create an application in JDeveloper, you can choose to base the application on a template. Although not a requirement, WebCenter Portal's Framework application template makes all the appropriate connection wizards and tag libraries readily visible and available in the New Gallery and Component palette. When you consume a service task flow or component, the necessary libraries are automatically added to the project.

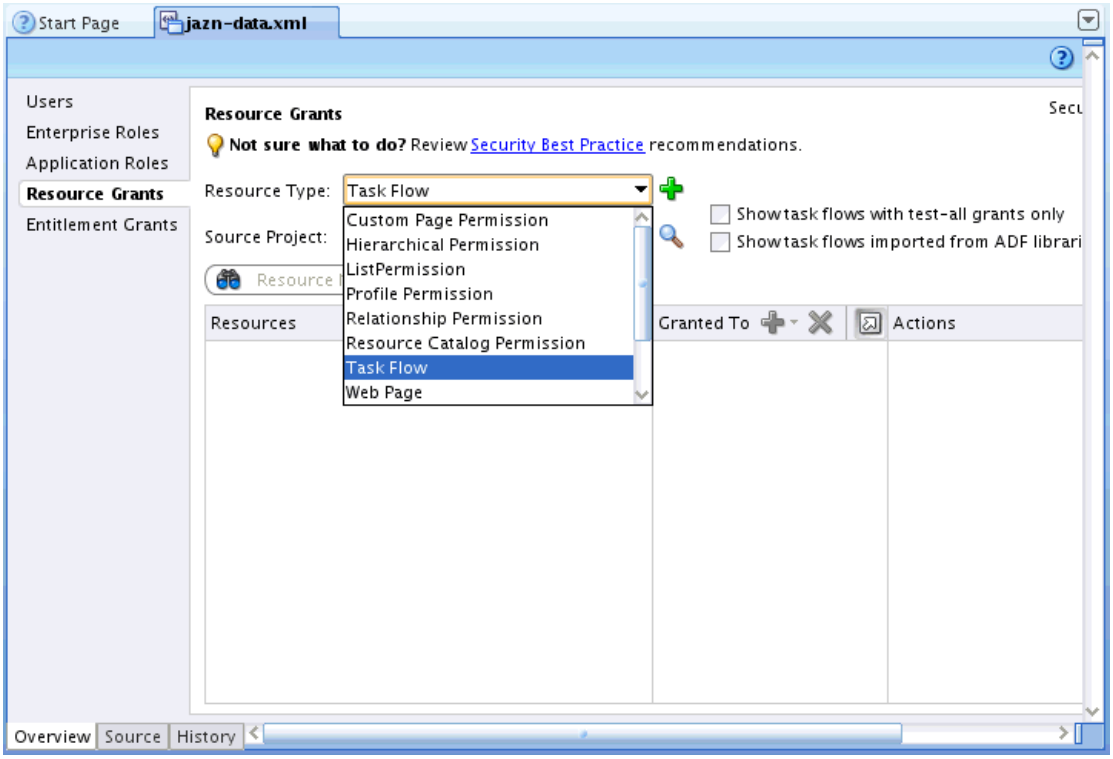
Depending upon the service you plan to consume, your application must meet certain prerequisites. For example, if the service must know the identity of users, then your application must provide some level of security with user authentication.

This section includes the following subsections:

- Section 7.2.1.1, "Implementing Security for Services"
- Section 7.2.1.2, "Setting Up SSL-Protected Connections for Services"

7.2.1.1 Implementing Security for Services

Some services must know the identity of the user (for example, the Search service needs the user's identity for saving searches). For these services, you must at least configure your application to authenticate users such that they have distinct identities for the purposes of user customization and preferences.



ADF security is configured by default if you created your application using WebCenter Portal's Framework application template.

See Also:

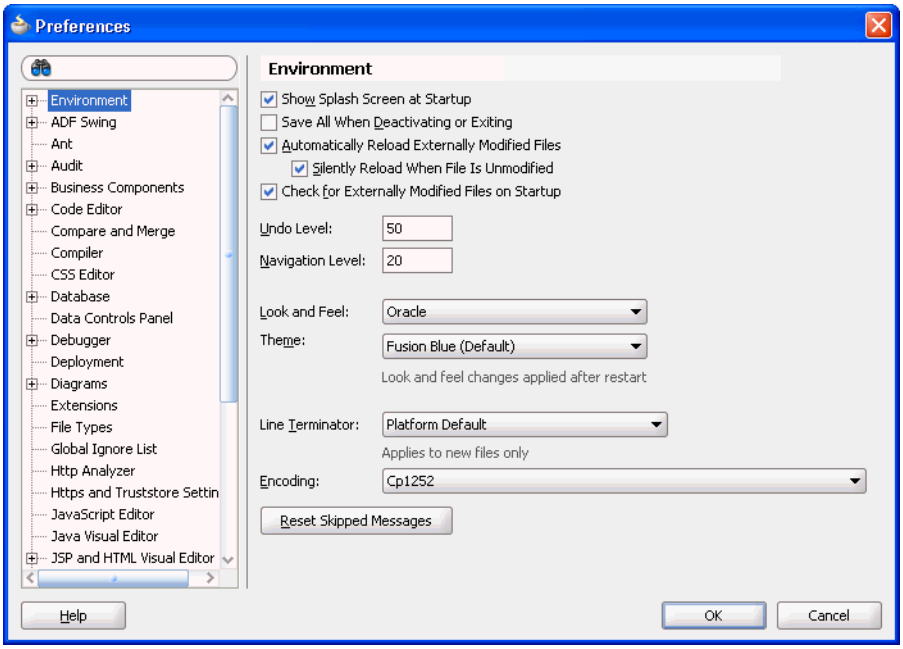
- Section 69.3, "Configuring ADF Security" for details on how to implement a basic security solution for your Framework application
- Chapter 69, "Securing Your WebCenter Portal: Framework Application" for details on how to implement a complete security solution for your Framework application

After you configure ADF security for your application, you can open the `jazn-data.xml` file and modify your sample user's privileges for each task flow. To open the ADF Security Policies Editor, locate the file in the Application Resources panel and double-click its name, or select Application - Secure - Resource Grants (Figure 7–2). The Resource Type dropdown controls the set of grants that are shown in the table. You can show only the grants for a particular permission type by selecting it from the list.

Figure 7–2 ADF Security Policies in the jazn-data.xml File

7.2.1.2 Setting Up SSL-Protected Connections for Services

If you are setting up a connection in JDeveloper for a service, and the connection is being made to an SSL-protected endpoint (with a valid certificate from a trusted certificate authority) then you need prepare your environment accordingly.



> **Note:** This Preferences setting change is required only for connections made using Integrated WLS as the default server. If you are deploying to a Managed Server, this settings change is not required.

To set preferences for SSL-protected service connections:

1. From the JDeveloper tool bar, select **Tools > Preferences**.

   The Preferences dialog displays (Figure 7–3).

Figure 7–3 Preferences Dialog

2. On the Preferences dialog, click **Credentials** (Figure 7–4).

Figure 7–4 Credentials Pane

3. Change the value of **Client Trusted Certificate Keystore** to:

   `<JAVA_HOME>/jre/lib/security/cacerts`

   where `<JAVA_HOME>` is the location of the Java home directory.

4. Click **OK**.

7.2.2 Setting Up a Database Connection

Many services require a connection to a database schema where relevant information is stored. For example, with the Links service, relationship mapping information, such as what object is linked to what other object, is stored in the database.

Table 7–3 lists the services that require a database connection.

Table 7–3 Associated Data Source

Service	Data Source
Activity Graph	Activities
Activity Stream	WebCenter Portal
Analytics	Activities
Blogs	WebCenter Portal
Comments	WebCenter Portal
Documents (including wikis and blogs) that want to include Comments and Activity Stream	WebCenter Portal
Links	WebCenter Portal
Lists	WebCenter Portal
Oracle Portal Adapter	PORTAL (name of the Oracle Portal schema)
People Connections	WebCenter Portal

Table 7–3 (Cont.) Associated Data Source

Service	Data Source
Polls	WebCenter Portal
Tags	WebCenter Portal

See Also:

- Section 3.5, "Installing Database Schemas" for information about installing the schemas
- "Deploying the Application to a WebLogic Managed Server" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* for data source considerations when deploying your application to a production environment

To create the database connection:

1. In the Application Navigator, expand the **Application Resources** panel.
2. Right-click **Connections**, then click **Database.**
3. Enter the following information for your database connection:
   - **Connection Name**: `webcenter/CustomPortal` or `activities/CustomPortal`

     Note: Oracle recommends that you use these names for ease of deployment to a Framework managed server.

     - If your application contains task flows that use the WebCenter Portal schema, then name the database connection `webcenter/CustomPortal`.
     - If the application contains task flows that use the Activities schema, then name the database connection `activities/CustomPortal`.

   - **Connection Type**: `Oracle (JDBC)`
   - **Username:** `username`
   - **Password**: `password`
   - **Host**: *host where you install the WebCenter Portal schema*; for example, `localhost`
   - **JDBC Port:** *port*; for example, `1521`
   - **SID**: *system identifier for the database with the same JDBC*; for example, `ORCL`

     Note: If the **Save Password** checkbox is not selected, then when deploying from JDeveloper to a managed server or the Integrated WebLogic Server, you must manually create the data source after deployment.

     For detailed information on how to create a JDBC data source for Oracle WebLogic Server, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

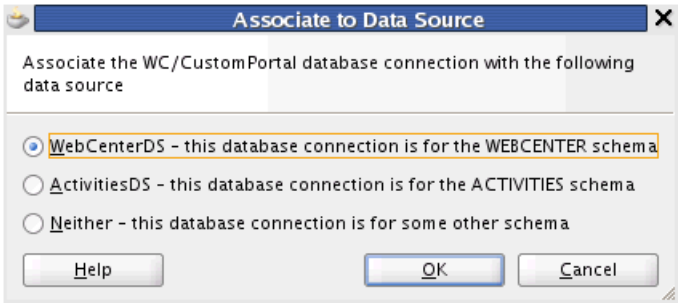


Figure 7–5 Database Connection

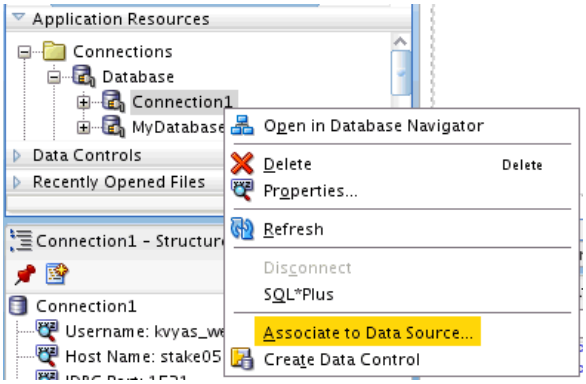
4. Click **OK**.
5. In the Associate to Data Source dialog, select the appropriate schema.
   - If you named the connection `webcenter/CustomPortal`, then select to associate this connection to the WebCenter Portal schema.
   - If you named the connection `activities/CustomPortal`, then select to associate this connection to the Activities schema.

   Click **OK** (Figure 7–6).

Figure 7–6 Associating to Data Source from the Connection Wizard

The data source association applies separately to each project in the workspace. If there is more than one WebCenter Portal project in the workspace, then the dialog displays a dropdown list allowing the user to choose which project to configure.



Note: While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control.

See *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* for more information.

7.2.2.1 Associating Existing Database Connections

For existing database connections, you can associate data sources by right-clicking the connection and selecting **Associate to Data Source** (Figure 7–7).

Figure 7–7 Associating to Data Source for Existing Connections

7.2.3 Setting Up an External Application Connection

When a service interacts with an application that handles its own authentication, you can associate that application with an external application definition to allow for credential provisioning.

The following services permit the use of an external application to connect with the service and define authentication for it:

- Documents
- Events
- Instant Messaging and Presence
- Mail
- RSS Viewer (when using a secured RSS feed)

See Also:

- Chapter 30, "Integrating the Documents Service," Chapter 35, "Integrating the Instant Messaging and Presence Service," Chapter 36, "Integrating the Mail Service," and Chapter 53, "Integrating the RSS Service" for more information about setting up the external application for a service
- Section 69.13, "Working with External Applications" for more information about external applications in general

7.3 Extending Your Framework Application with Custom Components

This section introduces the Resource Action Handling Framework and describes how to register a resource viewer. It includes the following subsections:

- Section 7.3.1, "Introducing the Resource Action Handling Framework"
- Section 7.3.2, "Registering a Resource Viewer"
- Section 7.3.3, "Creating a Resource Authorizer Class"
- Section 7.3.4, "Specifying the View Handler and Navigation Behavior"

7.3.1 Introducing the Resource Action Handling Framework

Custom components, just like out-of-the-box services, manage and own resources. As such, they must make declarations that enable their resources to be accessible to the services that invoke other services (for example, the Search, Tags, Links, and Recent Activities services). WebCenter Portal provides a *Resource Action Handling framework* for custom components and services that expose resources to be viewed, searched, and tagged.

For example, the Resource Action Handling framework enables the Search service to look up and follow the mechanism to render a resource for any given service. Other facilities of the Resource Action Handling framework allow for authorization of resources to be declared and enforced when access is made.

The following resources invoke resource viewers using the Resource Action Handling framework:

- Search
- Tags
- Links
- Wikis and Blogs
- Recent Activities
- People Connections
  - Activity Stream (invoking itself)
  - Connections (invoking itself)
  - Feedback (invoking itself)
  - Profile (invoking Tags, Tagged Items, and itself)
  - Message Board (invoking itself)
- External links pointing into WebCenter Portal (from, for example, mail, notifications, documents, RSS feeds, or REST XML)

The following resources own task flows that can be invoked by the Resource Action Handling framework.

- Announcements
- Discussions
- Documents, including wikis and blogs
- Events
- Lists
- Mail
- Notes
- Page
- People Connections
  - Activity Stream - Main View
  - Connections
  - Feedback
  - Profile
  - Profile Gallery
  - Message Board
- Spaces (URL rewriter that maps to `/webcenter/spaces/Space1Name`)
- Tags - Tag Center

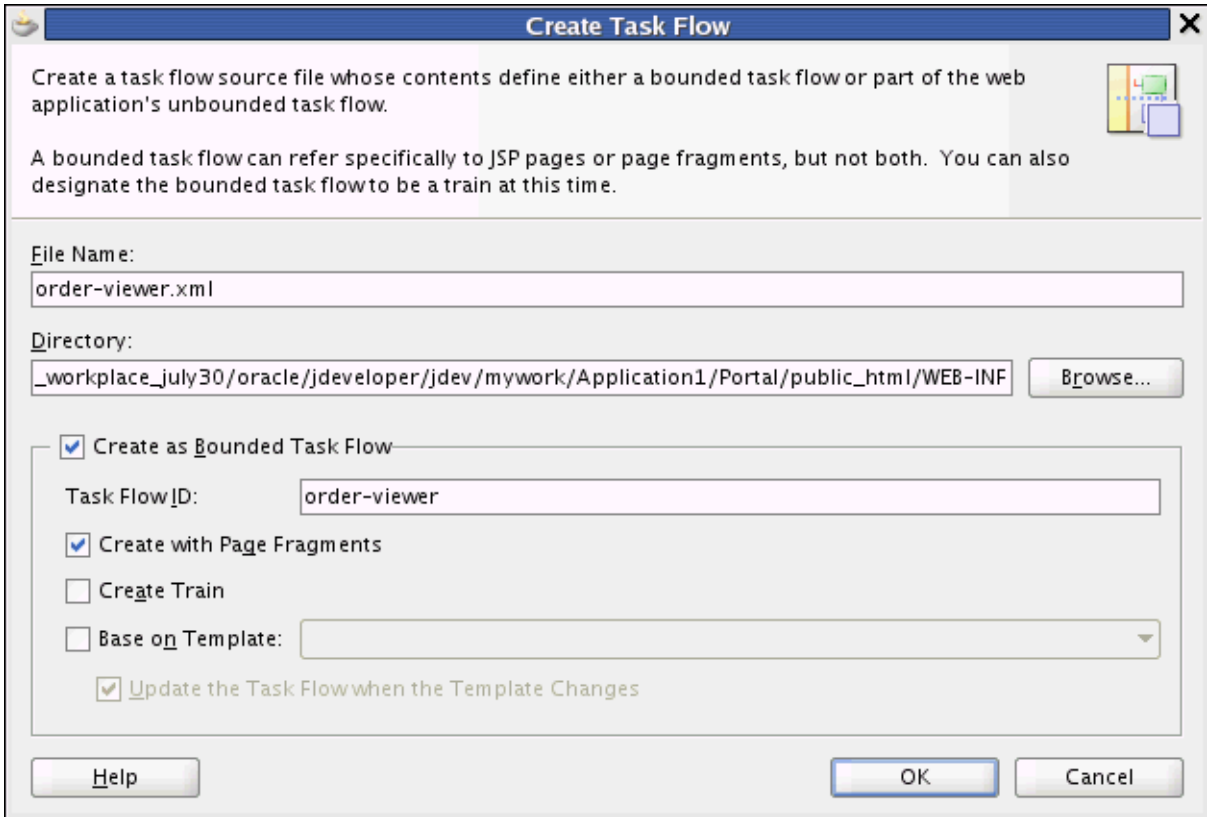
> **See Also:** *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal* for more information on the Resource Action Handling and rewriter interfaces

7.3.2 Registering a Resource Viewer

You must register a resource viewer to enable custom resources to be rendered using Search or Tags, or to make the resources linkable to and from each other.

In the `service-definition.xml` file, you can define a resource viewer for any service to render that service's resources. The viewer can be a task flow or a URL rewriter acting on the resource ID.

For example, suppose a discussion forum message is found through the Search service. Clicking the result link launches the resource viewer that was declared for the Discussions service (by looking up the `service-definition.xml` of the Discussions service). By default, the target is rendered in a dialog.



You can declare a resource mini-view to specify a resource viewer that is used for any inline popups displayed for this service. If the mini-view is not specified, then the resource view is used for inline popups.

Note: A sample `service-definition.xml` is included with Framework applications. This file enables developers to declare their resource viewers and their implementations of interfaces for interacting with the Links and Search services; for example, the QueryManager interface implementation.

To register a custom resource viewer:

1. In the Application Navigator, right-click the **Page Flows** node for the project and select **New** from the context menu.
2. Under **Categories**, select **JSF**, then **ADF Task Flow**, and click **OK**.
3. In the Create Task Flow dialog, change **File Name**, for example, to `order-viewer.xml`. The Task Flow ID should automatically update to `order-viewer` (Figure 7–8).

Figure 7–8 Create Task Flow Dialog for Resource Viewer

4. Click **OK**.

   Ensure that the `order-viewer.xml` file is created under `..\public_html\WEB-INF`.
5. From the Component Palette, ensure that ADF Task Flow is selected and drag **View** onto the task flow to create a page fragment.
6. Rename the page fragment to `order-viewer`, and click in an open area of the canvas to accept the change.
7. Define a JSFF file for your page fragment.
8. Double-click the page fragment.
9. Click **OK** in the Create New JSF Page Fragment dialog.
10. Go to the Source view in the editor and paste an `af:outputText` tag inside of the `jsp:root` element.

Example 7–1 provides a very simple resource viewer. You could create a much more complex viewer.

Example 7–1 Simple Resource Viewer

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:outputText value="Rendering #{pageFlowScope.resourceId}"
                 inlineStyle="font-size:5"/>
</jsp:root>
```

11. Add a `resourceId` input parameter to the task flow, and set the value to `#{pageFlowScope.resourceId}`.
12. After the task flow is defined, you must register it in the `service-definition.xml` file. In the Application Navigator, expand **Application Resources**, **Descriptors** and **ADF META-INF**.
13. Double-click `service-definition.xml` to open it in the editor.
14. In the file, you see a service definition that has been commented out. Uncomment it by removing the `<!--` and `-->` tags around it.
15. Set the `id` attribute to the service identifier.

    For example, the service identifier used when defining the Tagging Button could be `mycompany.myproduct.myapp.mycomponent`.
16. Set the `taskFlowId` in the `<resource-view>` element to `/WEB-INF/order-viewer.xml#resource-viewer`.

    This identifier is the task flow path and file name concatenated with the task flow identifier declared in the Create Task Flow dialog. You can omit the remaining tags.
17. The `<resource-view>` declaration has a class specification for the Resource Authorizer. This provides various ways to specify the resource view and determine which tagged objects are visible (and searchable) to users.

Example 7–2 Specifying a Task Flow ID in a resource-view Declaration

```
<resource-view taskFlowId="/somepath/somefile.xml#someId"
               authorizerClass="some.service.id.Authorizer1"/>
```

The Search, Tags, and Discussions services use this type of declaration. Instead of having a view ID (JSPX page), the service supplies a task flow to render the resource.

- The attribute `taskFlowId` signifies that the renderer is a task flow.
- A task flow is used to render the resource specified by the resource ID.
- The task flow honors a `resourceId` input parameter and uses that to render the resource.

Example 7–3 Specifying a URL Rewriter Class Name (1)

```
<resource-view
urlRewriterClass="oracle.webcenter.framework.resource.IdentityResourceUrlRewriter"
               authorizerClass="some.service.id.Authorizer5"/>
```

or

Example 7–4 Specifying a URL Rewriter Class Name (2)

```
<resource-view
urlRewriterClass="oracle.webcenter.framework.resource.MessageFormatResourceUrlRewr
iter"
               authorizerClass="some.service.id.Authorizer4">
  <parameters>
    <!-- This starts from the context root which would be /webcenter -->
    <parameter name="message" value="/content/conn/UCM/path/{0}"/>
  </parameters>
</resource-view>
```

or

Example 7–5 Specifying a URL Rewriter Class Name (3)

```
<resource-view
urlRewriterClass="oracle.webcenter.framework.resource.MyResourceUrlRewriter"
               authorizerClass="some.service.id.Authorizer6">
  <parameters>
    <parameter name="myParam" value="myValue"/>
  </parameters>
</resource-view>
```

Some services use a URL rewriter to treat the resource ID as a URL and rewrite the URL in an appropriate fashion. A URL rewriter changes the resource ID into a URL that can be launched with a `goLink`. Two `ResourceUrlRewriters` are provided:

- `oracle.webcenter.framework.resource.IdentityResourceUrlRewriter` is for Search with Oracle SES. It takes the `resourceId` value as a URL as is.
- `oracle.webcenter.framework.resource.MessageFormatResourceUrlRewriter` is for Documents. It takes in a `message` parameter (in the `service-definition`). The `message` parameter contains a {0}, which is replaced with the value of the `resourceId`.

The `urlExternal` parameter applies to all URL rewriters. This parameter's value determines whether the JSPX that consumes a resource action handler link should open a new window.

Some resources, like pages and wikis, can have no resource viewer but may allow dubbing their resource IDs as page view IDs (Example 7–6).

Example 7–6 No Resource Viewer (Resource ID as Page View ID)

```
<resource-view authorizerClass="some.service.id.Authorizer3"/>
```

18. Your service should look similar to the one shown in Example 7–7.

Example 7–7 Sample Service Definition for Resource View

```
<service-definitions>
  <service-definition id="mycompany.myproduct.myapp.mycomponent"
                      version="11.1.1.0.0">
  <resource-view taskFlowId="/somepath/somefile.xml#someId"

authorizerClass="mycompany.myproduct.myapp.mycomponent.ResourceAuthorizer"/>
  <resource-type>Custom Object</resource-type>
  <object-types>
    <object-type name="customcomponent123"
```

```
                displayName="Display Name"
                description="Description"/>
  </object-types>

<resource-bundle-class>mycompany.myproduct.myapp.mycomponent.resource.ComponentMes
sageBundle
</resource-bundle-class>
  <name>My Custom Component</name>
  <description>My Custom Component's Description</description>
  <icon>/mycompany/myproduct/myapp/mycomponent/component.png</icon>
  </service-definition>
 ...
</service-definitions>
```

19. Save the `service-definition.xml` file.

7.3.3 Creating a Resource Authorizer Class

The Resource Authorizer interface uses Java interfaces and classes to return useful information about service resources. For example, the `oracle.webcenter.framework.resource.ResourceAuthorizer` interface contains a method that returns the status (available or not available) for a unique resource ID (Example 7–8).

Example 7–8 Method for Returning Status Against a Unique Resource ID

```
/*
 * Check if the passed in resourceIds are viewable by the current user.
 *
 * @param resourceId - the resourceId to check
 * @return - a <code>ResourceInfo</code> with a ResourceStatus
 * of RESOURCE_IS_AVAILABLE if the passed in resourceId
 * is viewable by current user, otherwise returns
 * <code>RESOURCE_IS_NOT_AVAILABLE</code>.
 */
ResourceInfo getResourceInfo(String resourceId, Scope scope);

/*
 * Check if the passed in resourceIds are viewable by the current user.
 *
 * @param resourceIds - the resourceIds to check
 * @return - a List of <code>ResourceInfo</code> with a ResourceStatus
 * of RESOURCE_IS_AVAILABLE if the passed in resourceId
 * is viewable by current user, otherwise returns
 * <code>RESOURCE_IS_NOT_AVAILABLE</code>.
 */
List<ResourceInfo> getResourceInfo(List<String> resourceIds, Scope scope);
```

The `oracle.webcenter.framework.resource.ResourceInfo` interface exposes the following method:

```
public ResourceStatus getResourceStatus();
```

The `oracle.webcenter.framework.resource.ResourceInfo.ResourceStatus` enumeration includes the following possible values:

Example 7–9 Possible ResourceStatus Values

```
/**
```

```
 * Used to describe a related object's status.
 *
 * Certain operations may be performed by relationship service depending
 * on what object status it receives from the service.  For example,
 * if it receives {@link #RESOURCE_DOES_NOT_EXIST} it may remove all
 * relationships associated with this object from the relationship schema
 * so future calls are not wasted on this object.
 */
 public enum ResourceStatus
 {
   /**
    * Used to describe a resource that is available.
    */
   RESOURCE_IS_AVAILABLE,

   /**
    * Used to describe a resource that does not exist.
    */
   RESOURCE_DOES_NOT_EXIST,

   /**
    * Used when the user does not have view access on the resource.
    */
   USER_DOES_NOT_HAVE_ACCESS;
 }
```

The only method in the `oracle.webcenter.framework.resource.ResourceUrlRewriter` interface writes the URL, after a unique identifier is passed in. This URL can be an absolute URL or it can be one relative to the faces context root of the owning application.

Example 7–10 Resource URL Rewriter Method

```
public String rewriteUrl(String id);
```

7.3.4 Specifying the View Handler and Navigation Behavior

You can develop your own resource action view handler -- for example, to cause resources to display in a new tab on the current page -- and specify whether you want to use the ADF inline popup, navigate using the DefaultResourceActionHandler (which opens in the same browser window to display the resource full screen navigation) or use the PopUpResourceActionHandler (which opens a new browser popup window).

Clicking a RAH-enabled link or button in a Framework application invokes the built-in default resource action view handler. This opens the resource in a resource viewer task flow by navigating from the browser to the resource using the same browser window.

You can change this behavior in `adf-config.xml` by specifying either the built-in popup view handler or a custom view handler in the `<resource-handler>` element. Additionally, you can specify whether the default action should invoke the view handler or display as an ADF inline popup in the current window.

Example 7–11 shows the XML added to `adf-config.xml` to declare that `MyAppResourceActionHandler` should be used as the view handler and that in the first instance, the resources should be displayed using an ADF inline popup.

Example 7–11 Specifying a Custom View Handler

```
<wpsC:adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
   <resource-handler
       class="com.mycompany.myapp.MyAppResourceActionHandler"
       display-as-popup="true" />
</wpsC:adf-service-config>
```

where the `wpsC:` namespace is defined as follows:

```
xmlns:wpsC="http://xmlns.oracle.com/webcenter/framework/service"
```

Along with the `DefaultResourceActionHandler`, the RAH framework also includes the `PopUpResourceActionHandler`, which invokes a new browser popup when navigating, rather than performing a full browser window navigation. This is similar to the behavior of WebCenter Portal applications in previous releases.

Example 7–12 shows how to specify the popup view handler.

Example 7–12 Specifying the PopUp View Handler

```
<wpsC:adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
    <resource-handler
class="oracle.webcenter.framework.resource.view.PopUpResourceActionHandler" />
</wpsC:adf-service-config>
```

Applications can invoke their own resource action view handlers by creating a class implementing the `ResourceActionHandler` interface or by extending the `AbstractResourceActionHandler` base class and specifying the new view handler in the class attribute of `<resource-handler>` in `adf-config.xml`. In the following scenarios, the custom view handler class is invoked when a RAH link is clicked:

- The ADF inline popup is not being used.
- The **Maximize** button is clicked on the ADF inline popup.

> **See Also:** *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal* for the service framework for more information about creating a custom resource action view handler; in particular, the `AbstractResourceActionHandler` class

In the `<resource-handler>` tag, the `display-as-popup` attribute defines the initial behavior for actioning an RAH link. This can be overridden on the RAH link itself in the `resourceActionBehavior` tag using the `useResourcePopup` attribute with the values of `always`, `never` or `appDefined`.

If `useResourcePopup` is not set, or if it is set to `appDefined` on the RAH link, then the `display-as-popup` attribute in `adf-config.xml` is considered. If this is set to `true`, then RAH invokes the ADF inline popup instead of invoking the resource action view handler. This displays a mini-resource-view of the resource in an ADF inline popup within the current page. The user can close or maximize this. If the user clicks the **Maximize** button, then the popup is closed and the resource action view handler is invoked.

By default, the ADF inline popup is used in Framework applications only for specific cases for some task flows where a full navigation does not make sense. For example, search results may include the resource's author. When you click this user name link,

you see the popup summary profile of the author without navigating away from the search result.

These task flows have `useResourcePopup` set to `always` in their `resourceActionBehavior` tags. You can change this by customizing the task flow.

In deployed applications, the `<resource-handler>` settings in `adf-config.xml` can be added and updated using WLST commands. For command syntax and examples, see the sections, "setWebCenterServiceFrameworkConfig" and "getWebCenterServiceFrameworkConfig" in *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference*.

7.4 Configuring General Settings for Your Services

Optionally, you can enable users to set the time zone, the date and time format, the language (locale), and the accessibility mode for the services you add to your application. You can provide these capabilities through the WebCenter Portal General Settings service. This service contains values that you can access either directly from the JSF page(s) in your Framework application or indirectly through an API. The General Settings service covers the following areas:

- **Time Zone:** By default, displays the time defined by the server running the application. This is based on `java.util.Timezone`; for example, `GMT+0800`. It also supports the format `Region/Country`; for example, `Europe/Amsterdam`.
- **Date/Time:** By default, configured to the style `java.text.DateFormat.SHORT`. This is based on `java.text.DateFormat`; for example, `java.text.DateFormat.MEDIUM`. Supported values are `SHORT`, `MEDIUM`, `LONG` and `FULL`.
- **Language:** By default, defined by the locale of the user's browser. This is based on `java.util.Locale`; for example, `fr-CA`.
- **Accessibility Settings:** A value to use with the `accessibility-mode` setting in the `trinidad-config.xml` file. Valid values are `default`, `inaccessible`, or `screenReader`.
- **Application Skin:** A value to use with the `skin-family` setting in the `trinidad-config.xml` file. This is based on the Trinidad `skin-family` attribute. Valid values are defined by skins included with the application.

To use the service directly from your application, use Expression Language in your JSF pages to access the `generalSettings` managed bean. The style is based on the `java.util.Timezone`, and the pattern is based on `java.text.SimpleDateFormat`.

When you add `generalSettings` as the value attribute of an ADF component, for example `af:activeOutputText`, you can open the Expression Builder, then navigate to **JSF Managed Beans > generalSettings** to view the preference values for the bean.

The General Settings service supports both pattern-based and style-based formats. If a pattern is not specified, then the style is used. By default, the patterns are not specified or null.

Figure 7–9 shows the Insert EL Expression dialog with General Settings.

Figure 7–9 Expression Builder for the generalSettings JSF Managed Bean

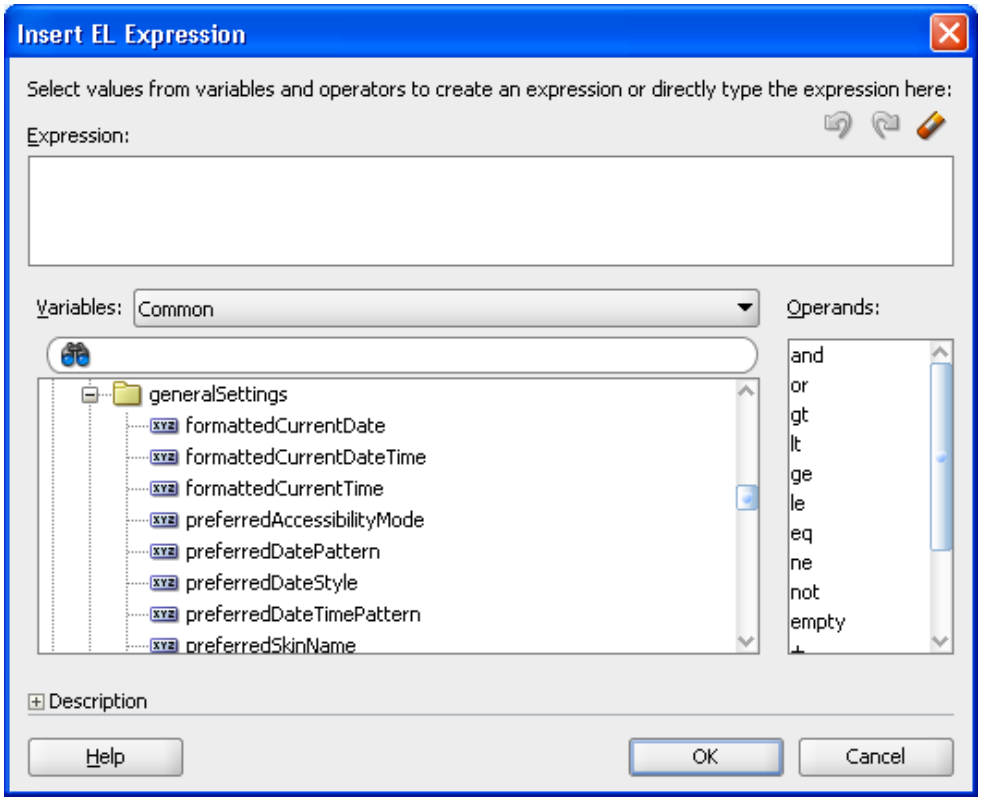


Table 7–4 describes the preference values for the General Settings service.

Table 7–4 General Settings Managed Bean Preference Values and Descriptions

General Settings Preference Value	Description
`formattedCurrentDate`	Displays the current date in the user's selected locale.
`formattedCurrentDateTime`	Displays the current date and time in the user's selected locale.
`formattedCurrentTime`	Displays the current time in the user's selected locale.
`preferredAccessibilityMode`	Preferred accessibility mode (`default`, `inaccessible`, or `screenReader`) for use in the `accessibility-mode` setting in `trinidad-config.xml`.
`preferredDateStyle`	Java date style to be used in `dateStyle` attributes when displaying dates and times.
`preferredTimeStyle`	Java time style to be used in `timeStyle` attributes when displaying dates and times.
`preferredDatePattern`	Java date pattern to be used when displaying dates, and not times.The pattern must be a valid `java.text.SimpleDateFormat` pattern; for example: `dd-MMM-yyyy`. This takes precedence over `preferredDateStyle`.
`preferredTimePattern`	Java time pattern to be used when displaying times, and not dates. This takes precedence over `preferredTimeStyle`.

Table 7–4 (Cont.) General Settings Managed Bean Preference Values and Descriptions

General Settings Preference Value	Description
`preferredDateTimePattern`	Java date/time pattern to be used when displaying dates and times. This takes precedence over `preferredDateStyle` and `preferredTimeStyle`.
`userTimeZone`	Java time zone to be used in `timeZone` attributes when displaying dates and times.
`preferredSkinName`	Preferred skin name to use with the `skin-family` setting in `trinidad-config.xml`.

For example, to display the current date and time in the user's selected locale, time zone, and format, add the following to your page:

Example 7–13 Code for Displaying Current Date and Time in User's Locale

```
<af:outputText value="#{generalSettings.formattedCurrentDateTime}"/>
```

Or, to display a specific date and time:

Example 7–14 Code for Displaying Specified Date and Time

```
<af:outputText value="#{row.dateTimeValue}">
    <af:convertDateTime type="both"
                        dateStyle="#{generalSettings.preferredDateStyle}"
                        timeStyle="#{generalSettings.preferredTimeStyle}"
                        timeZone="#{generalSettings.userTimeZone}"
                        locale="#{facesContext.externalContext.requestLocale}" />
                        pattern="#{generalSettings.preferredDateTimePattern}"
    </af:outputText>>
```

To take advantage of the preferred accessibility mode, you must add an EL (Expression Language) expression to the application's `trinidad-config.xml` file to set the accessibility mode; for example:

Example 7–15 Setting the Accessibility Mode in trinidad-config.xml

```
<accessibility-mode>#{generalSettings.preferredAccessibilityMode}</accessibility-m
ode>
```

7.4.1 Building a Preferences User Interface

You can build a user interface using the General Settings API to enable users to either accept the default settings or apply their desired settings. The API contains the same preference values described in Table 7–4.

Any service in WebCenter Portal that displays a date and time uses the settings configured in the General Settings service. For information on using the General Settings Service API to build a preferences user interface, see the Javadoc for `oracle.webcenter.generalsettings`. Specifically, the `oracle.webcenter.generalsettings.model` package contains APIs to get and set preference values for each of the settings. Use these APIs to build a custom user interface to allow users to view and set their preferred values.

> **See Also:** *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*

7.4.2 Using General Settings to Specify the User's Locale

By default, ADF obtains the user's locale from the user's browser settings. You can change this behavior to have the user's preferred locale be set in the application using a Preferences UI.

To make the behavior change, include `oracle.webcenter.generalsettings.model.filter.GeneralSettingsLocaleFilter` as a servlet filter in `web.xml` and `adfBindings`. This servlet filter sets the default locale (ADF Locale) from the General Settings service Locale preference instead of from the user's browser.

Add the General Setting locale filter to `web.xml` with the following rules:

Define the filter. For example:

```
<filter>
   <description>
      WebCenter General Settings locale setting.
   </description>
   <filter-name>
      generalSettingsLocaleFilter
   </filter-name>
   <filter-class>

oracle.webcenter.generalsettings.model.filter.GeneralSettingsLocaleFilter
   </filter-class>
</filter>
```

Add the filter after the `adfBindings` filter with the same servlet-name. For example:

```
<filter-mapping>
   <filter-name>
      generalSettingsLocaleFilter
   </filter-name>
   <servlet-name>Faces Servlet</servlet-name>
</filter-mapping>
```

If this filter *is not* set, then the locale is sourced first from the client browser locale setting, and then from the ADF locale setting.

If this filter *is* set, then the locale is sourced from the General Settings service. If the General Settings locale preference does not exist, then it reverts to the non-filter default behavior.

8

Introducing the AviTrust Portal Framework Sample Application

As a companion to this guide, a sample enterprise application was developed using Oracle Fusion Middleware 11g Release 1 (11.1.1.5), which includes Oracle WebCenter Portal: Framework and Oracle WebCenter Portal: Spaces. The application, called the AviTrust Portal Demonstration for WebCenter Portal, is referenced in various chapters throughout this guide to illustrate points and provide typical use cases for Oracle developers. It is intended to serve as a powerful learning tool for understanding the new portal features and services available in the latest release of WebCenter Portal.

In this chapter, you'll learn about these features and services, as well as take a quick, high-level tour of the components that were built using WebCenter Portal: Framework.

This chapter includes the following sections:

- Section 8.1, "About the AviTrust Portal Framework Application for WebCenter"
- Section 8.2, "Downloading the AviTrust Portal Framework Application"
- Section 8.3, "Browsing Portal Framework Features at Runtime"
- Section 8.4, "Accessing and Using the Resource Manager"
- Section 8.5, "In-Context Editing of Web Content at Runtime"
- Section 8.6, "Exposing Social Computing Services"
- Section 8.7, "WebCenter Framework Components in the AviTrust Portal Demo"

8.1 About the AviTrust Portal Framework Application for WebCenter

The AviTrust Portal Demo for WebCenter is a robust, rich-media portal application built for the enterprise, which demonstrates some of the advanced features available in Oracle Fusion Middleware, as well as WebCenter Portal: Framework. The application is based on a hypothetical online banking and financial services website -- the AviTrust Listening Bank.

Using this public-facing, extranet portal (shown in Figure 8–2), customers can browse and navigate various banking services offered by the AviTrust Bank, such as opening checking and savings accounts or applying for loans, through the bank website. Customers can also take advantage of a wide range of banking and financial services tailored for both small businesses and larger commercial enterprises, like setting up custom online accounts for access to the portal.

In this portal application, WebCenter Portal and WebCenter Portal: Framework are used to provide a host of Web 2.0 capabilities that include content-driven navigation, personalization scenarios, and integration of new WebCenter Portal: Services,

including polls, blogs, RSS, discussion forums, tags, links, social networking and activity streams. These services are directly embedded into the AviTrust sample portal application.

By design, the AviTrust banking portal application was created (hypothetically) to reduce transaction costs and offer a wide range of convenient banking services to its online customers.

For example, the AviTrust banking portal allows authenticated customers to:

- Log in securely to browse various banking services and online offers
- Open checking and savings accounts
- Apply for loans online and take advantage of other banking services available for small businesses and large enterprises
- Participate in online forum discussions, wikis, polls, blogs and other social computing activities

8.2 Downloading the AviTrust Portal Framework Application

To view and run the demo application, you need to install Oracle JDeveloper 11*g* (11.1.1.4) and the Oracle WebCenter Portal extension (11.1.1), as described in Section 3.2, "Installing WebCenter Portal's Extension for Oracle JDeveloper." You then need to download the application for this demonstration. Once the application is installed and running, you can view the application at design time in Oracle JDeveloper and at runtime by logging in as a user or administrator.

The AviTrust Portal Demo source distribution is available via the WebCenter Oracle Technology Network (OTN) page for Demos and Samples.

Sample files to import into your WebCenter Portal application, which include both project and archive files, available for download as a ZIP (or tgz) archive, will be made available here.

`http://www.oracle.com/technetwork/middleware/webcenter/portal/documentation/avitrust-522536.html`

The ZIP archive also includes instructions on how to load and install the project content.

Sample code for developers and administrators is available at `http://www.oracle.com/technetwork/indexes/samplecode/index.html`

Release downloads for Oracle WebCenter Portal Developers are available at

`http://www.oracle.com/technetwork/middleware/webcenter/portal/downloads/index.html`

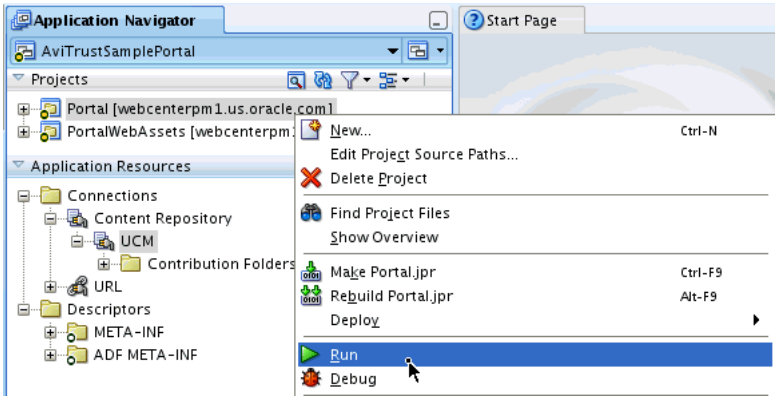
8.3 Browsing Portal Framework Features at Runtime

Once you have downloaded and installed the AviTrust sample portal application, you can run the application and navigate to the components that were built using WebCenter Portal. This section will take you on a visual tour of the application and show you how the components were built using WebCenter: Framework.

The section focuses on how the various Oracle WebCenter Portal components display at runtime. You can examine the application at design time in Oracle JDeveloper. For more information on how you can add a service or feature to your application, refer to the appropriate chapter in this guide.

In broad outline, some of the new features illustrated by the AviTrust sample application in this release of WebCenter Portal include:

- Improved portal navigation, with pages based on multiple levels of navigation and content based on different page templates. For information about how to expose the navigation model in your portal, see Chapter 14, "Visualizing Your Portal Navigation."
- Publication of HTML content from Oracle WebCenter Content by means of Oracle Content Presenter. For more information, see Chapter 29, "Creating Content Presenter Display Templates."
- Content integration with in-context editing of HTML documents stored on Oracle Content Server, as well as in-context editing of Site Studio definition files. Use of content-driven navigational links For information on how to create the navigation model for your portal, refer to Chapter 11, "Building a Navigation Model for Your Portal."
- Personalization, which enables developers to render content from the Content Presenter, based on a personalization scenario. For more information, refer to Chapter 67, "Personalizing WebCenter Portal Applications."
- Resource management, enabling developers to manage portal resources, like pages, templates, catalogs, and skins, at runtime. For more information, see Chapter 13, "Adding Resources to Your Portal."
- Integration of WebCenter services, like polls, forums, blogs and wikis, for enhanced user experience in social computing. For more information, see Chapter 37, "Integrating the Polls Service."



8.3.1 Exploring the AviTrust Sample Portal Home Page

To understand how the components of the banking portal were constructed, you can begin by launching and deploying the application in JDeveloper and then taking a look at the AviTrust Sample Portal Home page, as displayed in a web browser. The Home page will serve to illustrate some of the powerful, new features available in WebCenter Portal.

To view these features:

1. Open the AviTrust Sample Portal application in Oracle JDeveloper.
2. In Application Navigator, select the `Portal [webcenterpm1.us.oracle.com]` project and right-click the **Run** icon, as shown in Figure 8–1.

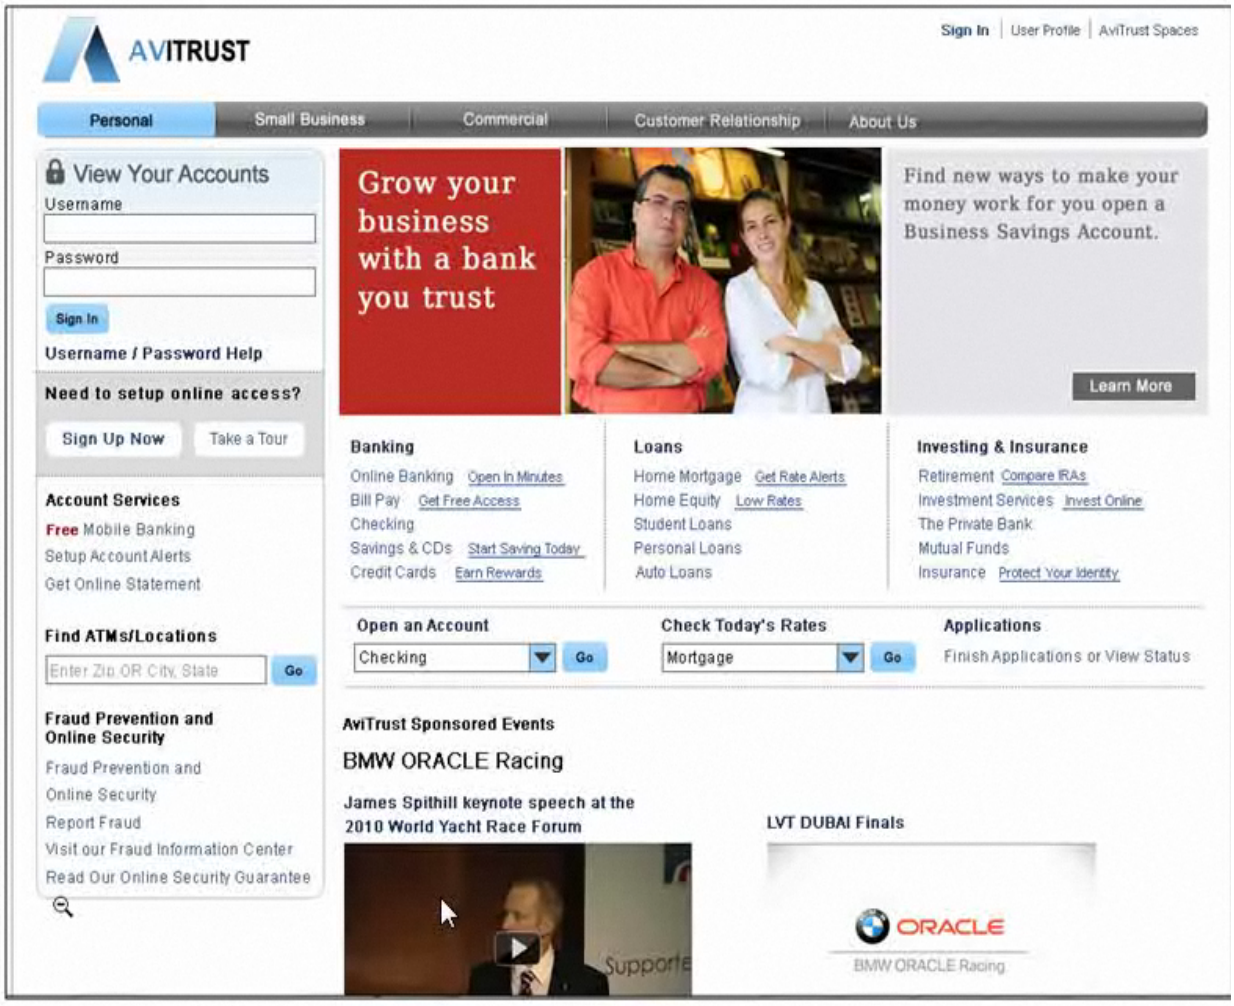


Figure 8–1 The AviTrust Sample Portal Application Launched in Oracle JDeveloper

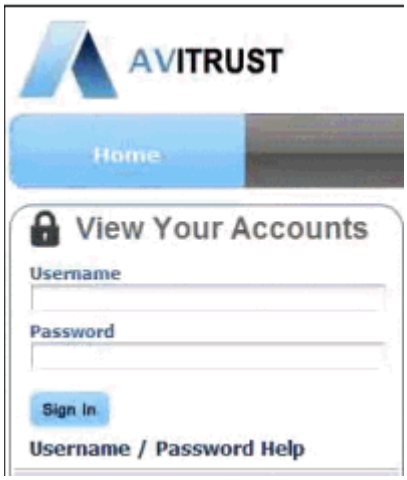
If the Integrated WebLogic Server is not running, this action starts the server and (re)deploys the application. By default, the file `index.html` (or another page that it redirects to) displays in the browser.

The Home page of the sample portal application now appears in a web browser, as shown in Figure 8–2.

Figure 8–2 The AviTrust Home Page Displayed in a Web Browser



****

On the portal Home page, secure user login is provided for authenticated bank customers by two points of entry:

- Either by clicking the Sign-In link in the upper right portion of the portal
- Or by entering their User Name and Password in the designated fields in the left portion of the Home page (shown in Figure 8–3).

In addition, administrators can set up security for authenticated users and provide delegated administration, while users manage their account and banking transactions. For more information, see Chapter 69, "Securing Your WebCenter Portal: Framework Application."

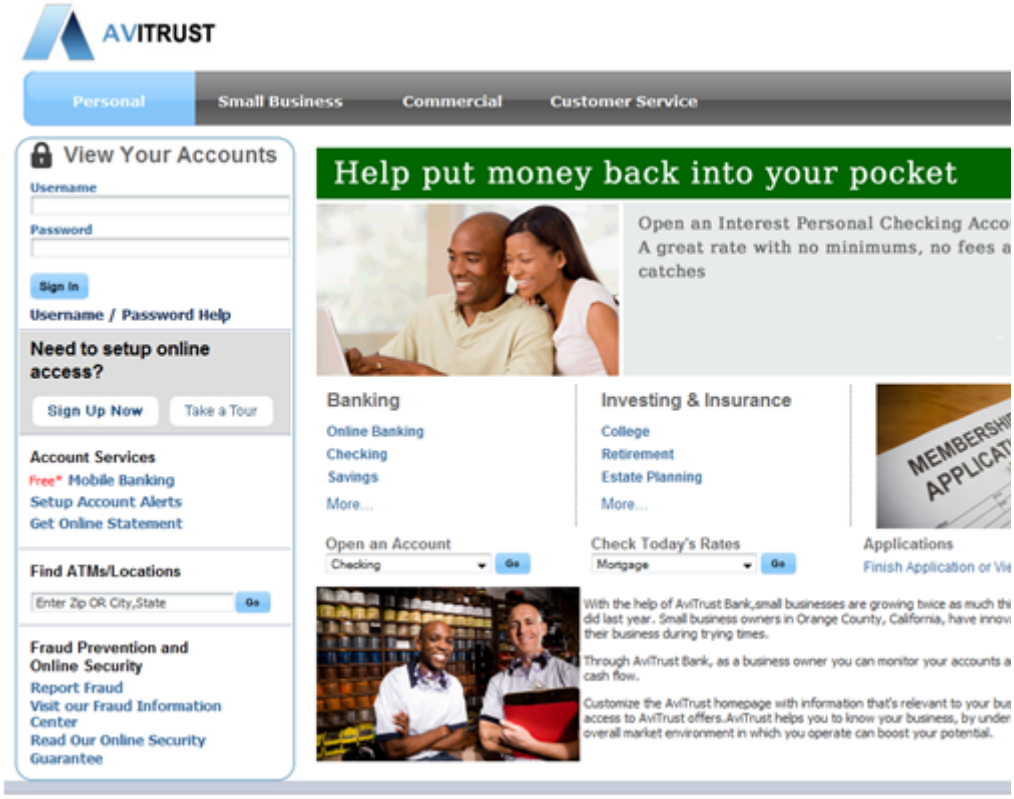
Figure 8–3 Secure Customer Login to Accounts in the AviTrust Home Page

8.3.2 Navigating the Site Using Tabs

Tabbed navigation provides banking customers with the most flexible and intuitive way of exploring the site.

The navigation model, rendered as a fly out menu on the template header, is based on an HTML template and a Cascading Style Sheet (CSS) file created by the AviTrust graphics design team. With four tabs embedded in the navigational bar (shown in Figure 8–4), customers can easily browse and access other pages and levels of information and services available on the banking website.

Figure 8–4 The Navigation Bar on the Home Portal Page with Four Tabs



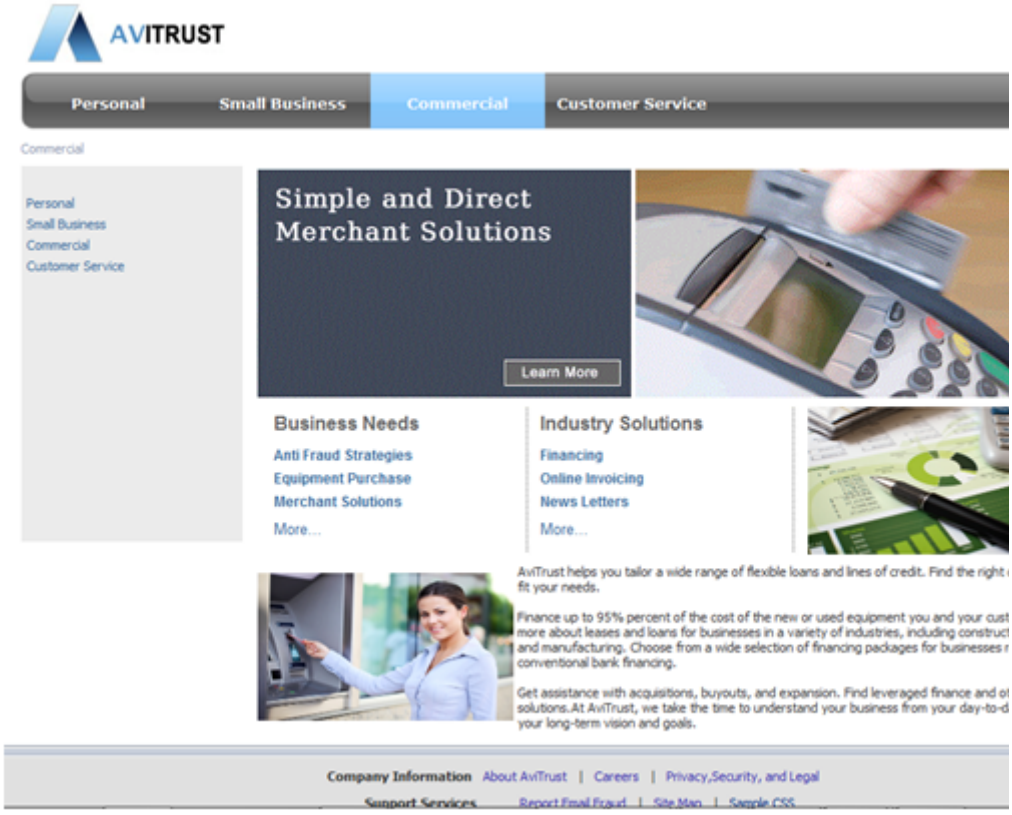
To navigate the site using tabs:

1. Move your cursor over the **Personal** tab in the navigation bar at the top of the page. A group of banking services are displayed, with links that customers can then click to access pages specific to their personal banking needs in the portal, as shown in Figure 8–5.

   Note that as you move your cursor over this and the other tabs in the navigation bar (illustrated subsequently in Figure 8–6, Figure 8–7, and Figure 8–8), the AviTrust Portal Application uses a different site template. There is a notable switch from the horizontal top-level, tab-style navigation to a hybrid model. This model uses horizontal tabs on the top and vertical links for side navigation. The WebCenter navigation components here are designed to be flexible yet easy to manage for purposes of branding partner and sub sites.

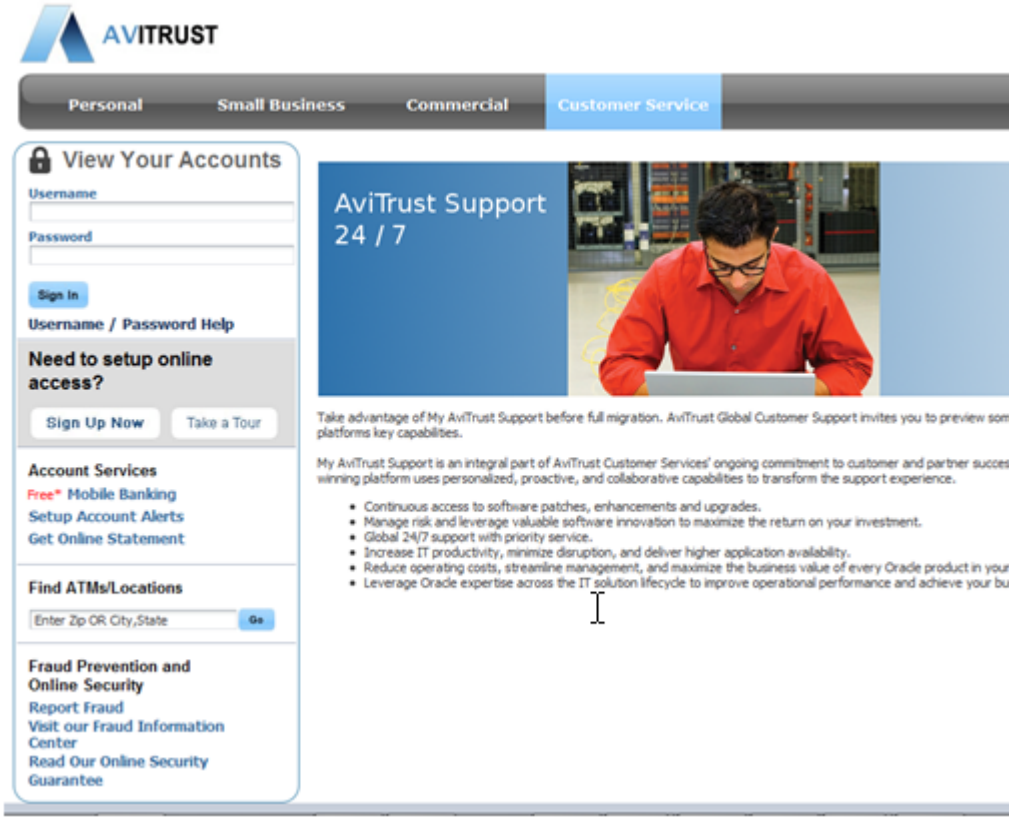
   For information on how to create the navigation model for your portal, refer to Chapter 11, "Building a Navigation Model for Your Portal."

Figure 8–5 The Personal Tab Selected in the Navigation Bar with Links to Other Pages and Services



2. Now moving your cursor over the **Small Business** tab in the navigation bar at the top of the page, you find another group of banking services displayed, this time with links that customers can click to access pages specific to the needs of small businesses in the portal, as shown in Figure 8–6.

Figure 8–6 The Small Business Tab Selected in the Navigation Bar with Links to Other Pages and Services

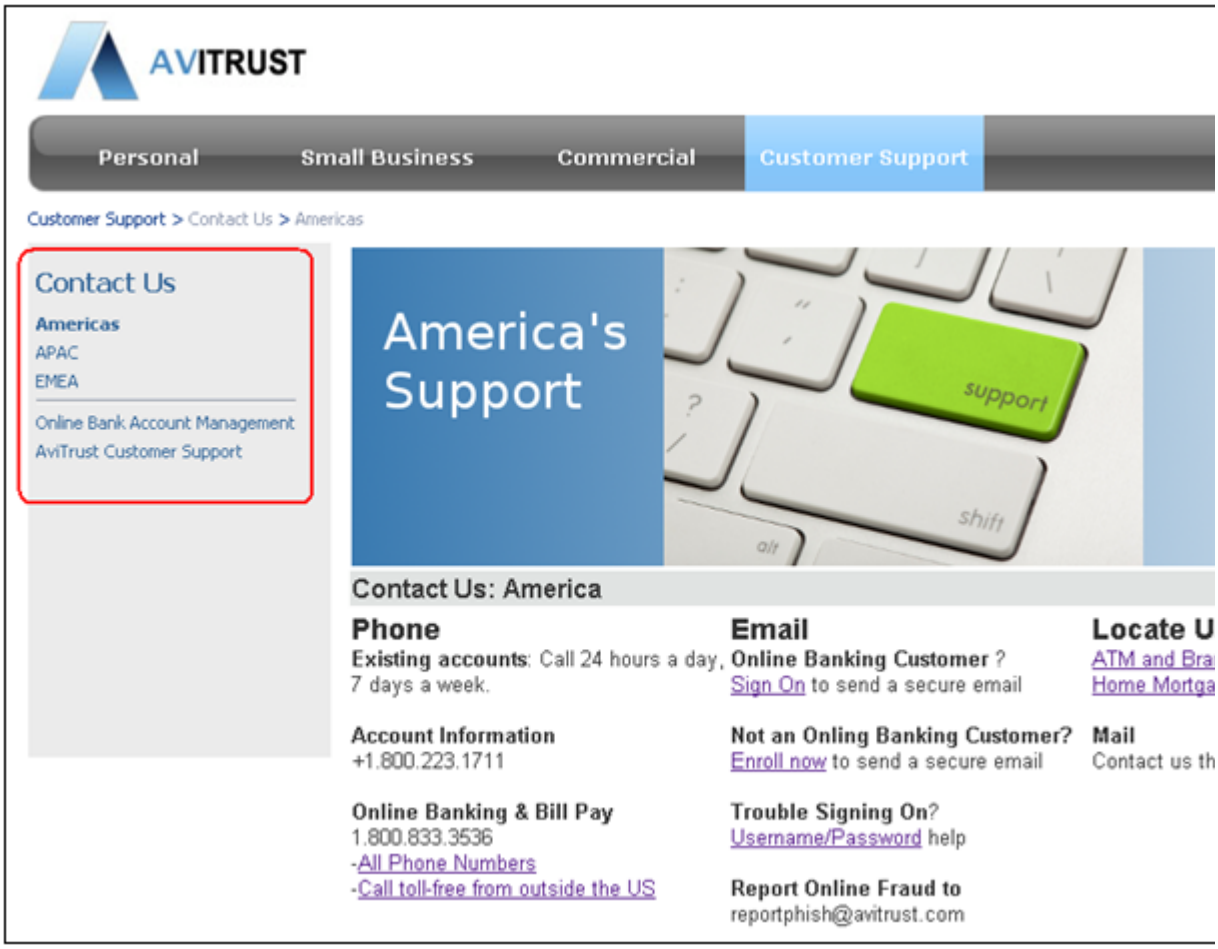


3. If you move your cursor over the **Commercial** tab in the navigation bar at the top of the page, your web browser will display another group of banking services, with links that commercial customers can click to access pages specific to commercial banking needs in the portal, as shown in Figure 8–7.

Figure 8–7 The Commercial Tab Selected in the Navigation Bar with Links to Other Pages and Services

4. By moving your cursor over the **Customer Support** tab in the navigation bar at the top of the page, your web browser will display yet another group of banking services, with links that users can click to access customer support pages in the portal, as shown in Figure 8–8.

Figure 8–8 The Customer Support Tab Selected with HTML Contents Displayed



In each case, customers browsing and accessing the AviTrust portal will find ease of access in navigating to pages for information that are relevant to their various banking needs.

5. Click the **Americas** link on the **Contact Us** page, as shown in Figure 8–9. Note that the pages under Contact Us, like Americas, APAC and EMEA, are based on a different template, which provides customer navigational links on the left side of the page.

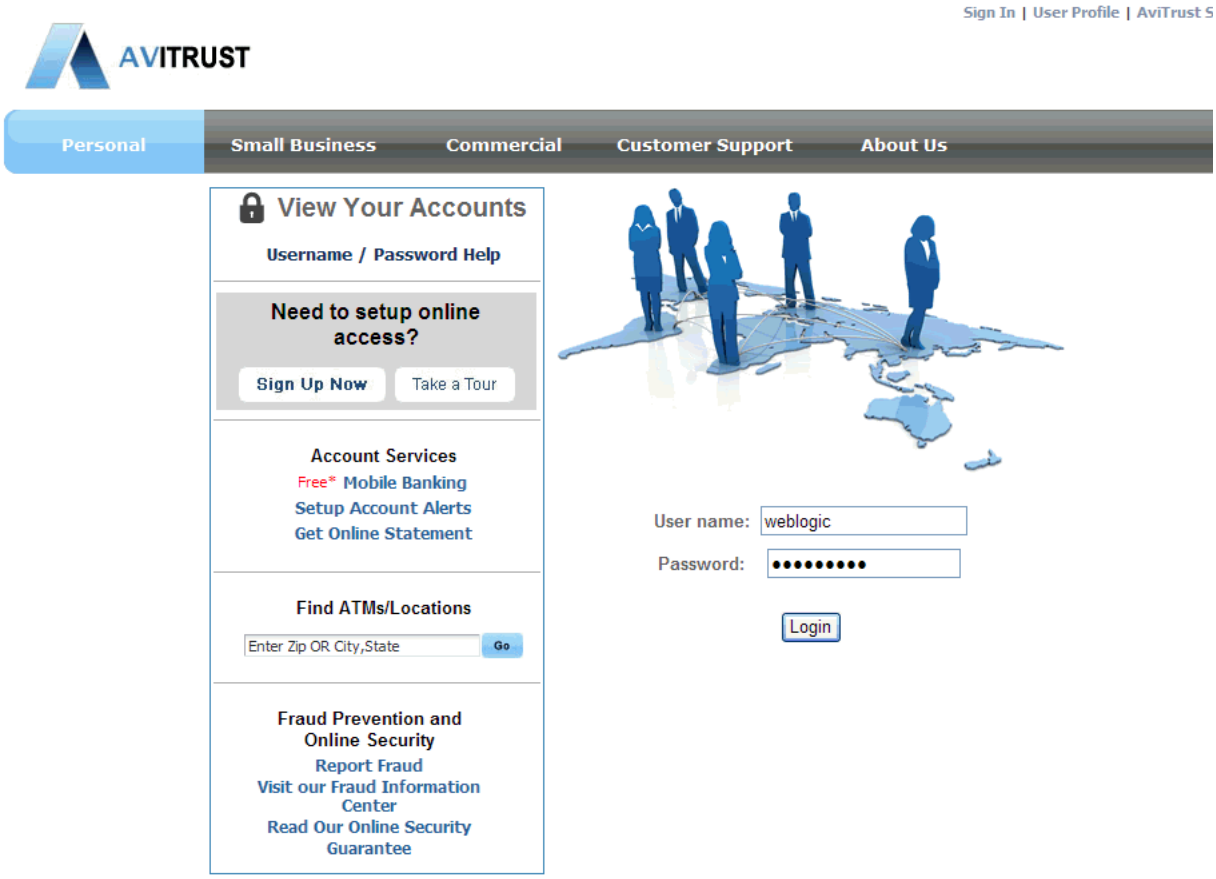
   The bread crumb on the top of the page lets you identify your current location within the site, and also provides users with easy access back to the top-level pages.

Figure 8–9 The America's Support Page Following the Bread Crumb from the Contact Us Link

8.4 Accessing and Using the Resource Manager

The AviTrust Portal application demonstrates how users or administrators with appropriate privileges can easily manage portal resources at runtime.

At runtime, the Resource Manager provides access to administration tools for the resources available to the portal. For example, using the Resource Manager, the site administrator can perform the following tasks:



- Create new resources, like navigation models, page templates and mashup styles
- Edit existing resources
- Upload resources exported from other applications, among other tasks

For more information, see Chapter 13, "Adding Resources to Your Portal."

To access and use the Resource Manager at runtime:

1. Click the Sign-In link in the upper right corner of the Home page. A page appears with fields to enter User Name and Password, shown in Figure 8–10.

Figure 8–10 The Login Page Displayed in a Web Browser

2. Log in with the following credentials:

   Username: `weblogic`

   Password: `welcome1`

   The Administration Console now appears in the web browser. As an administrator, you can make changes at runtime and manage portal resources accordingly.

3. In the Administration Console, click the Resources tab and select the Pages node in the Structure menu, shown in Figure 8–11. You can now create sub pages, specify the order and display of those pages, as well as perform editing tasks on those pages. <

   For more information, see Section 9.11.2, "Runtime WebCenter Portal Administration Console."

Figure 8–11 The Administration Console with Pages Selected

4. In the Administration Console, click the Resources tab and select the Skins node in the Look and Layout menu, shown in Figure 8–12. You can now edit, change or modify the skins used in the portal.

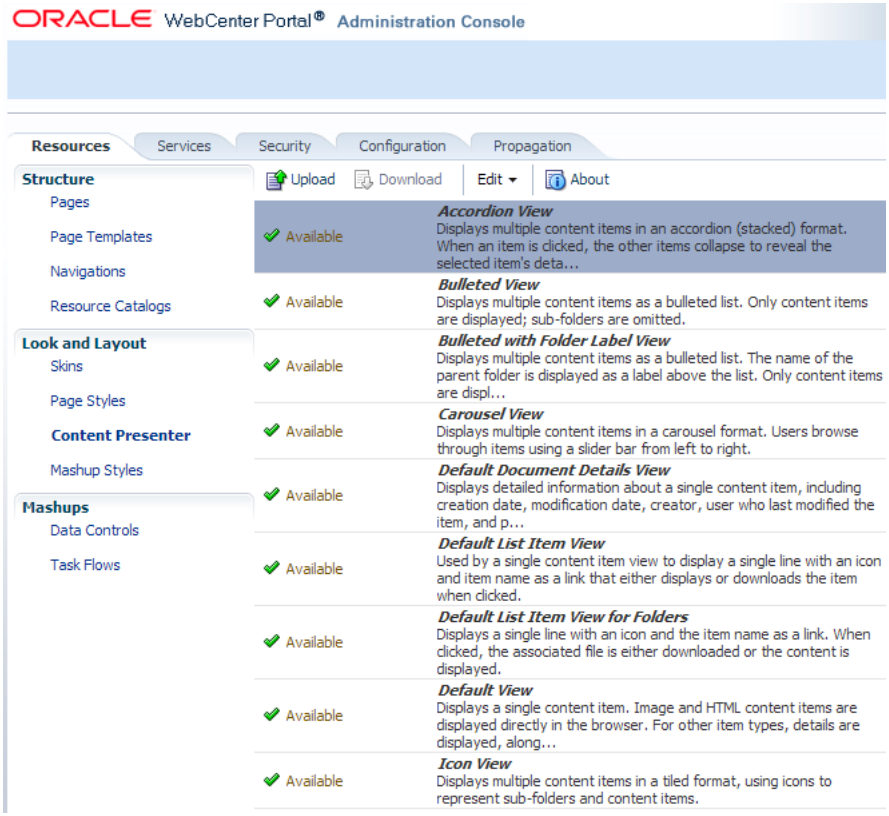


Figure 8–12 The AviTrust Skin Selected in the Look and Layout Menu

For more information, see Chapter 15, "Creating and Managing Skins."

5. In the Administration Console, click the Resources tab and select the Content Presenter node in the Look and Layout menu, shown in Figure 8–13. You can now change the look and layout of your portal, using the Content Presenter to upload or edit item, folder or labels views.

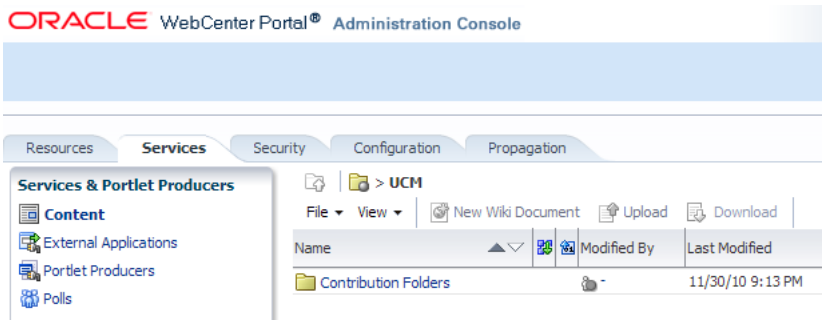

Figure 8–13 The Content Presenter Node Selected in the Look and Layout Menu

For more information, see Chapter 29, "Creating Content Presenter Display Templates."

6. In the Administration Console, click the Services tab and select the Content node in the Services & Portlet Producers menu, shown in Figure 8–14.

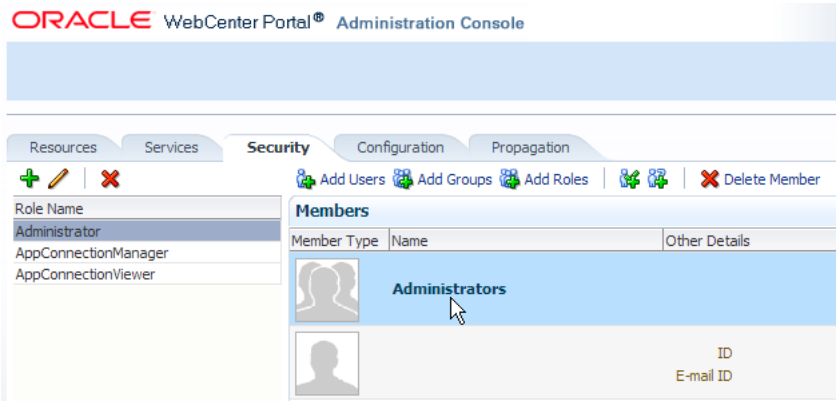

Figure 8–14 The Content Node Selected in the Services & Portlet Producers Menu

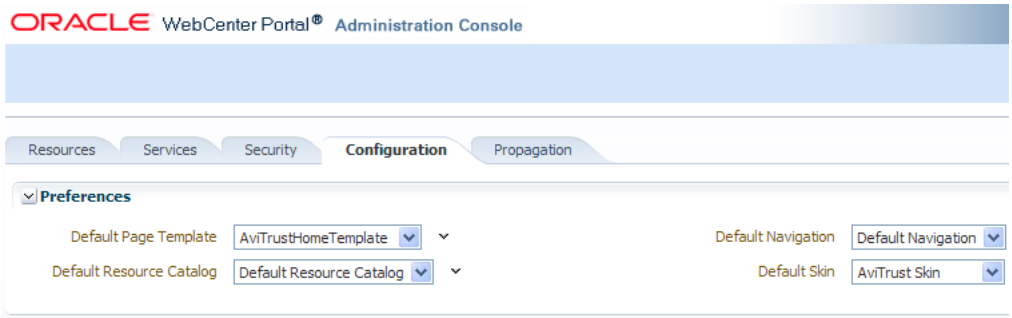
The Services tab with Contribution folder selected enables you to access content stored in Oracle WebCenter Content on Oracle Server.



7. In the Administration Console, click the Security tab and select the Administrator node in the Role Name menu, shown in Figure 8–15. In so doing, you can set security access and privileges for the portal Administrator.

Figure 8–15 The Security Tab Selected in the Administrator Node

8. In the Administration Console, click the Configuration tab and select the Default Page Template node in the Preferences menu, shown in Figure 8–16. In so doing, you can change the default page template to another template of your choice.

Figure 8–16 The Configuration Tab Selected in the Preferences Menu

8.5 In-Context Editing of Web Content at Runtime

All portals need to enable content authors to make changes quickly and easily at runtime. Using WebCenter Portal's direct integration with Oracle Enterprise Content Management (ECM), authors can create and edit HTML documents with a minimum of effort.

For example, you can retrieve a template entry for a press release and then ensure that your new press release follows your corporate standard, thus easily evolving the site at runtime and still professionally managing the source content for your entire site.

To accomplish this, you log in to the AviTrust Portal as a content author who has privileges to edit content in a web browser, following these steps:

1. Log in with the following credentials:

   Username: `contentadmin`

   Password: `welcome1`

2. Click the **Customer Support** tab.

3. Navigate to the center of the portal and press `CTRL+SHIFT+C` on your keyboard.

This takes you into content contribution mode for runtime editing. A dotted line appears around the content to be edited, shown in Figure 8–17.

Figure 8–17 In-Context Editing Enabled on the AviTrust Customer Support Page

4. Navigate to the upper right corner in the dotted area of the page and click the pencil icon on the top right hand side corner, as shown in Figure 8–18. This launches Site Studio Contributor, which enables you to edit the selected web content.

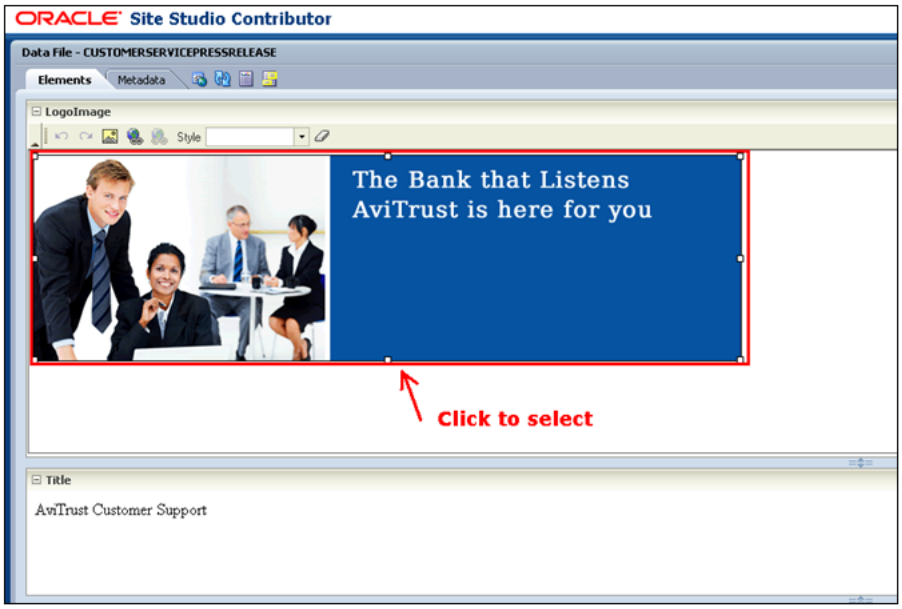


Figure 8–18 The Edit Pencil Selected to Enable Runtime Editing of Web Content

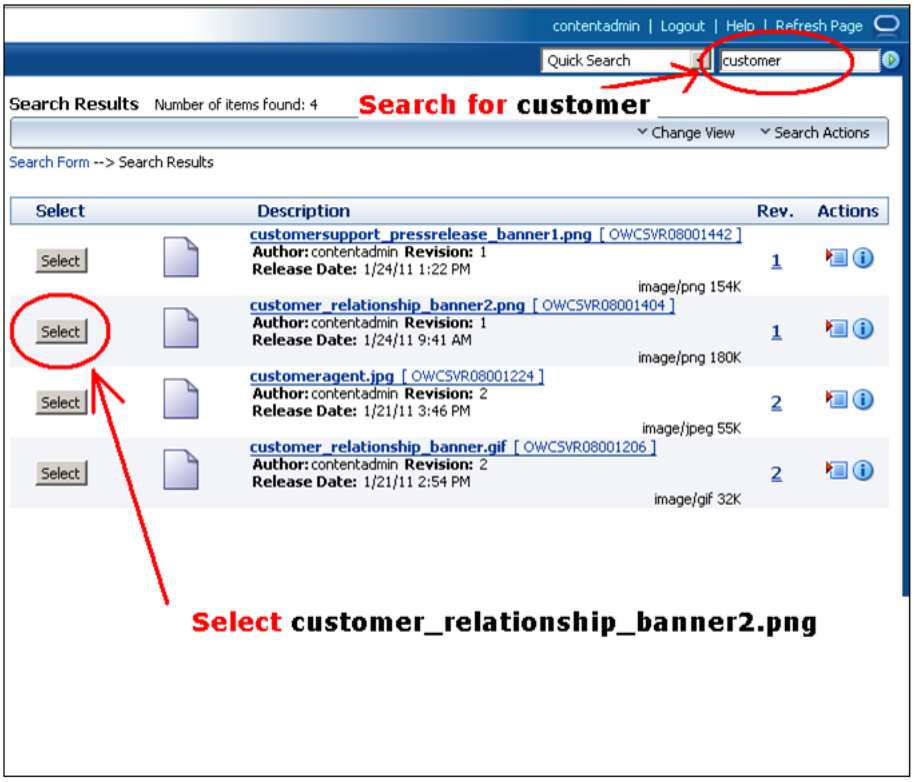
5. In Oracle Site Studio Contributor, click to select the banner image and then delete it, shown in Figure 8–19.

   Note that you can easily replace the images or edit text through the Site Studio Contributor.

Figure 8–19 Oracle Site Studio Contributor With the Content to be Edited



6. Click the image icon (shown in Figure 8–20) to add a new image from the ECM repository.

Figure 8–20 The Add Image Icon Selected

7. Open the Search form and in the search field in the upper right portion of the form, enter the keyword `customer` in the ECM console, as shown in the Figure 8–21, and select the image `customer_relationship_manager2.png`. You will now be able to search any new images uploaded by the content management team and choose an image from the list.

Figure 8–21 Searching for the Keyword Customer in the ECM Console

8. Once the image is replaced, click Save and Close in Oracle Site Studio Contributor, as shown in Figure 8–22.

Figure 8–22 The Save and Close Button Selected in Oracle Site Studio Contributor

9. Click the refresh icon (shown in Figure 8–23).

   You can now refresh the content to see the new image.

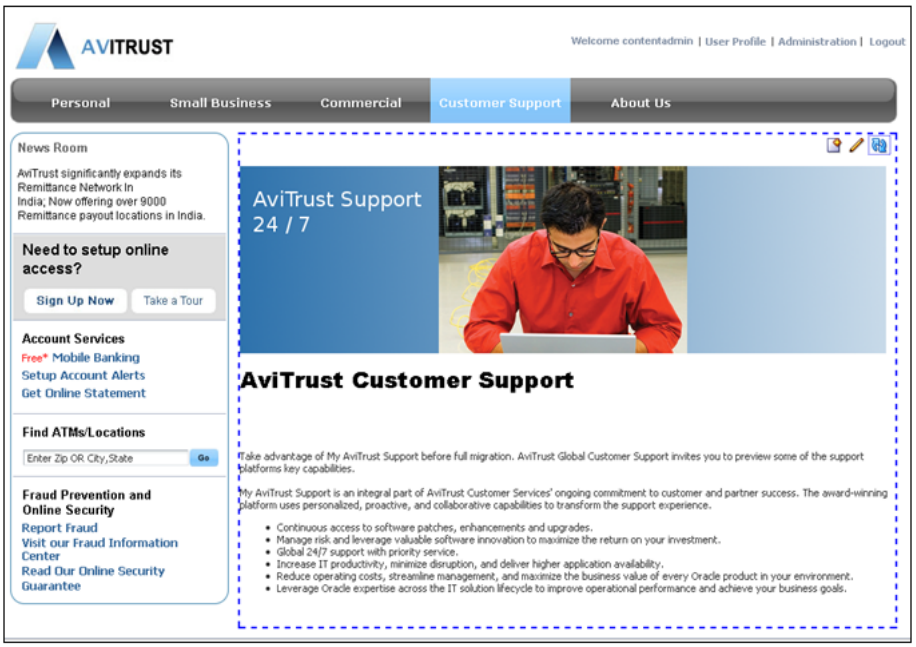


Figure 8–23 The Refresh Icon Selected

10. Press `CTRL+SHIFT+C` again on your keyboard.

    Since you have finished in-context editing of the content stored in ECM, you can come out of contribution mode. The newly edited banner image and content now appears on the AviTrust Customer Support page, as shown in Figure 8–24.

Figure 8–24 The Newly Edited Banner Image and Content on the Customer Support Page

8.6 Exposing Social Computing Services

WebCenter Portal exposes a comprehensive set of social computing services. These include ready-to-use task flows and portlets, enabling developers to become more productive. These services are designed to work together, so that you can add polls, blogs, threaded discussions, wikis and other social computing services to your site with a minimum of effort at runtime.

The **Polls service** lets you create, edit, and take online polls on your application pages. Polls let you survey your audience (such as their opinions and their experience level), check whether they can recall important information, and gather feedback on the efficacy of presentations.For more information, see Chapter 37, "Integrating the Polls Service."

In one scenario, for example, let's suppose an executive at the AviTrust Listening bank wants to poll members of the Online Small Business Community. The executive asks

the website administrator to create a new Poll at runtime on the Polls Administration tab. The website administrator creates the poll and puts it on the home page of the community. A customer then takes the poll and the bank executive views the results. In this case, the poll is implemented at runtime, without having to make changes in JDeveloper at design time.

In another scenario, a small business customer may want to host an event for other customers. In the AviTrust banking portal, the customer creates an Event wiki page, using a specific template to define when and where the event is supposed to take place. Another customer can edit the wiki page by adding a requested agenda item or other information about the event.

The **Wiki service** provides a means for customers to work simultaneously on documents and share ideas, either in the context of communities or as individuals. Customers can use wiki syntax directly, or edit wiki pages as you would any text in a word processor. All changes and versions are tracked within Oracle ECM. Thus, wiki content becomes a true enterprise content resource.

For more information, refer to Chapter 32, "Integrating Wikis and Blogs."

8.6.1 Adding a Discussion Forum

The AviTrust sample application illustrates how easily you can add a **Discussion Forum**, similar to adding other social computing services, like polls, blogs and wikis, to your portal at runtime.

For more information, refer to Section 25.3.2, "Examples: Customizing Task Flows for Custom Framework Applications."

To create, edit and manage the content for a Small Business Forum in the AviTrust banking portal:

1. Log in with the following credentials:

   Username: `contentadmin`

   Password: `welcome1`

2. Click the Small Business tab.
3. Navigate to the Forums link (shown in Figure 8–25) and click it.

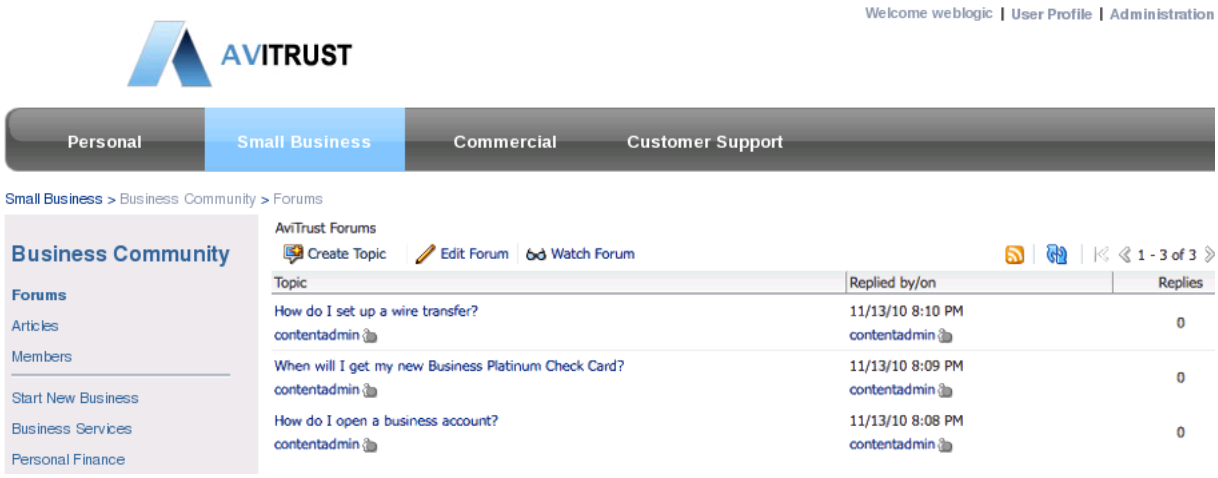

Figure 8–25 The Forums Link in the Small Business Page

4. Navigate from the Small Business link to the Business Community page and click Forums, as shown in Figure 8–26. A list of AviTrust discussion topics and frequently-asked forum questions now appears

   As the content administrator, you can create a topic for the forum, edit its contents and observe the customer activity, such as replies and exchanges, on the forum itself.

Figure 8–26 The Forum Page to Create a Topic and Edit the Content of a Forum Discussion

8.7 WebCenter Framework Components in the AviTrust Portal Demo

Now that you've taken a brief tour of the AviTrust Portal Demo for WebCenter, you can check out these features in depth and use them yourself by referring to the relevant chapters in this guide.

Table 8–1 describes at a high level the Oracle WebCenter Portal features that are included in the AviTrust Portal Demo for WebCenter.

To learn more about the different features, refer to the relevant chapter.

Table 8–1 WebCenter Portal Framework Features in the AviTrust Portal Demo for WebCenter

Feature	Location in the Demo	Chapter
Portal Navigation	Users can navigate the portal using tabs in the navigation bar. Developers can add content-driven navigational links to the portal, like pages, portlets, task flows, files, external applications or web pages in the navigation model.	Chapter 14, "Visualizing Your Portal Navigation."
Content Integration	Authenticated users can edit in-context HTML documents stored on Oracle Content Server, as well as in-context editing of Site Studio definition files.	Chapter 11, "Building a Navigation Model for Your Portal.">
Personalization	Administrators can render content based on a personalization scenario, using the Content Presenter. Content can be based on a query result derived from the a scenario deployed in the Personalization engine.	Chapter 67, "Personalizing WebCenter Portal Applications."

Table 8–1 (Cont.) WebCenter Portal Framework Features in the AviTrust Portal Demo for WebCenter

Feature	Location in the Demo	Chapter
Resource Management	Portal resources, like pages, catalogs, and skins, can be managed at runtime, using Administration capabilities.	Chapter 13, "Adding Resources to Your Portal.""
Integration of WebCenter Services	Administrators can take advantage of social computing services, like polls, blogs, forums and wikis.	Chapter 32, "Integrating Wikis and Blogs."

Part II

Setting Up Your Portal Structure

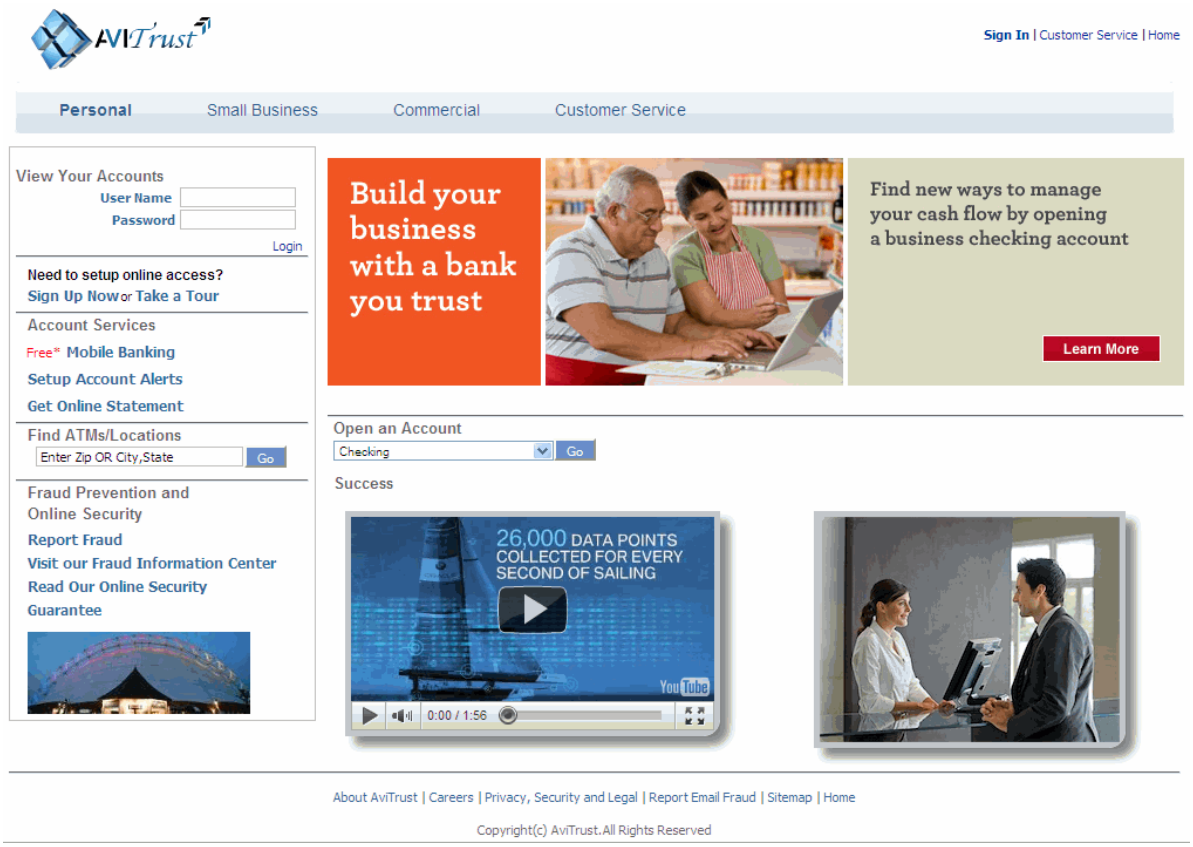
Part II contains the following chapters:

- Chapter 9, "Understanding Framework Applications"
- Chapter 10, "Understanding the WebCenter Portal Life Cycle"
- Chapter 11, "Building a Navigation Model for Your Portal"
- Chapter 12, "Designing the Look and Feel of Your Portal"
- Chapter 13, "Adding Resources to Your Portal"
- Chapter 14, "Visualizing Your Portal Navigation"
- Section 15, "Creating and Managing Skins"
- Chapter 16, "Creating and Managing Resource Catalogs"
- Chapter 17, "Adding and Using the Resource Manager"

9

Understanding Framework Applications

This chapter introduces the architecture, components, and features of a WebCenter Portal: Framework application. This chapter includes these topics:



- Section 9.1, "What is a Framework Application?"
- Section 9.2, "What is Oracle WebCenter Portal: Framework?"
- Section 9.3, "What is the Portal Life Cycle?"
- Section 9.4, "Creating a WebCenter Portal: Framework Application"
- Section 9.5, "Understanding the Features of a WebCenter Portal: Framework Application"
- Section 9.6, "Developing Your Portal's Look and Feel"
- Section 9.7, "Changing Default Portal Preferences"
- Section 9.8, "Using Iterative and Round-Trip Development Techniques"
- Section 9.9, "What is the Application Sources Folder?"
- Section 9.10, "Running and Testing a Portal"
- Section 9.11, "WebCenter Portals at Runtime"
- Section 9.12, "How are WebCenter Portal Files Organized?"
- Section 9.13, "Changing the Default Home Page and Login/Logout Target Pages"
- Section 9.14, "Basic Portal Development Tasks"

9.1 What is a Framework Application?

A WebCenter Portal: Framework application is a portal. From an end user perspective, a portal is a web site with **pages** that are organized by tabs or some other form(s) of **navigation**. Each page can contain a nesting of **sub-pages** that are related hierarchically. Any page can contain multiple portlets, task flows, or other elements, giving users access to different information and tools in a single place. An administrator can modify a portal at runtime by, for example, adding new pages or changing the look and feel. If authorized through **delegated administration**, individual users can modify their view of a portal as well.

Figure 9–1 shows an example portal. It includes navigation (tabs, bread crumbs, links), content (portlets, task flows, images), administration features, and so on.

Figure 9–1 Example WebCenter Portal: Framework Application

Portal end users may also see **personalized** views of a portal page. A personalized view is a view that has been modified with content that is based on information collected about that user. For example, a site that sells books might "remember" that you recently purchased several detective novels, and based on that information, recommend several other similar kinds of detective novels when you next log in to that site. See Chapter 67, "Personalizing WebCenter Portal Applications."

A portal presents diverse content and applications to users through a consistent, unified web-based interface. Portal administrators and users can customize portals, and content can be presented based on user preferences or personalization. Each portal is associated with a web application that contains all of the resources required to run portals on the web.

As you can see, some key elements of portals include pages and sub-pages, navigation, delegated administration and other security features, runtime customization, and personalization.

Portals also typically include features like:

- **Search** – Enterprise and web-based search facilities
- **Content Integration** – Creation, management, and delivery of content to the portal through integration with an enterprise content management system, like Oracle WebCenter Content.
- **Single Sign-On** – Allows users to log on once for all applications within the portal.

- **Look and Feel Management** – Allows developers to create custom page templates and users to apply different skins to customize their portal experience. The portal includes tools to ensure a consistent look and feel across the portal.

9.2 What is Oracle WebCenter Portal: Framework?

Oracle WebCenter Portal: Framework adds a number of portal-specific features to a Framework application, like page hierarchies and navigation models, as explained in this section.

- Section 9.2.1, "How Do I Add Oracle WebCenter Portal: Framework to a Project?"
- Section 9.2.2, "What Features Does the Oracle WebCenter Portal: Framework Provide?"

9.2.1 How Do I Add Oracle WebCenter Portal: Framework to a Project?

If you create a Framework application using the WebCenter Portal: Framework Application template, the framework is automatically included. No further steps are required. See also Section 5.2, "Creating a Framework Application."

Note: Migrating a non-portal Framework application to a Framework application is not supported.

9.2.2 What Features Does the Oracle WebCenter Portal: Framework Provide?

Oracle WebCenter Portal: Framework adds a number of portal-specific features to a Framework application. These features are included by default when you create a new application using the WebCenter Portal: Framework Application template. See also Section 5.1, "What Are Application Templates?."

The basic features provided by the framework include:

- **Page hierarchies** – Traditional ADF page security allows you to control page security on a page-by-page basis. However, portals typically include many pages – in some cases hundreds of pages – and it's not always practical to specify access to individual pages. The page hierarchy organizes pages into a tree structure, with a parent-child relationship between pages. This hierarchical structure allows the convenient propagation or inheritance of security settings from pages to sub pages. See Section 9.5.1, "Understanding Pages, Page Templates, and the Portal Page Hierarchy."
- **Navigation models** – A navigation model provides the back-end data to the navigation user interface that is displayed in the portal. Navigation models are highly flexible, with a wide set of APIs that control navigation to pages, task flows, external sites, portlets, and specific content items. These APIs let you control all aspects of the way the navigation user interface is rendered. For example, you can add a tree navigation UI by including a simple EL expression in a portal page or page template. WebCenter also provides runtime tooling for configuring and modifying navigation models. See Section 9.5.3, "Understanding the Navigation Model and the Navigation Registry."
- **Navigation Registries** – A navigation *registry* defines the set of elements that a user can add to a navigation at runtime using the Resource Manager. See also Chapter 17, "Adding and Using the Resource Manager" and Chapter 11, "Building a Navigation Model for Your Portal."

- **Delegated administration** – Delegated administration provides a mechanism for securing portal resources based on user roles. For example, you can allow users in one role (managers, for instance) to access all portal features, but deny certain features to users in another role (employees, for instance). Page hierarchies are the primary container for delegated administration. In both the design time and runtime environments, you apply delegated administration to a page hierarchy, and the specific security assignments are automatically propagated down through the hierarchy through pages and sub pages. See Chapter 69, "Securing Your WebCenter Portal: Framework Application."
- **Customization** – Users can customize their own portal pages by, for example, adding or removing portlets, changing skins, or rearranging the portal layout. See Section 17, "Adding and Using the Resource Manager."
- **Page templates** – Page templates allow you to define entire page layouts and apply them to pages to create a consistent layout across the portal. When you create pages using a template, they all inherit the defined layout. For more information, see Chapter 12, "Designing the Look and Feel of Your Portal." See also "Using Page Templates" in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.
- **Catalogs and the Catalog Registry** – Catalogs are arbitrary collections of task flows, portlets, content items, and other elements that can be added to an application at runtime. A catalog *registry* defines the set of items that are available for inclusion in your resource catalog. See Chapter 16, "Creating and Managing Resource Catalogs."
- **Skins** – Skins define the colors, fonts, images, and some dimensional details like heights and widths, of your application components to present a consistent look and feel across the portal. See Chapter 15, "Creating and Managing Skins."
- **Portal Preferences** – You can change default preferences for a portal, including default navigation model, page template, and other components. See Section 9.7, "Changing Default Portal Preferences."

JDeveloper includes tooling for portal development. This tooling includes editors for creating and modifying page hierarchies, navigation models, catalogs and the catalog registry, page templates, page styles, skins, and delegated administration. In addition, runtime tools are provided to allow end users and administrators to perform some of these functions. See also Section 9.11.2, "Runtime WebCenter Portal Administration Console."

9.3 What is the Portal Life Cycle?

The portal life cycle describes the process of creating a portal from development through deployment to a production server. Many actors participate in the life cycle including software developers, content modelers, content contributors, IT administrators, portal site administrators. For detailed information on managing all the stages of the portal life cycle, see Chapter 10, "Understanding the WebCenter Portal Life Cycle."

9.4 Creating a WebCenter Portal: Framework Application

Use the WebCenter Portal: Framework Application template to create a new framework application in JDeveloper. Application templates are a standard JDeveloper feature, and the portal template simply configures the application with the required portal components and features.

Tip: The Framework application template is basically identical to the Framework application template in earlier versions of WebCenter, but with certain portal-specific features added in. In addition to these portal features, framework applications include all of the features you'll find in a traditional Framework application, like task flows, data controls, security features, ADF Faces layout components, and so on.

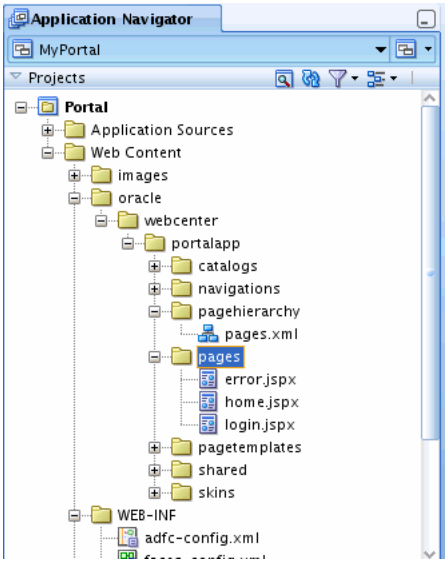
The basic steps for creating a framework application are described in Section 5, "Creating Framework and Portlet Producer Applications."

9.5 Understanding the Features of a WebCenter Portal: Framework Application

This section discusses some of the main portal features you'll need to know about.

- Section 9.5.1, "Understanding Pages, Page Templates, and the Portal Page Hierarchy"
- Section 9.5.2, "Securing Your Portal Pages"
- Section 9.5.3, "Understanding the Navigation Model and the Navigation Registry"
- Section 9.5.4, "Understanding Resource Catalogs and the Catalog Registry"
- Section 9.5.5, "Other Design Time Folders"
- Section 9.5.6, "Tips for More Advanced Development Use Cases"

9.5.1 Understanding Pages, Page Templates, and the Portal Page Hierarchy



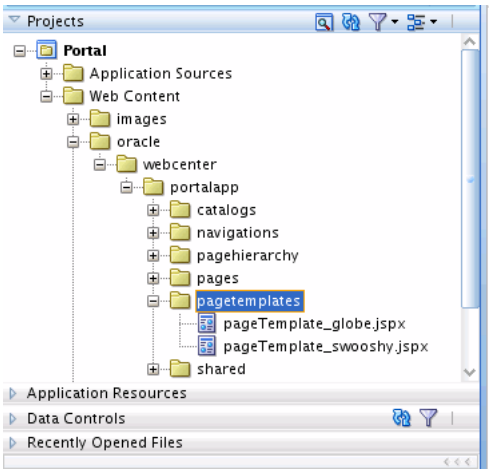
This section introduces three related pieces of the Oracle WebCenter Portal: Framework: pages, page templates, and page hierarchies.

A portal consists of one or more *pages*, and pages play a crucial role in a portal's structure and organization. Generally, a page is a container for one or more entities like task flows, portlets, and content. Pages also typically include a navigation interface, like a navigation tree, tabs, or bread crumbs. In a Framework application, you can find a set of default pages in the Portal project under the folder `oracle/webcenter/portalapp/pages`, as shown in Figure 9–2. The placement of these pages is for organizational purposes, and new pages do not necessarily need to be created under the pages folder.

Note: For important information on the organization of files in Framework applications, see Section 9.12, "How are WebCenter Portal Files Organized?."

Note: For pages to be used in the page hierarchy, they must be located under `oracle/webcenter/portalapp`.

Figure 9–2 Contents of the pages Folder

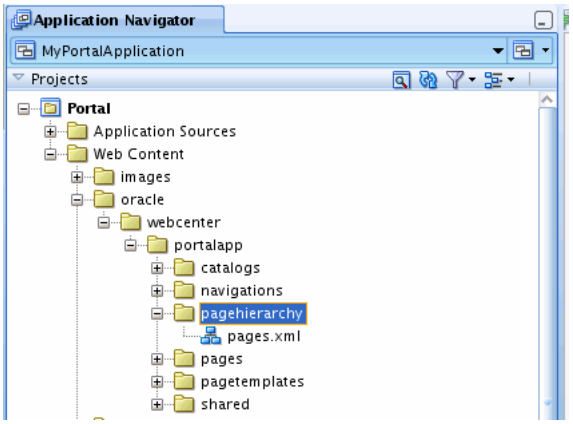


A *page template* lets you specify view elements that you wish to be common to all of your pages. A page template is a JSPX file that includes ADF layout components and other elements. Typically, page templates define a page layout, with headers, footers, and content areas. In addition, the page template usually specifies the positioning and style of the navigation UI for your pages. For example, if you want all of your pages to include the same set of tabs, or if you want each page to have a tree navigation panel and bread crumbs, you can add these components to the template.

> **Tip:** Page templates are referenced by the pages that use them. If you change the underlying page template, all the pages that reference the template automatically inherit the change.

You can find the page template folder in `oracle/webcenter/portalapp/pagetemplates`, as shown in Figure 9–3. Notice that the folder contains two default page templates that are included out of the box.

Figure 9–3 Contents of the pagetemplates Folder



A *page hierarchy* is a logical structure that arranges pages through a set of parent-child relationships, where any page can have one or more sub pages. This hierarchical

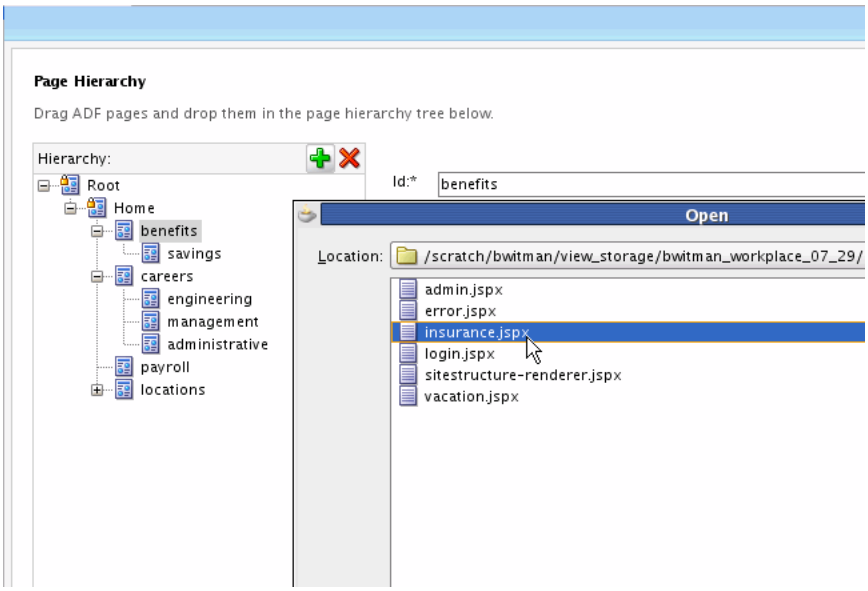
model not only helps define the overall structure of the portal, but also allows child pages to inherit the security policies specified by their parent. The ability for pages to propagate security policies down the hierarchy is particularly convenient for very large portals with dozens or even hundreds of pages: you don't have to set security for every page. Note that when you create a new page, its security policy is automatically set based on where it resides in the page hierarchy.

You can find the page hierarchy files in the `oracle/webcenter/portalapp/pagehierarchy` folder, as shown in Figure 9–4.

Figure 9–4 Contents of the pagehierarchy Folder

> **Note:** The page hierarchy files are XML files that contain the metadata that define the page hierarchy structure. It is not recommended that you attempt to edit these files directly; rather, use the Page Hierarchy editor to create and work with page hierarchies, as explained below.

A basic page hierarchy model is included with applications created from the WebCenter Portal: Framework Application template. You can modify the page hierarchy with the Page Hierarchy editor in JDeveloper. To access this editor:



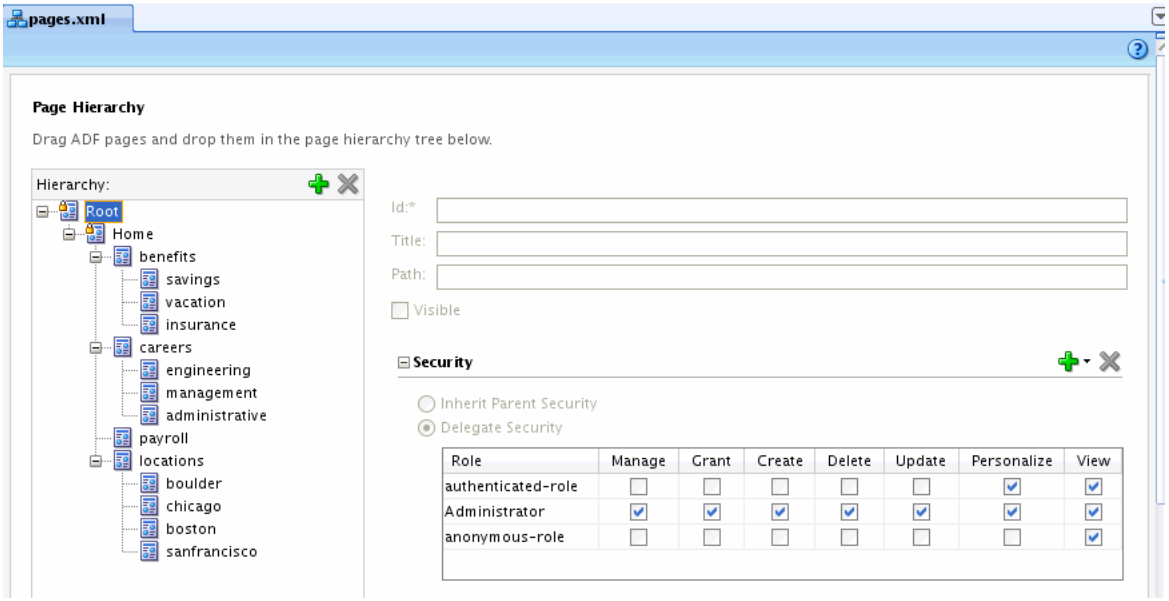
1. Open the portal project in the Application Navigator, as shown in Figure 9–4.
2. Right-click the `pagehierarchy` folder.
3. Select **Edit Page Hierarchy** from the menu.

> **Tip:** You can also bring up the Page Hierarchy editor by right-clicking a portal page file (JSPX file) and selecting **Edit Page Hierarchy** from the menu or by opening a page hierarchy file directly.

After you have created pages for your portal, use the editor to build up the site structure. You can drag and drop pages (one or several at a time) from anywhere in the `oracle/webcenter/portalapp` folder in the Application Navigator directly into the Page Hierarchy editor and position them in the hierarchy as you wish.

Alternatively, you can use the **Add** button located above the hierarchy pane. Clicking this button pops up a dialog that allows you to choose a page from within your project. This page is added as a child of the page that is currently selected in the editor, as shown in Figure 9–5.

Figure 9–5 Adding a Page to the Page Hierarchy



In the editor, you can rearrange page nodes within the tree display simply by dragging and dropping them. For large hierarchies, you may also find it useful to use the Change Parent dialog by right-clicking a page in the hierarchy and choosing **Change Parent Page**. This dialog allows you to choose a new parent for the selected page from a separate window, instead of having to scroll through a hierarchy that may be too large to view all at once.

> **Tip:** Right-click a node in the Page Hierarchy editor and select **Go to Page** to open the associated JSPX (portal page) file.

> **Note:** For each new level you create in the page hierarchy, a `pagehierarchy/pages/*Pages.xml` file is created. These files contain a reference to the pages in that level. For more information, see Section 69.6.2, "Building a Page Hierarchy."

Figure 9–6 shows the structure of a simple human resources site that includes top level pages Benefits, Careers, Payroll, and Location. The Benefits, Careers, and Location pages each have multiple child pages.

Figure 9–6 Page Hierarchy Editor

Notice how this hierarchy is realized when you run the portal, shown in Figure 9–7. In this example, the pages use the default page template, which includes a navigation bar. The bar is rendered as tab-like links across the page. Because this navigation UI was added to the page template, it will appear consistently on all pages that use the template. In addition to the default navigation component, you could add a navigation tree, bread crumbs, or other styles of navigation UI to the page template. In many cases, the template will include two or more navigation components.

For more information on page templates, see Section 12, "Designing the Look and Feel of Your Portal." For more information on the default navigation model and on creating navigation models and user interfaces, see Section 11, "Building a Navigation Model for Your Portal."

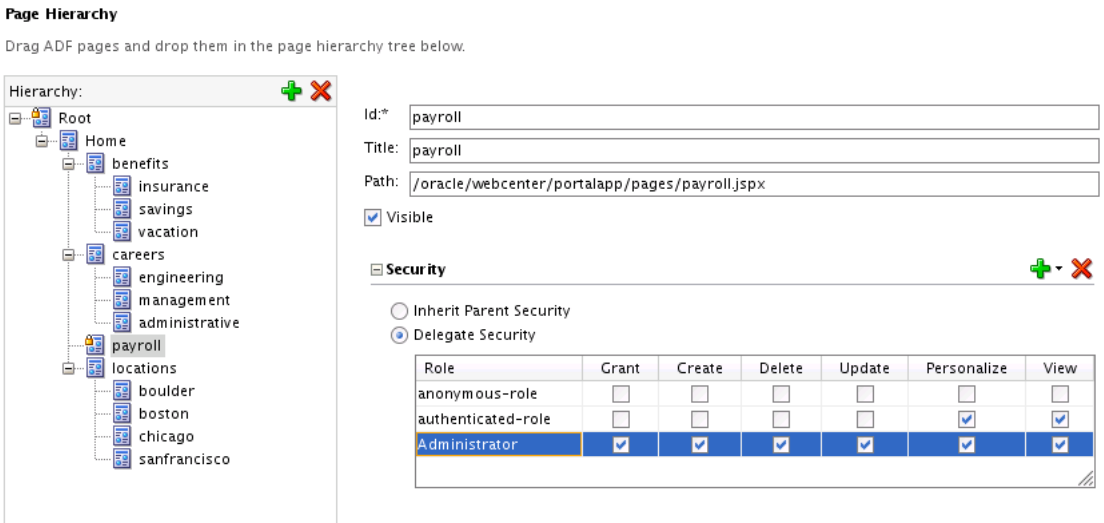
Figure 9–7 Portal Navigation Bar

For more information on page hierarchies, see Section 69.6.2, "Building a Page Hierarchy."

9.5.2 Securing Your Portal Pages

Note: See also Section 5.6, "How Is a Framework application Security Configured by Default?."

At design time, you can set up security for your portal's pages in the Page Hierarchy editor. As mentioned previously, the page hierarchy defines the structural relationships between pages (parent-child) and it allows for child pages to inherit the security policies of their parents.



> **Note:** You can secure pages either through the ADF page security model or through the hierarchical WebCenter Portal page security model. When a page is added to the page hierarchy, it implies that it's secured through the hierarchical security model. See also Section 69.6, "Using the Page Hierarchy Security Editor."

As shown in Figure 9–8, the Page Hierarchy editor includes a Security section that lets you specify role-based security policies for pages. The security interface lets you decide whether you want the policies to be inherited or delegated. If you specify inheritance, then the security policies for that page will be inherited from its parent page. If you delegate security, then that policy will override the parent's security and the policy will be propagated to all child pages that are inheriting security.

> **Tip:** A small padlock icon appears next to pages for which the inherited security settings are overwritten. In other words, you'll see this icon to indicate pages that have delegated security set on them.

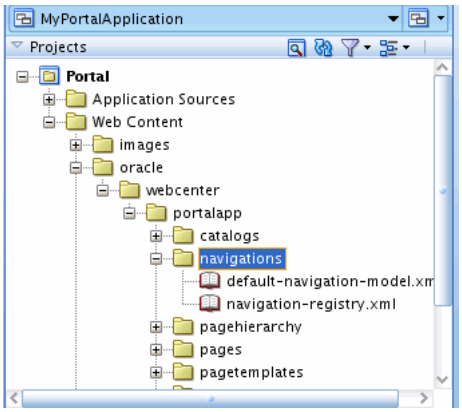
For example, in Figure 9–8, the Payroll page is configured so that Administrators have full access to the page, while authenticated users can only view and personalize the page. Anonymous users cannot access the page at all. Later, in Section 9.5.3, "Understanding the Navigation Model and the Navigation Registry," we'll discuss how the security policy set for a page also affects the appearance of the navigation UI. In this example, because the Payroll page is only available to Administrators and authenticated users, the navigation UI will only show the Payroll page link to authenticated users and Administrators. For all other users, the Payroll link will not show up at all.

Figure 9–8 Security Setting for the Payroll Page

9.5.3 Understanding the Navigation Model and the Navigation Registry

It's important to distinguish the navigation model from the page hierarchy. First, the page hierarchy specifies a parent-child relationship between pages. As discussed previously, pages can have one or more child pages. Secondly, the page hierarchy allows for security policies to be inherited from parent pages to child pages, or sub pages, down through the hierarchy. Note that page hierarchy only specifies a relationship between pages; other resources, like task flows, portlets, and external links cannot be included in a page hierarchy.

The page hierarchy provides a security inheritance model that allows administrators to easily control security on portals that have a very large number of pages. For example, if your portal has 100 pages, you can specify security policies on the root of the page hierarchy, and all 100 pages will inherit those policies. Then, if you wish to modify the settings on any page below the root, you can do that, and those settings will propagate to any of that page's sub-pages. You can also override the inherited settings and apply security settings to individual pages anywhere in the hierarchy.



The navigation model, by contrast, defines a navigational structure, keeps track of navigational data, and provides that data to the view layer of the application. While a page hierarchy only consists of pages, a navigation model can consist of a variety of resources, like task flows, pages, external links, and others.

It's important to note that the navigation model is aware of the security policies that have been applied to the elements (pages, links, task flows, and so on) that the navigation model controls. If the authenticated user is not authorized to see a particular page, the navigation model, by default, hides any navigational links to that page. For any resources that do not have security defined in the portal, like external links, the developer has to control visibility manually. One way to do this is to add an EL expression to the page or page template to control visibility (show/hide) of the resource. For more information, see Chapter 14, "Visualizing Your Portal Navigation."

For example, if your portal pages include a tree navigation UI, that UI asks the navigation model questions like: what pages or other elements can the user navigate to and what is the current navigational state of the portal. The first question informs which links the UI can display. The second informs the UI how to display those links. If the navigation view is a tree, the model tells the UI, for example, which page is currently selected. This allows the tree UI to display the node representing that page correctly, as an open folder for example, or as a selected page.

In JDeveloper, use the Navigation Editor to modify the navigation model. To open the editor, double-click the file `default-navigation-model.xml` in the `navigations` folder, shown in Figure 9–9.

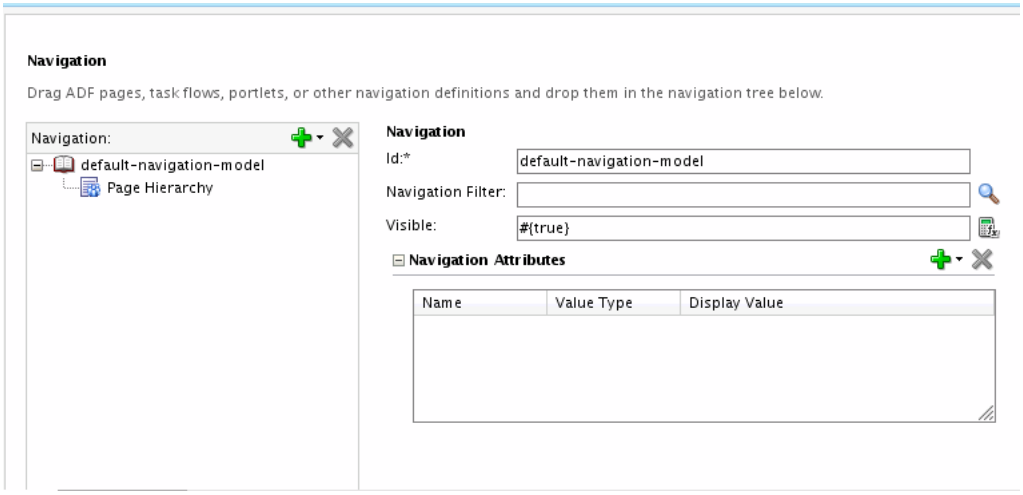


Figure 9–9 Contents of the navigations Folder

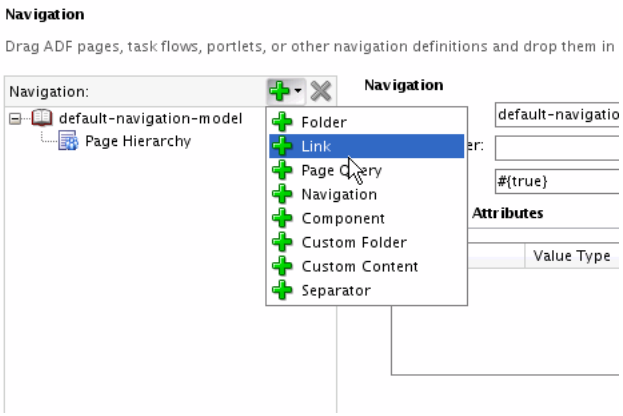
The `navigation-registry.xml` file is used by the Resource Manager when a user creates or edits a navigation model. The registry defines the superset of all items that are available to be included in a model that you create or edit. You can create multiple navigation models for an application, but an application can only have one navigation registry file. For more information on the navigation model, the Navigation Editor, and the registry, see Chapter 11, "Building a Navigation Model for Your Portal."



The default navigation model, shown in Figure 9–10, includes one node called Page Hierarchy. By default, this node points to the default page hierarchy file, `pages.xml`, in the pagehierarchy folder. This node tells the navigation model to refer to the page hierarchy's structure and communicate that structure to the navigation UI so that it can be rendered. As seen previously in Figure 9–7, the default UI displays the page hierarchy as tab-like links. The information provided by the model allows each link to display its sub-page links in a drop-down menu whenever the mouse pointer hovers over it.

Figure 9–10 The Default Navigation Model

The navigation model can include several kinds of navigation elements. As we've seen, the model can include both page hierarchies and single pages. But you can also create navigation to other elements, like links to external web pages or specific content.

Figure 9–11 Adding a Link to the Navigation Model

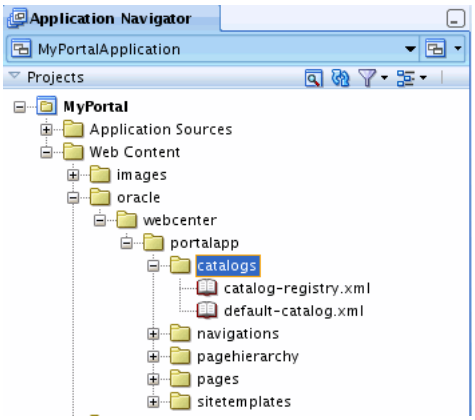
For more information, see Chapter 11, "Building a Navigation Model for Your Portal."

9.5.4 Understanding Resource Catalogs and the Catalog Registry

A catalog specifies a collection of an otherwise unrelated group of elements, like layout components, task flows, portlets, documents, and others, that an authorized user can add to a portal at runtime. Oracle WebCenter Portal's Composer uses catalogs at runtime to determine which elements an authorized user can add to a portal page.

The Framework application template includes a default resource catalog (`default-catalog.xml`) and a catalog registry file (`catalog-registry.xml`). These files are located in `oracle/webcenter/portalapp/catalogs`.

When a user edits pages at runtime using Composer, the default catalog file specifies all of the items that are available to be added to a page. The catalog registry file is used by the Resource Manager when a user creates or edits a resource catalog. The registry defines the superset of all items that are available to be included in a catalog that you create or edit.



You can create multiple catalogs for an application, but an application can only have one catalog registry file. For more information, see Chapter 16, "Creating and Managing Resource Catalogs."

At development time, you can edit existing catalogs using the Resource Catalog editor. To open the editor, open the catalog file (for example, `default-catalog.xml`) in the `catalogs` folder in Application Navigator, as shown in Figure 9–12.

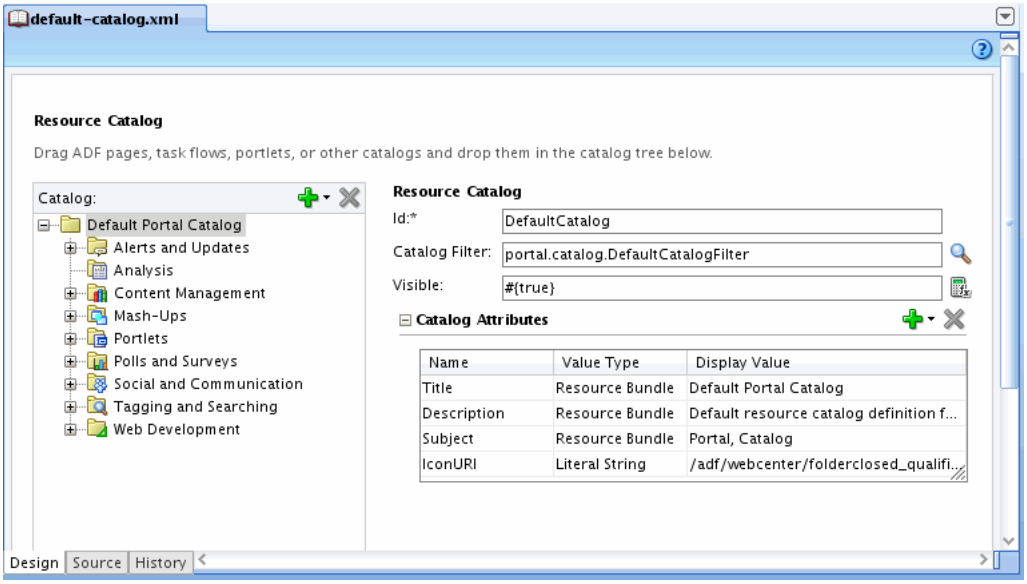
To create a new catalog, select **New** from the File menu. In the New Gallery dialog, select **Portal** under the Web Tier node. Then, select **Application Resource Catalog** and click **OK**. Use the Create Application Resource Catalog dialog to create the new catalog.

> **Tip:** You can also edit navigation registries using the Resource Catalog editor.

Figure 9–12 Contents of the catalogs Folder

The Resource Catalog editor is shown in Figure 9–13.

Figure 9–13 Resource Catalog Editor in JDeveloper



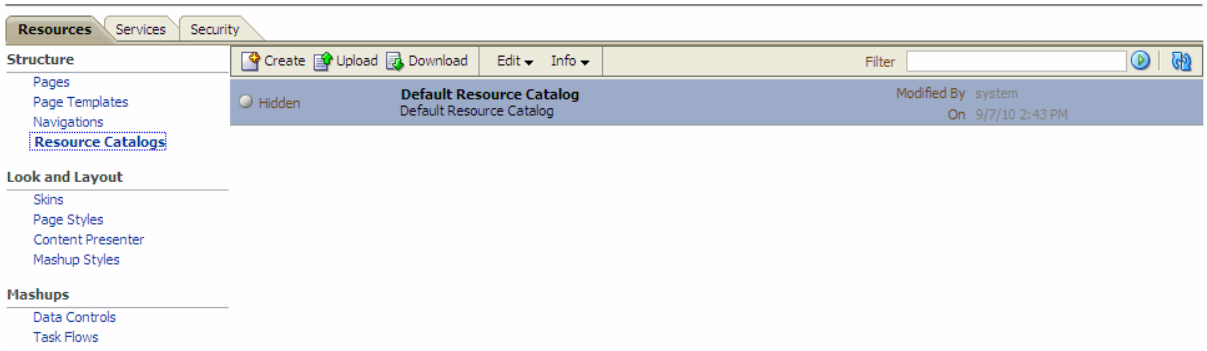


Figure 9–14 shows the resource catalog editor in the runtime administration tool.

Figure 9–14 Resource Catalogs Editor at Runtime

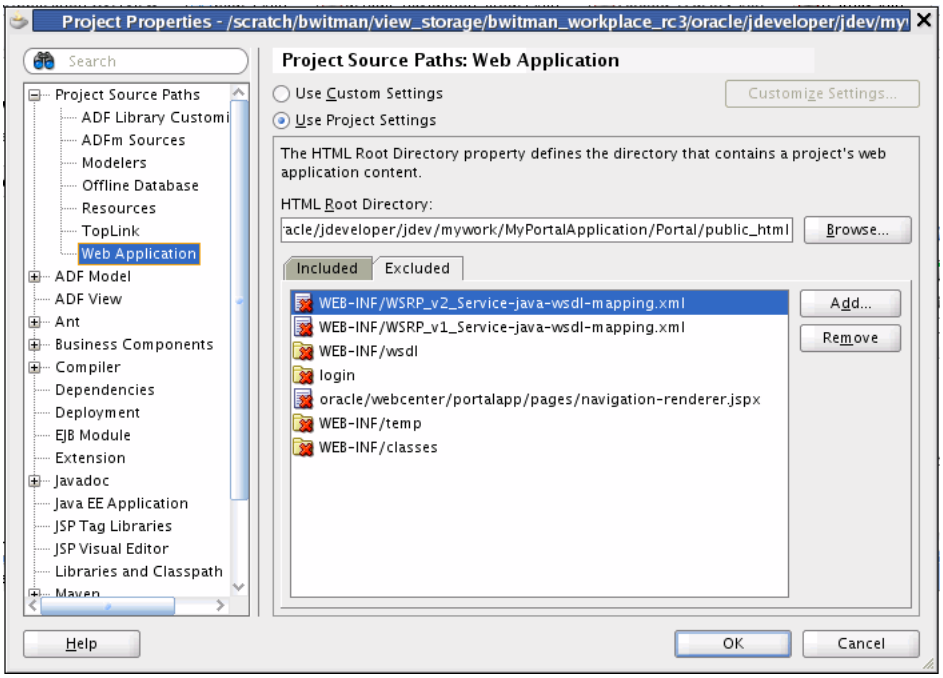
For example you can create separate catalogs for each of several departments.

Tip: Individual catalog entries can be shown or hidden based on user roles.

9.5.5 Other Design Time Folders

Other folders you'll see in the Application Navigator at design time are:

- **images** – Contains images that are referenced by the page template.
- **WEB-INF** – Contains configuration files used by the web application. These files are generally typical files found in all ADF-based web applications.
- **Page Flows** – Another standard ADF folder that contains the `adfc-config.xml` config file.



9.5.6 Tips for More Advanced Development Use Cases

By default, a few files are excluded from view in the Application Navigator. These files are excluded because it is unlikely you'll ever need to edit them. However, because there are some use cases where you might want to edit them, you need to be able to add them back to the JDeveloper UI.

To locate the excluded files:

1. Right-click the project folder and select **Project Properties** from the menu.
2. In the Project Properties dialog, select **Web Application** under the Project Source Paths node.
3. Select the Excluded tab, as shown in Figure 9–15.

Figure 9–15 The Exclude Tab

4. Select an element from the excluded list and click **Remove** to remove it from the excluded list. As a result, the element is automatically included in the appropriate folder in the Application Navigator.

As an example, the `navigation-renderer.jspx` file is used to render resources in the context of a page template. If you wanted to change the way an external URL is displayed within a page, you would first remove the `navigation-renderer.jspx` file from the excluded list in order for it to appear under the `pages` folder in the Application Navigator. Then, you could open the page and edit it as desired.

9.6 Developing Your Portal's Look and Feel

You can design the look and feel by adding certain presentation elements, such as banners, navigations, and footers, around the content area. Once you settle on a look and feel that is suitable for your portal structure, you can save these settings as a page template, which can be used to create a portal. In addition, you may want use the same settings across pages in your portal. With the use of page templates and page styles, you can achieve some consistency across pages in your portal. See Chapter 12, "Designing the Look and Feel of Your Portal."

You can also develop custom skins for your portal. A skin is a style sheet based on the CSS 3.0 syntax specified in one place for an entire application. Instead of providing a style sheet for each component in your application or inserting a style sheet on each page, you can create one skin for the entire application. Every component automatically uses the styles as described by the skin. When you use a skin, you do not have to make design-time changes to portal pages to change their appearance. See Chapter 15, "Creating and Managing Skins."

Although the basic look and feel design can be created in JDeveloper at design time, the Resource Manager enables administrators and users with the appropriate privileges to continue developing the portal's look and feel after the application has been deployed. For example, the Resource Manager lets you add and remove pages, add navigation user interfaces, and change the page templates, skins, and page styles. For more information about these and other Resource Manager features, see Chapter 17, "Adding and Using the Resource Manager."

9.7 Changing Default Portal Preferences

A Framework application includes a set of preferences that specify certain default portal components. This section describes these preferences and explains how to change their default values.

9.7.1 What Are the Default Portal Preferences?

Table 9–1 lists the portal preferences and their default settings.

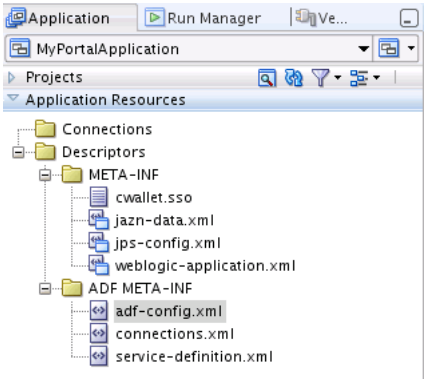


Table 9–1 Default Preferences

Preference	Default Setting
Navigation Model	`/oracle/webcenter/portalapp/navigations/default-navigation-model.xml`
Resource Catalog	`/oracle/webcenter/portalapp/catalogs/default-catalog.xml`
Page Template	`/oracle/webcenter/portalapp/pagetemplates/pageTemplate_globe.jspx`
Navigation Renderer	`/oracle/webcenter/portalapp/pages/navigation-renderer.jspx`
Skin	`portal`

9.7.2 How to Change the Default Preferences at Design Time

To change the default preferences at design time, directly edit the `adf-config.xml` file. To locate this file in JDeveloper, open the **Application Resources** part of the Application Navigator. Then, open the **Descriptors** folder and the **ADF META-INF** folder, as shown in Figure 9–16.

Figure 9–16 Location of the adf-config.xml File in JDeveloper

For example, to change the default navigation model file, edit the value of this preference:

```
<portal:preference id="oracle.webcenter.portalapp.navigation.model"
   desc="Default Navigation Model"
   value="/oracle/webcenter/portalapp/navigations/default-navigation-model.xml"
   resourceType="navigation" display="true"
/>
```

Preferences can also be changed at runtime under the **Configurations** tab of the Administration page. From this page, you can configure the default page template, skin, resource catalog, and navigation component in a runtime application. For details, see "Configuring Application Defaults" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

9.8 Using Iterative and Round-Trip Development Techniques

Iterative development is a productivity feature that helps speed up the development process. Iterative development lets you make and save changes to your Framework application in JDeveloper while the app is running on the Integrated WebLogic Server and immediately see the effect of those changes simply by refreshing the current page in your browser. The iterative development feature is enabled by default in a framework application. For more information, see Section 1.5.3, "Enabling Iterative Development."

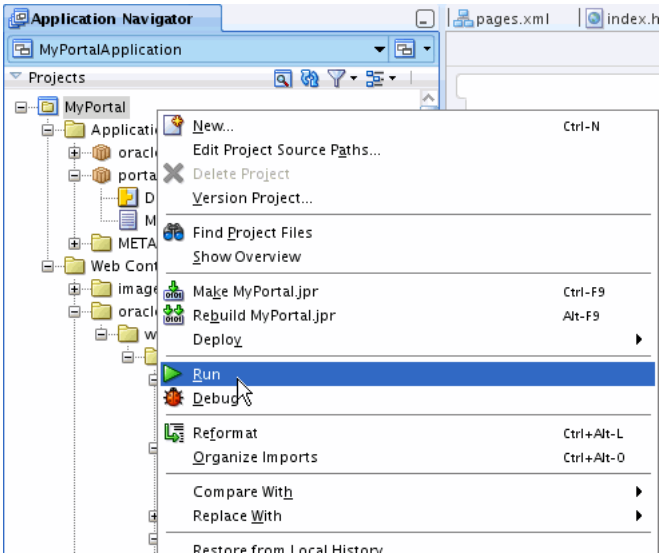
Round-trip development refers to features and techniques that allow you to retrieve resources from a deployed, runtime portal back to JDeveloper for maintenance or enhancement. After modifying a resource in JDeveloper, you can use the Resource Manager to upload the resource back to the deployed portal. WebCenter Portal's round-trip development features provide a simple, convenient way to modify portal resources without redeploying the entire application.

For more information on round-trip development, see Section 17.3, "Enabling Runtime Administration of Your Portal" and Section 17.4, "Enabling Round-Trip Development of Resources."

9.9 What is the Application Sources Folder?

The Application Sources folder appears as one of two top-level portal project folders generated by JDeveloper when you create a portal. In addition to any Java classes you write for your application, Application Sources includes:

- **oracle.webcenter.portalapp** – Includes XML definition files for pages, page templates, page catalogs, navigations. A page definition file specifies ADF bindings, page parameters, and permission settings. Page definition files specify various mappings and bindings that are used by pages and page templates. For example, the page definition file specifies the page's parent and child pages, if any. The file also specifies security policy information, like the operations that are permitted on the page. Default page definition files are created automatically when you add a portal page to a page hierarchy.
- **portal** – Includes resource bundles, source code, and other Java artifacts.
- **META-INF** – Includes files for specifying data bindings and page template metadata.



9.10 Running and Testing a Portal

JDeveloper provides several ways to run an application:

- Right-click the portal project name in the Application Manager and select **Run**, as shown in Figure 9–17. If the server is not running, this action starts the server and (re)deploys the application.

  Tip: You can change the default portal home page. For details, see Section 9.13, "Changing the Default Home Page and Login/Logout Target Pages."

Figure 9–17 Running the Portal

- Right-click a page in the pages folder in the Application Manager and select **Run**, as shown in Figure 9–17. If the server is not running, this action starts the server, (re)deploys the application, and displays the selected page.

Figure 9–18 Running a Page

- You can also run a portal by selecting **Run** <*portal name*> from the Run menu.

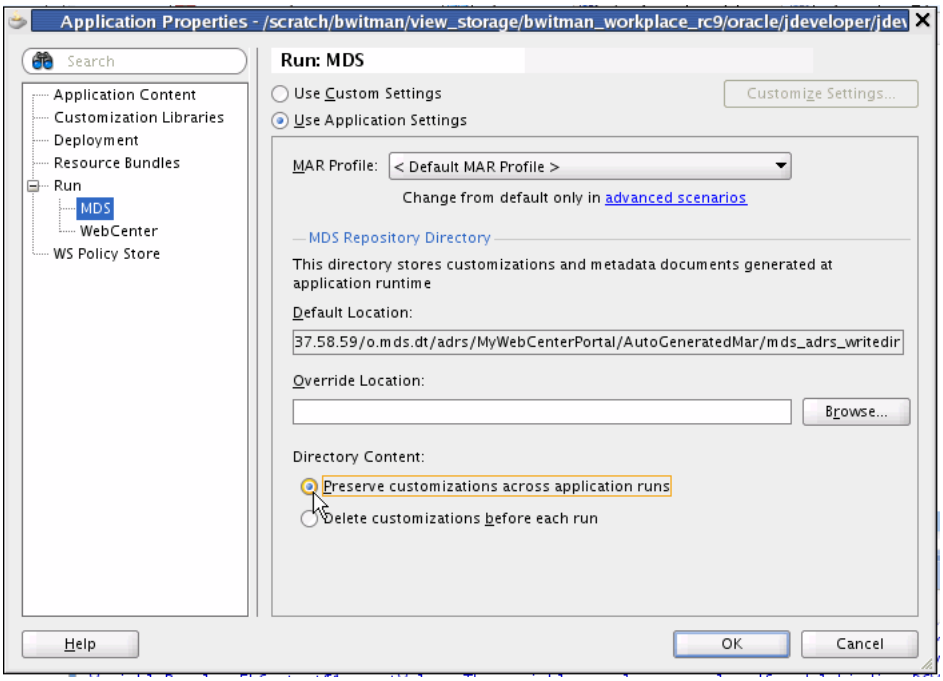
9.11 WebCenter Portals at Runtime

Oracle WebCenter Portal: Framework provides a number of interesting runtime features.

- Section 9.11.1, "Preserving Runtime Customizations on the Integrated WebLogic Server"
- Section 9.11.2, "Runtime WebCenter Portal Administration Console"
- Section 9.11.3, "How Security Settings Affect the Runtime Portal?"
- Section 9.11.4, "Runtime Editing of Portal Resources"

9.11.1 Preserving Runtime Customizations on the Integrated WebLogic Server

If you are using the Integrated WebLogic Server in a development environment (running the portal through JDeveloper) any changes you make to the portal at runtime (using the Resource Manager) are discarded upon redeployment by default. For example, if you use the Resource Manager to make changes like adding entitlements to a page, changing the layout, or modifying the navigation model, these changes will not be preserved the next time you redeploy the application. For more information on the Resource Manager, see Chapter 17, "Adding and Using the Resource Manager."



Note: The information in this section only applies to a portal that is running with the Integrated WebLogic Server in a development environment. When you deploy the portal to a production environment, runtime changes are never discarded.

Note: Customizations are not preserved by default as a convenience for developers working in the JDeveloper environment. When you modify a file at runtime, a new version of the file is written to the MDS write directory. This new version then takes precedence over the version in JDeveloper. At that point, if you change a setting in JDeveloper and click Refresh in your browser, the change will not show up. Therefore, while you're working in JDeveloper, it's much more convenient and natural not to preserve runtime customizations.

It is possible to change the default behavior, and preserve runtime customizations between runs. For example, you may wish to do this to enable certain testing scenarios. To allow customizations to be preserved between application deployments (runs):

1. Select **Application Properties** from the Application Menu.
2. In the Application Properties dialog, select **MDS** under the Run node.
3. Under Directory Content, select **Preserve customizations across application runs** to disable the default, which is to discard customizations before each run. See Figure 9–19.

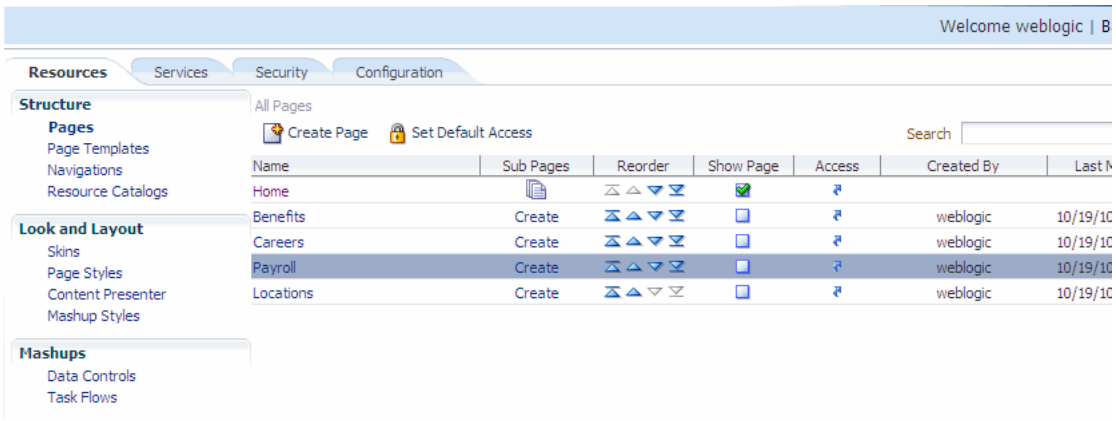


Figure 9–19 Selecting Preserve Customizations Across Application Runs

9.11.2 Runtime WebCenter Portal Administration Console

The WebCenter Portal Administration Console lets you work with resources, services, security, and portal configurations. The WebCenter Portal Administration Console is located at this URL: `http://<server>:<port>/<context_root>/admin`, and is shown in Figure 9–20.

Figure 9–20 The WebCenter Portal Administration Console

Tip: You can change the default URL for the WebCenter Portal Administration Console by editing the `<url-pattern>` attribute of the `<servlet-mapping>` element in the `web.xml` file. The default `<url-pattern>` is `admin`, but you can change it to something else if you want.

For more information on the Resource tab (the Resource Manager), see Section 9.11.4, "Runtime Editing of Portal Resources" and Chapter 17, "Adding and Using the Resource Manager." Security topics are discussed in Chapter 69, "Securing Your WebCenter Portal: Framework Application."

9.11.3 How Security Settings Affect the Runtime Portal?

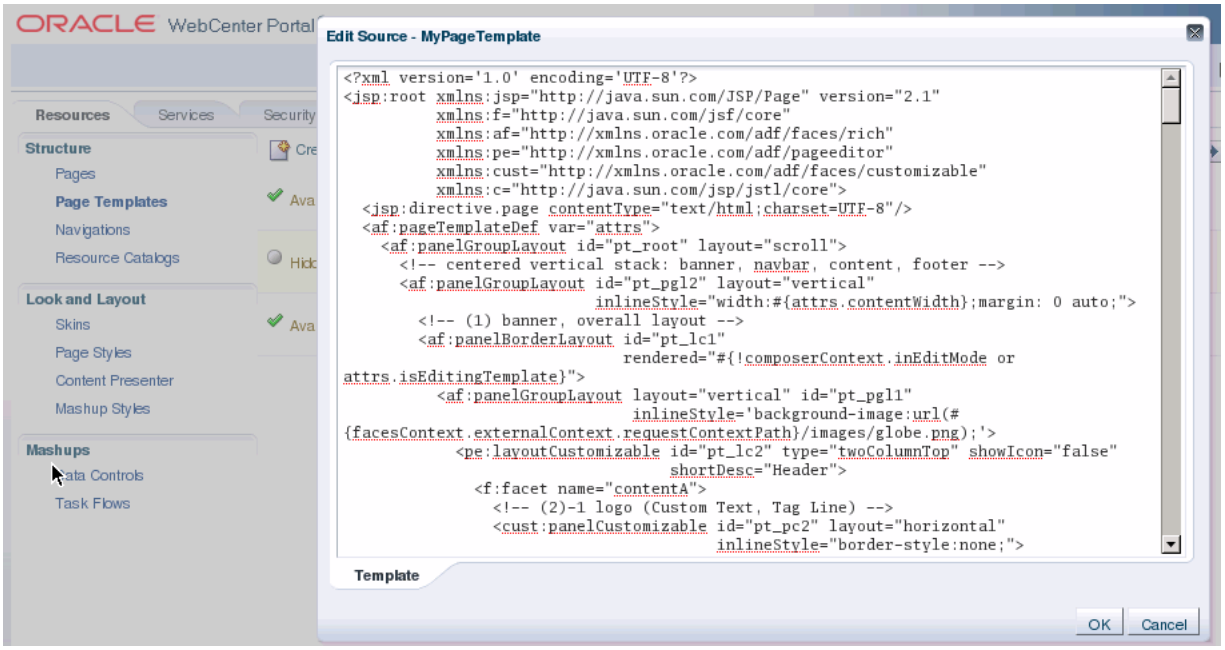
Role based security policies control which pages, resources, and navigational elements visitors can see and manipulate (create, delete, update, and so on). The design time (JDeveloper) page editor lets you set these policies on pages or hierarchies of pages, as discussed in Section 9.5.2, "Securing Your Portal Pages." Oracle WebCenter Portal: Framework respects these security polices in the following ways:

- Pages (and certain other resources, like task flows) can only be viewed by users who are authorized to see them. The same principle holds for operations users can perform on pages, like Grant, Create, Delete, Update, and Personalize.
- Navigation to a resource (like a page or task flow) is hidden if that page is unavailable to the authenticated user. For example, if a user is not authorized to visit the **Payroll** page, the link to that page will not show up in any of the navigational user interfaces.
- Resources that are available within a Resource Catalog are adjusted based on security policies. If a user is not authorized to access a particular resource, such as a task flow, that resource will not appear in the Resource Catalog.

9.11.4 Runtime Editing of Portal Resources

The WebCenter Portal Administration Console includes a Resources tab that lets you work with several portal-specific features at runtime:

- Pages
- Page templates
- Navigation models



- Resource Catalogs
- Skins
- Page styles
- Content Presenter display templates
- Mashup styles
- Data controls
- Task flows

Using the Resource Manager, portal users can also download resources, or an entire application, from the runtime environment, edit them in JDeveloper, and then upload them back into the deployed application. For more information on downloading and uploading resources, see Section 17.3, "Enabling Runtime Administration of Your Portal" and Section 17.4, "Enabling Round-Trip Development of Resources."

The Edit Source feature in the Resource Manager lets you edit the source code of resources in the runtime application. For example, if you upload a portal resource (like a page template), you can then edit it directly in the Resource Manager. Just select the resource, and choose Edit Source from the Edit menu. A source editing window appears, as shown in Figure 9–21.

Note: Some resources, like the `default-navigation-model`, are not editable. If you want to edit these resources, make a copy first and edit the copy.

Figure 9–21 Editing a Page Template Source File at Runtime

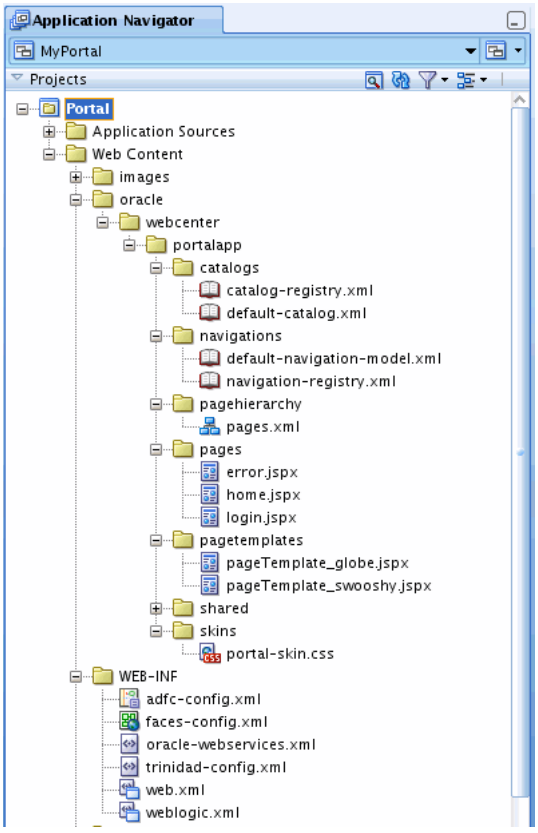
9.12 How are WebCenter Portal Files Organized?

When you run through the Framework application wizard, a large number of project artifacts are configured and installed in the project directory. JDeveloper presents a

streamlined view of your project. You can also view your portal project directly on your filesystem.

- Section 9.12.1, "Understanding the Organization of a WebCenter Portal: Framework Application"
- Section 9.12.2, "Viewing Your Portal Project on the Filesystem"
- Section 9.12.3, "Viewing Your Portal Project in JDeveloper"

9.12.1 Understanding the Organization of a WebCenter Portal: Framework Application



This section explains how a Framework application is organized, and then why it is organized the way it is.

9.12.1.1 How is a WebCenter Portal: Framework Application Organized?

When you create a new Framework application in JDeveloper, a large number of files are automatically placed in the project. You can see these files organized in the Application Navigator view in JDeveloper.

Looking at the Application Navigator, the first thing you will notice is that a framework application consists of one project, which is called (by default) **Portal**, as shown in Figure 9–22. You can, of course, change this name when you create the application or anytime afterwards. Most of the files in a project are placed in the `<application_root>/<project_root>/public_html/oracle/webcenter/portalapp` directory.

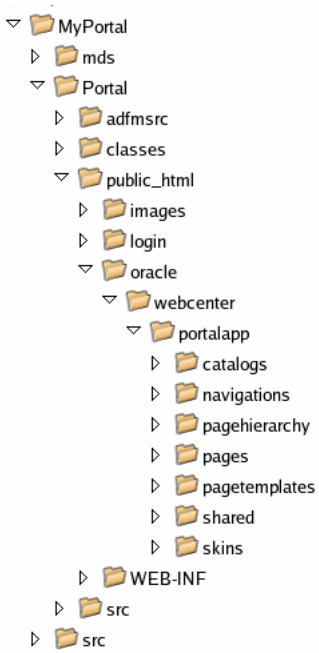
Figure 9–22 WebCenter Portal: Framework Application in the Application Navigator

9.12.1.2 Why Is a WebCenter Portal: Framework Application Organized the Way It Is?

It is important to understand the following distinctions between files that are stored in your application:

> **Note:** It is important to understand these distinctions because some files, like XML files, you might not expect to find under `public_html`. (Because in a standard web application, most files under this directory are directly URL accessible from a browser once the application is deployed.) Developers must keep in mind that portal files require this particular structure; you must not attempt to create portal artifacts in other locations.

- Files located in the `<application_root>/<project_root>/public_html/oracle/webcenter/portalapp` directory:
  - are deployed to the Metadata Services (MDS) repository.
  - can be registered as portal resources and managed at runtime with the Resource Manager.
  - are generally secured using WebCenter Permissions (if they are portal resources).
- Files located elsewhere under `<application_root>/<project_root>/public_html`:
  - are deployed to the application WAR file.
  - cannot be registered as portal resources and therefore cannot be managed with the Resource Manager.
  - are secured using the native permission class of the artifact.



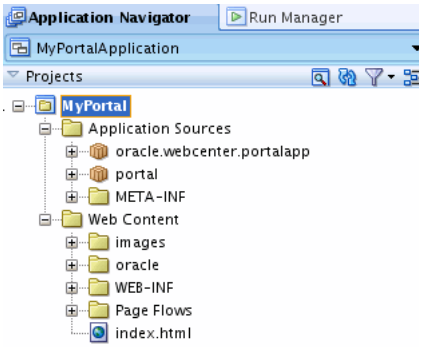
It is important to understand that a Framework application is structured this way specifically so that you can make informed decisions when you create your own pages. In some cases, specifically with JSPX pages, you might not want to create a page under `oracle/webcenter/portalapp`. It depends on the intended use of the page in your application.

9.12.2 Viewing Your Portal Project on the Filesystem

The simplest way to locate your project files on the file system is to select a file or folder in the Application Navigator and then select **Copy Path** from the Edit menu. This function places the path to the file or folder on the clipboard, which you can then paste into a command shell or file browser.

Figure 9–23 shows the filesystem organization of a sample Framework application. Many of the project's files are organized under the `public_html` folder.

Figure 9–23 Sample WebCenter Portal: Framework Application on the Filesystem



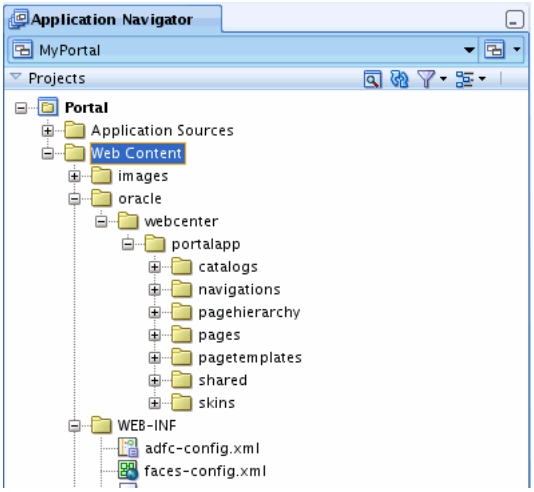
As you will see, JDeveloper presents a somewhat different, more streamlined view of your project, as discussed in the next section, Section 9.12.3, "Viewing Your Portal Project in JDeveloper."

9.12.3 Viewing Your Portal Project in JDeveloper

The intent of the project view in JDeveloper is to present the project files that a developer is likely to work with. These files include pages, page hierarchies, navigation models, page templates, catalogs, XML configuration files, Java source files, images, and so on.

In JDeveloper, portal projects are organized into two folders: Application Sources and Web Content, as shown in Figure 9–24.

Figure 9–24 Organization of a Portal Project in JDeveloper



The **Application Sources** folder is primarily a repository for source code and page definition files. See also Section 9.9, "What is the Application Sources Folder?."

The **Web Content** folder contains all of the files that make up your web project, like pages, page hierarchies, navigation models, and so on. These are the files that you will actively create and modify as you develop your Framework application.

Figure 9–25 shows the basic structure of the Web Content folder. Note that many of the files you will create and modify are located in the `oracle/webcenter/portalapp` sub folder. This folder's contents – catalogs, navigations, page hierarchy, pages, skins, and pagetemplates – make up the basic components of a portal. For detailed information on these portal components, see Section 9.12.1, "Understanding the Organization of a WebCenter Portal: Framework Application."

Figure 9–25 The Web Content Folder

Tip: If you prefer to view the local file system hierarchy in the Application Navigator, click the **Navigator Display Options** icon in the Projects panel and select **Group by Directory**.

The **PortalWebAssets** project includes static application resources like HTML and image files. By separating the static resources into a separate project, it is possible to deploy those resources to a dedicated server. For more information, see Section 5.4, "Understanding the PortalWebAssets Project.".

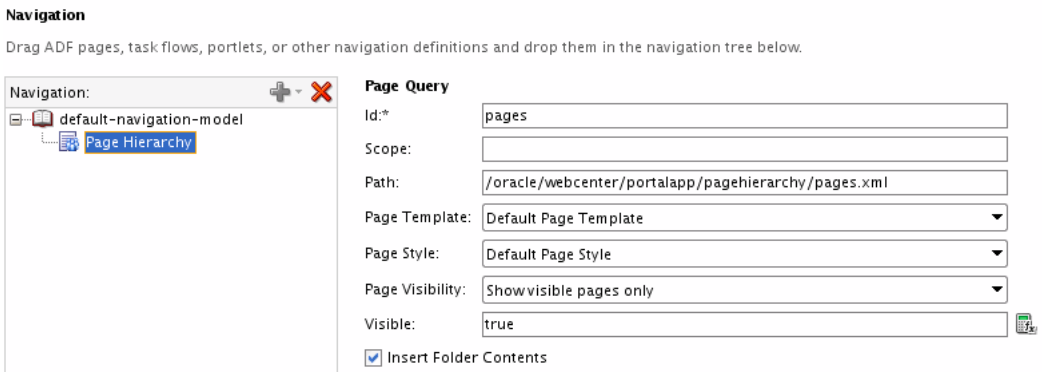
9.13 Changing the Default Home Page and Login/Logout Target Pages

The file `oracle/portalapp/pages/home.jspx` is the default home page for a new Framework application. This section explains how to change this default home page to another page or any navigable resource like a URL, portlet, or task flow.

- Section 9.13.1, "Understanding How the Home Page is Specified"
- Section 9.13.2, "How to Change the Default Home Page"
- Section 9.13.3, "How is the Default Index Page Specified?"
- Section 9.13.4, "Specifying the Target Page After a Login or Logout"

9.13.1 Understanding How the Home Page is Specified

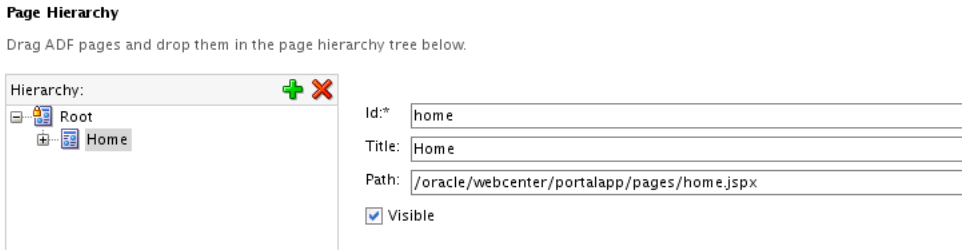
The default Framework application includes an `index.html` file, which is located in the portal project directory. This index file contains the following redirect statement:



```
<meta http-equiv="refresh" content="0;url=./faces/pages_home" />
```

Note: The redirect statement in `index.html` refers to the portal navigation model, not to a page as you might expect. Pointing the redirect to the navigation model allows the `currentSelection` attribute to be set properly, which allows the current selection to be highlighted in the user interface.

The URL element `pages_home` refers to the "home" page specified in the page hierarchy. (The prefix "`pages_`" is added to the folder name simply to ensure a unique ID.) As Figure 9–26 shows, the **Insert Folder Contents** checkbox is selected in the Navigation dialog. The **Insert Folder Contents** option replaces the specified folder ("`home`" in this case) with the *contents* of the folder. Therefore, in this example, the portal looks for a folder called "`home`" in the page hierarchy. Note too that Page Hierarchy is specified as an element in the navigation model.



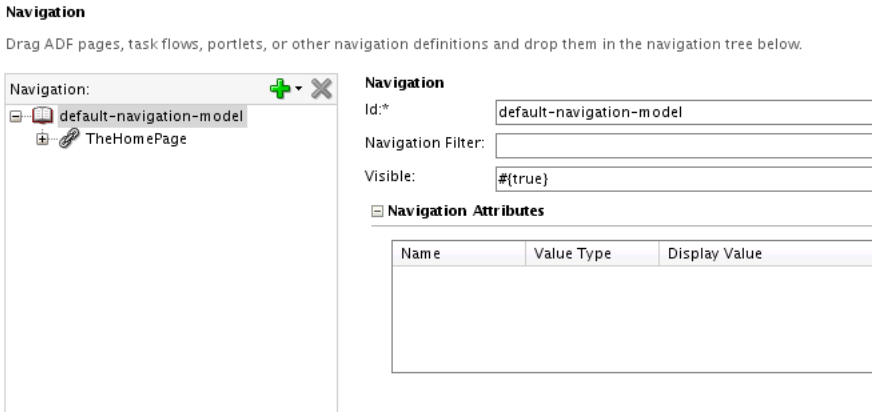
To help you understand how the default portal home page is specified, note that in the navigation model a default node called `pages` is created by default. This node's navigation path points to the page hierarchy file, `pages.xml`, as shown in Figure 9–26.

Figure 9–26 The Default Navigation Model

Upon navigating to `pages.xml`, the node called `home` is located, and that node's path is `/oracle/webcenter/portalapp/pages/home.jspx`, as shown in Figure 9–27.

Figure 9–27 The Default Page Hierarchy

9.13.2 How to Change the Default Home Page



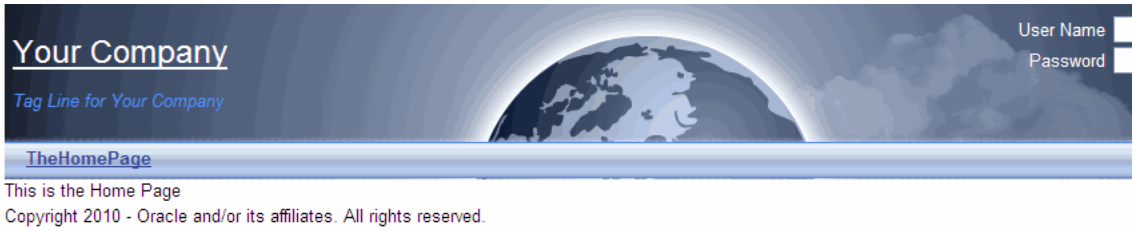
To change the default home page, simply change the redirect statement in `index.html` to the pretty URL of another resource that is referenced in the navigation

model. For example, you might create a new home page and redirect to it – a common use case. Simply specify the new page to be your portal's home page by changing the redirect in `index.html` to the new page's pretty URL. (You can drag the new page in the navigation model to create a page link element.) For example, if the link ID in the navigation model is `TheHomePage`:

```
<meta http-equiv="refresh" content="0;url=./faces/TheHomePage" />
```

where `./faces/TheHomePage` is the pretty URL that points to the link element defined in the navigation model.

Figure 9–28 Navigation Model with New Home Page Element



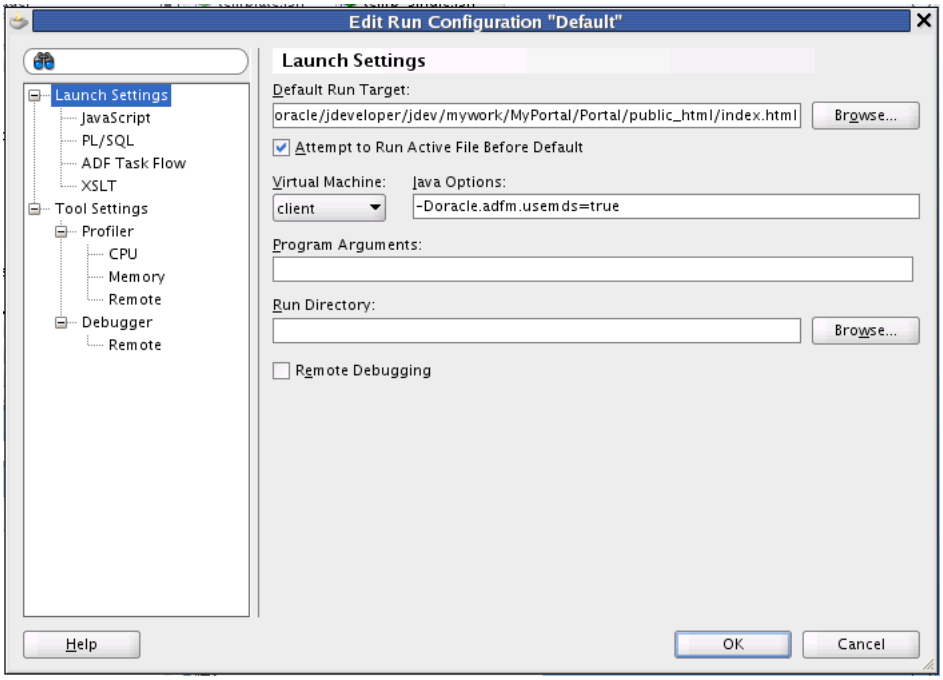
Using this example, if access the portal in a browser using this URL:

```
http://myserver:myport/MyPortalApp-Portal-context-root
```

the portal will render a home page that contains the content from the new home page, as shown in Figure 9–29.

Figure 9–29 The Oracle Website Displays as the Content for the Portal Home Page

9.13.3 How is the Default Index Page Specified?



The default index page for the Integrated Weblogic Server instance is `index.html`. A new portal project includes this file, by default, in the `Web Content` folder.

To change the default index file, `index.html` to another file, you have two choices. One way to change this default index file is to edit the `<welcome-file-list>` element in the `web.xml` file:

```
<welcome-file-list>
    <welcome-file>/index.html</welcome-file>
</welcome-file-list>
```

Another way to change the default index page is to use the Edit Run Configuration "Default" dialog box. To access this dialog, open the project properties dialog, then, select the **Run/Debug/Profile** option. Click **Edit** to bring up the Edit Run Configuration "Default" dialog where you can change the default index page, as shown in Figure 9–30.

Figure 9–30 Edit Run Configuration "Default" Dialog

9.13.4 Specifying the Target Page After a Login or Logout

To specify the target page after a login or logout, edit the `<navigation-rule>` element in the `WebContent/WEB-INF/faces-config.xml` configuration file in your portal project, as shown in Example 9–1. You can change the target pages to any other navigation resource's pretty URL or Faces page.

Example 9–1 Specifying the Target Page for Login and Logout

```
<navigation-rule>
    <from-view-id>*</from-view-id>
    <navigation-case>
      <from-outcome>login_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
    <navigation-case>
      <from-outcome>logout_success</from-outcome>
      <to-view-id>/pages_home</to-view-id>
      <redirect/>
    </navigation-case>
</navigation-rule>
```

For example, to redirect the user to a post-logout page follow these steps:

1. Create the post-logout page and add content to it. For example:

   `/oracle/webcenter/portalapp/pages/postlogout.jspx`

2. Modify the navigation rule in `faces-config.xml`. For example:

```
<navigation-case>
  <from-outcome>logout_success</from-outcome>
  <to-view-id>/oracle/webcenter/portalapp/pages/postlogout.jspx</to-view-id>
  <redirect/>
</navigation-case>
```

After a successful logout, the user is redirected to the specified page.

9.14 Basic Portal Development Tasks

This section lists some of the basic tasks involved with developing Framework applications.

- Set up an integrated team development environment with source control, a common database, and common content repository.
- Create a Framework application using the WebCenter Portal: Framework Application template.
- Design the overall structure of your portal, sketching out the top level pages and sub pages that will comprise your portal.
- Consider security for your portal. Decide which pages users will be allowed to visit. Create appropriate roles to accommodate these decisions.
- Begin thinking about your portal's overall look and feel, and begin working on a page template.
- Consider which WebCenter Portal services you want to include in your portal. For example, do you want to add a wiki or a blog or an activity stream? See Section 2.4, "Introducing Oracle WebCenter Portal: Services."
- Create pages based on your overall portal structure. The pages can be blank at this point, but creating them now allows you to begin assembling the page hierarchy.
- Create a page hierarchy using the Page Hierarchy editor.
- Create a navigation model. Think about the kinds of resources you want users to be able to navigate to. Examples include pages, external URLs, task flows, and content folders.
- Add navigation UI to the page template. Oracle WebCenter Portal: Framework provides several options for navigation UI. The most commonly used option is to use EL directly in the page template. WebCenter also provides navigation task flows and a Java API for navigation.
- Begin applying security policies to the page hierarchy. Start by applying policies to the root node of the hierarchy. Those policies will be inherited by all other pages in the hierarchy. Then, fine-tune the security settings on individual pages or on sub-branches of the overall hierarchy.
- Work on the pages themselves, adding and configuring portlets, task flows, content, and other features.

10

Understanding the WebCenter Portal Life Cycle

This chapter discusses tasks, tools, and techniques for managing a WebCenter Portal: Framework application throughout its life cycle.

- Section 10.1, "What is the WebCenter Portal Life Cycle?"
- Section 10.2, "What Are the Major Life Cycle Tasks?"
- Section 10.3, "Who Participates in the Portal Life Cycle?"
- Section 10.4, "Understanding the Build and Test Environments"
- Section 10.5, "Understanding the Staging and Production Environments"
- Section 10.6, "Tools for Managing the Life Cycle"
- Section 10.7, "Configuring a Nightly Build Script"
- Section 10.8, "Setting Up a Staging or Production Environment for the First Time"
- Section 10.9, "Moving a WebCenter Portal: Framework Application to an Existing Environment"
- Section 10.10, "Deploying to Managed Servers"
- Section 10.11, "Deploying and Configuring the Application on Targeted Servers"
- Section 10.12, "Building and Deploying Personalization for WebCenter Portal Files"
- Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production"
- Section 10.14, "Propagating Content From Oracle WebCenter Content"
- Section 10.15, "Managing Security Through the Life Cycle"
- Section 10.16, "Migrating Portlet Preferences"
- Section 10.17, "Rolling Back Production Site Changes"

10.1 What is the WebCenter Portal Life Cycle?

The portal life cycle refers to the path a portal takes from development through production. The phases of the life cycle typically include development, testing, staging, and production. Each phase requires certain tasks to be performed. Some tasks are performed only once, like setting up a content repository. Others are performed more frequently, like nightly builds. The phases of the portal life cycle are described in Table 10–1.

Table 10–1 Portal Life Cycle Phases

Life Cycle Phase	Primary Actors/Roles	Description
Development	■ Developers ■ Content Modelers ■ Content Contributors	The development portal is primarily source control and file-based. Developers work locally in JDeveloper and deploy to the Integrated WebLogic server. The development portal typically employs test data and content. Some of the features that are developed in this phase of the life cycle include: ■ portlets ■ task flows ■ shared libraries ■ skins ■ navigation models ■ page templates ■ display templates ■ content models ■ data transfer and interportlet communication ■ security The code from the development environment is built (usually nightly) and deployed to a clean, independent, targeted environment. WebCenter provides a build script that can be adapted for this purpose. See Section 10.7, "Configuring a Nightly Build Script."

Table 10–1 (Cont.) Portal Life Cycle Phases

Life Cycle Phase	Primary Actors/Roles	Description
Testing	■ Developers ■ QA Engineers ■ IT Administrators	The development portal is built (usually nightly) and deployed to an independent testing environment. The test environment typically includes a Metadata Service (MDS) and policy store that are database-based, and a dedicated Oracle WebCenter Content instance. The testing environment may contain test data and test content that will not become part of the production portal. Portlet producers may be shared between the test and development environments. However, if the usage load is high, Oracle recommends that separate instances be created. See also Chapter 62, "Testing and Deploying Your Portlets."
Staging	■ Site Managers ■ IT Administrators ■ Content Contributors	The staging environment provides a stable environment where final configuration and testing takes place before the portal is moved to production. Content contributors add content and refine the portal structure. Typically, the staging environment includes a dedicated Oracle WebCenter Content server, as well as dedicated portlet producer server(s). The staging server is often maintained as a mirror of the production site.
Production	■ Site Managers ■ IT Administrators ■ Content Contributors	A production portal is live and available to end users. A portal in production can be modified with tools like the Resource Manager and Oracle WebCenter Portal's Composer. For instance, an administrator might add additional portlets to a portal or reconfigure the contents of a portal. Individual users with proper authorization can also customize their view. See *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. WebCenter provides a propagation tool for migrating metadata to the production environment. See Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production." Content is provisioned using Oracle WebCenter Content replication tools. See Section 10.14, "Propagating Content From Oracle WebCenter Content." WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 10.16, "Migrating Portlet Preferences."

10.2 What Are the Major Life Cycle Tasks?

Each phase of the life cycle requires actors (developers, administrators, content contributors, and others) to perform certain tasks. This provides an overview of the kinds of tasks that are performed during each phase of the portal life cycle.

- Section 10.2.1, "One-Time Setup Tasks"
- Section 10.2.2, "Development Environment Tasks"
- Section 10.2.3, "Nightly Build Environment Tasks"
- Section 10.2.4, "Testing Environment Tasks"
- Section 10.2.5, "Stage Environment Tasks"
- Section 10.2.6, "Production Environment Tasks"

10.2.1 One-Time Setup Tasks

You must perform certain preparatory steps to set up the development, build/test, stage, and production environments. Table 10–2 provides a general list of these preliminary setup tasks and the environments to which they apply. See also Section 10.7, "Configuring a Nightly Build Script" and Section 10.8, "Setting Up a Staging or Production Environment for the First Time."

Table 10–2 Typical One-Time Setup Tasks

Setup Task	Development	Build/Test	Stage	Production
Install JDeveloper	Yes	No	No	No
Install Oracle WebCenter Portal	Yes	Yes	Yes	Yes
Install Oracle WebLogic Server; create a domain and managed servers	No	Yes	Yes	Yes
Create required database schemas using RCU	No	Yes	Yes	Yes
Install and configure Oracle WebCenter Content	Yes	Yes	Yes	Yes
Install identity management components, such as Oracle Access Manager	No	Yes	Yes	Yes
Create the required Oracle Platform Security Services policies in the policy store	No	Yes	Yes	Yes
Create required user credentials in the credential store	No	Yes	Yes	Yes
Create connections to back end servers	Yes	Yes	Yes	Yes
Create build scripts	Yes	No	No	No
Create deploy and configure scripts	No	No	Yes	Yes
Integrate/configure Personalization for WebCenter Portal	Yes	Yes	Yes	Yes

* For more information on Personalization for WebCenter Portal, see "Managing Personalization for WebCenter Portal" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* and Chapter 67, "Personalizing WebCenter Portal Applications."

Another technique for setting up an environment for the first time is to clone an existing instance. Typically, this strategy is used to clone a production instance from a stage instance. For detailed information on this "test to production" technique, see "Moving from a Test to a Production Environment" in the *Oracle Application Server Administrator's Guide*.

10.2.2 Development Environment Tasks

In a development environment, each developer has a local JDeveloper instance that is connected to a source control system and a shared Oracle WebCenter Content repository. Developers store metadata and code in source control. Portlets are deployed independently to a producer server and consumed by the portal.

In a development environment, developers typically build and run the application locally using the Integrated WebLogic Server. Both MDS and the Policy Store are file-based in the local development environment.

For more information, see Chapter 1, "Developer's Quick Start Guide," Chapter 3, "Preparing Your Development Environment," and Chapter 4, "Working Productively in Teams."

10.2.3 Nightly Build Environment Tasks

On a daily basis, developers work in JDeveloper and run code changes locally on the Integrated WebLogic Server, and code changes are checked into a source control system.

If you wish to set up a build environment that produces a clean environment that is built each night, there are certain tasks that must be performed with each build, including:

- Creating schema (typically with Oracle Repository Creation Utility – RCU)
- Creating and setting up the domain
- Creating and configuring managed servers
- Deploying the application

WebCenter provides sample build scripts that you can modify and use for your environment. See Section 10.7, "Configuring a Nightly Build Script." Nightly builds are usually made available to people within the organization, like QA engineers, technical writers, managers, and others. See also Section 10.4, "Understanding the Build and Test Environments."

For information on integrating Personalization for WebCenter Portal into your development environment, see Section 67.2, "Integrating Personalization in Your Application."

10.2.4 Testing Environment Tasks

Usually, the testing environment is a mirror of the nightly build environment that is accessed by QA engineers. The tasks involved in providing a clean test environment are usually the same as creating a clean build environment. See also Section 10.4, "Understanding the Build and Test Environments."

10.2.5 Stage Environment Tasks

Runtime tools play a bigger role in the staging environment than in the development environment. Nonetheless, occasional updates from development will need to be deployed to the stage environment. To facilitate these more intermittent updates, WebCenter provides a set of deploy and configure scripts that you can copy and modify to suit your environment. The deploy and configure scripts isolate the information that is variable between environments, like the server names, ports, content management connections, and so on. For more information, see Section 10.5.1, "Provisioning the Staging Environment" and Section 10.11, "Deploying and Configuring the Application on Targeted Servers." See also Chapter 62, "Testing and Deploying Your Portlets."

For information on integrating and configuring WebCenter Personalization, see "Personalization for WebCenter Portal Prerequisites" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

10.2.6 Production Environment Tasks

When changes are tested and approved in the stage environment, they need to be pushed to the production environment. WebCenter provides a Propagation tool in the WebCenter Portal Administration Console that moves all portal metadata from the staging to the production server. For more information, see Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production."

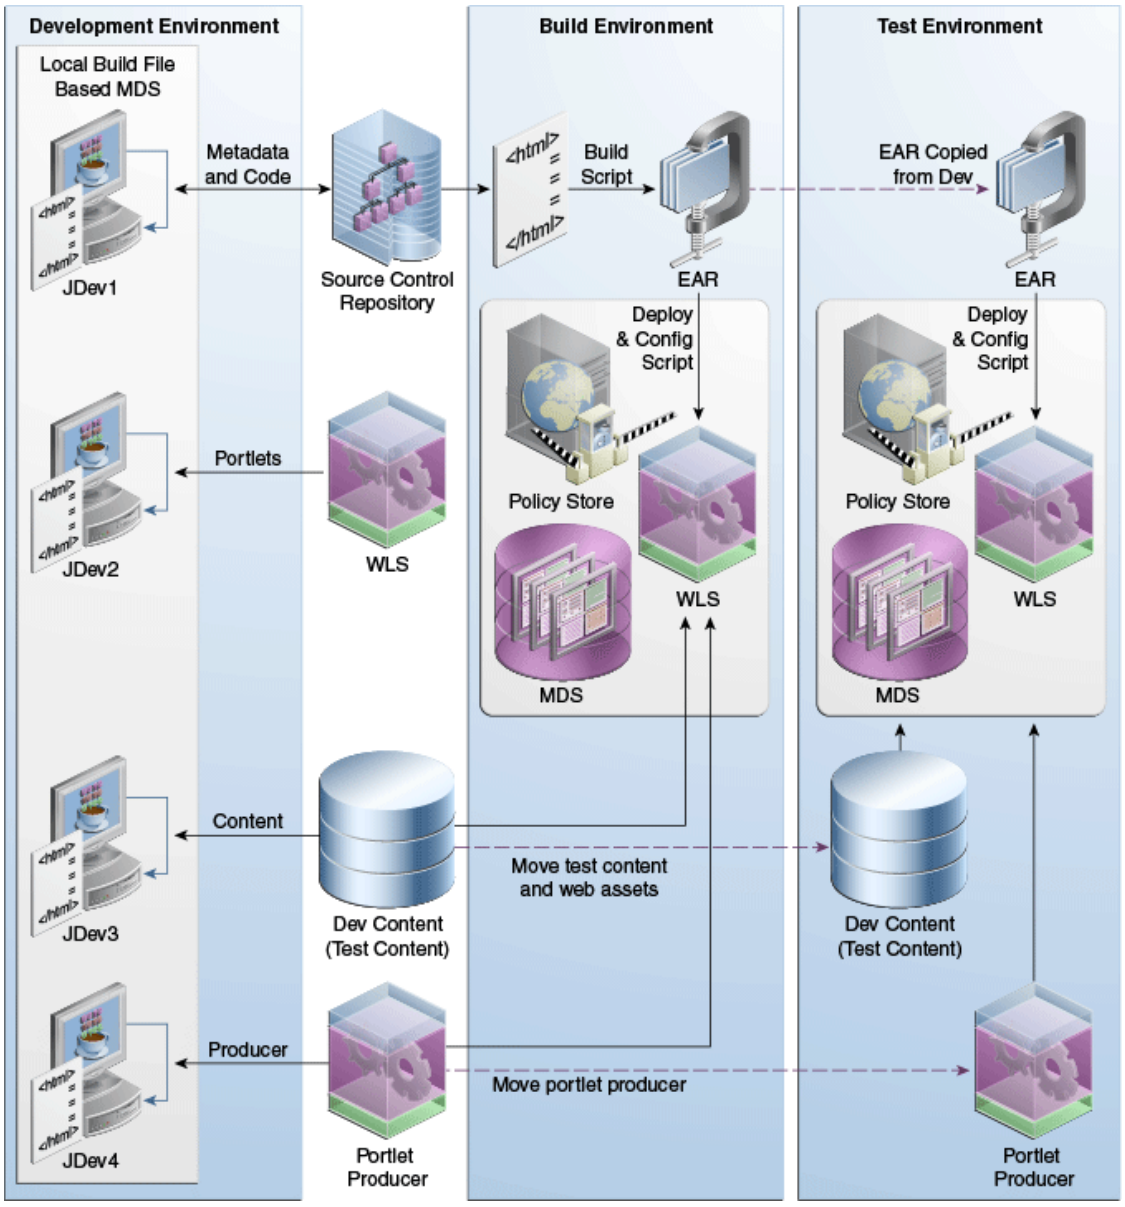
WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 10.16, "Migrating Portlet Preferences."

10.3 Who Participates in the Portal Life Cycle?

Many different people participate in the portal life cycle. In general, these people (the primary actors in Table 10–1) fall into one or more of these general roles:

- **Developer** – Uses JDeveloper and the build scripts described in Section 10.7, "Configuring a Nightly Build Script."
- **IT Administrator** – Uses the deploy and configuration scripts described in Section 10.11, "Deploying and Configuring the Application on Targeted Servers."
- **Site managers** – Have administrative privileges for the Framework application. Site managers use the WebCenter Portal Administration Console to modify the layout, content, and security settings of the portal. See also *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* and Section 10.15, "Managing Security Through the Life Cycle."
- **Content modelers** – Uses Oracle WebCenter Content's Site Studio designer to model content. Refer to Site Studio and Oracle WebCenter Content documentation for more information.
- **Content contributors** – Develops whatever content appears in or is available from the portal, including images, document files, video and audio content, and so on.

10.4 Understanding the Build and Test Environments



Although developers typically build and run locally, an automated nightly build environment is recommended. The build environment represents a clean deployment of the Framework application.

To set up the build environment, back end servers and connections must be installed and created once. For example, the build environment requires WebLogic Server instance, and typically includes access to an installed Oracle WebCenter Content instance. In addition, the build environment includes a database-based MDS and policy store.

Figure 10–1 illustrates the general flow from development to build to test environments.

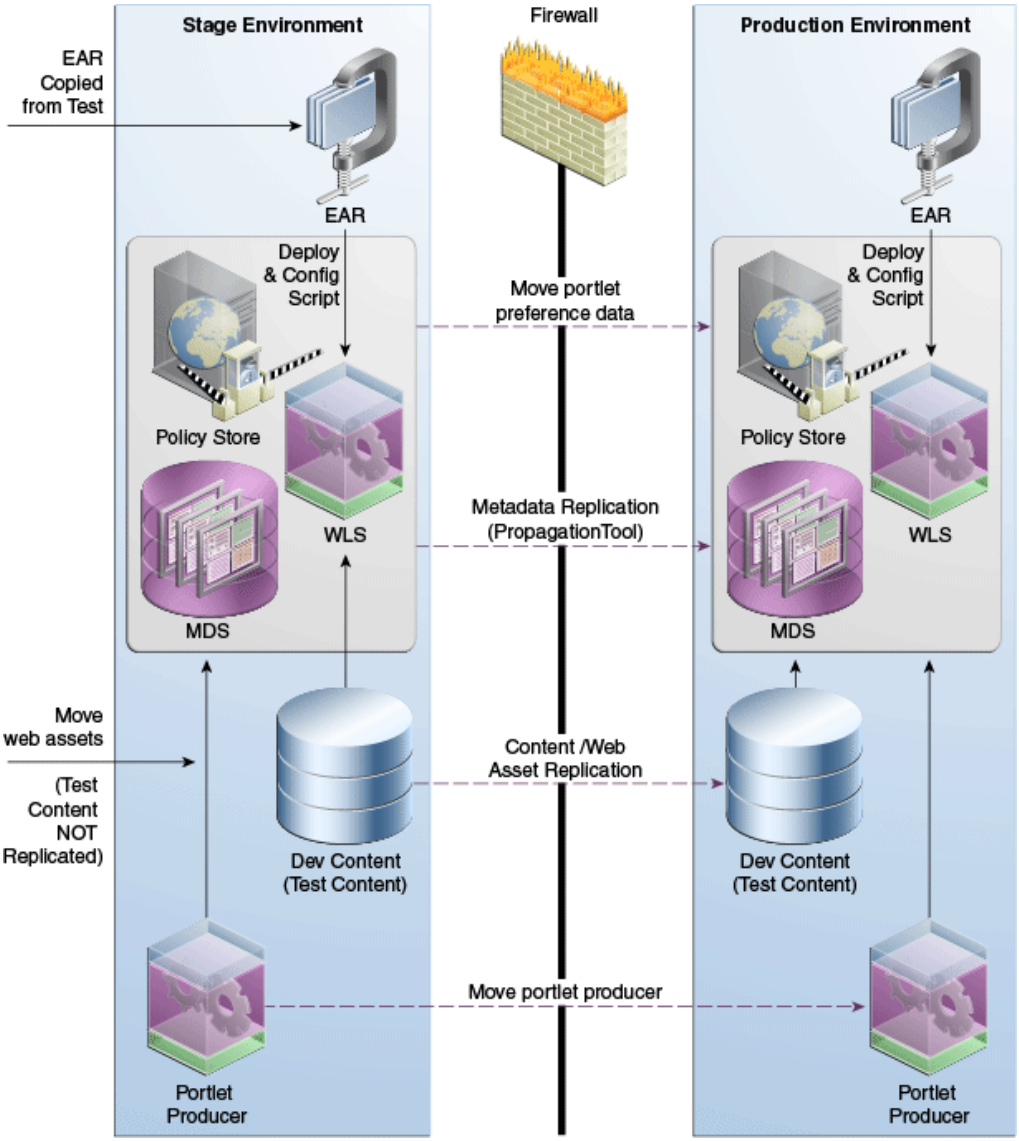
Note: Figure 10–1 does not depict all possible portal features. For example, Personalization for WebCenter Portal is not depicted in the diagram. For more information, see Section 10.12, "Building and Deploying Personalization for WebCenter Portal Files."

Figure 10–1 Flow from Development to Build to Test Environments

A common practice is to use Ant-based build scripts to construct the EAR from source control and deploy it. The EAR includes metadata, code, and seeded policies. The build script also packages into the EAR metadata customizations made to portlets. See Section 10.7, "Configuring a Nightly Build Script." Some tasks performed by the build scripts include:

- creating schema (with RCU)
- setting up the managed server and domain
- building and deploying the EAR
- performing other setup tasks

The best practice is to use Oracle WebCenter Content archive tools to move Oracle WebCenter Content test content and web assets between the environments. See Section 10.14, "Propagating Content From Oracle WebCenter Content." For information on deploying portlets, see Chapter 62, "Testing and Deploying Your Portlets."



For information on integrating Personalization for WebCenter Portal into your development environment, see Section 67.2, "Integrating Personalization in Your Application."

10.5 Understanding the Staging and Production Environments

This section discusses the staging and production phases of the portal life cycle. Figure 10–2 illustrates the general flow from staging to production environments.

> **Note:** Figure 10–2 does not depict all possible portal features. For example, Personalization for WebCenter Portal is not depicted in the diagram. For more information, see Section 10.12, "Building and Deploying Personalization for WebCenter Portal Files."

Figure 10–2 Flow from Staging to Production Environments

10.5.1 Provisioning the Staging Environment

The staging environment provides a stable environment where final configuration and testing takes place before the portal is moved to production. Typically, the staging environment includes a dedicated Oracle WebCenter Content server, as well as dedicated portlet producer server(s). For a list of typical setup tasks, see Table 10–2.

If you are setting up the staging environment for the first time, see Section 10.8, "Setting Up a Staging or Production Environment for the First Time." For information on making incremental changes to the staging environment, see Section 10.11, "Deploying and Configuring the Application on Targeted Servers."

If you wish, you can move Oracle WebCenter Content content and web assets between the testing and staging environment using Oracle WebCenter Content archive tools. See Section 10.14, "Propagating Content From Oracle WebCenter Content." For information on migrating portlets, see Section 10.16, "Migrating Portlet Preferences."

For a complete list of requirements, dependencies, and options for WebCenter Personalization, see "Personalization for WebCenter Portal Prerequisites" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

10.5.2 Adding Content to the Staging Environment

Content developers can add content directly to the staging server using Oracle WebCenter Content content contribution tools and/or the Documents service. Content workflow features of Oracle WebCenter Content can be used to manage content approvals. WebCenter also provides runtime tools for creating and editing content. For example, you can:

- Edit existing Oracle WebCenter Content region data files
- Create new Oracle WebCenter Content region data files
- Edit existing HTML content
- Upload new images

In addition, the Documents service provides folder-based creation and editing of HTML content and other file types. See also Chapter 30, "Integrating the Documents Service."

10.5.3 Moving the Portal from Staging to Production

Once the staging environment is fully provisioned and tested, it can be moved to the production environment and made accessible to users. In a live production environment, you can make incremental updates to metadata, content, and web assets using automated scripts and/or replication techniques.

Typically, these updates are performed by a site manager rather than by individual content contributors. For more information, see Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production."

Any content model or region definition changes can be pushed to the production server by the site manager. Oracle WebCenter Content Replication can be used to replicate content between the stage and production server. See Section 10.14, "Propagating Content From Oracle WebCenter Content."

WebCenter provides WLST commands for importing and exporting portlet preferences. For more information, see Section 10.16, "Migrating Portlet Preferences."

10.6 Tools for Managing the Life Cycle

WebCenter Portal is built on top of JDeveloper and Oracle ADF, which provide several benefits in the life cycle management of your application:

- **Development framework:** JDeveloper and Oracle ADF provide the tools and framework you can use to build and update your application. Adding portlets, content, and customization capabilities to your Framework application is simply a matter of dragging and dropping the appropriate objects in either a source or WYSIWYG environment.
- **Iterative Development:** WebCenter provides an iterative development feature that greatly increases team productivity. See Section 1.5, "Preparing for Iterative Development."
- **Round-Trip Development:** Round-trip development refers to features and techniques that allow you to retrieve resources from a deployed, runtime portal back to JDeveloper for maintenance or enhancement. For more information on round-trip development, see Section 17.3, "Enabling Runtime Administration of Your Portal" and Section 17.4, "Enabling Round-Trip Development of Resources."
- **Enterprise deployment:** When you are ready to deploy your application to a production environment, you can use the deployment scripts provided by WebCenter. For more information, see Section 10.11, "Deploying and Configuring the Application on Targeted Servers" and Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production." For more information about deployment, see Chapter 70, "Deploying and Testing Your WebCenter Portal: Framework Application."

  Note: WebCenter Portal: Services typically require some back end, such as Oracle WebCenter Portal's Discussions Server, to be available in the deployment environment.

- **Standards-based administration:** Browser-based tools enable administrators to deploy, configure, and manage Framework applications and WebCenter Portal: Services. In addition, tools built on industry standards-based JMX methods offer administrators granular control and monitoring mechanisms for health status, performance, and popularity. Tools for obtaining historical performance and status reporting over time (within a single Oracle Application Server context) are also provided. Framework application metrics are delivered using the familiar Application Server Control monitoring and management interface. For more information, see *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

10.7 Configuring a Nightly Build Script

When you create a Framework application, an Ant build script and properties file are created automatically for you in the main application directory on the filesystem. These files are:

- `build.xml`– Includes a standard set of targets for cleaning, compiling, building, and deploying the application. You can check this file into source control so that it is available to the developers.
- `build.properties` – Specifies the location of the JDeveloper workspace file (`.jws` file) for your application and the output folder for the application WAR file. Note that the `build.xml` file includes the `build.properties` file, which

enables `build.xml` to pick up these environment-specific variables. You can customize the properties file to match the setup and environment variables used in your build environment.

Before running the build script, be sure `JAVA_HOME` and `ANT_HOME` environment variables are set properly. For example:

```
JAVA_HOME = /path_to_your_java_installation/jdk
ANT_HOME = /path_to_your_ant_installation
```

To build and deploy your application, use the ant target `all`. For example:

```
ant all
```

If you are using Personalization for WebCenter Portal to provide personalization features for your portal, you must perform a manual update to the `build.xml` file. For details, see Section 10.12.1, "Building the WCPS MAR File."

10.8 Setting Up a Staging or Production Environment for the First Time

For detailed information on setting up and provisioning a staging or production environment for the first time, see "Moving Oracle WebCenter Portal to a New Production Environment," in the *Oracle Application Server Administrator's Guide*. See also Section 10.15, "Managing Security Through the Life Cycle" for information on moving security policies and credentials to an environment for the first time.

10.9 Moving a WebCenter Portal: Framework Application to an Existing Environment

In this scenario, you have a working production environment with Oracle WebCenter Portal installed and configured and you want to test changes in your applications or configuration before rolling those changes into the production environment. For example, you have modified existing security policies or configuration.

Oracle recommends that you use the deploy and configure scripts to update existing environment. Sample scripts are provided with WebCenter, and you are free to modify them to suit your environment. For detailed information, see Section 10.11, "Deploying and Configuring the Application on Targeted Servers" and Section 10.12, "Building and Deploying Personalization for WebCenter Portal Files."

WebCenter provides a Propagation tool that is built in to the WebCenter Portal Administration Console. The Propagation tool is for moving your application from the staging environment to the production environment. See Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production."

For information on moving Oracle WebCenter Content content, see Section 10.14, "Propagating Content From Oracle WebCenter Content."

For information on moving security policies and credentials, see Section 10.15, "Managing Security Through the Life Cycle."

For more information, see "Moving Oracle WebCenter Portal to an Existing Production Environment," in the *Oracle Application Server Administrator's Guide*.

10.10 Deploying to Managed Servers

Framework application developers working in JDeveloper typically deploy their application locally to the Integrated WebLogic Server. For other phases of the life cycle – testing, staging, and production – deployment to a suitable managed server is recommended. Or, for portlet development, you need to deploy to the Services Producer Managed Server. For more information on deploying to managed servers, see Section 70.3, "Deploying a Framework Application to a WebLogic Managed Server." See also "Templates for WebCenter Portal or Portlet Producer Applications" in the *Oracle Fusion Middleware Installation Guide for Oracle WebCenter Portal* and "Creating and Provisioning a WebLogic Managed Server Instance" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

10.11 Deploying and Configuring the Application on Targeted Servers

During its life cycle, a typical portal is deployed to testing, staging, and production servers. This section describes a technique for deploying and configuring a Framework application on a targeted server.

- Section 10.11.1, "Introduction"
- Section 10.11.2, "Using the Deploy and Configure Script"

10.11.1 Introduction

WebCenter provides a configurable script that allows you to easily deploy and configure your application to these server instances. The build and deploy script takes a simple properties file parameter that specifies the server and connection information for the targeted server. You only need to create this properties file one time for each targeted server. Then, you execute the deploy and configure script with the appropriate properties file as a parameter.

Oracle recommends that you use the scripts described in this section to deploy your application rather than using ojdeploy. The best practice is to use the Ant task provided by JDeveloper to build your application, and then to use the scripts described in this section to deploy and configure the application. The ojdeploy command-line utility allows you to deploy your application from JDeveloper without starting the JDeveloper IDE.

Note: The propagation tool, described in Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production," is primarily used by site administrators to push approved site structure changes to production without incurring any downtime.

Tip: The build and deploy script isolates the information that is variable between environments, like the server names, ports, content management connections, database connections, and so on. Most aspects of the Framework application do not need to change when you redeploy it to another server. For example, the name of the application doesn't change.

10.11.2 Using the Deploy and Configure Script

The deploy and configure script described in this section is primarily used when the production application is mostly read only and live. In this scenario, content

contributors make active changes to the staged application and receive content approval before that content is moved to production. Oracle recommends that you use automatic content replication so that content is moved from stage to production after appropriate workflow approvals. See Section 10.14, "Propagating Content From Oracle WebCenter Content."

Security changes are not affected by the deploy and configure scripts. To push site structure changes to production, administrators can use the propagation tool, as described in Section 10.13, "Using the Propagation Tool to Propagate From Staging to Production." See also Section 10.15, "Managing Security Through the Life Cycle."

To deploy and configure your application to a target environment:

1. In a terminal window, go to the directory that contains the deploy and configure scripts. These scripts are called: `create_profile.csh` and `deploy_and_config.csh`. These files reside in `WEBCENTER_HOME/webcenter/scripts/stage2prod`, where `WEBCENTER_HOME` is the directory where WebCenter is installed.

   Note: The deploy and configure scripts in `stage2prod` are samples only. You are free to develop your scripts in a different location (after copying the sample and making changes to it for your deployed environment).

2. First, you need to provide some target environment-specific information in the `setup.properties` file, like the target server URL, user name, and password. Simply open the file `setup.properties` and add the appropriate values for the target environment. A sample file is shown in Example 10–1.

   Note: For WebLogic Sever deployments, you can ignore properties listed under WebSphere Server properties. See also, "Using the Deploy and Configure Script for Applications Deployed on WebSphere" in the *Oracle Fusion Middleware Third-Party Application Server Guide*.

Example 10–1 Sample setup.properties File

```
# Adminserver
admin.jmx.url=t3\://hostname\:7001
admin.user=weblogic
admin.password=welcome1

# Application
webcenter.app.name=webapp
webcenter.app.server=WC_CustomPortal
webcenter.app.version=V2.0
```

3. Update the `create_profile.csh` and `deploy_and_config.csh` to reflect the deployed environment.

   ```
   setenv WC_HOME <webcenter_home>
   setenv SCRIPTS_DIR <scripts_home>
   ```

   `WC_HOME` is the WebCenter Home and `SCRIPTS_DIR` is where the scripts are located. By default, the scripts are here: `$WC_HOME/webcenter/scripts/stage2prod`. If you copied the scripts to another location, then set `SCRIPTS_DIR` to that location.

4. Run the `create_profile` script. The input to this script is the `setup.properites` file. For example, in a Linux environment, enter:

   ```
   ./create_profile.sh
   ```

   This script examines your application environment and produces an output properties file called `profile.properties`.

5. If you wish, rename the output file, `profile.properties` to a name that reflects the target environment. For example, if the target environment is your stage environment, you might call the file output file `wstage.properties`.

   The `profile.properties` file specifies all the configuration information needed to run the portal on the target environment. For example, it includes settings for content management repository, omni portlet, WSRP producers, Personalization for WebCenter Portal and others. Example 10–2 shows a sample `profile.properties` file.

Example 10–2 Sample profile.properties File

```
webcenter.wcps.app.name=wcps-services
webcenter.wcps.app.server=WC_Utilities
admin.jmx.url=t3\://hostname\:7001
doclib.Content.cis.socket.host=hostname
app.mds.jndi=jdbc/mds/SpacesDS
webcenter.app.archive=/net/hostname/scratch/webapp.ear
doclib.Content.cis.socket.port=9444
webcenter.wcps.archive=/net/hostname/scratch/wcps.mar
webcenter.app.name=webapp
admin.user=weblogic
app.mds.repository=mds-SpacesDS
app.mds.partition=wcps-services
webcenter.app.version=V2.0
web.OmniPortlet.url=http\://hostname\:7101/portalTools/omniPortlet/providers/omniP
ortlet
app.restart=false
webcenter.app.server=WC_CustomPortal
```

> **Note:** All properties in the `profile.properties` must have a value. If a property is not needed, delete it or comment it out rather than leave the value empty.

6. Run `create_profile` to create a properties file for each of your target environments. For example, you might create one each for your test, stage, and production environments.

7. Run the `deploy_and_confg` script. The input to this script is the `profile.properties` file (or whatever you renamed the file). For example, in a Linux environment, might enter:

   ```
   ./deploy_and_config.csh
   ```

The `deploy_and_config` script takes one of two "modes" as input. These modes are `deploy_config` and `p13n_metadata`. For example:

```
./deploy_and_config.csh p13n_metadata
```

The `deploy_config` mode is the default mode if no input is passed to `deploy_and_config.csh`. The `deploy_config` mode does the deployment and configuration tasks. If you only need to update the update of personalization metadata, you can override the default behavior by passing in `p13n_metadata` as the input to the script.

This script deploys and configures the Framework application to run on the target environment.

10.11.3 Managing Post-Deployment Changes

All WebCenter Portal configuration changes performed after the application is deployed are stored as customizations in MDS. For example, if your application had some connections defined in `connections.xml`, and you then deployed the application on another managed server, and performed configurations using Oracle Enterprise Manager Fusion Middleware Control Console or WLST, then these changes are stored in MDS as customizations. Subsequently, if you deploy a newer EAR file, the connection changes you performed earlier would still be in effect, and will override the connection definition within the EAR file. The configuration changes performed with the Fusion Middleware Control Console or WLST persist after a redeployment. See also "Oracle WebCenter Portal Administration Tools" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

> **Note:** Portlet Producer application customizations are also stored in MDS. When you deploy a portlet producer, the customizations are uploaded to the currently configured producer connection. Oracle recommends that you use the deploy and configure scripts to manage the producer connections (rather than reconfiguring them after deployment and then redeploying the application). The deploy and configure scripts ensure that the producer customizations are redeployed correctly whenever the connection information changes.

10.12 Building and Deploying Personalization for WebCenter Portal Files

This section explains how to build and deploy Personalization for WebCenter Portal files.

> **Note:** For information on integrating and configuring WebCenter Personalization, see "Personalization for WebCenter Portal Prerequisites" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

- Section 10.12.1, "Building the WCPS MAR File"
- Section 10.12.2, "Deploying WCPS Files to a Server"
- Section 10.12.3, "Deploying WCPS Files to an Archive File"
- Section 10.12.4, "Importing and Exporting MAR Files"

10.12.1 Building the WCPS MAR File

WebCenter provides an Ant task for building the WCPS MAR file. Oracle recommends that you add this task to your nightly build script if you are using WCPS.

1. Create an Ant build script for your Framework application. For details, see Section 10.7, "Configuring a Nightly Build Script."
2. Open the `build.xml` file in an editor.
3. Add an Ant target for the `build-mar` task to the `build.xml` file, as shown in Example 10–3.

> **Note:** The Ant task supports nested `<fileset>` elements to specify the locations under which to scan for scenario and namespace XML files. This element supports all the standard Ant fileset semantics. Table 10–3 illustrates the use of `<fileset>`.

Example 10–3 Example deploy-wcps-mar Target Element

```
<target name="build-wcps-mar">
<taskdef name="build-mar"
        classname="oracle.wcps.tools.ant.BuildMARTask"
        uri="oracle:webcenter:wcps"> <classpath> <pathelement
path="${oracle.jdeveloper.home}/jdev/extensions/oracle.wcps.tools.common/oracle.wcps.tools.ant.jar"
/>
</classpath>
</taskdef>
<basename property="application.name"
         file="${oracle.jdeveloper.workspace.dir}"/>
<wcps:build-mar xmlns:wcps="oracle:webcenter:wcps"
               destFile="deploy/${application.name}-wcps.mar"
               appName="${application.name}"
               scenarionamespace="SomeThingElse"
               failonfilescanerror="false" failonempty="true"> <fileset
dir="${oracle.jdeveloper.workspace.dir}">
<include name="Portal/**/*.xml"/>
<exclude name="Portal/public_html/**"/>
</fileset>
</wcps:build-mar>
</target>
```

4. Add the task to the `depends` attribute on the `all` target. For example:

   ```
   <target name="all" depends="deploy,build-wcps-mar"/>
   ```

5. Save the `build.xml` file.

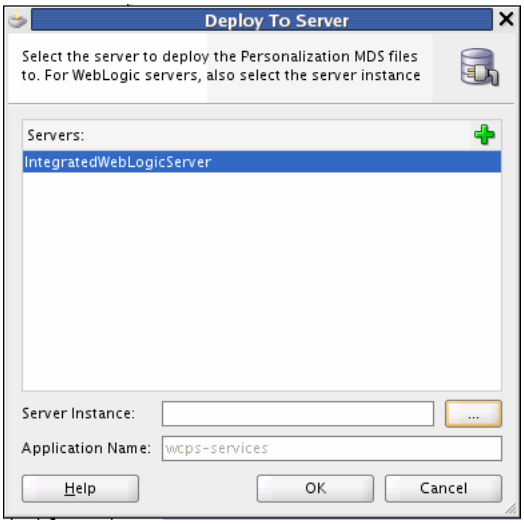
This `build-mar` Ant task supports the attributes listed in Table 10–3.

Table 10–3 Attributes Supported by the Ant Task

Attribute	Required	Description
destfile	Yes	The location of the `.mar` file to write. It will be overwritten if it exists.
appname	Yes	The application name. Typically, the base name of the `.jws` file.
scenarionamespace	No	The scenario namespace. Defaults to the application name, same (just as JDeveloper does).
failonfilescanerror	No	(Boolean) Specifies whether to have the task fail the build if it cannot scan a specified file. Defaults to true.
fileonempty	No	(Boolean) Specifies whether to have the task fail the build if no WCPS files are found. Defaults to `false`.

Note that if you do not set `failonfilescanerror="false"`, you might see errors similar to this one:

```
BUILD FAILED:
Unable to read
C:\opt\jdev-applications\Application1\Model\classes\.data\00000000\00000000.jdb
```



Either narrow your file sets (for example, use `*.xml`) or specify `failonfilescanerror="false"`, in which case it will just display a warning.

10.12.2 Deploying WCPS Files to a Server

To deploy WCPS files to a server:

1. In JDeveloper, open your portal project. If you want to use WLST commands to perform this deployment, see Section 10.12.4, "Importing and Exporting MAR Files."
2. From the Application menu, select **Deploy Personalization Files** and then select **To Server.**
3. In the Deploy to Server dialog, select the server to which you want to deploy the service. See Figure 10–3.

Figure 10–3 The Deploy To Server Dialog

Note: Optionally, click the **Add** button to add a server to the list.

4. Click the "**...**" button to select a specific server instance. For example, the running DefaultServer.
5. Click **OK** when you are finished.
6. Check, the Message - Log window for details on the deployment. The log will indicate if the deployment of the metadata files was completed successfully.

10.12.3 Deploying WCPS Files to an Archive File

You can deploy your WCSP files to a metadata archive (MAR) file on the file system. To deploy to a MAR file:

1. In JDeveloper, open your portal project.
2. From the Application menu, select **Deploy Personalization Files** and then select **To Filesystem.**
3. In the Deploy to Filesystem dialog, select **Create Metadata Archive** and specify a location and name for the MAR file.

The MAR file can then be updated to the server using command line utilities described in Section 10.12.4, "Importing and Exporting MAR Files."

10.12.4 Importing and Exporting MAR Files

To update a WCPS server with new files from a Metadata Archive (MAR) file, use the following WLST commands to connect to the server and import the metadata.

```
wlst:> connect('<username>', '<password>', 't3://admin-server-hostname:7001')
wlst:> importMetadata(application='wcps-services', server='WC_Utilities',
fromLocation='<mar file>', remote='true')
```

To export the WCPS from the server into a MAR file on the filesystem, use these WLST commands to connect to the server and export the metadata:

```
wlst:> connect('<username>', '<password>', 't3://admin-server-hostname:7001')
wlst:> exportMetadata(application='wcps-services', server='WC_Utilities',
toLocation='<mar file>', remote='true')
```

For more information on MDS WLST commands, refer to the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference* on the Oracle Technology Network.

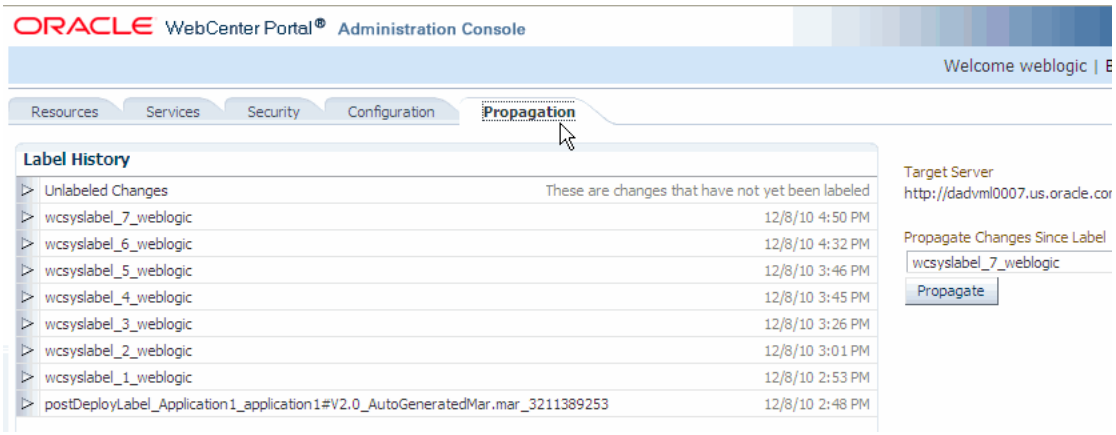
If you're running on the IntegratedWebLogicServer in a development environment, the connect URL is `t3://localhost:7101` and the server is `DefaultServer`.

10.13 Using the Propagation Tool to Propagate From Staging to Production

The WebCenter Portal Administration Console includes a propagation tool for moving portal metadata from a staging to a production server. Site administrators use this tool occasionally to push approved site structure changes to the production server without incurring any downtime.

> **Note:** The Propagation tool supports propagating portal metadata and Personalization for WebCenter Portal files. For more information, see Section 10.13.4, "Propagating WCPS Files."

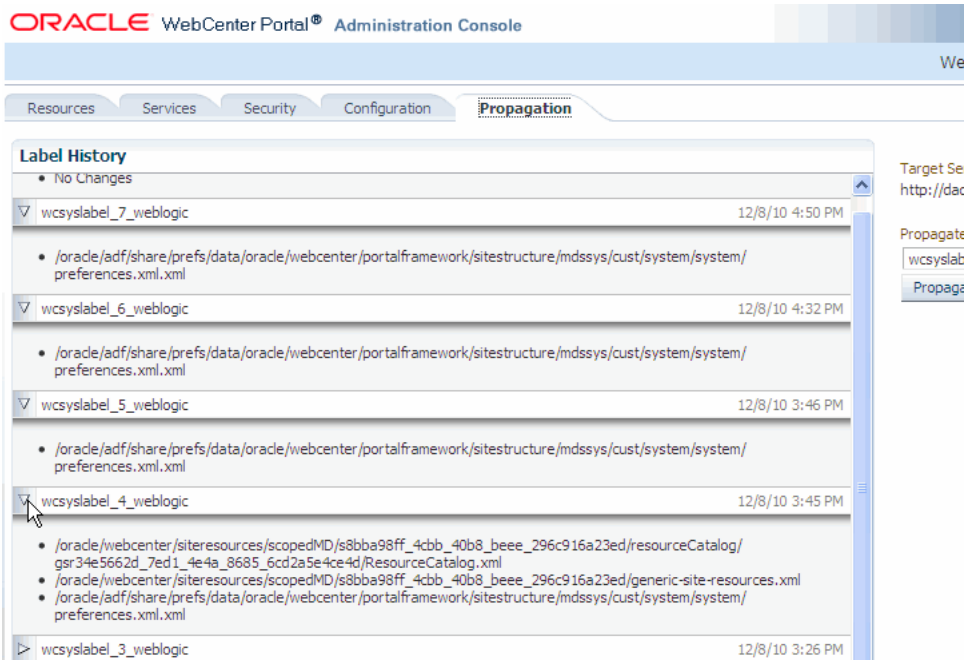
> **Note:** WebCenter provides WLST commands for importing and exporting portlet preferences. Use these commands to replicate portlet preference data between the stage and production servers. For more information, see Section 10.16, "Migrating Portlet Preferences."



- Section 10.13.1, "Introduction to the Propagation Tool"
- Section 10.13.2, "Configuring the Propagation Tool"
- Section 10.13.3, "Propagating Portal Metadata"
- Section 10.13.4, "Propagating WCPS Files"

10.13.1 Introduction to the Propagation Tool

WebCenter provides a propagation tool to move a portal metadata from staging to production. In practice, the staging environment and the production remain identical until changes are made to the staged portal. When the changes are tested and approved, an administrator uses the propagation tool to "push" the changes to the production server. This transfer does not require the production server to be restarted.



When properly configured, the Propagation tool shows up as a tab in the WebCenter Portal Administration Console, as shown in Figure 10–4.

Figure 10–4 The Propagation Tab

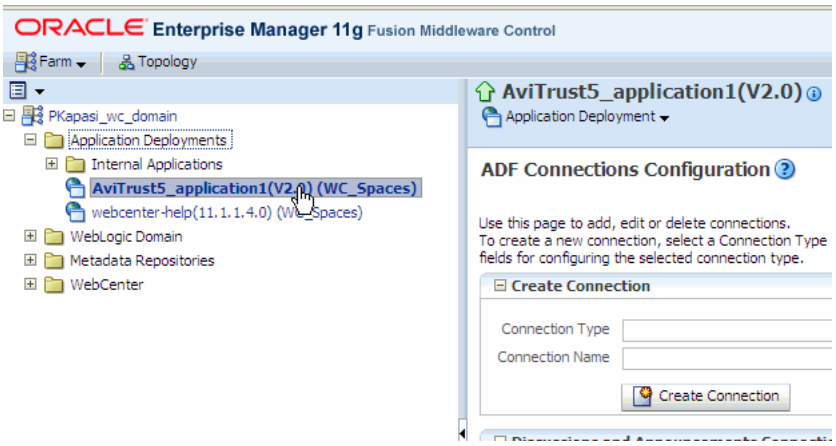
The Label History part of the Propagation tab lists the labels that were created for each propagation, labels created outside of the Propagation tab, such as labels created during deployment and labels created using WLST. Each label includes a list of files that change since the last propagation was performed. To view the contents of a label, click the arrow button to the left of the label name, as shown in Figure 10–5.

Figure 10–5 The Propagation Tab with Labels Opened

10.13.2 Configuring the Propagation Tool

> **Note:** If you are using the Propagation tool and if any of the MDS document file names contain multi-byte NLS characters, the stage machine should be configured for that NLS.

The Propagation tab only shows up in the WebCenter Portal Administration Console if the portal deployed to the staging server has a URL Connection configured. This URL connection must point to the production server and it must be named `ProductionURLConnection`.



You have two choices for configuring the URL Connection: you can use the Fusion Middleware Control Console or Oracle WebLogic Scripting Tool (WLST). This section explains both techniques.

10.13.2.1 Configuring the URL Connection With Oracle Enterprise Manager Fusion Middleware Control Console

To configure the URL Connection with the Fusion Middleware Control Console:

1. In a browser, open the Fusion Middleware Control Console for your staging server domain. For details on starting the Fusion Middleware Control Console see *Oracle Enterprise Manager Administrator's Guide*.
2. In the navigation tree, open the Application Deployments folder and click on the application. See Figure 10–6.
3. In the application pane on the right, open the **Application Deployment** menu, then select **Configure ADF Connections** from the **ADF** submenu. The ADF Connections Configuration panel opens, as shown in Figure 10–6.

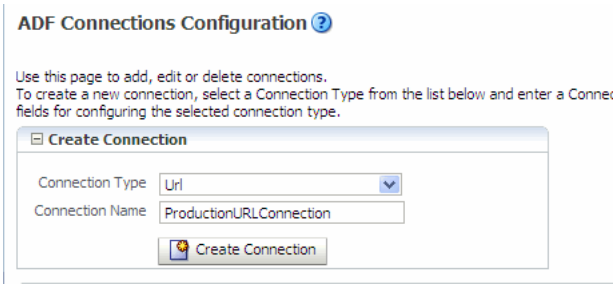


Figure 10–6 Selecting the Application in the Fusion Middleware Control Console

4. In the Create Connection box, select the URL connection type and enter `ProductionURLConnection` as the Connection Name. See Figure 10–7.

> **Note:** You must name the connection `ProductionURLConnection`. The name is case sensitive.

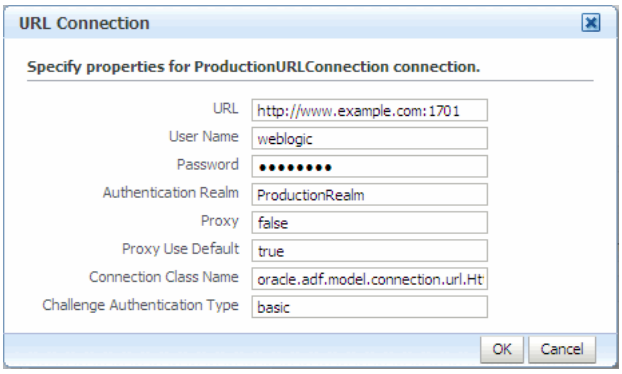

Figure 10–7 Create Connection

5. In the URL Connections box, click **Edit**.
6. Complete the URL Connection dialog box as follows.
   - **URL** – Enter the URL (including hostname and port number) of the production server.
   - **Username** – Enter a username for the connection.
   - **Password** – Enter a password for the connection.
   - **Authentication Realm** – You must enter a value for the Authentication Realm. Do not leave this field blank. You can enter any arbitrary string, such as `ProductionRealm`.

     You can accept the default values for the remaining fields. See Figure 10–8.

Figure 10–8 URL Connection Dialog

7. Click **OK** after you complete the URL Connection dialog.
8. Click **Apply** in the upper-right corner of the Fusion Middleware Control Console window.

10.13.2.2 Configuring the URL Connection with WLST

You can use a Oracle WebLogic Scripting Tool (WLST) command to create the URL Connection. Note that the parameters to the command are equivalent to the values entered in the URL Connection dialog in the Fusion Middleware Control Console, described in the previous section, Section 10.13.2.1, "Configuring the URL Connection With Oracle Enterprise Manager Fusion Middleware Control Console."

The following is an example of the WLST command with sample values specified for each parameter. Replace these values with values that pertain to your production server:

```
adf_createHttpURLConnection(appName='portalApp', name='ProductionURLConnection',
url='http://production_adminserver_host:7001', user='weblogic',
password='password_for_weblogic', realm='ProductionRealm'
```

For information on WLST, see the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference* on the Oracle Technology Network.

10.13.3 Propagating Portal Metadata

Use the propagation tool when you want to move changes made on the staging portal to the production portal.

1. Be sure the propagation tool is configured, as described in Section 10.13.2, "Configuring the Propagation Tool." To use the propagation tool, you must have Administrator's privileges.
2. Open the WebCenter Portal Administration Console. By default, the administration console is located at this URL:

   `http://<server>:<port>/<context_root>/admin`

For more information on using the WebCenter Portal Administration Console, see "Using the WebCenter Portal Administration Console" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

3. Select the Propagation tab.

> **Note:** If you don't see the Propagation tab it could be because you don't have administrator's privileges or the propagation tool was not configured properly as explained in Section 10.13.2, "Configuring the Propagation Tool."

4. Click **Propagate** to transfer the files to the production server.

10.13.4 Propagating WCPS Files

The propagation tool supports moving Personalization for WebCenter Portal files from staging to production. The propagation tool automatically exports metadata from the application's MDS repository on the source server, then imports the metadata to the application's MDS repository on the target server.

The ability for the propagation tool to move WCPS files depends on the following conditions:

- The Framework application's MDS repository must point to the same database as the `mds-wcpsDS` datasource. This is the default configuration. See, for example, Figure 10–2 for a general illustration. In general, propagation will work correctly if you do not change the default database configuration.
- On both the source and destination servers, the application's MDS store must use the same partition name as the MDS store for `wcps-services`. In a standard portal configuration, this partition is `webcenter-portal`.

Note: Typically, there is a one to two minute delay between when the propagation tool is initialized and when the WCPS REST services are notified of the MDS changes. This delay does not occur when you use the WLST commands to propagate WCPS files, as explained in Section 10.12.4, "Importing and Exporting MAR Files."

10.14 Propagating Content From Oracle WebCenter Content

Oracle recommends that you use either manual or automated replication to move content from one environment to another. Another option is to manually propagate content; however, this option is only recommended if the source and target servers are unable to communicate with each other.

For detailed information on the tools and options for propagating Oracle WebCenter Content content, see "Managing System Migration and Archiving" in the *Oracle WebCenter Content System Administrator's Guide for Content Server*. That chapter explains how to propagate Oracle WebCenter Content content by exporting and importing archive files. In addition, the chapter explains how to set up and use replication. Replication can automate the export, import, and transfer functions. For example, you can use replication to automatically export from one content server instance, transfer the archive to another computer, and import to another content server instance.

10.15 Managing Security Through the Life Cycle

This section discusses techniques for migrating security policies and credentials from one environment to another. Migration can be either automatic or manual. Automatic migration is typically used when the application is first deployed. Manual migration is used on redeployment.

10.15.1 Migrating Security Policies for First-Time Deployment

When `jazn-data.xml` with application policies is packaged in the EAR file, Oracle Platform Security Services (OPSS) performs policy migration based on the application configuration settings in `weblogic-application.xml`. Example 10–4 shows the recommended settings in `weblogic-application.xml` to achieve automatic policy migration for first-time deployment.

Example 10–4 Settings for Automatic Policy Migration (weblogic-application.xml)

```
<wls:application-param>
    <wls:param-name>jps.policystore.migration</wls:param-name>
    <wls:param-value>MERGE</wls:param-value>
</wls:application-param>

<wls:application-param>
    <wls:param-name>jps.policystore.removal</wls:param-name>
    <wls:param-value>OFF</wls:param-value>
</wls:application-param>

<wls:listener>

<wls:listener-class>oracle.security.jps.wls.listeners.JpsApplicationLifecycleListe
ner</wls:listener-class>
</wls:listener>
```

JpsApplicationLifecycleListener must be specified in `weblogic-application.xml` to enable policy and credential migration. Oracle recommends that `jps.policystore.migration` should be set to `MERGE`. With this configuration, polices packaged in `jazn-data.xml` will be always migrated during fist time deployment. Oracle also recommends that `jps.policystore.removal` should be set to `OFF` so that application policies are not deleted from the policy store when the application is undeployed.

10.15.2 Migrating Security Policies On Redeployment

On redeployment, it is important to avoid overwriting policy changes made on the production system. When `jps.policystore.migration` parameter is set to `MERGE`, all new policies from the stage environment will be merged with production policies. With this setting, any changes made to existing policies, such as changing permissions for a role, deleting a role, or removing membership of a role, will not be migrated during redeployment, because such migration would cause a conflict.

If you want to overwrite the production policies with the staging environment security policies packaged in `jazn-data.xml`, use the `migrateSecurityStore` WLST command. See *Oracle Fusion Middleware Application Security Guide* for details on `migrateSecurityStore` command.

10.15.3 Migrating Credentials for First-Time Deployment

Application credential migration support is similar to application policy migration. JpsApplicationLifecycleListener supports credential migration in application deployment and redeployment with extra security enforcements.

With application credentials in cwallet.sso and packaged in an EAR file in the `META-INF/` directory, OPSS will perform credential migration to system credential store based on the configuration settings in `weblogic-application.xml`.

Example 10–4 shows the recommended settings in `weblogic-application.xml` to achieve automatic credential migration for first-time deployment.

Example 10–5 Settings for Automatic Credential Migration (weblogic-application.xml)

```
<wls:application-param>
    <wls:param-name>jps.credstore.migration</wls:param-name>
    <wls:param-value> MERGE </wls:param-value>
</wls:application-param>
```

Oracle recommends that `jps.credstore.migration` should be set to `MERGE` so that at deployment and redeployment time all new credentials will be migrated. This setting will only migrate new credential key/value from `cwallet.sso`. Modification done to existing credential keys will not be migrated.

10.15.4 Migrating Credentials On Redeployment

If credentials are modified on stage and need to be moved to production, use the command `migrateSecurityStore` to migrate modified credentials. See *Oracle Fusion Middleware Application Security Guide* for details on `migrateSecurityStore` command.

10.16 Migrating Portlet Preferences

WebCenter provides WLST commands for importing and exporting portlet preferences. Exported preferences (customizations and personalizations) can be imported into a target application – for example, exported from the staging application and imported into the production application. For more information, see `exportPortletClientMetadata` and `importPortletClientMetadata` in "Oracle WebCenter Portal Custom WLST Commands" in the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference*. Also ensure that export and import are enabled. See Chapter 61, "Coding Portlets."

See also Chapter 62.3, "Deploying a Portlet Producer Application to an Oracle WebLogic Managed Server Instance."

10.17 Rolling Back Production Site Changes

In rare instances, it might be necessary to roll back changes that are pushed to the production server from staging. The propagation model described in this chapter assumes that you are making a small number of changes to the staging instance and then pushing them to production using the propagation tool. If you ever need to roll back those changes, Oracle recommends that you manually undo the changes on the staging instance and push the modified staging instance back to production, after adequate validation and testing. By this process, you will have "rolled back" the original changes and the production system will be reverted to its original state.

11

Building a Navigation Model for Your Portal

This chapter describes how to create the navigation model in your WebCenter Portal: Framework application. Navigation models define the content, structure, and metadata of your portal navigation.

This chapter includes the following sections:

- Section 11.1, "Introduction to Navigation Models"
- Section 11.2, "Creating a Navigation Model"
- Section 11.3, "Adding Resources to a Navigation Model"
- Section 11.4, "Selecting the Default Navigation Model"
- Section 11.5, "Editing the Navigation Renderer"
- Section 11.6, "Setting the REDIRECT_OPTIONS Context Parameter"
- Section 11.7, "Enabling Runtime Administration of Navigation Models"
- Section 11.8, "Working with WebCenter Portal: Spaces Navigation Models"

For information about how to expose the navigation model in your portal, see Chapter 14, "Visualizing Your Portal Navigation."

11.1 Introduction to Navigation Models

Typically, portals provide information from various different sources. Information may be provided by pages, portlets, task flows, content repositories, and external pages. Users need a way to easily move through this information and quickly access the specific information that they need. You provide this access to information through your portal navigation.

The *navigation model* defines the content, structure, and metadata of the navigation. When you create the navigation model, you specify the items to include and the hierarchy of those items. Navigation models can include the following resources:

- Pages (individual pages and page hierarchies)
- Content (individual content items or the results of a content query)
- Other navigation models
- Portlets
- Task flows
- External applications
- External links

For more information, see Section 11.3, "Adding Resources to a Navigation Model."

You can also add resources that are dynamically generated. These are:

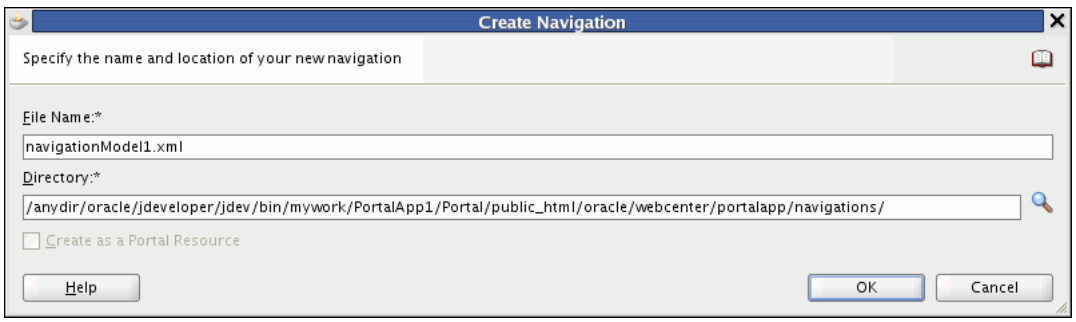
- Custom Resources
- Components
- Custom Folders
- Custom Content

For more information, see Section 11.3.7, "How to Extend Navigation Model Data."

When you create a new Framework application, a navigation model is created for you (`default-navigation-model.xml`). You can build on this seeded navigation model or create your own. You might even want to create different navigation models for different user types.

> **Note:** If you create your own navigation model, rather than extend the seeded navigation model, we recommend that you set your navigation model as the default navigation model. For more information, see Section 11.4, "Selecting the Default Navigation Model."

After you have created your navigation model, you can expose it on any page template in your portal either through the built in navigation task flows, or through your own navigation UI. For more information, see Chapter 14, "Visualizing Your Portal Navigation."



11.2 Creating a Navigation Model

If the default navigation model provided out of the box does not meet your requirements, you can create your own navigation model.

To create a navigation model:

1. In the Application Navigator, right-click the node where you want to create the navigation model (for example `/oracle/webcenter/portalapp/navigations`) and choose **New**.
2. In the New Gallery, expand **Web Tier**, select **Portal** and then **Navigation**, and click **OK**.
3. In the Create Navigation dialog (Figure 11–1), in the **File Name** field, enter a name for the XML file that represents the navigation, for example `myNavigation.xml`.

Figure 11–1 The Create Navigation Dialog

4. In the **Directory** field, enter the full directory path of the location under which to create the file.

   Note: In a Framework application, to expose the new navigation model in the runtime Resource Manager, you must create the navigation model under the *Application_Root*`/Portal/public_html/oracle/webcenter/portalapp` directory. By default WebCenter Portal includes a separate `navigations` directory.

5. Select **Create as a Portal Resource** to add the navigation model to the resources registry, allowing it to be managed at runtime through the Resources Manager.

   Note: This option is available only if the directory you entered is the *Application_Root*`/Portal/public_html/oracle/webcenter/portalapp` directory or one of its subdirectories.

   Tip: If you do not select this option now, you can add the navigation model to the resources registry later by right clicking it and choosing **Create Portal Resource**.

6. Click **OK**.

   The new navigation model opens in Design view (Figure 11–2).

Figure 11–2 A Navigation Model in Design View

7. In the Design view for the navigation model, select the new navigation model in the Navigation column and define general properties as required:

- In the **Navigation Filter** field, enter the name of a Java class to use to filter out selected resources in the navigation model based on specific criteria. The Java class should implement the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface.

  Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed when the navigation model is rendered on a page.

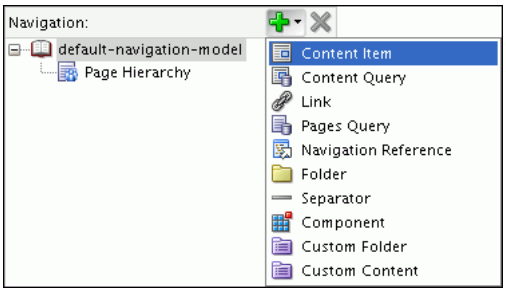
  Note: You can also conditionally hide individual resources in the model by specifying an EL expression in the **Visible** field for the resource.

- In the **Visible** field, specify whether the navigation model is available for use in the application. This field takes an EL value. The default is `#{true}`, which means the navigation model can be used by other users and is available in dropdown lists of navigation models.
- Use the Navigation Attributes section to set display options for the navigation model as desired. The options available are the same as those for individual resources. For more details about the different display options, see Section 11.3.9, "How to Set Display Options for a Resource.".

8. Save the navigation model definition file.

   Now that you have created the navigation, you can add resources to it. For more information, see Section 11.3, "Adding Resources to a Navigation Model."

11.3 Adding Resources to a Navigation Model



To define the content of your navigation model you can add resources to the default navigation model, `default-navigation-model.xml`. The default navigation model is created automatically when you create an application using WebCenter Portal's Framework application template.

You can also create your own custom navigation model and add resources to that. For more information, see Section 11.2, "Creating a Navigation Model."

You can add resources to a navigation model in two ways:

- Drag and drop resources from different areas in JDeveloper onto the navigation model in Design view.
- Use the options on the **Add new node** menu in the Design view for the navigation model (Figure 11–3).

Figure 11–3 The Add New Node Menu

In the Design view for the navigation model you can also modify and remove existing resources.

This section includes the following subsections:

- Section 11.3.1, "How to Drag and Drop a Resource onto a Navigation Model"
- Section 11.3.2, "How to Add a Content Item to a Navigation Model"
- Section 11.3.3, "How to Add Content Based on the Results of a Query to a Navigation Model"
- Section 11.3.4, "How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model"
- Section 11.3.5, "How to Add a Page Hierarchy to a Navigation Model"
- Section 11.3.6, "How to Embed Another Navigation Model Within a Navigation Model"
- Section 11.3.7, "How to Extend Navigation Model Data"
- Section 11.3.8, "How to Organize Resources in a Navigation Model"
- Section 11.3.9, "How to Set Display Options for a Resource"

11.3.1 How to Drag and Drop a Resource onto a Navigation Model

You can add the following resources to a navigation model by dragging and dropping them onto the desired location in the Design view for navigation model:

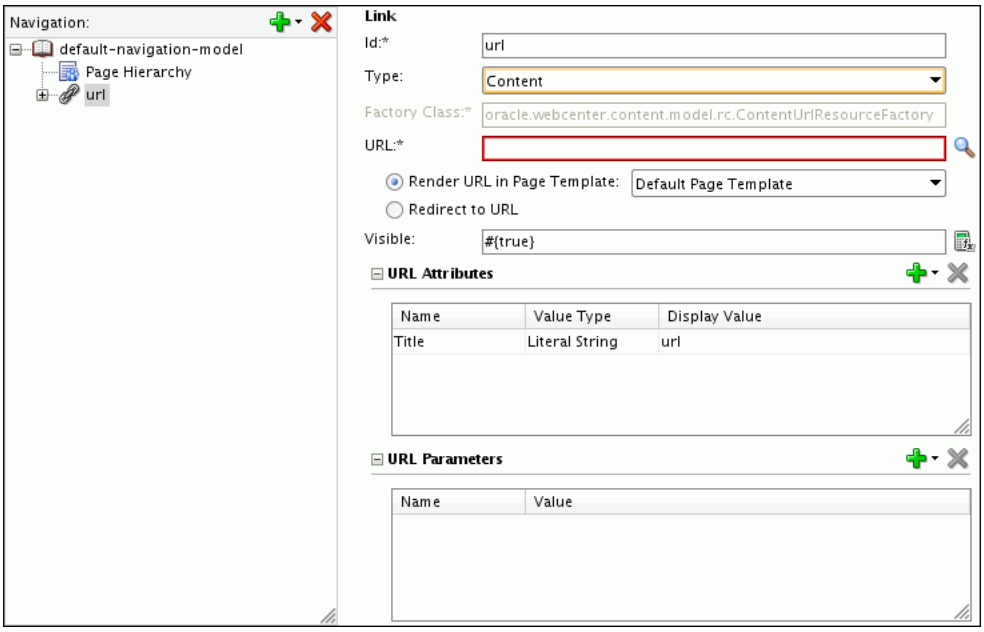
- **Content**—You can drag a content item from an Content Server connection in the Application Resources pane or Resource Palette onto a navigation model.
- **Pages**—When you drag a page from the Application Navigator onto a navigation model, you are prompted to choose whether to add just the page itself or to add a page query that includes the page its subpages.
- **Portlets**—You can drag a portlet from the Application Resources pane or Resource Palette onto a navigation model.
- **Task flows**—You can drag a task flow from the Application Resources pane or from the Resource Palette onto a navigation model.
- **External applications**—You can drag an external application from the Application Resources pane or Resource Palette onto a navigation model.
- **URLs**—You can drag a URL connection from the Application Resources pane or Resource Palette onto a navigation model.
- **Navigation models**—You can drag a navigation model from the Application Navigator and embed it in another navigation model.

11.3.2 How to Add a Content Item to a Navigation Model

In your navigation model, you can include links to individual content items within an existing content repository connection, or you can include a folder to provide access to all its contents.

You can also include a set of documents that match particular query criteria to a navigation model. For more information, see Section 11.3.3, "How to Add Content Based on the Results of a Query to a Navigation Model."

To add a content item:



Tip: To add a content item to a navigation model you can also drag and drop it into the Design view for the navigation model.

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Content Item**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–4 Adding a Content Item to a Navigation Model

5. In the **URL** field, enter or browse for the URL to access the resource. If you enter the URL manually, use the following format:

   `content://Content_Connection_Id/Document_Id`

   Note: If the following is true, you must make sure that an appropriate connection is added to the application (in the Application Resources pane) to ensure that the resource is available at runtime:

   - You manually entered the URL
   - The connection exists in the Resource Palette

6. Select **Render URL in Page Template**, to render the resource in the current page, using the specified page template.

   Select **Redirect to URL**, to overwrite the current page with the resource when it is selected in the navigation.

7. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed when the navigation model is rendered on the page.

8. In the URL Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

9. If you want to use a Content Presenter display template to display the content item, in the URL Parameters section, click the **Add** icon, and choose **templateView**.

10. In the **Value** field for the **templateView** parameter, enter the display template view ID to use for rendering the content item, for example:

    ```
    oracle.webcenter.content.templates.default.detail
    ```

    Note: If you display a wiki page in a Framework application using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 32.3.5, "Displaying Wiki Page Links Within Content Presenter."

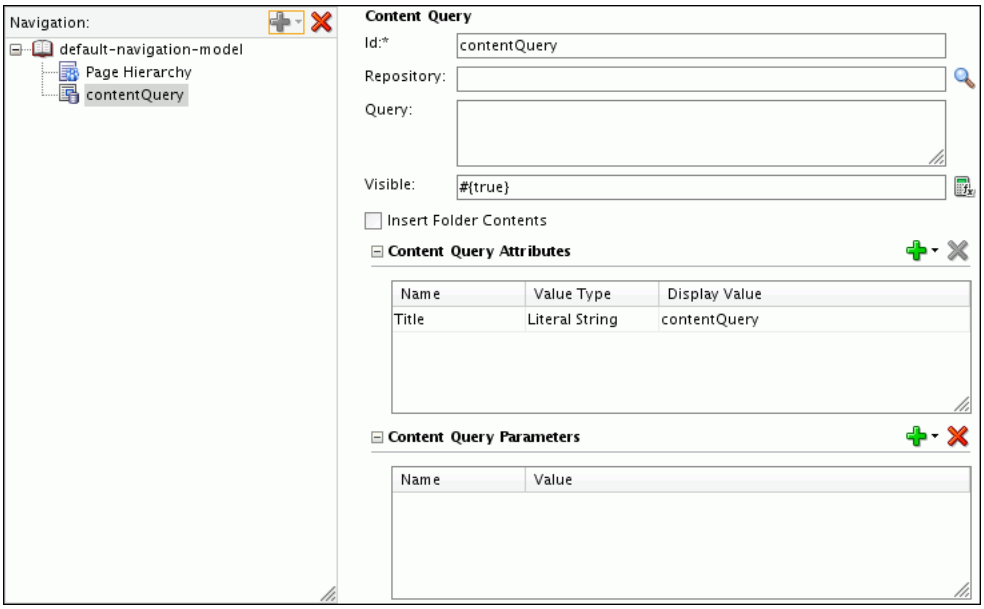
11. Add further parameters, as required. For information about additional Content Presenter parameters, see Section 31.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates."

12. Save the navigation model definition file.

11.3.3 How to Add Content Based on the Results of a Query to a Navigation Model

You can add a content query to a navigation model to include all documents that match specific search criteria.

Note: To add a single file, or all the files within a particular folder, to a navigation model, see Section 11.3.4, "How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model."



To add a content query:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Content Query**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–5 Adding a Content Query to a Navigation Model

5. In the **Repository** field, enter or browse for the content repository whose content you want to search.

   Note: If the following is true, you must make sure that the appropriate connection is added to the application (in the Application Resources pane) to ensure that the resource is available at runtime:

   - You manually entered the repository name
   - The connection exists in the Resource Palette

6. In the **Query** field, enter the query criteria to identify the content to include in the navigation model, for example:

```
select * from cmis:document WHERE cmis:name LIKE 'Foo%'
```

For more information about how to format the query and for more examples, see *Oracle Fusion Middleware Content Management REST Service Developer's Guide*.

7. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

8. Select **Insert Folder Contents** to display the results of the query directly in the navigation, rather than displaying them under a folder.
9. In the Content Query Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."
10. If you want to use a Content Presenter display template to display the results of the content query, in the URL Parameters section, click the **Add** icon, and choose **templateView**.
11. In the **Value** field for the **templateView** parameter, enter the display template view ID to use for rendering the results of the content query, for example:

    ```
    oracle.webcenter.content.templates.default.list.simple
    ```

    Note: If you display a wiki page using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 32.3.5, "Displaying Wiki Page Links Within Content Presenter."

12. Add further parameters, as required. For information about additional Content Presenter parameters, see Section 31.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates."

    Note: If you include links to the same portlet twice in a navigation model, the first link specifying parameter values and the second not, any parameters set for the first link are retained and also used for the second. To ensure that parameters are not used for the second link, you must explicitly set the parameter values to null.

13. Save the navigation model definition file.

11.3.4 How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model

You can add links to the following types of resources to a navigation model:

- **External Link:** Hypertext link to any external web page.

  Note: If you use the External Link option to include a `mailto:` link in your navigation, your navigation UI must explicitly handle this type of link. For information, see Section 12.2.3, "What You Should Know About Creating Page Templates for WebCenter Portal Applications."

- **External Application:** Link to any registered external application.
- **Page:** Link to any JSPX page in the application.

  This option enables you to add a link to a single page to the navigation model. For information about how to include an entire page hierarchy, see Section 11.3.5, "How to Add a Page Hierarchy to a Navigation Model."

- **Task Flow:** Link to any task flow in the application, or to a WebCenter Portal task flow (available in the Resource Palette).

  Note: If you provide navigation directly to a task flow in this way, users cannot customize the task flow. If you want users to be able to customize the task flow, add it to a page and add that page to the navigation model.

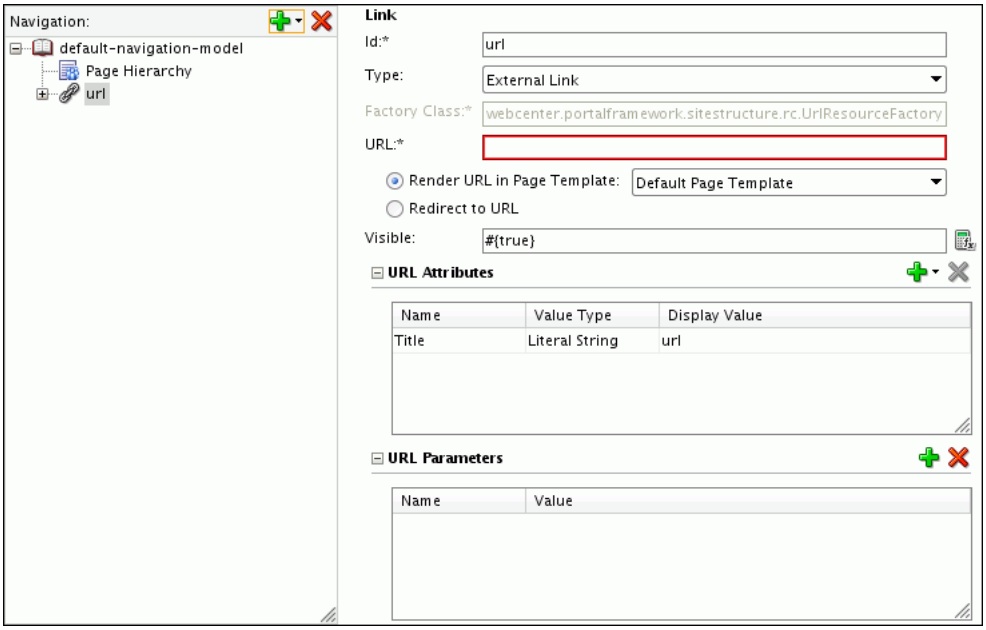
- **Portlet:** Link to a portlet in any registered portlet producer.

  Note: If you provide navigation directly to a portlet in this way, users cannot customize the portlet. If you want users to be able to customize the portlet, add it to a page and add that page to the navigation model.

- **Other:** Link to a custom resource. For more information, see Section 11.3.7.1, "How to Add a Link to a Custom Resource."

To add a link to a page, portlet, task flow, external application, or web page:

Tip: To add a portlet, task flow, external application, or web page to a navigation model you can also drag and drop it into the Design view for the navigation model.



To add a link to a single page, drag the page into the Design view for the navigation model and choose **Page Link** from the popup menu.

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Link**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

> **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–6 Adding a Link to a Navigation Model

5. From the **Type** dropdown list, select the type of resource that you want to add to the navigation model: **External Link**, **External Application**, **Page**, **Taskflow**, **Portlet**.
6. The **Factory Class** field is automatically populated with the appropriate factory class for the resource type and cannot be edited.

> **Note:** If you are adding a resource of type **Other**, the **Factory Class** field is editable and you must enter the factory class of the resource. For more information, see Section 11.3.7.1, "How to Add a Link to a Custom Resource."

7. In the **URL** field, enter or browse for the URL to access the resource. Table 11–1 provides the URL format to use for the different resource types.

Table 11–1 Format for URL Different Resource Types

Resource Type	Location in Application	URL Format
External Link	None	Absolute or relative path to web page **Note:** If you use the External Link option to include a `mailto:` link in your navigation, your navigation UI must explicitly handle this type of link. For information, see Section 12.2.3, "What You Should Know About Creating Page Templates for WebCenter Portal Applications."
External Application	External application connection in the Application Resources pane	`extapp://External_Application_Id`

Page	Application Navigator	`page://Path_to_Page/Page_Name`
		For example:
		`page://oracle/webcenter/portalapp/pages/myPage.jspx`

Task Flow from an ADF Library	Resource Palette	`taskflow://Path_to_TaskFlow/TaskFlow_Definition_File_Name#TaskFlow_Id`
Task Flow Within the Application	Application Navigator	`taskflow://Path_to_TaskFlow/TaskFlow_Definition_File_Name#TaskFlow_Id`
Portlet	Portlet producer connection in the Application Resources pane or in the Resource Palette	`portlet://Producer_Id/Portlet_Id`

Note: If the following is true, you must make sure that an appropriate connection is added to the application (in the Application Resources pane) to ensure that the resource is available at runtime:

- You manually entered the URL (without using drag and drop or the Choose a Resource dialog)
- The link **Type** is **External Application**, or **Portlet**
- The connection exists in the Resource Palette

8. Select **Render URL in Page Template**, to render the resource in the current page, using the specified page template.

   Select **Redirect to URL**, to overwrite the current page with the resource when it is selected in the navigation.

9. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed when the navigation model is rendered on the page.

10. In the URL Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."
11. In the URL Parameters section, enter values, as desired, for any parameters supported by the selected resource.
12. Save the navigation model definition file.

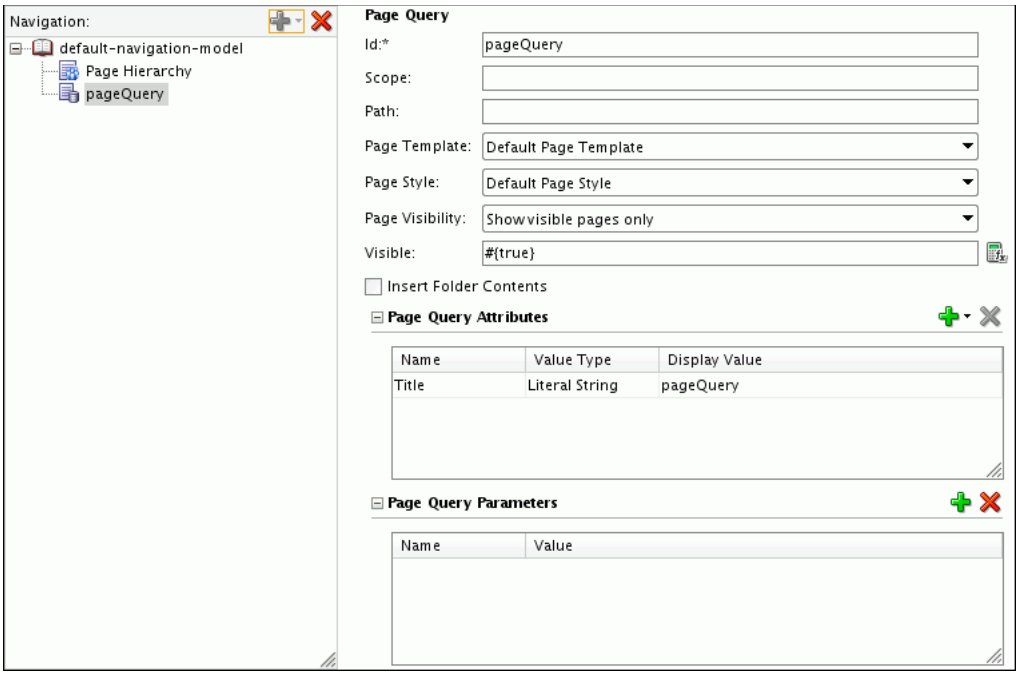
11.3.5 How to Add a Page Hierarchy to a Navigation Model

You can add a hierarchy of pages to the navigation model. All pages below the selected page in the hierarchy are included in the navigation model.

Although there is only a single page hierarchy within an application, in a navigation model you can use any node within the application page hierarchy as the starting point.

> **Note:** If you just want to include a single page in the navigation model, use the Link navigation type. For more information, see Section 11.3.4, "How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model."

To add a page hierarchy:



> **Tip:** To add a section of the page hierarchy to a navigation model, you can drag and drop a page (which has been added to the page hierarchy) from the Application Navigator into the Design view for the navigation model. Choose **Page Query** from the popup menu that appears.

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Page Query**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   > **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–7 Adding a Page Query to a Navigation Model

5. The **Scope** field is not applicable to Framework applications (the scope is always the current application), so you can leave this field empty.

   Scope is used in WebCenter Portal: Spaces to determine whether to display all the pages in the Home space or a specific space if a particular page is not specified as the root of the page query.

6. In the **Path** field, enter the path and file name of the XML file that corresponds to the page within the page hierarchy that you want to use as the starting point of the page query. For example:

   ```
   /oracle/webcenter/portalapp/pagehierarchy/pages/pages.xml
   /oracle/webcenter/portalapp/pagehierarchy/pages/productsPages.xml
   ```

7. From the **Page Template** dropdown list, select the page template to use to display the resource when it is selected in the navigation.

8. From the **Page Style** dropdown list, select the style of page to include in the navigation model. For example, if you select **Wiki**, only pages that use the Wiki page style are included in the navigation..

9. From the **Page Visibility** dropdown list, select whether to include pages even if they have been flagged as hidden in the hierarchy.

10. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

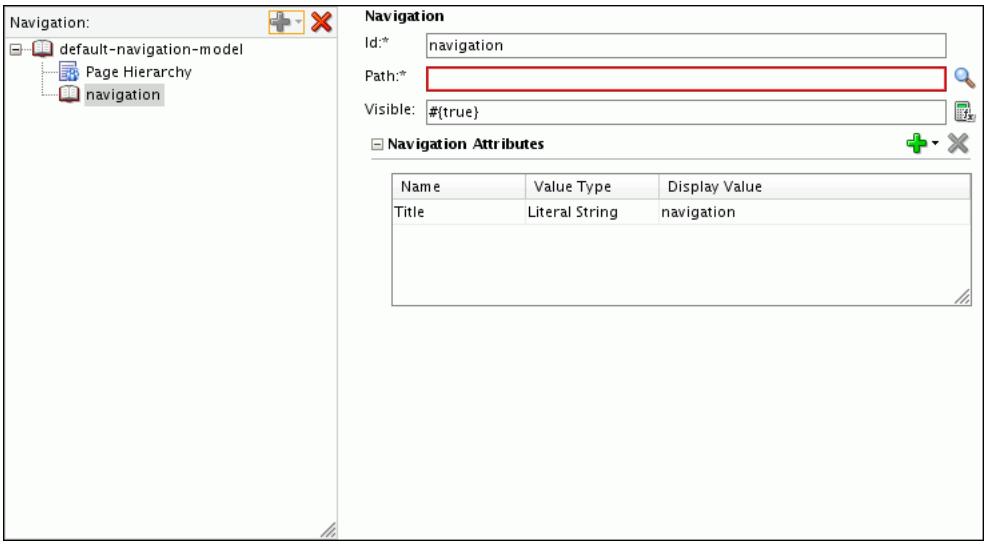
> **Note:** Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

11. Select **Insert Folder Contents** to display the subpages in the hierarchy directly in the navigation rather than displaying them under a folder for the parent page.
12. In the Page Query Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."
13. In the Page Query Parameters section, enter values, as desired, for any parameters supported by the page template.
14. Save the navigation model definition file.

11.3.6 How to Embed Another Navigation Model Within a Navigation Model

You can nest navigation models within each other. For example, if you have a complex navigation model, it might be easier to break it down into several separate models and then nest them all within a single overarching navigation model. You can also use nested navigation models to delegate the development of navigation models to different users or to control access to different parts of the navigation.

To embed another navigation model within a navigation model:



> **Tip:** To embed another navigation model within a navigation model you can also drag and drop the navigation model that you want to embed from the Application Navigator into the Design view for the navigation model.

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Navigation**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   > **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–8 Embedding Another Navigation Model Within a Navigation Model

5. In the **Path** field, enter or browse for the location and file name of the navigation model definition file for the navigation model that you want to embed, for example:

   `/oracle/webcenter/portalapp/navigations/myNavigation2.xml`

6. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

7. In the Navigation Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

8. Save the navigation model definition file.

11.3.7 How to Extend Navigation Model Data

As well as adding known resources to your navigation model, you can also add resources to the model that are dynamically generated at runtime.

This section includes the following subsections:

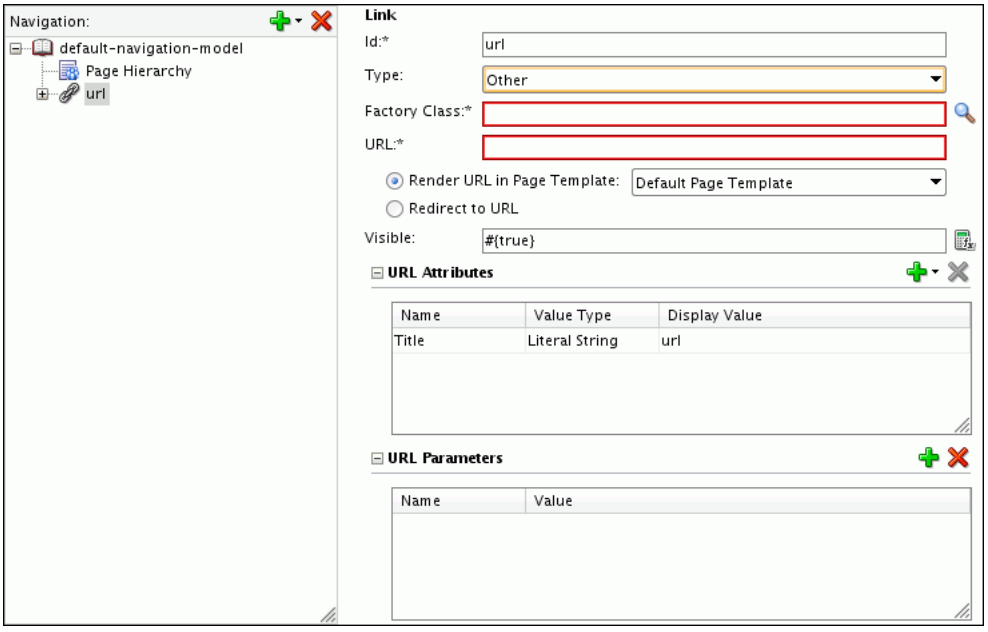
- Section 11.3.7.1, "How to Add a Link to a Custom Resource"
- Section 11.3.7.2, "How to Add a Component to a Navigation Model"
- Section 11.3.7.3, "How to Add a Custom Folder to a Navigation Model"
- Section 11.3.7.4, "How to Add a Custom Content Provider to a Navigation Model"

11.3.7.1 How to Add a Link to a Custom Resource

You can add links to various WebCenter Portal-supported resources, such as pages, portlets, and task flows, by adding a link of the appropriate Type and identifying the URL of the resource. For more information, see Section 11.3.4, "How to Add a Page, Portlet, Task Flow, External Application, or Web Page to a Navigation Model."

If you want to link to a third party resource, you can do so by adding a link of type Other, and specifying the third-party `URLResourceFactory` implementation class.

To add a link to a custom resource:



1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Link**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   > **Tip:** If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

5. From the **Type** dropdown list, select **Other**.

Figure 11–9 Adding a Custom Resource to a Navigation Model

6. In the **Factory Class** field, enter or browse for the `URLResourceFactory` implementation class that can resolve the URL for the custom resource.
7. In the **URL** field, enter the URL to access the resource.

8. Select **Render URL in Page Template**, to render the resource in the current page, using the specified page template.

   Select **Redirect to URL**, to overwrite the current page with the resource when it is selected in the navigation.

9. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

10. In the URL Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

11. In the URL Parameters section, enter values, as desired, for any parameters supported by the selected resource.

12. Save the navigation model definition file.

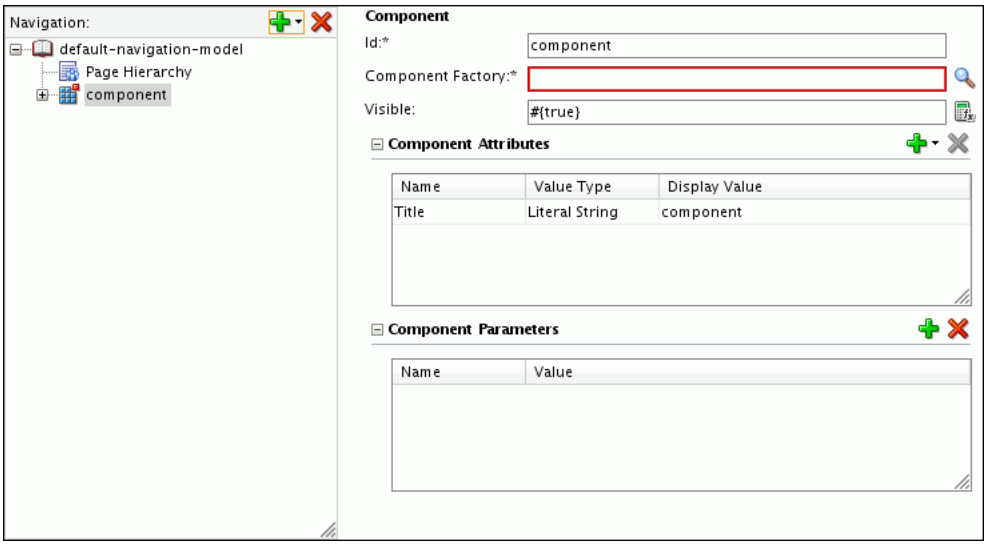
11.3.7.2 How to Add a Component to a Navigation Model

You can add a custom component to a navigation model. You can add a variety of components, such as simple ADF Faces components, compound objects containing two or more components, and JSF Verbatim tags that let you add arbitrary HTML content inside them. An example for arbitrary HTML that you can add to your catalog is a YouTube video.

To add a custom component:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.

2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.



3. Click the **Add new node** icon and choose **Component**.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–10 Adding a Custom Component to a Navigation Model

5. In the **Component Factory** field, enter or browse for the Java class that implements the `oracle.adf.rc.component.ComponentFactory` interface and creates an instance of the component based on a set of parameters, for example, `oracle.adf.rc.component.XmlComponentFactory`.

   As you type the name, the field autocompletes with valid factory classes from the classpath.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

6. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

7. In the Component Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

8. In the Component Parameters section, add the parameters that define the component.

   For example, if you are adding an XML component, click the **Add** icon in the Parameters section and select **xml**. In the new row that is displayed, specify the XML code for the component in the **Value** field.

   Note: The **xml** parameter is displayed only if you selected `oracle.adf.rc.component.XmlComponentFactory` as the component factory.

To ensure that the component works properly, you must specify the custom component ID to be #, and provide the namespace, as shown in the following example:

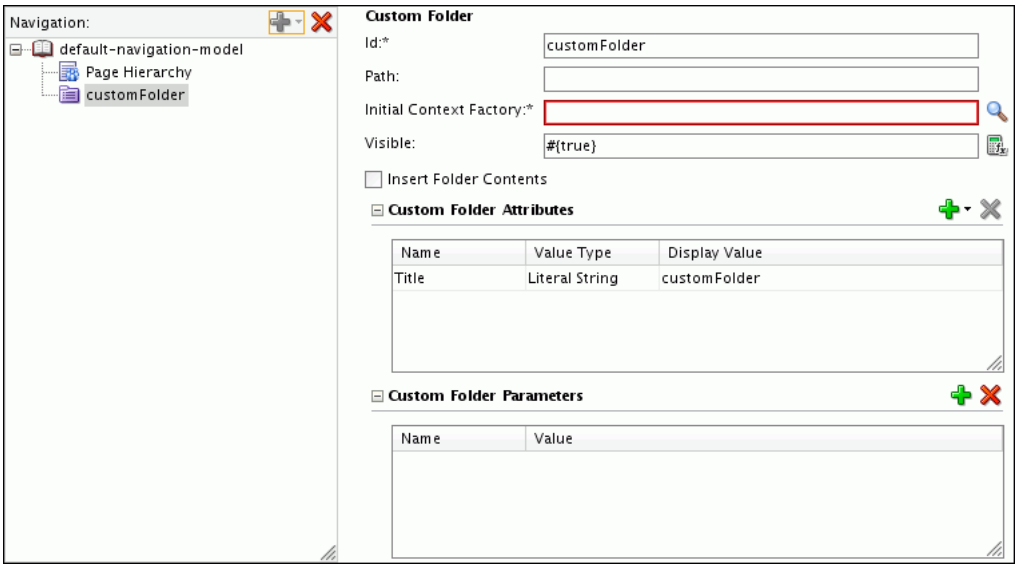
```
<cust:panelCustomizable id="#"
xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"/>
```

The # value ensures that a unique ID is generated dynamically for the component.

9. Save the navigation model definition file.

11.3.7.3 How to Add a Custom Folder to a Navigation Model

You can add a custom folder to a navigation model that is configured to display its content dynamically at runtime. A custom folder is not added as a folder with resources; it contains only a reference to the factory class, which displays the resources dynamically.



To add a custom folder:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.
2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.
3. Click the **Add new node** icon and choose **Custom Folder**.
4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–11 Adding a Custom Folder to a Navigation Model

5. In the **Path** field, enter the MDS path for the custom folder.

6. In the **Initial Context Factory** field, enter or browse for the Java class that implements the `javax.naming.spi.InitialContextFactory` interface and generates the folder based on a set of parameters.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

7. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

8. Select **Insert Folder Contents** to display the contents of the custom folder directly in the navigation rather than displaying them under the folder.

9. In the Custom Folder Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

10. In the Custom Folder Parameters section, add the parameters that were defined while implementing the factory class. You can bind these parameters to other artifacts in the application.

11. Save the navigation model definition file.

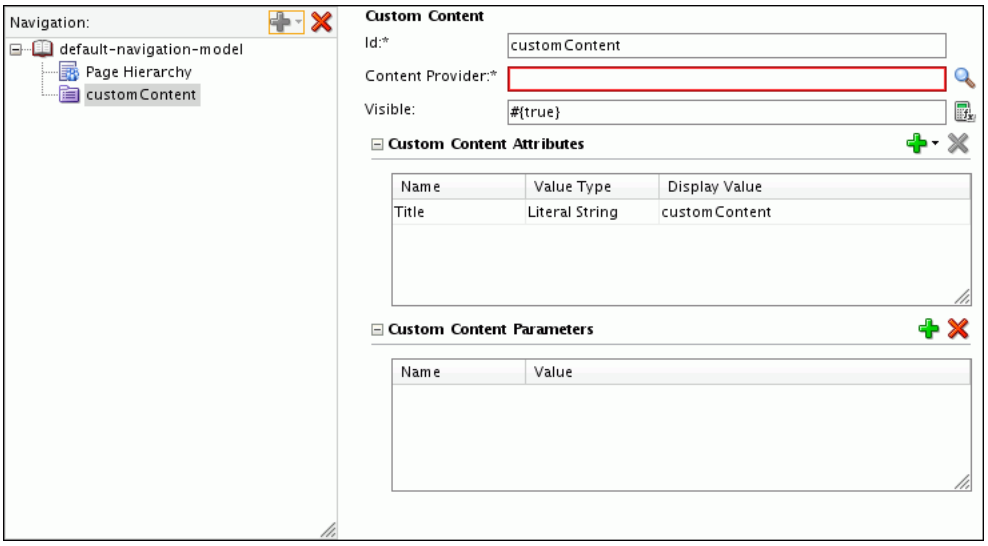
11.3.7.4 How to Add a Custom Content Provider to a Navigation Model

A custom content provider dynamically generates zero or more navigation items at runtime. It is very similar to a custom folder, except that, for custom folders, the folder is always displayed when the navigation model is rendered at runtime, even if it is empty. With custom content providers however, the folder is displayed at runtime only if it has content inside it.

To add custom content provider:

1. In the Application Navigator, right-click the navigation model to which you want to add the resource, and choose **Open**.

2. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the resource.



3. Click the **Add new node** icon and choose **Custom Content**.

4. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

   If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

   Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

Figure 11–12 Adding a Custom Content Provider to a Navigation Model

5. In the **Content Provider** field, enter or browse for the Java class that implements the `oracle.adf.rc.spi.plugin.catalog.CustomContentProviderV2` interface.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

6. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.

   Note: Resources are automatically filtered based on security. If a user does not have access to a particular resource, it is not displayed in the navigation when it is rendered on the page.

7. In the Custom Content Attributes section, specify any desired display options for the resource. For more information, see Section 11.3.9, "How to Set Display Options for a Resource."

   Note: Typically for custom content, you will not need to specify any attributes, because the attributes for the resources generated by the content provider will be specified by the content provider.

8. In the Custom Content Parameters section, define the parameters on the folder. The parameters you define here are passed to and interpreted by the `CustomContentProviderV2` implementation.

9. Save the navigation model definition file.

11.3.8 How to Organize Resources in a Navigation Model

You can add folders to your navigation model to create subsets of resources or to group similar resources. You can also add separators to divide the navigation model into distinct groupings of resources. Folders and separators enable you to break up the items in the navigation model when it is rendered on in a page, making it easier to locate items.

You can also rearrange items within the navigation model by dragging them up and down in relation to each other and dragging them inside other items to indicate hierarchy.

To organize resources:

1. In the Application Navigator, right-click the navigation model whose resources you want to organize, and choose **Open**.
2. To add a folder or separator:
   a. In the Design view for the navigation model, in the Navigation column on the left side, select the node in the navigation model under which you want to add the folder or separator.
   b. Click the **Add new node** icon and choose **Folder** or **Separator**.
   c. The **Id** field is automatically populated with a generated ID. You can keep this ID, but you will probably want to change it to something slightly more descriptive. The ID must be unique within the navigation model.

      If the resource is at the top level of the navigation model, the ID must not be `wc_navtitle` or `wcnav_externalId`; these IDs are reserved.

      Tip: If the ID is not unique, or you enter any invalid characters in the ID, the border of the field becomes red.

   d. In the **Visible** field, specify whether the resource is displayed in the navigation. The default value is the EL expression `#{true}`, which means the resource is displayed to all users at all times. Enter `false` or `#{false}` to hide the resource from all users at all times, or enter an EL expression to specify the conditions under which the resource is displayed. If the field is empty, the value defaults to `true`.
3. To move a resource within the navigation model, select the item and drag it to the desired position.
4. To indent one resource (child item) under another (parent item), select the child item and drag it over the top of the parent item.
5. To re-parent a resource, right click it and choose **Change Parent**.
6. Save the navigation model definition file.

11.3.9 How to Set Display Options for a Resource

You can specify various display options for resources to determine their appearance and behavior when the navigation is rendered on a page. The display options available depend on the type of the resource.

To set display options for a resource:

1. In the Application Navigator, right-click the navigation model that contains the resource for which you want to set display options, and choose **Open**.

2. In the Design view for the navigation model, in the Navigation column on the left side, select the resource.
3. In the URL Attributes panel, click the **Add** icon and choose the attribute that you want to set. Table 11.2 lists the available attributes.

Table 11–2 Resource Attributes

Attribute	Description
Title	The title displayed for the resource when the navigation model is rendered on a page.
AccessKey	A key mnemonic (single character) that users can enter to access the resource without using the mouse.
Description	A description of the resource.
IconURI	An icon to visually represent the resource. This is displayed next to the Title when the navigation model is rendered on a page.
Subject	Keywords to facilitate searching of the resource.
Target	The location on the container page where the resource is displayed when it is selected, either in the same browser window (`_self`), a new window (`_blank`), or a popup (`_popup`), or any other location supported by the navigation UI. **Note:** Popups are not supported for pages.
ToolTip	Text that displays to provide additional information about the resource when users hover the mouse over the Title.
Modified	The date of the last modification of the resource. This attribute is used for site map creation.
ChangeFrequency	How frequently the resource is likely to change: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`. This attribute is used for site map creation.
Significance	The priority of this resource relative to other resources in the navigation model, within the range `0.0` to `1.0`. This attribute is used for site map creation.
ExternalId	An ID to enable a direct reference to a node in the navigation model from a static link in the page. Nodes in the default navigation model with this attribute defined can be accessed using `/faces/wcnav_externalId/`*`externalId`* from an `af:goLink` component in a page or using `/wcnav_externalId/`*`externalId`* from an External Link navigation item in the navigation model. The alternative is to access the node by its hierarchy, which is faster, but may change as the application develops. To directly access a node in a non-default navigation model, you must specify the path of the navigation model by setting the wcnav.modelPath URL parameter, for example: `/faces/wcnav_externalId/myNavigationItem?wcnav.modelPath=/oracle/webcenter/siteresources/scopedMD/s7f446cab_f622_4b68_a83e_b7eaf28b52ec/navigation/gsr0271c712_721a_4565_9f0e_755784a7093b/myProjectNavigationModel.xml`

4. From the **Value Type** dropdown list, choose:
   - **Literal String**—to specify a string as the value for the attribute

- **Resource Bundle**—to use a resource bundle to provide localized values for the attribute.

5. In the **Display Value** field, enter the value for the attribute. If you are using a resource bundle, click the **Browse** icon to select the resource bundle to search for the localized value.
6. Save the navigation model definition file.

11.4 Selecting the Default Navigation Model

The default navigation model provides a convenient way to select a navigation model that should be used by default by an application. Page template designers can then reference this default navigation model without having to know its actual name. For example, in navigation EL expressions, the default navigation model is often referenced, such as in `#{navigationContext.defaultNavigationModel}`.

When you first create a Framework application, the seeded navigation model, `default-navigation-model.xml`, is set as the default navigation model. If you subsequently create your own navigation model, rather than having to explicitly reference this navigation model whenever you want to use it, you can set it as the default.

You can set the default navigation model for an application by editing the `oracle.webcenter.portalapp.navigation.model` preference in the `adf-config.xml` file.

To select the default navigation model:

1. In the Application Resources pane of the Application Navigator, right-click the **adf-config.xml** file, and choose **Open**.

   Tip: To locate the `adf-config.xml` file, expand the **Descriptors** node, and then the **ADF META-INF** node.

2. Click the **Source** tab.
3. Locate the ADF preference with the following `id`:

   ```
   oracle.webcenter.portalapp.navigation.model
   ```

4. Set the `value` attribute to the path of the navigation model that you want to use as the default for the portal, for example:

   ```
   value="oracle/webcenter/portalapp/navigations/myNavigationModel.xml"
   ```

   Example 11–1 shows an example of the complete preference element.

Example 11–1 The Default Navigation Model ADF Preference

```
<portal:adf-portal-config>
  <preferences>
    ...
    <preference id="oracle.webcenter.portalapp.navigation.model"
        desc="Default Navigation Model"
        value="oracle/webcenter/portalapp/navigations/myNavigationModel.xml"
        resourceType="navigation" display="true"/>
    ...
  </preferences>
</portal:adf-portal-config>
```

5. Save the `adf-config.xml` file.

11.5 Editing the Navigation Renderer

The navigation renderer is a JSPX page renders non-page navigation resources, including:

- Portlets
- Content
- External links
- External applications
- Task flows

To change how these resources are rendered, you can edit the navigation renderer page. For example, you may also want to add an image before or after the navigation renderer task flow or change from a flow to a stretch layout.

The navigation renderer page is hidden by default, so you must first show it in your application before you can edit it.

Note: In the vast majority of cases, you should be able to edit the existing navigation renderer to meet your requirements. However, if required, you can create your own navigation renderer page. For example, the navigation renderer expects a `content` facet. If you want to use a different facet, you can create your own page and place the navigation renderer task flow in the appropriate location for your template.

If you choose to create your own navigation renderer page, it must include a navigation renderer region that contains the navigation renderer task flow.

To set your page as the navigation renderer for the application, edit the navigation renderer ADF preference (`oracle.webcenter.portalapp.navigation.renderer`) to point to the appropriate file. For detailed instructions for how to edit an ADF preference, see Section 11.4, "Selecting the Default Navigation Model."

To edit the navigation renderer:

1. In the Application Navigator, right-click the application project and choose **Project Properties**.
2. Expand the **Project Source Paths** node and select **Web Application**.
3. Select the **Excluded** tab.
4. Select the navigation renderer file (`navigation-renderer.jspx`) and click **Remove** to remove it from the list of excluded files.
5. Click **OK**.

   The navigation renderer JSPX file is now listed in the Application Navigator under the following node:

   `/oracle/webcenter/portalapp/pages/`

6. Right click **navigation-renderer.jspx** and choose **Open**.
7. Click the **Source** tab and edit the file as required.
8. When you are finished, save the `navigation-renderer.jspx` file.

11.6 Setting the REDIRECT_OPTIONS Context Parameter

If your application does not use partial page refresh (PPR), the URL in the browser changes whenever a user navigates to a resource in the navigation model. However, the URL shown by the browser does not reflect the current page; it shows the URL of the last page shown.

To enable the browser to display the URL of the current page, you can set the `oracle.webcenter.navigationframework.REDIRECT_OPTIONS` context parameter in the `web.xml` file.

> **Note:** Setting the `oracle.webcenter.navigationframework.REDIRECT_OPTIONS` context parameter affects performance by adding an extra request/response for every navigation.

To set the REDIRECT_OPTIONS context parameter:

1. In the Application Navigator, right-click the **web.xml** file and choose **Open**.
2. In the Overview Editor, expand the Context Initialization Parameters section.
3. Click the Create Context Initialization Parameter icon.
4. In the **Name** field, enter `oracle.webcenter.navigationframework.REDIRECT_OPTIONS`.
5. In the **Value** field, enter `toPrettyURL`.

   This adds the following to the `web.xml` file:

```
<context-param>
 <param-name>oracle.webcenter.navigationframework.REDIRECT_OPTIONS</param-name>
 <param-value>toPrettyURL</param-value>
</context-param>
```

6. Save the `web.xml` file.

11.7 Enabling Runtime Administration of Navigation Models

The Resource Manager in a Framework application enables users with administrative privileges to create and modify portal resources, including navigation models, at runtime. By exposing navigations in the Resource Manager, you allow administrators to manage these navigations at runtime. If you want to create and expose more navigations after deploying the application, you can export them from JDeveloper to the runtime application.

> **Note:** If you create a navigation model at runtime and do not import it back into the design time environment, your new navigation model may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To expose a navigation in the Resource Manager, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

You can also control exactly which resources users can add to navigation models at runtime by editing the navigation registry file, `navigation-registry.xml`.

For more information about the runtime features of navigation models, see the chapter "Working with Navigations" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

This section includes the following subsections:

- Section 11.7.1, "How to Edit the Navigation Registry File"
- Section 11.7.2, "How to Enable Further Development of Deployed Navigation Models"

11.7.1 How to Edit the Navigation Registry File

The navigation registry is a Resource Catalog specifically for registering which resources users can add to navigation models at runtime. Each Framework application contains one navigation registry file, `navigation-registry.xml`, which is created when you create the application. You can edit this file to change which resources to include. For example, if you do not want users to be able to embed other navigation models at runtime, you can remove the Navigation Reference resource from the navigation registry.

To edit the navigation registry:

1. In the Application Navigator, right-click the `navigation-registry.xml` file.

   Tip: You can find this file under *`Application_Root`*`/oracle/webcenter/portalapp/navigations`.

2. Edit the file the same way as any other Resource Catalog. For more information, see Section 16.2.3, "How to Manage Content in the Resource Catalog."

   You can add the following resources to the navigation registry:

   - Folder
   - Link
     - Task Flow
     - Portlet
     - Content
     - Other
   - Resource Catalog
   - Component
   - Custom Folder
   - Custom Content

   You can also modify and remove existing resources in the navigation registry, and rearrange resources in the registry.

3. When you are finished, save the `navigation-registry.xml` file.

11.7.2 How to Enable Further Development of Deployed Navigation Models

Seeded navigation models cannot be modified or deleted in the Resource Manager. Users with administrative privileges can make a copy of a seeded navigation model and edit or delete it, or they can create their own navigation models.

If users create or edit navigation models at runtime, you may find that you need to bring them back into JDeveloper for further enhancement. You can do this by downloading the navigation model from the deployed application, editing it in JDeveloper, and uploading it back to the application. At design time, this type of round-trip development includes importing the downloaded navigation model, editing it in JDeveloper, and exporting it so that it can be uploaded back to the deployed application.

In addition, if you create a new navigation model after you have deployed your application, you can export the navigation model from JDeveloper and upload it into the deployed application.

This section describes how to import and export navigation models in JDeveloper. It includes the following subsections:

- Section 11.7.2.1, "Importing a Navigation Model"
- Section 11.7.2.2, "Exporting a Navigation Model"

For more information about round-trip development, see Section 17.4, "Enabling Round-Trip Development of Resources."

11.7.2.1 Importing a Navigation Model

When you download a navigation model from the Resource Manager, an EAR file is created. On importing the EAR file in JDeveloper, the files from the EAR file are extracted to the folder `*Application_Root*/Portal/public_html/oracle/webcenter/siteresources/scopedMD/*scope_GUID*`. You can open the navigation model and edit it as you would any other navigation model at design time. The updated navigation model must then be exported to the deployed application.

For detailed steps to import a resource, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

11.7.2.2 Exporting a Navigation Model

You would need to perform an export for the following reasons:

- To expose a new navigation model in an already deployed application.
- To copy back a navigation model that you imported from a deployed application and modified.

When you export a navigation model from JDeveloper, an EAR file is created. Users with administrator privileges can then upload this EAR file to a deployed application using the Resource Manager.

For detailed steps to export a resource, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

11.8 Working with WebCenter Portal: Spaces Navigation Models

Out of the box, WebCenter Portal: Spaces provides seeded navigation models that you can use in your spaces. If these default navigation models do not suit your requirements, you can build your own navigation models within WebCenter Portal:

Spaces. For more information, see the section "Working with Navigation" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

However, WebCenter Portal: Spaces may not provide all the controls to create a navigation model that provides all the functionality that you require. In such cases, in JDeveloper you can edit navigation models originally created in WebCenter Portal: Spaces, and then upload them back into WebCenter Portal: Spaces.

WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, such as navigation models, to WebCenter Portal: Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build custom navigation models and other types of resources for WebCenter Portal: Spaces.

When working with WebCenter Portal: Spaces navigation models in JDeveloper, you should consider the following:

- All the resources required for a WebCenter Portal: Spaces navigation model exist within WebCenter Portal: Spaces. Therefore, you should really only use JDeveloper to restructure WebCenter Portal: Spaces navigation models and perform minor edits. First, you should create as much of the navigation model in WebCenter Portal: Spaces as possible and add the required resources. You can then use JDeveloper to refine the order of the resources and set all required attributes and parameters.
- If you do want to use JDeveloper to add resources to a WebCenter Portal: Spaces navigation model, you should obtain the resource ID from WebCenter Portal: Spaces by accessing the About dialog for the resource. For more information, see the section "Viewing Information About a Resource" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.
- When adding resources to a WebCenter Portal: Spaces navigation model, you must manually enter the path to the resource. You cannot use the Browse icon. For example, to enter a link to a page, you must identify the ID of the page in WebCenter Portal: Spaces and then enter that value manually as `page://`*`pathToXmlFile`*.

12

Designing the Look and Feel of Your Portal

When building a portal, it is important to decide on a look and feel for your portal. You may also want to ensure that the look and feel is consistent across the portal. You can achieve this kind of consistency across portal pages by using page templates and page styles.

This chapter provides information about creating and managing page templates and page styles. It also explains how to create mashup styles that can be used to create task flows at runtime. It includes the following subsections:

- Section 12.1, "Introduction to Page Templates and Styles"
- Section 12.2, "Working with Page Templates"
- Section 12.3, "Working with Page Styles"
- Section 12.4, "Working with Mashup Styles"

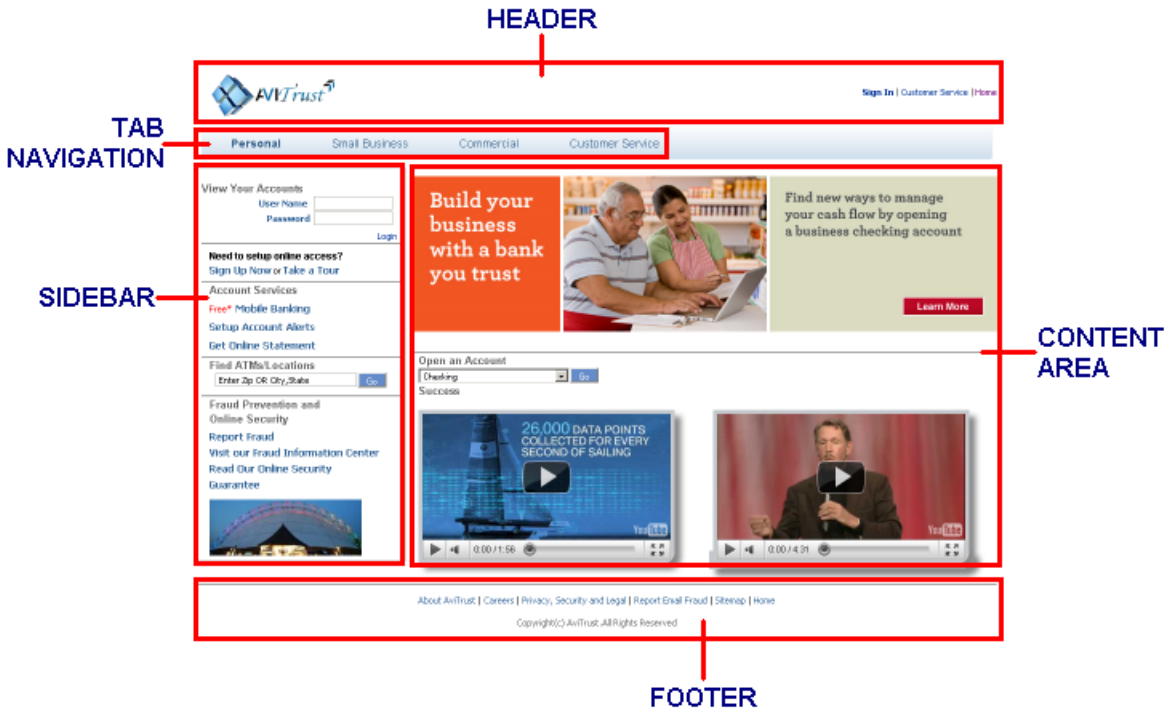
12.1 Introduction to Page Templates and Styles

Page templates define how individual pages and groups of pages display on a user's screen. When you use page templates to display pages, the pages are always consistent in structure and layout across the application. For example, a Side Navigation - Flow page template provides a navigation panel on the left side of the page, and the size of every component in the main content area is calculated based on the size of its children.

Page styles, on the other hand, determine the layout, and at times the initial content, for a new page in your portal. For example, the Web Page style provides a one-column layout and enables users to expose external web content in their application; a Blank page style provides a one-column layout and has few restrictions on the types of content users can add to the pages that are based on it.

Page templates and page styles are JSPX pages that you can create and publish in JDeveloper. While page templates can be used to create portal pages at design time and runtime, page styles are used only when creating pages at runtime. This section describes the different page templates and styles that you can create at design time. It includes the following subsections:

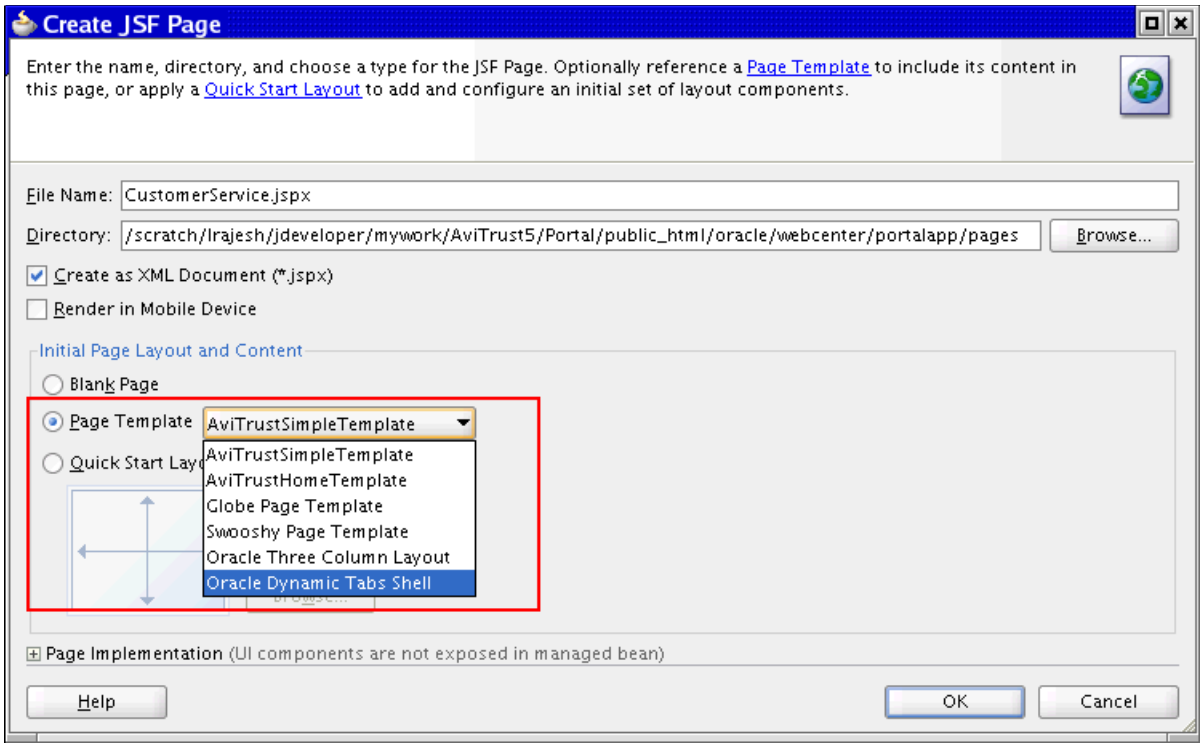
- Section 12.1.1, "Page Templates"
- Section 12.1.2, "Page Styles"
- Section 12.1.3, "Mashup Styles"
- Section 12.1.4, "Content Presenter Display Templates"



Note: Skins also contribute to the look and feel of your portal by specifying the application background color, screen fonts, and, with some skins, the shapes and images used for application buttons and icons. However, skins are not discussed in this chapter. For information, see Chapter 15, "Creating and Managing Skins."

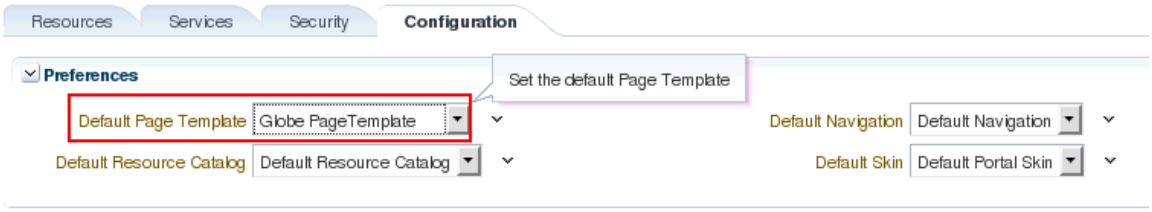
12.1.1 Page Templates

A page template typically defines the layout and default navigation model for pages in a portal application. It provides a uniform look and feel. Figure 12–1 shows a sample portal based on a page template, which provides the following:



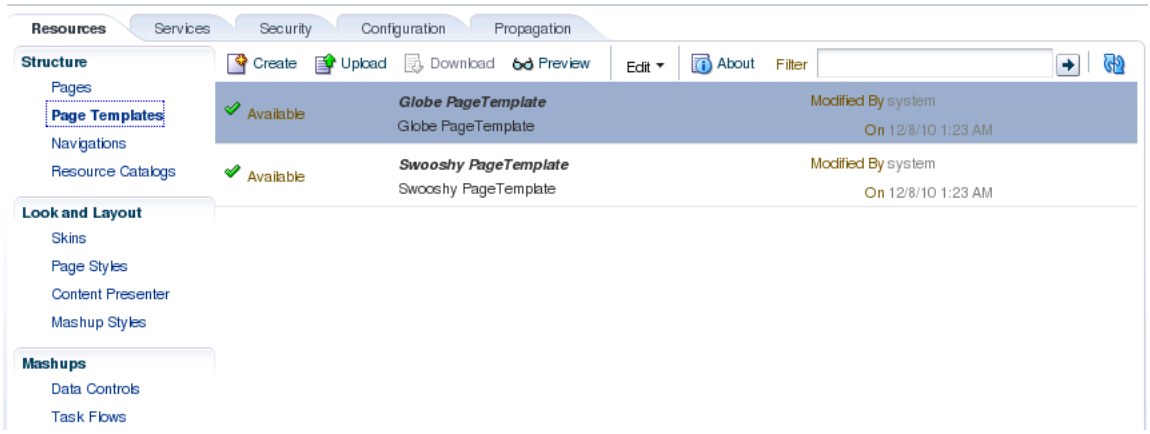
- Header with the company logo and the Sign In, Customer Service, and Home links.
- Default tab navigation to access different resources in the portal.
- Sidebar with a login task flow and some useful links.
- Footer with a copyright statement and a few disclaimer statements.
- A central area for adding content.

Figure 12–1 Sample Portal that Uses a Page Template



Page templates are reference-based and use inheritance. That is, if you change the page template, then all pages that reference that template automatically inherit the change. You can create and publish page templates in JDeveloper, and they can be used to create pages both at design time and runtime. At design time, you can choose a page template in the Create JSF Page dialog, shown in Figure 12–2.

Figure 12–2 Page Template Option in the Create JSF Page Dialog



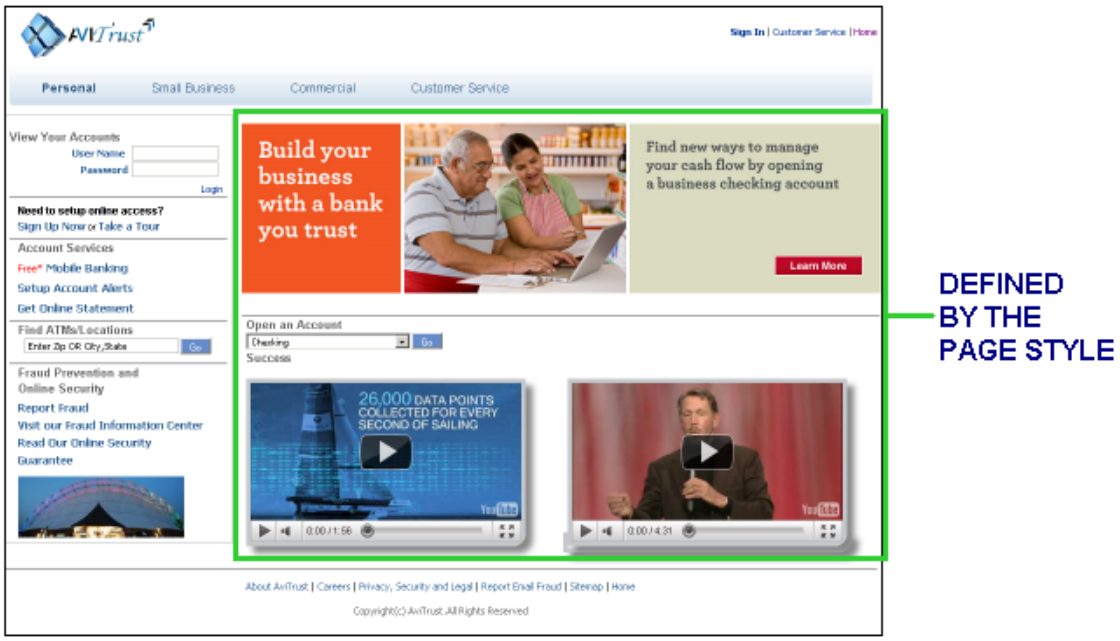
At runtime, you can apply a page template by selecting it in the application's Configuration page, as shown in Figure 12–3.

Figure 12–3 Page Template Option in the Application's Configuration Page

An administrator or delegate can manage the exposed page templates in the Resource Manager, shown in Figure 12–4.

Figure 12–4 Page Templates in the Resource Manager

For more information, see Section 12.2, "Working with Page Templates."



12.1.2 Page Styles

A page style is a JSPX page used for pages created at runtime. It describes the layout of a newly created page and may also dictate the type of content that the page supports.

When a user creates a page using a page style, the layout and initial content are copied from the page style to the newly created page. Unlike page templates, page styles are not reference-based, that is, if you change a page style, the change is not inherited in pages that use the style.

Typically, a page style contains components that enhance the usefulness and appearance of a given page. These include an in-place HTML text editor, images, layout boxes, hyperlinks, and so on. Content contributors can further populate the page with content. Figure 12–5 shows a sample portal page that is based on a page style.

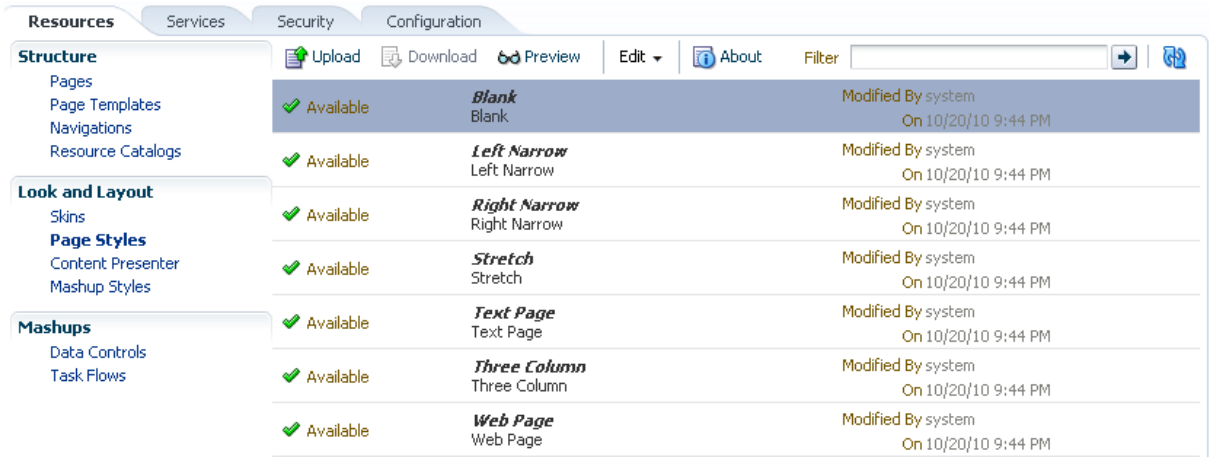


Figure 12–5 Sample Page that Uses a Page Style

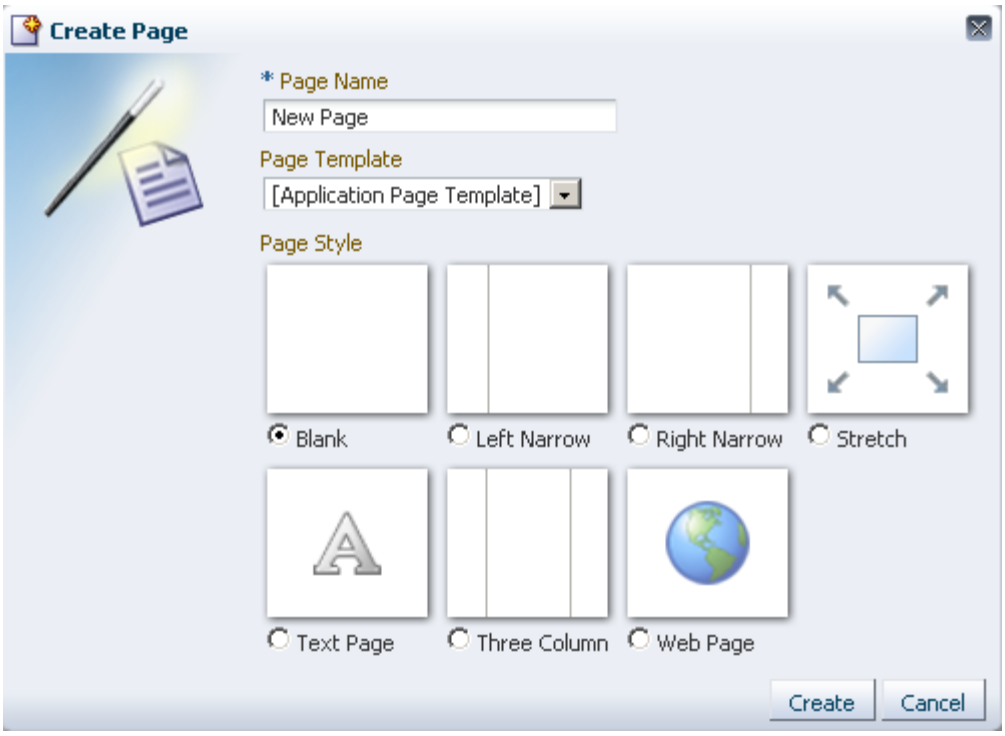
You create page styles in JDeveloper, but they are only used at runtime to create pages. Page styles that you expose in the application can be used and managed as follows:



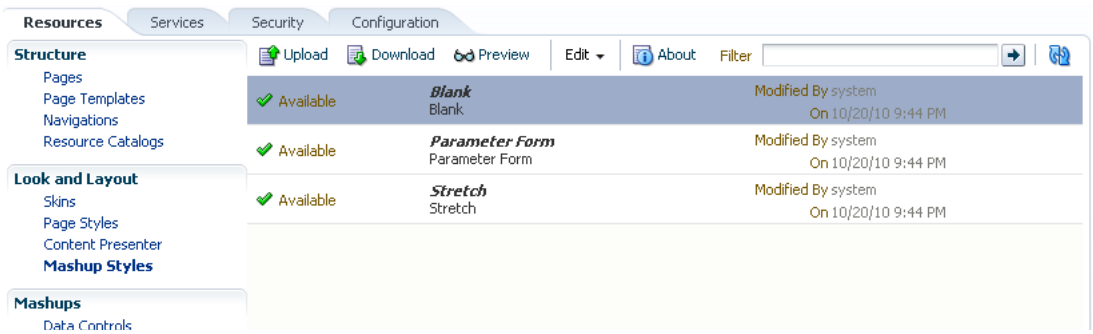
- An administrator or delegate can manage the exposed page styles in the Resource Manager, shown in Figure 12–6.

Figure 12–6 Page Styles in the Resource Manager

- A user can create pages based on the available page styles. The Create Page option is available in the Resource Manager. It is also available in other application pages that contain the `Page - Create New` task flow. When a user clicks the Create Page option, the Create Page dialog displays a set of predefined styles, as shown in Figure 12–7. The user can choose a style and create a page based on that. As the layout is already in place in the new page, the user only needs to add content to different areas of the page.

Figure 12–7 Create Page Dialog with Default Styles

For more information about creating page styles in JDeveloper, see Section 12.3, "Working with Page Styles." For information about managing page styles at runtime, see "Working with Page Styles" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.



12.1.3 Mashup Styles

Mashup styles are not very different from page styles, except that they are used at runtime to create task flows, also known as business mashups.

Mashup styles are used only at runtime to create mashups, but they can be created and published in JDeveloper. For more information, see Section 12.4, "Working with Mashup Styles."

Only an administrator or delegate can create and manage the exposed mashup styles in the runtime Resource Manager, shown in Figure 12–8.

Figure 12–8 Mashup Styles in the Resource Manager

Mashup styles are displayed in the Create New Task Flow dialog box (Figure 12–9), which is invoked by clicking Create on the Resource Manager - Task Flows page. The user can choose a style and create a mashup based on that style. For more information, see "Creating and Managing Task Flows" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

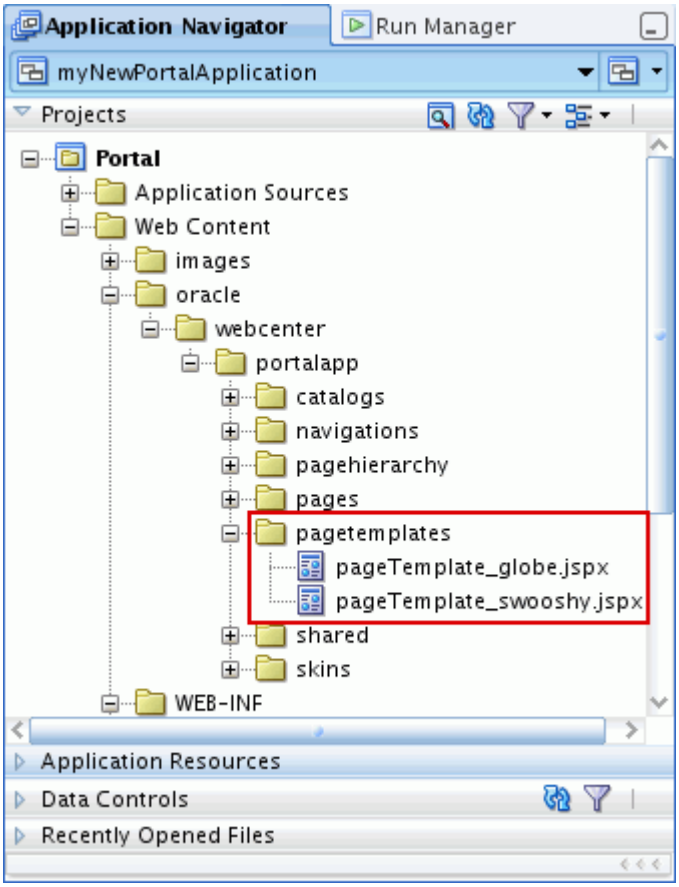
Figure 12–9 Create New Task Flow Dialog with Default Styles

12.1.4 Content Presenter Display Templates

Content Presenter display templates are used to define how Content Presenter renders content items on a Framework application page. Similar to page styles and mashup styles, Content Presenter templates can also be managed at runtime in the Resource Manager. These templates are not discussed in this chapter. For details, see Chapter 29, "Creating Content Presenter Display Templates."

12.2 Working with Page Templates

You can create any number of custom page templates and expose them to users in the Create JSF Page dialog. This section provides information about creating page templates and enabling runtime administration of page templates. It includes the following subsections:



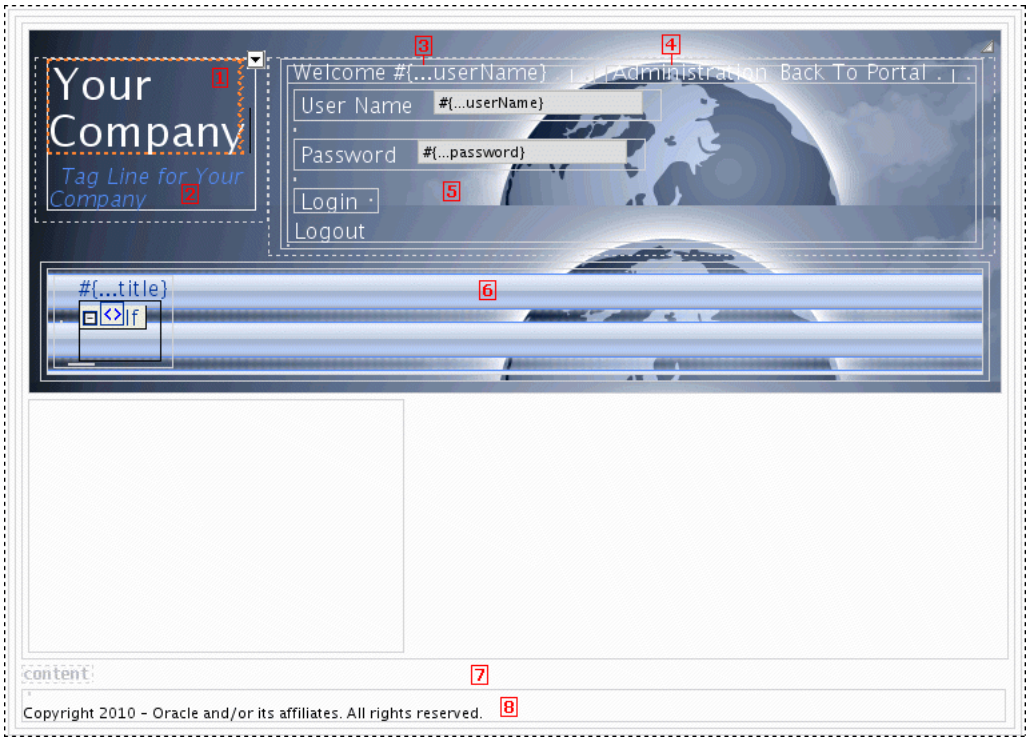
- Section 12.2.1, "Introduction to the WebCenter Portal Application Seeded Page Templates"
- Section 12.2.2, "How to Create a Page Template"
- Section 12.2.3, "What You Should Know About Creating Page Templates for WebCenter Portal Applications"
- Section 12.2.4, "Enabling Runtime Switching of Page Templates"
- Section 12.2.5, "How to Edit a Page Template"
- Section 12.2.6, "How to Delete a Page Template"
- Section 12.2.7, "How to Enable Runtime Administration of a Page Template"
- Section 12.2.8, "How to Enable Further Development of Deployed Page Templates"

- Section 12.2.9, "How to Create and Manage WebCenter Portal: Spaces Page Templates"

12.2.1 Introduction to the WebCenter Portal Application Seeded Page Templates

When you create an application using the WebCenter Portal Application template, and select the **Configure the application with standard Portal features** option, two seeded templates are added to your application: `pageTemplate_globe.jspx` and `pageTemplate_swooshy.jspx`.

Figure 12–10 The Seeded Page Templates in the Application Navigator



These templates both offer essentially the same functionality but with different graphics. They include the following:

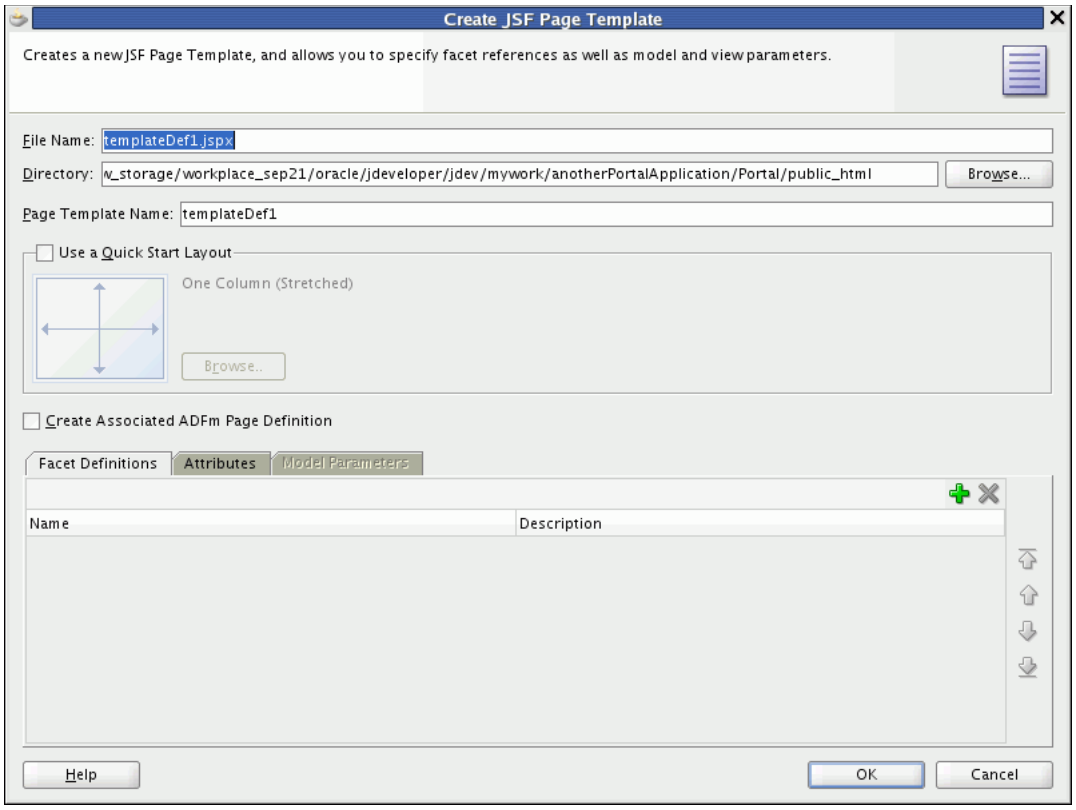
1. Link to the portal home page
2. Tag line
3. Welcome message
4. Link to the seeded Administration page
5. Login area that converts to a logout link when users are logged in
6. Navigation bar
7. Area for adding content to pages based on the template
8. Copyright notice

Figure 12–11 shows the `pageTemplate_globe.jspx` page template with each of the above features called out.

Figure 12–11 The pageTemplate_globe.jspx Seeded Page Template

You can edit this default page template to meet your particular requirements, or, more typically, you can create your own. If you choose to create your own page template, the seeded page templates are still a useful tool for you to discover the different things you can achieve in your own templates.

12.2.2 How to Create a Page Template



The following section focuses on the aspects of page templates that are specific to WebCenter Portal applications. For general information about JSF page templates, see the section "Using Page Templates" in the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

To create a page template:

1. In the Application Navigator, right-click the node where you want to create the page template (for example, `/oracle/webcenter/portalapp/pagetemplates`) and choose **New**.
2. In the New Gallery, expand **Web Tier**, select **JSF** and then **JSF Page Template**, and click **OK**.
3. In the Create JSF Page Template dialog (Figure 12–12), in the **File Name** field, enter a name for the JSPX file that represents the page template, for example `myCompanyPageTemplate.jspx`.

   The file name identifies the page template in the Application Navigator.

Figure 12–12 The Create JSF Page Template Dialog

4. In the **Directory** field, enter the full directory path of the location under which to create the page template.

   Note: In a WebCenter Portal application, to expose the new page template in the runtime Resource Manager, you must create the page template in the *Application_Root*`/Portal/public_html/oracle/webcenter/portalapp` directory.

   ---

5. In the **Page Template Name** field, enter a display name for the page template.

   The display name is shown in the **Page Template** dropdown list of the Create JSF Page wizard to enable users to select this template to use for a newly created page. For this reason, you should make the page template name something that helps users quickly identify which type of pages this template should be used for.

6. Select **Use a Quick Start Layout** if you want to use one of the predefined layouts for your page template.

7. Select **Create Associated ADFm Page Definition** to use ADFm Model data bindings in the page template.

   Associating a page definition with the page template enables you to include objects that have model elements to them (for example, task flows and portlets) in the page template. It also enables users to switch to a different page template at runtime.

Note: The seeded page templates all have associated page definitions, therefore it is highly recommended that you select this option when creating page templates in WebCenter Portal applications. Within an application page templates must either all have associated page definitions or none have associated page definitions.

If you have a combination of page templates with and without associated page definitions, users will not be able to switch templates at runtime.

After selecting this option, you can click the **Model Parameters** tab and click the **New** icon to define the model parameters for data bound components set with the ADFm declarative data binding layer. The values for these parameters can be set at runtime by the calling page.

Note: By default, the page template definition name is based on the page template name. Do not create the page definition with a different name.

8. Click the **Facet Definitions** tab to define the areas in the page template where content can be inserted to pages built using the template. A page template that is intended for use in a WebCenter Portal application must contain at least one facet definition called `content`.
   a. Click the **New** icon to add a new row to the **Facet Definitions** tab.
   b. In the **Name** field for the new facet definition, enter `content`.
   c. In the **Description** field, enter a brief description for the facet definition, for example `Main content area`.
   d. Create additional facet definitions as required.
   e. For information about how to add the facets to the required location in the page template, see step 12.

   Example 12–1 shows the `content` facet definition in the `<af:xmlContent>` section of the `pageTemplate_globe.jspx` seeded WebCenter Portal application page template.

Example 12–1 Content Facet in the Globe Seeded Page Template

```
<af:xmlContent>
  <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
    <display-name>Globe Page Template</display-name>
    <facet>
      <description>Facet for content</description>
      <facet-name>content</facet-name>
    <facet>
    ...
  </component>
</af:xmlContent>
```

9. Click the **Attributes** tab and click the **New** icon to define attributes for passing values from pages that use the template to the template itself. These values can be

used by the page template to drive what is actually displayed on individual pages that use the template.

For example, the `pageTemplate_globe.jspx` seeded WebCenter Portal application page template includes a link to the seeded Administration page. If the current page *is* the Administration page, then this link does not need to be displayed. The template uses an attribute, called `isAdminPage`, to identify whether the current page is the seeded Administration page. The value of this attribute, set by pages that use the template, determines whether or not to display the link to the Administration page.

Example 12–2 shows the `isAdminPage` attribute definition in the page template.

Example 12–2 Attribute Definition in the Globe Seeded Page Template

```
<af:xmlContent>
  ...
    <attribute>
      <attribute-name>isAdminPage</attribute-name>
      <attribute-class>java.lang.Boolean</attribute-class>
      <default-value>#{false}</default-value>
    </attribute>
  ...
</af:xmlContent>
```

Example 12–3 shows how the page template uses the value of the `isAdminPage` attribute to determine whether or not to render the link to the seeded Administration page.

Example 12–3 Conditional Value for Rendering the Administration Page Link

```
<af:pageTemplateDef var="attrs">
  ...
  <af:goLink id="pt_glnk1" text="Administration"
             destination="/admin"
             rendered="#{attrs.showAdmin !attrs.isAdminPage}"
             inlineStyle="font-size:small; color:White;"/>
```

Example 12–4 shows how the seeded Administration page sets the `isAdminPage` attribute to `true`, ensuring that the page template does not render the link when users are viewing the Administration page.

Example 12–4 Setting the Value of a Page Template Attribute

```
<af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}" id="pt1">
  <f:attribute name="isAdminPage" value="#{true}"/>
```

The seeded page templates include the following additional attributes:

```
<attribute>
  <attribute-name>contentWidth</attribute-name>
  <attribute-class>java.lang.String</attribute-class>
  <default-value>960px</default-value>
</attribute>

<attribute>
  <attribute-name>showNavigation</attribute-name>
  <attribute-class>java.lang.Boolean</attribute-class>
  <default-value>#{true}</default-value>
</attribute>
```

```
<attribute>
  <attribute-name>showGreetings</attribute-name>
  <attribute-class>java.lang.Boolean</attribute-class>
  <default-value>#{securityContext.authenticated}</default-value>
</attribute>

<attribute>
  <attribute-name>showLogin</attribute-name>
  <attribute-class>java.lang.Boolean</attribute-class>
  <default-value>#{true}</default-value>
</attribute>

<attribute>
  <attribute-name>showAdmin</attribute-name>
  <attribute-class>java.lang.Boolean</attribute-class>
  <default-value>
    #{WCSecurityContext.userInAppRole['Administrator']}
  </default-value>
</attribute>
```

10. Click **OK**.

    The page template is created and opened in the visual editor.

11. Drag components from the Component Palette and drop them onto the page template in the visual editor.

    Navigation UI is a very important aspect of a page template. For information about adding navigation UI to your page template, see Chapter 14, "Visualizing Your Portal Navigation."

    For information about adding other resources to your page template, for example, portlets, task flows, or content, see Chapter 13, "Adding Resources to Your Portal."

    Other features you might want to provide in your page template include a login/logout area or a search field. The seeded page templates include an example of a login form.

    Throughout your page templates, you can use expression language (EL) expressions to specify a variable value instead of a constant value. For descriptions of common EL expressions, see Appendix G, "Expression Language Expressions."

12. For areas on the page template where users can place their own content in pages based on the template:

    a. Drag the **FacetRef** component from the Component Palette and drop it onto the appropriate location on the page template.

    b. In the Insert Facet Ref dialog, from the **Facet Name** dropdown list, select the facet that you want to use for this area of the page template. If you enter a new facet name, JDeveloper creates a new facet definition in the page template definition file.

    Example 12–5 shows how the content facet is included in the `pageTemplate_globe.jspx` seeded WebCenter Portal application page template.

Example 12–5 The content Facet in the Globe Seeded Page Template

```
<af:pageTemplateDef var="attrs">
  <af:panelGroupLayout id="pt_root" layout="scroll">
    <af:panelGroupLayout id="pt_pg12" layout="vertical">
      ...
      <af:facetRef facetName="content"/>
```

```
      ...
    </af:panelGroupLayout>
  </af:panelGroupLayout>
  ...
<af:pageTemplateDef>
```

12.2.3 What You Should Know About Creating Page Templates for WebCenter Portal Applications

When creating page templates for use in WebCenter Portal applications, consider the following:

- To ensure that the page template can be exposed in the Resource Manager, create the page template JSPX file inside the `/oracle/webcenter/portalapp` directory. Out of the box there is already a `pagetemplates` subdirectory in which you can store your page templates.
- The seeded page templates are a valuable source of examples of features that you can include in your own page templates. Even if you do not intend to base your page templates on the seeded ones at all, it is still worth studying them for ideas. For example, the seeded page templates include a login form that you might want to reuse. The seeded templates also include a good example of navigation UI.
- In the Create Page Template dialog, you must select the **Create Associated ADFm Page Definition** option. If you do not select this option, users will not be able to switch between page templates at runtime. For page template switching to work, one of the following conditions must be met:
  - All page templates in the application have associated page definitions.
  - None of the page templates in the application have associated page definitions.

  Therefore, because the seeded page templates provided with the WebCenter Portal Application template have associated page definitions, for page template switching to work, any other page templates created within the application must also have associated page definitions for page template.
- Your page template must include at least one facet definition, and that facet definition must be called `content`.
- If the navigation model referenced by the page template includes External Link navigation items that use `mailto:` links, you must explicitly handle these in the page template. Example 12–6 uses JSTL to inspect the navigation item's `externalURL` to see if it starts with the string `mailto:`. If it does, an ADF Faces `goLink` component is used to render the link.

Example 12–6 Rendering a mailto: Link

```
...
<c:choose>
  <c:when test="${fn:startsWith(node.externalURL, 'mailto:')}">
    <af:goLink id="pt_gl_mail" text="#{node.title}"
               destination="#{node.externalURL}"/>
  </c:when>
  <c:otherwise>
    ...
  </c:otherwise>
</c:choose>
...
```

- If your page template includes a Content Presenter task flow to display a content item, you must manually modify the task flow properties to display the content, as follows:
  - `datasource`: *`connection_name`*#dDocName:*`content_ID`*
  - `datasourceType`: `dsTypeSingleNode`
  - `taskFlowInstId`: A unique identifier

  For more information about Content Presenter task flow properties, see Table 31–4, " Content Presenter Task Flow Parameters".
- If you are making a page template available for runtime management, any dependent objects of the page template, such as images, JavaScripts, style sheets, or HTML files, must be stored under the following directory, which is the default content directory for page templates created at design time:

  ```
  Application_Root/Portal/public_html/oracle/webcenter/portalapp/shared
  ```

  In addition, as a best practice, it is recommended to store dependent objects in resource-specific subdirectories under the `shared` directory. For example, images for a page template named `Template1` could be stored in:

  ```
  /oracle/webcenter/portalapp/shared/pageTemplates/Template1
  ```

  This avoids any potential conflict when additional resources are imported from runtime.

  When adding the resource as a portal resource, you must ensure that the **Content Directory** points to the appropriate `shared` directory.

  To reference dependent objects in your page template, use the following format:

  ```
  /oracle/webcenter/portalapp/shared/objectFileName
  ```

  For example:

  ```
  <af:image
  source="/oracle/webcenter/portalapp/shared/pageTemplates/Template1/logo.gif"
  id="pt_12">
  ```

12.2.4 Enabling Runtime Switching of Page Templates

When you create a page, you select a specific page template to use for that page. This adds a static reference to the page template to the JSPX file for the page. For example:

```
<af:pageTemplate
    viewId="/oracle/webcenter/portalapp/pagetemplates/pageTemplate_globe.jspx"
    value="#{bindings.pageTemplateBinding}"
    id="pt1">
  <f:facet name="content"/>
</af:pageTemplate>
```

A binding of the page template is created in the page's page definition file. For example:

```
<executables>
  <variableIterator id="variables"/>
  <page path="oracle.webcenter.portalapp.pagetemplates.pageTemplate_globePageDef"
        id="pageTemplateBinding" Refresh="ifNeeded"/>
</executables>
```

To use a different page template for the page, you must change both these references.

You can also change these references to use EL expressions to enable runtime switching of the page template.

> **Note:** You can switch between page templates at runtime only if the page template was created with an associated page definition.

To enable runtime switching of page templates:

1. In the Application Navigator, right-click the JSPX file for the page, and choose **Open**.
2. Click the **Source** tab.
3. Replace the following code:

```
<af:pageTemplate viewId="pathToPageTemplate"
                 value="#{bindings.pageTemplateBinding}"
                 id="ptId">
  <f:facet name="content"/>
</af:pageTemplate>
```

   with:

```
<af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}"
                 id="ptId">
  <f:facet name="content"/>
</af:pageTemplate>
```

4. Right-click the JSPX file and choose **Go to Page Definition**.
5. Click the **Source** tab.
6. Replace the following code:

```
<page path="pathToPageTemplatePageDef"
      id="pageTemplateBinding" Refresh="ifNeeded"/>
```

   with:

```
<page viewId="${preferenceBean.defaultPageTemplate}"
      id="pageTemplateBinding" Refresh="ifNeeded"/>
```

7. In the Application Resources pane of the Application Navigator, right-click the `adf-config.xml` file, and choose **Open**.

   > **Tip:** To locate the `adf-config.xml` file, expand the **Descriptors** node, and then the **ADF META-INF** node.

8. Click the **Source** tab.
9. Locate the ADF preference with the following id:

```
oracle.webcenter.portalapp.pagetemplate.pageTemplate
```

10. Set the `value` attribute to the page template to apply to the page. For example:

```
<portal:preference
  id="oracle.webcenter.portalapp.pagetemplate.pageTemplate"
  desc="Default Page Template"
  value="/oracle/webcenter/portalapp/pagetemplates/pageTemplate_globe.jspx"
```

```
resourceType="Template" display="true"/>
```

12.2.5 How to Edit a Page Template

You can make changes to your page template after its initial creation. Any changes you make are automatically rolled out to any pages that use the page template.

To edit a page template:

1. Locate the page template that you want to edit.
2. Right-click the page template and choose **Open**.
3. In the visual editor make any changes to the layout and content of the page template.
4. To add new facet definitions or attributes, select the `af:pageTemplateDef` tag in the Structure window and use the Property Inspector.
5. Save the page template definition file.

   If iterative development is enabled, any changes that you make to page templates can be seen immediately in the running application. For more information about iterative development, see Section 1.5, "Preparing for Iterative Development."

12.2.6 How to Delete a Page Template

If a page template is no longer required within your portal, you can delete it. When you delete a page template, attempting to run any page that has a direct reference to the page template will produce exceptions.

To delete a page template:

1. Locate the page template that you want to delete.
2. Right-click the page template and choose **Delete**.
3. The Confirm Delete dialog identifies if the page template is used within the application. Click **Show Usages** for more details.

   You can use this information to determine whether you really want to delete the template.
4. Click **Yes** to continue and delete the page template. Click **No** to cancel the operation.

12.2.7 How to Enable Runtime Administration of a Page Template

The Resource Manager in a WebCenter Portal application enables users with administrative privileges to create and modify portal resources, including page templates, at runtime. By exposing page templates in the Resource Manager, you allow administrators to manage these templates at runtime. If you want to create and expose more page templates after deploying the application, you can export them from JDeveloper to the runtime application.

Note: If you create a page template at runtime and do not import it back into the design time environment, your new page template may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To expose a page template in the Resource Manager, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

For more information about the runtime features of page templates, see the chapter "Working with Page Templates" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

12.2.8 How to Enable Further Development of Deployed Page Templates

Seeded page templates cannot be modified or deleted in the Resource Manager. However, users with administrative privileges can make a copy of a seeded page template and edit or delete it, or they can create their own page templates.

If users create or edit page templates at runtime, you may find that you need to bring them back into JDeveloper for further enhancement. You can do this by downloading the page template from the deployed application, editing it in JDeveloper, and uploading it back to the application. At design time, this type of round-trip development includes importing the downloaded page template, editing it in JDeveloper, and exporting it so that it can be uploaded back to the deployed application.

In addition, if you create a new page template after you have deployed your application, you can export the page template from JDeveloper and upload it into the deployed application.

This section describes how to import and export page templates in JDeveloper. It includes the following subsections:

- Section 12.2.8.1, "Importing a Page Template"
- Section 12.2.8.2, "Exporting a Page Template"

For more information about round-trip development, see Section 17.4, "Enabling Round-Trip Development of Resources."

12.2.8.1 Importing a Page Template

When you download a page template from the Resource Manager, an EAR file is created. On importing the EAR file in JDeveloper, the files from the EAR file are extracted to the folder `*Application_Root*/Portal/public_html/oracle/webcenter/siteresources/scopedMD/scope_GUID`. You can open the page template and edit it as you would edit any other page template at design time. The updated page template must then be exported to the deployed application.

For detailed steps to import a resource, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

12.2.8.2 Exporting a Page Template

You would need to perform an export for the following reasons:

- To expose a new page template in an already deployed application.
- To copy back a page template that you imported from a deployed application and modified.

When you export a page template from JDeveloper, an EAR file is created. Users with administrator privileges can then upload this EAR file to a deployed application using the Resource Manager. Once uploaded, the page template can be managed and used to create application pages.

For detailed steps to export a resource, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

12.2.9 How to Create and Manage WebCenter Portal: Spaces Page Templates

Out of the box, WebCenter Portal: Spaces provides seeded page templates that you can use in your spaces. If these default page templates do not suit your requirements, you can build your own page templates within WebCenter Portal: Spaces. For more information, see the chapter "Working with Page Templates" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

However, WebCenter Portal: Spaces may not provide all the controls to create a page template that provides all the functionality that you require. In such cases, you can create your own page template in JDeveloper and then upload it to WebCenter Portal: Spaces. You can also download an existing page template from WebCenter Portal: Spaces, edit it in JDeveloper, or use one of the sample page templates as your starting point, and then upload it back into WebCenter Portal: Spaces.

WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, such as page templates, to WebCenter Portal: Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build custom page templates and other types of resources for WebCenter Portal: Spaces. For details, see Section 56, "Extending the Spaces Application Using JDeveloper."

When creating or editing page templates in JDeveloper for use in WebCenter Portal: Spaces, consider the following:

- The page template must include a facet definition called `content`.
- The page template must include at least one UI component with `class="WCPGTEMPLATE"`. The runtime editing of skins enables the targeting of the template background in a basic tab; it depends on this style being there.

12.3 Working with Page Styles

Page styles are JSPX pages. You can create any number of custom page styles and expose these to users in the Create Page dialog. This section provides information about creating page styles and enabling runtime administration of page styles. It includes the following sections:

- Section 12.3.1, "How to Create a Page Style"
- Section 12.3.2, "How to Enable Runtime Administration of a Page Style"
- Section 12.3.3, "How to Enable Further Development of Deployed Page Styles"
- Section 12.3.4, "How to Create and Manage Page Styles for Spaces"

12.3.1 How to Create a Page Style

You can either create a page style from scratch or use an ADF page template to create it, then design it with the required layout components. However, there are a few prerequisites for creating a page style to be used in a custom application.

Requirements for Page Styles Exposed as Portal Resources

- To ensure that the style can be exposed in the Resource Manager, create the page style JSPX file inside the `/oracle/webcenter/portalapp` directory. You can

either create a subdirectory for page styles, for example `pagestyles`, or save the page style in the `pages` directory that is available out-of-the-box.

A page style can be exposed in the runtime Resource Manager only if it is present within the `/oracle/webcenter/portalapp/` structure.

- If a page style is based on a page template, then while designing the page style JSPX, add the `content` facet, or any other facet defined in the page template, to contain page content.
- To make the page customizable, add a `Page Customizable` component within the content facet. As the `Page Customizable` contains a child `Panel Customizable` component by default, users can add content to the page at runtime.
- To enable dynamic selection of the ADF template to be used for the page style, in the page style JSPX, specify an EL value for `pageTemplate`. Set the `value` attribute with an EL expression to a managed bean method that returns the page template ID, as shown in the following example:

  ```
  <af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}" id="T">
  ```

  This is useful in scenarios where the ADF template to be used is determined based on criteria such as the current user or scope.
- You may want to ensure that a new page created from a page style has the same look and feel as the portal it resides in. For this, you can configure the page style to use an ADF template based on the currently-applied page template. To achieve this, you must insert an EL reference to the page template's page definition in the page style's page definition file, as shown in the following example:

  ```
  <page viewId="#{preferenceBean.defaultPageTemplateViewId}"
        id="pageTemplateBinding" Refresh="ifNeeded"/>
  ```

- Create a managed bean with a method that returns the currently-applied page template ID, as shown in the following example:

  ```
  public class siteTemplatesManager {
      final private String templateA = "/templateA.jspx";
      final private String templateB = "/templateB.jspx";
      private String currentSiteTemplateViewId;

      public siteTemplatesManager() {
          super();
          currentSiteTemplateViewId = templateA;
      }
      public String gettemplateViewId() {
          return currentSiteTemplateViewId;
      }
      public void settemplateAViewId(ActionEvent ae) {
          currentSiteTemplateViewId = templateA;
      }
      public void settemplateBViewId(ActionEvent ae) {
          currentSiteTemplateViewId = templateB;
      }
  }
  ```

Section 19.6.1, "How to Create Templates for Pages Created at Runtime" describes in detail how to create a page style.

Example 12–7 shows the code for a sample page style, `/oracle/webcenter/portalapp/pages/pageStyles/TemplateFlowingTwoC`

olumn.jspx, which creates a basic page designed to flow and provide two columns that are 35 percent and 65 percent in proportion. Example 12–8 shows the associated page definition file, /oracle/webcenter/portalapp/pages/pageStyles/TemplateFlowingTwoColumnPageDef.jspx.

> **See Also:** Section 19.3.4.2, "Custom Styles" for information about where custom page styles and their page definitions can be stored and how to ensure that these styles show up in the Create Page dialog at runtime.

Example 12–7 Source Code of a Custom Page Style

```
<?xml version='1.0' encoding='utf-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"
xmlns:f="http://java.sun.com/jsf/core"
xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
xmlns:trh="http://myfaces.apache.org/trinidad/html" version="2.1">
  <jsp:directive.page deferredSyntaxAllowedAsLiteral="true"/>
  <jsp:directive.page contentType="text/html;charset=utf-8"/>
  <f:view>
    <af:document title="#{pageDocBean.title}" id="docrt">
      <af:form usesUpload="true" id="f1">
        <af:pageTemplate value="#{bindings.pageTemplateBinding.templateModel}"
        id="T">
          <f:facet name="content">
            <pe:pageCustomizable id="pc11">
              <af:panelGroupLayout id="pgl1" layout="scroll"
              styleClass="replace_with_scheme_name"
              inlineStyle="replace_with_inline_style">
                <trh:tableLayout id="tl1" width="100%">
                  <trh:rowLayout id="rl1">
                    <trh:cellFormat id="cf1" width="35%" valign="top">
                      <cust:panelCustomizable id="hm_pnc1" layout="scroll"/>
                    </trh:cellFormat>
                    <trh:cellFormat id="cf2" width="65%" valign="top">
                      <cust:panelCustomizable id="hm_pnc2" layout="scroll"/>
                    </trh:cellFormat>
                  </trh:rowLayout>
                </trh:tableLayout>
                <trh:tableLayout id="tl2"/>
              </af:panelGroupLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

Example 12–8 Page Definition of the Custom Page Style

```
<pageDefinition version="11.1.1.41.30" id="TemplateFlowingTwoColumnPageDef"
  Package="oracle.webcenter.siteresources.scopedMD.s8bba98ff_4cbb_40b8_beee_
296c916a23ed.pageStyle.gsr2b052c53_0eba_43fd_81e2_7f12dbb885a5">
```

```
  <parameters/>
  <executables>
    <page viewId="#{preferenceBean.defaultPageTemplate}"
          id="pageTemplateBinding" Refresh="ifNeeded"/>
    <taskFlow id="pageeditorpanel"
taskFlowId="#{pageEditorBean.pageEditorPanel}"/>
  </executables>
</pageDefinition>
```

12.3.2 How to Enable Runtime Administration of a Page Style

By exposing page styles in the Resource Manager, you allow administrators to manage them at runtime. You can create and export additional page styles even after deploying the application, without having to redeploy it. At runtime, the Resource Manager provides an option to upload the page styles that you exported.

> **Note:** If you create a page style at runtime and do not import it back into the design time environment, your new page style may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To expose a page style in the Resource Manager, it must have a valid entry in the application's `generic-site-resources.xml` file. Use the following options on the context menu of a page style JSPX file to register or deregister a page style in the Resource Manager:

> **Note:** The Resource Manager-specific options are displayed on the context menu only if you created the page style in the `/oracle/webcenter/portalapp` directory.

- **Create Portal Resource**: Creates an entry for the page style in the `generic-site-resources.xml` file.

  While creating an entry, you must set the attributes described in Table 12–1. The attributes in this table are specific to page styles. For the generic steps that are common to all resources, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

Table 12–1 Page Style Properties

Property	Description
Display Name	The display name for the page style.
Resource Type	The type of resource being exposed. This is a read-only field that is populated automatically based on certain internal validations on the JSPX file.

Table 12–1 (Cont.) Page Style Properties

Property	Description
Icon URL	The path to the image that you want to display alongside the page style name in the Create Page dialog. This is an optional setting. Specify the absolute path to the image file. For example, for a page style that is imported from WebCenter Portal: Spaces, the Icon URL is of the following format: *APPLICATION_ROOT*/oracle/webcenter/siteresources/scopedMD/shared/*FILE_NAME*
Description	A description for the page style.
Content Directory	The directory containing dependent objects of the page style, such as images, JavaScripts, style sheets, or HTML files. Objects associated with a resource are rendered only if they are stored in the `/oracle/webcenter/portalapp/shared` directory.

- **Update Portal Resource**: Edit the attributes that you defined while creating page style entries. For more information, see Section 17.2.3, "How to Update Portal Resource Properties."
- **Remove Portal Resource**: Remove the entry for the selected page style from the `generic-site-resources.xml` file. For more information, see Section 17.2.4, "How to Remove a Resource from the Resource Manager."

12.3.3 How to Enable Further Development of Deployed Page Styles

Seeded page styles cannot be modified or deleted at runtime. However, users with administrator privileges can make a copy of a seeded page style and edit its properties or delete it.

The Edit Source option in the Resource Manager enables users to modify the content of a copied or custom page style at runtime. However, as text editing is easier in JDeveloper than in the runtime source editor, users may choose to download a page style, edit it in JDeveloper, and upload it back to the deployed application. At design time, this type of round-trip development includes importing the downloaded page style, editing it in JDeveloper, and exporting it so that it can be uploaded back to the deployed application.

This section describes how to import and export page styles in JDeveloper.

12.3.3.1 Importing a Page Style

When you download a page style from the Resource Manager, an EAR file is created containing the following objects:

- Page style JSPX file
- Page definition file
- The `generic-site-resources.xml` file
- The content directory referenced by the page style. By default, this directory is `oracle/webcenter/siteresources/scopedMD/shared`. The EAR file will not contain this folder if the shared directory has no content.

The `generic-site-resources.xml` file contains metadata that helps identify the type of resource being imported. The metadata is also used when you export the page style back to the runtime application.

On importing the EAR file in JDeveloper, the files from the EAR are extracted to the folder *`Application_Root`*`/Portal/public_html/oracle/webcenter/siteresources/scopedMD/<`*`scope_GUID`*`>`. You can open the page style and edit it as you would edit any other page at design time. The updated page style must then be exported to the deployed application.

> **Note:** If you imported a page style from WebCenter Portal: Spaces but want to use it in a Framework application, ensure that you delete the WebCenter Portal: Spaces-specific privilege mapping from the page definition file. This means that you remove the `<permission>` element from the style's page definition. You may get errors if you retain the privilege mapping.

For the detailed steps to import a resource, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

12.3.3.2 Exporting a Page Style

You would need to perform an export for the following reasons:

- To expose a new page style in an already deployed application.
- To copy back a page style that you imported from a deployed application and modified.

When you export a page style from JDeveloper, an EAR file is created containing the page style JSPX, its page definition file, the `generic-site-resources.xml` file, and a `shared` folder containing the images associated with the page style. Users with administrator privileges can then upload this EAR file to a deployed application using the Resource Manager. Once uploaded, the page style can be managed and used to create application pages.

For the detailed steps to import a resource, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

12.3.4 How to Create and Manage Page Styles for Spaces

Out of the box, Spaces provides several seeded page styles. If these default styles do not suit your requirements, you can build your own page styles within Spaces. For more information, see the chapter "Working with Page Styles" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

However, Spaces may not provide all the controls to create a page style that provides all the functionality that you require. In such cases, you can create your own page style in JDeveloper and then upload it to Spaces. You can also download an existing page style from Spaces, edit it in JDeveloper, or use one of the sample page styles as your starting point, and then upload it back into Spaces. In JDeveloper, you can create a page style just like any other JSPX page and upload it to Spaces.

Oracle WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, such as page styles, to Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the

`WebCenterSpacesResources` project to build custom page styles and other types of resources for Spaces.

The primary tasks of creating and editing page styles are the same for Framework applications and Spaces applications, but you must make a few additional considerations for Spaces applications. This section covers the special considerations for page styles to be consumed in Spaces.

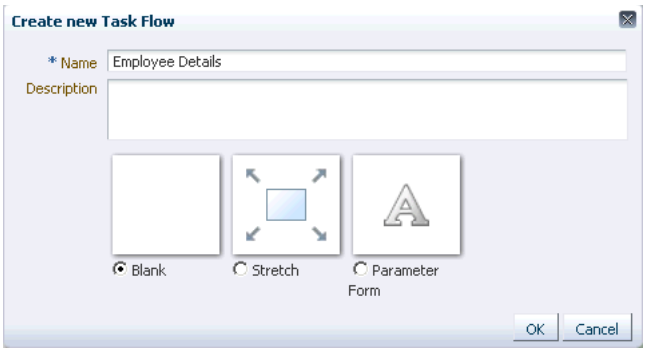
Requirements for Page Styles Used in Spaces

Use the `CustomPagePermission` class to map permissions explicitly for the page style, as shown in the following example:

```
<permission
permissionClass="oracle.webcenter.page.model.security.CustomPagePermission"
target="ps_targetusage">
  <privilege-map operation="administer" privilege="manage"/>
  <privilege-map operation="create" privilege="create"/>
  <privilege-map operation="delete" privilege="delete"/>
  <privilege-map operation="edit" privilege="update"/>
  <privilege-map operation="personalize" privilege="personalize"/>
  <privilege-map operation="view" privilege="view"/>
</permission>
```

For the general page style prerequisites, see "Requirements for Page Styles Exposed as Portal Resources". For the procedure to create a page style, see Section 12.3.1, "How to Create a Page Style."

12.4 Working with Mashup Styles



Mashup styles are ADF task flows that can be used as templates to create new task flows at runtime. However, a mashup style can have only a single view fragment. In addition, if the mashup style refers to code, for example, using an EL value, then that code must be present in the deployed application.

You may choose to create mashup styles for the following purposes:

- To provide a specific, consistent layout for task flows.
- To seed a Parameter Form or UI picker that can in turn be used in the task flows created from the mashup style, for example, a mashup style with a space picker drop down. When a task flow based on this style is populated with an Activity Stream task flow, the picker drop down can be wired to an input parameter on the Activity Stream task flow. The Activity Stream task flow then displays activities specific to the selected space.
- To provide a predefined UI that can be bound separately to data, for example, you can create a flowing data layout in the mashup style, create a task flow from it, drop a data control, then bind the flowing data layout to the data control.

The Resource Manager provides a Task Flows page in which users with administrative privileges can create and manage task flows. When a user clicks Create on the Task Flows page, The Create new Task Flow dialog, shown in Figure 12–13, displays the seeded mashup styles available to users.

Figure 12–13 Seeded Mashup Styles

Note: Managing ADF Task Flows

Just like how you manage mashup styles at runtime, you can create and manage task flows also in the Resource Manager. The Resource Manager - Task Flows page enables users to create, edit, delete, import, and export task flows.

You cannot export a custom task flow created in JDeveloper as a portal resource, but you can import a task flow created at runtime, modify it, and export it back to the runtime application. The steps to import, modify, and export task flows are the same as those for mashup styles. Therefore, the export, import, and edit tasks in this section are applicable for task flows and mashup styles.

For information about adding and exporting custom task flows, see Section 13.3, "Adding Custom Task Flows to Your Portal."

This section describes how to create mashup styles and configure them to be exposed at runtime. It contains the following tasks:

- Section 12.4.1, "How to Create a Mashup Style"
- Section 12.4.2, "How to Enable Runtime Administration of Mashup Styles"
- Section 12.4.3, "How to Enable Further Development of Mashup Styles in a Deployed Application"
- Section 12.4.4, "How to Create and Manage Mashup Styles for Spaces"

12.4.1 How to Create a Mashup Style

Creating a mashup style is the same as creating a task flow, but you create mashup styles only so that they can be used as templates to create task flows at runtime. Mashup styles can be consumed at runtime only if you expose them in the Resource Manager.

Requirements for Mashup Styles Exposed as Portal Resources

To expose a mashup style in the Resource Manager, you must consider the following requirements when creating a mashup style in JDeveloper:

- Create the task flow definition XML file inside the `/oracle/webcenter/portalapp` directory. You can either create a subdirectory for mashup styles, for example `mashupstyles`, or save the mashup style directly in the `portalapp` directory.

- Create *only one* view fragment for a task flow that will be used as a mashup style, and create a page definition for this JSFF view fragment.
- Add a `Panel Customizable` component to the view fragment from the Composer tag library. This ensures that task flows based on this mashup style can be populated at runtime.

Example 12–9 shows the code for a sample mashup style that enables records from a bug details database to be listed in the Activity Stream format. The style is created based on knowledge of the data source being accessed and the columns available in the data source. In this example:

- `dataPresenter.dummyData.collectionModel` is a null data source that must be replaced with the appropriate data control reference when the mashup style is used at runtime.
- `#{row.`*`COLUMN`*`}` entries are placeholders that will reference data columns from the data controls when the mashup style used.
- `#{empty row.COLUMN ? '#{row.COLUMN}' : row.COLUMN}` is used to display `#{row.COLUMN}` in the task flow created using this mashup style until `dataPresenter.dummyData.collectionModel` is replaced and data is properly bound. Using a construct like this ensures that task flows created from this mashup style give users a hint about the available data slots.

Example 12–9 Sample Mashup Style

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
          xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:panelGroupLayout id="pgl1">
    <cust:panelCustomizable id="pc1">
      <table border="0" width="100%">
        <af:iterator id="i1"
                     value="#{dataPresenter.dummyData.collectionModel}"
                     var="row">
        <tr class="PortletText1">
          <td width="16px">
            <af:image id="img1"

source="http://abc.mycompany.com:80/webcenter/content/conn/UCM/Public/images/wiki/
#{row.IMAGE}"/>
          </td>
          <td>
           <af:outputText id="otCol1"
                          value="#{empty row.PLAYER1 ? '#{row.PLAYER1}' :
row.PLAYER1}"
                          inlineStyle="color:#333333; font-size:12px;
font-weight:bold;"/>
           <af:spacer id="spacer1" width="5px"/>
           <af:outputText id="otCol2"
                          value="#{empty row.MESSAGE ? '#{row.MESSAGE}' :
row.MESSAGE}"
                          inlineStyle="color:#333333; font-size:12px;"/>
          <af:spacer id="spacer2" width="5px"/>
          <af:goLink id="gl1"
                       destination="https://bug.mycompany.com/pls/bug/webbug_
edit.edit_info_top?rptno=#{empty row.RPTNO ? '#{row.RPTNO}' : row.RPTNO}"
```

```
                        targetFrame="_blank"
                        text="#{empty row.RPTNO ? '#{row.RPTNO}' : row.RPTNO"/>
          </td>
        </tr>
        <tr>
          <td></td>
          <td>
            <af:outputText id="otCol3"
                           value=""#{empty row.BUG_SUBJECT ? '#{row.BUG_SUBJECT}'
: row.BUG_SUBJECT}"
                           inlineStyle="color:#666666; font-size:12px;"/>
          </td>
        </tr>
        <tr>
          <td></td>
          <td>
            <af:outputText id="otCol4"
                           value="#{empty row.TIMEOFDAY ? '#{row.TIMEOFDAY}' :
row.TIMEOFDAY}"
                           inlineStyle="color:#666666; font-size:10px;"/>
          </td>
        </tr>
        </af:iterator>
      </table>
    </cust:panelCustomizable>
  </af:panelGroupLayout>
</jsp:root>
```

For detailed information about ADF task flows, see "Creating ADF Task Flows" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

12.4.2 How to Enable Runtime Administration of Mashup Styles

By exposing mashup styles in the Resource Manager, you allow administrators to manage these styles and create task flows based on these styles. You can also export selected mashup styles from JDeveloper so that administrators can modify or delete them at runtime.

Managing mashup styles at runtime is similar to managing page styles. For more information, see "Working with Page Style Resources" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

> **Note:** If you create a mashup style at runtime and do not import it back into the design time environment, your new mashup style may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To expose a mashup style in the Resource Manager, it must have a valid entry in the application's `generic-site-resources.xml` file. Use the following options on the context menu of a task flow definition XML file to register or deregister the mashup style in the Resource Manager:

Note: The Resource Manager-specific options are displayed on the context menu only if you created the mashup style in the `/oracle/webcenter/portalapp` directory.

- **Create Portal Resource**: Creates an entry for the mashup style in the `generic-site-resources.xml` file.

  While creating an entry, you must set the attributes described in Table 12–2. The attributes in this table are specific to mashup styles. For the generic steps that are common to all resources, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

Table 12–2 Mashup Style Properties

Property	Description
Display Name	The display name for the style.
Resource Type	The type of resource being exposed. You must select `Mashup Style` here.
Icon URL	The path to the image that you want to display alongside the mashup style name in the Create a new Task Flow dialog. This is an optional setting. Ensure that the image is in the class path and can be accessed at runtime.
Description	A description for the mashup style.

- **Update Portal Resource**: Edit the attributes that you defined while creating an entry for the mashup style. For more information, see Section 17.2.3, "How to Update Portal Resource Properties."
- **Remove Portal Resource**: Remove the entry for this mashup style from the `generic-site-resources.xml` file. For more information, see Section 17.2.4, "How to Remove a Resource from the Resource Manager."

12.4.3 How to Enable Further Development of Mashup Styles in a Deployed Application

Seeded mashup styles cannot be modified or deleted in the Resource Manager. However, users with administrator privileges can make a copy of a seeded mashup style and edit its properties or delete it.

The Edit Source option in the Resource Manager enables users to modify the content of a copied or custom mashup style at runtime. However, as text editing is easier in JDeveloper than in the runtime source editor, users may choose to download a mashup style, edit it in JDeveloper, and upload it back to the deployed application. At design time, this type of round-trip development includes importing the downloaded mashup style, editing it in JDeveloper, and exporting it so that it can be uploaded back to the deployed application.

This section describes how to export and import mashup styles in JDeveloper.

12.4.3.1 Importing Mashup Styles

When you download a mashup style from the Resource Manager, an EAR file is created containing the following objects:

- Task flow definition file
- View fragment JSFF file

- View fragment page definition file
- The `generic-site-resources.xml` file
- The content directory referenced by the mashup style. By default, this directory is `oracle/webcenter/siteresources/scopedMD/shared`. The EAR file will not contain this folder if the `shared` directory has no content

The `generic-site-resources.xml` file contains metadata that helps identify the type of resource being imported. This metadata is also used when you export the mashup style back to the runtime application.

On importing the EAR file in JDeveloper, the files from the EAR are extracted to the folder *`Application_Root`*`/Portal/public_html/oracle/webcenter/siteresources/scopedMD/<`*`scope_GUID`*`>`. You can open the mashup style and edit it as you would edit any other task flow at design time. The updated mashup style must then be exported to the runtime application.

Note: When updating a runtime mashup style in JDeveloper, if the icon URL points to a location in the application classpath, you may see an error message prompting you to place the icon in the *`APPLICATION_ROOT`*`/oracle/webcenter/siteresources/scopedMD` directory.

To proceed with updating the mashup style, you can provide a null value for the icon URL, and replace the correct value at runtime after uploading the mashup style.

For the detailed steps to import a resource, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

12.4.3.2 Exporting Mashup Styles

You would need to perform an export for the following reasons:

- To expose a new mashup style in an already deployed application.
- To copy back a mashup style that you imported from a deployed application and modified.

When you export a mashup style from JDeveloper, an EAR file is created containing the task flow definition file, the view fragment JSFF, its page definition file, the `generic-site-resources.xml` file, and a `shared` folder containing the image used for the mashup style. Users with administrator privileges can then upload this EAR file to a deployed application using its Resource Manager. Once uploaded, the mashup style can be managed and used to create task flows.

For the detailed steps, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

12.4.4 How to Create and Manage Mashup Styles for Spaces

Out of the box, Spaces provides several seeded mashup styles. If these default styles do not suit your requirements, you can build your own mashup styles within Spaces. For more information, see the chapter "Managing Mashup Styles" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

However, Spaces may not provide all the controls to create a mashup style that provides all the functionality that you require. In such cases, you can create your own

mashup style in JDeveloper and then upload it to Spaces. You can also download an existing mashup style from Spaces, edit it in JDeveloper, or use one of the sample mashup styles as your starting point, and then upload it back into Spaces.

Oracle WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, such as mashup styles, to Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build custom mashup styles and other types of resources for Spaces.

The primary tasks of creating and editing mashup styles are the same for Framework applications and Spaces applications. For the procedure to create a mashup style, see Section 12.4.1, "How to Create a Mashup Style."

For the general mashup style prerequisites, see "Requirements for Mashup Styles Exposed as Portal Resources".

13

Adding Resources to Your Portal

When building up the content of your WebCenter Portal: Framework application, you can bring in content from various resources, including:

- Pages
- Portlets and pagelets
- WebCenter Portal service task flows and custom task flows
- Content from UCM
- External applications

Adding content to your Framework application is no different from adding content to any other web application.

This chapter includes the following sections:

- Section 13.1, "Adding Pages to Your Portal"
- Section 13.2, "Adding Service Task Flows to Your Portal"
- Section 13.3, "Adding Custom Task Flows to Your Portal"
- Section 13.4, "Adding Content from Content Server to Your Portal"
- Section 13.5, "Adding Portlets to Your Portal"
- Section 13.6, "Adding Pagelets to Your Portal"
- Section 13.7, "Adding External Applications to Your Portal"
- Section 13.8, "Adding Data Controls to Your Portal"

13.1 Adding Pages to Your Portal

A portal is made up of pages that provide the structure of the portal and expose the content. If you create your portal using WebCenter Portal's Framework application template, a home page and several other pages are created for you. You can create your own pages to construct the rest of your portal.

For more information, see Section 5.3, "Adding Pages to a Portal."

After creating the pages, you can organize them into a page hierarchy to determine the structure of the pages. The page hierarchy also determines the security for those pages.

For more information, see Section 69.6, "Using the Page Hierarchy Security Editor."

If you want users to be able to edit pages at runtime, you can add Composer components to the pages.

For more information, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."

13.2 Adding Service Task Flows to Your Portal

WebCenter Portal services enrich portals and web sites with enterprise 2.0 capabilities, including social computing services, personal productivity services, online awareness and communications, content integration, and web analytics. WebCenter Portal services expose their functionality through task flows. For more information about WebCenter Portal services and task flows, see Section 2.4, "Introducing Oracle WebCenter Portal: Services."

If you create your portal using WebCenter Portal's Framework application template, all the appropriate WebCenter Portal service connection wizards and tag libraries are readily visible and available in the New Gallery and Component Palette. When you consume a WebCenter Portal service task flow or component, the necessary libraries are automatically added to the project. Depending on the service you plan to consume, your application must meet certain prerequisites. For example, if the service must know the identity of users, then your application must provide some level of security with user authentication. For more information, see Chapter 7, "Preparing Your Application for WebCenter Portal Services."

For more information about the individual WebCenter Portal services and their task flows, refer to Table 13–1.

Table 13–1 WebCenter Portal Services - More Information

WebCenter Portal Service	More Information
Activity Graph	Chapter 46, "Integrating the Activity Graph Service"
Analytics	Chapter 47, "Integrating the Analytics Service"
Announcements	Chapter 33, "Integrating the Announcements Service"
Blogs	Chapter 32, "Integrating Wikis and Blogs"
Discussions	Chapter 34, "Integrating the Discussions Service"
Documents	Chapter 30, "Integrating the Documents Service"
Events	Chapter 52, "Integrating the Events Service"
Instant Messaging and Presence (IMP)	Chapter 35, "Integrating the Instant Messaging and Presence Service"
Links	Chapter 43, "Integrating the Links Service"
Lists	Chapter 48, "Integrating the Lists Service"
Mail	Chapter 36, "Integrating the Mail Service"
Notifications	Chapter 49, "Integrating Notifications"
People Connections	Part VI, "Working with the People Connections Service"
Polls	Chapter 37, "Integrating the Polls Service"
Recent Activities	Chapter 50, "Integrating the Recent Activities Service"
RSS	Chapter 53, "Integrating the RSS Service"
Search	Chapter 45, "Integrating the Search Service"
Tags	Chapter 44, "Integrating the Tags Service"
Wikis	Chapter 32, "Integrating Wikis and Blogs"

Table 13–1 (Cont.) WebCenter Portal Services - More Information

WebCenter Portal Service	More Information
Worklist	Chapter 51, "Integrating the Worklist Service"

13.3 Adding Custom Task Flows to Your Portal

Task flows, like pages, are containers in which you can add components such as portlets, content, and other task flows. You can add task flows to pages or other task flows. Task flows created in JDeveloper can be included in Resource Catalogs so that users can add them to pages or other task flows at runtime.

You can drag and drop a custom task flow into a Resource Catalog so that it is available to users to add to pages or task flows at runtime. For more information, see Section 16.2.3.7, "Dragging and Dropping a Resource into the Catalog." When you deploy the application, the task flow is also deployed to the target instance.

For detailed information about creating different types of ADF task flows, see "Creating ADF Task Flows" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

Exposing Task Flows Created in JDeveloper to a Deployed Application

If you created a custom task flow in JDeveloper and want to expose it in an already deployed application, you must deploy the project containing the task flow as an ADF shared library to the runtime application. Once the library containing the task flow is accessible to the application, it is displayed in the runtime Resource Registry and can be added to custom Resource Catalogs from there.

> **Note:** Permissions to view or edit a task flow are not provisioned by default when you create the task flow. To ensure that a task flow is visible at runtime, prior to deploying as a shared library, you must grant at least the View privilege on the task flow. For more information, see Section 24.6.1, "Granting Permissions on Task Flows."

For the steps to deploy an application to a Framework application, see "Deploying the Application to a WebLogic Managed Server" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. However, while running the Install Application Assistant, on the Choose targeting style page, select **Install this deployment as a library**.

For the steps to deploy an application to a WebCenter Portal: Spaces instance, see Section 56.2.3, "Rebuilding the Spaces Shared Library List."

13.4 Adding Content from Content Server to Your Portal

To provide access to the content in your Content Server content repository, you must create a connection to the Content Server. For more information, see Section 27.2.1, "How to Create a Content Repository Connection Based on the Oracle Content Server Adapter."

With a connection to Content Server established, you can use the Documents service, which includes task flows that provide a user-friendly interface to manage, display, and search documents at runtime. For more information, see Chapter 30, "Integrating the Documents Service."

Next, add one of the content task flows to your portal to expose the content from Content Server. Content task flows include Content Presenter and the Documents service task flows:

- Content Presenter
- Document Explorer
- Document List Viewer
- Document Manager
- Document Navigator
- Folder Viewer
- Recent Documents
- Document Viewer
- Document Mini Properties
- Document Properties
- Rich Text Editor
- Document Upload
- Document Version History

For more information about the Content Presenter task flow, see Section 31.1, "Understanding the Content Presenter Task Flow." For more information about the Documents service task flows, see Section 31.2, "Understanding the Documents Service Task Flows."

If you use the Content Presenter task flow, you may also want to create your own Content Presenter display templates. Content Presenter display templates define how content repository items should be rendered on a page. For more information, see Chapter 29, "Creating Content Presenter Display Templates."

13.5 Adding Portlets to Your Portal

A portlet is a reusable web component that can draw content from many different sources. Portlets provide a way of presenting data from multiple sources in a meaningful and related way. For more information about portlets, see Chapter 58, "Overview of Portlets."

To add a portlet to your portal, you must first register the portlet's producer with the Framework application. For more information, see Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application."

After you have registered the portlet producer, you can then simply drag and drop any portlets that you want to include in your portal onto the appropriate page. For more information, see Section 64.3, "Adding Portlets to a Page."

For information about how to create portlets, see Chapter 60, "Creating Portlets with the Portlet Wizard."

13.6 Adding Pagelets to Your Portal

A pagelet is similar to a portlet, but while portlets were designed specifically for portals, pagelets can be run on any web page, including within a portal or other web application. Pagelets can be used to expose platform-specific portlets in other web environments.

For more information about adding pagelets to your portal, see Section 63.2, "Using Pagelets in Web Applications."

13.7 Adding External Applications to Your Portal

If the resources you add to your portal require access to applications that define their own authentication processes, you can add external applications to replicate a single sign-on experience for users.

For example, your portal might include portlets that point to applications that require a separate login. Or, if your portal includes the Mail service, you must identify an external application to map the mail server user to the portal user so that the user does not have to log in separately every time.

The first time a portal user accesses the external application, he or she is prompted for a user name and password for the application. These credentials are then mapped to the portal user and stored securely in a credential store. The credential store subsequently supplies these credentials during authentication to the external application. Unless the external application's credentials change, the user supplies the credentials only once as the mapped information is read from the credential store for future requests.

For more information, see Section 69.13, "Working with External Applications."

13.8 Adding Data Controls to Your Portal

Data controls are used to retrieve information from different data sources and create user interface (UI) components within your Framework application. A data control provides you with easy-to-use methods that you can drag and drop onto JSF pages to publish content as ADF components, such as URLs, files, and folders. To add content from the data sources to JSF pages, you must first create connections to the data sources, then use the connections to create data controls based on the repositories.

You can create custom data controls to connect different data sources and add them to your application pages or task flows. For detailed information about data controls, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

Some WebCenter Portal services provide data controls for creating customized visualizations of the services. For information about consuming these data controls in your application, see Section 7.1.3, "Using WebCenter Portal Data Controls."

Exposing Data Controls for Consumption in an Already Deployed Application

The runtime Resource Registry in a Framework application or WebCenter Portal: Spaces contains a `Design Time Data Controls` folder by default. This folder exposes the seeded WebCenter Portal service data controls and any other data controls that were added to the application before it was deployed. To expose a new data control in an already deployed Framework application or WebCenter Portal: Spaces, you must deploy the project containing the data control as an ADF shared library to the runtime application. Once the library containing the data control is accessible to the application, it is displayed in the runtime Resource Registry and can be added to custom Resource Catalogs from there.

For the steps to deploy an application to a Framework application, see "Deploying Applications Using the WLS Administration Console" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. However, while running the Install

Application Assistant, on the Choose targeting style page, select **Install this deployment as a library**.

For the steps to deploy an application to a WebCenter Portal: Spaces instance, see Section 56.2.3, "Rebuilding the Spaces Shared Library List."

14

Visualizing Your Portal Navigation

This chapter shows you how to take the navigation model that has been defined for your WebCenter Portal: Framework application and expose it in the pages of the portal.

This chapter includes the following sections:

- Section 14.1, "Introduction to Navigation Visualization"
- Section 14.2, "Adding Built-in Navigation Task Flows to a Page Template"
- Section 14.3, "Programmatically Adding Navigation to a Page Template"
- Section 14.4, "Using Portal Navigation to Create a Sitemap."

For an introduction to navigation in WebCenter Portal: Framework applications, see Section 11, "Building a Navigation Model for Your Portal."

For information about how to define the navigation model for your portal, see Section 11.2, "Creating a Navigation Model" and Section 11.3, "Adding Resources to a Navigation Model."

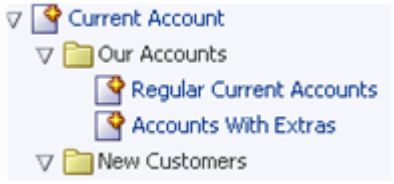
14.1 Introduction to Navigation Visualization

The *navigation visualization* determines how the navigation appears in the portal. For example, navigation can be provided as a set of tabs along the top of each page, or perhaps as a tree structure along the side of the page. Another common navigation visualization is to provide a "master-detail" navigation, for example, tabs along the top of the page, with each tab having additional navigation provided as a tree structure along the side of the page.

Typically, you add navigation visualization to page templates, so that it can be defined in one place and propagated consistently across the whole portal. However, you can also add navigation visualization to individual pages.

WebCenter Portal provides several built-in navigation task flows that you can add to your portal's page templates to visualize the navigation. For more information, see Section 14.2, "Adding Built-in Navigation Task Flows to a Page Template."

The built-in navigation task flows provide a quick way to test your navigation model, but they provide a fairly simple navigation visualization. It is more likely that you will require a more advanced visualization. To do this, you must create your own navigation UI using ADF navigation components and the WebCenter Portal navigation APIs. For more information, see Section 14.3, "Programmatically Adding Navigation to a Page Template."



14.2 Adding Built-in Navigation Task Flows to a Page Template

You can add navigation to a page template by dragging one of the built-in navigation task flows from the Resource Palette onto the appropriate location of the template.

WebCenter Portal provides three navigation task flows to help visualize portal navigation. These are:

- **Navigation - Tree task flow**—Tree navigations display navigational links in a hierarchical structure and often contain multiple-level hierarchies (Figure 14–1). Tree navigations can provide relatively simple access to a complex structure. Typically, a tree-style navigation is displayed on the side of the page.

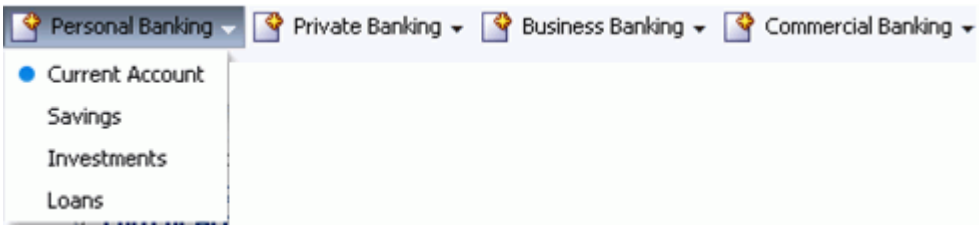


Figure 14–1 Navigation - Tree Task Flow

- **Navigation - Menu task flow**—Menu navigations display navigational links as a series of tabs, menus, bars, buttons, choices, or as a list, usually horizontally across the top or bottom of a page (Figure 14–2). Menu navigation is appropriate when linking to pages and documents, and where the number of items is known, such that there is enough room to display all the options that are available. Menu navigation is useful if you want to have a dropdown menu on the top of your application.

> **Note:** The Navigation Menu task flow can render only two levels of navigation.

Figure 14–2 Navigation - Menu Task Flow

- **Navigation - Breadcrumb task flow**—Breadcrumb navigations display a series of horizontal or vertical links that show users their current position in the navigation hierarchy (Figure 14–3). Breadcrumbs are particularly useful for deep hierarchies, say four levels or more, to enable users to easily navigate back to a specific place in the hierarchy.

Figure 14–3 Navigation - Breadcrumb Task Flow

Additional navigation task flows are available to download from Oracle Technology Network, at:

http://www.oracle.com/technetwork/middleware/webcenter/samples-196325.zip

The zip file contains the following navigation task flows:

- List Navigation—Renders a navigation model in a vertical list format. Folders and their items are rendered as dropdown menus. Empty folders are not rendered.
- Menu with Links Navigation—Renders a navigation model in a horizontal menu format. For top level navigation items, folders are rendered as dropdown menus, navigable links with no children are rendered as a top level link. Empty folders are not rendered.
- Tree Navigation—Renders a navigation model in a vertical collapsed tree format.

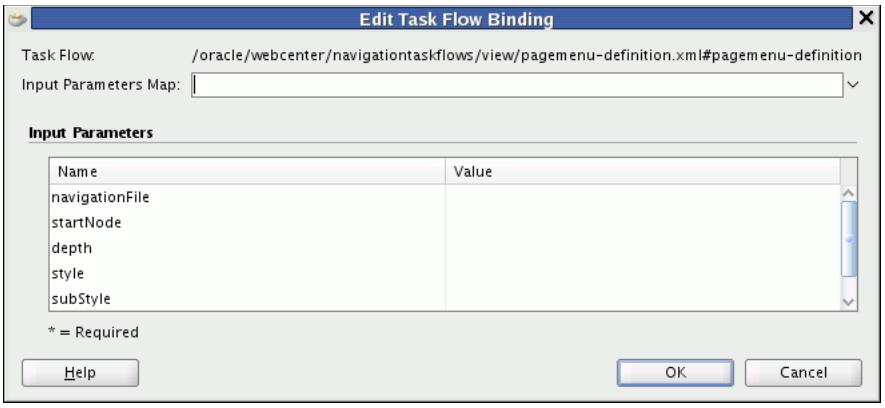
Download the zip file and extract its contents locally. You can then upload one or more of the EAR files to your application, as described in Section 17.4.4, "How to Upload a Resource Using the Resource Manager."

This section includes the following subsections:

- Section 14.2.1, "How to Add a Navigation Task Flow to a Page Template"
- Section 14.2.2, "Navigation Task Flow Parameters"
- Section 14.2.3, "What You May Need to Know About Navigation Task Flow Style Classes"

14.2.1 How to Add a Navigation Task Flow to a Page Template

The steps for adding a navigation task flow are the same for all navigation task flows.



To add a navigation task flow:

1. Open the page template to which you want to add the navigation task flow.
2. In the Resource Palette, expand the **WebCenter Portal - Services Catalog**. Under **Task Flows**, select the desired navigation task flow and drag it onto the desired location of the template.
3. From the menu that displays, choose **Region** to open the Edit Task Flow Binding dialog.

   You may be prompted to add the Navigation Task Flows library to the project. Confirm by clicking **Add Library**.
4. In the Edit Task Flow Binding dialog (Figure 14–4), if necessary, specify parameter values for the task flow. For more information, see Section 14.2.2, "Navigation Task Flow Parameters."

> **Note:** You can use EL expressions as values of any of the navigation task flow binding parameters. For more information, see Appendix G, "Expression Language Expressions."

Figure 14–4 The Edit Task Flow Binding dialog for the Navigation - Menu Task Flow

5. Click **OK**.

14.2.2 Navigation Task Flow Parameters

Table 14–1 lists and describes task flow binding parameters applicable to the Navigation - Tree task flow.

Note: You can use EL expressions for the values of any of the navigation task flow binding parameters. For more information, see Appendix G, "Expression Language Expressions."

Table 14–1 Navigation - Tree Task Flow Binding Parameters

Parameter	Default Value	Description
navigationFile	/oracle/webcenter/portalapp/navigations/default-navigation-model	The navigation model to associate with this task flow. You can provide the actual navigation model definition file, omitting the .xml, for example: /oracle/webcenter/portalapp/navigations/myNavigationModel You can also enter an EL expression, for example: #{navigationContext.defaultNavigationModel}
startNode	/	The point in the navigation model at which to start the navigation. For example: ■ To use a specific page as the starting point, or root, of the navigation, enter the path to the page, for example: pages_home ■ To use the currently selected page as the root of the navigation, use the following EL expression: #{navigationContext.navigationModel['modelPath=*path*'].currentSelection.prettyUrl} ■ To use a particular level of the path to the currently selected page as the root, use the following EL expression: #{navigationContext.navigationModel['modelPath=*path*'].currentSelection.prettyUrlPath[*level*]} where: *path* is the path to the navigation model XML file (omitting the trailing .xml), for example: /oracle/webcenter/portalapp/navigations/myNavigationModel *level* is the level in the path at which to start.
showRoot	none	Specifies whether to render the starting point of the navigation (root) in the tree. Enter one of the following: ■ none—Do not render the root ■ node—Render the root ■ box—Render the root as the header in a box

Table 14–1 (Cont.) Navigation - Tree Task Flow Binding Parameters

Parameter	Default Value	Description
`depth`	`1`	The number of levels shown when the tree is initially rendered. Enter one of the following: ■ `1`—Show top level nodes only; all other notes are initially collapsed ■ `2`—Expand the first level of child nodes ■ `3`—Expand the first and second level of child nodes ■ `all`—Expand all nodes **Note:** This parameter applies only if the `style` parameter is set to `collapsed`. If the `style` parameter is set to `expanded`, then all nodes are shown regardless of the value of this parameter.
`style`	`collapsed`	The style of the navigation. Enter one of the following: ■ `collapsed`—Render the given levels (as specified by the `depth` parameter) as initially collapsed ■ `expanded`—Render all tree nodes, expanded to show all children ■ `list`—Render a flat list of top level resources. If any of the top-level resources are folders, the content of those folders is provided in dropdown menus. **Note:** Entering `list` overrides the `depth` and `showRoot` parameters.
`showIcons`	`true`	Specifies whether to render icons for each resource. Enter `true` or `false`.
`navigationEditMode`	Not used	Not used

Table 14–2 lists and describes task flow binding parameters applicable to the Navigation - Menu task flow.

Table 14–2 Navigation - Menu Task Flow Binding Parameters

Parameter	Default Value	Description

`navigationFile`	`/oracle/webcenter/portalapp/navigations/default-navigation-model`	The navigation model to associate with this task flow. You can provide the actual navigation model definition file, omitting the `.xml`, for example:
		`/oracle/webcenter/portalapp/navigations/myNavigationModel`
		You can also enter an EL expression, for example:
		`#{navigationContext.defaultNavigationModel}`

`startNode`	`/`	The point in the navigation model at which to start the navigation.
		For example:
		■ To use a specific page as the starting point, or root, of the navigation, enter the path to the page, for example:
		`pages_home`
		■ To use the currently selected page as the root of the navigation, use the following EL expression:
		`#{navigationContext.navigationModel['modelPath=`*`path`*`'].currentSelection.prettyUrl}`
		■ To use a particular level of the path to the currently selected page as the root, use the following EL expression:
		`#{navigationContext.navigationModel['modelPath=`*`path`*`'].currentSelection.prettyUrlPath[`*`level`*`]}`
		where:
		`path` is the path to the navigation model XML file (omitting the trailing `.xml`), for example:
		`/oracle/webcenter/portalapp/navigations/myNavigationModel`
		`level` is the level in the path at which to start.

`depth`	Not used	Not used

Table 14–2 (Cont.) Navigation - Menu Task Flow Binding Parameters

Parameter	Default Value	Description
`style`	`menu`	The style for rendering the first level of resources. Enter one of the following: `tabs`, `bar`, `buttons`, `choice`, `list`, `menu` **Notes:** ■ If the resource being rendered is non-navigable, for example, a folder, then it cannot be displayed as a tab, bar, button, choice, or list. It can be displayed only if the `style` parameter is set to `menu`. ■ If `style` is set to `menu`, then a folder is rendered with one level of dropdown menu. ■ If `style` is set to `menu` and `subStyle` is set to `menu`, then a folder is rendered with two levels of dropdown menu. ■ If a navigable item is rendered with `style` and `subStyle` set to `menu`, the item is rendered twice, once as a dropdown menu, and once as a link to the item itself.
`subStyle`	`menu`	The style for rendering the second level of navigation items if applicable. If `style` is set to `menu`, enter `menu` or `donotdisplay`. If `style` is set to any other value, enter `tabs`, `bar`, `buttons`, `choice`, `list`, or `donotdisplay`.
`showIcons`	`true`	Specifies whether to render icons for each resource. Enter `true` or `false`.

Table 14–3 lists and describes task flow binding parameters applicable to the Navigation - Breadcrumb task flow.

Table 14–3 Navigation - Breadcrumb Task Flow Binding Parameters

Parameter	Default Value	Description
navigationFile	/oracle/webcenter/portalapp/navigations/default-navigation-model	The navigation model to associate with this task flow. You can provide the actual navigation model definition file, omitting the .xml, for example: /oracle/webcenter/portalapp/navigations/myNavigationModel You can also enter an EL expression, for example: #{navigationContext.defaultNavigationModel}
startNode	/	The point in the navigation model at which to start the navigation. For example: ■ To use a specific page as the starting point, or root, of the navigation, enter the path to the page, for example: pages_home ■ To use the currently selected page as the root of the navigation, use the following EL expression: #{navigationContext.navigationModel['modelPath=*path*'].currentSelection.prettyUrl} ■ To use a particular level of the path to the currently selected page as the root, use the following EL expression: #{navigationContext.navigationModel['modelPath=*path*'].currentSelection.prettyUrlPath[*level*]} where: *path* is the path to the navigation model XML file (omitting the trailing .xml), for example: /oracle/webcenter/portalapp/navigations/myNavigationModel *level* is the level in the path at which to start.
showRoot	false	Specifies whether to show the start node (root) in the breadcrumbs. Enter true or false.
style	horizontal	Specifies whether to display breadcrumbs horizontally or vertically. Enter horizontal or vertical.

14.2.3 What You May Need to Know About Navigation Task Flow Style Classes

WebCenter Portal provides a style class for each of the navigation task flows that you can use to change the appearance of the task flows. To use these style classes, add them to the skin CSS file used by the application, for example portal-skin.css.

- WCTreeNav—Use to change the appearance of the Navigation - Tree task flow
- WCMenuNav—Use to change the appearance of the Navigation - Menu task flow
- WCBreadcrumbNav—Use to change the appearance of the Navigation - Breadcrumb task flow.

Example 14–1 shows what to add to the skin CSS file to change the background color for the Navigation - Menu task flow.

Example 14–1 Changing the Background Color of the Navigation - Menu Task Flow

```
.WCMenuNav af|menuBar {
  background-color: red;
}
```

For more information about skins, see Chapter 15, "Creating and Managing Skins."

14.3 Programmatically Adding Navigation to a Page Template

If the built-in navigation task flows do not meet your requirements, you can use the APIs provided with WebCenter Portal to create your own UI for your navigation model.

Note: Any task flow that uses the navigation model to trigger navigation within an application must include a `parent-action` activity, named `wcnav_parentAction`, in the task flow definition that propagates the `wcnav_outcome` to the root level, as follows:

```
<parent-action id="wcnav_parentAction">
  <root-outcome>wcnav_outcome</root-outcome>
</parent-action>
```

WebCenter Portal provides two sets of APIs for adding navigation to your portal:

- Expression Language (EL) APIs—Use EL expressions to obtain the navigation model and navigation resources.
- REST APIs—Use standard HTTP methods to point to the navigation model and navigation resources, returning a standard representation of any retrieved object. REST APIs can be used when using client-side programming languages, for example JavaScript + HTML, or environments, for example an iPhone.

This section includes the following subsections:

- Section 14.3.1, "Using the Navigation Expression Language APIs"
- Section 14.3.2, "Using the Navigation REST APIs"

14.3.1 Using the Navigation Expression Language APIs

WebCenter Portal provides a set of expression language (EL) APIs that you can use to obtain the navigation model and represent that navigation model as a runtime model. The runtime models can be bound directly to ADF Faces navigation components.

The available navigation EL expressions are listed in full in Section G.5, "ELs Related to Navigation."

This section includes the following subsections:

- Section 14.3.1.1, "Introduction to the Navigation Context"
- Section 14.3.1.2, "Introduction to the Navigation Runtime Model"
- Section 14.3.1.3, "Introduction to the Navigation Resource"
- Section 14.3.1.4, "How to Render the Navigation Model as a List of Links"
- Section 14.3.1.5, "How to Render the Navigation Model as a Tree"
- Section 14.3.1.6, "How to Render the Navigation Model as a Three-Level Menu"

- Section 14.3.1.7, "How to Render the Navigation Model as Breadcrumbs"
- Section 14.3.1.8, "How to Render Master-Detail Navigation"

> **Note:** This section includes some examples of how to use the navigation EL APIs. For a full working example, see the default page templates (`pageTemplate_globe.jspx` and `pageTemplate_swooshy.jspx`) created when you create an application using the WebCenter Portal: Framework Application template.

14.3.1.1 Introduction to the Navigation Context

The Navigation Context is the entry point to access all navigation elements within your system. Specifically, it enables you to access navigation models via preference, state, and direct reference, as well as providing the hooks to create custom UI to actually navigate to the resource.

Navigation Model Access

- Default navigation model (preference)—This is the model specified by the ADF preference `oracle.webcenter.portalapp.navigation.model` in the `adf-config.xml` file. This enables you to define the general model to be used throughout your application and enables you to change the value in one place rather than having to go to each page and page template to set the value. The EL expression to retrieve the default navigation model is:

  ```
  #{navigationContext.defaultNavigationModel}
  ```

  > **Note:** For more information about how to set the `oracle.webcenter.portalapp.navigation.model` preference, see Section 11.4, "Selecting the Default Navigation Model."

- Current navigation model (state)—This model is the one used to navigate to the current view and, if it is not set, returns the default navigation model. Your application may contain multiple navigation models. The EL expression to retrieve the current navigation model is:

  ```
  #{navigationContext.currentNavigationModel}
  ```

  Using this expression enables you to have a single value within a page template (for example, for displaying breadcrumbs) and have it display the correct value without having to select a specific navigation model.

- Direct navigation model access (direct reference)—You can also select a specific navigation model by passing in the path to the XML definition of the model. The EL expression to retrieve a specific navigation model is:

  ```
  #{navigationContext.navigationModel['modelPath=path']
  ```

  where *`path`* is the path to the navigation model definition file, for example:

  ```
  #{navigationContext.navigationModel['modelPath=/oracle/webcenter/portalapp/navigations/myNavigation']}
  ```

  > **Note:** You do not need to include the `.xml` file name extension.

Resource Navigation

Use these ELs for core bean operations for binding the navigation model to the UI component's `actionListener` attribute. For example:

```
#{navigationContext.processAction}
```

Examples

Example 14–2 creates a simple tree UI using the Navigation Context to access the current navigation model and render the tree using `<af:outputText/>`.

Example 14–2 Simple Tree Navigation UI

```
<af:tree var="node"
    value="#{navigationContext.currentNavigationModel.treeModel['startNode=/,
    includeStartNode=true,
    depth=1']}"
    id="t1">
  <f:facet name="nodeStamp">
    <af:outputText value="#{node.title}" id="ot1"/>
  </f:facet>
</af:tree>
```

Example 14–3 uses the Navigation Context's `processAction` listener to handle navigation for an ADF `commandImageLink` component, passing in the current node as the parameter called *node* as an attribute to the `actionListener`.

Example 14–3 Binding the Navigation Model to the UI Component

```
<af:tree var="node"
    value="#{navigationContext.currentNavigationModel.treeModel['startNode=/,
           includeStartNode=true,
           depth=1']}"
    id="t1">
  <f:facet name="nodeStamp">
    <af:commandImageLink text="#{node.title}"
        id="sm_c1b"
        actionListener="#{navigationContext.processAction}"
        inlineStyle="#{node.selected ? 'font-weight:bold;' : ''}">
      <f:attribute name="node" value="#{node}"/>
    </af:commandImageLink>
  </f:facet>
</af:tree>
```

14.3.1.2 Introduction to the Navigation Runtime Model

The Navigation Runtime Model exposes the underlying XML definition as runtime models, as well as providing direct access to individual nodes. The runtime models take into account such factors as security and visibility to produce a session-specific representation that can be bound to UI objects.

Note: Note the difference between the *navigation model* that you create to define the content, structure, and metadata of the navigation and the *navigation **runtime** model* that determines how the navigation model behaves at runtime.

You can access the whole model by using the default runtime model (`defaultTreeModel`, `defaultListModel`, `defaultMenuModel`, and `defaultSiteMap`), or access a specific sub-tree using the various parameters when creating the runtime model. For example:

```
#{navigationContext.defaultNavigationModel.menuModel['startNode=home,
    includeStartNode=false, depth=2']}
```

For more information about the underlying ADF Faces MenuModel, TreeModel, and ListModel, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Model Access

You can create the following runtime models based on the underlying navigation model:

- UI Models
  - Tree model

    ```
    #{navigationContext.defaultNavigationModel.defaultTreeModel}
    #{navigationContext.defaultNavigationModel.treeModel['parameters']}
    ```

  - Menu model

    ```
    #{navigationContext.defaultNavigationModel.defaultMenuModel}
    #{navigationContext.defaultNavigationModel.menuModel['parameters']}
    ```

  - List model

    ```
    #{navigationContext.defaultNavigationModel.defaultListModel}
    #{navigationContext.defaultNavigationModel.listModel['parameters']}
    ```

- Search Engine Model
  - Sitemap

    ```
    #{navigationContext.defaultNavigationModel.defaultSiteMap}
    #{navigationContext.defaultNavigationModel.siteMap['parameters']}
    ```

Resource (or Node) Access

You can access specific nodes within the navigation model using the follow EL expressions:

- `#{navigationContext.defaultNavigationModel.currentSelection}`
- `#{navigationContext.defaultNavigationModel.rootNode}`
- `#{navigationContext.defaultNavigationModel.node['path']}`

Examples

Example 14–4 renders the current navigation model's menu model as a breadcrumb.

Example 14–4 Rendering the Navigation Model as a Menu Model

```
<af:breadCrumbs id="bc1"
    var="node"
    value="#{navigationContext.currentNavigationModel.defaultMenuModel}">
  <f:facet name="nodeStamp">
    <af:commandNavigationItem id="cni1"
        text="#{node.title}"
```

```
        actionListener="#{navigationContext.processAction}"
        partialSubmit="true">
      <f:attribute name="node" value="#{node}"/>
    </af:commandNavigationItem>
  </f:facet>
</af:breadCrumbs>
```

Example 14–5 produces a Sitemap for the application based on the default navigation model.

Example 14–5 Producing a Sitemap

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"  version="2.1"
    xmlns:f="http://java.sun.com/jsf/core">
  <jsp:directive.page contentType="text/xml;charset=UTF-8" />
  <f:view>
    ${navigationContext.defaultNavigationModel.defaultSiteMap}
  </f:view>
</jsp:root>
```

For more information about Sitemaps, see Section 14.4, "Using Portal Navigation to Create a Sitemap."

14.3.1.3 Introduction to the Navigation Resource

The Navigation Resource provides access to individual properties against each node within the navigation model. These fall into the following categories:

- **Attributes**—Common properties that the user can specify against any navigation element and are used for rendering the node on the page, including:
  - **Title**—The title displayed for the node when the navigation model is rendered on a page.
  - **AccessKey**—A key mnemonic (single character) that users can enter to access the node without using the mouse.
  - **Description**—A description of the node.
  - **IconURI**—An icon to visually represent the node. This is displayed next to the Title when the navigation model is rendered on a page.
  - **Subject**—Keywords to facilitate searching of the node.
  - **Target**—The location on the container page where the node is displayed when it is selected, either in the same browser window (`_self`), a new window (`_blank`), or a popup (`_popup`), or any other location supported by the navigation UI.
  - **ToolTip**—Text that displays to provide additional information about the node when users hover the mouse over the Title.
  - **Modified**—The date of the last modification of the node. This attribute is used for Sitemap creation.
  - **ChangeFrequency**—How frequently the node is likely to change: always, hourly, daily, weekly, monthly, yearly, never. This attribute is used for Sitemap creation.
  - **Significance**—The priority of this resource relative to other nodes in the navigation model, within the range 0.0 to 1.0. This attribute is used for Sitemap creation.

  - **ExternalId**—An ID to enable a direct reference to any node in the navigation model from a static link in the page.

- **Parameters**—User-defined properties that are specific to each node. These are name/value pairs and can contain any value.
- **State**—Built-in properties that you can query and use to navigate to the node. For example:
  - Type of node, for example, folder or separator
  - Whether the node is navigable
  - The path to the node
  - Parent, child, or sibling node access
  - Whether the node is the currently selected node within the navigation model or on the selected node's path

  For a complete list, see Section G.5, "ELs Related to Navigation."

Examples

Example 14–6 renders an ADF `commandImageLink` component with various attributes.

Example 14–6 Rendering a commandImageLink with Attributes

```
<af:commandImageLink text="#{node.title}"
    id="cil1"
    actionListener="#{navigationContext.processAction}"
    shortDesc="#{node.attributes['ToolTip']}"
    accessKey="#{node.attributes['AccessKey']}"
    inlineStyle="#{node.selected ? 'font-weight:bold;' : ''}">
  <f:attribute name="node" value="#{node}"/>
</af:commandImageLink>
```

Example 14–7 accesses values passed from a resource to the corresponding page through parameters.

Example 14–7 Passing Node Values to Page Parameters

homePageDef.xml

```
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
    version="11.1.1.55.96" id="homePageDef"
    Package="oracle.webcenter.portalapp.pages">
  <parameters>
    <parameter id="NavigationParameter"
        value="#{navigationContext.currentNavigationModel.currentSelection.parameters
            ['MyNavParam']}"/>
  </parameters>
```

Example 14–8 conditionally displays breadcrumb links based on whether you can navigate to the node. It also bases the UI component on the type of the node.

Example 14–8 Conditionally Displaying Navigation Nodes

```
<af:breadCrumbs id="bc1"
                var="node"
                value="#{navigationContext.currentNavigationModel.defaultMenuModel}">
  <f:facet name="nodeStamp">
```

```
    <af:switcher facetName="#{node.navigable}" id="swn1">
      <f:facet name="true">
        <af:commandNavigationItem id="cni1" text="#{node.title}"
                                  actionListener="#{navigationContext.processAction}"
                                  partialSubmit="true">
          <f:attribute name="node" value="#{node}"/>
        </af:commandNavigationItem>
      </f:facet>
      <f:facet name="false">
        <af:outputText value="#{node.title}" rendered="#{!node.separator}" id="ot3"/>
      </f:facet>
    </af:switcher>
  </f:facet>
</af:breadCrumbs>
```

14.3.1.4 How to Render the Navigation Model as a List of Links

One common way to visualize a portal's navigation is as a list of links. Clicking a link navigates to the resource associated with it.

Example 14–9 retrieves the list model for the current navigation model and renders it vertically on the page. The code iterates through the navigation model, binding each node in turn to an ADF `commandImageLink` component. If a node contains children, a second iterator renders those children on the page. If a node is not navigable, it is not rendered as a link. The currently selected node is displayed in bold.

Example 14–9 Navigation as a List of Links

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:iterator id="i1"
               value="#{navigationContext.currentNavigationModel.listModel['startNode=/,
                     includeStartNode=false']}"
               var="node">
    <af:panelGroupLayout layout="vertical">
      <af:commandImageLink id="cil2" text="#{node.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node.navigable}"
                           inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandImageLink>
      <af:iterator id="i2" value="#{node.children}" var="node2">
        <af:panelList id="pl1">
          <af:commandImageLink id="cil3" text="#{node2.title}"
                               actionListener="#{navigationContext.processAction}"
                               action="pprnav"
                               icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                               disabled="#{not node2.navigable}"
                               inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
            <f:attribute name="node" value="#{node2}"/>
          </af:commandImageLink>
        </af:panelList>
      </af:iterator>
    </af:panelGroupLayout>
  </af:iterator>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

14.3.1.5 How to Render the Navigation Model as a Tree

Another common way to visualize portal navigation is as a tree structure. A navigation tree is typically listed down the side of the page, so it is a useful way of displaying the entire navigation hierarchy. Users can navigate immediately to any node in the navigation. The advantage of using a tree structure over a simple list of links, is that users can expand and collapse the different nodes of the navigation model.

To include a tree structure in your page template, you can bind the ADF Faces `tree` navigation component to your navigation model. Example 14–10 shows how to do this.

Example 14–10 Navigation as a Tree

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp2" height="20px"/>
  <af:tree id="tree1" var="node" initiallyExpanded="true"
           value="#{navigationContext.currentNavigationModel.treeModel['includeStartNode=false']}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node.navigable}"
                           inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

14.3.1.6 How to Render the Navigation Model as a Three-Level Menu

You can also render your navigation as a menu. In a menu, the top level of navigation is displayed. When the user hovers the mouse over a particular node, if that node has children, they are displayed as a popup menu.

Figure 14–11 retrieves the list model for the current navigation model and renders it vertically on the page. The code iterates through the navigation model. If a node contains children, then a second iterator iterates through those children. Nodes without children are rendered as menu items. In the second level of the navigation model, if any of the nodes have children, then a third iterator is executed. Again, nodes without children are rendered as menu items. At the third level of the navigation mode, nodes are rendered as menu items. Non-navigable nodes are not rendered as links. The currently selected node is displayed in bold.

Example 14–11 Navigation as a Menu

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:menuBar id="mb1">
    <af:iterator id="i1"
                 value="#{navigationContext.currentNavigationModel.listModel['startNode=/,
                       includeStartNode=false']}"
                 var="node">
      <af:switcher id="s1"
                   facetName="#{empty node.children ? 'leafNode' : 'parentNode'}">
        <f:facet name="parentNode">
          <af:menu id="m1" text="#{node.title}"
```

```
              inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
          <af:iterator id="i2" value="#{node.children}"
                       var="node2">
            <af:switcher id="s2"
                         facetName="#{empty node2.children ? 'leafNode' : 'parentNode'}">
              <f:facet name="parentNode">
                <af:menu id="m2" text="#{node2.title}"
                         inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
                  <af:iterator id="i3" value="#{node2.children}"
                               var="node3">
                    <af:commandMenuItem id="cml3"
                                        text="#{node3.title}"
                                        actionListener="#{navigationContext.processAction}"
                                        action="pprnav"
                                        icon="#{node3.attributes[pageFlowScope.tnBean.iconKey]}"
                                        disabled="#{not node3.navigable}"
                                        inlineStyle="#{node3.onSelectedPath ?
                                                       'font-weight:bold;' : ''}">
                      <f:attribute name="node" value="#{node3}"/>
                    </af:commandMenuItem>
                  </af:iterator>
                </af:menu>
              </f:facet>
              <f:facet name="leafNode">
                <af:commandMenuItem id="cml1"
                                    text="#{node2.title}"
                                    actionListener="#{navigationContext.processAction}"
                                    action="pprnav"
                                    icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                                    disabled="#{not node2.navigable}"
                                    inlineStyle="#{node2.onSelectedPath ?
                                                   'font-weight:bold;' : ''}">
                  <f:attribute name="node" value="#{node2}"/>
                </af:commandMenuItem>
              </f:facet>
            </af:switcher>
          </af:iterator>
        </af:menu>
      </f:facet>
      <f:facet name="leafNode">
        <af:commandMenuItem id="cml2" text="#{node.title}"
                            actionListener="#{navigationContext.processAction}"
                            action="pprnav"
                            icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                            disabled="#{not node.navigable}"
                            inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
          <f:attribute name="node" value="#{node}"/>
        </af:commandMenuItem>
      </f:facet>
    </af:switcher>
  </af:iterator>
 </af:menuBar>
 <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

14.3.1.7 How to Render the Navigation Model as Breadcrumbs

To provide users with a quick way of orientating themselves within the portal navigation, you can provide a trail of breadcrumbs on the page. Breadcrumbs show the current location in the portal and the path taken through the navigation to get

there. Users can then quickly return to any point along that path. Breadcrumbs are typically used on a page in addition to other forms of navigation.

To include breadcrumbs in your page template, you can bind the ADF Faces `breadCrumbs` navigation component to your navigation model. Example 14–12 shows how to do this.

Example 14–12 Navigation as Breadcrumbs

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <af:breadCrumbs id="bc1" var="node"
                  value="#{navigationContext.currentNavigationModel.menuModel[
                        'includeStartNode=false']}">
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:breadCrumbs>
  <af:spacer id="sp2" height="20px"/>
</af:panelGroupLayout>
```

14.3.1.8 How to Render Master-Detail Navigation

Often portals provide a "master-detail" navigation visualization, for example, as tabs along the top of the page, with each tab having additional navigation provided as a tree structure along the side of the page.

The master-detail navigation in Example 14–13 uses the same navigation model for the master and detail navigation. The master navigation renders the top level of the navigation model as a list of links along the top of the page. The detail navigation renders the children of the currently selected top level node as a tree.

Example 14–13 Master-Detail Navigation Using a Single Navigation Model

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <!-- Master -->
  <af:navigationPane id="np1" var="node" hint="bar" level="1"
                     value="#{navigationContext.navigationModel[
                           'modelPath=/oracle/webcenter/portalapp/navigations/master-detail.xml']
                           .defaultMenuModel}">
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}"
                                inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">

        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:navigationPane>
  <af:spacer id="sp2" height="20px"/>
  <!-- Setup the parameters for detail query -->
```

```
  <c:set value="startNode=/${navigationContext.navigationModel[
              'modelPath=/oracle/webcenter/portalapp/navigations/master-detail.xml']
              .currentSelection.prettyUrlPath[1]}, includeStartNode=false"
         var="currSel" scope="session"/>
  <!-- Detail -->
  <af:tree id="tree1" var="node2" initiallyExpanded="true"
           value="#{navigationContext.navigationModel[
                 'modelPath=/oracle/webcenter/portalapp/navigations/master-detail.xml']
                 .treeModel[currSel]}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node2.title}"
                           actionListener="#{navigationContext.processAction}"
                           action="pprnav"
                           icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                           disabled="#{not node2.navigable}"
                           inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node2}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

The example above can also be written to use two different navigation models, one for the master navigation, and one for the detail navigation. Example 14–14 shows how.

Example 14–14 Master-Detail Navigation Using Multiple Navigation Models

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:spacer id="sp1" height="20px"/>
  <!-- Master -->
  <af:navigationPane id="np1" var="node" hint="bar" level="1"
                     value="#{navigationContext.navigationModel[
                           'modelPath=/oracle/webcenter/portalapp/navigations/master.xml']
                           .defaultMenuModel}">
    <f:facet name="nodeStamp">
      <af:commandNavigationItem id="cil1" text="#{node.title}"
                                actionListener="#{navigationContext.processAction}"
                                action="pprnav"
                                icon="#{node.attributes[pageFlowScope.tnBean.iconKey]}"
                                disabled="#{not node.navigable}"
                                inlineStyle="#{node.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node}"/>
      </af:commandNavigationItem>
    </f:facet>
  </af:navigationPane>
  <af:spacer id="sp2" height="20px"/>
  <!-- Setup the parameters for detail query -->
  <c:set value="startNode=/${navigationContext.navigationModel[
              'modelPath=/oracle/webcenter/portalapp/navigations/master.xml']
              .currentSelection.prettyUrlPath[1]}, includeStartNode=false"
         var="currSel" scope="session"/>
  <!-- Detail -->
  <af:tree id="tree1" var="node2" initiallyExpanded="true"
                      value="#{navigationContext.navigationModel[
                            'modelPath=/oracle/webcenter/portalapp/navigations/master.xml']
                            .treeModel[currSel]}">
    <f:facet name="nodeStamp">
      <af:commandImageLink id="cil2" text="#{node2.title}"
                           actionListener="#{navigationContext.processAction}"
```

```
                          action="pprnav"
                          icon="#{node2.attributes[pageFlowScope.tnBean.iconKey]}"
                          disabled="#{not node2.navigable}"
                          inlineStyle="#{node2.onSelectedPath ? 'font-weight:bold;' : ''}">
        <f:attribute name="node" value="#{node2}"/>
      </af:commandImageLink>
    </f:facet>
  </af:tree>
  <af:spacer id="sp3" height="20px"/>
</af:panelGroupLayout>
```

14.3.2 Using the Navigation REST APIs

Oracle WebCenter Portal provides REST APIs to access and manipulate the navigation model of your application. Use the navigation REST APIs to create your own interface for visualizing the navigation model. You would typically use REST when creating Rich Internet Applications that are client-side scripted and require the ability to interact with data from a server-side application. For example, the WebCenter Portal iPhone App uses WebCenter Portal REST APIs to interact with a WebCenter Portal: Spaces application.

For an introduction to the REST APIs, see Chapter 54, "Using Oracle WebCenter Portal REST APIs."

The starting point for using the navigation REST APIs, as with other WebCenter Portal REST APIs, is to send a `GET` request to the Resource Index:

```
http://host:port/rest/api/resourceIndex
```

The response to this request provides the entry point URI (`href`) for the navigation REST APIs, identified by the link element with the following `resourceType`:

```
urn:oracle:webcenter:navigations
```

Sending a `GET` request to this entry point URI returns a list of navigation models within the application, for example:

```
<sitestructure>
  ...
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/default-navigation
  </navigation-list>
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/admin-navigation
  </navigation-list>
  <navigation-list>
    oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed/
    navigations/myNavigation
  </navigation-list>
  ...
</sitestructure>
```

Using this information, you can start to retrieve information about specific navigation models and the resources within them, using the URIs listed in Table 14–4.

Table 14–4 REST URI Model for Navigation

REST URI	Returns
`.../api/navigations`	All navigation models in the application.
`.../api/navigations/default-navigation-model`	The properties of the default navigation model.
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*	The properties of the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources`	All root resources under the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*	The specified resource (*`resourceID`*) from the specified navigation model (*`modelId`*).
`...api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*`/children`	A navigation tree listing all the children of the specified resource (*`resourceId`*) from the specified navigation model (*`modelId`*).
`.../api/navigations/`*`pathToModel`*`/`*`modelId`*`/resources/`*`pathToResource`*`/`*`resourceId`*`/children?depth=`*`dep`*	A navigation tree listing the children of the specified resource (*`resourceId`*) from the specified navigation model (*`modelId`*) up to a specified level (*`dep`*).

Each navigable resource has a `prettyURL` element that you can use to drill down further in the navigation model hierarchy.

14.4 Using Portal Navigation to Create a Sitemap

When a search engine crawls a web site, it parses the HTML for standard links (for example, `<a href="url">text</a>`). However, ADF-based web sites generate links as JavaScript, which when executed in a browser, cause the page change or navigation. These JavaScript links cannot be interpreted by search engines.

Some popular search engines, such as Google and Bing, support Sitemaps. A Sitemap is an XML file that lists URLs for a site along with additional metadata about each URL (for example, when it was last updated, how often it usually changes, and how important it is relative to other URLs in the site), so that search engines can more intelligently crawl the site. By submitting a Sitemap to a search engine, or by referencing the Sitemap in your `robots.txt` file, you can feed a list of pages into the search engine for indexing.

For more information about Sitemaps, go to:

`http://sitemaps.org/`

WebCenter Portal applications can provide a Sitemap URL that you can register with search engines to get them to index your set of pages. If the user-agent of the search engine matches one supported by ADF, the HTML is returned for the request instead of the JavaScript.

Note: Currently, the only user-agent registered with ADF is Google's googlebot.

You can create a Sitemap for your application based on a navigation model, as shown in Example 14–15.

Example 14–15 Creating a Sitemap

```
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          Xmlns:f=http://java.sun.com/jsf/core">
  <jsp:directive.page contentType="text/xml;charset=UTF-8" />
  <f:view>
    ${navigationContext.defaultNavigationModel.defaultSiteMap}
  </f:view>
</jsp:root>
```

15

Creating and Managing Skins

Skins define the appearance of an application. You can use skins to achieve some level of consistency across pages in your application, and to get your company's preferred look and feel.

This chapter describes how to create and manage skins. It includes the following sections:

- Section 15.1, "Overview of Skins"
- Section 15.2, "Creating a Skin in JDeveloper"
- Section 15.3, "Editing portal-skin.css"
- Section 15.4, "Enabling Runtime Administration of Skins"
- Section 15.5, "Applying Skins to WebCenter Portal: Framework Applications"
- Section 15.6, "How to Create and Manage Spaces Skins"
- Section 15.7, "Deploying a Skin as a Separate Shared Library"
- Section 15.8, "Conditionally Changing Skins for Users"
- Section 15.9, "Troubleshooting Problems with Skins"
- Section 15.10, "Files Relates to Skins"

15.1 Overview of Skins

Skins help you define the colors, fonts, images, and some dimensional details like the height and width of your application components to represent your company's preferred look and feel.

Skins are based on the Cascading Style Sheet (CSS) specification. A skin is a CSS file containing various skin selectors that define the styles of your application components. You can adjust the look and feel of any component by changing its style-related properties. Use of a skin in an application helps you to avoid specifying styles for each component individually or inserting a style sheet on each page. Every component automatically uses the styles defined in the skin. Skins help you to change an application's appearance without changing the portal pages themselves.

ADF Faces skins drive the look and feel of WebCenter Portal applications. Out-of-the-box, ADF Faces provides various built-in skins, such as `fusion`, `blafplus-rich`, `blafplus-medium`, and `simple`. By default, Framework applications use the `portal` skin, which extends the `fusionFx-v1.desktop` skin.

If the built-in skin available in your application does not meet your business requirements, you can create your own custom skins in Oracle JDeveloper. While

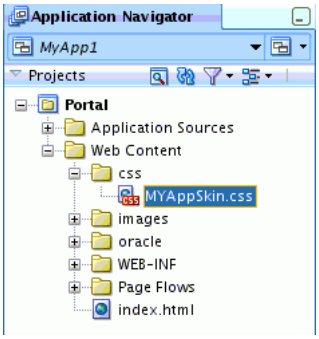
working with custom skins, you may need to edit the following skin-related files: `adf-config.xml`, `trinidad-config.xml`, and `trinidad-skins.xml`. For information about these files, see Section 15.10, "Files Relates to Skins."

Oracle WebCenter Portal supports runtime administration of skins to help application users continue developing a portal even after the application has been deployed. When you enable runtime administration, authorized application users can create and manage skins at runtime, without redeploying the application. You can bring runtime-created skins back into design time, edit them, and upload them into the deployed application. For information, see Section 15.4, "Enabling Runtime Administration of Skins."

In JDeveloper, you can create new skins for use in WebCenter Portal's Spaces application. In JDeveloper, you can also edit skins originally created in Spaces, and upload the edited skins back into Spaces. For information, see Section 15.6, "How to Create and Manage Spaces Skins."

15.2 Creating a Skin in JDeveloper

By default, Framework applications use the `portal` skin, which is defined in the `portal-skin.css` file. You can easily edit this file to suit your requirements. However, if you want to use a custom skin in your application, you must create a CSS file and define the required skin selectors.



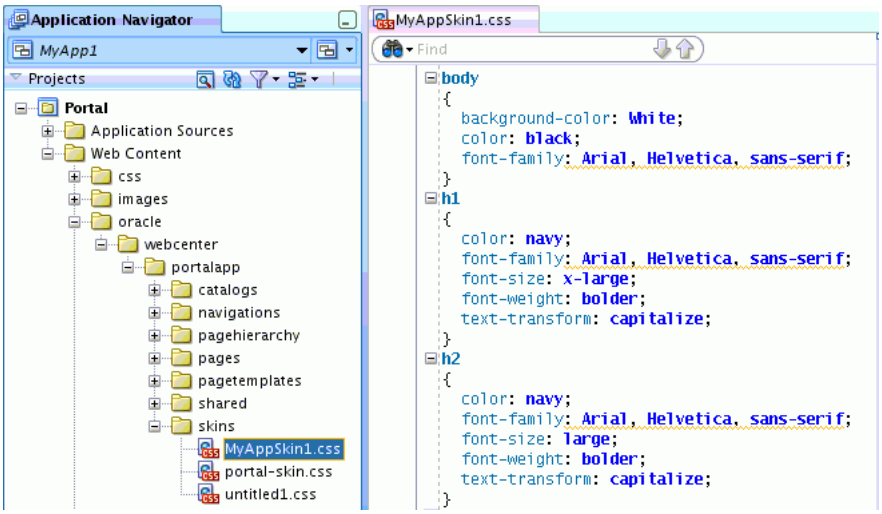
This section includes the following subsections:

- Section 15.2.1, "What You Should Know About Skin Creation"
- Section 15.2.2, "How to Create a CSS File"
- Section 15.2.3, "How to Define Skin Selectors"

15.2.1 What You Should Know About Skin Creation

When you create a CSS file, by default, JDeveloper places it under the *`APPLICATION_ROOT`*`/Portal/public_html/css` folder on the file system. In Application Navigator, the skin is displayed in the folder hierarchy as shown in Figure 15–1.

Figure 15–1 A Skin Created at the Default Location in JDeveloper



However, skins created at this default location cannot be managed at runtime. To enable authorized application users to be able to manage a skin at runtime, you must expose it as a portal resource in the Resource Manager. For a skin to be exposed as a portal resource, you must create it at the following path:

`APPLICATION_ROOT``/Portal/public_html/oracle/webcenter/portalapp/skins`

In Application Navigator, the skin is listed in the folder hierarchy as shown in Figure 15–2.

Figure 15–2 A Skin Created as a Portal Resource

After creating a CSS file, you must define the required ADF Faces skin selectors for the required components in your application. For example, you can use the `.AFDefaultFontFamily:alias` selector to specify the font family for your application as follows:

```
.AFDefaultFontFamily:alias {
font-family: Tahoma, Verdana, Helvetica, sans-serif;
}
```

The images related to a skin exposed as a portal resource must be stored at the following location:

APPLICATION_ROOT`/Portal/public_html/oracle/webcenter/portalapp/shared`

To avoid any conflicts or images getting overwritten, as a best practice you can store images in a subdirectory under the `shared` directory. To add image reference, you can use the format shown in the following example:

```
.AFBrandingBarLogo {
  background-image:
url('/oracle/webcenter/portalapp/shared/skins/images/image1.gif');
```

15.2.2 How to Create a CSS File

To create a CSS file:

1. Open your application in Oracle JDeveloper.
2. Make sure that CSS Level 3 and ADF Faces are selected.
   a. From the menu bar, choose **Tools** > **Preferences** > **CSS Editor**.
   b. From the **Support CSS Level** list, select **CSS Level 3**.
   c. For **Supported Components,** select **ADF Faces Extension**.
3. Select the **Portal** project, and from the **File** menu, choose **New**.

4. In the New Gallery dialog under **Categories**, expand **Web Tier**, then select **HTML**.
5. Select **CSS File**, and click **OK**.
6. In the Create Cascading Style Sheet dialog, in the **File Name** field, enter a name for your skin.
7. In the **Directory** field, enter the path where you want to create the CSS file. You can use the **Browse** button to specify the path.

   Note: In a Framework application, to be able to expose a skin in the runtime Resource Manager, you must create the skin under the `skins` root directory or in its subdirectory at the following path:

   APPLICATION_ROOT`/Portal/public_html/oracle/webcenter/portalapp/skins`

8. Click **OK**.

   The skin's CSS file opens in the Source View.

   You can now define the required skin selectors for the skin. For information, see Section 15.2.3, "How to Define Skin Selectors."

15.2.3 How to Define Skin Selectors

Use the ADF Faces skin selectors to define the look and feel of the different components in your application.

For information about:

- ADF Faces skin selectors in general, refer to the "Skin Style Selectors" section in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*. Also refer to Oracle JDeveloper's online help for information about the selectors that you can use in a skin. These are documented in the "Skin Selectors for Fusion's ADF Faces Components" and "Skin Selectors for Fusion's Data Visualization Tools Components" topics in JDeveloper's online help.
- Defining ADF Faces component style selectors, see sections "Defining Skin Style Properties" and "Changing the Style Properties of a Component" in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

15.3 Editing portal-skin.css

This section includes the following subsections:

- Section 15.3.1, "What You Should Know About portal-skin.css"
- Section 15.3.2, "How to Edit portal-skin.css"

15.3.1 What You Should Know About portal-skin.css

By default, a Framework application is configured to use the `portal-skin.css` skin file. This skin file provides a skeleton structure of various useful skin selectors, and contains commented-out entries that describe the purpose of each skin selector (Figure 15–3).

Figure 15–3 The portal-skin.css File

You can easily modify `portal-skin.css` to customize the default skin settings as per your requirements. You can add any new skin selectors to the file. You can also override the default settings of a skin selector by specifying the required values. For example, to set a font size of 16px for your application content, search for the `.AFDefaultFont:alias` skin selector and add the code marked in bold in the following example:

```
.AFDefaultFont:alias
{
font-size:16px;
}
```

15.3.2 How to Edit portal-skin.css

To edit `portal-skin.css`:

1. Open your application in JDeveloper.
2. In Application Navigator, navigate to the following folder path: **Portal** > **Web Content** > **oracle** > **webcenter** > **portalapp** > **skins**.
3. Right-click `portal-skin.css` and choose **Open**.
4. In the visual editor, search for the skin selector you want to edit, and add the required settings.

   For information about skin selectors, see Section 15.2.3, "How to Define Skin Selectors."
5. Save `portal-skin.css`.

15.4 Enabling Runtime Administration of Skins

This section includes the following subsections:

- Section 15.4.1, "What You Should Know About Enabling Runtime Administration of Skins"
- Section 15.4.2, "How to Enable Runtime Administration of a Skin"
- Section 15.4.3, "How to Enable Further Development of Deployed Skins"
- Section 15.4.4, "Creating a Skin in JDeveloper and Making it Available at Runtime"
- Section 15.4.5, "How to Create and Manage Skins at Runtime"

15.4.1 What You Should Know About Enabling Runtime Administration of Skins

The Resource Manager in a Framework application enables users with administrative privileges to create and modify portal resources, including skins, at runtime. By exposing skins in the Resource Manager, you allow administrators to manage these skins at runtime. If you want to create and expose more skins after deploying the application, you can export them from JDeveloper to the runtime application. At runtime, the Resource Manager provides an option to upload the skins that you exported.

Note: If you create a skin at runtime and do not import it back into the design time environment, your new skin may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To enable runtime administration of a skin, you must add it as a portal resource to the Resource Manager. For a skin to be added as a portal resource, it must be located in the *APPLICATION_ROOT*`/Portal/public_html/oracle/webcenter/portalapp/skins` directory.

While exposing a skin as a portal resource, you must set certain attributes (Figure 15–4). Table 15–1 describes the attributes that are specific to skins. For information about generic attributes, refer to Section 17.2.1, "How to Add a Resource to the Resource Manager."

Note: The Content Directory field must point to *APPLICATION_ROOT*`/Portal/public_html/oracle/webcenter/portalapp/shared` directory or a subdirectory underneath. This is the path where the dependent objects of a resource, such as images, JavaScripts, style sheets, and HTML files, must be stored. Only the objects located at this path are included in the export archive of a skin and uploaded at runtime.

Figure 15–4 Creating a Skin as a Portal Resource

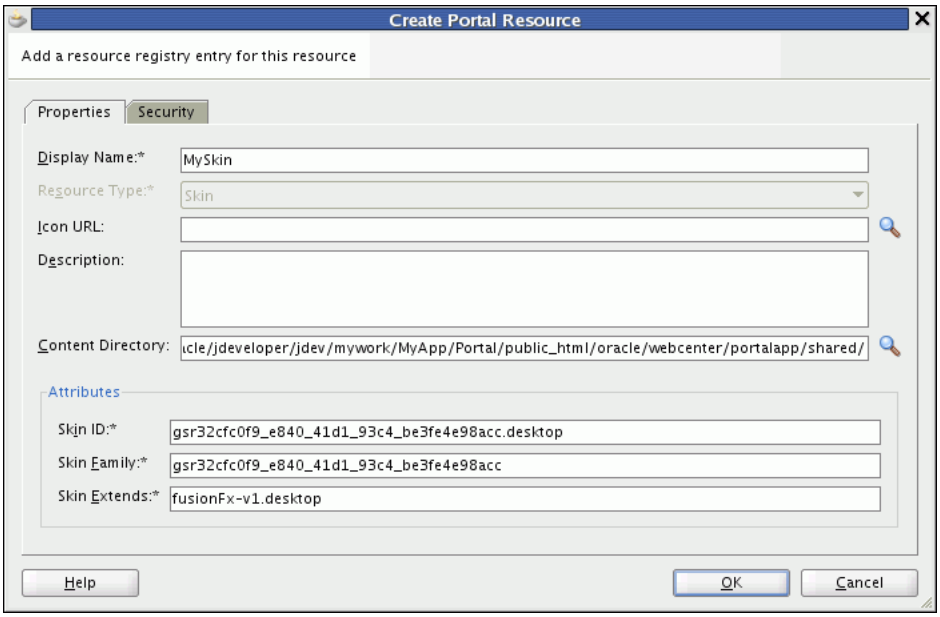


Table 15–1 Skin-Specific Attributes

Property	Description
`Skin ID`	Specifies the unique identifier of a skin. Typically, it is a combination of the skin family and the render kit, for example `BrightBlue.desktop`.
`Skin Family`	Specifies the family to which a skin belongs. It is an identifier that can be used by a number of skins with different renderkits. For example, you could have a family named `BrightBlue`. It can be used with renderkit `desktop` or `mobile`. Skin Family is really the value that `trinidad-config.xml` uses to find the matching skin in its specific attributes. You must ensure that the `Skin Family` attribute is unique. For Framework applications, the default skin is `portal-skin.css` file, with the skin family as `portal`. Ensure that you do not use `portal` as the skin family ID for any other skin.
`Skin Extends`	Specifies the ID of the skin being extended. If creating a new skin, `fusionFx-v1.desktop` is the most common skin to extend. Table 15–2 lists the skin IDs of the built-in skins available in Spaces.

Note: Skins are identified internally by skin IDs. While adding an existing custom skin as a portal resource in JDeveloper, you must not change the values of the `Skin ID`, `Skin Family`, and `Skin Extends`. Otherwise, when you upload the skin into your application, it will be included as a new skin, and the existing skin will not be replaced.

Extending Spaces Skins

You can bring your Spaces skins into JDeveloper for further development (Section 15.6, "How to Create and Manage Spaces Skins"). You can also create new skins in JDeveloper for use in the Spaces application. You create a new skin by extending an existing skin. In JDeveloper, you can extend a built-in ADF Faces skin like `blafplus-rich.desktop`, `fusion.desktop`, or `fusionFx-v1.desktop`. You can also choose to extend one of the built-in skins available in Spaces. Table 15–2 lists the skin IDs of the built-in skins available in Spaces.

Table 15–2 IDs of Built-in Skins in Spaces

Built-in Skin in Spaces	Skin ID
Fusion FX	`webcenter-fusion.desktop`
Spaces FX	`webcenterfx.desktop`

15.4.2 How to Enable Runtime Administration of a Skin

Use the following options on the context menu of a skin's CSS file to register, update, or deregister a skin in the Resource Manager:

- **Create Portal Resource**: Select to expose the skin as a portal resource. This creates an entry for the skin in the application's `generic-site-resources.xml` file. At runtime, the skin is then available for selection.

  For information, see Section 17.2.1, "How to Add a Resource to the Resource Manager." While creating a skin entry, you must specify the skin-specific attributes described in Table 15–1.

- **Update Portal Resource**: Select to edit the attributes that you defined while creating skin entries. For information, see Section 17.2.3, "How to Update Portal Resource Properties."

- **Remove Portal Resource**: Select to remove the entry for the skin from the `generic-site-resources.xml` file. For information, see Section 17.2.4, "How to Remove a Resource from the Resource Manager."

15.4.3 How to Enable Further Development of Deployed Skins

When you enable runtime administration of resources, authorized users can create new skins and modify existing ones at runtime. If users create or edit skins at runtime, you may find that you need to bring them back into JDeveloper for further enhancement. This type of round-trip development involves:

- Downloading the skin from the deployed application to get the skin's EAR file
- Importing the skin's EAR file into JDeveloper
- Editing the skin in JDeveloper
- Exporting the edited skin as an EAR file in JDeveloper
- Uploading the EAR file back into the deployed application

This section describes how to import and export skins in JDeveloper. It includes the following sections:

- Section 15.4.3.1, "Importing a Skin"
- Section 15.4.3.2, "Exporting a Skin"

For generic information about downloading and uploading a resource in a deployed application, see the sections "Downloading a Resource" and "Uploading a Resource" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

15.4.3.1 Importing a Skin

When you download a skin from a deployed application, an EAR file is created containing the skin's CSS file and the `generic-site-resources.xml` file, which contains the metadata specific to the downloaded skin.

After downloading a skin, you must import the EAR file into JDeveloper. On importing, the CSS file is extracted to the following path:

APPLICATION_ROOT`/Portal/public_html/oracle/webcenter/siteresources/scopedMD/`*scope_GUID*`/`

For detailed steps to import a resource, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

After importing a skin, you can edit its CSS file as you would any other skin file at design time. For information about editing a skin, see Section 15.2.3, "How to Define Skin Selectors." The updated skin must then be exported to the deployed application.

> **Note:** If you download a skin from a deployed application and then import and modify it in JDeveloper, you must not change values of the following attributes: `Skin Family`, `Skin ID`, and `Skin Extends`. Otherwise, when you upload the skin into the deployed application, the existing skin will not be replaced.

Note: If you edit or add images (or other dependant objects like JavaScripts and HTML files) in an imported skin, the images must be placed at the following path, which is the default content directory for skins created at runtime:

```
APPLICATION_ROOT/Portal/public_
html/oracle/webcenter/siteresources/scopedMD/shared/
```

Images must always be placed directly under or in a subdirectory of the directory set as the content directory of a portal resource. You can find out the content directory path from the Update Portal Resource dialog.

To prevent any conflicts, you may want to put your images in a subdirectory under the `shared` directory. For example, you may put images in the `skins/images` subdirectory. In such a case, you must update the content directory path to point to the new location.

Once you add your images, you can reference them in the CSS file as shown in the following example:

```
.AFBrandingBarLogo {
background-image:
url('/oracle/webcenter/siteresources/scopedMD/shared/skins/images/i
mage1.gif');
}
```

For more information, see Section 15.2.1, "What You Should Know About Skin Creation."

15.4.3.2 Exporting a Skin

You may need to export a skin in the following situations:

- To copy back a skin that you imported from a deployed application and modified it.
- To expose a new skin in a deployed application.

When you export a skin in JDeveloper, an EAR file is created containing the skin's CSS file and the `generic-site-resources.xml` file. Users with administrator privileges can then upload this EAR file to a deployed application by using the Resource Manager. Once uploaded, the skin can be managed and applied at runtime.

For detailed steps to export a resource, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

15.4.4 Creating a Skin in JDeveloper and Making it Available at Runtime

Even after you have deployed your Framework application, you can create new skins at design time and make them available at runtime. This involves the following steps:

1. Creating the skin in JDeveloper, as described in Section 15.2, "Creating a Skin in JDeveloper."
2. Adding the skin as a portal resource by using the Create Portal Resource option, as described in Section 15.4.2, "How to Enable Runtime Administration of a Skin."
3. Exporting the skin as a portal resource in JDeveloper, as described in Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

4. Uploading the skin to the runtime application using the Resource Manager, as described in the section "Uploading a Resource" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

15.4.5 How to Create and Manage Skins at Runtime

With runtime administration enabled in your Framework application, authorized users can use the Resource Manager to perform the following tasks: create a new skin, edit a skin, edit the source code, copy, set security, show or hide, set attributes, delete, upload, and download a skin.

Figure 15–5 shows the Resource Manager, with the Edit menu for a skin displayed.

Figure 15–5 Managing Skins at Runtime

For information about how to access the Resource Manager, see Section 17.3.2, "How to Use the Resource Manager at Runtime." The procedures for working with skins in a deployed Framework application are same as those in the Spaces application. For generic information about creating and managing a skin at runtime, see the "Working with Skins" chapter in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

15.5 Applying Skins to WebCenter Portal: Framework Applications

You can choose to apply a different skin to your Framework application. If runtime administration is enabled, authorized users can change the skin at runtime.

This section includes the following subsections:

- Section 15.5.1, "Applying a Skin at Design Time"
- Section 15.5.2, "Applying a Skin at Runtime"

15.5.1 Applying a Skin at Design Time

At design time, to switch to a different skin that has been created as a portal resource, directly edit the `adf-config.xml` file. For information about the attributes that you can set in `adf-config.xml`, see Section 15.10.1, "adf-config.xml."

To apply a skin created as a portal resource to your Framework application at design time:

1. In JDeveloper, open `adf-config.xml` of your application.

To locate this file, in the Application Navigator, expand **Application Resources** > **Descriptors** > **ADF META-INF**.

2. Under `<portal:preferences>`, search for the following skin properties:

```
<portal:preference id="oracle.webcenter.portalapp.skin"
                   desc="Default Portal Skin" value="portal"
                   resourceType="Skin" display="true"/>
```

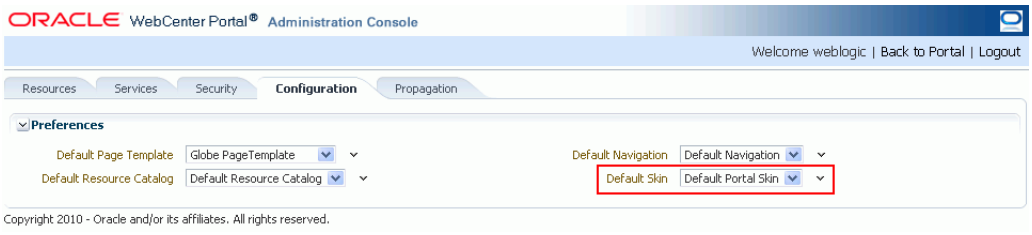
3. In the `value` property, specify the family name of the skin that you want to apply to your application.

   This value must be same as the value specified for the `Skin Family` attribute in the Create Portal Resource or Update Portal Resource dialog of the required skin.

4. Optionally, in the `desc` property, specify a description of the skin you want to apply.

5. Save `adf-config.xml`.

Note: If you want to apply a skin created at any other location other than *APPLICATION_ROOT*`/Portal/public_html/oracle/webcenter/portalapp/skins`, you must register the skin in the `trinidad-skins.xml` file and configure your application to use the skin. For information, see the chapter "Customizing the Appearance Using Styles and Skins" in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.



15.5.2 Applying a Skin at Runtime

If you enable runtime administration of resources, you do not necessarily need to manually register a skin for your application. You can apply the desired skin at runtime in your deployed application.

To apply a skin at runtime in a deployed Framework application:

1. Log on as the application administrator, and navigate to the WebCenter Portal Administration Console.
2. Click the **Configuration** tab.
3. From the **Default Skin** list, select the desired skin Figure 15–6.

Figure 15–6 Applying a Skin at Runtime

15.6 How to Create and Manage Spaces Skins

Out-of-the-box, WebCenter Portal's Spaces application provides certain default skins. If these default skins do not suit your requirements, you can build your own skins

within Spaces. For information, see the chapter "Working with Skins" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

However, Spaces may not provide all the controls to create a skin with all the functionality that you require. In such cases, you can create your own skin in JDeveloper and then upload it into Spaces. You can also download an existing skin from Spaces and edit it in JDeveloper, or use one of the sample skins as your starting point, and then upload it back into Spaces.

WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, including skins, to Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build custom skins and other types of resources for Spaces.

15.7 Deploying a Skin as a Separate Shared Library

When you use a custom skin for your Framework application, as a best practice you must deploy the custom skin as a separate shared library. This is especially important when you want your Framework application to consume a portlet that renders using the same skin as your application.

15.7.1 About Skin Sharing

WebCenter Portal: Framework provides various default skins. All WebCenter Portal skin artifacts are available in the shared library, `oracle.webcenter.skin`. The shared library is packaged as an EAR, and includes several skin JARs that contain the following types of files:

- `.css` file, the skin selector file
- `.png`, the image files
- `.js`, the javascript file
- `trinidad-skins.xml`, the skin definition file

By default, the `oracle.webcenter.skin` shared library is referenced by all Framework applications and Portlet Producer applications. Therefore, all skins are available through the classpath. When you use a portlet in your Framework application, the portlet is rendered using the skin defined for your application. Therefore, to achieve skin sharing, the same skin must be accessible through the shared library, to both the Framework application and the Portlet Producer application.

However, there may be a case where you modified `portal-skin.css` in your Framework application. So, the skin available in the shared library is not the same as the updated version available in the Framework application. If the skin's version in the Framework application is not identical to the skin in the shared library, skin sharing between Framework application and Portlet Producer application will fail because the Portlet producer can access only the original version of the skin packaged in the shared library, while the Framework application uses the modified skin. The Framework application renders with the latest skin changes, while the portlet within the same application renders with the original skin from the shared library. This behavior is called skin coordination.

Instead of using the default skin, you may create a new custom skin in your Framework application, either as a portal resource or define it in the `trinidad-skins.xml` with a unique skin family ID. If your application uses a portlet, the portlet producer will not be able to find the custom skin in the shared library. This causes a skin mismatch problem, and the portlet is rendered with a bare bone, simple skin rather than the custom skin used by the Framework application.

Therefore, whenever you modify a skin or create a custom skin for your Framework applications, you must deploy the new or modified skin as a shared library.

15.7.2 How to Deploy a Skin as a Separate Shared Library

To deploy a skin as a shared library:

1. Ensure that a copy of `trinidad-skins.xml` is available in the `WEB-INF` folder of your Framework application. If not, create a new one.
2. Update `trinidad-skins.xml` to point to the newly created skin CSS file.
3. Create a new `MANIFEST.MF` file in the project and provide the details for the new shared library.

   The following is a sample code in a `MANIFEST.MF` file:

   ```
   Manifest-Version: 1.0
    Ant-Version: Apache Ant 1.7.1
    Created-By: 1.6.0 (Sun Microsystems, Inc.)
    Extension-Name: oracle.webcenter.customskin
    Implementation-Title: oracle.webcenter.customskin
    Implementation-Version: 11.1.1
    Implementation-Vendor: Oracle
    Specification-Title: Custom WebCenter shared library
    Specification-Version: 11.1.1
   ```

4. Create a new deployment profile:
   a. Right-click the **Portal** project, then choose **New**.
   b. In the New Gallery dialog, choose **General** > **Deployment Profile** > **Shared Library JAR File**, and click **OK**.
   c. In the Create Deployment Profile dialog, in the **Deployment Profile Name** field, enter the profile name and click **OK**.
   d. In the Edit JAR Deployment Profile Properties dialog, ensure that **Include Manifest File** checkbox is selected.
   e. In the **Additional Manifest Files to Merge into MANIFEST.MF** section, use the **Add** button to add `trinidad-skins.xml` and the desired skin CSS file in the shared library.
   f. Click **OK**.
   g. In the Project Properties dialog, click **OK**.
5. Right-click the **Portal** project, choose **Deploy**, then select the JAR shared library deployment profile name.
6. In the Deploy dialog, select **Deploy to a Weblogic Application Server**, and click **Next**.
7. Select the WebLogic Server that hosts your portlet producer, and click **Next**.
8. Ensure that **Deploy as a Shared Library** is selected, then click **Finish**.

9. Update `/META-INF/weblogic-application.xml` for both the Framework application and the Portlet Producer application to reference the custom skin shared library.

```
<library-ref>
    <library-name>Custom_Library_Name</library-name>
    <specification-version>Library_Version</specification-version>
  </library-ref>
```

10. Redeploy both the Framework application and the Portlet Producer application.

    The custom skin can now be shared between these applications.

> **Note:** The custom skin shared library must be deployed, and must appear as "Active" on the WebLogic Server console before true skin sharing can be achieved. If there is any issue with the shared library JAR (like incorrect manifest or incorrect version), the deployed shared library will not show up in the WebLogic Server console as "Active".

> **Note:** If you have multiple skin files, you can put all skin artifacts into one shared library JAR, and merge the two `trinidad-skins.xml` files into a single file. You can keep using this shared library for all your custom skins development.

15.8 Conditionally Changing Skins for Users

You can assign different skins per user, page, application, and so on, without impacting the actual application logic. To conditionally set a skin, you use the `<skin-family>` entry in the `trinidad-config.xml` file.

You can use EL expressions that can be evaluated dynamically to determine the skin to display. For example, if you want to use the German skin when the user's browser is set to the German locale, and to use the English skin otherwise, use the following `<skin-family>` entry in the `trinidad-config.xml` file:

```
<skin-family>#{facesContext.viewRoot.locale.language=='de' ?
'german' : 'english'}</skin-family>
```

For more information, see the "How to Configure a Component for Changing Skins Dynamically" section in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

> **Note:** The default value of `<skin-family>` is `#{preferenceBean.defaultTrinidadSkin}`. If you change the default value, your application users cannot set skins at runtime in the Resource Manager.

You can also use the `SkinSetting` API to set the skin for a user conditionally. Refer to the API for information about the calls you can use. The API is available here:

http://download.oracle.com/docs/cd/E15523_01/apirefs.1111/e15995/oracle/webcenter/generalsettings/model/SkinSetting.html

15.9 Troubleshooting Problems with Skins

This section provides information to assist you in troubleshooting problems you may encounter while using skins.

Problem

Your application does not reflect skin changes made at design time.

Solution

During development, after you make changes to a skin, you can see your CSS changes without restarting the server. The `CHECK_FILE_MODIFICATION` context parameter requires the server to check the timestamp on a skin and reload it if the skin has changed. This setting is automatically set to `true` if iterative development is enabled for your application. If iterative development is not enabled, ensure that `CHECK_FILE_MODIFICATION` is set to `true` in `WEB-INF/web.xml`, as shown in the following example:

```
<context-param>
<param-name>org.apache.myfaces.trinidad.CHECK_FILE_MODIFICATION</param-name>
<param-value>true</param-value>
</context-param>
```

Problem

Skin selectors appear encoded and compressed when you open a skin's CSS file in a browser.

Solution

By default, class names in a CSS file are compressed to reduce the overall size of the file. So, the skin selectors you see, for example in the Firebug extension of Firefox, are encoded values bearing little relationship to the original names. For example, a CSS file may contain an entry that looks like:

```
 .x123 {color: #534741}
```

It is easier to examine a CSS file when the compression is turned off. You can disable compression by setting the value of `DISABLE_CONTENT_COMPRESSION` context parameter to `true` in `WEB-INF/web.xml`, as shown in the following code:

```
<context-param>
<param-name>org.apache.myfaces.trinidad.DISABLE_CONTENT_COMPRESSION</param-name>
<param-value>true</param-value>
</context-param>
```

With the compression turned off, the entry may look like:

```
.af_panelFormLayout_label-cell
{
color: #534741
}
```

For better performance, it is recommended that you turn on CSS compression in a production environment. If you turn off CSS compression, it may lead to skin mismatching, as described in the next problem scenario.

Problem

When you run a page containing a portlet, the portlet is rendered without any styles or formatting.

Solution

When your application consumes a portlet based on an ADF application, the portlet producer tries to match the skin of your application. If the skins match, the producer uses your application's skin.

Skin compression is not taken into account during skin matching. If the skin compression settings differ but the skins match, the producer returns IDs like ".x123" and expects to find these values in your application; whereas your application may return values like ".af_panelFormLayout_label-cell". Therefore, no styles are found and the portlet rendering fails.

Your application and portlet producers must use the same skin compression settings. If your application uses an uncompressed skin, your portlet producer also must use an uncompressed skin.

Problem

Style sheet files (CSS) within the MDS folder structure (`oracle/webcenter/portalapp`) do not take effect as specified in `trinidad-skins.xml`.

Solution

For style sheet files (CSS) within the MDS folder structure, prefix "`mds:`" to the path in `trinidad-skins.xml`, as shown in the following example:

```
<skin>
   <id>myskin2.desktop</id>
   <family>myskin2</family>
   <render-kit-id>org.apache.myfaces.trinidad.desktop</render-kit-id>
 <style-sheet-name>mds:/oracle/webcenter/portalapp/css/skin.css</style-sheet-name>
   <extends>fusion.desktop</extends>
</skin>
```

15.10 Files Relates to Skins

This section includes the following subsections that describe the files that are created or modified when you create or modify skins:

- Section 15.10.1, "adf-config.xml"
- Section 15.10.2, "trinidad-config.xml"
- Section 15.10.3, "trinidad-skins.xml"

15.10.1 adf-config.xml

You can leverage the Framework application's preference mechanism, and there is built-in support for defining a preference for skins to be used at runtime, in `adf-config.xml`. This file is located in the `META-INF` directory. Example 15–1 shows the default skin preferences available in `adf-config.xml`.

Example 15–1 Skin Preferences in adf-config.xml

```
<portal:preference id="oracle.webcenter.portalapp.skin"
```

```
desc="Default Portal Skin" value="portal"
resourceType="Skin" display="true"/>
```

In `adf-config.xml`, you can define the following properties for your skin:

- `preference id` - the hard-coded value used in the Portal Preferences API as a key to lookup the preference value of the skin to be used in an application.
- `desc` - description of the skin. At runtime, this value shows up as the display name of the skin.
- `value` - the family name of the skin used in the application. This value must be same as the value specified for the `Skin Family` attribute in the Create Portal Resource or Update Portal Resource dialog of the required skin. If you want your application to use a different skin, specify the required skin family name here.
- `resourceType` - the type of the resource; in this case, a skin.
- `display` - specifies whether the skin is listed in the skin picker at runtime.

15.10.2 trinidad-config.xml

In JDeveloper, when you create a Framework application, a starter `trinidad-config.xml` file is automatically created in the `/WEB-INF` directory. Example 15–2 shows a starter `trinidad-config.xml` file.

Example 15–2 Starter trinidad-config.xml File Created by JDeveloper

```
<?xml version="1.0" encoding="US-ASCII"?>
<trinidad-config xmlns="http://myfaces.apache.org/trinidad/config">
  <skin-family>#{preferenceBean.defaultTrinidadSkin}</skin-family>
</trinidad-config>
```

In the `trinidad-config.xml`, you can set `<skin-family>` that determines which skin to use, and if necessary, under what conditions. The `trinidad-config.xml` file has a simple XML structure that enables you to define element properties using the JSF Expression Language (EL) or static values.

Note: The default value of `<skin-family>` is `#{preferenceBean.defaultTrinidadSkin}`. If you change the default value, your application users cannot set skins at runtime in the Resource Manager.

15.10.3 trinidad-skins.xml

The `trinidad-skins.xml` file is required for any skin that is provided as a JAR. The file is usually bundled with each skin JAR to provide a lookup between skin ID and the actual path of the skin. However, for a skin created as a portal resource in a Framework application, a separate runtime API is used to lookup the location of a skin. Therefore, this file is not needed for such skins.

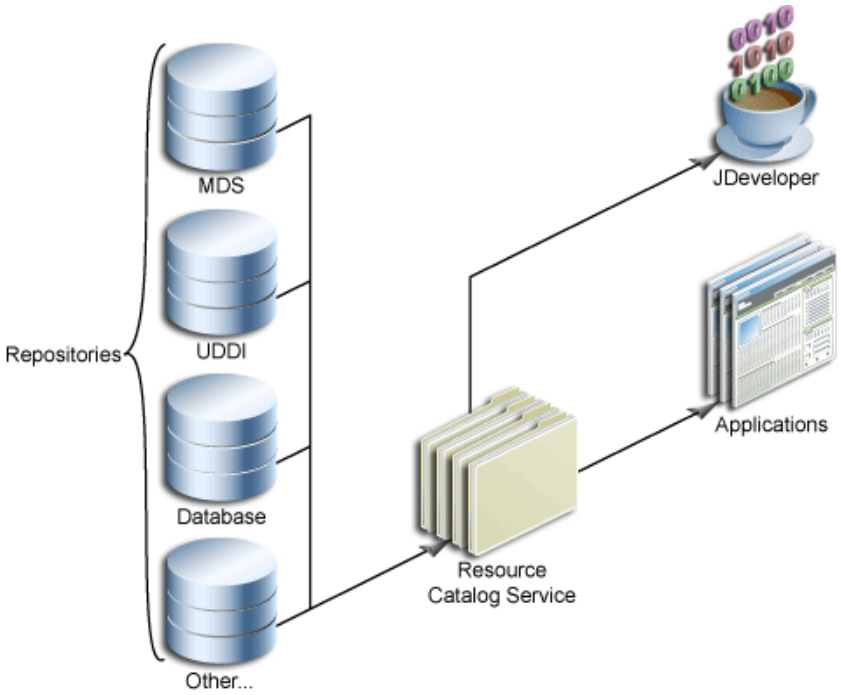
For more information about `trinidad-skins.xml`, see the chapter "Customizing the Appearance Using Styles and Skins" in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

16

Creating and Managing Resource Catalogs

Resource Catalogs define and organize the resources available for inclusion in a page, page template, or task flow. You can create them in JDeveloper so that they are deployed with the application. Resource Catalogs can also be created and edited in the runtime Resource Manager. This chapter describes the default Resource Catalog and explains how to customize this catalog and create new catalogs in JDeveloper.

For information about managing Resource Catalogs at runtime, see "Working with Resource Catalogs" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.



This chapter contains the following sections:

- Section 16.1, "Overview of Resource Catalog"
- Section 16.2, "Creating a Custom Resource Catalog"
- Section 16.3, "Managing a Resource Catalog and Enabling Runtime Administration"
- Section 16.4, "Filtering Items in the Resource Catalog"
- Section 16.5, "Configuring Multiple Resource Catalogs"

16.1 Overview of Resource Catalog

The Resource Catalog, also known as *Oracle Business Dictionary*, provides a consolidated view of the contents of one or more otherwise unrelated repositories in a unified search and browse user interface. Resources originate in their source repository and are then exposed through the Resource Catalog as shown in Figure 16–1.

Figure 16–1 Resource Catalog Overview

When using JDeveloper, you see two types of Resource Catalogs—design time Resource Catalogs and runtime Resource Catalogs.

Design time Resource Catalogs are available in the Resource Palette and are like favorites lists for developers. The WebCenter Portal - Services Catalog is a design time catalog that is available out-of-the-box when you install the WebCenter Portal extension bundle. You can add task flows and data controls from this catalog to a Framework application. In addition to the WebCenter Portal - Services Catalog, you can define connections and create catalogs to organize resources exposed by those connections. Such resources can be re-used in any application that you are developing.

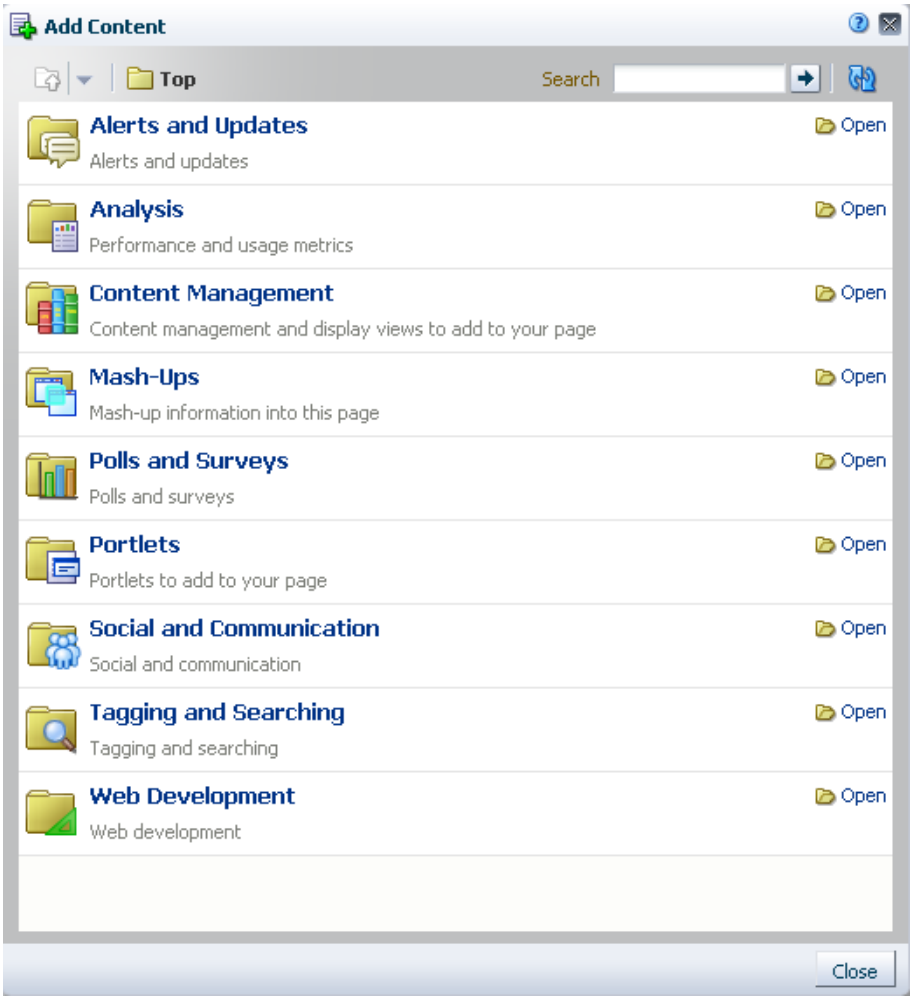
See Also:

- Section 3.2, "Installing WebCenter Portal's Extension for Oracle JDeveloper"
- Oracle JDeveloper online Help for more information about the Resource Palette and catalogs.

  To locate this information in Oracle JDeveloper, from the **Help** menu, select **Table of Contents**. In Help Center, expand **JDeveloper Basics** and select **Working with the Resource Palette**.

Runtime Resource Catalogs are available for populating pages or page templates and task flows in deployed Spaces and Framework applications. In Spaces applications, the Resource Catalogs determine the resources available when populating pages and task flows in Composer. In addition to this, the Resource Catalogs in Framework applications also determine the resources available when creating page templates and other Resource Catalogs in the Resource Manager.

See Also:



- Section 20.1, "Designing Editable Pages Using Composer Components"
- Section 12.2, "Working with Page Templates"

Default Resource Catalog Configuration

When you add a `Page Customizable` component to the page, a default Resource Catalog with the catalog definition file, `default-catalog.xml`, is configured in the application. Depending on the type of application you created, the catalog definition file is created in one of the following folders:

- In a Framework application, the `default-catalog.xml` file is located in the *`APPLICATION_ROOT`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory. The Resource Catalog in this case contains the folders shown in Figure 16–2.

Figure 16–2 Default Resource Catalog

- In a non-portal WebCenter application, the `default-catalog.xml` file is located in the *`APPLICATION_ROOT`*`/Portal/src/portal` directory. The Resource Catalog in this case contains the **ADF Faces Components** folder, which contains ADF Faces components that a user can add to the page.

If you have registered a portlet producer with your application, then that producer's portlets are displayed in a Portlets folder in the Resource Catalog. If you have not registered any producer, the Portlets folder is hidden.

You can create custom catalogs or modify the default catalog and include components relevant to your business. For more information, see Section 16.2, "Creating a Custom Resource Catalog" and Section 16.2.3, "How to Manage Content in the Resource Catalog."

16.2 Creating a Custom Resource Catalog

Most businesses may require that users and groups have access to only those resources that they can add to a page. To address this need, you can configure multiple Resource Catalogs in your application. To configure multiple Resource Catalogs, you must first create custom catalogs with all the required resources.

This section describes how to create a custom Resource Catalog. It contains the following subsections:

- Section 16.2.1, "How to Create a Custom Resource Catalog"
- Section 16.2.2, "How to Define Connections to Resources"
- Section 16.2.3, "How to Manage Content in the Resource Catalog"
- Section 16.2.4, "How to Expose Data Controls Created at Design Time"
- Section 16.2.5, "How to Expose Data Controls Created at Runtime"
- Section 16.2.6, "How to Control Visibility of Portlets in the Resource Catalog"
- Section 16.2.7, "How to Configure the Default Resource Catalog for an Application or Page"
- Section 16.2.8, "What You May Need to Know When Defining a Resource Catalog"
- Section 16.2.9, "How to Define Task Flow Parameters and Attributes of the Enclosing Show Detail Frames for Task Flows"

16.2.1 How to Create a Custom Resource Catalog

The New Gallery dialog provides an option to create a Resource Catalog. Using this option, you can create a blank catalog and populate it with resources of your choice.

To create a catalog definition:

1. Open your application in Oracle JDeveloper.
2. Select the Portal project, and from **File** menu, choose **New**.
3. In the New Gallery dialog, expand **Web Tier**, select **Portal**, then **Application Resource Catalog**, and click **OK**.
4. In the File Name field in the Create Application Resource Catalog dialog, provide a name for the catalog, for example, `users-catalog.xml`.
5. In the Directory field, specify the location for the new catalog definition XML file.

   Catalog definition files must be saved in the Resource Catalog root directory or a subdirectory of the root. The default root directory in a Framework application is *`APPLICATION_ROOT`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs`, and in a non-Framework application is *`APPLICATION_ROOT`*`/Portal/src/portal`.

> **Note:** In a Framework application, to expose the new catalog in the runtime Resource Manager, you must create the catalog in the *APPLICATION_ROOT*/Portal/public_html/oracle/webcenter/portalapp directory.

For example, if the Resource Catalog root is:

```
C:\JDeveloper\mywork\RCSampleApp\Portal\public_
html\oracle\webcenter\portalapp\catalogs
```

You could create your catalog here or create a subdirectory for it. For example:

```
C:\JDeveloper\mywork\RCSampleApp\Portal\public_
html\oracle\webcenter\portalapp\catalogs\mycatalogs
```

6. Select the Create as Portal Resource option to expose the catalog in the Resource Manager.

> **Note:** This option is displayed in a Framework application if you specified the directory to be *APPLICATION_ROOT*/Portal/public_html/oracle/webcenter/portalapp or a subdirectory of portalapp.

7. Click **OK**.

   The new catalog definition file opens in the Overview Editor.

8. In the right half of the Overview Editor, define catalog properties as follows:
   - In the Catalog Filter field, specify the name of the filter you want to apply to the catalog. This field is optional. For more information, see Section 16.4, "Filtering Items in the Resource Catalog."
   - In the Visible field, specify whether the Resource Catalog must be displayed. This attribute takes an EL value. The default value is `#{true}`, which means that the catalog is displayed to all users at all times.
   - Use the Catalog Attributes section to define the following attributes on the catalog.
     - **Title**: A display name for the catalog.
     - **Description**: A short description of the catalog. This text appears below the catalog name in the Resource Manager.
     - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
     - **IconURI**: Specify the URI for an icon to display alongside the catalog name in the Resource Manager.
     - **Tool Tip**: Use to specify the tool tip to be displayed when you move the mouse over this catalog name.

> **Note:** Catalog attributes are defined within the `<schema>` element in the catalog definition XML file. In addition to the out-of-the-box attributes, you can expose custom attributes on the catalog by defining them within the `<schema>` element.

9. Save the catalog definition file.

You can now populate your catalog with resources. See Section 16.2.3, "How to Manage Content in the Resource Catalog" for details about adding different types of resources.

> **Tip:** If you do not want to add resources from scratch, as a starting point, you could copy the contents of `default-catalog.xml` into your new catalog definition.

16.2.2 How to Define Connections to Resources

Many resources, such as WebCenter Portal services and portlets, are accessed through connections defined in your application's `connections.xml` file. Therefore, you must create connections before adding such resources to the Resource Catalog.

You can create connections to resources in different ways. This section describes how to create a connection from the Resource Palette. For information about additional ways to create connections, see Section 7.2, "Preparing Your Framework Application to Consume Services" and Section 64.2, "Registering Portlet Producers with a WebCenter Portal: Framework Application."

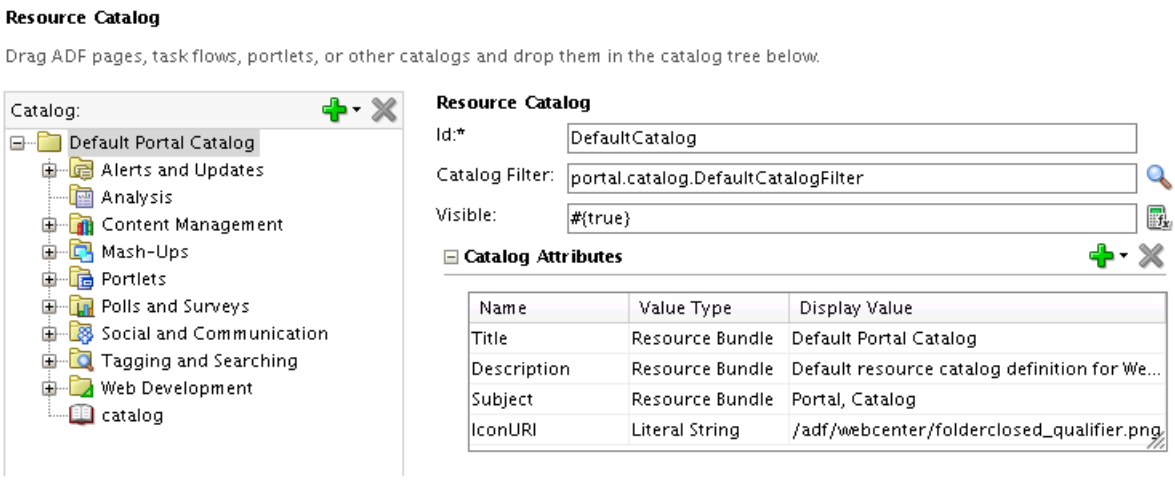
To create a connection from the Resource Palette:

1. From the Resource Palette, click the **New** icon in the upper left corner.
2. Choose **New Connection** and then the type of connection you want to create.

   The wizard for your connection type appears.
3. Step through the wizard filling in the necessary information about the connection.

   When you click **Finish**, the connection should appear in the Resource Palette under **Connections**.
4. Right click your connection in the Resource Palette and choose **Add to Application** from the context menu.

   Alternatively, you can drag and drop the connection from the Resource Palette to the Application Resources panel of the Application Navigator.



16.2.3 How to Manage Content in the Resource Catalog

You can add or remove catalog resources as required by your business.

> **Tip:** If you are creating a Resource Catalog from scratch, you can refer to the default catalog definition file to get an idea of how resources are included in the catalog.

Typically, catalog definition files are available in the *`APPLICATION_ROOT`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory. The Design view of a catalog definition file, shown in Figure 16–3, provides options to add, modify, and delete catalog content.

Figure 16–3 Catalog Definition File Design View

You can add resources to a catalog in two ways:

- Use the options on the Add menu in the Resource Catalog Overview Editor.
- Drag and drop resources from different areas in the IDE onto the catalog definition file.

The left half of the XML editor contains the Catalog section, which displays the hierarchical structure of components in the catalog. The right half of the page provides fields to define attributes and parameters on a selected resource.

Note: If you are using a standalone version of Composer (that is, Composer without WebCenter Portal: Framework), you can add a resource to the catalog by directly adding a `<resource>` element to the source of the catalog definition file. For more information, see Section C.3.12, "resource."

See Also: For details about the catalog definition file and its attributes:

- Section C.2, "XML Schema"
- Section C.3, "Catalog Definition Attributes"

This section explains how to manage catalog resources. It contains the following sections:

- Section 16.2.3.1, "Adding a Folder"
- Section 16.2.3.2, "Adding a Link"
- Section 16.2.3.3, "Adding a Resource Catalog"
- Section 16.2.3.4, "Adding a Component"
- Section 16.2.3.5, "Adding a Custom Folder"
- Section 16.2.3.6, "Adding a Custom Content Provider"
- Section 16.2.3.7, "Dragging and Dropping a Resource into the Catalog"
- Section 16.2.3.8, "Editing a Resource"

- Section 16.2.3.9, "Deleting a Resource"
- Section 16.2.3.10, "Rearranging Resources in the Catalog"

16.2.3.1 Adding a Folder

You can create folders to group similar resources, thereby organizing the catalog better.

To add a folder:

1. Open the catalog definition file in JDeveloper.

   This file is typically available in the *APPLICATION_ROOT*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory.

2. From the **Add** menu in the Catalog section, select **Folder**.

   A `folder` element is added to the catalog. The right side of the page displays fields to define the new folder's attributes and parameters.

3. The `Id` field is populated with the value `folder` by default. You can specify a different value, but the ID must be unique within the catalog definition file.

4. In the `Visible` field, you can specify an EL value to conditionally display this folder to specific users or groups. This attribute takes an EL value. The default value is `#{true}`, which means that the resource is displayed in the catalog at all times.

5. Optionally, in the Folder Attributes section, you can define the following attributes by choosing them from the **Add** menu, shown in Figure 16–4:

Figure 16–4 Folder Attributes

   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

   Selecting an option on the Add menu creates a new row in the Folder Attributes table. You can use this row to specify the name, type, and value for the new attribute.

16.2.3.2 Adding a Link

You can add the following types of links to a catalog:

- **Task Flow**: Link to a WebCenter Portal service task flow (in the Resource Palette) or a custom task flow created in Oracle JDeveloper (in the Application Navigator).
- **Portlet**: Link to any registered portlet producer. See Chapter 64, "Consuming Portlets" for detailed information about registering portlet producers and adding portlets to the page.
- **Content**: Link to a file or directory from an existing Content Repository connection.
- **Other**: Link to a custom component that you create by providing the XML code for that component.

To add a link:

1. From the **Add** menu in the Catalog section, select **Link**.

   A `url` element is added to the catalog. The right side of the page displays fields to define the new link's attributes and parameters.

2. The `Id` field is populated with the value `url` by default. You can specify a different value, but the ID must be unique within the catalog definition file.

3. From the Type list, shown in Figure 16–5, select the type of resource that you want to create. You can choose from `Taskflow`, `Portlet`, `Content`, and `Other`.

Figure 16–5 Types of Links

Notes:

- You can also add task flows and portlets to the catalog by dragging and dropping them from the Resource Palette or Application Resources pane onto the Catalog section in the Design view of the catalog definition file. The associated attributes are populated automatically when the resource is added to the catalog. See Section 16.2.3.7, "Dragging and Dropping a Resource into the Catalog."
- If you added an ADF task flow to the catalog and want to export the catalog to an already deployed application, then you must deploy the task flow as a shared library to the deployed application. For more information, see Section 13.3, "Adding Custom Task Flows to Your Portal."

4. If you are adding a custom resource, then specify the factory class of the component. For all other resource types, the `Factory Class` value is populated as soon as you select the type.

   The factory classes for the available resource types are as follows:

- Task flow: `oracle.webcenter.portalframework.sitestructure.rc.TaskFlowResourceFactory`
- Portlet: `oracle.webcenter.portalframework.sitestructure.rc.PortletResourceFactory`
- Content: `oracle.webcenter.content.model.rc.ContentUrlResourceFactory`

For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

5. In the URL field, specify the URL to access the resource. Table 16–1 provides the URL format to be used for each resource type.

Table 16–1 URL Format for the Different Resource Types

Resource Type	Location in the Application	URL Format
Task Flow from an ADF Library.	Resource Palette	**`taskflow://`***`Path_to_Task_Flow/Task_Flow_Definition_File_Name#Task_Flow_ID`*
Task Flow Within the Application.	Application Navigator	**`taskflow://`***`Path_to_Task_Flow/Task_Flow_Definition_File_Name#Task_Flow_ID`*
Portlet	Portlet producer connection in the Application Resources pane or in the Resource Palette	**`portlet://`***`Producer_ID/Portlet_ID`*
Content	Content Repository connection in the Application Resources pane	**`content://`***`Content_Connection_ID/Document_ID`*

Click the **Browse** icon next to the URL field to open the Choose Resource dialog, which enables you to add a resource of the selected type from the application or the Resource Palette.

Note: If you entered the URL for a portlet or content type resource manually, and if the connection for that resource is available only in the Resource Palette, then ensure that you first add the connection to the application.

---

6. In the `Visible` field, you can specify a true or false value, or an EL value to conditionally display this link to specific users or groups. The default value is `#{true}`, which means that the resource is displayed in the catalog at all times.
7. Optionally, in the URL Attributes section, you can define the following attributes by choosing them from the **Add** menu:
   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

Selecting an option on the Add menu creates a new row in the Folder Attributes table. You can use this row to specify the name, type, and value for the new attribute.

8. Use the URL Parameters section to define parameters on the resource. You can bind these parameters to other artifacts in the application. Click the **Add** icon to create a new row in the Parameters table.

16.2.3.3 Adding a Resource Catalog

You can include another Resource Catalog inside the selected catalog. When you add another catalog, only a pointer to this catalog is included in the catalog definition file. The actual catalog contents are inserted only at runtime.

To add a Resource Catalog:

1. From the **Add** menu in the Catalog section, select **Catalog Reference**.

   A new node titled `catalog` is added to the catalog. The right side of the page displays fields to define the new folder's attributes and parameters.

2. The `Id` field is populated with the value `catalog` by default. You can specify a different value, but the ID must be unique within the catalog definition file.

3. In the Path field, specify the MDS path to the catalog definition file, for example, `\oracle\webcenter\portalapp\catalogs\custom-catalog.xml`.

   You can use the Browse icon to browse application folders and select the catalog definition file.

4. In the `Visible` field, you can specify an EL value to conditionally display this catalog to specific users or groups. This attribute takes an EL value. The default value is `#{true}`, which means that this resource is displayed in the catalog at all times.

5. Optionally, in the Catalog Attributes section, you can define the following attributes by choosing them from the **Add** menu:

   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

   Selecting an option on the Add menu creates a new row in the Catalog Attributes table. You can use this row to specify the name, type, and value for the new attribute.

16.2.3.4 Adding a Component

You can add a custom component to the catalog. You can add a variety of components, such as simple ADF Faces components, compound objects containing two or more components, and JSF Verbatim tags that let you add arbitrary HTML content inside them. An example for arbitrary HTML that you can add to your catalog is a YouTube video.

To add a custom component:

1. From the **Add** menu in the Catalog section, select **Component**.

A `component` element is added to the catalog. The right side of the page displays fields to define the component's attributes and parameters.

2. The `Id` field is populated with the value `component` by default. You can specify a different value, but the ID must be unique within the catalog definition file.
3. In the Component Factory field, specify the name of a Java class that implements the `oracle.adf.rc.component.ComponentFactory` interface and creates an instance of the component based on a set of parameters, for example, `oracle.adf.rc.component.XmlComponentFactory`.

   As you type the name, the field auto-completes with valid factory classes from the classpath. You can also use the Browse icon to select a class.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."
4. In the `Visible` field, you can specify an EL value to conditionally display this component to specific users or groups. This attribute takes an EL value. The default value is `#{true}`, which means that this resource is displayed in the catalog at all times.
5. Optionally, in the Component Attributes section, you can define the following attributes by choosing them from the **Add** menu:
   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

   Selecting an option on the Add menu creates a new row in the Catalog Attributes table. You can use this row to specify the name, type, and value for the new attribute.
6. Use the Component Parameters section to add parameters that were defined when implementing the factory class.

   For example, if you are adding an XML component, click the **Add** icon in the Parameters section and select **xml**. In the new row that is displayed, specify the XML code for the component in the value field.

   Note: The xml option is displayed only if you selected `oracle.adf.rc.component.XmlComponentFactory` as the component factory.

   To ensure that the component works properly, you must specify the custom component ID to be `#`, and provide the namespace, as shown in the following example:

```
<cust:panelCustomizable id="#"
xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable"/>
```

   The `#` value ensures that a unique ID is generated dynamically for the component.

16.2.3.5 Adding a Custom Folder

You can add a folder using a Resource Catalog adapter so that the folder is populated dynamically. A custom folder is not added as a folder with resources to the catalog; it contains only a reference to the factory class, which displays the resources dynamically.

To add a custom folder:

1. From the **Add** menu in the Catalog section, select **Custom Folder**.

   A `customFolder` element is added to the catalog. The right side of the page displays fields to define the folder's attributes and parameters.

2. The `Id` field is populated with the value `customFolder` by default. You can specify a different value, but the ID must be unique within the catalog definition file.

3. In the Initial Context Factory field, specify the name of a Java class that implements the `javax.naming.InitialContextFactory` interface and generates the folder based on a set of parameters.

   For more information, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

4. In the `Visible` field, you can specify an EL value to conditionally display this folder to specific users or groups. This attribute takes an EL value. The default value is `#{true}`, which means that this resource is displayed in the catalog at all times.

5. Select **Insert Folder Contents** to display the contents of the custom folder directly in the catalog rather than displaying them under the folder.

6. Optionally, in the Custom Folder Attributes section, you can define the following attributes by choosing them from the **Add** menu:

   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

   Selecting an option on the Add menu creates a new row in the Catalog Attributes table. You can use this row to specify the name, type, and value for the new attribute.

7. Use the Custom Folder Parameters section to add parameters that were defined while implementing the factory class. You can bind these parameters to other artifacts in the application. Click the **Add** icon in the Parameters section to create a new row in the Parameters table.

   You may see a dropdown menu on the Add icon if the factory class exposes parameters, for example, Content Presenter-specific factory classes provide a `templateView` parameter.

16.2.3.6 Adding a Custom Content Provider

A custom content provider dynamically generates zero or more catalog entries at runtime. Catalog entries include folders, links, custom folders, components, and so on.

When you add a Custom Folder, a folder is created in the catalog and is displayed at runtime even if it is empty. However, when you add a Custom Content element, a folder is created in the catalog, but is displayed at runtime only if it has components inside it. Except for this difference, a custom content provider is similar to a custom folder.

To add a custom content provider:

1. From the **Add** menu in the Catalog section, select **Custom Content**.

   A `customContent` element is added to the catalog. The right side of the page displays fields to define the folder's attributes and parameters.

2. The `Id` field is populated with the value `customFolder` by default. You can specify a different value, but the ID must be unique within the catalog definition file.

3. In the Content Provider field, specify the fully qualified name of a class that implements the interface `oracle.adf.rc.spi.plugin.catalog.CustomContentProviderV2`.

   You can use the Browse icon to see a list of classes that implement this interface. Also, see Section C.4, "Factory Classes Available for Adding Dynamic Resources to the Catalog."

4. In the `Visible` field, you can specify an EL value to conditionally display this folder to specific users or groups. This attribute takes an EL value. The default value is `#{true}`, which means that this resource is displayed in the catalog at all times.

5. Optionally, in the Component Attributes section, you can define the following attributes by choosing them from the **Add** menu:

   - **Title**: A label to be used for the resource in the catalog. This attribute is defined by default. You can change its value, if required.
   - **Description**: A description of this resource.
   - **Subject**: Keywords to facilitate keyword searching of the Resource Catalog.
   - **ToolTip**: The tool tip to be displayed when you move the mouse over this resource name in the catalog.
   - **IconURI**: The icon to be displayed next to the resource name in the catalog.

   Selecting an option on the Add menu creates a new row in the Catalog Attributes table. You can use this row to specify the name, type, and value for the new attribute.

6. Use the Custom Content Parameters section to define parameters on the folder. The parameters you define here are passed to and interpreted by the `CustomContentProviderV2` implementation. Click the **Add** icon in the Parameters section to create a new row in the Parameters table.

16.2.3.7 Dragging and Dropping a Resource into the Catalog

In addition to the resources mentioned in the previous sections, you can add the following resources by dragging them and dropping them onto a selected folder in the catalog definition file:

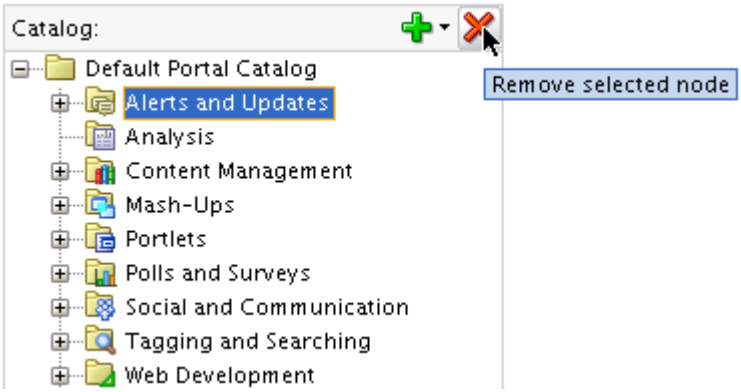
- Portlets, from the Application Resources pane or the Resource Palette.
- Content from the Oracle WebCenter Portal's Content Service for Oracle WebCenter Content, from the Application Resources pane or the Resource Palette.

- Task flows, from the Application Resources pane or the Resource Palette.

  Note: If you add an ADF task flow to the catalog and want to export the catalog to an already deployed application, then you must deploy the task flow as a shared library to the deployed application.

  For more information, see Section 13.3, "Adding Custom Task Flows to Your Portal."

- Another catalog definition file, from the Application Navigator.



16.2.3.8 Editing a Resource

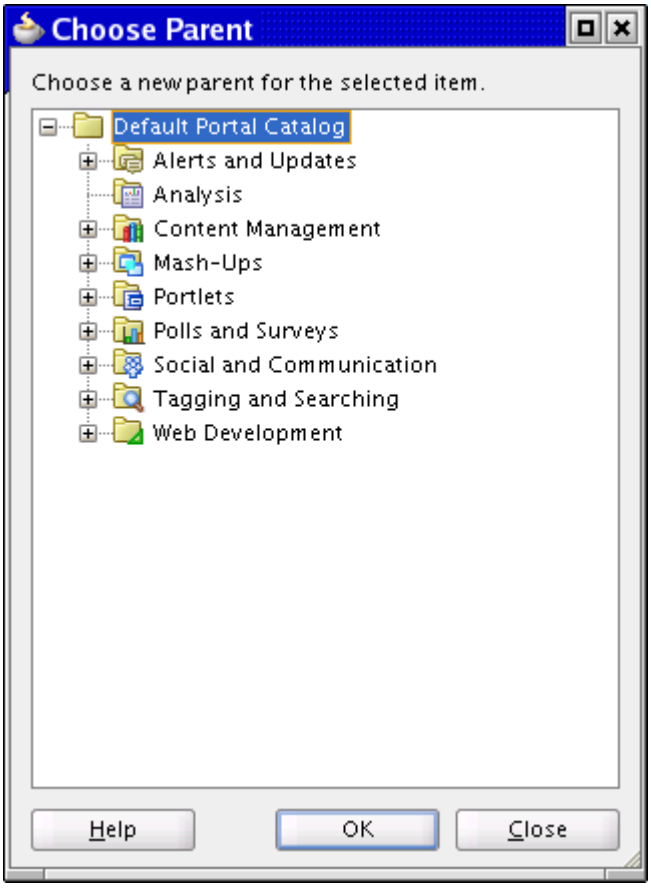
To edit a resource, select it in the Catalog section of the catalog definition file. The resource's attributes and parameters are displayed in the right half of the page. You can edit values for these attributes and parameters and save the catalog definition file. For details about a resource's attributes and parameters, see the section about adding that resource to the catalog.

16.2.3.9 Deleting a Resource

To delete a resource, select it in the Catalog section of the catalog definition file and click the **Remove selected node** icon, shown in Figure 16–6.

Figure 16–6 Delete Option in the Resource Catalog

16.2.3.10 Rearranging Resources in the Catalog



While organizing resources in the catalog, you can move a resource to a different folder in the hierarchy. You can rearrange resources in the following ways:

- Drag and drop them from one folder into another.
- Use the Change Parent context menu option to move a resource to a different folder.

To rearrange a resource using the Change Parent option:

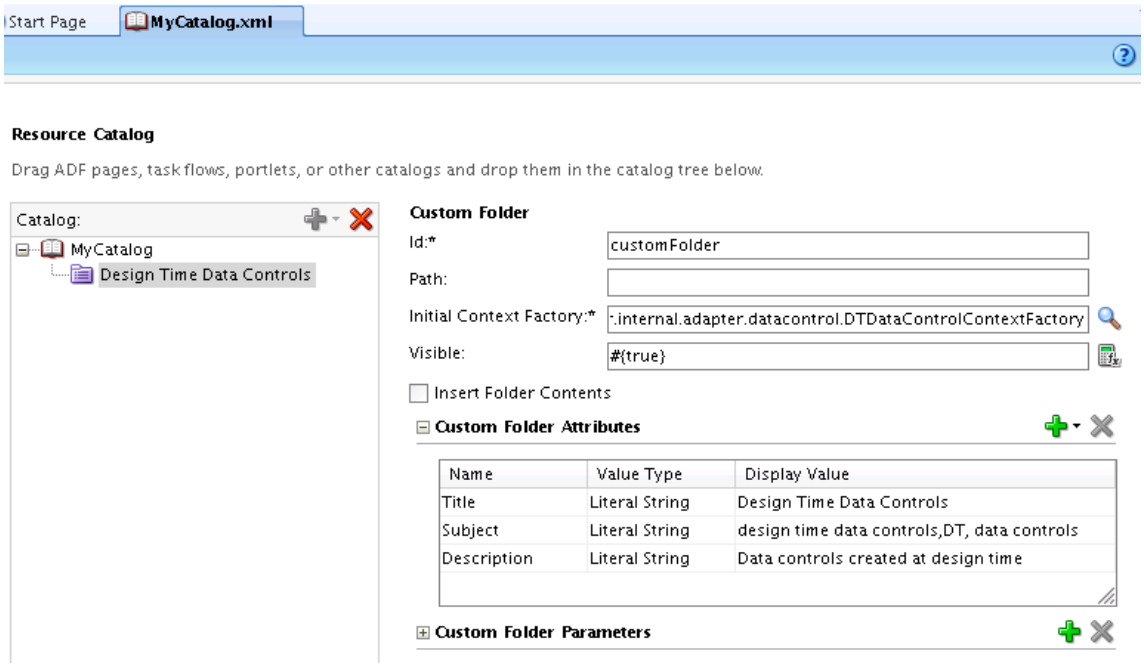
1. Right-click the resource in the Catalog section of the catalog definition file and select **Change Parent** from the context menu.
2. In the Change Parent dialog, shown in Figure 16–7, select the folder in which to include the resource.

Figure 16–7 Change Parent Dialog

3. Click **OK**.

> **Note:** The OK button is enabled only when you select a valid location for the resource.

16.2.4 How to Expose Data Controls Created at Design Time



Oracle WebCenter Portal: Framework exposes a large number of service data controls that can be added to application pages and task flows. In addition, you may have created SQL or Web Services data controls in JDeveloper. To enable users to add these data controls to pages and task flows, you must expose the data controls in the Resource Catalog. For this, you must add a `customFolder` entry in your catalog definition file, as shown in the following example and Figure 16–8:

```
<customFolder id="dtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DTDataCon
trolContextFactory">
  <attributes>
    <attribute value="Design Time Data Controls" attributeId="Title"/>
    <attribute value="Data controls created at design time"
attributeId="Description"/>
    <attribute value="design time data controls,DT, data controls"
attributeId="Subject"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png"
attributeId="IconURI"/>
```

```
  </attributes>
</customFolder>
```

Figure 16–8 Design Time Data Controls Folder in the Catalog Definition File Overview

To expose the `customFolder` as a translatable resource in the catalog, the folder's string attributes must be stored as resource strings in a resource bundle. For this, the catalog definition file must have a `resourceBundle` attribute and each translatable attribute must have an `isKey` attribute. Then the attribute value is saved in a resource bundle, as shown in the following example:

The resourceBundle attribute on the catalog definition:

```
<catalogDefinition id="DefaultCatalog" visible="#{true}"

resourceBundle="oracle.webcenter.portalapp.catalogs.DefaultCatalogBundle"
                  definitionFilter="portal.catalog.DefaultCatalogFilter"
                  xmlns="http://xmlns.oracle.com/adf/rcs/catalog">
```

The `isKey` attribute defined on the attributes of a translatable resource:

```
<customFolder id="dtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DTDataCon
trolContextFactory">
  <attributes>
    <attribute value="DATACONTROL_FOLDER.TITLE" isKey="true" attributeId="Title"/>
    <attribute value="DATACONTROL_FOLDER.DESCRIPTION" attributeId="Description"
isKey="true"/>
    <attribute value="DATACONTROL_FOLDER.KEYWORDS" attributeId="Subject"
isKey="true"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png" isKey="false"
attributeId="IconURI"/>
  </attributes>
</customFolder>
```

For more information about using resource bundles, see Section 22.12, "Configuring Runtime Resource String Editing."

At runtime, the catalog displays a folder titled `Design Time Data Controls` irrespective of whether the application has any design-time data controls.

In a deployed application, the Resource Manager allows you to add design-time data controls individually to custom catalogs. Out-of-the-box catalogs cannot be edited at runtime. For more information, see "Adding Resources" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

Exposing Custom Data Controls in an Already Deployed Application

If you created SQL or Web Services data controls in your application, and want to expose them in an already deployed application, you must perform the following steps:

- Package the application into an ADF shared library.
- Deploy the application to the WebLogic Server instance. For more information, see Section 56.2.3, "Rebuilding the Spaces Shared Library List."

When you perform this configuration, the deployed data controls are available in the Design Time Data Controls folder in the runtime Resource Registry. Users can add the data controls from the registry to any custom Resource Catalog, from where they can be consumed in pages and task flows.

16.2.5 How to Expose Data Controls Created at Runtime

Users can create data controls at runtime in the Resource Manager. If you want your Resource Catalog to dynamically display data controls created at runtime, add a `customFolder` entry in your catalog definition file, as shown in the following example:

```
<customFolder id="rtDataControls"

factoryClass="oracle.webcenter.datacomposer.internal.adapter.datacontrol.DataControlContextFactory">
  <attributes>
    <attribute value="Runtime Data Controls" attributeId="Title"/>
    <attribute value="Data controls created at runtime"
attributeId="Description"/>
    <attribute value="runtime data controls,RT,data controls"
attributeId="Subject"/>
    <attribute value="/adf/webcenter/folderlists_qualifier.png"
attributeId="IconURI"/>
  </attributes>
</customFolder>
```

To expose this folder as a translatable resource, the folder's string attributes must be stored as resource strings in a resource bundle. See Section 16.2.4, "How to Expose Data Controls Created at Design Time" for an example of how to create translatable resources.

At runtime, the catalog displays a folder titled `Runtime Data Controls` irrespective of whether the folder has any data controls.

16.2.6 How to Control Visibility of Portlets in the Resource Catalog

Out-of-the-box, a Resource Catalog displays portlets from all the available producers irrespective of whether the portlets are secured or not. As a result, users are allowed to

consume even secured portlets to which they do not have access. When a user adds such a portlet to a page, the portlet component is added, but it does not display any content. To ensure that users view and consume only those portlets that they can access, you can control the visibility of portlets in the Resource Catalog. Implement the `PortletItemSecurityHelper` interface to display portlets conditionally in the Resource Catalog, based on the user's permissions.

To control portlet visibility:

1. Implement the `PortletItemSecurityHelper` interface in your own item security helper class, for example, `CustomPortletSecurityHelper.java`.

   Example 16–1 shows a sample implementation of the `PortletItemSecurityHelper` interface. The following assumptions are made for the purpose of this example:

   - Grants are defined for each portlet to control who can see it.
   - A permission class, `PortletVisibilityPermission`, is defined to check a user's permissions on the portlet.

Example 16–1 Sample Implementation of PortletItemSecurityHelper

```
public class CustomPortletSecurityHelper extends PortletItemSecurityHelper
{
    public boolean canView(String producerId, String portletId)
    {
        String permissionPath = producerId + '/' + portletId;
        PortletVisibilityPermission permission = new PortletVisibilityPermission
(permissionPath, VIEW_ACTION);
        try
        {
          // throws AccessControlException if the permission is not granted
          JpsAuth.checkPermission(permission);
          canView = true;
          sLogger.logp(Level.FINE, SOURCE_CLASS, method,
                       "PortletVisibilityPermission check passed. Producer={0},
Portlet={1} Action=view",
                       new Object[]{producerId, portletId});
        }
        catch(AccessControlException ace)
        {
          canView = false;
          sLogger.logp(Level.FINE, SOURCE_CLASS, method,
                       "PortletVisibilityPermission check passed. Producer={0},
Portlet={1} Action=view",
                       new Object[]{producerId, portletId});
        }
        return canView;
    }
}
```

2. Create an `rc_ext.xml` file in the application's `META-INF` directory, and add the following code to register the implementation with the Resource Catalog:

```
<extension xmlns:="http://xmlns.oracle.com/adf/rc/extension"
           id="your.extension.id"
           name="Your Extension Name"
           version="11.1.1.4.0">
  <item-security-helper class="your.implementation.class.name"/>
</extension>
```

At runtime, when a user clicks Add Content in Composer, the Resource Catalog displays only those portlets on which the user has permissions.

16.2.7 How to Configure the Default Resource Catalog for an Application or Page

You can configure the default catalog at the application and page levels in the following ways:

- Registering it in the application's `adf-config.xml` file. This is an application-wide setting. For more information, see "Registering the Catalog in the adf-config.xml File".
- If you have multiple catalogs, by adding the `CatalogSelector`, which includes the logic to determine which catalog is shown for a specific page or locale. For more information, see Section 16.5.1, "How to Configure Multiple Resource Catalogs."
- If your application page contains Composer components, then by specifying the catalog name in the `Catalog` attribute on the `Page Customizable` component. You can specify a static or EL value. For more information, see Section B.1.1, "Page Customizable."

Registering the Catalog in the adf-config.xml File

To register a Resource Catalog in the `adf-config.xml` file so that it is used as the default catalog for the application:

1. Open the application's `adf-config.xml` file.
2. Change the `catalog-name` attribute value in the `<rcv:rcv-config>` element and specify the custom catalog name, as shown in the following example:

```
<rcv:rcv-config>
  <rcv:default-catalog
catalog-name="/oracle/webcenter/portalapp/catalogs/myCustomCatalog.xml"/>
</rcv:rcv-config>
```

   The `catalog-name` attribute identifies the catalog to be used as the default one.

   The path you specify is relative to the Resource Catalog root directory, for example, if you saved your new catalog definition as `C:\JDeveloper\mywork\RCSampleApp\Portal\Public_Html\oracle\webcenter\portalapp\catalogs\myCustomCatalog.xml`, then the `catalog-name` value would be `/oracle/webcenter/portalapp/catalogs/myCustomCatalog.xml`. The name uses the `/` separator because it represents a part of an MDS path.

   Note: For information about the Resource Catalog-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

3. Save the `adf-config.xml` file.

16.2.8 What You May Need to Know When Defining a Resource Catalog

To correctly implement Resource Catalogs, you must know where the application looks for the definitions and the XML schema upon which the definitions are based. See Appendix B, "Composer Component Properties and Files" for further information.

16.2.9 How to Define Task Flow Parameters and Attributes of the Enclosing Show Detail Frames for Task Flows

At runtime, when you add a task flow from the Resource Catalog to your application page in Composer, the task flow is automatically enclosed in a `Show Detail Frame` component. You can initialize attributes, such as the title, height, or width, associated with the enclosing `Show Detail Frame` by defining those attributes in the catalog definition file that contains the task flow. To differentiate the task flow's properties from the enclosing `Show Detail Frame`'s properties, you must use **`attr.`** as a prefix for `Show Detail Frame` properties.

For example, if a user adds a task flow to a page with a dark background setting, the task flow continues to use the background setting of the enclosing `Show Detail Frame` component. This may not be the look the user wants. To enable the user to change the `Show Detail Frame`'s background property, you must initialize and expose the background attribute in the Resource Catalog. At runtime, while editing the task flow's properties, a user can also change the `Show Detail Frame`'s background attribute.

Similarly, you can also initialize task flow parameters. You can define such parameters in the catalog definition file using an EL expression. At runtime, while editing the task flow's properties, a user can also change values for the exposed parameters. To differentiate the task flow's properties from the initialized parameters, you must use **`parameter.`** as a prefix for such parameters.

To initialize task flow parameters and `Show Detail Frame` properties:

1. Open the catalog definition file that contains the task flow.
2. Within the task flow's `<url>` or `<resource>` element, add an `<attribute>` entry for each parameter and `Show Detail Frame` attribute you want to define.

   The `attributeId` for a parameter must contain the parameter name along with a prefix of **`parameter.`**; the `attributeId` for a `Show Detail Frame` attribute must contain the attribute name along with a prefix of **`attr.`** as shown in the following example:

```
<url visible="#{true}"
factoryClass="oracle.webcenter.portalframework.sitestructure.rc.TaskFlowResourc
eFactory"
     id="wallMiniView"

url="taskflow://oracle/webcenter/peopleconnections/wall/controller/taskflows/Wa
llViewer.xml#WallViewer">
  <attributes>
    <attribute value="WALL_MINIVIEW.TITLE" attributeId="Title" isKey="true"/>
    <attribute value="WALL_MINIVIEW.DESCRIPTION" attributeId="Description"
isKey="true"/>
    <attribute value="#{securityContext.userName}"
attributeId="parameter.userName"/>
    <attribute value="false" attributeId="attr.stretchContent"/>
    <attribute value="never" attributeId="attr.showResizer"/>
  </attributes>
  <contents/>
</url>
```

> **Note:** Include the `isKey` attribute and set it to `true` only if the value is coming from a resource bundle. If not included, the `isKey` value defaults to `false`.

3. Save the catalog definition file.

16.3 Managing a Resource Catalog and Enabling Runtime Administration

The Resource Manager in a Framework application enables users with administrative privileges to create and modify application resources at runtime. By exposing catalogs in the Resource Manager, you allow administrators to manage these catalogs at runtime. You can also export selected catalogs from JDeveloper so that administrators can modify or delete them at runtime

This section outlines the tasks you can perform in JDeveloper to enable runtime administration of your catalogs. It contains the following sections:

- Section 16.3.1, "Managing Resource Manager Entries"
- Section 16.3.2, "Enabling Further Development of Deployed Resource Catalogs"
- Section 16.3.3, "Working with Spaces Resource Catalogs"

16.3.1 Managing Resource Manager Entries

In JDeveloper, use the Resource Manager-specific options on the context menu on a catalog definition file as follows:

- Create Portal Resource: Creates an entry for the catalog in the Resource Manager. The catalog can then be selected for use during page, template, and task flow creation.

  You must set certain attributes while creating an entry. Optionally, you can specify who can revise and delete the selected catalog in the Resource Manager. For more information, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

- Update Portal Resource: Edit the attributes that you defined while creating Resource Manager entries. For more information, see Section 17.2.3, "How to Update Portal Resource Properties."

- Remove Portal Resource: Remove the entry for this catalog from the Resource Manager registry. For more information, see Section 17.2.4, "How to Remove a Resource from the Resource Manager."

16.3.2 Enabling Further Development of Deployed Resource Catalogs

Out-of-the-box Resource Catalogs cannot be modified or deleted at runtime. However, users with administrator privileges can make a copy of an out-of-the-box Resource Catalog and edit its properties or delete it.

> **Note:** If you create a resource catalog at runtime and do not import it back into the design time environment, your new resource catalog may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

The Edit Source option in the Resource Manager enables users to modify the content of a copied or custom Resource Catalog at runtime. However, as text editing is easier in JDeveloper than in the runtime source editor, users may choose to download a Resource Catalog, edit it in JDeveloper, and upload it back to the deployed application. At design time, this type of round-trip development includes importing the downloaded Resource Catalog, editing it in JDeveloper, and exporting it so that it can be uploaded back to the deployed application.

This section describes how to import and export Resource Catalogs in JDeveloper. For information about modifying catalog content, see Section 16.2.3, "How to Manage Content in the Resource Catalog."

16.3.2.1 Exporting a Resource Catalog

To expose a Resource Catalog in an already deployed application, you must export it from JDeveloper, then upload to the application using the runtime Resource Manager. When you export a catalog in JDeveloper, an EAR file is created with the catalog definition file and the `generic-site-resources.xml` file. The `generic-site-resources.xml` file contains metadata that helps identify the type of resource, a Resource Catalog in this case, so that the resource is displayed under the correct category in the Resource Manager.

For generic information, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

16.3.2.2 Importing a Resource Catalog

When you expose a Resource Catalog at runtime, users with privileges can add or delete components to suit their business requirements. However, to perform more complex tasks, such as applying catalog filters or adding custom resources that are not available in the deployed application, the runtime catalog must be downloaded, imported into JDeveloper and edited, exported from JDeveloper, and uploaded back to the runtime application.

> **Note:** To expose custom resources, such as task flows created in JDeveloper, that are not available in the deployed application, along with exporting the catalog you must also deploy the resource as a shared library.

When a user downloads a catalog from a deployed application, an EAR file is created containing the catalog definition XML file and the `generic-site-resources.xml` file. The `generic-site-resources.xml` file contains metadata specific to the Resource Catalog. This helps in identifying the type of resource, a Resource Catalog in this case. To edit the Resource Catalog in JDeveloper, you must first import the EAR file. On importing, the catalog definition file is extracted to the `siteResources` folder.

If the resource was downloaded from WebCenter Portal: Spaces, it is extracted to *`APPLICATION_ROOT`*`/oracle/webcenter/siteresources/scopedMD/guid`, where `guid` is the GUID of the space from which the resource was downloaded. Otherwise, the imported resource is created in *`APPLICATION_ROOT`*`/oracle/webcenter/portalapp`. You can open the catalog definition file and edit it as you would any other catalog at design time. The updated catalog must then be exported to the runtime application.

For generic information, see Section 17.4.2, "How to Import a Portal Resource into JDeveloper."

For information about downloading a catalog from the deployed application, see "Uploading and Downloading a Resource Catalog" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

16.3.3 Working with Spaces Resource Catalogs

Out-of-the-box, WebCenter Portal: Spaces provides several default Resource Catalogs for people to use. If these default catalogs are not suitable, you can build catalogs of your own within WebCenter Portal: Spaces. For details, see the chapter "Working with the Resources that Compose a Portal or Community" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

If you want to create a Resource Catalog that is beyond the editing capabilities of WebCenter Portal: Spaces, you can create the catalog in JDeveloper and then upload it to WebCenter Portal: Spaces. You do not have to develop the catalog from scratch, you can export an existing catalog from WebCenter Portal: Spaces and edit it in JDeveloper, or use one of the out-of-the-box catalogs as your starting point.

Oracle WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources, such as Resource Catalogs, to WebCenter Portal: Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build custom catalogs and other types of resources for WebCenter Portal: Spaces. For details, see Section 56, "Extending the Spaces Application Using JDeveloper."

16.4 Filtering Items in the Resource Catalog

If you want to arrange catalog content so that it is essentially the same for all users, but displays different subsets of the content to different users, then you can configure your Resource Catalog to filter out selected items based on specific criteria.

For example, if two users `A` and `B` have different privileges on a page, you can configure your application to display the entire catalog to user `A` and only a subset of items in the catalog to user `B`.

You can filter resources in the catalog either at the catalog level or at the individual resource level. This section explains both procedures. It contains the following sections:

- Section 16.4.1, "Resource-Level Filtering"
- Section 16.4.2, "Catalog-Level Filtering"

16.4.1 Resource-Level Filtering

You can display a resource conditionally by specifying an EL value for the `Visible` attribute on the resource. For information about editing the Visible attribute, see Section 16.2.3, "How to Manage Content in the Resource Catalog."

16.4.2 Catalog-Level Filtering

To apply a filter on the catalog, you must implement the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface. Additionally, you must associate this filter with the Resource Catalog.

To implement the `CatalogDefinitionFilter`:

1. From the **File** menu, choose **New**.

2. In the New Gallery dialog, expand **General**, select **Java**, and then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, specify a name for the class, for example, `CatalogFilter`.
4. Under the Optional Attributes section, add the `oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter` interface.
5. Click **OK**.
6. Specify the logic for filtering items.

   Note: When implementing the filter logic it is common to want information about the current user and current page. This information can be obtained from the `FacesContext`.

   Example 16–2 shows a sample `CatalogDefinitionFilter` implementation. It is configured to hide the `Discussions` folder (`forumsFolder`) for user `jdoe` from the custom catalog, `users-catalog.xml`, described in Section 16.2, "Creating a Custom Resource Catalog." The entire catalog, with the `ADF Faces Components` and `Discussions` folders, is shown to all other users.

Example 16–2 Sample Showing CatalogDefinitionFilter Implementation

```
package webcenter;

import oracle.adf.rc.catalog.CatalogElement;
import oracle.adf.rc.spi.plugin.catalog.CatalogDefinitionFilter;

import java.util.Hashtable;

import javax.faces.context.ExternalContext;
import javax.faces.context.FacesContext;

public class CatalogFilter implements CatalogDefinitionFilter {

  public boolean includeInCatalog(CatalogElement element, Hashtable env) {

    ExternalContext ectx =
FacesContext.getCurrentInstance().getExternalContext();

    if ("jdoe".equals(ectx.getRemoteUser()) &&
"forumsFolder".equals(element.getId()))
      return false;
    else
      return true;
  }

}
```

7. Open the catalog definition file.
8. Select the root node in the Catalog section, and set the Catalog Filter field to the name of the Java class you created, for example, `webcenter.CatalogFilter`.

   This adds a `definitionFilter` attribute in Source view of the file.
9. Save the catalog definition file.

16.5 Configuring Multiple Resource Catalogs

You can expose different catalogs to different users based on specific criteria, such as the page being edited, the user, or the user role. This section describes how to associate multiple Resource Catalogs with your application. It contains the following subsections:

- Section 16.5.1, "How to Configure Multiple Resource Catalogs"
- Section 16.5.2, "What Happens at Runtime"

16.5.1 How to Configure Multiple Resource Catalogs

To use multiple catalogs, you must implement the `ResourceCatalogSelector` API to select the appropriate catalog for the user and the page being edited. You must include the `catalog-selector` entry in your application's `adf-config.xml` file to specify the name of your `ResourceCatalogSelector` class. If you do not specify a `catalog-selector`, the default catalog is used for all editable pages and all users see the same content. If you specify a `catalog-selector`, the default catalog is used only when the specified selector returns null.

To implement multiple Resource Catalogs:

1. Create your custom catalogs by performing the steps outlined in Section 16.2, "Creating a Custom Resource Catalog."
2. Implement the `oracle.adf.rc.model.config.ResourceCatalogSelector` interface in your own Resource Catalog selector class, for example, `CatalogSelector.java`.

   Example 16–3 shows a catalog selector implementation where a custom Resource Catalog, `admin-catalog.xml`, is shown to `ahunold` who has administrator privileges, and `users-catalog.xml` is shown to users `sking` and `jdoe`. If there is a problem with rendering either of these catalogs, then the default catalog is shown to users.

Example 16–3 Sample ResourceCatalogSelector Showing Entries for Multiple Resource Catalogs

```
package webcenter;

import javax.faces.context.FacesContext;

import java.util.Map;

import javax.faces.component.UIViewRoot;
import javax.faces.context.FacesContext;
import javax.faces.context.ExternalContext;

import oracle.adf.rc.model.config.ResourceCatalogSelector;
import oracle.adf.rc.model.dc.RCVContext;

import oracle.adf.rc.model.config.ResourceCatalogSelector;

/**
 * CatalogSelector is a sample implementation of the ResourceCatalogSelector
 * interface.
 *
```

```
 * This implementation is based on the authenticated user
 */
public class CatalogSelector implements ResourceCatalogSelector {
  public CatalogSelector() {
  }

  /**
   * Returns the Id of the catalog that must be used for the current
   * user.
   *
   * @param context a Map cont
   * @return id of the catalog to be used for the current user or
   *         null if the default catalog must be used.
   */
  public String getCatalogName(Map context) {
    // if no catalog is selected, return null & ensure that the Composer uses the
    // default catalog defined in the rcv-config
    String retval = null;

    // get information about the current user.
    FacesContext fctx = FacesContext.getCurrentInstance();
    ExternalContext ectx = fctx.getExternalContext();
    String user = ectx.getRemoteUser();

    if (user == null || user.length() == 0) {
      // user name is not available so use the default catalog
      retval = null;

    }
    else if (user.equals("jdoe") || user.equals("sking")  ) {
      // return users-catalog for users jdoe and sking
      retval = "users-catalog";

    }
    else if (user.equals("ahunold")) {
      // return admin-catalog for user ahunold
      retval = "admin-catalog";

    }

    return retval;

    }
}
```

3. In your `adf-config.xml` file, enter the name of the class you created for selecting a Resource Catalog with the `<rcv:catalog-selector>` tag as show in the following example:

```
<rcv:rcv-config>
<rcv:default-catalog
catalog-name="/oracle/webcenter/portalapp/catalogs/default-catalog.xml"/>
<rcv:catalog-selector class-name="webcenter.CatalogSelector"/>
</rcv:rcv-config>
```

   The value for `catalog-name` corresponds to the default catalog definition file with the MDS path.

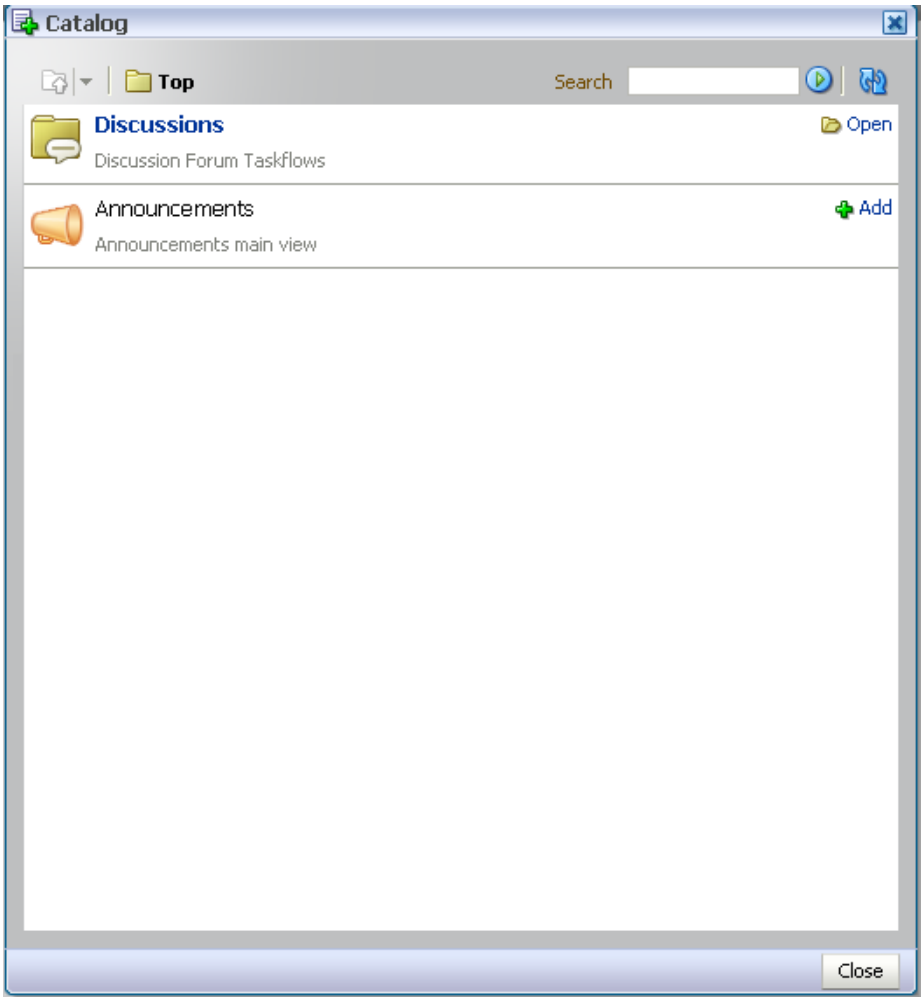
Note: For information about the Resource Catalog-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

16.5.2 What Happens at Runtime

Different catalogs are displayed to users based on the criteria you specified.

Based on the `ResourceCatalogSelector` implementation in Example 16–3, Figure 16–9 and Figure 16–10 show the two catalogs that are shown to user `sking` or `jdoe` and to administrator `ahunold` respectively.

Figure 16–9 Catalog Displayed to sking and jdoe



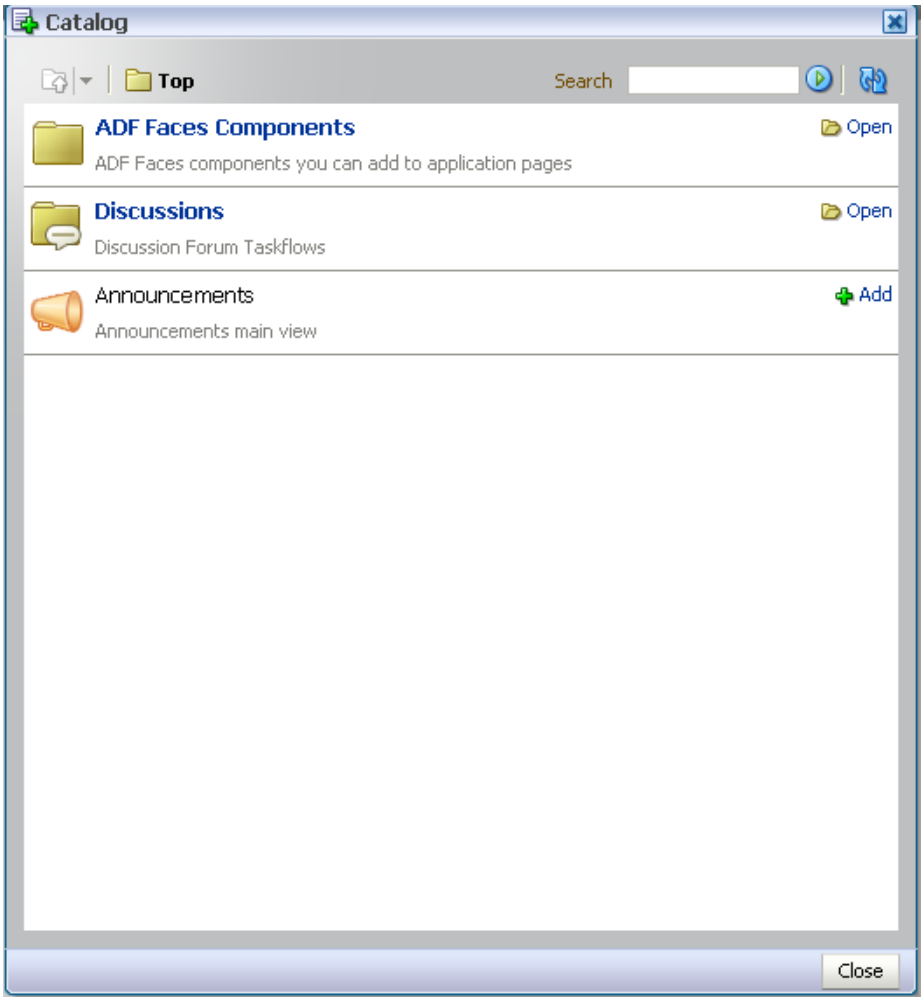


Figure 16–10 Resource Catalog Displayed to the ahunold

16.6 Troubleshooting Problems with the Resource Catalog

This section provides information to assist you in troubleshooting problems you may encounter while using the Resource Catalog.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

Resource Catalog is empty.

Solution

The default catalog is not available to MDS. Ensure that the deployment profile contains the necessary entries to copy the default catalog file. Also, ensure that in the MDS section of `adf-config.xml`, a namespace entry points to the default catalog file.

Problem

A project task flow does not appear in the Resource Catalog.

Solution

The task flow must be packaged as an ADF Library (JAR file) and added to the project. You must also ensure that the task flow ID is given in the following format:

```
taskflow://Path_to_Task_Flow/Task_Flow_Definition_File_Name#Task_Flow_ID
Ex.
taskflow://oracle/webcenter/peopleconnections/wall/controller/taskflows/WallViewer
.xml#WallViewer
```

17

Adding and Using the Resource Manager

This chapter explains how to enable users to administer portal resources at runtime using the Resource Manager.

Using the Resource Manager users can also download runtime portal resources (from WebCenter Portal: Framework applications or WebCenter Portal: Spaces) and import them into Oracle JDeveloper for further development. These resources can then be exported from JDeveloper and uploaded back into the deployed application. Portal resources can also be created from scratch in JDeveloper and uploaded to the deployed application.

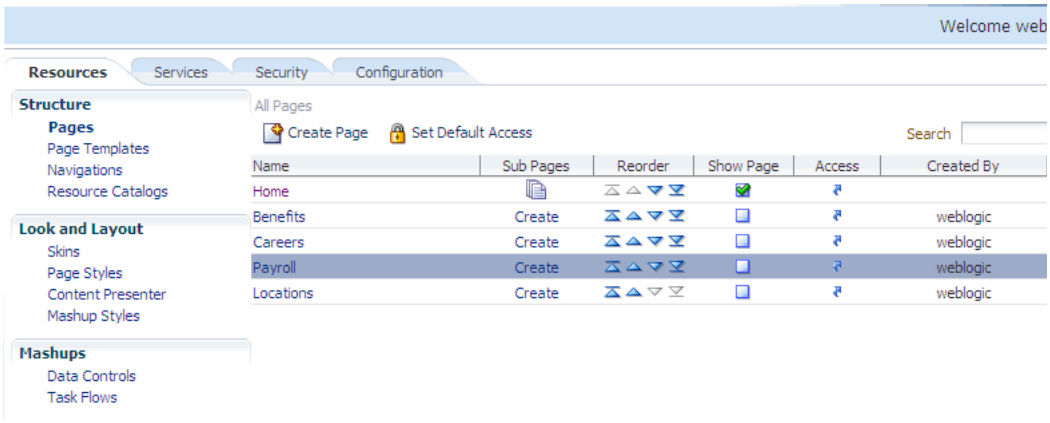
This chapter includes the following subsections:

- Section 17.1, "Introduction to Runtime Resource Management"
- Section 17.2, "Working with Portal Resources in JDeveloper"
- Section 17.3, "Enabling Runtime Administration of Your Portal"
- Section 17.4, "Enabling Round-Trip Development of Resources"

For information about using the Resource Manager to administer portal resources at runtime, see the chapter "Working with the Resources that Compose a Portal or Community" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

17.1 Introduction to Runtime Resource Management

A portal is a constantly evolving application. While the initial framework for the portal is designed prior to deployment, this really acts as a starting point. The design of the portal is likely to be enhanced by the actual users of the portal.



This runtime resource management provides:

- **Runtime development**—Continue developing your portal after deployment by creating resources, such as pages, skins, and data controls at runtime. For more information, see Section 17.3.2, "How to Use the Resource Manager at Runtime."
- **Round-trip development**—Pull resources from the deployed portal into JDeveloper for further development and then upload the enhanced resources back into the running application. For more information, see Section 17.4, "Enabling Round-Trip Development of Resources."
- **Iterative development**—Supply a running portal with new or improved visualizations of metadata-only resources from JDeveloper without the need to redeploy or restart the application. For more information, see Section 1.5, "Preparing for Iterative Development."

- **Extension of WebCenter Portal: Spaces**—Build and manage new resources for WebCenter Portal: Spaces in JDeveloper and package them on a periodic basis for distribution to the runtime portal. For more information, see Chapter 56, "Extending the Spaces Application Using JDeveloper."

WebCenter Portal enables runtime resource management through the Resource Manager. Using the Resource Manager, users with the appropriate privileges can continue developing the portal after the application has been deployed (Figure 17–1).

Figure 17–1 The Resource Manager in a WebCenter Portal: Framework Application

At runtime, users with the appropriate privileges can create and edit:

- Pages
- Page templates
- Navigation models
- Resource Catalogs
- Skins
- Page styles
- Content Presenter display templates
- Mashup styles
- Data controls
- Task flows

Using the Resource Manager, portal users can also download resources, or an entire application, from the runtime environment, edit them in JDeveloper, and then upload them back into the deployed application.

Users can also create resources from scratch in JDeveloper, export them as portal resources, and then upload them into the deployed portal. This is a very useful way of creating more fully functional portal resources for use in WebCenter Portal: Spaces.

This process is known as round-trip development. For more information, see Section 17.4, "Enabling Round-Trip Development of Resources."

17.2 Working with Portal Resources in JDeveloper

For a resource to be included in the Resource Manager and therefore available for runtime administration, it must be created as a portal resource.

To create a resource as a portal resource it must be located in the `oracle/webcenter/portalapp` directory of the application project.

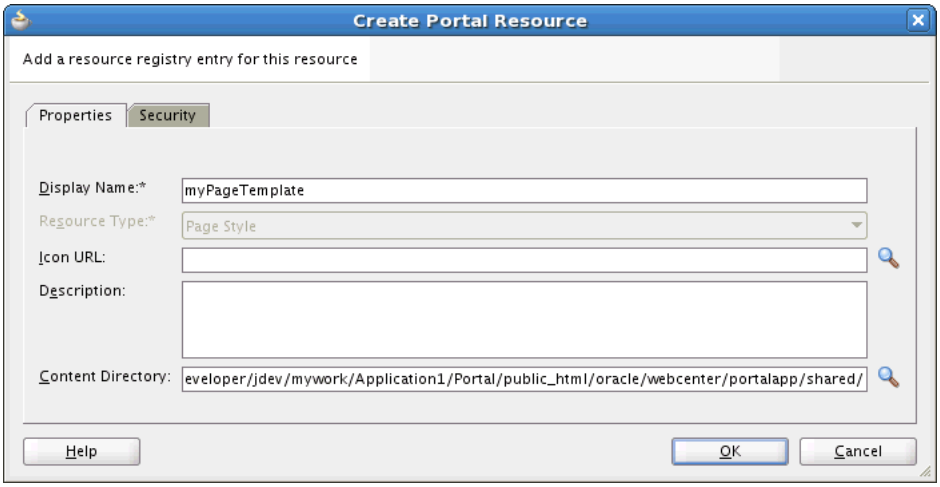
This section includes the following subsections:

- Section 17.2.1, "How to Add a Resource to the Resource Manager"
- Section 17.2.2, "What You May Need to Know About the Content Directory"
- Section 17.2.3, "How to Update Portal Resource Properties"
- Section 17.2.4, "How to Remove a Resource from the Resource Manager"

17.2.1 How to Add a Resource to the Resource Manager

To enable runtime administration of a resource it must be included in the Resource Manager. To do this, you need to identify the resource as a portal resource.

To add a resource to the Resource Manager:



1. In the Application Navigator, right-click the resource that you want to include in the Resource Manager and choose **Create Portal Resource**.

   Note: If you do not see the **Create Portal Resource** option in the context menu, the resource is not under the `oracle/webcenter/portalapp` directory. To move the resource to the correct directory, right-click it, choose **Refactor**, and then **Move**.

2. In the Create Portal Resource dialog (Figure 17–2), in the **Display Name** field, edit the name if required.

   This is the name that is listed in the Resource Manager at runtime, so make sure that users are able to easily identify the resource from the display name.

Figure 17–2 The Create Portal Resource Dialog

3. The **Resource Type** field identifies the kind of resource you are adding to the Resource Manager. You cannot edit this field.

4. In the **Icon URL** field, enter the path and file name of an image to use as a graphical representation of the resource.

   For page styles, this icon is displayed in the Create Page dialog.

5. In the **Description** field, enter a description for the resource. This description should help users determine if they want to use the resource in their application.

   The description is displayed in the About dialog for the resource and in the Resource Manager at runtime.

6. In the **Content Directory** field, enter or browse for the directory where dependent objects for the resource, such as images, JavaScripts, style sheets, and HTML files, are stored. For more information, see Section 17.2.2, "What You May Need to Know About the Content Directory."

   Note: The folder specified here is included in the export archive when the resource is exported, so any dependent objects created under the folder are pushed into the target system.

   This field appears only for resources that can include such dependent objects.

   ---

7. If you want to specify resource-level security for the resource, click the **Security** tab. Otherwise, skip to step 11.

   Resource-level security enables you to override the application-level security for individual resources to specify who can edit and delete the resource at runtime.

8. Select **Override default access policy** (Figure 17–3).

Figure 17–3 Create Portal Resource - Security Tab

9. Click the **Add permissions to new role** icon and select the role for which you want to grant permissions.

10. Select the **Manage** checkbox to grant full access to the resource at runtime. Users with the role can edit and delete the resource.

    Select the **Update** checkbox to grant the permission to edit the resource at runtime. Users with the role can edit the resource, but they cannot delete it.

Note: The user must also have the appropriate permissions to access the Resource Manager. For more information, see Section 17.3.1, "How to Add the Resource Manager Task Flow."

11. Click **OK**.

    The resource is added to the Resource Manager and users with the appropriate privileges can manage the resource at runtime.

17.2.2 What You May Need to Know About the Content Directory

If you are making a resource available for runtime management, any dependent objects referenced by the resource, such as images, JavaScripts, style sheets, or HTML files, must be stored under the following directory:

APPLICATION_ROOT/Portal/public_html/oracle/webcenter/portalapp/shared

In addition, as a best practice, it is recommended to store dependent objects in resource-specific directories under the `shared` directory. For example, images for a page template named `Template1` could be stored in:

APPLICATION_ROOT/Portal/public_
html/oracle/webcenter/portalapp/shared/pageTemplates/Template1

This avoids any potential conflict when additional resources that include dependent objects are imported from runtime.

To reference dependent objects in a resource, use the following format:

/oracle/webcenter/portalapp/shared/*object*

For example:

```
<af:image
source="/oracle/webcenter/portalapp/shared/pageTemplates/Template1/logo.gif"
id="pt_12">
```

When adding the resource as a portal resource (as described in Section 17.2.1, "How to Add a Resource to the Resource Manager"), you must ensure that the **Content Directory** points to the appropriate `shared` directory.

Note: For runtime-created resources, the default content directory is `/oracle/webcenter/siteresources/scopedMD/shared`.

17.2.3 How to Update Portal Resource Properties

You can update the details of resources in the Resource Manager.

To update portal resource properties:

1. In the Application Navigator, right-click the resource that you want to edit and choose **Update Portal Resource**.
2. In the Update Portal Resource dialog, edit the fields as necessary.

   For information about the fields in this dialog, see Section 17.2.1, "How to Add a Resource to the Resource Manager."
3. Click **OK**.

17.2.4 How to Remove a Resource from the Resource Manager

If you no longer want users to be able to administer a particular resource at runtime, you can remove it from the Resource Manager.

To remove a resource from the Resource Manager:

1. In the Application Navigator, right-click the resource that you want to remove and choose **Remove Portal Resource**.
2. In the Remove Portal Resource dialog, click **Yes** to confirm that you want to remove the resource from the Resource Manager.

   The resource is removed from the Resource Manager and can no longer be edited or downloaded at runtime. The resource itself is not deleted, so it is still available for use within the Framework application.

17.3 Enabling Runtime Administration of Your Portal

You can enable portal administrators to manage resources at runtime by adding the Resource Manager to a page in your portal.

If you use WebCenter Portal's Framework application template to create your application, an Administration page is automatically included in the application. This page includes a tab for the Resource Manager.

If you prefer, you can add the Resource Manager to any other page in your application by adding the List of Resource Types task flow to that page.

This section includes the following subsections:

- Section 17.3.1, "How to Add the Resource Manager Task Flow"
- Section 17.3.2, "How to Use the Resource Manager at Runtime"

17.3.1 How to Add the Resource Manager Task Flow

For applications created using WebCenter Portal's Framework application template, the Resource Manager task flow is available out of the box through the WebCenter Portal Administration Console (Resources tab). For details, see the section "Managing Application Resources" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

In addition, just like other task flows, you can add the Resource Manager task flow to your application pages. This might be especially useful if you are not using WebCenter Portal's Framework application template, and the WebCenter Portal Administration console is therefore not part of your project.

When you add the Resource Manager task flow to a page, anyone with view access to the page can view the task flow and perform view related operations on resources, such as viewing resource properties, previewing resources, and so on. For users to be able to perform other operations on resources, such as creating new resources, editing resources, or deleting resources, they must have the appropriate permissions on the type of resource they want to work with. These permissions can be provisioned using the Role Manager task flow. For more information, see Section 69.4, "Using the Role Manager Task Flow." By default, the `Administrator` role has manage access on all resource types exposed in the Resource Manager task flow.

To add the Resource Manager task flow:

1. Open the page to which you want to add the Resource Manager.

2. In the Resource Catalog, expand the **WebCenter Portal - Services Catalog** and then **Task Flows**.
3. Select the **List of Resource Types** task flow and drag it to the desired location on the page.
4. From the menu that displays, select **Region**.

   You may be prompted to add the Resource Manager library to the project. Confirm by clicking **Add Library**.
5. The Resource Manager task flow is added to the page.
6. To enable users to upload and download resources at runtime, the `usesUpload` property for the form that contains the Resource Manager task flow must be set to true:

```
<af:form id="f1" usesUpload="true">
```

17.3.2 How to Use the Resource Manager at Runtime

At runtime, the Resource Manager provides access to administration tools for the resources available to the portal. For example, the administrator can create new resources (navigation models, page templates, mashup styles, and so on), edit existing resources, upload resources exported from other applications, and so on.

Table 17–1 lists the types of resources that you can manage at runtime and provides links to the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* where you can find out more about working with these resources at runtime.

Table 17–1 WebCenter Portal Resources That Can Be Managed at Runtime

Resource	Description	Documentation
Pages	Create and manage pages for your application.	"Building Pages"
Page Templates	Define how individual pages and groups of pages display on a user's screen	"Working with Page Templates"
Navigation Models	Define how to link together information from multiple sources, such as spaces, pages, content repositories, and even external Web pages	"Working with Navigation"
Resource Catalogs	Define the components and connections that WebCenter Portal: Spaces users can add to their pages, page templates, and task flows.	"Working with Resource Catalogs"
Skins	Define the appearance and look and feel, including colors and fonts, of a specific space or the entire application.	"Working with Skins"
Page Styles	Define the layout of a newly created page and may also dictate the type of content the page supports.	"Working with Page Styles"
Content Presenter Display Templates	Manage the templates for presenting content.	"Publishing Content Using Content Presenter"

Table 17–1 (Cont.) WebCenter Portal Resources That Can Be Managed at Runtime

Resource	Description	Documentation
Mashup Styles	Manage the templates available for creating task flows	"Managing Mashup Styles"
Data Controls	Create and manage data controls, which connect to and read data from external repositories, particularly for use in business mashups.	"Creating and Managing Data Controls"
Task Flows	Create and manage task flows based on a selected mashup style.	"Creating and Managing Task Flows"

This section includes the following subsections:

- Section 17.3.2.1, "Accessing the Resource Manager"
- Section 17.3.2.2, "Creating a Resource"
- Section 17.3.2.3, "Uploading and Downloading a Resource"
- Section 17.3.2.4, "Editing a Resource"
- Section 17.3.2.5, "Copying a Resource"
- Section 17.3.2.6, "Setting Security for a Resource"
- Section 17.3.2.7, "Deleting a Resource"
- Section 17.3.2.8, "Showing or Hiding a Resource"
- Section 17.3.2.9, "Editing the Source Code of a Resource"
- Section 17.3.2.10, "Setting Properties on a Resource"
- Section 17.3.2.11, "Previewing a Resource"

Note: The process for working with pages at runtime is different from other resources. For more information, see the section "Working with Pages" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*

17.3.2.1 Accessing the Resource Manager

To access the Resource Manager at runtime, users can navigate to the built-in Administration page (if it is available in the application) and click the **Resources** tab. If the Administration page is not included in the application, you must direct users to the page that includes the Resource Manager.

17.3.2.2 Creating a Resource

Users may want to create custom resources at runtime if the resources available in the Framework application do not meet their requirements.

At runtime, users can create certain resources from scratch. There are some resources that users can create only by extending an existing resource. For example, at runtime, users can create a task flow from scratch, but can create a skin only by extending an existing skin. Other resources, such as Content Presenter display templates, cannot be created at runtime.

Table 17–2 describes the support available for creating resources at runtime.

Table 17–2 Support for Creating Resources at Runtime

Resource	Users Can Create the Resource at Runtime?	How Can the Resource Be Created?
Pages	Yes	From scratch and by creating a copy of an existing page
Page Templates	Yes	Only by creating a copy of an existing page template
Navigation Models	Yes	From scratch and by creating a copy of an existing navigation model
Resource Catalogs	Yes	From scratch and by creating a copy of an existing Resource Catalog
Skins	Yes	Only by creating a copy of an existing skin
Page Styles	Yes	Only by creating a copy of an existing page style and editing the source
Content Presenter Display Templates	No	NA
Mashup Styles	Yes	Only by creating a copy of an existing mashup style and editing the source
Data Controls	Yes	From scratch and by creating a copy of an existing data control
Task Flows	Yes	From scratch and by creating a copy of an existing task flow

To create a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left navigation panel, select the type of resource that you want to create.
3. On the menu bar, click **Create**.
4. In the resulting dialog, enter details for the resource.

   These details depend on the type of resource you are creating. For links to the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* where you can find out more about creating resources at runtime, see Table 17–1.
5. Click **Create**.

   The newly created resource is listed in the Resource Manager. The gray icon next to a resource indicates that it is not yet published an hence is not available to users for use. For information about publishing resources, see Section 17.3.2.8, "Showing or Hiding a Resource."

Note: If you create resources at runtime and do not import them back into the design time environment, your new resources may be lost when the application is redeployed. For more information, see the "Preserving Resource Customizations" section in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

17.3.2.3 Uploading and Downloading a Resource

The Upload and Download options enable post-deployment, round-trip application development. These actions greatly simplify the process of bringing new or revised resources from JDeveloper into your application and pushing them back into development from your application to JDeveloper as needed.

For more information, see Section 17.4, "Enabling Round-Trip Development of Resources."

17.3.2.4 Editing a Resource

Authorized users can edit Framework application resources using the Resource Manager, regardless of whether they were created at design time or runtime, or have been uploaded to the application after deployment.

To edit a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to edit.
3. In the right panel, select the resource that you want to edit.
4. From the menu bar, click **Edit** and then choose **Edit**.
5. In the resulting dialog, edit the details for the resource.

   These details depend on the type of resource you are editing. For links to the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* where you can find out more about editing resources at runtime, see Table 17–1.
6. Click **OK**.

17.3.2.5 Copying a Resource

At runtime, users can create a copy of a resource. This feature is useful for:

- Creating a backup of a resource
- Updating a resource while keeping the original in use
- Using an existing resource as the starting point for a new resource.

You can create a copy of all types of resources except pages and Content Presenter display templates. When you create a copy of a resource, the copy is marked as hidden.

To copy a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to copy.
3. In the right panel, select the resource that you want to copy.

4. From the menu bar, click **Edit** and then choose **Copy**.
5. In the Copy dialog, in the **Display Name** field, enter a name for the new resource.
6. In the **Description** field, enter a description of the new resource.
7. Click **Copy**.

17.3.2.6 Setting Security for a Resource

Users can use security settings to specify who can revise and remove a selected resource. By default, resource access is controlled by application-level permissions. The Security Settings dialog provides a way of overriding application-level permissions and defining specific permissions on a selected resource.

To set security for a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource for which you want to set security.
3. In the right panel, select the resource for which you want to set security.
4. From the menu bar, click **Edit** and then choose **Security Settings**.
5. In the Security Settings dialog, select **Use Custom Permissions** to define who may manage and update the selected resource.

   To inherit access settings from those defined for the application, select **Use Application Permissions**.
6. Click **Add Users** or **Add Groups** to select the user or group to whom you want to grant resource access.
7. Select the **Manage** checkbox to grant full access to the resource. Such users can edit and delete the resource.

   Select the **Update** checkbox to grant the permission to edit the resource. Such users can edit the resource, but they cannot delete it.
8. To revoke access, select the user or group and click **Delete Access**.
9. Click **Set Access**.

17.3.2.7 Deleting a Resource

When a resource is no longer required in an applications, users may delete it. Users can delete resources created at runtime or design time, and uploaded resources.

To delete a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to delete.
3. In the right panel, select the resource that you want to delete.
4. From the menu bar, click **Edit** and then choose **Delete**.
5. In the Delete confirmation dialog, click **Delete**.

17.3.2.8 Showing or Hiding a Resource

All resources, whether created at runtime or design time, can be marked as hidden or available. For all resources that are available for use, a green tick mark and the word

"Available" appear next to the resource's name in the Resource Manager. A gray icon and the word "Hidden" next to a resource's name indicate that the resource is marked as hidden and cannot be used in the application.

When you create or upload a resource, by default it is marked as hidden. A hidden resource is not available for use in the application. You can still use hidden resources in the Resource Manager, for example, to copy them or to use them as the starting point for another resource.

To show or hide a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to show or hide.
3. In the right panel, select the resource that you want to show or hide.
4. From the menu bar, click **Edit** and then choose **Show** or **Hide**, depending on whether the resource is current shown or hidden.

   If the resource was previously hidden, the **Show** option displays in the **Edit** menu. When you choose **Show**, the resource becomes available for use in the application (indicated by a green tick mark and the word "Available" next to the resource)

   If the resource was previously shown, the **Hide** option displays in the **Edit** menu. When you choose **Hide**, the resource becomes unavailable for use in the application (indicated by a gray icon and the word "Hidden" next to the resource).

17.3.2.9 Editing the Source Code of a Resource

To give you more control over resource editing at runtime, the Resource Manager provides the **Edit Source** option. You can use this option to edit the underlying source code of all your resources except data controls. The changes are saved to the MDS, and available immediately.

You may want to edit a resource's source code to make advanced edits to its code without having to having to go through the entire round-trip development cycle. For more information about round-trip development, see Section 17.4, "Enabling Round-Trip Development of Resources."

You can even use the **Edit Source** option to create a resource from scratch, by creating the resource and then replacing its default source code with your own original code. Note, however, that due to the heavy hand-coding requirement, this scenario is not recommended.

To edit the source code of a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource for which you want to edit the source code.
3. In the right panel, select the resource for which you want to edit the source code.
4. From the menu bar, click **Edit** and then choose **Edit Source**.
5. In the Edit Source dialog, edit the code as required.

   The XML syntax in the code is validated and an error message is displayed if you miss any tags or add them incorrectly. Validation is not performed for non-XML files, such as CSS files.
6. Click **Edit Source**.

17.3.2.10 Setting Properties on a Resource

Each type of resource has certain associated properties that define its display properties, availability, and attributes. Authorized users can edit these properties for resources created or uploaded at runtime by using the Edit Properties dialog. Users cannot edit properties for resources created at design time.

To set properties on a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource for which you want to set properties.
3. In the right panel, select the resource for which you want to set properties.
4. From the menu bar, click **Edit** and then choose **Edit Properties**.
5. In the **Display Name** field, edit the display name for the resource.
6. In the **Description** field, edit the description for the resource.
7. In the **URI Icon** field, enter a standard URI path to an icon to represent the resource, for example:

   ```
   /myCompany/webcenter/page/images/myimage.png
   ```

   You can either specify an absolute URL or a relative URL that points to an image located somewhere in the application.
8. In the **Category** field, enter a category name to help classify the resource within the application.
9. In the Attributes section, enter values for any custom attributes for the resource by entering the **Name** and an appropriate **Value** for the attribute. For information about the custom attributes that can be added for the different resources, see the appropriate chapter for the resource type as listed in Table 17–1.
10. Click **OK**.

17.3.2.11 Previewing a Resource

You can preview page templates, mashup styles, and task flows to check how they look while you are editing them.

To preview a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to preview.
3. In the right panel, select the resource that you want to preview.
4. From the menu bar, click **Preview**.
5. When you have finished previewing the resource, click **Close**.

17.4 Enabling Round-Trip Development of Resources

If you enable runtime administration of your portal resources, you need to be able to pull those resources back into JDeveloper. For example, if a portal user adds a new navigation model, you may want to further refine it. To do this, you need to download the resource from the deployed application, using the Resource Manager. You then import the resource into JDeveloper, carry out your development work, export the

resource, and finally upload it back into the deployed application. This is known as round-trip development.

You can do this with resources in any deployed WebCenter Portal application that includes the Resource Manager, including WebCenter Portal: Spaces.

Note: WebCenter Portal provides a special JDeveloper workspace (`DesignWebCenterSpaces.jws`) to help you develop and upload resources to WebCenter Portal: Spaces. Chapter 56, "Extending the Spaces Application Using JDeveloper" tells you where to find the sample workspace and explains how to use the `WebCenterSpacesResources` project to build resources for use in WebCenter Portal: Spaces.

The process for round-trip development works as follows:

1. Build Framework application in JDeveloper
2. Deploy application
3. Users add/edit resources and add content to the portal at runtime
4. Download resource to an EAR file using the Resource Manager.

   See Section 17.4.1, "How to Download a Resource Using the Resource Manager"
5. Import EAR file into JDeveloper

   See Section 17.4.2, "How to Import a Portal Resource into JDeveloper"
6. Edit resource in JDeveloper
7. Export resource to EAR file

   See Section 17.4.3, "How to Export a Portal Resource from JDeveloper"
8. Upload resource to deployed application using the Resource Manager

   See Section 17.4.4, "How to Upload a Resource Using the Resource Manager"
9. Repeat from step 3.

In addition, after the deployment of the application, developers can continue to create and edit resources in JDeveloper and upload those resources to the deployed application periodically.

Figure 17–4 illustrates the round-trip development process described above.

Figure 17–4 Round-Trip Development

This section includes the following subsections:

- Section 17.4.1, "How to Download a Resource Using the Resource Manager"
- Section 17.4.2, "How to Import a Portal Resource into JDeveloper"
- Section 17.4.3, "How to Export a Portal Resource from JDeveloper"
- Section 17.4.4, "How to Upload a Resource Using the Resource Manager"

17.4.1 How to Download a Resource Using the Resource Manager

To edit a resource in JDeveloper, you first need to use the Resource Manager in the deployed application to create an EAR file that contains all the metadata for the resource.

To download a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to download.
3. In the right panel, select the resource that you want to download.
4. From the menu bar, click **Download**.
5. In the Download dialog (Figure 17–5), in the **Archive File Name** field, enter a name for the export archive (EAR) file.
6. Specify where you want to save the export archive file:
   - **Save to my computer**—Click to save the export archive file to your local file system.
   - **Save to WebCenter Portal server**—Click to save the export archive file to a remote server file system. In the **Path** field, enter the server path.

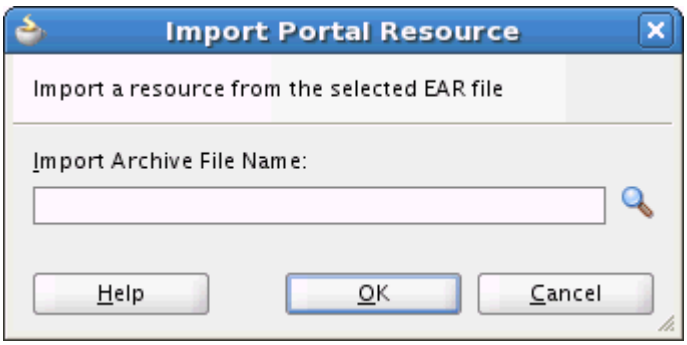
Figure 17–5 The Download Resource Dialog

7. Click **Download**.

   If you selected **Save to my computer**, you may be prompted to save the file and select the location for the saved file.

17.4.2 How to Import a Portal Resource into JDeveloper

When you have the EAR file, you must then import it into JDeveloper, where you can edit it.



You must import the resource into an application that uses WebCenter Portal's Framework application template or that includes the appropriate technology scopes.

Note: When you import a portal resource into JDeveloper, if the resource already exists, the resource in JDeveloper is overwritten with the one from the archive. The original resource is saved to a temporary location, which is identified in the log.

To import a portal resource into JDeveloper:

1. In the Application Navigator, right-click the **Portal** project of the application into which you want to import the resource, and choose **Import Portal Resource**.
2. In the Import Portal Resource dialog (Figure 17–6), in the **Import Archive File Name** field, enter or browse for the archive file that contains the resource that you want to import.

Figure 17–6 The Import Portal Resource Dialog

3. Click **OK**.
4. If the selected archive file contains a content directory, a popup dialog requests whether you want to overwrite the existing target content directory with the content directory from the archive file. Click **Yes** to overwrite the target content directory with the content directory from the archive file. Click **No** to update the target content directory with only new files from the archive content directory, that is files that do not already exist in the target directory.

   The imported resource is created in:

   Application_Root`/oracle/webcenter/siteresources/scopedMD/s8bba98ff_4cbb_40b8_beee_296c916a23ed`

   The resource is automatically created as a portal resource.

17.4.3 How to Export a Portal Resource from JDeveloper

After editing the resource, you must export it to create an EAR file that can be uploaded to the deployed application.

Note: If you edit or add dependent objects to an imported runtime-created resource, those objects must be placed at the following path, which is the default content directory for resources created at runtime:

```
/oracle/webcenter/siteresources/scopedMD/shared
```

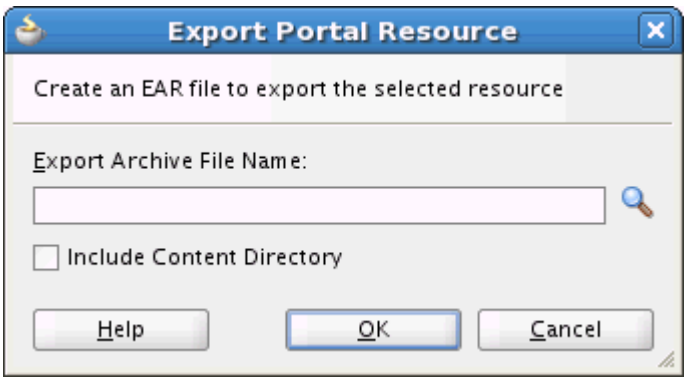
Dependent objects must always be placed directly under or in a subdirectory of the directory set as the content directory of a portal resource. You can find out the content directory path from the Update Portal Resource dialog.

To prevent any conflicts, you may want to place dependent objects in a subdirectory under the shared directory. For example, images for a page template named `Template1` could be stored in a `pageTemplates` subdirectory. In such a case, you must update the content directory path to point to the new location.

You can reference dependent objects in a portal resource as shown in the following example:

```
<af:image
source="/oracle/webcenter/siteresources/scopedMD/shared/pageTemplat
es/Template1/logo1.gif" id="pt_12">
```

To export a a portal resource from JDeveloper:



1. In the Application Navigator, right-click the resource that you want to export and choose **Export Portal Resource**.

   Note: If you do not see the **Export Portal Resource** option in the context menu, the resource is not a portal resource. For information about how to create the resource as a portal resource, see Section 17.2.1, "How to Add a Resource to the Resource Manager."

2. In the Export Portal Resource dialog (Figure 17–7), in the **Export Archive File Name** field, enter or browse for the path and file name for the export file.

   If you select an existing file, the contents of the file will be overwritten.

Figure 17–7 The Export Portal Resource Dialog

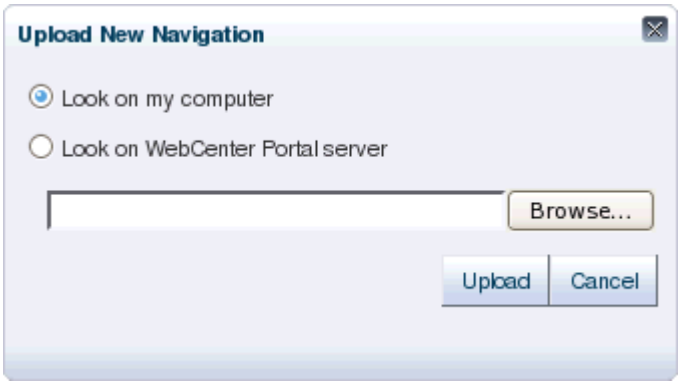
3. Select **Include Content Directory** to include the directory identified as the resource's content directory in the export archive file.

Note: This checkbox appears only for portal resources that point to a valid content directory.

The entire resource content directory is included in the export archive file; you cannot select individual files. On import, if a content directory is detected in the archive file, the user can specify whether to overwrite all files in the target content directory, or just add any new ones.

4. Click **OK**.

   The export archive contains the files that make up the resource, for example, the `.jspx` file, the page definition, and (optionally) the content directory pointed to by the resource, if it is not empty. The archive also contains the `generic-site-resources.xml` file and the registry file with just the information about the exported resource.



17.4.4 How to Upload a Resource Using the Resource Manager

The final step is to take the EAR file of the updated resource and use the Resource Manager to upload the resource back into the deployed application.

To upload a resource:

1. In your Framework application, navigate to the Resource Manager. For more information, see Section 17.3.2.1, "Accessing the Resource Manager."
2. In the left panel, select the type of resource that you want to upload.
3. From the menu bar, click **Upload**.
4. In the Upload dialog (Figure 17–8), specify the location of the resource archive file. Depending on the location of your EAR file, select:
   - **Look on my computer**—Select if the archive is located on your local file system. Enter the path to the EAR file or use the **Browse** button.
   - **Look on WebCenter Portal server**—Select if the archive is located on a remote server. Enter the path to the EAR file.

Figure 17–8 The Upload Resource Dialog

5. Click **Upload**.
6. Click **Yes** in the Confirm Replace dialog.

7. If the export archive file includes a content directory, the Overwrite Content Directory dialog displays. Click **Yes** to import all files from the content directory of the export archive or click **No** to import only new files from the content directory.

Part III

Customizing Your Application and Extending Customization Options

Part III contains the following chapters:

- Chapter 18, "Introduction to Composer"
- Chapter 19, "Enabling Runtime Creation and Management of Pages"
- Chapter 20, "Enabling Runtime Editing of Pages Using Composer"
- Chapter 21, "Extending Runtime Editing Capabilities Using Composer"
- Chapter 22, "Performing Advanced Composer Configurations"
- Chapter 23, "Performing Composer-Specific MDS Configurations"
- Chapter 24, "Modifying Default Security Behavior of Composer Components"
- Chapter 25, "Customizing Task Flows"

18

Introduction to Composer

Oracle WebCenter Portal's Composer is a fully-integrated page editor for adding and editing page content at application runtime. This chapter introduces Composer and describes the various tasks it supports at runtime.

To understand the functions of Composer, let us first look at a typical application development lifecycle, which comprises the following stages:

- Application developers create applications at *design time*.

  Design time traditionally represents an IDE-based environment for creating or editing applications. For WebCenter Portal, Oracle JDeveloper provides the design-time environment.

- Application administrators deploy these applications to managed servers.
- End users access the deployed applications at *runtime*.

  Runtime represents a browser-based environment used for accessing web applications.

You can see that each stage involves different categories of users. Many times, some or all of these users may want to modify pages at runtime. For example, consider a dashboard-like application that displays information pertaining to the logged-in user, for example a worklist and a mail task flow. The page developer creates the dashboard page and populates it with the required components and task flows. An application administrator deploys the application to a customer site. At the customer site, people at different levels in the organization view the dashboard and make the following requests:

- Department administrators want to add a "Department News" task flow.
- LOB administrators want to add an "Expense Incurred by Self/Directs" task flow.
- The country site administrator wants to add a task flow displaying the respective country's operations or rules.

In addition, content contributors, moderators, and end users may want to add, delete, or modify page artifacts based on the business needs. In a typical application development environment, these requests are passed on to the page developer. The developer modifies the application in the development environment and redeploys it to the customer site.

Rather than pushing simple modifications back to the developer, Composer, in conjunction with Metadata Services (MDS), provides an editing tool that enables business users to edit application pages at runtime. Changes made at runtime are saved as metadata, separate from the base application definitions. This concept of editing application pages at runtime is referred to as *design time at runtime*. It minimizes the need to modify the application at design time and redeploy it.

Composer provides components for controlling an application's design time at runtime behavior. This chapter describes the basic concepts and terminology you'll need to use Composer effectively. It includes the following subsections:

- Section 18.1, "Application and User Customizations"
- Section 18.2, "View and Edit Modes of a Page"
- Section 18.3, "Customizing Capabilities in Page View Mode"
- Section 18.4, "Editing Capabilities in Design View in Page Edit Mode"
- Section 18.5, "Editing Capabilities in Source View in Page Edit Mode"
- Section 18.6, "Composer Components"
- Section 18.7, "Security and Composer"

18.1 Application and User Customizations

When a user modifies a page at runtime, the changes are typically available only to that user. You can configure your application to make runtime modifications available to all or a subset of users accessing the page. Consider an example of a dashboard page displaying details about the expenses incurred by the members of an LOB. If the LOB administrator modifies the page and adds some expensing guidelines, the changes must be visible to all members. To address such requirements, Composer enables you to edit pages in different modes so that changes are saved as *user customizations* (that affect only the individual user's view of the page) or *application customizations* (that affect everyone's view of the page).

To save a user's changes as user or application customizations requires that they be saved separately at the back end. In the metadata domain, MDS allows for the saving of customizations in separate layers on top of the base application definitions. Depending on the business requirement, you can save changes in a single layer or in multiple layers.

In a single-layer configuration, changes are saved as application customizations to a common layer that is accessible to all users. In this case, you cannot allow for changes to be saved as user customizations.

In a multiple-layer configuration, changes are saved at separate locations based on specified criteria such as the mode in which the page is edited, the user editing the page, or the user role. In this type of configuration, each customization layer is insulated from the other, but the layers can be stacked over each other to provide flexibility during upgrades. For example, a user may want to change the default theme of the page being viewed. It is expected that this change be saved only for this user, without affecting others' view of the page. Therefore, you can set up things so that changes made by end users who have Personalize privilege on the page are saved as user customizations, and changes made by logged-in users with customization-level privileges are saved as application customizations. You can decide which tasks are available to users with Personalize and Customize/Edit privileges respectively.

For more information about MDS and customization layers, see Section 23.1, "Introduction to MDS."

18.2 View and Edit Modes of a Page

When a user opens an application page in a browser, the page opens in *View mode*. Additionally, Composer provides access to another mode called *Edit mode* to enable

users with appropriate privileges to edit application pages. These modes can be described as follows:

- View mode—The default view of a page when opened in a browser. In this mode, users can perform tasks such as rearranging components, collapsing and expanding components, and changing the layout. Typically, changes made to a page in View mode are available for the user alone and are saved as user customizations.
- Edit mode—The mode typically available to authenticated users with access privileges to edit page content. In addition to the tasks that can be performed in View mode, Composer provides controls for switching to Edit mode and performing tasks such as adding components, deleting components, and editing component properties. Typically, changes made to the page in Edit mode are saved as application customizations and are available for all users accessing the page.

18.3 Customizing Capabilities in Page View Mode

Composer enables users to customize pages in View and Edit modes. This section provides an overview of user customization tasks you can enable for users in page View mode. Such tasks include rearranging components, collapsing and expanding components, and changing the page layout. You can enable the capabilities described in this section by adding the following Composer design-time components to a page: `Panel Customizable`, `Show Detail Frame`, `Custom Actions`, and `Layout Customizable`. For information about these components, see Section 18.6, "Composer Components." Changes made to a page in View mode are available only to the user making these changes.

This section includes the following subsections:

- Section 18.3.1, "Rearrange Components"
- Section 18.3.2, "Change the Layout"
- Section 18.3.3, "Expand and Collapse Components"

Note: For a detailed description of the editing tasks that you can perform on a page, see "Building Pages" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

18.3.1 Rearrange Components

This capability allows users to organize page components so that the content most useful to them displays at the top of the page. Users can rearrange components in two ways:

- Dragging and dropping

  Users can rearrange components by dragging and dropping them within the `Panel Customizable` component or across `Panel Customizable` components on the page. As it is difficult to identify a `Panel Customizable` component in View mode, users can simply drag the component over the spot they want to place it. A solid box indicates a receptive drop location.

- Using the Actions menu

  The Move actions on a `Show Detail Frame` or portlet component enable users to move these components within a parent `Panel Customizable` component. If a `Panel Customizable` has multiple child components, then a child `Show`

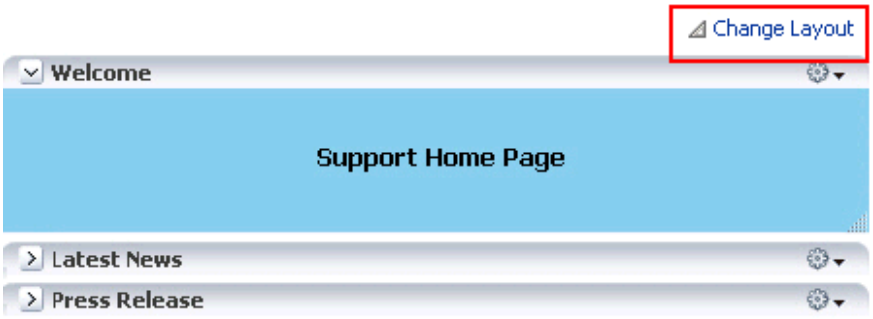
`Detail Frame` or portlet can be moved to the left and right or above and below, relative to the position of other child components. Figure 18–1 shows a sample `Show Detail Frame` component with Move Up and Move Down actions. In this example, selecting **Move Down** moves the Latest News component immediately below the Press Release component.

Figure 18–1 Actions Menu on a Show Detail Frame

18.3.2 Change the Layout

This capability allows users to switch between a set of predefined layouts provided by Composer. Through the use of the **Change Layout** icon, users can choose among eight different layouts to suit their needs and preferences. The `Layout Customizable` component in the Composer library enables the display of a **Change Layout** icon on the page, as shown in Figure 18–2.

Figure 18–2 Change Layout Icon



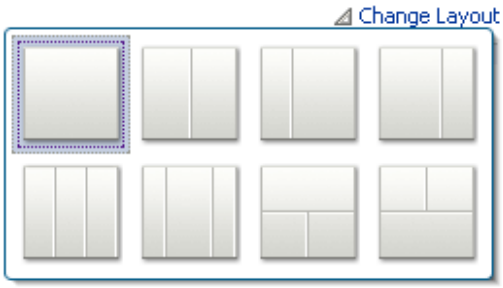


Figure 18–3 shows the layout options available with the `Layout Customizable` component. A gray colored border highlights the layout currently applied to the page or area.

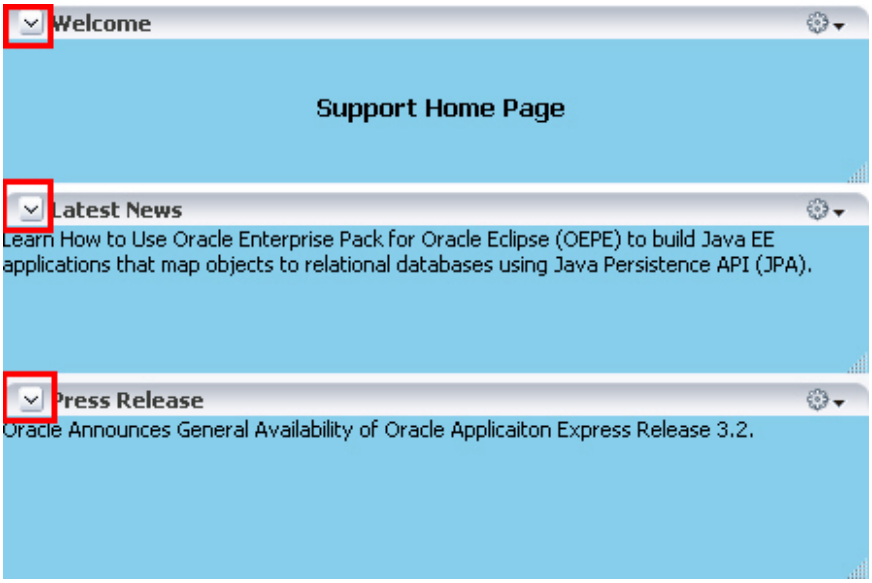
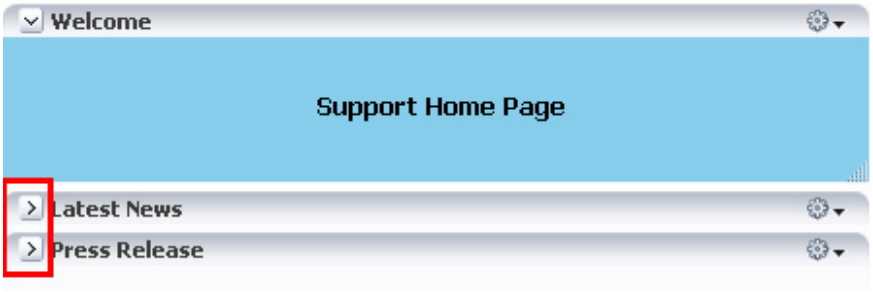
Figure 18–3 Layout Options



18.3.3 Expand and Collapse Components

By enabling expand and collapse components on a page, you can include more detailed information on a page without cluttering its visual appearance. Users can collapse and expand the components as desired.



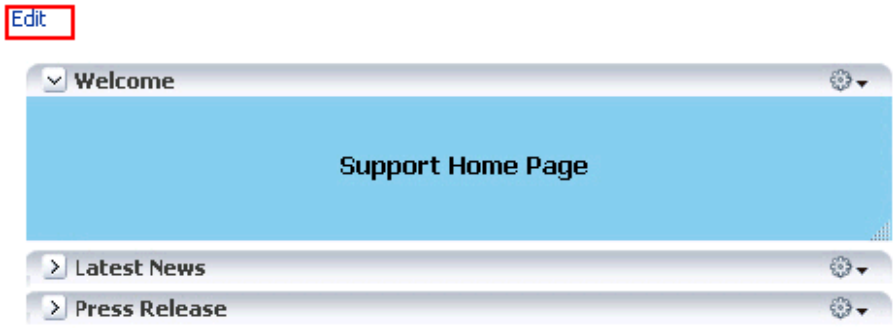
A **Collapse** icon on the header of a `Show Detail Frame` or portlet enables users to collapse such a component and display only its header. Figure 18–4 shows the **Collapse** icons on three `Show Detail Frame` components.

Figure 18–4 Collapse Icon on a Show Detail Frame

The **Expand** icon on a collapsed component enables users to disclose the component so that it displays the header and content. Figure 18–5 shows the **Expand** icons on two collapsed `Show Detail Frame` components.

Figure 18–5 Expand Icon on a Show Detail Frame

18.4 Editing Capabilities in Design View in Page Edit Mode



Composer's Edit mode provides a wide range of application customization capabilities. In Edit mode users can add content, edit page and component properties, delete components, rearrange components, change the page layout, and so on.

You can provide the capabilities described in this section to your application by adding the following Composer design-time components to a page: `Change Mode Link` or `Change Mode Button`, `Page Customizable`, `Panel Customizable`, `Show Detail Frame`, `Custom Actions`, and `Layout Customizable`. For more information about these components, see Section 18.6, "Composer Components."

The `Change Mode Link` or `Change Mode Button` switches the page to Edit mode. In Edit mode, users can add content to the page, edit component properties, edit page properties, and so on. The `Page Customizable` component on a page enables these editing capabilities.

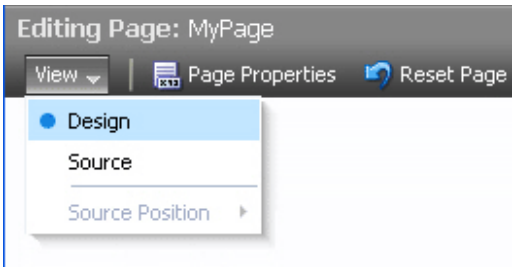


Figure 18–6 shows a `Change Mode Link` on an application page. When users click the `Change Mode Link` or `Change Mode Button`, the page opens in Composer.

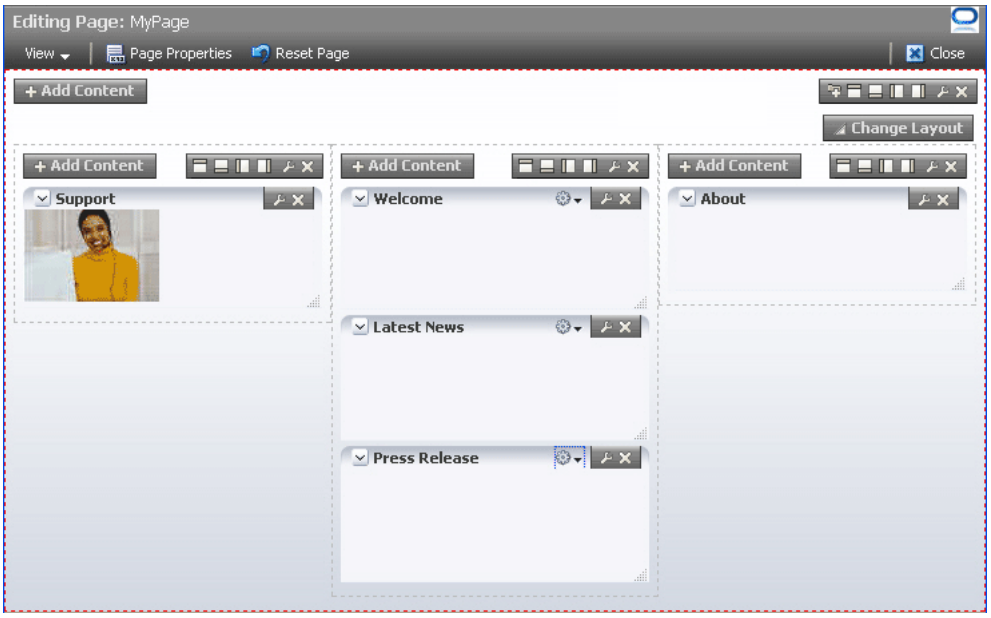
Figure 18–6 Edit Link While in View Mode

The default Composer toolbar displays the name of the page being edited, a status indicator, View menu, Page Properties button, Reset Page button, and a Close icon. The View menu (Figure 18–7) provides two viewing options—**Design** and **Source**. Users can perform various editing tasks in these views.

Figure 18–7 View Menu in Composer



Composer

****

Design view (shown in Figure 18–8) is the default page view that provides a WYSIWYG rendering of the page and its content, where Edit and Delete controls are directly selectable on each component. In Design view users can also perform such tasks as adding content, editing page and component properties, changing page layout, and deleting components.

Figure 18–8 Design View of a Page

For information about the Source view, see Section 18.5, "Editing Capabilities in Source View in Page Edit Mode."

This section describes the editing capabilities that Composer provides in the Design view in page Edit mode. It contains the following topics:

- Section 18.4.1, "Add Content"
- Section 18.4.1.2, "Add Box Components Adjacent to Existing Ones"
- Section 18.4.2, "Rearrange Page Content"
- Section 18.4.3, "Edit Component Properties and Parameters"
- Section 18.4.4, "Reset and Override Component Properties in the Current Layer"
- Section 18.4.5, "Edit Resource Strings"

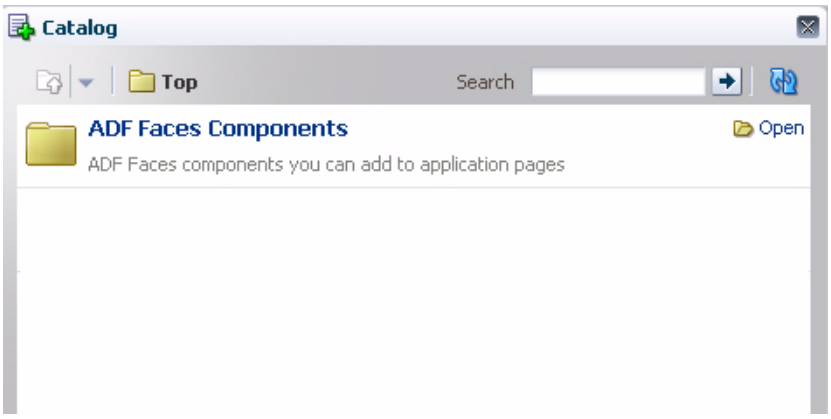
- Section 18.4.6, "Show or Hide Components"
- Section 18.4.7, "Delete Components"
- Section 18.4.8, "Change the Layout"
- Section 18.4.9, "Edit Page Properties"
- Section 18.4.10, "Wire Components to Page Parameters"
- Section 18.4.11, "Reset Page"
- Section 18.4.12, "Reset Application Customizations on Detecting Errors"
- Section 18.4.14, "Manage Application Customizations"

> **Note:** You can restrict users from performing all or some of these tasks by securing the application and applying customization restrictions on components. For more information, see Section 18.7, "Security and Composer."

Composer provides most of these capabilities in the Source view as well. The individual sections mention whether a capability is available in both modes or only in Design mode.

For a detailed description of the runtime editing tasks that users can perform on a page, see "Building Pages" and "Adding and Configuring Page Layout Components" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

18.4.1 Add Content



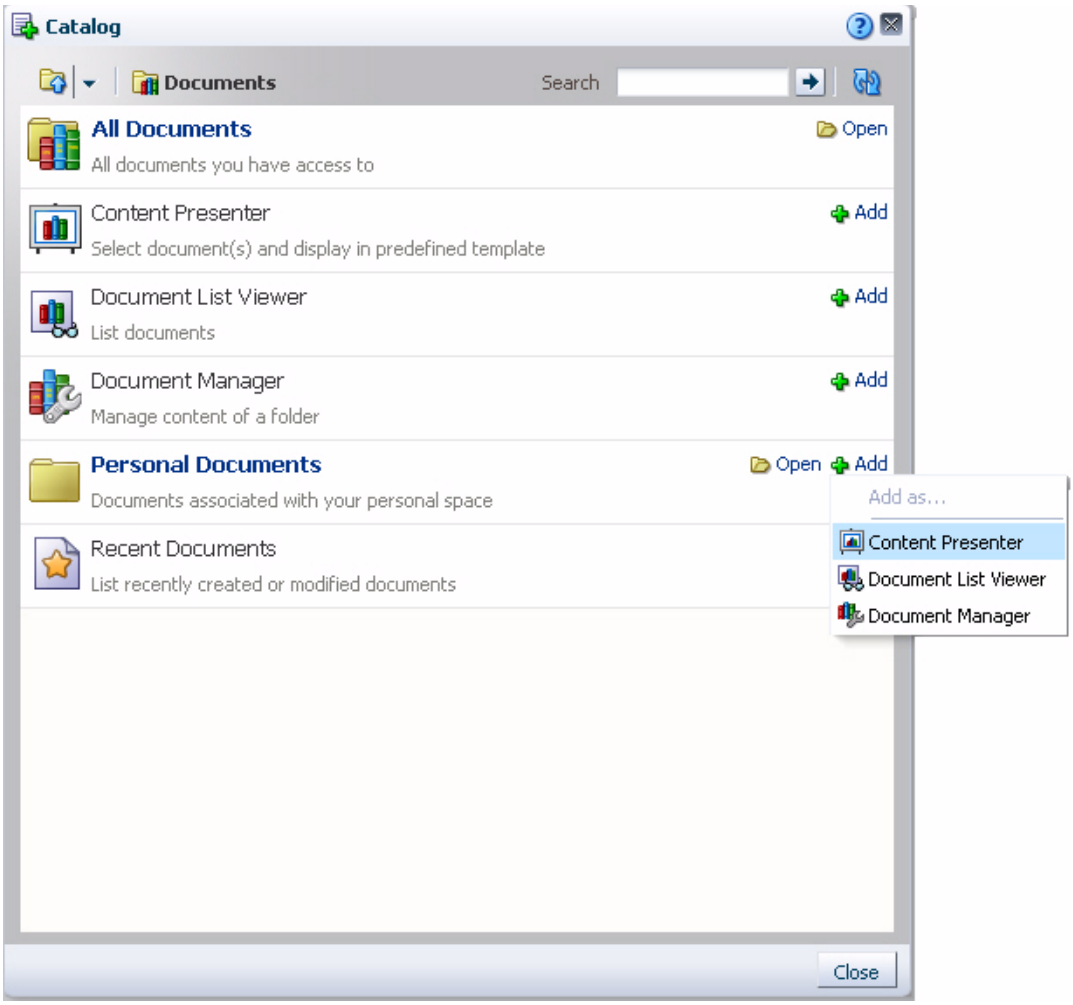
Users may want to add custom content to the page, such as a portlet displaying news, for example, or stock updates. Composer enables users to add content within any container in page Design view and Source view. WebCenter Portal's Resource Catalog, also known as *Oracle Business Dictionary*, contains resources that users can add to a page. These include documents, Oracle ADF components, portlets, and task flows. The catalog can be invoked in the following ways:

- In Design view, by clicking the **Add Content** button on any container component on the page.
- In Source view, by selecting a container component and clicking the **Add Content** button on the Source view toolbar.

> **Notes:** If you restrict customization on a container component, then users cannot add components inside it at runtime. See Section 24.1, "Applying Component-Level Restrictions by Defining Customization Policies" for more information.

Figure 18–9 shows the default catalog available in a Framework application that is not configured with portal features.

Figure 18–9 Resource Catalog



The Resource Catalog contains folders and components. An **Open** link next to an item in the catalog indicates that the item is a folder. Users can drill down into the folder by clicking this link. An **Add** link next to an item indicates that the item can be added to the page. An Add link can appear next to a component or a folder. The component is added as the first child in the container on which the Add Content link was clicked.

Note: The **Top** icon in the Resource Catalog enables users to return to a top-level folder.

If you configure drop handlers for adding resources to the page, the Add link shows a context menu with different options for adding the component to the page (Figure 18–10). For more information, see Section 21.6, "Configuring Event Handlers for Composer UI Events."

Figure 18–10 Context Menu with Drop Handlers for Adding a Component

Depending on its configuration, the Resource Catalog exposes all or a subset of the following components to users:

> **Note:** For information about Resource Catalog configurations, see Chapter 16, "Creating and Managing Resource Catalogs."

- ADF Faces Components

  The ADF Faces Components folder provides `Box` and `Movable Box` components that are analogous to the JDeveloper design time components `Panel Customizable` and `Show Detail Frame`. In JDeveloper, these components are available in the Composer tag library.

  > **Note:** `Panel Customizable` and `Show Detail Frame` components added to the page at design time continue to be called the same. These components are not denoted as `Box` and `Movable Box` components respectively at runtime.

This folder also provides `Image`, `HTML Markup`, `Hyperlink`, `Text`, and `Web Page` components that are analogous to the JDeveloper design time components `Go Image Link`, `Output Text`, `Go Link`, `Rich Text Editor`, and `Inline Frame` respectively. In JDeveloper, these components are available in the ADF Faces tag library.

The **ADF Faces Components** folder in the catalog contains these components, as shown in Figure 18–11.

Figure 18–11 ADF Faces Components You Can Add to the Page

- Task Flows

  Users can add custom task flows and out-of-the-box WebCenter Portal service task flows to the page. A task flow added to a page is automatically enclosed in a `Movable Box` component. As a result, the task flow displays a header with options to move or delete the component.

  Note: The Movable Box component surrounding a task flow is displayed only if the task flow is displayed on the page. That is, if you do not grant even View permission on a task flow, the Movable Box surrounding it is also not displayed on the page.

- Portlets

  The **Portlets** folder lists all the registered producers. Users can navigate to the required portlet and add it to the page. The Portlets folder exposes portlets from any Java-PDK or WSRP producer that was registered in Oracle JDeveloper. For information about registering portlet producers, see Chapter 64, "Consuming Portlets."

- Documents

  The **Content Management** folder lists documents and folders from the Documents service that users can add to the page.

See "Adding and Configuring Page Layout Components" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* for detailed information.

18.4.1.1 Add a Tab Set or a Tab to a Box Component

The toolbar on the `Box` component provides an option (Figure 18–12) to add a tab or a set of tabs to the `Box` component. Use tabs to add content regions as separate layers on the page. Each new tab is placed as a layer below the currently selected tab and contains a region that can be populated with content.

Figure 18–12 Add Tab Set or a Tab Icon on a Box Component

When a user clicks the Add a Tab Set or a Tab icon on the Box component, Composer adds a tab around the `Box` component. In the Source view, the `Box` component is nested inside a `Show Detail Item` component, which in turn is nested inside a `Panel Tabbed` component, as shown in Figure 18–13. Users can add any number of tabs in this way.

Figure 18–13 Tab Component in Source View

The first tab that a user adds will surround the selected `Box` component. Each subsequent tab will contain a new `Box` component inside it.

Users can delete a tab by clicking the Delete icon on a tab in Design view. On deleting the last tab, the `Panel Tabbed` component is deleted from the page. Alternatively, the tab set can be deleted by deleting the `Panel Tabbed` component in the Source view. To delete only the tab without deleting the `Box` inside it, users must move (cut and paste) the `Box` outside the `Panel Tabbed` component first and then delete the `Panel Tabbed` component.

18.4.1.2 Add Box Components Adjacent to Existing Ones

A toolbar on the `Box` component in Design view provides options to add another `Box` component before or after the component. This capability enables users to modify the layout of components on the page.

When a user clicks an Add icon on the `Box` component, Composer adds another `Box` component before or after it and surrounds both `Box` components with a `Panel Group Layout`. Depending on the icon used, the new `Box` component is added to the left, right, above, or below the original `Box` component, and the `layout` attribute on the parent `Panel Group Layout` component is set to `horizontal` or `vertical`. Users can add many contiguous `Box` components in this way. Every time the orientation changes for new a `Box` component, a new `Panel Group Layout` with the appropriate layout setting (horizontal or vertical) is added around the new and the existing `Box` components.

Note: The Add icons are not rendered on the component if:

- The `allowAction` attribute on the `Panel Customizable` component is set to `false`
- The `Panel Customizable` is stretched
- The `Panel Customizable` component is restricted

For more information, see Chapter 24, "Modifying Default Security Behavior of Composer Components."

Users can delete `Box` components that they added using the Add icons, in both Design and Source view.

Note: If the `Panel Group Layout` has only two `Box` components and you delete one of them, then the `Panel Group Layout` is also deleted.

The `Box` component toolbar contains the following Add Box icons in addition to the Edit icon:

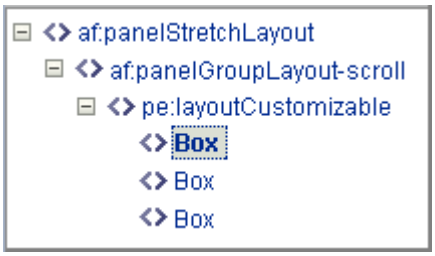
- Add Box Above
- Add Box Below
- Add Box Left
- Add Box Right

18.4.1.2.1 Add Box Above Clicking the **Add Box Above** icon (Figure 18–14) adds a `Box` component above the selected `Box` component. The `layout` attribute on the `Panel Group Layout` is set to `vertical`.

Figure 18–14 Add Box Above Icon on a Box Component

Figure 18–15 shows how the Box component appears in Source view before adding another Box component adjacent to it.

Figure 18–15 Box Component Before Adding Another One Adjacent to It



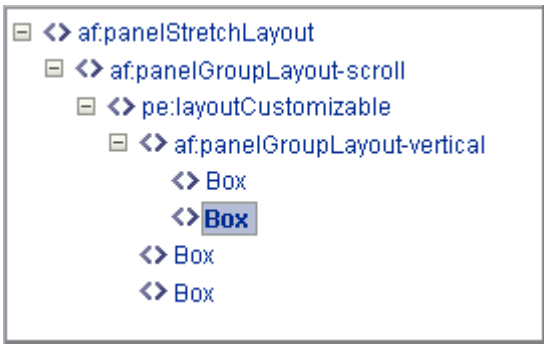


Figure 18–16 shows the two Box components vertically aligned in the component navigator.

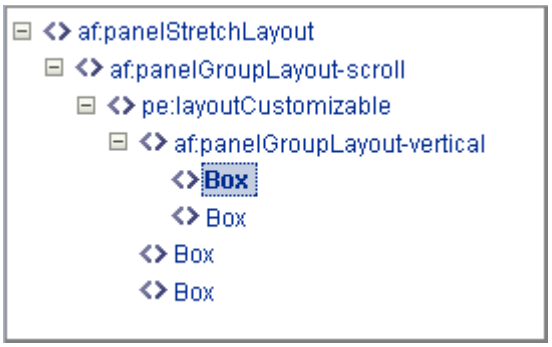
Figure 18–16 Box Component Added Above

Users can click the **Add Box Above** icon repeatedly to add many contiguous Box components vertically within the same parent Panel Group Layout.



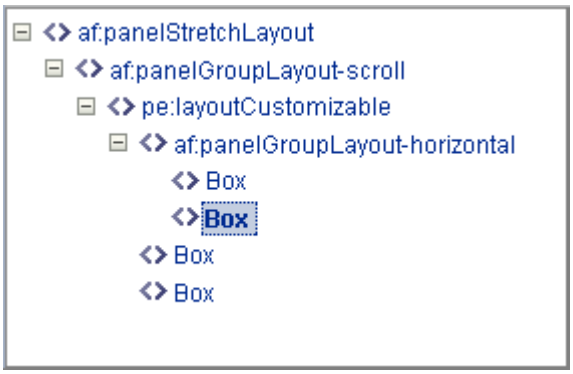
18.4.1.2.2 Add Box Below Clicking the **Add Box Below** icon (Figure 18–17) adds a Box component below the selected Box component. The layout attribute on the Panel Group Layout is set to vertical.

Figure 18–17 Add Box Below Icon on a Box Component

Figure 18–18 shows the two Box components vertically aligned in the component navigator.

Figure 18–18 Box Component Added Below

Users can click the **Add Box Below** icon repeatedly to add many contiguous `Box` components vertically within the same parent `Panel Group Layout`.



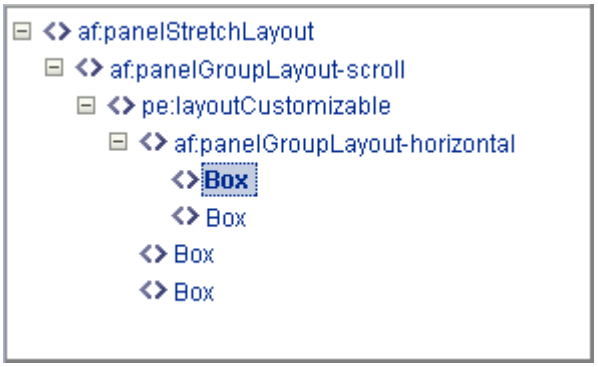
18.4.1.2.3 Add Box Left Clicking the **Add Box Left** icon (Figure 18–19) adds another `Box` component to the left of the selected `Box` component. The `layout` attribute on the `Panel Group Layout` is set to `horizontal`.

Figure 18–19 Add Box Left Icon on a Box Component

Figure 18–20 shows the two `Box` components horizontally aligned in the component navigator.

Figure 18–20 Box Component Added to the Left

Users can click the **Add Box Left** icon repeatedly to add many contiguous `Box` components horizontally within the same parent `Panel Group Layout`.



18.4.1.2.4 Add Box Right Clicking the **Add Box Right** icon (Figure 18–21) adds another `Box` component to the right of the selected `Box` component. The `layout` attribute on the `Panel Group Layout` is set to `horizontal`.

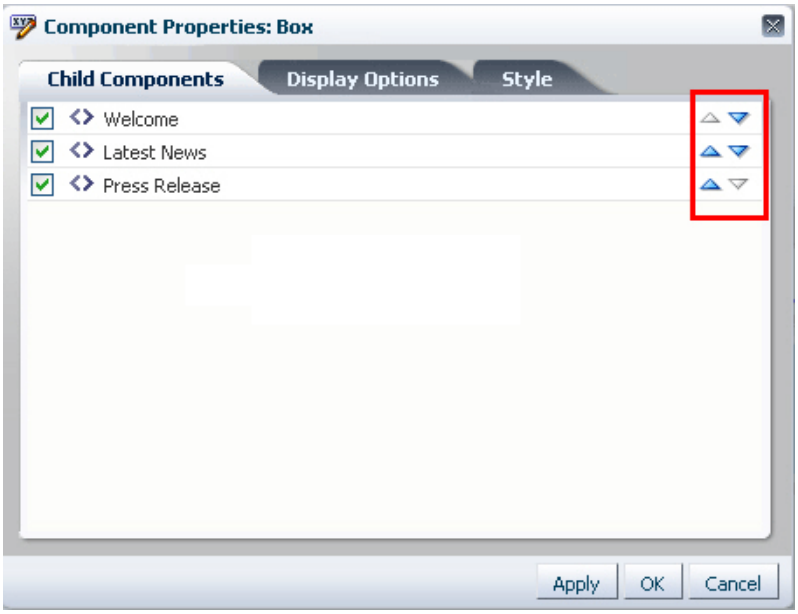
Figure 18–21 Add Box Right Icon on a Box Component

Figure 18–22 shows the two `Box` components horizontally aligned in the component navigator.

Figure 18–22 Box Component Added to the Right

Users can click the **Add Box Right** icon repeatedly to add many contiguous `Box` components horizontally within the same parent `Panel Group Layout`.

18.4.2 Rearrange Page Content



This capability allows users to organize page components based on where they are easiest to use; for example, users can move content most useful to them to the top of the page. In Design view, users can rearrange content on the page in the following ways:

- Drag and drop a component within the same `Panel Customizable` component or across `Panel Customizable` (or `Box`) components on the page.
- Use the Move actions on the Actions menu of a `Show Detail Frame` or portlet to move it within the parent `Panel Customizable` component. Depending on the number of child components in the `Panel Customizable` and how these components are oriented, a component can be moved to the left and right, or up and down.
- To resequence components within a container, in the Component Properties dialog for the container, click the Child Components tab and use the up and down arrows shown against each child component (Figure 18–23).

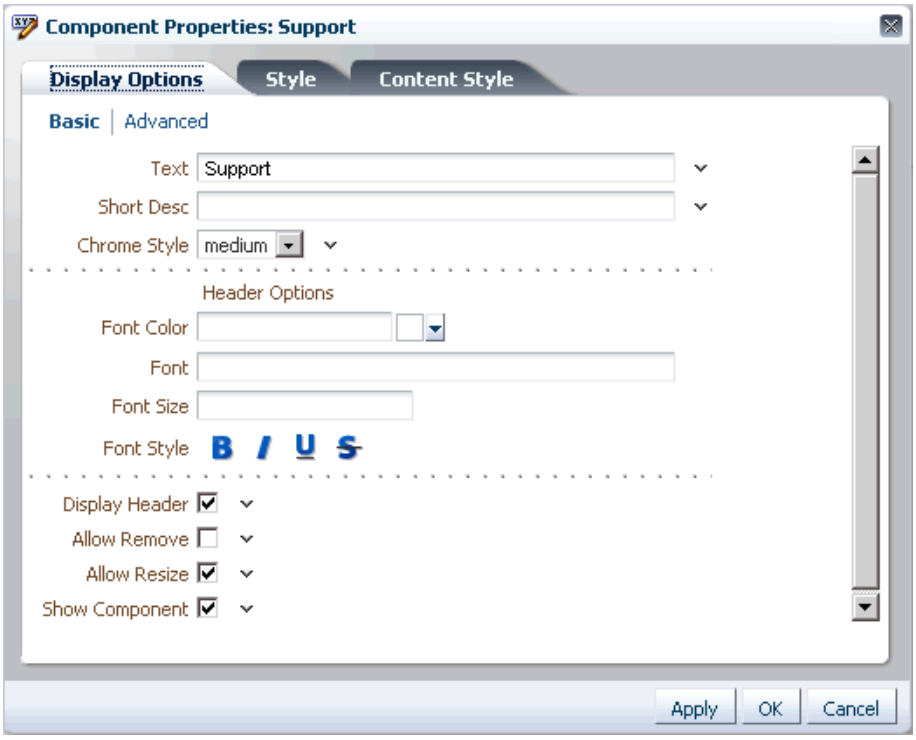
Notes: A component on which customization is restricted, can be rearranged inside its parent container if the parent is customizable.

The Child Components tab displays a list of direct child components at the top (Components list) of the tab, followed by a list of all facets defined for the component (Fixed Components list). There are no up and down arrows against facet components as these components cannot be rearranged. The Fixed Components list is displayed only if the component contains facets.

Figure 18–23 Resequencing Options on the Child Components Tab of a Container

18.4.3 Edit Component Properties and Parameters

The Component Properties dialog enables users to edit component properties and the parameters associated with components, such as portlets and task flows. The Component Properties dialog is accessible in both Design view and Source view.



Note: A component cannot be edited if:

- The `Id` attribute was not set for the component at design time
- The component or any of its attributes have been restricted

  For information about restricting customization, see Chapter 24, "Modifying Default Security Behavior of Composer Components."
- It is a component from the ADF Faces library

In Design view, clicking the **Edit** icon on a component displays the Component Properties dialog, shown in Figure 18–24.

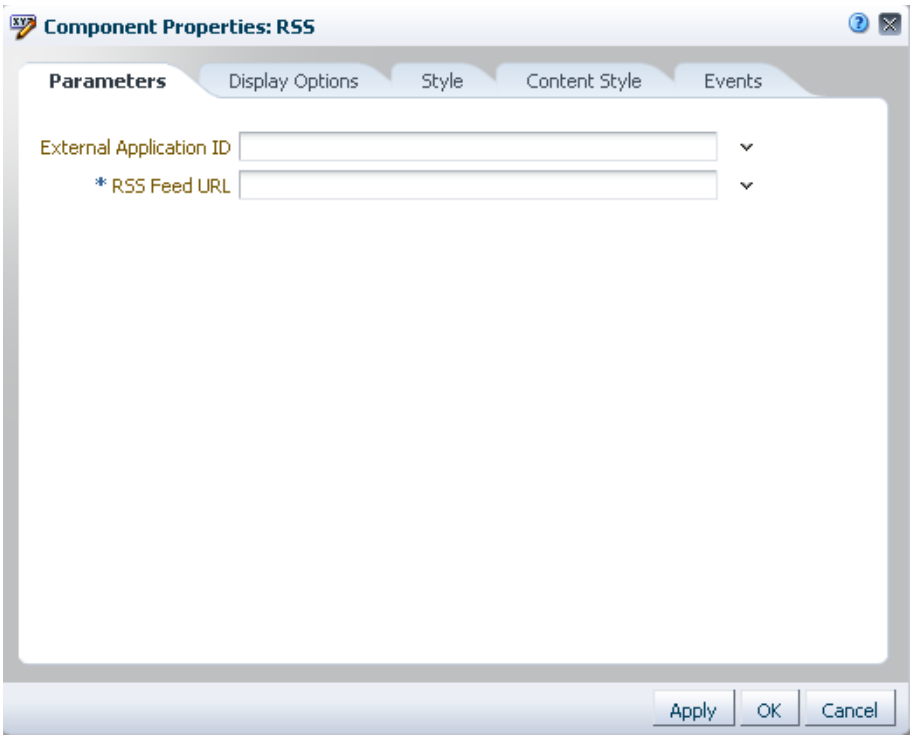


Figure 18–24 Component Properties Dialog

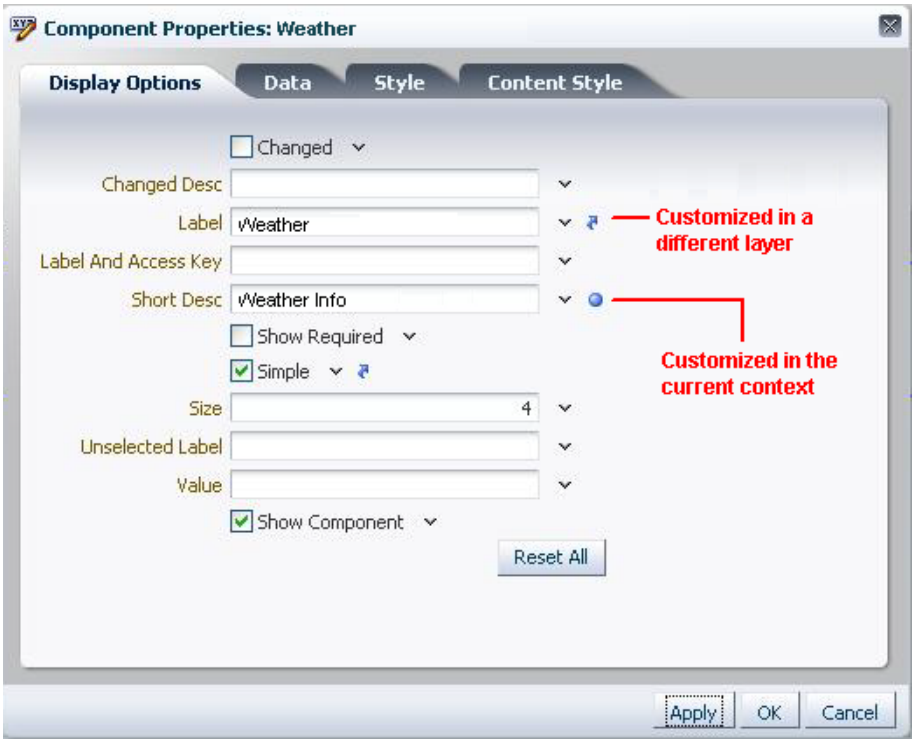
The Display Options tab enables users to edit visual properties, such as background and title.

The Parameters tab (Figure 18–25) enables users to edit parameters for components such as portlets and task flows.

Figure 18–25 Parameters tab in the Component Properties Dialog

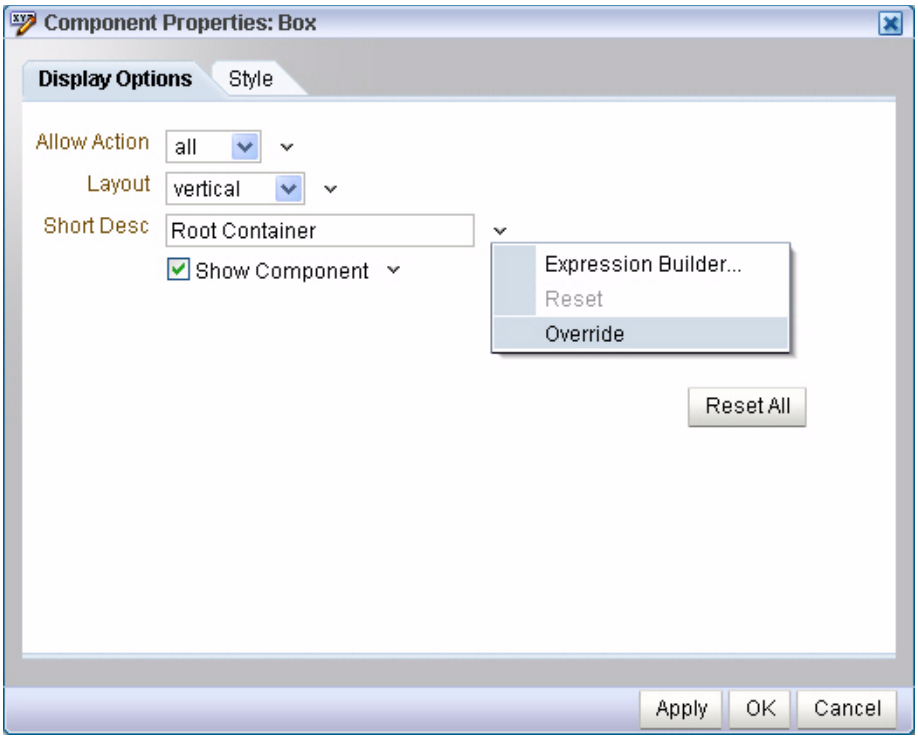


Visual Indication of Component Property Customization

An icon next to a property on the Display Options tab indicates that the property has been edited at runtime. Two different icons are used to indicate changes made in the current context and in a different layer. Figure 18–26 shows the two different icons used to indicate that the property was updated.

Note: Visual indication of property customization is relevant only if you have configured multiple customization layers in your application. For information, see Section 23.3, "Adding Customization Layers to View and Edit Modes: Example."

Figure 18–26 Visual Indication of Property Customization



The Component Properties dialog also enables users to reset visual properties in the current context. For more information, see Section 18.4.4, "Reset and Override Component Properties in the Current Layer."

18.4.4 Reset and Override Component Properties in the Current Layer

Users can reset and override application customizations made to a component's properties in the current layer. The Component Properties dialog provides options to reset a particular property or all properties on that panel in the Component Properties dialog.

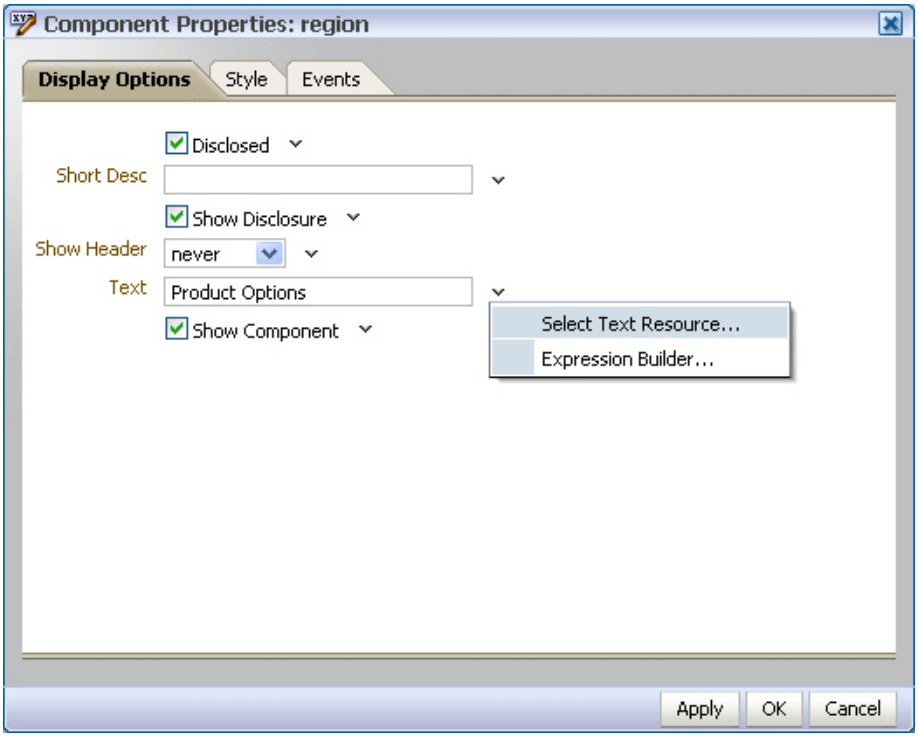
An **Override** option on the context menu for a property (Figure 18–27) enables users to use a value from another layer as a fixed value for the current layer. For example, a user edits the `Short Desc` property on a `Movable Box` component in layer `X` and sets it to `First Frame`. A user editing this component in another layer, `Y`, can choose `First Frame` as the fixed value for `Short Desc` in layer `Y`. All users that are accessing the component in layer `Y` will see this value henceforth. The value for `Short Desc` does not change in layer `Y` even if it is changed in layer `X`. When a user enters a value for a property, the Override option for that property is grayed out.

Figure 18–27 Reset and Override Options in the Component Properties Dialog

A **Reset** option on the context menu for a property enables users to reset that property to its original state. The Reset option is grayed out when the property has not yet been edited in that layer, or when the user has chosen to override the property with the displayed value, which comes from another layer.

A **Reset All** button enables users to reset all properties on the Display Options tab. Users can reset only application customizations applied to visual properties, which are rendered on the Display Options tab.

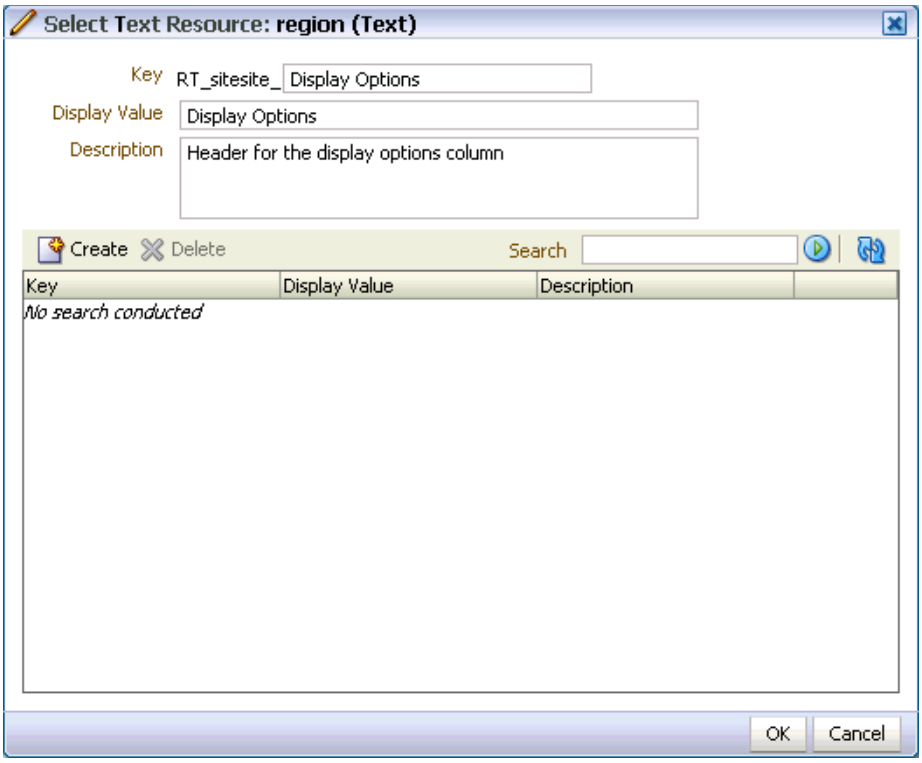
Note: The Reset option and the Reset All button are not available if the component was created newly or none of the attributes were modified in the current layer.



18.4.5 Edit Resource Strings

Component properties edited in Composer are available only in the current language. For example, if you add a task flow to your page, the task flow title you enter in Composer is available only in the current language. As a result, users in different locales do not see the translated values for such properties. To provide language support for component properties edited at runtime, Composer enables users to edit resource strings for properties that take String values. This is similar to the resource string editor feature provided by JDeveloper. Changes made to resource strings in Composer are saved into an application override bundle. This bundle is sent for translation and the translated versions are imported back into the application. This way, users are able to see the property values in their language.

For more information about the override bundle and configuring resource string editing in existing (release 11.1.1) Framework applications, see Section 22.12, "Configuring Runtime Resource String Editing."



At runtime, for component display options that can take String values, the Edit menu next to the property field provides a Select Text Resource option, as shown in Figure 18–28. Users can select this option to edit resource strings for properties.

Figure 18–28 Select Text Resource Option on an Attribute

The Select Text Resource dialog (Figure 18–29) provides options to search existing resources, edit or delete resource keys, and add new resource key/value pairs.

Figure 18–29 Select Text Resource Dialog

The Select Text Resource dialog displays the following:

- Key field: For specifying a new key name or modifying the existing name. This is a String value used for uniquely identifying a locale-specific object in the resource bundle.

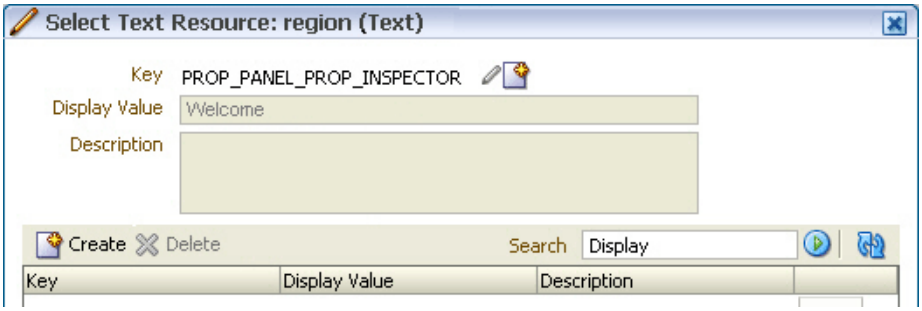
  The key name is automatically prefixed with the MDS layer to which the resource belongs. The prefix helps distinguish keys created at runtime from those created at design time.

  The **Edit** and **New Key/Value** icons (Figure 18–30), displayed for existing keys, enable users to perform the following tasks:

  – **Edit**: Modify the key value for an existing resource string. The string with new values is saved into the override bundle.

  – **New Value/Key**: Create key and value pairs in the application override bundle.

Figure 18–30 Icons for Creating and Editing Resource String Keys



Users can edit only strings that were created in the same MDS layer. Other strings appear as read-only, as shown in Figure 18–31.

Note: When you try to override the default content in the resource bundle by directly entering values in the Select Text Resource dialog, the changes do not take effect and the page may appear blank.

Therefore, it is recommended that you create a new resource string instead of directly entering values in the Select Text Resource dialog.

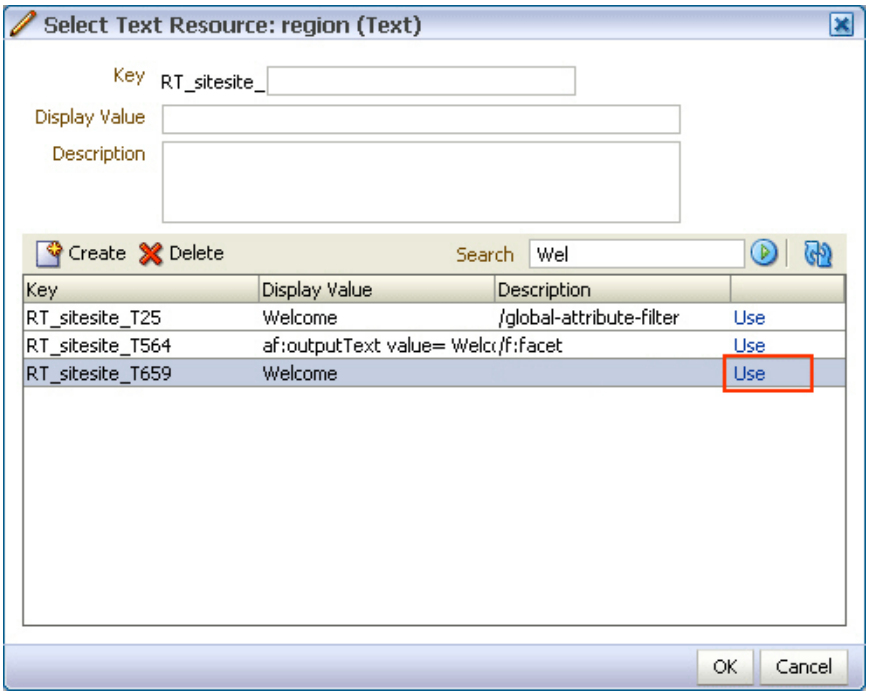
Figure 18–31 Read-Only Resource Strings in the Select Text Resource Dialog

- Display Value field: For specifying a resource string to translate for display in the UI or modifying an existing string.
- Description field: For specifying a translatable description of the resource or modifying an existing description.
- Search field: For searching existing resources. Users can search for strings that were created in the same layer, in a different MDS layer, or resource bundles defined and used in a JSPX file at design time.
- Search results table: For displaying search results, editing strings, and specifying values for new strings.

  Users can edit strings that were created in the same layer. Other strings created at design time or in a different MDS layer can only be used for the property, but not edited.

  A link or a status indicator toggle displays in the last column and enables users to promote a string to be the active, to-be-translated resource (Figure 18–32) or identifies a string as the active resource (Figure 18–33).

Figure 18–32 Use Link on a Resource String



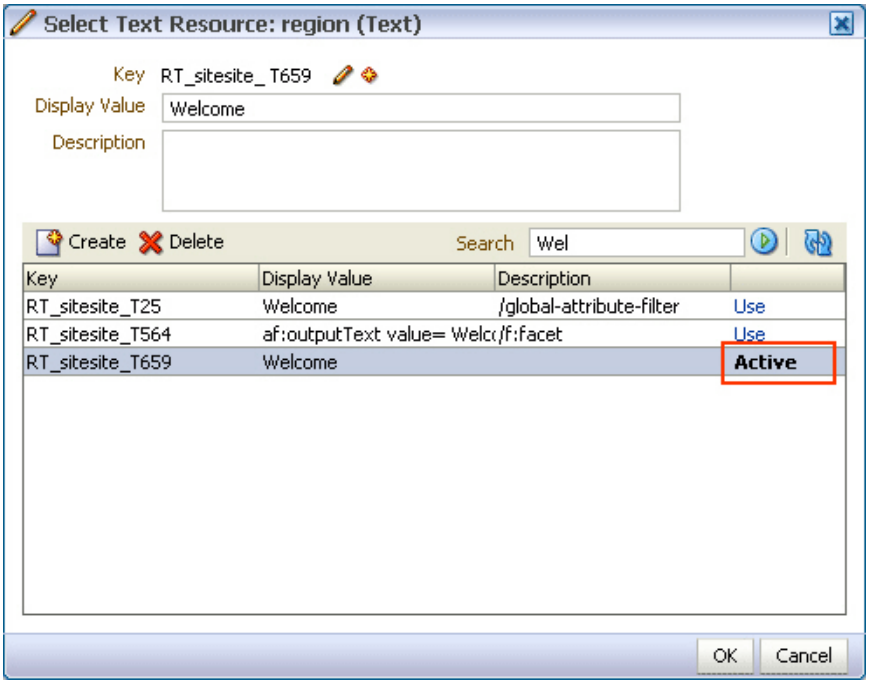


Figure 18–33 Active Status on a Resource String

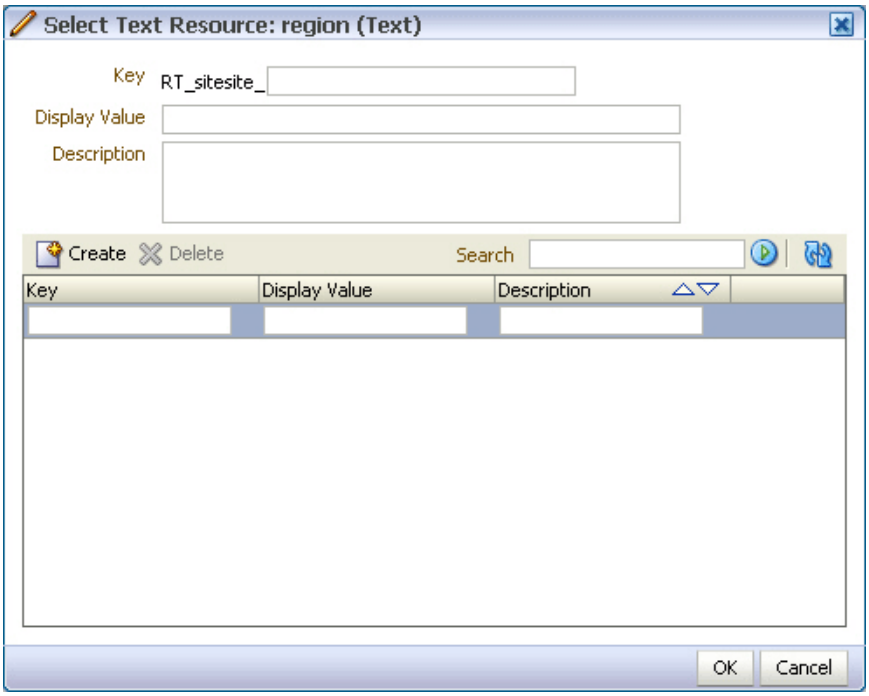


Note: When searching for resource strings created at design time, Composer searches for the `c:set` tag that is used when specifying resource strings in JSPX files.

The following example shows the `c:set` element used for defining the `ComposerBundle` in a JSPX page:

```
<c:set var="portalBundle"
        value="#{compBundle['test.resource.ComposerBundle']}"/>
```

- Create button: For creating a new resource string. On clicking the **Create** button, the search results table provides a new row with input fields for creating a new resource. Users can double click inside the row and create a new string by specifying values for the Key, Display Value, and Description, as shown in Figure 18–34, and then click **OK**.

Figure 18–34 Fields for Creating a New Resource String in the Search Results Table

Users can just create inactive strings that get saved to the override bundle. Clicking the **Use** button in the last column selects this string for use as the current property value.

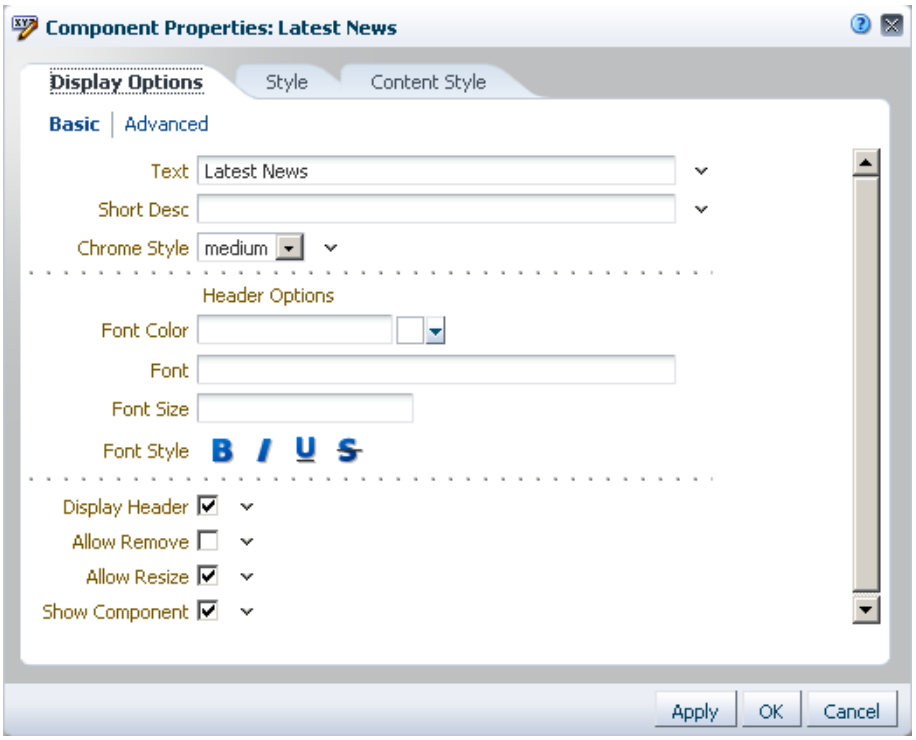
- Delete button: For deleting a selected resource from the search results table.
- Refresh: For refreshing the search results table.

Notes

- Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down.
- The search criteria in the resource string editor is case-sensitive.

- To search for the description of a resource string, the user must provide the complete string value in the search criteria.
- The resource string editor does not display string descriptions for entries created in Properties bundle or List Resource bundle formats in JDeveloper.
- The option to edit resource strings is disabled for properties on the Parameters and Events tabs.

  If the EL value for an ADF resource is referenced in a page definition parameter such as page parameter, task flow parameter, or portlet parameter, then the binding EL returns an empty value. Users must avoid referencing ADF resource EL values in page definition parameters.



18.4.6 Show or Hide Components

Users can choose to show and hide components selectively on the page using various options. Users can hide or show a component in the following ways:

Note: Show or hide behavior is tied to the component's `rendered` property. When a user hides a component, its `rendered` property is set to `false` and vice versa. If the `rendered` attribute on a component has an EL value, then that value is lost on using the show or hide option. The value is set to `true` or `false`.

- Click the **Edit** icon on the component. In the Component Properties dialog, clear the Show Component check box (Figure 18–35).

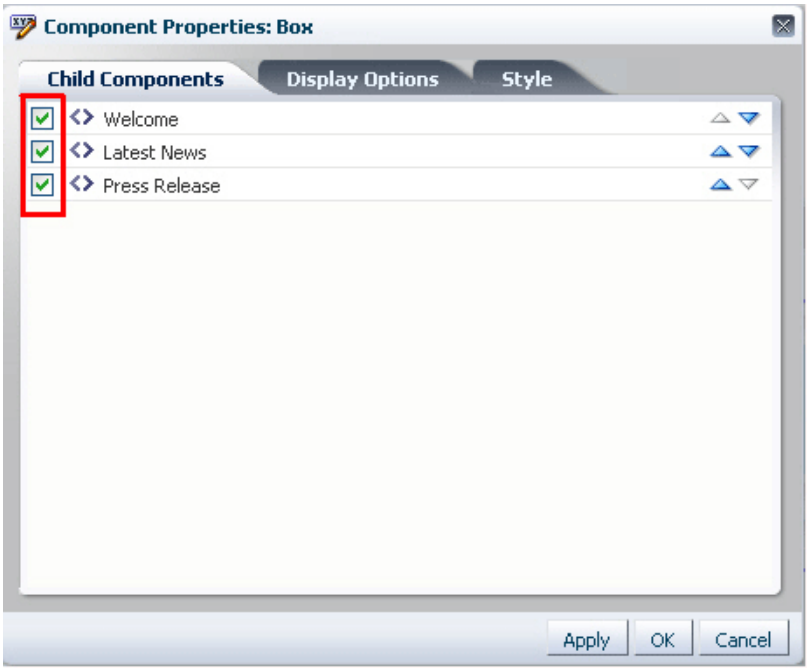


Figure 18–35 Show Component Option in the Component Properties Dialog

Checking the Show Component check box and clicking Apply or OK in the dialog renders the component on the page again.

- Click the **Edit** icon on the component's container. On the Child Components tab in the Component Properties dialog, click the Hide Component link shown against the component name.

Figure 18–36 Hide Component Link in a Container's Component Properties Dialog

When a component is hidden, the Component Properties dialog for its container displays a Show Component link against that component. Clicking this link and then clicking Apply or OK in the dialog displays the component again.

18.4.7 Delete Components

Users can delete a component from the page by clicking the **Delete** icon on its header.

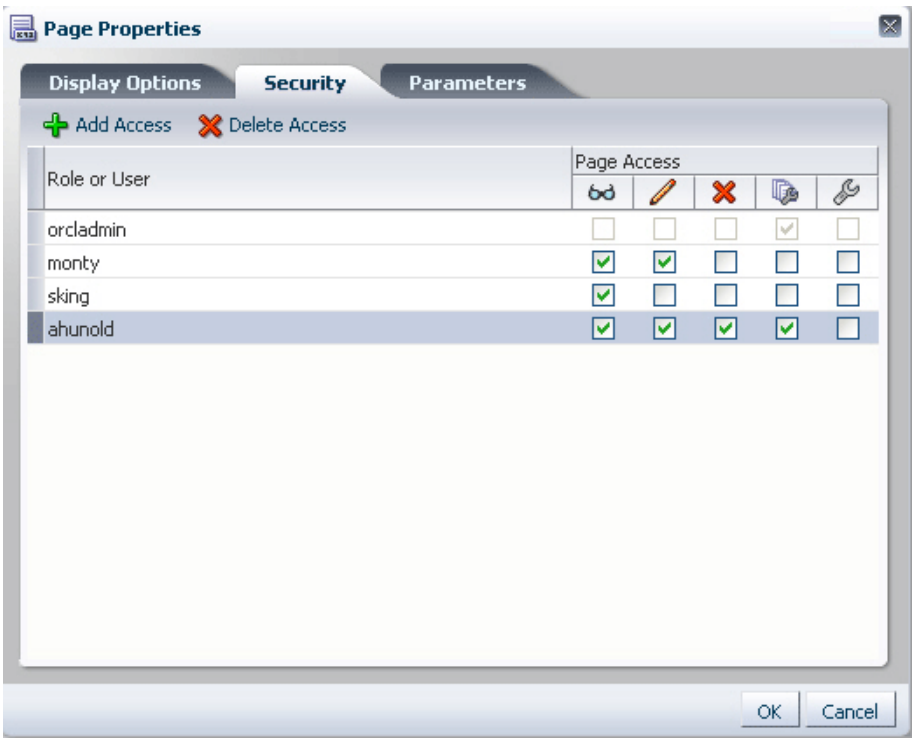
A Delete dialog prompts users to confirm deletion.

Note: If you defined customization restrictions on a component, then the **Delete** icon is disabled for the component at runtime. For more information, see Section 24.1.1, "How to Define Type-Level Customization Policies."

18.4.8 Change the Layout

In Design view, the **Change Layout** icon enables users to select a layout from a set of eight predefined layouts. The default page layout is `threeColumn`.

In Source view, users can select the `Layout Customizable` component and view its properties. The layout options are displayed in the Component Properties dialog. Users can select any predefined layout and click Apply or OK.



Note: Predefined layout options are available to users only if you have added a `Layout Customizable` component to the page at design time. For more information, see Section 18.6.5, "Layout Customizable."

18.4.9 Edit Page Properties

Users can access the **Page Properties** dialog from both Design view and Source view. In this dialog, users can create or edit a page's parameters and display properties. For pages created at runtime in a secured application, a Security tab enables users with Grant privilege to edit page access privileges for other users.

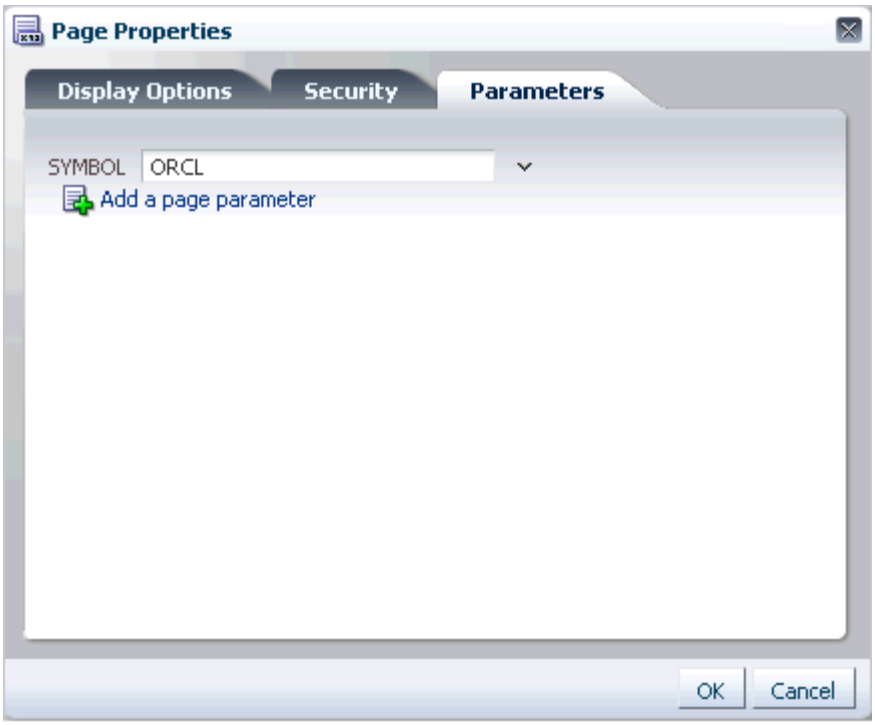


Figure 18–37 shows the Security tab in the Page Properties dialog.

Figure 18–37 Security Tab on the Page Properties Dialog

On the Parameters tab (Figure 18–38), users can create page parameters that can be linked to component properties, thereby enabling any component on the page to adapt to the page context. For example, suppose that a page has a parameter called `SYMBOL` with the default value `ORCL`. This page contains the Stock Chart, Stock Price, and Company Info task flows. The task flows can be linked with the page parameter so that all the task flows respond to a change in the value of `SYMBOL` and are updated accordingly.

Figure 18–38 Parameters Tab on the Page Properties Dialog

See "Building Pages" and "Wiring Pages, Task Flows, Portlets, and UI Components" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* for detailed information about editing page settings.

18.4.10 Wire Components to Page Parameters

Composer enables users to link portlets and task flows with page parameters so that these components can read the page parameters and change their behavior accordingly.

Users can wire portlet and task flow parameters to page parameters using the Component Properties dialog. For more information, see "Wiring Pages, Task Flows, Portlets, and UI Components Together" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

In addition to wiring components and page parameters, Composer also enables users to pass values for display options and parameters through page URLs. For more information, see "Passing Parameter Values Through the Page URL" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

18.4.11 Reset Page

The **Reset Page** button is available on the page in both Design view and Source view. This button invokes the Reset Page dialog that provides options to remove edits made to a page in the current layer or tip layer and reset it to a previously saved version or its original, out-of-the-box state.

Note: The **Reset Page** button is a default add-on rendered on the Composer toolbar. You can disable this button if you do not want users to reset the page. For information, see Section 21.2.5, "How to Selectively Display Add-Ons."

Roll Back to a Specific Label

If your application is configured to use a database store, a new version of the page is generated each time a user saves application customizations. If a sandbox is configured for your application, by creating a label with the `SAVE_LABEL_%` convention you can ensure that Composer resets the page as follows:

- If there is only one label name following the `SAVE_LABEL_%` convention, then Composer resets the page to its state in that label.
- If there is no label name following the `SAVE_LABEL_%` convention, then Composer resets the page to its original, out-of-the-box state.
- If there are multiple labels following the `SAVE_LABEL_%` convention, then Composer resets the page to its state in the latest label among these.

To roll back to a specific label, you must have configured your application to use a sandbox. Specifically, the namespace of the page being customized must be defined in the `<metadata-namespaces>` section in the application's `adf-config.xml` file. For more information, see Section 23.2.1, "How to Enable Composer Sandbox Creation."

Rolling back to a specific label is useful if your application has dependencies on the customization metadata and resetting the page to its original state can cause issues.

Notes:

- Users can only reset application customizations done on a page. Components defined in the base page or a shared component's page are left intact.
- When a user resets a page, components added to the page at runtime are removed. However, if the page uses a template, then components added inside `Panel Customizable` components on the template are not removed.

Example 18–1 shows the sample code to create a label with a `SAVE_LABEL_` prefix.

Example 18–1 Code to Create a Label Prefixed with SAVE_LABEL_

```
import oracle.mds.versioning.VersionHelper;
import oracle.mds.naming.Namespace;

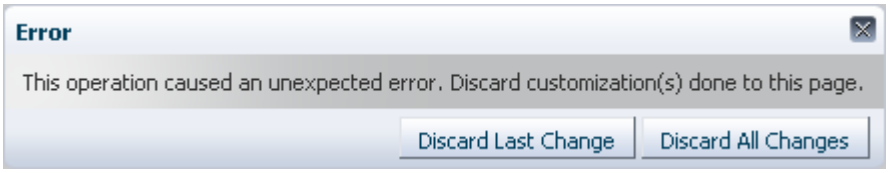
....
long labelNumber = (long)(Math.random() * 1000000000);
String savedlabel = "SAVE_LABEL_" + labelNumber;

MDSInstance mdsInstance =
(MDSInstance)ADFContext.getCurrent().getMDSInstanceAsObject();

VersionHelper vh = VersionHelper.get(mdsInstance);

Namespace[] validNamespaces = new Namespace[1];
```

```
Namespace pageNamespace = Namespace.create(<pagePath or taskflow path>,
NamespaceRestriction.CUSTOMIZATIONS);



validNamespaces[0] = pageNamespace;
vh.createLabel(savedlabel, null, validNamespaces);
```

18.4.12 Reset Application Customizations on Detecting Errors

Composer provides a mechanism to alert users to customization errors that may cause a page to break. Users are alerted about errors in the following ways:

- If the change is saved to MDS, an Error dialog, shown in Figure 18–39, provides the option to roll back only the last change or all changes that users made in the current context.

Figure 18–39 Error Dialog Prompting Users to Discard Changes

- If the change is not yet saved to MDS, an Error dialog, shown in Figure 18–40, simply informs users that an error occurred and the page will be reloaded.

Figure 18–40 Error Dialog Informing Users About Page Reload

Errors occurring while performing the following operations may cause the page to break:

- Pasting a component at the wrong position while using the Cut and Paste options; for example, pasting a table column outside the table.
- Adding components or task flows; for example, adding a task flow that calls a Web service, which in turn gives an error.
- Moving `Show Detail Frame` components on the page using the drag-and-drop method.

18.4.13 Create Labels On Saving Application Customizations

A Save and Label button on the Composer toolbar, shown in Figure 18–41, enables users to save their application customizations in a new label. Labels created in Composer are stored with a prefix of `composer_`, that is, a label created with the name `myLabel` is stored as `composer_myLabel`.

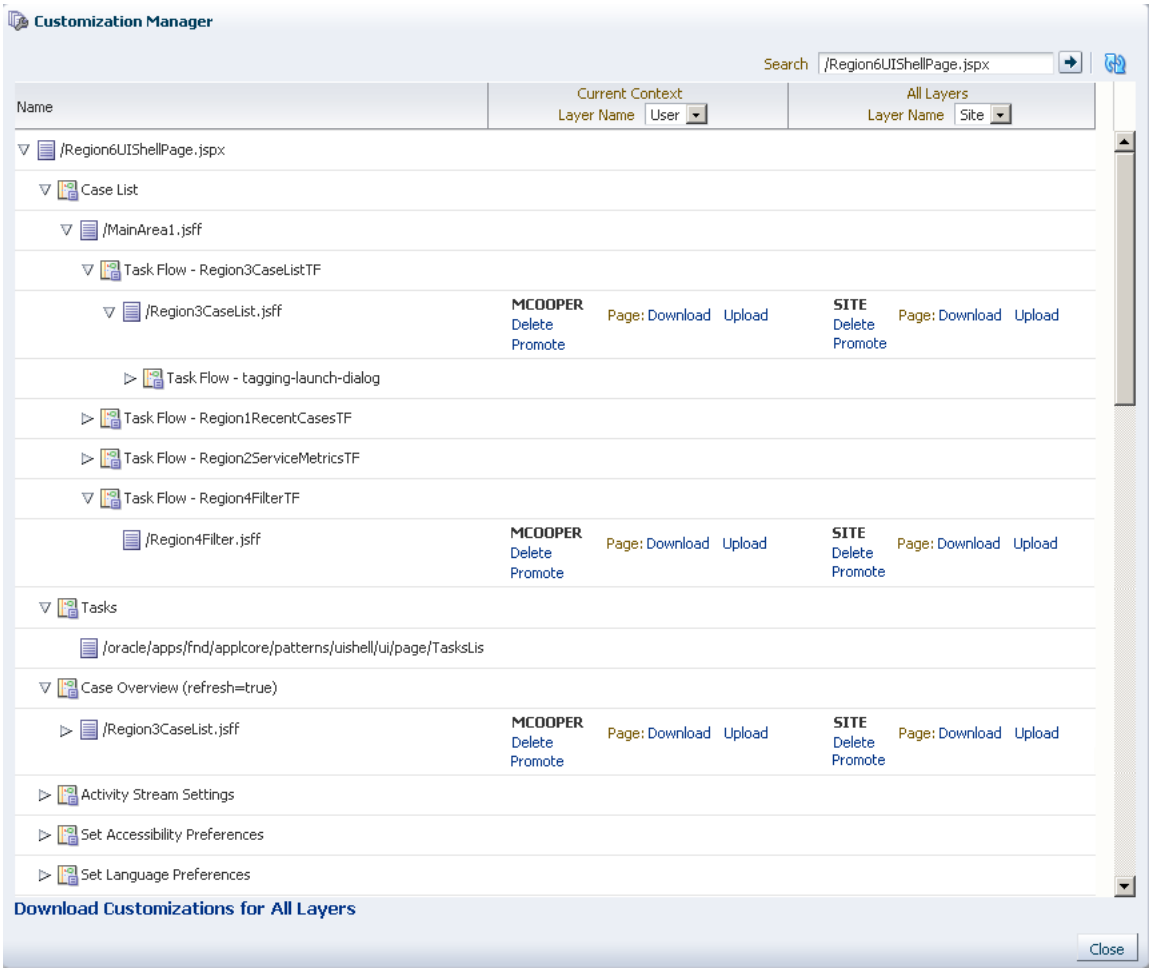
Creating labels enables users to reset customizations on a selected object to those from a selected label. This can be achieved using the Promote link in Customization Manager. For more information, see the section titled Promote Customization Metadata.

Note: The Save and Label button is displayed only if you have configured a sandbox with an MDS database store for your application and set the `allowLabel` attribute on the `Page Customizable` component to `true`. For more information about this attribute, see Section B.1.1, "Page Customizable."

Figure 18–41 Save and Label Button on the Composer Toolbar

18.4.14 Manage Application Customizations

The Customization Manager is a Composer add-on panel that enables users to manage customization metadata for objects such as XML documents, pages, page fragments, and task flows on the page. It displays a list of all such objects on the page, and provides details about the layers in which these objects are customized. Users can download customization metadata for a selected object, edit it, and upload the revised metadata file. Additionally, the Customization Manager also provides options to delete customizations and promote customizations from a previously saved label.



The Customization Manager is not available by default in your custom application. You can enable it by performing certain configurations. For more information, see Section 21.2.4, "How to Display the Customization Manager Add-On." If you configure your application to display the Customization Manager add-on, the Composer toolbar displays a Customization Manager button, as shown in Figure 18–42.

Figure 18–42 Customization Manager Button

Clicking the Customization Manager button invokes the Customization Manager dialog, shown in Figure 18–43.

Figure 18–43 Customization Manager Dialog

The Customization Manager displays Delete, Promote, Download, and Upload links against each customized page, fragment, or XML document in each layer. Users can specify a JSPX, JSFF, or XML file name in the search field to view customization details about objects in that file and manage those customizations. To search for a file, you must specify the absolute path to the file, for example, `/oracle/webcenter/portalapp/pages/home.jspx`.

Note: In case of a deeply nested task flow or a task flow with a cyclic dependency, Customization Manager displays a maximum depth of ten task flows.

Users can manage customizations in the current MDS context in which the application is running. The Current Context column displays options to manage customizations in the selected layer. The dropdown menu lists the layers in which the page or fragment was customized. This column is useful for all users who want to manage customizations they have made. The All Layers column displays options to manage customizations in all layers in the application. This column is useful for administrators who want to manage customizations made in all layers.

Notes:

- If you have configured a sandbox for your application, all Customization Manager operations are performed in the sandbox; for example, when a user uploads a customization document, it is stored in the sandbox until the user saves or discards changes made during that session.
- You can customize the Customization Manager to only display options of your choice. For example, you can show or hide the Download, Delete, or Upload links. Further, you can choose to show details for the current context only or for all layers only.

  You can make these settings using parameters on the Customization Manager task flow. By enabling parameter support on the task flow, you can enable users also to customize the Customization Manager at runtime. For more information, see Section 21.8, "Defining Property Filters."

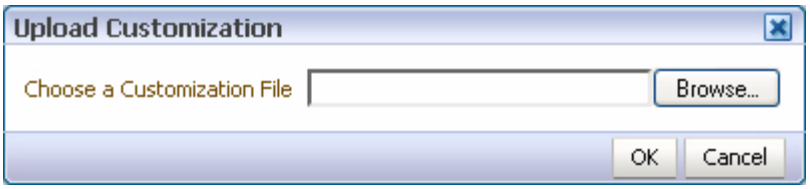
This section describes the capabilities provided by the Customization Manager. It contains the following subsections:

- Download Customization Metadata
- Download Customization Metadata for All Customized Objects
- Upload Customization Metadata
- Delete Customization Metadata
- Promote Customization Metadata

Download Customization Metadata

A Download link enables users to download the customization document for the selected page, fragment, or XML document from the selected layer. This is useful if a user wants to edit customization metadata for a component or inspect the customization metadata. For example, if a page displays errors, the user can download the customizations, review them, and send them to Oracle Support Services, if required. This helps in diagnosing any customization issues on the page.

The Save dialog lets users select a location for saving the document. Users can edit this file locally and upload it to the site again. For information about uploading files, see Upload Customization Metadata.



Download Customization Metadata for All Customized Objects

The Download Customizations for All Layers link at the bottom of the page enables users to download a ZIP file containing all customization documents shown in the Customization Manager.

Upload Customization Metadata

An Upload link enables users to upload a customization document for the selected artifact, such as page, fragment or XML document, in a specific layer. Figure 18–44 shows the Upload Customization dialog that lets users select the file they want uploaded.

Figure 18–44 Upload Customization Dialog

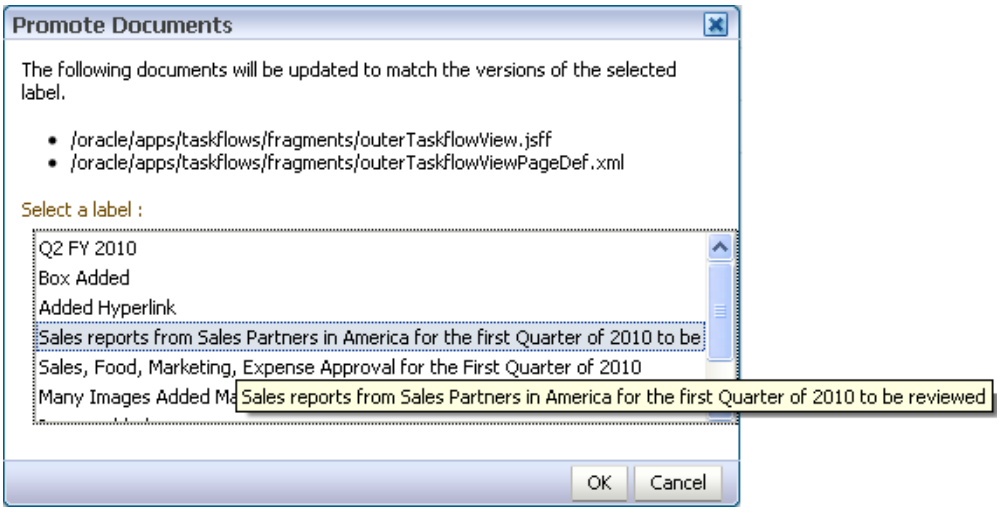
The artifact is then customized based on the metadata in the uploaded document.

Note: The `usesUpload` attribute on the `Form` tag on the page controls the display of Upload links in Customization Manager. If you set `usesUpload` to `false`, the Upload links will not work.

Delete Customization Metadata

A Delete link enables users to delete the customization document for the selected artifact from a specific layer.

Promote Customization Metadata



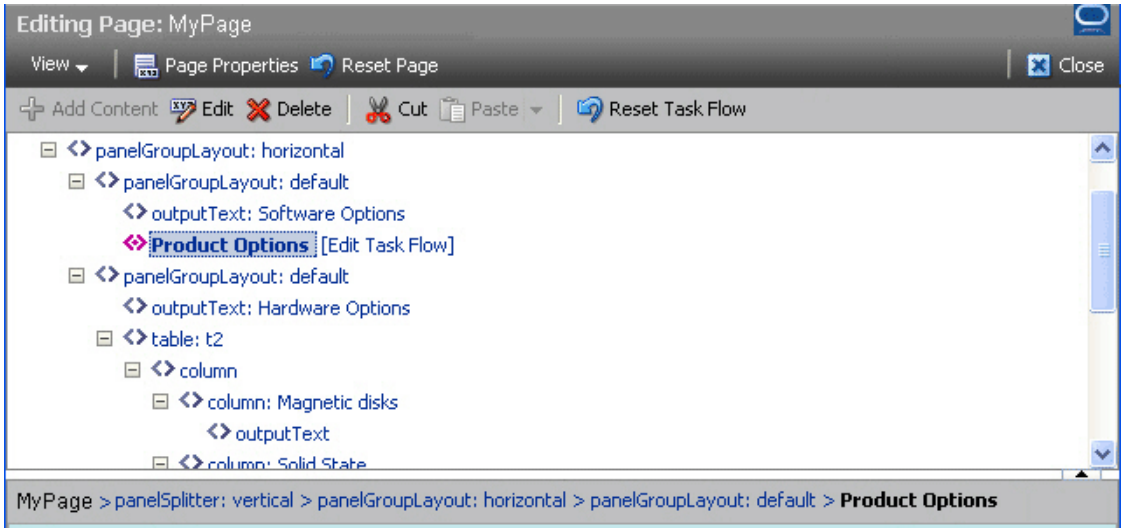
While customizing a page, users can save application customizations at any point and create a new label to save those customizations. A Promote link in the Customization Manager enables users to select a label and reset application customizations on the selected page or task flow to those from the label.

Notes: The Promote option is available only in sandbox-enabled applications.

For more information about the Save and Label option in Composer, see Section 18.4.13, "Create Labels On Saving Application Customizations."

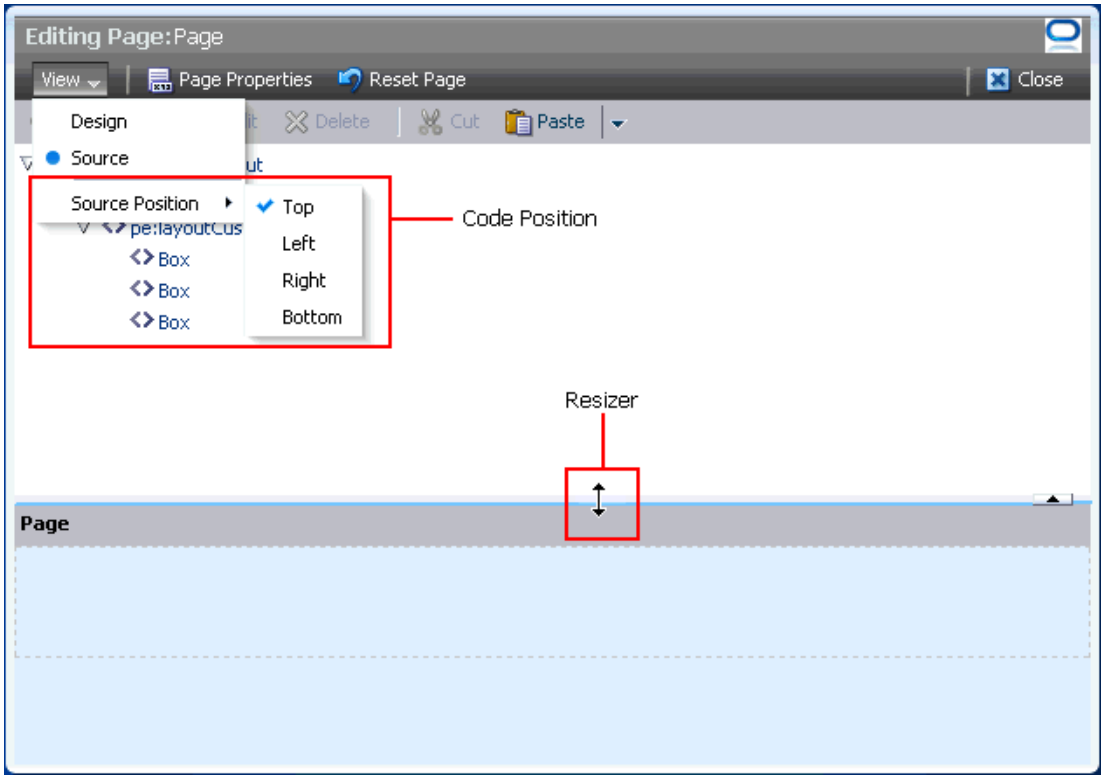
The Promote link invokes the Promote Documents dialog, which lists all available labels and the files that will be promoted, as shown in Figure 18–45.

Figure 18–45 Select a Label Dialog



Users can select a label and promote that label to the sandbox for the selected artifact. This means that application customizations for the selected artifact are reset to those from the specified label. If a task flow is selected, then all page fragments and page definitions are promoted. If a page or fragment is selected, then the page or fragment and its page definition are promoted. Users can select a label from any available layer and promote customizations from that label. For example, if an application has layers MCOOPER, JDOE, and SITE, and a user working in the MCOOPER layer clicks the Promote link for a page, the Promote dialog lists all labels available in all three layers.

18.5 Editing Capabilities in Source View in Page Edit Mode



Source view (Figure 18–46) provides a WYSIWYG and a hierarchical rendering of page components in a component navigator. Add Content, Edit, Delete, Cut, and Paste controls are available on the Source view toolbar provide specific operations in Composer. In Source view, users can access and modify properties of components that are not otherwise selectable in Design view. For example, many ADF Faces components can be edited only in Source view. Users can also edit components within a task flow.

Figure 18–46 Source View of a Page

By default, the component navigator displays at the top of the page within Composer. Users can choose to display it at the bottom, left, or right using the **Source Position** option on the **View** menu (Figure 18–47). Users can also drag the border on the edge of the component navigator to alter its height or width.

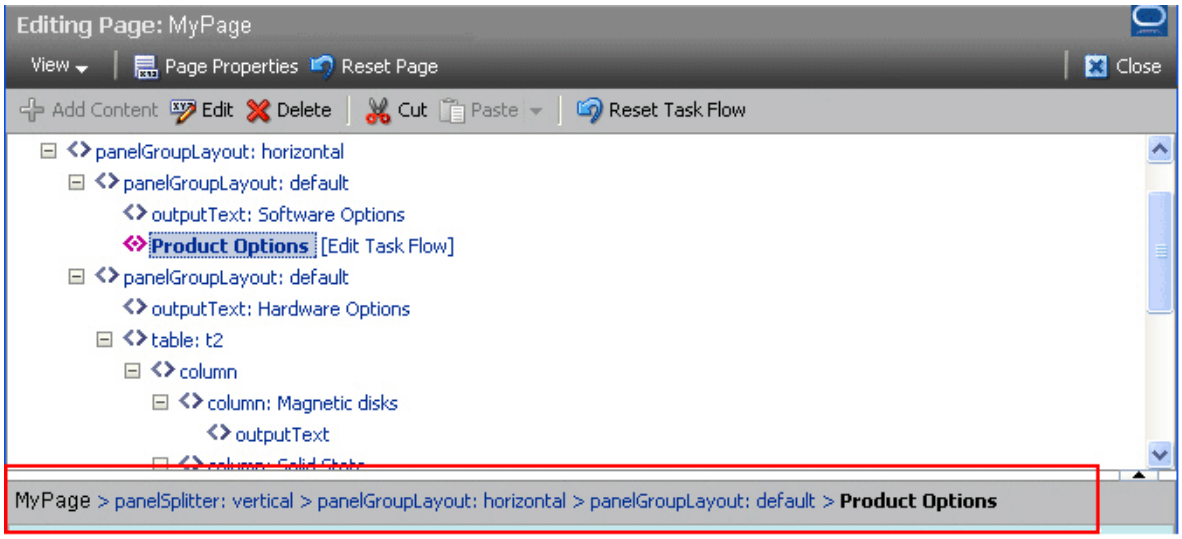


Figure 18–47 Source Position Option on the View Menu

At the root of the component navigator is the direct child of the `Page Customizable` component at design time. When a node is selected in the component navigator, the corresponding component is selected on the page. Similarly, when a component is selected directly on the page, the corresponding node is selected in the component navigator.

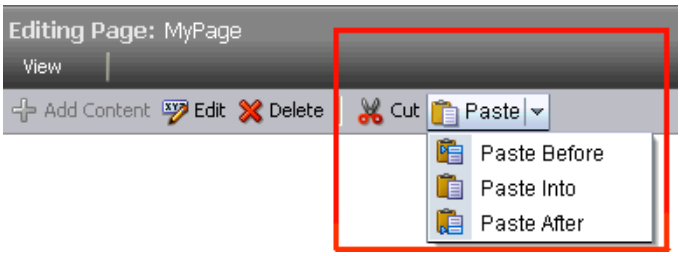
A gray area located between the component navigator and the page displays a bread crumb trail for the selected component (Figure 18–48). The bread crumb trail shows how the component is nested on the page. When no component is selected, the bread crumb bar displays just the page name. The container names are links that when clicked highlight the selected component.

Figure 18–48 Bread Crumbs for a Component Selected in Page Source View

Task flows that can be edited have Edit Task Flow links next to them. On clicking an Edit Task Flow link, the component navigator displays the hierarchy of components within the task flow's page or fragment. Users can edit this page or fragment and click Close to zoom out of the task flow. For more information, see Section 18.5.2, "Edit Content Inside a Task Flow." Similarly, declarative components display Open links that enable users to edit components inside the selected declarative component's facets.

Similar to Design view, in Source view also users can perform such tasks as adding components, editing page and component properties, changing page layout, and deleting components. Users can select a component on the page or in the component navigator and click the buttons on the Source view toolbar to perform these tasks. To edit or delete a component, users can also select options on the context menu for the component. In addition to these tasks, users can perform the following tasks in page Source view:

- Section 18.5.1, "Rearrange Page Content Using Cut and Paste Options"
- Section 18.5.2, "Edit Content Inside a Task Flow"
- Section 18.5.3, "Edit Content Inside a Declarative Component"
- Section 18.5.4, "Show or Hide Components"



Notes:

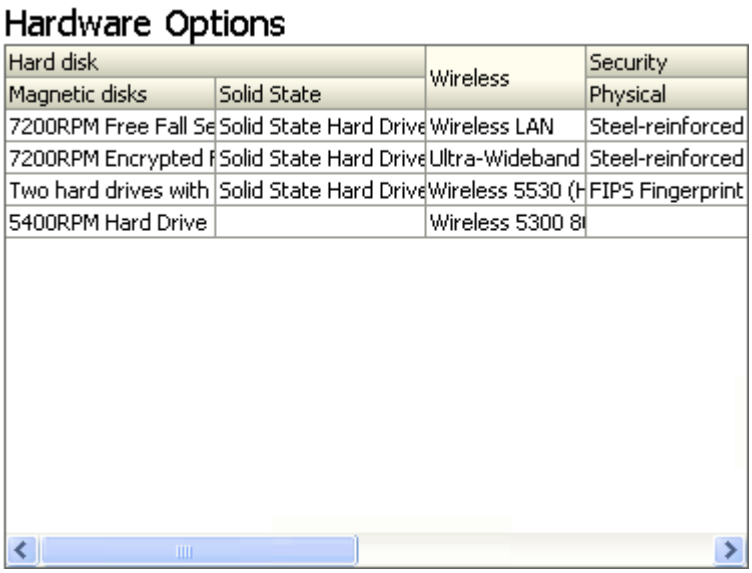
- The **Save** button is provided on the Composer toolbar (both in Design view and Source view) only if the application is configured to use a sandbox. For more information about sandboxes, see Section 23.2, "Using Composer Sandbox."
- You can restrict users from performing all or some of these tasks by securing the application and applying customization restrictions on components. For more information, see Section 18.7, "Security and Composer."

18.5.1 Rearrange Page Content Using Cut and Paste Options

Users can rearrange components on a page using the Cut and Paste options on the Source view toolbar (Figure 18–49). A Paste menu enables users to paste a component into, before, or after any other component in the component navigator.

Figure 18–49 Cut and Paste Options on the Source View Toolbar

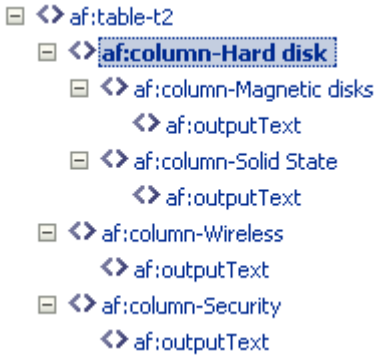
The Cut and Paste buttons are grayed out if the user selects a component that does not support a cut or paste operation. Cut and paste operations are not supported under the following conditions:



- The target component is not on the same page as the cut component.
- The target component is nested inside the cut component.
- The target component is located before or after a faceted component, that is, a component inside a facet.
- The parent of the target component is not customizable.
- The parent of the cut component is not customizable.

Notes: A component on which customization is restricted can be rearranged inside its parent container if the parent is customizable.

Example



If your customizable page contains an ADF Faces `Table` component, then in Composer's Source view, users can resequence or move columns within or across tables and column groups. Consider a sample application created for selling computer accessories. The application home page has two tables containing details about the software and hardware offerings. The Hardware Options table contains four columns. The Hard disk column in turn contains the Magnetic disks and Solid State columns inside a column group, as shown in Figure 18–50.

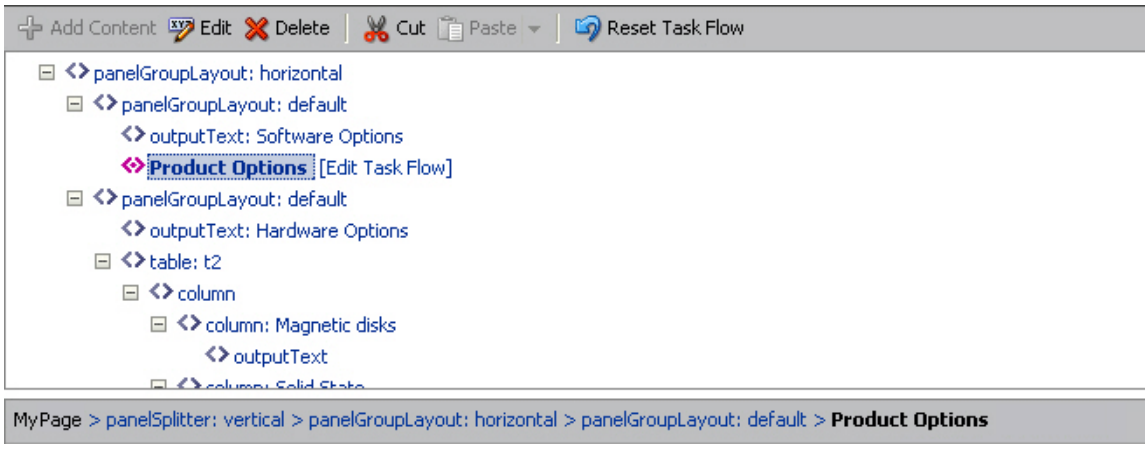
Figure 18–50 Table in the Sample Application

Users can switch to Source view and resequence the Magnetic disks and Solid State columns within the Hard disk column or move them out of the column group and paste them next to any other column (the Wireless column, for example). Figure 18–51 shows the table structure in the component navigator.

Figure 18–51 Table Columns in Source View

Users can select a column and click **Cut**, then select another column and click **Paste Before** or **Paste After**.

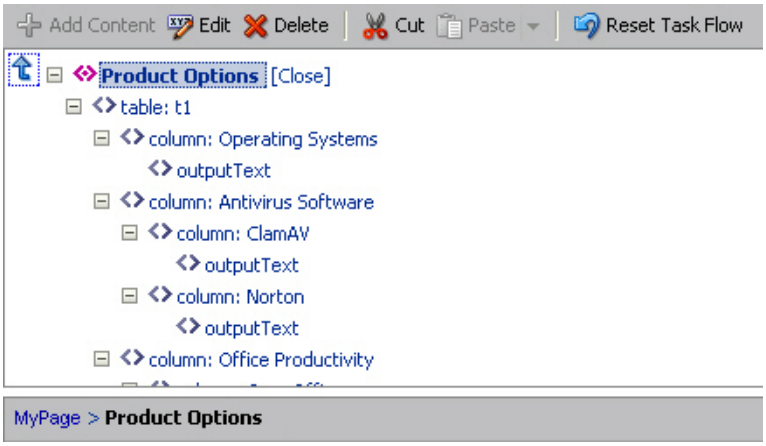
18.5.2 Edit Content Inside a Task Flow



Oracle ADF Task flows consist of one or more views and each view in a task flow is associated with a page or page fragment. When you add a task flow to your page, the content on the fragment associated with the current view is displayed on the page. Composer enables users to edit components on the page or fragment used for the current view of a task flow. Since changes are made to the task flow's page or fragment, they are reflected in all places where the task flow's page or fragment is used.

The Source view provides an option to open a task flow and display only components on its page or fragment in the component navigator. Users can edit the page or fragment and close the task flow to navigate back to the page containing the task flow.

Users with Customize permission on a task flow can edit its page or fragment.

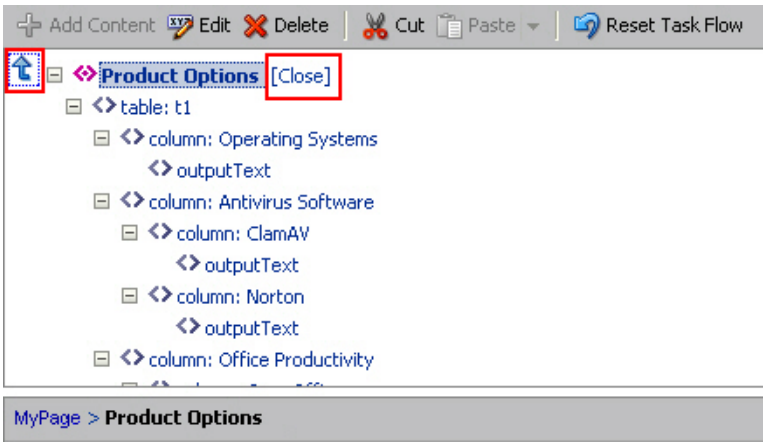


Each task flow in the component navigator displays an **Edit Task Flow** link next to it, as shown in Figure 18–52.

Figure 18–52 Edit Task Flow Link on a Task Flow

Clicking the **Edit Task Flow** link results in the Source view zooming in to display the task flow's page and its components, as shown in Figure 18–53.

Figure 18–53 Components Within a Task Flow

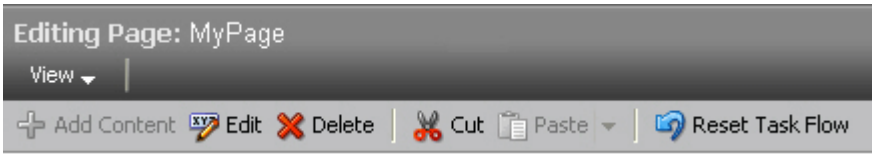


Users can select components on the task flow's page and edit them in Composer just like editing any other page components. However, Composer does not support moving components from one task flow to another.

If multiple users attempt to edit the same task flow at the same time, a concurrency warning appears in Composer that alerts each user to the others. However, this warning is displayed only if a sandbox is configured in the application. For information about how changes are saved in such cases, see "What Happens During Concurrent Edits".

Clicking the Up arrow or **Close** link next to an open task flow (Figure 18–54) results in the component navigator displaying the page containing the task flow.

Figure 18–54 Options to Zoom Out of a Task Flow



18.5.2.1 Reset Task Flow

The **Reset Task Flow** button on the Source view toolbar (Figure 18–55) invokes the Reset Task Flow dialog that provides options to remove application customizations made to a task flow and reset it to a previously-saved version or to its original out-of-the-box state. You can ensure that the task flow is reset to its state in a previously-saved label only if your application is configured to use a database store. The **Reset Task Flow** button is rendered only on zooming into a task flow.

> **Note:** If you disable the **Reset Page** button in your application, the **Reset Task Flow** button is also disabled. Users cannot reset task flows after they make changes. For more information, see Section 18.4.11, "Reset Page."

Figure 18–55 Reset Task Flow Button

Roll Back to a Specific Label

If your application is configured to use a database store, a new version of the task flow is generated each time a user saves application customizations. If a sandbox is configured for your application, by creating a label with the `SAVED_LABEL_%` convention you can ensure that Composer resets the task flow as follows:

- If there is only one label name following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its state in that label.
- If there is no label name following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its original, out-of-the-box state.
- If there are multiple labels following the `SAVED_LABEL_%` convention, then Composer resets the task flow to its state in the latest label among these.

To roll back to a specific label, you must have configured your application to use a sandbox. Specifically, the namespace of the task flow being customized must be defined in the `<metadata-namespaces>` section in the application's

`adf-config.xml` file. For more information, see Section 23.2.1, "How to Enable Composer Sandbox Creation."

Rolling back to a specific label is useful if your application has dependencies on the customization metadata and resetting the task flow to its original state may cause issues.

When a user resets a task flow, the following changes occur:

- Only the currently selected fragment is reset. Other fragments of the task flow are not reset.
- Nested task flows are not affected by the reset operation.
- When a task flow is reset, changes are reflected on all pages consuming this task flow.
- Components added to the task flow at runtime are removed. However, if the task flow's page or fragment uses a template, then components added inside `Panel Customizable` components on the template are not removed.

Example 18–2 shows the sample code to create a label with a `SAVE_LABEL_` prefix.

Example 18–2 Code to Create a Label Prefixed with SAVE_LABEL_

```
import oracle.mds.versioning.VersionHelper;
import oracle.mds.naming.Namespace;

. . .
long labelNumber = (long)(Math.random() * 1000000000);
String savedlabel = "SAVE_LABEL_" + labelNumber;

MDSInstance mdsInstance =
(MDSInstance)ADFContext.getCurrent().getMDSInstanceAsObject();

VersionHelper vh = VersionHelper.get(mdsInstance);

Namespace[] validNamespaces = new Namespace[1];
Namespace pageNamespace = Namespace.create(<pagePath or taskflow path>,
NamespaceRestriction.CUSTOMIZATIONS);

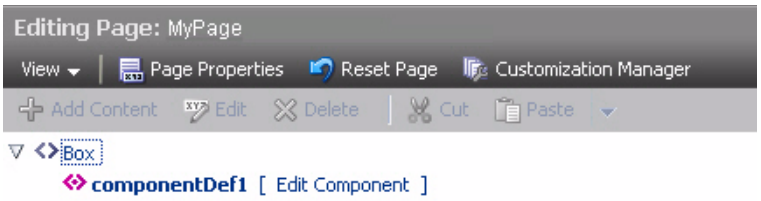
validNamespaces[0] = pageNamespace;
vh.createLabel(savedlabel, null, validNamespaces);
```

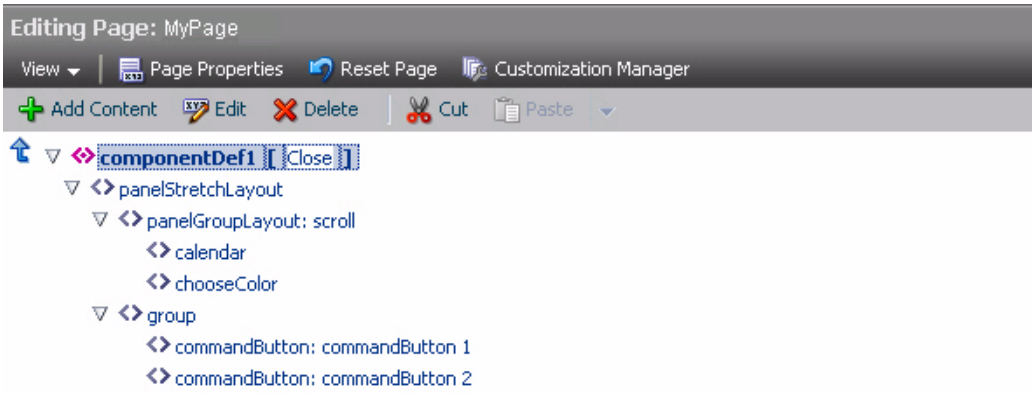
18.5.3 Edit Content Inside a Declarative Component

If the application page contains declarative components, users can edit these components in Composer. Editing declarative components is similar to editing task flows. For more information, see Section 18.5.2, "Edit Content Inside a Task Flow."

Figure 18–56 and Figure 18–57 show the Edit Component and Close options available on declarative components.

Figure 18–56 Edit Option On a Declarative Component





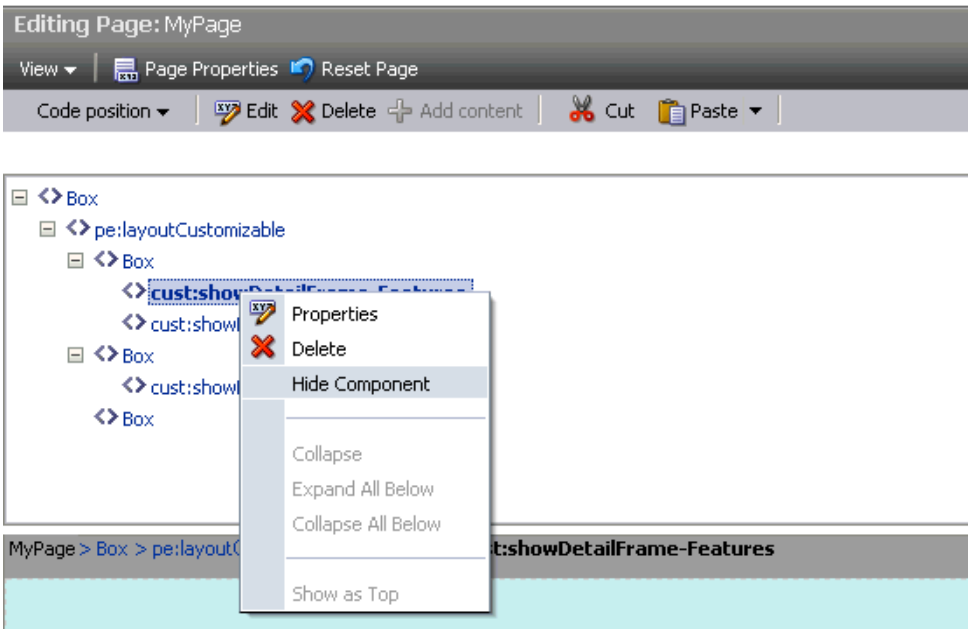


Figure 18–57 Close Option Displayed While Editing a Declarative Component

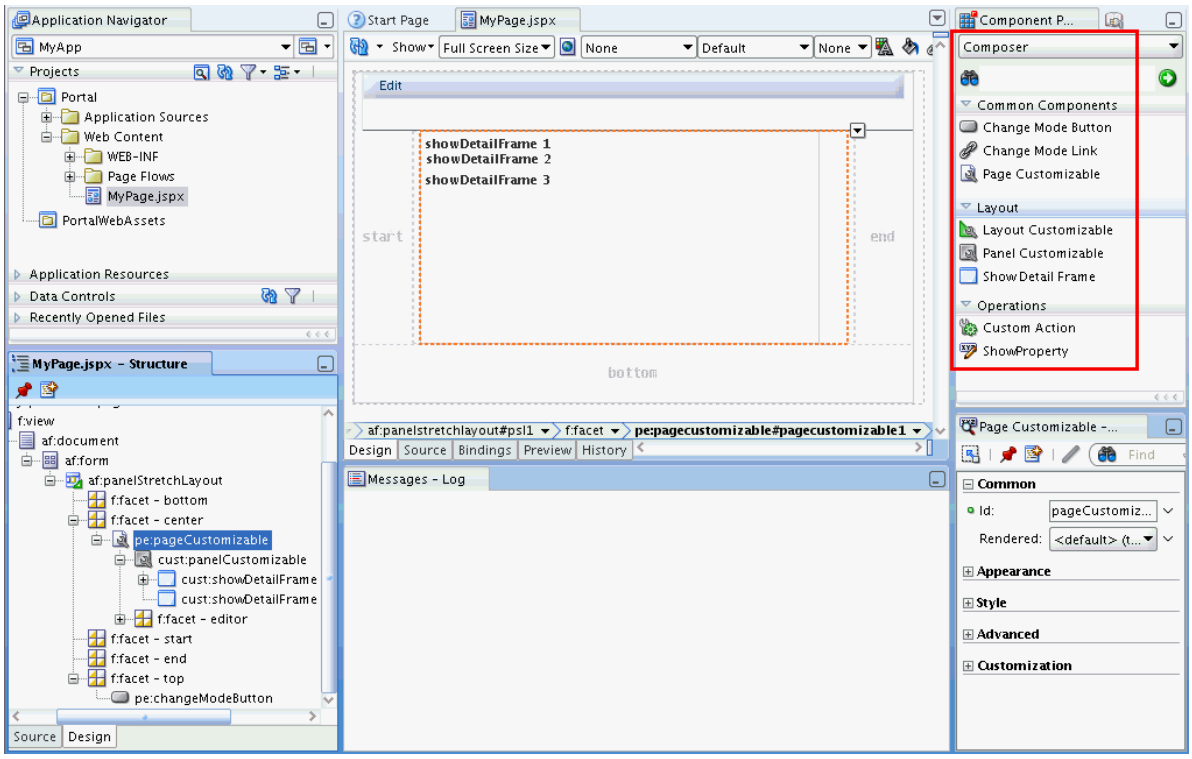
18.5.4 Show or Hide Components

To hide a component, right-click the component in the component navigator or on the page and choose Hide Component on the context menu (Figure 18–58).

Figure 18–58 Hide Component Option in Source View of the Page

A hidden component is not displayed on the page, but appears grayed out in the component navigator. The context menu for a hidden component displays a Show Component option. Choosing this option renders the component on the page again.

Note: Show or hide behavior is tied to the component's `rendered` property. When a user hides a component, its `rendered` property is set to `false` and vice versa. If the `rendered` attribute on a component has an EL value, then that value is lost on using the show or hide option. The value is set to `true` or `false`.



18.6 Composer Components

To make any JSPX document (`*.jspx`) editable at runtime, you must add Composer components to your page in Oracle JDeveloper at application design time.

Note: Composer works only with JSPX pages and ADF Faces. You cannot add these components to JSP pages. For information about adding Composer components to your page, see Section 20.1, "Designing Editable Pages Using Composer Components."

The Composer tag library (Figure 18–59) available from the Component Palette provides components that you can add to make a page editable.

Figure 18–59 Composer Tag Library in the Component Palette

Composer

****

This section provides an overview of the Composer components that are used to enable page editing. It contains the following subsections:

- Section 18.6.1, "Page Customizable"
- Section 18.6.2, "Change Mode Link and Change Mode Button"
- Section 18.6.3, "Panel Customizable"
- Section 18.6.4, "Show Detail Frame"
- Section 18.6.5, "Layout Customizable"

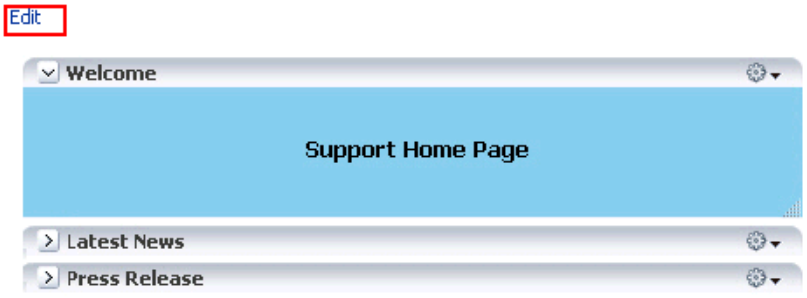
For more information about these components and other Composer components such as `Custom Action`, see Appendix B, "Composer Component Properties and Files."

18.6.1 Page Customizable

The `Page Customizable` component defines the editable area of a page. Within this area, you can edit component properties, add content to the page, arrange content, and so on.

Adding a `Page Customizable` component enables the runtime inclusion of Composer on the page. Users can edit pages in Composer using page-related controls available across the top of the page, **Add Content** buttons on components, and **Edit** icons on each editable page component, as shown in Figure 18–60.

Figure 18–60 Page Customizable Component



To enable runtime editing for multiple application pages in one operation, add a `Page Customizable` component to the ADF page template used for those pages. This avoids the need to manually add a `Page Customizable` to each page. For more information about adding the `Page Customizable` component, see Section 20.1.2, "How to Enable Runtime Customization Using a Page Customizable."

18.6.2 Change Mode Link and Change Mode Button

The `Change Mode Link` or `Change Mode Button` component provides an easy way to switch from View mode of the page to Edit mode. Figure 18–61 shows a `Change Mode Link` component on the page.

Figure 18–61 Change Mode Link Component

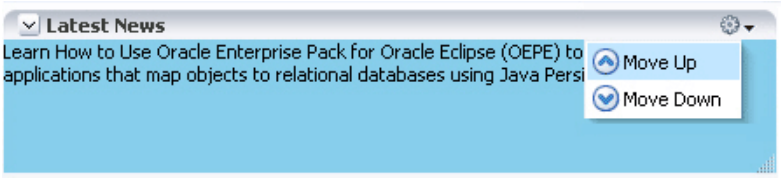
For more information about using `Change Mode Link` or `Change Mode Button`, see Section 20.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button."

18.6.3 Panel Customizable

A `Panel Customizable` defines an area of the page onto which users can add components at runtime. Users can move or minimize `Show Detail Frame` components and portlets that are added as child components of a `Panel Customizable`. Users can also drag and drop these components into another `Panel Customizable` component on the page.

In Edit mode, the `Panel Customizable` component is rendered as a box with dotted lines. In fact, a `Panel Customizable` is referred to as a `Box` in the runtime Resource Catalog. An **Add Content** button appears on each `Panel Customizable` component on the page, as shown in Figure 18–62. You can use this button to open the Resource Catalog Viewer and add components within the `Panel Customizable`.

Figure 18–62 Panel Customizable Component



For more information, see Section 20.1.4, "How to Define Editable Areas of a Page Using Panel Customizable Components."

18.6.4 Show Detail Frame

A `Show Detail Frame` component renders a border or chrome around its child component along with a header that contains icons to enable users to perform some operations. The actions available on this menu enable users to move the component, along with its content, to new positions on the page (Figure 18–63). Users can also drag and drop `Show Detail Frame` components from one `Panel Customizable` component to another on the page. Note that a `Show Detail Frame` must be included inside a `Panel Customizable` component for it to be movable.

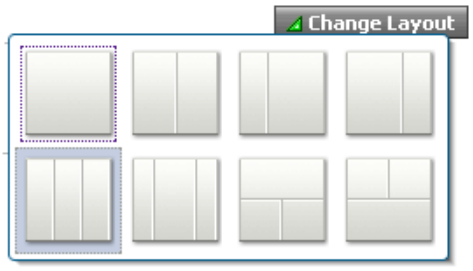
Figure 18–63 Show Detail Frame Component

A `Show Detail Frame` component enables the following actions:

- Collapse and expand the component
- Move content to different positions on the page
- If you add a task flow as a child component, then along with custom actions it enables task flow navigation using the Actions menu.
- If you add an ADF Faces `Rich Text Editor` as a child component, then it enables end users to edit and save text in the `Rich Text Editor`.

You can add your own UI controls to further customize the display of content by using facets of the `Show Detail Frame`. For information about using these facets, see Section 22.1, "Enabling Custom Actions on a Show Detail Frame Component by Using Facets."

For information about adding this component to a page, see Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components."



18.6.5 Layout Customizable

The `Layout Customizable` component is a container that enables end users to lay out its child components in several predefined ways (for example, two column, three column, and so on). You can design your page in such a way that all components on the page are enclosed in a `Layout Customizable` component. In such a case, the layout is applied to the entire page.

Access predefined layouts using the layout changer. By default, the layout changer displays as a small green icon both in page View mode and page Edit mode. By using

the `Layout Customizable` component attributes you can choose to display the layout changer as an icon, text, or icon and text. In addition, you can decide whether to show or hide the layout changer in View mode. Figure 18–64 shows a Layout Customizable component and the predefined layouts that display when users click the layout changer.

Figure 18–64 Layout Customizable Component

For more information, see Section 20.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable."

18.7 Security and Composer

In an application that is accessed by end users, application developers, and administrators, it may not be advisable to allow all users to perform all editing tasks. For example, you may want to allow end users to only customize their view of the page by performing tasks like rearranging components or hiding areas they do not want to see. On the other hand, application developers must be allowed to update content on the page, component properties, and so on. The ability to customize a page, component, or component attribute is inherited from security definitions at the tag, page, component, and attribute levels. However, you can override the default security definitions at various levels in keeping with your business requirement.

You can define application security on many levels, including on a page, an operation, a component, or a component attribute. There are several ways in which one can restrict application customizations on a component. Composer determines if a component can be customized by honouring these rules. For example, before users can customize components, the components' sources of security restrictions are queried to determine if application customization is allowed. If a component does not permit application customization, Composer considers it restricted; that is, Composer treats the component as if it were explicitly secured. Table 18–1 describes Composer behavior to reflect application customization restrictions.

Table 18–1 Customization Restrictions on Composer Components

Restriction	Behavior
The page (and its contents) is open for all customizations	Composer allows editing of components without restrictions.
The page is restricted	Composer displays but none of the options, for example **Page Properties** button and **Edit** icon, are accessible.
Some operations are restricted	Composer displays but the options corresponding to the restricted operations are disabled.
A component is restricted	The **Edit** icon is not rendered on the component and its properties cannot be edited.

Table 18–1 (Cont.) Customization Restrictions on Composer Components

Restriction	Behavior
A component's attributes are restricted	The restricted attributes are not displayed in Composer. Composer's API enables the developer to determine if a component's attributes are restricted or not.

Depending on the privileges granted while implementing security, users can perform different user and application customization tasks when they log in to the application.

> **Note:** In a secured application, it is recommended that you check all users' privileges and enable the Edit link or button on the page only for privileged users. Unauthenticated users who stumble into page Edit mode can change component properties.
>
> You can enable the Edit link or button for selected users by specifying an EL value for the `rendered` attribute on the `Change Mode Link` or `Change Mode Button` component. For more information, see Section B.1.2, "Change Mode Link and Change Mode Button."

This section describes the default security behavior of Composer components. It contains the following subsections:

- Section 18.7.1, "Page and Task Flow Security"
- Section 18.7.2, "MDS Customization Restrictions"
- Section 18.7.3, "Component Action-Level Security"

For information about overriding default security behavior, see Chapter 24, "Modifying Default Security Behavior of Composer Components."

18.7.1 Page and Task Flow Security

The application's `jazn-data.xml` file is the repository for page-level and task flow-level security information. Composer references this file and enables editing capabilities based on a user's privileges:

- A user with the Personalize privilege on a page or task flow can perform only the user customizations described in Section 18.3, "Customizing Capabilities in Page View Mode."
- A user with the Edit or Customize privilege can perform all runtime editing tasks such as adding content, editing component properties, and deleting components. Composer and WebCenter Portal Customizable Components do not differentiate between Edit and Customize privileges.

> **Notes:** Composer and WebCenter Portal Customizable Components support cascading of privileges with Grant being a super set of all privileges. A user with Grant privilege on a page or task flow is considered to have Edit, Personalize, and View privileges. A user with Personalize privilege is considered to additionally have the View privilege.

Table 18–2 explains Composer behavior based on page- and task flow-level privileges. Only those privileges that are relevant to Composer and WebCenter Portal

Customizable Components are listed in this table. The Grant privilege is not listed as it is a super set of all privileges. Users with the Grant privilege can perform all editing tasks.

Table 18–2 Mapping of Page or Task Flow Privileges to Composer Behavior

Privilege	Composer Behavior
Edit or Customize	Users can switch to Edit mode of the page, where Composer is invoked, and edit the page. Users with either the Edit or Customize privilege can perform all runtime editing tasks. With the Edit or Customize privilege on a page or task flow, users can: ■ Add content ■ Edit component properties ■ Rearrange content ■ Delete components in Composer ■ Personalize or customize a portlet ■ Move a portlet or task flow in View mode. This is persisted as a user customization. ■ Expand and collapse a task flow or portlet in View mode. This is persisted as a user customization. ■ Resize a column of a table in a task flow. This is persisted as a user customization. ■ Reset the page to its original state ■ Delete components in View mode Note: You can perform all or some of these tasks depending on whether you have page-level or task flow-level privileges. If users do not have the Edit or Customize privilege on a page but try to edit it, a message appears stating that they do not have permission to do so. If users do not have the Edit or Customize privilege on a task flow, the Edit option is not displayed for the task flow in Source view.
Personalize	In View mode, users with a Personalize privilege on the page can: ■ Rearrange content ■ Personalize a portlet ■ Move a portlet or task flow in View mode. This is persisted as a user customization. ■ Expand and collapse a task flow or portlet in View mode. This is persisted as a user customization. ■ Resize a column of a table in a task flow. This is persisted as a user customization. ■ Delete components in View mode **Note**: Having Personalize permission does not enable users to perform portlet customizations. If users without Personalize, Edit, or Customize permission try to edit a page, a message appears stating that they do not have permission to do so.
View	Users with the View privilege can only view the page or task flow, but not perform user or application customizations.

18.7.1.1 Task Flow Security

When you add a task flow to a customizable page, Composer provides options for editing the task flow and components on the task flow's page. In a secured application, Composer provides editing capabilities based on the privileges provisioned on the customizable page and the task flow. For more information about task flow privileges and Composer's behavior, see Table 18–2.

On an application page, components can be located directly on the JSPX page or on page fragments inside shared components such as task flows. Restrictions on components inside a task flow are derived from the page fragment. To understand task flow security better, consider an example of a page containing a task flow, which in turn contains another task flow, as shown in Figure 18–65.

Figure 18–65 Structure of a Page Containing Nested Task Flows

Components on this page inherit security as follows:

- `Component1`, `Component2`, and `Region3` inherit security definitions from `Document.jspx`.
- `ComponentA`, `ComponentB`, and `RegionC` inherit security definitions from `region3.jsff`.
- `ComponentX` and `ComponentY` inherit security definitions from `regionC.jsff`.

Task flows do not support cascading of permissions. That is, page permissions are not inherited by components inside a task flow. However, users who do not have Edit or Customize permission on the page cannot customize task flows on the page.

For example, if you grant Edit or Customize permission on `Document.jspx` and `regionC.jsff` but not on `region3.jsff`, then users can customize `Component1`, `Component2`, `RegionC`, `ComponentX`, and `ComponentY`, but not `ComponentA`, `ComponentB`, and `RegionC`.

In a secured application, task flow permissions are stored in the application's `jazn-data.xml` file. The list of available actions for a task flow is defined by the task flow permission class, `oracle.adf.controller.security.TaskFlowPermission`. The permission

class defines task flow-specific actions that it maps to the task flow's operations. By default, only View permission is provisioned on task flows. To enable users to edit a task flow at runtime, you must ensure that Customize permission is granted on the task flow. For more information, see Section 20.3.1.1, "Considerations for Adding Task Flows" **and Section 24.6, "Implementing Task Flow Security."**

For more information about task flows and their security behavior, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

18.7.2 MDS Customization Restrictions

Framework applications have a default MDS configuration that restricts application customization on all application objects. To enable runtime page editing, you must make this default restriction inactive by adding a `Page Customizable` component to the page. A `Page Customizable` component enables application customization on all components under it. However, it does not enable customization on components of a nested page or fragment. For example, if the `Page Customizable` is used in a page template and has a `Facet Ref` inside it, then customization is not enabled by default on the components inside the `Facet Ref`.

You can enable application customization on a set of attributes for the component using MDS type-level restrictions or instance-level restrictions. Type-level restrictions are applicable to a specified component type across instances. At runtime, attributes for which you have enabled customization are shown as editable properties in Composer, and restricted attributes are not displayed in the Component Properties dialog for the selected component. For information, see Section 24.1, "Applying Component-Level Restrictions by Defining Customization Policies."

18.7.3 Component Action-Level Security

`Panel Customizable` and `Show Detail Frame` components enable the placement of restrictions on individual supported actions. For example, one can specify a restriction on whether the current user is allowed to minimize the `Show Detail Frame`.

It is left to you to enforce restrictions on the actions on a component. You can specify restriction on component actions in `adf-config.xml`. If a restriction is specified and applicable to the current user, the `Panel Customizable` or `Show Detail Frame` does not render the action.

For information about applying action-level restrictions, see Section 24.5, "Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions."

19

Enabling Runtime Creation and Management of Pages

This chapter describes how to use the Page service to create and manage pages at runtime. It includes the following sections:

- Section 19.1, "Introduction to Page Creation and Management"
- Section 19.2, "Creating Pages and Task Flows"
- Section 19.3, "Defining Values for the Page - Create New Task Flow Parameters"
- Section 19.4, "How to Create Task Flow View Pages"
- Section 19.5, "Managing Pages"
- Section 19.6, "Introduction to Custom Styles and Templates"
- Section 19.7, "Customizing Page Service Views"
- Section 19.8, "Advanced Information for the Page Service"
- Section 19.9, "Page Service Samples"

19.1 Introduction to Page Creation and Management

The Page service enables you to create new pages and task flows in your application at runtime. You can base your pages on default or custom styles and templates. You can create them with either the Page - Create New task flow or the Page service APIs.

After you create pages or task flows, users can view and manage them with either the Page service data control or the Page service APIs. The APIs provide a means of defining a work area within the application, called a scope. Scopes are useful for categorizing custom pages that are of interest to a specific team or community (similar to a Group Space in Oracle WebCenter Portal: Spaces).

Table 19–1 describes the developer tools included with the Page service.

Table 19–1 Page Service Developer Tools

Tool	Description
Page - Create New task flow	A task flow for creating pages or task flows at runtime.

Table 19–1 (Cont.) Page Service Developer Tools

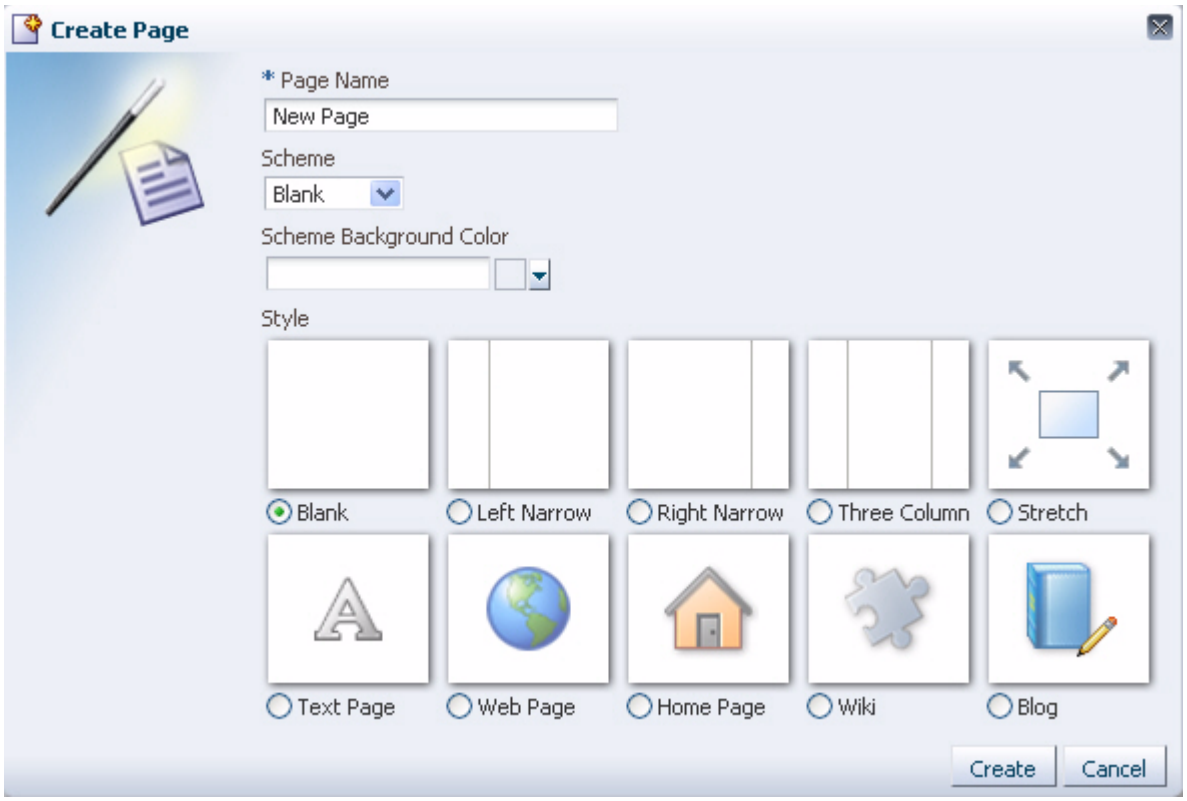
Tool	Description
PageServiceDC data control	A data control for viewing or deleting information about listed pages and task flows at runtime. **PageServiceDC** is available in design time after you add the Page service libraries to your application. By default, the Page service libraries are added to the application when you use the WebCenter Portal application template or when you add the Page - Create New task flow.
Page service APIs	APIs for creating and managing pages and task flows at runtime.

The Page service is integrated with many Oracle WebCenter Portal: Services, such as the Links, Search, and Tags services. You can track the most recent changes in pages with the Recent Activities service. Because it is preconfigured to work with the Recent Activities service, the Page service automatically produces the information that the Recent Activities service uses to display the most recent additions, changes, or deletions in pages.

For more information about the services at runtime, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

19.2 Creating Pages and Task Flows

You can create pages and task flows at runtime with either the Page - Create New task flow or the Page service APIs.



> **Note:** The Page - Create New task flow provides a means of creating pages and task flows and editing task flow parameters. To execute operations, such as copy, rename, create scope, and so on, you must use the Page service APIs along with the Page - Create New task flow. The Page service APIs provide the flexibility of customization within the Page service.

The Page - Create New task flow enables you to invoke the Create Page dialog at runtime. The Create Page dialog in turn enables users to create pages based on predefined styles, schemes, and templates.

Page styles, schemes, and templates provide both a default page structure that describes the areas where you can place content (that is, the page layout) and a background color and image that contribute to a page look and feel. You can select the page style, scheme, scheme background color, and template when you create a page. You can additionally enhance the usefulness and presentability of a page using page layout components. These include an in-place HTML text editor, images, layout boxes, hyperlinks, and so on.

Figure 19–1 shows the Create Page dialog at runtime.

Figure 19–1 Create Page Dialog with Default Styles

Some page styles include properties that suggest a particular use for the page. For example, the Web Page style includes a configurable property for specifying a URL. Among its many uses, the Web Page style provides a means of embedding wiki or blog pages and exposing external Web content within your application.

In many cases, you can switch the page scheme, scheme background color, and layout when you revise a page. You can also start with a blank page and create layout, look, and feel from the start.

At runtime, you can view a list of pages created through the Page - Create New task flow and create, copy, update or delete those pages.

For more information, see the section "Working with Page Layouts, Styles, and Schemes" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

19.2.1 How to Create Pages

This section describes how to add the Page - Create New task flow to your application to enable the creation of pages at runtime. It contains the following subsections:

- Section 19.2.1.1, "How to Add the Page - Create New Task Flow"
- Section 19.2.1.2, "Setting Security for the Page Service"
- Section 19.2.1.3, "How to Create Pages at Runtime"
- Section 19.2.1.4, "Structure of Pages Created at Runtime"
- Section 19.2.1.5, "How to Access Pages Created at Runtime"

19.2.1.1 How to Add the Page - Create New Task Flow

To add the Page - Create New task flow to your WebCenter application:

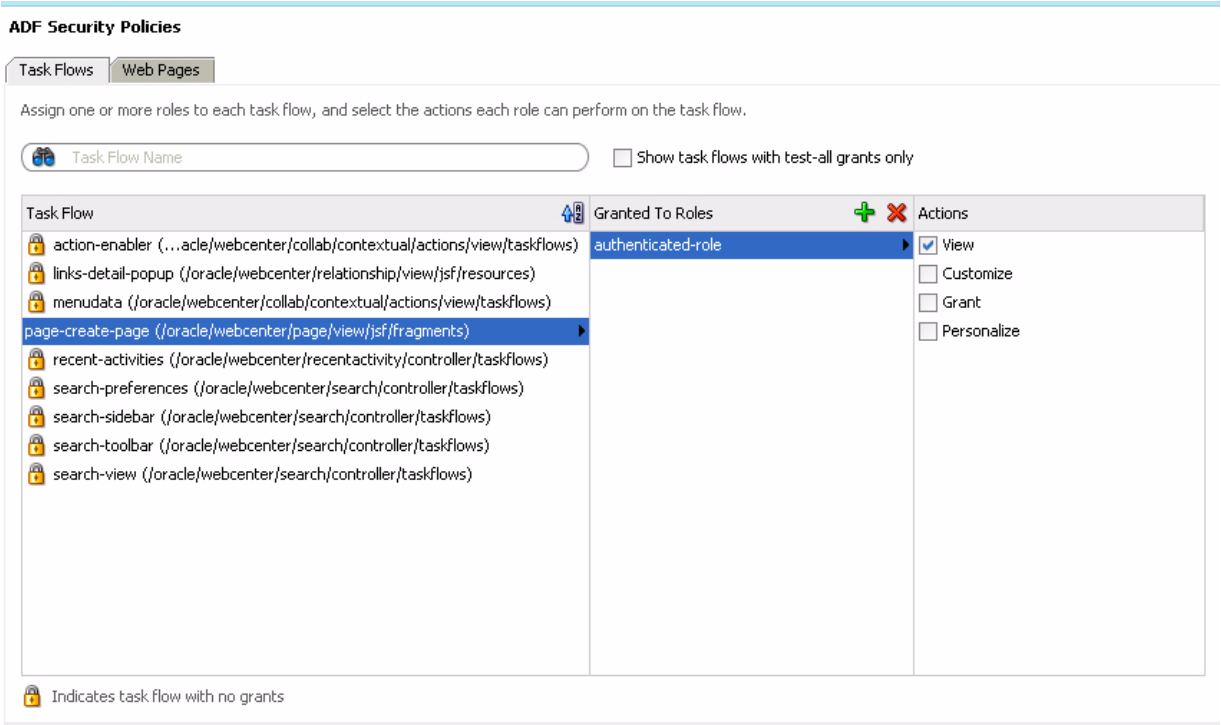
1. Follow the steps described in Section 5.3, "Adding Pages to a Portal."
2. Open the customizable page on which you want to add the service.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
4. Drag and drop the **Page - Create New** task flow onto your page.
5. When prompted, select **Region** as the way to create the task flow.
6. Click **OK**.
7. Save your page.
8. Run your application to see that Create Page is now on the page.
9. Click **Create Page**.

   The Create Page dialog opens (see Figure 19–1).
10. Enter a page name, then select the scheme, the scheme background color, and the template.
11. Click **Create**.

    A page is created based on the selected information. For more details on where the page is created, see Section 19.2.1.4, "Structure of Pages Created at Runtime."

Note: After you add the task flow, you can edit task flow parameters. For information about Page - Create New task flow parameters, see Section 19.3, "Defining Values for the Page - Create New Task Flow Parameters."

For detailed information about pages, such as how to delete pages created at runtime, see Section 19.5, "Managing Pages."



19.2.1.2 Setting Security for the Page Service

The Page service does not require its own, specific configuration of ADF security. It follows the security set up for the Framework application. In a non-secured application, all pages created in the Create Page dialog appear in the data control, viewable by everyone. In a secured application, users see only the pages they create or the pages to which they are granted privileges.

To secure your application and the Page - Create New task flow:

1. Follow the steps in Section 7.2.1.1, "Implementing Security for Services."
2. After you add the **Page - Create New** task flow to an application page, double-click the `jazn-data.xml` file in Application Resources to open the ADF Security Policies Editor.
3. If necessary, click the **Task Flow** tab to bring it forward.
4. In the **Task Flow** column, select **page-create-new** task flow (Figure 19–2).

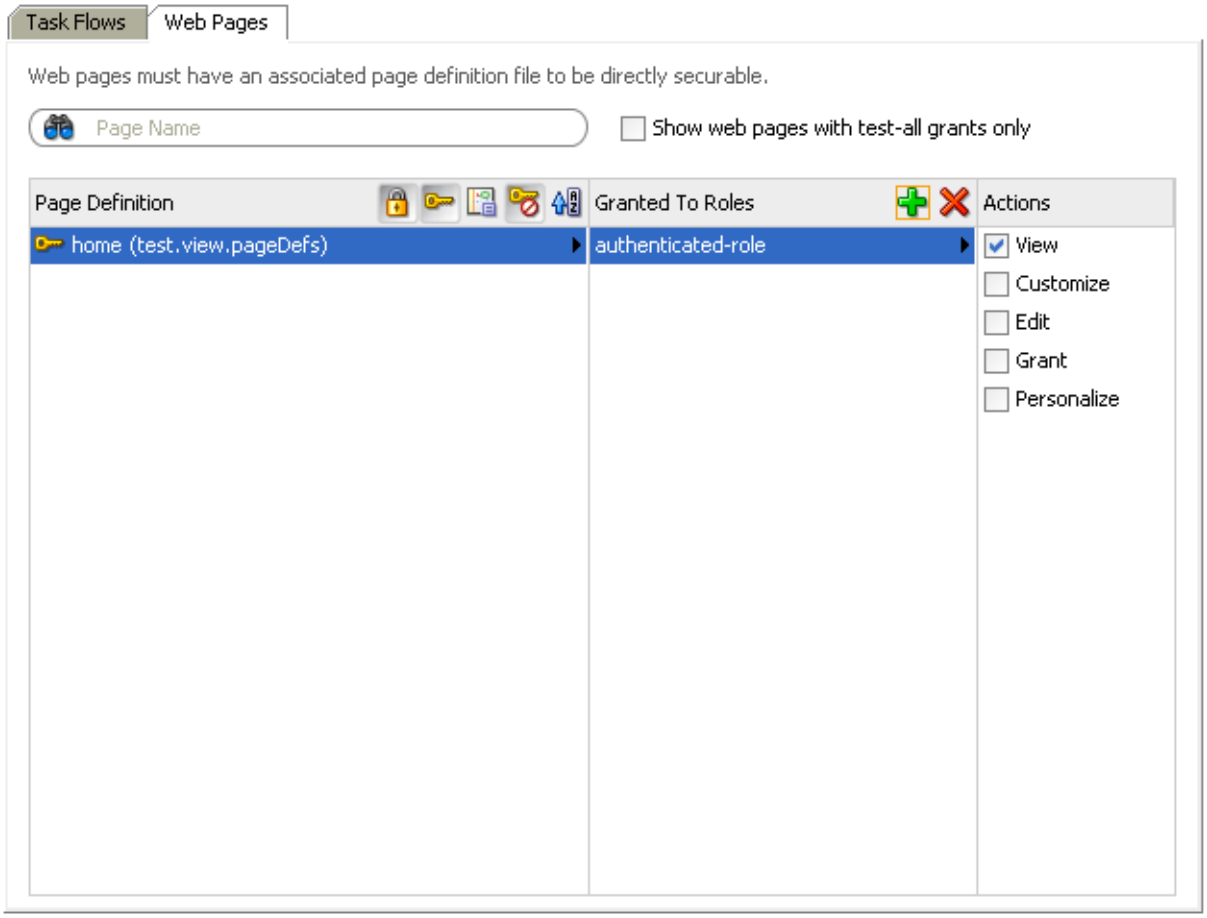


Figure 19–2 Adding Privileges to the Page - Create New Task Flow

5. Under **Granted to Roles**, click the **Add** icon to add a user role on which to grant task flow access privileges.
6. After you have added user roles, select a role in the ADF Security Policies dialog and then, under Actions, select the privileges to apply to the selected role.
7. Click the **Web Pages** tab to apply security to the page on which you added the Page - Create New task flow (Figure 19–3).

   Follow the same procedure outlined in steps 3 through 6: select a page, add roles, apply privileges.

Figure 19–3 Adding Privileges to Page with the Page - Create New Task Flow

Note: The **PageServiceDC** data control does not require any security setting for a secure or non-secure application.

19.2.1.3 How to Create Pages at Runtime

For detailed information, see the chapter "Introducing the Page Service and Oracle Composer" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

19.2.1.4 Structure of Pages Created at Runtime

The pages you create at runtime using the Page - Create New task flow or the Page service APIs are stored in the `mds` folder, located under your application root. Table 19–2 provides examples of the default formats used for page and task flow file names.

Table 19–2 Default File Name Formats

File Type	Format
Page	`Page<N>.jspx` (value of N starts from 1) For example: `Page1.jspx`, `Page2.jspx`, `Page<N>.jspx`
Page Definition	`Page1PageDef.xml`, `Page2PageDef.xml`, `Page<N>PageDef.xml`

Table 19–2 (Cont.) Default File Name Formats

File Type	Format
Task Flow View pages	`Page1.jsff`, `Page2.jsff`, `PageN.jsff`
Task Flow View Page Definitions	`Page1PageDef.xml`, `Page2PageDef.xml`, `Page<N>PageDef.xml`
Task Flow Definitions	`Page1.xml`, `Page2.xml`, `Page<N>.xml`

When you use the Page service APIs to create pages, you can provide a custom value for the file name format. For example: myPage<N>.jspx (value of N starts from 1)

The following examples show the structure of a page (`Page1.jspx`) and its associated page definition (`Page1PageDef.xml`) created at runtime by the user `user1`.

Example 19–1 Page Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.jspx
```

Example 19–2 Page Definition Created Under a Default Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1PageDef.xml
```

Example 19–3 Page Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.jspx
```

Example 19–4 Page Definition Created Under a Custom Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1PageDef.xml
```

In Example 19–4, the `scopeGUID` is a unique ID assigned to a specific scope by the Page service.

Example 19–5 Task Flow View Page Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.jspx
```

Example 19–6 Task Flow Definition Created Under a Default Scope

```
mds\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1.xml
```

Example 19–7 Task Flow View Page Definition Created Under a Default Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\s8bba98ff_4cbb_40b8_beee_
296c916a23ed\user\user1\Page1PageDef.xml
```

Example 19–8 Task Flow View Page Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.jspx
```

Example 19–9 Task Flow Definition Created Under a Custom Scope

```
mds\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1.xml
```

Example 19–10 Task Flow Page Definition Created Under a Custom Scope

```
mds\pageDefs\oracle\webcenter\page\scopedMD\<scopeGUID>\Page1PageDef.xml
```

In Example 19–10, the `scopeGUID` is a unique ID assigned to a specific scope by the Page service.

19.2.1.5 How to Access Pages Created at Runtime

To access pages with a default scope, enter the following URL:

```
http://<server>:<port>/<app name>/faces/oracle/webcenter/page/scopedMD/s8bba98ff_
4cbb_40b8_beee_296c916a23ed/user/<user guid>/Page1.jspx
```

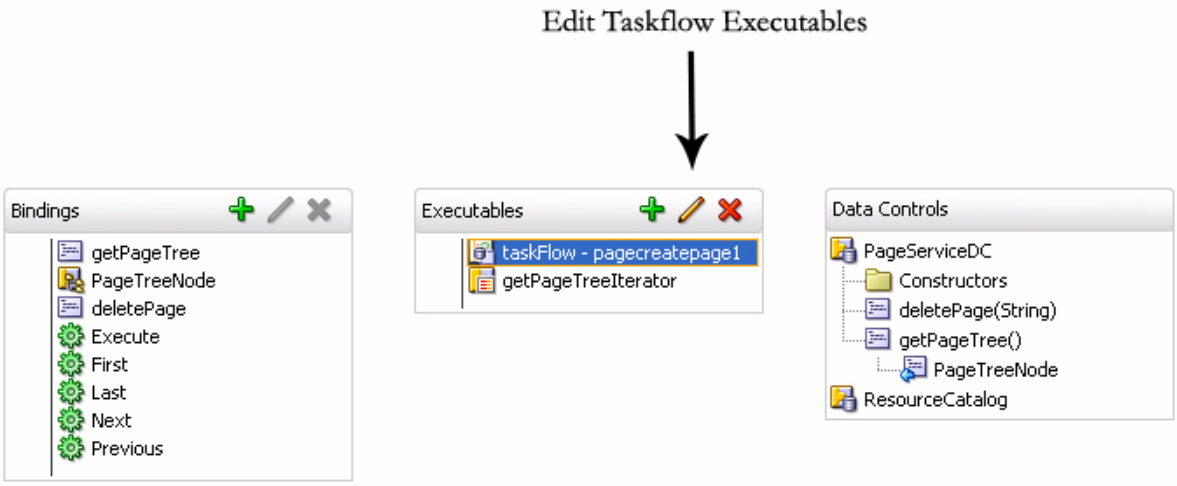
To access pages with a custom scope, enter the following URL:

```
http://<server>:<port>/<app name>/faces/oracle/webcenter/page/scopedMD/<scope
guid>/Page1.jspx
```

19.3 Defining Values for the Page - Create New Task Flow Parameters

This section describes how to access and define values for Page - Create New task flow parameters. It contains the following subsections:

- Section 19.3.1, "How to Access Page - Create New Task Flow Parameters"
- Section 19.3.2, "Setting Scope in a Page - Create New Task Flow"
- Section 19.3.3, "Setting an Outcome Parameter"
- Section 19.3.4, "Specifying Styles"
- Section 19.3.5, "Specify an ADF Template"
- Section 19.3.6, "Showing a Command Link"
- Section 19.3.7, "Displaying an Image"
- Section 19.3.8, "Customizing the Label"



19.3.1 How to Access Page - Create New Task Flow Parameters

To access Page - Create New task flow parameters:

1. Go to the Application Navigator and right-click the `.jspx` page with the Page - Create New task flow.
2. Select **Go to Page Definition**, and scroll to select the **Create Page** task flow.
3. Click the **Edit** (pencil) icon to edit any of the parameters.

   The Page Data Binding Definition in the design view is shown in Figure 19–4.

Figure 19–4 Page Data Binding Definition

The **Edit Task Flow Binding** dialog opens, as shown in Figure 19–5.

Figure 19–5 Edit Task Flow Binding for the Page - Create New Task Flow

The following optional Page - Create New parameters are available:

- `scopename`

  For information, see Section 19.3.2, "Setting Scope in a Page - Create New Task Flow."

- `outcome`

  For information, see Section 19.3.3, "Setting an Outcome Parameter."

- `templatefile`

  For information, see Section 19.3.4, "Specifying Styles."

- `adftemplate`

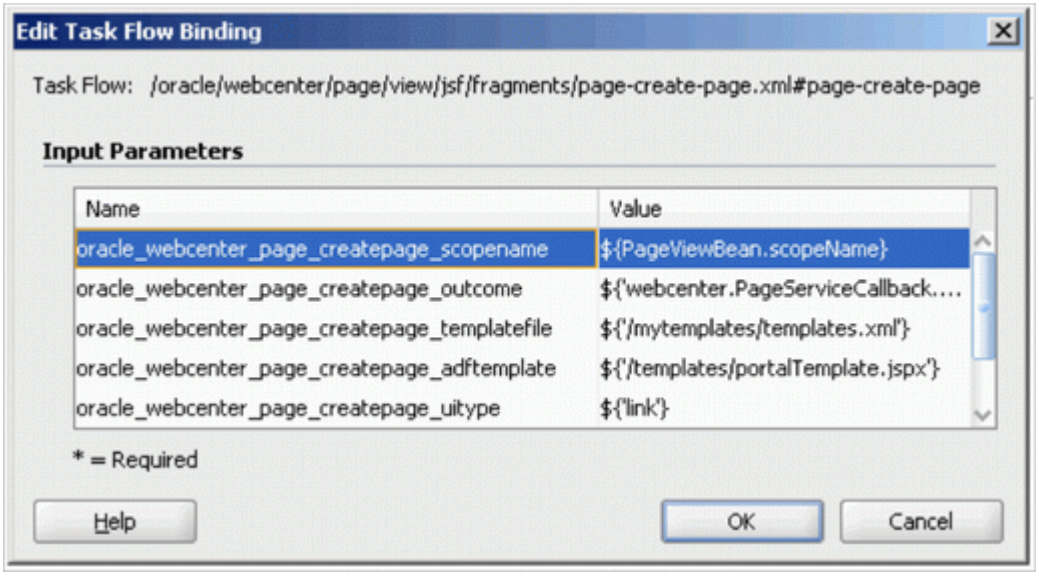
For information, see Section 19.3.5, "Specify an ADF Template."

- `uitype`

  For information, see Section 19.3.6, "Showing a Command Link."

- `icon`

  For information, see Section 19.3.7, "Displaying an Image."



- `label`

  For information, see Section 19.3.8, "Customizing the Label."

19.3.2 Setting Scope in a Page - Create New Task Flow

By default, the pages and task flows you create using the Page - Create New task flow are stored in the default scope. To assign a specific scope to the Page - Create New task flow, the scope name must be assigned to the `oracle_webcenter_page_createpage_scopename` parameter, as shown in Figure 19–6.

Figure 19–6 oracle_webcenter_page_createpage_scopename Parameter

In Figure 19–6, `PageViewBean` is a custom managed bean that is invoking the `getScopeName()` method to fetch the value of `scopeName`. It uses the Page service API. By doing this, the Page - Create New task flow creates all pages and task flows under the specified scope, rather than default scope.

The following example code highlights only the creation of scope. If a scope already exists, then users can get the scope name from the `Scope` object.

Example 19–11 Creating a Scope for Application Pages

```
import oracle.webcenter.framework.service.Scope;
import oracle.webcenter.framework.service.ScopeAlreadyExistsException;
import oracle.webcenter.framework.service.ServiceContext;

public class PageViewBean {
    private String scopeName;

    public String getScopeName() {
```

```
        String scopeName = "MyScope";
        ServiceContext sContext = ServiceContext.getContext();
        try {
            Scope scope =
                sContext.createScope(scopeName); // Creates a new scope
            this.scopeName = scope.getName(); // Returns the scope name
            sContext.setScope(scope); // Setting the Scope. This step is
important.
        } catch (ScopeAlreadyExistsException scopeExistsException) {
            System.out.println("Scope Already Exists...");
        }
        return this.scopeName;
    }

    public void setScopeName(String scopeName) {
        this.scopeName = scopeName;
    }

}
```

19.3.3 Setting an Outcome Parameter

The outcome parameter defines a Java method that is called after the page is created. In this method, you can add dynamic content to the page, refresh the user interface that calls up the dialog to confirm creation of a new page, or initiate browser navigation to the newly created page. To specify a Java method to invoke after page creation (that is, it is called after users click the **Create** button in the Create Page dialog), enter the following in the Edit Task Flow Binding dialog:

```
oracle_webcenter_page_createpage_outcome = ${'view.MyTestClass.go'}
```

You can define the method either with a String parameter or with no parameter. The String parameter value is the new page's name with full path. If the method is defined both ways, then the one with a parameter is invoked.

In the following example, the method `go(String newPagePath)` is invoked. This method redirects users to the newly created page with the Java class `MyTestClass.java`. The value of `newPagepath` is passed by the Page service.

```
package view;

import javax.faces.context.ExternalContext;
import javax.faces.context.FacesContext;
import javax.faces.event.ActionEvent;

public class MyTestClass {
    public MyTestClass() {
    }

    /*
       This method is executed only when there is no other go(String newPagePath)
method with a String argument .
    */
    public void go() {
        System.out.println("go() method without parameters executed.");
    }

    /*
       This method is prioritized and executed even when there are other go()
```

```
methods without arguments.
    */
    public void go(String newPagePath) {
        System.out.println("go(String newPagePath) method with parameter
executed.");
        try {
            FacesContext context = FacesContext.getCurrentInstance();
            String viewID = context.getViewRoot().getViewId();
            System.out.println("ViewID=" + viewID);

            ExternalContext extCtx = context.getExternalContext();
            String targetURI =
                extCtx.getRequestContextPath() + "/faces" + viewID;
            System.out.println("Navigate to: " + targetURI);
            extCtx.redirect(targetURI);
            context.responseComplete();
        } catch (Exception ee) {
            System.out.println("Error: " + ee.toString());
        }

    }
}
```

19.3.4 Specifying Styles

The Page service provides out-of-the-box styles that are packaged within the Page service libraries. You can use these styles or create your own custom styles.

This section describes how to apply out-of-the-box styles and custom styles. It contains the following subsections:

- Section 19.3.4.1, "Out-of-the-Box Styles"
- Section 19.3.4.2, "Custom Styles"

> **Note:** For more information about styles, see Section 19.6, "Introduction to Custom Styles and Templates."

19.3.4.1 Out-of-the-Box Styles

The following out-of-the-box-styles are provided (see Figure 19–1):

- Blank
- Left Narrow
- Right Narrow
- Three Column
- Stretch
- Text Page
- Web Page

To associate out-of-the-box styles with the Page - Create New task flow, use the optional parameter `oracle_webcenter_page_createpage_templatefile`. Use the parameter value to specify the location of the file that contains the list of out-of-the-box styles.

To associate out-of-the-box styles with the Page - Create New task flow:

1. Create a folder named `mystyles` under your Framework application's `public_html` folder.
2. Within `mystyles`, create a file named `default_pageservice_styles.xml`.
3. Add entries for all the out-of-the-box styles using the `templateDef` element.

   The `templateDef` element takes the following attributes:

   - `name`: This attribute specifies the path to the `.jspx` page that defines a page style. When you use the default styles, you must specify the path to the page that defines the style you intend to use. The default page style page files are located within the Page service libraries. For example:

     ```
     name="/oracle/webcenter/page/pstemplates/TemplateThreeColumn.jspx"
     ```

     `TemplateThreeColumn.jspx` is the page within the Page service library that defines the Three Column Template style.

   - `title`: The value you enter for `title` is used as the able for the style in the Create Page dialog. You can modify the title of an out-of-the-box style to any name. For example: `title="Three Column Layout"` or `title="Sales Standard"`.

   - `icon`: This attribute specifies an image icon for a style.

     For out-of-the-box styles, if you do not specify an icon for a style, then the Page service automatically uses the default icons assigned to each out-of-the-box style.

   Example 19–12 shows the content of a sample `default_pageservice_styles.xml` file that lists the other out-of-the-box styles:

Example 19–12 Sample default_pageservice_styles.xml File

```
<?xml version="1.0" encoding="UTF-8" ?>
 <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateThreeColumn.jspx"
title="Three Column Layout" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateText.jspx"
title="Text Page" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateStretch.jspx"
title="Stretch" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateWeb.jspx"
title="Web Page" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateBlank.jspx"
title="Blank" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateNarrowLeft.jspx"
title="Left Narrow Column Layout" />
  <templateDef name="/oracle/webcenter/page/pstemplates/TemplateNarrowRight.jspx"
title="Right Narrow Column Layout" />
 </templatesDef>
```

4. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
5. Set the `oracle_webcenter_page_createpage_templatefile` parameter value to `${'/mystyles/default_pageservice_style.xml'}`.

   For example:

   ```
   oracle_webcenter_page_createpage_templatefile = ${'/mystyles/default_
   pageservice_style.xml'}
   ```

6. Click **OK**.

19.3.4.2 Custom Styles

In this example, you associate a custom style, labeled **News**, with the Page - Create New task flow.

To associate a custom style with the Page - Create New task flow:

1. Define your custom style in a `.jspx` file (for example, `NewsTemplate.jspx`).

   Note: For information about how to create ADF templates, see Section 19.6, "Introduction to Custom Styles and Templates."

2. Add an entry for the custom style in an XML file (for example, `custom_pageservice_style.xml`).

   For example:

```
<?xml version="1.0" encoding="UTF-8" ?>
  <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
    <templateDef name="NewsTemplate.jspx" title="News" icon="/images/news.png"
/>
  </templatesDef>
```

   Note: For more information about the syntax to use for `templateDef` element and the style-related `.xml` file, see Section 19.3.4.1, "Out-of-the-Box Styles."

3. Save the `custom_pageservice_style.xml` under a folder in your application's `public_html` folder.

   For example:

```
…/public_html/mystyles/custom_pageservice_style.xml
```

4. The following files must be placed in the same folder as `custom_pageservice_style.xml`:

   - The file that defines the custom style, for example, `NewsTemplate.jspx`.
   - The page definition file of the custom style file, for example, `NewTemplatePageDef.xml`.
   - The ADF Template (for example, `defaultTemplate.jspx`) on which the custom style file is based. This step is applicable only if you are using ADF templates.

     Note: If you specify the location of an ADF template using the `oracle_webcenter_page_createpage_adftemplate` as described in following section, then you *do not* need to put this file (`defaultTemplate.jspx`) under the `mystyles` folder. You can specify a different location for the file by following Section 19.3.5, "Specify an ADF Template."

5. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."

6. Set the `oracle_webcenter_page_createpage_templatefile` parameter to `${'/mystyles/custom_pageservice_style.xml'}`, where `mystyles` is a folder under the `public_html` folder of your application.

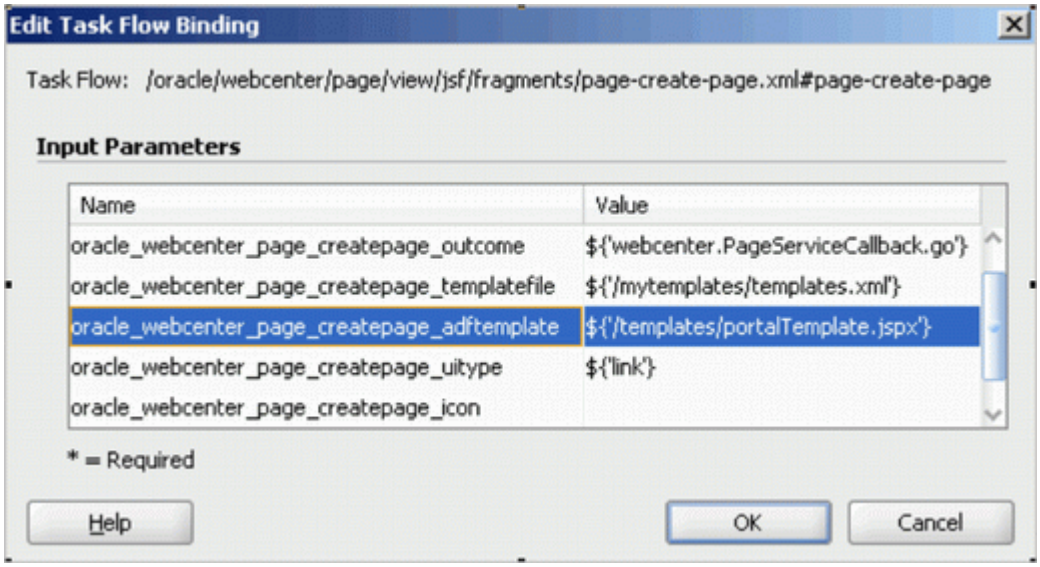
   For example:

   ```
   oracle_webcenter_page_createpage_templatefile = ${'/mystyles/custom_
   pageservice_style.xml'}
   ```

19.3.5 Specify an ADF Template

When you want to use the same template for both design time and runtime pages, you can use an ADF template. All that is required is to point the Page - Create New task flow to the template location.

To associate an ADF template with the Page - Create New task flow:



1. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
2. In the Value column next to the `oracle_webcenter_page_creatpage_adftemplate` parameter, enter the path to the ADF template.

   For example:

   ```
   ${'templates/portalTemplate.jspx'}
   ```

   In Figure 19–7, an ADF template called `portalTemplate.jspx` is used.

Figure 19–7 oracle_webcenter_page_createpage_adftemplate Parameter

ADF templates can be in your application's `public_html` folder. In this case, the path of `portalTemplate.jspx` is `../public_html/templates/portalTemplate.jspx`.

3. Click **OK**.

19.3.6 Showing a Command Link

By default, the Page - Create New task flow is rendered as a command *button*. You can instead specify that it is rendered as a command *link* (Figure 19–8).

Figure 19–8 Command Link

To render the Page - Create New task flow as a command link:

1. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
2. Revise the `oracle_webcenter_page_createpage_uitype` parameter to the following value: `${'link'}`.

   For example:

   ```
   oracle_webcenter_page_createpage_uitype = ${'link'}
   ```

3. Click **OK**.

19.3.7 Displaying an Image

You can associate an icon with the Page - Create New task flow button or link. For example, Figure 19–9 shows the task flow rendered as a command *link* with a page icon.

Figure 19–9 Command Link with a Page Icon

Figure 19–10 shows the task flow rendered as a command *button* with a page icon.

Figure 19–10 Command Button with a Page Icon

To specify an icon for the Page - Create New task flow button or link:

1. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
2. Revise the `oracle_webcenter_page_createpage_icon` parameter to the following value: `{'/images/page.jpg'}`.

   For example:

   ```
   oracle_webcenter_page_createpage_icon = ${'/images/page.jpg'}
   ```

3. Click **OK**.

19.3.8 Customizing the Label

By default, the label for the Page - Create New task flow command button or link is **Create Page**. You can provide your own value using the `oracle_webcenter_page_createpage_label` parameter value.

Figure 19–11 shows the task flow rendered as a command button with a custom label.

Figure 19–11 Custom Label

To change the command button or link label:

1. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
2. Revise the `oracle_webcenter_page_createpage_label` parameter to your preferred string value.

   For example:

   ```
   oracle_webcenter_page_createpage_label = ${'Create New Page'}
   ```

3. Click **OK**.

19.4 How to Create Task Flow View Pages

The following types of objects are required for the creation of a task flow view page:

- Task flow view page (JSFF file)
- Page definition of view page
- Task flow definition XML file, which defines the task flow

To enable the creation of task flow view pages through the Page - Create New task flow:

1. At design time, add a **Page - Create New** task flow to your page (`home.jspx`).
2. Open the Edit Task Flow Binding dialog as described in Section 19.3.1, "How to Access Page - Create New Task Flow Parameters."
3. Change the label on the Create Page button or link by revising the value specified for the `oracle_webcenter_page_createpage_label` parameter.

   For example:

   ```
   oracle_webcenter_page_createpage_label = ${'Create Task Flow'}
   ```

4. Click **OK**.
5. Create an XML file (for example, `custom_taskflow_styles.xml`) to contain entries for all the task flow styles.

   For example:

   ```
   <?xml version='1.0' encoding="UTF-8"?>
   <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
     <templateDef name="mytaskflow_view.jsff" title="News"
   icon="/images/news.png" type="taskflow"/>
   </templatesDef>
   ```

   The element `templateDef` in the XML file contains the following attributes:

   - `name`: to specify the name of the task flow view page
   - `title`: to specify the label to associate with the task flow view page style in the Create Page dialog.
   - `icon`: to specify the image icon for the task flow

Note: For sample attribute syntaxes, see step 3 in Section 19.3.4.1, "Out-of-the-Box Styles."

6. Under your application's `public_html` folder, create a folder (for example, `mystyles`) and add the `custom_taskflow_styles.xml` file to it.
7. Make sure that the following files are also under the `mystyles` folder:
   - `mytaskflow_view.jsff` (task flow view page)
   - `mytaskflow_viewPageDef.xml` (task flow view page definition)
   - `mytaskflow_view.xml` (task flow definition)
8. Open the Edit Task Flow Binding dialog again, and provide the path to the XML file you created in step 5 to the `oracle_webcenter_page_createpage_templatefile` parameter.

   For example:

   ```
   oracle_webcenter_page_createpage_templatefile=${'/mystyles/custom_taskflow_
   styles.xml' }
   ```

   In this example, `mystyles` is a folder under the `public_html` folder of your application.
9. Run the `home.jspx` page, and then click the **Create Task Flow** button.
10. Enter the title of the task flow, select the **News** style (see Section 19.3.4.2, "Custom Styles"), and then click **Create**.

    The new task flow view page is rendered.

For information on where the task flows are created, see section Section 19.2.1.4, "Structure of Pages Created at Runtime."

19.5 Managing Pages

You can manage pages using either the Page service data control or the Page service APIs. This section contains the following subsections:

- Section 19.5.1, "Using the Page Service Data Control to Manage Pages"
- Section 19.5.2, "Using the Page Service APIs to Manage Pages and Task Flows"

19.5.1 Using the Page Service Data Control to Manage Pages

You can customize Page service views with the Page service data control. The data control enables you to view information about existing pages at runtime and delete any of the listed pages. The Page service data control, `PageServiceDC`, is included in the Page service libraries and is available at design time after you add the libraries to the application.

For more information about the Page service data control, see Section 19.8.2, "Using the Page Service Data Control."

19.5.2 Using the Page Service APIs to Manage Pages and Task Flows

The Page service provides APIs to manage pages and task flows. These include APIs to delete pages and task flows, change the hidden status, change the page scheme (name, background color, background image), and copy pages.

For more information about Page service APIs, see Section 19.8.1, "Using the Page Service Java APIs."

19.6 Introduction to Custom Styles and Templates

At runtime, when users click the Create Page option, the Create Page dialog displays a set of predefined styles for creating the page (see Figure 19–1). Users select one of these page styles to create a page based on the associated style template. The *style* provides a special look and feel to your pages. The *template* provides the page layout. Templates are the ADF pages on which runtime pages are based. Pages can be based on default or custom styles and templates.

To provide custom selections for the Create Page dialog, you must define them, for example, in `/mytemplates/templates.xml`. Place the directory `/mytemplates` under the web content root.

If you choose *not* to use the default options available with the Create Page dialog, then you can use the following types of custom templates in your application:

- Page and page fragment templates for use with runtime pages
- ADF templates for use as the base for page and page fragment templates
- Templates to be used by the Create Page dialog itself

This section explains how to customize the Page - Create New task flow to use different templates for the Create Page dialog and for the new pages that you create at runtime. It contains the following subsections:

- Section 19.6.1, "How to Create Templates for Pages Created at Runtime"
- Section 19.6.2, "Using ADF Templates"
- Section 19.6.3, "Creating Styles for the Create Page Dialog"

Note: For more information about the `templates.xml` file, see Section 19.3.4, "Specifying Styles."

19.6.1 How to Create Templates for Pages Created at Runtime

You can create custom page templates according to your design requirements and associate page styles with these templates. If you want to restrict the style options in the Create Page dialog or provide a different set of styles, then you must perform the following high-level tasks:

- Create pages or page fragments to be used as templates for the different page styles.
- Edit the Create Page dialog parameter to specify new page styles.

This section steps you through both procedures. It contains the following subsections:

- Section 19.6.1.1, "How to Create a Page or Page Fragment Style"
- Section 19.6.1.2, "How to Edit Create Page Dialog Styles"

19.6.1.1 How to Create a Page or Page Fragment Style

To create a page or page fragment style:

1. In Oracle JDeveloper, create a JSF template with all necessary information, such as header, welcome message, login/logout links, and so on.

2. When creating pages, create a page (JSPX) based on that template.

   When creating task flows, create a page fragment (JSFF) based on that template.

   When creating a page based on a template, the Page service actually copies the template and creates a new page based on it.

3. Put all the necessary content in the JSPX or JSFF file.

   For example, if there is a facet where you would like to display content, you can drop a Page Customizable component from Composer around it to make the page editable at runtime. Make sure you set the correct values for the `document title`, `styleClass`, and `inlineStyle` attributes.

   Note: If this page or page fragment will be used as a template for pages that can be customized at runtime, then you must ensure that the `ID` attribute on all components on this page or fragment is set to a unique value.

   Example 19–13 shows the sample code of a page fragment style, `pstemplateview.jsff`.

Example 19–13 Sample Code of a New Page Style

```
<?xml version='1.0' encoding='utf-8'?>

          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
     <jsp:directive.page contentType="text/html;charset=utf-8"/>
     <f:loadBundle basename="oracle.webcenter.page.view.resource.PGUIBundle"
                   var="res"/>
     <f:view>
       <af:document title="#{pageDocBean.title}" id="docrt">
         <af:form usesUpload="true" id="f1">
           <af:pageTemplate
viewId="/oracle/webcenter/page/pstemplates/defaultTemplate.jspx" id="T">
             <f:facet name="content">
               <pe:pageCustomizable id="pcl1">
                 <af:panelStretchLayout id="psl2"
                                        styleClass="replace_with_scheme_name"
                                        inlineStyle="replace_with_inline_style">
                   <f:facet name="center">
                     <af:panelGroupLayout id="pgl1"
                                          layout="scroll">
                       <pe:layoutCustomizable id="lc1"
                                 showLayoutChanger="#{pageServiceBean.isEditMode}"
                                 text="Change Layout"
                                 showIcon="false"
                                 type="threeColumnNarrow"
                                 shortDesc="Layout Changer">
                         <cust:panelCustomizable id="mainC"/>
                         <f:facet name="contentA">
                           <cust:panelCustomizable id="cnta"/>
                         </f:facet>
                         <f:facet name="contentB">
```

```
                        <cust:panelCustomizable id="cntb"/>
                      </f:facet>
                    </pe:layoutCustomizable>
                  </af:panelGroupLayout>
                </f:facet>
              </af:panelStretchLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
```

Note: The page definition file of the JSPX page, which defines the style, must contain the following syntax for the `id` and `Package` attributes. The Page service replaces these values with the relevant values when creating a page based on a custom style:

```
<?xml version="1.0" encoding="UTF-8" ?>
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
                version="11.1.1.41.30"
                id="ps_pagedefusage"
                Package="ps_package">
```

Alternatively, the JSPX or JSFF template file that you are creating can be based on an ADF template.

Example 19–14 shows the sample code of an ADF template.

Note: If you choose to design your own ADF templates and want to set page style, then you must have a `Panel Group Layout` or `Panel Stretch Layout` component as a direct child of the `Page Customizable`. Additionally, you must set the placeholder for `styleClass` and `inlineStyle`, as shown in **bold** below. The page style values replace the placeholder text.

Example 19–14 Sample Code of a Page Style that uses an ADF Template

```
<?xml version='1.0' encoding='utf-8'?>
<!-- Copyright (c) 2006, 2008, Oracle and/or its affiliates.

px"
                value="#{bindings.shellTemplateBinding}" id="T">
```

```
          <f:facet name="content">
            <pe:pageCustomizable id="pcl1">
              <af:panelStretchLayout id="psl2"
                                     styleClass="replace_with_scheme_name"
                                     inlineStyle="replace_with_inline_style">
                <f:facet name="center">
                  <af:panelGroupLayout id="pgl1"
                                       layout="scroll">
                    <pe:layoutCustomizable id="lc1"

showLayoutChanger="#{pageServiceBean.isEditMode}"
                                           text="#{uib_o_w_w_r_WebCenter.LABEL_
CHANGE_LAYOUT}"
                                           showIcon="false" type="oneColumn"
                                           shortDesc="#{uib_o_w_w_r_
WebCenter.LABEL_CHANGE_LAYOUT}">
                      <cust:panelCustomizable id="mainC"/>
                      <f:facet name="contentA">
                        <cust:panelCustomizable id="cnta"/>
                      </f:facet>
                      <f:facet name="contentB">
                        <cust:panelCustomizable id="cntb"/>
                      </f:facet>
                    </pe:layoutCustomizable>
                  </af:panelGroupLayout>
                </f:facet>
              </af:panelStretchLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

Example 19–15 shows the sample code of a page style, `NewsTemplate.jspx`, that is based on an ADF template, `portalTemplate.jspx`. The `viewId` attribute of the `af:pageTemplate` tag provides the name of the ADF template used.

For information about using ADF templates, see the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

Example 19–15 Sample Code of a Page Style on an ADF Template

```
<?xml version='1.0' encoding='utf-8'?>
<!-- Copyright (c) 2006, 2008, Oracle and/or its affiliates.
All rights reserved. -->
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"

          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=utf-8"/>
  <f:loadBundle basename="oracle.webcenter.page.view.resource.PGUIBundle"
                var="res"/>
  <f:view>
    <af:document title="#{pageDocBean.title}">
```

```
      <af:form usesUpload="true">
          <af:pageTemplate viewId="/mytemplates/portalTemplate.jspx"
 value="#{bindings.pageTemplateBinding}">
      <f:facet name="pageContent">
            <pe:pageCustomizable id="pgc1">
              <af:panelStretchLayout id="psl1"
                                     styleClass="#{pageDocBean.CSSStyle}"
                                     inlineStyle="#{pageDocBean.inlineStyle}">
                <f:facet name="center">
                  <af:panelGroupLayout id="pgl1" layout="scroll">
                    <pe:layoutCustomizable id="lc1"
                        showLayoutChanger="#{pageServiceBean.isEditMode}"
                                          text="#{res['TEMPLATE.CHANGE_LAYOUT']}"
                                          showIcon="false" type="oneColumn"
                                          shortDesc="#{res['TEMPLATE.CHANGE_
LAYOUT']}">
                      <cust:panelCustomizable id="mainC">
                        <cust:showDetailFrame id="sdf2"
                                              showMinimizeAction="none"
                                              showMoveAction="none"
                                              showRemoveAction="none"
                                              displayHeader="false"
                                              displayShadow="false"
                                              stretchContent="false"
                                              shortDesc="#{null}"
                                              background="light"
                                              showResizer="never"
                                              text="Text">
                          <af:richTextEditor id="rtepc" clientComponent="true"
                                             simple="true" label="#{null}"
                                             rows="20" readOnly="false"
                                             contentStyle="width:100%;"/>
                        </cust:showDetailFrame>
                      </cust:panelCustomizable>
                      <f:facet name="contentA">
                        <cust:panelCustomizable id="cnta"/>
                      </f:facet>
                      <f:facet name="contentB">
                        <cust:panelCustomizable id="cntb"/>
                      </f:facet>
                    </pe:layoutCustomizable>
                  </af:panelGroupLayout>
                </f:facet>
              </af:panelStretchLayout>
              <f:facet name="editor">
                <pe:pageEditorPanel/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:pageTemplate>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

To display a different style, or use a different template for a style, you must define it, for example, in `/mytemplates/templates.xml`. Place the directory `/mytemplates` under the web content root. For more information about the `templates.xml` file, see Section 19.3.4, "Specifying Styles."

Example 19–16 shows a sample `templates.xml` file.

Example 19–16 templates.xml File

```
<?xml version='1.0' encoding="UTF-8"?>
<templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
  <templateDef name="TemplateBlank.jspx"
               title="Blank"/>
  <templateDef name="TemplateNarrowLeft.jspx"
               title="Left Narrow Column Layout"/>
  <templateDef name="TemplateNarrowRight.jspx"
               title="Right Narrow Column Layout"/>
  <templateDef name="TemplateThreeColumn.jspx"
               title="Three Column Layout"/>
  <templateDef name="TemplateStretch.jspx"
               title="Stretch"/>
  <templateDef name="TemplateText.jspx"
               title="Text"/>
  <templateDef name="TemplateWeb.jspx"
               title="Web"/>
  <templateDef name="NewsTemplate.jspx"
               title="News"/>
</templatesDef>
```

19.6.1.2 How to Edit Create Page Dialog Styles

To edit the styles for the Create Page dialog and add a reference to the new page style:

1. Create the `/mytemplates/templates.xml` file, commenting out `templateDef` entries for any default page styles that you do not want to display.
2. In the `templateDef` entry for the style that you want to associate with a different template, edit the `name` and `type` attributes, as shown in the following example:

   ```
   <templateDef name="pstemplateview.jsff"
                title="News"
                icon="/images/news.png"
                type="taskflow"/>
   ```

   where

   - `name` is the name of the page style that you want to use.
   - `title` is the label displayed for the style in the Create Page dialog.
   - `type` is the type of page style. It can take the value `page` or `task flow`. The default value `page`, creates a page based on the style's associated template. The value `task flow` creates a task flow view of a page based on the style's associated template.
3. If you want to add a new style to the Create Page dialog, add a `templateDef` entry, as shown in the following example:

   ```
   <templateDef name="pstemplateview3.jsff"
                title="Rich Text"
                type="taskflow"
                forGroupSpace="false"/>
   ```

4. Save the XML file.

At runtime, the Create Page dialog displays the styles you specified. The pages and task flow page views users create using those styles are based on the JSPX or JSFF templates you defined.

19.6.2 Using ADF Templates

If your page template is based on an ADF template, you can configure the page creation task flow to use a different ADF template depending on different criteria, such as user or scope.

You can specify the ADF template to use for runtime page creation in either of the following ways:

- By using the `oracle_webcenter_page_createpage_adftemplate` parameter in the page creation task flow (see Section 19.3.4, "Specifying Styles").
- By using the `ADFTemplateViewID` parameter in the `createPage()` and `createTaskflow()` APIs.

Any JSPX page template that is based on an ADF template contains an `af:pageTemplate` tag with the `viewId` attribute. The `viewId` attribute contains the name of the ADF template. Example 19–15 shows a page template that is based on the ADF template `portalTemplate.jspx`.

When you specify an ADF template name for use during page creation, the Page service searches for the `af:pageTemplate` tag in the page template and updates the `viewId` attribute with the value you provided.

This section describes how to specify which ADF template to use under a given circumstance. It contains the following subsections:

- Section 19.6.2.1, "How to Specify the ADF Template Name Using the Task Flow Parameter"
- Section 19.6.2.2, "How to Specify the ADF Template Name Using API Parameters"

19.6.2.1 How to Specify the ADF Template Name Using the Task Flow Parameter

To specify the ADF template name using the task flow parameter:

1. Open the JSPX file containing the Page - Create New task flow.
2. Right-click the page name and select **Go to Page Definition**.
3. In the page definition file, under Executables, select the Create Page task flow, and click the **Edit** icon on the header.
4. The Edit Task Flow Binding dialog opens with the list of input parameters supported by the task flow.
5. Set the `oracle_webcenter_page_createpage_adftemplate` parameter.

   If you define a constant value, for example `${'/mytemplates/defaultTemplate2.jspx'}`, then this ADF template is used for all pages created using the create page task flow.

   However, by providing an EL value for the parameter, you can ensure that a different ADF template is used based on different criteria, such as user or scope.

   For example, assume you have two users, `user1` and `user2`, and want to use a different ADF template for pages created by each user. You must enter the value `${MyClass.ADFTemplate}` for the `oracle_webcenter_page_createpage_adftemplate` parameter and define the method `MyClass.getADFTemplate()` so that it returns different ADF templates based on which user has logged in.

6. Click **OK**.

19.6.2.2 How to Specify the ADF Template Name Using API Parameters

To specify the ADF template name using API parameters:

1. Create a page or a task flow, and specify the ID of the ADF template view activity.

   The page or task flow is subsequently created based on that ADF template.

   To create a page:

   ```
   PageService.createPage(
        String pageType, String nameFormat, String title,
        String pageTemplate, String pageTemplatePath,
        String ADFTemplateViewID,
        String cssStyle, String schemeBGImage, String schemeBGColor)
   ```

   where `ADFTemplateViewID` is the ID of the ADF template view activity.

   To create a task flow:

   ```
   PageService.createTaskflow(
        String nameFormat, String title,
        String pageTemplate, String pageTemplatePath,
        String ADFTemplateViewID,
        String cssStyle, String schemeBGImage, String schemeBGColor)
   ```

   where `ADFTemplateViewID` is the ID of the ADF page template view activity.

19.6.3 Creating Styles for the Create Page Dialog

To use your own page styles, define them in `/mytemplates.templates.xml` file. If you want to maintain a separate XML file with a different set of page styles, you can create an XML file and reference that from the Page - Create New task flow. For example, to display two different options to two users with different privileges, then you must create two XML files and define different styles in each XML file. You can then ensure that the Create Page dialog displays the respective options to each user.

This section describes how to create and reference a new style for the runtime Create Page dialog. It contains the following subsections:

- Section 19.6.3.1, "How to Create a Style for the Create Page Dialog"
- Section 19.6.3.2, "How to Reference a New Style from the Page - Create New Task Flow"

19.6.3.1 How to Create a Style for the Create Page Dialog

To create a style for the Create Page dialog:

1. In the `/mytemplates` directory, create an XML file, for example `templates2.xml`.
2. Add a `templatesDef` element, and within that add a `templateDef` entry for each style that you want to include in the Create Page dialog.

   Example 19–17 shows the code entered into sample XML file `templates2.xml` that references the `pstemplateview.jsff` fragment you created in the previous section.

Example 19–17 Sample Code for the Create Page Dialog Style

```
<?xml version="1.0" encoding="UTF-8" ?>
```

```
- <templatesDef xmlns="http://xmlns.oracle.com/webcenter/page">
<templateDef name="pstemplateview.jsff" title="News" icon="/images/news.png"
             type="taskflow" />
  </templatesDef>
```

where

- `name` is the name of the page or page fragment to use as a template.
- `title` is the label for the style in the Create Page dialog.
- `type` is the type of template. It can take that value `page` or `taskflow`. The default value `page` creates a page based on the style's associated template. The value `taskflow` creates a task flow view of a page based on the style's associated template.

3. Save the XML file.

19.6.3.2 How to Reference a New Style from the Page - Create New Task Flow

To reference the new XML file from the Page - Create New task flow:

1. Open the JSPX page that contains the Page - Create New task flow.
2. Right-click the JSPX page, and select **Go to Page Definition**.
3. In the page definition file, under Executables, select the Create Page task flow, and click the **Edit** icon on the header.

   The Edit Task Flow Binding dialog opens with the list of input parameters supported by the task flow.
4. Provide the template file name for the `oracle_webcenter_page_createpage_templatefile` parameter.

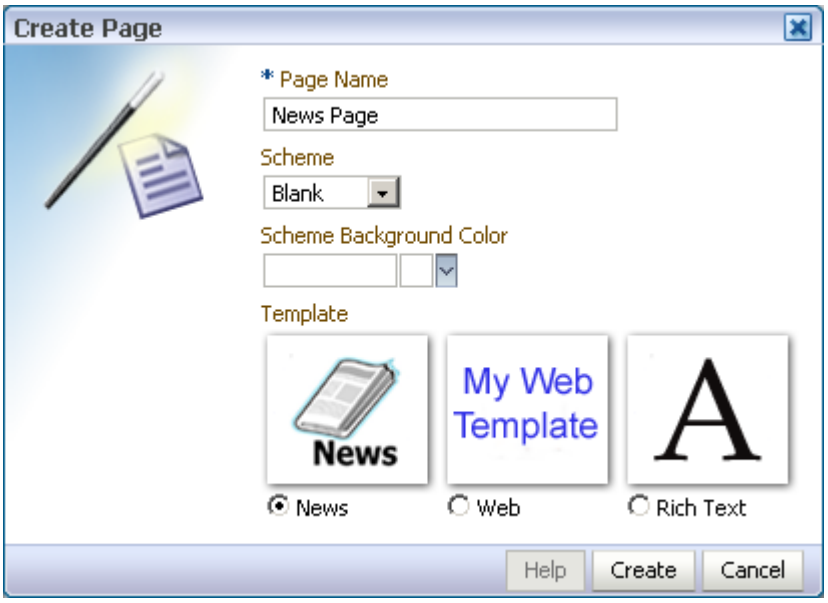
   If you define a constant value, for example `${'/mytemplates/templates2.xml'}`, then this template is used for the Create Page dialog always.

   However, by providing an EL value for the parameter, you can ensure that a different template is used for the dialog based on different criteria, such as user or scope.

   For example, assume you have two users, `user1` and `user2`, and want to display a different page style to each user. In this case, you must have two templates for the Create page dialog. Let us say you have created a new template, `templates2.xml`, and updated the default template, `templates.xml`. You can then specify `${TemplateBean.template}` for the `oracle_webcenter_page_createpage_templatefile` parameter.

   To use this value, you must first create the managed bean, `TemplateBean.java`, with method `getTemplate()`, which returns `templates.xml` for `user1` and `templates2.xml` for `user2`. At runtime, user1 and user2 are each shown different options in the Create Page dialog, as shown in Figure 19–12 and Figure 19–13.

Figure 19–12 Create Page Dialog using the templates.xml Style



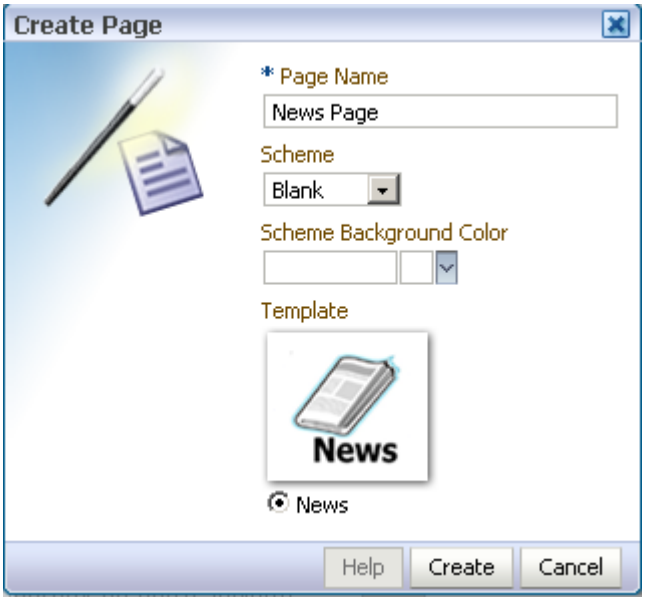


Figure 19–13 Create Page Dialog using the templates2.xml Style

5. Click **OK**.
6. Click **Save All** to save your work.

19.7 Customizing Page Service Views

This section describes various ways to customize Page service views. It contains the following subsections:

- Section 19.7.1, "Rendering Pages with ADF Faces Components"
- Section 19.7.2, "Managing User Security on Pages and Task Flows"

19.7.1 Rendering Pages with ADF Faces Components

You can use ADF Faces components to render runtime pages. For example, you can use ADF Faces components to render pages as tabs, links, and image links—or thumbnail views of pages. This section provides some examples of the types of pages you can create using ADF Faces components. It contains the following subsections:

- Section 19.7.1.1, "Rendering Pages as Tabs Using ADF Faces Components"
- Section 19.7.1.2, "Rendering Pages as Links Using ADF Faces Components"
- Section 19.7.1.3, "Rendering Pages as Image Links Using ADF Faces Components"

19.7.1.1 Rendering Pages as Tabs Using ADF Faces Components

When you design your application to render pages as tabs, you can use a range of ADF Faces components to accomplish this. This section provides information about the ADF Faces components that support rendering pages as tabs. It contains the following subsections:

- Section 19.7.1.1.1, "Rendering Pages as Tabs Using af:navigationPane"
- Section 19.7.1.1.2, "Rendering Pages as Tabs Using af:panelTabbed"

19.7.1.1.1 Rendering Pages as Tabs Using af:navigationPane Example 19–18 illustrates how pages can be rendered as tabs using `navigationPane` components.

Here a method called `pages` from a custom bean (`MyPageServiceBean`) is used to get the list of pages. For more information about getting the list of pages with the Page service API, see the `getPages()` method in Page service API section.

Example 19–18 Rendering Pages as Tabs Using af:navigationPane

```
<af:navigationPane id="tabs">
  <af:forEach var="tab" items="#{MyPageServiceBean.pages}">
    <af:commandNavigationItem text="#{tab.title}"  id="cni1"/>
    </af:forEach>
  </af:navigationPane>
```

The output of the code depicted in Figure 19–18 renders as a series of tabs (Figure 19–14).

Figure 19–14 Render Pages as Tabs

19.7.1.1.2 Rendering Pages as Tabs Using af:panelTabbed Example 19–19 illustrates how pages can be rendered as tabs using `navigationPane` components.

Here a method called `pages` from a custom bean (`MyPageServiceBean`) is used to get the list of pages. For more information about getting list of pages using Page service API, see the `getPages()` method in Page service API section.

Example 19–19 Rendering Pages as Tabs Using af:panelTabbed

```
<af:panelTabbed id="pt1" >
    <af:forEach var="tab" items="#{ MyPageServiceBean.pages}">
        <af:showDetailItem text="#{tab.title}" id="sdi1"/>
     </af:forEach>
   </af:panelTabbed>
```

The output of the code in Example 19–19 renders as a series of tabs (Figure 19–15).

Figure 19–15 Render Pages as af:panelTabbed Component

19.7.1.2 Rendering Pages as Links Using ADF Faces Components

This section provides examples of using ADF Faces Components to render pages as different types of links. It includes the following subsections:

- Section 19.7.1.2.1, "Rendering Pages as Links Using af:commandLink"
- Section 19.7.1.2.2, "Rendering Pages as Links Using af:goLink"

19.7.1.2.1 Rendering Pages as Links Using af:commandLink Example 19–20 illustrates how pages can be rendered as links using `af:commandLink`.

Example 19–20 Rendering Pages as Links Using af:commandLink

```
<af:panelGroupLayout id="pgl1" layout="vertical">
  <af:forEach var="tab" items="#{MyPageServiceBean.pages}">
     <af:commandLink text="#{tab.title}" id="cl1"/>
   </af:forEach>
</af:panelGroupLayout>
```

The output of the code depicted in Example 19–20 renders as a list of links (Figure 19–16).

Figure 19–16 Render Pages as Links

19.7.1.2.2 Rendering Pages as Links Using af:goLink Example 19–21 illustrates how pages can be rendered as links using `af:goLink`.

Example 19–21 Rendering Pages as Links Using af:goLink

```
<af:panelGroupLayout id="pgl2" layout="vertical">
     <af:activeOutputText value="List Of Pages" id="aot2"
                          inlineStyle="font-weight:bold; font-size:small;"/>
      <af:forEach var="tab" items="#{pageServiceBean.pages}">
```

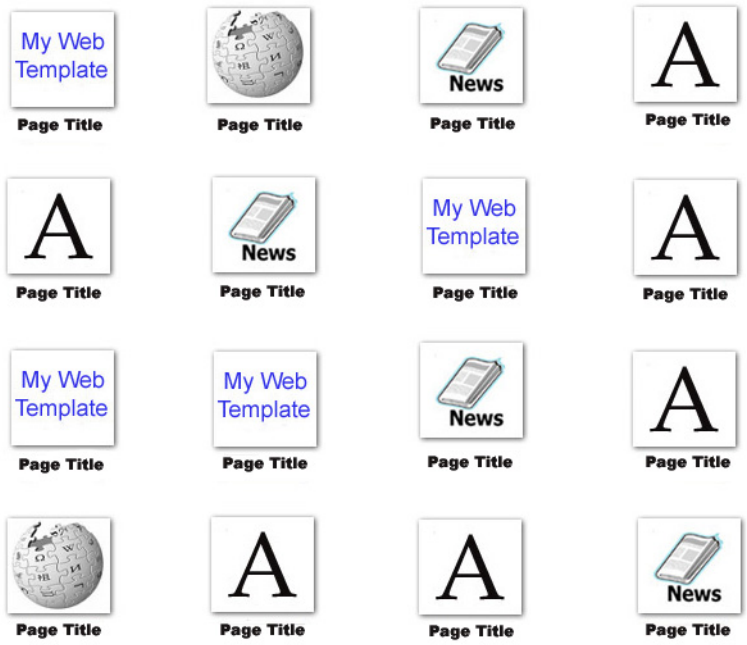
```
        <af:goLink text="#{tab.title}" id="gl1"/>
      </af:forEach>
    </af:panelGroupLayout>
```

The output of the code depicted in Example 19–21 renders as a list of links (Figure 19–16).

19.7.1.3 Rendering Pages as Image Links Using ADF Faces Components

Image links are linked thumbnail views of a page that users click to access the full page view. Example 19–22 illustrates how pages can be rendered as image links.

Example 19–22 Rendering Thumbnail Views of Pages



```
  <af:panelGroupLayout id="pg1_11" layout="scroll">
          <af:panelGroupLayout id="pg11" layout="horizontal" halign="center"
                               valign="middle">
            <h:panelGrid id="ds" columns="4" cellpadding="10" cellspacing="5"
                         style="text-align: center;" rowClasses="bottomAlign">
              <af:forEach varStatus="stat" begin="0"
end="#{MyPageServiceBean.pageCount}">
                <af:panelGroupLayout id="sdsd" layout="vertical"
                                     halign="center">
                  <af:commandImageLink text="" id="cil1"
                                       icon="/<image_name>}"/>
                  <af:activeOutputText value="Page Title" id="aot3"/>
                </af:panelGroupLayout>
              </af:forEach>
            </h:panelGrid>
          </af:panelGroupLayout>
        </af:panelGroupLayout>
```

In Example 19–22, `pageCount` is a method from a custom bean (`MyPageServiceBean`) that gets the number of pages in the current scope. Users must write this method on their own using the other methods from Page service APIs.

In Example 19–22, `<image_name>` is the name of the image with which you associate your page.

The output of the code in Example 19–22 is rendered as a linked series of thumbnail views of a page (Figure 19–17).

Figure 19–17 Render Pages as Image Links

19.7.2 Managing User Security on Pages and Task Flows

You can manage access to pages and task flows either through the Security Panel, which is a part of Composer, or through Page service APIs.

For more information about runtime security, see the "Setting Page Access" section in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

For more information about setting page access with the Page service APIs, see *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*.

19.8 Advanced Information for the Page Service

This section describes the APIs and data controls available for the Page service. It includes the following sections:

- Section 19.8.1, "Using the Page Service Java APIs"
- Section 19.8.2, "Using the Page Service Data Control"

19.8.1 Using the Page Service Java APIs

This section provides information about Page service Java APIs. It includes information about the location of these APIs, how to make your application ready to use them, and how to use them to create pages. It contains the following subsections:

- Section 19.8.1.1, "Configuration Settings Required for Using Page Service APIs"
- Section 19.8.1.2, "Introduction to the Page Service APIs"
- Section 19.8.1.3, "How to Set up Your Application to Use the Page Service APIs"
- Section 19.8.1.4, "Example: How to Create a Page"

19.8.1.1 Configuration Settings Required for Using Page Service APIs

To use the Page service APIs, you must perform the following steps:

1. Confirm that you have the following entries in your adf-config.xml file:

```
<namespace path="/oracle/webcenter/page/scopedMD"
metadata-store-usage="WebCenterFileMetadataStore"/>
<namespace path="/pageDefs"
metadata-store-usage="WebCenterFileMetadataStore"/>
<namespace path="/mytemplates"
metadata-store-usage="WebCenterFileMetadataStore"/>
```

   If these entries do not exist in adf-config.xml, add them using a text editor.

2. Configure the .cpx file to use dynamic page mapping:

```
<Application xmlns="http://xmlns.oracle.com/adfm/application"
             version="11.1.1.51.35" id="DataBindings" SeparateXMLFiles="false"
             Package="view" ClientType="Generic"
             PageMapClass="oracle.jbo.uicli.mom.DynamicPageMapImpl"
             BasePageDefPackageName="pageDefs">
  <definitionFactories>
    <factory nameSpace="http://xmlns.oracle.com/adf/controller/binding"

className="oracle.adf.controller.internal.binding.TaskFlowBindingDefFactoryImpl
"/>
    <dtfactory
className="oracle.adf.controller.internal.dtrt.binding.BindingDTObjectFactory"/
>
  </definitionFactories>
  <pageMap/>
    <page path="/page1.jspx" usageId="view_page1PageDef"/>
  </pageMap>
  <pageDefinitionUsages/>
    <page id="view_page1PageDef" path="view.pageDefs.page1PageDef"/>
  </pageDefinitionUsages>
  <dataControlUsages>
    <dc id="PageServiceDC"
        path="oracle.webcenter.page.internal.model.PageServiceDC"/>
  </dataControlUsages>
</Application>
```

   If these entries do not exist in your .cpx file, add them using a text editor.

19.8.1.2 Introduction to the Page Service APIs

The Page service APIs are located in the `oracle.webcenter.page.model.PageService` class.

The Page service provides the following APIs:

- createPage - see Section 19.8.1.4, "Example: How to Create a Page"
- deletePage
- createTaskflow - see Example 19–23, "Using Page Service APIs to Create a Task Flow View Page"
- deleteTaskflow
- createScope
- deleteScope

- copyPage
- getPageList - see Example 19–24, "Using Page Service APIs to Get a List of Pages"
- setPageTitle - see Example 19–25, "Using Page Service APIs to Set the Page Title"
- changeHiddenStatus
- changePageScheme - see Example 19–26, "Using Page Service APIs to Set the Page Scheme"
- setPageAccess

For more information about the Page service APIs, see *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*.

Example 19–23 Using Page Service APIs to Create a Task Flow View Page

```
PageDef createTaskflow(String nameFormat, String title, String pageTemplate,
  String pageTemplatePath, String cssStyle, String schemeBGImage, String
schemeBGColor)
  throws DuplicateNameException, InvalidNameException, LockUnavailableException;
```

where

- `nameFormat` is the name format of the task flow; it can contain a subpath, such as `users/UserA/taskflow{0}.jspx`.
- `title` is the title of the task flow.
- `pageTemplate` is the template used for the task flow.
- `pageTemplatePath` is the path for the task flow template.
- `cssStyle` is the cascading style sheet file for this task flow.
- `schemeBGImage` is the background image for the custom scheme.
- `schemeBGColor` is the background color for the custom scheme.

It returns the `PageDef` of the newly created task flow and throws the following:

- `InvalidNameException` if the name supplied cannot be used for update.
- `DuplicateNameException` if the page with the same name already exists.
- `LockUnavailableException` if another page or task flow operation is in progress.

Example 19–24 Using Page Service APIs to Get a List of Pages

```
PageDef getPageList(String path)
```

where

- `path` the path under which you want to see a list of all page that the user can view. If you do not specify a path, it returns a list of all pages that the user can view in the current scope.

It returns the list of all pages that are not hidden in the current scope or under a specific path.

Example 19–25 Using Page Service APIs to Set the Page Title

```
setPageTitle(String pagepath, String title)
  throws InvalidNameException, ObjectChangedException, LockUnavailableException,
oracle.webcenter.framework.translations.exception.TranslationsException;
```

where

- `pagepath` is the path of the page for which you want to change the title.
- `title` is the new name of the page.

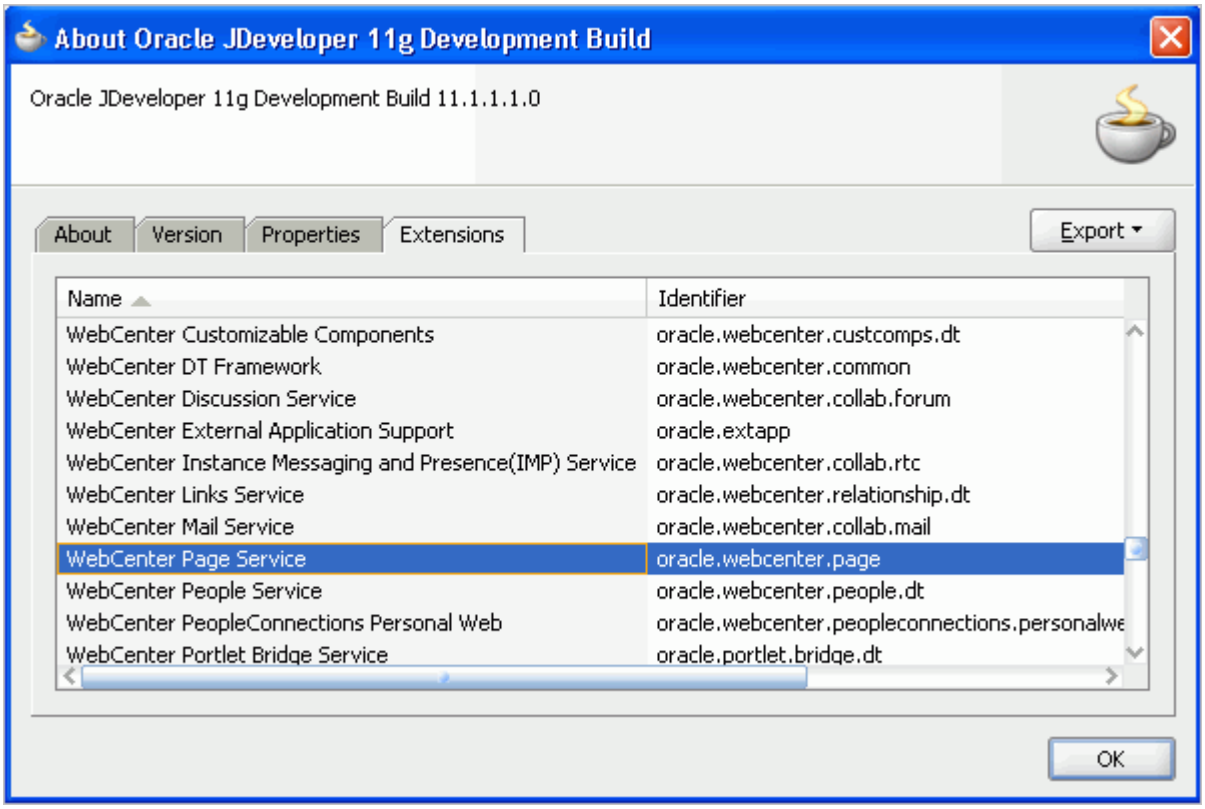
It updates the name of the page and throws the following:

- `InvalidNameException` if the name supplied cannot be used for update.
- `ObjectChangedException` if the page has changed since it was last retrieved.
- `LockUnavailableException` if another page operation is in progress.

Example 19–26 Using Page Service APIs to Set the Page Scheme

```
setPageScheme(String pagepath, String schemeName, String schemeBGImage, String
schemeBGColor, String otherCSS)
```

where



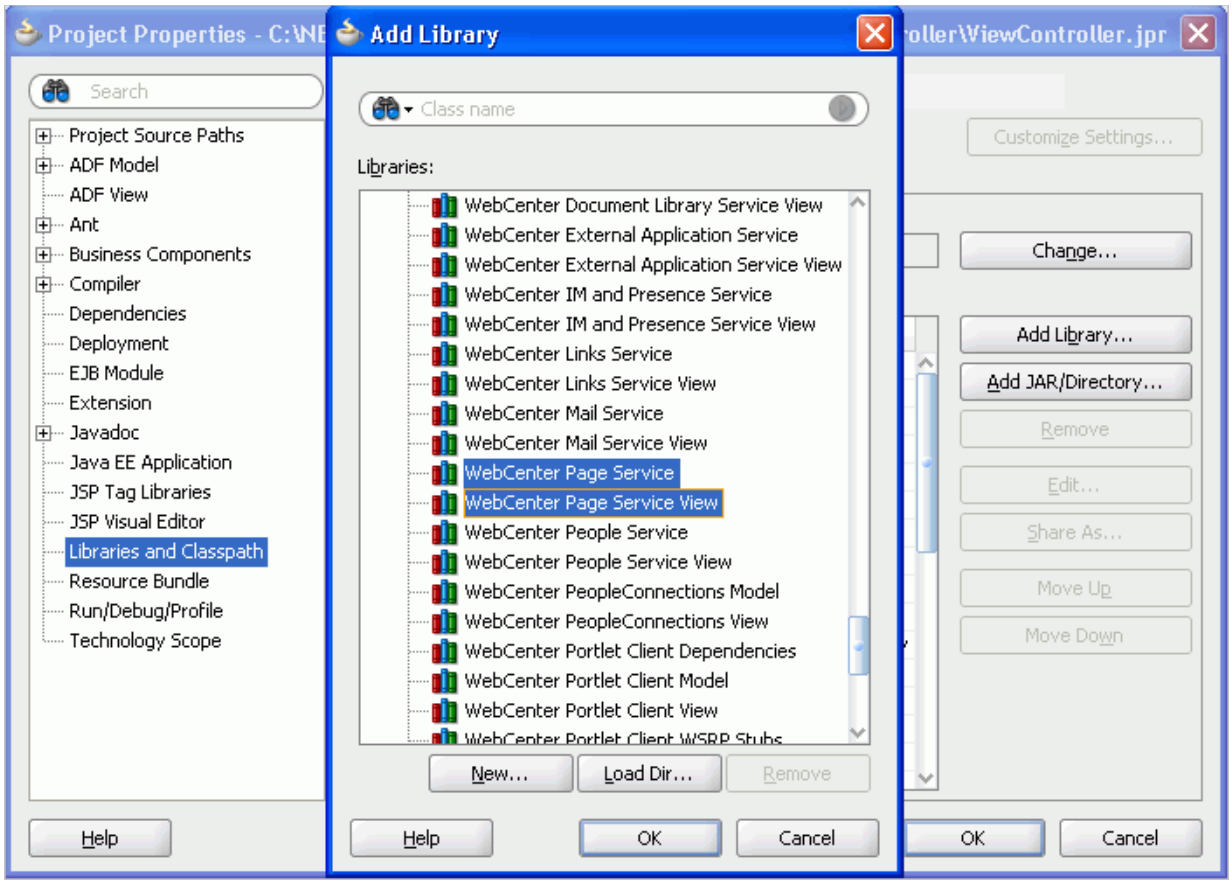
- `pagepath` the path of the page for which you want to change the scheme.
- `schemeName` the name of the CSS for the page.
- `schemeBGImage` the background image for the custom scheme.
- `schemeBGColor` the background color for the custom scheme.
- `otherCSS` any other CSS attributes you want to specify.

It updates the page's scheme properties in the jspx page.

19.8.1.3 How to Set up Your Application to Use the Page Service APIs

To use the Page service APIs, WebCenter Portal's Page service extension must be present in your JDeveloper application. In JDeveloper, go to the **Help - About** menu, and click the **Extensions** tab. Look for the WebCenter Page Service, as shown in Figure 19–18.

Figure 19–18 JDeveloper Extensions



Note: For information about adding the WebCenter Portal's extensions, see Chapter 3, "Preparing Your Development Environment."

After confirming that the Page service is included with the WebCenter Portal's extensions, you must add the Page service libraries to the project.

To add Page service libraries to your project:

1. Right-click your **ViewController** project and select **Project Properties** and then **Libraries and Classpath**.
2. Click **Add Library** and select the **WebCenter Page Service** and **WebCenter Page Service View** libraries, as shown in Figure 19–19.

Figure 19–19 Adding Page Service Libraries

3. Click **OK**.

If you do not want to use JDeveloper as the code editor, then you can set the CLASSPATH to the following jar files:

- `Jdev_Home/jdeveloper/webcenter/jlib/pagem.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/pages.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/page-service-view.jar`
- `Jdev_Home/jdeveloper/webcenter/jlib/page-service-skin.jar`

19.8.1.4 Example: How to Create a Page

This section provides an example of how to create a page using the Page service APIs. Your requirements may call for different methods. Use the way the `createPage` method is invoked in this sample code as a model for invoking the methods you require on the `PageService` object.

Typically, pages created using Page service APIs are based on templates. Before you start creating pages using the APIs, you must ensure that each template file, for example `MyPageTemplate1.jspx`, has a page definition file, in this case `MyPageTemplate1PageDef.xml`, in the same directory as the JSPX page.

Example 19–27 shows how to use the `createPage() API` to create a scope named `MyScope`, create an MDS session instance, instantiate the Page service class with this new scope, and then create a page within this scope. The new page is created based on the `MyPageTemplate1.jspx` template.

Example 19–27 Sample Showing How to Create a Page

```
...

public void createMyPage
{
    try
    {
      MDSSession mdsSess =
(MDSSession)ADFContext.getCurrent().getMDSSessionAsObject();
      PageServiceConfig config = new PageServiceConfig(mdsSess, "defaultScope");
      mPageService = PageServiceFactory.createInstance(config);

      String pageNameFormat ="Page{0}.jspx";
      String pageTitle ="New Page";

      //
      // The template used to create the new page is
/mytemplates/MyPageTemplate1.jspx
      // path "/mytemplates" should be defined as a MDS namespace.
      // Also MyPageTemplate1.jspx should have a pageDef called
"MyPageTemplate1PageDef.xml and
      // it has the same path as the jspx file.

      PageDef newPage = mPageService.createPage(
        "personaluserpage", pageNameFormat, pageTitle,
        "MyPageTemplate1.jspx",
        "/mytemplates/",
        null, null, null);

    }
    catch(Exception e)
    {
      // Handle exception
    }
}

...
```

> **Note:** Pages and task flows created using Page service APIs do not have permissions granted by default. You must explicitly define permissions on the page.

For more information about the Page service APIs, see *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*.

19.8.2 Using the Page Service Data Control

The Page service data control enables you to view information about existing pages at runtime and delete any of the listed pages.

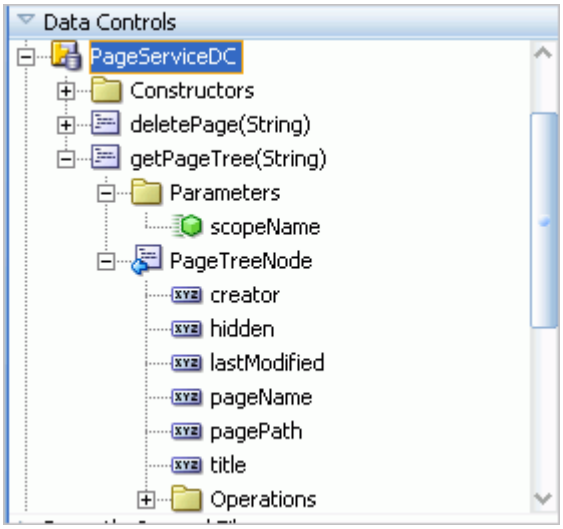
This section describes how to add a Page service data control to a project and how to use it to view, edit, and delete pages. It contains the following subsections:

- Section 19.8.2.1, "How to Add the Page Service Data Control"
- Section 19.8.2.2, "How to View, Edit, and Delete Pages at Runtime"

19.8.2.1 How to Add the Page Service Data Control

This section provides an example of adding the Page service data control at design time.

To add a Page service data control to your project:



1. Ensure that you can see the PageServiceDC in the Application Navigator.

   The PageServiceDC appears in the Application Navigator after you have performed either of the following actions:

   - Added the **Page - Create New** task flow to your project (see Section 19.2.1.1, "How to Add the Page - Create New Task Flow").
   - Added the **Page Data Control** as described in Section 7.1.3, "Using WebCenter Portal Data Controls.".

2. In the Data Controls panel of the Application Navigator, expand **PageServiceDC**, as shown in Figure 19–20.

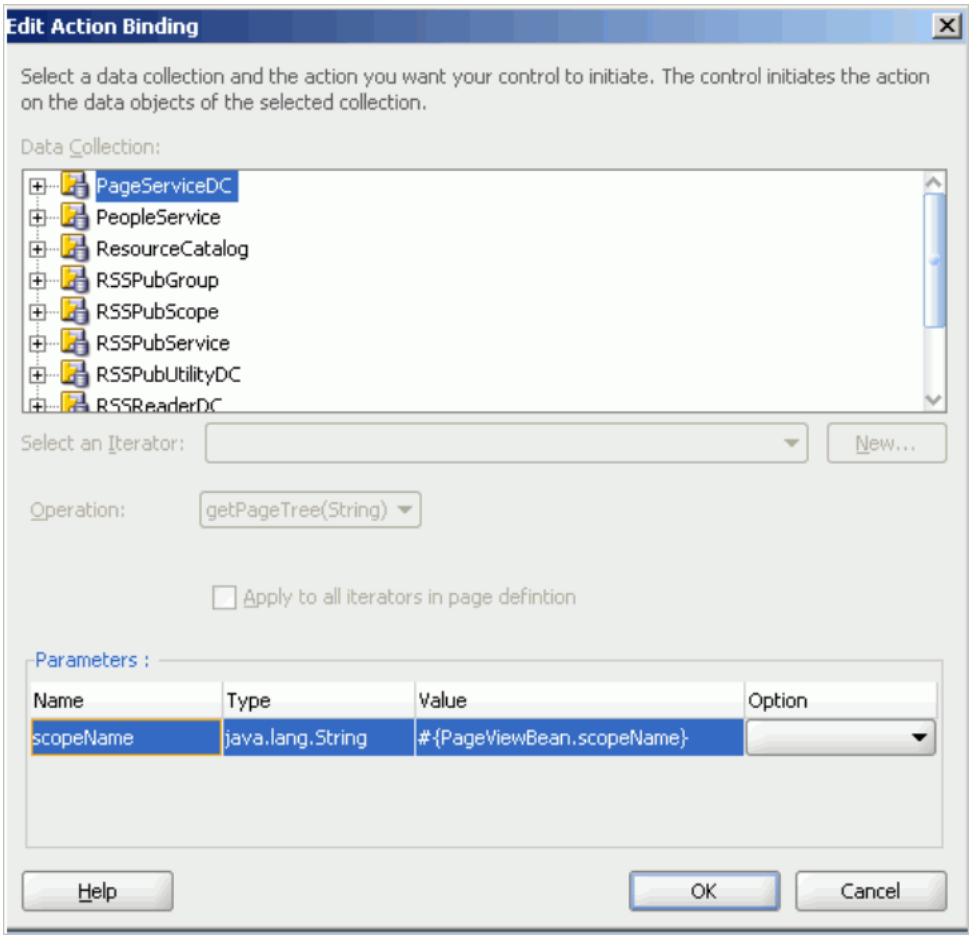


Figure 19–20 Page Service Data Control

3. Under **getPageTree()**, drag **PageTreeNode** and drop it on the page.
4. From the **Create** menu, select **Table**, and then select **ADF Read-only Table**.
5. In the dialog, enter the `scopeName` parameter to view all the pages listed under the specified scope.

   If you do not enter any value, then the data control takes the default scope. In Figure 19–21, the scope value is fetched from a custom managed bean.

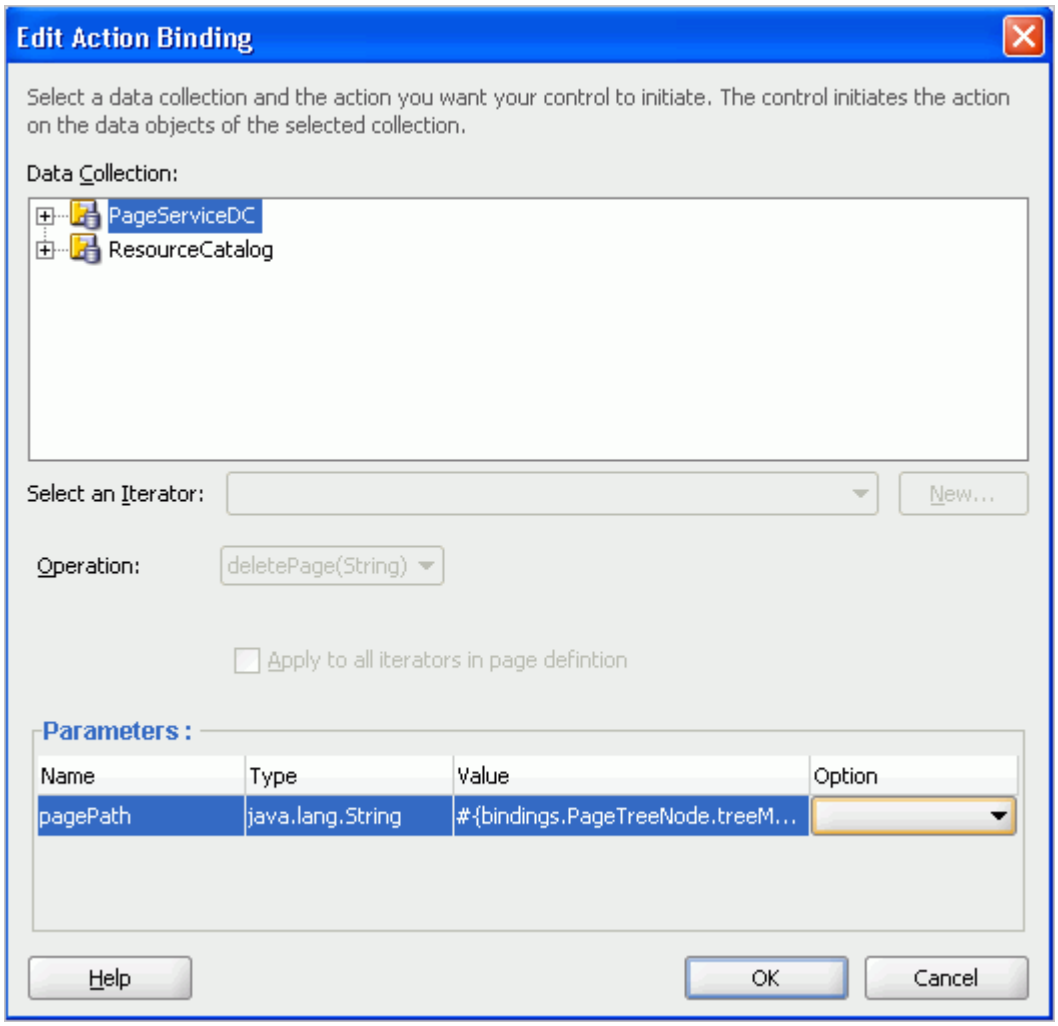

Figure 19–21 scopeName Parameter

6. Add a new column to the table you created at step 4.
7. To add a column for deleting pages at runtime, drag the **deletePage(string)** method and drop it in the new column.
8. From the **Create** menu, select **Methods**, and then select **ADF Link**.
9. In the Parameters section of the Edit Action Binding dialog, shown in Figure 19–22, specify the following value for the `pageName` parameter:

   ```
   #{bindings.PageTreeNode.treeModel.rowData.pagePath}
   ```

Figure 19–22 Edit Action Binding Dialog

10. Click **OK**.
11. From the Data Controls panel, expand **PageServiceDC**, **getPageTree()**, **PageTreeNode**, and then **Operations**.
12. Drag **Execute** and drop it on the page as an **ADF Button**.
13. In the Source view, set the button's `Text` attribute to `Refresh`.

    This provides a refresh feature on the list of pages to enable users to refresh the list after they have added a page or deleted one from the list.
14. Optionally, to display pages as links that invoke page Edit mode, view the page source and replace the `outputText` element in the table's page path column with a `goLink` as follows:

    Replace

    ```
    <af:outputText value="#{row.pagePath}"/>
    ```

    with

    ```
    <af:goLink destination="/faces#{row.pagePath}" text="#{row.title}"
    targetFrame="_top"/>
    ```

15. Save your page, and run it to your browser.
16. The created data control table should look something like Figure 19–23.

Figure 19–23 Sample Data Control Table

title	pageName	pagePath	creator	lastModified	hidden	
myPersonalPage	Page1.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
FinancePage	Page2.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
HRPage	Page3.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
MarketingPage	Page4.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage
OperationsPage	Page5.jspx	/oracle/webcenter/pa	steve	10/7/2008	false	deletePage

19.8.2.2 How to View, Edit, and Delete Pages at Runtime

To view a page, follow the link generated from step 14 in the previous section. If the application has been secured properly, then an edit link should render on the page at runtime.

To delete a page, click the **deletePage** button in the row of the relevant page. This button was generated from in step 7 in the previous section. Click the Refresh button for the table to remove the deleted page row from the table.

For detailed information about how to view, edit, and delete pages at runtime, see the chapter "Creating, Editing, and Deleting Pages" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

19.9 Page Service Samples

The Custom Portal Demo sample illustrates some Page service functionality, including the following:

- How to add the Page - Create New task flow
- How to configure task flow parameters
- How to use an ADF template
- How to use custom styles
- How to manage pages

The Custom Portal Demo sample is posted on the Oracle WebCenter Suite 11g Demonstrations and Samples page on the Oracle Technology Network (OTN) at: `http://www.oracle.com/technetwork/middleware/webcenter/overview/index.html`

20

Enabling Runtime Editing of Pages Using Composer

Oracle WebCenter Portal's Composer provides components for controlling the application's design time at runtime behavior. This chapter describes how to add Composer components to your application page, thereby enabling runtime editing in the page.

For more information about Composer, see Chapter 18, "Introduction to Composer."

This chapter contains the following sections:

- Section 20.1, "Designing Editable Pages Using Composer Components"
- Section 20.2, "Designing Editable Pages Using Composer Components: Example"
- Section 20.3, "Populating Pages with Content"
- Section 20.4, "Troubleshooting Composer Problems"

20.1 Designing Editable Pages Using Composer Components

The Composer tag library provides design-time components that you can add to a page in Oracle JDeveloper to enable page editing at runtime. When you create a page with Composer components at design time, at runtime Composer provides options for entering page edit mode and modifying the page according to your requirements.

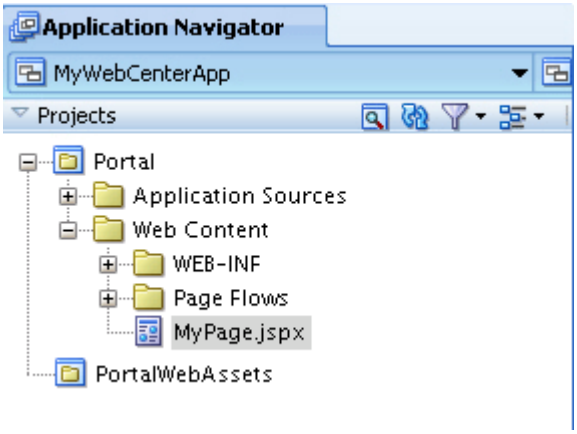
You can enable customizations in Framework applications and non-Framework applications. Within an application, you can enable customization of the following types of pages:

- A regular JSPX page, not based on a page template
- A JSPX template page
- A JSPX page based on a page template

For more information about Composer components and their attributes, see Section 18.6, "Composer Components."

This section explains how to add Composer components to a page at design time to make it editable at runtime. It contains the following subsections:

- Section 20.1.1, "How to Create a Customizable Page"
- Section 20.1.2, "How to Enable Runtime Customization Using a Page Customizable"
- Section 20.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button"



- Section 20.1.4, "How to Define Editable Areas of a Page Using Panel Customizable Components"
- Section 20.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable"
- Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components"
- Section 20.1.7, "How to Create a Page Template for Creating Customizable Pages"
- Section 20.1.8, "How to Enable Customization in a Populated Page"
- Section 20.1.9, "What Happens When You Add Composer Components"
- Section 20.1.10, "What Happens at Runtime"
- Section 20.1.11, "What You May Need to Know When Designing Editable Pages"

20.1.1 How to Create a Customizable Page

The steps for creating a customizable JSPX page in your Framework application are available in Section 5.3, "Adding Pages to a Portal."

When you create a new page in JDeveloper, it is listed in the Application Navigator under **Web Content** as shown in Figure 20–1. Additionally, the page is opened in the editor and becomes the active editor panel.

Figure 20–1 New Customizable Page (MyPage.jspx) Shown in the Application Navigator

Security Considerations

By default, a Framework application is configured with ADF security. A default user name and password (weblogic/weblogic1) are created automatically for you.

To enable users to edit a page in a secured application, you must grant Edit or Customize privileges on the page to the required users or roles. For more information about granting permissions, see Section 69.4, "Using the Role Manager Task Flow."

If ADF security is not enabled in your application, you can test how user privileges impact runtime customization capabilities by implementing security and configuring your application to authenticate users so that they have distinct identities. For the steps to implement a basic security model in your application, see Section 69.3, "Configuring ADF Security."

20.1.2 How to Enable Runtime Customization Using a Page Customizable

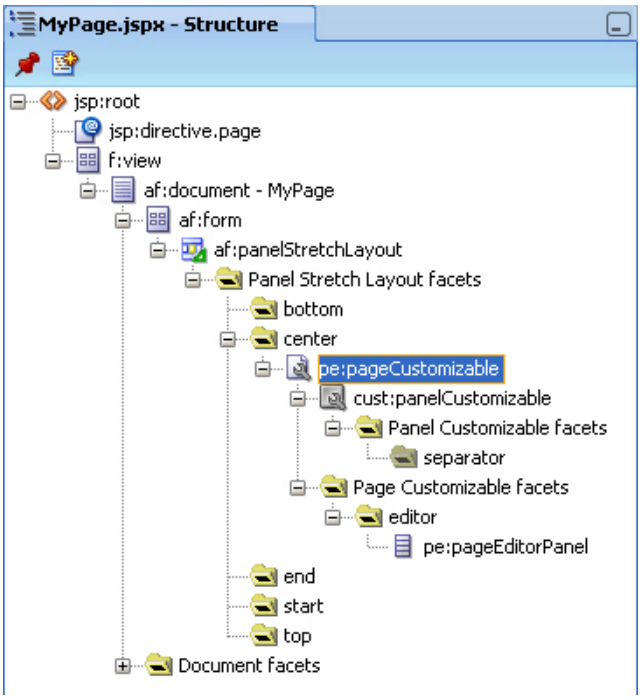
Adding a `Page Customizable` component to the page ensures that Composer is invoked when users switch to Edit mode of the page. When you add a `Page Customizable` component, some configuration files are updated automatically with the default Composer-specific settings. For more information, see Section 20.1.9, "What Happens When You Add Composer Components."

> **Note:** For considerations you must make before adding a `Page Customizable` to the page, see Section 20.1.11, "What You May Need to Know When Designing Editable Pages."

To add a Page Customizable component to the page:

1. Open a customizable JSPX page.
2. In the Component Palette, select **ADF Faces** and drag a **Panel Stretch Layout** component onto the page.

   > **Notes:** The `Panel Stretch Layout` component stretches the child in the `center` facet to fill all of the available space. This holds true when users resize the browser.



3. In the Component Palette, select **Composer**.
4. Add a **Page Customizable** component to the `center` facet of the `Panel Stretch Layout`.

   You must ensure that the `Page Customizable` is nested inside an `af:form` element. The `Page Customizable` is a rich client component that requires the rich client framework to function properly.
5. The required attributes for a `Page Customizable` component are populated with default values when you add the component to the page.

   You can define or modify attribute values by referring to Table B–1 in Section B.1, "Composer Component Properties."
6. Save the page.

   By default, a `Panel Customizable` component is added as a child component and the `Page Editor Panel` is added as a facet in the `Page Customizable` component, as shown in Figure 20–2.

Figure 20–2 Page Customizable Component

Example 20–1 shows the `pe:pageCustomizable` tag in the page source view.

Example 20–1 Page Customizable Component in the Page Source View

```
<pe:pageCustomizable id="pageCustomizable1"
  <cust:panelCustomizable id="panelcustomizable1"
                          layout="scroll"/>
  <f:facet name="editor">
    <pe:pageEditor id="pep1"/>
  </f:facet>
</pe:pageCustomizable>
```

20.1.3 How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button

To enable users to switch to Edit mode of a page easily, you must add a `Change Mode Link` or `Change Mode Button` component to the page.

Note: An alternative way to enable switching to Edit mode is by using the Change Mode API. For more information about this API, see *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal*.

For things you should consider before adding a `Page Customizable` to the page, see Section 20.1.11, "What You May Need to Know When Designing Editable Pages."

To add a Change Mode Link or Change Mode Button component:

1. From the Component Palette, select **Composer**.

2. In the Structure window, within the `top` facet of the `Panel Stretch Layout` that you added in the previous section, drag a **Change Mode Link** or **Change Mode Button** component.

   You must ensure that the `Change Mode Link` or `Change Mode Button` is nested in an `af:form` element. The `Change Mode Link` or `Change Mode Button` component is a rich client component that requires the rich client framework to function properly.

   Notes:

   - If you have not used a `Panel Stretch Layout` on your page, then add the `Change Mode Link` or `Change Mode Button` component above the `Page Customizable` component in the Structure window. This ensures that the `Change Mode Link` or `Change Mode Button` is displayed properly at runtime.
   - Use a `Change Mode Link` or `Change Mode Button` only when you have a `Page Customizable` on the page. You may have problems running a page that contains a `Change Mode Link` or `Change Mode Button` but no `Page Customizable` component.

3. The required attributes for a `Change Mode Link` or `Change Mode Button` component are set by default when you add the component to the page.

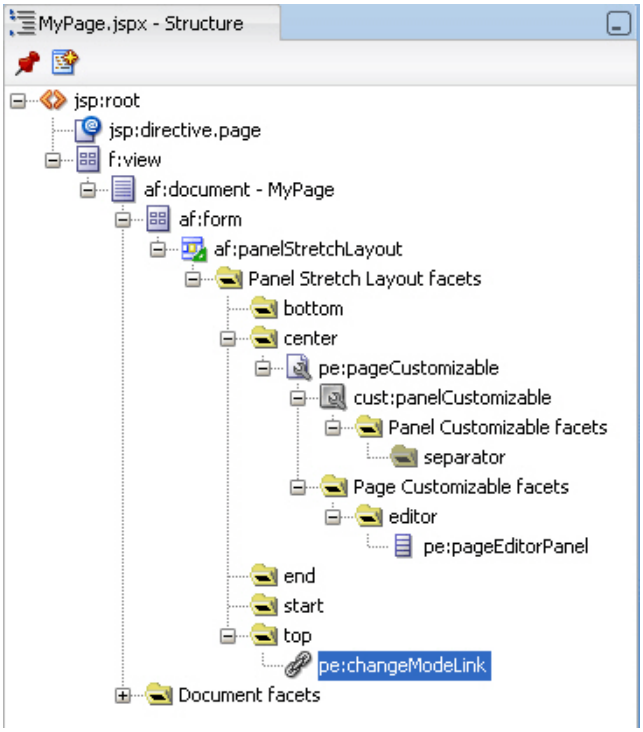
   Optionally, you can set any other attributes by referring to Table B–2 in Section B.1, "Composer Component Properties."

   Note: In a secured application, it is recommended that you check all users' privileges and enable the Edit link or button on the page only for privileged users. Unauthenticated users who stumble into page Edit mode can change component properties, though the changes will not be saved.

   You can enable the Edit link or button for selected users by specifying an EL value for the `rendered` attribute on the `Change Mode Link` or `Change Mode Button` component. For more information, see Section B.1.2, "Change Mode Link and Change Mode Button."

   The `pe:changeModeLink` or `pe:changeModeButton` tag displays within the `af:form` tag in the Structure window, as shown in Figure 20–3.

Figure 20–3 Change Mode Link



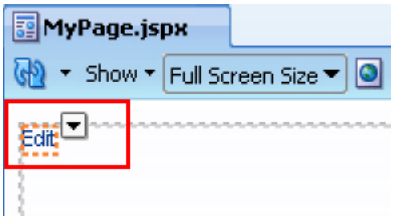


Figure 20–4 shows the `Change Mode Link` in the Design view of the page in JDeveloper.

Figure 20–4 Change Mode Link in Design View

20.1.4 How to Define Editable Areas of a Page Using Panel Customizable Components

The `Panel Customizable` component is required for page composition or content management tasks, such as adding, arranging, or removing portlets or regions. By default, one `Panel Customizable` component is automatically added as a direct child of the `Page Customizable` component. You can add more `Panel Customizable` components within this `Panel Customizable` component according to your requirements.

It is only within a `Panel Customizable` component that you can drag and drop components at runtime.

Note: For considerations you must make before adding a `Page Customizable` to the page, see Section 20.1.11, "What You May Need to Know When Designing Editable Pages."

To add a `Panel Customizable` component to the page:

1. From the Component Palette, select **Composer**.
2. Drag a **Panel Customizable** component to the Structure window and drop it at any suitable location within the form.

   You must ensure that the `Panel Customizable` is nested in an `af:form` element. The `Panel Customizable` component is a rich client component that requires the rich client framework to function properly.

   Notes:

   - A `Page Customizable` component contains one direct child `Panel Customizable` component by default. Do not add another `Panel Customizable` as a direct child component of the `Page Customizable`. If the `Page Customizable` has multiple child components, only the first child component is picked up while running the page.
   - Ensure that you do not delete the root `Panel Customizable` component on the page, because at runtime you can drop components *only* inside a `Panel Customizable` component.

3. The required attributes for a `Panel Customizable` component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–6 in Section B.1, "Composer Component Properties."

   Notes: If you select `stretch` layout for the `Panel Customizable`, then the first child component is stretched to fill up available space in the `Panel Customizable` component. Any other child components are ignored, though they are not removed from the page.

20.1.5 How to Enable Layout Customization for a Page Using a Layout Customizable

Use the `Layout Customizable` component to enable the runtime definition or modification of the layout of components on a page or an area of a page. Use this component only if you want to allow users to customize the layout at runtime. For static layouts, use an alternative component, such as a `Panel Group Layout` or `Panel Stretch Layout`.

To add a `Layout Customizable` component:

1. From the Component Palette, select **Composer**.
2. Drag a **Layout Customizable** component to the Structure window and drop it inside the `Panel Customizable` component.

   The target `Panel Customizable` component must be a child of the `Page Customizable` component.

   Ensure that the `Layout Customizable` is nested in an `af:form` element. The `Layout Customizable` is a rich client component and requires the rich client framework to function properly.

Note: You can delete the direct child `Panel Customizable` in the `Page Customizable` and add the `Layout Customizable` as a direct child of the `Page Customizable`. However, you must ensure that the `Page Customizable` has only one direct child component.

3. The required attributes for a `Layout Customizable` component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–3 in Section B.1, "Composer Component Properties."

   Note: To ensure that the `Layout Customizable` component is clearly visible on the page at runtime, provide a descriptive label for the component by using the `Text` attribute.

   The `pe:layoutCustomizable` tag is located inside a `cust:panelCustomizable` tag in the Structure window as shown in Figure 20–5. A child `Panel Customizable` component is added by default in the `Layout Customizable` component. Additionally, a `Panel Customizable` component is added within each facet of the `Layout Customizable` component. These `Panel Customizable` components enable you to add content inside the `Layout Customizable` component at runtime.

   The `Panel Customizable` added as a direct child provides the main area—the central area in a layout at runtime. The `Panel Customizable` components added within the two default `Layout Customizable` facets provide the two content areas, `A` and `B`. When you select a predefined layout at runtime, these three areas are arranged to display content in the selected pattern. See Predefined Layout Types for more information about how the content is laid out for each layout type.

   Note: In a `oneColumn` layout, `A` and `B` are rendered only if the `Panel Customizable` components contain child components.

Figure 20–5 Layout Customizable Component

20.1.6 How to Enable Component Customization Using Show Detail Frame Components

When you want to enable customizations such as property editing, moving, minimizing, or removing components, you can drop a `Show Detail Frame` component inside a `Panel Customizable` component on the page. You can then add a component inside the `Show Detail Frame`.

> **Note:** Each `Show Detail Frame` component should have only one direct child component. If you add multiple child components, then only the first one is rendered. The other direct child components are not rendered at design time or runtime.
>
> If multiple components must be enclosed in a `Show Detail Frame`, then add a grouping component like `Panel Group Layout` or `Panel Customizable` to the `Show Detail Frame` component and then include the ADF Faces components or other content within this grouping component.

Use the `Show Detail Frame` component to enable customizations in View and Edit modes of the page. Changes made in View mode are available to that user only, and changes made in Edit mode are available to all application users.

To add a Show Detail Frame component to the page:

1. From the Component Palette, select **Composer**.

2. Drag a **Show Detail Frame** component to the Structure window and drop it inside a `Panel Customizable` component.

   The `Show Detail Frame` should be nested in a `Panel Customizable` component on the page.

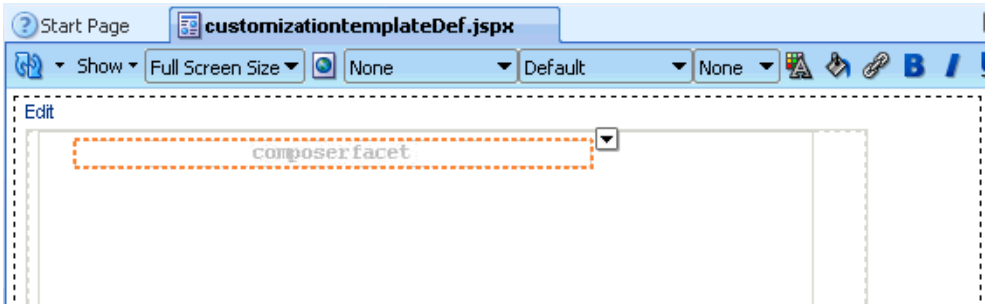
3. The required attributes for a `Show Detail Frame` component are set by default when you add the component to the page.

   Optionally, you can set any other attributes by referring to Table B–7 in Section B.1, "Composer Component Properties."

   The `cust:showDetailFrame` tag is added inside the `cust:panelCustomizable` tag as show in Figure 20–6.

Figure 20–6 Show Detail Frame Component

For a better understanding of this type of task, see Section 20.2, "Designing Editable Pages Using Composer Components: Example."



20.1.7 How to Create a Page Template for Creating Customizable Pages

If you plan to create many customizable pages in your application, you can base the pages on an ADF page template in which you have enabled customization. By adding Composer components to the template itself, you can save the effort required to add these components to each customizable page.

To create a page template and enable customization on it:

1. In the Application Navigator in JDeveloper, go to the Portal project of the application in which you want to create the template, right click the Portal project, and choose **New**.
2. In the New Gallery, expand **Web Tier,** select **JSF** and then **JSF Page Template,** and click **OK.**
3. In the Create JSF Page Template dialog, enter a file name for the template, select a layout, and declare a new facet.
4. Click **OK**.
5. In the template, add a **Change Mode Link** or **Change Mode Button** component above the `Panel Stretch Layout` component.
6. Add a **Page Customizable** component within the `center` facet of the `Panel Stretch Layout` component.
7. Delete the child `Panel Customizable` component from the `Page Customizable` and add a `Panel Group Layout` component in its place.
8. Set the `layout` attribute on the `Panel Group Layout` to `scroll`.
9. Add a `Facet Ref` component inside the `Panel Group Layout` and specify the same name that you used to declare the facet in step 3. The template displays the facet as shown in Figure 20–7.

Figure 20–7 New Page Template File

10. Save the template file.

You can now create customizable pages based on this template. Once you create a page, you can add a `Panel Customizable` or `Layout Customizable` component inside the facet displayed on the new page. You can then add page content within the `Panel Customizable` or `Layout Customizable` component.

20.1.8 How to Enable Customization in a Populated Page

When you have an existing ADF application with JSPX pages that are populated with content, and you want to enable customization, you can do so by moving all content inside a `Page Customizable` component.

You must first add the `Page Customizable`, then a `Layout Customizable`, and then the required hierarchy of `Panel Customizable` and `Show Detail Frame` components. Drag each of the existing components and drop them onto suitable locations inside the `Page Customizable`.

Notes:

- Ensure that the `Page Customizable` component has only one direct child component.

  When you add multiple direct child components, only the first child component is rendered at runtime. The first child component is stretched to fit the page. All other direct child components are ignored and not rendered on the page.

- Use a `Layout Customizable` component only if you want to allow users to customize the layout at runtime. For static layouts, use an alternative component, such as a `Panel Group Layout` or `Panel Stretch Layout`

- For best results, move components using the Structure window and *not* by editing the source code.

20.1.9 What Happens When You Add Composer Components

When you add a `Page Customizable` component to the page, the following configurations are performed automatically:

- A default Resource Catalog definition file, `default-catalog.xml`, is configured in the application. The `default-catalog.xml` file is located in the *`Application_Root`*`/Portal/src/portal` directory. To add components to the default Resource Catalog available to end users of your application, see Chapter 16, "Creating and Managing Resource Catalogs."

  In a Framework application, the `default-catalog.xml` file is located in the *`Application_Root`*`/Portal/public_html/oracle/webcenter/portalapp/catalogs` directory out-of-the-box, even without creating a page and adding a `Page Customizable` component.

- A Resource Catalog Viewer is configured for the application. At runtime, Composer provides users the option to add resources from this viewer to the page.

- The `web.xml` file available in the *`Application_Root`*`/`*`Project_Name`*`/public_html/WEB-INF` directory is updated to configure the MDS JSP provider.

- The `ComposerChangeManager` is configured in the application's `web.xml` file. For more information, see Section 22.11, "Configuring the Persistence Change Manager."

- When you create an application, a minimal `adf-config.xml` file is also created. When you add a `Page Customizable` to an application page, the required configuration is added to the `adf-config.xml` file. For example, change persistence is configured in the `adf-faces-config` section in this file. For more information, see Section 22.11, "Configuring the Persistence Change Manager."

- The `DataBindings.cpx` file in the *`Application_Root`*`/Portal/adfmsrc/portal` directory, is updated to enable the presence of task flows on the page.

- The page definition file is updated with the binding for the Composer task flow, which is available as part of the WebCenter Portal extension JAR file. Example 20–2 shows the code in the page definition file after a `Page Customizable` component is added to an application page.

Example 20–2 Page Definition File After Adding Page Customizable Component

```
<?xml version="1.0" encoding="UTF-8" ?>
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel"
                version="11.1.1.57.95" id="rcpagePageDef"
                Package="portal.pageDefs">
  <parameters/>
  <executables>
    <variableIterator id="variables"/>
    <taskFlow id="pageeditorpanel"
              taskFlowId="#{pageEditorBean.pageEditorPanel}"
              xmlns="http://xmlns.oracle.com/adf/controller/binding"/>
  </executables>
  <bindings/>
</pageDefinition>
```

See Also: Section B.2, "Composer-Specific Files and Configurations" for information about files that are created or modified when you add Composer components.

20.1.10 What Happens at Runtime

At runtime, users can perform all the tasks described Section 18.3, "Customizing Capabilities in Page View Mode" and Section 18.4, "Editing Capabilities in Design View in Page Edit Mode."

Each Composer component provides runtime capabilities that are described in Section 18.6, "Composer Components."

Note: Runtime customizations that you perform on a page are not carried over when you deploy the application to a target server.

20.1.11 What You May Need to Know When Designing Editable Pages

When adding Composer components to your customizable page, consider the following:

- To enable users to edit a page in a secured application, you must explicitly grant Edit or Customize privileges on the page to the required users or roles. For more information about granting permissions, see Section 69.4, "Using the Role Manager Task Flow."
- To enable runtime customization of components, add only one `Page Customizable` to a page.

  Note: Do *not* add a second `Page Customizable` component to your page. Only the first `Page Customizable` component is picked up when you run the page.

- Ensure that the `Page Customizable` component has only one direct child component.

  When you add multiple direct child components, only the first one is rendered at runtime. The first child component is stretched to fit the page. All other direct child components are ignored.

- Place all components you want to be customizable within the `Page Customizable` component.
- To enable runtime editing, you *must* ensure that the `ID` attribute is defined on all components on the page. Runtime editing of components that have no `ID` value is not supported in Composer.

  If your page includes components with no `ID` value, then you may encounter problems while editing the page in Composer.
- To enable View mode user customization, place a `Show Detail Frame` component within a `Panel Customizable` component.
- Use a `Show Detail Frame` to enclose a single child only. If you must enclose multiple components in a `Show Detail Frame`, then place a grouping component, such as a `Panel Group Layout` or `Panel Customizable`, within the `Show Detail Frame` component and then place the ADF Faces components or other content within this grouping component.
- Portlets need not be placed within `Show Detail Frame` components. Portlets come equipped with a header and display options that are similar to `Show Detail Frame` components.

20.2 Designing Editable Pages Using Composer Components: Example

In this example, assume you want to create a page that is customizable at runtime. The page is named `MyPage.jspx` in a Framework application named `MyWebCenterApp`.

To create a customizable page:

1. Create a Framework application named `MyWebCenterApp` by performing the steps in Section 5.1, "What Are Application Templates?."
2. Create a JSPX page named `MyPage.jspx` by performing the steps in Section 5.3, "Adding Pages to a Portal."
3. Add a `Panel Stretch Layout` to `MyPage.jspx`.

   Note: The `Panel Stretch Layout` component stretches the child in the center facet to fill all the available space in the browser. This is true even if you resize the browser. Therefore, by placing your components within this child component, you can ensure that the customizable portion of your page occupies the complete browser area.

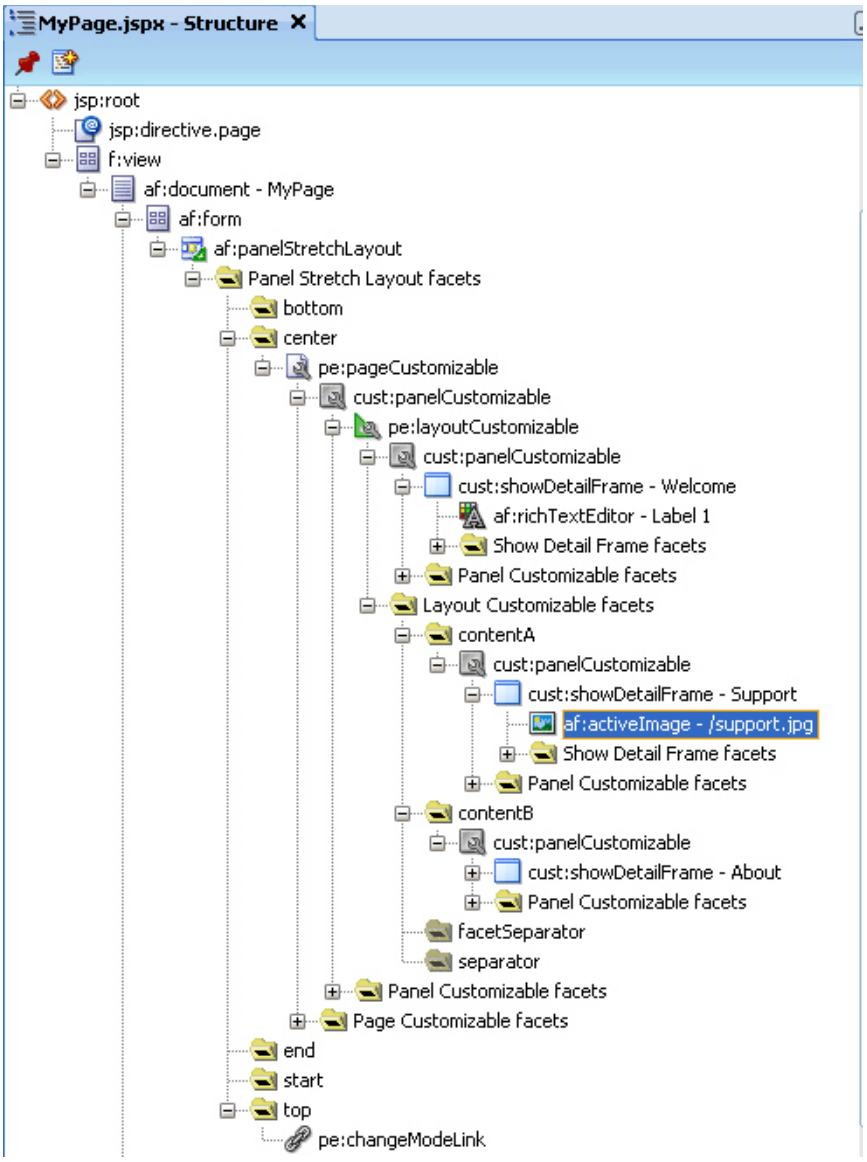
4. Add a `Page Customizable` to the center facet by following the steps in Section 20.1.2, "How to Enable Runtime Customization Using a Page Customizable."
5. Set the border color of the `Page Customizable` to `blue` to differentiate the editable area from other noneditable areas.

   Under the Style category in the Property Inspector for the `Page Customizable`, click the Box tab and set the `Border Color` attribute to `Blue`.
6. Set the border color of child `Panel Customizable` to `red`.

   Under the Style category in the Property Inspector for the `Panel Customizable`, click the Box tab and set the `Border Color` attribute to `Red`.

7. Add a `Change Mode Link` to the top facet of the `Panel Stretch Layout` by performing the steps in Section 20.1.3, "How to Enable Switching Between Page Modes Using a Change Mode Link or Change Mode Button."

8. Inside the `Panel Customizable` that is a direct child of the `Page Customizable`, add a `Layout Customizable` component by following the steps in Section 20.1.5, "How to Enable Layout Customization for a Page Using a Layout Customizable."



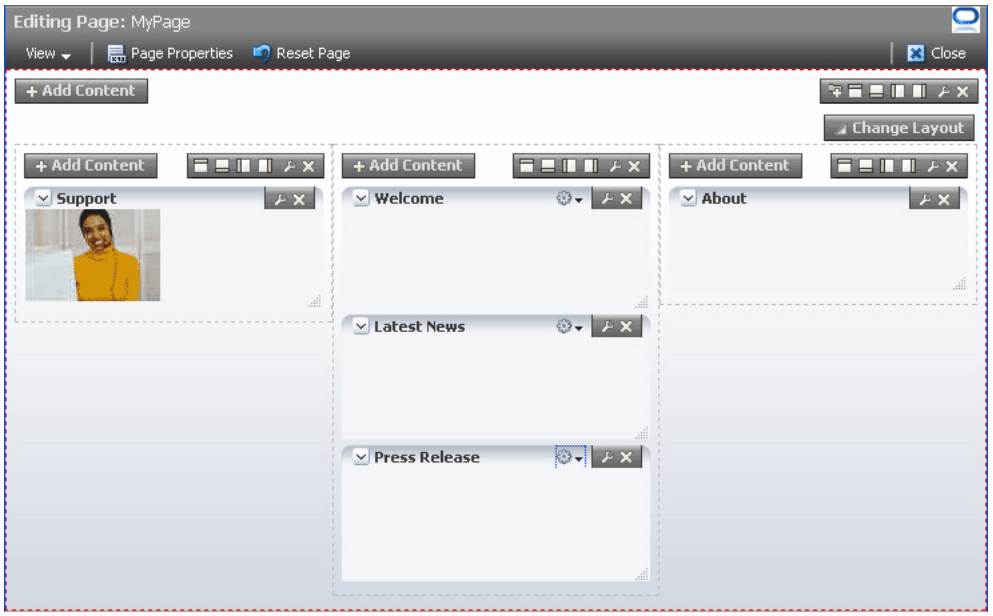
9. Add `Show Detail Frame` components inside each `Panel Customizable` on the page by performing the steps in Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components," and set the

10. For the sake of this example, add a `Rich Text Editor` and an `Image` component inside two of the `Show Detail Frame` components nested in the `Layout Customizable`.

    Drag and drop each of these components from the **ADF Faces** tag library to the required location on the page.

    The hierarchy of components on the page is as shown in Figure 20–8.

Figure 20–8 Component Hierarchy in MyPage.JSPX



11. Grant Edit or Customize permission on the page to the required users and roles. For more information about granting permissions, see Section 69.4, "Using the Role Manager Task Flow."

12. Run `MyPage.jspx`.

    The page opens in View mode. Click the **Edit** link on the page to enter Edit mode. The page opens in Composer. In Composer, you can perform all editing tasks described in Section 18.4, "Editing Capabilities in Design View in Page Edit Mode."

    Figure 20–9 shows how the page appears in Edit mode at runtime.

Figure 20–9 MyPage Opened in Composer

Composer

****

If your application is not configured with ADF security, then to use this sample page in other examples in this guide, configure ADF security on the application.

To configure security in your application:

1. Configure ADF Security with form-based authentication, generating a default login page.

   For more information, see Section 69.3, "Configuring ADF Security."

2. Create three users `ahunold`, `sking`, and `jdoe`.

   For the detailed procedure, see Section 69.2, "Creating an Application Role."

When you run `MyPage.jspx`, a login screen is displayed. You can log in with any of the three user names that you created.

20.3 Populating Pages with Content

After you create an editable page with the required Composer components, you can populate the page with content just like a regular JSPX page. However, there are certain limitations and recommendations that you must be aware of when adding content to your Composer-enabled page.

Populating editable pages at design time is like populating any other ADF Faces page. You can drag and drop components from different areas of the IDE onto the page. You can add components like portlets, task flows, and ADF Faces components.

When you drag and drop a component anywhere inside a `Page Customizable` component, the `Id` attribute is set to a unique value. The `Id` attribute is required for editing a component and persisting its changed state. When you add a component to a page at runtime, the `Id` attribute is set automatically.

20.3.1 What You May Need to Know When Adding Content to the Page

Consider the following when adding content to your editable page:

- Add components inside `Panel Customizable` components that are nested in the `Page Customizable` component. This ensures that the components can be edited at runtime.
- You can include any Oracle ADF Faces component or task flow as child component of a `Show Detail Frame` component. However, portlets contain headers similar to those provided by `Show Detail Frame` components and can be added to `Panel Customizable` components directly. There are no additional benefits to including portlets in `Show Detail Frame` components.
- For components that you want to make selectable in Source view in Composer, ensure that the component is compliant with rich client framework and generates a client side component.
- If your page has the ADF Faces components `Output Text` and `Output Formatted` nested inside a `Page Customizable` component, then ensure that you set the `clientComponent` attribute value. If this attribute value is not set, then you may encounter errors while trying to move or rearrange components on the page at runtime.
- To consume portlets in your editable page, you must first register the portlet producers with your application. See Chapter 64, "Consuming Portlets" for details.

20.3.1.1 Considerations for Adding Task Flows

Users can personalize, customize, and edit task flows that are added to a customizable page. In a secured application, users with Customize permission on the task flow can also edit components on the task flow's page.

Consider the following points when adding task flows to your customizable page:

- To provide a consistent user experience in terms of look and feel, layout design, and interaction, and to avoid problems, such as too much white space, too many scroll bars, or slow, jerky, and unpredictable responses when displaying large data sets, ensure that the task flows are created by following the guidelines in Appendix D, "Guidelines for Creating Task Flows to Be Used in Composer-Enabled Pages."
- In a secured application, to enable users to view task flow content in Composer, ensure that the task flow has a `TaskFlowPermission` grant in the application's `jazn-data.xml` file, with at least `View` action provisioned. You must set this explicitly as it is not enabled by default.
- In a secured application, to enable users to edit components on the task flow's page, ensure that the task flow has a `TaskFlowPermission` grant in the application's `jazn-data.xml` file, with `Customize` action provisioned. You must set this explicitly as it is not enabled by default.
- Ensure that you specify valid values for all required parameters on the task flow.

For more information, see Section 0.1, "Implementing Task Flow Security."

20.4 Troubleshooting Composer Problems

This section provides information to assist you in troubleshooting problems you may encounter while using Composer.

Configuring ADF Logging for Composer

While creating your applications in JDeveloper, you can use the JDeveloper debugging tools to easily find errors in your web pages or page definition files. You can also set up the Java logger to display Java diagnostic messages. For detailed information about configuring logging, see the chapter titled "Testing and Debugging ADF Components" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*. To configure logging for Composer, perform the tasks in that guide and ensure that the `oracle.adf.view.page.editor` and `oracle.adfinternal.view.page.editor` packages are configured in the `logging.xml` file, with the desired logging level.

Problem

When you run a page, the following error displays:

```
java.lang.IllegalStateException: The expression
"#{bindings.pageeditorpanel.regionModel}"
(that was specified for the RegionModel "value" attribute of the region component
with id "pePanel")
evaluated to null. This is typically due to an error in the configuration of the
objects referenced by this expression. If it helps, the expression
"#{bindings.pageeditorpanel}" evaluates to "null". If it helps, the expression
"#{bindings}" evaluates to "view_untitled1PageDef". Now using an empty RegionModel
instead.
```

Solution

This error occurs if a page containing the `Page Customizable` component does not have the required task flow binding in its page definition file. Ensure that the page definition file contains the following valid entry under the `<executables>` node:

```
<taskFlow id="pageeditorpanel"
taskFlowId="#{pageEditorBean.pageEditorPanel}"xmlns="http://xmlns.oracle.com/adf/c
ontroller/binding"/>
```

This error may also occur if your page is based on a page template and that page template contains the `Page Customizable` component. In such a case, the `af:pageTemplate` tag does not contain the `value="#{bindings.pageTemplateBinding}"` attribute.

Ensure that the page definition file has the following entry under the `<executables>` node:

```
<page path="view.pageDefs.templateDef1PageDef"
id="pageTemplateBinding" Refresh="ifNeeded"/>
```

Problem

Users cannot switch to Edit mode. The Edit link (`Change Mode Link` or `Change Mode Button`) appears disabled.

Solution

The user may have only view privilege on the page. Ensure that the user has the edit privilege on the page. For the page template on which the page is based, it is sufficient to have only view privilege.

Problem

Users encounter an exception while wiring events in the Component Properties dialog in Composer.

Solution

This error occurs if your application page includes both ADF Data Visualization components and Composer components.

Register the `DvtElementObjectFactory` class with the Oracle ADF `FactoryManager` object by adding the following code to the application class that gets loaded the earliest:

```
...
import oracle.adfdt.model.dvt.objects.DvtElementObjectFactory;
import oracle.adfdt.model.managers.FactoryManager;
...
static
{
FactoryManager.getInstance().registerFactory(new DvtElementObjectFactory());
}
```

21

Extending Runtime Editing Capabilities Using Composer

This chapter describes how to use Composer's declarative and programmable extensibility mechanism to customize runtime capabilities to suit your business needs. It contains the following sections:

- Section 21.1, "Overview of Extensibility Options"
- Section 21.2, "Creating Composer Add-Ons"
- Section 21.3, "Creating Custom Property Panels"
- Section 21.4, "Extending the Expression Builder"
- Section 21.5, "Configuring Custom LOVs or Pickers for Task Flow Parameters"
- Section 21.6, "Configuring Event Handlers for Composer UI Events"
- Section 21.7, "Configuring Drop Handlers in the Resource Catalog"
- Section 21.8, "Defining Property Filters"
- Section 21.9, "Enabling Parameter Support on the Customization Manager Task Flow"
- Section 21.10, "Customizing the Composer Toolbar"
- Section 21.11, "Enabling Direct Select in Design View"
- Section 21.12, "Troubleshooting Problems with Composer Extensibility Features"

21.1 Overview of Extensibility Options

Composer provides a framework on which to build customizable application pages. In addition to its default capabilities, you can extend the Composer framework to augment the runtime capabilities available to end users. You must configure the extensions in your application's `adf-config.xml` file and the Composer extension file, `pe_ext.xml`. For information about these files, see Section 21.1.8, "Configuration Files."

This section describes the options available for extending Composer runtime capabilities declaratively. It contains the following subsections:

- Section 21.1.1, "Composer Add-Ons"
- Section 21.1.2, "Composer Custom Property Panels"
- Section 21.1.3, "Composer Events Handlers"
- Section 21.1.4, "Drop Handlers."

- Section 21.1.5, "Component Property Filters"
- Section 21.1.6, "Customization Manager"
- Section 21.1.7, "Composer Toolbar Customization"

21.1.1 Composer Add-Ons

The default view of the Composer toolbar (Figure 21–1) includes the following buttons:

- **View**: Allows the user to switch between Design and Source view.
- **Page Properties**: Opens the Page Properties dialog, allowing the user to edit metadata for the host page.
- **Reset Page**: Reverts any changes made to the page in the current edit session.
- **Close**: Exits Design view and returns the user to the standard UI.

Figure 21–1 Default Add-Ons on the Composer Toolbar

Composer

****

The Page Properties and Reset Page buttons are examples of add-ons. Click these buttons to display panels for editing page properties and resetting page customizations. Typically, add-ons are custom task flows that are rendered as buttons on the Composer toolbar in page Edit mode. You can create add-ons that appear along with the Page Properties and Reset Page add-ons. For example, you can create an add-on to display page revision history so that it displays a Revisions button on the Composer toolbar. Clicking this button would display the page's revision history. You can also replace the Page Properties and Reset Page add-ons with custom add-ons that you create.

The process of configuring custom add-ons includes creating the task flows, packaging them into JAR files, and defining them in the Composer extension file. For more information, see Section 21.2, "Creating Composer Add-Ons."

21.1.2 Composer Custom Property Panels

The Component Properties dialog displays categories of attributes on different tabs. Each tab can be referred to as a property panel. The default Component Properties dialog in Composer is analogous to the Oracle JDeveloper Property Inspector. You can create and register custom property panels for a component, populate them with component properties, and display them as tabs along with the default tabs in the Component Properties dialog.

The process of configuring custom property panels includes creating them as task flows, packaging them into JAR files, and defining them in the Composer extension file. For more information, see Section 21.3, "Creating Custom Property Panels."

21.1.3 Composer Events Handlers

Composer provides an intuitive user interface for editing pages at runtime. This includes such UI components as the Save, Close, and Delete buttons. When a user

clicks a button or icon in Composer, an event handler ensures that a specific action is performed. An event handler is the code that is called back by Composer when a Composer event is invoked. Each UI event in Composer is associated with an event handler. Sometimes it may be necessary to augment Composer's innate capabilities by performing a different action or multiple actions on invoking an event. For example, when a user clicks Save, in addition to the save operation that Composer provides by default, you might want to configure the application to perform additional tasks such as cleaning up cached information and connections to resources. You can accomplish this with event handlers. For more information, see Section 21.6, "Configuring Event Handlers for Composer UI Events."

21.1.4 Drop Handlers

The Resource Catalog provides resources that users can add to their pages. An Add link next to a resource name enables users to add it to the page. Composer provides *drop handler*s to handle the add operation in the catalog. By default, a drop handler is configured for each resource in the catalog. If you want to provide complete control of the drop action to the resource, you can create additional drop handlers for that resource. The Add link then displays a context menu with different options for adding the resource to the page. You can create one or more drop handlers to handle different flavors for resources in your catalog.

You can add the following types of drop handlers:

- Java classes registered with Composer and called when users click an Add link in the Resource Catalog. In this case, the resource is added to the page based on the data flavor selected.
- Task flows registered with Composer and called when users click an Add link in the Resource Catalog. In this case, a task flow is invoked, which enables users to decide what information from the resource must be displayed on the page.

For more information, see Section 21.7, "Configuring Drop Handlers in the Resource Catalog."

21.1.5 Component Property Filters

The Component Properties dialog displays properties of a selected component. By default, Composer filters certain component properties and displays a subset of properties to users. You can define filters declaratively to further hide properties that the user need not see, or to show properties that are hidden. For more information, see Section 21.8, "Defining Property Filters."

21.1.6 Customization Manager

Customization Manager is a task flow that enables users to download, upload, reset, and delete application customizations on objects like pages and task flows. You can configure the Customization Manager either in Composer or outside of it, on some administrative page. For information about configuring and using Customization Manager, see Section 21.9, "Enabling Parameter Support on the Customization Manager Task Flow."

21.1.7 Composer Toolbar Customization

The default Composer toolbar displays elements on two rows. The first row displays the page name and status indicator, and the second row displays the View menu, Page Properties button, Reset Page button, and Close button, as shown in Figure 21–2.

Figure 21–2 Composer Toolbar with Default Elements

You can customize the toolbar by adding, deleting, or rearranging elements. You can also override existing elements with custom elements. For example, you can remove the message showing the page name if you do not want users to see the name of the page they are editing.

For information about customizing the Composer toolbar, see Section 21.10, "Customizing the Composer Toolbar."

21.1.8 Configuration Files

Before you start with the extensibility configurations described in this chapter, there are two important configuration files that you must know about. Most of the extensions discussed in this chapter are defined in these files:

- Composer extension file (`pe_ext.xml`)

  The Composer extension file, `pe_ext.xml`, enables you to extend the editing capabilities provided by Composer. Within this file you can add elements to register new Composer add-ons and custom property panels, selectively render panels, register event handlers, and define property filters. The `pe_ext.xml` file is not available in your application by default. You must create it the first time you perform such tasks as including add-ons, property panels, or event handlers. Create this file in the `META-INF` directory under the project's Web context root or in the *`application_home/project`*`/src/META-INF` directory. When you run the application, the `pe_ext.xml` file is picked up from the JAR file included in the application classpath. Your application can include more than one extension file. However, you must ensure that the JARs containing the extension files are available on the application classpath so that the `pe_ext.xml` files are picked up for processing. Every JAR with a `pe_ext.xml` in its `META-INF` folder is processed, and the Composer extensions are loaded and combined. For information about the different elements you can define in `pe_ext.xml` to extend Composer capabilities, see Section B.2.1, "pe_ext.xml."

- Application's `adf-config.xml` file

  The `adf-config.xml` file specifies application-level settings that are usually determined at deployment and often changed at runtime. When you perform such tasks as registering new add-ons and custom property panels in Composer, or creating customization layers, you must add appropriate entries in the `adf-config.xml` file. The `adf-config.xml` file is created automatically when you create an application, and when you add a `Page Customizable` component to the page, certain configurations are added to this file.

  For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

21.2 Creating Composer Add-Ons

Composer provides the following default add-ons for runtime editing:

- Page Properties

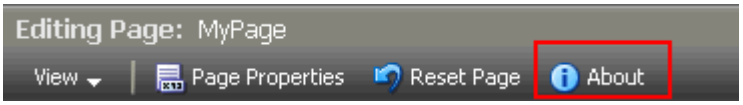
This dialog opens when users click the Page Properties button on the Composer toolbar. The Page Properties dialog displays the current page's properties and enables users to modify property values.

- Reset Page

  The Reset Page dialog opens when users click the Reset Page button on the Composer toolbar. The Reset Page dialog enables users to remove application customizations made to a page and reset it to a previously-saved version or to its original out-of-the-box state. For more information, see Section 18.4.11, "Reset Page."

In addition to these, you can register new add-ons with Composer. For example, you can create an add-on to display page revision history so that it displays a Revisions button on the Composer toolbar. Clicking this button would display the page's revision history.

This section contains the following topics:



- Section 21.2.1, "How to Create and Register Add-Ons"
- Section 21.2.2, "What Happens at Runtime"
- Section 21.2.3, "How to Exclude Composer Default Add-Ons"
- Section 21.2.4, "How to Display the Customization Manager Add-On"
- Section 21.2.5, "How to Selectively Display Add-Ons"

21.2.1 How to Create and Register Add-Ons

You can create and register custom task flows that can be invoked from buttons on the Composer toolbar. All registered add-ons have an associated button that displays on the toolbar.

This section steps through the procedure of creating an add-on and registering it with Composer. It includes an example that demonstrates how to create an add-on that displays information about the application. The example add-on renders an **About** button on the Composer toolbar (Figure 21–3) that users can click to invoke a task flow that contains information about the application.

Figure 21–3 About Button on the Composer Toolbar

This section contains the following subsections:

- Section 21.2.1.1, "Creating an Add-On Task Flow"
- Section 21.2.1.2, "Registering Add-Ons with Composer"
- Section 21.2.1.3, "Registering Add-Ons in adf-config.xml"

21.2.1.1 Creating an Add-On Task Flow

Composer add-ons are task flows you create using JSPX pages or page fragments.

To create an add-on:

1. In your application project, create a JSFF file called `custompanelview.jsff`:

a. From the **File** menu, select **New**.

b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page** or **JSF Fragment**.

c. Click **OK**.

2. Design the fragment by adding code similar to what is shown in Example 21–1.

Example 21–1 Sample code in the JSFF Fragment

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:panelGroupLayout id="pnlgrp1" layout="vertical" halign="center">
    <af:spacer id="sp1" height="20" />
    <af:image id="customimage"
              source="/images/DemoLogo.jpg"
              shortDesc="Demo Logo"/>
    <af:spacer id="sp2" height="20"/>
    <af:outputText id="output1" value="This is a sample shopping cart application
based on Oracle ADF Framework.
It also uses the Oracle WebCenter Portal: Framework to enable collaboration,
application customization and user customization features."/>
    <af:spacer id="sp3" height="20"/>
    <af:outputText id="output2" value="Build : 11.1.1"
                   inlineStyle="font-weight:bold;"/>
  </af:panelGroupLayout>
</jsp:root>
```

Note: At runtime, the add-on panel is automatically sized to fit the content in this fragment.

3. Create a task flow definition called `custom-panel-task-flow`:

a. From the **File** menu, choose **New**.

b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **ADF Task Flow**.

c. Click **OK**.

4. Drop the `custompanelview.jsff` fragment that you created onto the task flow definition.

See Also: "Getting Started with ADF Task Flows" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* for information about creating task flows.

5. Save the task flow definition file.

Optionally, if you create the task flow in one application but want to consume it in another application, you must first package the task flow in an ADF library and add the resulting JAR in the consuming application.

To package the task flow in an ADF library:

1. Create a deployment profile for the task flow:

a. Right-click **Portal** project and choose **New**.

b. In the New Gallery, expand **General**, select **Deployment Profile**, and then **ADF Library JAR File**, and click **OK**.

c. In the Create Deployment Profile -- ADF Library JAR File dialog, enter a name for your deployment profile and click **OK**.

d. In the ADF Library JAR Deployment Profile Properties dialog, click **OK**.

e. In the Project Properties dialog, click **OK**.

2. In the Application Navigator, right-click the project folder, choose **Deploy**, *deployment profile name*, **to**, and then choose **to ADF Library JAR file**. This creates a **deploy** folder including the JAR file, in the project folder located at `<Application_Root>\Portal\deploy\`.

You can add this JAR file to any application in which you want to consume the add-on.

21.2.1.2 Registering Add-Ons with Composer

After you create the task flows, you must register them with Composer so that they are displayed on the Composer toolbar along with the default options.

To register an add-on with Composer:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *APPLICATION_HOME*`\Portal\src\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<addon-config>` element in the file, with a nested `<panels>` element.

3. Add one `<panel>` element for each task flow that you want to register as an add-on.

   Any number of panels can be declared under the `<panels>` element in the extension file.

   Example 21–2 shows the code of the extension file with a `<panel>` entry.

Example 21–2 Composer Extension File

```
<?xml version="1.0" encoding="US-ASCII" ?>
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <panels>
      <panel name="oracle.custom.panel" title="About"

icon="http://myforums.oracle.com/jive3/images/question-pts-available-16x16.gif"

taskflow-id="/WEB-INF/custom-panel-task-flow.xml#custom-panel-task-flow" />
    </panels>
  </addon-config>
</pe-extension>
```

For more information about the `addon-config` and other nested elements, see Section B.2.1.1, "addon-config."

4. Optionally, register event handlers for the custom panel by adding an `event-handlers` element within the `panel` element as shown in the following example:

```
<event-handlers>
  <event-handler event="close">
    oracle.custom.TaskFlowEventHandler
  </event-handler>
</event-handlers>
```

   For more information, see Section 21.6, "Configuring Event Handlers for Composer UI Events."

5. Save the `pe_ext.xml` file.

21.2.1.3 Registering Add-Ons in adf-config.xml

To register an add-on, you must add a reference to it in the application's `adf-config.xml` file. Add the `addon-panels` entry to define new add-ons.

To register add-ons in the `adf-config.xml` file:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the following namespace within the `adf-config` element in the file:

```
xmlns:pe="http://xmlns.oracle.com/adf/pageeditor/config"
```

3. Add a `<pe:page-editor-config>` entry with the namespace and include `<pe:addon-panels>` inside it.

   When you register a custom add-on, the default add-ons are not displayed in Composer by default. To display all the default add-ons, you must set the `show-default-addons` attribute on the `<pe:addon-panels>` tag to `true`. The default value for this attribute is `false`.

   Within `<pe:addon-panels>`, add `<pe:addon-panel>` entries for the new panels, as shown in Example 21–3.

   The `name` attribute must contain the name you used to register the panel in the Composer extension file.

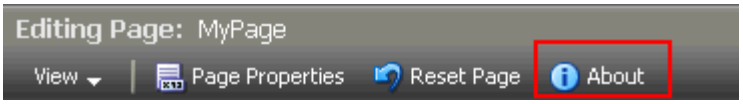
Example 21–3 New Add-On Referenced in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">

    <pe:addon-panel name="oracle.custom.panel" />

  </pe:addon-panels>
</pe:page-editor-config>
```

> **Note:** If you do not specify any `<addon-panel>` entries under `<addon-panels>`, then only the default options are displayed in Composer.



For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

21.2.2 What Happens at Runtime

Custom add-ons that you register with Composer are rendered on the Composer toolbar along with the default add-ons.

In the example, an About button is rendered on the Composer toolbar (Figure 21–4).

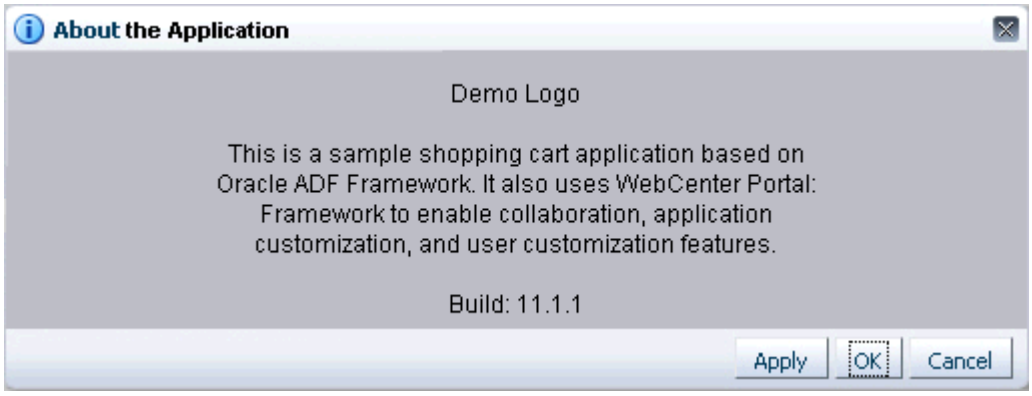


Figure 21–4 About Button in Composer Toolbar

Clicking this button displays the About the Application task flow (Figure 21–5).

> **Note:** The add-on panel is automatically sized to fit the content inside the task flow.

Figure 21–5 About the Application Task Flow

21.2.3 How to Exclude Composer Default Add-Ons

You can choose to show or hide the Page Properties, Reset Page, and Customization Manager buttons on Composer toolbar. To hide any of these add-ons, you must set the `show-default-addons` attribute on `<pe:addon-panels>` to `true`, add an entry for the default add-on you want to hide, and set the `rendered` attribute on that add-on to `false`.

Example 21–4 shows the code to hide the Page Properties add-on.

Example 21–4 The adf-config.xml File with the Reset Page Option Excluded

```
<pe:addon-panels show-default-addons="true">
  <!-- Hide the Reset Page add-on -->
  <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.page-reset"
rendered="false"/>

  . . .

</pe:addon-panels>
```

The excluded add-on (Reset Page) is not displayed on the Composer toolbar. The other default add-ons are displayed on the toolbar in the default order.

21.2.4 How to Display the Customization Manager Add-On

The Customization Manager is a Composer add-on that enables users to manage application customizations on task flows, pages, and page fragments on a given page. For more information, see Section 18.4.14, "Manage Application Customizations."

The Customization Manager add-on is available in the Composer library, but is not rendered by default. You can enable it by configuring it in your application's `adf-config.xml` file using a `<pe:addon-panel>` element inside `<pe:page-editor-config>`, as shown in the following example:

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">
    <pe:addon-panel
name="oracle.adf.pageeditor.addonpanels.customization-manager"/>

    . . .

  </pe:addon-panels>
  . . .
</pe:page-editor-config>
```

This configuration ensures that the Composer toolbar displays the Customization Manager button as shown in Figure 21–6.

Figure 21–6 Customization Manager Button

21.2.5 How to Selectively Display Add-Ons

Depending on your business requirement, you may need to selectively hide the add-ons available to different users in Composer. To selectively hide an add-on, you must set the `show-default-addons` attribute on `<pe:addon-panels>` to `true`, add an entry for the default add-on you want to hide, and set the `rendered` attribute for that add-on to `false` using an EL expression, as shown in Example 21–5.

Example 21–5 rendered Attribute Setting in the adf-config.xml File

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels show-default-addons="true">
    <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.page-reset"
                    rendered="#{securityBean.userInPageResetRole}" />
    . . .
  </pe:addon-panels>
  . . .
</pe:page-editor-config>
```

In this example, the `securityBean` backing bean returns either `true` or `false`, depending on the role of the logged-in user. If the returned value is `false`, Composer does not display the Reset Page button on the Composer toolbar. If the returned value is `true`, Composer displays the Reset Page button.

Note: If you hide the Reset Page button on the Composer toolbar, the Reset Task Flow button displayed while editing task flow content is also hidden.

The default value for `rendered` is `true`. That is, if you do not specify a `rendered` attribute for an add-on, the add-on is always displayed.

21.3 Creating Custom Property Panels

Composer displays the properties of a component in the Component Properties dialog when a user clicks the **Edit** icon on the component. The Component Properties dialog provides a series of tabs. Each tab displays a group of related attributes. The attributes have associated values that control a component's behavior and visual style properties. For example, the Style tab displays the component's style-related properties, such as width, height, and background color.

Similarly, when a user clicks the **Page Properties** button, a Page Properties dialog opens with its own series of tabs. These tabs contain display-related page properties, page parameters, and security settings.

You can create and register custom property panels to render along with the tabs displayed in the Component Properties or Page Properties dialog. In addition, you can remove the default panels or replace them with custom property panels. For example, you can develop a friendlier property panel for an `Image` component by displaying a picker for its `Source` property. This would make it easier for users to select an image from the available options.

This section describes how to create custom property panels. It also describes how to exclude, override, and selectively render default property panels. It contains the following subsections:

- Section 21.3.1, "How to Create and Register Custom Property Panels"
- Section 21.3.2, "What Happens at Runtime"
- Section 21.3.3, "How to Override Default Property Panels"
- Section 21.3.4, "How to Exclude Default Property Panels"
- Section 21.3.5, "How to Selectively Render Property Panels"
- Section 21.3.6, "How to Display Properties and Parameters in a Custom Property Panel"

21.3.1 How to Create and Register Custom Property Panels

Creating a custom property panel is similar to creating an add-on. That is, you create custom property panels as task flows and register them in the Composer extension file. However, while Composer add-ons are configured using the `addon-panels` element in the `adf-config.xml` file, custom property panels are configured using the `property-panels` element in the extension file itself.

You can configure a custom property panel to display in the Component Properties dialog always. Alternatively, you can configure the panel to display only when a particular component or task flow is selected for editing.

This section describes how to create and register a custom property panel. It contains the following subsections:

- Section 21.3.1.1, "Creating a Custom Property Panel"

- Section 21.3.1.2, "Registering a Custom Property Panel for a Component"
- Section 21.3.1.3, "Registering a Custom Property Panel for a Task Flow"

21.3.1.1 Creating a Custom Property Panel

Property panels provide a means of editing page or component properties. For example, a user can click the **Edit** icon on a selected task flow and modify its parameter values and change its visual attributes in the Component Properties dialog.

Composer enables you to associate property panels with components and task flows. When a user clicks the **Edit** icon on the component or task flow, Composer opens the Component Properties dialog and displays the custom property panels you associated with the object along with the default property panels.

The steps for creating a custom property panel and declaring it in the Composer extension file are similar to those for creating and declaring Composer add-ons. For detailed information, see Section 21.2.1.1, "Creating an Add-On Task Flow" and Section 21.2.1.2, "Registering Add-Ons with Composer."

Example 21–6 shows a sample property panel declaration in the `pe_ext.xml` file.

Example 21–6 Custom Property Panel Declaration in pe_ext.xml

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <panels>
      <panel name="sample-panel" title="Sample Panel"
             taskflow-id="/WEB-INF/sample_task_flow.xml#sample_task_flow"/>
    </panels>
  </addon-config>
</pe-extension>
```

After you create a custom panel and declare it in the `pe_ext.xml` file, you must configure it using the `<property-panels>` element, as shown in Example 21–7. This ensures that the panel displays automatically in the Composer Component Properties and Page Properties dialog.

Example 21–7 Custom Property Panel Configuration in pe_ext.xml

```
<addon-config>
  <panels>
    . . .
  </panels>
  <property-panels>
    <property-panel name="samplepanel">
      <panel name="sample-panel" rendered="true"/>
    </property-panel>
  </property-panels>
</addon-config>
```

Use one `<panel>` element to register each custom panel. A `<panel>` corresponds to a tab in the Component Properties dialog. You can add any number of `<panel>` elements.

21.3.1.2 Registering a Custom Property Panel for a Component

When you register a custom panel in the extension file, you can associate the panel with a component or a task flow. The custom property panel then renders only for that component or task flow. This section describes how to register a property panel for a specific component.

To register a property panel for a component:

1. Create a Composer extension file, `pe_ext.xml`, if it does not already exist.

   For information about creating the extension file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

2. Add a `<property-panels>` element inside the `<addon-config>` section in the `pe_ext.xml` file.

3. Add a `<property-panel>` declaration within the `<property-panels>` element.

   You can have multiple `<property-panel>` entries.

4. Within the `<property-panel>` element, add a `<component>` element to specify the runtime class name of the component (optional) and a `<panel>` element to specify the name you used to declare the panel in the `<addon-config>` section of the file.

   Example 21–8 shows a custom property panel that is associated with a `Command Button` component by specifying the component's fully qualified class name. For information about Oracle ADF components and their runtime classes, see *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

Example 21–8 Code to Register a Property Panel for a Component

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="cmdbtn">

<component>oracle.adf.view.rich.component.rich.nav.RichCommandButton</component>
        <panel name="prop.panel.cmdbtn" />
        <panel name="prop.panel.generic" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

> **Note:** When registering a property panel, if you do not associate it with a component or task flow (discussed in the next section), the registered panel is rendered at all times in the Component Properties and Page Properties dialogs.
>
> To configure multiple property panels for a component, you can include multiple `<panel>` elements within a `<property-panel>` element. For more information about the `<property-panels>` element and its nested elements, see Section B.2.1.2, "property-panels."

All the default panels, such as Child Components, Style, and Parameters, are displayed along with the custom panels you define.

21.3.1.3 Registering a Custom Property Panel for a Task Flow

You can define a custom property panel for a task flow by registering it with the Composer extension file. Example 21–9 shows the sample code used to register a custom property panel for a task flow.

A custom property panel registered for a specific task flow appears only when its associated task flow is selected. Otherwise, default property panels appear.

> **Note:** Use task flow-specific custom property panels only to customize task flow parameters or any other aspect related to how the task flow works.
>
> A custom property panel does not function if it is associated with a task flow rendered using the Oracle JSF Portlet Bridge.

To register a property panel for a task flow:

1. Add a `<property-panels>` element within the `<addon-config>` element in the `pe_ext.xml` file.

   For information about creating the extension file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

2. Add a `property-panel` declaration within this.

   You can have multiple `property-panel` entries.

3. Add `taskflow-id` and `panel` elements within the `property-panel` element.

   Add the `taskflow-id` element to specify the task flow name. Add the `panel` element to specify the name you used to declare the property panel in the `addon-config` section of the file.

   Example 21–9 shows a custom property panel associated with a `dashboard` task flow.

Example 21–9 Code to Register a Property Panel for a Task Flow Instance

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="dashboard">
        <taskflow-id>/WEB-INF/dashboard-taskflow#prop-panel</taskflow-id>
        <panel name="dashboard.prop-panel" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

Notes:

- If you do not associate a custom property panel with a component or task flow (using the `<component>` or `<taskflow-id>` tag), then the registered panel is rendered for all pages, task flows, and components in the Component Properties and Page Properties dialogs.

  You can register multiple `panel` elements within a `property-panel` element. For more information about the `property-panels` element and its nested elements, see Section B.2.1.2, "property-panels."

- To enable end users to edit the attributes and parameters on a custom property panel, in the panel's task flow fragment you must add a `Show Property` components for each property that you want to expose. The value attribute on a `Show Property` component is tied to a managed bean that contains the logic to read and write values for the properties and parameters. For more information, see Section 21.3.6, "How to Display Properties and Parameters in a Custom Property Panel."

21.3.2 What Happens at Runtime

If you associated the custom property panel with a specific component or task flow, at runtime the panel renders as a tab in the Component Properties dialog invoked from the specified component or task flow. If you did not associate the custom property panel with a specific component or task flow, at runtime the custom property panel renders as a tab in both the Page Properties and Component Properties dialogs for all pages, components, and task flows.

Note: In the Component Properties and Page Properties dialogs, custom panels are sized by the tab component containing the task flows. The size of the tab component itself is determined by a rule in the currently-applied skin. This rule is called `af|panelTabbed.Tab`.

21.3.3 How to Override Default Property Panels

The Component Properties dialog in Composer displays the following panels by default: Display Options, Child Components, Events, Style, Content Style, and Parameters. You can override a particular panel by using the default panel's name when you declare and register the custom panel in the `pe_ext.xml` file. For information about the default panels, see Section B.3, "Composer Default Add-Ons and Property Panels."

Example 21–10 shows the code to override the Display Options panel with a panel defined using a task flow called `custom-panel-task-flow`.

Example 21–10 Sample Code to Override a Default Panel

```
<addon-config>
  <panels>
    <panel name="oracle.adf.pageeditor.pane.generic-property-inspector"
title="Sample Panel"

icon="http://myforums.oracle.com/jive3/images/question-pts-available-16x16.gif"
```

```
taskflow-id="/WEB-INF/custom-panel-task-flow.xml#custom-panel-task-flow" />
  </panels>
  <property-panels>
    <property-panel name="samplepanel">
      <panel name="oracle.adf.pageeditor.pane.generic-property-inspector"
rendered="true"/>
    </property-panel>
  </property-panels>
</addon-config>
```

21.3.4 How to Exclude Default Property Panels

Out-of-the-box, all default property panels are displayed along with custom property panels that you configure. To hide a default property panel in the Page Properties or Component Properties dialog, you can add a line specifically for that panel and and set the `rendered` attribute to `false`.

Example 21–11 shows the `rendered` attribute set to `false` for the Content Style property tab of a `Command Button` component. For information about default property panels, see Section B.3, "Composer Default Add-Ons and Property Panels."

Example 21–11 rendered Attribute for a Property Panel

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <addon-config>
    <property-panels>
      <property-panel name="cmdbtn">
        <component>oracle.rich.CommandButton</component>
        <panel name="prop.panel.cmdbtn" />
        <panel name="oracle.adf.pageeditor.pane.content-style-editor"
rendered="false" />
      </property-panel>
    </property-panels>
  </addon-config>
  . . .
</pe-extension>
```

21.3.5 How to Selectively Render Property Panels

Custom property panels registered in the application are rendered in the Component Properties dialog when users click the **Edit** icon on a specified component. You can configure your application to render a property panel selectively based on different criteria like the role of a logged-in user, the page being viewed, and so on. To display property panels selectively, you can use an EL value in the `property-panel`'s `rendered` attribute as shown in the following example:

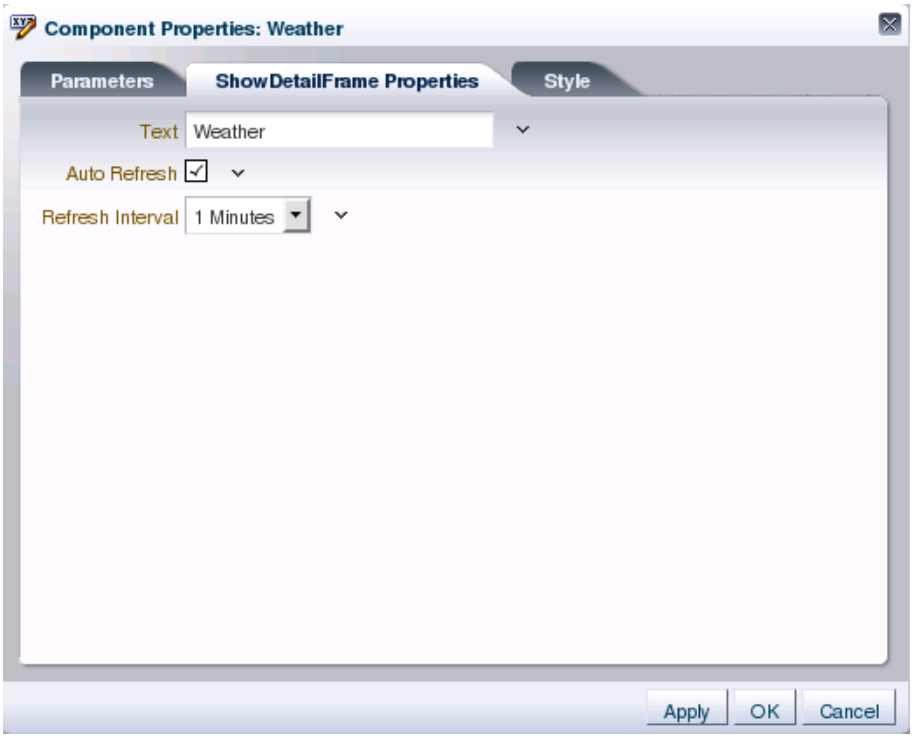
```
<property-panel name="global-but-just" rendered="#{bean.showProperty}">
```

21.3.6 How to Display Properties and Parameters in a Custom Property Panel

If you are building a custom property panel for a component, you can use `Show Property` components, available from the Composer tag library, to expose the component's attributes on the custom panel. In the page fragment defining the custom panel task flow, you must add one `Show Property` component for each attribute that you want to expose. `Show Property` is a declarative component that reads a property value on the component or task flow (for which you have created the custom panel), and displays an input field for that property in the custom panel. Users can edit property values in the panel using the input fields.

For more information about custom panels, see Section 21.3.1.1, "Creating a Custom Property Panel."

To add a `Show Property` component:



1. Open the page fragment that you created for the custom panel task flow.
2. From the Component Palette, select **Composer**.
3. Drag and drop a `Show Property` component for each component attribute that you want to expose in the custom panel.
4. To ensure that the attribute displays correctly in the custom panel, set the attributes on each `Show Property` component by referring to Section B.1.7, "Show Property."

> **Note:** You can use the `Show Property` component even on pages outside of Composer.

Example

Consider an example of a weather widget that is included inside a `Show Detail Frame` component. A custom property panel is created to enable users to edit the Text, Auto Refresh, and Refresh Interval attributes on the weather widget. It includes three fields for users to provide values for these attributes. To enable users to set the three attributes on the weather widget, one `Show Property` component is added for each attribute that is exposed in the panel. When a user edits the weather widget at runtime, the Component Properties dialog displays the custom panel with the three attributes, as shown in Figure 21–7.

Figure 21–7 Custom Panel to Display Show Detail Frame Component Properties

The weather widget is consumed in a page along with a `Poll` component as shown in the following example:

```
<cust:showDetailFrame text="Weather" id="sdf1" contentStyle="height:220.0px;"
                      partialTriggers="p1">
  <af:region value="#{bindings.weathertaskflowdefinition1.regionModel}"
             id="r1"/>
  <af:poll id="p1" interval="60000"/>
</cust:showDetailFrame>
```

The `Poll` component is used to deliver refreshed content to the weather widget at fixed intervals. The default interval is 60000 milliseconds.

The custom panel contains three `panelLabelandMessage` components to provide input fields for the `Text`, `Auto Refresh`, and `Refresh Interval` attributes. The fields on this panel are implemented as follows:

- A `showProperty` component is added to each `panelLabelandMessage` component as shown in the following example:

  ```
  <!-- Input field for setting the Text attribute, which displays on the
  component header -->
  <af:panelLabelAndMessage label="Text" id="plam2">
    <pedc:showProperty label="Text" id="sp1" simple="true"
                       value="#{sdfCustomPanel.text}"/>
  </af:panelLabelAndMessage>

  <!-- Checkbox to enable auto refresh, which controls whether the widget must be
  refreshed -->
  <af:panelLabelAndMessage label="Auto Refresh" id="plam3">
    <pedc:showProperty label="Auto Refresh" id="sp2" simple="true"
                       type="boolean" autoSubmit="true"
                       value="#{sdfCustomPanel.autoRefresh}"/>
  </af:panelLabelAndMessage>

  <!-- LOV to display values for Refresh Interval when auto refresh is enabled
  -->
  <af:panelLabelAndMessage label="Refresh Interval" id="plam4">
    <pedc:showProperty label="Refresh Interval" id="sp3" simple="true"
                       type="list" disabled="#{!sdfCustomPanel.autoRefresh}"
                       value="#{sdfCustomPanel.refreshInterval}"
                       selectItems="#{sdfCustomPanel.selectItems}"

  binding="#{sdfCustomPanelRequestBean.refreshIntervalShowProp}"/>
  </af:panelLabelAndMessage>
  ```

  where `sdfCustomPanel` references a managed bean, `SDFCustomPanelBean.java`.

- The task flow definition of the custom panel contains a reference to the bean:

  ```
  <managed-bean id="mb1">
    <managed-bean-name id="mb1_name">sdfCustomPanel</managed-bean-name>
    <managed-bean-class id="mb1_
  class">portal.weather.panel.SDFCustomPanelBean</managed-bean-class>
    <managed-bean-scope id="mb1scope">session</managed-bean-scope>
  </managed-bean>
  ```

- The `SDFCustomPanelBean.java` bean provides the logic to handle values for the different attributes exposed in the panel. In the bean, the `SelectionContext` API is used to read and write values for each attribute as follows:

- Get hold of the selected component, that is, the component on which the properties are displayed; in this example, a `Show Detail Frame` component, as the weather widget is included inside one.
- Read the attribute value on the selected component.
- Get the attribute value that the user specifies and set that value for the component attribute.

For example, the `Refresh Interval` attribute is enabled only if `Auto Refresh` in selected, and it displays a dropdown menu with the values defined in the managed bean. The `Poll` component on the page is wired to the `Show Property` component so that the widget refresh is driven by the value of the Show Property component. The code to handle the value for the `Refresh Interval` property is as follows:

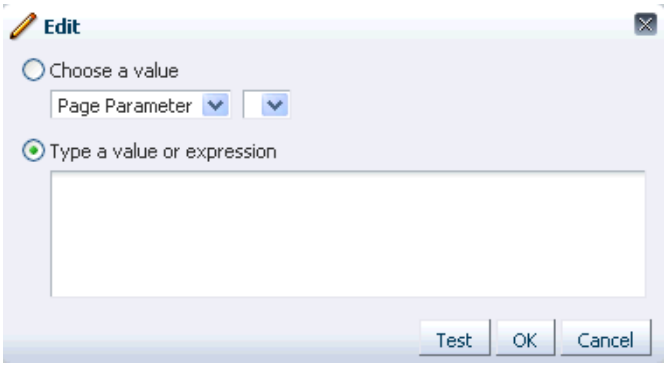
```
. . .
/** Set the refresh interval attribute value on the component
public void setRefreshInterval(String _refreshInterval)
{
  this._refreshInterval = _refreshInterval;
}
**/

public String getRefreshInterval()
{
  if (_autoRefresh == true && _refreshInterval != null)
    return _refreshInterval;

  // Get hold of the component whose properties you want to edit
  SelectionContext selCtx =
    Context.getCurrentInstance().getSelectionContext();
  UIComponent selComp = selCtx.getSelectedComponent().getUIComponent();
  if (selComp instanceof ShowDetailFrame)
  {
    // Get the refresh interval value specified for the Poll component
    RichPoll pollComp = (RichPoll) selComp.findComponent("p1");
    if (_autoRefresh == false)
      _refreshInterval = "Refresh interval not applicable";
    else if (pollComp.getInterval() < 0)
      _refreshInterval = "60000";
    else
      _refreshInterval = Integer.toString(pollComp.getInterval());
  }

  return _refreshInterval;
}
. . .
public List<SelectItem> getSelectItems()
{
  return _selectItems;
}
. . .
private static List<SelectItem> _selectItems;
static
{
  _selectItems = new ArrayList<SelectItem>();
  SelectItem si = new SelectItem("60000", "1 Minutes");
  _selectItems.add(si);
  si = new SelectItem("120000", "2 Minutes");
  _selectItems.add(si);
```

```
    si = new SelectItem("180000", "3 Minutes");
    _selectItems.add(si);
  }
```



- When a user selects a value for the `Refresh Interval` property and clicks Apply in the Component Properties dialog, the save listener is called and the `save` event handler ensures that the value is saved back to the bean. The relevant code in the save event handler implementation is as follows:

```
public void save()
{
  . . .
  if (_autoRefresh)
  {
    aa = new AttributeComponentChange("interval", Integer.parseInt(_
refreshInterval));
    changeManager.addComponentChange(context, pollComp, aa);
    aa.changeComponent(pollComp);
  }
  else
  {
    aa = new AttributeComponentChange("interval", new Integer(-1));
    changeManager.addComponentChange(context, pollComp, aa);
    aa.changeComponent(pollComp);
  }
}
```

21.4 Extending the Expression Builder

All properties on the Parameters and Display Options tabs in the Component Properties dialog can take Expression Language (EL) expressions. The Expression Builder option available on such parameters opens the Edit dialog, which is a simple expression builder as shown in Figure 21–8. The expression builder is particularly useful when you want a value that is retrievable but otherwise unknown, for example, when you want a value to be the name of the current user or the current application skin.

Figure 21–8 Expression Language Editor

You can customize the expression builder to provide more options by making the necessary entries in the Composer extension file, `pe_ext.xml`. You can also configure Composer to disable EL or protect existing EL from overwrite.

This section explains how to extend the expression builder to add custom capabilities. It contains the following subsections:

- Section 21.4.1, "How to Extend the Expression Builder"
- Section 21.4.2, "How to Protect Expression Language"
- Section 21.4.3, "What Happens at Runtime"

21.4.1 How to Extend the Expression Builder

You can extend the expression builder by adding custom options to the expression value dropdown list. Custom options must be defined and included in the `pe_ext.xml` file. For each new option you want to add, you must define and include a `<selector>` element in the `pe_ext.xml` file.

To configure custom options in the Composer extension file:

1. Create a Java bean, for example `UserInformation.java`, with the logic to populate the expression dialog with your custom options. Example 21–12 shows the code of a sample Java bean used to display a new string, `User Name`, as a custom value in the expression dialog.

Example 21–12 Sample Code to Add a Custom Value in the Expression Dialog

```
package view;

import java.util.ArrayList;
import java.util.List;

import oracle.adf.view.page.editor.elbuilder.ELParameter;
import oracle.adf.view.page.editor.elbuilder.ELParameterValue;

public class UserInformation implements ELParameter {
  public String getName() {
    return mName;
  }

  public List<ELParameterValue> getValues() {
    if (mValues == null)
      {
        mValues = new ArrayList<ELParameterValue>();
        for(String[] args : mValueList)
          {
            mValues.add(new ELParameterValue(args[0], args[1]));
          }
      }
       return mValues;
  }
  private static String[][] mValueList =
    {new String[]{"User Name", "#{securityContext.userName}"}};

  private String mName = "User Name";
  private List<ELParameterValue> mValues;  }
```

2. Add an `<elbuilder-config>` element in the `pe_ext.xml` file to register the bean.

   For information about creating the extension file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

3. Add a `<selector>` element within the `<elbuilder-config>` section, and provide details about the bean you created, as shown in the following example:

```
<elbuilder-config>
```

```
  <!-- define selector -->
  <selector id="UserInformation">
    view.UserInformation
  </selector>

  <!-- include selector -->
  <selectors>
    <selector id="UserInformation" rendered="true"/>
  </selectors>
</elbuilder-config>
```

You can have multiple `<selector>` entries for different custom options.

Custom options display for all attributes by default. You can use the `rendered` attribute on `<selector>` to display an option conditionally, based on specific criteria.

4. Save the `pe_ext.xml` file.

21.4.2 How to Protect Expression Language

You can configure Composer to disable EL or protect existing EL from overwrite within an application or a specific .jspx page. This is especially useful when exposing elements to end users in Design view as described in Section 21.11, "Enabling Direct Select in Design View."

To define settings for an application, modify the following elements in adf-config.xml within the `<pe:page-editor-config>` tag:

- `<pe:allow-el>` defines whether or not EL can be run in application pages. The default is true.
- `<pe:protect-el>` defines whether or not EL in form elements is read-only. The default is false.

To define behavior for a specific .jspx page, use the following elements within the `<pe:pageCustomizable>` tag:

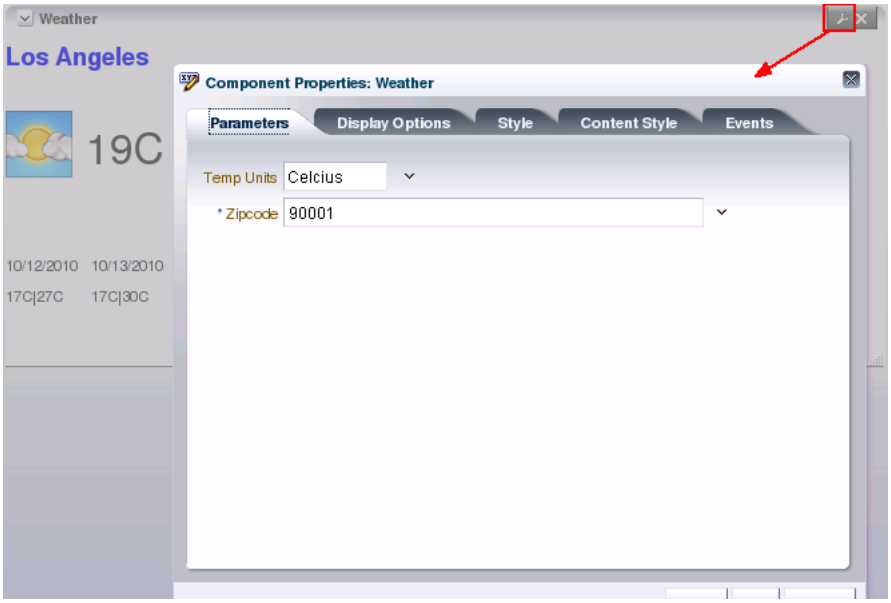
- `allowEL` (boolean) defines whether or not EL can be run in application pages. The default is true.
- `protectEL` (boolean) defines whether or not EL in form elements is read-only. The default is false.

The settings defined in the .jspx page override any settings defined in adf-config.xml.

21.4.3 What Happens at Runtime

The selector in the runtime expression builder displays the custom value along with the default values, as shown in Figure 21–9.

Figure 21–9 Expression Builder Displaying a Custom Value



If EL is disabled, the expression builder will not be accessible, and EL will not be allowed in property fields.

If EL is protected, any EL already present as an attribute value cannot be changed in either the Parameters or Display Options tabs. (EL picked from a LOV is allowed.)

21.5 Configuring Custom LOVs or Pickers for Task Flow Parameters

Typically, while editing a task flow parameter in Composer, the user enters a value in the text box provided in the Component Properties dialog, as shown in Figure 21–10. However, many a time the user is confused about what value to specify in a particular field. Rather than leave them guessing, as a developer who knows the values that each parameter can take, you can make it easier for users by listing all valid options, wherever possible. You can configure Composer to display a list of values (LOV) or a picker against any parameter.

Figure 21–10 Parameters Tab on the Component Properties Dialog for a Task Flow

You can display a predefined set of values for a parameter using the following options:

- Static LOV

  To display a list of predefined values.

- Dynamic LOV

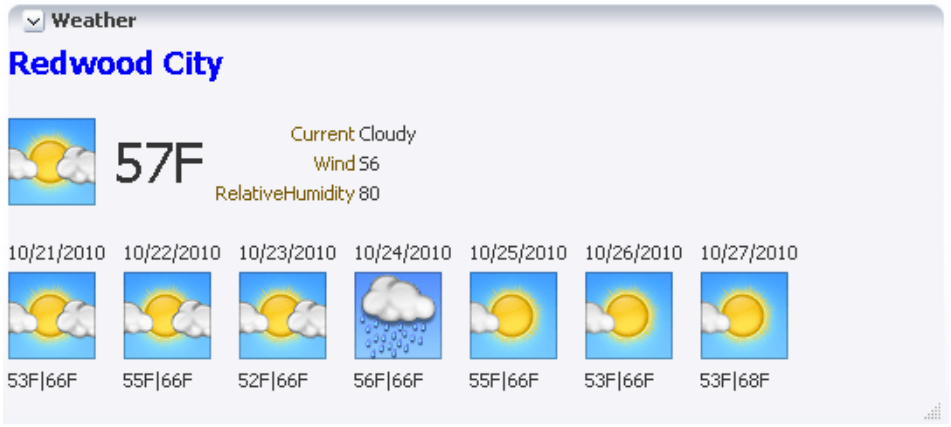
  To display a list of values generated by evaluating an EL value that is computed when the page is run.

- Global LOV

  To display a global list of values that can be used in any task flow in the application.

- Picker

  To display all values in a picker format, for example, a document picker.



This section describes how to configure different types of LOVs for task flow parameters. It contains the following subsections:

- Section 21.5.1, "How to Configure an LOV"
- Section 21.5.2, "What Happens at Runtime"

Example Used to Describe the Procedures in This Section

Some of the procedures in this section use the example of a simple weather task flow, `weather-task-flow-definition`, which displays weather information for a selected city, as shown in Figure 21–11.

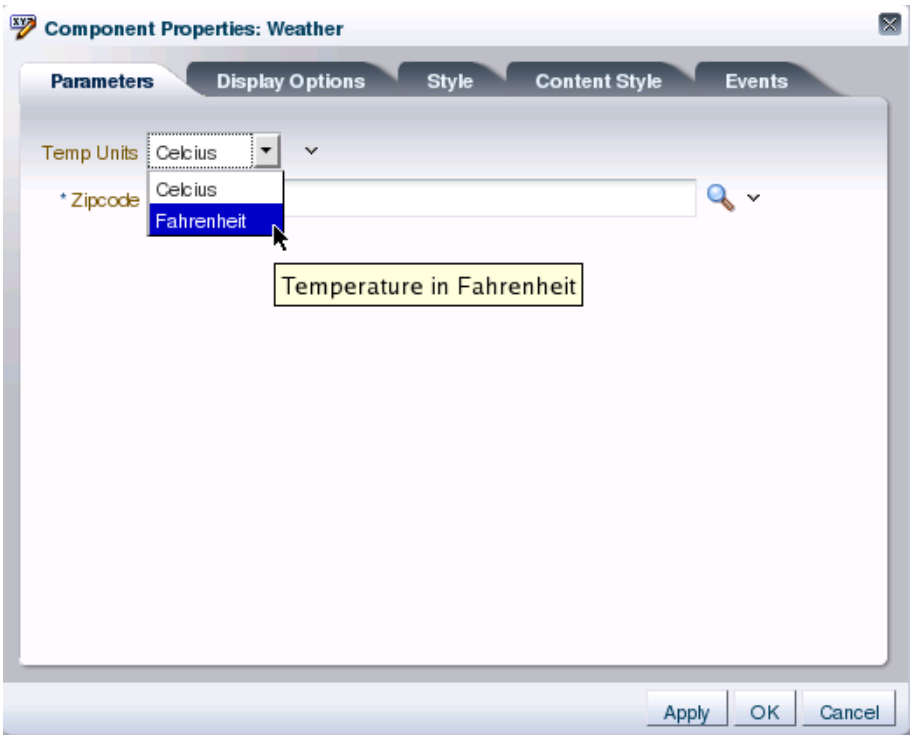


Figure 21–11 Weather Task Flow

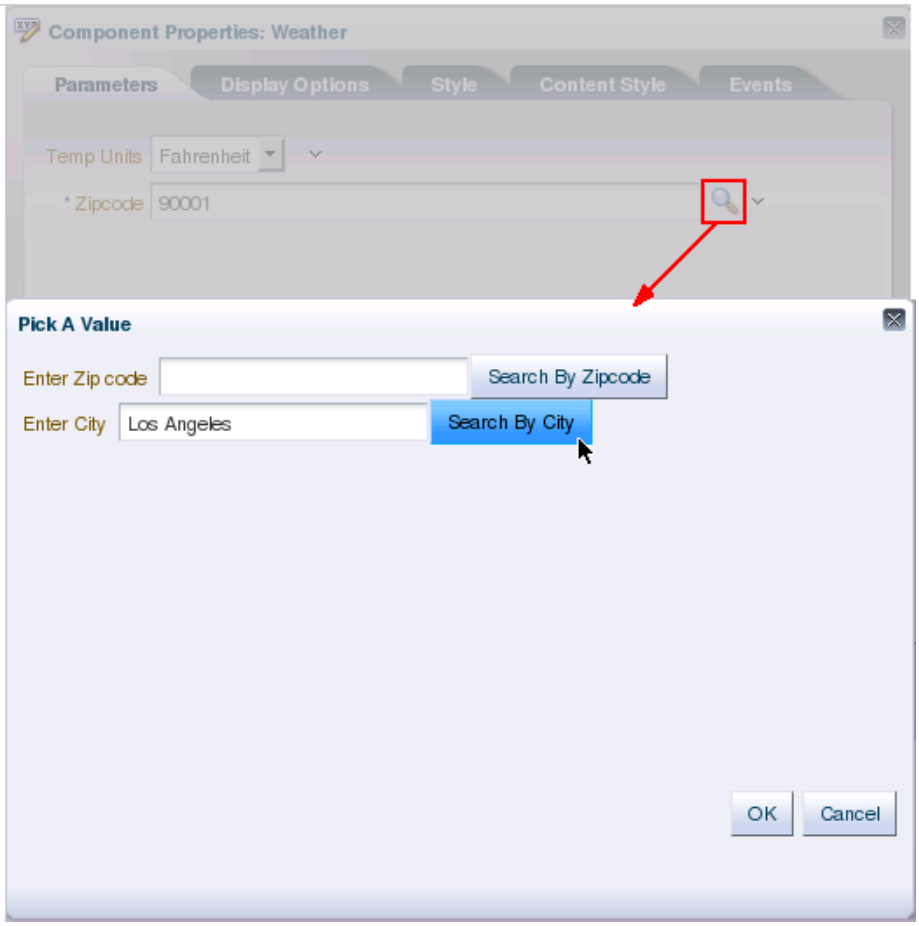
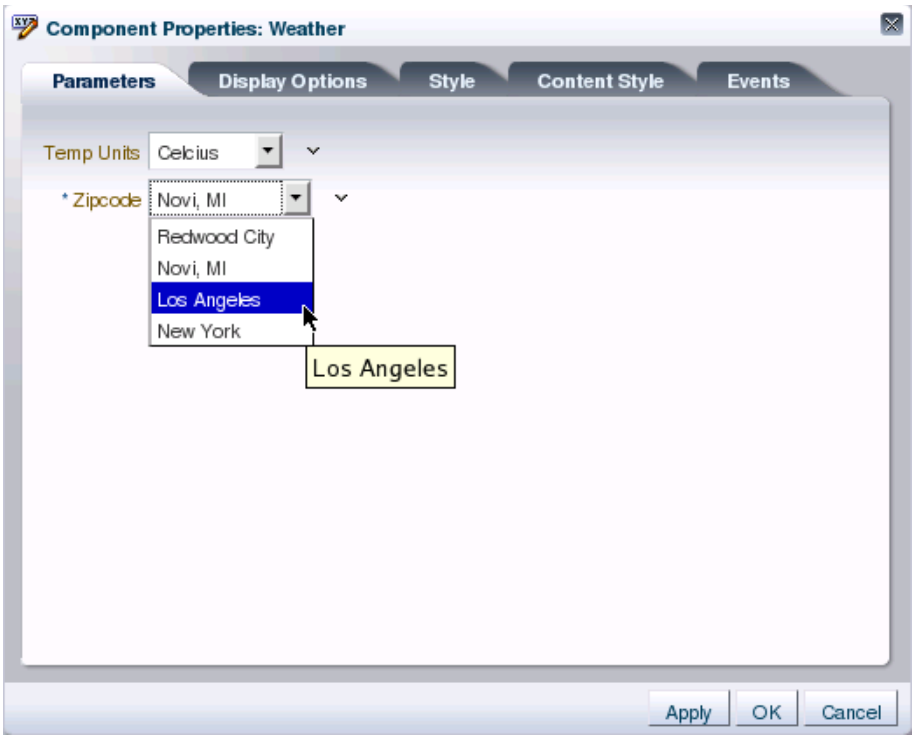
The task flow provides two parameters, `zipCode` and `tempUnits`, that users can modify to display weather details for a selected city and in a selected temperature unit (Fahrenheit or Celsius) respectively. This weather task flow example is used to explain how to configure the following types of LOVs:



- A static LOV with the values `Celsius` and `Fahrenheit` for the `tempUnits` parameter, as shown in Figure 21–12.

Figure 21–12 Static LOV for the tempUnits Parameter



- A picker with two fields that enable users to specify a city name or ZIP code (Figure 21–13) to view corresponding details in the weather task flow.

Figure 21–13 City Picker for the zipCode Parameter

- Alternatively, a dynamic LOV for the `zipCode` parameter to display values (Figure 21–14) based on an EL value that is evaluated at runtime.

Figure 21–14 Dynamic LOV for the zipCode Parameter

The weather task flow includes a task flow definition file, `weather-task-flow-definition.xml`, with the code shown in Example 21–13.

Example 21–13 The weather-task-flow-definition.xml FIle

```
<?xml version="1.0" encoding="US-ASCII" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2">
  <task-flow-definition id="weather-task-flow-definition">
    <default-activity id="defaultactivity1">weather</default-activity>
    <input-parameter-definition id="inputparam1">
      <name id="inputparam1name">zipcode</name>
      <value>#{pageFlowScope.zipcode}</value>
      <class>java.lang.String</class>
      <required/>
    </input-parameter-definition>
    <input-parameter-definition id="inputparam2">
      <name id="ip2name">tempUnits</name>
      <value>#{pageFlowScope.tempUnits}</value>
      <class>java.lang.String</class>
    </input-parameter-definition>
    <view id="weather">
      <page>/weather.jsff</page>
    </view>
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

The parameters, shown in **bold** text, are defined in such a way that values provided by users at runtime are stored in a session bean, `pageFlowScope`, from where they can be read by other components.

When you edit the task flow at runtime, the Parameters tab displays two input text fields to provide parameter values. The following sections explain how to enable LOVs for these task flow parameters so that users can choose from a list of predefined of options.

21.5.1 How to Configure an LOV

This section describes how to configure different types of LOVs for task flow parameters. It includes the following subsections:

- Section 21.5.1.1, "Configuring a Static LOV"
- Section 21.5.1.2, "Configuring a Dynamic LOV"
- Section 21.5.1.3, "Configuring a Picker"
- Section 21.5.1.4, "Configuring an LOV from a Global List"

21.5.1.1 Configuring a Static LOV

Use a static LOV to display a list of predefined values against a parameter. You can configure a static LOV by defining an `<lov-config>` section with nested `<enumeration>` elements in the Composer extension file, `pe_ext.xml`. This section uses the weather task flow example and describes how to configure a static LOV for the `tempUnits` parameter.

To configure a static LOV:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and include the task flow definition with nested `<enumeration>` elements, as shown in the following code example:

```
<lov-config>
  <!-- Entry for the task flow in which you are configuring the LOV -->
  <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">

    <!-- Specifying the parameter for which you want to define a static LOV -->
    <input-parameter-definition>
      <name>tempUnits</name>
      <!-- List of values to be displayed for the parameter -->
      <enumeration inline="true">
        <item>
          <name>Celcius</name>
          <value>c</value>
          <description>Temperature in Celcius</description>
        </item>
        <item>
          <name>Fahrenheit</name>
          <value>f</value>
```

```
          <description>Temperature in Fahrenheit</description>
        </item>
      </enumeration>
    </input-parameter-definition>

  </task-flow-definition>
</lov-config>
```

You can configure any number of static LOVs within the `<lov-config>` section.

> **Note:** To allow translatable strings to be provided for a parameter name, you can use an EL value for the name, for example, `#{resourceBundle.temp_units}`.

3. Save the file.

21.5.1.2 Configuring a Dynamic LOV

Use a dynamic LOV to display a list that is generated dynamically at runtime by evaluating an EL value. This section uses the weather task flow example and describes how to configure a dynamic LOV for the `zipCode` parameter. To keep the example simple, the managed bean only provides static values that are displayed on the `Zipcode` field at runtime.

To configure a dynamic LOV:

1. Create a bean, for example, `weatherBean`, and define the list of values for the `Zipcode` parameter. The following example shows the relevant code snippet:

```
package portal.weather;

  . . .

  public List<SelectItem> getCitiesList() {
    return citiesList;
  }

  private static final String F = "&deg;F";
  private static final String C = "&deg;C";
  private static final String [][] selectItems = {{"Redwood City", "94065"},
                                                  {"Novi, MI", "48375"},
                                                  {"Los Angeles", "90001"},
                                                  {"New York", "10036"}};

  private static final List<SelectItem> citiesList = new
ArrayList<SelectItem>();
    static {
      for (String[] city : selectItems){
        citiesList.add(new SelectItem(city[1], city[0]));
    }
  }
```

2. Register `weatherBean` in the application's `faces-config.xml` file, as shown in the following example:

```
<managed-bean>
  <managed-bean-name>weatherBean</managed-bean-name>
  <managed-bean-class>portal.weather.WeatherBean</managed-bean-class>
  <managed-bean-scope>request</managed-bean-scope>
```

```
</managed-bean>
```

3. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *APPLICATION_HOME*`\Portal\adfmsrc\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

4. Add an `<lov-config>` section, include the task flow definition with an `<enumeration>` element, and reference the managed bean for the parameter value, as shown in the following example:

```
<lov-config>
  <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">
    <input-parameter-definition>
      <name>zipcode</name>
      <value>90001</value>
      <enumeration items="#{weatherBean.citiesList}"/>
    <input-parameter-definition>
  </task-flow-definition>
</lov-config>
```

   You can configure any number of dynamic LOVs within the `<lov-config>` section.

5. Save the file.

21.5.1.3 Configuring a Picker

Typically, a picker enables users to select a value from a popup dialog that displays all available options, for example, a color picker or date picker. Configuring a picker for a task flow parameter involves the following high level tasks:

- Create the picker task flow with a UI of your choice.
- Define parameters on the picker task flow. These parameters are used to populate the main task flow parameter (the one for which you are configuring the picker).
- Configure the main task flow parameter to display the picker that you created. You must add this configuration in the `pe_ext.xml` file.

This section explains these steps in detail using the weather task flow as an example. It shows how to configure a city picker for the `zipCode` parameter. The picker task flow enables users to specify the city name and get the ZIP code for that place. The ZIP code from the picker is then pushed to the Zipcode field in the weather task flow. This section includes the following subsections:

- Section 21.5.1.3.1, "Creating the Picker Task Flow"
- Section 21.5.1.3.2, "Registering the Picker for a Task Flow Parameter"

21.5.1.3.1 Creating the Picker Task Flow

Create a picker task flow with a JSFF fragment. Design the fragment to display fields or options of your choice.

To create the picker task flow:

1. In your application project, create an ADF task flow, for example, `weather-picker-task-flow-definition`:
   a. From the **File** menu, choose **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **ADF Task Flow**.
   c. Click **OK**.
2. Add a `view` object to the task flow, for example, `weatherPicker`.
3. Double-click the view to create the `weatherPicker.jsff` fragment.

   See Also: "Getting Started with ADF Task Flows" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework* for information about creating task flows.

4. Design the fragment with components of your choice. Example 21–14 shows a sample task flow containing two `Input Text` components that enable users to search for ZIP codes in an XML file, and two UI controls, `OK` and `Cancel`.

Example 21–14 Sample code in the Picker JSFF Fragment

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:f="http://java.sun.com/jsf/core">
  <af:panelStretchLayout id="psl1">
    <f:facet name="center">
      <af:panelGroupLayout id="pgl1" layout="vertical">

        <af:panelGroupLayout id="pgl2" layout="horizontal">
          <!-- Text field and Search button to search for a city by specifying the
ZIP code -->
          <af:inputText label="Enter Zip Code" id="it1"
                        value="#{pageFlowScope.weatherPicker.searchZipcode}"/>
          <af:commandButton text="Search By Zipcode" id="cb1"

actionListener="#{pageFlowScope.weatherPicker.zipcodeSearch}"/>
        </af:panelGroupLayout>

        <af:panelGroupLayout id="pgl3" layout="horizontal">
          <!-- Text field and Search button to search for a city by specifying the
city name -->
          <af:inputText label="Enter City" id="it2"
                        value="#{pageFlowScope.weatherPicker.searchCity}"/>
          <af:commandButton text="Search By City" id="cb2"

actionListener="#{pageFlowScope.weatherPicker.citySearch}"/>
        </af:panelGroupLayout>

        <!-- Output components to display the result from the search -->
        <af:outputFormatted value="#{pageFlowScope.weatherPicker.city}"
                            id="of2"/>
        <af:outputFormatted value="#{pageFlowScope.weatherPicker.zipcode}"
                            id="of3"/>

      </af:panelGroupLayout>
    </f:facet>
    <f:facet name="bottom">
      <af:panelGroupLayout layout="horizontal" halign="end" id="pkrPgl">
```

```
        <!-- OK button -->
        <af:commandButton action="ok"

actionListener="#{pageFlowScope.weatherPicker.populateReturnValue}"
                          text="#{Bundle.OK_BUTTON_TEXT}" id="okBtn"/>
        <af:spacer width="5" id="s1"/>

        <!-- Cancel button -->
        <af:commandButton
actionListener="#{pageFlowScope.weatherPicker.closePickerPopup}"
                          text="#{Bundle.CANCEL_BUTTON_TEXT}"
                          id="cnclBtn"/>
      </af:panelGroupLayout>
    </f:facet>
  </af:panelStretchLayout>
</jsp:root>
```

The action listeners on the `OK` and `Cancel` buttons reference a managed bean, `weatherPicker`. This bean also contains the logic to populate the parameter on the main task flow with the value specified in the picker.

5. Create the bean that you referenced in the picker task flow definition and add the logic to return values to the main task flow.

   The following example shows the relevant code snippet of the `weatherPicker` bean, which contains the logic to search for a city by name and return the ZIP code:

```
package portal.weather.picker;

. . .

  public void populateReturnValue(ActionEvent ae) {
    Map map =
(Map)RequestContext.getCurrentInstance().getPageFlowScope().get("outParam");
    if (map != null)
      map.put("outParamVal", _zipcode);
  }

  public void closePickerPopup(ActionEvent ae) {
    UIComponent component = ae.getComponent();
      while (!(component instanceof RichPopup))
        component = component.getParent();
        if (component != null)
          ((RichPopup)component).cancel();
  }
  . . .
```

6. Register the `weatherPicker` bean in the task flow definition file, as shown in the following example:

```
<managed-bean id="pickerbean">
  <managed-bean-name id="pickerbeanname">weatherPicker</managed-bean-name>
  <managed-bean-class
id="pickerbeanclass">portal.weather.picker.WeatherPicker</managed-bean-class>
  <managed-bean-scope id="pickerbeanscope">pageFlow</managed-bean-scope>
</managed-bean>
```

7. Define two input parameters, `inParamVal` and `outParam`, on the picker task flow, as shown in the following example:

```
<!-- Parameter used to store the value that must be passed to the main task
flow -->
<input-parameter-definition id="pickerip1">
  <name id="pickerip1name">outParam</name>
  <value>#{pageFlowScope.outParam}</value>
  <class>java.util.Map</class>
</input-parameter-definition>

<!-- Parameter used to store the value specified by the user in the picker -->
<input-parameter-definition id="pickerip2">
  <name id="pickerip2name">inParamVal</name>
  <value>#{pageFlowScope.inParamVal}</value>
  <class>java.lang.String</class>
</input-parameter-definition>
```

These parameters are referenced in `pageFlowScope` and will be used to read and populate the main task flow parameter, `zipCode`. When a user clicks the picker icon next to the Zip Code field, the current value of the field is passed to the session bean using `inParamVal`. When a user specifies a city name in the picker task flow and clicks OK, the bean gets the ZIP code for that city and passes it to the main weather task flow using `outParam`.

8. Define task flow return activities and control flow rules for the `OK` and `Cancel` buttons. These activities and rules ensure that control is returned to the task flow when either of the buttons is clicked. You can define task flow return activities and control flow rules as shown in the following example:

```
<!-- The outcome to be returned to the task flow if a user clicks OK -->
<task-flow-return id="ok">
  <outcome id="ok1">
    <name id="okayed">ok</name>
  </outcome>
</task-flow-return>
<!-- The outcome to be returned to the task flow if a user clicks Cancel -->
<task-flow-return id="cancel">
  <outcome id="cancel1">
    <name id="canceled">cancel</name>
  </outcome>
</task-flow-return>

<!-- Rules to pass control flow to the ok activity if the user clicks OK and to
the cancel activity if the user clicks Cancel -->
<control-flow-rule id="flowrule1">
  <from-activity-id id="fromactivity1">weatherPicker</from-activity-id>
  <control-flow-case id="flowcase1">
    <from-outcome id="fromoutcome1">ok</from-outcome>
    <to-activity-id id="toactivity1">ok</to-activity-id>
  </control-flow-case>
  <control-flow-case id="flowcase2">
    <from-outcome id="fromoutcome2">cancel</from-outcome>
    <to-activity-id id="toactivity2">cancel</to-activity-id>
  </control-flow-case>
</control-flow-rule>
```

The task flow definition will now have code similar to the following example:

```
<?xml version="1.0" encoding="US-ASCII" ?>
<adfc-config xmlns="http://xmlns.oracle.com/adf/controller" version="1.2">
  <task-flow-definition id="weather-picker-task-flow-definition">
    <default-activity id="pickeractivity1">weatherPicker</default-activity>
    <input-parameter-definition id="pickerip1">
```

```
      <name id="pickerip1name">outParam</name>
      <value>#{pageFlowScope.outParam}</value>
      <class>java.util.Map</class>
    </input-parameter-definition>
    <input-parameter-definition id="pickerip2">
      <name id="pickerip2name">inParamVal</name>
      <value>#{pageFlowScope.inParamVal}</value>
      <class>java.lang.String</class>
    </input-parameter-definition>
    <managed-bean id="pickerbean">
      <managed-bean-name id="pickerbeanname">weatherPicker</managed-bean-name>
      <managed-bean-class
id="pickerbeanclass">portal.weather.picker.WeatherPicker</managed-bean-class>
      <managed-bean-scope id="pickerbeanscope">pageFlow</managed-bean-scope>
    </managed-bean>
    <view id="weatherPicker">
      <page>/weatherPicker.jsff</page>
    </view>
    <task-flow-return id="ok">
      <outcome id="ok1">
        <name id="okayed">ok</name>
      </outcome>
    </task-flow-return>
    <task-flow-return id="cancel">
      <outcome id="cancel1">
        <name id="canceled">cancel</name>
      </outcome>
    </task-flow-return>
    <control-flow-rule id="flowrule1">
      <from-activity-id id="fromactivity1">weatherPicker</from-activity-id>
      <control-flow-case id="flowcase1">
        <from-outcome id="fromoutcome1">ok</from-outcome>
        <to-activity-id id="toactivity1">ok</to-activity-id>
      </control-flow-case>
      <control-flow-case id="flowcase2">
        <from-outcome id="fromoutcome2">cancel</from-outcome>
        <to-activity-id id="toactivity2">cancel</to-activity-id>
      </control-flow-case>
    </control-flow-rule>
    <use-page-fragments/>
  </task-flow-definition>
</adfc-config>
```

9. Save the task flow definition file.

21.5.1.3.2 Registering the Picker for a Task Flow Parameter To display a custom picker for a task flow parameter, you must configure the picker for that parameter in the Composer extension file, `pe_ext.xml`.

To configure a picker for a task flow parameter:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):
   a. From the **File** menu, select **New**.
   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.
   c. Click **OK**.

Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and include the task flow definition with an `<enumeration>` element referencing the picker task flow, as shown in the following code example:

```
<?xml version="1.0" encoding="UTF-8"?>
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
  <lov-config>
    <task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-defini
tion">
      <!-- Parameter for which you defined the picker -->
      <input-parameter-definition>
        <name>zipCode</name>
        <value>null</value>
        <!-- enumeration items coming from the picker task flow -->
        <enumeration
picker="/WEB-INF/weather-picker-task-flow-definition.xml#weather-picker-task-fl
ow-definition"/>
      </input-parameter-definition>
    </task-flow-definition>
  </lov-config>
</pe-extension>
```

   You can configure pickers for any number of parameters within the `<lov-config>` section.

3. Save the file.

When you edit the main task flow at runtime, the Component Properties dialog displays a magnifier icon next to that parameter. Clicking the icon invokes the picker task flow, in which users can select a value.

21.5.1.4 Configuring an LOV from a Global List

If you want to reuse an LOV in different task flow parameters within the application, you can define the LOV at a global level and reference it from the task flow parameters.

To configure an LOV from a global list:

1. If it does not already exist, create the Composer extension file, `pe_ext.xml` in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_HOME`*`\Portal\adfmsrc\META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `pe_ext.xml`.

2. Add an `<lov-config>` section and list the values within an `<enumeration>` element (outside of the task flow definition), as shown in the following code example:

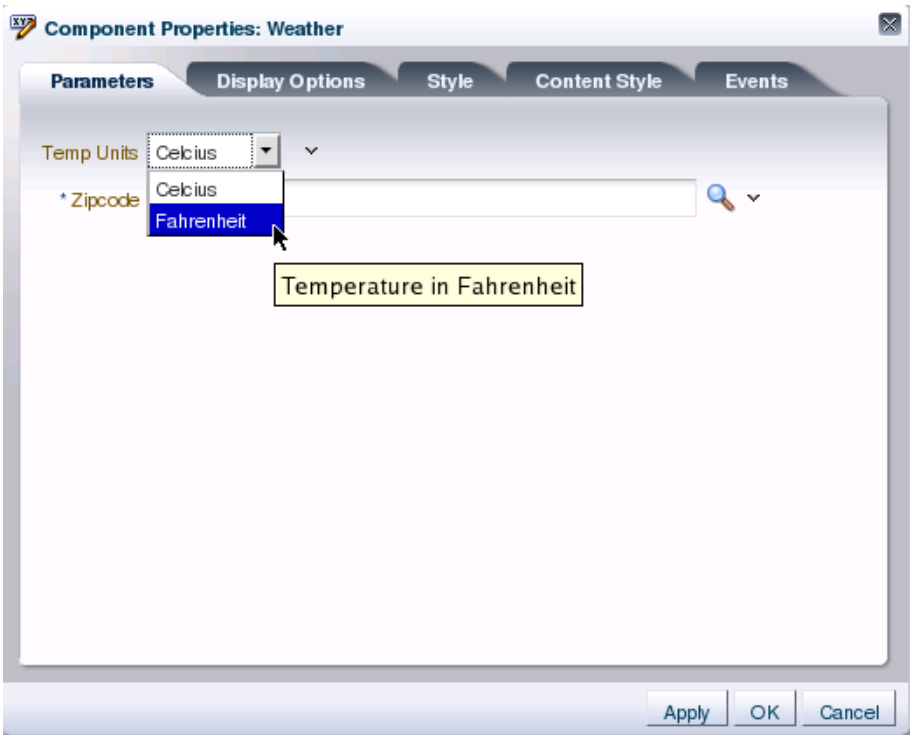
```
<lov-config>
<!-- Global enumerations ->
  <enumeration id="temperature">
    <item>
      <name>Celcius</name>
```

```
      <value>c</value>
      <description>Temperature in Celcius</description>
    </item>
    <item>
      <name>Fahrenheit</name>
      <value>f</value>
      <description>Temperature in Fahrenheit</description>
    </item>
  </enumeration>
  <task-flow-definition . . . >
  . . .
<lov-config>
```

You can configure any number of global LOVs within the `<lov-config>` section.

3. Reference this global LOV from any input parameter definition in the `pe_ext.xml` file, as shown in the following example:

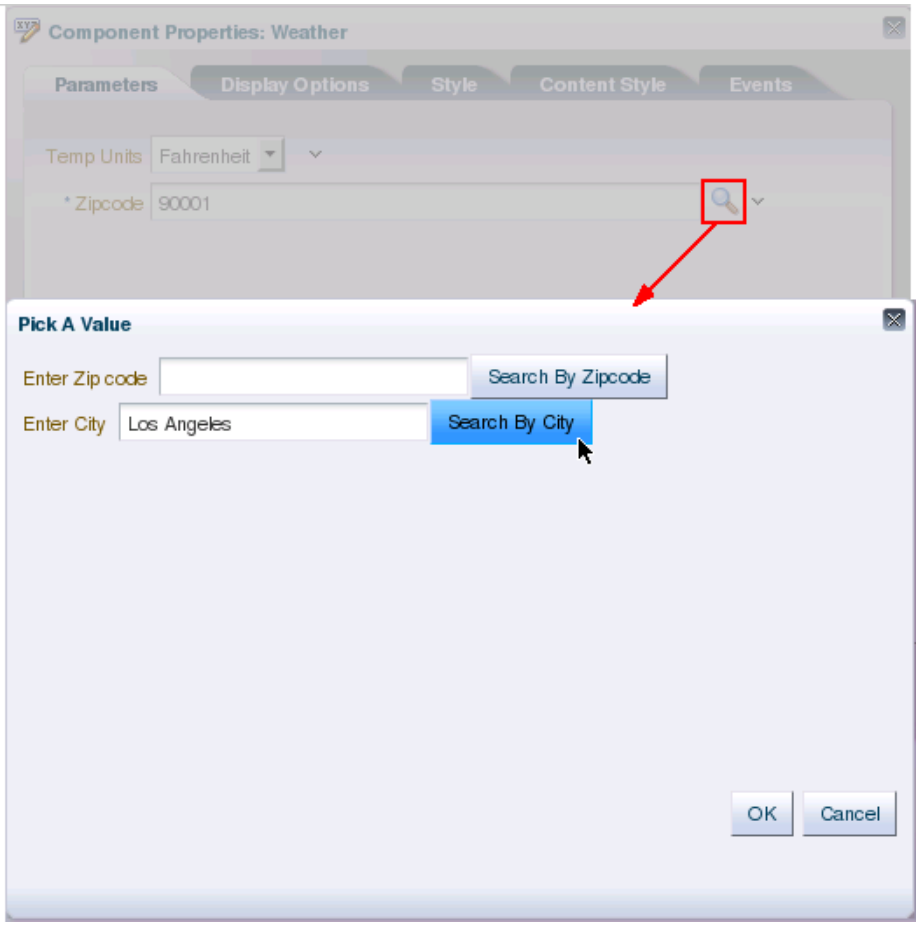
```
<task-flow-definition
taskflow-id="/WEB-INF/weather-task-flow-definition.xml#weather-task-flow-definition">
  <input-parameter-definition>
    <name>tempUnits</name>
    <value>Celsius</value>
    <enumeration ref="temperature"/>
  </input-parameter-definition>
</task-flow-definition>
```



4. Save the file.

21.5.2 What Happens at Runtime

Depending on the type of LOV you configured for the task flow parameter, users will see different options to specify parameter values.



The Temp Units field, shown in Figure 21–15, lists values from the static LOV that you defined in the `pe_ext.xml` file.

Figure 21–15 Static LOV

If you configured a picker for the Zipcode field, the field shows a magnifier icon to its right. This icon invokes a picker, as shown in Figure 21–16, that allows users to select a city by providing a name or ZIP code.

Figure 21–16 Picker Task Flow Configured for the Zipcode Field

21.6 Configuring Event Handlers for Composer UI Events

Event handlers are Java classes registered with Composer and called when a users performs an action on the page. For example, when a user clicks a **Save** button, Composer calls back into the application code to give the application a chance to respond to the Save action—or *event*. In addition to the event handlers that Composer provides by default, you might want to configure the application to perform additional workflows. This is useful in performing application-specific tasks on such events. Moreover, this is the recommended approach to, for example, save the changes on a custom property panel.

Composer provides a means of registering event handlers for different events. This section describes how. It contains the following subsections:

- Section 21.6.1, "How to Create and Register Handlers for Composer UI Events"
- Section 21.6.2, "What Happens When You Create and Register Event Handlers"

21.6.1 How to Create and Register Handlers for Composer UI Events

When you register an event handler with Composer, it is called when the corresponding event is fired in the Composer UI. This section describes how to create an event handler and register it with Composer. It contains the following subsections:

- Section 21.6.1.1, "UI Events that Support Event Handler Registration"

- Section 21.6.1.2, "Creating a Save Event Handler: Example"
- Section 21.6.1.3, "Registering an Event Handler with Composer"

21.6.1.1 UI Events that Support Event Handler Registration

Table 21–1 lists the UI events for which Composer currently supports registering of handlers.

Table 21–1 Events for Which Registering Handlers are Supported

Event	Cause	Event Type	Listener Interface to Be Implemented	Method to Be Implemented	Event Parameters
Save	Invoked when a user clicks the **Save** or **Save and Label** button on the Composer toolbar, or the **Apply** or **OK** button in the Component Properties dialog or Page Properties dialog.	`save`	`oracle.adf.view.page.event.SaveListener`	`processSave`	`SaveEvent`
Close	Invoked when a user clicks the **Close** button on the Composer toolbar.	`close`	`oracle.adf.view.page.event.CloseListener`	`processClose`	`CloseEvent`
Deletion	Invoked when a user deletes the component.	`delete`	`oracle.adf.view.page.event.DeletionListener`	`processDeletion`	`DeletionEvent` Get the deleted component using `DeletionEvent`'s `getComponent` method.
Addition	Invoked when a user adds a component to the page from the Resource Catalog by clicking the **Add** button against an item.	`add`	`oracle.adf.view.page.event.AdditionListener`	`processAddition`	`AdditionEvent`
Selection	Invoked when a user selects: ■ The **Edit** icon on a Panel Customizable or Show Detail Frame component in Design view ■ A component on the page or in the hierarchy in Source view	`select`	`oracle.adf.view.page.event.SelectionListener`	`processSelection`	`SelectionEvent`
Attribute Modification	Invoked when a user changes an attribute.	`attribute-change`	`oracle.adf.view.page.editor.event.AttributeChangeListener`	`processAttributeChange`	`AttributeChangeEvent`

21.6.1.2 Creating a Save Event Handler: Example

To register an event with Composer, you must first create a Java class and implement the appropriate listener for the event handler. This section describes the steps to create a Save event handler. You can perform similar steps to create event handlers for all the supported events listed in Table 21–1.

A Save event handler is called when a user clicks the **Save** button on the Composer toolbar or the **Apply** or **OK** button in the Component Properties or Page Properties dialog. A Save event handler must implement `oracle.adf.view.page.editor.event.SaveListener`. The `isCommit` method of the Save event can be used to differentiate between changes made to the page and to component properties. A value of `true` implies that the user clicked the Save button on the Composer toolbar to save changes made to the page. A value of `false` implies that the user clicked the Apply or OK button in the Component Properties dialog to save changes made to component properties.

To create a Save event handler:

1. In JDeveloper, select the **Portal** project, and from the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, specify a name for the class, for example, `SaveHandler`.
4. Under the Optional Attributes section, add the `oracle.adf.view.page.editor.event.SaveListener` interface.

   Note: If you are not able to see the `oracle.adf.view.page.editor` classpath, make sure that Composer is included in the project's libraries and classpath. To do this, right-click the project in the Application Navigator and select **Project Properties**. In the Project Properties dialog, select **Libraries and Classpath**, and add **Composer** to the list.

5. Click **OK**.

   The Java class source looks like the following:

```
package view;

import javax.faces.event.AbortProcessingException;

import oracle.adf.view.page.editor.event.SaveEvent;
import oracle.adf.view.page.editor.event.SaveListener;

public class SaveHandler implements SaveListener {
  public Class1() {
    super();
  }
  public void processSave(SaveEvent saveEvent) throws AbortProcessingException
{
// Your implementation goes here
  }
}
```

   You must declare the `processSave` method as `throws AbortProcessingException` because the method may throw this exception if

the event must be canceled. You can include the reason for canceling this event in the Exception object when you create it.

On throwing this exception, further processing of this event is canceled and the listeners that are in the queue are skipped.

You can create event handlers for all supported events by performing steps similar to these.

Tip: You can use the `SaveEvent.isCommit` method to

21.6.1.3 Registering an Event Handler with Composer

After creating and implementing an event handler, you must register it with Composer. Registration is necessary for ensuring that the handler is called back by Composer when the corresponding event occurs in the UI.

Register event handlers in the Composer extension file, `/META-INF/pe_ext.xml`. For more information about creating this file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

To register an event handler:

1. In the application's `pe_ext.xml` file, add the following entries:

```
<event-handlers>
  <event-handler event="save">view.SaveHandler</event-handler>
</event-handlers>
```

   The values you provide for the `event` attribute and between the `event-handler` tags are unique to the type of event being entered and the name you specified for the event class.

2. Save the file.

21.6.2 What Happens When You Create and Register Event Handlers

At runtime, registered event handlers are called according to the sequence in the extension file and according to the order in which they were found on the class path. Composer's native event handler is called last.

On invocation of an event handler's `process`*`EventName`* method, if an event handler throws `AbortProcessingException`, then the event is canceled and no further event handlers are called, including Composer's native event handlers.

If, however, an error occurs while instantiating an event handler, then Composer continues with the next event handler. A warning message is logged.

21.6.3 Performing Additional Composer Event Handler Configurations

For every UI event triggered on the page in Composer, the corresponding event handler calls back a method from a listener registered with the application. By performing some additional configurations, you can specify the sequence in which event handlers must be executed and configure a listener to terminate a process or notify Composer that the event has been handled.

Specify a Sequence Number for an Event Handler

By specifying the sequence for event handlers, you can decide on the order in which the event handlers, and therefore the listeners, are called. You can assign a sequence

number to a listener or modify the default value by defining a `sequence` attribute against the registered event handler in the `pe_ext.xml` file.

To specify a sequence number for a listener:

1. In the application's `pe_ext.xml` file, locate the `event-handler` element for the handler that you want to sequence.
2. Add a `sequence` attribute as follows:

```
<event-handlers>
  <event-handler event="save" sequence="101">view.SaveHandler</event-handler>
</event-handlers>
```

   The value for the `sequence` attribute must be a positive integer. If you do not define this attribute, the event handler is internally assigned a default sequence number of `100`.

   Composer built-in listeners and listeners with no sequence numbers are assigned a default sequence number of `100`. If you want your event handler to be called before other event handlers, you must specify a value lesser than `100`.

3. Save the file.

Stop Event Processing and Notify Composer

You can configure an event handler to terminate processing of the current event and all subsequent events by throwing an exception. For this, you must declare the method used while implementing the listener as `throws AbortProcessingException`. In addition, you can configure the handler to notify Composer that the event has been processed by using the `Event.setEventHandled(true)` method.

For example, you can configure a `delete` event handler to terminate the current event and all pending delete events and throw an exception when a user attempts to delete a component in Composer. To enable this, you must implement the `DeletionListener` interface as shown in Example 21–15.

Example 21–15 DeletionListener Implementation

```
public class DeleteHandler implements DeletionListener
{
  ...
  public void processDeletion(DeletionEvent delEvent) throws
AbortProcessingException
  {
    // Get the component that must be deleted
    UIComponent comp = delEvent.getComponent();

    if (comp != null)
    {
      try
      {
        // Assuming that a custom method, handleDelete(comp), handles deletion of
        // a component and returns true on successful deletion and false in case
        // of failure
        boolean deleteSucceeded = handleDelete(comp);

        // If deletion failed, then notify Composer that the delete event
        // has been handled. No further events are processed.
        if (!deleteSucceeded)
          delEvent.setEventHandled(true);
      }
```

```
      catch (Exception e)
      {
       // Catch Exception throw by handleDelete(comp) and handle it by throwing
       // AbortProcessingException to stop processing of delete events.
       throw new AbortProcessingException(e)
      }
    }
  }
  ...
}
```

21.7 Configuring Drop Handlers in the Resource Catalog

Drop handlers are Java classes registered with Composer and called when users click an Add link in the Resource Catalog. A drop handler declares the data flavors it can handle. Each resource in the catalog has a flavor. When a user clicks an Add link next to a resource, Composer queries all the registered drop handlers to check if they can handle the flavor. If only one drop handler can handle that flavor, then control is passed to that drop handler and the resource is added to the page immediately. If more than one drop handler can handle the flavor, then a context menu displays available drop handlers to users. The resource is dropped on the page when a user selects a Java drop handler from the context menu.

An example for a resource with multiple Java drop handlers is the Personal Documents subfolder available within the Documents folder, if you configured the Documents service in your catalog. This subfolder can be added as a Content Presenter, Document List Viewer, or Document Library.

> **Note:** The `AdditionListener` mechanism used to handle an `Add` operation in release 11.1.1.1 is still available, but now Composer calls drop handlers first to handle an `Add` operation in the catalog. It is recommended that you convert existing `AdditionListeners` to drop handlers.

This section describes the procedure to create and register drop handlers in your application. It contains the following subsections:

- Section 21.7.1, "How to Create and Register Java Drop Handlers"
- Section 21.7.2, "What Happens at Runtime"

21.7.1 How to Create and Register Java Drop Handlers

This section describes how to create a sample drop handler for adding XML content from the Resource Catalog and register the drop handler with Composer. It includes the following subsections:

- Section 21.7.1.1, "Creating a Drop Handler"
- Section 21.7.1.2, "Registering a Drop Handler with Composer"

21.7.1.1 Creating a Drop Handler

To create a drop handler with Composer, you must first extend the abstract base class, `DropHandler`, and implement the `getName()`, `getAcceptableFlavors()`, and `handleDrop()` methods. This section describes an example to add an XML

component called `Test` to the Resource Catalog and create a drop handler named `Custom XML` for adding XML content.

To create a drop handler:

1. In JDeveloper, select the **Portal** project, and from the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, specify a name for the class, for example, `TestDropHandler`.
4. In the Extends field, enter or browse to select the `Drophandler` class, `oracle.adf.view.page.editor.drophandler.DropHandler`.

   Note: If you are not able to see the `oracle.adf.view.page.editor` classpath, make sure that Composer is included in the project's libraries and classpath. To do this, right-click the project in the Application Navigator and select **Project Properties**. In the Project Properties dialog, select **Libraries and Classpath**, and add **Composer** to the list.

5. Add the required import statements and click **OK**.

   The Java class source must look like the following:

```
package test;

import java.awt.datatransfer.DataFlavor;
import java.awt.datatransfer.Transferable;

import java.io.ByteArrayInputStream;

import javax.faces.component.UIComponent;
import javax.faces.context.FacesContext;

import javax.xml.parsers.DocumentBuilder;
import javax.xml.parsers.DocumentBuilderFactory;

import oracle.adf.rc.component.XmlComponentFactory;
import oracle.adf.view.page.editor.drophandler.DropEvent;
import oracle.adf.view.page.editor.drophandler.DropHandler;

import org.apache.myfaces.trinidad.change.AddChildDocumentChange;
import org.apache.myfaces.trinidad.change.ChangeManager;
import org.apache.myfaces.trinidad.change.DocumentChange;
import org.apache.myfaces.trinidad.context.RequestContext;

import org.w3c.dom.Document;
import org.w3c.dom.DocumentFragment;

public class TestDropHandler extends DropHandler {
    public TestDropHandler() {
        super();
    }

    public String getName() {
        return null;
    }
```

```
    public DataFlavor[] getAcceptableFlavors() {
        return new DataFlavor[0];
    }

    public boolean handleDrop(DropEvent dropEvent) {
        return false;
    }
}
```

6. Implement the `getName()` method as follows to return the name of the drop handler:

```
public class TestDrophandler extends DropHandler {
    public TestDrophandler() {
        super();
    }

    public String getName() {
        return "Custom XML";
    }
. . .
```

This value (`Custom XML`) appears in the context menu on the Add link next to the XML component in the Resource Catalog.

7. Implement the `getAcceptableFlavors()` method as follows to get a list of supported data flavors for the XML component:

```
public class TestDropHandler extends DropHandler
{
  private static final DataFlavor[] ACCEPTABLE_FLAVORS =
  { XmlComponentFactory.XML_STRING_FLAVOR };

    . . .

    public DataFlavor[] getAcceptableFlavors() {
    return ACCEPTABLE_FLAVORS;
    }
    . . .
```

8. Implement the `handleDrop(DropEvent)` method as shown in the following sample file to handle the drop event and add the XML component to the page.

```
public class TestDropHandler extends DropHandler
{
  . . .

  public boolean handleDrop(DropEvent de) {
    Transferable transferable = de.getTransferable();
    UIComponent container = de.getContainer();
    int index = de.getDropIndex();

    try {
        FacesContext context = FacesContext.getCurrentInstance();
        RequestContext rctx = RequestContext.getCurrentInstance();

        String fragMarkup = null;

        // Get the TransferData from the Transferable (expecting a String)
        Object data = getTransferData(transferable);
```

```
        if (data instanceof String) {
          fragMarkup = "<?xml version='1.0' encoding='UTF-8'?>" + (String)data;
        } else {
            return false;
        }

        // Get a DocumentBuilder
        DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
        factory.setNamespaceAware(true);
        factory.setValidating(false);
        DocumentBuilder builder = factory.newDocumentBuilder();

        // Parse the xml string into a Document object using DocumentBuilder
        byte[] markupBytes = fragMarkup.getBytes();
        Document newDoc =
        builder.parse(new ByteArrayInputStream(markupBytes));

        // Transform the Document into a DocumentFragment
        DocumentFragment docFrag = newDoc.createDocumentFragment();
        docFrag.appendChild(newDoc.getDocumentElement());

        // Create an "add child" document change, that is, insert the fragment
        DocumentChange change = null;
        if (index < container.getChildCount()) {
        // Get the ID of the component we'll be adding just before
           String insertBeforeId = container.getChildren().get(index).getId();
           change = new AddChildDocumentChange(insertBeforeId, docFrag);
        } else {
            change = new AddChildDocumentChange(docFrag);
        }

        // Apply the "add child" DocumentChange using ChangeManager
        ChangeManager changeManager = rctx.getChangeManager();
        changeManager.addDocumentChange(context, container, change);

        // Refresh the target container using PPR
        rctx.addPartialTarget(container);

        // Mark the drop as completed.
        return true;
        } catch (Exception e) {
            return false;
        }
    }
```

In this example, a `DropEvent` parameter is passed to the `handleDrop` method. This parameter has three attributes that can be described as follows:

- `transferable`, like `DataFlavor`, is a standard Java class that contains the data being added.
- `container` is the container into which component must be dropped.
- `index` is the position of the component inside the container. For example, first, second, and so on.

9. Save the `TestDropHandler.java` file.

21.7.1.2 Registering a Drop Handler with Composer

After implementing the drop handler, you must register it with Composer. Registration is necessary for ensuring that the handler is called by Composer when a user clicks an Add link in the catalog. Register drop handlers in the Composer extension file, `/META-INF/pe_ext.xml`. For more information about creating this file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

To register a drop handler:

1. In the `pe_ext.xml` file, add the following entries:

```
<drop-handlers>
  <drop-handler>test.TestDropHandler</drop-handler>
</drop-handlers>
```

   where `TestDropHandler` is the name of the drop handler implementation.

2. Save the file.

You can register any number of drop handlers in the extension file by adding that many `<drop-handler>` elements.

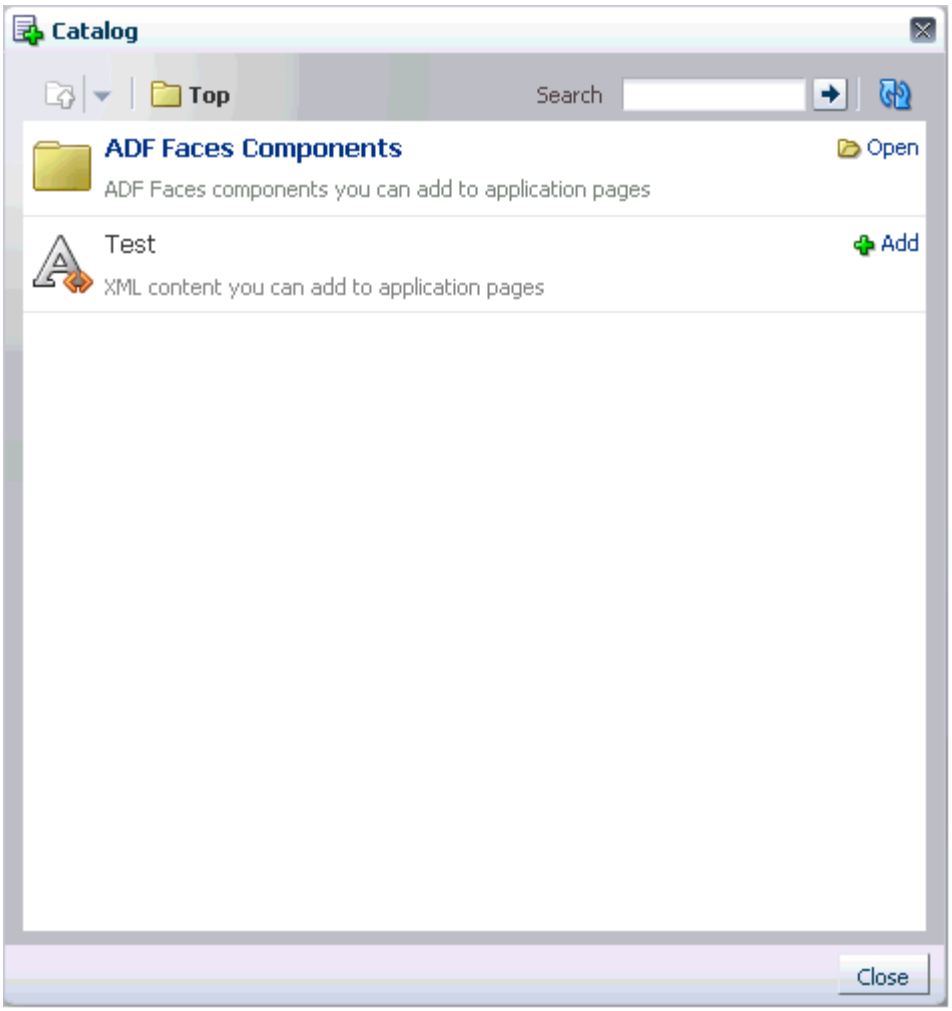
21.7.1.3 Adding an XML Component to the Resource Catalog

Since you created a drop handler for XML components generated by the `XmlComponentFactory` class, you can test how the drop handler works at runtime by adding an XML component to the Resource Catalog and then adding that component to your page at runtime.

To add an XML component to the catalog:

1. Open the default catalog definition file, `default-catalog.xml`.

   For information about the location of this file, see "Default Resource Catalog Configuration".



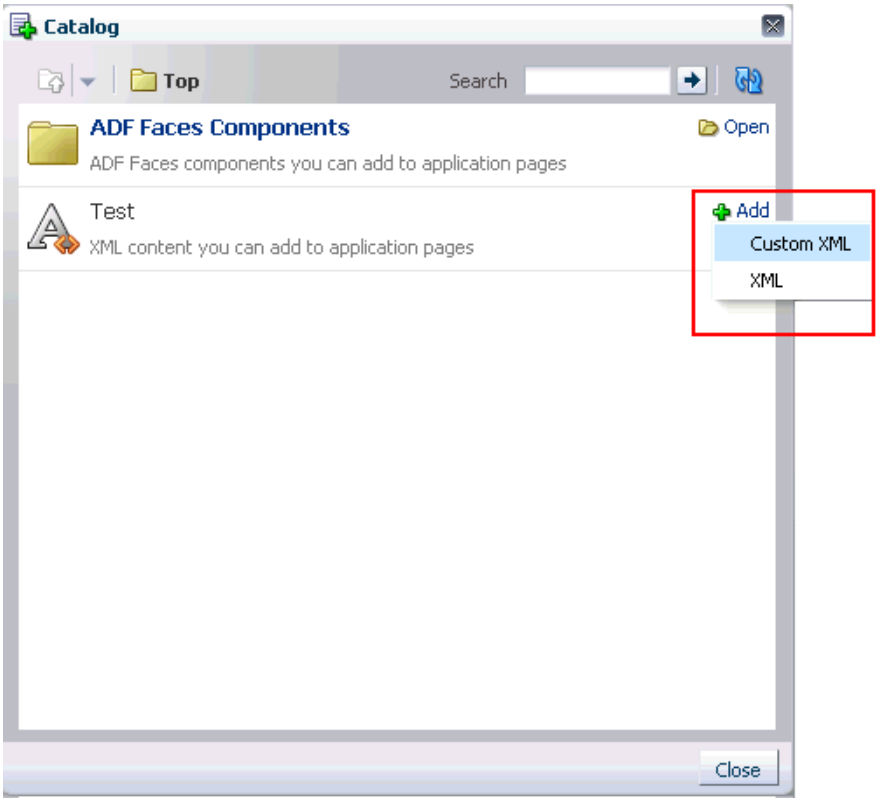
2. Add the following code within the `<contents>` section of the file:

```
<component id="pc" factoryClass="oracle.adf.rc.component.XmlComponentFactory">
  <attributes>
    <attribute attributeId="Title" value="Test"/>
    <attribute attributeId="Description" value="XML content you can add to
application pages"/>
    <attribute attributeId="IconURI" value="/adf/pe/images/elementtext_
qualifier.png"/>
    </attributes>
    <parameters>
      <parameter id="xml">
        <af:outputText value="Hello!"
xmlns:af="http://xmlns.oracle.com/adf/faces/rich"/>
      </parameter>
    </parameters>
</component>
```

3. Save the `default-catalog.xml` file.

   At runtime, the Resource Catalog shows the XML component, as shown in Figure 21–17. For more information, see Section 16.2.3.4, "Adding a Component."

Figure 21–17 XML Component in the Catalog



21.7.2 What Happens at Runtime

When a user clicks the Add link against a component in the catalog, all drop handlers supporting that flavor are displayed as options on the context menu of the Add link. However, if only a single drop handler is available to handle that flavor, then the resource is added to the page immediately.

Figure 21–18 shows the context menu displayed on clicking the Add link of the `Test` XML component with the `Custom XML` option and the default XML option.

Figure 21–18 Drop Handlers on an XML Component in the Catalog

21.8 Defining Property Filters

Some component properties are not displayed in Composer's Component Properties dialog because they are filtered out by default. The default filters are defined in the `<filter-config>` section of the Composer's extension file (/META-INF/pe_ext.xml).

Global filters filter attributes for all components. They are defined using the `<global-attribute-filter>` tag. Tag-level filters filter attributes for a specified component only. They are defined using the `<taglib-filter>` tag.

> **Note:** In an extension file, you can have any number of `<taglib-filter>` tags under `<filter-config>`, but you can have only one `<global-attribute-filter>` tag to define all global attribute filters.

You can define additional filters to hide more properties in the Component Properties dialog. This section describes how. It contains the following subsections:

- Section 21.8.1, "How to Define Property Filters"
- Section 21.8.2, "What Happens at Runtime"
- Section 21.8.3, "How to Remove Property Filters"

21.8.1 How to Define Property Filters

Composer defines a built-in filter configuration. You can use the extension file, `pe_ext.xml`, to define additional property filters and to delete filters. You can define any number of filters, even for a single tag, in different extension files. Composer merges the filtering information from all the extension files.

> **Note:** For information about creating the `pe_ext.xml` file, see Section 21.2.1.2, "Registering Add-Ons with Composer."

To define property filters in an extension file, use the `filter-config` element. The following elements are defined for the contained `attribute` tags.

- The `label` element allows you to override the default label for the element in the UI. You can use EL to retrieve localized strings or display different labels in design and source view.
- The `view` element can be used to filter attributes in specific tags for a specific view (`design` or `source`).
- The `filtered` element can be used to display an attribute even if it is globally filtered. To restore a globally filtered element, use `filtered="false"`.

In the `pe_ext.xml` file, add the `filter-config` element as shown in the following example:

```
<filter-config>
   <global-attribute-filter>
    <attribute name="readOnly" filtered="false" label="Read Only"/>
    <attribute name="required" filtered="false" label="Mandatory"/>
    <attribute name="shortDesc" filtered="false" label="#{Bundle.PNL_TB_
SHORTDESC}"/>
  </global-attribute-filter>

  <taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="goLink">
      <attribute name="accessKey" view="design"/>
      <attribute name="targetFrame" filtered="false" view="source"/>
      <attribute name="destination" filtered="false"
label="#{pageEditorPanelBean.layoutView ?  'Where do you want to surf?' :
'Destination'}"/>
    </tag>
    <tag name="inputText">
      <attribute name="all" view="design"/>
      <attribute name="label" label="Field Name" filtered="false" />
      <attribute name="readOnly" filtered="false" />
      <attribute name="required" filtered="false" />
      <attribute name="rendered" filtered="false" />
      <attribute name="wrap" filtered="false" />
    </tag>
  </taglib-filter>
</filter-config>
```

Save the file.

21.8.2 What Happens at Runtime

At runtime, when you edit a component's properties, the properties that were filtered out are not rendered in the Component Properties dialog.

21.8.3 How to Remove Property Filters

You can remove global and tag-level filters so that previously filtered properties are now rendered in the Component Properties dialog. This is useful for displaying properties that are filtered out by Composer's built-in filters or by another extension file defined elsewhere the application.

> **Note:** After you remove a property filter, it is rendered in the Component Properties dialog even if a filter is defined for that property in another extension file.

To remove a property filter:

1. Edit the Composer extension file, `pe_ext.xml`, available in the `META-INF` directory.

   You can remove property filters by editing entries in this file.

2. Search for the attribute from which to remove the filter, and set `filtered` to `false` in the `<attribute>` tag as shown in the following example:

```
<pe-extension xmlns="http://xmlns.oracle.com/adf/pageeditor/extension">
. . .
<filter-config>
  <global-attribute-filter>
    <attribute name="accessKey" filtered="false" />
    <attribute name="attributeChangeListener" />
    . . .
  </global-attribute-filter>
  <taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="activeCommandToolbarButton">
      . . .
      <attribute name="windowWidth" filtered="false"/>
    </tag>
  </taglib-filter>
</filter-config>
</pe-extension>
```

3. Save the file.

21.9 Enabling Parameter Support on the Customization Manager Task Flow

If you enable parameter passing on the task flow, administrators can customize Customization Manager by setting certain parameters. By default, an administrator cannot pass parameters to the Customization Manager task flow in Composer. Table 21–2 describes the parameters supported by the Customization Manager task flow.

Table 21–2 Customization Manager Task Flow Parameters

Parameter Name	Value	Description
defaultPage	Page URI	Used to specify the default page to be managed. If this value is null, the current page will be used.

Table 21–2 (Cont.) Customization Manager Task Flow Parameters

Parameter Name	Value	Description
dynamicNodeMap	`Map<String,List<CustomizationManagerNode>>`	Used to return a list of pages, XML documents, or task flows on a given page or fragment, using the following format: `Page1.jspx -> List of {CustomizationManagerTaskFlowNode or CustomizationManagerPageNode or CustomizationManagerXMLNode }` Use `CustomizationManagerTaskFlowNode` to pass dynamic taskflows in that page. Use `CustomizationManagerPageNode` to pass page template of the page. Use `CustomizationManagerXMLNode` to pass any XML documents owned by this page.
showBase	true/false Default: false	Used to show or hide the column for the base document.
showCurrentLayers	true/false Default: true	Used to show or hide the column showing details about the currently used layer.
showAllLayers	true/false Default: true	Used to show or hide the column showing details about layers other than the current one.
showLayersforCurrent	`Map<String,List<String>>`	Used to specify a list of layers that must be available in the Current Context column. This parameter takes the layer name and list of layer values and patterns that must be shown in the Current Context column. See Example 21–16 for more information.
showLayersforAll	`Map<String,List<String>>`	Used to specify a list of layers that must be available in the All Layers column. This parameter takes the layer name and list of layer values and patterns that must be shown in the All Layers column. See Example 21–16 for more information.
labelPrefixes	`List<String>`	Used to specify a list of space-separated label prefixes that must be displayed in the Promote dialog. Only those labels created with the specified prefixes are displayed in the Promote dialog. By default, all the labels are displayed.

Table 21–2 (Cont.) Customization Manager Task Flow Parameters

Parameter Name	Value	Description
maxDepth	String	Used to restrict the depth of a task flow hierarchy in the Customization Manager. The default value is `10`. Consequently, if you have a task flow with cyclic dependency, this parameter prevents a stack overflow by limiting the depth to ten nested task flows. You can display a maximum nesting of 10 task flows. Customization Manager displays only a depth of 10 even if you specify avalue higher than 10.
showDownload	true/false Default: true	Used to show or hide the Download link.
showUpload	true/false Default: true	Used to show or hide the Upload link.
showDelete	true/false Default: true	Used to show or hide the Delete link.
showPromote	true/false Default: true	Used to show or hide the Promote link.

Note: The implementation of `Map` and `List` must be `Serializable` for Customization Manager to work correctly in a cluster-based environment. Typically, `ArrayList` and `HashMap` are `Serializable`.

This section describes the steps to enable parameter editing on the Customization Manager task flow. It contains the following subsections:

- Section 21.9.1, "How to Set the Customization Manager Task Flow Parameters"
- Section 21.9.2, "What Happens When You Enable Parameter Support"

21.9.1 How to Set the Customization Manager Task Flow Parameters

To pass parameters to the Customization Manager task flow, you must define the `parameters` attribute as part of the Customization Manager add-on panel configuration in your application's `adf-config.xml` file.

To enable parameter editing on the task flow:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the following namespace within the `adf-config` element in the file:

   ```
   xmlns:pe="http://xmlns.oracle.com/adf/pageeditor/config"
   ```

3. Add a `<pe:page-editor-config>` entry with the namespace and include an `<pe:addon-panels>` entry.

Within <pe:addon-panels>, add an <pe:addon-panel> entry for the default Customization Manager panel and define the parameters attribute by setting it to appUtilBean.customizationManagerParams, as shown in Example 21–16.

Example 21–16 Customization Manager Add-On Referenced in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:addon-panels>
    <pe:addon-panel name="oracle.adf.pageeditor.addonpanels.customization-manager"
parameters="#{AppUtilBean.customizationManagerParams}"/>
    . . .
  </pe:addon-panels>
</pe:page-editor-config>
```

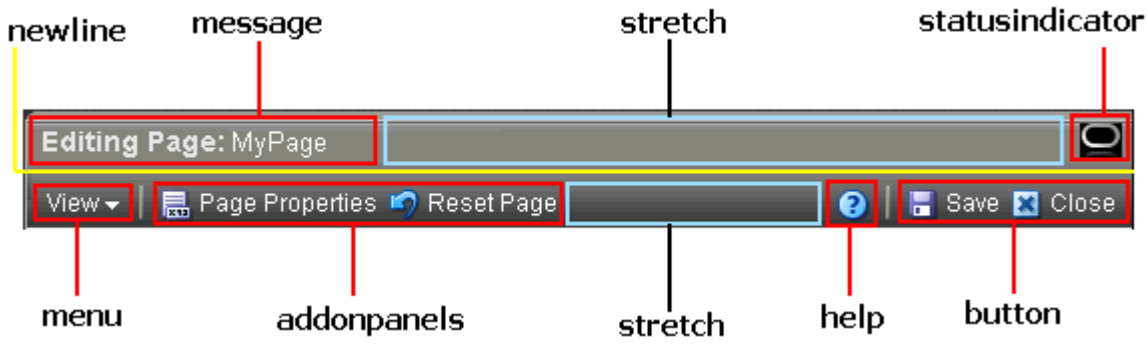
where AppUtilBean is a sample implementation of the AppUtilBean class, and is as shown in the following example:

```
public Map<String, Object> getCustomizationManagerParams()
{
  Map<String, Object> paramMap = new HashMap<String, Object>();
  Map<String, List<String>> showLayersForCurrent = new HashMap<String,
List<String>>();
  showLayersForCurrent.put("user", Arrays.asList("admin%", "weblogic"));
  paramMap.put("showLayersForCurrent", showLayersForCurrent);

  Map<String, List<String>> showLayersForAll = new HashMap<String,
List<String>>();
  showLayersForAll.put("enterprise", Arrays.asList("Frys"));
  paramMap.put("showLayersForAll", showLayersForAll);

  return paramMap;
}
```

4. Save the adf-config.xml file.



21.9.2 What Happens When You Enable Parameter Support

Customization Manager displays options to users based on the new parameter settings.

21.10 Customizing the Composer Toolbar

You can customize the default Composer toolbar by adding, removing, or rearranging elements and overriding existing elements. To enable toolbar extensibility, the Composer toolbar elements have been grouped into sections. You can work with these sections to customize your toolbar. Each section has a specific name and contains one or more elements inside it, as shown in Figure 21–19.

Figure 21–19 Composer Toolbar

Notes: The Save button is displayed on the toolbar only if the application is configured to use a sandbox. For more information, see Section 23.2, "Using Composer Sandbox."

The Help icon is displayed on the toolbar only if you have configured a help provider in your application or hooked up help from Composer panels or dialogs. For more information, see Section B.4, "Composer Help Topic IDs."

The Composer toolbar is created using the ADF Faces `Toolbox` tag. Each row in the toolbar is a `Toolbar` tag. Consequently, UI components such as separator bars are inherited from the `Toolbar` component.

Table 21–3 describes the toolbar areas.

Table 21–3 Toolbar Areas

Section or Area	Description
`message`	Area containing the message with the page name.
`statusindicator`	Area containing the status indicator.
`menu`	Area containing the View menu that allows users to switch between Design view and Source view.
`addonpanels`	Area containing Composer add-ons. The add-ons are all displayed in a sequence within this area. For more information, see Section 21.2, "Creating Composer Add-Ons."
`help`	Area containing the Help icon.
`button`	Area containing the Save and Close buttons.
`stretch`	Wide space between two sections.
`newline`	A line break between sections. All sections after a line break are pushed to a new line on the toolbar.

Using toolbar sections, you can customize the Composer toolbar in the following ways:

- Rearrange and hide built-in elements
- Add new sections with custom elements

- Modify default sections to display custom elements

This section describes the steps to customize the Composer toolbar. It contains the following sections:

- Section 21.10.1, "How to Rearrange or Hide Toolbar Elements"
- Section 21.10.2, "What Happens at Runtime"
- Section 21.10.3, "How to Add New Sections to the Toolbar"
- Section 21.10.4, "How to Override a Toolbar Section to Display Custom Content"

21.10.1 How to Rearrange or Hide Toolbar Elements

Use the `toolbarLayout` attribute on a `Page Customizable` component to control which toolbar sections are displayed and the order in which they appear.

To customize the toolbar for all editable pages in the application, you can create a template, add a `Page Customizable` component to the template, and specify the `toolbarLayout` attribute against the `Page Customizable` component. You can then base all the pages in the application on that template.

If you do not specify a value for `toolbarLayout`, this attribute is internally set to `message stretch statusindicator newline menu addonpanels stretch help button`, which is the default layout for the Composer toolbar sections.

To customize the toolbar on an application page:

1. Open your customizable JSPX page in JDeveloper and select the `Page Customizable` component in the Structure window.
2. In the Property Inspector, specify space-separated values for the `toolbarLayout` attribute.

   The section names in Table 21–3 are valid values for this attribute.

   Note: You can add only one `stretch` value per row on the toolbar. If you add more than one `stretch` value, only the first one is displayed; all others are ignored.

   In Source view, the `toolbarLayout` attribute appears as shown in the following example:

```
<pe:pageCustomizable id="pageCustomizable1"
                     toolbarLayout="button stretch statusindicator menu"
  <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
  <f:facet name="editor">
    <pe:pageEditorPanel id="pep1"/>
  </f:facet>
</pe:pageCustomizable>
```

3. Save the JSPX file.

21.10.2 What Happens at Runtime

At runtime, the toolbar displays the sections you specified in the order you specified them (Figure 21–20).

Figure 21–20 Customized Composer Toolbar

21.10.3 How to Add New Sections to the Toolbar

You can add custom sections by creating facets and specifying the facet names in the `toolbarLayout` attribute. Populate the new facets with elements you want to display on the toolbar. The following example shows you how to create a section; specifically, how to add a **Report a Bug** button that opens a popup that enables users to report a bug.

To add a custom section:

1. Open the JPSX page for which you want to customize the toolbar.
2. Add a `facet` inside the `Page Customizable` and name it `bugreport`.
3. Add a `Command Toolbar Button` component inside the facet and set the `text` attribute to `Report a Bug`.
4. To add an image to the button, specify the path to the image using the `icon` attribute.
5. Add the `Show Popup Behavior` component to invoke a popup on clicking the `Command Toolbar Button`.

   In Source view, the `Page Customizable` would appear as follows:

```
<pe:pageCustomizable id="pageCustomizable1"
             toolbarLayout="message stretch bugrep newline menu stretch button"
  <f:facet name="bugrep">
    <af:commandToolbarButton id="cmd1" text="Report a bug"
                             icon="/images/bug.png"
                             clientComponent="true">
      <af:showPopupBehavior popupId="p1" triggerType="action"/>
    </af:commandToolbarButton>
  </f:facet>
. . .
  <af:popup id="p1">
    <af:dialog id="dlg1" title="File a Bug"
               affirmativeTextAndAccessKey="File">
      <af:panelFormLayout labelWidth="30%" id="pfl1">
        <af:inputText id="it0" maximumLength="80"
                      label="Product/Component" required="true"/>
        <af:inputText id="it1" maximumLength="80" label="Subject"
                      required="true"/>
        <af:inputText id="it2" rows="3" label="Problem" required="true"/>
        <af:inputText id="it3" rows="3" label="Steps" required="true"/>
      </af:panelFormLayout>
    </af:dialog>
  </af:popup>
  . . .
</pe:pageCustomizable>
```

6. Save the page.

   At runtime, the Composer toolbar displays a **Report a Bug** button, as shown in Figure 21–21.

Figure 21–21 Composer Toolbar with Custom Section

Clicking the Report a Bug button displays the File a Bug dialog that enables users to report a bug.

21.10.4 How to Override a Toolbar Section to Display Custom Content

You can display custom content in a default toolbar section by adding a facet of the same name as the section and populating it with custom content. The facet content overrides the content of the default section. For example, to display a custom message to users in place of the `Editing Page: Page_Name` message, you can create a custom facet named `message` and include an `Output Text` component with the text you want to display to users. The `Output Text` component then displays in place of the default message. The following example shows a `Page Customizable` component with a custom toolbar message:

```
<pe:pageCustomizable id="pageCustomizable1"
                     toolbarLayout="message newline button stretch statusindicator
menu"
  <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
  <f:facet name="message">
    <af:outputText value="Welcome!"/>
  </f:facet>
  <f:facet name="editor">
    <pe:pageEditorPanel id="pep1"/>
  </f:facet>
</pe:pageCustomizable>
```

Figure 21–22 shows the Composer toolbar displayed for the page at runtime.

Figure 21–22 Composer Toolbar with a Custom Message

21.11 Enabling Direct Select in Design View

Direct select allows you to extend specific customization capabilities from Composer Source view to Design view, allowing users to modify elements from within the page at runtime. This allows you to put more control in the hands of the business user, while creating a safe environment where no damage can be done to the underlying application.

All direct select functionality is available in Source view, but business users do not have the knowledge or experience to use Source view safely and effectively. These users could easily break the page and circumvent application logic.

Using direct select, you can enable a small number of chosen components to be selectable and editable. For example, changing the order of fields in a form, changing the labels on form fields, changing column names in a table, or hiding specific fields in a form.

For more information on direct select functionality, see Section 21.11.2, "What Happens at Runtime."

21.11.1 How to Enable and Configure Direct Select

This section explains how to enable and configure direct select in your application.

1. First you must enable direct select for the Design view in Composer. In adf-config.xml, inside the `<pe:page-editor-config>` tag, add the `<pe:enable-design-views>` tag to define the available views. The possible constant values are:

   - `all`: Makes all views available and displays a toolbar with buttons to switch between views.
   - `add-content` (default): Makes the legacy Design view the only available view.
   - `select`: Makes the Select view the only available view.
   - `select add-content`: Limits the available views to only the Select and legacy Design views (additional views will be added in future releases). Displays the toolbar with buttons to switch between views.

   You can also use EL to determine the appropriate view, as shown in the example below:

   ```
   <pe:enable-design-views>#{testBean.designViews}</pe:enable-design-views>
   ```

   Note: This setting defines the default for the application. You can override this setting in any `pageCustomizable` tag using the `designViews=""` attribute.

   By default the hot key to open and close Design view is Ctrl-Shift-S. To change or disable the hot key, add a `<pe:component-view-switch-key>` tag inside the `<pe:page-editor-config>` tag. For example:

   ```
   <pe:component-view-switch-key>
     <pe:enabled>true</pe:enabled>
     <pe:key-sequence>ctrl shift l</pe:key-sequence>
   </pe:component-view-switch-key>
   ```

2. In pe-ext.xml, add the `<selection-config>` tag to enable or disable direct select for specific components and define associated operations. To make a component selectable, you must define operations within this tag. (If no operations are defined and selection is enabled for a component, selecting the component will display an empty frame.)

   Within the `<selection-config>` tag, you can configure direct select globally using `<global-filter>` and by namespace and tag using `<selection-taglib-filter>`. The `<selection>` tag has two required attributes:

   - `view`: Defines the view to be configured in the tag. In the current release, the only accepted value is `design` (direct select cannot be disabled in source view).
   - `enabled`: Sets whether or not direct select is enabled in the specified view.

   Available operations are defined within `<operation>` tags under each specific component. The following elements are used to define operations:

- `name`: Defines the operation (standard or custom) to be executed. The operation name is the same as the property panel ID. For a list of standard operations, see Section B.3.2, "Default Property Panels." For custom operations, the name is the same as the custom panel ID. For details on custom operations, see Section 21.3, "Creating Custom Property Panels."
- `label` (optional): Sets the tab label in the popup window. The default label is the operation name.
- `filtered`: Set to `false` to include the operation in the popup window.

Note: It is a recommended practice to provide selection for a small number of components at first, then add more as functionality is tested and learned. This can be done easily by globally disabling selection in the `<global-filter>` tag and enabling selection for individual components using `<selection-taglib-filter>` as shown in the example that follows.

```
<selection-config>
  <global-filter>
    <selection view="design" enabled="false"/>
  </global-filter>

  <selection-taglib-filter
   namespace="http://xmlns.oracle.com/adf/faces/customizable">
    <tag name="showDetailFrame">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.sdfprop"
                 label="SDF Change Property"
                 filtered="false"/>
    </tag>
  </selection-taglib-filter>

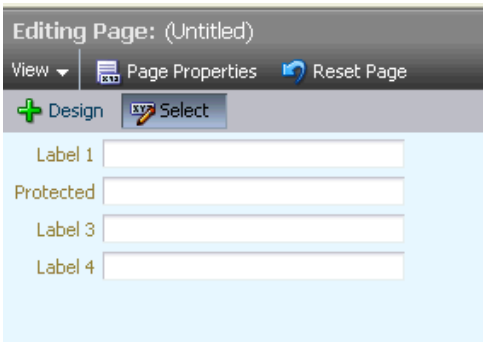
  <selection-taglib-filter namespace="http://xmlns.oracle.com/adf/faces/rich">
    <tag name="goLink">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.generic-property-inspector"
                 label="Change Property"
                 filtered="false"/>
      <operation name="oracle.adf.pageeditor.pane.inline-style-editor"
                 label="Inline Style"
                 filtered="false"/>
    </tag>
    <tag name="commandButton">
      <selection view="design" enabled="true"/>
      <operation name="oracle.adf.pageeditor.pane.generic-property-inspector"
                 label="Change Property"
                 filtered="false"/>
    </tag>
  </selection-taglib-filter>
</selection-config>
```

To further simplify the user experience, direct select allows you to filter specific attributes for a tag so that a smaller set is displayed. For details, see Section 21.8.1, "How to Define Property Filters."

3. To enable or disable direct select for a specific component within a .jspx page, add the `<f:attribute name="pe-select" value="true|false">` tag within the component tag as shown in the example that follows. The setting in this tag

overrides the setting in the `<selection-config>` for the component in the pe_ext.xml file. (As noted above, to enable direct select, operations must be defined for the component in the pe_ext.xml file, or selecting it will open an empty dialog.)

```
<af:panelGroupLayout id="pgl2" layout="vertical">
<f:attribute name="pe-select" value="false"/>
  <af:inputText id="it6" label="Unselectable" value="Enter here..."/>
  <af:goLink id="gl1" destination="http://www.oracle.com" text="Oracle"/>
  <af:inputText id="it7" label="Selectable(override)" value="Enter here...">
    <f:attribute name="pe-select" value="true"/>
  </af:inputText>
</af:panelGroupLayout>
```

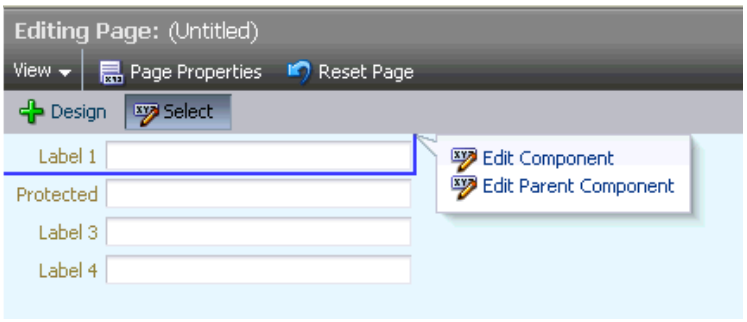


4. To disallow the use of Expression Language in form fields and protect existing EL from overwrite, see Section 21.4.2, "How to Protect Expression Language."

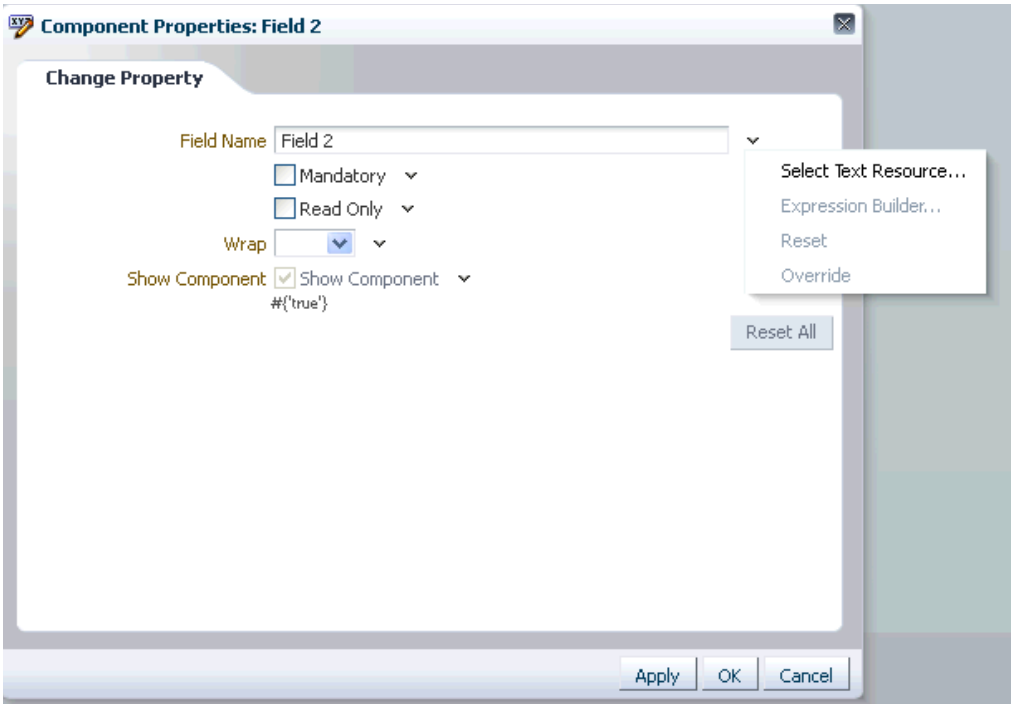
For more information on specific elements, see the following sections in Appendix B, "Composer Component Properties and Files":

- Section B.2.1.8, "selection-config"
- Section B.2.2.5, "enable-design-views"
- Section B.2.2.6, "allow-el and protect-el"

21.11.2 What Happens at Runtime



When direct select is enabled, the outward presentation of the page at runtime does not appear any different to the end user. When a user with the appropriate permissions clicks Ctrl-Shift-S, the page opens in Design view.



Design view includes the Composer toolbar. If more than one view is enabled, the page also includes a second toolbar with **Design** and **Select** buttons to switch between views, as shown in the image above. If only a single view is enabled, these buttons are not displayed.

> **Note:** If 'select' is defined as the only available view, users have no way to add content from Design view. If 'add-content' is defined as the only available view, the user experience is the same as if direct select was not enabled.

To edit the properties for a component, the user selects an enabled element and clicks **Edit Component** or **Edit Parent Component** (when applicable).

The **Component Properties** popup window allows the user to edit properties defined for the component and access other operations configured for the component. If the user chose Edit Parent Component, a Manage Children tab is included in the window. If EL is not allowed or is protected from overwrite, the Expression Builder and Override options are not available, as shown in the image below. This image also includes an example of a field that is protected from edit (Show Component).

Multiple operations are shown in tabs in the popup window. The order of tabs is defined in the panel registration. If an operation references a panel that is not registered for the enclosing component, the tab for that operation will not be displayed. For details on panel registration, see Section 21.3, "Creating Custom Property Panels."

21.12 Troubleshooting Problems with Composer Extensibility Features

This section provides information to assist you in troubleshooting problems you may encounter while using the Composer extensibility features.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

You created an add-on, but it does not appear on the Composer toolbar.

Solution

Ensure the following:

- The `pe_ext.xml` file is in `/META-INF` folder in a JAR file or the application and is available in the class path.
- The task flow binding ID specified while registering the panel in `pe_ext.xml` is correct.
- An `<pe:addon-panel>` entry exists under the `<pe:page-editor-config>` section in the `adf-config.xml` file.
- If the add-on is in a JAR file, ensure that the JAR file is created as an ADF Library.

For information about add-ons, see Section 21.2, "Creating Composer Add-Ons."

Problem

You have registered a custom property panel. However, it does not appear in the Component Properties dialog when your select a component to display its properties.

Solution

Ensure the following:

- The `pe_ext.xml` file is in `/META-INF` folder in a JAR file or the application and is available in the class path.
- The task flow binding ID specified while registering the panel in `pe_ext.xml` is correct.
- The `property-panel` registration is correct and is specified against the component you want the panel to appear against. Further, the fully qualified class name of the component is correctly specified using the `component` node.
- A duplicate property panel registration is not overriding your panel entry.
- If the panel is configured to use the rendered attribute, ensure that the value or EL evaluates to `true`.
- If the add-on is in a JAR file, ensure that the JAR file is created as an ADF Library.

For information about custom property panels, see Section 21.3, "Creating Custom Property Panels."

Problem

You do not see some properties of a component in the Component Properties dialog.

Solution

Ensure that the component properties are not filtered or restricted. For more information, see Section 21.8.1, "How to Define Property Filters" and Section 24.4, "Applying Attribute-Level Security."

22

Performing Advanced Composer Configurations

This chapter describes how to perform certain advanced Composer configurations to enhance the end user experience. It contains the following sections:

- Section 22.1, "Enabling Custom Actions on a Show Detail Frame Component by Using Facets"
- Section 22.2, "Enabling Custom Actions on a Show Detail Frame Component By Using Facets: Example"
- Section 22.3, "Enabling Custom Actions on a Task Flow"
- Section 22.4, "Enabling Custom Actions that Display on Task Flows in the Component Navigator"
- Section 22.5, "Configuring a Keyboard Shortcut to Access Composer"
- Section 22.6, "Creating Event-Enabled Task Flows"
- Section 22.7, "Configuring an Application Page to Display in Source View by Default"
- Section 22.8, "Disabling the Source View Menu for an Application"
- Section 22.9, "Disabling Task Flow Zoom Capability"
- Section 22.10, "Applying Styles to Components"
- Section 22.11, "Configuring the Persistence Change Manager"
- Section 22.12, "Configuring Runtime Resource String Editing"

22.1 Enabling Custom Actions on a Show Detail Frame Component by Using Facets

You can use the `Show Detail Frame` component's facets to define and display custom actions on `Show Detail Frame` components. For example, if your `Show Detail Frame` contains a list of services provided in your application, you can add a custom action, `Show Detailed Information`, which opens up a task flow containing details about the various services.

For information about the facets supported by `Show Detail Frame` components, see Section B.1.5, "Show Detail Frame Component."

Oracle JDeveloper displays all facets available to the `Show Detail Frame` component in the Structure window, however, only those that contain UI components appear activated.

To add a Show Detail Frame facet, perform the following steps:

1. Right-click a `Show Detail Frame` component in the Structure window, and select **Facets - Show Detail Frame**.
2. Click the arrow to the right of this option.
3. From the list of supported facets, select the facet you want to add.

   Note: A check mark next to a facet name means the facet is already inserted in the `Show Detail Frame` component. Selecting that facet name again would result in the facet getting deleted from the page.

   The `f:facet` element for that facet is inserted in the page.
4. Add components in the facet according to your design requirements.

   For an end-to-end example of creating and using `Show Detail Frame` facets, see Section 22.2, "Enabling Custom Actions on a Show Detail Frame Component By Using Facets: Example."

22.2 Enabling Custom Actions on a Show Detail Frame Component By Using Facets: Example

Assume a JSPX page, `Page1`, with a `Panel Customizable` component. Inside the `Panel Customizable` is a `Show Detail Frame` component (`showDetailFrame1`). Inside the `Show Detail Frame` is an ADF task flow. The `Panel Customizable` has two other `Show Detail Frame` components, one above and the other below `showDetailFrame1`. The task flow displays two `Output Text` components on the page.

You can configure an `Additional Actions` facet on the `Show Detail Frame` component to display a **Customize** action on the Actions menu along with the **Move Up** and **Move Down** actions. At runtime, the **Customize** action enables users to customize the text in the `Output Text` components. This section describes the steps you take to achieve this effect. It contains the following subsections:

- Section 22.2.1, "How to Create an ADF Task Flow"
- Section 22.2.2, "How to Include an Additional Actions Facet"
- Section 22.2.3, "How to Create a Redirection Page"
- Section 22.2.4, "How to Create Navigation Rules Between Pages"
- Section 22.2.5, "What Happens at Runtime"

22.2.1 How to Create an ADF Task Flow

To create an ADF task flow:

1. From the **File** menu, select **New**.
2. In the **New** dialog, select **JSF** under Web Tier node, and select **ADF Task Flow** under Items.
3. Click **OK**.
4. In the Create Task Flow dialog, click **OK** to create a task flow definition file by accepting the default values.

5. From the **ADF Task Flow** tag library in the Component Palette, drop two view elements, **view1** and **view2**, onto the task flow definition file.
6. Drop a **Control Flow Case** from `view1` to `view2`.
7. Click the first view element and then click the second view element to draw the control flow line.

   Name this control flow case `next`.
8. Similarly, drop a **Control Flow Case** from `view2` back to `view1` and name it `prev`.
9. Create a backing bean called `BackingBean.java` to contain values for two variables `view1` and `view2`.

   `view1` and `view2` are initialized with `initialValue1` and `initialValue2` respectively. Ensure that the code of the bean is as show in the following example:

```
package view;

public class BackingBean {
    public BackingBean() {
    }

    private String view2 ="initial Value1";
    private String view1 = "initial Value2";

    public void setView2(String view2) {
        this.view2 = view2;
    }

    public String getView2() {
        return view2;
    }

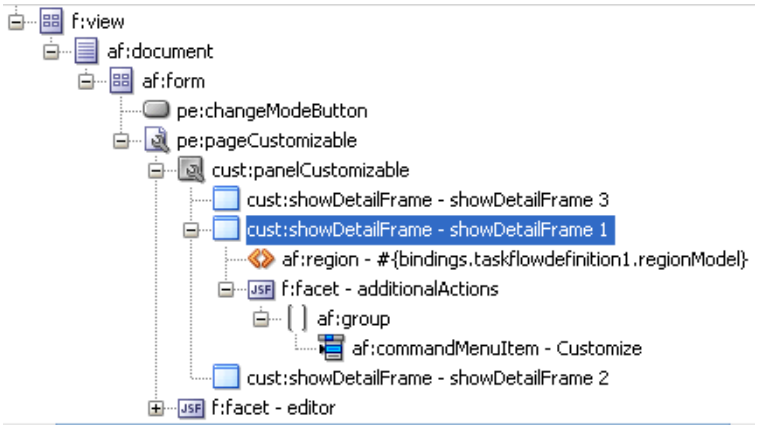
    public void setView1(String view1) {
        this.view1 = view1;
    }

    public String getView1() {
        return view1;
    }
}
```

10. In the task flow definition file, double-click **view1** to create the page fragment (`view1.jsff`) for that element.
11. Add a **Panel Group Layout** and two **Output Text** components to `view1.jsff`.
12. Specify the `Value` for the first `Output Text` component to be `#{backingBean.view1}`, and specify the `Value` for the second `Output Text` component to be `#{backingBean.view2}`.
13. Save `view1.jsff`, and close it.
14. In the task flow definition file, double-click **view2** to create the page fragment (`view2.jsff`) for that element.
15. Add just one **Output Text** component to `view2.jsff`, and specify `Value` to be `#{backingBean.view2}`.
16. Save `view2.jsff`, and close it.

22.2.2 How to Include an Additional Actions Facet

To include an Additional Actions facet:



1. Create a JSPX page, `Page1.jspx`, with a `Panel Customizable` component and a nested `Show Detail Frame` component.
2. Add two more `Show Detail Frame` components, above and below the existing `Show Detail Frame` component.

   The purpose of adding three `Show Detail Frame` components is to enable the display of `Move Up` and `Move Down` actions along with the additional action on the first `Show Detail Frame` component, `showDetailFrame1`.
3. Add the task flow definition file that you created in the previous step inside `showDetailFrame1`.
4. Right-click the first `Show Detail Frame` in the Structure window, and select **Facets - Show Detail Frame**.
5. Click the arrow to the right of this option, and from the list of supported facets, select **Additional Actions**.

   The `f:facet-additionalActions` element for that facet is inserted in the page.
6. Add a **Panel Group Layout** inside the `Additional Actions` facet, and add a **Button** component inside the `Panel Group Layout` component.
7. Set the `Text` attribute for the `Button` to `Customize`, and specify `customize` as the `Action` value.

   The page in the structure navigator should appear as shown in Figure 22–1.

Figure 22–1 Page1.jspx in Structure Navigator

8. Save the page.

22.2.3 How to Create a Redirection Page

To create the redirection page:

1. Create a JSPX page called `Page2.jspx`, and add two **Input Text** components and a **Button** component.

2. Specify the `Value` for the first `Input Text` component to `#{backingBean.view2}`, and set the `Value` attribute for the second `Input Text` component to `#{backingBean.view1}`.

   The purpose of adding `Input Text` components with references to the backing bean is to enable the passing of a user's input to the bean so that it can be reflected in the `Output Text` components on `Page1.jspx`.

3. On the `Button` component, set the `Text` attribute to `OK` and specify `back` as the `Action` value.

4. Save the page.

   You can now enable switching between the two pages by defining navigation rules.

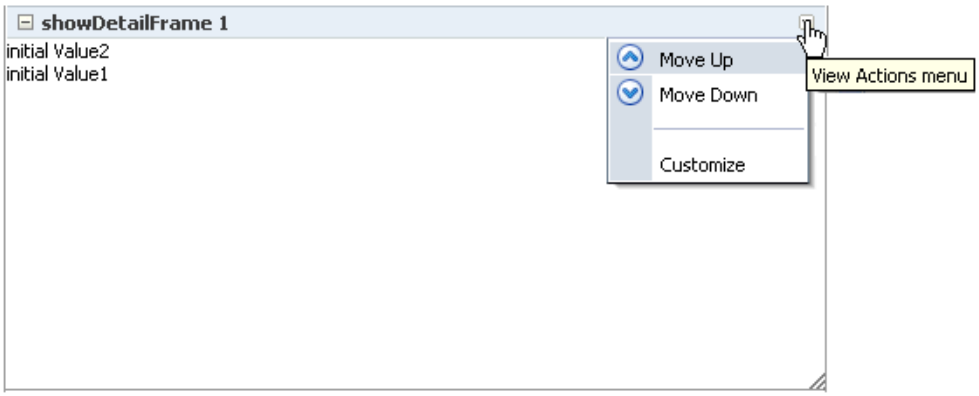
22.2.4 How to Create Navigation Rules Between Pages

To define navigation rules between the pages:

1. In the Application Navigator, under the project's WEB-INF folder, double-click the **faces-config.xml** file to open it.
2. Click the **Overview** tab to view the file in Overview mode.
3. Click the **Add** button in the Managed Bean section.
4. In the Create Managed Bean dialog, specify `backingBean` as the name.
5. For the Class Name field, click the **Browse** button adjacent to it and browse to the `BackingBean` Java class that you created earlier. Click **OK**.
6. Click **OK**.
7. From the Scope list, select **session** and click **OK**.
8. Select the **Navigation Rules** tab on the page.
9. In the From Views table, select **Page1.jspx**.
10. Under Navigation Cases, select **Page2.jspx** in the To View ID column, **customize** in the From Outcome column, and **true** in the Redirect column.
11. In the From Views table, select **Page2.jspx**.
12. Under Navigation Cases, select **Page1.jspx** in the To View ID column, **back** in the From Outcome column, and **true** in the Redirect column.

    In Source view, these entries appear as follows:

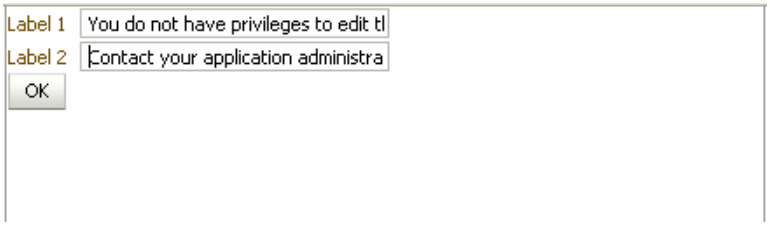
```
<managed-bean>
    <managed-bean-name>backingBean</managed-bean-name>
    <managed-bean-class>view.BackingBean</managed-bean-class>
    <managed-bean-scope>session</managed-bean-scope>
  </managed-bean>
  <navigation-rule>
  <from-view-id>/Page1.jspx</from-view-id>
  <navigation-case>
    <from-outcome>customize</from-outcome>
    <to-view-id>/Page2.jspx</to-view-id>
      <redirect/>
    </navigation-case>
  </navigation-rule>
  <navigation-rule>
    <from-view-id>/Page2.jspx</from-view-id>
  <navigation-case>
```



```
    <from-outcome>back</from-outcome>
    <to-view-id>/Page1.jspx</to-view-id>
      <redirect/>
    </navigation-case>
  </navigation-rule>
```

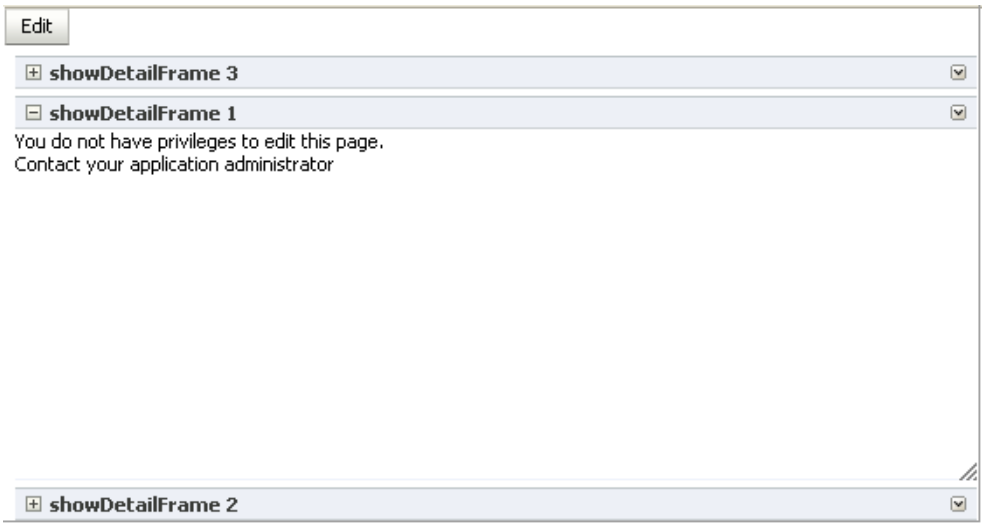
13. Save the file.

22.2.5 What Happens at Runtime



In JDeveloper, run `Page1.jspx`. The Actions menu on the `showDetailFrame1` component displays the Customize action, as shown in Figure 22–2.

Figure 22–2 Customize Action on the Actions Menu



Clicking Customize takes you to `Page2.jspx` (Figure 22–4), where you can update the values for `Label1` and `Label2`.

Figure 22–3 Page with Option to Edit Text

Clicking **OK** takes you back to `Page1.jspx`, which reflects the recent text changes, as shown in Figure 22–4.

Figure 22–4 Page1 with Updated text

22.3 Enabling Custom Actions on a Task Flow

You can customize a task flow by including it in a `Show Detail Frame` component. The `Show Detail Frame` component provides certain default actions to rearrange, show, and hide components. Further, you can define custom actions to trigger the desired navigational flow within the task flow at runtime. There are two ways in which you can enable custom actions on a task flow:

- Enable custom actions directly on the task flow so that they are displayed on the `Show Detail Frame` component's Actions menu.
- Enable custom actions on the `Show Detail Frame` component enclosing the task flow so that they are displayed on the `Show Detail Frame` component's Actions menu.

This section describes both approaches. It includes the following subsections:

- Section 22.3.1, "How to Enable Custom Actions Directly on a Task Flow"
- Section 22.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow"
- Section 22.3.3, "What Happens at Runtime"
- Section 22.3.4, "How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example"

22.3.1 How to Enable Custom Actions Directly on a Task Flow

Perform the steps in this section if you want the task flow to be self-contained, without the need to inherit global custom actions defined at the application level. You can define custom actions on a task flow by configuring a `<customComps-config>` section with a nested `<customActions>` element in the `adf-settings.xml` file. The additional custom actions specified in the `adf-settings.xml` file are displayed on the `Show Detail Frame` component that surrounds this task flow.

Typically, task flows are packaged and deployed as ADF libraries. When you create an `adf-settings.xml` file containing custom actions for a task flow, this file is also packaged in the ADF library.

To enable custom actions on a task flow:

1. If it does not already exist, create the `adf-settings.xml` file in the `META-INF` directory under the project's Web context root (for example, in the *`APPLICATION_ROOT`*`/Portal/src/META-INF` directory):

   a. From the **File** menu, select **New**.

   b. In the New Gallery dialog, expand **General**, select **XML**, then **XML Document**.

   c. Click **OK**.

   Name the file `adf-settings.xml`.

2. Add a `<custComps-config>` section in the file, with a nested `<customActions>` element.

3. Add one `<customAction>` element for each internal task flow action that you want to display as a custom action on the `Show Detail Frame` Actions menu.

   You can add any number of custom actions under the `<customActions>` element.

   Example 22–1 shows the code of the `adf-settings.xml` file with a `<customAction>` entry.

Example 22–1 The custComps-config Section in an adf-settings.xml File

```
<cust:custComps-config
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <customActions>
   <customAction action="next" location="chrome"
                 rendered="true"
                 icon="/adf/webcenter/editheader_ena.png"
                 text="Next"

taskFlowId="/WEB-INF/task-flow-definition.xml#task-flow-definition"
                 shortDesc="next"/>
    <customAction action="prev" location="chrome"
                 rendered="true"
                 icon="/adf/webcenter/editheader_ena.png"
                 text="Previous"
 taskFlowId="/WEB-INF/task-flow-definition.xml#task-flow-definition"
                 shortDesc="prev"/>
  </customActions>
 </cust:custComps-config>
```

Custom action definitions are similar at the task flow-level and application-level, except for the `taskFlowId` attribute that is used in the task flow-level setting. This attribute is used to identify the task flow on which the custom action must be defined. As an ADF library may have multiple task flows, this attribute helps identify the task flow that must render the custom action.

Notes:

- If you are defining an icon for the custom action, you must ensure that the image you specify is available in the project root folder.
- You can define custom actions for the internal actions defined in all task flows on your page; however, at runtime, the `Show Detail Frame` displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

4. Save the `adf-settings.xml` file.

22.3.2 How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow

You can define custom actions for a task flow on the enclosing `Show Detail Frame` component. When these actions are invoked at runtime, they trigger the desired navigational flow in the task flow. For example, you can define a custom action on a `Show Detail Frame` that specifies that the target task flow fragment opens in a separate browser window rather than inside the `Show Detail Frame`.

You can specify custom actions on `Show Detail Frame` components by adding `Custom Action` components as children of a `Show Detail Frame` component on the page. Custom actions defined in this way would be available only on the `Show Detail Frame` instance, which has the custom action as its child. Alternatively, you can specify custom actions in the application's `adf-config.xml file`. Custom actions defined in this way are available on all `Show Detail Frame` instances in the application.

This section provides information about defining custom actions on a `Show Detail Frame`. It includes the following subsections:

- Section 22.3.2.1, "Defining Custom Actions at the Instance Level"
- Section 22.3.2.2, "Defining Custom Actions at the Global Level"
- Section 22.3.2.3, "Configuring Custom Actions that Display Task Flow Views in a Separate Browser Window"

22.3.2.1 Defining Custom Actions at the Instance Level

Define custom actions on a particular `Show Detail Frame` component instance using the `Custom Action` component. You can find the `Custom Action` component in the Composer tag library. Custom actions are stored in the JSPX page definition file of the page that contains the `Show Detail Frame`.

To define custom actions at the instance level:

1. From the Component Palette, select **Composer**.
2. Drag a **Custom Action** and drop it on the page inside the `Show Detail Frame` component, below the `af:region` element.

   Add one `Custom Action` component for each internal task flow action you want to display as a custom action on the `Show Detail Frame` Actions menu.

Note: Add `Custom Action` components below the `af:region` element. You may face problems if the region is not the first child component of the `Show Detail Frame`.

3. Define attributes for the `Custom Action` by referring to Table B–9 in Section B.1, "Composer Component Properties."

   Ensure that you populate the `Action` attribute of each `Custom Action` with the correct ADFc outcomes of the associated task flow. The code should be similar to the one shown in Example 22–2.

Example 22–2 Custom Action Code

```
<cust:showDetailFrame text="showDetailFrame 1" id="sdf1">
  <af:region value="#{bindings.taskflowdefinition1.regionModel}"
             id="r1"/>
  <cust:customAction action="navigatefromview1" id="ca1"
                     location="both" icon="/Logo1.JPG"
                     text="View1 Action"
                     shortDesc="Custom View1 Action"/>
  <cust:customAction action="navigatefromview2"
                     location="both" id="ca2"
                     icon="/Logo2.JPG" text="View2 Action"
                     shortDesc="Custom View2 Action"/>
</cust:showDetailFrame>
```

Notes: You can add custom actions for all of the task flow's ADFc outcomes, but depending on the task flow view that is displayed, several or none of the custom actions are available at runtime.

If you define a custom action without a corresponding task flow action, then the custom action is not rendered on the `Show Detail Frame` header at runtime.

See Also: "Creating a Task Flow" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*

4. Save and run the page.

At runtime, when you select an action from the `Show Detail Frame`'s Actions menu, the associated control flow rule is triggered and the target task flow fragment is rendered.

22.3.2.2 Defining Custom Actions at the Global Level

Defining custom actions at the global level means making those custom actions available for all `Show Detail Frame` instances in an application. Though global-level custom actions are available on all `Show Detail Frame` components in an application, at runtime the header of any `Show Detail Frame` displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

Define global-level custom actions in your application's `adf-config.xml` file.

To define custom actions at the global level:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under Descriptors in the Application Resources panel.
2. Define custom actions using the `<customActions>` element with nested `<customAction>` tags for each action, as shown in Example 22–3.

   Tip: To render a custom action only in page Edit mode, you can set the `rendered` attribute on the `<customAction>` tag to `#{composerContext.inEditMode}`. This returns a value of `true` if the page is in Edit mode.

Example 22–3 Custom Actions Definitions in the adf-config.xml File

```
<cust:adf-config-child
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <enableSecurity value="true" />
  <customActions>
    <cust:customAction action="forward" displayName="Move Forward"
                       location="menu" rendered="true"
                       icon="/move_forward.png"/>
    <cust:customAction action="backward" tooltip="Move Backward"
                       location="chrome" rendered="true"
                       icon="/move_backward.png"/>
  </customActions>
</cust:adf-config-child>
```

Notes:

- If you implemented restrictions on the `Show Detail Frame` component's actions by performing the steps in Section 24.5, "Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions," you already have a `cust:customizableComponentsSecurity` section in the `adf-config.xml` file. You can define custom actions in that section itself instead of the `cust:adf-config-child` section shown in Example 22–3.
- If you are defining an icon for the custom action, you must ensure that the image you specify is available in the project root folder.
- You can define custom actions for the internal actions defined in all task flows on your page; however, at runtime, the header of any `Show Detail Frame` displays only those custom actions that correspond to the ADFc outcomes of the current view of the task flow.

3. Save the `adf-config.xml` file.

For additional information about defining custom actions, see Section 22.3.4, "How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example."

Resolving Conflicts Between Global-Level and Instance-Level Custom Actions

Each custom action is uniquely identified by the value of its `action` attribute. If you have defined custom actions with the same `action` attribute value at the global and instance levels, then there may be conflicts in how these custom actions are invoked at runtime, depending on other attribute values. At such times, the `inheritGlobalActions` attribute of the `Show Detail Frame` defines the

behavior of other custom action attributes (other than the `action` attribute) as follows:

> **Note:** Regardless of the `inheritGlobalActions` setting (`true` or `false`) on the `Show Detail Frame` component:
>
> - The `rendered` attribute is not inherited even if it is not specified at the instance level.
> - The `location` attribute at the global or instance level should be set to the same value at both the global and instance levels.

- If `inheritGlobalActions=true`, or you have not specified a value for `inheritGlobalActions` (defaults to `false`), the behavior of custom action attributes is as follows:
  - If you defined a custom action attribute at the global and instance levels, then the attribute value specified at the instance level is used.
  - If you defined a custom action attribute only at the instance level, then that attribute value is used.
  - If you defined a custom action attribute only at the global level, then that value is ignored and the default value is used.
- If `inheritGlobalActions=true`, the behavior of custom action attributes is as follows:
  - If you defined a custom action attribute at the instance level, then its value is used regardless of whether the same attribute is specified at the global level.
  - If you defined a custom action attribute only at the global level, then that value is used.
  - If you have not defined a custom action attribute at the global or instance levels, then the attribute's default value is used.

After you have designed your application pages, you must deploy the application to the production environment. For more information, see Chapter 70, "Deploying and Testing Your WebCenter Portal: Framework Application."

> **Note:** Runtime customizations that you perform on the page in the development environment are not carried over when you deploy the application to a target server.

22.3.2.3 Configuring Custom Actions that Display Task Flow Views in a Separate Browser Window

Custom actions typically display the target task flow views in place, inside the `Show Detail Frame` component. However, you can define a custom action to display a task flow view in a separate browser window.

To display a task flow view in a separate browser window, the control flow rule to that view must be prefixed with `dialog:` in the task flow definition file and in the `action` attribute of the custom action corresponding to that view. The following example shows an `action` attribute definition:

```
<cust:customAction action="dialog:Next" id="ca1"
                   location="both" icon="/move_forward.png"
                   text="Next Action"
```

```
                    shortDesc="Next Action"/>
```

Setting Properties on the Popup Window

For a command component inside a task flow region, you can specify the default behavior using the `useWindow`, `windowEmbedStyle`, `windowHeight`, `windowWidth`, and `returnListener` attributes. The command component may have other such attributes that you can use. If you specify a return listener, on closing the dialog a particular action event is called to decide on the next navigation outcome. By default, without this setting, a dummy `Rich Command Link` component is created to trigger the task flow action.

When you define a listener on a command component, you must also configure the custom action to call the action event on this component. The `actionComponent` attribute on a custom action definition (global- and instance-level) enables you to specify the ID of the command component that must be queued for the action event. When the `actionComponent` attribute is specified, the `Show Detail Frame` component queues the action event on this component. Since this command component is inside your task flow, you change its attribute values at any time.

Example

Consider an example where you have included a task flow inside a `Show Detail Frame` component and defined a `Simple Edit` custom action corresponding to the task flow's navigation outcomes. A `Command Button` component inside the task flow is configured to launch a modal inline popup of size `300x200` on clicking the `Simple Edit` custom action. A return listener is configured on the command component so that it is called whenever the popup is closed.

The source code of the Command Button component inside the region is as follows:

```
<af:commandButton text="dialog:simpleEditPoup"
                  id="SDFCustomActionCmd_simpleEditPoup"
                  action="dialog:simpleEditPoup" useWindow="true"
                  windowEmbedStyle="inlineDocument" windowWidth="300"
                  windowHeight="200"
                  windowModalityType="applicationModal"

returnListener="#{pageFlowScope.recentPagesBean.refreshMainView}"
                  visible="false"/>
```

Example 22–4 shows how you can specify a global custom action corresponding to the task flow outcome by defining the custom action in the `adf-config.xml` file. The ID of the `Command Button` component is specified against the `actionComponent` attribute on the custom action.

Example 22–4 Global Custom Action Defined in the adf-config.xml File

```
<customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <enableSecurity value="true"/>
    <customActions>
     <customAction action="dialog:simpleEditPoup"
                   text="Simple Edit"
                   shortDesc="Simple Edit"
                   location="menu"
                   rendered="#{!changeModeBean.inEditMode}"
                   icon="/adf/pe/images/editproperties_ena.png"
                   actionComponent="SDFCustomActionCmd_simpleEditPoup"/>
    </customActions>
```

```
</customizableComponentsSecurity>
```

Example 22–5 shows how you can specify an instance-level custom action corresponding to the task flow outcome by adding a `Custom Action` component from the Composer tag library to the JSPX page. The ID of the `Command Button` component is specified against the `actionComponent` attribute on the custom action.

Example 22–5 Instance-Level Custom Action Defined in the JSPX Page

```
<cust:showDetailFrame id="sdf_for_RecentPagesTF1"
                      text="Recent Pages" stretchContent="false"
                      showResizer="never">
  <af:region id="RecentPagesTF1"
             value="#{bindings.regionBinding1.regionModel}"/>
  <cust:customAction action="dialog:simpleEditPoup"
                     text="My Simple Edit"
                     shortDesc="Simple Edit"
                     location="menu"
                     rendered="#{!changeModeBean.inEditMode}"
                     icon="/adf/pe/images/editproperties_ena.png"
                     actionComponent="SDFCustomActionCmd_simpleEditPoup"/>
</cust:showDetailFrame>
```

Note: A custom action that is launched in a popup dialog is sent as a new request to server. If you are using a Composer sandbox and are in Edit mode of a page, ensure that this request is launched in View mode by adding code in your servlet filter so that a new sandbox is not created for this page.

22.3.3 What Happens at Runtime

Custom actions configured in the `adf-settings.xml` file are merged with the custom actions configured in the `adf-config.xml` file and all actions relevant to the current view of the selected task flow are displayed on the parent `Show Detail Frame` component's Actions menu.

If you enabled custom actions at a global level, then the header of any `Show Detail Frame` displays these custom actions if they correspond to the navigation outcomes of the current view of the child task flow.

If you prefixed the `action` attribute value with `dialog:`, then the target view of the task flow opens in a separate browser window.

22.3.4 How to Enable Custom Actions On a Show Detail Frame Enclosing a Task Flow: Example

In this example, assume that your application contains a task flow, `customactions`, residing inside a `Show Detail Frame`. The task flow includes three view elements, `view_gadget`, `edit_settings`, and `about_gadget`, and three associated control flow rules, `ViewGadget`, `EditSettings`, and `AboutGadget`. Your object is to define custom actions so that the control flow rules are available as actions on the Actions menu of the `Show Detail Frame` component.

In this example, the control flow rules are added in such a way that users can navigate back and forth between the three views. Each view element has an associated page fragment of the same name:

- The `view_gadget.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `View Gadget`.
- The `edit_settings.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `Edit Gadget Settings`.
- The `about_gadget.jsff` fragment has a `Panel Stretch Layout` component. The center facet of this component is populated with an `Active Output Text` component whose `Value` attribute is set to `About This Gadget`.

To enable custom actions on the task flow:

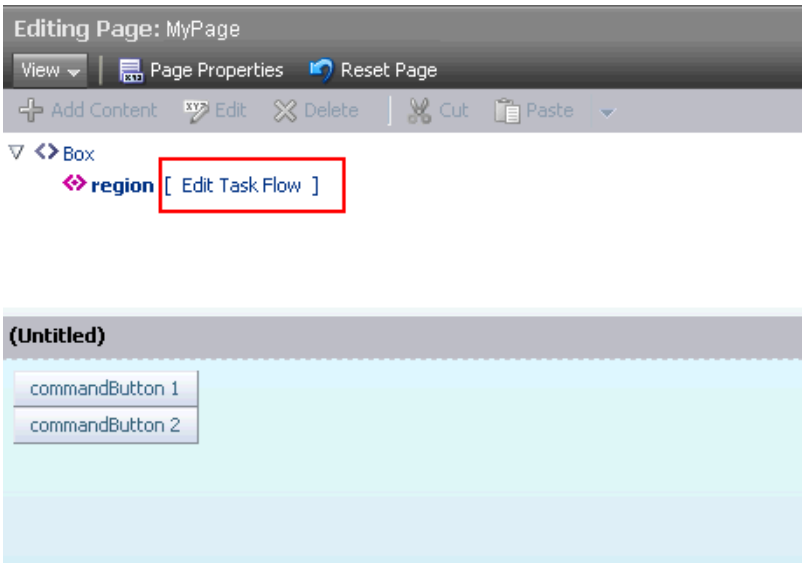
1. Place the `customactions` task flow inside a `Show Detail Frame` component on a customizable page, `MyPage.jspx`.

   For information about creating a customizable page, see Section 20.1.1, "How to Create a Customizable Page."

2. Add a `Custom Action` component from the Composer tag library as a child of the `Show Detail Frame` component, and set the `Action` and `Text` attributes to `ViewGadget` and `View Gadget` respectively.
3. Add two more `Custom Action` components to the `Show Detail Frame`:
   - Set the `Action` and `Text` attributes for the first component to `EditSettings` and `Edit Settings` respectively.
   - Set the `Action` and `Text` attributes for the second component to `AboutGadget` and `About Gadget` respectively.
4. Save and run `MyPage.jspx`.

   The `view_gadget` page fragment is rendered in the `Show Detail Frame` component (named **My Gadget**) on the page. The Actions menu displays the **About Gadget** and **Edit Settings** options. Click **About Gadget** to navigate to the `about_gadget` fragment. Note that the Actions menu now displays the navigation rules for the other two fragments (Figure 22–5).

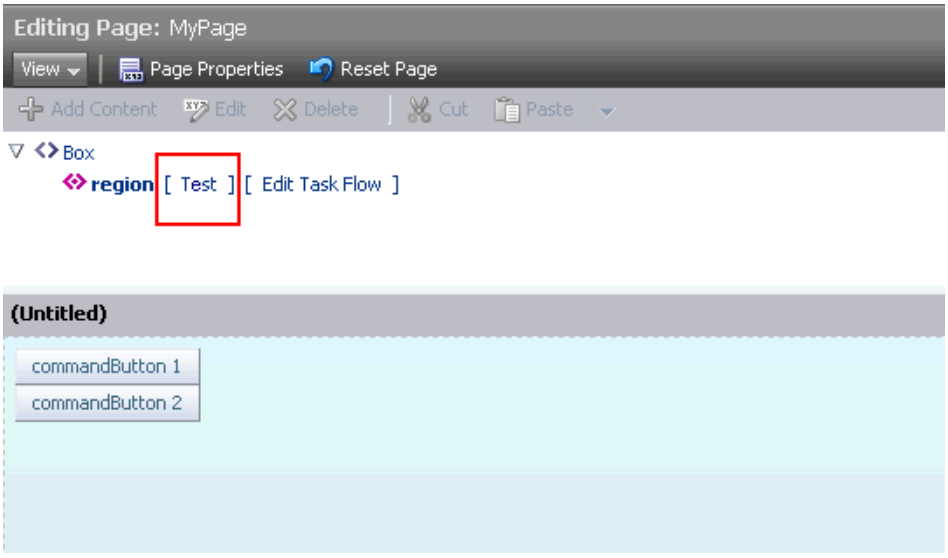
Figure 22–5 Custom Actions on a Show Detail Frame Enclosing a Task Flow



To see this in action, look at the sample application, `CustomActions.jws`, on the Oracle WebCenter Portal 11g Demonstrations and Samples page on the Oracle Technology Network (OTN):

`http://webcenter.oracle.com`

22.4 Enabling Custom Actions that Display on Task Flows in the Component Navigator



The component navigator in Composer Source view provides an option to zoom into a task flow and display the components on its page or fragment, as shown in Figure 22–6.

Figure 22–6 Edit Action on a Task Flow Instance

Users can zoom in, edit the page or fragment, and zoom out of the task flow to navigate back to the page containing the task flow. In addition to the Edit Task Flow and Close links displayed next to a task flow name, you can configure your application to also display custom actions next to a task flow name, as shown in Figure 22–7.

Figure 22–7 Custom Action on a Task Flow Instance

This section describes the procedure to enable custom actions on task flows in the component navigator. It contains the following sections:

- Section 22.4.1, "How to Configure Custom Actions in the Component Navigator"
- Section 22.4.2, "What Happens at Runtime"

22.4.1 How to Configure Custom Actions in the Component Navigator

To display custom actions against a task flow in the component navigator, you must create a Java bean that defines the custom action behavior and call this bean from the application page containing the task flow. This section describes the steps to do so in detail. It contains the following subsections:

- Section 22.4.1.1, "Defining the Logic for the Custom Action"
- Section 22.4.1.2, "Creating a JSPX Page Containing the Custom Action"
- Section 22.4.1.3, "Calling the JSPX Page from the Application Page Containing the Task Flow"

22.4.1.1 Defining the Logic for the Custom Action

To begin with, you must decide on the custom action you want to provide to users and create a Java bean with the logic to be implemented when a user selects the custom action. This section describes the steps to implement simple logic to display a message to users on clicking the custom action. The sample bean also contains the code to display the Close/Edit Task Flow links along with the custom link.

To create a Java bean:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.
3. In the Create Java Class dialog, enter `BackingBean` in the **Name** field and click **OK**.

   The `BackingBean.java` file displays in Source view.
4. Import the required libraries as follows:

```
import javax.faces.application.FacesMessage;
import javax.faces.context.FacesContext;
import javax.faces.event.ActionEvent;
import oracle.adf.view.page.editor.sourceview.ComponentInfo;
```

5. Add the following code:

```
public class BackingBean {
  public BackingBean() {
  }

  public void action(ActionEvent actionEvent) {
      FacesContext context = FacesContext.getCurrentInstance();
      context.addMessage(null,
                         new FacesMessage(FacesMessage.SEVERITY_INFO, "Sample
message to test whether the custom action works.",
                                          null));
  }

  public boolean isRendered() {
      return ComponentInfo.isRegion();
```

```
  }

  public String getZoomText() {
      return ComponentInfo.isRootNode() ? "Close" : "Edit Task Flow";
  }
}
```

With this logic, the sample message you defined is displayed when a user clicks the custom action link against a task flow region.

Use the `isRegion()` API to ensure that the custom action link is displayed only against task flow regions on the page. Use the `isRootNode()` API to ensure that the Edit Task Flow or Close link is displayed against the root component of the task flow.

6. Save the bean.

22.4.1.2 Creating a JSPX Page Containing the Custom Action

This section describes the procedure to create a JSPX page containing the custom action that you want to display to users in Composer.

To create the JSPX page:

1. In your application project, create a JSPX file called `customList.jspx`:
   a. From the **File** menu, select **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page**.
   c. Enter a name for the page and click **OK**.
2. Design the custom action UI using components like `Output Text` and `Command Link`, as shown in the following sample page:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <af:componentDef var="attrs" componentVar="component">
    <af:panelGroupLayout id="dc_pgl1" rendered="#{backingBean.rendered}">
      <af:outputText value="[" id="dc_ot1"/>
      <af:commandLink text="Test" id="dc_cl1"
                      actionListener="#{backingBean.action}"
                      binding="#{backingBean.customLink}"/>
      <af:outputText value="]" id="dc_ot2"/>
      </af:panelGroupLayout>
    </af:componentDef>
</jsp:root>
```

This sample creates a custom action called `Test`. The `actionListener` and `binding` attributes on this action are bound to `BackingBean`, which you created earlier.

3. To ensure that the default Edit Task Flow/Close options are also displayed next to the task flow, you must define a facet called `zoom`, as shown in the following example:

```
<af:xmlContent>
  <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
    <facet>
```

```
        <facet-name>zoom</facet-name>
      </facet>
    </component>
  </af:xmlContent>
```

4. Include the `zoom` facet in the page content as shown in the following example:

```
<af:outputText value="[" id="dc_ot3"/>
<af:facetRef facetName="zoom"/>
<af:outputText value="]" id="dc_ot4"/>
```

The source of the `customLink.jspx` page is as follows:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <af:componentDef var="attrs" componentVar="component">
    <af:panelGroupLayout id="dc_pgl1" rendered="#{backingBean.rendered}">
      <af:outputText value="[" id="dc_ot1"/>
      <af:commandLink text="Test" id="dc_cl1"
                      actionListener="#{backingBean.action}"
                      binding="#{backingBean.customLink}"/>
      <af:outputText value="]" id="dc_ot2"/>
      <af:outputText value="[" id="dc_ot3"/>
      <af:facetRef facetName="zoom"/>
      <af:outputText value="]" id="dc_ot4"/>
      </af:panelGroupLayout>
      <af:xmlContent>
        <component xmlns="http://xmlns.oracle.com/adf/faces/rich/component">
          <facet>
            <facet-name>zoom</facet-name>
          </facet>
        </component>
      </af:xmlContent>
    </af:componentDef>
</jsp:root>
```

5. Save the JSPX page.

22.4.1.3 Calling the JSPX Page from the Application Page Containing the Task Flow

Let us assume that you have a simple JSPX page, `MyPage.jspx`, containing a task flow. The source of the page is as shown in the following example:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:pe="http://xmlns.oracle.com/adf/pageeditor"
          xmlns:cust="http://xmlns.oracle.com/adf/faces/customizable">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <f:view>
    <af:document id="d1">
      <af:form id="f1">
        <af:panelStretchLayout topHeight="50px" id="psl1">
          <f:facet name="top">
            <pe:changeModeLink id="cml1"/>
```

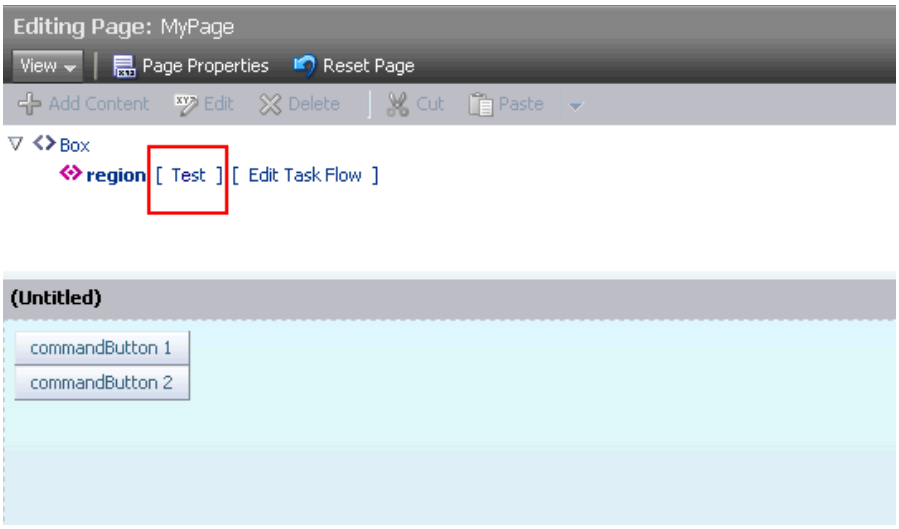
```
          </f:facet>
          <f:facet name="center">
            <!-- id="af_one_column_header_stretched"  -->
            <pe:pageCustomizable id="pageCustomizable1">
              <cust:panelCustomizable id="panelCustomizable1" layout="scroll">
                <af:region value="#{bindings.taskflowdefinition1.regionModel}"
                           id="r1"/>
              </cust:panelCustomizable>
              <f:facet name="editor">
                <pe:pageEditorPanel id="pep1"/>
              </f:facet>
            </pe:pageCustomizable>
          </f:facet>
        </af:panelStretchLayout>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

The task flow, `taskflowdefinition1`, contains the following `view.jsff` fragment:

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
  <af:panelGroupLayout layout="scroll" id="pgl1">
    <af:commandButton text="commandButton 1" id="cb1"/>
    <af:commandButton text="commandButton 2" id="cb2"/>
  </af:panelGroupLayout>
</jsp:root>
```

To display the custom action that you created, you must ensure that the `customLink.jspx` page is called from within Composer. Use the `sourceViewNodeAction` attribute on the `Page Customizable` component to reference the JSPX page containing the custom action.

The `Page Customizable` tag appears as follows in the page source:



```
<pe:pageCustomizable id="pageCustomizable1"
                     sourceViewNodeAction="/customLink.jspx">
```

The `sourceViewNodeAction` attribute can take the name of a JSPX file or an EL value that evaluates to a JSPX file name.

22.4.2 What Happens at Runtime

When you run `MyPage.jspx` to the browser and open the page in Composer Source view, the component navigator displays a Test link and an Edit Task Flow link next to each task flow instance on the page. Figure 22–8 shows `MyPage.jspx` in the component navigator, with the Test link highlighted. Clicking the Test link displays a sample message to the user.

Figure 22–8 Custom Action Displayed Against a Task Flow in the Component Navigator

Composer

****

22.5 Configuring a Keyboard Shortcut to Access Composer

Typically, users enter page Edit mode by clicking the Edit link or button on the page. You can now configure your application to enable users to enter page Edit mode using keyboard shortcuts. Further, you can configure your application to run some other event on using the shortcut keys. This section explains how to enable a keyboard shortcut to Composer and configure an event handler for the shortcut keys. It includes the following subsections:

- Section 22.5.1, "How to Enable Linkless Entry Into Edit Mode"
- Section 22.5.2, "How to Configure an Event Handler for the Shortcut Key"
- Section 22.5.3, "What Happens at Runtime"

22.5.1 How to Enable Linkless Entry Into Edit Mode

You can configure linkless entry into page Edit mode by adding a `<pe:mode-switch-key>` element to the application's `adf-config.xml` file. The default keyboard shortcut configured when you set the `<pe:mode-switch-key>` element is `ctrl+shift+E`. Users can use this key sequence to toggle between page View and Edit modes. However, you can configure a key of your choice by adding a `<pe:key-sequence>` property.

To add the `<pe:mode-switch-key>` property:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the `<pe:mode-switch-key>` property and set its value to `true`, as shown in Example 22–6. The example shows the `<pe:key-sequence>` property with the shortcut value `ctrl+E`.

Example 22–6 Enabling Linkless Edit Mode Entry

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
```

```
  <pe:mode-switch-key>
    <pe:enabled>true</pe:enabled>
    <pe:key-sequence>ctrl E</pe:key-sequence>
  </pe:mode-switch-key>
. . .
</pe:page-editor-config>
```

3. Save the file.

22.5.2 How to Configure an Event Handler for the Shortcut Key

Use the `<pe:mode-switch-handler>` element to specify the event that must be triggered on using the shortcut keys, as shown in the following example:

```
<pe:mode-switch-key>
  <pe:enabled>true</pe:enabled>

<pe:mode-switch-handler>#{PageEditorBean.handleModeSwitch}</pe:mode-switch-handler
>
</pe:mode-switch-key>
```

where, `handleModeSwitch` uses the `ModeChangeEvent` method to provide the logic to toggle between two modes, as shown in the following sample:

```
public void handleModeSwitch(ModeChangeEvent editMode)
  {
    // Your implementation to handle mode change goes here
  }
```

22.5.3 What Happens at Runtime

Users can access the application page and enter Edit mode by using the configured shortcut.

22.6 Creating Event-Enabled Task Flows

Composer provides a means of contextually wiring task flow events. You can wire a contextual event to an action handler to enable the passing of values from a producer component to a consumer component when the event is triggered on the producer.

For events to be available at runtime, event capability must be included in the task flow at design time. When you add event-enabled task flows to your customizable page, each task flow's Component Properties dialog includes an Events tab, where much of the wiring activity takes place. For information about including event capabilities, see "Creating Contextual Events" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

22.7 Configuring an Application Page to Display in Source View by Default

When a user invokes Composer by clicking the Edit button or link on a page, the page opens in Design view by default. If your business so requires, you can configure your application pages to display in Composer Source view by default.

22.7.1 How to Configure an Application Page to Display in Source View by Default

The `Edit Mode view` attribute on the `Page Customizable` component enables you to select either Design view or Source view as the default page view in Edit mode.

To open a page in Source view by default:

1. Open your JSPX page in JDeveloper.
2. Select the **Page Customizable** component in the Structure Navigator.
3. In the Property Inspector, click the **Edit Mode view** attribute dropdown list and select **source**.

> **Note:** To open the page in Source view for selected users only, you can specify an EL value for the `Edit Mode view` attribute.

4. Save the page.

Setting the Source View Position and Size

By default, the component navigator in Source view is displayed at the top of the page, and its default height is `200` pixels. You can specify a different position or size for the component navigator using the `sourceViewPosition` and `sourceViewSize` attributes respectively on the `Page Customizable` component. For more information about these attributes, see Section B.1.1, "Page Customizable."

22.7.2 What Happens at Runtime

When a user clicks the Edit link or button on the page, Composer opens the page in Source view.

22.8 Disabling the Source View Menu for an Application

By default, the View menu is enabled in Composer-enabled pages, providing all users with access to Source view. You can disable the View menu if you want to prevent users from being able to edit any page components other than task flows, portlets, and layout components. This section contains the following subsections:

- Section 22.8.1, "How to Disable the Source View Menu"
- Section 22.8.2, "What Happens at Runtime"

> **Note:** For information about the editing capabilities in Source view, see Section 18.5, "Editing Capabilities in Source View in Page Edit Mode."

22.8.1 How to Disable the Source View Menu

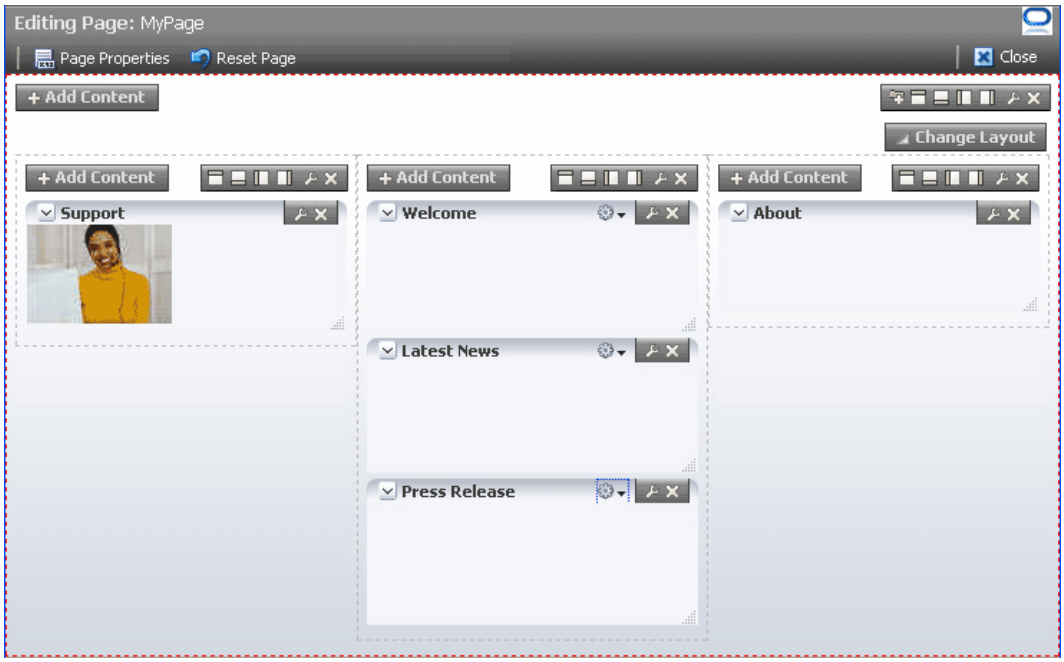
You can disable the View menu by setting the `<pe:enable-source-view>` entry to `false` in the application's `adf-config.xml` file.

> **Note:** For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

To disable Source view:

1. Open the application's `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the `enable-source-view` property and set its value to `false`, as shown in Example 22–7.

Example 22–7 Disabling Source View in adf-config.xml



```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:enable-source-view>false</pe:enable-source-view>
</pe:page-editor-config>
```

3. Save the file.

22.8.2 What Happens at Runtime

When a user switches to page Edit mode, the page is rendered in Design view but the View menu is not displayed to the user, as shown in Figure 22–9.

Figure 22–9 Design View of Page without View Menu

Composer

****

22.9 Disabling Task Flow Zoom Capability

You can disable the capability to zoom into task flows in the application by setting the `<pe:enable-zoom>` property to `false` in the application's `adf-config.xml` file.

> **Note:** For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

To disable task flow zoom capability:

1. Open the `adf-config.xml` file, located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the `<pe:enable-zoom>` property and set its value to `false`, as shown in Example 22–8.

Example 22–8 Disabling Task Flow Zoom Capability in adf-config.xml

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">
  <pe:source-view>
    <pe:enable-zoom>false</pe:enable-zoom>
  </pe:source-view>
</pe:page-editor-config>
```

3. Save the file.

The ability to zoom into task flows is disabled in the entire application.

22.10 Applying Styles to Components

You can change the look and feel of Composer components by applying different styles to the component header and content using one of the following methods:

- Build a skin using style selectors, and apply the skin to a Framework application. For more information about style selectors and skins, see the chapter "Customizing the Appearance Using Styles and Skins" in *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.
- Use JDeveloper style properties to specify style information through the Property Inspector. For more information, see Understanding contentStyle and inlineStyle Properties.

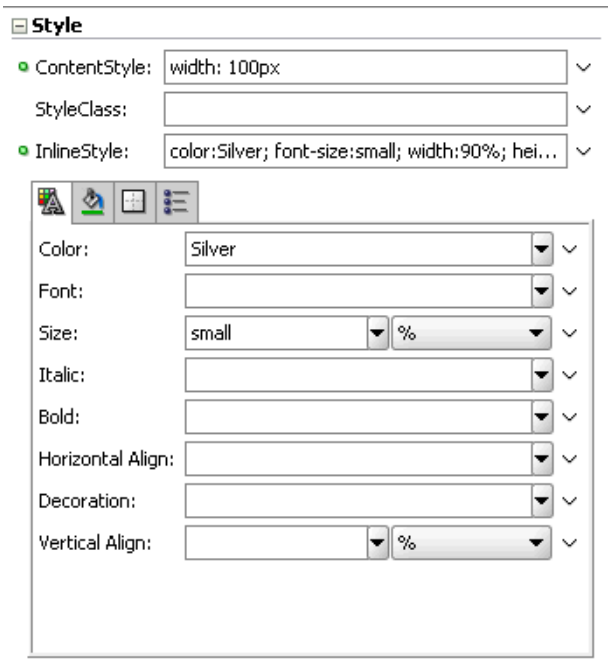
> **Notes:** Using JDeveloper style properties overrides the style information from the skin CSS. However, when you define a style property using JDeveloper, this style overrides styles for the selected component only—child components continue to use the styles specified in the skin.

You can adjust the look and feel of `Page Customizable`, `Panel Customizable`, `Layout Customizable`, and `Show Detail Frame` components at design time by changing the style-related properties `inlineStyle` and `styleClass`.

`Show Detail Frame` components have another associated style property, `contentStyle`, which defines the style for the content inside the component. The `styleClass` property enables you to select an extra style from the skin, whereas the `inlineStyle` and `contentStyle` properties override the comparable styles specified in the application skin for that particular instance of the component.

The `inlineStyle` property overrides `styleClass`. Additionally, properties set on a component instance affect only that instance of the component. Other component instances in the application are not affected.

Note: The `background` property is also useful in adjusting the look and feel of `Show Detail Frame` components. It is used to provide a dark, medium, or light color scheme for the component instance. Unlike `inlineStyle`, `contentStyle`, and `styleClass` properties, the `background` property works with skins. Depending on which value is specified for a component instance's `background` property, the skin applies the relevant style.



Understanding contentStyle and inlineStyle Properties

The style properties `inlineStyle` and `contentStyle` are alike in the types of attributes they support. They differ in their range of influence. While `inlineStyle` provides style information for the *entire component*, `contentStyle` provides style information only for *component content*. The `contentStyle` property is available to `Show Detail Frame` components but not to `Panel Customizable` components.

The `inlineStyle` property applies CSS to the root of the component, that is, the topmost DOM element. It does not override styles on child elements that are picking up color, font, and so on from a skin. For example, if a component header is skinned, then setting `inlineStyle` does not affect the component header. The `contentStyle` applies CSS to the DOM element that surrounds the *content* part of the component. In a `Show Detail Frame`, content refers to the area below the header.

On component content, the value specified for `contentStyle` takes precedence over the value specified for `inlineStyle`. Additionally, `contentStyle` on a component instance takes precedence over both `inlineStyle` and the `contentStyle` values of a parent component (such as a portlet nested in a `Panel Customizable` component).

Figure 22–10 Defining Styles for contentStyle and inlineStyle in the Property Inspector

22.11 Configuring the Persistence Change Manager

To persist user and application customizations across sessions, your application must be configured to use the change persistence framework. When you add Composer components to a customizable page, Composer configures the application to use `ComposerChangeManager` so that changes made to a page at runtime are persisted appropriately.

The default change persistence behavior in release 11.1.1.1 applications is to save Edit mode changes to MDS. View mode changes are not persisted and are available only for that session. To persist View mode changes also to MDS so that they are available across sessions, you can configure your 11.1.1.1 applications to use `ComposerChangeManager`.

This section describes the default change manager configuration in new Framework applications containing Composer-enabled pages and explains how to configure existing release 11.1.1.1 applications to use `ComposerChangeManager`. It contains the following sections:

- Section 22.11.1, "Overview of the Default Change Manager Configuration"
- Section 22.11.2, "How to Configure ComposerChangeManager in Existing 11.1.1.1 Applications"

22.11.1 Overview of the Default Change Manager Configuration

The first time you add a Composer component to your application page, Composer does the following to enable change persistence:

- Adds the `CHANGE_PERSISTENCE` context parameter to the `web.xml` file, and sets the value to `ComposerChangeManager`. This context parameter registers the `ChangeManager` class to be used to handle persistence, as shown in the following example:

```
<context-param>
  <param-name>org.apache.myfaces.trinidad.CHANGE_PERSISTENCE</param-name>

<param-value>oracle.adf.view.page.editor.change.ComposerChangeManager</param-va
lue>
</context-param>
```

- Sets the `persistent-change-manager` element in the `adf-config.xml` file to the `MDSDocumentChangeManager`. Composer configures `MDSDocumentChangeManager` within the `adf-faces-config` section as follows:

```
<adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
  <persistent-change-manager>
    <persistent-change-manager-class>
      oracle.adf.view.rich.change.MDSDocumentChangeManager
    </persistent-change-manager-class>
  </persistent-change-manager>
  . . .
</adf-faces-config>
```

  The `taglib-config` section in the file lists component tags and attributes that are persisted by default, as shown in the following example:

```
<adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
    ...
    <taglib-config>
```

```
    <taglib uri="http://xmlns.oracle.com/adf/faces/customizable">
      <tag name="showDetailFrame">
        <persist-operations>all</persist-operations>
        <attribute name="expansionMode">
          <persist-changes>true</persist-changes>
        </attribute>
        <attribute name="contentStyle">
          <persist-changes>true</persist-changes>
        </attribute>
      </tag>
      <tag name="panelCustomizable">
        <persist-operations>all</persist-operations>
      </tag>
    </taglib>
    <taglib uri="http://xmlns.oracle.com/adf/pageeditor">
      <tag name="layoutCustomizable">
        <persist-operations>all</persist-operations>
        <attribute name="type">
          <persist-changes>true</persist-changes>
        </attribute>
      </tag>
    </taglib>
  </taglib-config>
</adf-faces-config>
```

You can further enable change persistence for other tags and attributes by defining them in this section and setting the `persist-changes` attribute to `true`. For more information, see Section 24.4.1, "How to Define Change Persistence at the Component Level."

For a list of ADF Faces components and attributes that are implicitly persisted, see the chapter titled "Allowing User Customizations at Runtime" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

ComposerChangeManager

A `ChangeManager` class is required for persisting application customizations performed by end users. `ComposerChangeManager` handles change persistence both within a session and across sessions (to MDS). It delegates a users changes to the appropriate change manager as follows:

- View mode changes are routed to `FilteredPersistenceChangeManager` to ensure that implicit customizations, such as column resizing and header collapse, work according to the filter rules configured in the application's `adf-config.xml` file.
- Edit mode changes are routed to `MDSDocumentChangeManager` to ensure that both implicit and explicit customizations are always persisted and available across sessions.

Notes: When you add Composer components to your application page, the option to enable customizations for the duration of the session (in the Project Properties dialog) is disabled. This is because changes in Composer-enabled application pages must be persisted across sessions, to MDS.

22.11.2 How to Configure ComposerChangeManager in Existing 11.1.1.1 Applications

Release 11.1.1.1 Framework applications containing Composer-enabled pages use `MDSDocumentChangeManager` for persisting Edit mode changes by default. Since Composer now provides `ComposerChangeManager` to persist user and application customizations, you can configure your existing applications to use `ComposerChangeManager` so that user customizations (in View mode) are also persisted to MDS.

This section contains the following sections:

- Section 22.11.2.1, "Updating CHANGE_PERSISTENCE Context Parameter in the web.xml File"
- Section 22.11.2.2, "Adding Relevant Entries to the adf-config.xml File"

22.11.2.1 Updating CHANGE_PERSISTENCE Context Parameter in the web.xml File

You must update the `CHANGE_PERSISTENCE` context parameter to `ComposerChangeManager`.

To modify the `CHANGE_PERSISTENCE` parameter:

1. Open your application's web.xml file from the *`Application_Root`*`\`*`Project_Name`*`\public_html\WEB-INF` directory.
2. Locate `org.apache.myfaces.trinidad.CHANGE_PERSISTENCE` and update it to the following:

```
<context-param>
  <param-name>org.apache.myfaces.trinidad.CHANGE_PERSISTENCE</param-name>

<param-value>oracle.adf.view.page.editor.change.ComposerChangeManager</param-va
lue>
</context-param>
```

3. Save the `web.xml` file.

22.11.2.2 Adding Relevant Entries to the adf-config.xml File

You must configure change persistence in the `adf-faces-config` section of your application's `adf-config.xml` file.

To configure change persistence in the `adf-config.xml` file:

1. Open the `adf-config.xml` file.

   The `adf-config.xml` file is located in the ADF `META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add the following code under the `adf-config` section:

```
<adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
  <persistent-change-manager>

<persistent-change-manager-class>oracle.adf.view.rich.change.MDSDocumentChangeM
anager</persistent-change-manager-class>
  </persistent-change-manager>
  <taglib-config>
    <taglib uri="http://xmlns.oracle.com/adf/faces/customizable">
      <tag name="showDetailFrame">
        <persist-operations>all</persist-operations>
        <attribute name="expansionMode">
          <persist-changes>true</persist-changes>
```

```
        </attribute>
        <attribute name="contentStyle">
          <persist-changes>true</persist-changes>
        </attribute>
      </tag>
      <tag name="panelCustomizable">
        <persist-operations>all</persist-operations>
      </tag>
    </taglib>
    <taglib uri="http://xmlns.oracle.com/adf/pageeditor">
      <tag name="layoutCustomizable">
        <persist-operations>all</persist-operations>
        <attribute name="type">
          <persist-changes>true</persist-changes>
        </attribute>
      </tag>
    </taglib>
  </taglib-config>
</adf-faces-config>
```

This ensures that `MDSDocumentChangeManager` is used to persist View mode changes to component tags and attributes listed in the `taglib-config` section. By default, the following View mode changes are persisted:

- `Panel Customizable` component: Rearranging of components within the container or across containers.
- `Show Detail Frame` component: Expanding, collapsing, and resizing of components.

You can enable change persistence for other tags and attributes by defining them in this section and setting the `persist-changes` attribute to `true`. For more information, see Section 24.4.1, "How to Define Change Persistence at the Component Level."

3. Save the `adf-config.xml` file.

Note: When you configure `ComposerChangeManager`, implicit customizations on many components may stop working in View mode as the components may not be added to `adf-config.xml` for the `FilteredPersistenceChangeManager` to pick up.

22.12 Configuring Runtime Resource String Editing

Component properties edited in Composer are available only in the current language. For example, if you add a task flow to your page, the task flow title you enter in Composer is available only in the current language. As a result, users in different locales do not see the translated values for such properties. To provide language support for component properties edited at runtime, Composer now provides users the option to edit resource strings for component display options that can take String values. This is similar to the resource string editor feature provided by ADF Faces in JDeveloper. Changes made to resource strings in Composer are saved into an override bundle, which gets translated along with other resource bundles in the application. The translated versions are then imported back into the application. This way, users are able to see the property values in their language.

Note: Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down.

Release 11.1.1.1 Framework applications containing Composer-enabled pages do not support editing of resource strings at runtime. You can enable resource string editing in your existing application by performing a few simple configurations. This section describes the steps to enable resource string editing in an existing release 11.1.1.1 application. It contains the following sections:

- Section 22.12.1, "Overview of the Resource String Editor"
- Section 22.12.2, "How to Enable the Resource String Editor in Your Application"
- Section 22.12.3, "How to Configure the Override Bundle"
- Section 22.12.4, "What Happens at Runtime"

22.12.1 Overview of the Resource String Editor

At runtime, for component display options that can take String values, the Edit menu next to the property field provides a Select Text Resource option. Clicking this option opens the resource string editor, which provides options to search existing resources, edit or delete resource keys, and add new resource key/value pairs. For information about editing resource strings at runtime, see Section 18.4.5, "Edit Resource Strings."

Changes made to resource strings in Composer are saved into an application override bundle. This bundle is sent for translation and the translated versions are imported back into the application. This way, users are able to see the property values in their language.

The `ComposerOverrideBundle.xlf` is an empty XLIFF file that is packaged with Composer libraries. This bundle becomes available to the application when you add Composer components to the page at design time. At runtime, Composer uses this bundle internally to read from and write to the application override bundle while editing resource strings.

New and updated property values are saved into the override bundle. A user must specify a key, value, and description for each string being created or modified. All resource string changes made in an application are saved in a single override bundle. To distinguish runtime changes made in different layers, the key value is prefixed with the MDS layer name and value and must be in the format, `RT_<`*`MDS Layer Name`*`><`*`MDS Layer Value`*`>_`*`Key Name`*. For example, `RT_sitewebcenter_WELCOME_MESSAGE`. For a selected property, users can search and use resource strings created in any MDS layer. However, they can edit only those resource strings that were created in the same MDS layer. In addition to searching the override bundle, users can also search for strings created and used in the JSPX page at design time. Internally, Composer searches for all resource bundles defined using `c:set` tags in the JSPX file.

Runtime resource string changes in English are saved to the default application override bundle. Users can change the language and create or edit a resource string in that language. A separate override bundle is created for each language in which a user writes a resource string and the file name is suffixed with the initials for that language. For example, resource strings edited in French in `Application1` are saved in a bundle named `Application1OverrideBundle_fr.xlf`.

Current Limitations of the Resource String Editor

- Composer supports creation of around 500 resource strings at runtime. Beyond this number, application performance slows down
- The search criteria in the resource string editor is case-sensitive.
- To search for the description of a resource string, the user must provide the complete string value in the search criteria.
- The resource string editor does not display string descriptions for entries created in Properties bundle or List Resource bundle formats in JDeveloper.
- The option to edit resource strings is disabled for properties on the Parameters and Events tabs.

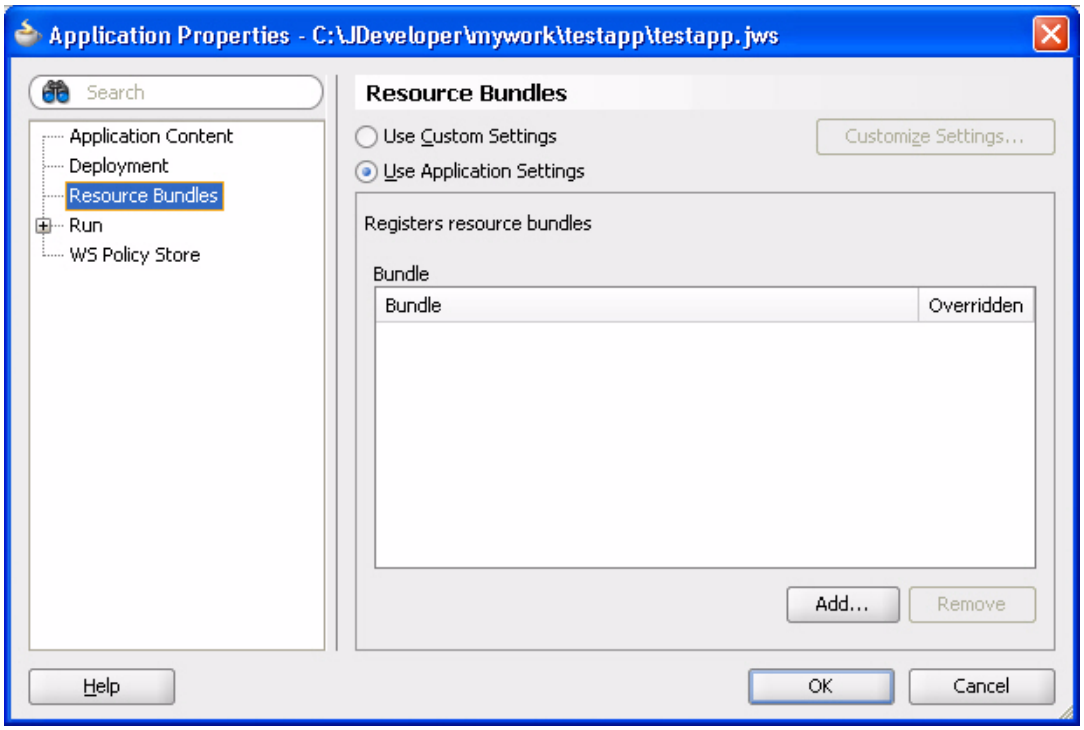
  If the EL value for an ADF resource is referenced in a page definition parameter, such as page parameter, task flow parameter, or portlet parameter, then the binding EL returns an empty value. Users must avoid referencing ADF resource EL values in page definition parameters.

22.12.2 How to Enable the Resource String Editor in Your Application

To enable resource string editing in your application, you must add a `<pe:resource-string-editor>` element in the `<pe:page-editor-config>` section of your application's `adf-config.xml` file, as follows:

```
<pe:page-editor-config>
  <pe:resource-string-editor>
    <pe:enabled>true</pe:enabled>
  </pe:resource-string-editor>
</pe:page-editor-config>
```

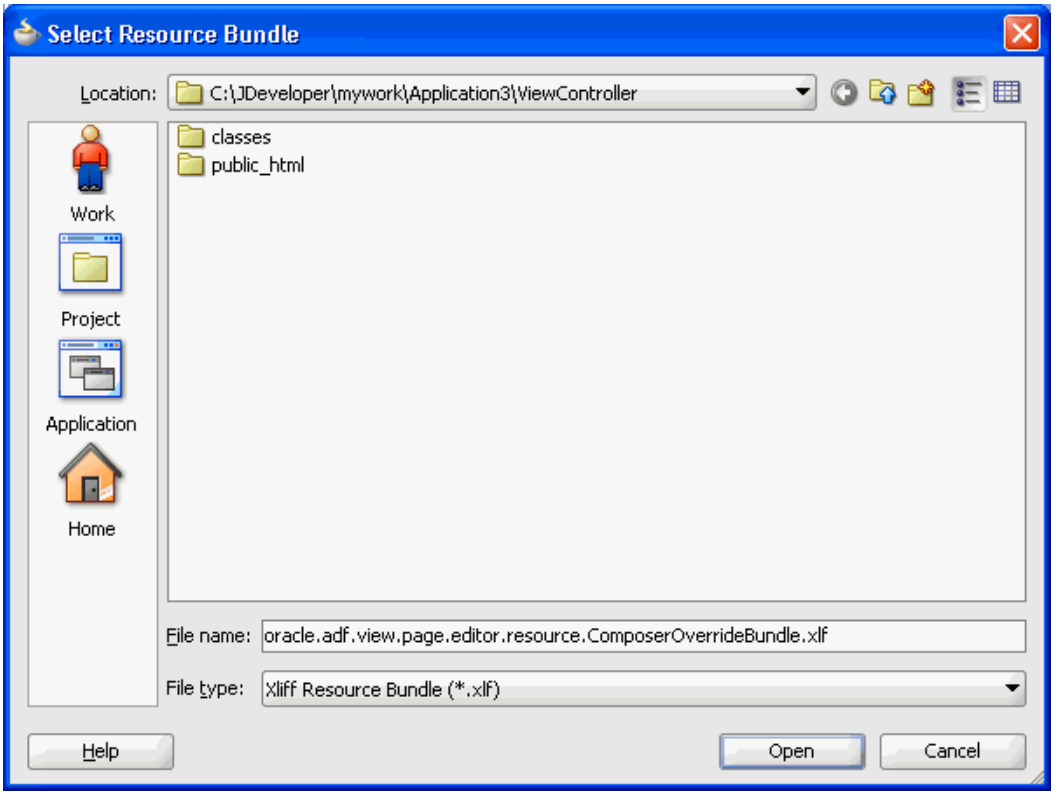
If you want to enable resource string selectively, based on specific criteria, such as the page being edited or the user or role, you can use an EL value for the `enabled` attribute.



22.12.3 How to Configure the Override Bundle

If you enable resource string editing in your application, you must configure your application to use the override bundle, `oracle.adf.view.page.editor.resource.ComposerOverrideBundle.xlf`, which is available in the `pageeditor.jar` file. This override bundle is used for reading and writing to the application override bundle when users create or edit resource strings at runtime.

To configure the override bundle:



1. Open your application in JDeveloper.
2. Form the Application menu, select Application Properties.
3. Select Resource Bundles in the left panel of the Application Properties dialog (Figure 22–11).

Figure 22–11 Application Properties Dialog

4. Click the **Add** button.
5. In the File Name field in the Select Resource bundle dialog, enter `oracle.adf.view.page.editor.resource.ComposerOverrideBundle.xlf`, as shown in Figure 22–12, and click **Open**.

Figure 22–12 Select Resource Bundle Dialog

6. In the Application Properties dialog, select the **Override** check box.

   This ensures that the file is available to users at runtime.

7. Click **OK**.

Repeat the steps in this section to expose any of the resource bundles in your application to users at runtime.

> **Note:** To make a resource bundle accessible for runtime read and write operations, you must ensure that the Override option is selected for that bundle in the Application Properties dialog.
>
> You can make properties bundles, list resource bundles, and XLIFF resource bundles accessible at runtime.

22.12.4 What Happens at Runtime

When a user clicks the **Edit** icon next to a property that takes a String value, the Select Text Resource option is available. Clicking this option opens the resource string editor in which the user can create, modify, or delete resource strings. For more information, see Section 18.4.5, "Edit Resource Strings."

22.13 Troubleshooting Problems with Advanced Composer Configurations

This section provides information to assist you in troubleshooting problems you may encounter on performing advanced Composer configurations.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

You added a global- or instance-level `Custom Action`. However, it neither displays on the chrome or in the **Action** menu on the `Show Detail Frame`.

Solution

Ensure the following:

- The first child of the `Show Detail Frame` must be `af:region`.
- The view currently displayed on the task flow must have an outcome in its task flow definition file that matches the action of `Custom Action`.
- If the action has the prefix `dialog:`, the outcome in the task flow definition must also have the same prefix.

For information, see Section 22.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow."

Problem

Composer is not working on ADF application pages. Errors are reported in the logs when using WebCenter Portal's Resource Catalog or Component Properties dialog. None of the customizations are saved. Objects are not getting added from the catalog.

Solution

Composer is compatible with the `MDSDocumentChangeManager` and `ComposerChangeManager`. You must set the `CHANGE_PERSISTENCE` context parameter in the `web.xml` file to either of these. The following example shows how to set CHANGE_PERSISTENCE to `MDSDocumentChangeManager`:

```
<context-param>
 <param-name>org.apache.myfaces.trinidad.CHANGE_PERSISTENCE</param-name>
 <param-value>oracle.adf.view.rich.change.MDSDocumentChangeManager</param-value>
</context-param>
```

When you configure Composer, the value of `CHANGE_PERSISTENCE` is changed to `oracle.adf.view.page.editor.change.ComposerChangeManager`.

23

Performing Composer-Specific MDS Configurations

This chapter describes how to create customization layers for saving changes made to the page at runtime. It also describes how to enable Composer sandbox creation to provide users the option to preview their changes before saving them to the back end. It contains the following sections:

- Section 23.1, "Introduction to MDS"
- Section 23.2, "Using Composer Sandbox"
- Section 23.3, "Adding Customization Layers to View and Edit Modes: Example"

23.1 Introduction to MDS

Most industries customize their enterprise applications to serve different audiences and domains. Problems can arise when an application is modified at the site level. For example, upgrading an application with site-level customizations may lead to data loss or data-merge errors. Consequently, a new version of the application cannot be deployed until all merge conflicts are reconciled.

In the metadata domain, MDS provides the customization feature to address such problems. The customization feature allows for the creation of nonintrusive customization layers that are applied on top of the base application definitions. Customization layers, or layered changes, are described in their own documents and are stored separately from the base application definition. At runtime, applicable customizations are loaded from the metadata store and layered over the base metadata definition to produce the desired effect. Product upgrades and patches affect only the base metadata definition, so customizations continue to function properly.

Customization Layers

MDS enables clients to specify multiple customization types. For example, you can add customizations to runtime modes, application or user roles, application states, or any client specified criteria. Each such customization type is called a *customization layer* and is depicted using a `CustomizationClass`. A `CustomizationClass` is the interface MDS uses to identify the customization layer to be overlaid on the base definition. For example, you can configure your application to save customizations based on the departments to which users belong. You can create a customization layer called `DepartmentCC` in which application customizations made by users in different departments are stored in different folders within the layer. Another example would be to configure MDS to save View mode changes as user customizations in one layer and Edit mode changes as application customizations in another layer or vice versa.

Customization layers are applied in order of precedence, that is, if the same change is made in two different layers that apply to the given user and session, the change defined in the higher precedence layer is applied first.

When you implement a `CustomizationClass`, you must register it with the MDS. The MDS provides a means of associating a list of `CustomizationClass` types with a single `MetadataObject`. This is called the *fine-grained* association. The MDS also provides the means of associating a list of `CustomizationClass` types with a set of `MetadataObjects`. This is called the *coarse-grained* association. For information about the `CustomizationClass` and about creating a customization layer, see Section 23.3, "Adding Customization Layers to View and Edit Modes: Example."

Composer Sandbox

Typically, in a Framework application, runtime customizations are saved immediately in the *JDEV_HOME*/jdev/*system_directory*/o.mds.dt/adrs/*application_name*/AutoGeneratedMar/mds_adrs_writedir directory. Changes made in both View and Edit modes are saved in this way. However, in certain circumstances, users might first want to apply customizations in their own view and evaluate whether to keep or cancel the changes before actually saving them to the back end. You can configure Composer to create a *sandbox* if you are using a database repository to store customizations. For information about creating a sandbox, see Section 23.2, "Using Composer Sandbox."

23.2 Using Composer Sandbox

A sandbox is a temporary storage layer for saving runtime page customizations until they are committed to the back end. If you configure a sandbox, a Save button is displayed on the Composer toolbar to enable users to save their changes. In a sandbox-enabled application, if a user clicks Close without first saving changes, a Close Confirm dialog prompts the user to save or cancel changes before closing Composer.

User customizations made in View mode are saved immediately. As such changes are available only to the user modifying the page, there is no particular value in reviewing such changes before saving.

Since Edit mode customizations are available to all users who access the page, you can enable a sandbox so that a user can experiment with page customizations and assess them before committing them. If you enable a sandbox for the application, a Save button is displayed on the Composer toolbar in both Design view and Source view of the page.

This section discusses the steps you can take to enable sandbox creation and describes runtime behavior of a sandbox-enabled application. It contains the following subsections:

- Section 23.2.1, "How to Enable Composer Sandbox Creation"
- Section 23.2.2, "What Happens at Runtime"
- Section 23.2.3, "How to Disable Sandbox for an Application"
- Section 23.2.4, "How to Destroy Stale Sandboxes"
- Section 23.2.5, "How to Enable Application Sandbox Creation"
- Section 23.2.6, "What Happens When You Enable Application Sandbox Creation"

23.2.1 How to Enable Composer Sandbox Creation

You can enable a sandbox only if your application uses a database store. Therefore, you must ensure that you have configured a database store before performing the steps in this section. For information about setting up a database store, see *Oracle Fusion Middleware Configuring and Managing JDBC Data Sources for Oracle WebLogic Server*.

This section describes how to enable the creation of a Composer sandbox. It contains the following subsections:

- Section 23.2.1.1, "Updating Your Application's adf-config.xml File"
- Section 23.2.1.2, "Updating Your Application's web.xml File"
- Section 23.2.1.3, "Selecting a Database Store for Your Application"
- Section 23.2.1.4, "Enabling a Full Page Refresh at Runtime"

23.2.1.1 Updating Your Application's adf-config.xml File

By default, sandbox creation is enabled for all namespaces that are mapped to the default customization store (defined in the `<mds-config>` section of the `adf-config.xml` file). You can, however, enable sandbox for a selected number of namespaces only. To do this, you must add a `<pe:sandbox-namespaces>` element to the `adf-config.xml` file, and then define the namespaces for which you want to support sandbox creation.

> **Note:** For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

To configure sandbox creation in `adf-config.xml`:

1. Open the `adf-config.xml` file located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Under the `<metadata-namespaces>` element, ensure that `<namespace>` elements are defined for all metadata for which you want to enable sandbox creation, as shown in Example 23–1.

Example 23–1 Namespace Definitions in the adf-config.xml File

```
<!-- Your jspx customizations alone go here -->
   <namespace path="/pages" metadata-store-usage="WebCenterFileMetadataStore">
     <namespace-restriction type="CUSTOMIZATIONS"/>
   </namespace>
<!-- Your pagedef customizations alone go here -->
   <namespace path="/pageDefs" metadata-store-usage="WebCenterFileMetadataStore">
     <namespace-restriction type="CUSTOMIZATIONS"/>
     </namespace>
```

3. Add the `<pe:sandbox-namespaces>` element within the `<pe:page-editor-config>` section and add individual `<pe:namespace>` tags for all namespaces for which you want to enable sandbox creation, as show in Example 23–2.

Example 23–2 Configuring Namespaces for Sandbox Creation

```
<pe:sandbox-namespaces>
```

```
  <pe:namespace path="/pages"/>
  <pe:namespace path="/pageDefs"/>
</pe:sandbox-namespaces>
```

4. Save the `adf-config.xml` file.

23.2.1.2 Updating Your Application's web.xml File

To ensure that a sandbox is configured when you are in Edit mode of a page, you must create a filter in your application's `web.xml` file and set the appropriate filter mappings. All requests are then routed through this filter, and a sandbox is created for all Edit mode customizations. If you are using a file system metadata store, then there is no action performed on a filtered request.

> **Note:** For information about the Composer-specific configurations you can make in `web.xml`, see Section B.2.4, "web.xml."

This section provides the example of defining a Composer-specific filter and its relevant filter mappings in your application's `web.xml` file. It describes how to add the filter, `WebCenterComposerFilter`.

To define a Composer-specific filter and the filter mappings:

1. Open the *`application_root`*`/Portal/public_html/WEB-INF/web.xml` file.
2. Add `WebCenterComposerFilter` before the `adfBindings` filter:

```
<filter>
  <filter-name>composerFilter</filter-name>

<filter-class>oracle.adf.view.page.editor.webapp.WebCenterComposerFilter</filte
r-class>
</filter>
```

3. Add corresponding `<filter-mapping>` elements before the filter mapping for `AdfBindingFilter` as shown in Example 23–3.

Example 23–3 Filter Mappings for Composer-Specific Filter

```
<filter-mapping>
  <filter-name>composerFilter</filter-name>
  <servlet-name>Faces Servlet</servlet-name>
  <dispatcher>FORWARD</dispatcher>
  <dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

The `<url-pattern>` tag is used to specify the pages that must pass through the `WebCenterComposerFilter` so that sandbox creation can be enabled when a page goes into Edit mode.

> **Note:** The order in which you define filters is important. Requests pass through these filters sequentially and if they are not defined in the correct order, the application will not run as designed. Your `web.xml` file must have the `WebCenterComposerFilter` implementation first, followed by the `AdfBindingFilter` implementation.

4. Save the `web.xml` file.

23.2.1.3 Selecting a Database Store for Your Application

To enable sandbox creation, your application must be configured to use a database store. Therefore, while deploying your application to a WebLogic Managed Server, ensure that you select a database repository and specify a partition name for the application.

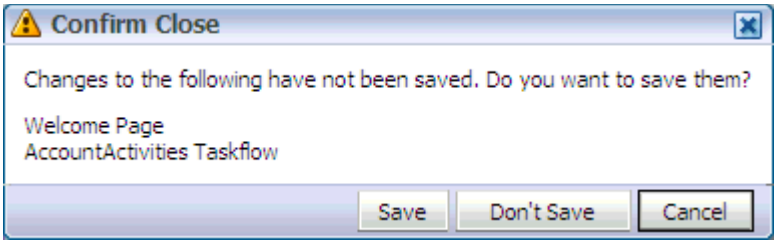
For information about deploying your application from JDeveloper to a WebLogic Managed Server, see Section 70.3.4.1, "Deploying to a Managed Server Using Local Data Sources."

23.2.1.4 Enabling a Full Page Refresh at Runtime

When you enable sandbox creation in your application, you must ensure that a full page refresh is performed on entering and exiting page Edit mode. For the detailed steps to be performed, see Section 23.3.7, "How to Redirect the Servlet to Enable Switch Between MDS Customization Layers."

23.2.2 What Happens at Runtime

When a user switches to page Edit mode, the presence of a **Save** button on the Composer toolbar indicates that sandbox creation is enabled for the application. Changes made to the page or shared components on the page are not saved until the user clicks Save. Once saved, the customizations are available to all application users. If the **Save** button is not rendered, then sandbox is not available and each change is committed immediately.



When editing component properties in the Component Properties dialog, clicking **Apply** results in the following:

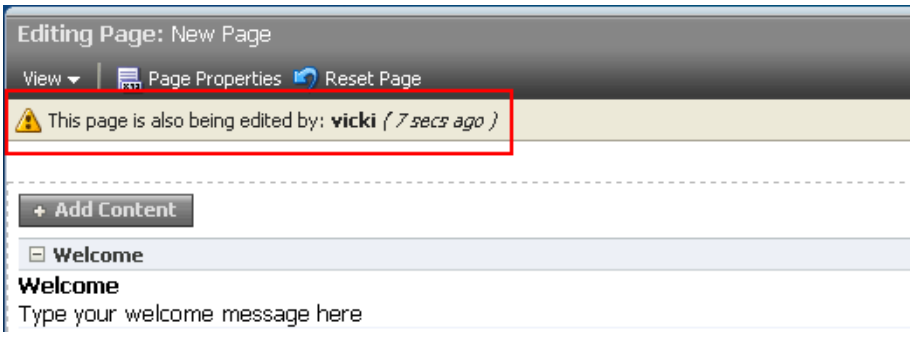
- If the sandbox is not available, then the page is refreshed to display the changes made to component properties and changes are saved to the back end.
- If the sandbox is available, then the page is refreshed to display the changes made to component properties. To save changes, user must click **Save**.

Clicking **Save** or **Close** on the page results in the following events:

- On clicking **Save**, the sandbox is committed and a new sandbox is created. The page remains in Edit mode.
- On clicking **Close**, either of the following two events can occur:
  - If there are no changes since the last Save operation, then the sandbox is destroyed and Composer is closed, taking the user back to View mode.
  - If there are unsaved changes, then a Close Confirmation dialog lists the page name and unsaved task flow names, as shown in Figure 23–1.

Figure 23–1 Confirm Close Dialog in Composer

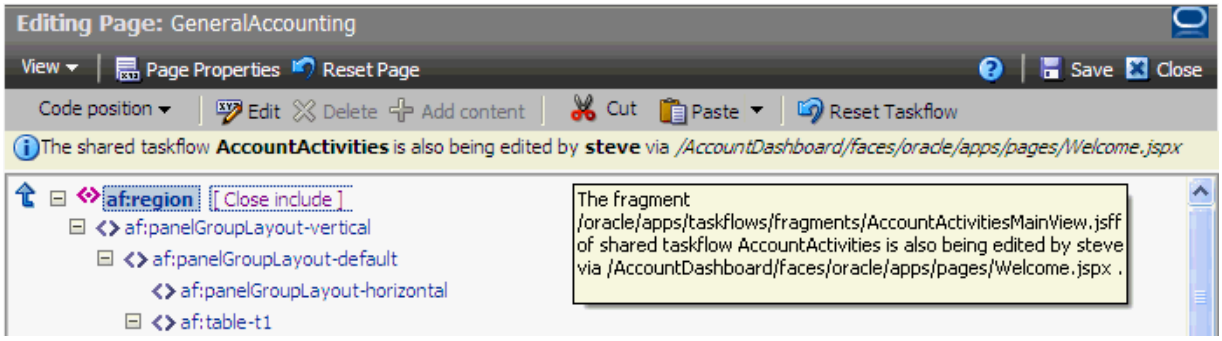
Users can select from the following options:



* Click **Save** to commit the sandbox and close Composer.
* Click **Don't Save** to destroy the sandbox and close Composer.
* Click **Cancel** to close the dialog and return to Composer without saving the changes.

Notes: If a user navigates away from a page while editing it and then returns to the page, any unsaved changes are lost.

What Happens During Concurrent Edits



If two or more users are editing the same page or task flow using the same customization layer, then the page displays a message to each user that another user is editing the page or task flow, as shown in Figure 23–2.

Figure 23–2 Page Concurrency Message

If two or more users have zoomed into a task flow at the same time in the same customization layer and are editing it, then a concurrency message appears, as shown in Figure 23–3.

Figure 23–3 Task Flow Concurrency Message

Note: If a user zoomed into a task flow, made some customizations, and zoomed out of the task flow, then the task flow concurrency message continues to display to other users until that user saves the customizations.

Changes that are saved last overwrite prior changes. For example, if users A and B are editing a page or task flow simultaneously, then concurrency issues are handled as follows:

- If A saves the page or task flow first, then A's changes are committed to MDS. Later, when B saves the page or task flow, A's changes are overwritten with B's changes.
- If A deletes a component while B is trying to personalize (say move) that same component in View mode, a WebCenter error page is displayed to B. B has to simply navigate back to the original page. The deleted component does not appear, and B can continue working on other components.

23.2.3 How to Disable Sandbox for an Application

To ensure that changes are committed to the back end immediately, you can disable the sandbox.

To disable sandbox:

1. Open the `adf-config.xml` file located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Under the `<pe:page-editor-config>` element, add the `<pe:disable-sandbox>` attribute and set it to `true`.
3. Save `adf-config.xml`.

23.2.4 How to Destroy Stale Sandboxes

When users edit a page at runtime, if the browser closes unexpectedly or the user navigates away from the page, the sandbox used in that session is still available. Any other user accessing the same page continues to see a concurrency message that another user is editing the same page. You can destroy such stale sandboxes to free some space in the database store and enhance performance.

You can ensure that a stale sandbox is destroyed when:

- A session times out.

  The `<session-timeout>` element in the application's `web.xml` file defines the time duration after which the sandbox is destroyed. To ensure this happens, you must configure `WebCenterComposerSessionListener` in your application's `web.xml` file. This listener is called when a session times out. It creates a new sandbox when the same user enters page Edit mode.

- The user logs in to Edit mode of the page again, with the same user name.

  In this case, a new sandbox is created when the same user switches to Edit mode.

To configure `WebCenterComposerSessionListener`:

1. Open the *`application_root`*`/Portal/public_html/WEB-INF/web.xml` file.
2. Define a new listener, `WebCenterComposerSessionListener`, as shown in the following example:

```
<listener>
  <description>Composer Http Session Listener</description>
  <display-name>Composer Http Session Listener</display-name>
  <listener-class>
    oracle.adf.view.page.editor.webapp.WebCenterComposerSessionListener
```

```
    </listener-class>
  </listener>
```

3. Save the `web.xml` file.

For information about the Composer-specific configurations you can make in `web.xml`, see Section B.2.4, "web.xml."

23.2.5 How to Enable Application Sandbox Creation

Consider an example where you have created an application that displays a banner at the top of the page, a sidebar on the left with options to manage pages, and the page at the center of the browser window. You may want to enable users to edit the page in Composer and edit the sidebar using some other mechanism such as updating an XML file. Enabling Composer sandbox in such a case only saves changes to page content but not the sidebar. If you enable the application sandbox, then all changes made at runtime are saved at one time, to one location. If you enable sandbox creation at the application level, then Composer does not create its own sandbox when page Edit mode is invoked. Instead, the application sandbox is used. That is, a user interface provided by the application is used for committing and destroying the sandbox. To enable the application to provide a sandbox for Composer, you must first perform a set of configurations.

Another example where it is useful to enable the application sandbox is if you want users to edit page content, but ensure that the page is saved only on approval from the manager. By using an application sandbox, changes made by a user are in the sandbox until the manager approves the changes. The page is saved on approval.

To enable an application sandbox for use in Composer:

1. Implement a `ComposerSessionOptionsFactory` class to provide `MDSSessionOptions` for each request.

   For information about performing this task, see Section 23.3.4, "How to Implement the ComposerSessionOptionsFactory Class."

2. Register your implementation with Composer.

   For information about performing this task, see Section 23.3.5, "How to Register the Implementation with Composer."

3. Configure `WebCenterComposerFilter`.

   For information about performing this task, Section 23.3.6, "How to Configure WebCenterComposerFilter."

23.2.6 What Happens When You Enable Application Sandbox Creation

At runtime, the application-defined user interface enables users to save their changes to the back end or close Composer without saving the changes. In this case, Composer has no control over when customizations are canceled or committed to the back end.

23.3 Adding Customization Layers to View and Edit Modes: Example

You can apply customizations to a metadata object based on client-defined criteria. For example, you can customize an application and the metadata objects that it uses based on an end user's permissions, an application's deployment location (also called *localization*), or a specific industry domain. Each such category—permissions, localization, and domain—denotes a customization layer, and each is depicted using a `CustomizationClass`. A `CustomizationClass` is the interface MDS uses to

identify the customization layer to be overlaid on the base definition. See Section 23.3.3, "How to Create a Custom UserCC Tip Layer" for an example.

When you implement a `CustomizationClass`, you must also register it with the MDS. The MDS provides the ability to associate a list of `CustomizationClass` types with a single `MetadataObject`. This is called *fine-grained* association. The MDS also provides the ability to associate a list of `CustomizationClass` types with a set of `MetadataObjects`. This is called the *coarse-grained* association.

A customizable application can have multiple customization layers. You can select the layer to which you want to apply customizations. The layer you choose to customize is called the tip layer. When you drop Composer components onto a JSF page, the ADF configures a default `SiteCC` (`site`) tip layer in the application. Consequently, the `adf-config.xml` file is updated to include the `SiteCC` customization class. This tip layer stores all customizations made to the page.

This section explains through example how adding customization tip layers to View and Edit runtime modes provides user customization capabilities to all users and application customization capabilities to selected users. To enable application customizations in the Edit mode, the `site` tip layer is added. To enable user customization in the View mode, the `user` tip layer is added. By default, the `user` tip layer is applied on top of the `site` tip layer. The `user` tip layer stores all user customizations made in the View mode in a specific location created for the user who made them. Such changes are visible only to that user. The `site` tip layer stores all application customizations made in the Edit mode and are visible to all users.

To enable tip layers at runtime, Composer provides the `WebCenterComposerFilter` filter and supplies a means of defining an abstract factory for creating the MDS `SessionOptions` object. This object provides applicable customization layers at runtime and enables users to perform user customizations (View mode) or application customizations (Edit mode) based on their role. When creating a new MDS session, the `MDSSession.createSession` method of this object is used to specify the session options.

This section provides an example exercise for creating, implementing, and registering customization layers, configuring `WebCenterComposerFilter`, and switching between MDS customization layers. It contains the following subsections:

- Section 23.3.1, "How to Add Composer to a JSF Page"
- Section 23.3.2, "How to Create a Custom SiteCC Tip Layer"
- Section 23.3.3, "How to Create a Custom UserCC Tip Layer"
- Section 23.3.4, "How to Implement the ComposerSessionOptionsFactory Class"
- Section 23.3.5, "How to Register the Implementation with Composer"
- Section 23.3.6, "How to Configure WebCenterComposerFilter"
- Section 23.3.7, "How to Redirect the Servlet to Enable Switch Between MDS Customization Layers"
- Section 23.3.8, "What Happens at Runtime"

23.3.1 How to Add Composer to a JSF Page

This section describes how to add the `Page Customizable` component to a JSF page. The purpose of this exercise is to provide Composer in the Edit mode at runtime so that the `admin` user can perform customizations at the site level. This section includes the addition of a `Change Mode Link` to enable switching from View mode to Edit mode at runtime.

To add Composer to a JSF Page:

1. Open the JSPX page and select **Composer** from the Component Palette.
2. Select **Change Mode Link** and drop it onto the page.
3. Select **Page Customizable** and drop it onto the page.

   The Source view should like this:

```
<af:form id="f1">
  <pe:changeModeLink id="cml1"/>
  <pe:pageCustomizable id="pageCustomizable1">
    <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
      <f:facet name="editor">
        <pe:pageEditor id="pep1"/>
      </f:facet>
  </pe:pageCustomizable>
</af:form>
```

   When you drop these components onto the page, the default `SiteCC` tip layer is extended by the ADF. Consequently, the `adf-config.xml` file is updated with this customization class:

```
<cust-config>
  <match>
    <customization-class name="oracle.adf.share.config.SiteCC" />
  </match>
</cust-config>
```

> **Note:** If you want your application to use `UserCC` as the default tip layer, you can simply replace `oracle.adf.share.config.SiteCC` with `oracle.adf.share.config.UserCC` in the `cust-config` section of the `adf-config.xml` file. However, to use `UserCC` as the default tip layer, you must have secured your application. You cannot implement a `UserCC` tip layer without provisioning users and roles in your application.

23.3.2 How to Create a Custom SiteCC Tip Layer

This section describes how to create a custom `SiteCC` tip layer, `site`, in which all site-level customizations performed in Edit mode are stored. In this sample application, site-level customizations are stored in the `/mds/mdssys/cust/site/webcenter/`*`pagename`*`.jspx.xml`directory.

To create the `site` tip layer:

1. From the File menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `SiteCC`.
4. In the **Extends** field, enter `CustomizationClass`.

   This imports `oracle.mds.cust.CustomizationClass`.
5. Click **OK.**

   The `SiteCC.java` file is rendered in the Source view.

6. To implement the `getCacheHint`, `getName`, and `getValue` methods, double-click the bulb on the left corner and select **Implement Methods**.
7. In the Implement Methods dialog, click **OK**.
8. In the Source view, press `Enter` after `public class SiteCC extends CustomizationClass`, and add the following `string`:

```
{
  private static final String DEFAULT_LAYER_NAME = "site";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "webcenter";
```

The following libraries are imported:

```
import oracle.mds.core.MetadataObject;
import oracle.mds.core.RestrictedSession;
import oracle.mds.cust.CacheHint;
```

9. Update the code as shown in **bold** here:

```
public class SiteCC extends CustomizationClass
{
  private static final String DEFAULT_LAYER_NAME = "site";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "webcenter";
  //Note: You can provide any site name.

  public CacheHint getCacheHint()
  {
    return CacheHint.ALL_USERS;
  }

  public String getName()
  {
    return mLayerName;
  }

  public String[] getValue(RestrictedSession mdsSession, MetadataObject mo)
  {
    return new String[] { mLayerValue };
  }
}
```

10. Save the `SiteCC.java` file.

23.3.3 How to Create a Custom UserCC Tip Layer

This section describes an example showing how to create a custom `user` tip layer for a user, `scott`. This layer is applied on top of the `site` layer. The user customizations that a user performs in View mode are saved in this `user` tip layer in a folder created specifically for the logged-in user. In this example, the user customizations performed in View mode are saved in the `/mds/mdssys/cust/user/scott/`*`pagename`*`.jspx.xml`directory.

> **Note:** For illustration purpose, this example describes a simple scenario where a `UserCC` tip layer is created for just one user, `scott`. In a real life application, you can configure the `UserCC` layer to return the name of the user who requested the page.

To create the user tip layer:

1. From the File menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `UserCC`.
4. In the **Extends** field, enter `CustomizationClass`.

   This imports the `oracle.mds.cust.CustomizationClass`.
5. Click **OK.**

   The `UserCC.java` file displays in the Source view.
6. To implement the `getCacheHint`, `getName`, and `getValue` methods, double-click the bulb on the left corner and select **Implement Methods**.
7. In the Implement Methods dialog, click **OK**.
8. In the Source view, press `Enter` after `public class UserCC extends CustomizationClass`, and add the following `string`:

```
{
  private static final String DEFAULT_LAYER_NAME = "user";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "scott"; //The name of the logged-in user
in this example. The logged-in user name can be acquired dynamically.
```

   The following libraries are imported:

```
import oracle.mds.core.MetadataObject;
import oracle.mds.core.RestrictedSession;
import oracle.mds.cust.CacheHint;
```

9. Update the code as shown in **bold** here:

```
public class UserCC extends CustomizationClass
{
  private static final String DEFAULT_LAYER_NAME = "user";
  private String mLayerName = DEFAULT_LAYER_NAME;
  private String mLayerValue = "scott";

  public CacheHint getCacheHint()
  {
    return CacheHint.USER;
  }

  public String getName()
  {
    return mLayerName;
  }

  public String[] getValue(RestrictedSession mdsSession, MetadataObject mo)
  {
    return new String[]{mLayerValue};
  }
}
```

10. Save the `UserCC.java` file.

23.3.4 How to Implement the ComposerSessionOptionsFactory Class

In this section, the `ComposerSessionOptionsFactory` class provided by the ADF is implemented to supply MDS `SessionOptions` for each HTTP request.

To implement the `ComposerSessionOptionsFactory` class:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppsSessionOptionsFactoryImpl`.
4. Click **OK.**

   The `AppsSessionOptionsFactoryImpl.java` file is rendered in the Source view.
5. Import the following libraries:

```
import oracle.adf.view.page.editor.mds.ComposerSessionOptionsFactory;
import oracle.adf.view.page.editor.mode.ModeContext;
import oracle.mds.config.CustClassListMapping;
import oracle.mds.config.CustConfig;
import oracle.mds.core.SessionOptions;
import oracle.mds.cust.CustClassList;
import oracle.mds.cust.CustomizationClass;
```

6. Add the following code to implement the `ComposerSessionOptionsFactory` class and provide `SessionOptions`:

```
public class AppsSessionOptionsFactoryImpl
  implements ComposerSessionOptionsFactory
{

  public SessionOptions createSessionOptions(SessionOptions
defaultSessionOptions, String mode)
  {
    CustomizationClass[] custLayer;
    CustConfig custConfig = null;

    if (ModeContext.EDIT_MODE.equals(mode))
    {
      //Mode is Edit, change to SiteCC
      custLayer = EDIT_LAYER;
    }
    else
    {
      //Mode is View, change to UserCC + SiteCC
      custLayer = VIEW_LAYER;
    }

    try
    {
      CustClassList custClassList = new CustClassList(custLayer);
      CustClassListMapping custClassListMapping =
        new CustClassListMapping("/", null, null, custClassList);
      custConfig = new CustConfig(new CustClassListMapping[]
        { custClassListMapping });
    }
    catch (Exception e)
```

```
    {
      e.printStackTrace();

    }
if(defaultSessionOptions.getServletContextAsObject() != null)
{
    return new SessionOptions(defaultSessionOptions.getIsolationLevel(),
                              defaultSessionOptions.getLocale(), custConfig,
                              defaultSessionOptions.getVersionContext(),
                              defaultSessionOptions.getVersionCreatorName(),
                              defaultSessionOptions.getCustomizationPolicy(),

defaultSessionOptions.getServletContextAsObject());
  }
    else
    {
      return new SessionOptions(defaultSessionOptions.getIsolationLevel(),
                              defaultSessionOptions.getLocale(), custConfig,
                              defaultSessionOptions.getVersionContext(),
                              defaultSessionOptions.getVersionCreatorName(),
                              defaultSessionOptions.getCustomizationPolicy());
    }
  }

  //Edit mode SiteCC
  private static final CustomizationClass[] EDIT_LAYER =
    new CustomizationClass[]
    { new SiteCC() };

  //View mode SiteCC + USerCC
  private static final CustomizationClass[] VIEW_LAYER =
    new CustomizationClass[]
    { new SiteCC(), new UserCC() };

}
```

23.3.5 How to Register the Implementation with Composer

For the `site` and `user` customization layers to function, you must register the `ComposerSessionOptionsFactory` class with Composer. For example, if the concrete class is `view.AppsSessionOptionsFactoryImpl`, the following snippet must be added to the `adf-config.xml` file located in the `/.adf/META-INF` folder in your application directory:

```
<pe:page-editor-config xmlns="http://xmlns.oracle.com/adf/pageeditor/config">

<pe:session-options-factory>view.AppsSessionOptionsFactoryImpl</pe:session-options
-factory>
</pe:page-editor-config>
```

23.3.6 How to Configure WebCenterComposerFilter

You must configure the `WebCenterComposerFilter` filter in the `web.xml` file located in the `Portal/public_html/WEB-INF` folder in your application directory. This filter registers Composer's concrete `SessionOptionsFactory` with the ADF for every HTTP request. When the filter receives a call from the ADF, it forwards the request to the application and gets the `SessionOptions` with the new customized

layer. If you have not set the `Sandbox` or `VersionContext` in the `SessionOptions`, then Composer sets its own Sandbox and returns it to the ADF. For more information on Sandbox, see Section 23.2.1, "How to Enable Composer Sandbox Creation." The `composerFilter` and its filter mapping must be configured before `ADFBindingFilter`. For example, see the following `web.xml` file:

```
....

  <!-- WebCenterComposerFilter goes here -->
  <filter>
    <filter-name>composerFilter</filter-name>

<filter-class>oracle.adf.view.page.editor.webapp.WebCenterComposerFilter</filter-c
lass>
  </filter>
  <filter>
    <filter-name>adfBindings</filter-name>
    <filter-class>oracle.adf.model.servlet.ADFBindingFilter</filter-class>
  </filter>
.....
  <!-- WebCenterComposerFilter mapping goes here -->
  <filter-mapping>
    <filter-name>composerFilter</filter-name>
    <servlet-name>Faces Servlet</servlet-name>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
  </filter-mapping>
  <filter-mapping>
    <filter-name>adfBindings</filter-name>
    <servlet-name>Faces Servlet</servlet-name>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
  </filter-mapping>
....
```

Note: The order in which you define filters is important. Requests pass through these filters sequentially and if they are not defined in the correct order, the application will not run as designed. Your `web.xml` file must have the `WebCenterComposerFilter` implementation first, followed by the `AdfBindingFilter` implementation.

For information about the Composer-specific configurations you can make in `web.xml`, see Section B.2.4, "web.xml."

23.3.7 How to Redirect the Servlet to Enable Switch Between MDS Customization Layers

To redirect the servlet, that is, to refresh the full page at runtime, you must create:

- The `AppNavigationUtils` class, which calls the `AppNavigationUtils.redirectToSamePage()` method
- The `AppCloseHandler` CloseListener, which uses the `AppNavigationUtils` class
- The `AppModeBean`, which displays Edit mode

This section describes how to create these objects. It contains the following subsections:

- Section 23.3.7.1, "How to Create the AppNavigationUtils Class"
- Section 23.3.7.2, "How to Create AppCloseHandler"
- Section 23.3.7.3, "How to Register the AppCloseHandler"
- Section 23.3.7.4, "How to Create AppModeBean"

23.3.7.1 How to Create the AppNavigationUtils Class

To create the `AppNavigationUtils` class:

1. From the File menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppNavigationUtils` and click **OK**.

   The `AppNavigationUtils.java` file is rendered in the Source view.
4. Import the following libraries:

```
import javax.faces.context.FacesContext;
import javax.servlet.http.HttpServletRequest;
```

5. Add the following code:

```
public class AppNavigationUtils
{

  public static void redirectToSamePage()
  {
    HttpServletRequest request =
(HttpServletRequest)FacesContext.getCurrentInstance().getExternalContext().getR
equest();
    String url = request.getRequestURL().toString();
    String _adfCtrlState = request.getParameter("_adf.ctrl-state");
    url = url + "?_adf.ctrl-state="+ _adfCtrlState;
    System.out.println(url);
    try
    {
      FacesContext.getCurrentInstance().getExternalContext().redirect(url);
      FacesContext.getCurrentInstance().responseComplete();
    }
    catch(Exception e)
    {
      e.printStackTrace();
    }
  }
}
```

23.3.7.2 How to Create AppCloseHandler

To create `AppCloseHandler`:

1. From the File menu, choose **New**.

2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.

3. In the **Name** field, enter `AppCloseHandler` and click **OK**.

   The `AppCloseHandler.java` file displays in the Source view.

4. Import the following libraries:

```
import oracle.adf.view.page.editor.event.CloseEvent;
import oracle.adf.view.page.editor.event.CloseListener;
```

5. Add the following code:

```
public class AppCloseHandler
  implements CloseListener
{

  public void processClose(CloseEvent closeEvent)
  {
    AppNavigationUtils.redirectToSamePage();
  }
}
```

23.3.7.3 How to Register the AppCloseHandler

After creating `AppCloseHandler`, you must register it in the Composer extension file, `pe_ext.xml`.

To register the event handler:

1. In the `pe_ext.xml` file, add the following entries:

```
<event-handlers>
  <event-handler event="close">view.AppCloseHandler</event-handler>
</event-handlers>
```

2. Save the file.

For more information about event handlers, see Section 21.6, "Configuring Event Handlers for Composer UI Events."

23.3.7.4 How to Create AppModeBean

To create `AppModeBean`:

1. From the **File** menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.

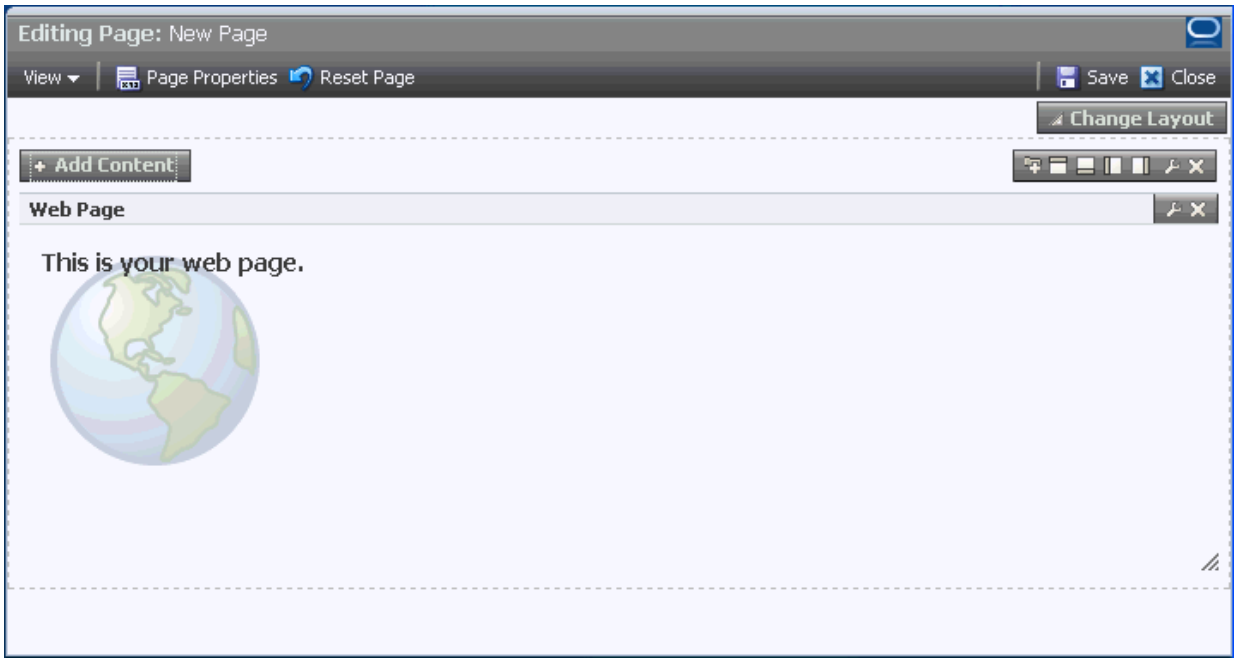
3. In the **Name** field, enter `AppModeBean` and click **OK**.

   The `AppModeBean.java` file displays in the Source view.

4. Import the following libraries:

```
import javax.faces.event.ActionEvent;
import oracle.adf.view.page.editor.mode.ModeContext;
```

5. Add the following code:



```
public class AppModeBean
{

  public void edit(ActionEvent actionEvent)
  {
    ModeContext.getCurrent().setEditMode();
    AppNavigationUtils.redirectToSamePage();
  }
}
```

23.3.8 What Happens at Runtime

To see how the `site` customization layer functions, first run the JSF page in a browser. Then log in to the page as `admin`, and click the **Edit** link to switch to Edit mode. At runtime, customize the page. For example, drop a Web page, movable box, or an image onto the page. The page should look like Figure 23–4.

Figure 23–4 Customized Page

Go to `/mds/mdssys/cust/site/webcenter` in your application directory, and open the *`pagename`*`.jspx.xml` file. This is where the site-level customizations (application customizations) that you made to the page are stored.

To use the `user` customization layer, log in to the page as `scott` and personalize the page in View mode. Then go to `/mds/mdssys/cust/user/scott` in your application directory, and open the *`pagename`*`.jspx.xml` file. This is where the user-level customizations that you made to the page are stored.

23.4 Troubleshooting MDS-Related Problems with Composer

This section provides information to assist you in troubleshooting MDS-related problems you may encounter while using Composer.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

Your application is configured to use MDS sandbox. When you run the application, the sandbox either does not work or generates exceptions.

Solution

Ensure the following:

- A database repository is used. Sandbox works only with a database-based repository, and not with a file-based repository.
- Ensure that the order of filters in `web.xml` is correct. The `<filter>` entries must be in the correct order for sandbox to work correctly.

For information, see Section 23.2, "Using Composer Sandbox."

24

Modifying Default Security Behavior of Composer Components

You can override the default security definitions at various levels in keeping with your business requirement. For information about the default security behavior of Composer components, see Section 18.7, "Security and Composer."

This chapter describes how to override the default security behavior of Composer components. It contains the following subsections:

- Section 24.1, "Applying Component-Level Restrictions by Defining Customization Policies"
- Section 24.2, "Applying a Component Instance-Level Customization Restriction By Using Security Roles: Example"
- Section 24.3, "Applying Tag-Level Security Using the customizationAllowed Attribute"
- Section 24.4, "Applying Attribute-Level Security"
- Section 24.5, "Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions"
- Section 24.6, "Implementing Task Flow Security"
- Section 24.7, "Overriding Composer's Default Security Policies"

24.1 Applying Component-Level Restrictions by Defining Customization Policies

By default, the MDS restricts application customization of page components, that is, users cannot customize components or their attributes at runtime. To enable application customization, you must lift the default restrictions on components and their attributes. When you add a `Page Customizable` component to the page and populate it with content, the default customization restrictions on the `Page Customizable` and all its child components are lifted. However, in some instances, such as when the `Page Customizable` component is part of the template used for the page, you may need to explicitly allow application customization of components and their attributes. This section describes how to apply MDS type-level restrictions or instance-level restrictions on components and their attributes. It contains the following subsections:

- Section 24.1.1, "How to Define Type-Level Customization Policies"
- Section 24.1.2, "How to Define Instance-Level Customization Policies"

Note: For information about creating customizable pages using page templates, see Section 20.1.7, "How to Create a Page Template for Creating Customizable Pages."

24.1.1 How to Define Type-Level Customization Policies

When you apply type-level restrictions on a component, all instances of the component are restricted. This is useful if you want to allow only a specific set of users to edit a particular component or its attributes while restricting all other users from editing it. For example, if you want to allow only a page creator or application administrator to change the page layout at runtime, you can define type-level restrictions on the `Layout Customizable` component and enable only users with `admin` role to edit this component.

You can enable type-level restrictions on components and their attributes in a standalone XML file and then register this file in the `mds-config` section of the `adf-config.xml` file or in an `mds-config.xml` file. The standalone XML file contains annotations that match the types for which customization restrictions must be specified.

You can create an `mds-config.xml` file in your application's `META-INF` directory and register the standalone file in the `mds-config.xml` file.

To enable application customization of selected components or attributes at the type level:

1. Create an XML document, for example `standalone.xml`, add the following code, and replace the text in bold with appropriate values:

```
<?xml version="1.0" encoding="UTF-8" ?>
<grammarMetadata xmlns="http://xmlns.oracle.com/bali/xml/metadata"
                 xmlns:mds="http://xmlns.oracle.com/mds"
                 namespace="tag_namespace">
  <elementMetadata elementName="component_name">
    <mds:customizationAllowed>true</mds:customizationAllowed>
      <attributeMetadata attributeName="attribute_name">
        <mds:customizationAllowedBy>security_roles</mds:customizationAllowedBy>
      </attributeMetadata>
  </elementMetadata>
</grammarMetadata>
```

   The `<customizationAllowedBy>` tag can appear only once. Multiple values can be specified as a space-separated list of allowed policies as part of the declaration. To enable or disable application customization for specific users or roles, the users or roles must be included in the customization policy of the MDS session. For more information, see Section 24.2.3, "How to Customize the SessionOptions Object to Include Customization Policy."

   The `<customizationAllowed>` tag takes a Boolean as its value. A value of `true` for this tag means that anyone can customize the specified component, so long as other inherited customization polices allow it.

   The `<customizationAllowedBy>` tags do not serve any purpose if the same object has been tagged with `<customizationAllowed>false</customizationAllowed>`. Additionally, the customization must be allowed at the top level of the object tree. Otherwise the default behavior dictates that no customization can be permitted at a lower level.

2. Register this XML file in either of the following ways:

To register the XML file in the `adf-config.xml` file, add the `type-config` element inside the `mds-config` section using the following format:

```
<mds-config xmlns="http://xmlns.oracle.com/mds/config">
  <type-config>
    <standalone-definitions>
      <classpath>File_Path/standalone.xml</classpath>
    </standalone-definitions>
  </type-config>
</mds-config>
```

Create an `mds-config.xml` file in your application's `META-INF` folder and add a `type-config` element inside the `mds-component-config` section of the file in the following format:

```
<?xml version="1.0" encoding="UTF-8" ?>
<mds-component-config version="11.1.1.000"
xmlns="http://xmlns.oracle.com/mds/config">
  <type-config>
    <standalone-definitions>
      <classpath>File_Path/standalone.xml</classpath>
    </standalone-definitions>
  </type-config>
</mds-component-config>
```

3. Make the standalone files and associated XSDs available in a shared library JAR file; otherwise MDS cannot load them.

   At runtime, MDS searches all `mds-config` instances in the `META-INF` directories and loads all the customization restrictions specified in standalone files.

24.1.2 How to Define Instance-Level Customization Policies

Instance-level restrictions are useful if you want to allow or restrict customization of a particular instance of a component. The code for instance-level customization policies is similar to that used in the type-level policy definitions. However, instance level policies override type-level policies. That is, instance-level restrictions hold true irrespective of the restrictions from the type. For example, if you have used a form with some UI elements in your login page and in other pages such as a user preferences page, you may want to allow users to customize all instances of the form except on the login page. For this, you can allow customization of the form at the type level and restrict customization only on the instance in the login page.

You can enable customization on a component or any of its attributes at the instance level. To apply customization restriction at the component level, you can set the `customizationAllowed` and `customizationAllowedBy` attributes on the component in JDeveloper (see Section 24.1.1, "How to Define Type-Level Customization Policies"). To apply restrictions on a component's attributes, perform the steps described in this section.

Instance-level policies for component attributes are defined in an RDF file. The RDF file is picked up by MDS, and the policies are implemented.

To define instance-level customization policies:

1. Create an RDF file with the same name as the JSPX file, but using the RDF extension, for example `main.jspx.rdf`.

   Create this file in the *`application_home`*`/project/public_html/mdssys/mdx` folder. Creating the RDF file in this folder structure ensures that the file is picked up by MDS and the policies defined here are implemented.

2. Include tags in the following format to apply restrictions on a component's attribute:

   tag_id(xmlns(*tag_prefix*=*tag_namespace*))/@*tag_prefix*:*attribute_name*

   The following example shows how to apply a restriction on a `Go Image Link` component and the `text` attribute of a `Command Button` component:

```
<?xml version="1.0" encoding="UTF-8"?>
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
xmlns:dc="http://purl.org/dc/elements/1.1/">
<rdf:Description rdf:about="/"/>
<!-- Opens the customization on a tag with ID 'gil1'.  -->
<rdf:Description rdf:about="gil1">
  <customizationAllowed
xmlns="http://xmlns.oracle.com/mds">false</customizationAllowed>
</rdf:Description>

<!-- Restricts customizations on a commandButton component's 'text' attribute.
-->
<rdf:Description rdf:about="cb1/@text">
  <customizationAllowed
xmlns="http://xmlns.oracle.com/mds">false</customizationAllowed>
</rdf:Description>
```

At runtime, these policies are read and the artifacts are enabled for customization accordingly.

24.2 Applying a Component Instance-Level Customization Restriction By Using Security Roles: Example

This section explains how you can use component-level restrictions to limit access to certain component functions, based on different user roles and responsibilities. Specifically, it describes how to apply an instance-level customization restriction to a `Panel Customizable` component to provide customization access to only users with `admin` role. That is, when a user with `admin` role logs into the system at runtime, the user can customize the `Panel Customizable` on which the instance-level customization is applied.

In Composer's Property Inspector, the properties of the `Panel Customizable` are not displayed to users who do not have `admin` privileges. The Edit icon or menu item is disabled on restricted components. These users cannot drop any `Movable Box` into the `Panel Customizable` because of the applied restriction. Moreover, they cannot rearrange the `Show Detail Frames` inside this `Panel Customizable`.

To restrict a functionality based on user roles is one way to apply customization restrictions. You can also use expression language expressions (ELs), which provide roles-based results, to enable or restrict access to a component function.

> **Note:** MDS customization restrictions are natively honored only by `Panel Customizable`, `Show Detail Frame`, and `Layout Customizable` components, and not ADF Faces components, such as `Splitter` and `showDetailItem`.

This section contains the following subsections:

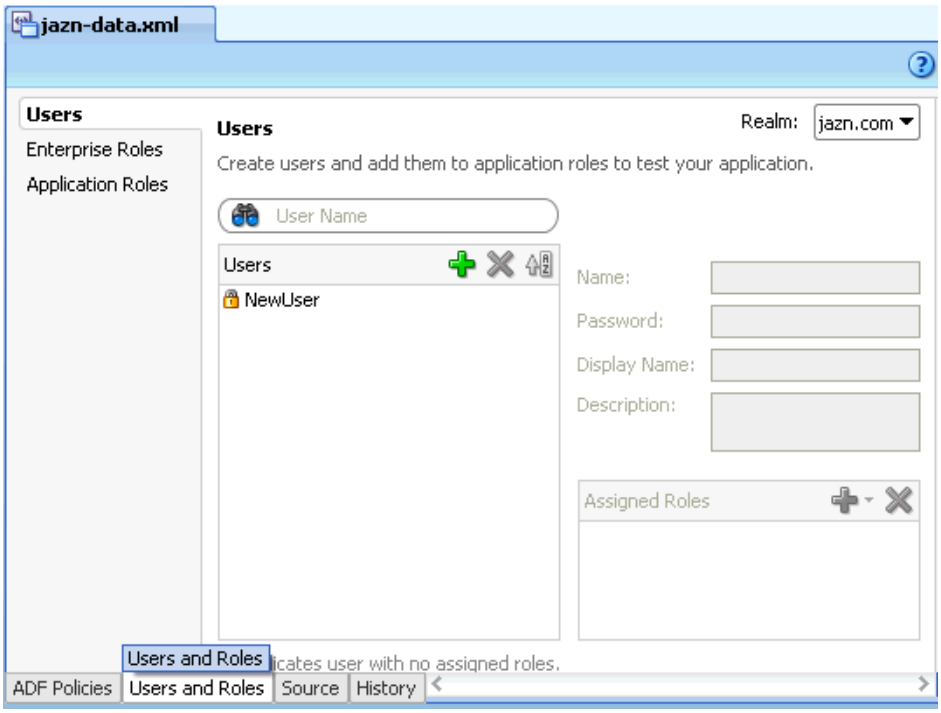
- Section 24.2.1, "How to Configure ADF Security"

- Section 24.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File"
- Section 24.2.3, "How to Customize the SessionOptions Object to Include Customization Policy"
- Section 24.2.4, "How to Register the Implementation with Composer"
- Section 24.2.5, "How to Configure WebCenterComposerFilter"
- Section 24.2.6, "How to Apply an Instance-Level Customization Restriction"
- Section 24.2.7, "What Happens at Runtime"

24.2.1 How to Configure ADF Security

Before applying an instance-level customization restriction, you must secure your application using ADF security. For information, see Section 69.3, "Configuring ADF Security."

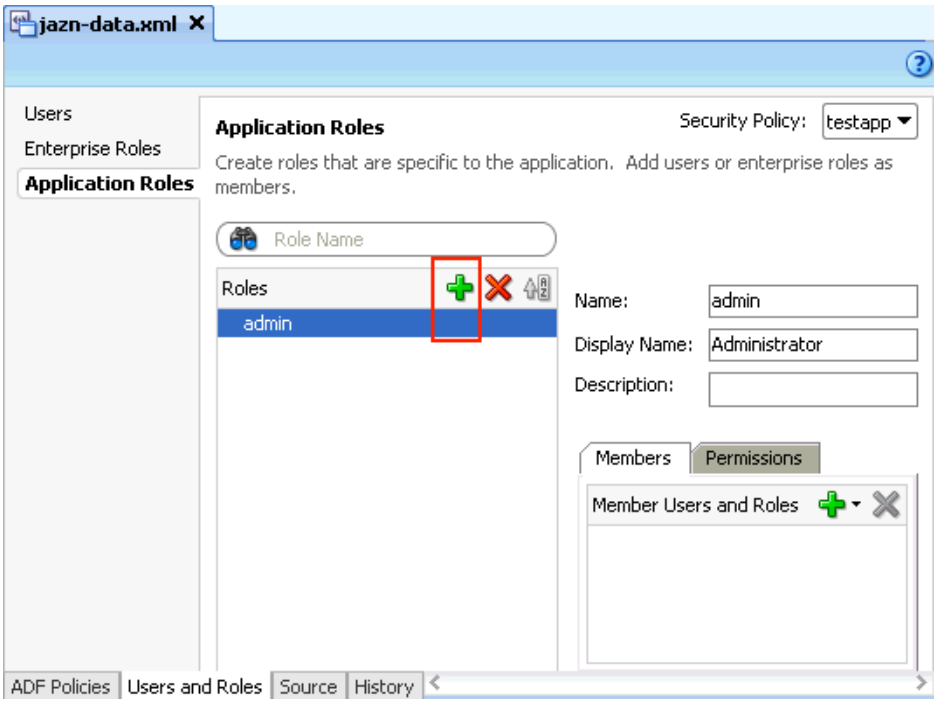
24.2.2 How to Define Roles and Grant Privileges in the jazn-data.xml File



In a previous section, a customization restriction is applied to a `Panel Customizable` component so that, at runtime, only the user with `admin` role can access all the features of `Panel Customizable`, and therefore, can customize its attributes.

In this section, two roles, `admin` and `customer`, are created and page permissions are granted to both users. Users with `admin` role can customize the `Panel Customizable` (`panelCustomizable1`) component. However, because of the customization restriction you applied in an earlier section, users with `customer` role do not have the rights to customize `panelCustomizable1`, and these users cannot use all the features of `panelCustomizable1`.

To create roles in the `jazn-data.xml` file:



1. In the Application Resources panel, right-click the **jazn-data.xml** file and select **Open**.
2. Click the **Users and Roles** tab at the bottom of the editor to open the Users section of the file, shown in Figure 24–1.

Figure 24–1 The jazn-data.xml File

3. Click the **Application Roles** tab.
4. In the Application Roles page, click the **New Application Role** icon in the Roles table, shown in Figure 24–2.

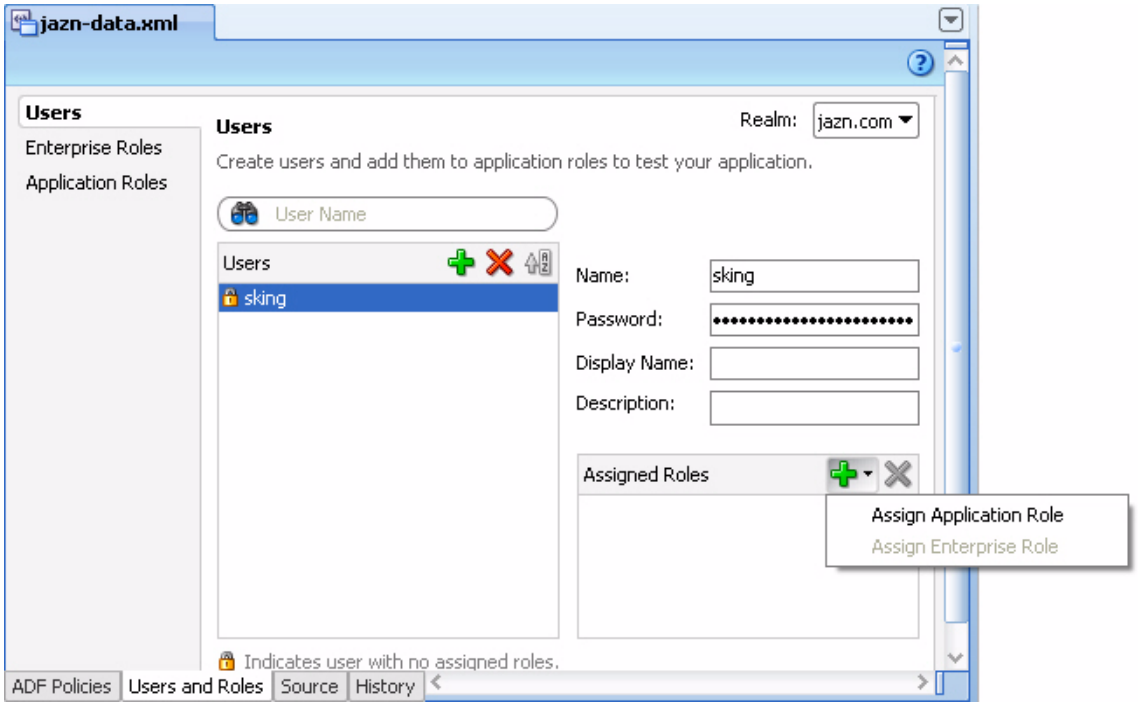


Figure 24–2 Roles Section in the jazn-data.xml File

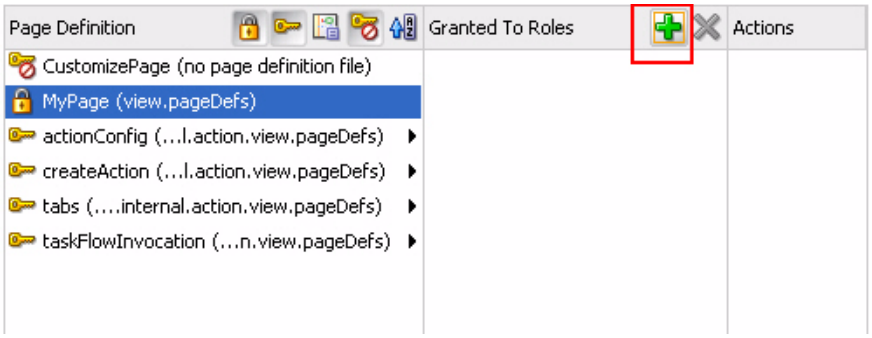
5. In the **Name** field, specify the user name, `admin`.



6. Optionally, in the Display Name and Description fields, specify a display name and description for the new role.
7. Repeat steps 3 through 6 to add another role, `customer`.
8. Click the **Users** tab.
9. In the Users page, create new users by clicking the **New User** icon and specifying credentials, and assign roles to these users by clicking the **Assign Roles** icon in the Assigned Roles table and selecting **Assign Application Role**, as shown in Figure 24–3.

Figure 24–3 Users Section in the jazn-data.xml File

10. Click the **ADF Policies** tab at the bottom of the page.
11. Select the **Web Pages** tab on the page.
12. From the list of page definitions, select the page on which you want to grant privileges, as shown in Figure 24–4.

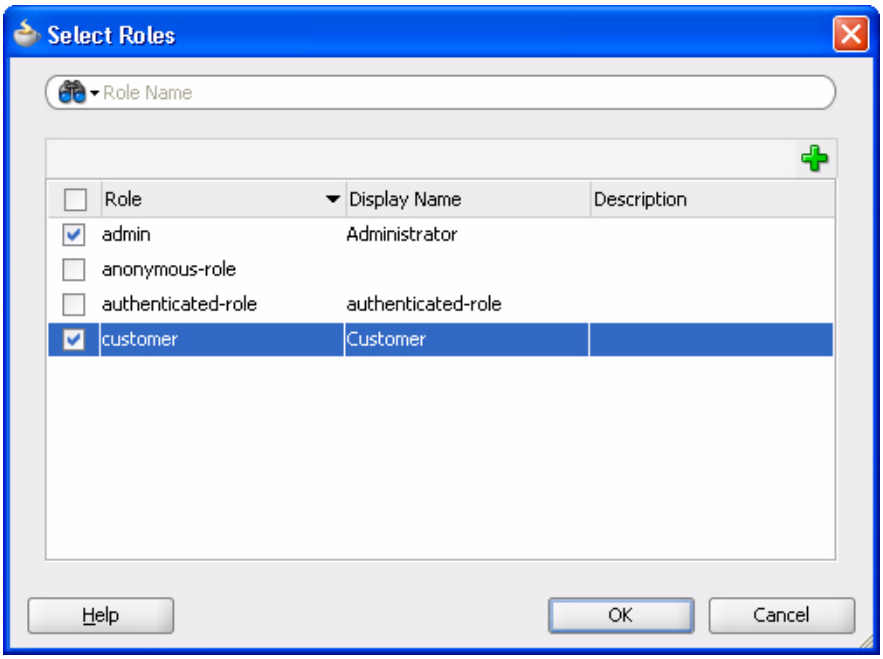


Figure 24–4 Page Definitions in the jazn-data.xml File

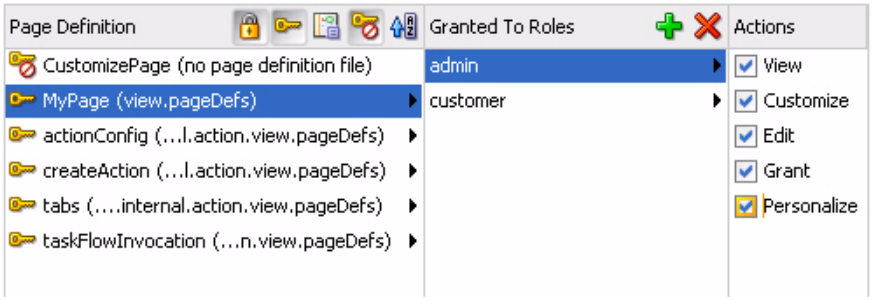
13. In the Granted to Roles column, click the **Add Application Role** icon.



14. In the Select Roles dialog (Figure 24–5), select the `admin` and `customer` roles and click **OK**.

Figure 24–5 Select Roles Dialog

15. Select each role and grant all the permissions (View, Customize, Edit, Grant, Personalize), as shown in Figure 24–6.

Figure 24–6 Permissions List in the jazn-data.xml File

For more information about creating users and roles, see the section *"Enabling ADF Security in a Fusion Web Application"* in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

24.2.3 How to Customize the SessionOptions Object to Include Customization Policy

To enable the expected runtime behavior of the `Panel Customizable` component, where only the user with `admin` role has access to all capabilities of the `Panel Customizable`, including the ability to customize it, the MDS session for this request must include the user roles in its customization policy. To achieve this, the following customization policy is included in the `SessionOptions` object:

```
SecurityContext stx = ADFContext.getCurrent().getSecurityContext();
  cPol = new CustomizationPolicy(stx.getUserRoles());
```

Then the MDS session is created with this customization policy.

To implement the `ComposerSessionOptionsFactory` class:

1. From the File menu, choose **New**.
2. In the New Gallery dialog, expand **General**, select **Java**, then **Java Class**, and click **OK**.

   The Create Java Class dialog opens.
3. In the **Name** field, enter `AppsSessionOptionsFactoryImpl`.
4. Click **OK.**

   The `AppsSessionOptionsFactoryImpl.java` file is rendered in the Source view.
5. Import the following libraries:

```
import oracle.adf.share.ADFContext;
import oracle.adf.share.security.SecurityContext;
import oracle.adf.view.page.editor.mds.ComposerSessionOptionsFactory;
import oracle.adf.view.page.editor.mode.ModeContext;
import oracle.mds.config.CustClassListMapping;
import oracle.mds.config.CustConfig;
import oracle.mds.core.SessionOptions;
import oracle.mds.cust.CustClassList;
import oracle.mds.cust.CustomizationClass;
import oracle.mds.cust.CustomizationPolicy;
```

6. Add the following code to implement the `ComposerSessionOptionsFactory` class and provide `SessionOptions`:

```
public class AppsSessionOptionsFactoryImpl
implements ComposerSessionOptionsFactory
{
  public AppsSessionOptionsFactoryImpl()
  {
  }
  public SessionOptions createSessionOptions(SessionOptions sessionOptions,
                                             String mode)
  {
    CustomizationClass[] custLayer;
    CustConfig custConfig = null;
    CustomizationPolicy cPol = null;

    if (ModeContext.EDIT_MODE.equals(mode))
    {
      //Mode is Edit, change to SiteCC
      custLayer = EDIT_LAYER;
    }
    else
    {
      //Mode is View, change to UserCC + SiteCC
      custLayer = VIEW_LAYER;
    }
    try
    {
      CustClassList custClassList = new CustClassList(custLayer);
      CustClassListMapping custClassListMapping =
        new CustClassListMapping("/", null, null, custClassList);
      custConfig = new CustConfig(new CustClassListMapping[]
```

```
            { custClassListMapping });
      SecurityContext stx = ADFContext.getCurrent().getSecurityContext();
      cPol = new CustomizationPolicy(stx.getUserRoles());
    }
    catch (Exception e)
    {
      e.printStackTrace();
    }
    if(sessionOptions.getServletContextAsObject() != null)
    {
      return new SessionOptions(sessionOptions.getIsolationLevel(),
                                sessionOptions.getLocale(), custConfig,
                                sessionOptions.getVersionContext(),
                                sessionOptions.getVersionCreatorName(),
                                cPol == null ?
sessionOptions.getCustomizationPolicy() : cPol,
                                sessionOptions.getServletContextAsObject());
    }
    else
    {
      return new SessionOptions(sessionOptions.getIsolationLevel(),
                                sessionOptions.getLocale(), custConfig,
                                sessionOptions.getVersionContext(),
                                sessionOptions.getVersionCreatorName(),
                                cPol == null ?
sessionOptions.getCustomizationPolicy() : cPol);
    }
  }
  //Edit mode SiteCC
  private static final CustomizationClass[] EDIT_LAYER =
    new CustomizationClass[]
    { new SiteCC() };
  //View mode SiteCC + USerCC
  private static final CustomizationClass[] VIEW_LAYER =
    new CustomizationClass[]
    { new SiteCC(), new UserCC() };
}
```

24.2.4 How to Register the Implementation with Composer

Perform the steps described in Section 23.3.5, "How to Register the Implementation with Composer" to register the `ComposerSessionOptionsFactory` class implementation, where user roles were included in the MDS session's customization policy.

24.2.5 How to Configure WebCenterComposerFilter

To configure `WebCenterComposerFilter`, perform the steps described in Section 23.3.6, "How to Configure WebCenterComposerFilter."

24.2.6 How to Apply an Instance-Level Customization Restriction

In this section, you enable application customization for particular role on a `Panel Customizable` component. At runtime, only the specified role, for example `admin`, can access all the features of the `Panel Customizable`, including customizing its attributes. Users with any other roles can use only a limited set of component features.

To apply an instance-level customization restriction:

1. In the JSPX page, add a **Change Mode Link** component from the Composer tag library.
2. Add a **Page Customizable** component below the `Change Mode Link` component.
3. Apply an instance-level customization restriction on the component `Panel Customizable` in the Page Customizable.

   This restriction is stored in the following directory: `public_html/mdssys/mdx/<pagename>.jspx.rdf`.

   The Source view should look like this:

```
<pe:changeModeLink id="cml1"/>
<pe:pageCustomizable id="pageCustomizable1">
  <cust:panelCustomizable id="panelCustomizable1" layout="scroll"/>
    <f:facet name="editor">
      <pe:pageEditorPanel id="pep1"/>
    </f:facet>
</pe:pageCustomizable>
```

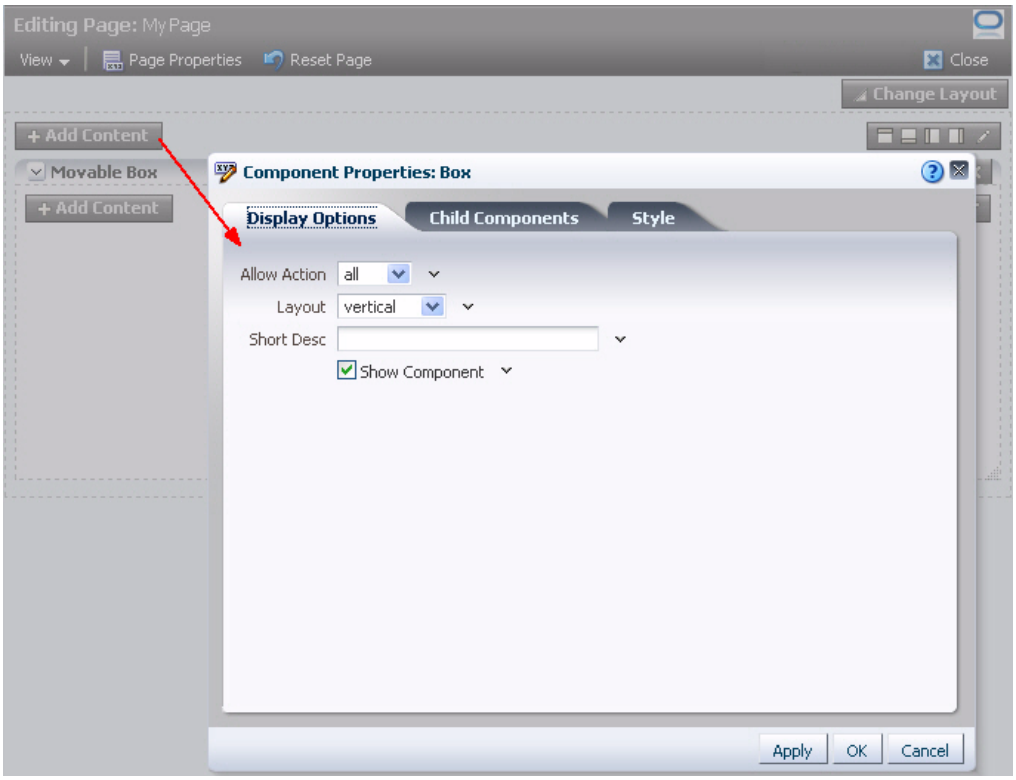
   The design view should look like Figure 24–7.

Figure 24–7 Design View: Customization Allowed

4. Add a `Show Detail Frame` component within the `Panel Customizable` and include another `Panel Customizable` component as a child of the `Show Detail Frame` component.

> **Note:** This step is for illustration purpose only as it is easier to explain runtime behavior by showing multiple components. For detailed information on how to add Composer components, see Section 5.3, "Adding Pages to a Portal."

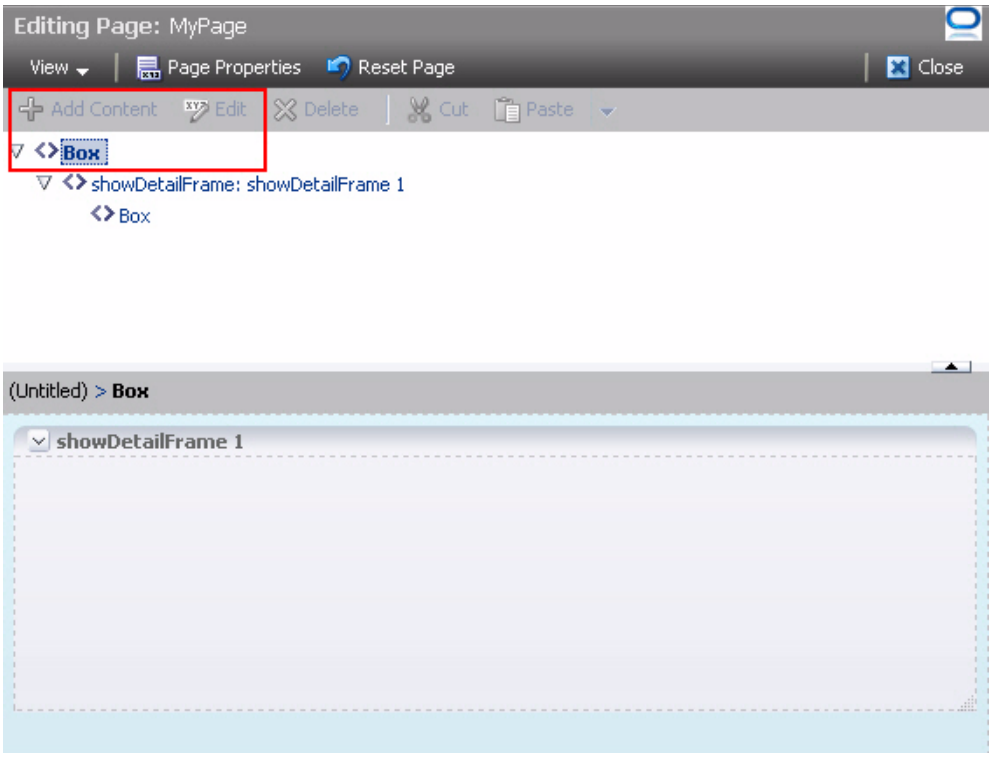
24.2.7 What Happens at Runtime



What happens at runtime is influenced by which user is logged on. To see the difference, log in as one user and then the other. For example:

In the Application Navigator, right-click the JSPX page and select **Run**.

Log in to the page as a user with `admin` role, and switch to Edit mode. The **Add Content** button and the **Edit** icon are displayed on the outer and inner `Panel Customizable` components. As a user with `admin` role, you can switch to Source



view and access the properties of the outer `Panel Customizable`, as shown in Figure 24–8. That is, users with `admin` role can edit this component.

Figure 24–8 Edit Mode for admin

Log in to the page as a user with `customer` role, and switch to Edit mode. The **Add Content** button and the **Edit** icon are not available on the outer `Panel Customizable`. That is, this component is not editable for users with `customer` role. In Source view, the Add Content and Edit icons are grayed out for the component, as shown in Figure 24–9.

Figure 24–9 Restricted Component in Page Source View

24.3 Applying Tag-Level Security Using the customizationAllowed Attribute

By default, a `Page Customizable` component enables application customization on all components under it. You may want to change this to restrict customization on some components. The `Page Customizable` component does not enable customization on components that are on a nested page or fragment. You must enable customization on such components manually. To address such requirements, MDS provides the `customizationAllowed` and `customizationAllowedBy` attributes. These attributes can be used to enable or restrict customization on specific component instances on a page.

The `customizationAllowed` attribute controls whether the component can be customized at runtime. If you set this attribute to `false`, then the component cannot be customized at runtime. That is, in the Component Properties dialog the properties are grayed out and do not allow editing.

The `customizationAllowedBy` attribute specifies the roles for which customization is enabled.

This section provides examples of enabling and restricting customization on a component. It contains the following subsections:

- Section 24.3.1, "How to Enable Application Customization on an Image Component"
- Section 24.3.2, "How to Restrict Customization on an Image Component"

For more information, see "Extended Metadata Properties" in *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

24.3.1 How to Enable Application Customization on an Image Component

To enable application customization on an Image component:

1. In the `MyPage.jspx` page that you created in Section 20.2, "Designing Editable Pages Using Composer Components: Example," add an ADF Faces Image component, for example, `brandingImage.gif`, inside the `Panel Customizable` called `panelCustomizable1`.

   Application customization is enabled automatically on the `Image` component since it is nested inside a `Page Customizable` component.

2. Run `MyPage.jspx`.
3. Switch to Edit mode of the page.
4. From the **View** menu, select **Source** to switch to Source view of the page.
5. Select the image in the component hierarchy in the Source View panel and click the **Show the properties of Image** icon.

   The Component Properties dialog displays the image properties. You can edit any available property in this dialog. Edit a property and click **OK**. The property's editable value demonstrates that application customization is enabled on the component.

24.3.2 How to Restrict Customization on an Image Component

You can restrict customization of an image on the page by setting the `customizationAllowed` attribute to `false` on the image component.

To restrict customization on the Image Component:

1. In Oracle JDeveloper, select the `Image` component that you added in the previous section, and in the Property Inspector set the value for **customizationAllowed** to `false`.
2. Run `MyPage.jspx`.
3. Switch to page Edit mode.
4. From the **View** menu, select **Source** to switch to the Source view of the page.
5. Select the image in the component hierarchy in the Source View panel, and click the **Show the properties of Image** icon.

   In the Component Properties dialog, the properties are grayed out and cannot be edited.

24.4 Applying Attribute-Level Security

You can choose whether specific component attributes can be customized at runtime. Additionally, you can specify whether the changes made to an attribute must be persisted to a persistence store, such as MDS. You can apply attribute-level security in the following ways:

- By defining property filters
- By persisting changes at the component level

For information about applying property filters, see Section 21.8.1, "How to Define Property Filters."

This section describes how to persist changes at the component level. It contains the following subsections:

- Section 24.4.1, "How to Define Change Persistence at the Component Level"
- Section 24.4.2, "What Happens at Runtime"

24.4.1 How to Define Change Persistence at the Component Level

If your application is configured to use `FilteredPersistenceChangeManager` to persist changes, you can use the `persist-changes` attribute in the `adf-config.xml` file to specify whether changes to a specific attribute must be persisted.

> **Note:** For information about change persistence, see Section 22.11, "Configuring the Persistence Change Manager."
>
> For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

Example 24–1 shows a sample `adf-config.xml` file with `persist-changes` attributes defined for some attributes.

Example 24–1 Using the persist-changes Attribute in the adf-config.xml File

```
<adf-config xmlns="http://xmlns.oracle.com/adf/config">
  <adf-faces-config xmlns="http://xmlns.oracle.com/adf/faces/config">
    <persistent-change-manager>
      <persistent-change-manager-class>
       oracle.adf.view.rich.change.MDSDocumentChangeManager
      </persistent-change-manager-class>
    </persistent-change-manager>
    <taglib-config>
      <taglib uri="http://xmlns.oracle.com/adf/pageeditor">
        <tag name="imageLink">
          <attribute name="destination">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
        <tag name="customAction">
          <attribute name="text">
            <persist-changes>true</persist-changes>
          </attribute>
          <attribute name="icon">
            <persist-changes>true</persist-changes>
          </attribute>
        </tag>
      </taglib>
    </taglib-config>
  </adf-faces-config>
</adf-config>
```

24.4.2 What Happens at Runtime

If you set `persist-changes` to `true`, then a change made to the component attribute is persisted in any instance of that component. If you set `persist-changes` to `false`, then even if you change the attribute value in the Component Properties dialog at runtime, the change is not saved.

24.5 Applying Action-Level Restrictions on Panel Customizable and Show Detail Component Actions

The ability of a user to perform actions on `Panel Customizable` and `Show Detail Frame` components is inherited from page security. Inheritance is based on the value of the application-wide switch, `enableSecurity`, in the `adf-config.xml` file. If you select the WebCenter Portal - Framework Application template when you create your application, then the `adf-config.xml` file is located in the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.

This section describes how to apply action-level restrictions on `Panel Customizable` and `Show Detail Frame` component actions. It contains the following subsections:

- Section 24.5.1, "How to Add an enableSecurity Section to adf-config.xml"
- Section 24.5.2, "Defining Security at the Actions Category Level"
- Section 24.5.3, "Defining Security at the Actions Level"

24.5.1 How to Add an enableSecurity Section to adf-config.xml

The `enableSecurity` element is not available by default in `adf-config.xml`. To override or extend the page-level security inheritance for `Panel Customizable` and `Show Detail Frame` components, you must add the `customizableComponentsSecurity` section in the `adf-config.xml` file, as shown in Example 24–2, and set the `enableSecurity` element in that section to `true`.

Example 24–2 enableSecurity Element in the Customizable Components Security Section in adf-config.xml

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>
    <cust:actionsCategory>
       ......................................
</cust:customizableComponentsSecurity>
```

Restrictions on actions can be implemented at the following levels:

- **Page level**: You can define security for WebCenter Portal Customizable Components so that page-level privileges are inherited by these components. This is the default behavior.

  By default, customizable components inherit allowable actions from the defined page-level permissions, such as edit, personalize, or customize. That is, a user who has edit, personalize, or customize privileges on a page can perform View mode user customizations on that page. The `enableSecurity` element enables you to override the security inheritance behavior. It can take either of the following values:

  - `true`: If set to `true` (the default when not specified), then the ability of a user to modify a component is first determined from the page permissions and then adjusted according to the current set of actions defined for that type of permission. For example, if a user has customize permission, then the actions that constitute the customize category (move, customize, and so on) are available to the user, but they are overridden by the actions that are defined in the `adf-config.xml` file.

  - `false`: If set to `false`, then all actions are available to users. A user's page permissions and actions configured in `adf-config.xml` are ignored.

- **Actions category level**: You can define security on all actions for `Panel Customizable` and `Show Detail Frame` components.

  You can add an `actionsCategory` element in the `adf-config.xml` file to define security on multiple actions simultaneously. Depending on the `actionCategory` attributes that you enable, appropriate privileges are provided on the components.

- **Actions level**: You can define security on individual actions for `Panel Customizable` and `Show Detail Frame` components.

  You can use the `actions` element in the `adf-config.xml` file to enable or disable individual actions. Depending on the `actions` attributes that you enable, appropriate privileges are provided on the components.

Notes:

- If you set `enableSecurity` to `true` in the `adf-config.xml` file and define restrictions on actions or action categories, then for these restrictions to take effect you must grant Personalize or Customize privilege on the page, in addition to View privilege.

  If you are not using the `enableSecurity` element or it is set to `false`, then page-level permissions are honored. In such a case, having View privilege on the page is sufficient as all customizable components actions are rendered by default on the page.

- Privileges can be inherited from the parent only. Inheritance from a component in any other position in the hierarchy is not supported.

- Restrictions defined at the actions category level or actions level are applicable to all instances of the `Panel Customizable` or `Show Detail Frame` component across the application. You cannot apply restrictions on a single instance of the component.

You can define security for component actions at the application level if `enableSecurity` is set to `true` in the `adf-config.xml` file. A value of `true` implies that permission checks are made in addition to the `actionsCategory` and `actions` values specified in the `adf-config.xml`.

24.5.2 Defining Security at the Actions Category Level

You can add an `actionsCategory` element in the customizable components actions security section in the `adf-config.xml` file to define security on multiple `Panel Customizable` and `Show Detail Frame` components actions. Depending on the `actionsCategory` attributes that you enable, appropriate privileges are provided on the components.

The `actions` and `actionsCategory` elements in the `adf-config.xml` file have certain default mappings. Table 24–1 describes the different `actionsCategory` attributes and the actions they support by default.

For information about the Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

Table 24–1 Actions Categories and Actions Mapping

actionsCategory	Actions Supported
`personalizeActionsCategory`	showMoveAction showRemoveAction showMinimizeAction showResizer allowAction
`customizeActionsCategory`	showEditAction showAddContentAction showSplitAction

The behavior of components based on a combination of `personalizeActionsCategory` and `customizeActionsCategory` settings is as follows:

- If both `personalizeActionsCategory` and `customizeActionsCategory` are set to `false`, then users cannot move, expand, collapse, delete, resize, or edit `Show Detail Frame` components and they also cannot edit or delete `Panel Customizable` components or add content inside them.
- If `personalizeActionsCategory` is set to `true` and `customizeActionsCategory` is set to `false`, then users can move, expand, collapse, delete, or resize `Show Detail Frame` components but not edit them. Additionally, they can delete `Panel Customizable` components and rearrange components inside them but not edit them or add components to the page.

  Note: The `allowAction` setting, along with other actions settings, controls the ability to add content to the page and move or rearrange content on the page. For more information, see Section 24.5.3, "Defining Security at the Actions Level."

- If both `personalizeActionsCategory` and `customizeActionsCategory` are set to `true`, then users can move, expand, collapse, delete, resize, and edit `Show Detail Frame` components and they can also edit and delete `Panel Customizable` components and add content inside them. Users can add content from the Resource Catalog using the **Add Content** button, add Box components using the Add Box icons, and move components from other `Panel Customizable` components by dragging and dropping them.

  Note: It is not recommended that you set `personalizeActionsCategory` to `false` and `customizeActionsCategory` to `true` as privileges cascade from Grant to Customize to Personalize to View. That is, when you enable Customization, the user must already have Personalize privilege on the page.

Example 24–3 shows the `actionsCategory` entry that you can add to the customizable components actions security section in the `adf-config.xml` file.

Example 24–3 actionsCategory Element in the Customizable Components Security Section

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>

  <cust:actionsCategory>
    <cust:actionCategory name="personalizeActionsCategory" value="true"/>
    <cust:actionCategory name="customizeActionsCategory" value="false"/>
  </cust:actionsCategory>

  <cust:actions>
  ......................................
  </cust:actions>

</cust:customizableComponentsSecurity>
```

You can also use EL for these element values, as shown in Example 24–4.

Example 24–4 EL Used in Customizable Components an actionCategory Entry

```
<cust:actionsCategory>
  <cust:actionCategory name="personalizeActionsCategory"
value="#{appBusinessRules.InsideCorpNetwork}"/>
</cust:actionsCategory>
```

For reference, the managed bean, `appBusinessRules`, is defined as shown in Example 69–7 in Section 69.15, "Overriding Inherited Security on Portlets and Customizable Components."

24.5.3 Defining Security at the Actions Level

You can use the `actions` element in the customizable components actions security section of the `adf-config.xml` file to show or hide individual `Show Detail Frame` actions. Depending on the `actions` attributes that you enable, appropriate privileges are provided on the `Show Detail Frame` components.

For information about Composer-specific configurations you can make in `adf-config.xml`, see Section B.2.2, "adf-config.xml."

The `allowAction` setting, along with other actions settings, controls the ability to add content to the page and move or rearrange page content.

In Composer, users can add and arrange content in the following ways:

- Add `Box` components using the **Add Box** icons.
- Add content inside a `Box` component, from the Resource Catalog, using the **Add Content** button.
- Move `Show Detail Frame` components within a `Panel Customizable` component by using the Move Up and Move Down actions on the `Show Detail Frame` component's Actions menu.
- Drag and drop `Show Detail Frame` components across `Panel Customizable` components.

Table 24–2 explains the ability to add content depending on the `allowAction` and `showAddContentAction` settings.

Table 24–2 Actions Settings for Adding Content to a Page

allowAction Setting	showAddContentAction Setting	Add Content Button Displayed?
`true`	`true`	Yes
`true`	`false`	No
`false`	true	No
`false`	`false`	No

Table 24–3 explains the ability to add content using the Add Box icons depending on the `allowAction` and `showSplitAction` settings.

Table 24–3 Actions Settings for Rearranging Content on a Page

allowAction Setting	showSplitAction Setting	Add Box Icons Displayed?
`true`	`true`	Yes
`true`	`false`	No
`false`	`true`	No
`false`	`false`	No

Table 24–4 explains the ability to move content on the page depending on the `allowAction` and `showMoveAction` settings.

Table 24–4 Actions Settings for Moving Content on a Page

allowAction Setting	showMoveAction Setting	Move Content on the Page?
`true`	`true`	Yes
`true`	`false`	No
`false`	`true`	No
`false`	`false`	No

Note:

- If you define security both at the actions category level and actions level and the values for some actions contradict, then a value of `false` takes precedence over `true`. For example, if you set `personalizeActionsCategory` to `true` and `allowAction` to `false`, then users cannot add content to their application pages at runtime. Similarly, if you set `personalizeActionsCategory` to `false` but set `allowAction` to `true`, then too users cannot add content to their application pages at runtime.
- Restrictions using actions settings are applicable only in Design view of a page. That is, if you set an action, such as `showEditAction` or `showRemoveAction`, on `Show Detail Frame` components to `false`, then users cannot edit or delete such components in Design view of the page. However, users can still select such components in Source view and edit or delete them.

Example 24–5 shows the `actions` entry that you can add to the customizable components actions section of the `adf-config.xml` file. You can use EL for element values.

Example 24–5 action Elements in the Customizable Components Security Section

```
<cust:customizableComponentsSecurity
xmlns="http://xmlns.oracle.com/adf/faces/customizable/config">
  <cust:enableSecurity value="true"/>

  <cust:actionsCategory>
    ....................................
  </cust:actionsCategory>

  <cust:actions>
    <cust:action name="showMinimizeAction" value="true"/>
    <cust:action name="showMoveAction" value="false"/>
  </cust:actions>

</cust:customizableComponentsSecurity>
```

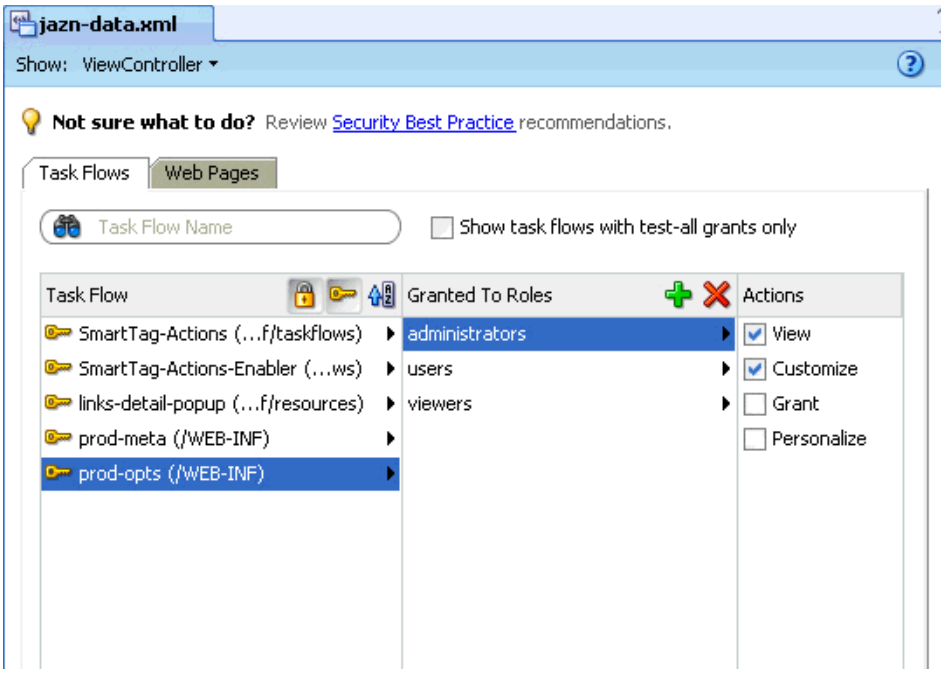
24.6 Implementing Task Flow Security

Since editing task flow permissions has a far reaching impact on the task flow editing experience, the Edit permission on task flows is disabled by default. In fact, no permissions are provisioned on task flows by default. To ensure that only users with appropriate permissions can edit a task flow, you can implement task flow security by performing the following two tasks in the Composer context:

- Explicitly grant Edit, Customize, or Grant permission on the task flow.
- Enable Composer to check for a task flow's permissions and allow only users with appropriate permissions to edit or customize the task flow.

This section explains how to apply restrictions and enable permission checks on task flows. It includes the following subsections:

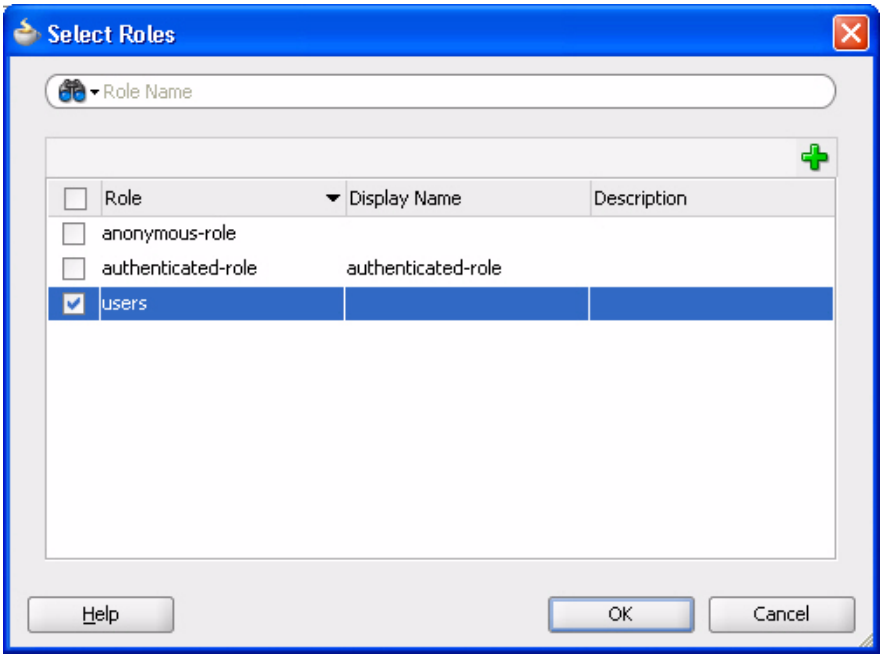
- Section 24.6.1, "Granting Permissions on Task Flows"
- Section 24.6.2, "Enabling Task Flow Permission Check"



24.6.1 Granting Permissions on Task Flows

You can define the access policy for a task flow by creating permission grants in the Resource Grants page of the `jazn-data.xml` file overview editor. The grants you create will appear as metadata in the policy store section of the file. These grants, or permissions, control the ability to zoom into and edit the task flow in Composer.

To grant or revoke permissions on a task flow in the `jazn-data.xml` file:



1. From the Application menu, select **Secure**, and then **ADF Policies**.
2. In the `jazn-data.xml` file, select the task flow in the Overview editor and click the **Add** button in the Granted to Roles column, shown in Figure 23–12.

Figure 24–10 Task Flow Security Region in the jazn-data.xml File

3. In the Select Roles dialog (Figure 23–13), select the application roles to which you want to grant permissions or create a new role by clicking the **Add** button.

Figure 24–11 Select Roles Dialog

4. Click **OK**.
5. Select one or more permissions in the Actions column.
6. Save the `jazn-data.xml` file.

Note: The permission grant would appear as follows in the source view of the file:

```
<permissions>
  <permission>

<class>oracle.adf.controller.security.TaskFlowPermission</class>

<name>/WEB-INF/task-flow-definition.xml#task-flow-definition</name>
    <actions>customize,view</actions>
  </permission>
</permissions>
```

The `TaskFlowPermission` class defines task flow-specific actions that it maps to the task flow's operations.

For more information about Composer's behavior based on task flow permissions, see Section 18.7.1, "Page and Task Flow Security."

For more information about defining permission grants on task flows, see the section titled "How to Define Security Policies for ADF Bounded Task Flows" in the *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

24.6.2 Enabling Task Flow Permission Check

When a user tries to edit a task flow, Composer does not check the task flow's permissions by default. To enhance task flow security, you must configure Composer to check for a task flow's permissions and allow only users with the required privileges to edit it. You can do so by setting the `check-permission` property on the `<pe:task-flow-security>` element in the application's `adf-config.xml` file, as shown in the following example:

```
<pe:page-editor-config>
  <pe:security-config>
    <pe:task-flow-security check-permission="true" />
  </pe:security-config>
</pe:page-editor-config>
```

For more information about `adf-config.xml` settings, see Section B.2.2, "adf-config.xml."

Note: In earlier releases, you could enable permission checks on task flows by running the server with the following JVM parameter:

`-Doracle.composer.enableTaskflowPermissionCheck=true`

However, this method is now deprecated. For backward compatibility, Composer checks for the `enableTaskflowPermissionCheck` flag first, and then the setting in the `adf-config.xml` file.

24.7 Overriding Composer's Default Security Policies

Composer performs the following security checks to enable customization:

- Regions on the page have been granted edit or customize privilege.

- Task flows have been granted edit or customize privilege.

  Note: This is an optional security setting, which is not enabled by default.

- A component is not nested in an iterator.
- MDS customization restrictions have been applied on components and attributes.

Users can customize pages and task flows only if all the above criteria are met. By default, Composer uses `pagePolicy` to perform page-level security checks.

There may be situations where you want to perform different security checks; probably add a few application-level checks to what Composer already provides. You can do so by overriding Composer's default security policy with a custom policy. This section explains how to do this. It includes the following sections:

- Section 24.7.1, "How to Create a Custom Security Policy"
- Section 24.7.2, "How to Register a Custom Policy with Composer"
- Section 24.7.3, "What Happens at Runtime"

24.7.1 How to Create a Custom Security Policy

You can create custom policies by extending Composer's base security classes. Depending on whether you want to check pages or task flows, you can extend the following base security classes:

- Page Policy:
  `oracle.adf.view.page.editor.security.BasePageSecurityPolicy`
- Task Flow Policy:
  `oracle.adf.view.page.editor.security.TaskflowPermissionPolicy`

To take you one step further, you can configure your policy in such a way that Composer's default checks are performed in case the custom checks are not applicable or do not provide the desired results. For this, you must extend the `DefaultPageSecurityPolicy` class and call the `super.isCustomizable()` method, as shown in Example 24–6.

Example 24–6 Custom Policy Extending DefaultPageSecurityPolicy

```
public class CustomPageSecurityPolicy extends DefaultPageSecurityPolicy
{
  . . .

  public boolean isCustomizable()
  {
    // Security checks that this custom page policy must perform should go here
    . . .
    // If we cannot determine the security policy, chain it to Composer's default
implementation
    return super.isCustomizable();
  }
}
```

24.7.2 How to Register a Custom Policy with Composer

To configure a custom policy to override the Composer security policy, you must include the `<pe:security-config>` section in the application's `adf-config.xml` file and register the custom security policy.

To register a custom security policy:

1. Open the application's `adf-config.xml` file from the `ADF META-INF` folder under `Descriptors` in the Application Resources panel.
2. Add a `<pe:page-editor-config>` section if it does not already exist, and add the following code inside it:

```
<pe:security-config>
  <pe:security-policies>
    <pe:security-policy name="optional_unique_name" override="composer_
security_policy_name">
      <pe:policy-class>fully_qualified_custom_policy_class_
name</pe:policy-class>
    </pe:security-policy>
  </pe:security-policies>
</pe:security-config>
```

   where,

   `override` specifies the default policy to be overridden. Options are `pagePolicy` and `taskflowPolicy`.

   For information about task flow policies, see Section 24.6, "Implementing Task Flow Security."

   Note: Out-of-the-box policies that are not mentioned here will continue to be checked by default.

   `<pe:policy-class>` specifies the name of the custom policy class.

3. Save the `adf-config.xml` file.

24.7.3 What Happens at Runtime

Composer performs the security checks defined in your custom policy and enables customization on components accordingly.

24.8 Troubleshooting Problems with Composer Components Security

This section provides information to assist you in troubleshooting security-related problems you may encounter while using Composer components.

For information about configuring logging, see "Configuring ADF Logging for Composer".

Problem

The `Show Detail Frame` and `Panel Customizable` do not show the **Edit** icon, or the `Panel Customizable` does not show the **Add Content** button. Also, you are not able to move the `Show Detail Frame` out of a `Panel Customizable` component or drop it into another `Panel Customizable` component.

Solution

Ensure that the `Panel Customizable` is not restricted by using MDS and the component actions are not secured by using entries in `adf-config.xml`.

Problem

You are not able to grant permissions on task flows in the `jazn-data.xml` file.

Solution

Ensure that you run the server with the Java startup parameter, as mentioned in Section 24.6, "Implementing Task Flow Security."

25

Customizing Task Flows

You can extend or alter the look and feel and functionality of Oracle WebCenter Portal task flows using the Oracle JDeveloper Customization Developer role. When you apply task flow customizations to a deployed Framework application, the customizations apply to all instances of that task flow in the application. You do not need to deploy customizations for individual task flow instances.

In Oracle WebCenter Portal: Spaces, task flow customizations are deployed at application-level, so any customizations that you make will apply to all spaces. To customize a taskflow for a specific space only, you must use runtime Spaces administration tools for taskflow customization as explained in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*. If your customization involves minor modifications like adding text, hiding existing content or rearranging existing content, you can also use runtime administration tools. If your customization requires complex layout changes to be applied to all instances of a space, use the development-based customization approach explained in this chapter.

> **Note:** While you can perform view-level customizations to Framework applications, such as task flow customization, ADF model and Controller customizations are not supported in this release. To learn more about the different customization types, see the *Oracle Fusion Middleware Java EE Developer's Guide for Oracle Application Development Framework*.

This chapter includes the following sections

- Section 25.1, "Preparing for Task Flow Customization": Before you can customize task flows, you must enable your application to accept these customizations.
- Section 25.2, "Configuring the JDeveloper Customization Developer Role": After you have enabled customization for your application, you must configure the customization layer values to use in the JDeveloper Customization Developer role.
- Section 25.3, "Customizing Oracle WebCenter Portal Task Flows": The instructions in this section describe how to customize task flows in WebCenter Portal: Spaces or a WebCenter Portal: Framework application. The examples in this section demonstrate WebCenter Portal task flow customization using the JDeveloper Customization Developer role.
- Section 25.4, "Applying Task Flow Customizations to Deployed WebCenter Portal Applications": Once you complete a task flow customization, you must apply it to the deployed WebCenter Portal application by following the steps in this section.

- Section 25.5, "Removing Customizations from Deployed WebCenter Portal Applications": To revert task flow behavior or look and feel to the original deployment, remove the task flow customizations using the steps in this section.
- Section 25.6, "Catalog of WebCenter Portal Task Flows": This section lists WebCenter Portal task flows available for customization.

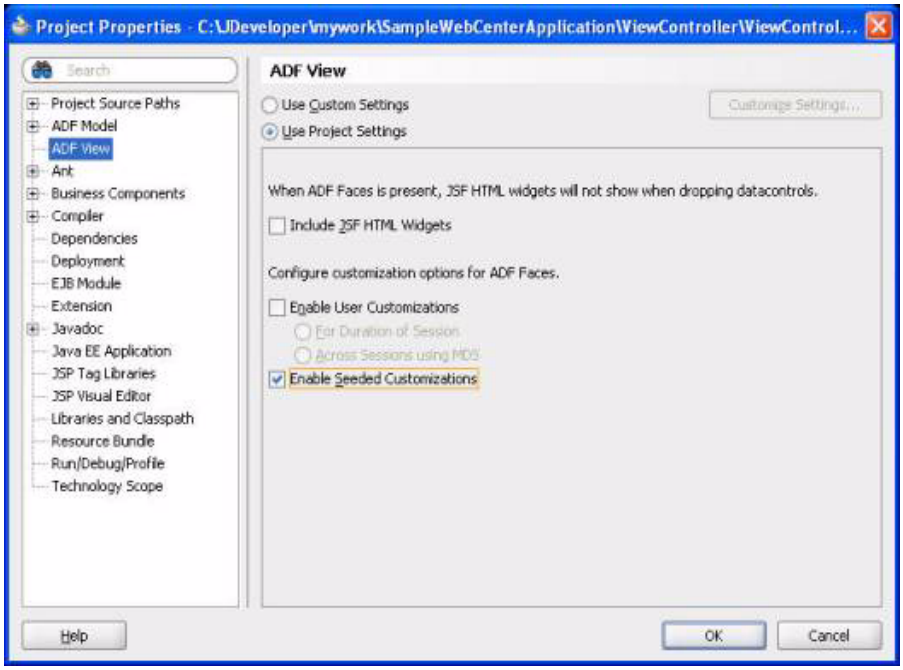
25.1 Preparing for Task Flow Customization

The steps below prepare WebCenter Portal applications for customizing task flows.

1. In JDeveloper, install the WebCenter Portal Customization JDeveloper Extension. To do so, choose **Help** > **Check for Updates**.
2. In the Check for Updates wizard, click **Next**.
3. On the Search for Updates page, select the **Oracle Fusion Middleware Products update center**, and click **Next**.
4. On the Updates page, in the Available Updates field, enter `webcenter`.
5. Select the **Oracle WebCenter Portal Customization Framework Design Time** extension and click **Finish**.

Note: If you have not already installed the latest version of the Oracle WebCenter Portal Framework and Services Design Time extension, you must install it before the customization extension.

25.1.1 WebCenter Portal: Spaces: Create a New Task Flow Customization Application



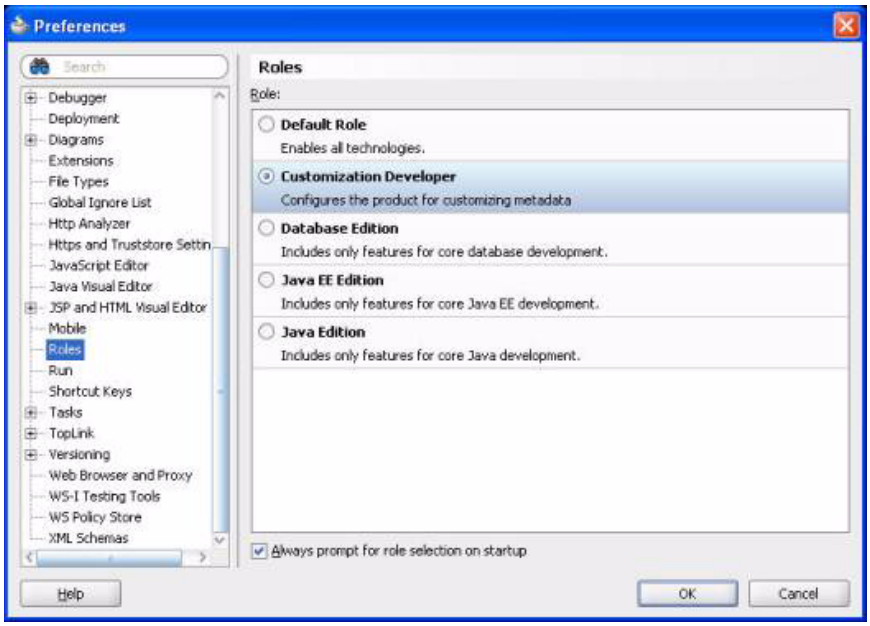
If you are customizing task flows in WebCenter Portal: Spaces, open JDeveloper and create a new WebCenter Spaces Task Flow Customization Application.

25.1.2 WebCenter Portal: Framework Application: Enable Customization

To enable task flow customization in your Framework application, first ensure that you have created your application using the WebCenter Portal: Framework Application template. (For information on creating a new Framework application, see Section 5.2, "Creating a Framework Application.") Then follow the steps below.

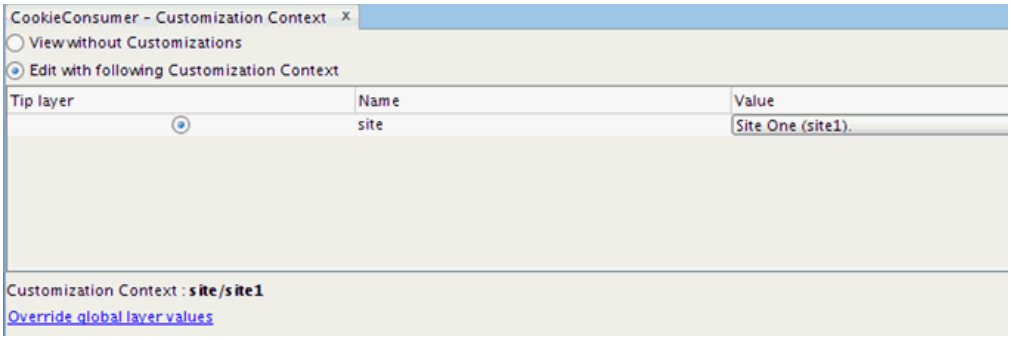
1. In the Application Navigator, right-click the **ViewController** project, and choose **Project Properties**.
2. In the Project Properties dialog, select **ADF View**, then select the **Enable Seeded Customizations** checkbox. Click **OK** and save your files.

Figure 25–1 Enabling Seeded Customizations



25.2 Configuring the JDeveloper Customization Developer Role

After you have enabled customization for your application as described in Section 25.1, "Preparing for Task Flow Customization", you must configure the customization layer values to use in the JDeveloper Customization Developer role.

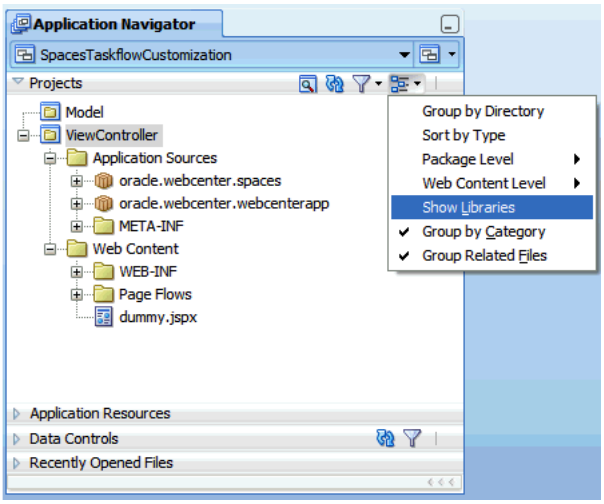


1. In JDeveloper, choose **Tools** > **Preferences** > **Roles**, select the **Customization Developer** role, then click **OK**.

Figure 25–2 Selecting the Customization Developer Role

2. JDeveloper prompts you to restart. Choose **Yes** to restart JDeveloper in the Customization Developer role.
3. For custom Framework applications, go to the **Customization Context** window and click **Override global layer values**.

Figure 25–3 Customization Context: Override Global Layer Values



Enter the configuration for your application's customization class. For applications using the default ADF site customization class, use the following code:

```
<cust-layers xmlns="http://xmlns.oracle.com/mds/dt">
  <cust-layer name="site" id-prefix="s">
    <cust-layer-value value="site" display-name="Site" id-prefix="s"/>
  </cust-layer>
</cust-layers>
```

4. Ensure that **Show Libraries** is enabled in the dropdown (on the far right) of the **Projects** bar in JDeveloper navigator.

Figure 25–4 Navigator Display Options - Show Libraries

In the Customization Developer role, JDeveloper will display a red man next to your application name in the Application Navigator. You will also see a Customization Context window with **Edit with following Customization Context** selected and the customization layer name selected as `site`, and the layer value set to the value defined in `CustomizationLayerValues.xml`. These values indicate that you have successfully configured your application to enable customization of WebCenter Portal task flows.

25.3 Customizing Oracle WebCenter Portal Task Flows

JDeveloper's Customization Developer role is a powerful mechanism that allows you to customize the ADF Library without changing the code in base library JAR. Since both Oracle WebCenter Portal and Oracle ADF leverage MDS, you can use the Customization Developer role to extend WebCenter Portal: Spaces and WebCenter Portal: Services task flows. All WebCenter Portal task flows are packaged in the ADF Library so task flow customization is possible in JDeveloper design time. For instructions on configuring the Customization Developer role, see Section 25.2, "Configuring the JDeveloper Customization Developer Role"

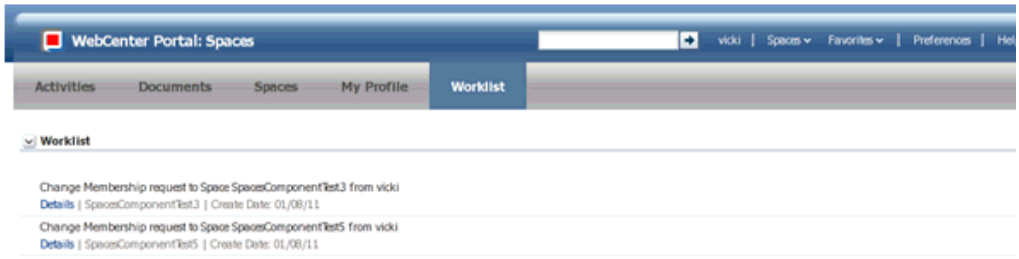
The use cases that can be achieved by task flow customization include:

- Change labels including column names for task flows.
- Change icons used in task flows, for example replacing the Edit and Refresh icons with new icons on the Discussions - Space Forums task flow.
- Change the order of table columns in a task flow.
- Remove an entire region or component, such as the Search box from primary tab.
- Show additional attributes using Expression Language, for example customizing the People Picker task flow to show an additional user profile attribute.

After you have prepared your application for customization as described in the previous sections, open the application and make any necessary customizations.

- For examples of task flow customization, see Section 25.3.1, "Examples: Customizing Task Flows for WebCenter Portal: Spaces" and Section 25.3.2, "Examples: Customizing Task Flows for Custom Framework Applications."
- For a list of customizable task flows, see Section 25.6, "Catalog of WebCenter Portal Task Flows."
- After you have completed your customizations, deploy them as explained in Section 25.4, "Applying Task Flow Customizations to Deployed WebCenter Portal Applications."

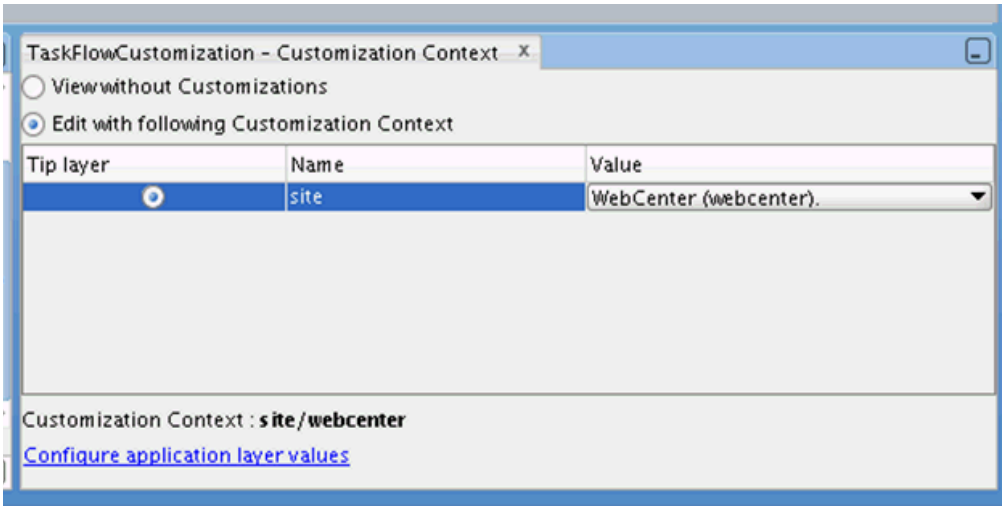
25.3.1 Examples: Customizing Task Flows for WebCenter Portal: Spaces



To customize task flows in WebCenter Portal: Spaces, open the application you created in Section 25.1.1, "WebCenter Portal: Spaces: Create a New Task Flow Customization Application" and make your customizations. The examples that follow explain two common customizations:

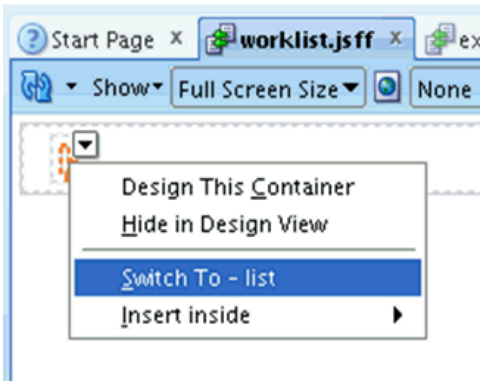
- Section 25.3.1.1, "Example: Customizing the Worklist Task Flow"
- Section 25.3.1.2, "Example: Customizing the Discussion Forums Task Flow"

25.3.1.1 Example: Customizing the Worklist Task Flow



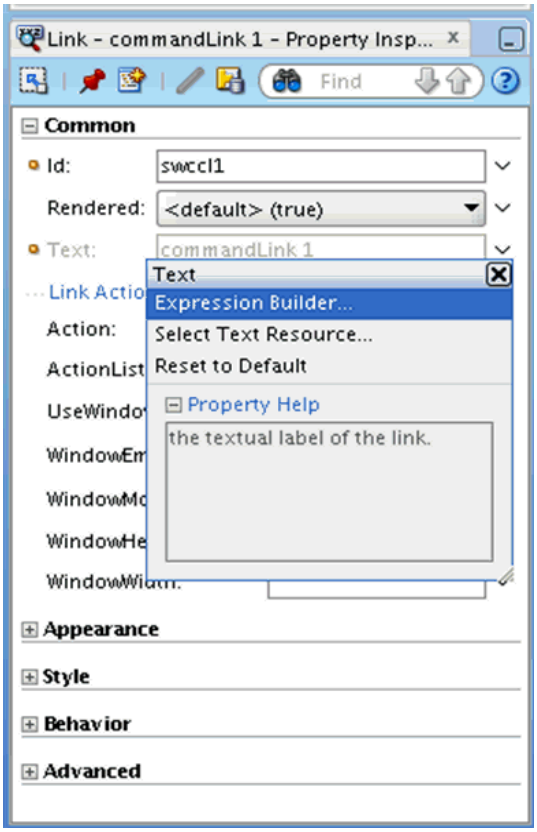
This example shows how to customize the Spaces Worklist task flow by replacing the two-row entry for each worklist item with a single row that provides a link to the worklist item details with a popup that displays the details that were previously shown on the second row. The following image shows a sample Worklist with the default two-row entry configuration.

Figure 25–5 Worklist - Before Customization



1. If you are not already using the Customization Developer role, switch to this role (choose **Tools** > **Preferences**, select **Role**, then select **Customization Developer Role** and restart JDeveloper).
2. Open your WebCenter Portal: Spaces Task Flow Customization Application.
3. In the Application Navigator, expand the **ViewController** project to view the **WebCenter Worklist Service View** library. (If you cannot see the library, right-click the ViewController project, choose Navigation Display Options in the Projects bar, and select Show Libraries.)
4. Ensure that the **Customization Context** panel is configured so that edits will be done with the WebCenter customization layer applied, as shown below.

Figure 25–6 Customization Context



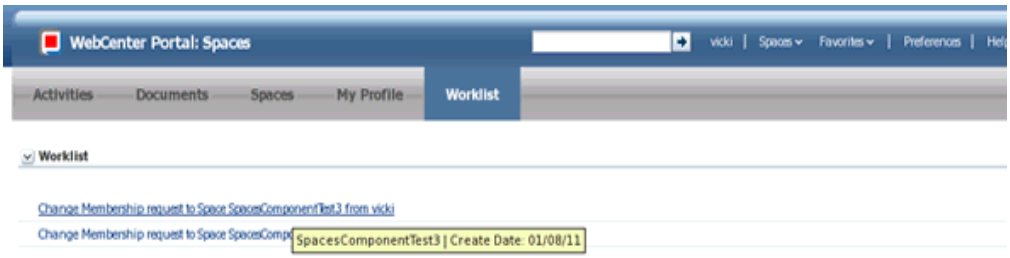
5. In the WebCenter Worklist Service View library open the **worklist.jsff** file under oracle.webcenter.worklist.view.jsf.fragments.
6. Switch to the list view facet of the view. Click the empty facet on the page and choose **Switch To - list**.

Figure 25–7 Switch To List View

7. In the Structure window, expand the structure tree to locate the `af:outputText - #{row.title}` component. Right-click the component and and choose **Insert Before af:outputText - #{row.title}** > **Link**.
8. In the Structure window, click on the newly created `af:commandLink` to open the Property Inspector dialog.
9. In the Property Inspector, click the down arrow next to the **Text** field and choose **Expression Builder**. Enter `#{row.title}` as the expression.

Figure 25–8 Property Inspector

10. Expand the Appearance section of the Property Inspector. Click the down arrow next to the **ShortDesc** field and choose **Expression Builder**. Enter `#{row.dateInfoSummary}` as the expression.
11. In the **ActionListener** field, enter `openTaskDetailsApp()`
12. Find the newly added `commandLink` and delete the following components:
    `af:outputText - #{row.title}`
    `af:panelGroupLayout`
13. The worklist.jsff.xml file that is generated (under the ADF Library Customizations node in the Application Navigator) should include code similar to the following:



Example 25–1 Updated worklist.jsff file

```
<mds:customization version="11.1.1.61.15"
                   xmlns:mds="http://xmlns.oracle.com/mds">
  <mds:insert parent="pg13" position="first
              xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
    <af:commandLink xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                text="#{row.title}" id="swccl1"
                shortDesc="#{row.dateInfoSummary}"
                actionListener="#{backingBeanScope.wlbbean.openTaskDetailsApp}"/>
  </mds:insert>
  <mds:replace node="ot2"/>
  <mds:replace node="pg14"/>
</mds:customization>
```

14. Deploy the metadata deployment profile to the WebCenter Portal: Spaces application as explained in Section 25.4, "Applying Task Flow Customizations to Deployed WebCenter Portal Applications."

The image below shows a sample Worklist after customization, with a single row and a popup.

Figure 25–9 Worklist - After Customization

25.3.1.2 Example: Customizing the Discussion Forums Task Flow

This example shows how you can customize the WebCenter Portal: Spaces Discussion Forums task flow to display a profile image for the user who initiated the discussion. The following image shows a sample Discussion Forum without the profile image.

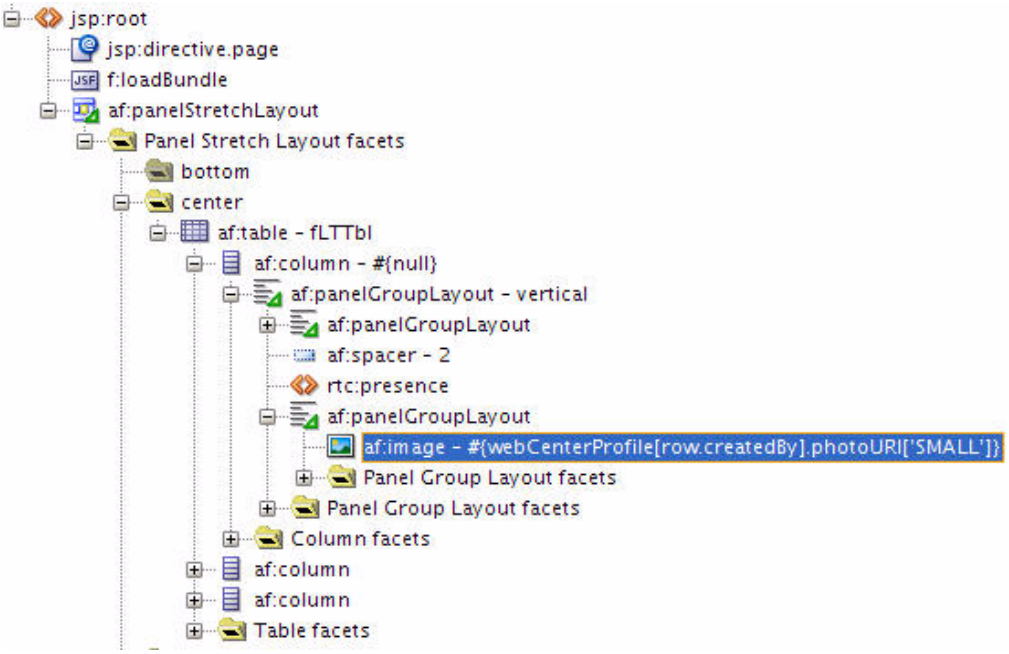


Figure 25–10 Discussion Forum - Before Customization

To customize the Discussion Forums task flow:

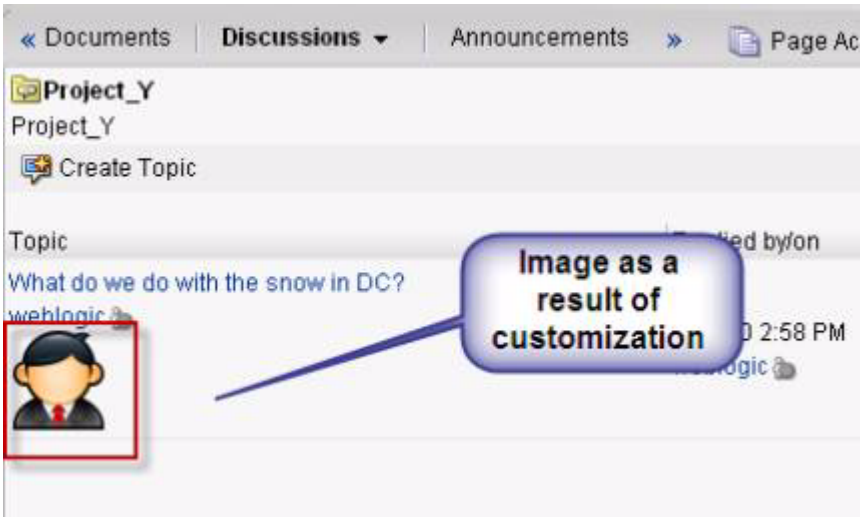
1. If you are not already using the Customization Developer role, switch to this role (choose **Tools** > **Preferences**, select **Role**, then select **Customization Developer Role** and restart JDeveloper).
2. Open your WebCenter Portal: Spaces Task Flow Customization Application.
3. In the Application Navigator, expand the **ViewController** project to view the **WebCenter Portal Discussion Services View** library. (If you cannot see the library, right-click the ViewController project, choose Navigation Display Options in the Projects bar, and select Show Libraries.)
4. In the WebCenter Portal Discussion Services View library, open the **ListTopics.jsff** file under oracle.webcenter.collab.forum.view.jsf.fragments.
5. In the Structure window, search for the `<rtc:presence>` tag on the page. This tag renders the user name.

Figure 25–11 Structure Window

6. Right-click the `rtc.:presence` tag, then choose **Insert After** > **ADF Faces** and select **Panel Group Layout** from the dialog.

7. In the Structure window, right-click the new **Panel Group Layout** and choose **Insert** > **Image Component**.
8. In the Property Inspector for the new Image component, set the Source property to `#{webCenterProfile[row.createdBy].photoURI['SMALL']}`. This EL will return the location of the image that the current user has set as their profile photo.
9. Save your files and rebuild the project.

   The ListTopics.jsff.xml file that is generated will contain the following code:



Example 25–2 Updated ListTopics.jsff.xml File

```
<mds:customization version="11.1.1.60.46" xmlns:mds="http://xmlns.oracle.com/mds">
 <mds:insert after="p1" parent="frmltpgl11"
             xmlns:af="http://xmlns.oracle.com/adf/faces/rich">
    <af:panelGroupLayout xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                    id="swcpgl1">
      <af:image xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
        source="#{webCenterProfile[row.createdBy].photoURI['SMALL']}" id="swci1"/>
    </af:panelGroupLayout>
  </mds:insert>
</mds:customization>
```

10. Deploy the metadata deployment profile to the Spaces application as explained in Section 25.4, "Applying Task Flow Customizations to Deployed WebCenter Portal Applications."

The following image shows a sample Discussion Forum after customization, with a profile image.

Figure 25–12 Discussion Forum - After Customization (With User Profile Image)

25.3.2 Examples: Customizing Task Flows for Custom Framework Applications

To customize task flows in a custom Framework application, first follow the instructions in Section 25.1.2, "WebCenter Portal: Framework Application: Enable Customization." The example that follows demonstrates a common customization.

25.3.2.1 Example: Customizing the Document Library - List View Task Flow

The example that follows shows how to customize the Document Library – List View task flow to add a new column called HTML Rendition. Before you perform these steps, ensure that you have prepared a customizable Framework application application as described in Section 25.1.2, "WebCenter Portal: Framework Application: Enable Customization.".

1. Open your custom Framework application in JDeveloper and confirm that you are using the Customization Developer role.
2. In the Resource Palette, under My Catalogs, expand the WebCenter Portal Services Catalog and open the Task Flows folder.
3. Right-click **Document Library – List View** and choose **Add to project**. If a confirmation dialog displays, click **Add Library**.
4. In the Application Navigator, expand the **ViewController** project to view the **WebCenter Document Library Services View** library. (If you cannot see the library, right-click the ViewController project, choose Navigation Display Options in the Projects bar, and select Show Libraries.)
5. In the WebCenter Portal Document Library Services View library, open the **docListViewerTableTemplate.jsff** file under oracle.webcenter.doclib.view.jsf.fragments.
6. Add a new column after `ITEM_NAME_COLUMN_HEADER`.
   a. In the Structure window, right-click the column with title `#{dlBndl.ITEM_NAME_COLUMN-HEADER}` and choose Copy and Paste to create a new ADF column component.
   b. In the Property Inspector for the new ADF column component, change the `headerText` property to "HTML Rendition".
   c. In the Structure window, expand the new column and delete the `af:image` component.
   d. Right click the `af:goLink` component inside `af:switcher -> f:facet – false` and choose **Go to property**.
   e. Change the values of the Text and Destination. For example:

```
Text=" Get Conversion (HTML)"
Destination="http://host:port/idcplg?IdcService=GET_DYNAMIC_CONVERSION
&amp;dID=#{item.dID}&amp;coreContentOnly=1#{item.portletLinkPostfix}"
```

7. Save your files.

25.4 Applying Task Flow Customizations to Deployed WebCenter Portal Applications

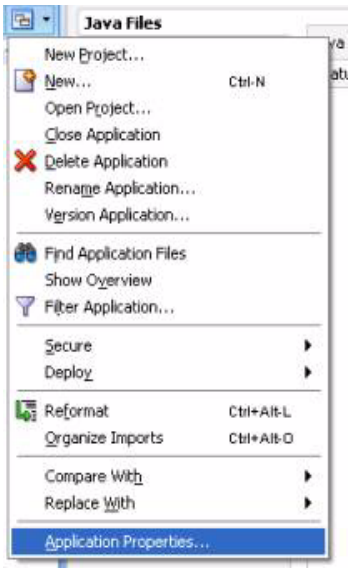
The previous sections explained how to customize WebCenter Portal task flows for different scenarios. The output of these exercises is the generated MDS customization. The customizations show up as `.xml.xml` or `.jsff.xml` files in the View project of the application under the `libraryCustomization` package. These customization documents are essentially instructions for MDS to apply changes on top of the base document that is shipped to show the customized behavior at runtime.

Once you complete a task flow customization, you must apply it to the deployed WebCenter Portal application (Framework or Spaces). To see customizations

performed on task flows in JDeveloper at runtime, you must import these customizations to the MDS repository of the deployed application.

> **Note:** This process updates the runtime WebCenter Portal application metadata repository; back up the MDS schema before performing these steps. Also, it is a best practice to test your customizations in a development or stage environment first.

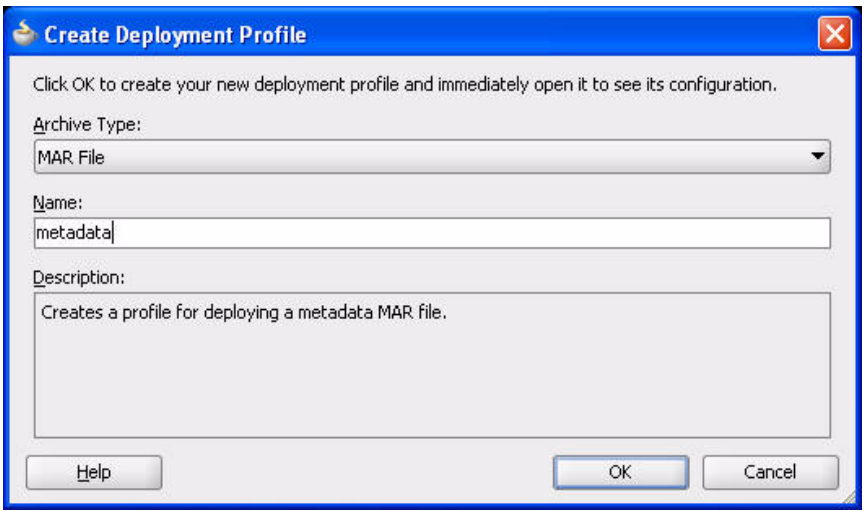
To import WebCenter Portal task flow customizations to the MDS repository, use the steps in the following sections:



- Section 25.4.1, "Creating a Metadata Deployment Profile for Custom WebCenter Portal Applications"
- Section 25.4.2, "Deploying Task Flow Customizations Directly from JDeveloper"
- Section 25.4.3, "Deploying Task Flow Customizations Using WLST"

25.4.1 Creating a Metadata Deployment Profile for Custom WebCenter Portal Applications

Use the steps that follow to create a metadata deployment profile for your custom WebCenter Portal application. (These steps are not necessary if you are using the WebCenter Portal: Spaces Task Flow Customization Application.)

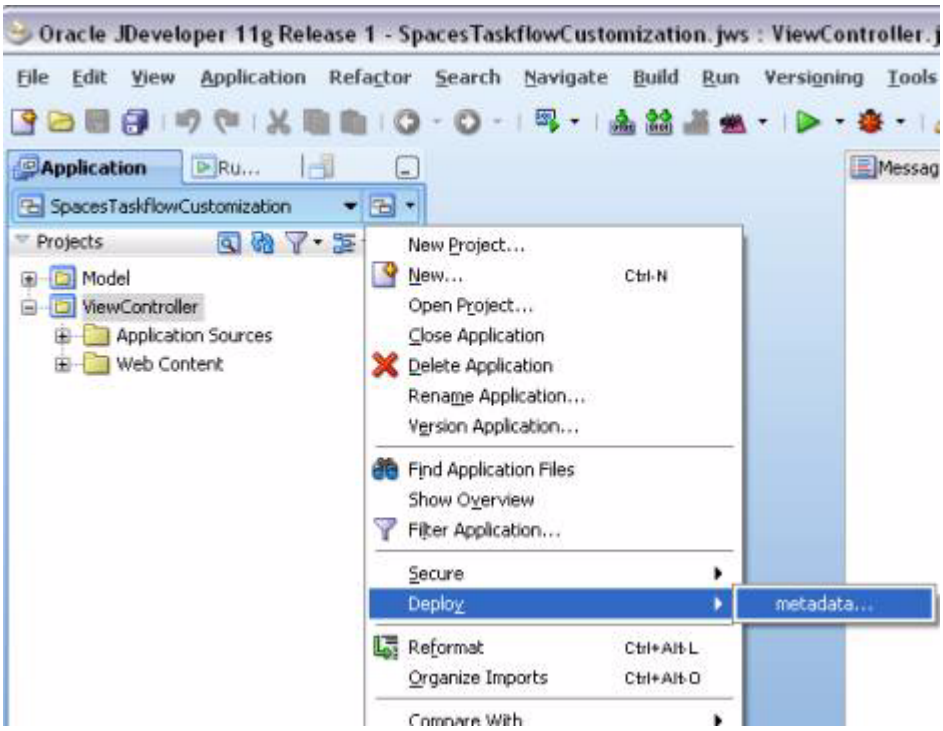


1. In the Application Navigator, from the Application Menu, choose **Application Properties**.

Figure 25–13 Application Properties

2. Choose **Deployment** and create a deployment profile by using the MAR File archive type.

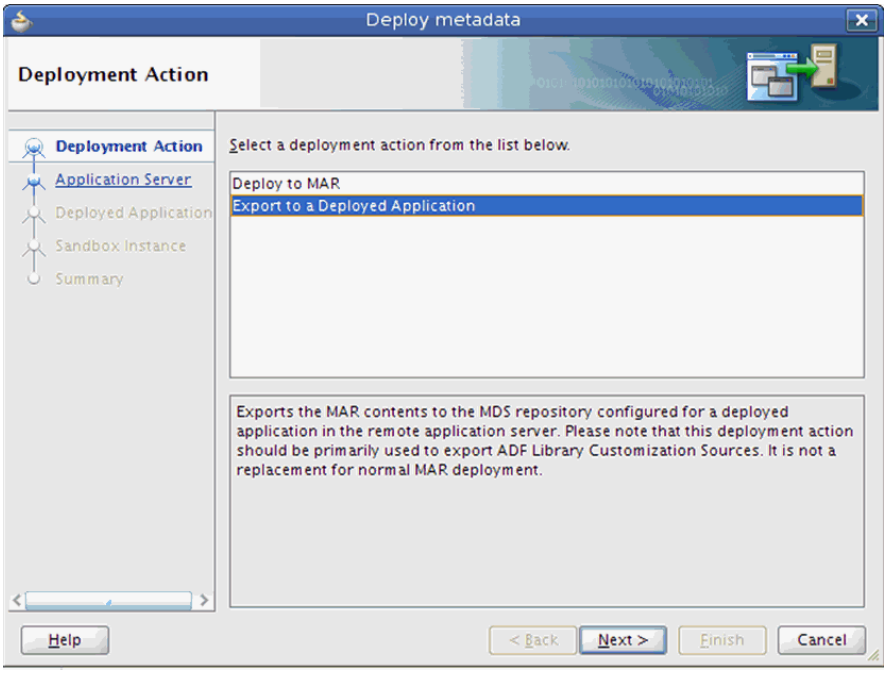
Figure 25–14 Creating a Deployment Profile



3. Click **OK** to close the Create Deployment Profile dialog.
4. Click **OK**, then click **OK** again to finish creating the Deployment Profile.

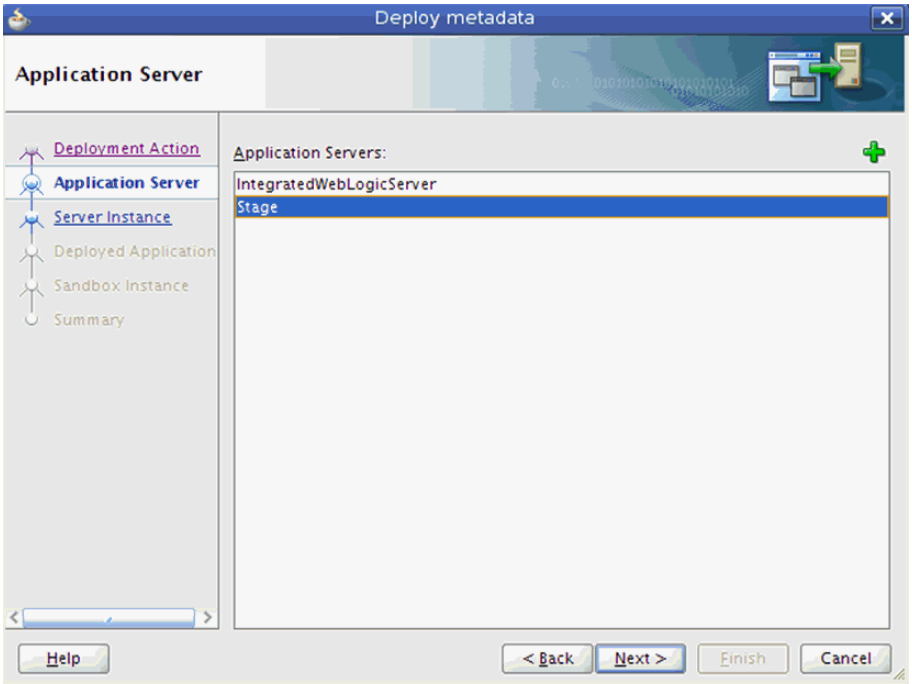
25.4.2 Deploying Task Flow Customizations Directly from JDeveloper

Use the steps that follow to deploy your task flow customizations directly from JDeveloper.



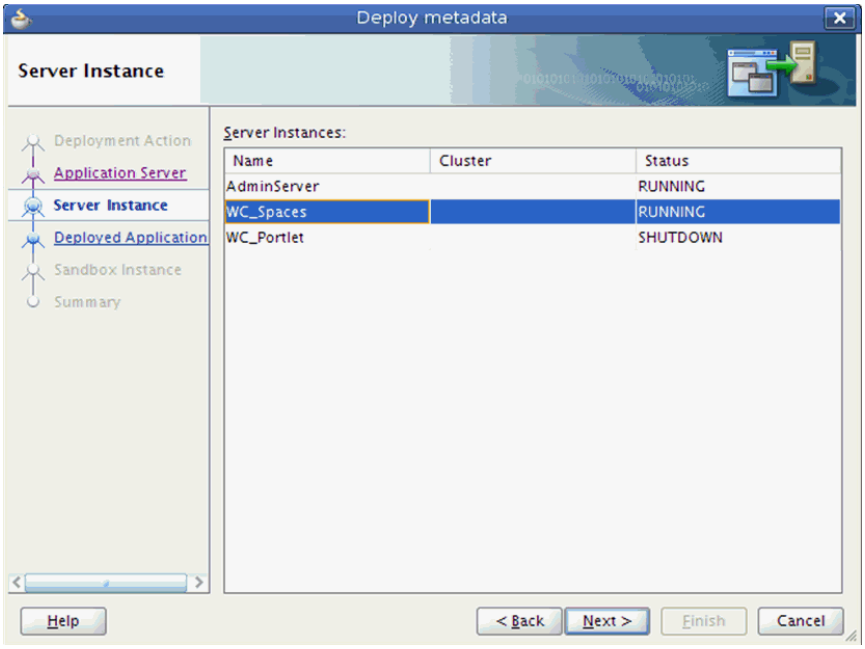
1. In the Application Navigator, from the Application Menu, choose **Deploy** > **metadata** (`metadata` is the name of the Deployment Profile).

Figure 25–15 Deploying the "metadata" Deployment Profile



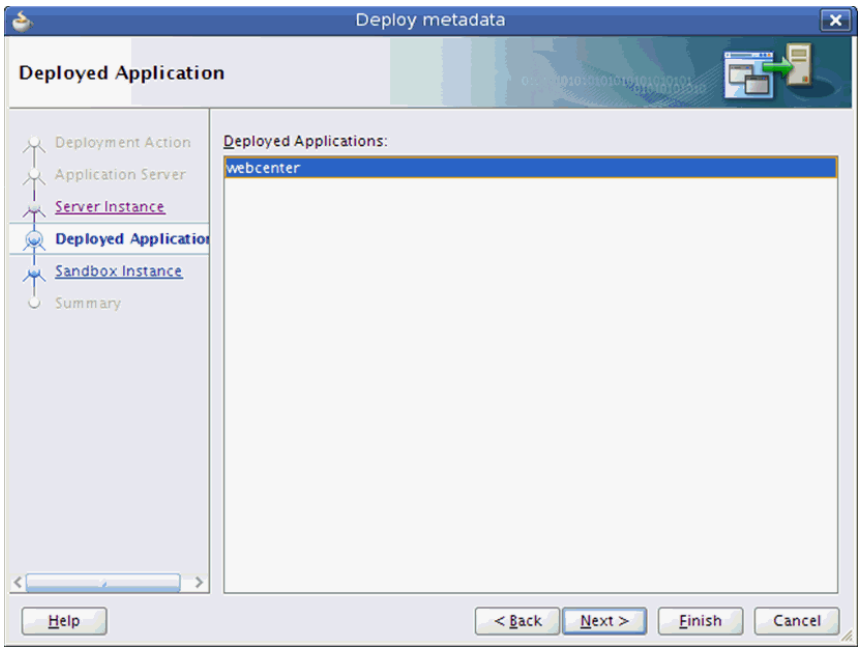
2. In the **Deploy metadata** dialog, select **Export to a Deployed Application** and click **Next**.

Figure 25–16 Deploy Metadata Dialog



3. On the **Application Server** page, select the application server connection for the instance to which you are deploying or create a new connection by clicking the "+" icon. Click **Next**.

Figure 25–17 Deploy Metadata: Application Server

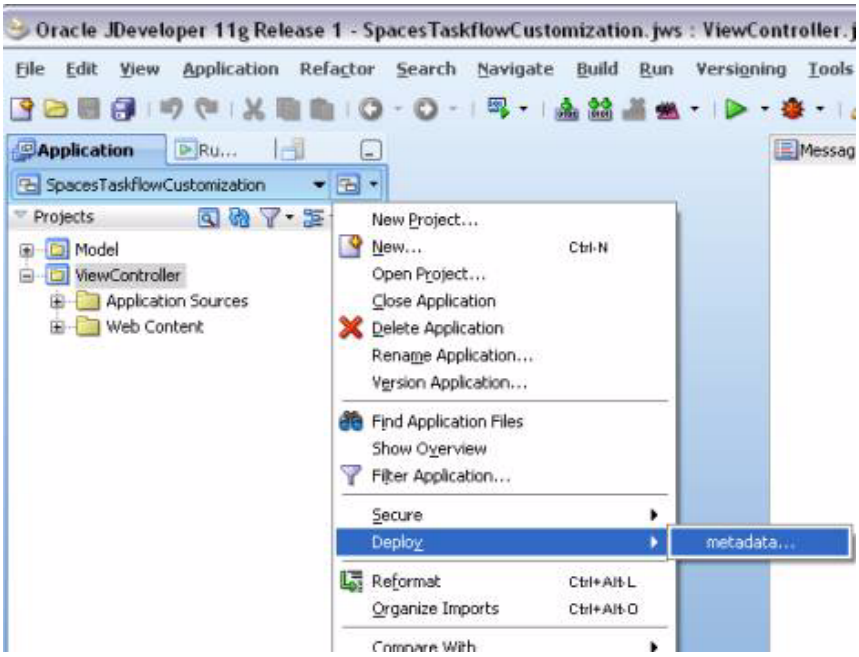


4. On the **Server Instance** page, select the server on which the application you are customizing is deployed. For a high availability installation with multiple servers hosting a single application, the customizations only need to be deployed to one server. Click **Next**.

Figure 25–18 Deploy Metadata Dialog: Server Instance

5. On the **Deployed Application** page, select the application to which the customizations should be deployed. Click **Next**.

Figure 25–19 Deploy Metadata: Deployed Applications



6. Click **Finish** to deploy the customization.

25.4.3 Deploying Task Flow Customizations Using WLST

Use the steps that follow to deploy task flow customizations using WLST.

1. In the Application Navigator, from the Application Menu, choose **Deploy** > **metadata** (`metadata` is the name of the Deployment Profile).

Figure 25–20 Deploying the "metadata" Deployment Profile

2. In the Deploy metadata dialog, choose Deploy to MAR file, then click **Finish**.

   Tip: Alternatively, you can export the metadata to a deployed application by selecting the **Export to Deployed Application** option, configuring the connection details of the server on which the application is deployed, and selecting the appropriate application.

3. JDeveloper creates the MAR file in the application directory of your *JDEV_USER* home directory. Copy this MAR file, which contains the customizations, to the directory where the application is deployed. Maintain a backup of this file so that you always have a version of the customizations for this application.
4. Use the MDS WLST import command to import the task flow customizations to the application's MDS repository.

Example 25–3 Command Line for Importing Customizations

```
wls:/weblogic/serverConfig>importMetadata(application='webcenter',
server='WC_Spaces',
fromLocation='/path/metadata.mar',
docs='/**')
```

For more information on MDS WLST commands, refer to the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference* on the Oracle Technology Network.

25.5 Removing Customizations from Deployed WebCenter Portal Applications

You can revert task flow behavior or look and feel to the original deployment by removing task flow customizations.

Use the MDS WLST `deleteMetadata` command to remove the applied customizations. The `deleteMetadata` command needs to exercise with caution as incorrect use of this command may cause the loss of metadata documents. The sample command below removes the customization created in Section 25.3.1.2, "Example: Customizing the Discussion Forums Task Flow."

Example 25–4 Command to Delete the Customization Metadata from a Deployed WebCenter Portal Application

```
deleteMetadata(application='webcenter',server='WC_Spaces',
docs='/oracle/webcenter/webcenterapp/view/taskflows/discussionServices/**',
excludeBaseDocs='true')
```

For more details on MDS WLST commands, refer to the *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference* on the Oracle Technology Network.

25.6 Catalog of WebCenter Portal Task Flows

The following task flows have been validated for view-level customizations. You can find these task flows in the libraries or JAR files and definition paths specified in Table 25–1.

Note: To customize analytics task flows, you must add the following JARs to the project:

JDEV_HOME`/webcenter/modules/oracle.webcenter.framework_11.1.1/analytics-reporting-service-view.jar`

JDEV_HOME`/webcenter/modules/oracle.webcenter.framework_11.1.1/analytics-reporting-service-model.jar`

Table 25–1 WebCenter Portal Task Flows

Description	Library/JAR Files	Definition Path
adfpage-renderer	WebCenter Portal: Framework	`oracle/webcenter/portal/framework/navigation/renderer/adfpage-renderer.xml`
Activity Stream - Mini View	WebCenter Portal Activity Streaming Service View	`oracle/webcenter/activitystreaming/controller/taskflows/activity-streaming-miniview.xml`
Activity Stream - Main View	WebCenter Portal Activity Streaming Service View	`oracle/webcenter/activitystreaming/controller/taskflows/activity-streaming-mainview.xml`
Analytics - Console	Task flows included in `analytics-reporting-service-view.jar` and `analytics-reporting-service-model.jar`	`oracle/webcenter/analytics/view/jsf/taskflows/seeded/analytics-console.xml`

Part IV

Integrating and Publishing Content

Part IV contains the following chapters:

- Chapter 26, "Introduction to Integrating and Publishing Content"
- Chapter 27, "Managing Content Repository Connections"
- Chapter 28, "Working with Content Data Controls"
- Chapter 29, "Creating Content Presenter Display Templates"
- Chapter 30, "Integrating the Documents Service"
- Chapter 31, "Adding Content Task Flows and Document Components to a Portal Page"
- Chapter 32, "Integrating Wikis and Blogs"

26

Introduction to Integrating and Publishing Content

There are several ways to integrate content into a WebCenter Portal: Framework application. The method you choose is dependent on the requirements of the application and how you want to expose content to end users.

You can integrate content into a Framework application using any of the following methods (for more information, see the references at the end of this chapter):

- **Content data controls** use JCR adapters to enable read-only access to content in a Content Server, Oracle Portal, or SharePoint content repository, and maintain tight control over the way the content displays in a Framework application.

  This functionality is available primarily for backward compatibility with prior releases, and for requirements outside the capability of Content Presenter or the Documents service and its task flows.

- **Content Management Interoperability Services (CMIS) REST APIs** surface and manage content in Content Server.

- **Content Presenter** enables you to precisely customize the selection and presentation of content in a Framework application. The Content Presenter task flow is available only when the connected content repository is Content Server and your WebCenter Portal administrator has completed the prerequisite configuration. With Content Presenter, you can select a single item of content, contents under a folder, a list of items, query for content, or select content based on the results of a Personalization Conductor scenario, and then select a template to render the content on a page in a Framework application. Content Presenter has no dependency on the Documents service for adding or managing the content it displays.

- **Documents service** task flows and components offer a variety of formats to display folders and files, including wikis and blogs, on a page in a Framework application. You can choose the task flows appropriate for your application to provide features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in in Content Server, Oracle Portal, or SharePoint content repositories.

> **Note:** The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 3.6, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

Using Documents service task flows and document components (such as links, previews, and images), you can add content to the application, and also provide end users with content and Documents service task flows built into the application to manage, display, and search documents at runtime.

Table 26–1 provides a comparative overview of these methods to help you select the most appropriate method for your needs.

Table 26–1 Methods of Integrating Content into a Framework Application

	Content Data Controls	Content Management REST APIs	Content Presenter	Documents Service
Repository	Content Server Oracle Portal SharePoint	Content Server	Content Server	Content Server Oracle Portal SharePoint
Content Types	Folders and content files.	Folders and content files with support for metadata properties.	Folders and content files with support for metadata properties. Supports Oracle Site Studio region definitions-based content.	Folders and content files. Content Server only: supports folder and content file metadata properties.
Content Display	Surface content using ADF render components: ADF Go Link, ADF Go Button, ADF Image, and ADF inline frame functions.	Surface content using REST APIs and custom client or server side application code. Surface content through single item selection, by folder, and by query results.	Task flow-based component intended primarily for rendering content. Surface content through single item selection, by folder, and by query results. Surface content in display templates: either built-in templates or custom display templates developed in JDeveloper. Reuse Oracle Site Studio display templates for Site Studio content. Supports WebCenter Personalization Services Conductor scenario (query results).	Task flow-based components intended primarily for collaborating and managing content. Content Server only: ■ Document preview ■ View links ■ View images ■ View file information (properties, version history) ■ View metadata

Table 26–1 (Cont.) Methods of Integrating Content into a Framework Application

	Content Data Controls	Content Management REST APIs	Content Presenter	Documents Service
Content Management	None.	Manage content using REST APIs and custom client or server side application code. Create, update, delete folders and content files and associated metadata fields.	In-context contribution editing for HTML and Site Studio content.	Manage content through graphical user interface. Create, update, delete folders and content files. Content Server only: ▪ Manage associated metadata properties ▪ Item-level security ▪ Oracle Workflow (WebCenter Portal: Spaces only) ▪ View metadata
Benefits	Standard JCR API integrates with many different content repositories.	Flexible REST-based APIs useful for client-side style development.	Flexible display using display templates. Oracle Site Studio support.	Choice of task flows to provide easy UI access to managing content.
Limitations	Read-only content. No Oracle Site Studio support.	Content must reside in Oracle Content Server repository. No Oracle Site Studio support.	Content must reside in Content Server repository.	No Oracle Site Studio support.

The following chapters provide information that you will need for *any* method you use:

- "Managing Content Repositories" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* to configure and manage content repositories used by WebCenter Portal applications.
- Chapter 27, "Managing Content Repository Connections" to configure and edit content repository connections that provide access to decentralized content.

The following chapter provides information about using *content data controls*:

- Chapter 28, "Working with Content Data Controls" to use Java Content Repository (JCR) data controls to enable read-only access to any content repository.

The following manual provides information about using *CMIS (Content Management Interoperability Services) REST APIs*:

- *Oracle Fusion Middleware Content Management REST Service Developer's Guide*

The following chapters provide information about using *Content Presenter*:

- Chapter 29, "Creating Content Presenter Display Templates"
- Chapter 31, "Adding Content Task Flows and Document Components to a Portal Page"

- "Publishing Content Using Content Presenter" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* to work with content at runtime in WebCenter Portal applications.

The following chapters provide information about using the *Documents service*, which includes the Documents service task flows, document components (links, inline frames, and images), wikis, and blogs:

- Chapter 30, "Integrating the Documents Service"
- Chapter 31, "Adding Content Task Flows and Document Components to a Portal Page"
- Chapter 32, "Integrating Wikis and Blogs"
- "Working with the Documents Service Task Flows and Document Components" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* to work with content at runtime in WebCenter Portal applications.

27

Managing Content Repository Connections

There are several ways to integrate content into a WebCenter Portal: Framework application. For more information, see Chapter 26, "Introduction to Integrating and Publishing Content."

This chapter discusses how to configure connections to content repositories to provide access to the content, and how to add content to pages in a Framework application.

This chapter includes the following sections:

- Section 27.1, "Overview of Content Adapters"
- Section 27.2, "Configuring Content Repository Connections"
- Section 27.3, "Editing Content Repository Connections"
- Section 27.4, "Using an Existing Repository Connection for a New WebCenter Portal: Framework Application"

27.1 Overview of Content Adapters

In your Framework application, you can use the following adapters:

- Oracle WebCenter Content: Content Server: The Content Server adapter is used to integrate content from an automated information system managed by Content Server. This system enables sharing, managing, and distributing of business information through a Web site as a common access point.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

- Oracle Portal: The Oracle Portal adapter is used to integrate content from a content repository located in the Oracle Portal schema.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

- Oracle WebCenter Adapter for SharePoint: This adapter is used to integrate content from the Microsoft SharePoint 2007 repository.

  You must install this adapter, as described in Section 3.6, "Installing the Oracle WebCenter Adapter for SharePoint."

- File System: The File System adapter is used to add content located on your operating system's file system to JSF pages.

  This adapter is bundled with Oracle WebCenter Portal extension bundle, so it is integrated by default.

Note: The File System adapter is intended to be used in the development environment only.

27.2 Configuring Content Repository Connections

Content repository connections are required to access the repository content to be published on JSF pages. These connections are also required to access the repository content through the WebCenter Portal REST API.

This section describes how to configure content repository connections based on Oracle WebCenter Content: Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file system adapters. Content Presenter can connect to and retrieve content available in Content Server content repositories. With JCR data controls, you can connect to Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file systems.

Connections can be created under Application Resources in the Application Navigator and under IDE Connections in the Resource Palette.

This section includes the following subsections:

- Section 27.2.1, "How to Create a Content Repository Connection Based on the Oracle Content Server Adapter"
- Section 27.2.2, "How to Create a Content Repository Connection Based on the Oracle Portal Adapter"
- Section 27.2.3, "How to Create a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint"
- Section 27.2.4, "How to Create a Content Repository Connection Based on the File System Adapter"
- Section 27.2.5, "What Happens When You Create a Repository Connection"
- Section 27.2.6, "What You May Need to Know When Creating a Repository Connection"

27.2.1 How to Create a Content Repository Connection Based on the Oracle Content Server Adapter

This section describes how to configure a Content Server-based content repository connection. To successfully perform the subsequent steps, you must use Content Server release 11.1.1.4.0 or 10.1.3.5.1. The release 11.1.1.4.0 or 10.1.3.5.1 are required for Content Presenter. For information about how to configure Content Server for Oracle WebCenter Portal, see "Oracle WebCenter Content: Content Server Prerequisites" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

For an overview of the prerequisites and tasks required to get Content Server working in WebCenter Portal applications (Spaces and Framework applications), see the section "Configuration Roadmap for Content Server" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To create a Content Server-based repository connection:

1. In Oracle JDeveloper, open your Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection**, then **Content Repository**.

3. In the Create Content Repository Connection dialog, specify a connection name for the connection; for example, `MyOCSConnection`.

   Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **Oracle Content Server** from the **Repository Type** box.

5. Select **Set as primary connection for Documents service**, to make this connection the primary (default) connection for all content management operations through the Documents service or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a Documents service task flow, that value overrides this setting.

   Note: To be able to set a connection as primary (default) connection for the Documents service, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Under **Configuration Parameters**, enter values for the parameters, as shown in Table 27–1 and Figure 27–1.

Table 27–1 Configuration Parameters for Content Server

Configuration Parameters	Values
RIDC Socket Type	Determines whether the client library connects on the Content Server listener port or the Web server filter. It accepts `socket`, `socketssl`, `web`, or `jaxws`. `socket`: Uses an `intradoc` socket connection to connect to the Content Server. The client IP address must be added to the list of authorized addresses in the Content Server. This corresponds to the `SocketHostAddressSecurityFilter` setting in the Content Server configuration file. `socketssl`: Uses an `intradoc` socket connection to connect to the Content Server that is secured using the SSL protocol. The client's certificates must be imported in the server's trust store for the connection to be allowed. `web`: Uses an HTTP(S) connection to connect to the Content Server. `JAX-WS` - Uses an HTTP(S) connection to connect to Content Server. Table 27–2 includes more information on the configuration parameters required for each RIDC socket type.
Server Host Name	Host name of the system where the Content Server is running. For example: `mycontentserver.mycompany.com`.
Content Server Listener Port	Port of the server specified in the **Server Host Name** field. This corresponds to the `IntradocServerPort` setting in the Content Server configuration file, which defaults to port `4444`.

Table 27–1 (Cont.) Configuration Parameters for Content Server

Configuration Parameters	Values
URL of the Web Server Plugin	If the RIDC socket type is `web`, then the URL must be: For Content Server release 11.1.1.4.0: `http://host_name:port_number/_dav/web_root/plugin_root`. For example: `http://mycontentserver:4444/_dav/cms/idcplg` For Content Server release 10.1.3.5: `http://host_name:port_number/web_root/plugin_root`. For example: `http://mycontentserver:4444/cs/idcplg`
Web Server Context Root	The Web server context root for Content Server to integrate advanced metadata and Site Studio capabilities in the Framework application. The format of the Web server context root is `/context_root`. For example, `/cs`.
Admin Username	The user name with administrative rights for the Content Server instance. It defaults to `sysadmin`.
Admin Password	The password for the Content Server admin user. For example: `password`. This is needed for `web` connection only.
KeyStore File Location	Location of key store that contains the private key used to sign the security assertions. The key store location must be an absolute path. For example: `c:\keys\keystore.xyz`.
KeyStore Password	The password required to access the keystore.
Private Key Alias	The client private key alias in the keystore. The key is used to sign messages to the server. The public key corresponding to this private key must be imported in the server keystore.
Private Key Password	The client private key password required to retrieve the key from the keystore.
JAX-WS Client Security Policy	Enter the client security policy to be used when the **RIDC Socket Type** is **JAX-WS**. The JAX-WS client security policy can be any valid OWSM policy, but must match the security policy configured for the Content Server's Native Web Services IdcWebLogin service. For more information about the IdcWebLogin service, see "WebCenter Content Web Services" in the *Oracle WebCenter Content Developer's Guide for Content Server*. For information about predefined security policies, see the section "Security Policies" in *Oracle Application Server Web Services Security Guide*. For information about configuring a security policy on client side, see the section "Configuring Clients" in *Oracle WebCenter Content Developer's Guide for Content Server*. For information about configuring a security policy on the server side, see the section "Configuring WS-Security through WS-Policy" in *Oracle WebCenter Content Developer's Guide for Content Server*.
Cache Invalidation Interval	The interval (in minutes) used by WebCenter caches to automatically detect external Content Server content changes. This allows WebCenter to automatically clear cached items when changes to those items are made directly in the Content Server UI. The interval is in minutes. A value of `0` disables cache invalidation. The minimum valid value to enable cache invalidation is `2`.

Table 27–1 (Cont.) Configuration Parameters for Content Server

Configuration Parameters	Values
Binary Cache Maximum Entry Size	The maximum size (in bytes) for WebCenter caching of Content Server binary documents. Documents larger than this size are not cached by WebCenter. The unit is bytes and defaults to `102400` (`100 Kb`).

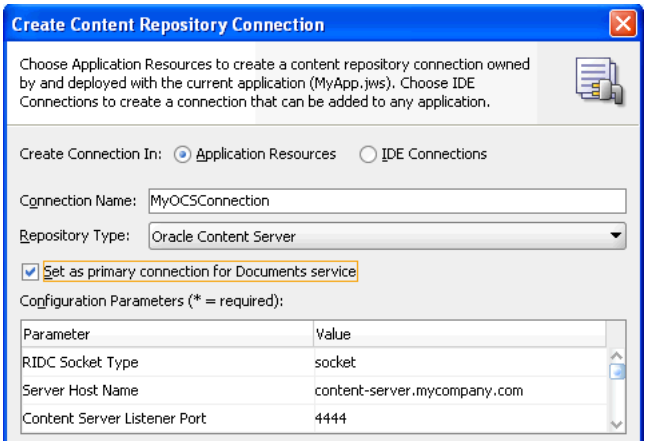

Table 27–2 Content Server Connection Parameters for Each RIDC Socket Type

Connection Parameters	RIDC Socket Type: web	RIDC Socket Type: socket	RIDC Socket Type: socketssl	RIDC Socket Type: jaxws
Server Host Name	Not Applicable	Mandatory for Content Presenter Defaults to local host.	Mandatory for Content Presenter Defaults to local host.	Not Applicable
Content Server Listener Port	Not Applicable	Port specified for the incoming provider in the server. Defaults to `4444`.	Port specified for the `sslincoming` provider in the server. Defaults to `4444`.	Not Applicable
URL of the Web Server Plugin	Mandatory	Not Applicable	Not Applicable	Mandatory Use format: `http://`*`hostname:port`*`/web_root` For example: http(s)://*`myhost.com:9044`*`/idcnativews`
Web Server Context Root	Optional	Optional	Optional	Optional
JAX-WS Client Security Policy	Not Applicable	Not Applicable	Not Applicable	Mandatory, unless Global Policy Attachment is used, in which case it should be left empty. This is the name of an OWSM client security policy. This policy must match the corresponding server side policy applied on the Content Server. For information about security policies, see the section "Security Policies" in *Oracle Application Server Web Services Security Guide*.

Table 27–2 (Cont.) Content Server Connection Parameters for Each RIDC Socket Type

Connection Parameters	RIDC Socket Type: web	RIDC Socket Type: socket	RIDC Socket Type: socketssl	RIDC Socket Type: jaxws
Admin Username	Mandatory	Optional Defaults to `sysadmin`	Optional Defaults to `sysadmin`	Optional Defaults to `weblogic`
Admin Password	Mandatory	Not Applicable	Not Applicable	Whether the password is used or not depends on the selected JAX-WS security policy.
Key Store and Private Key	Not Applicable	Not Applicable	Mandatory	Not Applicable
Identity Propagation	Not supported at runtime	Supported For testing purpose, connects as guest if no/invalid user name is specified.	Supported For testing purpose, connects as guest if no/invalid user name is specified.	Supported, provided that the JAX-WS security policy supports identity propagation.
External Application	Mandatory	Supported Password is not used.	Supported Password is not used.	Supported Whether the password is used or not depends on the selected JAX-WS security policy.
User Name and Password	Supported	Supported The password is not verified during the test connection operation.	Supported The password is not verified during the test connection operation.	Supported Whether the password is used or not depends on the selected JAX-WS security policy.

Figure 27–1 Content Repository Connection - Content Server

7. In the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. If the network connection or the content repository

server to which you are trying to connect is slow, then consider overriding the default value specified in this field.

8. Select the applicable authentication method. See Section 27.2.6.1, "What You Should Know About Using Identity Propagation and External Application Authentication Methods" for information. If you select the Identity Propagation authentication method, then you must configure secure socket layer (SSL) in Content Server. For information, see the section "Oracle WebCenter Content: Content Server - Security Considerations" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

9. **User Name** and **Password** fields under the **Specify login credentials for the current JDeveloper session** checkbox are optional for the Identity Propagation authentication method. In a secured application when Identity Propagation is the chosen authentication method, selecting the Specify login credentials for the current JDeveloper session checkbox lets you navigate to the authenticated content repository connection at design time. When this checkbox is selected, you can also validate if user name and password you specified can be authenticated.

   Note: If the **Specify login credentials for the current JDeveloper session** checkbox is selected, then the credentials you entered are used. If the checkbox is not selected, then the connection is tested using External Application credentials (if they exist), otherwise null credentials are used.

   If you have selected **External Application** for authentication and also specified either public or shared credentials, then you can leave these fields blank, as the public or shared credentials can be used to login at design time. However, if you have selected **External Application** but have not specified public or shared credentials, then you must specify user name and password here.

10. Click **Test**.

    During testing user name and password are used (if specified). If they are not specified, but an external application is defined with either shared or public credentials, then this is used. Otherwise the guest user is used.

11. Click **OK**.

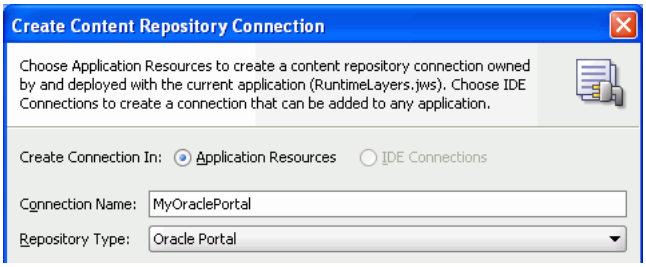
12. In the Application Resources panel, expand the repository connection you just created. The Connection Credentials dialog displays.

    Note: The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an External Application service that uses public or shared credentials.

13. Enter the **User Name** and **Password** for the Content Server connection and click **OK**. The connection displays under the Application Resources panel.

27.2.2 How to Create a Content Repository Connection Based on the Oracle Portal Adapter

This section describes how to create a content repository connection based on the Oracle Portal adapter. Before creating a repository connection, see Section 27.2.6, "What You May Need to Know When Creating a Repository Connection". You can use this connection to configure a content data control that will enable you to add content from the Oracle Portal repository to JSF pages.



To create an Oracle Portal repository connection:

1. In Oracle JDeveloper, open your Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection** and then **Content Repository**.
3. In the Create Content Repository Connection dialog, specify a name for the connection; for example, `MyOraclePortal`.

   Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **Oracle Portal** from the **Repository Type** box, as shown in Figure 27–2.

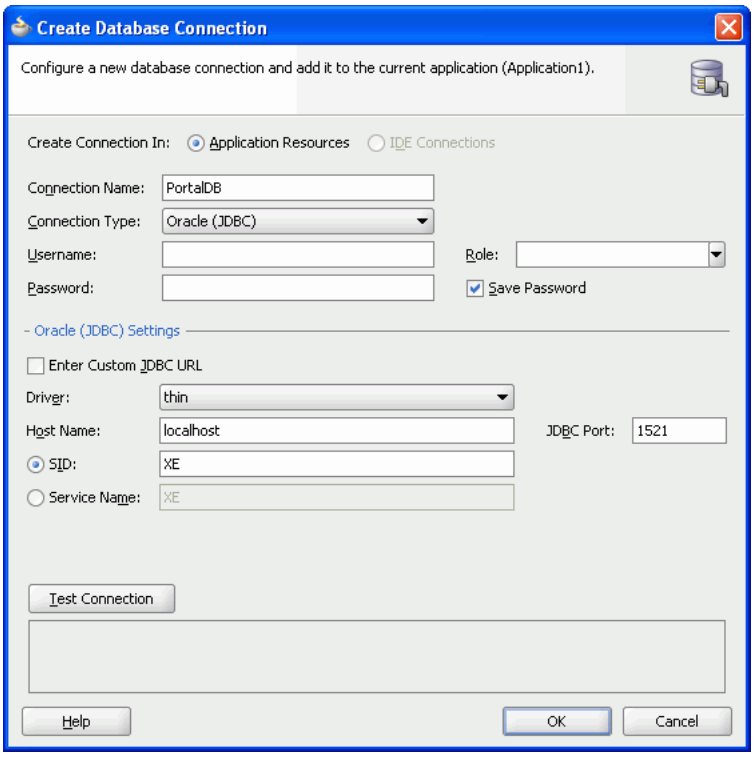
Figure 27–2 Content Repository Connection - Oracle Portal

5. Select **Set as primary connection for Documents service** to make this connection the primary (default) connection for all content management operations through the Documents service or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a Documents service task flow, that value overrides this setting.

   Note: To be able to set a connection as primary (default) connection for the Documents service, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Select a connection from the **Database Connection** list, or create a new connection to the Oracle Portal schema:
   a. In the Create Database Connection wizard, specify the connection name and type.
   b. Enter the database user name and password of the Oracle Portal schema. By default, the user is PORTAL.

c. Under **Oracle (JDBC) Settings**, if you intend to specify a custom JDBC URL, then select the **Enter Custom JDBC URL** checkbox, and specify the database URL of the Portal schema in the `jdbc` format:



```
jdbc:oracle:thin:@dbhost:dbport:dbsid
```

d. If you did not perform the above step, then select a driver, enter the host name, JDBC port, SID, and service name, as shown Table 27–3 and Figure 27–3.

Table 27–3 Parameters for Creating Oracle Portal-based Content Data Control

Parameters	Description
Driver	There are two types of drivers: thin and oci8. The thin driver can be used to connect to Oracle Database release 8*i* or later databases with TCP/IP network protocols. This driver is included in the default Oracle JDBC library for all projects. The oci8 driver is used when creating a Java application that runs against an Oracle Application Server. This is a thick driver optimized for the Oracle Database. It is a mix of Java and native code. This driver handles any database protocol (TCP, IPX, BEQ, and so on). It is recommended for applications that are run from the computer on which they are stored.
Host Name	Name of the Oracle Database. Use an IP address or a host name that can be resolved by TCP/IP; for example, `myserver`. The default value is `localhost`.
JDBC Port	Value to identify the TCP/IP port.
SID	Unique system identifier of an Oracle database instance.
Service Name	The service name for an Oracle database instance.

Figure 27–3 Create Database Connection

e. Click **OK**.

7. In the Create Content Repository Connection dialog, in the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. If the network connection or the content repository server to which you are trying to connect is slow, then consider overriding the default value specified in this field.

8. Select the applicable authentication method. See Section 27.2.6.1, "What You Should Know About Using Identity Propagation and External Application Authentication Methods" for information.

9. Select the **Specify login credentials for current JDeveloper session** checkbox and enter the Oracle Portal single sign-on user name and password for logging in to your portal instance. The Oracle Portal single sign-on user name and password entered here are used to test the connection and are functional only at design time. Then click **OK**.

Note: If the **Specify login credentials for current JDeveloper session** checkbox is selected, then the credentials you entered are used. If the checkbox is not selected, then the connection is tested using External Application credentials (if they exist), otherwise null credentials are used.

If you have selected **External Application** for authentication and also specified either public or shared credentials, then you can leave these fields blank, as the public or shared credentials can be used to login at design time. If you specified both public and shared credentials for the external application, then the public credentials have higher precedence. However, if you have selected **External Application** but have not specified public or shared credentials, then you must specify user name and password here.

10. In the Application Resources panel, expand the repository connection you just created. The Connection Credentials dialog displays.

Note: The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an External Application service that uses public or shared credentials.

11. Enter the user name and password for Oracle Portal connection and click **OK**. The connection displays under the Application Resources panel.

See Also: To create a data control using this connection, perform the procedure described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".

27.2.3 How to Create a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint

The Oracle WebCenter Adapter for SharePoint extracts and searches content within a Microsoft SharePoint 2007 repository. The adapter accesses the repository using the Microsoft SharePoint SOAP interfaces. Oracle recommends that you study Section 27.2.6.3, "What You Should Know About Oracle WebCenter Adapter for SharePoint." before configuring and using Oracle WebCenter Adapter for SharePoint.

This section includes the following subsections:

- Section 27.2.3.1, "Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint"
- Section 27.2.3.2, "Mapping Microsoft SharePoint Content and Services"

27.2.3.1 Creating a Content Repository Connection Based on the Oracle WebCenter Adapter for SharePoint

To create a repository connection based on Oracle WebCenter Adapter for SharePoint:

1. In Oracle JDeveloper, open your Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection**, then **Content Repository**.

3. In the Create Content Repository Connection dialog, specify a connection name for the connection; for example, `MySPConnection`.

   Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **JCR SharePoint Adapter** from the **Repository Type** box.

   Note: This option displays only if the extension for Oracle WebCenter Adapter for SharePoint is installed.

5. Select **Set as primary connection for Documents service**, if you intend to make it the default connection for the Documents service. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection for the Documents service. If a Document Library task flow is used without any `connectionName` input parameter, then this connection is used. For information about the Documents service, see Chapter 30, "Integrating the Documents Service."

   Note: To be able to set a connection as primary connection for the Documents service, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Under **Configuration Parameters**, enter the **SharePoint URL** which is the web address of the SharePoint site to which you want to connect. For example, `http://mysharepoint.mycompany.com`, as shown in Figure 27–4.

Figure 27–4 Content Repository Connection - Oracle WebCenter Adapter for SharePoint

7. Enter an integer value representing the number of characters for the LIKE limit. If no value is set, the LIKE limit defaults to `64` characters as the limit for search pattern strings that are passed to the Microsoft SharePoint Server. If the value is set to zero, then the full string is passed to the server. That is, the LIKE limit is disabled. This parameter is optional. Oracle recommends that it be left to its

default state. For related information, see Section 27.2.6.3, "What You Should Know About Oracle WebCenter Adapter for SharePoint."

8. In the **Login Timeout (ms)** field, specify the time in milliseconds. This timeout determines how long the application must wait when trying to establish a session with the content repository. Oracle recommends that there is a fast network connection between the deployed application and the Microsoft SharePoint repository. If the network connection or the content repository server to which you are trying to connect is slow, then consider overriding the default value specified in this field.
9. Select the **External Application** authentication method. For information about this authentication method, see Section 27.2.6.1, "What You Should Know About Using Identity Propagation and External Application Authentication Methods."

> **Note:** Oracle WebCenter adapter for Microsoft SharePoint does not support the **Identity Propagation** authentication method. Therefore, the **External Application** authentication method lets you use a single shared set of credentials for all users when accessing the repository. You can also configure this option to enable each user to enter their own login credentials when accessing the repository the first time by omitting both the Shared and Public credentials in the External Application configuration. The system then reuses each unique credential on subsequent access requests.

10. Select the **Specify login credentials for the current JDeveloper session** checkbox and specify **User Name** and **Password**. This step is optional, and only required if you want to override the **External Application** authentication credentials created in the previous step. Moreover, this override only applies to the JDeveloper design time.
11. Click **OK**.
12. Optionally, to test the connection, expand the repository connection you just created, in the Application Resources panel. The Connection Credentials dialog displays.

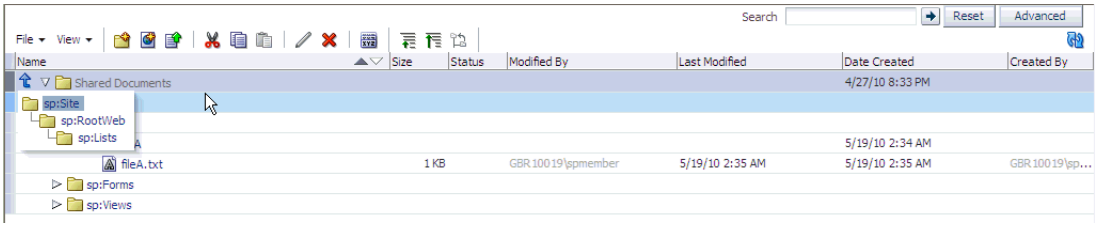
> **Note:** The Connection Credentials dialog displays if you do not save the credentials, that is, you do not select the **Specify login credentials for the current JDeveloper session** checkbox, or if you do not specify an External Application service that uses public or shared credentials.

13. Enter the **User Name** and **Password** for this connection and click **OK**. The connection displays under the Application Resources panel.

    This step is optional.

27.2.3.2 Mapping Microsoft SharePoint Content and Services

The Oracle WebCenter Adapter for SharePoint is designed to map the content managed in SharePoint servers, such as sites, lists, list items, metadata, documents, as well as content services delivered by Microsoft SharePoint, such as search and security.



The adapter maps content and content services that are relevant to the JCR standard. In other words, the adapter does not map the Microsoft SharePoint graphical user interface (GUI) and the application-level functions that are not part of the JCR

standard. For example, the adapter does not map the GUI application logic of the Microsoft SharePoint server (not covered by JCR), but it provides GUI-relevant metadata so that JCR or Java applications can restore some of the GUI logic such as SharePoint lists, if that is the goal of the application.

Default JCR Location of the Microsoft SharePoint Documents Libraries

For a SharePoint Services v3 Team Site, the Shared Documents Library appears at path: `/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files`, as shown in Figure 27–5.

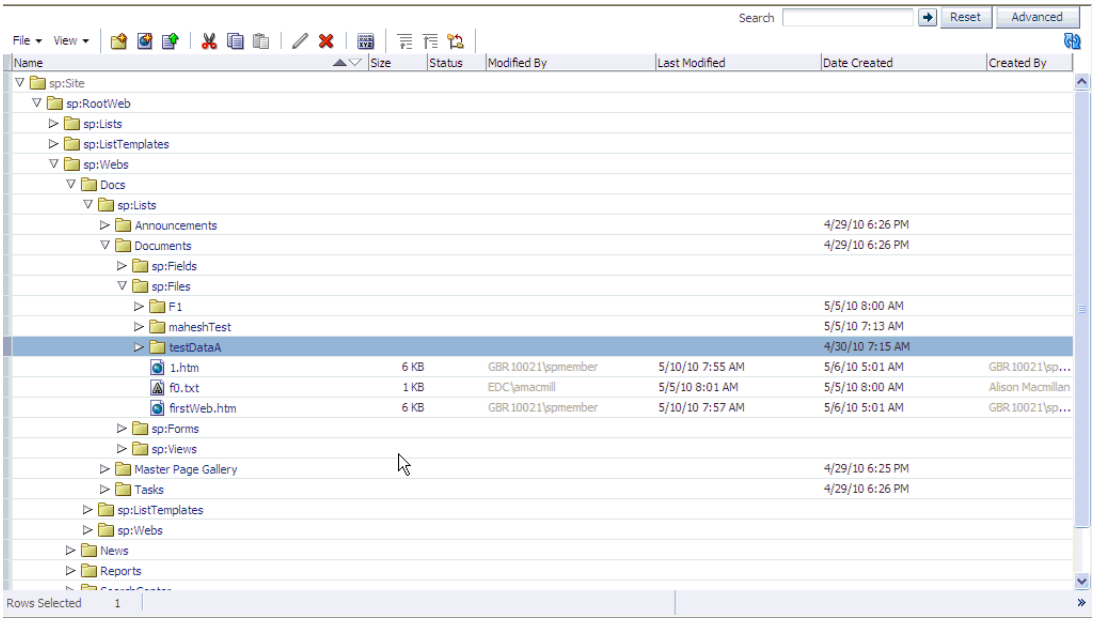


Figure 27–5 The Shared Documents Library Path for a SharePoint Services v3 Team Site

For the MOSS 2007 site created during installation, the Documents Center Document Library appears at path: `/sp:Site/sp:RootWeb/sp:Webs/Docs/sp:Lists/Documents/sp:Files`, as shown in Figure 27–6. This path reflects the structure where the Documents Center is a subsite in the SharePoint main site.

Files are JCR nodes of primary type `nt:file`, and of mix-in type `sp:File`. Folders are JCR nodes of primary type `nt:folder` and of mix-in type `sp:Folder`. The `sp:` mix-ins are similar to `nt:unstructured` in their definitions.

Figure 27–6 The Documents Center Document Library Path for MOSS 2007 Site

27.2.4 How to Create a Content Repository Connection Based on the File System Adapter

This section describes the procedure to create a content repository connection based on the file system adapter. The File System adapter is intended to be used in the development environment only.

To create a File System repository connection:

1. In Oracle JDeveloper, open your Framework application.
2. In the Application Resources panel, right-click **Connections** and choose **New Connection** and then **Content Repository**.
3. In the Create Content Repository Connection dialog, enter a name for the connection; for example, `MyConnection`.

   Tip: You can choose between creating application-specific connections in the Application Resources panel and creating common connections in the Resource Palette (IDE Connections).

4. Select **File System** from the **Repository Type** box.
5. Select **Set as primary connection for Documents service** to make this connection the primary (default) connection for all content management operations through the Documents service or Content Presenter. Selecting this option writes a configuration to the `adf-config.xml` file that identifies this connection as the default connection. If `connectionName` parameter is specified for a Documents service task flow, that value overrides this setting.

   Note: To be able to set a connection as primary (default) connection for the Documents service, you must select the **Application Resources** option in **Create Connection In**. This is because connections created as IDE connections cannot be used directly, they must be added to applications.

6. Under **Configuration Parameters**, select the **Base Path** row, and enter the path to the folder in which your content is placed, for example, `C:\MyContent`.

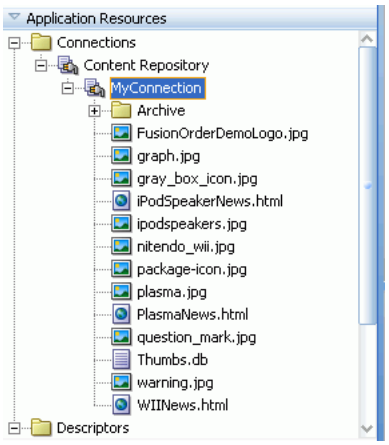
   Note: The following must be considered while creating a file system connection:

   - The base path value is used as the root (`"/"`) for the file system-based data control in Section 28.5, "Integrating Content Using Content Data Controls".
   - When you work on a UNIX system, the File System adapter inherits the case-sensitive file name characteristic of UNIX systems. So, on UNIX systems, you must ensure that references to files follow the same case as that used in the original file names. For example, suppose the `Test.html` file was created on a Microsoft Windows system. When you reference this file on a Linux system, you must ensure that you use `Test.html`, and not `test.html` or `TEST.html`.

7. Leave the **Login Timeout (ms)** field blank.

8. Click **Test Connection** to check whether you have entered the connection details correctly. You should see a `Success!` status, as shown in Figure 27–7.

Figure 27–7 File System Connection



9. Click **OK**.

10. In the Application Resources panel, expand the repository connection you just created.

27.2.5 What Happens When You Create a Repository Connection

When you create a connection to a repository, the contents in the main directory of the repository display under the Content Repository connection in the Application Resources panel, as shown in Figure 27–8. You can double-click folders and files to view them.

Figure 27–8 Application Resources

You can use repository connections to create JCR data controls that enable integration of the repository content with JSF pages. See Section 28.2, "Configuring Content Data Controls for JCR Adapters" and Section 28.5, "Integrating Content Using Content Data Controls" for information. These connections can also be consumed through the Documents service and Content Presenter task flows. See Chapter 30, "Integrating the Documents Service" for information.

27.2.6 What You May Need to Know When Creating a Repository Connection

This section includes:

- Section 27.2.6.1, "What You Should Know About Using Identity Propagation and External Application Authentication Methods"
- Section 27.2.6.2, "What You Should Know About Oracle Portal"
- Section 27.2.6.3, "What You Should Know About Oracle WebCenter Adapter for SharePoint"

27.2.6.1 What You Should Know About Using Identity Propagation and External Application Authentication Methods

The Create Content Repository Connection dialog provides the following options for authentication methods:

- **Identity Propagation**: If you select this option, no credentials are passed to the repository. The repository connector instead uses the current user's identity as determined from the Java security context. This must only be used when the application and the repository use the same identity store to authenticate users.

  To apply this authentication method, it is best to configure security for your application using the Configure ADF Security wizard since repositories may support only authenticated users or provide only limited access to the public or guest user. See Section 28.4, "Securing a Content Repository Data Control".

- **External Application**: The External Application method can be used in all other cases where the current user identity should not be propagated directly to the repository. For more information, see Section 69.13, "Working with External Applications" and Section 30.3, "Setting Security for the Documents Service."

  The External Application service allows different types of credentials to be associated with a connection:

- Public credentials are used whenever an application is not secured, or the user has not yet logged in.
- Shared credentials are used for any authenticated user.
- If shared credentials are not specified, then mapped credentials can be used to obtain a result similar to identity propagation when the application and content repository do not use the same user store. In that case the external application service provides runtime screens through which users can provide their credentials for accessing the content repository. Those credentials are securely stored and used for any future connection that this user tries to establish.

If you intend to configure the External Application service, then click **New** to launch the Register External Application wizard and do the following:

a. Specify name of the external application.

b. In the **Login URL** field, enter the URL of the external application; for example, `http://content-server.mycompany.com/idc/`

> **Note:** This URL is optional and is required only to provide *click through login* to the content repository's own user interface. See the External Application service documentation for more information on how to configure click through login.

c. Then, under **Authentication Details**, select **Basic** from the list. Leave the fields under **Login Details** blank.

This option is selected when *click through login* is not required. If *click through login* is enabled, then you must select another option based on the authentication method used in the repository.

d. Accept the default values and click **Next**.

e. Enter shared credentials that can be used at design time and runtime. Do not specify shared credentials, if users must specify their own credentials.

f. Enter public credentials that can be used at design time and runtime. Specify public credentials only if you intend public users to view documents or contents.

Click **Finish**.

27.2.6.2 What You Should Know About Oracle Portal

The following should be considered while using the Oracle Portal adapter:

- To use Oracle Portal-based content data control capabilities, you can install Oracle Portal release 10.1.4.1, 10.1.4.2, or 11. If you use the Oracle Portal release 10.1.4.1, then you must update it with the required patches. Consult Oracle Application Server Release Notes for Microsoft Windows (for the required platform) for release 11.1.1.0.0 to know the exact patch number.
- Only `file`, `image`, `imagemap`, and `text` item types and custom types based on these item types are supported.
- The `portal:container` page type and its extensions are supported.

- Content is always exposed in the default language of the page group. For example, if there are three page groups with different default languages, then the content displays only for those default languages and not for any translations that exist.

27.2.6.3 What You Should Know About Oracle WebCenter Adapter for SharePoint

Consider the following while configuring and using Oracle WebCenter Adapter for SharePoint:

- The adapter does not support connecting to a Microsoft SharePoint repository configured to allow `anonymous` access.
- There should be a fast network connection between the application server instance on which the adapter is running and the Microsoft SharePoint repository.
- **Microsoft SharePoint versions**: Oracle WebCenter Portal supports the following Microsoft SharePoint versions:
  - Microsoft Office SharePoint Server (MOSS) 2007 SP2
  - Microsoft Windows SharePoint Services (WSS) version 3 SP2
- **Versioning Settings**: Oracle WebCenter Portal supports the following Microsoft SharePoint 2007 Document Library versioning settings:
  - Require Check Out : No
  - Content Approval : No
  - Document Version History : No versioning

  The adapter does not function correctly if any other Versioning Settings are configured. For example, upload operations fails if `Require CheckOut` is set to `yes`. If document version history or content approval are enabled, new versions or documents have restricted visibility.
- **Session-Based Memory Cache**: For performance reasons, Oracle WebCenter Adapter for SharePoint maintains a session-based memory cache. A Framework application, which uses this adapter, must configure an `Http Session time-out` in the application's `web.xml` file to ensure that any unused sessions are closed, and the adapter memory cache is released.
- **Mapping**: The mapping takes into account only those content artifacts and services, which are relevant and defined in the JCR API. Additionally, the adapter maps the content and services to the extent supported by native SharePoint web services, as the adapter does not rely on custom additional server-side components. Consequently:
  - Full text search only returns items that are indexed by the SharePoint server.
  - Set of searchable columns is limited.
  - A fixed set of node types is supported in searches.
  - Some searches require additional network round trip as the adapter does not receive the full information necessary to map results to JCR from the web services.

  The adapter exposes content from a Microsoft SharePoint server in a hierarchical way which is similar to the way by which the content is exposed by the native web interface. The items of the hierarchy have a primary type of either `nt:folder`, `nt:file`, or a specialization of these. Additional SharePoint specific characteristics are in some instances added by means of mixins, that is, `sp:Folder`, `sp:File`, and so on. The SharePoint specific name space, which is

identified by the `sp` prefix in these examples, is used for items controlled by the SharePoint server. Items controlled by the user - webs, documents, list items and the like - are in the default name space. The adapter allows write access to SharePoint document libraries. That is, it allows folders and files to be created within document libraries in correspondence with creating folders or uploading files to the native SharePoint web interface. Examples which demonstrate this hierarchical mapping are described in the next point.

- **Site Structure**: The structure mapping of a SharePoint site is as follows:
  - `/sp:Site`: The root element of the site.
  - `/sp:Site/sp:RootWeb`: The root web element.
  - `/sp:Site/sp:RootWeb/sp:Lists`: The path to the root of all lists in the site.
  - `/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files`: The path to the start of the file and folder hierarchy within a document library. In this example, the Shared Documents library is shown. All site document libraries are mapped under `/sp:Site/sp:RootWeb/sp:Lists`, each mapped by their own document library name.
  - `/sp:Site/sp:RootWeb/sp:Lists/Shared Documents/sp:Files/myFiles`: An example of a folder within the sites Shared Documents document library.
  - `/sp:Site/sp:RootWeb/sp:Webs/mySubSite`: A site's subsites are all mapped under `/sp:Site/sp:RootWeb/sp:Webs`. This example shows the path to a subsite named `mySubSite`. The subsite may itself contain Document Libraries.
  - The adapter does not support the `write` access to a SharePoint Document Library with settings that require one or more mandatory SharePoint columns.
- **Search and indexing**:
  - **JCR and native Microsoft SharePoint search**: The Oracle WebCenter Adapter for SharePoint uses the native SharePoint search web service to evaluate JCR queries. Features present in JCR 1.0 but not available in the SharePoint search service are usually ignored.
  - **Indexed items**: The native search finds only those items that are indexed by the Microsoft SharePoint server. Other items that may match the query criteria are ignored. By default, SharePoint Services 2007 is configured for search and full-text indexing of a limited set of document types. For more information, and information on how to enable search and indexing in more complex deployments, see Microsoft documentation.
  - **LIKE limit**: The SharePoint native query language uses a LIKE keyword that the adapter uses to constrain queries by URLs (document paths) that match a pattern. The native `LIKE` operator supports a pattern match on strings up to 64 characters. Therefore, the Oracle WebCenter Adapter for SharePoint applies a client-side filtering on result sets to ensure that the correct constraint on URL is applied. The adapter's LIKE limit parameter controls this feature, and if this limit is not set, it defaults to applying a 64 character limit. The parameter can be set to `0` to disable client-side filtering. The parameter can also be set to some other positive value to apply a different character limit. However, this limit can only be increased if the SharePoint instance supports LIKE tests on URLs greater than 64 characters.

- **Creation and Modification timestamps**: When displaying the contents of a SharePoint Document Library, the adapter reports the Creation and Modification timestamps as the times that the document was created on or last updated in the library. In the case of some document types, for example Microsoft Office documents, the native SharePoint search evaluates against the document metadata stored within each document. This can be different from the times when the document was uploaded or updated in the Document Library, and therefore, it appears to give misleading search results.
- **Combining search keywords**: The adapter does not support combining search keywords in an `OR` expression.
- **Search by Last Modifier**: The adapter does not support search by Last Modifier.
- **Supported JCR search operators and properties**: The adapter supports the following:
  * Relational operators for comparison: `=`, `>=`, `>`, `<=`, `<`, `LIKE`, `<>`, `IS NULL`, `IS NOT NULL`. Predicates, descendants, and self operators (`//`) are supported on the last location step.
  * Properties for comparison: Size, Author, Modified, URL, Title, `IsDocument`, `ContentClass`, `SiteName`, Description, `FileName`, `jcr:data`, `jcr:mimeType`, `jcr:created`, `jcr:lastModified`.

27.3 Editing Content Repository Connections

This section describes how you can edit a common or an application-specific content repository connection. This section includes the following subsections:

- Section 27.3.1, "How to Edit a Common Repository Connection"
- Section 27.3.2, "How to Edit a WebCenter Portal: Framework Application-Specific Content Repository Connection"

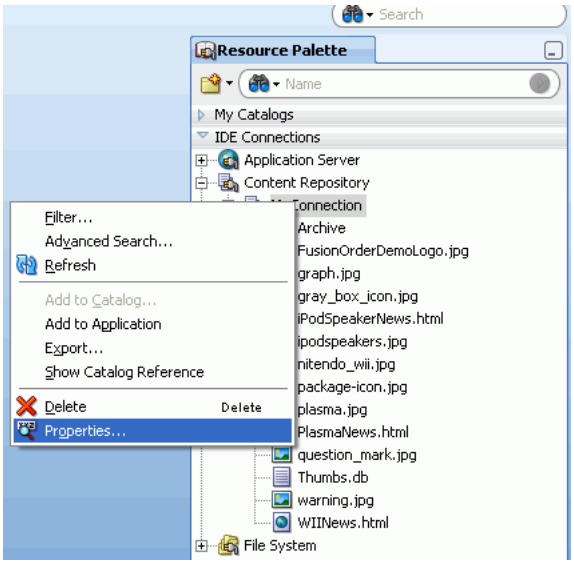
27.3.1 How to Edit a Common Repository Connection

Common repository connections (IDE connections) are created and edited under the Resource Palette.

To edit a common repository connection:

1. Under the Resource Palette, right-click the repository connection you intend to edit and choose **Properties**, as shown in Figure 27–9. The Edit Repository Connection dialog displays, as shown in Figure 27–10.

Figure 27–9 Resource Palette - Properties



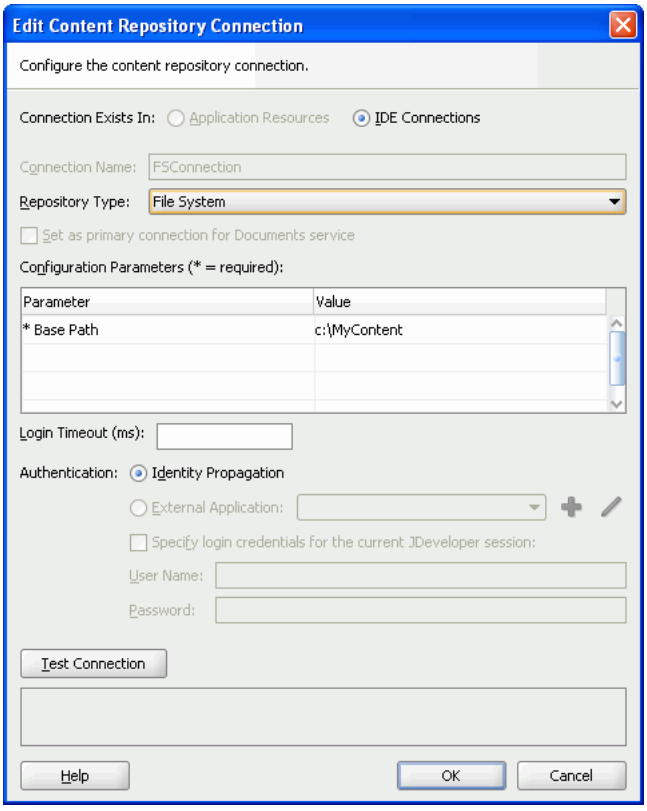


Figure 27–10 Edit Content Repository Connection

2. Change the appropriate parameters.
3. Test the connection and click **OK**.

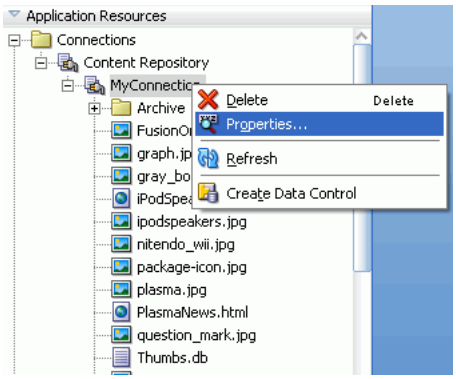
27.3.2 How to Edit a WebCenter Portal: Framework Application-Specific Content Repository Connection

Application-specific content repository connections exist under the Application Resources panel.

To edit a Framework application-specific content repository connection:

1. In the Application Resources panel, right-click the connection you intend to edit, and choose **Properties**, as shown in Figure 27–11. The Edit Content Repository Connection dialog displays, as shown in Figure 27–12.

Figure 27–11 Application Resources - Properties



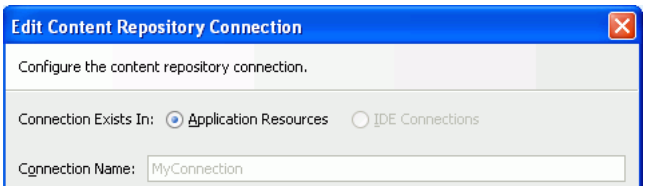


Figure 27–12 Edit Content Repository Connection

2. Change the appropriate parameters. Depending on the repository type, see the earlier sections that describe how to create repository connections. For example, for Content Server, see Section 27.2.1, "How to Create a Content Repository Connection Based on the Oracle Content Server Adapter".
3. Test the connection and click **OK**.

27.4 Using an Existing Repository Connection for a New WebCenter Portal: Framework Application

You can use an existing repository connection for any Framework application, if you created it as a common repository under the Resource Palette.

To use an existing repository connection:

1. In Oracle JDeveloper, open the Framework application for which you intend to use an existing repository connection.
2. Go to the Resource Palette and select the repository connection that you intend to use for a new application, for example `MyConnection_2`, and drop it under the Application Resources panel of the new application, as shown in Figure 27–13.

Tip: Alternatively, right-click the connection and choose **Add to Application**. The connection is displayed under the Application Resources panel.

Figure 27–13 Dragging an Existing Common Repository Connection (IDE Connection) to an Application

You can now configure a data control for your new application from this repository connection, as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".

28

Working with Content Data Controls

There are several ways to integrate content into a WebCenter Portal: Framework application. For more information, see Chapter 26, "Introduction to Integrating and Publishing Content."

JCR APIs enable independent access to content, regardless of the underlying repository or the type of the content; for example, documents, relational content, and so on. The JCR 1.0 API, as defined in JSR 170, provides a set of basic capabilities for reading, writing, browsing, and searching content. The JCR data controls also enable you to connect to and read from other JCR 1.0 repositories. To add content available in Oracle WebCenter Content: Content Server, Oracle Portal, Oracle WebCenter Adapter for SharePoint, and file systems to JSF pages, you first create connections to the repositories, then use the connections to create data controls based on the repositories.

This chapter includes the following sections:

- Section 28.1, "Overview of Content Data Controls"
- Section 28.2, "Configuring Content Data Controls for JCR Adapters"
- Section 28.3, "Editing Content Repository Data Controls"
- Section 28.4, "Securing a Content Repository Data Control"
- Section 28.5, "Integrating Content Using Content Data Controls"

28.1 Overview of Content Data Controls

A content data control is a container for all the data objects, collections, methods, and operations used to create user interface (UI) components within your Framework application. The data controls provide you with easy-to-use methods that you can drag and drop onto JSF pages to publish content as ADF components, such as URLs, files, and folders. While methods, parameters, and default attributes to publish content are similar across all JCR data controls, the content integration module gives you the flexibility to customize attributes based on your requirements.

Each type of content data control contains methods and parameters to publish content as links, tables, files, and folders, and to add search and advanced search capabilities for your content. Parameters include two types of attributes: default and custom. The default attributes are common across data controls based on File System, Oracle Portal, Oracle WebCenter Content: Content Server, and Oracle WebCenter Adapter for SharePoint. The custom attributes are repository-specific and can be added while creating content data controls.

The following sections describe the methods, parameters, and default attributes that are common across data controls based on File System, Oracle Portal, Oracle WebCenter Content: Content Server, and Oracle WebCenter Adapter for SharePoint:

- Section 28.1.1, "The getItems Method"
- Section 28.1.2, "The search Method"
- Section 28.1.3, "The advancedSearch Method"
- Section 28.1.4, "The getURI Method"
- Section 28.1.5, "The getAttributes Method"

28.1.1 The getItems Method

The `getItems` method returns the files and folders stored starting at a particular location in the repository. This method enables you to publish content in forms, tables, and hierarchical trees. Using this method, you can also create navigation lists and buttons.

Table 28–1 describes the parameters of the `getItems` method.

Table 28–1 Parameters of the getItems Method

Parameter	Description
`path`	Defines the starting point for `getItems`.
`type`	Specifies what should be returned: only files, only folders, or any object.

The `getItems` method returns the attributes described in Table 28–2.

Table 28–2 Return Attributes of the getItems Method

Parameter	Description
`icon16`	Provides a URI to the icon that the Documents service uses for an item.
`icon32`	Provides a URI to the icon that the Documents service uses for an item.
`ID`	Parameter to the Documents service task flows that require an ID.
`lastModified`	Describes the last modified date of an item.
`name`	Describes the name of the returned file or folder.
`path`	Describes the location of the returned file or folder within the content repository.
`URI`	The direct access URL of a file or folder.
`primaryType`	Describes whether the returned object is a file or folder or some other type.

28.1.2 The search Method

The `search` method enables you to create a simple search by name pattern or keyword.

Table 28–3 describes the parameters of the `search` method.

Table 28–3 Parameters of the search Method

Parameter	Description
`path`	Starting path of the search.

Table 28–3 (Cont.) Parameters of the search Method

Parameter	Description
isRecursive	Specifies whether only the specified folder (=false) or the whole tree starting at the specified path (=true) should be searched. The default value is false, that is, if this field is left blank, then the search is performed in the specified folder. Only if the value is true, the search is performed in the entire hierarchy.
keyword	Search keyword for full text search.
namePattern	Pattern search on name. Use the % wildcard to match any number of characters and the _ wildcard to match one character.

The search method returns the attributes described in Table 28–4.

Table 28–4 Return Attributes of the search Method

Parameter	Description
icon16	Provides a URI to the icon that the Documents service uses for an item.
icon32	Provides a URI to the icon that the Documents service uses for an item.
ID	Parameter to the Documents service task flows that require an ID.
lastModified	Describes the last modified date of an item.
name	Describes the name of the returned file or folder.
path	Describes the location of the returned file or folder within the content repository.
URI	The direct access URL of a file or folder.
primaryType	Describes whether the returned object is a file or folder or some other type.

28.1.3 The advancedSearch Method

The advancedSearch method enables you to perform an advanced search by creating a set of search criteria out of any available attribute.

Table 28–5 describes the parameters of the advancedSearch method.

Table 28–5 Parameters of the advancedSearch Method

Parameter	Description
path	Starting path of the search.
isRecursive	Specifies whether only the specified folder (=false) or the whole tree starting at the specified path (=true) should be searched. The default value is false, that is, if this field is left blank, then the search is performed in the specified folder. Only if the value is true, the search is performed in the entire hierarchy.
keyword	Search keyword for full text search.
namePattern	Pattern search on name. Use the % wildcard to match any number of characters and the _ wildcard to match one character.
matchAny	Specifies whether all predicates (=false) or any predicate (=true) should be matched.

Table 28–5 (Cont.) Parameters of the advancedSearch Method

Parameter	Description
`predicates`	A collection of `SimplePredicate` parameters that consist of attributes, comparators, and values.
`type`	Specifies what should be returned: only files, only folders, or any object.

The `advancedSearch` method returns the attributes described in Table 28–6.

Table 28–6 Return Attributes of the advancedSearch Method

Parameter	Description
`icon16`	Provides a URI to the icon that the Documents service uses for an item.
`icon32`	Provides a URI to the icon that the Documents service uses for an item.
`ID`	Parameter to the Documents service task flows that require an ID.
`lastModified`	Describes the last modified date of an item.
`name`	Describes the name of the returned file or folder.
`path`	Describes the location of the returned file or folder within the content repository.
`URI`	The direct access URL of a file or folder.
`primaryType`	Describes whether the returned object is a file or folder or some other type.

28.1.4 The getURI Method

The `getURI` method returns the URI attribute, which is the direct access URL of the file or folder. Its `path` parameter describes the path to the object. You can use this method to create links to content and to inline content in your page. The `getURI` method returns the `URI` attribute.

28.1.5 The getAttributes Method

The `getAttributes` method returns the list of attributes and their values for a given file or folder. Its `path` parameter describes the path to the object.

Table 28–7 describes the attributes that the `getAttributes` method returns.

Table 28–7 Return Attributes of the getAttributes Method

Parameter	Description
`name`	Name of the attribute.
`value`	Value of the attribute.

28.2 Configuring Content Data Controls for JCR Adapters

This section describes how to create a content data control based on a content repository connection:

- Section 28.2.1, "How to Configure a Content Repository Data Control"

- Section 28.2.2, "What Happens When You Configure a Content Repository Data Control"

28.2.1 How to Configure a Content Repository Data Control

The procedure to create content repository data controls is the same irrespective of the types of the connections that you use to create data controls. If you have not created a connection to your content repository, then see Section 27.2, "Configuring Content Repository Connections". In this section, a content data control is created using a Content Server-based connection.

To create a content data control using an existing content repository connection:

1. In the Application Navigator, select the **Portal** project, in which the project entries for the new data control should be created.

   You must do this to ensure that the data control definition is separate from the data control usage. When you select the **Portal** project, data control definition files are created in its sub folder, **Application Sources** and not in the **ViewController** project in which the user interface is created.

2. In the Application Resources panel, expand the **Connections** folder in which you created the repository connection.

3. Drag the repository connection that you intend to use for the new data control and drop it into the Data Controls panel.

   Alternatively, from the **File** menu, choose **New**. In the New Gallery, expand **Business Tier**, select **Content Repository** and then **Content Repository Data Control**, and click **OK**.

   The Create Content Repository Data Control dialog displays with the name of the connection selected in the **Connection Name** list.

   > **Note:** If you created your repository connection under the Resource Palette, then right-click the connection under the Resource Palette and choose **Create Data Control**. From the Resource Palette, you can also drag and drop the required connection onto the Data Controls panel.
   >
   > To add a new connection, click the **Create new content repository connection** icon to display the Create Content Repository Connection dialog. For more information, see Section 27.2, "Configuring Content Repository Connections".

4. In the **Data Control Name** field, enter a name for your data control, for example `MyDataControl`.

5. To add custom attributes, click **Add**. Then, enter a name for the attribute as it should appear in the Data Controls panel, select its type, and enter the JCR path.

   In Content Server, a metadata attribute named `dPropertyName` is mapped in the adapter as shown here:

   ```
   jcr:content/idc:metadata/idc:dPropertyName
   ```

   For example, if the property name is `dWorkflowState`, then it is mapped as `jcr:content/idc:metadata/idc:dWorkflowState`.

   In Oracle Portal, a metadata attribute is mapped in the adapter as shown here:

   ```
   portal:name of the attribute in Oracle Portal
   ```

Note: To retrieve the JCR paths of item attributes, run the `getAttributes` method on the required items. Then reenter the wizard to include those paths by right-clicking the respective data control in the Data Controls panel and choosing **Edit Definition**.

6. Click **OK**.

Note: The data controls include the predefined node types of JCR. These basic node types represent folders (`nt:folder`) and files (`nt:file`). These are derived from `nt:hierarchyNode`, which is a child of the `nt:base` supertype. Additional node types can be derived from the basic types to customize the experience to a particular repository.

28.2.2 What Happens When You Configure a Content Repository Data Control

When the data control is successfully configured, it shows under the Data Controls panel. Expand it in the Data Controls panel to see the hierarchical list of methods, parameters, and operations for the new data control, as shown in Figure 28–1. For detailed information on using the Data Control panel, see Chapter titled "Using Oracle ADF Model in A Fusion Web Application" of *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

Figure 28–1 Data Controls Panel - Content Server

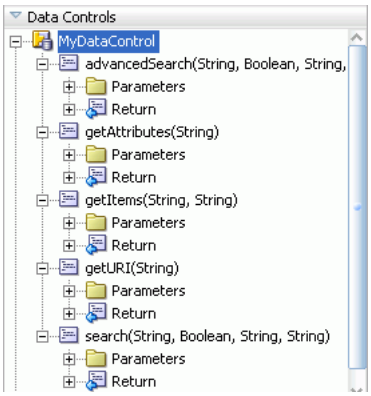

Table 28–8 describes the icons and object hierarchy of a data control.

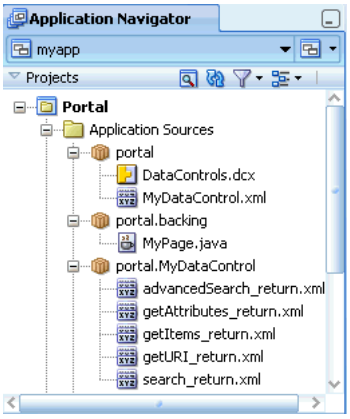
Table 28–8 The Data Controls Panel Icons and Object Hierarchy



Icon	Name	Description	Used to Create...
	Data Control	Represents a data control. You cannot use the data control itself to create UI components, but you can use any of the child objects listed under it. Depending on how your business services were defined, there may be multiple data controls.	Serves as a container for the other objects, and is not used to create anything
	Method	Represents an operation in the data control or one of its exposed structures that may accept parameters, perform some business logic and optionally return single value, a structure or a collection of those	Command components For methods that accept parameters: command components and parameterized forms
	Method Return	Represents an object that is returned by a custom method. The returned object can be a single value or a collection. A method return appears as a child under the method that returns it. The objects that appear as children under a method return can be attributes of the collection, other methods that perform actions related to the parent collection, and operations that can be performed on the parent collection.	For single values: text fields and selection lists For collections: forms, tables, trees, and range navigation components When a single-value method return is dropped, the method is not invoked automatically by the framework. A user either has to also create an invoke action as an executable, or drop the corresponding method as a button to invoke the method.
	Attribute	Represents a discrete data element in an object (for example, an attribute in a row). Attributes appear as children under the collections or method returns to which they belong. Only the attributes that were included in the view object are shown under a collection. If a view object joins one or more entity objects, that view object's collection will contain selected attributes from all of the underlying entity objects.	Label, text field, date and selection list components
	Operation	Represents a built-in data control operation that performs actions on the parent object. Data control operations are located in an Operations folder under collections or method returns, and also under the root data control node. The operations that are children of a particular collection or method return operate on those objects only, while operations under the data control node operate on all the objects in the data control. If an operation requires one or more parameters, they are listed in a Parameters folder under the operation.	UI components such as buttons or links
	Parameter	Represents a parameter value that is declared by the method or operation under which it appears. Parameters appear in the Parameters folder under a method or operation.	Label, text, and selection list components

The following files (Figure 28–2) are created under the **Portal** project:

- `DataControls.dcx`: Oracle JDeveloper creates this file the first time a data control is created. This file lists all the Oracle ADF data controls created under the current project. This file is required to initialize the data control.
- *`datacontrolname`*`.xml`: This file includes attributes, accessors, and operations of a data control.

- `advancedSearch_return.xml`: This file includes the return type definition for the `advancedSearch` method.
- `getAttributes_return.xml`: This file includes the return type definition for the `getAttributes` method.
- `getItems_return.xml`: This file includes the return type definition for the `getItems` method.
- `getURI_return.xml`: This file includes the return type definition for the `getURI` method.
- `search_return.xml`: This file includes the return type definition for the `search` method.
- `Return.xml`: This file defines the standard operations on collections.

Figure 28–2 Projects Panel - Portal Project

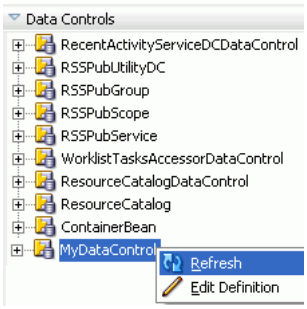
28.3 Editing Content Repository Data Controls

This section describes a generic procedure to edit content data controls that you configured as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".

To edit a content data control:

1. In Oracle JDeveloper, go to the application that contains your content data control.
2. Under Data Controls panel, right-click the data control you intend to edit, and choose **Edit Definition**, as shown in Figure 28–3. The Edit Content Repository Data Control dialog displays, as shown in Figure 28–4.

Figure 28–3 Edit Data Controls



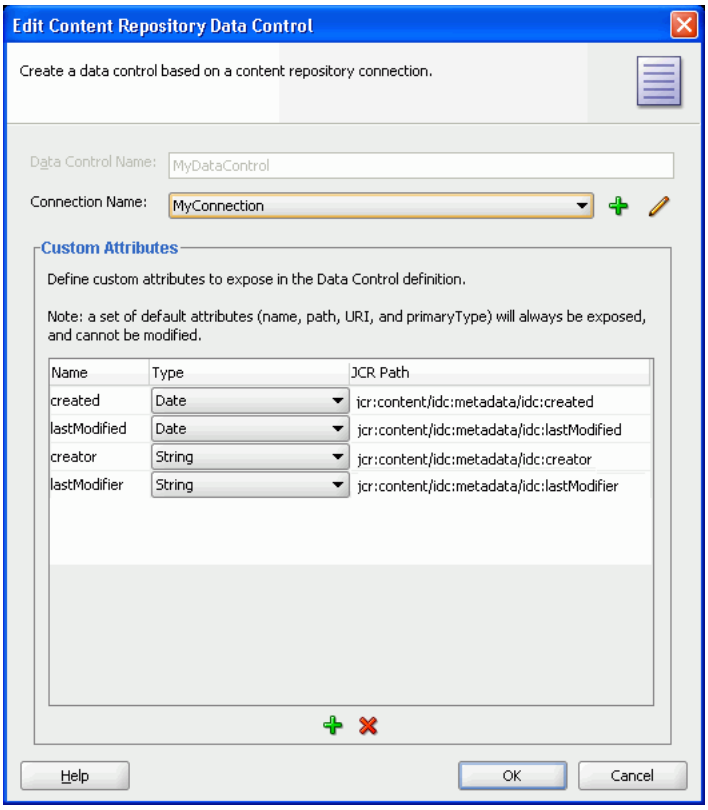


Figure 28–4 Edit Content Repository Data Control Dialog

3. To select a different connection, use the **Connection Name** list.
4. To add a connection, click the **Create new content repository connection** icon to display the Create Content Repository Connection dialog. Depending on the type of connection that you intend to create, see relevant sections in Section 27.2, "Configuring Content Repository Connections" for information about its configuration parameters.
5. To edit an existing connection, click the **Edit selected content repository connection** icon to display the Edit Content Repository Connection dialog. Depending on the type of connection that you intend to modify, see relevant sections in Section 27.2, "Configuring Content Repository Connections" for information about its configuration parameters.
6. To add or remove custom attributes, use the **Add new attribute** icon and the **Remove selected attribute** icon respectively in the Custom Attributes box.
7. Click **OK** to apply the changes.

28.4 Securing a Content Repository Data Control

You can enable security for your content repository connections. For information, see Chapter 69, "Securing Your WebCenter Portal: Framework Application".

28.5 Integrating Content Using Content Data Controls

In this section, you will use `getURI`, `getItems`, `search`, and `advancedSearch` methods of your data control. The basic procedure to use any data control method is to drag and drop it onto a page. When a method is dropped, its ADF Faces tag is added

to the source of the page, and the tag is displayed in the Structure window. For example, dropping the URI attribute of `getURI` as a Go Link adds an `af:goLink` to the page. The destination of the `af:goLink` is set to the EL expression `#{bindings.URI.inputValue}`. This EL expression ties the destination value of the `af:goLink` to the binding container's URI value.

In the page definition file, `methodIterator` is added to the `executables` element, and `methodAction` is added to the `bindings` element. The `methodIterator` and `methodAction` elements define which data control and method is to be used. The `NamedData` attribute of the `methodAction` defines what input parameter values should be provided to this method call. The path and type parameters are common across all data control methods. However, `NamedData` for search and `advancedSearch` includes additional parameters that are unique to those methods. For example, in the `advancedSearch` method, the `NamedData` can also be used to define the search predicates, whether the search is recursive, and so on.

The page definition includes the `AttrNames` element, which defines the attributes of the items available in the bindings container to ADF. These items are based on default attributes and custom attributes that were defined when creating the data control.

For detailed information on using the Data Control panel and working with page definition files, see the chapter "Using Oracle ADF Model in A Fusion Web Application" of *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

The examples in this section use the following data control methods:

- `getURI` to add textual and clickable image links to the repository folder.
- `getItems` to publish the repository content in an ADF table and tree.
- `search` and `advancedSearch` to display those items of the repository that match the search criteria.

This section includes the following subsections:

- Section 28.5.1, "How to Publish Content As Links"
- Section 28.5.2, "What Happens at Runtime"
- Section 28.5.3, "How to Publish Content in a Table"
- Section 28.5.4, "What Happens at Runtime"
- Section 28.5.5, "How to Publish Folder Content in a Tree"
- Section 28.5.6, "What Happens at Runtime"
- Section 28.5.7, "How to Add Search Capabilities to Content Repositories"
- Section 28.5.8, "What Happens at Runtime"
- Section 28.5.9, "What You May Need to Know When Using Search Capabilities"

28.5.1 How to Publish Content As Links

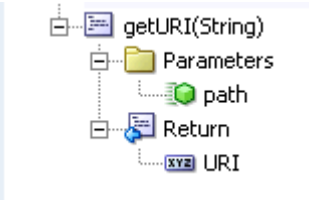
This section describes how to create hyperlinks to files stored in a file system and convert them into textual and image links. You use the **ADF Go Link** and the `getURI` method to create textual links and the Image of **ADF Faces** to create image links.

This section includes the following procedures:

- Section 28.5.1.1, "Publishing Content As a Textual Link"
- Section 28.5.1.2, "Creating a Clickable Image to Link to a Document"

Before you begin:

1. Configure a repository connection as described in Section 27.2, "Configuring Content Repository Connections".
2. Configure a data control as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".
3. Create a page as described in Section 5.3, "Adding Pages to a Portal."



28.5.1.1 Publishing Content As a Textual Link

In this section, you will use the **Oracle ADF Go Link** option of the `getURI` method to publish your content as a textual link. You will also create a link to show a specific item of a repository.

To publish content as a textual link:

1. In the Application Navigator, double-click a page, for example `myPage.jspx`, to open it in the visual editor.
2. In the Data Controls panel, under the repository connection, expand the **getURI (String)** method and expand **Return**. You should see the `URI` attribute, as shown in Figure 28–5.

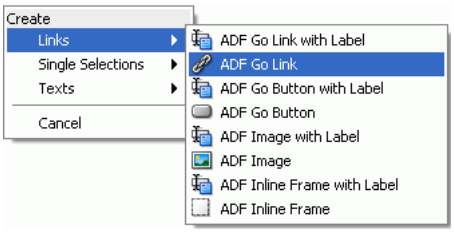


Figure 28–5 The URI Attribute of the getURI Method

3. To create a textual link, select the **URI** attribute and drop it on to the page, or in the Structure window under `af:form`. From the **Create** menu, choose **Links** and then **ADF Go Link**, as shown in Figure 28–6.

   If this is the first time you have dropped a node onto the page, then the Edit Action Binding dialog displays.

Figure 28–6 Oracle JDeveloper Context Menu for the getURI method

4. In the **Value** field of the **path** parameter, enter the path of the file for which you intend to create the link, as shown in Figure 28–7. You must enter a leading slash (`/`), for example `/PlasmaNews.html`. To modify or delete this path later, click the arrow icon next to the node in design mode and choose **Go to Binding** from the context menu.

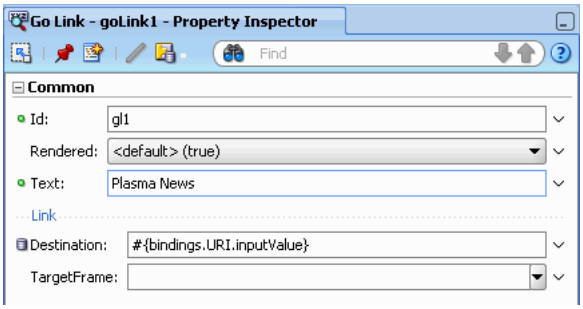

Figure 28–7 Edit Action Binding

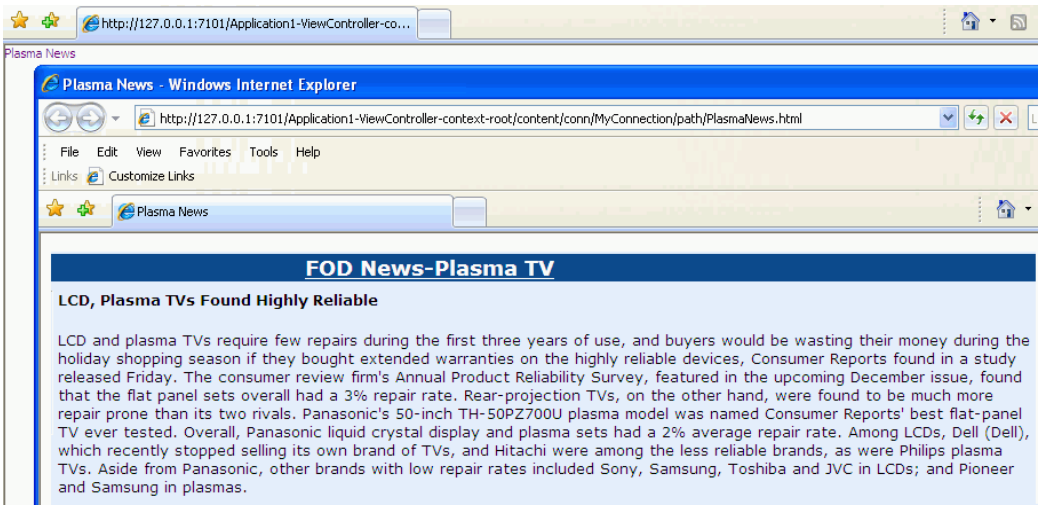
> **Note:** To grant edit, personalize, customize, and view permissions at the attribute level, see Section 28.4, "Securing a Content Repository Data Control".

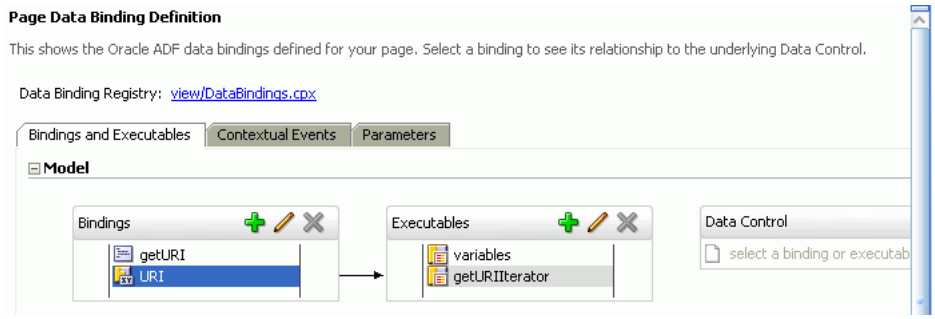


5. Click **OK**.
6. Right-click the page and select **Run**. In your browser, you should see the URL for the file path entered in the Edit Action Binding dialog without any formatting.
7. By default, the link displays the text `goLink1`. In the Structure window, select **af:goLink - goLink1** and view the properties in the Property Inspector.
8. In the **Text** field, enter a name for the link, for example, `Plasma News`, as shown in Figure 28–8.

Figure 28–8 Go Link Properties

9. Right-click your page and choose **Run**. The page appears in your browser window with the new link, as shown in Figure 28–9.

Figure 28–9 ADF Go Link in a Browser



10. Click the link to check that the correct file is displayed.

In Section 28.5.1.2, "Creating a Clickable Image to Link to a Document", you will extend this textual link into an image link.

To add a link to another item, in the same JSF page:

1. In the Application Navigator, right-click the page in which you created the ADF Go Link, and choose **Go to Page Definition**. The Page Data Binding Definition displays in the design view, as shown in Figure 28–10.

Figure 28–10 Page Data Binding Definition

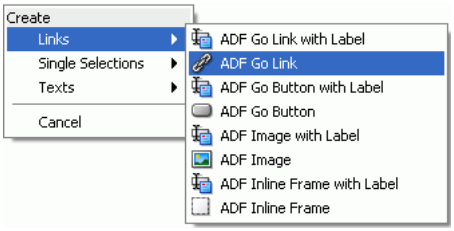
2. Go to the source view of the page definition.

3. In the `executables` element, add another `methodIterator` and change the `methodIterator id` and value of `Binds`, as shown in **Bold** in the following example:

```
<executables>
  <variableIterator id="variables"/>
  <methodIterator Binds="getURI.result" DataControl="MyDataControl"
     RangeSize="25" BeanClass="portal.MyDataControl.getURI_return"
     id="getURIIterator"/>
  <methodIterator Binds="getURI1.result" DataControl="MyDataControl"
    RangeSize="25" BeanClass="portal.MyDataControl.getURI_return"
    id="getURIIterator1"/>
  </executables>
```

4. In the `Bindings` element, add another `methodAction` and change the `methodAction id`, `ReturnName`, and `NDValue`, as shown in **Bold** in the following example:

```
<methodAction id="getURI"
  RequiresUpdateModel=true Action="invokeMethod" MethodName="getURI"
  IsViewObjectMethod="false" DataControl="MyDataControl"
  InstanceName="MyDataControl"
  ReturnName="MyDataControl.methodResults.getURI_MyDataControl_getURI_result">
  <NamedData NDName="path" NDValue="/PlasmaNews.html"
    NDType="java.lang.String"/>
</methodAction>
<methodAction id="getURI1"
  RequiresUpdateModel="true" Action="invokeMethod" MethodName="getURI"
  IsViewObjectMethod="false" DataControl="MyDataControl"
  InstanceName="MyDataControl"
  ReturnName="MyDataControl.methodResults.getURI_MyDataControl_getURI1_result">
  <NamedData NDName="path" NDValue="/FusionOrderDemoLogo.jpg"
    NDType="java.lang.String"/>
</methodAction>
```



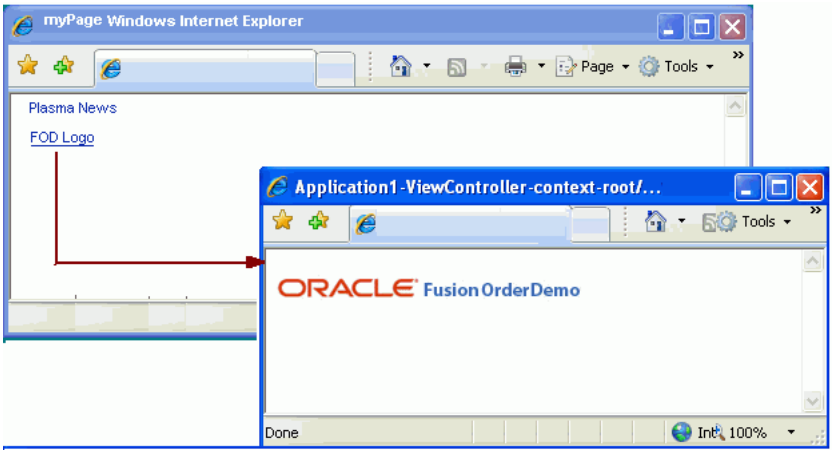
5. In the `Bindings` element, add another `attributeValues` tag to specify the new Id, as shown in **bold** in the following example:

```
<attributeValues
      IterBinding="getURIIterator"
      id="URI">
   <AttrNames>
      <Item Value="URI"/>
   </AttrNames>
</attributeValues>
<attributeValues
        IterBinding="getURIIterator1"
        id="URI1">
  <AttrNames>
        <Item Value="URI"/>
  </AttrNames>
</attributeValues>
```

6. In the Data Controls panel, under the repository connection, expand the **getURI (String)** method and expand **Return**. You should see the `URI` attribute.

7. To create a textual link, select the **URI** attribute and drop it on to the page, or in the Structure window under `af:form`. From the **Create** menu, choose **Links** and then **ADF Go Link**, as shown in Figure 28–11.

Figure 28–11 Oracle JDeveloper Context Menu for the getURI method



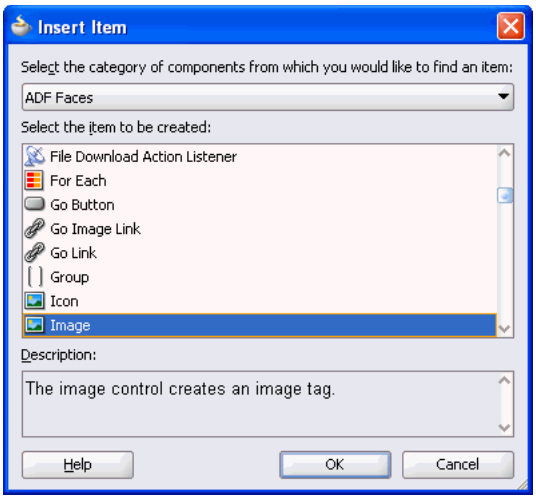
8. In the Structure window, double-click the new goLink; for example, **af:goLink2** to display the Go Link Properties window.

9. In the **Text** field, enter a display name for your new link; for example, `FOD Logo`.

10. In the **Destination** field, click the down arrow to display the Expression Builder dialog. Then, expand **ADF Bindings**, **bindings**, and **URI1**.
11. Double-click **inputValue** variable to create the `#{bindings.URI1.inputValue}` expression, and click **OK**. This expression is based on new elements that you added in `executables` and `bindings`.
12. Run your page. The new link should display content from the new path (`NDValue`) that you specified in step 4. Figure 28–12 shows the new link, `FOD Logo`, in addition to the `Plasma News` link that was added in the first part of Section 28.5.1.1, "Publishing Content As a Textual Link".

Figure 28–12 New Textual Link

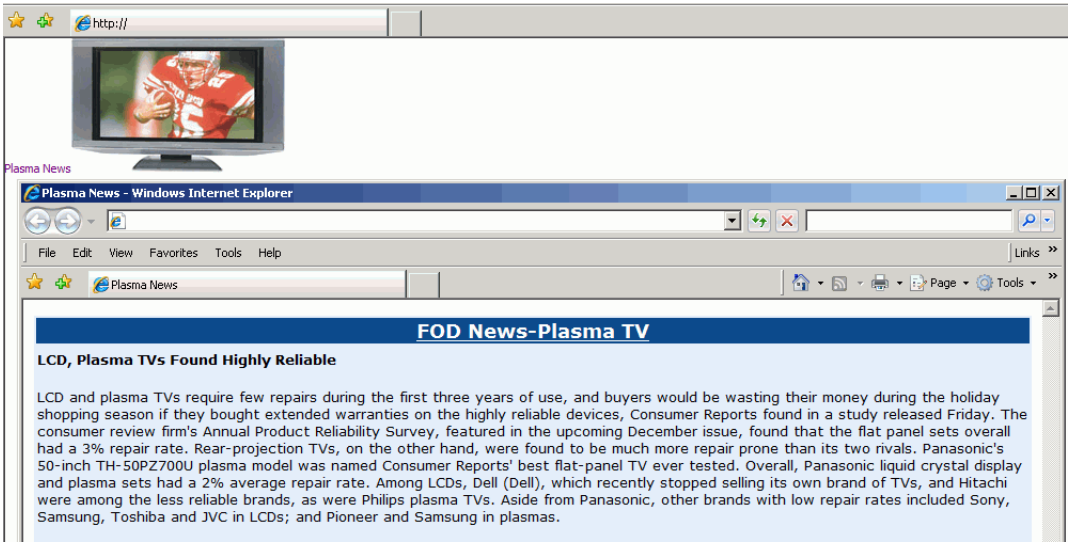
You can add as many links as required by following these steps.



28.5.1.2 Creating a Clickable Image to Link to a Document

In this section, you will use the Image option of ADF Faces to publish a document as a clickable image, that is, clicking the image object will display your document.

To publish content as a clickable image object:



1. In the Application Navigator, open the page, in which you created the ADF Go Link, by double-clicking it.
2. To convert the textual link that you created in the first part of Section 28.5.1.1, "Publishing Content As a Textual Link", in the Structure window, right-click **af:goLink - goLink1** and choose **Browse**. The Insert Item dialog displays.
3. From the **Select the item to be created** list, select **Image**, as shown in Figure 28–13.

Figure 28–13 Insert ADF Faces Item

4. Click **OK**. The Insert Image dialog displays.
5. Browse to the image file you intend to display as the image link; for example, `plasma.jpg`.
6. Click **Finish**.
7. Right-click your page and choose **Run**. Figure 28–14 shows a sample output.

Figure 28–14 ADF Object Image Link in a Browser

28.5.2 What Happens at Runtime

In the preceding examples, you created hyperlinks to files that are stored in a file system using **ADF Go Link** and converted them into textual and image links using the `getURI` method and the **Image** component of **ADF Faces**.

At runtime, the ADF framework uses the information from the page definition file to invoke the data control methods required by the page. For information about the page lifecycle, see the chapter "Understanding the Fusion Page Lifecycle" of *Oracle Fusion Middleware Fusion Developer's Guide for Oracle Application Development Framework*.

At runtime, the `getURI` data control method is invoked to convert the given path into a valid HTTP URI for the content repository for which the data control is configured. The returned URL is syntactically correct for the target repository, but is not guaranteed to find a resource, that is, the `getURI` method does not validate that the path corresponds to an existing JCR node. When the page is rendered and the clickable image or link is clicked, the application's get handler converts the HTTP URL into a JCR path and attempts to retrieve the content for the JCR path. The get handler also supplies `mimeType` information in the response `Content-Type` header, if such information is available from the repository. This is because in JCR, `jcr:mimeType` is an optional property of the `nt:resource` node type.

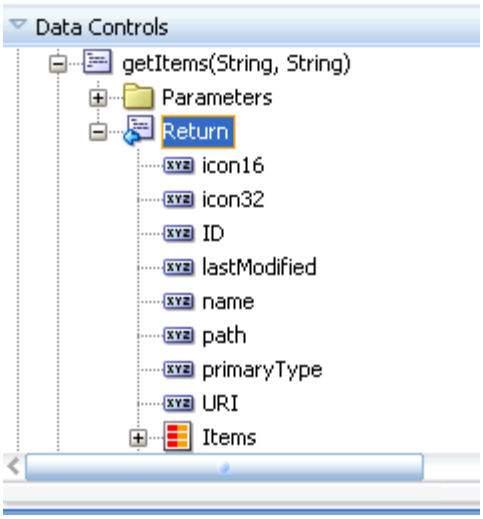
28.5.3 How to Publish Content in a Table

In this section, the `getItems` data control method is used to publish file and folder information in a table. This section describes the following procedures:

- Section 28.5.3.1, "Displaying Files and Folders in Read-Only Format"
- Section 28.5.3.2, "Displaying the Name Attribute As a Go Link"
- Section 28.5.3.3, "Configuring a Table to Show Only Files"

Before you begin:

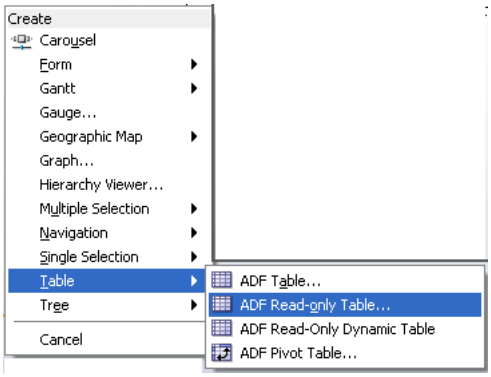
1. Configure a repository connection as described in Section 27.2, "Configuring Content Repository Connections".
2. Configure a data control as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".
3. Create a page as described in Section 5.3, "Adding Pages to a Portal."



28.5.3.1 Displaying Files and Folders in Read-Only Format

Here you will create a read-only ADF table using the `getItems` method.

To display folder content in a read-only table:



1. To open the page in the visual editor, double-click it in the Application Navigator.
2. In the Data Controls panel, under your data control, expand the **getItems** method and the **Return** node, as shown in Figure 28–15.

Figure 28–15 The Return node of the getItems method

3. To create a table that lists every file and folder available through this data control, drop the **Return** node on to the page or under `af:form` in the Structure window. From the **Create** menu, choose **Table** and then **ADF Read-only Table** , as shown in Figure 28–16.

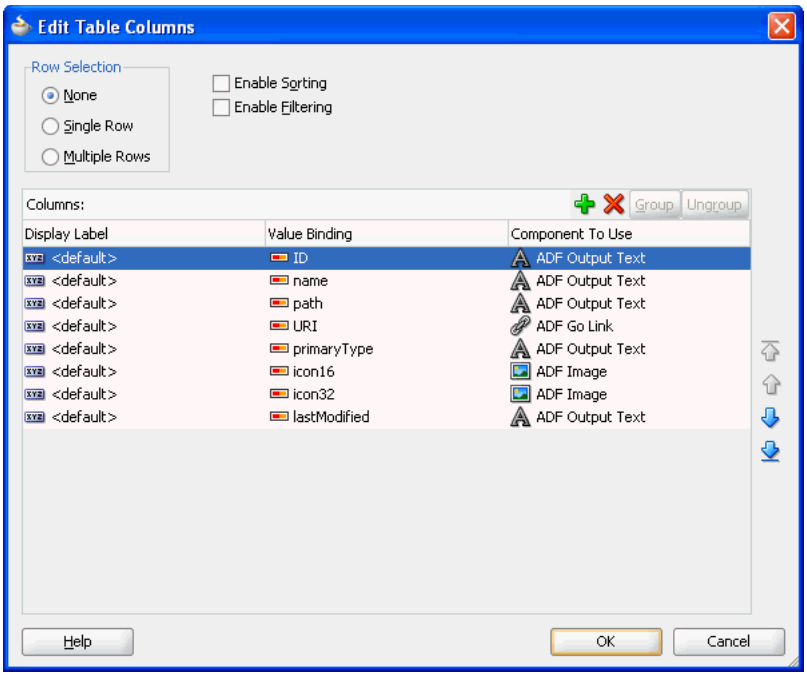


Figure 28–16 The Create Context Menu for getItems Method

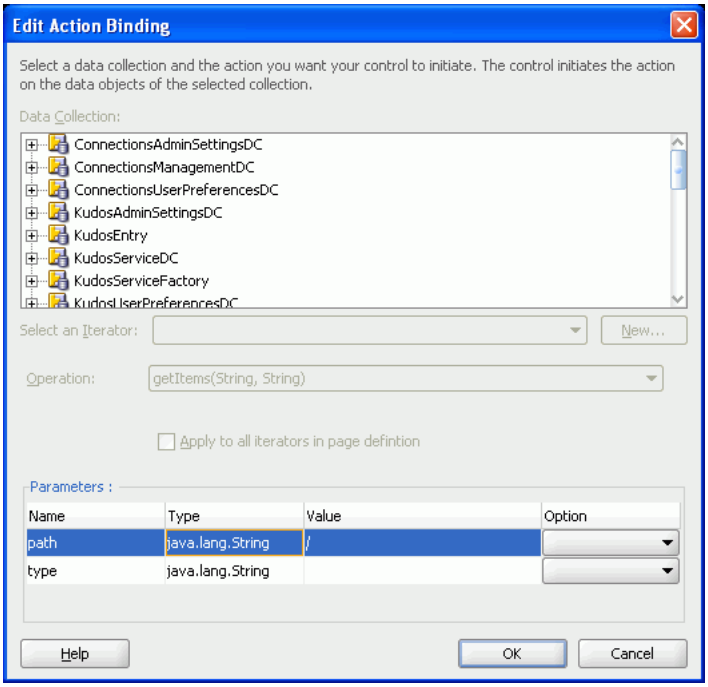
4. In the Edit Table Columns dialog, as shown in Figure 28–17, Select the row for the `getItems.name` **Value Binding** and enter an appropriate value for the **Display Label**; for example, `Name`.

   Repeat this step for the **path**, **URI**, **primaryType**, and **lastModified** attributes. Enter new display labels such as `name`, `Location`, `URL`, and so on, then click **OK.**

Figure 28–17 Edit Table Columns



5. If this is the first time you have dropped a node onto the page, the Edit Action Binding dialog displays.

   In the Edit Action Binding dialog, enter the path of the content directory as the `path` parameter, as shown in Figure 28–18. You must enter a leading slash (`/`). To modify or delete this path later, click the arrow icon next to the node in design mode and choose **Go to Binding** from the context menu.

   Leave the `type` parameter blank. This implies that the table displays both files and folders.

Figure 28–18 Edit Action Binding

6. Click **OK.** You should now see a table on the page that looks like Figure 28–19.

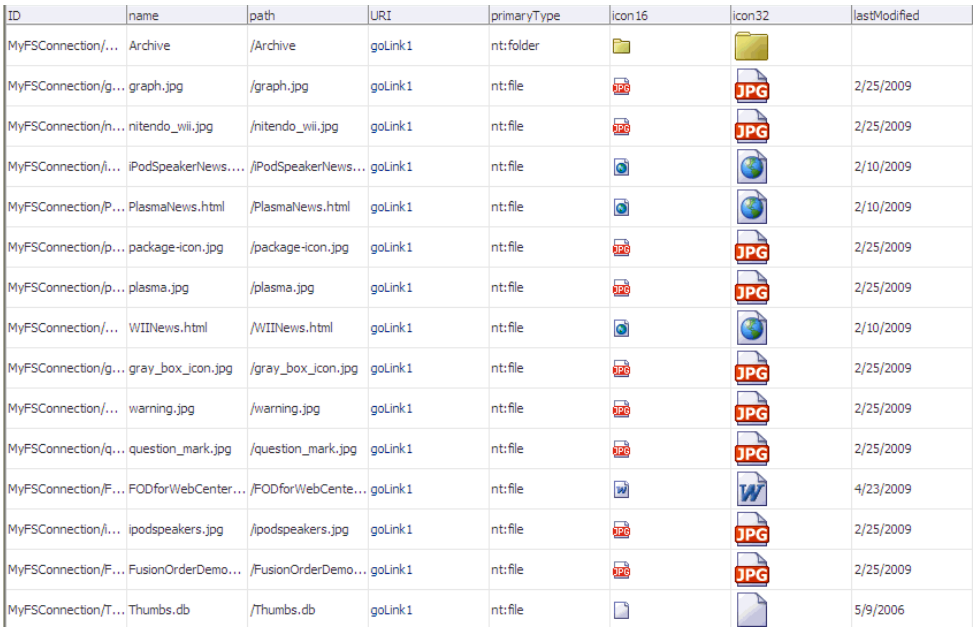


Figure 28–19 Read-Only Table for Publishing Folder Content

> **Note:** You can turn the page caching on or off. To do so, open the page definition and expand **executables**, and select **getItemsIterator** in the Structure window. Then, in the Property Inspector, set **CacheResults** to **true** or **false**, as required.

7. Run the page. You should see a list of all files and folders available in your content directory. Figure 28–20 shows a read-only table displaying both files and folders at runtime.

Figure 28–20 Files and Folders Displayed in a Read-Only Table

ID	name	path	URI	primaryType	icon16	icon32	lastModified
MyFSConnection/...	Archive	/Archive	goLink1	nt:folder			
MyFSConnection/g...	graph.jpg	/graph.jpg	goLink1	nt:file			2/25/2009

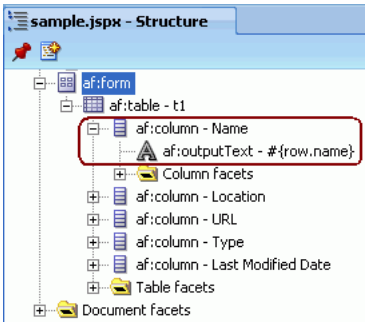
MyFSConnection/q...	question_mark.jpg	/question_mark.jpg	goLink1	nt:file			2/25/2009
MyFSConnection/F...	FODforWebCenter...	/FODforWebCente...	goLink1	nt:file			4/23/2009
MyFSConnection/i...	ipodspeakers.jpg	/ipodspeakers.jpg	goLink1	nt:file			2/25/2009
MyFSConnection/F...	FusionOrderDemo...	/FusionOrderDemo...	goLink1	nt:file			2/25/2009
MyFSConnection/T...	Thumbs.db	/Thumbs.db	goLink1	nt:file			5/9/2006

By default, the table displays file or folder attributes as read-only text (`af:outputText`). The next section describes how to display the `Name` attribute (`name`) as a Go Link (`af:goLink`).



28.5.3.2 Displaying the Name Attribute As a Go Link

In this section, you will convert the `Name` attribute of the table that you created in Section 28.5.3.1, "Displaying Files and Folders in Read-Only Format" into a link using an **ADF Go Link** component. You will also configure the table to show only the **Name** column.

To display the Name attribute as a Go Link:

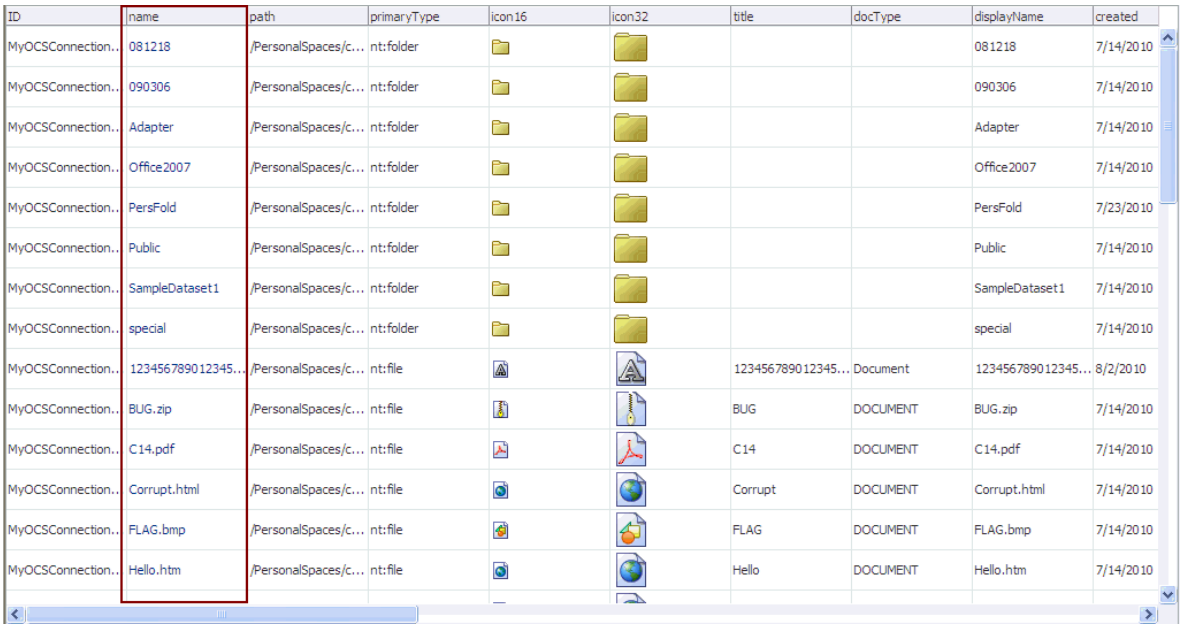
1. In the Structure window (Figure 28–21), expand the first column of the table (`af:column - Name`) to show the default display format `af:outputText - #{row.name}`.

Figure 28–21 Default Formatting for the Name Column

2. In the source view for the page, change the name column to use a go link. The link displays the name but links to the URI of the entry:

   Replace the `af:outputText` in **bold**

```
<af:column sortProperty="name" sortable="false"
```



```
      headerText="#{bindings.Return.hints.name.label}" id="c2">
   <af:outputText value="#{row.name}" id="ot1"/>
</af:column>
```

with an `af:goLink` as shown in **bold**:

```
af:column sortProperty="name" sortable="false"
     headerText="#{bindings.Return.hints.name.label}"
     id="c2">
  <af:goLink text="#{row.name}" id="goLink2"
     destination="#{row.bindings.URI.inputValue}"/>
</af:column>
```

3. In the Structure window, right-click `af:column - URL` and select **Delete**.
4. Right-click the page in the Application Navigator and choose **Run**. You should see a list of hyperlinked file and folder names like the one shown in Figure 28–22. This figure shows the `name` attribute as a link. Clicking a link in the **URI** column opens the respective file or folder and shows its contents.

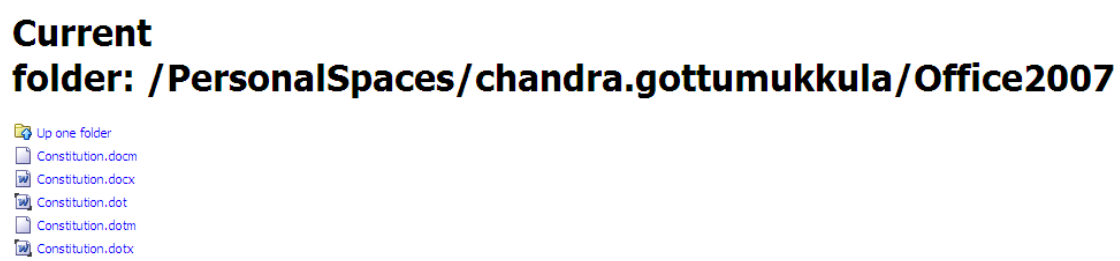


Figure 28–22 Folder Content Displayed as Hyperlinks

ID	name	path	primaryType	icon16	icon32	title	docType	displayName	created

5. Click a file name. The file you pick should appear in a browser window.
6. Click the name of a folder, the contents of the folder display, as shown in Figure 28–23.

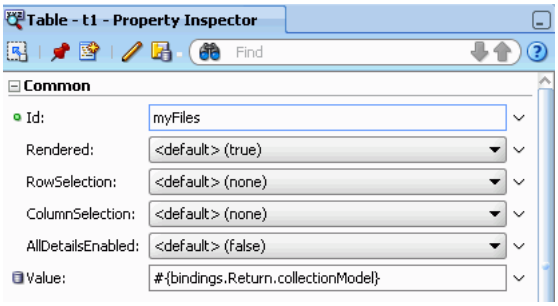

Figure 28–23 Folder Contents

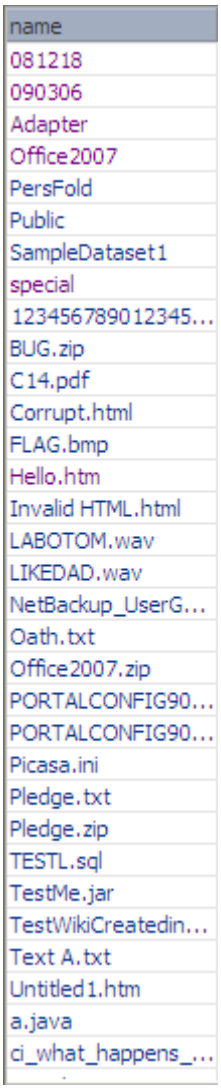
To configure the table to show only the Name column:



1. In the Structure window, under the **af:table - t1** node, delete all but the **Name** column.
2. Double-click the **af:table - t1** node to display the Property Inspector.
3. Under the **Common** tab, in the **Id** field, enter a name, for example `myFiles`, as shown in Figure 28–24.

Figure 28–24 Table Properties - Common Tab

4. Run the page to view the output. Figure 28–25 shows only one column of the table since other rows were removed from the Structure window at design time. This table shows both files and folders, because you left the `type` parameter blank when creating the table.

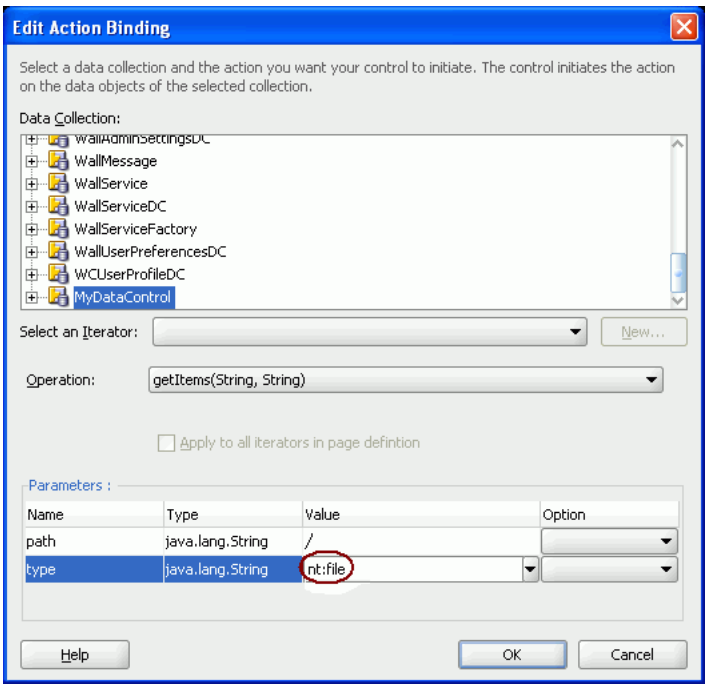
Figure 28–25 Files and Folders Displayed in a Single-Column Table

In the next section, the **Name** column will be configured to show only files.

28.5.3.3 Configuring a Table to Show Only Files

The `type` attribute is used to configure a table to show only files and not folders.

To configure the table to show files:



1. Right-click your page and choose **Go to Page Definition**.

   > **Note:** The `RangeSize` binding setting, which is used to control the number of items displayed on a page, is set to `10` by default in the page definition file. You can change it, as required, in the Property Inspector.

2. In the **Overview** tab, double-click **getItems** under **Bindings**. The Edit Action Binding dialog displays.

3. The **type** options are `nt:file` and `nt:folder`. To specify the display of only files, enter `nt:file` under the **Value** column, as shown in Figure 28–26, and click **OK**.

Figure 28–26 Display Files Only

4. Now run the page. Figure 28–27 shows only files in the single-column table because the column type is `nt:file`.

Figure 28–27 Files Displayed in a Single-Column Table

28.5.4 What Happens at Runtime

The `getItems` method of the JCR data control retrieves the child items of a JCR folder (type `nt:folder`). This method is called with a path to a folder and optionally a type to which the returned child nodes are restricted.

The `path` parameter must be the path of a folder. An exception to this rule is that the root of the repository does not have to be a folder. Hence, the `getItems` method can retrieve the child items for a path that corresponds to a folder, or that is the root of the repository. Otherwise the `getItems` method does not attempt to retrieve the child items and therefore the result set is never populated.

At runtime, the JCR data control calls the `Session.getItem` method. This method returns a JCR node. The data control then calls the `node.getNodes` to retrieve child nodes. The child nodes are filtered according to the specified type; for example, the `nt:file` type. The data control passes on these child nodes to ADF. The data control ensures that the JCR node object is adapted to ADF so that JCR properties are available as data control item attributes that can be consumed through the bindings container.

In the example, each row in the collection returned by the data control is stored as a row in the `af:table` table. However, a column is only displayed for each `af:column` defined in the `af:table`, and not for every possible ADF item attributes returned by the data control. In the first part of the example, the drag and drop action creates an `af:column` for every ADF attribute available for each ADF item returned by the data control.

If the `af:table` is modified to include only the `af:column` for the name, then at runtime it only requests the name of the ADF item. That is, the data control runs a method to fetch the name of the JCR node. At design time, when the name column is converted to an `af:goLink`, the destination of **Go Link** destination is set to the **URI** value of the item, as shown in the following syntax:

```
<af:goLink text="#{row.name}" destination="#{row.URI}"/>
```

At runtime, for each ADF item in the table, the data control runs methods to return both the JCR name of the item and its HTTP URL.

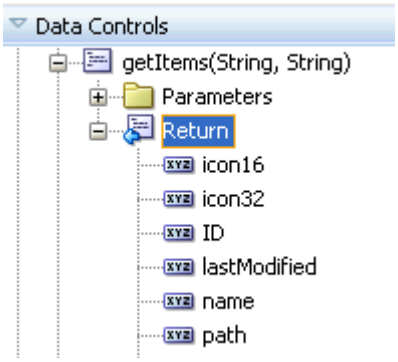
28.5.5 How to Publish Folder Content in a Tree

In this section, you will use the `getItems` method to publish content in a hierarchal tree format. This section describes the following procedures:

- Section 28.5.5.1, "Displaying Files and Folders in Read-Only Format"
- Section 28.5.5.2, "Displaying File Names As Hyperlinks"

Before you begin:

1. Configure a repository connection as described in Section 27.2, "Configuring Content Repository Connections".
2. Configure a data control as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".
3. Create a page as described in Section 5.3, "Adding Pages to a Portal."



28.5.5.1 Displaying Files and Folders in Read-Only Format

In this section, you will display your content in the tree format.

To display your content in the tree format:

1. In the Application Navigator, double-click your page to open it in the design view.
2. In the Data Controls panel, under your data control, expand the **getItems** method as shown in Figure 28–28.

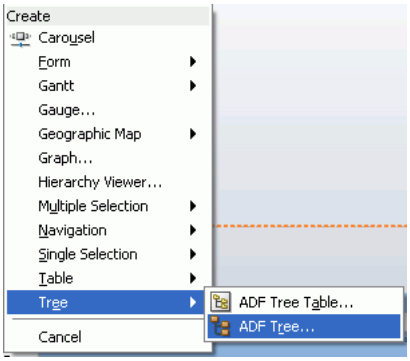


Figure 28–28 Parameters of the getItems Method

3. To display your content as an **ADF Tree**, select the **Return** node and drag it onto the page. From the Create menu, choose **Tree** and then **ADF Tree**, as shown in Figure 28–29.

   If this is the first time you have dropped a node onto the page, the Edit Action Binding dialog displays.

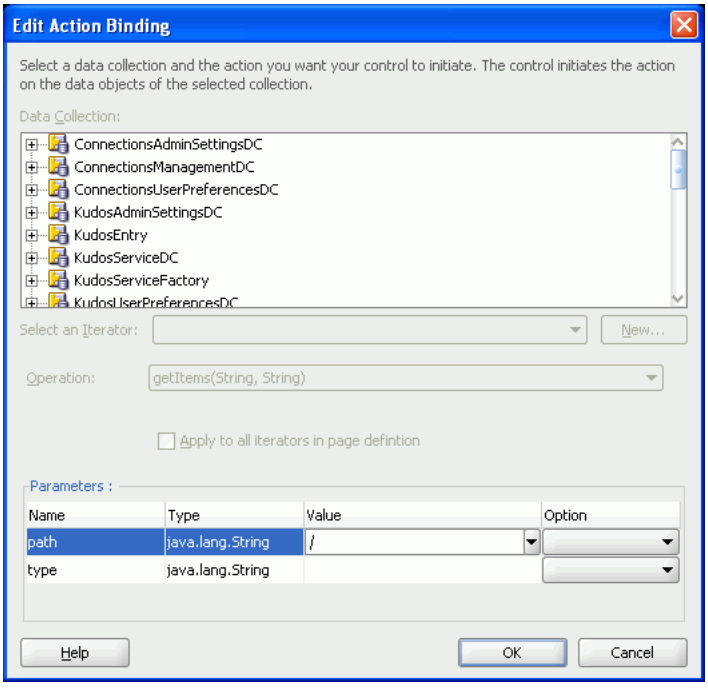

Figure 28–29 Oracle JDeveloper Create Menu for getItems

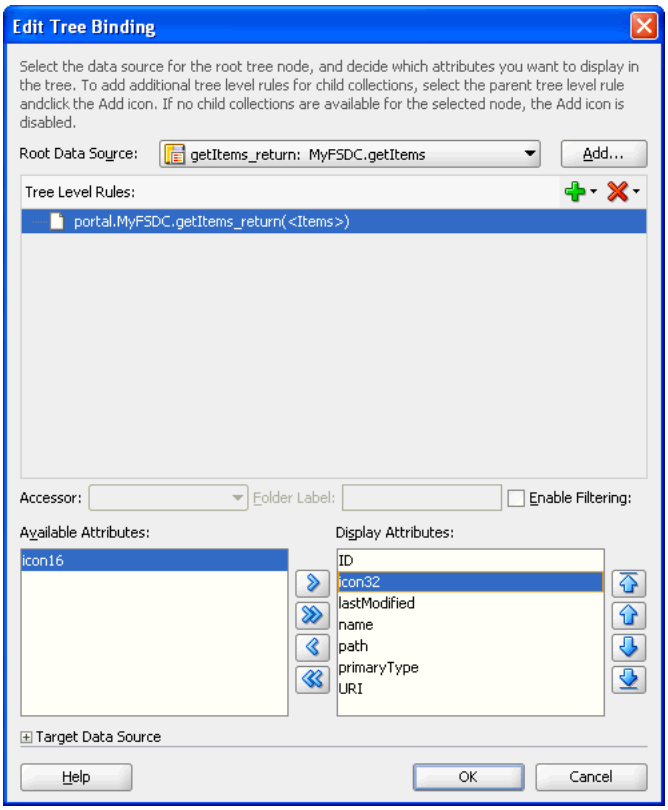
4. To create a tree that displays everything under the base path, enter the slash (`/`) for the `path` parameter, as shown in Figure 28–30. To modify or delete this path later, click the arrow icon next to the node in the design mode and choose **Go to Binding** from the context menu.

   Leave the `type` parameter blank to show both files and folders.

Figure 28–30 The Edit Action Binding Dialog



5. Click **OK**. The Edit Tree Binding dialog displays.

6. To show item names, paths, and types at runtime, under **Available Attributes**, select the desired attributes and move them to the **Display Attributes** list.

7. In the **Tree Level Rules** box, click the **Add Rule** icon and select **Items** to create a rule, as shown in Figure 28–31, which enables the tree to find its child items.

Figure 28–31 Edit Tree Binding

8. Click **OK.** A tree displays in the page that looks like Figure 28–32.

Figure 28–32 Tree for Navigating Folder Content

9. Run your page to display the results.

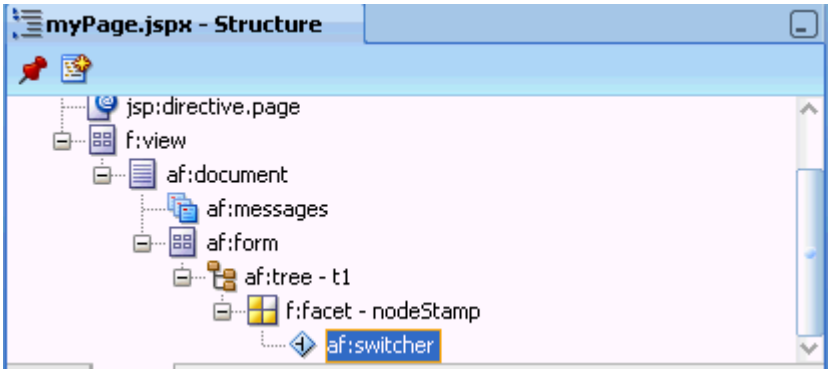
   When the page appears in your browser window, you should see a list of files and folders available through your data control. Figure 28–33 displays a tree of files and folders in the read-only format based on **ADF tree** dropped on the JSF page. Expand a branch to see the content in this subdirectory.

> **Note:** By default, the range size is `10`. To change the number of items displayed in the tree, edit the **RangeSize** property for the data control in the page definition file (*name*`PageDef.xml`).

Figure 28–33 Folder Content Displayed in a Tree

By default, the tree displays file and folder names as read-only text. The next section describes how to create hyperlinks to file names. In the following section, folder names will remain read-only text because they are required for navigation through the tree.

28.5.5.2 Displaying File Names As Hyperlinks



To create hyperlinks to file names and to keep folder names read-only, you need the `af:switcher` component with two facets: one for folders and one for files.

To use the Switcher component for folders and files:

1. In the Structure window, navigate to `f:facet - nodeStamp` and delete `af:outputText-#{node}`.
2. Right-click **nodeStamp** and choose **Insert inside f:facet - nodeStamp** and then **Browse**.
3. In the Insert Item dialog, from the dropdown list for selecting the category, select **ADF Faces**.
4. From the **Select the item to be created** list, select **Switcher**, and click **OK**.

   A Switcher is added under **f:facet - nodeStamp** in the Structure window, as shown in Figure 28–34.

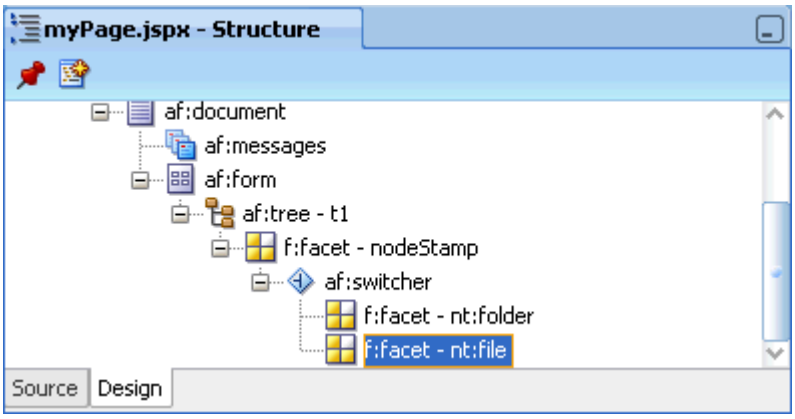


Figure 28–34 Output Text Converted to a Switcher Component

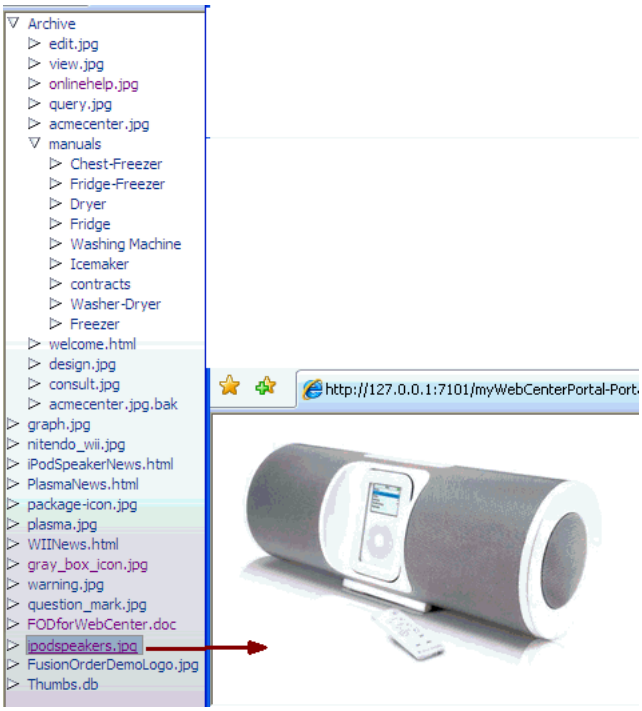
5. Double-click **af:switcher** to display the Property Inspector, if it is not displayed.



6. Under the **Common** tab, in the **FacetName** field, enter the expression `#{node.primaryType}`.
7. In the Structure window, insert two facets for the switcher. Right-click **af:switcher**, choose **Insert Inside af:switcher** and then **Facet**. The Insert Facet dialog displays.
8. Name the first facet `nt:folder` and click **OK**. Folder names require no additional formatting, so you can display the node names as plain text. Name the second facet `nt:file`. The facets look like Figure 28–35.

Figure 28–35 Switcher Component with Two Facets

9. Right-click **f:facet - nt:folder**, choose **Insert Inside f:facet - nt:folder** and then **Browse**.
10. In the Insert Item dialog, choose **ADF Faces** from the dropdown list.
11. From the **Select the item to be created** list select **Output Text** and click **OK**.
12. Double-click **af:outputText - outputText1** to display the Property Inspector, if it is not displayed already. Under the **Common** tab, in the **Value** field, enter the expression `#{node.name}`.
13. Right-click **f:facet - nt:file**, choose **Insert Inside f:facet - nt:folder** and then **Browse**.
14. In the Insert Item dialog, choose **ADF Faces** from the dropdown list.
15. From the **Select the item to be created** list select **Go Link** and click **OK**.
16. In the Structure window, double-click **af:goLink - goLink** to display the Property Inspector, if it is not already displayed.
17. Under the **Common** tab, in the **Text** field, enter the `#{node.name}` expression.
18. In the **Destination** field, enter the expression `#{node.URI}`.
19. From the **TargetFrame** list, select **_blank**.
20. Run the page. Figure 28–36 displays files names as hyperlinks, because the `nt:file` facet of the switcher under `af:tree` was converted to a link (`node.URI`). Clicking a link displays the respective item.

Figure 28–36 Tree with File Names as Hyperlinks

28.5.6 What Happens at Runtime

The JCR data control `getItems` method is designed to retrieve the child items of a JCR folder (type `nt:folder`). The method is invoked with a path to a folder and optionally a type to which the returned child nodes are restricted. The `path` parameter must be the path of a folder for the `getItems` method to retrieve the child items. An exception to this rule is that the root of the repository does not have to be a folder. Hence, the `getItems` method can retrieve the child items for a path that corresponds to a folder, or that is the root of the repository. Otherwise the `getItems` method does not attempt to retrieve the child items and therefore the result set is never populated. If the path is valid, then the data control invokes `JCR Session.getItem()` on this path which returns a JCR node, and then it invokes `node.getNodes()` to retrieve all child nodes. The child nodes are filtered according to the type supplied; for example, to return only the `nt:file` type child node. This is the result that is provided by the data control to ADF. The data control ensures that the JCR node object is adapted to ADF such that JCR properties are available as data control item attributes that can be consumed by way of the bindings container.

The `af:tree` renders each node in the collection returned by the data control as a node in its tree. In the first part of the example, it displays the `name`, `type`, and `URI` for each node. Each of these values is retrieved through the data control. When the switcher is added to the `af:tree` the node's `primaryType` value is used to differentiate how a node is rendered. If the node is of primary type `nt:folder`, then only its name is shown in the tree node. However if the node is of type `nt:file`, then the node renders `go:Link`, the destination of which is the node's URI. The data control `getItems` method is invoked again to retrieve the child nodes of any folder node in the tree.

28.5.7 How to Add Search Capabilities to Content Repositories

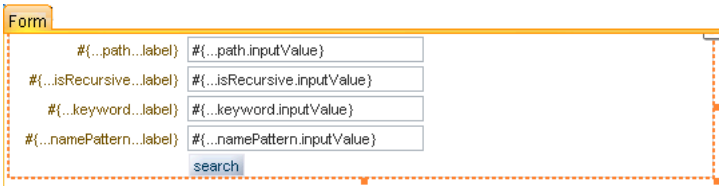
With the help of two examples, this section describes how to add simple and advanced search capabilities for the integrated content. The simple search enables users to search for the content based on name or content fragments in specific locations. The advanced search enables users to search by attribute values of the content.

This section contains the following:

- Section 28.5.7.1, "Adding Simple Search Capabilities"
- Section 28.5.7.2, "Adding Advanced Search Capabilities"

Before you begin:

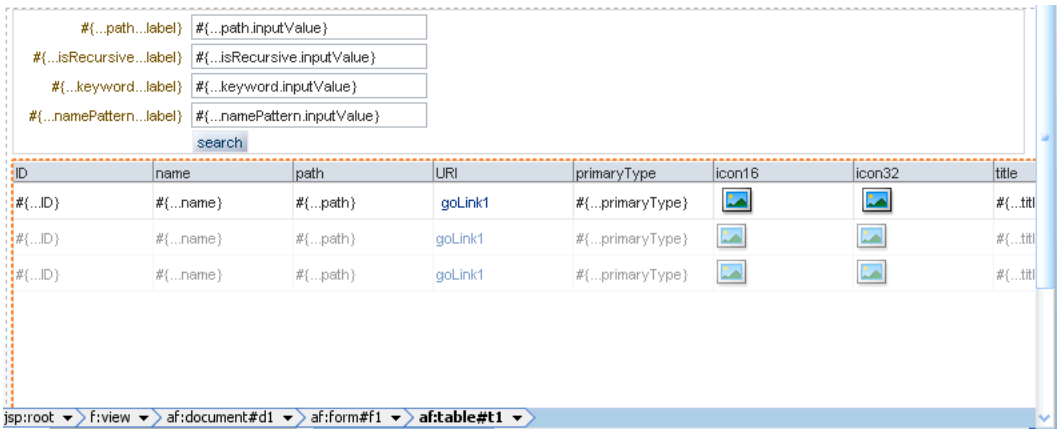
1. Configure a repository connection as described in Section 27.2, "Configuring Content Repository Connections".
2. Configure a data control as described in Section 28.2, "Configuring Content Data Controls for JCR Adapters".
3. Create a page as described in Section 5.3, "Adding Pages to a Portal."



28.5.7.1 Adding Simple Search Capabilities

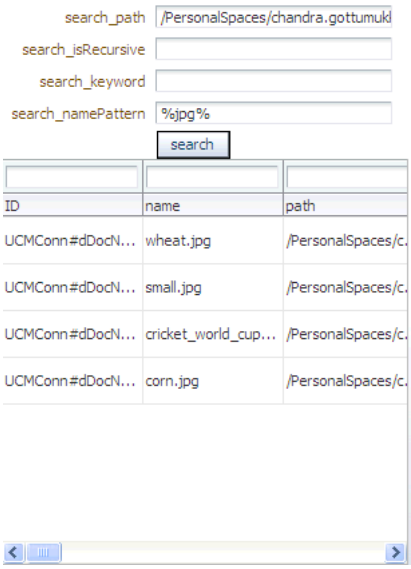
In this section, you will enable simple search capabilities in your page. This will let you perform wildcard (%) search.

To enable the search function:



1. In the Application Navigator, double-click your page to open it.
2. In the Data Controls panel, select the **search** node.
3. To enable users to perform a search by clicking a button, drag and drop the **search** node on your page. From the Create menu, choose **Parameters** and then **ADF Parameter Form**. The Edit Form Fields dialog displays.
4. Click **OK**. The ADF parameter form is added to the page, as shown in Figure 28–37

Figure 28–37 ADF Parameter Form in the Design View



5. To enable the display of search results in a read-only table, drag and drop the **Return** node onto the page. From the **Create** menu, choose **Table** and then **ADF Read-Only Table**. The Edit Table Columns dialog displays.
6. Click **OK**. A table similar to Figure 28–38 displays.

Figure 28–38 Table with Four Columns - search

7. Run this page and specify `/` for **search_path** and `%jpg%` for **namePattern**. All `.jpg` files stored in the root of your repository display, as shown in Figure 28–39.

Figure 28–39 Search Results for .jpg Files

28.5.7.2 Adding Advanced Search Capabilities

In this section, you will add advanced search capabilities to your page that will enable you to perform search based on the last modified dates of items located in your file system repository.

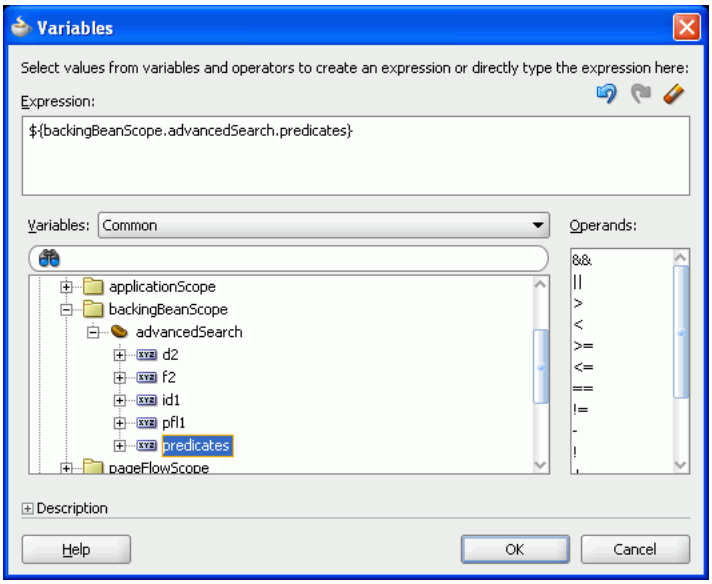
To enable the advanced search function:

1. In the Application Navigator, open your page in which you intend to create the advanced search function. The page must be automatically exposed in new managed bean, where name=`advancedSearch`, class=`AdvancedSearch`, package=`view`. (In the Create JSF Page dialog > Page Implementation > Automatically Expose UI Components in a New Managed Bean)

   In this example the page is called `advancedSearch.jspx`.

2. Double-click the page to open it.

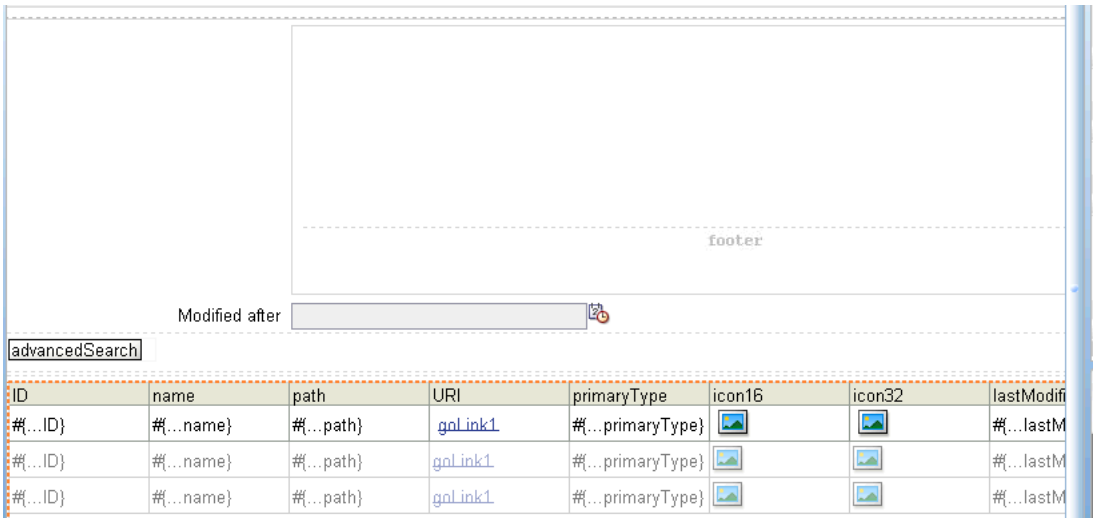
3. In the Component Palette, select **ADF Faces**.
4. From the list of **ADF Faces - Layout** components, drag **Panel Form Layout** onto the page.
5. From the Component Palette, drag **Input Date** into the **Panel Form Layout**.
6. In the Property Inspector, under the **Common** tab, set the **Label** to **Modified after**.
7. In the Application Navigator, under **portal.backing**, double-click **AdvancedSearch.java** to open it.
8. Add the following import declarations. These declarations are required for the `getPredicates` method, which will be added in the next step.



```
import java.util.ArrayList;
import java.util.Calendar;
import java.util.Date;
import java.util.List;
import oracle.vcr.datacontrol.search.Predicate;
import oracle.vcr.datacontrol.search.Operator;
```

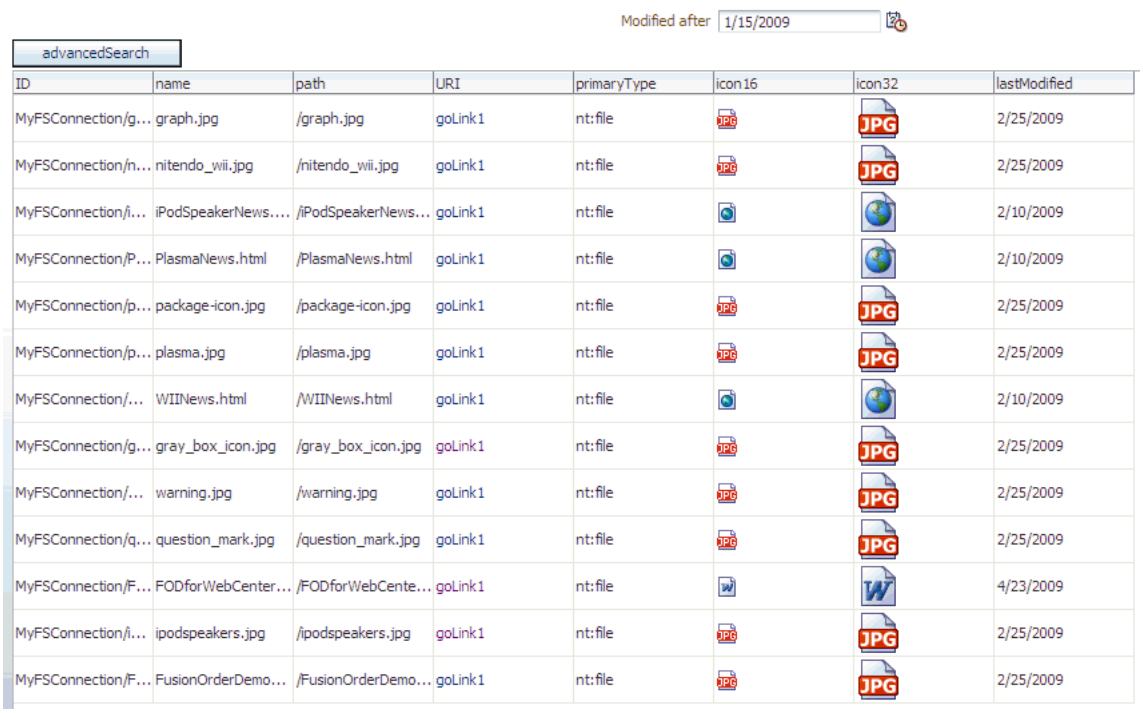
9. Add the following method to enable the advanced search based on last modified dates of the items stored in the repository:

```
public List<Predicate> getPredicates() {
        ArrayList<Predicate> predicates = new ArrayList<Predicate>();
        if (id1.getValue() != null && !id1.getValue().equals(""))
{
            Calendar cal = Calendar.getInstance();
            cal.setTime((Date)id1.getValue());
            predicates.add(new Predicate("jcr:content/jcr:lastModified"
                                         , Operator.GREATER_THAN
                                         , cal));
        }
        // ... other predicates
        if (predicates.size()>0)
            return predicates;
        return null;
    }
```



10. From the Data Controls panel, drag the **advancedSearch** node onto the page. From the Create menu, choose **Methods** and then **ADF Button**. The Edit Action Binding dialog displays.
11. For **Path**, specify the path to the directory in which the search will be performed; for example, `/`. For **isRecursive** specify `true`, and **matchAny** specify `false`.
12. For predicates, select the arrow next to the **Value** field and then select **Show El Expression Builder**. The Variables dialog displays.
13. Expand **ADF Managed Beans**, **backingBeanScope**, **advancedSearch** and select **predicates**. This adds the expression `${backingBeanScope.advancedSearch.predicates}`, as shown in Figure 28–40, and click **OK**.

Figure 28–40 Variables Dialog - predicates



14. Click **OK** in the Edit Action Binding dialog.
15. In the Data Controls panel, expand the **advancedSearch** node. Then drag **Return** and drop it onto the page, after the advancedSearch ADF button. From the Create menu, choose **Table** and then **ADF Read-only Table**.
16. In the Edit Table Columns dialog, edit labels of the columns, if needed. Then click **OK**. The Design view looks like Figure 28–41.

Figure 28–41 Advanced Search - Design View

17. In the Property Inspector, under the **Behavior** tab, set the `ContentDelivery` property to `immediate`.
18. To view the page in a browser, under the Application Navigator, right-click the page and choose **Run**. The `advancedSearch` page displays in the browser.
19. Enter a *last modified* date and click the **advancedSearch** button. The files modified after that date are displayed, as shown in Figure 28–42.

Figure 28–42 Advanced Search Results

MyFSConnection/F...	FusionOrderDemo...	/FusionOrderDemo...	goLink1	nt:file			2/25/2009

28.5.8 What Happens at Runtime

Clicking the **search** button at runtime invokes the `search` method and the values provided through the UI are used as the parameters for the search. At runtime, you can perform the wild (`%`) card search. For example, to search for files that have `.jpg` extension, enter `/` in the **search_path** field, enter `%jpg` in the namePattern field and then click **Search**. All files with the `.jpg` extension will display in the read-only table.

At runtime the JCR data control uses the given parameters to construct an `XPath` query for the given parameters. For the simple search example, the query is:

```
Non-recursive:
XPath query /jcr:root/element(*, nt:file)[jcr:like(ojcr:local-name(), '%jpg%')]

Recursive:
XPath query /jcr:root//element(*, nt:file)[jcr:like(ojcr:local-name(), '%jpg%')]
```

In the advanced search example, first a backing bean is added to the page, because the backing bean is required to construct the `predicate` parameter value of the `advancedSearch` method. Then the **Panel Form Layout UI** component is dropped onto the page. In this component, the `InputDate` component is dropped, which is used at runtime to supply the date-based search criterion. The `advancedSearch` method predicates parameter allows for a combination of predicates to be supplied to the `search` method. Each can specify the value of an item's properties that must apply for the search. In this example, only a modification date is tested in the predicates, but potentially multiple tests could be included, for example a modification date and a `mimeType`.

The backing bean's `getPredicates` method is hardcoded to construct the `predicates` method from the date provided by the page at runtime. At design time, the return value of the `predicates` method is bound into the predicates `advancedSearch` method parameter. At runtime this invokes the `getPredicates`

method before invoking the `advancedSearch` method to construct the correct `predicate` value.

At runtime the JCR data control uses the given parameters to construct an `XPath` query for the given parameters. For this example the query is:

```
/jcr:root//element(*, nt:hierarchyNode)[jcr:content/@jcr:lastModified >
xs:dateTime('2009-02-15T00:00:00.000+05:30')]
```

28.5.9 What You May Need to Know When Using Search Capabilities

Consider the following points while adding search capabilities:

- How certain operations work depends on the implementation of the adapter and the underlying repository. While read and query operations are similar, full text search works differently. Another example is, the file system and Oracle Portal adapters do not support search based on the `primaryType` attribute. The only supported way to search based on type is through the element (`*`, type) construct.
- If you use the Oracle Portal adapter, then the behavior of search functionality varies depending on whether Oracle Text is enabled or not. If Oracle Text is disabled, then the search is performed in the Oracle Portal content metadata. With Oracle Text turned on, all indexed content is searched, which includes the contents of files. This also applies to Content Server. That is, Content Server-based adapter performs full text index operation on its documents using Oracle Text.
- The Oracle Portal adapter does not support translations and only returns content in the base language of a page group. Searching across multiple page groups with different base languages is not supported.

29

Creating Content Presenter Display Templates

The Content Presenter task flow allows authorized users to retrieve content from Content Server and display it in a WebCenter Portal application in real time, without assistance from an IT Department or software developers. For example, you might want to display a list of the most recent Press Releases so users can browse them and click one to read it. You can place images (a photograph or a chart, for example) or add textual content to the portal.

> **Note:** Content Presenter can only be used with Content Server based content. No other repository connection types are supported.

Content Presenter renders content using a selected *display template*. The primary focus of this chapter is creating *Content Presenter display templates*. You can create a Content Presenter template to satisfy your particular content rendering requirements or to handle your own custom content properties.

This chapter includes these topics:

- Section 29.1, "Adding Content Presenter to an Application"
- Section 29.2, "What Is a Content Presenter Display Template?"
- Section 29.3, "Using the Out-of-the-Box Display Templates"
- Section 29.4, "Creating Content Presenter Display Templates"
- Section 29.5, "Using Content Presenter Display Templates in a Framework Application"
- Section 29.6, "What Happens at Runtime?"
- Section 29.7, "Performance Considerations for Content Presenter Display Templates"

29.1 Adding Content Presenter to an Application

You can add a Content Presenter task flow at design time or runtime. For details on adding Content Presenter at design time (using JDev), see Chapter 31, "Adding Content Task Flows and Document Components to a Portal Page." For details on adding and using Content Presenter at runtime, see "Publishing Content Using Content Presenter" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

29.2 What Is a Content Presenter Display Template?

A *Content Presenter display template* is a JSFF file (JSF page fragment) that defines how Content Presenter renders content items on a portal page. WebCenter provides several out-of-the-box display templates to get you started, and you can create your own templates.

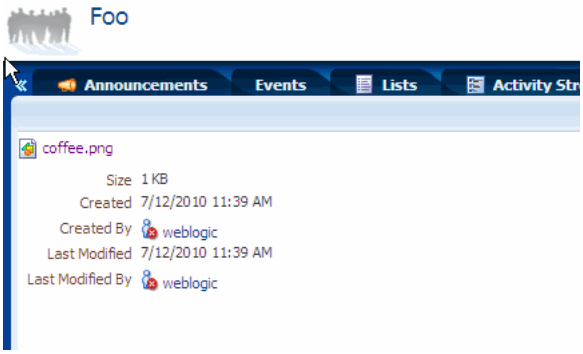
> **Tip:** You can find sample display templates in `$ORACLE_HOME/jdeveloper/webcenter/samples/contentpresenter`. These sample files were installed as part of WebCenter Portal's extension for Oracle JDeveloper.

Display templates can use the full set of Rich ADF components, so you can quickly and easily create robust and attractive templates to display your content. Note, however, that you are not required to use these components in your template.

A Content Presenter display template can handle either single content items, multiple content items, or combinations of the two. For example, a multiple content item template might render tabs for each item and then call a single item template to render the details of a selected item.

Each content item is associated with a specific *content type* defined in the Content Server repository. A content type defines the properties of the content item. Content types can map to Content Server profile definitions and Site Studio region definitions. Types are created on the Content Server. As a Content Presenter display template developer, you need to know the names of the properties defined for the associated content type so that you can define how to display the selected content item(s) on the page.

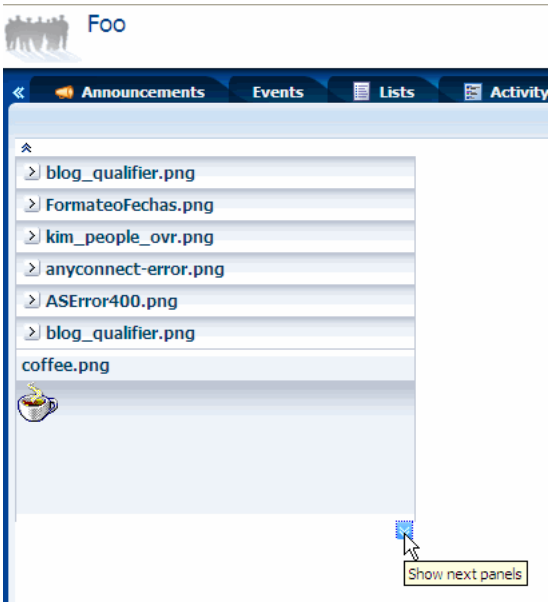
> **Tip:** One way to determine the properties for the existing content types defined in Content Server is to use the Content Presenter Configuration dialog in WebCenter Portal: Spaces. For a detailed description of this technique, see Section 29.4.5, "Discovering Content Type Property Names."



At runtime, an authorized end user can choose a display template in the Content Presenter Configuration dialog.

29.3 Using the Out-of-the-Box Display Templates

WebCenter Portal provides several out-of-the-box Content Presenter display templates. These pre-built templates provide options for displaying single content items and multiple content items.



For example, the Default Document Details View template displays detailed information about any single content item including creation date, modification date, created by username, modified by username, path and any comments. Figure 29.1 shows a content item displayed at runtime with this template.

Figure 29–1 Default Document Details View Display Template

Several options are provided for displaying multiple content items, such as the Accordion View, which Displays multiple content items in an accordion format. In this format, each item can be expanded to display its details, as shown in Figure 29–2.

Figure 29–2 Accordion View Display Template

For a complete list of out-of-the-box display templates, see Section 31.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates."

> **Tip:** If you intend to create a Content Presenter display template, a good practice is to copy one of the out-of-the-box templates and modify it.

29.4 Creating Content Presenter Display Templates

If the out-of-the-box display templates (see Section 29.3, "Using the Out-of-the-Box Display Templates") do not meet your needs, you can define custom Content Presenter templates.

This section discusses these topics:

- Section 29.4.1, "Overview"

- Section 29.4.2, "Defining Single-Item Display Templates"
- Section 29.4.3, "Defining Multiple-Item Display Templates"
- Section 29.4.4, "Using EL Expressions to Retrieve Content Item Information"
- Section 29.4.5, "Discovering Content Type Property Names"

29.4.1 Overview

Depending on your needs, the approach you take to defining Content Presenter display templates will vary. Typically, you define display templates for specific single items of content, then define a multiple content item display template that includes calls to the single item display templates.

Template definitions can include calls to other display templates in any of the following ways:

- A single content item display template can call another single content item display template.
- A multiple content item display template can call a single content item display template (as shown in the examples below).
- A multiple content item display template can call another multiple content item display template.

The basic tasks for creating Content Presenter display templates include:

- Deciding whether to create a single or multiple item display template. See Section 29.4.2, "Defining Single-Item Display Templates" and Section 29.4.3, "Defining Multiple-Item Display Templates."
- Deciding what kind of information you want to display with content items. WebCenter Portal provides a set of EL expressions designed to retrieve and display this information. See Appendix G, "Expression Language Expressions" and Section 29.4.4, "Using EL Expressions to Retrieve Content Item Information."
- Designing the look and feel of the template. In addition to standard JSFF constructs, display templates can use ADF components. See *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.
- Exporting the template as a portal resource. See Section 29.5.1, "Export a Content Presenter Display Template as a Portal Resource."

29.4.2 Defining Single-Item Display Templates

Examples of single content items for which you may want to create Content Presenter display templates are:

- Individual items to display with a specific look and feel on a page.
- Different views of a specific type of item (such as short and detailed views of an article).
- Different versions of a similar item (such as Press Releases that may be formatted differently for different groups, using a different set of properties).

The definition of a single content item display template uses the JSP tags listed in Table 29–1.

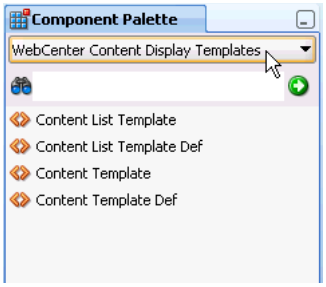
Table 29–1 Content Display Template Tags for Single Content Items

JSP Tag	Description	Example

`contentTemplateDef`	Required. Defines a single content item template.
	Attributes:
	`var` - Specifies the content node that will be rendered by this display template. In the template definition code, you can use the EL expressions described in Section 29.4.4.1, "Retrieving Basic Information About a Content Item" to retrieve required information about the node.
		`<dt:contentTemplateDef var="node">`
		`  <af:outputText value="#{node.name}" />`
		`</dt:contentTemplateDef>`

`renderProperty`	Optional. Retrieves and renders the string value(s) of the specified node property inline.
	Attributes:
	`id` - Identifies this component. This value must be unique within the closest parent component that is a naming container.
	`name` - Specifies the name of the property to get. If this is a system property (`cm_createdBy`, `cm_createdDate`, `cm_modifiedDate`, and `cm_path`) then the value on the node will be used. If not specified, then the `primaryProperty` will be used if defined.
	`node` - Specifies the node to use. This value can either be a bound attribute to a managed bean, or a request attribute variable.
	`blockSize` - Specifies the size of the blocks in bytes, to read the bytes of a binary property. Default is 2048 bytes.
	`startIndex` - Specifies the index (from 0) in the document's bytes at which to start printing. Defaults to 0.
	`endIndex` - Specifies the index (from 0) in the document's bytes at which to stop printing. Defaults to value of `blockSize`.
	`rendered` - Specifies whether or not this component should be rendered (during Render Response Phase), or processed on any subsequent form submit. The default value is `true`.
		`<!--`
		`  Handling of text-based primary`
		`  properties (HTML, text, etc.).`
		`-->`
		`<dt:contentTemplateDef var="node">`
		`  <cmf:renderProperty id="rp1"`
		`  name="#{node.primaryProperty.name}"`
		`  node="#{node}"/>`
		`</dt:contentTemplateDef>`

Table 29–1 (Cont.) Content Display Template Tags for Single Content Items



JSP Tag	Description	Example

`contentTemplate`	Optional. Nested under `contentTemplateDef`.
	Calls another single item template.
	Attributes:
	`node` - Required. Specifies the content repository node that should be displayed.
	`nodesHint` - Optional. When the display template is called in an iterating component, allows the pre-inclusion of all possible templates. This attribute is not needed when `contentTemplate` is used inside a `contentTemplateDef` tag.
	`view` - Optional. Specifies the target view name.
	`id` - Optional. Specifies the JSF component ID.
	`rendered` - Optional. Specifies whether the component should be rendered.
		`<dt:contentTemplateDef var="node">`
		`<af:outputText value="#{node.name}" >`
		`<dt:contentTemplate node="#{node}"`
		`view="templates.pressrelease.item"`
		`/>`
		`</af:outputText>`
		`</dt:contentTemplateDef>`

To define a display template for a single content item:

1. In JDeveloper, create a JSFF file:
   a. From the **File** menu, choose **New**.
   b. In the New Gallery dialog, expand **Web Tier**, select **JSF**, then **JSF Page Fragment**.
   c. Click **OK**.
   d. In the Create New JSF Page Fragment dialog, enter a name for the display template file.
   e. Set the Directory field to point to the oracle/webcenter/portalapp/pages folder of your portal web project. This directory must be set from the correct root path. In JDeveloper, the root path is *PROJECT_NAME* > Web Content. On the file system, the root path is *PROJECT_ROOT*/public_html. For example: *PROJECT_ROOT*/public_html/oracle/webcenter/portalapp/pages. A good practice is to first create a subfolder in `pages` and store the JSFF in the subfolder.
2. Select **View**, then **Component Palette** to open the Component Palette.
3. From the dropdown list at the top of the Component Palette (Figure 29–3):
   - Select **WebCenter Content Display Templates** for a list of display template tags.
   - Select **WebCenter Content Management Faces** for the `renderProperty` tag.

Figure 29–3 Content Display Template Tags in Component Palette

4. In Source view, drag and drop the required display template tags from the Component Palette onto the page to define your template. Refer to Table 29–1 for information about each tag and required parameter values.

Example 29–1 and Example 29–2 show sample single content item display template definitions. These examples illustrate a use case where a certain kind of document (a press release) is produced by two different departments inside a company, and each department has defined its own content type and properties. These sample Content Presenter display templates allow these two different content types to be displayed in a consistent manner.

The template shown in Example 29–1 handles a Press Release that uses a property named `xHeading` to describe the heading of the Press Release document, and `xDestinationUrl` to describe the location of the document. To learn how you can obtain these property names for a given content type, see Section 29.4.5, "Discovering Content Type Property Names."

Example 29–1 Sample Content Presenter Display Template for a Press Release Document

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
          version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
   <dt:contentTemplateDef var="node">
      <af:goImageLink text="#{node.propertyMap['xHeading'].value}"
                      id="gil1"
                      icon="#{node.icon.smallIcon}"
                      destination="#{node.propertyMap['xDestinationUrl'].value}"
                      targetFrame="_blank">
      </af:goImageLink>
   </dt:contentTemplateDef>
</jsp:root>
```

The template shown in Example 29–2 handles a Press Release that uses a property named `dDocTitle` to describe the heading of the Press Release document, and `xLinkUrl` to describe the location of the document.

Example 29–2 Sample Content Presenter Template for Another Press Release Document

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page"
          version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
```

```
   <dt:contentTemplateDef var="node">
      <af:goImageLink text="#{node.propertyMap['dDocTitle'].value}"
                      id="gil1"
                      icon="#{node.icon.smallIcon}"
                      destination="#{node.propertyMap['xLinkUrl'].value}"
                      targetFrame="_blank">
      </af:goImageLink>
   </dt:contentTemplateDef>
</jsp:root>
```

29.4.3 Defining Multiple-Item Display Templates

Examples of multiple content items for which you may want to create Content Presenter display templates are:

- A group of similar items that you want to display on a page, such as a list of books or an employee directory of pictures.
- Query results, such as all documents modified in the last week.
- A list of all documents in a Content Server folder.

The definition of a multiple content item display template uses the JSP tags listed in Table 29–2.

Table 29–2 Content Display Template Tags for Multiple Content Items

JSP Tag	Description	Example

`contentListTemplateDef`	Required. Defines the multiple content item template.
	
	Attributes:
	
	`var` - Specifies the content node that will be rendered by this display template. In the template definition code, you can use the EL expressions described in Section 29.4.4.1, "Retrieving Basic Information About a Content Item" to retrieve required information about the node.
		`<dt:contentListTemplateDef var="nodes">`
		`  <af:iterator value="#{nodes}" var="node">`
		`  <af:outputText value="#{node.name}" />`
		`  </af:iterator>`
		`</dt:contentListTemplateDef>`

Table 29–2 (Cont.) Content Display Template Tags for Multiple Content Items

JSP Tag	Description	Example

`contentListTemplate`	Optional. Nested under `contentListTemplateDef`.
	Calls another multiple item template.
	Attributes:
	`nodes` - Required. Provides the list of VCR nodes that should be displayed
	`category` - Required. Specifies the target template category.
	`view` - Required. Specifies the target view name.
	`id` - Optional. Specifies the JSF component ID.
	`rendered` - Optional. Specifies whether the component should be rendered.
		`<dt:contentListTemplateDef var="nodes">`
		`<!--`
		`Reuse the default bulleted list view, but indent it with a <blockquote>`
		`-->`
		`<f:verbatim>`
		`<blockquote>`
		`</f:verbatim>`
		`<dt:contentListTemplate nodes="#{nodes}"`
		`category="oracle.webcenter.content.templates.default.category"`
		`view="oracle.webcenter.content.templates.default.list.bulleted"/>`
		`<f:verbatim>`
		`</blockquote>`
		`</f:verbatim>`
		`</dt:contentListTemplateDef>`

`contentTemplate`	Optional. Nested under `contentListTemplateDef`.
	Calls a single item template.
	Attributes:
	`node` - Required. Specifies the content repository node that should be displayed.
	`nodesHint` - Optional. When the display template is called in an iterating component, allows the pre-inclusion of all possible templates. This attribute is usually required when `contentTemplate` is used inside a `contentListTemplateDef` tag.
	`view` - Optional. Specifies the target view name.
	`id` - Optional. Specifies the JSF component ID.
	`rendered` - Optional. Specifies whether the component should be rendered.
		`<dt:contentListTemplateDef var="nodes">`
		`<af:iterator rows="0" var="node"`
		`varStatus="iterator" value="#{nodes}">`
		`<dt:contentTemplate node="#{node}"`
		`view="templates.pressrelease.listitem"`
		`nodesHint="#{nodes}"/>`
		`</af:iterator>`
		`</dt:contentListTemplateDef>`

To define a display template for multiple content items:

1. In JDeveloper, create a JSFF file and open the Component Palette, as described in Step 1 through Step 3 in Section 29.4.2, "Defining Single-Item Display Templates".
2. In Source view, drag and drop the required display template tags from the Component Palette onto the page. Refer to Table 29–2 for information about each tag and required parameter values.

Example 29–3 shows a sample multiple content item display template definition.

Example 29–3 Sample display template definition for the display of multiple Press Releases (press-release-list-view.jsff)

This template definition iterates over the data items selected for display, and processes them according to the referenced view (`view="mycorp.content.templates.pressrelease.listitem"`).

```
<?xml version = '1.0'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:dt="http://xmlns.oracle.com/webcenter/content/templates">
   <dt:contentListTemplateDef var="nodes">
      <af:panelGroupLayout layout="scroll" id="nodeListPanel" valign="middle">
        <af:iterator rows="0" var="node" varStatus="iterator" value="#{nodes}">
           <dt:contentTemplate node="#{node}"
               view="mycorp.content.templates.pressrelease.listitem"
               nodesHint="#{nodes}"/>
        </af:iterator>
      </af:panelGroupLayout>
   </dt:contentListTemplateDef>
</jsp:root>
```

29.4.4 Using EL Expressions to Retrieve Content Item Information

This section describes the EL expressions that you can use in your Content Presenter display template definitions to retrieve and display specific information about content items.

Use the EL expressions described in the following tables as you define your Content Presenter display templates as explained in Section 29.4.2, "Defining Single-Item Display Templates" and Section 29.4.3, "Defining Multiple-Item Display Templates." These expressions are used with the JSP tags described in Table 29–1 and Table 29–2.

29.4.4.1 Retrieving Basic Information About a Content Item

The EL expressions listed in Table 29–3 allow you to display basic information about a content item in a display template.

Table 29–3 EL Expressions for Retrieving Basic Content Information

EL Expression	Description
`#{node.createdBy}`	Returns the user name of the node's creator.
`#{node.createdDate}`	Returns the node's creation date.
`#{node.hasParentNode}`	Returns `true` if the current node has a valid parent node ID, or a node that has no parent.
`#{node.icon}`	Returns the icon service defined in the current web application.
`#{node.id}`	Returns the node's identifier.
`#{node.isFolder}`	Returns `true` if this node is associated with a folder or container.
`#{node.isInherited}`	Returns `true` if this node is inherited by another object class definition.
`#{node.modifiedBy}`	Returns the user name of the node's last modifier.
`#{node.modifiedDate}`	Returns the node's last modification date.
`#{node.name}`	Returns the node's name.

Table 29–3 (Cont.) EL Expressions for Retrieving Basic Content Information

EL Expression	Description
`#{node.parentId}`	Returns the parent node's identifier.
`#{node.path}`	Returns the node's path.
`#{node.primaryProperty}`	Returns the node's primary property, if available.
`#{node.propertyMap}`	Creates and returns a map of wrapped property objects, keyed by property name. Properties can be accessed as `#{node.propertyMap['myProp']}` or `#{node.propertyMap.myProp}`.
`#{node.url}`	Returns an instance of the node property URL service for the primary property of this node (if any). By default, resolves to `#{node.url.renderUrl}`. This is a shortcut for `#{node.primaryProperty.url}`.

29.4.4.2 Working with Content Item Properties and Values

Use the EL expression described in Table 29–4 and Table 29–5 to perform actions on content item node properties and property values.

Tip: To determine the names of the properties defined for a given content type, see Section 29.4.5, "Discovering Content Type Property Names."

Table 29–4 EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp']'myProp'].asTextHtml}`	Returns this property as text or HTML if the type is text or HTML. If `isHTML` or `isPlainText` is `true`, the text or HTML is returned as a string.
`#{node.propertyMap['myProp'].hasValue}`	Returns `true` if a value is associated with this property.
`#{node.propertyMap['myProp'].icon}`	Returns the icon service defined in the current web application.
`#{node.propertyMap['myProp'].indexedName}`	Returns the indexed name of a multi-valued property. For example, if a multi-valued node property named `color` contains `blue`, `red`, `orange`, the indexed name of the `red` value is `color[1]`. The following EL expression references the color `orange` in this list: `#{node.propertyMap['color[2]'].value.stringValue}`
`#{node.propertyMap['myProp'].isAudio}`	Returns `true` if the property's mime type is 'audio/'.
`#{node.propertyMap['myProp'].isBinary}`	Returns `true` if the current property is of type `Property.BINARY`.
`#{node.propertyMap['myProp'].isBoolean}`	Returns `true` if the current property is of type `Property.BOOLEAN`.
`#{node.propertyMap['myProp'].isCalendar}`	Returns `true` if the current property is of type `Property.CALENDAR`.
`#{node.propertyMap['myProp'].isDouble}`	Returns `true` if the current property is of type `Property.DOUBLE`.
`#{node.propertyMap['myProp'].isExcel}`	Returns `true` if the property's mime type is 'application/vnd.ms-excel', 'application/excel', 'application/x-excel', or 'application/x-msexcel'.

Table 29–4 (Cont.) EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp'].isGIF}`	Returns `true` if the property's mime type is '`image/gif`'.
`#{node.propertyMap['myProp'].isHTML}`	Returns `true` if the property's mime type is '`text/html`'.
`#{node.propertyMap['myProp'].isImage}`	Returns `true` if the property's mime type is '`image/`'.
`#{node.propertyMap['myProp'].isJPEG}`	Returns `true` if the property's mime type is '`image/jpeg`'.
`#{node.propertyMap['myProp'].isLink}`	Returns `true` if the current property is of type `Property.LINK`.
`#{node.propertyMap['myProp'].isLong}`	Returns `true` if the current property is of type `Property.LONG`.
`#{node.propertyMap['myProp'].isMSWord}`	Returns `true` if the property's mime type is '`application/vnd.ms-word`' or '`application/msword`'.
`#{node.propertyMap['myProp'].isMultiValued}`	Returns `true` if this property is multi-valued.
`#{node.propertyMap['myProp'].isNested}`	Returns `true` if the current property is of type `Property.NESTED`.
`#{node.propertyMap['myProp'].isPDF}`	Returns `true` if the property's mime type is '`application/pdf`'.
`#{node.propertyMap['myProp'].isPlainText}`	Returns `true` if the property's mime type is '`text/plain`'.
`#{node.propertyMap['myProp'].isPNG}`	Returns `true` if the property's mime type is '`image/png`'.
`#{node.propertyMap['myProp'].isPowerPoint}`	Returns `true` if the property's mime type is '`application/vnd.ms-powerpoint`', '`application/mspowerpoint`', or '`application/x-mspowerpoint`'.
`#{node.propertyMap['myProp'].isPrimaryProperty}`	Returns `true` if this property is the primary property.
`#{node.propertyMap['myProp'].isRequired}`	Returns `true` if this property is required/mandatory.
`#{node.propertyMap['myProp'].isRestricted}`	Returns `true` if this property is restricted.
`#{node.propertyMap['myProp'].isRichText}`	Returns `true` if the property's mime type is '`text/richtext`'.
`#{node.propertyMap['myProp'].isString}`	Returns `true` if the current property is of type `Property.STRING`.
`#{node.propertyMap['myProp'].isTextBased}`	Returns `true` if this property is text-based (`isHTML`, `isPlainText`, `isString`, `isCalendar`, `isBoolean`, `isDouble`, `isLong`).
`#{node.propertyMap['myProp'].isVideo}`	Returns `true` if the property's mime type is '`video/`'.
`#{node.propertyMap['myProp'].isXML}`	Returns `true` if the property's mime type is '`text/xml`'.
`#{node.propertyMap['myProp'].isZip}`	Returns `true` if the property's mime type is '`application/zip`'.
`#{node.propertyMap['myRefNode'].linkAsNode}`	Returns the `myRefNode` property as a node, where `myRefNode` is a link property type. Properties can be referenced in EL expressions. **Example**: `#{node.propertyMap['myRefNode'].linkAsNode.primaryProperty.url.renderUrl}`

Table 29–4 (Cont.) EL Expressions for Content Item Node Properties

EL Expression	Description
`#{node.propertyMap['myProp'].name}`	Returns the property's name.
`#{node.propertyMap['myProp'].nestedProperty}`	Retrieves nested properties for this single-valued property, and returns a list of properties.
`#{node.propertyMap['myProp'].type}`	Returns the data type of this property value. For example: `String`, `Integer`, `Long`, and so on.
`#{node.propertyMap['myProp'].url}`	Returns a URL service for this property.
`#{node.propertyMap['myProp'].value}`	Returns the value service for this property.
#{node.propertyMap['myProp'].nestedProperties}	Returns elements from a static list. For example: `<af:iterator var="listItem" value="#{node.propertyMap['ARTICLE_RGD:Paragraphs'].nestedProperties}" varStatus="vs"> <af:outputText id="ot1" value='#{listItem[0].value}'/> <af:outputText id="ot3" value="#{listItem[1].value}"/> </af:iterator>`
`#node.propertyMap['regionDefName:elementName'].asTextHtml}`	Returns Site Studio data as HTML text. For example: `#node.propertyMap['RD_NEWS:LEAD'].asTextHtml}` The element name (`LEAD`) is prefixed by the Region Definition name (`RD_NEWS`). See also Section 29.4.7, "Referencing Site Studio Region Elements in a Custom View."

Table 29–5 EL Expressions for Content Item Node Property Values

EL Expression	Description
`#{node.propertyMap['myProp'].value.binaryValue}`	Returns custom attributes for a binary property type or attachment. Attributes available on `binaryValue` are: ■ `contentType` – Returns the mime type of the binary content (for example, `text` or `html`). ■ `name` – Returns the filename of the binary content (for example, `index.html`). ■ `size` – Returns the size of the binary content, or `-1` if the size is unavailable.
`#{node.propertyMap['myProp'].value.booleanValue}`	Returns the value of this property as `java.lang.Boolean`.
`#{node.propertyMap['myProp'].value.calendarValue}`	Returns the value of this property as `java.util.Calendar`.
`#{node.propertyMap['myProp'].value.doubleValue}`	Returns the value of this property as `java.lang.Double`.

Table 29–5 (Cont.) EL Expressions for Content Item Node Property Values

EL Expression	Description
`#{node.propertyMap['myProp'].value.longValue}`	Returns the value of this property as `java.lang.Long`.
`#{node.propertyMap['myProp'].value.orderedPosition}`	Returns the "index" of the property when the property is multi-valued. **Example**: `#{node.propertyMap['address[0]'].value.orderedPosition},`
`#{node.propertyMap['myProp'].value.stringValue}`	Returns the value of this property as `java.lang.String`. **Example**: `#{node.propertyMap['firstName'].value.stringValue}`

29.4.4.3 Working with Content Item Icons and URLs

Table 29–6 and Table 29–7 describe EL expressions for working with icons and URLs associated with content items and properties.

Table 29–6 EL Expressions for Content Item Node or Property Icons

EL Expression	Description
`#{node.icon.largeIcon}`	Returns a URL to an image resource for a large icon.
`#{node.propertyMap['myDoc'].icon.largeIcon}`	**Example**: `<af:image source="#{node.propertyMap['projectFolder'].largeIcon}"/>`
`#{node.icon.smallIcon}`	Returns a URL to an image resource for a small icon.
`#{node.propertyMap['myDoc'].icon.smallIcon}`	**Example**: `<af:image source="#{node.icon.smallIcon}" />`

Table 29–7 EL Expressions for Content Item Node URLs

EL Expression	Description
`#{node.url.downloadUrl}`	Creates a URL to the binary content. Forces a download, and the underlying operating system renders the content based on the content type. **Example**: `<af:goLink destination="#{node.url.downloadUrl}" targetFrame="_blank"/>`
`#{node.url.renderUrl}`	Creates a URL to the binary content. Allows the browser to render the content based on the content type. By default, `#{node.url}` resolves to `#{node.url.renderUrl}`. **Example**: `<af:goLink destination="#{node.url.renderUrl}" targetFrame="_blank"/>`

29.4.5 Discovering Content Type Property Names

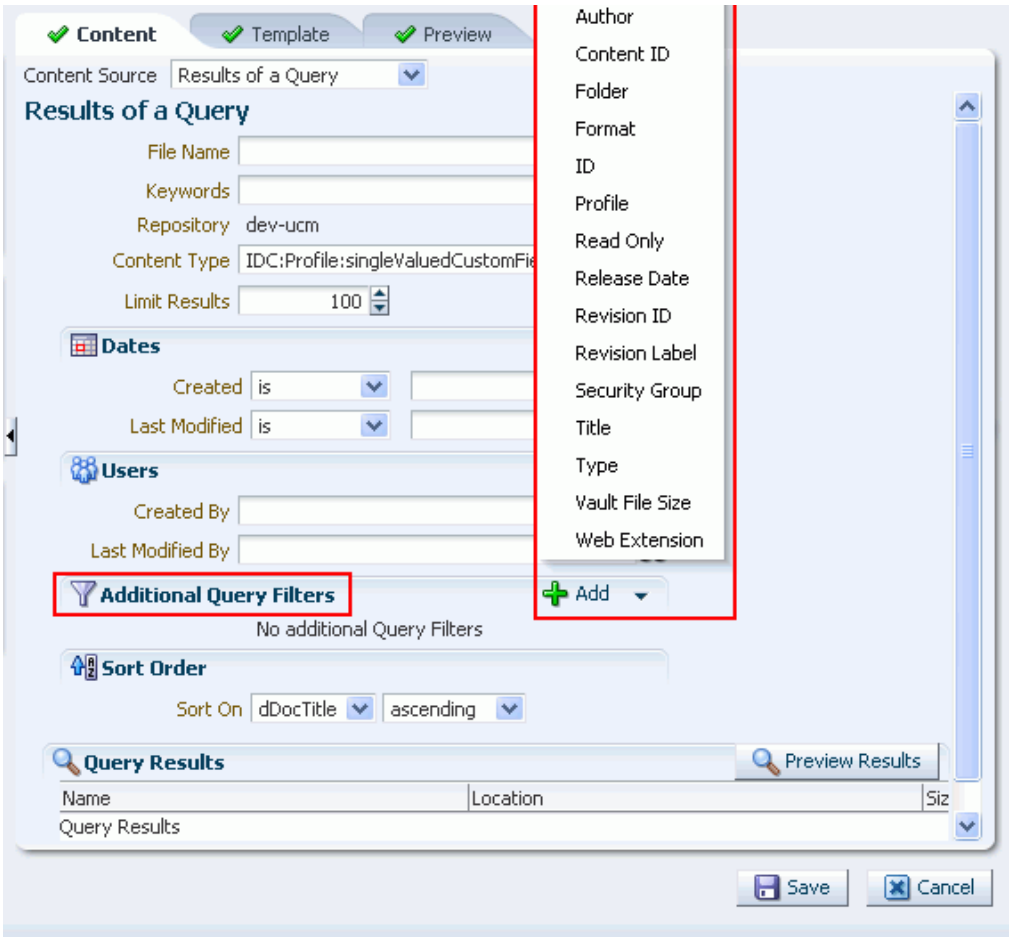
This section describes a useful technique for learning the property names of a content item's content type.

Note: You can also use REST services to obtain content type property names. For more information see the *Oracle Fusion Middleware Content Management REST Service Developer's Guide*.

Each content item is associated with a specific *content type* defined in the Content Server repository. Content types can map to Content Server profile definitions and Site Studio region definitions. Types are created on the Content Server. A content type defines the properties of the content item (see Table 29–8), and is identified when you register the template.

As a Content Presenter display template developer, you will need to know the names of the properties defined for the associated content type so that you can define how to display the selected content item(s) on the page.

One way to determine the properties for the existing content types defined in Content Server is to use the Content Presenter Configuration dialog in WebCenter Portal: Spaces:



1. Open the Content Presenter Configuration dialog. For instructions, refer to the section "Displaying Content Using the Content Presenter Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.
2. On the **Content** tab of the Content Presenter Configuration dialog, select **Results of a Query** to a view a list of content types.
3. Select the **Content Type** for the content item that you wish to display.
4. Next to **Additional Query Filters**, click **Add** to list all the properties that are defined for the selected content type (Figure 29–4).

Note: The list of property names shown in the dropdown list (Figure 29–4) are display names only. For example, the display name `Author` corresponds to the actual content type property name `dDocAuthor`.

To discover the actual property names that correspond to the display names, you must access them through the Content Server administration console, or contact your Content Server administrator.

When referencing the actual content type properties, you must include the leading letter `d` or `x` to reference the internal Content Server property name. The prefix `d` identifies a system property, and the prefix `x` identifies a user property. For example: `dDocAuthor` or `xCollectionID`.

Figure 29–4 Identifying Content Type Properties

29.4.6 Referencing External Files in Display Templates

In some cases, a display template needs to reference an external file, like a CSS file. All such references must be either an absolute path or a path that is relative to the root of the web application. For example:

- **absolute path** – `http://host:port/mypath/file.css`
- **relative path** – `/webcenter/mypath/file.css`

Do not use local references to external files. Local references to external files do not work because they are not included when you upload a Content Presenter display template to a WebCenter Portal: Spaces application, as explained in Section 29.5, "Using Content Presenter Display Templates in a Framework Application."

29.4.7 Referencing Site Studio Region Elements in a Custom View

You can use custom display templates to display Site Studio Region Definition elements. For example, you might have a Site Studio Region Definition called RD_NEWS with four elements: TITLE, LEAD, IMAGE, and BODY. A Content Presenter display template can reference these elements using the node property EL expression like this:

```
#node.propertyMap['RD_NEWS:LEAD'].asTextHtml}
```

Example 29–4 illustrates how these Site Studio Region elements can be included in a `contentTemplateDef` definition:

Example 29–4 Referencing Site Studio Region Elements in a Template

```
<dt:contentTemplateDef var="node">
   <af:panelGroupLayout layout="vertical" id="pgl3">
     <af:panelGroupLayout layout="horizontal" valign="top" inlineStyle="background-color:#FFF;
padding:10px;" id="pgl4">
         <af:panelGroupLayout layout="vertical" id="pgl2" valign="top">
            <af:outputText value="#{node.propertyMap['dInDate'].value.calendarValue}" id="ot3"
styleClass="bodytext" converter="javax.faces.DateTime"/>
          </af:panelGroupLayout>
          <af:spacer width="10px;" id="s1" inlineStyle="background-color:#DDD; color:white;"/>
          <af:panelGroupLayout layout="vertical" id="pgl1" valign="top">
             <af:outputText value="#{node.propertyMap['xTargetGroup'].value}" id="ot12"
inlineStyle="background-color:#0A9FC0; color:white; text-align:left; padding:5px;"/>
            <af:goLink text="#{node.propertyMap['RD_NEWS:TITLE'].asTextHtml}" id="gil1"
                destination="#{'/faces/home/news-viewer?news_
id='}#{node.propertyMap['dDocName'].value}" styleClass="newstitle"/>
           <af:outputText value="#{node.propertyMap['RD_NEWS:LEAD'].asTextHtml}" id="ot2"
styleClass="bodytext"/>
         </af:panelGroupLayout>
       <af:panelGroupLayout layout="vertical" id="pgl32" valign="top" styleClass="newsimage">
         <af:outputText value="#{node.propertyMap['RD_NEWS:IMAGE'].asTextHtml}" escape="false"
id="ot1"  inlineStyle="max-width:100px;"/>
       </af:panelGroupLayout>
     </af:panelGroupLayout>
     <af:panelGroupLayout layout="horizontal" id="aaaa">
     </af:panelGroupLayout>
   </af:panelGroupLayout>
</dt:contentTemplateDef>
```

For a complete, end-to-end example illustrating how to reference Site Studio Region elements in multiple templates, see the WebCenter Architecture Team blog entry at: `http://blogs.oracle.com/ATEAM_WEBCENTER/entry/content_presenter_cmis_complete`.

29.4.8 Using the Content Presenter Display Template

For information on using a display template in a Content Task flow, see Section 31.5, "Adding a Content Task Flow to a Page." See also Section 31.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates." For information on integrating a display template into a WebCenter Portal: Framework application, see the following section Section 29.5, "Using Content Presenter Display Templates in a Framework Application."

> **Note:** If you display a wiki page in a Framework application using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 32.3.5, "Displaying Wiki Page Links Within Content Presenter."

29.5 Using Content Presenter Display Templates in a Framework Application

This section explains how to make a Content Presenter display template available to Content Presenter in a Framework application.

- Section 29.5.1, "Export a Content Presenter Display Template as a Portal Resource"
- Section 29.5.2, "Upload the New Content Presenter Display Template"
- Section 29.5.3, "Test the New Content Presenter Display Template"

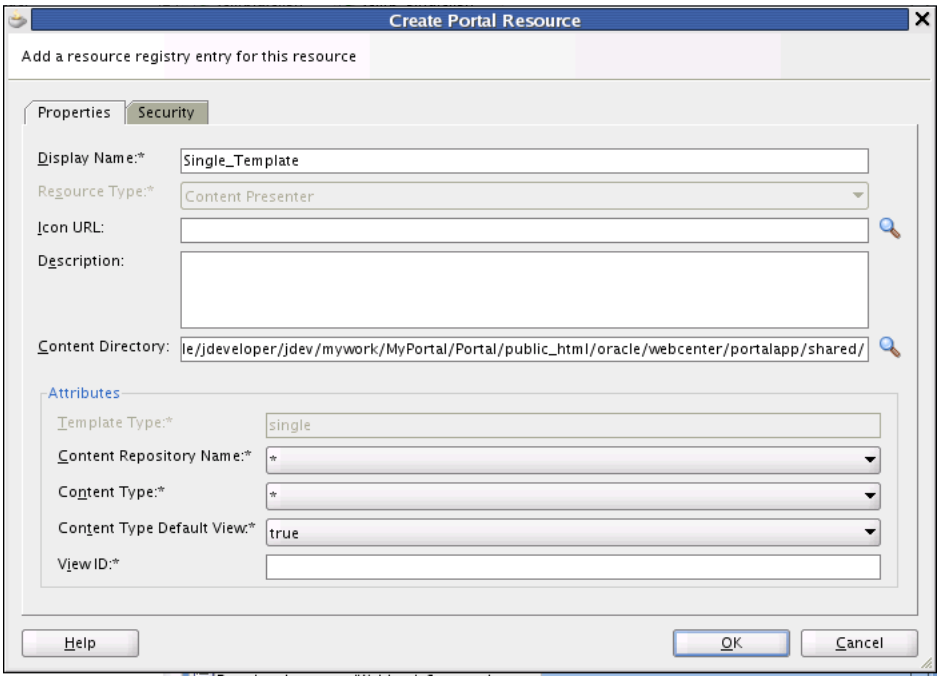
Note: If you are using a locally configured JDev environment to develop a Framework application, all you need to do to use a Content Presenter display template in your application is to export it as a portal resource, as explained in Section 29.5.1, "Export a Content Presenter Display Template as a Portal Resource." You do not need to perform the upload task as explained in Section 29.5.2, "Upload the New Content Presenter Display Template."

29.5.1 Export a Content Presenter Display Template as a Portal Resource

This section explains how to export a Content Presenter display template as a portal resource. This procedure is a prerequisite to adding a Content Presenter display template to a deployed WebCenter Portal: Spaces application and to Content Presenter at runtime.

1. Create a Content Presenter display template, as explained previously in Section 29.4, "Creating Content Presenter Display Templates."
2. In the Application Navigator, right-click the Content Presenter display template file (a JSFF file) and select **Create Portal Resource**.
3. Fill in the Create Portal Resource dialog. This dialog differs depending on whether you are creating a single or multiple-item template. The dialog for a single-item template is shown in Figure 29–5. The dialog for a multiple-item template is shown in Figure 29–6.

Figure 29–5 Create Portal Resource Dialog for a Single-Item Template



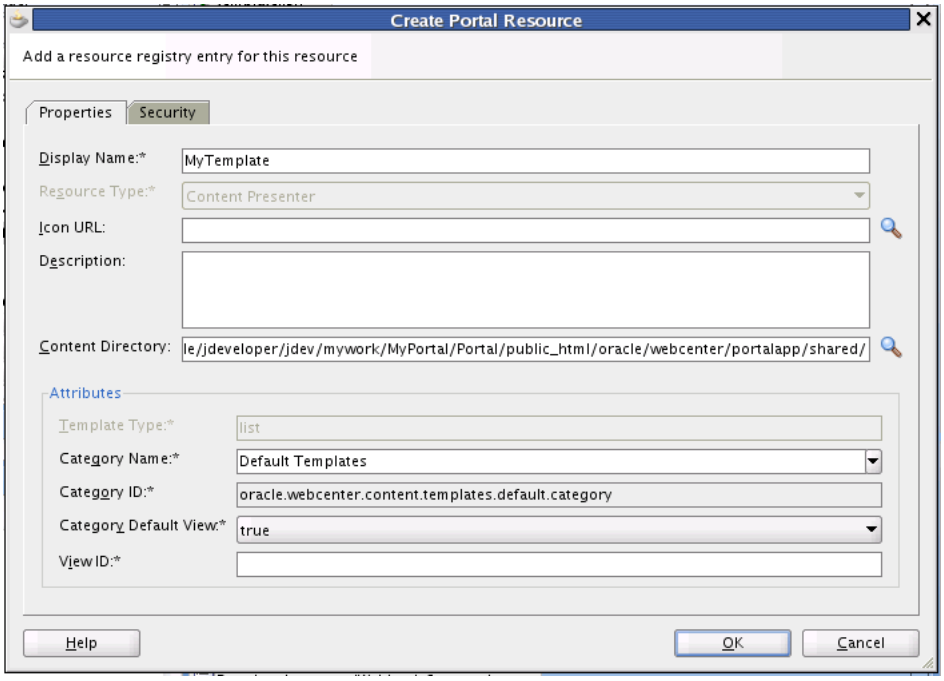


Figure 29–6 Create Portal Resource Dialog for a Multiple-Item Template

The default settings in the Create Portal Resource dialog are generally sufficient; however, you must enter a unique value in the View ID field. The Display Name is the name that appears in the display template drop down menu at runtime.

More On OTN

The View ID parameter is intended to be human-readable; therefore, it is not automatically generated for you. For example, you can use the View ID to programmatically refer to one template from another. For example, a multiple content item template could render tabs for each item and also call on a single item

template to be used below the selected tab to render the details of that item. As another example, you can include one template in another by passing the View ID as a parameter to the Content Presenter task flow. For a detailed example illustrating the latter use case, see the WebCenter Architecture Team blog entry at: `http://blogs.oracle.com/ATEAM_WEBCENTER/entry/content_presenter_cmis_complete`. See also Section 29.4.7, "Referencing Site Studio Region Elements in a Custom View."

Additional Attributes in the Create Portal Resource dialog for a **single item template** include:

- **Template Type** – Reflects whether the template is single or multi-item template.
- **Content Repository Name** – By default, the portal resource uses the repository associated with the application's default content connection. If you intend to export the portal resource for use in a WebCenter Portal: Spaces application, you must pick the repository that matches the one used by the WebCenter Portal: Spaces connection name(s).
- **Content Type** – Lets you pick a content type for which the template will be valid. The list of content types displayed in the menu depends on the selected content repository.
- **Content Type Default View** – If set to true, specifies that the display template is the default template to use for the given combination of repository and content type.
- **View ID** – A unique value that is used to refer to the template programmatically, as discussed previously in this section.

Additional Attributes in the Create Portal Resource dialog for a **multiple item template** include:

- **Template Type** – Reflects whether the template is single or multi-item template.
- **Category Name** – A name given to a category of display templates. Can be any name that describes the category or you can use the **Default Templates** category name.
- **Category ID** – An ID for the category. If you select **Default Templates** as the category name, this field will become read-only and populate with **oracle.webcenter.content.templates.default.category**. If you are creating a new category, this value can be any unique string. For example: **oracle.webcenter.content.templates.pressrelease.category**. If two resources have the same ID, they will be grouped together in the user interface.
- **View ID** – A unique value that is used to refer to the template programmatically, as discussed previously in this section.

Note: For more information on other fields in the Create Portal Resource dialog, see Section 17.4.3, "How to Export a Portal Resource from JDeveloper."

---

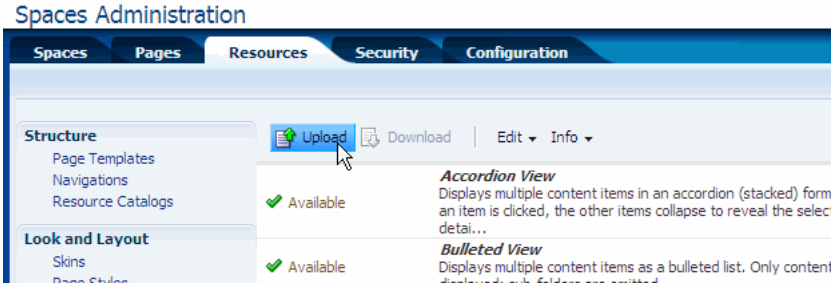
4. Click **OK** in the dialog when you are finished.
5. Right-click the Content Presenter display template (JSFF) file again, and this time select **Export Portal Resource**.

6. In the Export Portal Resource dialog, enter or browse to a directory in which to place the exported portal resource file. You can place this file anywhere on your file system.
7. Click **OK** in the Export Portal Resource dialog.

Now that your Content Presenter display template is exported as a portal resource, the next step is to upload it to your WebCenter Portal: Spaces application. After uploading the display template portal resource, it will be available in the list of display templates when you add a Content Presenter to your portal page.

29.5.2 Upload the New Content Presenter Display Template

You can upload a new display template to any deployed WebCenter Portal: Framework or WebCenter Portal: Spaces application that includes the Resource Manager. To upload a Content Presenter display template to a WebCenter Portal: Framework or WebCenter Portal: Spaces application, do the following:



Note: The repository connection names and details must be the same between the design time Framework application in which you developed the Content Presenter display template and the WebCenter Portal: Spaces application.

Note: Any references to external files in the display template must either be absolute or relative path references. See Section 29.4.6, "Referencing External Files in Display Templates."

---

1. Start your WebCenter Portal: Framework or WebCenter Portal: Spaces application.
2. Navigate to the page to which you want to add the Content Presenter display template.
3. Click **Administration**.
4. Select the **Resources** tab.
5. Under the Look and Layout heading (along the right side of the web page), click **Content Presenter**.
6. Select **Upload**, as shown in Figure 29–7.

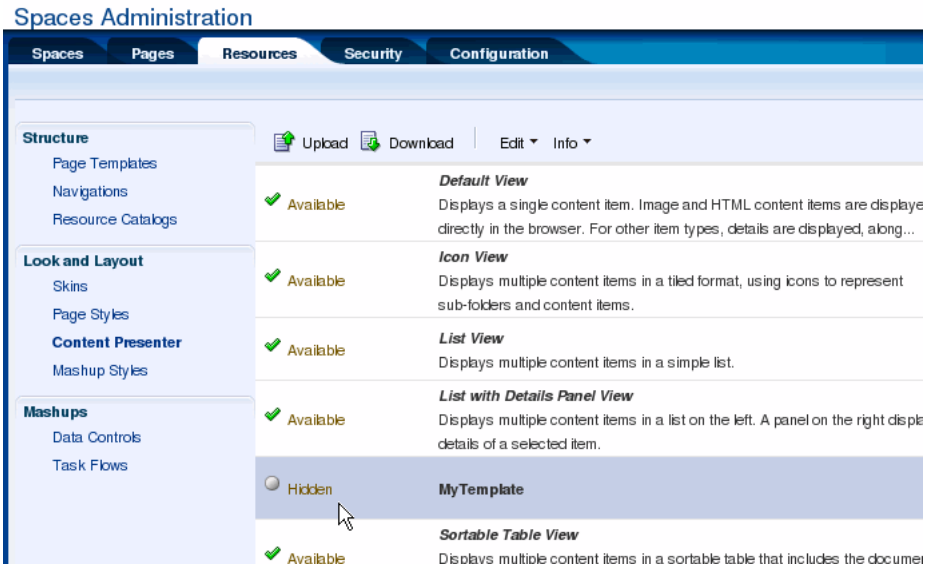


Figure 29–7 Uploading the Display Template Portal Resource

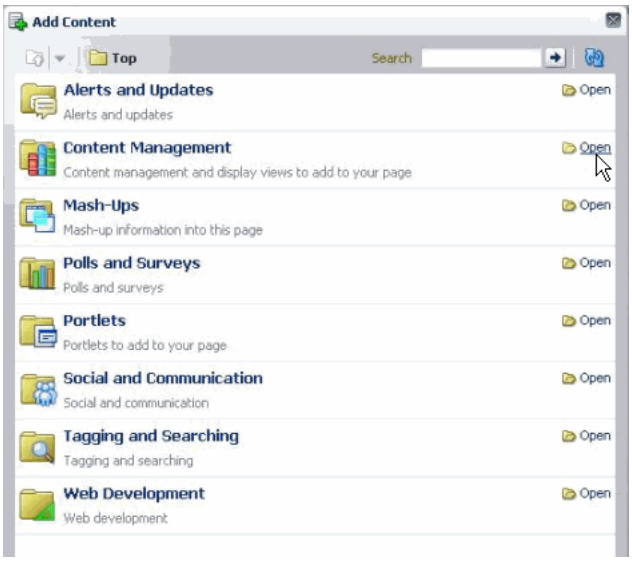
7. In the Upload dialog, navigate to the portal resource file you saved on your file system.

8. After you've selected the template file, click **OK**. If the operation is successful, an Information dialog appears with the message "Resource uploaded successfully."
9. Locate your Content Presenter display template in the list view of the Resources tab and select it from the list, as shown in Figure 29–8.

Figure 29–8 Toggling the Show/Hide State of a Template

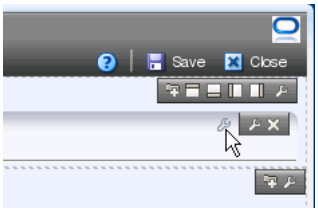
10. If the template state is currently hidden, select **Show** from the Edit menu. If a template is hidden, it won't be available for use in Content Presenter.



The new Content Presenter display template is now ready to be used with Content Presenter in a WebCenter Portal: Spaces application.

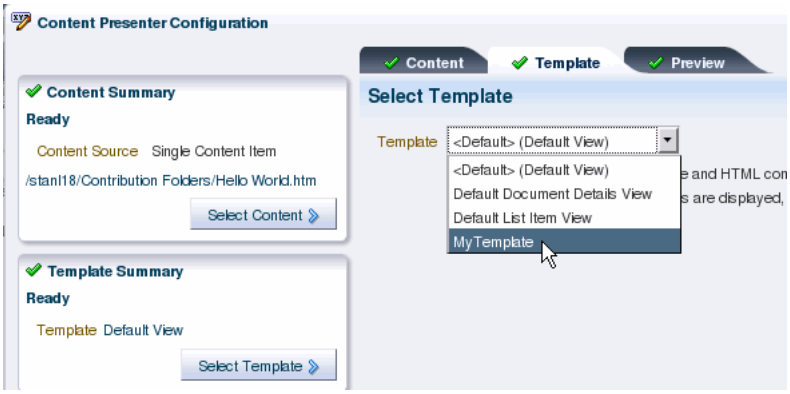
29.5.3 Test the New Content Presenter Display Template

This section explains how to test your Content Presenter display template with Content Presenter.



1. If it is not currently running, start the WebCenter Portal: Spaces application to which you added a Content Presenter display template. This application must have a Content Server connection that Content Presenter can use. If you just completed the setup procedures described in the previous sections, click the **Back to the Space** link in the upper right corner of the Administration page.
2. Navigate to the space in which you want to use the new Content Presenter display template. To do this, select the Spaces tab, and then select a space that you own or can edit.
3. Optionally, create a new page to test the display template. Select **Create a New Page** from the Page Actions menu. The, select **Save** and **Close**.
4. In the new or existing page, select **Edit Page** from the Page Actions menu.
5. Select an **Add Content** button in the part of the page where you want to add a Content Presenter.
6. In the Add Content dialog, open the **Content Management** folder, as shown in Figure 29–9.

Figure 29–9 Opening the Document Management Folder



7. In the Add Content dialog, click the **Add** button next to Content Presenter.
8. Close the Add Content dialog.
9. Select the task flow **Edit** icon in the Content Presenter tool bar (see Figure 29–10).

Figure 29–10 Selecting the Edit Icon

10. In the Content Presenter Configuration window, select the Template tab.
11. From the Template menu, select your Content Presenter display template, as shown in Figure 29–11.

Figure 29–11 Selecting the Content Presenter Display Template

The Content Presenter template will be applied to the Content Presenter instance. For more information on using Content Presenter and display templates, see Section 31.2, "Understanding the Documents Service Task Flows" and Section 29.3, "Using the Out-of-the-Box Display Templates".

29.6 What Happens at Runtime?

This section includes these topics:

- Section 29.6.1, "Runtime Overview"
- Section 29.6.2, "Identifying Display Templates for Selected Content Items"

29.6.1 Runtime Overview

After you have defined a Content Presenter display template, you can add a Content Presenter task flow to a page in your application, specifying the content and display template in the Content Presenter task flow parameters (see Section 31.6, "Modifying Content Task Flow Parameters" and Section 29.3, "Using the Out-of-the-Box Display Templates").

If you integrate the Documents Service in your application (see Chapter 30, "Integrating the Documents Service"), end users of your application can select content and your Content Presenter display templates in the Content Presenter Configuration dialog to include content on editable pages of the application, as described in "Publishing Content Using Content Presenter" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*. To understand how Content Presenter identifies which display templates to expose in the Content Presenter Configuration dialog, see Section 29.6.2, "Identifying Display Templates for Selected Content Items."

29.6.2 Identifying Display Templates for Selected Content Items

At runtime, after a user selects content in the Content Presenter Configuration dialog, Content Presenter checks the Resource Manager to identify the display templates that are suitable for the selected content item(s), then exposes the list of valid templates on the Template page in the Content Presenter Configuration dialog for the user to select. See also Chapter 17, "Adding and Using the Resource Manager."

For *single content item* templates, Content Presenter generates a list of valid templates using the following precedence order:

1. Check the Resource Manager for template definitions matching the content item's content repository and content type.
2. Add template definitions matching the default content repository (`*`) and specified content type.
3. Add template definitions matching inherited content types.
4. Add template definitions matching the default content repository (`*`) and default content type (`*`).

For *multiple content item* templates, Content Presenter generates a list of valid templates using the following precedence order:

1. Check the Resource Manager for template definitions associated with the selected template category.
2. Add template definitions associated with the default category (`*`).

For example, if the user selects multiple content items (such as the children of a folder, or the results of a search), the Content Presenter Configuration dialog shows a list of categories and the list of templates associated with that category and the default category, based on the repository of the content items.

Note: When a user selects a template in the Content Presenter Configuration dialog, that template is used to display the selected content item(s) in the running application. If that template is later deleted from the Resource Manager for any reason, Content Presenter will automatically select a "closest match" template to display the content item(s) using the precedence order above.

29.7 Performance Considerations for Content Presenter Display Templates

When content nodes are retrieved for display in a Content Presenter display template, most content item node property values are retrieved immediately along with the node, but some are loaded later only if needed. Other than the performance difference, the selective loading of node property values is transparent to the user or developer.

As a Content Presenter display template developer, you can optimize performance of your template if you are aware when different property values are loaded. For example, a typical list display template will render faster if you refer only to properties that are immediately loaded when the node is first retrieved and avoid properties that are loaded later when needed.

A secondary consideration is dependent on how the node is retrieved: through search versus fetched by parent ID. A property that may be loaded immediately on node retrieval for searches (such as "Results of a Query") may be loaded later for other retrieval methods (such as "Contents Under a Folder"). Table 29–8 shows whether or not node properties are loaded immediately upon node retrieval, by retrieval mechanism.

For information about the node properties listed in Table 29–8, see the *Oracle WebCenter Content Idoc Script Reference Guide*.

Table 29–8 Loading of Node Properties By Node Retrieval Mechanism

	Loaded When Node Is First Retrieved?		
OCS Global Profile Properties	**GET BY PARENT ID ("Contents Under a Folder")**	**SEARCH ("Results of a Query")**	**GET BY UUID ("Single Content Item" and "List of Items")**
`VaultFileSize`	**N**	Y	Y
`dCheckoutUser`	Y	**N**	Y
`dCreateDate`	Y	Y	Y
`dDocAccount`	Y	Y	Y
`dDocAuthor`	Y	Y	Y
`dDocName`	Y	Y	Y
`dDocTitle`	Y	Y	Y
`dDocType`	Y	Y	Y
`dFormat`	Y	Y	Y

Table 29–8 (Cont.) Loading of Node Properties By Node Retrieval Mechanism

OCS Global Profile Properties	Loaded When Node Is First Retrieved?		
	GET BY PARENT ID ("Contents Under a Folder")	SEARCH ("Results of a Query")	GET BY UUID ("Single Content Item" and "List of Items")
dID	Y	Y	Y
dInDate	Y	Y	Y
dIsCheckedOut	Y	N	Y
dOutDate	Y	Y	Y
dReleaseDate	Y	N	Y
dReleaseState	Y	N	Y
dRevClassID	Y	N	Y
dRevLabel	Y	Y	Y
dRevRank	Y	N	Y
dRevisionID	Y	Y	Y
dSecurityGroup	Y	Y	Y
dStatus	Y	N	Y
dWebExtension	Y	Y	Y
dWorkflowState	N	N	Y
idcPrimaryFile	Y	Y	Y
idcRenditions	N	N	Y
xCollectionID	Y	Y	Y
xComments	Y	Y	Y
xForceFolderSecurity	Y	Y	Y
xHidden	Y	Y	Y
xInihibitUpdate	Y	Y	Y
xReadOnly	Y	Y	Y

30

Integrating the Documents Service

There are several ways to integrate content into a WebCenter Portal: Framework application. For more information, see Chapter 26, "Introduction to Integrating and Publishing Content."

This chapter describes how to integrate the Documents service into a Framework application to both add content to the application, and to provide end users with content and Documents service task flows built into the application to manage, display, and search documents at runtime.

This chapter includes the following sections:

- Section 30.1, "Introduction to the Documents Service"
- Section 30.2, "Setting Up Connections"
- Section 30.3, "Setting Security for the Documents Service"
- Section 30.4, "Using the Documents Service with Other WebCenter Services"
- Section 30.5, "Setting Parameters to Upload Files to Content Repositories"
- Section 30.6, "Using Adapters with the Documents Service"

30.1 Introduction to the Documents Service

The Documents service provides features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in Content Server, Oracle Portal, or SharePoint content repositories. It provides these features through Documents service task flows, document components (links, inline frames, and images), wikis, and blogs.

> **Note:** The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 3.6, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

To integrate the Documents service into a Framework application, your WebCenter Portal administrator must set up a connection to the content repository that contains the documents you want to manage. If the content repository you wish to use requires authentication, ensure that you set up an external application when you configure the connection to your content repository, as discussed in Section 30.2, "Setting Up Connections."

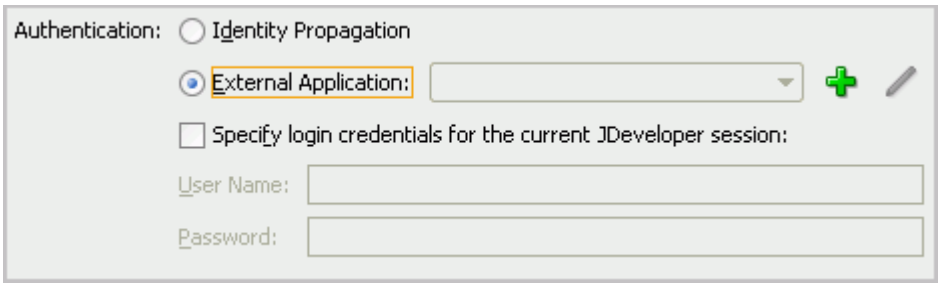
30.2 Setting Up Connections

Before you can use the Documents service and task flows, you must first set up the connection to the Content Server, Oracle Portal, or SharePoint content repository that contains the documents you want to manage. You can reuse connections you've created or create new ones.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, refer to the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

The choices made for application security and content repository connection authentication need to be compatible. For example, if the connection is configured to use External Application with only Public credentials defined, then there is no requirement for the application to enforce user authentication. For detailed information about connection configuration, see Section 27.2, "Configuring Content Repository Connections."

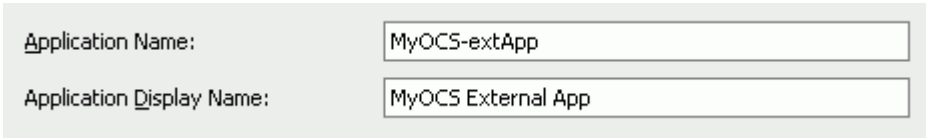
30.3 Setting Security for the Documents Service



The Documents service task flows support the same security options that are supported by the content repository connections. This service can also use an external application with dedicated user accounts to access remote content repositories, such as an Oracle Content Server or Oracle Portal. For more information about using security with content repositories, see Section 28.4, "Securing a Content Repository Data Control." For information about using external applications, see Section 69.13, "Working with External Applications."

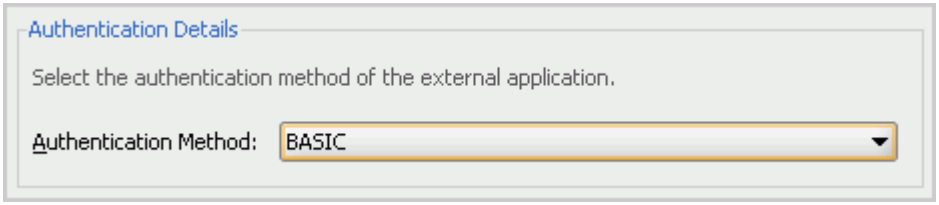
If you are using a content repository that handles its own authentication, such as Oracle Portal or Oracle Content Server, you can associate that content repository with an external application definition to allow for credential provisioning. You can modify your connection to your content repository to use an external application without shared or public credentials. When you do this, the External Application - Change Password task flow is automatically integrated to allow your end users to provide their credentials.

To register an external application for an existing content repository connection:



1. In the Application Resources pane, right-click your connection name and choose **Properties**.
2. In the Edit Content Repository Connection dialog box, under **Authentication**, select **External Application** (Figure 30–1).

Figure 30–1 Selecting External Application in the Content Repository Connection Dialog

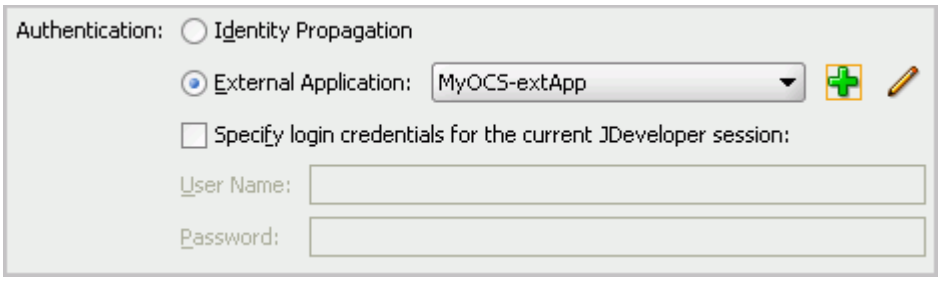


3. Click the green + (plus) sign to start the Register External Application wizard.
4. On the Name page, enter an **Application Name** and **Application Display Name**, (Figure 30–2) then click **Next**.

Figure 30–2 Naming the External Application

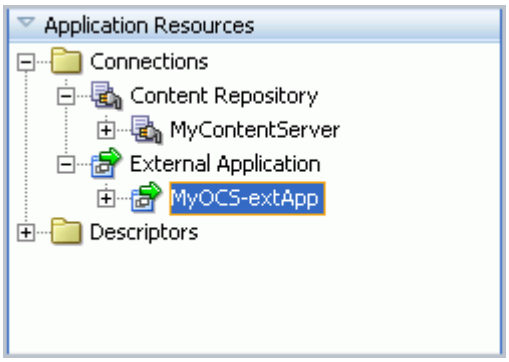
5. On the General page, under **Authentication Details**, choose **BASIC** from the **Authentication Method** list (Figure 30–3), then click **Next**.

Figure 30–3 Choosing the BASIC Authentication Method



6. On the Additional Fields page, click **Next**.
7. On the Shared Credentials page, click **Next**.
8. On the Public Credentials page, select **Specify Public Credentials**, then enter the **Username** and **Password** for the content repository (Figure 30–4).

Figure 30–4 Specifying the Public Credentials



9. Click **Finish**. You'll notice that your connection now uses the external application for authentication (Figure 30–5).

Figure 30–5 Using the New External Application

10. In the Edit Content Repository Connection dialog box, click **OK**. In the Application Resources panel, you'll notice the external application now displays (Figure 30–6).

Figure 30–6 External Application in the Application Resources Panel

If you do not apply security, and the content repository requires a login to access the content, the user will not be able to authenticate, and thus will see only public content at runtime.

30.4 Using the Documents Service with Other WebCenter Services

You can use the Documents service with a variety of other WebCenter services. For example, you can add tags to documents in your content repository, search across your application and retrieve documents in the results, or track recent changes to the content repository.

You can see an example of how to use the Documents service with the Tags service in Section 44.3.3, "Optional Way to Show Tags on Pages."

To learn more about how you can use these services together, refer to Section 2.4, "Introducing Oracle WebCenter Portal: Services."

Note: When you integrate the Documents service with the Search service, the Search service returns results from *all* content repository connections.

30.5 Setting Parameters to Upload Files to Content Repositories

The Document Manager, Document Explorer, and Folder Viewer task flows allow you to upload files into content repositories. WebCenter Portal: Framework uses Apache MyFaces Trinidad to handle file upload from a browser to the application server.

To change the default settings of Apache MyFaces Trinidad, you can add three parameters to the `web.xml` file. To edit this file, open the **ViewController** project of your application. Under **Web Content**, open the `web.xml` file. In the Overview, navigate to **Application > Context Initialization Parameters**, then click the green plus sign (**+**) to add the parameters and their values (as described in Table 30–1) or simply update the code in the Source view. After you've made your changes, save the `web.xml` file, then restart Oracle JDeveloper.

Table 30–1 Apache MyFaces Trinidad Parameters

Parameter	Description
`org.apache.myfaces.trinidad.UPLOAD_MAX_MEMORY`	The maximum amount of memory in bytes that a single file can use when uploaded.
`org.apache.myfaces.trinidad.UPLOAD_MAX_DISK_SPACE`	The maximum amount of disk space in bytes that a single file can use when uploaded.
`org.apache.myfaces.trinidad.UPLOAD_TEMP_DIR`	The directory in which the file being uploaded is temporarily stored.

For more information, see the Apache MyFaces Trinidad documentation at `http://myfaces.apache.org/trinidad/devguide/fileUpload.html`.

30.6 Using Adapters with the Documents Service

To learn more about using existing adapters for the content repository connections, see Chapter 27, "Managing Content Repository Connections."

31

Adding Content Task Flows and Document Components to a Portal Page

There are several ways to integrate content into a WebCenter Portal: Framework Application. For more information, see Chapter 26, "Introduction to Integrating and Publishing Content."

In a Framework application, you can add content from one or more connected content repositories to the application, using Content Presenter or the Documents service task flows to display the content in a variety of ways. As you develop your application, you can view, edit, and manage that content using the content task flows, in the same way that end users of the application will do. For information about viewing, editing, and managing content in content task flows, see "Working with Content" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

This chapter describes how to add content to a page in a Framework application using the content task flows and document components in the following sections:

- Section 31.1, "Understanding the Content Presenter Task Flow"
- Section 31.2, "Understanding the Documents Service Task Flows"
- Section 31.3, "Understanding Document Components"
- Section 31.4, "Adding a Selected Folder or File to a Page"
- Section 31.5, "Adding a Content Task Flow to a Page"
- Section 31.6, "Modifying Content Task Flow Parameters"
- Section 31.7, "Content Task Flow Parameters"

31.1 Understanding the Content Presenter Task Flow

Content Presenter enables you to precisely customize the selection and presentation of content in a WebCenter Portal application.

The Content Presenter task flow is available only when the connected content repository is Content Server and your WebCenter Portal administrator has completed the prerequisite configuration.

See Also:

- "Content Server Prerequisites" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- Section 27.2.1, "How to Create a Content Repository Connection Based on the Oracle Content Server Adapter"

The Content Presenter task flow allows you to select a single item of content, contents under a folder, a list of items, query for content, or select content based on the results of a Personalization Conductor scenario, and then select a template to render the content on a page in a WebCenter Portal application.

Content Presenter has no dependency on the Documents service for adding or managing the content it displays.

To add the Content Presenter task flow to a page, see Section 31.4, "Adding a Selected Folder or File to a Page" and Section 31.5, "Adding a Content Task Flow to a Page."

Note: If a page is based on a page template that includes a Content Presenter task flow to display a content item, the page template developer must manually modify the task flow properties to display the content in the page template, as follows:

- `datasource`: *`connection_name`*`#dDocName:`*`content_ID`*
- `datasourceType`: `dsTypeSingleNode`
- `taskFlowInstId`: A unique identifier

For more information about Content Presenter task flow properties, see Table 31–4, " Content Presenter Task Flow Parameters"

For information about creating a page template, see Section 12.2.2, "How to Create a Page Template."

31.2 Understanding the Documents Service Task Flows

The Documents service task flows provide a variety of formats to display folders and files, including wikis and blogs, on a page in a Framework application. You can choose the task flows appropriate for your application to provide features for accessing, adding, and managing folders and files; configuring and viewing file and folder properties; and searching file and folder content in Content Server, Oracle Portal, or SharePoint content repositories.

Note: The availability of SharePoint as a content repository requires the installation of the SharePoint adapter, as described in Section 3.6, "Installing the Oracle WebCenter Adapter for SharePoint." Administration for SharePoint is performed using WLST commands, not Oracle Enterprise Manager Fusion Middleware Control Console.

To add a Documents service task flow to a page in a Framework application, your WebCenter Portal administrator must first integrate the Documents service into the application by establishing a content repository connection, as described in Chapter 30, "Integrating the Documents Service" and Chapter 27, "Managing Content Repository Connections."

Using Documents service task flows and document components (such as links, previews, and images), you can add content to the application, and also provide end users with content and Documents service task flows built into the application to manage, display, and search documents at runtime.

Table 31–1 provides an overview of the Documents service task flows.

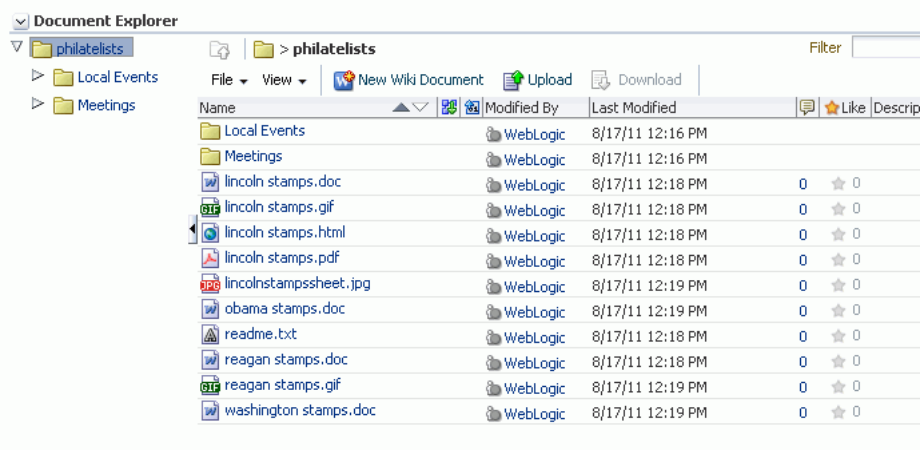
Table 31–1 Documents Service Task Flows

	Folder and File Listings	Individual Folders	Individual Files
Document Explorer task flow. Displays folders and files in two panes, combining the functionality of the Document Navigator and Folder Viewer task flows. It provides in-place previewing and editing, and robust management capabilities with an interface that should be familiar to users of Windows Explorer. Size: medium to full page width. See Figure 31–1.	X	X	
Document List Viewer task flow. Displays folders and files in a single pane as a flat listing. It provides preview and editing in separate window, and some management capabilities. Size: narrow to medium page width. See Figure 31–2.	X	X	
Document Manager task flow. Displays folders and files as specified by its `layout` property: `explorer`, `table`, or `treeTable`. The `explorer` layout is identical to the Document Explorer task flow, without the properties `showDocuments`, `showFolders`, and `treeNavCollapsed` . See Figure 31–3, Figure 31–4, and Figure 31–5.	X	X	
Document Navigator task flow. Displays a nested hierarchy of folders and files in a single pane, providing expand and collapse on folders to show the full hierarchy. Size: narrow to medium page width. See Figure 31–6.	X	X	
Folder Viewer task flow. Displays the contents of a folder in a single pane as a flat listing, providing in-place preview and editing, and robust document management capabilities with a straightforward interface that should be familiar to Windows users. Size: medium to full page width. See Figure 31–7.	X	X	
Recent Documents task flow. Displays a list of the files most recently created or modified in the current folder. See Figure 31–8.	X		
Document Viewer task flow. Displays a preview of a file, or file properties for files that do not support a preview. See Figure 31–9, Figure 31–10, Figure 31–11, and Figure 31–12.		X[1]	X
Document Mini Properties task flow. Displays the Basic properties of a file in a read-only view. See Figure 31–13.		X[1]	X
Document Properties task flow. Displays both Basic and Advanced properties of a file, along with an **Edit** button to allow you to modify property values. See Figure 31–14.		X[1]	X
Rich Text Editor task flow. Displays an HTML or wiki document in the Rich Text Editor.		X	X
Document Upload task flow. Displays the Upload dialog to allow users to upload new documents to the page.		X	X

Table 31–1 (Cont.) Documents Service Task Flows

	Folder and File Listings	Individual Folders	Individual Files
Document Version History task flow. Displays a list of versions of a file, allowing for deletion of a selected version. See Figure 31–15.			X
AutoVue task flow. Displays AutoVue markup for a file in a table of hyperlinked markup names (see "Collaborating on Documents Using AutoVue" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*).			X

[1] To show folder information in a Document Viewer, Document Mini Properties, or Document Properties task flow, you can set the task flow's `resourceID` property to the ID of the target folder. See Section 31.7, "Content Task Flow Parameters."



To add a Documents service task flow to a page, see Section 31.4, "Adding a Selected Folder or File to a Page" and Section 31.5, "Adding a Content Task Flow to a Page."

For detailed information about each Documents service task flow, click the links below to display the pertinent sections in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

- Understanding the Document Explorer Task Flow

  Figure 31–1 shows an example of the Document Explorer task flow. For information about setting properties for this task flow, see Section 31.7.2, "Document Explorer Task Flow Parameters."

Figure 31–1 Document Explorer Task Flow

- Understanding the Document List Viewer Task Flow

  Figure 31–2 shows an example of the Document List Viewer task flow. For information about setting properties for this task flow, see Section 31.7.3, "Document List Viewer Task Flow Parameters."

Figure 31–2 Document List Viewer Task Flow

- Understanding the Document Manager Task Flow

  Figure 31–3, Figure 31–4, and Figure 31–5 show examples of the three different layouts for the Document Manager task flow. The `explorer` layout (default) is identical to the Document Explorer task flow, without the properties `showDocuments`, `showFolders`, and `treeNavCollapsed` . For information about setting properties for this task flow, see Section 31.7.4, "Document Manager Task Flow Parameters."

Figure 31–3 Document Manager Task Flow: explorer Layout

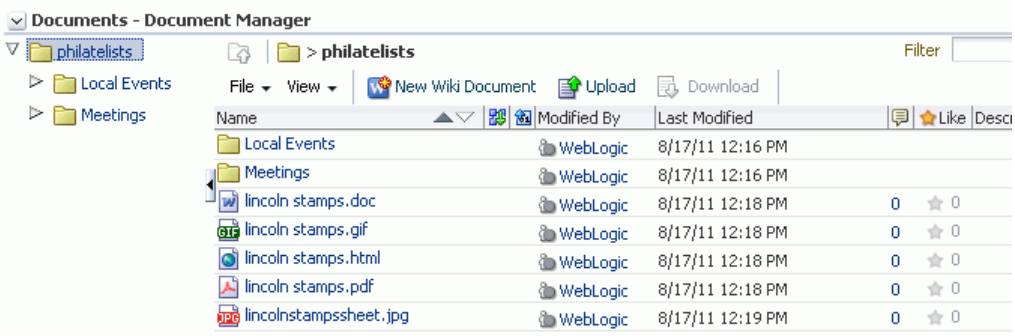


Figure 31–4 Document Manager Task Flow: table Layout

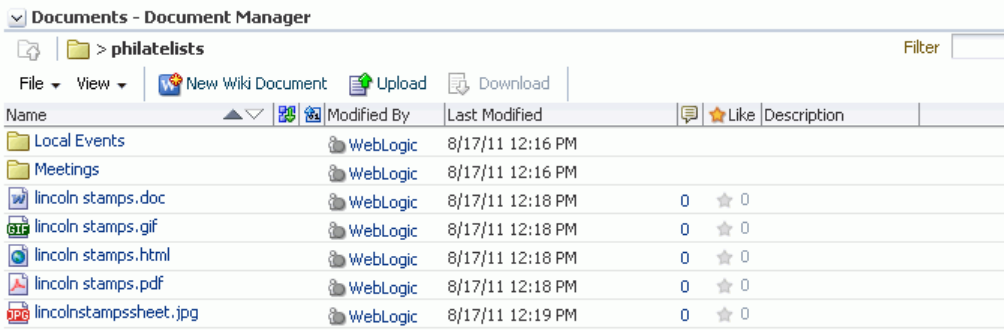

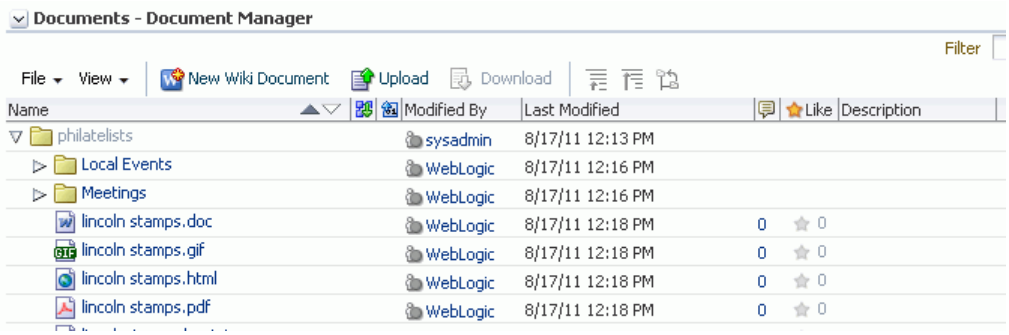

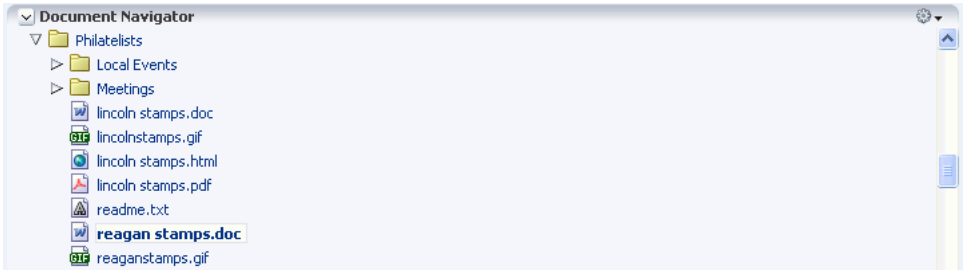

Figure 31–5 Document Manager Task Flow: treeTable Layout

- Understanding the Document Navigator Task Flow

  Figure 31–6 shows an example of the Document Navigator task flow. For information about setting properties for this task flow, see Section 31.7.5, "Document Navigator Task Flow Parameters."

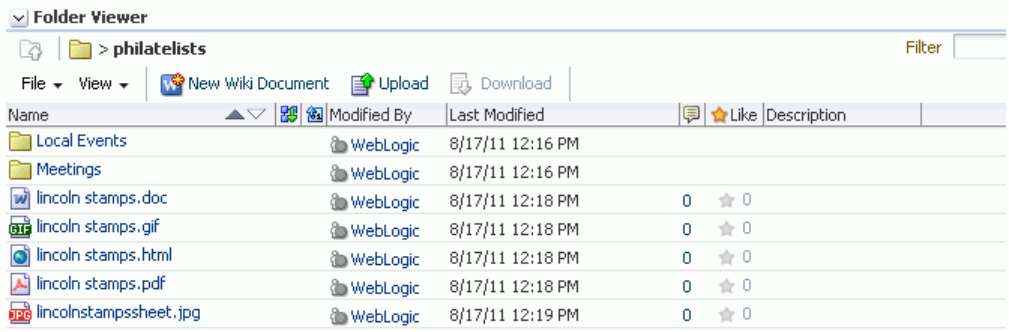

Figure 31–6 Document Navigator Task Flow

- Understanding the Folder Viewer Task Flow

  Figure 31–7 shows an example of the Folder Viewer task flow. For information about setting properties for this task flow, see Section 31.7.6, "Folder Viewer Task Flow Parameters."

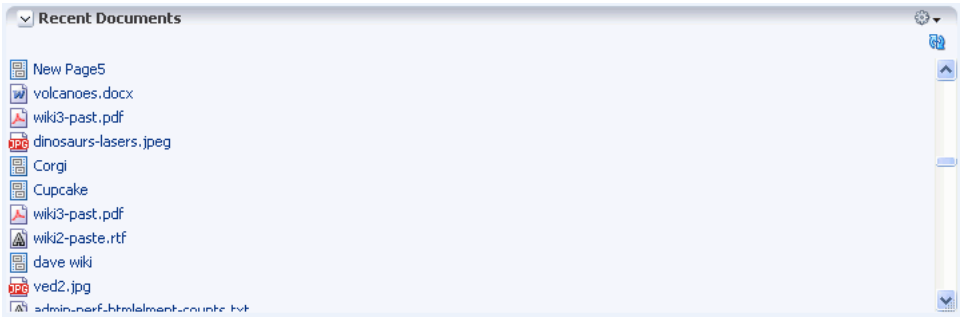

Figure 31–7 Folder Viewer Task Flow

- Understanding the Recent Documents Task Flow

  Figure 31–7 shows an example of the Recent Documents task flow. For information about setting properties for this task flow, see Section 31.7.7, "Recent Documents Task Flow Parameters."

Figure 31–8 Recent Documents Task Flow

- Understanding the Document Viewer Task Flow

  Figure 31–9, Figure 31–10, Figure 31–11, and Figure 31–12 show examples of the Document Viewer task flow for different file types. For information about setting properties for this task flow, see Section 31.7.8, "Document Viewer Task Flow Parameters."

Figure 31–9 Document Viewer Task Flow for Microsoft Office Word Document

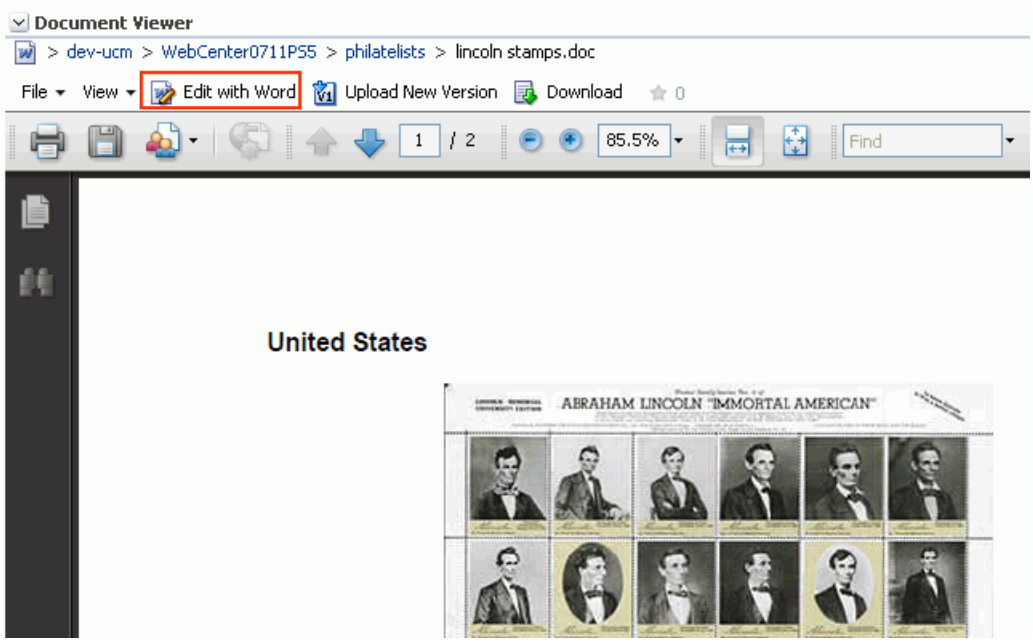

Figure 31–10 Document Viewer Task Flow for Image File

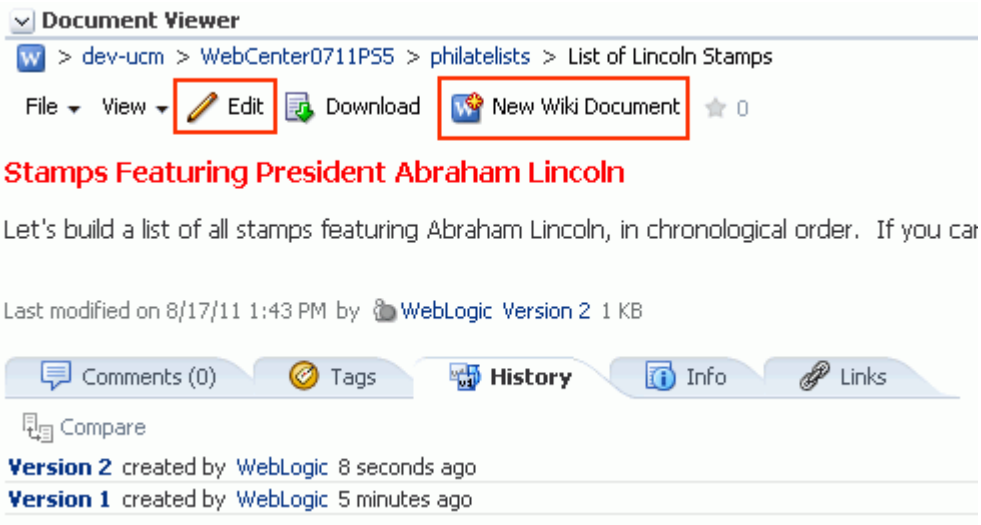
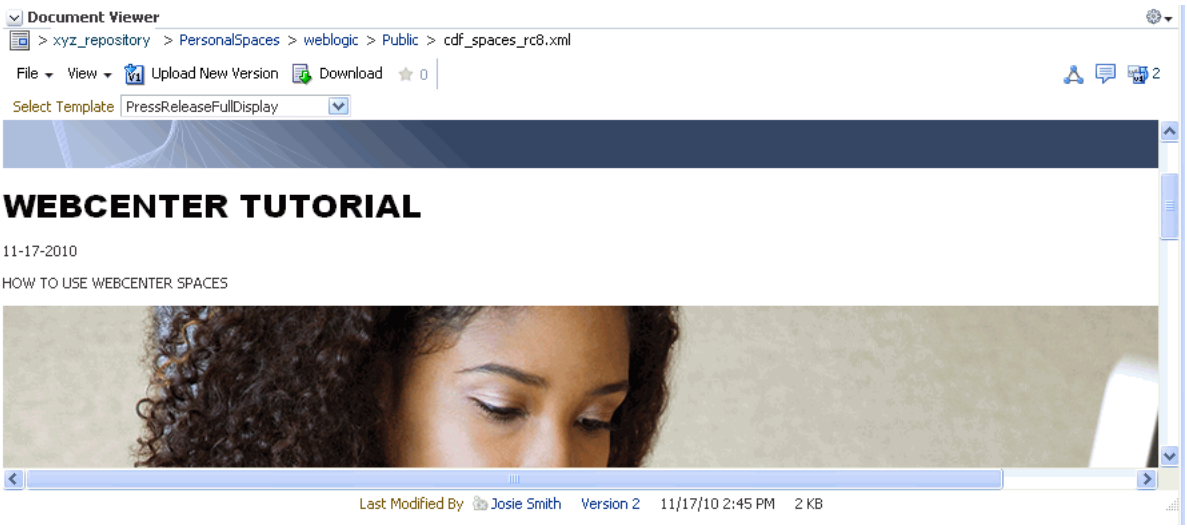
Figure 31–11 Document Viewer Task Flow for Wiki Document





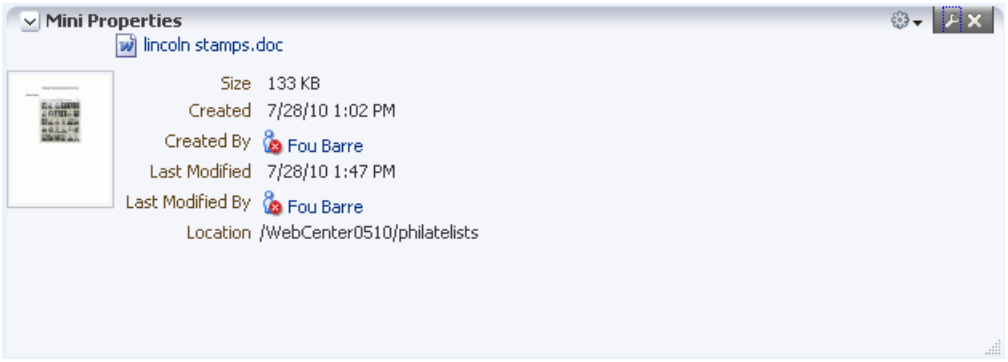


Figure 31–12 Document Viewer Task Flow for Site Studio File

- Understanding the Document Mini Properties Task Flow

  Figure 31–13 shows an example of the Document Mini Properties task flow. For information about setting properties for this task flow, see Section 31.7.9, "Document Mini Properties Task Flow Parameters."

Figure 31–13 Mini Properties Task Flow for File

- Understanding the Document Properties Task Flow

  Figure 31–14 shows an example of the Document Properties task flow. For information about setting properties for this task flow, see Section 31.7.10, "Document Properties Task Flow Parameters."

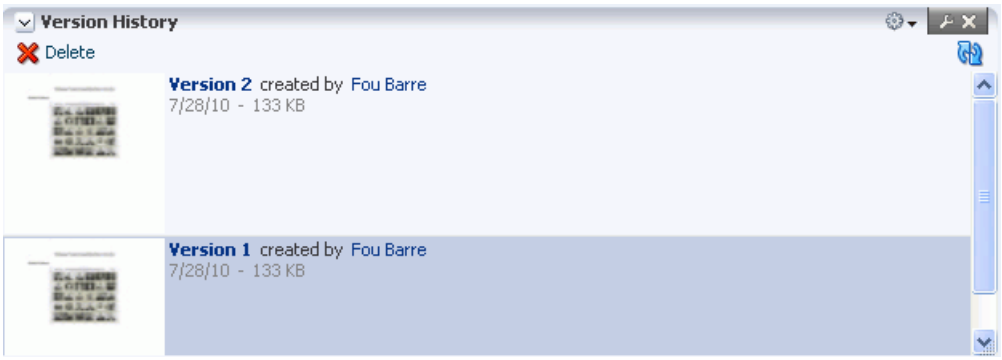

Figure 31–14 Document Properties Task Flow for File

- Understanding the Document Version History Task Flow

  Figure 31–15 shows an example of the Document Version History task flow. For information about setting properties for this task flow, see Section 31.7.13, "Document Version History Task Flow Parameters."

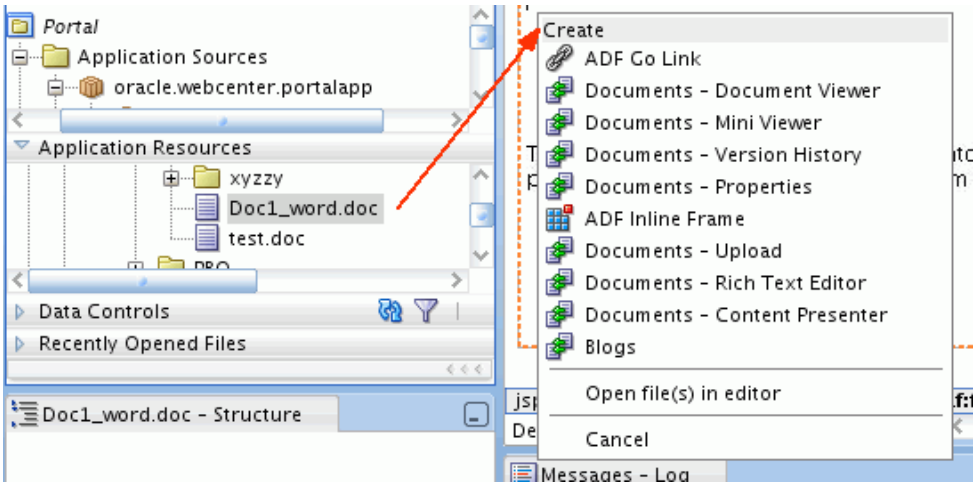

Figure 31–15 Version History Task Flow for File

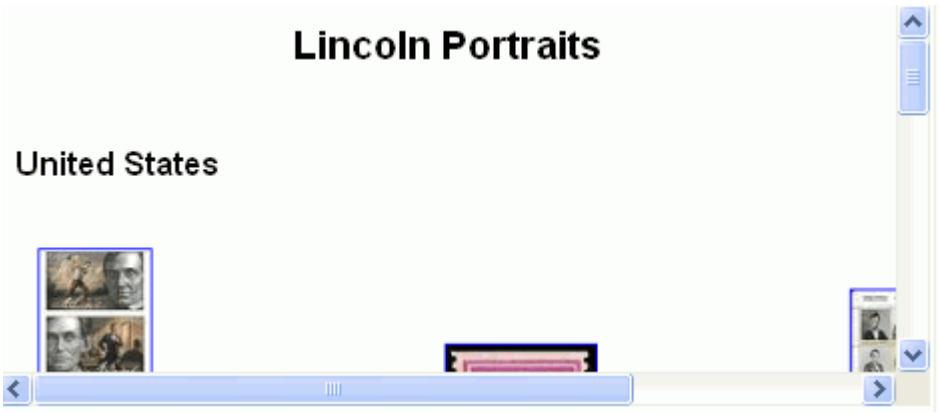
31.3 Understanding Document Components

The Documents service provides features for adding document components to a portal page. As described in Section 31.4, "Adding a Selected Folder or File to a Page", you can add a document component to a page as a container for a selected folder or file (Figure 31–16).

Figure 31–16 Adding File to Portal Page

Document components enable you to display an individual file on a page in a variety of ways, depending on the file type:



- A **Link** displays the name of a selected file as a link, which end users can click to display the file content in its native application (Figure 31–17).

Figure 31–17 Link Component (for Microsoft Word file)

- An **Inline Frame** displays the content of a selected file as a preview on the page (Figure 31–18).

Figure 31–18 Inline Frame Component (for HTML file)

- An **Image** displays a selected file as an image on the page (Figure 31–19).

Figure 31–19 Image Component (for JPEG file)

To add a document component to a page in a Framework application, you must first integrate the Documents service into the application by establishing a connection to a content repository, as described in Chapter 30, "Integrating the Documents Service."

Table 31–2 shows the document components available for the different content types.

Table 31–2 Components for Folders and FIles

Content Type	Document Components
Folder	Link (ADF Go Link)
Documents of various types (XML, PDF, JAVA, TXT, DOC, XLS, HTM)	Link (ADF Go Link)
Documents that can be rendered in a browser (HTML, flash, PDF and image)	Inline frame (ADF Inline Frame)
Images (PNG, JPG, GIF)	Link (ADF Go Link) Inline frame (ADF Inline Frame) Image (ADF Image)

To display a folder or file using one of these document components, see Section 31.4, "Adding a Selected Folder or File to a Page."

31.4 Adding a Selected Folder or File to a Page

If you want to add a content task flow to a page, independent of a specific folder or file, refer to Section 31.5, "Adding a Content Task Flow to a Page." This section describes how to display an individual folder or file from a connected content repository on a page, as shown inFigure 31–20 and Figure 31–21, by choosing the required container for the selected folder or file.

Figure 31–20 Adding Folder to Portal Page

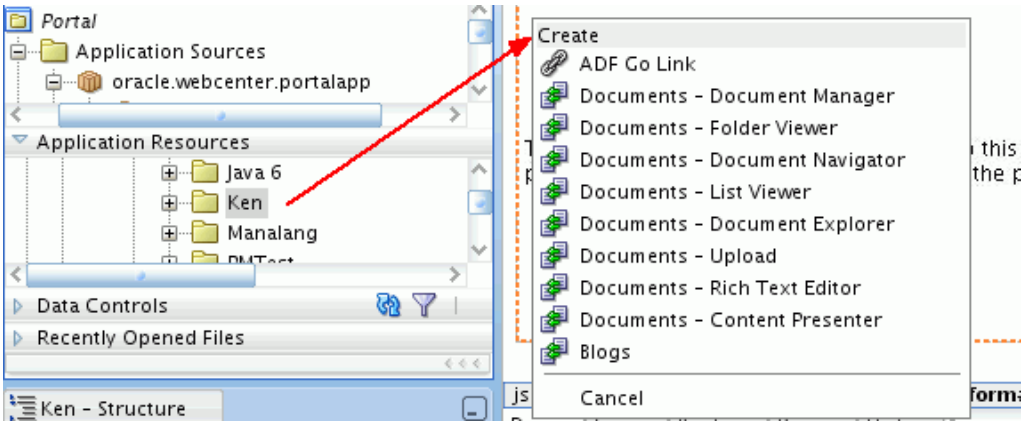


Figure 31–21 Adding File to Portal Page

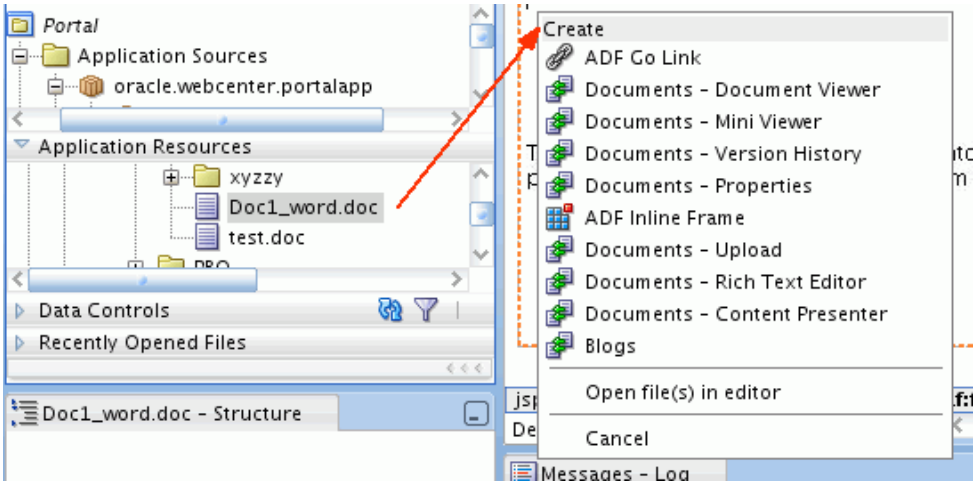

Table 31–3 lists all containers available for displaying folders and files on a portal page:

Table 31–3 Containers for Adding Individual Folders and Files to a Page

Root Folder	Folders	Individual Files
▪ Document Explorer ▪ Document List Viewer ▪ Document Manager ▪ Document Navigator ▪ Folder Viewer ▪ Recent Documents ▪ Document Viewer[1] ▪ Document Mini Properties[1] ▪ Document Properties[1] ▪ Document Upload ▪ Rich Text Editor	▪ Content Presenter ▪ Document Explorer ▪ Document List Viewer ▪ Document Manager ▪ Document Navigator ▪ Folder Viewer ▪ Document Viewer[1] ▪ Document Mini Properties[1] ▪ Document Properties[1] ▪ Document Upload ▪ Rich Text Editor	▪ Content Presenter ▪ Document Viewer ▪ Document Mini Properties ▪ Document Properties ▪ Rich Text Editor ▪ Document Upload ▪ Document Version History ▪ AutoVue ▪ Link component ▪ Inline Frame component ▪ Image component

[1] To show folder information in a Document Viewer, Document Mini Properties, or Document Properties task flow, you can set the task flow's `resourceID` parameter to the ID of the target folder. See Section 31.7, "Content Task Flow Parameters."

For more information about any of the containers listed in Table 31–3, see Section 31.1, "Understanding the Content Presenter Task Flow", Section 31.2, "Understanding the Documents Service Task Flows", and Section 31.3, "Understanding Document Components."

Note: When an item that is stored in a content repository is dropped onto a page, the Framework application instructs the browser to check whether the content is up-to-date before a cached copy, if available, displays in the browser. The default content validation process supports collaboration use cases that require real-time content exchange.

For static content or content that does not change frequently, content validation checks incur an unnecessary performance overhead. For static content, the following is recommended:

- **Oracle Content Server**: Use Content Presenter to display static content stored in Content Server. Content Presenter shows only the latest released version of content; it does not show any unreleased content that is in workflow
- **Other content repositories**, such as SharePoint: Ask your administrator to override the default content cache setting by editing the Web Tier `mod_wl_ohs` configuration file (`mod_wl_ohs.conf`). This is fully explained in "Setting the Cache-Control Response Header" in the white paper "Integrating the SharePoint 2007 Adapter with WebCenter Spaces" available from Oracle Technology Network at `http://www.oracle.com/technetwork/middleware/webcenter/overview/index.html`.

To add a selected folder or file to a page in a Framework application (see Section 5.2.1, "How to Create a Framework Application"):

1. Follow the steps in Section 7.2.1, "How to Prepare Your Application to Consume Services" to implement security.
2. If you want to add a Documents service task flow, create a content repository connection, which adds the Documents service to your application (see Chapter 30, "Integrating the Documents Service").
3. Create or open a page in your application where you want to add the task flow (see Section 5.3, "Adding Pages to a Portal").
4. Consider whether or not you want to allow end users of your application to edit the task flow that displays the folder or file:
   - To enable runtime editing of the page, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."
   - To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, add the task flow inside a Show Detail Frame Component (see Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components").

5. In the **Application Resources** panel, navigate to **Connections**, then **Content Repository**.
6. Locate the name of your connection, then expand it if desired to navigate to a specific folder or file.
7. Drag the folder or file to the page, and release the mouse button to display a menu of available task flows and document components, as shown in Figure 31–22 (root folder), Figure 31–23 (subfolder), and Figure 31–24 (individual file).

Figure 31–22 Adding Content Repository Root Folder to Portal Page

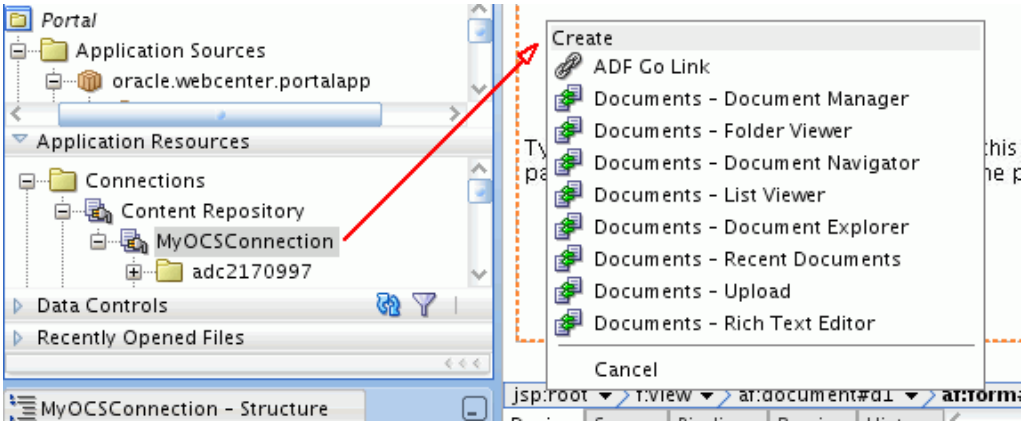

Figure 31–23 Adding Subfolder to Portal Page

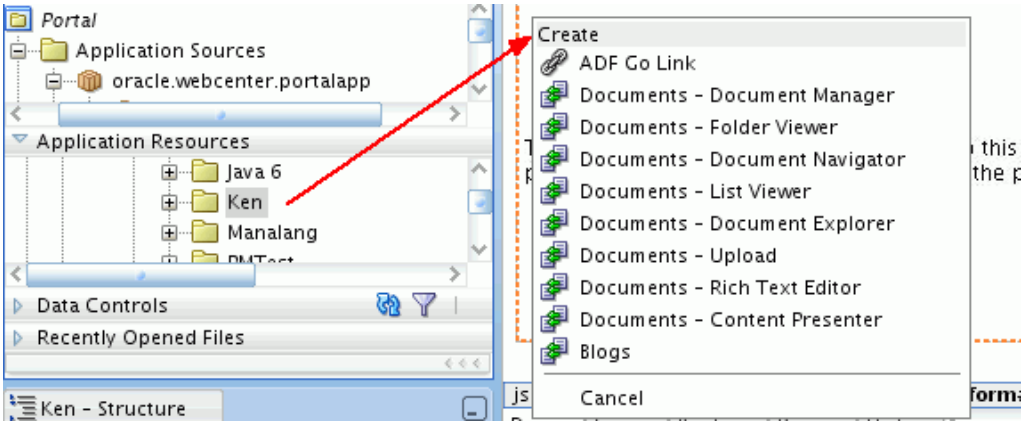

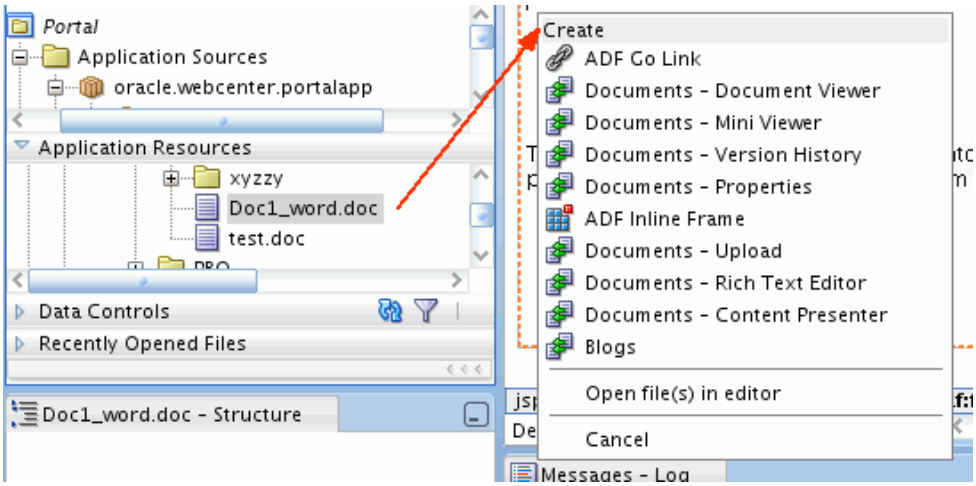

Figure 31–24 Adding File to Portal Page

8. Choose the content task flow or document component that you wish to use. If the folder or file you are adding to your page does not support a particular task flow, the task flow does not display in this menu.

> **Note:** The Content Presenter task flow is available only when the connected content repository is Content Server. When you select the Content Presenter task flow, the folder or file displays in a default display template for its type.

9. In the Edit Task Flow Binding dialog that displays when you select a task flow, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 31.7, "Content Task Flow Parameters."

10. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

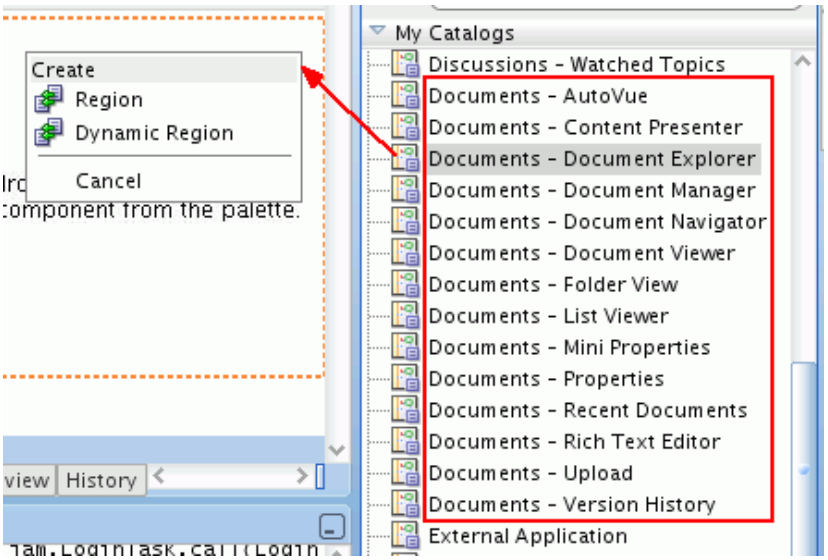
For information about viewing, editing, and managing content in content task flows, see "Working with Content" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

31.5 Adding a Content Task Flow to a Page

You may want to add an "empty" content task flow to a page, containing no folders or files. For example, in cases where you do not have a content repository connection, or want to use an EL expression as a parameter to dynamically bind to a target item.

See Chapter 26, "Introduction to Integrating and Publishing Content" for information about each content task flow to help you select the task flow most appropriate for your needs.

To add a content task flow to a page in a Framework application:



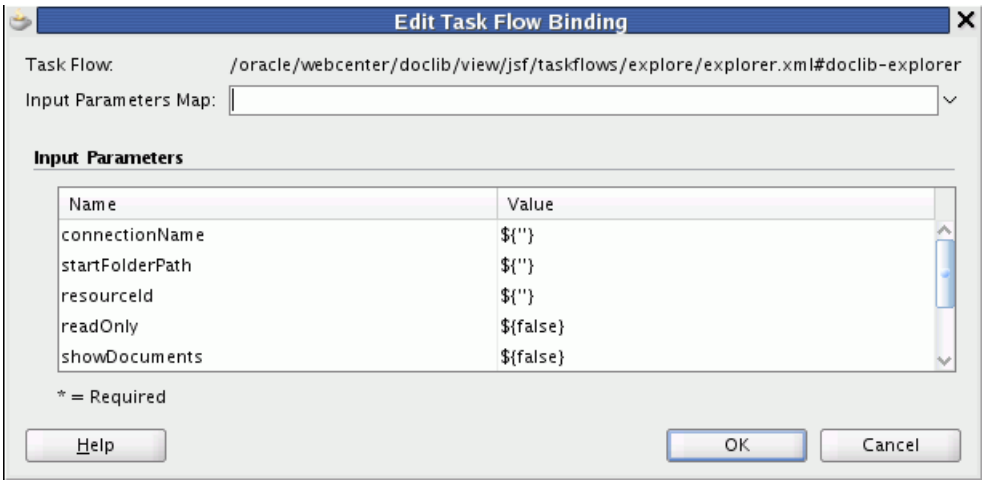
1. Follow the steps in Section 7.2.1, "How to Prepare Your Application to Consume Services" to implement security.

2. If you want to add a Documents service task flow, see Chapter 30, "Integrating the Documents Service".

3. Create or open a page in your application where you want to add the task flow (see Section 5.3, "Adding Pages to a Portal").

4. Before you add a task flow to your page, consider whether or not you want to allow end users of your application to edit the task flow:
   - To enable runtime editing of the page, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."
   - To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, add the task flow inside a Show Detail Frame Component (see Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components").
5. In the **Resource Palette**, expand **My Catalogs**, then **WebCenter Portal - Services Catalog**. Under **Task Flows**, select the desired content task flow and drag it onto your page (Figure 31–25), and release the mouse button.

Figure 31–25 Adding Standalone Documents Service Task Flow to JSF Page



Note: To allow end users of your application to customize a Content Presenter or Document List Viewer task flow using the **Edit** action, drag the task flow inside a Show Detail Frame Component (see Section 20.1.6, "How to Enable Component Customization Using Show Detail Frame Components").

Note: If you display a wiki page in a Framework application using a Content Presenter display template, by default any links within that wiki page are displayed in the Document Viewer. If you want to display wiki page links using Content Presenter, you must edit the `adf-config.xml` file. For more information, see Section 32.3.5, "Displaying Wiki Page Links Within Content Presenter."

6. From the menu that displays, choose **Region** to open the Edit Task Flow Binding dialog (Figure 31–26).

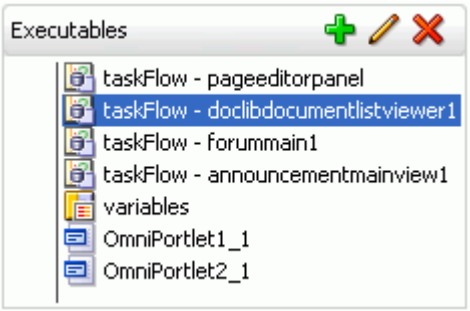
Figure 31–26 Specifying Parameters for Document Explorer Task Flow

7. In the Edit Task Flow Binding dialog, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 31.7, "Content Task Flow Parameters."
8. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

After you add a content task flow to a page, you can subsequently modify the parameters if required. See Section 31.6, "Modifying Content Task Flow Parameters".

For information about viewing, editing, and managing content in content task flows, see "Working with Content" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

Note: For information about adding custom actions to task flows, see Section 22.3.2, "How to Enable Custom Actions on a Show Detail Frame Enclosing a Task Flow."



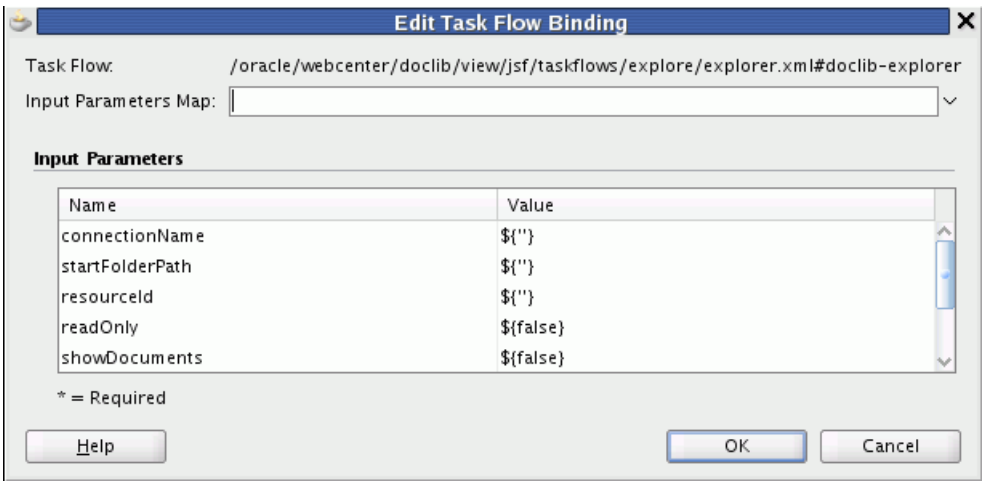
Note: By default, the task flow displays as full screen at runtime. You can use ADF layout components to modify this layout. To learn more about ADF layout components, refer to the *Oracle Fusion Middleware Web User Interface Developer's Guide for Oracle Application Development Framework*.

31.6 Modifying Content Task Flow Parameters

To modify the parameters of a content task flow after you have created the region:

1. Go to the Bindings view of your page (click the **Bindings** tab next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Select this task flow. Figure 31–27 shows an example of a Document List Viewer task flow in the **Executables** section.

Figure 31–27 Document List View Task Flow in the Bindings View



3. Next to the **Executables** heading, click the pencil icon to display the Edit Task Flow Binding dialog.
4. In the Edit Task Flow Binding dialog, specify parameter settings for the task flow. For more information, see Section 31.7, "Content Task Flow Parameters."

Note: For a Content Presenter task flow:

- If you want to allow end users of your application to select the content and display template using the Content Presenter Configuration dialog at runtime, you can leave all parameter values blank except for `taskFlowInstId`. Enter a task flow instance ID that is unique to your application (for example, `contentPresenterInstance1`).
- If you specify the content and a display template, note that Content Presenter does not support non-ASCII characters in files that are encoded using the non-UTF-8 character encoding. When users preview such files in Content Presenter, non-ASCII characters appear garbled.

Figure 31–28 Task Flow Binding Parameters

5. Click **OK** to add the parameters.

31.7 Content Task Flow Parameters

Each content task flow has its own set of parameters. You configure these values when you add the task flow to a page.

The following sections describe the parameters for the content task flows:

- Section 31.7.1, "Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates"
- Section 31.7.2, "Document Explorer Task Flow Parameters"
- Section 31.7.3, "Document List Viewer Task Flow Parameters"
- Section 31.7.4, "Document Manager Task Flow Parameters"
- Section 31.7.5, "Document Navigator Task Flow Parameters"
- Section 31.7.6, "Folder Viewer Task Flow Parameters"
- Section 31.7.7, "Recent Documents Task Flow Parameters"
- Section 31.7.8, "Document Viewer Task Flow Parameters"
- Section 31.7.9, "Document Mini Properties Task Flow Parameters"
- Section 31.7.10, "Document Properties Task Flow Parameters"
- Section 31.7.11, "Rich Text Editor Task Flow Parameters"
- Section 31.7.12, "Document Upload Task Flow Parameters"
- Section 31.7.13, "Document Version History Task Flow Parameters"

31.7.1 Content Presenter Task Flow Parameters and Out-of-the-Box Display Templates

The Content Presenter task flow is available when the connected content repository is Content Server. This task flow displays selected documents in out-of-the-box or custom display templates.

See Also:

- Section 31.1, "Understanding the Content Presenter Task Flow"
- Section 31.5, "Adding a Content Task Flow to a Page"

Table 31–4 describes the Content Presenter task flow parameters. Table 31–5 and Table 31–6 describe the out-of-the-box display templates for single and multiple content items, which can be specified as values for the `templateView` and `templateCategory` parameters.

Note: When you specify the content and a display template, note that Content Presenter does not support non-ASCII characters in files that are encoded using the non-UTF-8 character encoding. When users preview such files in Content Presenter, non-ASCII characters appear garbled.

If you want to allow end users of your application to select the content and display template using the Content Presenter Configuration dialog at runtime, you can leave all parameter values blank except for `taskFlowInstId`. Enter a task flow instance ID that is unique to your application (for example, `contentPresenterInstance1`).

At runtime, the parameters of a Content Presenter task flow on an editable page can be edited in two ways by end users with appropriate permissions:

- Click the configuration **Edit** icon for the task flow to display the Content Presenter Configuration dialog, where they can specify content and a display template. For end user information about the Content Presenter Configuration dialog, see the "Publishing Content Using Content Presenter" chapter in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.
- Click the properties **Edit** icon for the task flow to display the Component Properties dialog where they can set and modify task flow parameters. Parameters set in this way are generally intended for use at design time by developers creating a Framework application, or for advanced users who want to bind a parameter to an EL expression. If an end user modifies a parameter value in the Component Properties dialog, the new value overrides the value specified in the Content Presenter Configuration dialog.

Table 31–4 Content Presenter Task Flow Parameters

Parameter	Description

`datasource`	The data source of the content. The value depends on the value of `datasourceType`:
	■ When `datasourceType=dsTypeSingleNode`, set `datasource` to a single document node identifier in the format:
	`connection_name``#dDocName:`*`content_id`*
	Example:
	`myconnection.us.oracle.com#dDocName:STAN_IDC-007619`
	■ When `datasourceType=dsTypeFolderContents`, set `datasource` to a single folder node identifier in the format:
	`connection_name``#dCollectionID:`*`collection_id`*
	Example:
	`myconnection.us.oracle.com#dCollectionID:45535`
	■ When `datasourceType=dsTypeQueryExpression`, set `datasource` to a CMIS search expression.
	Examples:
	`select * from cmis:document where cmis:name like \'test%\'`
	`connectionName=`*`connection_name`*`#select * from cmis:document where cmis:createdBy = \'weblogic\'`
	Note: If `connectionName` is not specified, then the primary connection will be used.
	For more information about how to format the query and for more examples, see *Oracle Fusion Middleware Content Management REST Service Developer's Guide*.
	■ When `datasourceType=dsTypeMultiNode`, set `datasource` to a set of comma-delimited document node identifiers in the format:
	`connection_name``#dDocName:`*`content_id`*`, `*`connection_name`*`#dDocName:`*`content_id`*`, ...`
	Example: `myconn#dDocName:DOCUMENT_ID_12345,myconn#dDocName:DOCUMENT_ID_56789`
	■ When `datasourceType=dsTypeScenarioResults`, set `datasource` to point to a scenario in the format:
	`conductor-connection-name=`*`conductor_conn_name`*`,namespace=`*`scenario_namespace`*`,scenario-name=`*`scenario_name`*`,`*`inputparm1=value1,inputparm2=value2,`*` ...`
	Example:
	`conductor-connection-name=ConductorServiceLocal,namespace=CPNamespace,scenario-name=GetRelatedDocsScenario,topic=outdoors,interests=hiking`
	For information about the Personalization Conductor and scenarios, see Chapter 67, "Personalizing WebCenter Portal Applications."

Table 31–4 (Cont.) Content Presenter Task Flow Parameters

Parameter	Description
`datasource` (cont'd)	where: ■ *`connection_name`* = the name of the content repository connection. ■ *`content_id`* = the `Content ID` for the content specified on the content information page for the item in Content Server. ■ *`collection_id`* = the `dCollectionID` found in the URL for the folder information page in Content Server, or the `CollectionID` value on the content server. ■ *`conductor_connection_name`* = the name of the URL connection that points to the Personalization Conductor (this name must start with `Conductor`). This value must match the `Reference name` attribute value in the `connections.xml` file for this URL connection. For more information, see "Configuring Content Presenter" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal* and Appendix A, "Files for WebCenter Portal: Framework Applications" (for details about `connections.xml`). ■ *`namespace`* = the name of the namespace that contains the specified scenario. ■ *`scenario_name`* = the name of the scenario that Content Presenter will be using.
`datasourceType`	The data source type of the content. Valid values are: ■ `dsTypeSingleNode`: A single content item. ■ `dsTypeFolderContents`: The contents of a folder. ■ `dsTypeQueryExpression`: The results of a query. ■ `dsTypeMultiNode`: An ordered list of content items. ■ `dsTypeScenarioResults`: The results of the specified scenario. See Chapter 67, "Personalizing WebCenter Portal Applications."
`maxResults`	The maximum number of results to display when `datasourceType` is `dsTypeQueryExpression`. Default: `100`
`regionTemplate`	Specifies whether the display template is a Site Studio region definition template. This value is valid only with Content Server 11*g* or higher: ■ Selected: Display template is a Site Studio region definition template. The `templateView` value is set to the Content ID of the region template. ■ Cleared (default): Display template is not a Site Studio region definition template. For information about creating and using Site Studio region templates, see "Publishing Content Using Content Presenter" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces* and the Oracle Site Studio documentation library.

Table 31–4 (Cont.) Content Presenter Task Flow Parameters

Parameter	Description
`taskFlowInstId`	The unique identifier of this task flow instance, used internally to maintain the association of the task flow instance with its customization and personalization settings and to manage saved queries. The value is generated automatically when you add individual files or the content of folders to your page from the Application Resources Panel, displaying the content in a Content Presenter task flow. The value is blank when you add a Content Presenter task flow onto your page from the Resource Palette. Enter or edit this value to set the unique identifier for the task flow.
`templateCategory`	The display template category ID to use in rendering results for multiple content items. This ID may reference the default template category for an out-of-the-box display template (Table 31–6) or a custom category created for a display template for multiple content items that has been defined as described in Section 29.4, "Creating Content Presenter Display Templates".
`templateView`	The display template view ID to use in rendering results for single content items. Enter the view ID of a template that is configured in the Resource Manager for a specific content type, or for list-based templates by category ID. This ID may reference one of the out-of-the-box display templates (Table 31–5), a custom display template that has been defined as described in Section 29.4, "Creating Content Presenter Display Templates", or set to the contentID of a region template if the content is a region.

The out-of-the-box display templates provided by Oracle WebCenter are listed in Table 31–5 and Table 31–6.

Table 31–5 Out-of-the-Box Templates for Displaying Single Content Items

Single Content Item Display Templates	View ID	Description
Default Document Details View	`oracle.webcenter.content.templates.default.document.details`	Displays detailed information about any single content item including creation date, modification date, created by username, modified by username, path and any comments.
Default List Item View	`oracle.webcenter.content.templates.default.list.item`	Used by multiple content item views to display each individual item. Displays a single line with an icon and item name as a link that either displays or downloads the item when clicked.
Default View (default when no template is selected)	`oracle.webcenter.content.templates.default.detail`	Displays any single content item, either directly in the browser (images, HTML, text) or as a link that downloads the associated file when clicked.

Table 31–6 Out-of-the-Box Templates for Displaying Multiple Content Items

Multiple Content Item Display Templates	View ID	Description
Accordion View	`oracle.webcenter.content.templates.default.list.panel.accordion`	Displays multiple content items in an accordion format, where each item can be expanded to display its details.
Bulleted View	`oracle.webcenter.content.templates.default.list.bulleted`	Displays multiple content items in a bulleted list format. Only content items will be displayed; folder items will be omitted.
Bulleted with Folder Label View	`oracle.webcenter.content.templates.default.list.bulleted.label`	Displays multiple content items in a bulleted list format. The name of the folder containing the first item in the list will display as a label above the list. This template is intended to be used when datasourceType is set to dsTypeFolderContents to ensure that all items have the same parent folder. Only content items will be displayed; folder items will be omitted.
Carousel View	`oracle.webcenter.content.templates.default.list.carousel`	Displays multiple content items in a carousel format, where items can be browsed by moving a slider left or right.
Icon View	`oracle.webcenter.content.templates.default.list.tile`	Displays multiple content items in a tiled format with large icons and file names.
List View (default when no template is selected)	`oracle.webcenter.content.templates.default.list.simple`	Displays multiple content items in a simple list.
List with Details Panel View	`oracle.webcenter.content.templates.default.list.details.panel`	Displays multiple content items in a list on the left, with a panel to the right displaying the details of a selected item.
Sortable Table View	`oracle.webcenter.content.templates.default.list.tabular`	Displays multiple content items in a sortable table that includes the document name, date created, and date modified.
Tabbed View	`oracle.webcenter.content.templates.default.list.panel.tabbed`	Displays multiple content items as tabs that can be selected to display item details. content items in a simple list.

31.7.2 Document Explorer Task Flow Parameters

The Document Explorer task flow displays a list of folders and files in two panes: the left pane shows folders, and the right pane show the contents of the currently selected folder. It is a feature-rich documents task flow for viewing, managing, and collaborating on folders and files.

See Also:

- "Understanding the Document Explorer Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Explorer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–7 describes the Document Explorer task flow parameters.

Table 31–7 Document Explorer Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may wish to alter this value are: - The majority of end users have bigger screens, allowing for the display of more rows. - You want to fit this task flow into a smaller area of a page. **Note**: If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`readOnly`	Specifies whether to disable and hide all content management operations: - `${true}`: Disable content management. - `${false}` (default): Expose content management to users.
`resourceId`	The currently focused resource. This value can be a folder ID or a document ID. The `resourceId` value is checked for coherence with the `connectionName` and `startFolderPath` values, and influences their default values when they are not explicitly specified. For example, if `resourceId` alone is specified, the `connectionName` value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.

Table 31–7 (Cont.) Document Explorer Task Flow Parameters

Parameter	Description
`showDocuments`	Specifies whether the navigation tree shows documents and folders, or folders only: ■ `${true}`: Show documents and folders. ■ `${false}` (default): Show folders and hide documents.
`showFolders`	Specifies whether the navigation tree shows documents and folders, or documents only: ■ `${true}` (default): Show folders and documents. ■ `${false}`: Show documents and hide folders.
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current space's default root folder. But it is useful, for example, when you want the start folder to be other than a space's default root folder and when you want to display content from another space. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current Space.
`treeNavCollapsed`	Specifies whether to collapse or expand the panel containing the tree navigation: ■ `${true}` (default): Collapse panel. ■ `${false}`: Expand panel.

31.7.3 Document List Viewer Task Flow Parameters

The Document List Viewer task flow displays folders and files in a single pane as a flat listing. In this task flow, users can navigate a folder hierarchy, and customize search queries. While this task flow may be useful for a specific need, its search functionality is replicated and enhanced by the Content Presenter task flow.

See Also:

- "Understanding the Document List Viewer Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document List Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–8 describes the Document List Viewer task flow parameters.

Table 31–8 Document List Viewer Task Flow Parameters

Task Flow Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
`createdAfter`	A filtering value to limit the display of task flow content to folders and files created after a specified date and time. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZ'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`createdBefore`	A filtering value to limit the display of task flow content to folders and files created before a specified date and time. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZ'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`creator`	A filtering value to limit the display of task flow content to folders and files created by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then content created by any user is shown. Example: `${'monty'}`
`lastModifiedAfter`	A filtering value to limit the display of task flow content to folders and files last modified after a specified date and time. If no value is entered, then content modified in the last three months is shown. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01.00'}`
`lastModifiedBefore`	A filtering value to limit the display of task flow content to folders and files modified before a specified date and time. If no value is entered, then the last modification date is applied. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`lastModifier`	A filtering value to limit the display of task flow content to folders and files last modified by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then all modified documents are shown. Example: `${'monty'}`

Table 31–8 (Cont.) Document List Viewer Task Flow Parameters

Task Flow Parameter	Description
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may wish to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note**: If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current space's default root folder. But it is useful, for example, when you want the start folder to be other than a space's default root folder and when you want to display content from another space. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current Space.
`showFolders`	Specifies whether to show documents and folders, or documents only: ■ `${true}`: show folders and documents ■ `${false}` (default): show documents and hide folders
`taskFlowInstId`	The unique identifier for this task flow instance, used internally to maintain the association of the task flow instance with its customization and personalization settings and to manage saved queries. The value is generated automatically when you add individual files or the content of folders to your page from the Application Resources Panel, displaying the content in a Document List Viewer task flow. The value is blank when you add a Document List Viewer task flow onto your page from the Resource Palette. Enter or edit this value to set the unique identifier for the task flow.

[1] "TZ" is the time zone indicator. If the time being described is in UTC (Coordinated Universal Time), then the time zone indicator is "Z". If the time is from any other time zone, then TZ describes the offset from UTC of the time zone. For example, if the time is in California in December (Pacific Standard Time, PST), then the TZ indicator would be "-08:00".

31.7.4 Document Manager Task Flow Parameters

The Document Manager task flow displays folders and files as specified by its `layout` parameter: it may display folders and files in two panes (`explorer` layout), or a single pane showing only the content of the current folder (`table` layout), or a single pane showing the folder hierarchy starting from the root folder (`treeTable` layout). The `explorer` layout is identical to the Document Explorer task flow, without the properties `showDocuments`, `showFolders`, and `treeNavCollapsed`.

The Document Manager task flow provides comprehensive document management functionality, such as copying, moving, pasting, and deleting folders and files.

See Also:

- "Understanding the Document Manager Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Manager task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–9 describes the Document Manager task flow parameters.

Table 31–9 Document Manager Task Flow Parameters

Task Flow Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`layout`	A target layout for the task flow. Select from: - `${'explorer'}` (default): Displays folders and files in two panes; the left pane shows folders, and the right pane show the contents of the currently selected folder. This layout looks identical to the Document Explorer task flow, without the parameters `showDocuments`, `showFolders`, and `treeNavCollapsed`. See Figure 31–3. - `${'table'}`: Displays only the contents of the current folder in a single pane, with the capability to click a folder to drill down, refreshing the pane with the folder contents. See Figure 31–4. - `${'treeTable'}`: Displays the folder hierarchy in a single pane, beginning with the root folder, with the capability to expand and collapse folders. See Figure 31–5.

Table 31–9 (Cont.) Document Manager Task Flow Parameters

Task Flow Parameter	Description
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may wish to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note**: If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`readOnly`	Specifies whether to disable and hide all content management operations: ■ `${true}`: Disable content management. ■ `${false}` (default): Expose content management to users.
`resourceId`	The currently focused resource. This value can be a folder ID or a document ID. The `resourceId` value is checked for coherence with the `connectionName` and `startFolderPath` values, and influences their default values when they are not explicitly specified. For example, if `resourceId` alone is specified, the `connectionName` value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current space's default root folder. But it is useful, for example, when you want the start folder to be other than a space's default root folder and when you want to display content from another space. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current Space.

31.7.5 Document Navigator Task Flow Parameters

The Document Navigator task flow displays folders and files in a single pane, with the capability to expand and collapse folders to view folder hierarchy within the current folder. There are no menu options available to the end user for this task flow.

See Also:

- "Understanding the Document Navigator Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Navigator task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–10 describes the Document Navigator task flow parameters.

Table 31–10 Document Navigator Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may wish to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note**: If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`readOnly`	Specifies whether to disable and hide all content management operations: ■ `${true}`: Disable content management. ■ `${false}` (default): Expose content management to users.
`resourceId`	The currently focused resource. This value can be a folder ID or a document ID. The `resourceId` value is checked for coherence with the `connectionName` and `startFolderPath` values, and influences their default values when they are not explicitly specified. For example, if `resourceId` alone is specified, the `connectionName` value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
`showDocuments`	Specifies whether the navigation tree shows documents and folders, or folders only: ■ ${true} (default): Show documents and folders. ■ ${false}: Show folders and hide documents.

Table 31–10 (Cont.) Document Navigator Task Flow Parameters

Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current space's default root folder. But it is useful, for example, when you want the start folder to be other than a space's default root folder and when you want to display content from another space. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. Default: The root folder of the content repository configured with the specified connection for the current Space.

31.7.6 Folder Viewer Task Flow Parameters

The Folder Viewer task flow displays a listing of the contents of a folder in a single pane as a flat listing.

See Also:

- "Understanding the Folder Viewer Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Folder Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–11 describes the Folder Viewer task flow parameters.

Table 31–11 Folder Viewer Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 31–11 (Cont.) Folder Viewer Task Flow Parameters

Parameter	Description
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`pageSize`	The maximum number of rows to show in the task flow. If the listing of folders and files in the task flow is larger than the specified number of rows, the task flow displays a scroll bar. Default: `27` Typical scenarios where you may wish to alter this value are: ■ The majority of end users have bigger screens, allowing for the display of more rows. ■ You want to fit this task flow into a smaller area of a page. **Note**: If you set `pageSize` to a value that is too big for the size of the screen, the end user will experience difficulty coordinating the task flow scroll bar with the application scroll bar.
`readOnly`	Specifies whether to disable and hide all content management operations: ■ `${true}`: Disable content management. ■ `${false}` (default): Expose content management to users.
`resourceId`	The currently focused resource. This value can be a folder ID or a document ID. The `resourceId` value is checked for coherence with the `connectionName` and `startFolderPath` values, and influences their default values when they are not explicitly specified. For example, if `resourceId` alone is specified, the `connectionName` value will be inherited from it and the startFolderPath will be either the resource itself for a folder or the parent folder for a file.
`showFolders`	Specifies whether the navigation tree shows documents and folders, or documents only: ■ `${true}` (default): Show folders and documents. ■ `${false}`: Show documents and hide folders.

Table 31–11 (Cont.) Folder Viewer Task Flow Parameters

Parameter	Description
`startFolderPath`	The name of the folder to use as the root folder in the current task flow instance. This is a content-scoping parameter that assists with determining the source and range of content to display in the task flow instance. There is no need to set this value for task flows that display the content of the current space's default root folder. But it is useful, for example, when you want the start folder to be other than a space's default root folder and when you want to display content from another space. Example: ■ `${'/PersonalSpaces/monty/Public'}` ■ `${'/WebCenterB5/Proj_X/Specs'}` You can specify an EL expression to set this value. See "EL Expressions Relevant to the Documents Service" in Appendix B in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*. Default: The root folder of the content repository configured with the specified connection for the current Space.

31.7.7 Recent Documents Task Flow Parameters

The Recent Documents task flow displays a listing of the most recently created or modified files by the current user.

See Also:

- "Understanding the Recent Documents Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Recent Documents task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–12 describes the Recent Documents task flow parameters.

Table 31–12 Recent Documents Task Flow Parameters

Parameter	Description
`connectionName`	The name of the content repository connection. If no value is selected, the default connection specified by the application developer or administrator is used. For information about configuring content repository connections, see "Registering Content Repositories" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. Default: The connection selected as default in the Create Content Repository Connection dialog box by the application developer, which can be changed by the administrator.

Table 31–12 (Cont.) Recent Documents Task Flow Parameters

Parameter	Description
`groupSpace`	(Used in WebCenter Spaces only) The name of a space that is the source of the recently created or modified documents listed in the task flow. Valid values are: ■ no value or `${null}` (default): Displays documents for the entire connected content repository. ■ Display name or ID of a specific Space: Displays documents in that Space. ■ `${'all'}`: Displays documents from any Space, excluding non-Space documents.
`lastModifiedAfter`	A filtering value to limit the display of task flow content to folders and files last modified after a specified date and time. If no value is entered, then content modified in the last three months is shown. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01.00'}`
`lastModifiedBefore`	A filtering value to limit the display of task flow content to folders and files modified before a specified date and time. If no value is entered, then the last modification date is applied. The value uses the ISO 8601 format: `${'yyyy-mm-ddThh:mm:ss.sssTZD'}`[1] Example: `${'2011-03-17T18:24:36.000+01:00'}`
`lastModifier`	A filtering value to limit the display of task flow content to folders and files last modified by a particular user. Enter the user name as specified by the user login credentials. Only one user name may be entered. If no value is entered, then all modified documents are shown. Example: `${'monty'}`
`maxDocuments`	The maximum number of files to show. If no value or 0 is entered, then up to 10 of the most recently accessed documents are shown. Example: `${10}` Note that there is no single quote surrounding the value. Default: `${null}`
`mostRecentFirst`	Specifies the sort order of files in the task flow: ■ `${true}` (default): Most recent documents listed first. ■ `${false}`: Oldest documents listed first.

[1] "TZ" is the time zone indicator. If the time being described is in UTC (Coordinated Universal Time), then the time zone indicator is "Z". If the time is from any other time zone, then TZ describes the offset from UTC of the time zone. For example, if the time is in California in December (Pacific Standard Time, PST), then the TZ indicator would be "-08:00".

31.7.8 Document Viewer Task Flow Parameters

The Document Viewer task flow displays the contents of a folder or a preview of an individual file in the default template for its file type.

See Also:

- "Understanding the Document Viewer Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Viewer task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–13 describes the Document Viewer task flow parameters.

Table 31–13 Document Viewer Task Flow Parameters

Parameter	Description
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`initialSidebar`	Specifies the tabbed pane to have initial focus in the Document Viewer. Valid values are: ▪ `${'comments'}` (default). Displays the **Comments** pane (see "Viewing, Entering, and Deleting Comments on a File" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*). ▪ `${'tags'}`. Displays the **Tags** pane (see "Working with Tags" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*). ▪ `${'history'}`. Displays the **History** pane (see "Viewing and Deleting File Version History" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*). ▪ `${'docInfo'}`. Displays the **Info** pane (see "Viewing and Modifying Folder and File Properties" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*). ▪ `${'tags'}`. Displays the **Links** pane (see "Working with Links" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*). ▪ `${'autovue'}`. When Oracle AutoVue is installed, displays an **AutoVue** pane showing the AutoVue markup for the current document in a table of hyperlinked markup names (see "Collaborating on Documents Using AutoVue" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*).
`readOnly`	Specifies whether to disable and hide all content management operations: ▪ `${true}`: Disable content management. ▪ `${false}` (default): Expose content management to users.
`resourceID`	The currently focused resource. This value can be a folder ID or a document ID.

31.7.9 Document Mini Properties Task Flow Parameters

The Document Mini Properties task flow displays the basic properties of a selected file in a read-only view. This task flow is available for all file types.

See Also:

- "Understanding the Document Mini Properties Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Mini Properties task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–14 describes the Document Mini Properties task flow parameters.

Table 31–14 Document Mini Properties Task Flow Parameters

Parameter	Description
`resourceID`	The ID of the document for which to display basic properties.

31.7.10 Document Properties Task Flow Parameters

The Document Properties task flow displays both Basic and Advanced properties of a selected file, along with an **Edit** button to modify property values. This choice is available for all file types.

See Also:

- "Understanding the Document Properties Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Properties task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–15 describes the Document Properties task flow parameters.

Table 31–15 Document Properties Task Flow Parameters

Parameter	Description
`resourceID`	The ID of the document for which to display basic and advanced properties.
`readOnly`	Specifies whether or not to allow end user to edit document properties: ▪ `${true}`: Do not display **Edit** button in Basic and Advanced properties panes, thus disabling the ability for the end user to edit document properties. ▪ `${false}` (default): Display **Edit** button in Basic and Advanced properties panes, allowing end users to edit document properties.

31.7.11 Rich Text Editor Task Flow Parameters

The Rich Text Editor task flow displays an HTML or wiki document in the Rich Text Editor.

See Also:

- "Using the Rich Text Editor (RTE)" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Rich Text Editor task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–18 describes the Rich Text Editor task flow parameters.

Table 31–16 Rich Text Editor Task Flow Parameters

Parameter	Description
`destinationID`	The currently focused resource. This value can be a folder ID to create a new document in that folder, or a document ID (as shown in the properties pane of the Document Viewer task flow) to edit an existing document.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`
`initialSidebar`	Specifies a pane to display in the sidebar of the Document Viewer. Valid values are: ▪ `${'comments'}` (default). Displays a **Comments** pane (see "Viewing, Entering, and Deleting Comments on a File" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'history'}`. Displays a **History** pane (see "Viewing and Deleting File Version History" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'tags'}`. Displays a **Tags** pane (see "Working with Tags" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'links'}`. Displays a **Links** pane (see "Working with Links" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'recommendations'}`. Displays a **Recommendations** pane (see "Working with Recommendations" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'relatedItems'}`. Displays a **Related Items** pane (see "Working with Related Items (Links, Tags, and Recommendations)" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*) ▪ `${'docInfo'}`. Displays a **Properties** pane (see "Viewing and Modifying Folder and File Properties" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*)

31.7.12 Document Upload Task Flow Parameters

The Document Upload task flow displays the Upload dialog to allow users to upload new documents to the page.

See Also:

- "Uploading New Files" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Upload task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–18 describes the Document Upload task flow parameters.

Table 31–17 Document Upload Task Flow Parameters

Parameter	Description
`destinationID`	The currently focused resource. This value specifies a folder ID to upload a document into that folder.
`destinationSelectionEnabled`	Specifies whether or not the destination folder can be changed: ■ `${true}`: Display destination folder as an input text box along with a **Browse** button. ■ `${false}` (default): Display destination folder as read only text.
`featuresOff`	A list of disabled features for the task flow. Use commas or spaces to separate items. Valid values are exposed in the JavaDoc: `checkin`, `checkout`, `clipboard`, `close`, `delete`, `download`, `dnd`, `editwiki`, `editoffice`, `newfolder`, `newwiki`, `rename`, `upload`, `multifile-upload`, `profile-upload`, `search`, `advancedSearch`, `workflow`, `properties`, `history`, `comments`, `likes`, `links`, `tags`, `recommendations`, `autovue`, `title`, `related-items`, `social`, `sidebars`, `ils`. Example: `${'search, advancedSearch, clipboard, dnd, rename, newfolder, upload, newwiki, checkin, checkout, editoffice, edithtml, delete, sidebars, history'}`

31.7.13 Document Version History Task Flow Parameters

The Document Version History task flow displays a list of versions of a selected file in a read-only view. This task flow is available for all file types.

See Also:

- "Understanding the Document Version History Task Flow" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the Document Version History task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–18 describes the Document Version History task flow parameters.

Table 31–18 Version History Task Flow Parameters

Parameter	Description
`horizontalLayout`	Specifies the layout orientation for the version history information: ■ `${horizontal}`: Horizontal orientation. ■ `${vertical}` (default): Vertical orientation.
`resourceID`	The ID of the document for which to display version history.
`readOnly`	Specifies whether to disable and hide all content management operations: ■ `${true}`: Disable content management. `${false}` (default): Expose content management to users.

31.7.14 AutoVue Task Flow Parameters

The AutoVue task flow integrates the Oracle AutoVue functionality to allow users to review and collaborate on a document.

See Also:

- "Collaborating on Documents Using Oracle AutoVue" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*
- Section 31.5, "Adding a Content Task Flow to a Page"

Parameters that are unique to the AutoVue task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 31–19 describes the AutoVue task flow parameters.

Table 31–19 AutoVue Task Flow Parameters

Parameter	Description
`resourceId`	The ID of the document to display in the AutoVue task flow.

32

Integrating Wikis and Blogs

You can integrate the wiki and blog functionality in your WebCenter Portal: Framework applications to enable your application users to collaborate and share content and ideas.

This chapter describes how to integrate the wiki and blog functionality into your Framework applications. It includes the following sections:

- Section 32.1, "Introduction to Wikis and Blogs"
- Section 32.2, "Requirements for Wikis and Blogs"
- Section 32.3, "Integrating Wikis"
- Section 32.4, "Integrating Blogs"

32.1 Introduction to Wikis and Blogs

A wiki is a collection of useful content or information that users can browse, update, and remove, sometimes without the need for registration. This ease of interaction and the variety of operations make wiki an effective tool for collaborative authoring, where multiple people create written content together.

Blogs are typically personal records of an individual user's experience and opinions. The word *blog* is a contraction of the term *Web log*. It was coined to describe the online diaries spawned in the late 1990s. Blogs provide a useful tool for discussing and/or evangelizing any type of idea, strategy, or point of view. Blogs may be projected out to a select group of people or to a wider audience. Typically, each blog contains various blog posts, with the most recently added blog post displayed at the top. Blogs invite readers to comment on the overall concepts.

You can integrate wikis and blogs into your Framework applications using the Documents service. There is no limitation on the number of wiki pages or blogs that you can expose in an application.

32.2 Requirements for Wikis and Blogs

To support the wiki and blog functionality, the Documents service relies on Content Server. For wiki and blog functionality to be available in your Framework applications, the following prerequisites must be met:

- Content Server 11*g* must be installed and configured as the default content repository for WebCenter Portal. The wiki blog functionality is not available with Content Server 10*g*. For information about installing and configuring Content Server 11*g*, see the "Managing Content Repositories" chapter in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

- A connection to Content Server 11*g* must be established. For information, see Section 27.2.1, "How to Create a Content Repository Connection Based on the Oracle Content Server Adapter."
- Complete the steps covered in Section 7.2, "Preparing Your Framework Application to Consume Services", as needed. For example, you can use the Activity Stream feature to track activities such as when a blog or wiki document is created or updated. Application users can add comments on wiki documents and blog posts to express their views. To enable the Comments and Activities Stream features, you must register a connection to a database that has the `WebCenter` schema installed.

After completing these requirements, you can use the Documents service to add wikis and blogs to your Framework applications:

- To add wikis to your application, you will need to add a Documents service task flow that provides the **Add Wiki Document** action (such as the Document Explorer task flow). See Section 32.3, "Integrating Wikis."
- To add blogs to your application, you use the blog tasks flows. See Section 32.4, "Integrating Blogs."

If you want to convert wikis and blogs in your Framework applications into PDF, your application administrator must configure the WebCenter Conversion component, as described in "Enabling the Conversion of Wikis and Blogs into PDFs" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

32.3 Integrating Wikis

This following sections provide the information you need to add wiki documents to your Framework applications:

- Section 32.3.1, "What You Should Know About the Document Explorer Task Flow"
- Section 32.3.2, "Adding the Document Explorer Task Flow to Provide the Wiki Functionality"
- Section 32.3.3, "Modifying Document Explorer Task Flow Parameters"
- Section 32.3.4, "What Happens at Runtime"
- Section 32.3.5, "Displaying Wiki Page Links Within Content Presenter"

32.3.1 What You Should Know About the Document Explorer Task Flow

To provide your application users with the ability to add and manage wiki documents at runtime, you need to add the Document Explorer task flow to your Framework application. When you add this task flow at design time, it is built into the application for end users, and enables them to work with wiki documents at runtime.

The Document Explorer task flow has associated parameters. For information, see Section 31.7.2, "Document Explorer Task Flow Parameters."

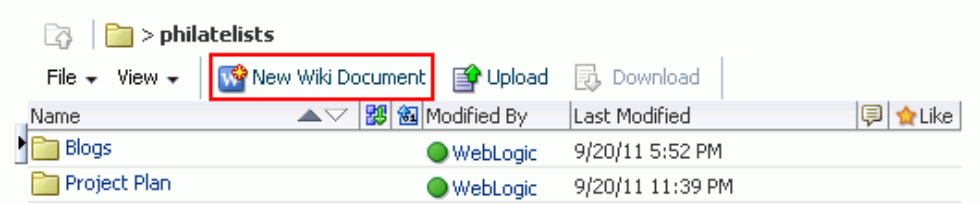
32.3.2 Adding the Document Explorer Task Flow to Provide the Wiki Functionality

To prepare your Framework application and add the Document Explorer task flow for enabling the wiki functionality:

1. Ensure that you have completed the requirements listed in Section 32.2, "Requirements for Wikis and Blogs."

Note: While setting up the connection, you must choose an authentication method. If you choose identity propagation, you must implement ADF security in your application and configure secure socket layer (SSL) on Oracle Content Server.

If you choose external application, you must specify the external application you want to use for authenticating users to Oracle Content Server.



For information, see Section 7.2.1.1, "Implementing Security for Services."

2. Create or open the JSF page in which you want to provide the wiki functionality (see Section 5.3, "Adding Pages to a Portal").
3. Choose a method for adding the Document Explorer task flow to the page:
   - To add the Document Explorer task flow prepopulated with a selected folder or file, see Section 31.4, "Adding a Selected Folder or File to a Page"
   - To add the Document Explorer task flow standalone as an "empty" task flow that you can populate using the task flow menus and actions, see Section 31.5, "Adding a Content Task Flow to a Page"

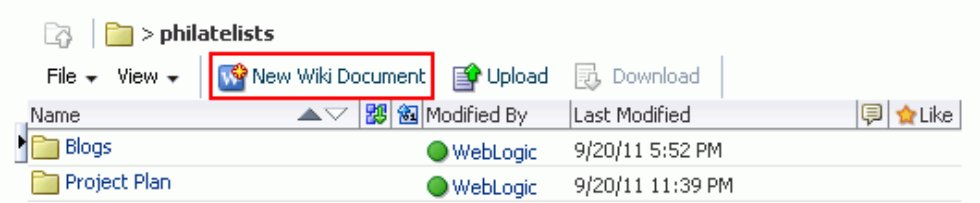
   For information about the parameters that you can set for the Document Explorer task flow, see Section 31.7.2, "Document Explorer Task Flow Parameters."

   When you run the page, the Document Explorer task flow displays in your default browser, as shown in Figure 32–1. Application users can create a wiki document by clicking **New Wiki Document**.

Figure 32–1 Creating a New Wiki Document

32.3.3 Modifying Document Explorer Task Flow Parameters

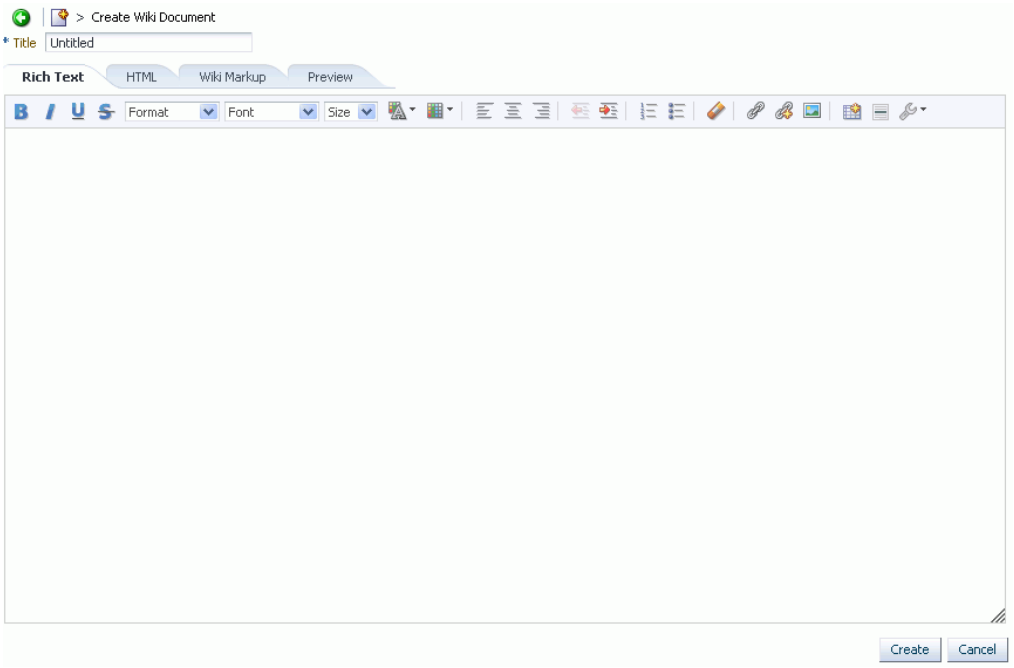
The way you modify parameters of a Document Explorer task flow is same as for any other Documents service task flow. For information, see Section 31.6, "Modifying Content Task Flow Parameters." For information about the specific parameters that you can modify, see Section 31.7.2, "Document Explorer Task Flow Parameters."



32.3.4 What Happens at Runtime

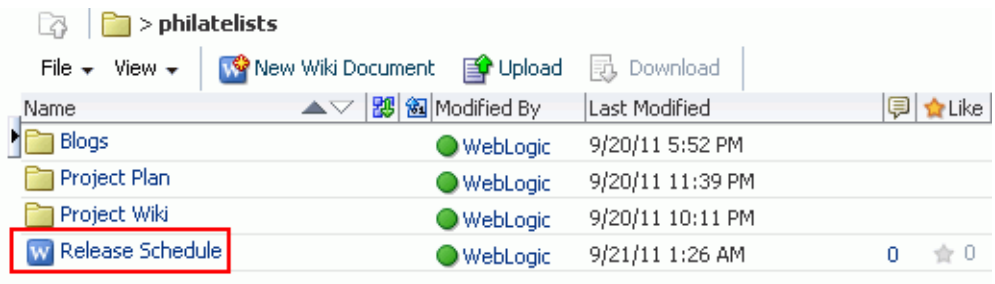
At runtime, authorized application users can create wiki documents in a Framework application in which the wiki functionality has been exposed. Users can also edit, download, rename, share, and subscribe to a wiki document and view its history and properties.

At runtime, the folder that you exposed through the Document Explorer task flow is shown as the root folder. Application users can create a wiki document by clicking



New Wiki Document (Figure 32–4), which opens the Rich Text Editor (RTE) (Figure 32–3), displaying a blank wiki document.

Figure 32–2 Creating a New Wiki Document



Users can add and edit wiki content using the Rich Text Editor (RTE), which is a fully-integrated HTML text editor (Figure 32–3).

Figure 32–3 Rich Text Editor Displaying New Wiki Document

By default, all wiki documents are created directly under the root folder (Figure 32–4).

Figure 32–4 Wiki Document Created Using New Wiki Document Action

At runtime, users can also choose to display a wiki document using Content Presenter.

The runtime procedures for adding and managing wiki documents in a Framework application are same as in WebCenter Portal: Spaces. For generic information, refer to the chapter "Working with Wiki Documents" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

32.3.5 Displaying Wiki Page Links Within Content Presenter

At runtime, when a wiki document is displayed using a Content Presenter display template, by default the links present in the wiki document render in the Document Viewer. You can configure your application to display such links within Content Presenter.

To open the links present in a wiki document within Content Presenter:

1. Open the `adf-config.xml` file. This file is located under `Descriptors/ADF META-INF` in the Application Navigator.
2. Update the `Namespace` entry as follows:

```
xmlns:wpsC="http://xmlns.oracle.com/webcenter/framework/service"
```

3. Update the `ResourceActionHandler` entry as follows:

```
<wpsC:adf-service-config
xmlns="http://xmlns.oracle.com/webcenter/framework/service">
      <resource-handler
class="oracle.webcenter.portalframework.sitestructure.handler.NavigationResourc
eActionHandler"/>
</wpsC:adf-service-config>
```

4. Save `adf-config.xml`.

32.4 Integrating Blogs

When you integrate the blogs functionality into your Framework application, authorized application users can create and manage blog posts. To enable the blog functionality, you need to add the blog task flows.

While integrating the Blogs task flow, you need to specify a folder on Oracle Content Server that will act as the container for your blog and contain all the blog posts.

This following sections provide the information you need to add blogs to a Framework application:

- Section 32.4.1, "Understanding the Blog Task Flows"
- Section 32.4.2, "Adding a Blog to a Page"
- Section 32.4.5, "Blog Task Flow Parameters"
- Section 32.4.4, "Modifying Blog Task Flow Parameters"
- Section 32.4.3, "What Happens at Runtime"

32.4.1 Understanding the Blog Task Flows

If you want to include a blog on a page, along with other page components, you can use the blog task flows to add one or more elements of a blog to a page. Table 32–1 lists and describes the blog task flows:

Table 32–1 Blog Task Flows

Blog Task Flow	Description	Example as Exposed on a Page
Blog Archives	Displays a composite list of blogs based on dates.	
Blog Banner	Displays a banner for the blog.	
Blog Digest	Displays a blog or blog post.	
Recent Blog Posts	Displays a list of most recent blog posts.	

Table 32–1 (Cont.) Blog Task Flows

Blog Task Flow	Description	Example as Exposed on a Page
Blogs	Displays a blog or blog post with a default design.	

32.4.2 Adding a Blog to a Page

To add a blog to a page in your Framework application:

1. Ensure that you have completed the requirements listed in Section 32.2, "Requirements for Wikis and Blogs."

   Note: While setting up the connection, you must choose an authentication method. If you choose identity propagation, you must implement ADF security in your application and configure secure socket layer (SSL) on Oracle Content Server.

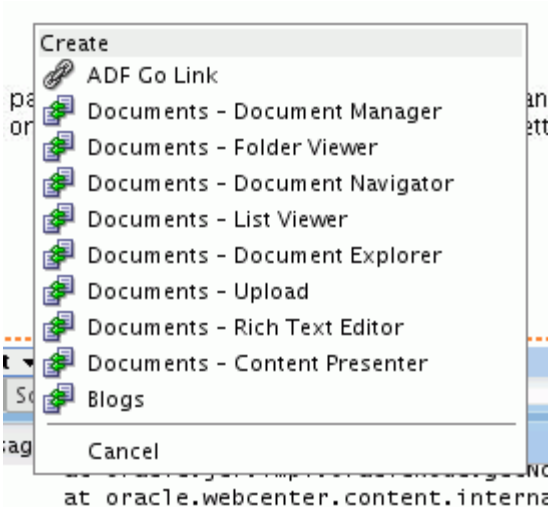
   If you choose external application, you must specify the external application you want to use for authenticating users to Oracle Content Server.

   For information, see Section 7.2.1.1, "Implementing Security for Services."

2. Create or open a page in your application where you want to expose the blog functionality (see Section 5.3, "Adding Pages to a Portal").
3. Before you add a blog task flow to your page, consider whether or not you want to allow your application users to edit the task flow. To enable runtime editing of the page, see Chapter 20, "Enabling Runtime Editing of Pages Using Composer."
4. Add a blog to the page using an existing folder, or by creating a new "empty" blog:
   - Section 32.4.2.1, "Establishing a Selected Folder as a Blog Folder"
   - Section 32.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows"

32.4.2.1 Establishing a Selected Folder as a Blog Folder

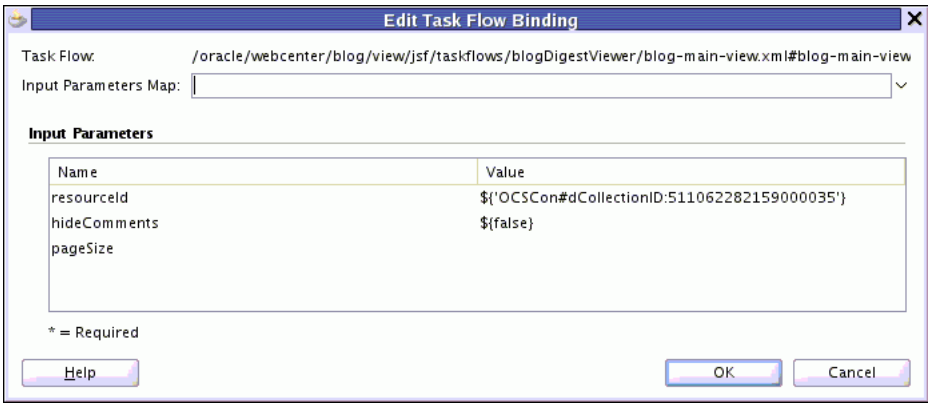
If you have an existing folder, perhaps already containing blog posts, you can establish that folder as a blog folder, instead of creating a new "empty" blog (see Section 32.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows"). At runtime, the blog displays the blog posts in that folder.



To expose a selected folder and its contents as a blog on a page:

1. In the **Application Resources** panel, navigate to **Connections**, then **Content Repository**.
2. Locate the name of your Content Server connection, then expand it to navigate to the folder that you want to establish as the blog folder.

   > **Tip:** You can expose any folder as a blog. To better organize your blogs, you may consider storing each blog folder in a parent folder; for example, a folder named **Blogs**. You can create a folder using either the Documents service interface or the Content Server console.
   >
   > Files stored in the blog folder are identified as blog posts in their metadata `Type` field. Uploading an HTML file into a blog folder does not expose it as as blog post, unless its `Type` is set to `blog`.



3. Drag the folder onto the page, and release the mouse button to display a menu listing all available task flows (Figure 32–5).

Figure 32–5 Menu of Available Task Flows for Selected Folder

4. From the menu, choose **Blogs** to open the Edit Task Flow Binding dialog (Figure 32–6).

Figure 32–6 Specifying Parameters for Blogs Task Flow

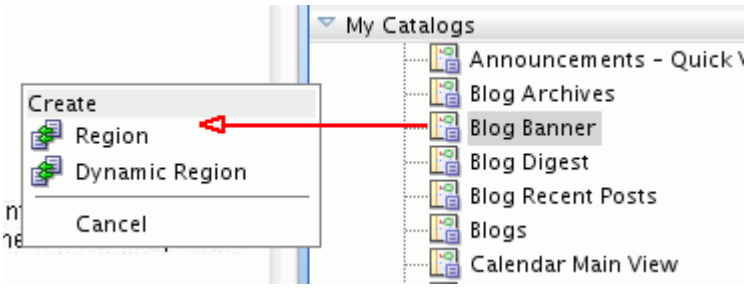
5. In the Edit Task Flow Binding dialog, the `resourceId` value is automatically populated with the resource ID of the selected folder. Click **OK** to accept the default task flow parameters, or modify the parameters as desired. For more information, see Section 32.4.5.5, "Blogs Task Flow Parameters."

6. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

The new blog is given the same name as the selected folder. Existing files under the folder become blog posts if the `Type` property of the file is set to `blog` (for more information about file properties in Content Server, see "Info Update Form" in *Oracle WebCenter Content User's Guide for Content Server*). As posts are added to the blog at runtime, the blog posts are stored in this folder.

32.4.2.2 Adding a Custom Blog to a Page Using the Blog Task Flows

You may want to add an "empty" blog task flow onto your page, either as one component on a page, or as the entire page. For example, in cases where you do not have a content repository connection, or want to use an EL expression as a parameter to dynamically bind to a target item, you may want to use this method instead of the method described in Section 32.4.2.1, "Establishing a Selected Folder as a Blog Folder." Additionally, the individual blog task flows enable you to customize the appearance of a blog.



To add a customized blog task flow to a page:

1. In the **Resource Palette**, expand the **WebCenter Portal - Services Catalog**. Under **Task Flows**, select the blog task flow that you want to add, drag it onto your page., and realease the mouse button.

   For information about each of the five blog task flows, see Section 32.4.1, "Understanding the Blog Task Flows."

2. From the menu that displays, choose **Region** (Figure 32–7).

Figure 32–7 Adding Blog Task Flow Using Resource Palette

3. In the Edit Task Flow Binding dialog, click **OK** to accept the default task flow parameters, or modify the parameters as desired. For information, see Section 32.4.5, "Blog Task Flow Parameters."
4. Repeat these steps for each blog task flow that you want to comprise your blog.
5. Save your page and the page definition file, then run your page to your browser by right-clicking the page (not the page definition file) and choosing **Run**.

Internally, the new blog is given the same name as the folder specified by the `resourceID`; however, the name visible on the page is the value you specify in the `Title` parameter of the Blog Banner task flow. Existing files under the folder become blog posts if the `Type` property of the file is set to `blog` (for more information about file properties in Content Server, see "Info Update Form" in *Oracle WebCenter Content User's Guide for Content Server*). As posts are added to the blog at runtime, the blog posts are stored in this folder.

32.4.3 What Happens at Runtime

At runtime, the folder specified by the `resourceID` parameter for the blog task flow is exposed as a blog on the page:

- If you created a blog as described in Section 32.4.2.1, "Establishing a Selected Folder as a Blog Folder", then the name of the folder that you exposed as a blog is displayed as the name of your blog in the blog banner.
- If you created a blog as described in Section 32.4.2.2, "Adding a Custom Blog to a Page Using the Blog Task Flows", then the name of the folder that you specify in the `resourceID` parameter of the blog task flow is the name of your blog internally; however, the name visible on the page is the value you specify in the `Title` parameter of the Blog Banner task flow.

Authorized users can create blog posts, and the posts are displayed on the blog page. Users can perform tasks such as edit, download, comment upon blog posts, and so on.

On the default blog page (Figure 32–8), and in the Blog Archives task flow, the **Archives** section provides links to blog posts by year and by month. Clicking a month displays all blog posts created during that month.

Figure 32–8 A Default Blog Page

A blog displays various details for each blog post. These include the blog post title, the blog post content, date of creation or modification, name of the user who created or last modified the post, and the number of comments on the blog post. Authorized users can click the **Edit Post** icon to edit a post, and click the **Post comments** link to enter comments on a blog post.

Clicking a blog post title opens the blog post to occupy the entire the blog page (Figure 32–9), providing controls to manage the blog post.

Figure 32–9 A Blog Post

The procedures for managing blogs at runtime in a Framework application is same as that for managing blogs in WebCenter Portal: Spaces. For information, see the "Working with Blogs" chapter in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

32.4.4 Modifying Blog Task Flow Parameters

The procedure for modifying the parameters of a Blogs task flow is same as any other Documents service task flow. For information, see Section 31.6, "Modifying Content

Task Flow Parameters." For information about the parameters that you can modify, see Section 32.4.5, "Blog Task Flow Parameters."

32.4.5 Blog Task Flow Parameters

Each blog task flow has its own set of parameters. You can configure these values when you add the task flow to your page, or modify the values at any time .

The following sections describe the parameters for the blog task flows:

- Section 32.4.5.1, "Blog Archives Task Flow Parameters"
- Section 32.4.5.2, "Blog Banner Task Flow Parameters"
- Section 32.4.5.3, "Blog Digest Task Flow Parameters"
- Section 32.4.5.4, "Blog Recent Posts Task Flow Parameters"
- Section 32.4.5.5, "Blogs Task Flow Parameters"

32.4.5.1 Blog Archives Task Flow Parameters

The Blog Archives task flow displays a composite list of blogs based on dates.

See Also: Section 32.4.1, "Understanding the Blog Task Flows."

Parameters that are unique to the Blog Archives task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 32–2 describes the Blog Archives task flow parameters.

Table 32–2 Blog Archives Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder.

32.4.5.2 Blog Banner Task Flow Parameters

The Blog Banner task flow task flow displays a banner for the blog.

See Also: Section 32.4.1, "Understanding the Blog Task Flows."

Parameters that are unique to the Blog Banner task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 32–3 describes the Blog Banner task flow parameters.

Table 32–3 Blog Banner Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder.
`imageURL`	(Optional) The background image to be used in the blog banner. When not specified, the background image will default to an image provided by the current skin.
`title`	(Optional) The title to be used for the blog banner. Default: The blog folder name.

32.4.5.3 Blog Digest Task Flow Parameters

The Blog Digest task flow displays a blog or blog post.

See Also: Section 32.4.1, "Understanding the Blog Task Flows."

Parameters that are unique to the Blog Digest task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 32–4 describes the Blog Digest task flow parameters.

Table 32–4 Blog Digest Task Flow Parameters

Parameter	Description
`resourceId`	The target blog resource to display. This can be either a folder ID, in which case the blog listing for this folder will display, or a document ID, in which case the blog post will display.
`year`	A Aour-digit number specifying the target year used to filter blog entries. Example: `2012`
`month`	A number from 1 to 12 specifying the target month used to filter blog entries. For this parameter to take effect, the Filter Year parameter must also be specified. Example: `10` (October)
`hideComments`	Specifies whether the Comments feature is exposed: ▪ Selected: Hide the Comments link and pane. ▪ Cleared (default): Show the Comments link and pane.
`pageSize`	The number of blog posts displayed in the Blog Digest Viewer before the Next and Previous icons are enabled. Default: `10`

32.4.5.4 Blog Recent Posts Task Flow Parameters

The Blog Recent Posts task flow displays a list of most recent blog posts.

See Also: Section 32.4.1, "Understanding the Blog Task Flows."

Parameters that are unique to the Blog Recent Posts task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 32–5 describes the Blog Recent Posts task flow parameters.

Table 32–5 Blog Recent Posts Task Flow Parameters

Parameter	Description
`resourceId`	The resource ID of the blog folder.
`recentPostListSize`	The number of recent posts to display. Default: `10`

32.4.5.5 Blogs Task Flow Parameters

The Blogs task flow displays a blog or blog post with a default design.

See Also: Section 32.4.1, "Understanding the Blog Task Flows."

Parameters that are unique to the Blogs task flow task flow are shown in the Edit Task Flow Binding dialog box when you add the task flow to a page. Table 32–6 describes the Blogs task flow task flow parameters.

Table 32–6 Blogs Task Flow Parameters

Parameter	Description
`resourceId`	The target blog resource to display. This can be either a folder ID, in which case the blog listing for this folder will display, or a document ID, in which case the blog post will display.
`hideComments`	Specifies whether the Comments feature is exposed: ■ Selected: Hide the Comments link and pane. ■ Cleared (default): Show the Comments link and pane.
`pageSize`	The number of blog posts displayed in the Blogs task flow before the Next and Previous icons are enabled. Default: `10`

Part V

Enabling Communication and Collaboration

Part V contains the following appendixes:

- Chapter 33, "Integrating the Announcements Service"
- Chapter 34, "Integrating the Discussions Service"
- Chapter 35, "Integrating the Instant Messaging and Presence Service"
- Chapter 36, "Integrating the Mail Service"
- Chapter 37, "Integrating the Polls Service"

33

Integrating the Announcements Service

This chapter explains how to integrate the Announcements service into a WebCenter Portal: Framework application at design time. For more information about managing and including announcements, see:

- "Managing the Announcements and Discussions Services" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- "Working with the Announcements Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

This chapter includes the following sections:

- Section 33.1, "Introduction to Announcements"
- Section 33.2, "Basic Configuration for the Announcements Service"
- Section 33.3, "Advanced Information for the Announcements Service"

33.1 Introduction to Announcements

The Announcements service lets you create and expose announcements on your application pages. Access to announcements boosts community participation, problem resolution, and knowledge sharing.

You can use the Links service to link announcements to other services, such as Events or Discussions. For example, suppose your company is announcing a new product, you can link from the announcement directly to a discussion forum, where potential customers can ask other customers about the product, or link to an instant messenger to speak directly with a customer service representative to purchase the product.

Announcements can show either forum-level announcements or global announcements (that is, system announcements not specific to a forum).

This section includes the following subsections:

- Section 33.1.1, "Understanding the Announcements Service"
- Section 33.1.2, "Requirements for Announcements"
- Section 33.1.3, "What Happens at Runtime"

33.1.1 Understanding the Announcements Service

With the Announcements service, you can do the following:

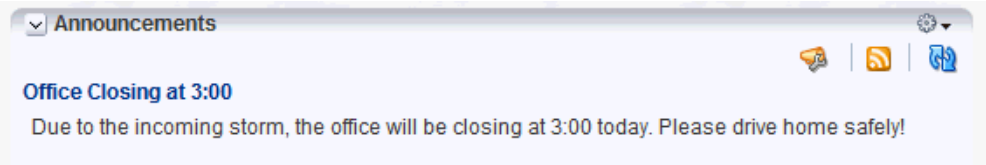
- Create announcements.
- Edit and delete existing announcement.

- Mail announcements.
- Personalize the Announcements view. You can select to display all announcements or only announcements sent today, this week, or this month. You can also view future, active, or expired announcements.
- Manage announcements, such as publishing announcements on a later date and specifying auto-expire on certain dates.

The Announcements service is integrated with many other services in WebCenter Portal, such as Activity Stream, RSS, and Instant Messaging and Presence, and you can link announcements to other services, such as Events and Discussions. For example, suppose your company is announcing a new product. You can link from the announcement directly to a discussion forum, where potential customers can ask other customers about the product, or link to an instant messenger where customers can chat with a customer service representative about the product. With WebCenter Portal live search, announcement titles are searchable, and with Oracle Secure Enterprise Search, announcement titles *and* text are searchable.

33.1.2 Requirements for Announcements

The Announcements service requires a discussions server. You must install and configure the discussions server that comes with Oracle Fusion Middleware.



> **See Also:** *Oracle Fusion Middleware Installation Guide for Oracle WebCenter Portal*

33.1.3 What Happens at Runtime

At runtime, users who have been granted the `create` permission can post announcements, and these announcements are visible to all users who have `view` permission. For example, an application administrator can use this service to announce the availability of a new feature or the plan to shut down the application temporarily for maintenance.

Figure 33–1 shows a sample announcement at runtime.

Figure 33–1 Sample Announcement in the Announcements - Quick View Task Flow

To view announcements in the Announcement Manager, ensure that the Announcements task flow has been added to your Framework application. Then log in to your application and click the **Open Announcement Manager** icon in the Announcements task flow (Figure 33–2).

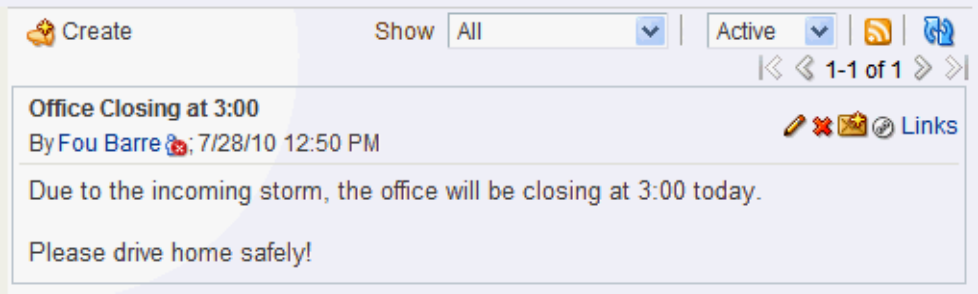


Figure 33–2 Open Announcement Manager Icon

Note: The **Open Announcement Manager** icon does not display if the user does not have the required privileges.

Figure 33–3 shows the sample announcement in the Announcement Manager.

Figure 33–3 Sample Announcement in the Announcement Manager

Application administrators in Framework applications can access the Announcement Manager, which provides **Create**, **RSS**, and **Refresh** icons, and **Show** dropdown lists to control the display of announcements on the page. **Edit**, **Delete**, **Mail**, and **Links** icons are available for each announcement in the list.

Depending on the privileges users have on the page and whether the required services in WebCenter Portal are configured in the application, users may see only a subset of these options in the Announcement Manager. For example, the **Delete** icon is displayed only to users with administrative privileges.

For more information about the service at runtime, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

33.2 Basic Configuration for the Announcements Service

This section describes required steps for adding this service to your Framework application. It includes the following subsections:

- Section 33.2.1, "Setting Up a Connection for Announcements"
- Section 33.2.2, "Adding the Announcements Service at Design Time"
- Section 33.2.3, "Setting Security for Announcements"

33.2.1 Setting Up a Connection for Announcements

To take advantage of the Announcements service, you must first create a connection to the discussions server from your application. To do so, ensure that you have the connection information for the discussions server.

33.2.1.1 Announcements Connections

The Announcements service requires a Discussion Forum connection to the discussions server. You can register additional Discussion Forum connections, but only one connection is active at a time.

When you create a Discussion Forum connection or set a connection as active, both the Announcements and Discussions services use this same connection. If you have an existing connection, then you can skip this section and see Section 33.2.2, "Adding the Announcements Service at Design Time."

If you do not have an existing connection, then you must create a new Discussion Forum connection.

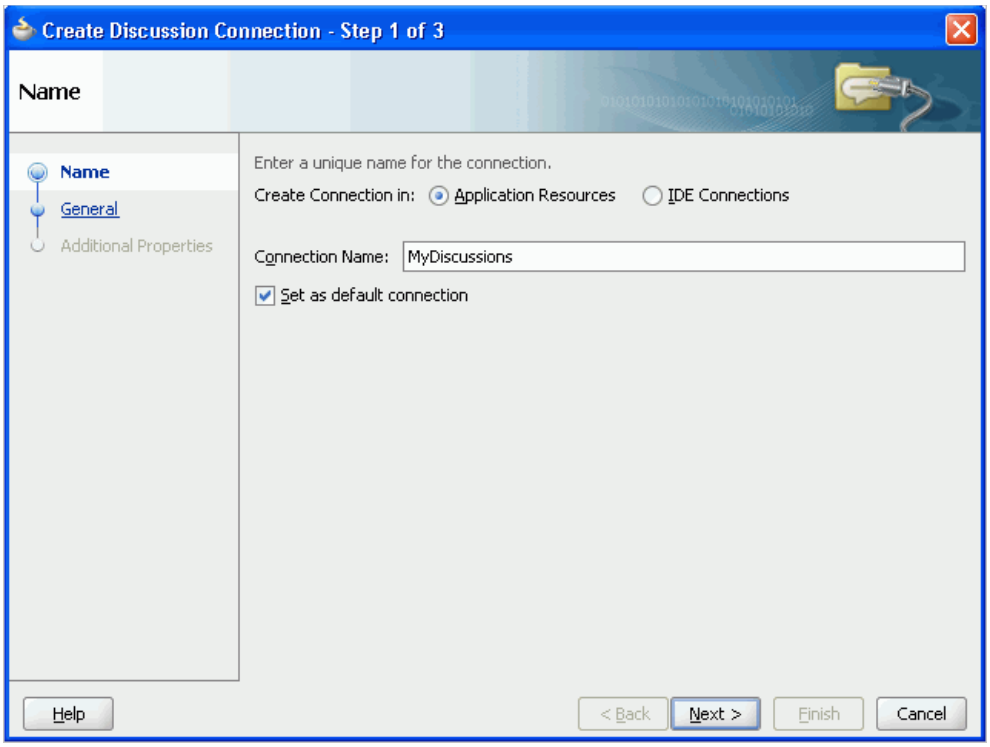
> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

33.2.1.2 How to Set Up Connections for Announcements

To set up the Announcements connection:

1. In Oracle JDeveloper, open the application in which you plan to consume Announcements.

   > **Note:** If you created a Discussion Forum connection for the Discussions service, then that is used by default for the Announcements service. No extra configuration is required.



2. In the Application Navigator, under Application Resources, right-click **Connections**, then select the new connection **Discussion Forum** from the list.
3. On the **Name** page, select to create the connection in **Application Resources**. (A connection in Application Resources is available only for that application, while a connection in IDE Connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE Connections so you do not need to re-create it.)

   > **Note:** If you create a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.

4. For **Connection Name**, enter a meaningful name; for example, `MyDiscussions`.
5. Select the **Set as default connection** checkbox. You can have multiple connections, but only one can be active (default). If you have different discussions servers (for example, for each page in a space), then do not select the checkbox, but the service requires that one connection be marked as the active connection (Figure 33–4).

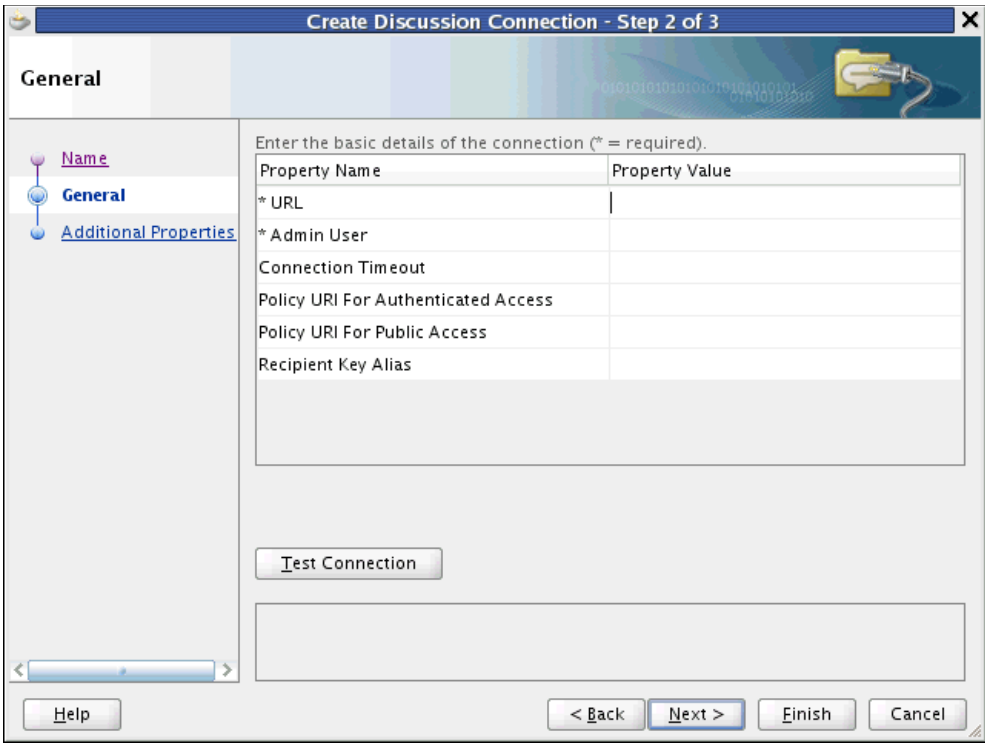
   > **Note:** After you create a connection as the active connection, you cannot edit it so that it is *not* the default. To use a different default connection, you must create a new connection and mark that as the default connection.

Figure 33–4 Create Discussion Connections, Step 1

6. Click **Next**.
7. On the **General** page, enter values for the required parameters:
   - `URL`: Enter the URL of the discussions server; for example: `http://discussions.example.com:8888/owc_discussions`.
   - `Admin User`: The user name of your discussions server administrator; for example, `admin`. This account is used by the Discussions and Announcement services to perform administrative operations on behalf of WebCenter Portal users.

     In WebCenter Portal: Spaces, this account is mostly used for managing space-related discussions and announcements. It is not necessary for this user to be a super admin. However, the user must have administrative privileges on the current root category for Spaces, that is, the category (on the discussions server) under which all space-related discussions and announcements are stored.

     Note: If your Framework application does not include space-related functionality, the administrator's user name is not required.
8. Optionally, enter a value for the other parameters:
   - `Connection Timeout`: Specify a suitable timeout for the connection. This is the length of time (in seconds) the application waits for a response from the discussions server before issuing a connection timeout message. The default is -1, which means that the service default is used. The service default is 10 seconds.



- `Policy URI for Authenticated Access`: Select the SAML token client policy this connection uses for authenticated access to the discussions server Web service. SAML (Security Assertion Markup Language) is an XML-based standard for passing security tokens defining authentication and authorization rights. An attesting entity (that has trust relationship with the receiver) vouches for the verification of the subject by method called sender-vouches. Options available are:
  - WSS 1.0 SAML Token Client Policy (oracle/wss10_saml_token_client_policy)
  - WSS 1.1 SAML Token With Message Protection Client Policy (oracle/wss11_saml_token_with_message_protection_client_policy)

  The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServiceAuthenticated` endpoint in the discussions server. Out-of-the-box, the default service policy is WSS 1.0 SAML Token Service Policy (oracle/wss10_saml_token_service_policy).
- `Policy URI for Public Access`: Select the client policy this connection uses to enforce message security and integrity for public access to the discussions server Web service. Options available are:
  - None - This is the default setting.
  - WSS 1.1 Message Protection Client Policy (oracle/wss11_with_message_protection_client_policy)

  The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServicePublic` endpoint in the discussions server. Out-of-the-box, a service policy is not configured for public access.
- `Recipient Key Alias`: Enter the recipient key alias to be used for message protected policies (applicable to the `OWCDiscussionsServicePublic` and `OWCDiscussionsServiceAuthenticated` endpoints). This is the alias to the certificate that contains the public key of the discussions server in the configured keystore.

  For more information, see the chapter "Configuring WS-Security for WebCenter Portal's Applications and Components" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

Figure 33–5 Create Discussions Connection, Step 2

9. Click **Test Connection**, and if it is successful, then click **Next**.
10. On the **Create Discussion Connection - Step 3 of 3** page, you can configure additional parameters. For example:

    `application.root.category.id`: (WebCenter Portal: Spaces only) The application root category ID on the discussions server under which all discussion forums are stored. For example, if set to 3, then all forums are stored inside the category 3.

    Note: To encrypt property values, such as passwords, click **Add Secured Property**.

11. Click **Finish**. Your connection should now appear as a node under **Application Resources - Connections**.

33.2.2 Adding the Announcements Service at Design Time

This section explains a basic incorporation of the Announcement service.

33.2.2.1 Announcements Service Task Flows

Both the Announcements and the Announcements - Quick View task flows display current announcements. The Announcements task flow additionally offers tools for managing announcements within the task flow. With the Announcements - Quick View task flow, you must click the **Open Announcement Manager** icon to manage announcements, and administrators can configure this task flow to remove all announcement management functionality.

Table 33–1 Announcements Service Task Flows

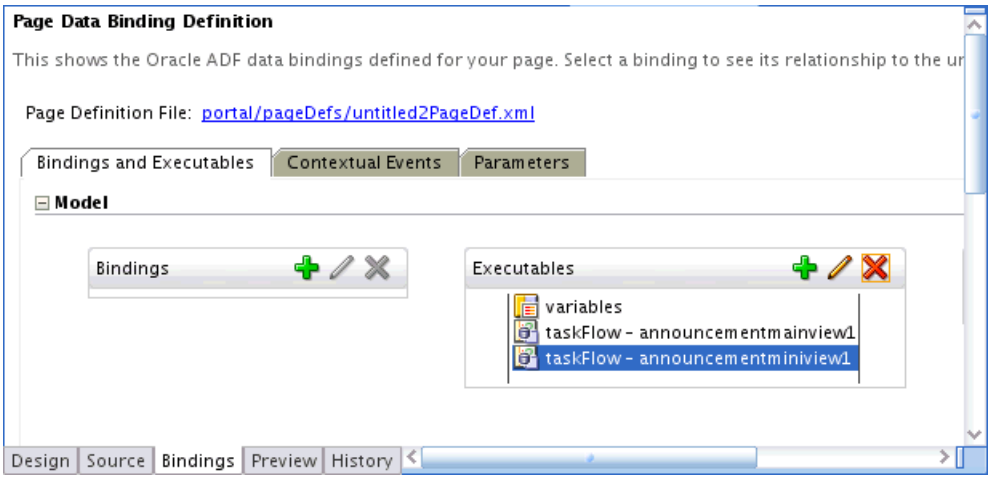
Task Flow	Description
Announcements	This task flow displays a view that allows the user to see all current announcements and perform operations based on their privileges. For a Moderator, all command buttons are shown, but for a Reader, only the refresh and personalization options are shown. The personalization option lets users select the number of days to display announcements. The `parentId` parameter is the forum ID in the discussions server under which announcements are maintained. Each Framework application should create a forum on the discussions server.
Announcements - Quick View	This task flow displays a view that shows various categories of quick links to announcements. The `parentId` parameter is the forum ID in the discussions server under which announcements are maintained. Each Framework application should create a forum on the discussions server. The look and feel of this view changes with the optional parameter values given for rendering the task flow region. For information on how to add this task flow, see Section 33.3.1, "How to Add the Announcements - Quick View Task Flow."

33.2.2.2 How to Add Announcements to Your Page

The Announcements task flow provides a complete view of your announcements. To add the Announcements task flow to your Framework application:

1. Follow the steps described in Chapter 3, "Preparing Your Development Environment" to implement security and create a new customizable page in your application.
2. Open the page on which you want to add the service.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
4. Drag **Announcements** from the Resource Palette and drop it onto the page inside of the `af:form` `begin` and `end` tags.
5. When prompted, select **Region** as the way to create the task flow (and confirm with **Add Library**). This operation may take a moment to complete.
6. In the Edit Task Flow Binding dialog, enter a value for the `parentId` parameter.

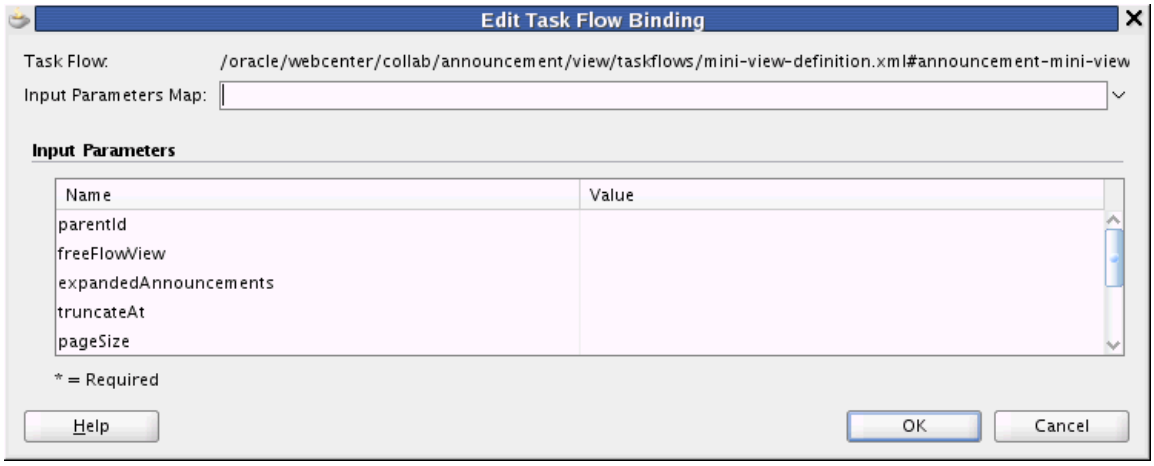
   The discussions server could be shared with multiple Framework applications. Each Framework application should create a forum on the discussions server. Enter that forum ID here as the `parentId`; for example, `${2}`.
7. Click **OK**.
8. Save and run your page.



33.2.2.3 How to Modify Announcements Service Task Flow Parameters

The Announcements service task flows have required and optional task flow binding parameters.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:



1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 33–6 shows an example of a Search task flow in the Executables section.

Figure 33–6 Page Data Binding Definition

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 33–7, revise the binding parameter values as required.

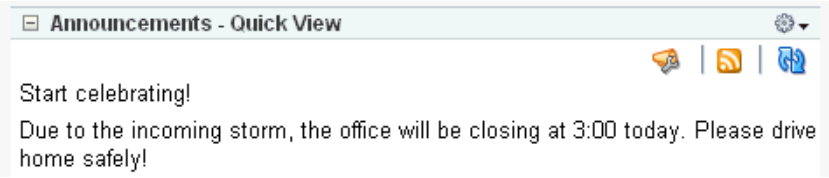
Figure 33–7 Edit Task Flow Binding Dialog for Announcements - Quick View

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

Table 33–2 describes the properties that are unique to the Announcements service task flows.

Table 33–2 Announcements Service Task Flow Parameters

Property	Description	Task Flow
`parentId`	The forum ID in the discussions server under which announcement objects are maintained. Each Framework application should create a forum on the discussions server. Enter that forum ID here; for example, `${2}`. If this parameter is not specified, then announcements default to global announcements.	Announcements Announcements - Quick View
`freeFlowView`	A Boolean value representing whether to remove the announcement title (subject) and show the announcement body as is. The default value is `${false}`, which means that the announcement list displays the title and body in plain text and the `truncateAt` and `expandedAnnouncements` parameters control it. Enter `${true}` to remove the announcement title and ignore the values for `truncateAt` and `expandedAnnouncements`.	Announcements - Quick View
`expandedAnnouncements`	The number of announcements to display announcement details (that is, the body of the announcement). Users can click the title to display the full announcement content in rich text mode. The value you enter for `expandedAnnouncements` is ignored if `freeFlowView` is set to `true`.	Announcements - Quick View
`truncateAt`	For announcements that display announcement body, this value specifies how many characters to display for each announcement. Enter an Expression Language (EL) expression. For example, when the value is set to the EL expression `${50}`, following their titles, announcements display no more than 50 characters. Users can click announcement titles to display the full announcement. If no value is specified, then it displays 200 characters. If a non-valid positive integer value is specified, then it displays all characters in plain text. This parameter takes effect with `expandedAnnouncements`. The value you enter for `truncateAt` is ignored if `freeFlowView` is set to `true`.	Announcements - Quick View
`pageSize`	The number of announcements to show in a page on Extended Quick View.	Announcements - Quick View
`visibleAnnouncements`	The number of announcements to show in the Quick View.	Announcements - Quick View
`hideToolbar`	A Boolean value representing whether to display the task flow personalization feature.	Announcements - Quick View
`navigateToAnnouncementViewer`	A Boolean value representing whether to launch the announcement in a popup or navigate to the Announcement Manager. The default behavior is to launch in a popup. Enter `true` to navigate to the Announcement Manager.	Announcements - Quick View
`expandAllAnnouncements`	A Boolean value representing whether to display details for all announcements in extended quick view. Default value is `false`, in which case announcements display the announcement title only.	Announcements - Quick View



You can change the look and feel of the Announcements - Quick View with the parameter values. For example, Figure 33–12 shows the Announcements - Quick View at runtime with the `freeFlowView` parameter set to false (or empty).

Figure 33–8 Announcements - Quick View with Optional Parameters

Figure 33–13 shows the Announcements - Quick View at runtime with the `freeFlowView` parameter set to `${true}`.

Figure 33–9 Announcements - Quick View with freeFlowView Parameter

33.2.3 Setting Security for Announcements

By default, authenticated users of Framework applications can view and participate in announcements. Any user who has logged in to a WebCenter Portal application can view announcements, and users with sufficient permissions can create announcements. To create announcements, you must be a moderator or administrator on the back-end discussions server.

In an unsecured Framework application, identity propagation cannot happen. A user is a *guest* (or *anonymous*) user who can view only public categories and forums. In an unsecured application, the `parentId` (forum ID) from which announcements are fetched should be a public forum. If the forum is not public, then an error is reported. If the `parentId` parameter is not specified at all, then WebCenter Portal cannot fetch global announcements (that is, announcements not scoped to a forum): global announcements are not available for public users. Rather than relying to global announcements, each Framework application should reserve its own forum ID.

In an ADF-secured Framework application, identity propagation is enabled. Based on the identity, appropriate permissions are matched and corresponding actions are enabled. The user name that you use to log in to the application is used to log in to the discussions server. The recommended approach is to have the discussions server and the Framework application point to the same identity store. This way, your users can log in to the application one time and automatically connect to the discussions server.

> **Note:** The Announcements services requires that the identity store be LDAP-based; that is, not file-based with `jazn-data.xml`.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."

33.3 Advanced Information for the Announcements Service

This section describes optional features available with this service. It includes the following subsections:

- Section 33.3.1, "How to Add the Announcements - Quick View Task Flow"
- Section 33.3.2, "Customizing Announcements Views"
- Section 33.3.3, "Obtaining Space RSS News Feed URL for the Announcements Service"

33.3.1 How to Add the Announcements - Quick View Task Flow

The Announcements - Quick View provides a snapshot (dashboard) view of the announcements (Figure 33–10).

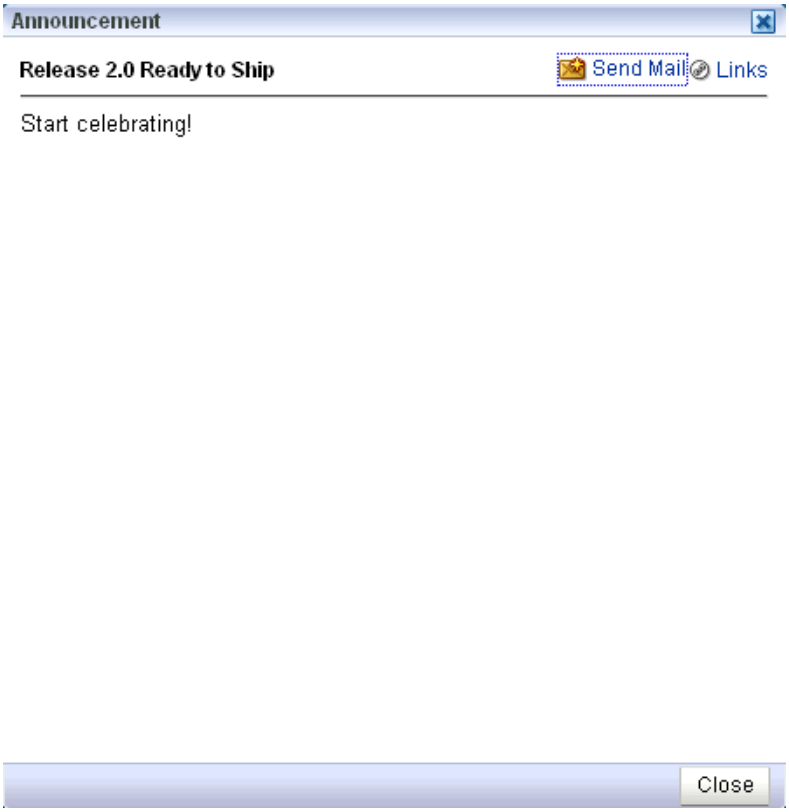


Figure 33–10 Announcements - Quick View

By default, announcements in the Announcements - Quick View task flow show announcement titles as links. But you can configure the task flow to display only announcement titles, titles with some amount of content, or only content.

Click an announcement to view it in a popup. From there, you can select the **Mail** icon to mail the announcement to anyone you choose or select the **Links** icon to link to this announcement (Figure 33–10).

Figure 33–11 Announcement Popup

The Announcements - Quick View task flow includes numerous parameters to customize your view. For example, you can remove the link to the Announcement Manager, to present announcements to end users where manage controls are not needed. The task flow lists 10 announcements by default, but you can change this number and how much of the announcement is displayed. The **More Announcements ...** link launches a popup containing the complete list of all announcements with pagination behavior. This is called the Extended Quick View (or Mini View).

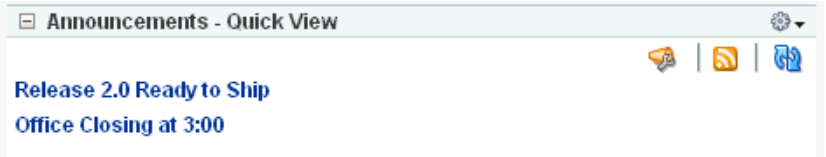
To add the Announcements - Quick View to your Framework application, follow the same instructions that you did for the Announcements task flow in Section 33.2.2, "Adding the Announcements Service at Design Time," but drag and drop Announcements - Quick View onto the page.

Table 33–2 describes the Announcements - Quick View parameters. The look and feel of the Announcements - Quick View changes with the values provided for these parameters. For more information, see Section 33.2.2.3, "How to Modify Announcements Service Task Flow Parameters."

33.3.2 Customizing Announcements Views

You can change the look and feel of the Announcements - Quick View with the parameter values. For example, Figure 33–12 shows the Announcements - Quick View at runtime with the `freeFlowView` parameter set to false (or empty).

Figure 33–12 Announcements - Quick View with Optional Parameters



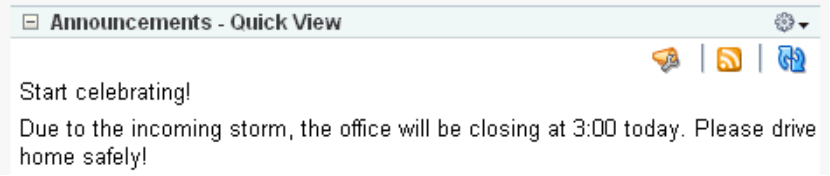


Figure 33–13 shows the Announcements - Quick View at runtime with the `freeFlowView` parameter set to `${true}`.

Figure 33–13 Announcements - Quick View with freeFlowView Parameter

33.3.3 Obtaining Space RSS News Feed URL for the Announcements Service

You can expose WebCenter Portal: Spaces functionality in a WebCenter Portal: Framework application. Your Framework application users can find out what is happening in a specific space through RSS news feeds.

Configure RSS news feeds for the Announcements service to enable users to view space announcements from within a Framework application. To obtain the space RSS news feed URL for the Announcements service, use either of the following APIs for Spaces:

- `getServiceRSSFeedURL`
- `getServiceRSSFeedURLbyGuid`

To obtain an RSS feed URL, you must identify the space (by name or GUID) and specify the service required (by service ID). The service ID for the Announcements service is `GroupSpaceWSClient.ANNOUNCEMENT_SERVICE_ID`.

For information about how to use these APIs, see Section 57.2.5.3.9, "Retrieving RSS Feed URLs for Space Services."

34

Integrating the Discussions Service

This chapter explains how to integrate the Discussions service in a WebCenter Portal: Framework application at design time. For more information about managing and including discussions, see:

- "Managing the Announcements and Discussions Services" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- "Working with the Discussions Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

This chapter includes the following sections:

- Section 34.1, "Introduction to Discussions"
- Section 34.2, "Basic Configuration for the Discussions Service"
- Section 34.3, "Advanced Information for the Discussions Service"

34.1 Introduction to Discussions

The Discussions service lets you expose discussion forums on your application pages, so users can create forums, post questions, and search for answers. For example, customers can share product reviews, or a customer service department can answer questions online. Discussion forums additionally provide the means to preserve and revisit discussions.

The back-end discussions server manages content in a hierarchy. At the top of the hierarchy are *categories*, below that are *forums*, and then *topics*. Within each topic are messages, and messages can be nested within messages.

Where categories are exposed in your application, authorized users can create multiple forums within a given scope and multiple topics under those forums. Where categories are not exposed, authorized users can create multiple topics under one forum within a given scope.

34.1.1 Understanding the Discussions Service

With the Discussions service, you can do the following (according to your permissions):

- Create a new discussion forum or a new topic.
- Navigate into a forum from a list of available forums.
- Edit, reply to, or delete an existing discussion forum, topic, or message.
- View the number of replies for a topic on the main forum view.

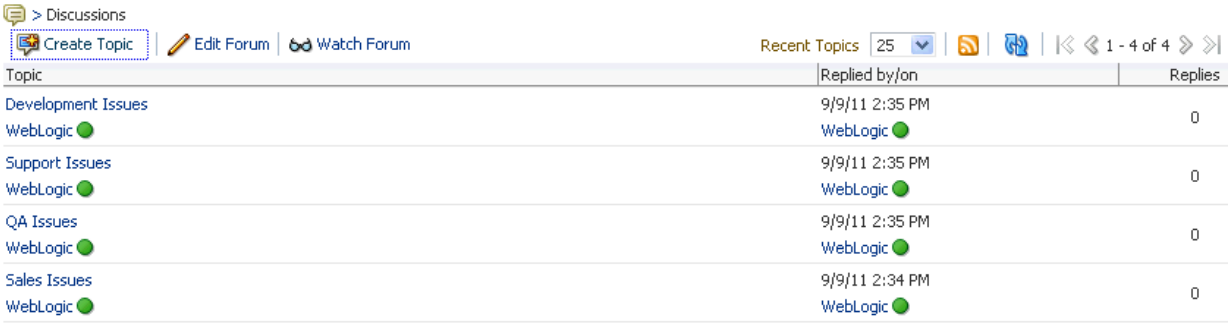
- Drill into a topic to read all replies by clicking the topic name.
- Add a "watch" to a topic or forum.
- View the following in a quick view:
  - Watched topics
  - Watched forums
  - Most popular (frequently viewed) topics
  - Most recent topics

> **Note:** In a secured application, Discussions permissions are allotted according to an individual user's assigned user role. A user can be a moderator, participant, or viewer. Some activities require moderator or participant roles. For more information, see Section 34.2.3, "Setting Security for Discussions."

The Discussions service is integrated with many WebCenter Portal services, such as Instant Messaging and Presence, RSS, and Search (to search within forums) services. Use the Mail service to archive mails into discussions as threads. Use the Links service to link to a discussion from any WebCenter Portal object.

34.1.2 Requirements for Discussions

The Discussions service requires a discussions server. Install and configure the discussions server that comes with Oracle Fusion Middleware.



> **See Also:** *Oracle Fusion Middleware Installation Guide for Oracle WebCenter Portal*

34.1.3 What Happens at Runtime

To create forums in Framework applications, you must be a moderator or administrator on the back-end discussions server. For more information, see "Granting Administrator Role for Oracle WebCenter Portal's Discussions Server" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

Figure 34–1 shows a discussion forum at runtime.

Figure 34–1 Discussion Forums Task Flow at Runtime

For more information about the service at runtime, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

34.2 Basic Configuration for the Discussions Service

This section describes required steps for adding the Discussions service to your application. It includes the following subsections:

- Section 34.2.1, "Setting up Connections for Discussions"
- Section 34.2.2, "Adding the Discussions Service at Design Time"
- Section 34.2.3, "Setting Security for Discussions"

34.2.1 Setting up Connections for Discussions

You must create a connection to the discussions server in your WebCenter Portal: Framework application. You can register additional Discussion Forum connections, but only one connection is active at a time.

When you create a Discussion Forum connection or set a connection as active, both the Announcements and Discussions services use this same connection. If you have an existing connection, then you can skip this section and see Section 34.2.2, "Adding the Discussions Service at Design Time."

If you do not have an existing connection, then you must create a new Discussion Forum connection.

34.2.1.1 Discussions Connections

The Discussions service requires a Discussion Forum connection to the discussions server.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle Developer, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

34.2.1.2 How to Set Up Connections for Discussions

Follow these steps to set up the discussions connection.

1. In Oracle JDeveloper, open the application in which you plan to consume discussion forums.

   > **Note:** If you created a Discussion Forum connection for the Announcements service, then that is used by default for the Discussions service. No extra configuration is required.

2. In the Application Navigator, under Application Resources, right-click **Connections**, then select the new connection **Discussion Forum** from the list.
3. On the **Name** page, select to create the connection in **Application Resources**. (A connection in Application Resources is available only for that application, while a connection in IDE Connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE Connections so you do not need to re-create it.)
4. For **Connection Name**, enter a unique name; for example, `MyDiscussions`.

5. Select the **Set the default connection** checkbox. You can have multiple connections, but only one can be active (default). If you have different discussions servers (for example, for each page in a space), then do not select the checkbox, but the service requires that one connection be marked as the default connection (Figure 34–2).

   Note: After you create a connection as the default connection, you cannot edit it so that it is *not* the default. To use a different default connection, you must create a new connection and mark that as the default connection.

Figure 34–2 Create Discussion Connections, Step 1

6. Click **Next**.

7. On the **General** page, enter values for the required parameters:

   - `URL`: Enter the URL of the discussions server hosting discussion forums and announcements. For example:
     `http://discuss-example.com:8888/owc_discussions`
   - `Admin User`: The user name of your discussions server administrator; for example, `admin`. This account is used by the Discussions and Announcement services to perform administrative operations on behalf of WebCenter Portal users.

     In WebCenter Portal: Spaces, this account is mostly used for managing space-related discussions and announcements. It is not necessary for this user to be a super admin. However, the user must have administrative privileges on the current root category for Spaces, that is, the category (on the discussions server) under which all space-related discussions and announcements are stored.

Note: If your Framework application does not include space-related functionality, then the administrator's user name is not required.

8. Optionally, enter a value for the other parameters:

   - `Connection Timeout`: Specify a suitable timeout for the connection. This is the length of time (in seconds) the application waits for a response from the discussions server before issuing a connection timeout message. The default is -1, which means that the service default is used. The service default is 10 seconds.
   - `Policy URI for Authenticated Access`: Select the SAML token client policy this connection uses for authenticated access to the discussions server Web service. SAML (Security Assertion Markup Language) is an XML-based standard for passing security tokens defining authentication and authorization rights. An attesting entity (that has trust relationship with the receiver) vouches for the verification of the subject by method called sender-vouches. Options available are:
     - WSS 1.0 SAML Token Client Policy (oracle/wss10_saml_token_client_policy)
     - WSS 1.1 SAML Token With Message Protection Client Policy (oracle/wss11_saml_token_with_message_protection_client_policy)

     The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServiceAuthenticated` endpoint in the discussions server. Out-of-the-box, the default service policy is WSS 1.0 SAML Token Service Policy (oracle/wss10_saml_token_service_policy).
   - `Policy URI for Public Access`: Select the client policy this connection uses to enforce message security and integrity for public access to the discussions server Web service. Options available are:
     - None - This is the default setting.
     - WSS 1.1 Message Protection Client Policy (oracle/wss11_with_message_protection_client_policy)

     The client policy specified must be compatible with the service policy that is configured for the `OWCDiscussionsServicePublic` endpoint in the discussions server. Out-of-the-box, a service policy is not configured for public access.
   - `Recipient Key Alias`: Enter the recipient key alias to be used for message protected policies (applicable to the `OWCDiscussionsServicePublic` and `OWCDiscussionsServiceAuthenticated` endpoints). This is the alias to the certificate that contains the public key of the discussions server in the configured keystore.

     For more information, see the chapter "Configuring WS-Security for WebCenter Portal's Applications and Components" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

Figure 34–3 Create Discussions Connection, Step 2

9. Click **Test Connection**, and if it is successful, then click **Next**.
10. On the **Create Discussion Connection - Step 3 of 3** page, you can configure additional parameters.

    `application.root.category.id`: (WebCenter Portal: Spaces only) The application root category ID on the discussions server under which all discussion forums are stored. For example, if set to 3, then all forums are stored inside the category 3.

    Note: To encrypt property values, such as passwords, click **Add Secured Property**.

11. Click **Finish**. Your connection should now appear as a node under **Application Resources - Connections**.

34.2.2 Adding the Discussions Service at Design Time

This section explains a basic incorporation of the Discussions service.

34.2.2.1 Discussions Task Flows

The Discussions service provides several task flows (Table 34–1) to enable you to include the service in a form that best suits your needs.

Table 34–1 Discussions Service Task Flows

Task Flow	Description
Discussion Forums	This task flow displays the Discussion Forums view, which allows the user to see all the discussions and their respective replies. It also allows users to perform various operations based on their privileges. A Moderator can perform create, read, update, and delete operations on all objects. A Participant can create a topic, edit a topic that has been created by him, and reply to a topic. A Viewer can only view objects. All watched forums and topics are accessible from this task flow. The Watched Forums and Watched Topics task flows provide more focussed views of watched forums or watched topics. The parameters alter the way the view appears. For more information, see Section 34.2.2.3, "How to Modify the Discussions Service Task Flow Parameters."
Discussions - Popular Topics	This task flow provides a view that allows users to see the most frequently viewed topics in the application under a given category ID or forum ID. For more information, see Section 34.3.1, "Adding the Discussions - Popular Topics Task Flow."
Discussions - Recent Topics	This task flow displays a view that allows users to see all the recent topics in the application given a category ID or forum ID. For more information, see Section 34.3.2, "Adding the Discussions - Recent Topics Task Flow."
Discussions - Watched Forums	This task flow displays a view that allows users to see all of their watched forums in the application under a given category ID. For more information, see Section 34.3.3, "Adding the Discussions - Watched Forums Task Flow."
Discussions - Watched Topics	This task flow displays a view that allows users to see all their watched topics in the application under a given category ID or forum ID. For more information, see Section 34.3.4, "Adding the Discussions - Watched Topics Task Flow."
Discussions - Quick View	This task flow displays a combined view of the Popular Topics, Recent Topics, Watched Topics, and Watched Forums task flows. Instead of adding four separate task flows, this single task flow presents all four views with a dropdown list so that end users can personalize it For more information, see Section 34.3.5, "Adding the Discussions - Quick View Task Flow."

34.2.2.2 How to Add Discussions to a Page

The Discussion Forums task flow provides a complete view of your discussions. To add the Discussion Forums task flow to your Framework application, follow these steps.

1. Follow the steps described in Section 7.2.1, "How to Prepare Your Application to Consume Services" to implement security and create a new customizable page in your application.
2. Open the page on which you want to add the Discussions service.
3. In the Resource Palette, expand **My Catalogs**, **WebCenter - Framework Services Catalog**, and **Task Flows**.

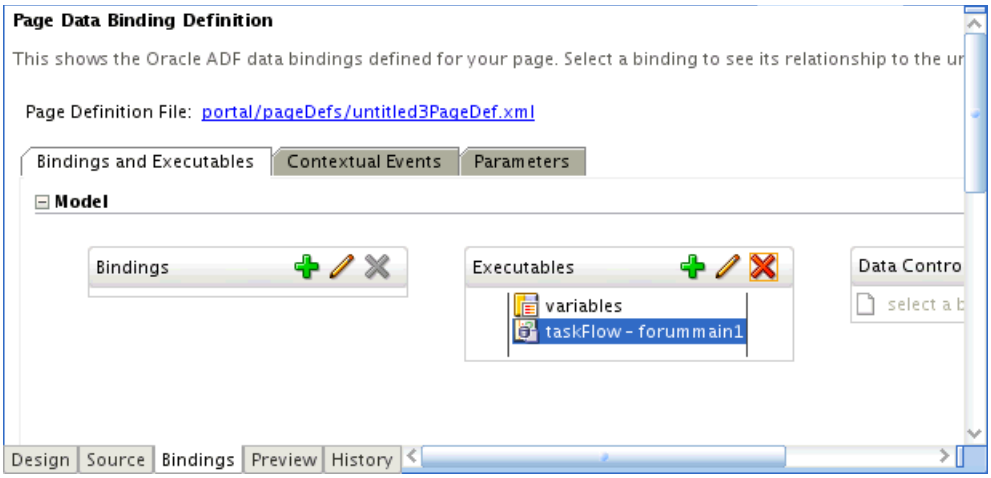
4. Drag **Discussions** from the Resource Palette and drop it onto the page.
5. When prompted, select **Region** as the way to create the task flow.
6. You may be prompted to add the discussions library to your project. If so, then click **Add Library**. This operation may take a moment to complete.
7. In the Edit Task Flow Binding dialog box, enter values for the parameters, and click **OK**. Table 34–2 describes the parameters.
8. Save and run your page.

Notes: If you created a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.

All instances of the Discussion Forums task flow in an application run against the same discussions server: it is unnecessary to add multiple Discussion Forums task flow instances. This is true for all service task flows that require connections to back-end servers, such as task flows from the Announcements or Mail services.

The Discussion Forums main view contains some features that require other services in your application.

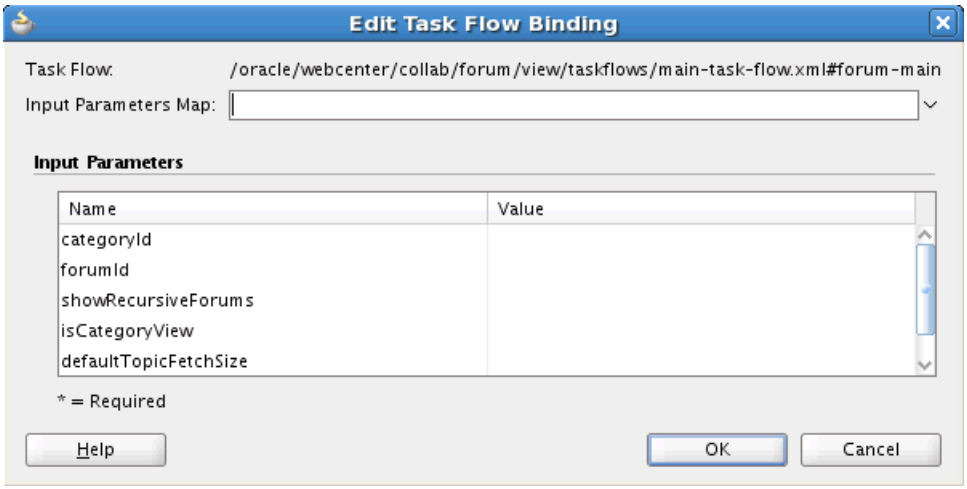
- For the links in the main view to work, you must have configured the Links service. For more information, see Chapter 43, "Integrating the Links Service."
- For users' presence indicators to work, you must have configured the WebCenter Portal Presence service. For more information, see Chapter 35, "Integrating the Instant Messaging and Presence Service."
- Oracle recommends that the discussions server and WebCenter Portal point to the same identity store. If the Framework application and the discussions page are configured to be secure, then upon logging in to the application, then the Discussions service respects those credentials in the discussions server.



34.2.2.3 How to Modify the Discussions Service Task Flow Parameters

The Discussions service task flows have optional task flow binding parameters.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:



1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 34–4 shows an example of a Search task flow in the Executables section.

Figure 34–4 Page Data Binding Definition

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 34–5, revise the binding parameter values as required.

Figure 34–5 Edit Task Flow Binding Dialog for Discussion Forums Task Flow

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

Table 34–2 describes the properties that are unique to the Discussions service task flows.

Table 34–2 Discussions Service Task Flow Parameters

Property	Description	Task Flow
`categoryId`	This optional parameter is an identifier for an existing category in Oracle WebCenter Portal's Discussion Server to which the view should be scoped. When no value is supplied, it defaults to the appropriate root category of the discussions server. (This root category ID can be overridden by supplying an additional property named `application.root.category.id` in the connection.) For testing purposes, you may want to create a category through the discussions server administrator interface and then reference that category identifier here.	■ Discussion Forums ■ Discussions - Quick View ■ Popular Topics ■ Recent Topics ■ Watched Forums ■ Watched Topics
`forumId`	This parameter is an identifier for an existing forum in your discussions server for which popular topics should be fetched. If both `categoryId` and `forumId` are given, then only `categoryId` is honored.	■ Discussion Forums ■ Popular Topics ■ Recent Topics ■ Watched Topics
`disableToolbar`	This parameter indicates whether the toolbar, including the Refresh icon, should be displayed. It can be `${true}`, `${false}`, or undefined. If you leave this parameter undefined, then the default behavior (false) is to show the toolbar.	■ Popular Topics ■ Recent Topics ■ Watched Forums ■ Watched Topics
`showRecursiveForums`	This parameter determines if you show forums either in a category only or in subcategories. True means all forums under a given category/subcategory are shown; false means only the category's direct child forums are shown. The default value is false. Note: A value of true can impact performance.	Discussion Forums
`isCategoryView`	A means of showing the forums grouped under the Category ID category or the topics specified under the Forum ID forum. True means you want the task flow to display the forums classified under `categoryId`; false, the default value, means you want the task flow to display the topics associated with the specified `forumId`. This parameter value works in combination with other parameters.	Discussion Forums
`defaultTopicFetchSize`	Sets the number of visible topics	Discussion Forums
`doNotAllowSelectingPageSize`	If set to true, users are not allowed to change the number of visible topics.	Discussion Forums
`visibleTopicsFetchSize`	Sets the number of visible watched topics.	■ Recent Topics ■ Watched Topics
`visibleForumsFetchSize`	Sets the number of visible watched forums.	Watched Forums
`doNotShowMoreLink`	If set to true, the **More** link is not visible.	■ Discussions - Quick View ■ Recent Topics ■ Watched Forums ■ Watched Topics

You can customize the look and feel of **Discussion Forums** views by changing parameter values. The following combinations are possible:

> **Note:** A *bidirectional link* connects back and forth. For example, when you create a link from a discussion topic to a document, a link from the document back to the topic also is created. Similarly, when you delete the link from the discussion topic to a document, the link from the document back to the topic automatically is deleted.

- `categoryId`: This displays the forums list view if there are multiple forums. If there is only one forum, then it drills into the forum and lists all topics with a bidirectional link enabled.
- `categoryId` and `forumId`: This displays the topics list view with a bidirectional link enabled.
- `isCategoryView` is set to `true`: This displays the topics list view with a bidirectional link enabled.
- `categoryId` and `forumId` and `isCategoryView` is set to `false`: This displays the topics list view, but a bidirectional link is not enabled.
- `categoryId` and `isCategoryView` is set to `true`: This displays the forums list view if there are multiple forums. If there is only one forum, then it displays that forum with a bidirectional link enabled.
- `forumId` and `isCategoryView` is set to `false`: This displays the topics list view, but a bidirectional link is not enabled.
- `categoryId` and `isCategoryView` is set to `false`: This is similar to when `categoryId` alone is given.
- `forumId` and `isCategoryView` is set to `true`: This is similar to when `forumId` and `isCategoryView` is set to false.
- `isCategoryView` = `true` or `false`: This is ignored. It goes with the default scope (that is, all forums listed under the root category) in a Framework application.
- `forumId`: This is similar to `forumId` and `isCategoryView` is set to false.

34.2.3 Setting Security for Discussions

By default, authenticated users of WebCenter Portal applications can view and participate in discussion forums. Any user who has logged in to a WebCenter Portal application can view discussions, and users with sufficient permissions can create forums and topics. To create forums, you must be a moderator or administrator on the back-end discussions server that provides the Discussions service.

In an unsecured Framework application, the user identity is not propagated to the discussions server; consequently, users are identified as GUEST (that is, as anonymous users) and can view only public categories and forums.

> **Note:** *Categories* and *forums* are server-side classifications that move from *category* to *forum* to *topic*. That is, a category can head a collection of forums, just as a forum can head a collection of topics.

In a secured Framework application, discussions permissions are allotted according to an individual user's assigned user role. For example, a user can be a moderator, participant, or viewer. A forum moderator can edit and delete any topics and messages within a forum. A forum participant can create topics and edit his or her own topics. A forum viewer can view topics and messages.

In an unsecured Framework application, identity propagation cannot happen. A user is a *guest* (or *anonymous*) user who can view only public categories and forums.

In an ADF-secured Framework application, identity propagation is enabled. Based on the identity, appropriate permissions are matched and corresponding actions are enabled. The user name that you use to log in to the application is used to log in to the discussions server. The recommended approach is to have the discussions server and the application point to the same identity store. When you run the page, you are presented with a login page for user credentials. Enter the credentials with the required privileges in the discussions server.

Note: The Discussions services requires that the identity store be LDAP-based; that is, not file-based with `jazn-data.xml`.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."

34.3 Advanced Information for the Discussions Service

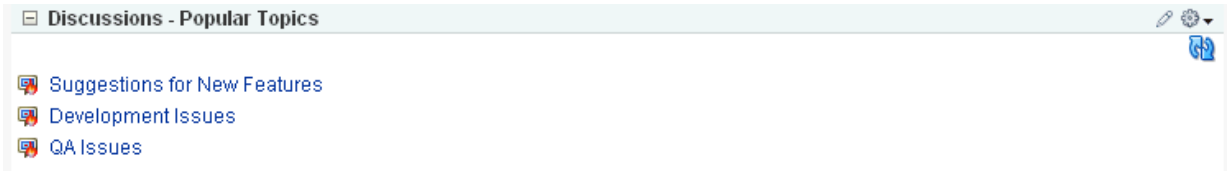
This section describes optional features available with this service. It includes the following subsections:

- Section 34.3.1, "Adding the Discussions - Popular Topics Task Flow"
- Section 34.3.2, "Adding the Discussions - Recent Topics Task Flow"
- Section 34.3.3, "Adding the Discussions - Watched Forums Task Flow"
- Section 34.3.4, "Adding the Discussions - Watched Topics Task Flow"
- Section 34.3.5, "Adding the Discussions - Quick View Task Flow"
- Section 34.3.6, "Obtaining Space RSS News Feed URL for the Discussions Service"
- Section 34.3.7, "Using Custom Discussions APIs"
- Section 34.3.8, "Using the Discussions Service REST APIs"
- Section 34.3.9, "Troubleshooting the Discussions Service"

34.3.1 Adding the Discussions - Popular Topics Task Flow

The Discussions - Popular Topics task flow provides a view that allows users to see the most frequently viewed discussion topics under a given category ID or forum ID.

Note: Popular topics are based on topic replies. The administrator is not able to determine popularity.



To add the Discussions - Popular Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in

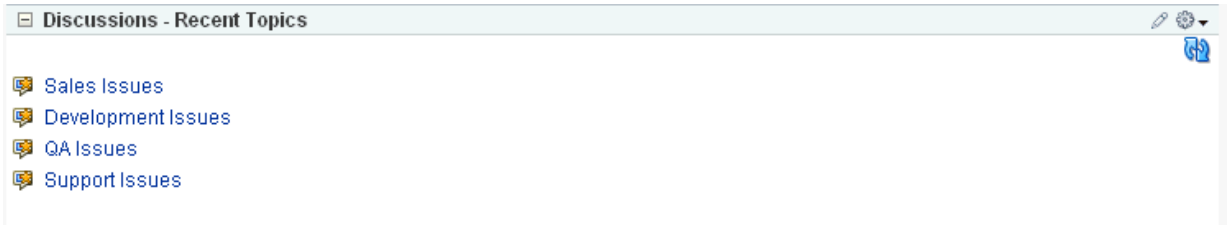
Section 34.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Popular Topics onto the page.

Table 34–2 describes the available parameters for this task flow.

Figure 34–6 shows how the Discussions - Popular Topics task flow looks at runtime.

Figure 34–6 Discussions - Popular Topics View at Runtime

34.3.2 Adding the Discussions - Recent Topics Task Flow



The Discussions - Recent Topics task flow displays a view that allows users to see all the recent topics (that is, topics posted within the past two days) given a category ID or forum ID.

To add the Discussions - Recent Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 34.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Recent Topics onto the page.

Table 34–2 describes the available parameters for this task flow.

Figure 34–7 shows how the Discussions - Recent Topics task flow looks at runtime. To view a topic post, simply click the relevant topic.

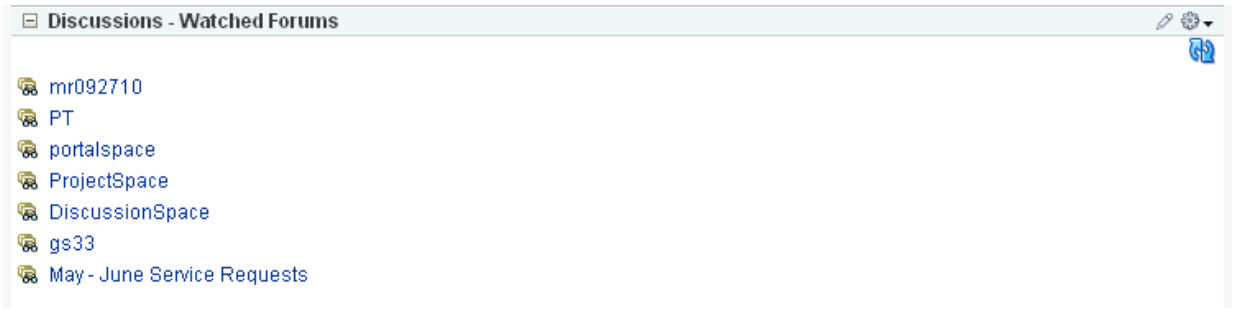
Figure 34–7 Discussions - Recent Topics View at Runtime

34.3.3 Adding the Discussions - Watched Forums Task Flow

The Discussions - Watched Forums task flow displays a view that allows users to see all of their watched forums under a given category ID.

You can watch discussion forums and topics to keep a close eye on the information most current and relevant to your efforts. The forums and topics you select to watch are personal, in that your selections appear on your view of watch lists. No other user is affected by the forums and topics you choose to watch.

When a user places a watch on a forum or a topic, whenever users add to that forum or topic, in addition to it appearing in the user's watched forums or topics list, the user receives an mail notification.



All watched forums and topics are accessible from the Forums task flow. The Watched Forums and Watched Topics task flows provide more focussed views of watched forums or watched topics.

To add the Discussions - Watched Forums task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 34.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Watched Forums onto the page.

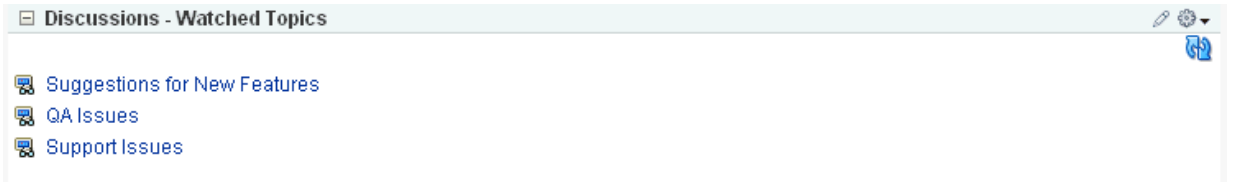
Table 34–2 describes the available parameters for this task flow.

Figure 34–8 shows how the Discussions - Watched Forums task flow looks at runtime.

Figure 34–8 Discussions - Watched Forums View at Runtime

For information on how to watch a forum or topic at runtime, see "Working with the Discussions Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces.*

34.3.4 Adding the Discussions - Watched Topics Task Flow



Similar to the Discussions - Watched Forums task flow, the Discussions - Watched Topics task flow displays a view that allows users to see all their watched topics under a given category ID or forum ID.

To add the Discussions - Watched Topics task flow to your Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 34.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Watched Topics onto the page.

Table 34–2 describes the available parameters for this task flow.

Figure 34–9 shows how the Discussions - Watched Topics task flow looks at runtime.

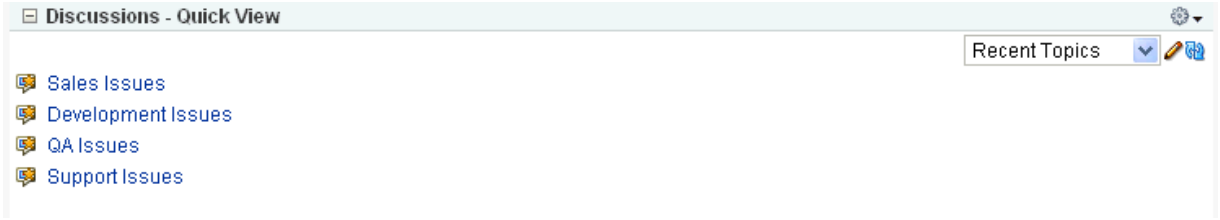
Figure 34–9 Discussions - Watched Topics View at Runtime

For information on how to watch a forum or topic at runtime, see "Working with the Discussions Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces.*

34.3.5 Adding the Discussions - Quick View Task Flow

The Discussions - Quick View task flow displays a combined view of the Popular Topics, Recent Topics, Watched Topics, and Watched Forums task flows. Instead of

adding four separate task flows, this single task flow presents all four views with a dropdown list so that end users can personalize it.



By default, Watched Topics are displayed. This task flow takes only one parameter: `categoryId`.

To add the Discussions - Quick View task flow to your WebCenter Portal: Framework application, follow the same instructions that you did for the Discussion Forums task flow in Section 34.2.2.2, "How to Add Discussions to a Page," but drag and drop Discussions - Quick View onto the page.

Table 34–2 describes the available parameters for this task flow.

Figure 34–10 shows how the Discussions - Quick View task flow looks at runtime.

Figure 34–10 Discussions - Quick View at Runtime

34.3.6 Obtaining Space RSS News Feed URL for the Discussions Service

You can expose WebCenter Portal: Spaces functionality in a Framework application. Your Framework application users can find out what is happening in a specific space through RSS news feeds.

Configure RSS news feeds for the Discussions service to enable users to view space discussions from within a Framework application. To obtain the space RSS news feed URL for the Discussions service, use either of the following Spaces APIs:

- `getServiceRSSFeedURL`
- `getServiceRSSFeedURLbyGuid`

To obtain an RSS feed URL, you must identify the space (by name or GUID) and specify the service required (by service ID). The service ID for the Discussions service is `GroupSpaceWSClient.DISCUSSION_SERVICE_ID`.

For information about how to use these APIs, see Section 57.2.5.3.9, "Retrieving RSS Feed URLs for Space Services."

34.3.7 Using Custom Discussions APIs

The back-end Oracle WebCenter Portal's Discussion Server includes APIs to further customize your application. To learn more about them, see the Jive Forums documentation on the Oracle Fusion Middleware documentation library (in the WebCenter Portal product area).

34.3.8 Using the Discussions Service REST APIs

WebCenter Portal provides REST APIs to support the Discussions service. Use the Discussions service REST APIs to post, read, update, and delete discussion forums, topics, and messages.

This section describes the REST APIs associated with the Discussions service. It includes the following subsections:

- Section 34.3.8.1, "Discussions Entry Point"
- Section 34.3.8.2, "Discussions Resource Type Taxonomy"
- Section 34.3.8.3, "Security Considerations"
- Section 34.3.8.4, "Discussions Resource Types"

For an introduction to the REST APIs, see Chapter 54, "Using Oracle WebCenter Portal REST APIs."

34.3.8.1 Discussions Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. To find the entry point for the Discussions service, find the link element with a `resourceType` of:

```
urn:oracle:webcenter:discussions:forums
```

The corresponding `href` or `template` element provides the URI entry point. The client sends HTTP requests to this entry point to work with the Discussions service.

For more information about the Resource Index, see Section 54.5.1, "The Resource Index."

For more information about resource types, see Section 54.5.2.1, "Resource Type."

34.3.8.2 Discussions Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 54.5.2.1, "Resource Type."

The taxonomy for the Discussions service is:

```
urn:oracle:webcenter:discussions:forums
   urn:oracle:webcenter:discussions:forum
   urn:oracle:webcenter:discussions:forum:topics
      urn:oracle:webcenter:discussions:forum:topic
      urn:oracle:webcenter:discussions:forum:topic:messages
         urn:oracle:webcenter:discussions:forum:topic:message
```

Beyond the service entry points, URL templates allow clients to pass query parameters to customize their requests and control the form of returned data.

Collection resources in the discussions resources support pagination (`startIndex` and `itemsPerPage`). Other query parameters are not supported (that is, `search` and `projection`).

34.3.8.3 Security Considerations

There are no specific security considerations for this service. For general security considerations, see Section 54.8, "Security Considerations for WebCenter Portal REST APIs."

34.3.8.4 Discussions Resource Types

This section provides the information about each resource type. It includes the following subsections:

- Section 34.3.8.4.1, "urn:oracle:webcenter:discussions:forums"
- Section 34.3.8.4.2, "urn:oracle:webcenter:discussions:forum"
- Section 34.3.8.4.3, "urn:oracle:webcenter:discussions:forum:topics"
- Section 34.3.8.4.4, "urn:oracle:webcenter:discussions:forum:topic"
- Section 34.3.8.4.5, "urn:oracle:webcenter:discussions:forum:topic:messages"
- Section 34.3.8.4.6, "urn:oracle:webcenter:discussions:forum:topic:message"

34.3.8.4.1 urn:oracle:webcenter:discussions:forums Use this resource type to identify the URI to use to read (`GET`) and write (`POST`) discussion forums. The response from a `GET` operation includes each forum in this collection of forums, and each forum includes links used to operate on that forum. The response from a `POST` operation includes the forum that was created in this collection of forums and a link to operate on that forum.

Navigation Paths to forums

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
```

Supported Methods for forums

The following methods are supported by this resource:

- `GET`
  - **request - body:** none, **Parameters**: `startIndex`, `itemsPerPage` (pagination)
  - **response - body:** forums
- `POST`
  - **request - body:** forum
  - **response - body:** forum

For more information, see Section 54.5.2.5, "Templates."

Resource Types Linked to From forums

Table 34–3 lists the resource types that the client can link to from this resource.

Table 34–3 Related Resource Types for forums

rel	resourceType
self	`urn:oracle:webcenter:discussions:forums`
	`urn:oracle:webcenter:discussions:forum`

34.3.8.4.2 urn:oracle:webcenter:discussions:forum Use this resource type to identify the URI to use to read (`GET`), update (`PUT`), and delete (`DELETE`) a specific discussion forum. The response from a `GET` operation includes the specific forum identified by the URI. The response from a `PUT` operation includes the modified version of the forum identified by the URI. The response from a `DELETE` operation is a 204.

Navigation Paths to forum

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      forum

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            forum

resourceindex
   activities
      forum
```

Supported Methods for forum

The following methods are supported by this resource:

- `GET`
  - **request - body:** none
  - **response - body:** forum
- `PUT`
  - **request - body:** forum
  - **response - body:** forum
- `DELETE`
  - **request - body:** none
  - **response - body:** none

Writable Elements for forum

Table 34–4 lists the writable elements for this resource.

Table 34–4 Writable Elements for forum

Element	Type	Required	Constraints	Description
`name`	String	Yes	1 or more characters	Name of the forum
`displayName`	String	No	1 or more characters	Name used in presentation
`description`	String	No	1 or more characters	Description of the forum

Read-only Elements for forum

Table 34–5 lists the read-only elements for this resource.

Table 34–5 Read-only Elements for forum

Element	Type	Description
`id`	Integer	ID of the forum

Table 34–5 (Cont.) Read-only Elements for forum

Element	Type	Description
parentId	Integer	ID of the parent category
createdBy	String	ID of the user that created the forum
author	personReference	User information about the user that created the forum, including GUID, ID, display name, and a link to the profile icon (same user as createdBy)
createdOn	Date	Date on which the forum was created
updatedBy	String	ID of the user that performed the last modification
modifiedBy	personReference	User information about the user that performed the last modification, including GUID, ID, display name, and a link to the profile icon (same user as updatedBy)
updatedOn	Date	Date on which the forum was last modified
webUrl	String	URL for direct access to the discussions server
topicCount	Integer	Number of topics
messageCount	Integer	Number of messages
locked	Boolean	True if this forum is locked
favorite	Boolean	True if this forum is marked as a favorite

Resource Types Linked to From forum

Table 34–6 lists the resource types that the client can link to from this resource.

Table 34–6 Related Resource Types for forum

rel	resourceType
self	urn:oracle:webcenter:discussions:forum
	urn:oracle:webcenter:discussions:forum:topics

34.3.8.4.3 urn:oracle:webcenter:discussions:forum:topics Use this resource type to identify the URI to use to read (GET) and write (POST) discussion topics. The response from a GET operation includes each topic in this collection of topics, and each topic includes links used to operate on that topic. The response from a POST operation includes the topic that was created in this collection of topics and a link to operate on that topic.

Navigation Paths to topics

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      topics

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
```

Supported Methods for topics

The following methods are supported by this resource:

- GET
  - **request - body:** none, **Parameters:** `startIndex`, `itemsPerPage` (pagination)
  - **response - body:** topics
- POST
  - **request - body:** topic
  - **response - body:** topic

For more information, see Section 54.5.2.5, "Templates."

Resource Types Linked to From topics

Table 34–7 lists the resource types that the client can link to from this resource.

Table 34–7 Related Resource Types for topics

rel	resourceType
self	`urn:oracle:webcenter:discussions:forum:topics`
	`urn:oracle:webcenter:discussions:forum:topic`

34.3.8.4.4 urn:oracle:webcenter:discussions:forum:topic Use this resource type to identify the URI to use to read (`GET`), update (`PUT`), and delete (`DELETE`) a specific discussion topic. The response from a `GET` operation includes the specific topic identified by the URI. The response from a `PUT` operation includes the modified version of the topic identified by the URI. The response from a `DELETE` operation is a 204.

Navigation Paths to topic

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      topics
         topic

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
               topic

resourceindex
   activities
      topicT
```

Supported Methods for topic

The following methods are supported by this resource type:

- GET
  - **Request—Body:** none
  - **Response—Body:** topic

- PUT
  - **Request—Body:** topic
  - **Response—Body:** topic
- DELETE
  - **Request—Body:** none
  - **Response—Body:** none

Writable Elements for topic

Table 34–8 lists the writable elements for this resource type.

Table 34–8 Writable Elements for topic

Element	Type	Required	Constraints	Description
subject	String	Yes	1 or more characters	Subject of the topic
body	String	No	0 or more characters	Contents of the topic

Read-only Elements for topic

Table 34–9 lists the read-only elements for this resource type.

Table 34–9 Read-only Elements for topic

Element	Type	Description
id	Integer	Identifier for the topic
parentId	Integer	Identifier for the parent message
forumId	Integer	Identifier for the forum under which this topic is posted
topicId	Integer	Identifier for the topic under which this topic is posted
createdBy	String	ID of the user who created the topic
author	personReference	User information about the user who created the topic, including GUID, ID, display name, and a link to the profile icon (same user as createdBy)
createdOn	Date	Date on which the topic was created
updatedBy	String	User who lasted updated the topic
updatedOn	Date	Date on which the topic was last updated
webUrl	String	URL for direct access to the discussions server
depth	Integer	Depth in the hierarchy of messages
messageCount	Integer	Number of child messages under this topic
numberOfReplies	Integer	Number of replies to this topic
favorite	Boolean	Whether the topic is marked as a favorite for the user
locked	Boolean	Whether the topic is locked
hidden	Boolean	Whether the topic is hidden

Table 34–9 (Cont.) Read-only Elements for topic

Element	Type	Description
`hasAttachment`	Boolean	Whether the topic has attachments

Resource Types Linked to From topic

Table 34–10 lists the resource types that the client can link to from this resource.

Table 34–10 Related Resource Types for topic

rel	resourceType
self	`urn:oracle:webcenter:discussions:forum:topic`
	`urn:oracle:webcenter:discussions:forum:topic:messages`

34.3.8.4.5 urn:oracle:webcenter:discussions:forum:topic:messages Use this resource type to identify the URI to use to read (`GET`) and write (`POST`) discussion topic messages. The response from a `GET` operation includes each message in this collection of messages, and each message includes links used to operate on that message. The response from a `POST` operation includes the message that was created in this collection of messages and a link to operate on that message.

Navigation Paths to messages

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      topics
         messages

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
               messages
```

Supported Methods for messages

The following methods are supported by this resource:

- `GET`
  - **request - body:** none, **Parameters:** `startIndex`, `itemsPerPage` (pagination)
  - **response - body:** messages
- `POST`
  - **request - body:** message
  - **response - body:** message

For more information, see Section 54.5.2.5, "Templates."

Resource Types Linked to From messages

Table 34–11 lists the resource types that the client can link to from this resource.

Table 34–11 Related Resource Types for messages

rel	resourceType
self	urn:oracle:webcenter:discussions:forum:topic:messages
	urn:oracle:webcenter:discussions:forum:topic:message

34.3.8.4.6 urn:oracle:webcenter:discussions:forum:topic:message Use this resource type to identify the URI to use to read (GET), update (PUT), and delete (DELETE) a specific discussion topic message. The response from a GET operation includes the specific message identified by the URI. The response from a PUT operation includes the modified version of the message identified by the URI. The response from a DELETE operation is a 204.

Navigation Paths to message

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   forums
      topics
         messages
            message

resourceindex
   spaces
      spaces:resourceindex
         spaces:forums
            topics
               messages
                  message
```

Supported Methods for message

The following methods are supported by this resource:

- GET
  - **request - body:** none
  - **response - body:** message
- PUT
  - **request - body:** message
  - **response - body:** message
- DELETE
  - **request - body:** none
  - **response - body:** none

Writable Elements for message

Table 34–12 lists the writable elements for this resource.

Table 34–12 Writable Elements for message

Element	Type	Required	Constraints	Description
`subject`	String	Yes	1 or more characters	Subject of this message
`body`	String	No	0 or more characters	Content of this message

Read-only Elements for message

Table 34–13 lists the read-only elements for this resource.

Table 34–13 Read-only Elements for message

Element	Type	Description
`id`	Integer	ID of the message
`parentId`	Integer	ID of the parent message
`forumId`	Integer	ID of the forum under which the message is posted
`topicId`	Integer	ID of the topic under which the message is posted
`createdBy`	String	ID of user that created the message
`author`	personReference	User information about the user that created the message, including GUID, ID, display name and a link to the profile icon (same user as `createdBy`)
`createdOn`	Date	Date on which the message was created
`updatedBy`	String	User that performed the last modification
`updatedOn`	Date	Date on which the message was last modified
`webUrl`	String	URL for direct access to the discussions server
`depth`	Integer	Depth in the hierarchy of messages
`messageCount`	Integer	Number of messages
`numberOfReplies`	Integer	Number of replies to this message
`hidden`	Boolean	True if this message is hidden
`hasAttachment`	Boolean	True if this message has attachments

Resource Types Linked to From message

Table 34–14 lists the resource types that the client can link to from this resource.

Table 34–14 Related Resource Types for message

self	`urn:oracle:webcenter:discussions:forum:topic:message`
	`urn:oracle:webcenter:discussions:forum:topic:messages`

34.3.9 Troubleshooting the Discussions Service

This section describes common problems and solutions for the Discussions service.

Problem

It can take several minutes to fetch data from recursive forums. For example, if you drop the Discussions task flow on the page with the `categoryId` and `forumId` parameters left blank and you set the `showrecursive` parameter to `${'true'}`, then it could take several minutes to scroll through all the forums.

Solution

The option to show recursive forums is not recommended for performance reasons.

Problem

Users can log on to WebCenter Portal but cannot log on to Oracle WebCenter Portal's Discussion Server.

Solution

Make sure that Oracle WebCenter Portal's Discussion Server is configured to use the same LDAP provider as the Framework application. Contact your administrator for details. For information about configuring LDAP, see the "Configuring the Identity Store" section in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

Problem

When you access a discussions forum from your Framework application, the following error message is displayed:

```
No default or active connection available for: Discussion Forum
```

Solution

Ensure the following:

- Ensure that you have created a Discussion Forum connection.
- Ensure the required Discussion Forum connection is marked as the default connection.

Problem

While performing certain operations on Discussions Forums task flows, you encounter error messages like "Forum not found" or "Topic not found."

Solution

Check the following:

- Ensure that the discussions server is up and running.
- Ensure the forum or topic exist on the discussions server.
- Ensure that you have the required privileges for the forum or topic that you are editing.

If all of these settings are fine and the problem persists, contact your administrator for details.

Problem

If you change the connection to use a different discussions server, and if you change the application root category ID from administrator-services-discussions, then you could see exceptions like, "Category Not Found."

Solution

Restart the managed server on which the Framework application is deployed.

35

Integrating the Instant Messaging and Presence Service

This chapter explains how to integrate the Instant Messaging and Presence (IMP) service in a WebCenter Portal: Framework application at design time.

For more information about managing and including instant messaging and presence, see:

- "Managing the Instant Messaging and Presence Service" in *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- "Working with the Instant Messaging and Presence Service" in *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

This chapter includes the following sections:

- Section 35.1, "Introduction to the IMP Service"
- Section 35.2, "Basic Configuration for the IMP Service"
- Section 35.3, "Advanced Information for the IMP Service"

35.1 Introduction to the IMP Service

The IMP service enables you to observe the presence status (online, offline, busy, or away) of other authenticated application users. It provides instant access to interaction options, such as instant messages and mails. Additionally, if your enterprise presence is unavailable (for example, when you are traveling), you can connect to a 3rd-party network presence service, such as Yahoo! Messenger.

Services in WebCenter Portal that have user names with the same identity can integrate with the IMP service; for example, Discussions, Documents, or Mail.

This section provides an overview of IMP features and requirements. It includes the following subsections:

- Section 35.1.1, "Understanding the IMP Service"
- Section 35.1.2, "Requirements for IMP"

35.1.1 Understanding the IMP Service

Figure 35–1 shows the Presence icon indicating a user who is online.

Figure 35–1 Presence Icon (Online)

Wherever a user is indicated, for example as the author of a document in the document library, you can click the icon to invoke a context menu (Figure 35–2).

Figure 35–2 Presence Icon Context Menu

The context menu can include the following actions:

- View Profile (This opens the selected user's profile page, with information such as mail ID and contact numbers.)
- Send Mail (This opens a compose window for the mail client set, either WebCenter Portal's Mail service or a local mail client.)
- Change Credentials (This works as an alternative to using an external application, visible only to the current user.)
- Send Instant Message (This opens the instant message client running on the computer, Microsoft Communicator.)

Next to a contact name is an icon that indicates the presence state of each contact.

For detailed information about the IMP service at runtime, including screen shots and descriptions of the presence status options, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

35.1.2 Requirements for IMP

The IMP service requires a back-end presence server. WebCenter Portal is certified with Microsoft Office Live Communications Server (LCS) 2005, Microsoft Office Communications Server (OCS) 2007, and Microsoft Lync 2010.

Note: Oracle Beehive Server connections are not supported in this release.

35.2 Basic Configuration for the IMP Service

This section describes the steps required for adding the IMP service to your application. It includes the following subsections:

- Section 35.2.1, "Setting up Connections for the IMP Service"
- Section 35.2.2, "Adding the IMP Service at Design Time"
- Section 35.2.3, "Setting Security for the IMP Service"

35.2.1 Setting up Connections for the IMP Service

After the presence server is properly installed and running, you must add a connection to it. This section describes how. It includes the following subsections:

- Section 35.2.1.1, "IMP Service Connections"
- Section 35.2.1.2, "How to Set Up Microsoft LCS Connections for the IMP Service"
- Section 35.2.1.3, "How to Set Up Microsoft OCS and Microsoft Lync Connections for the IMP Service"

35.2.1.1 IMP Service Connections

The IMP service requires an **Instant Messaging and Presence** connection to the presence server (Microsoft LCS, Microsoft OCS, or Microsoft Lync).

When a service in WebCenter Portal interacts with an application that handles its own authentication, you can associate that application with an external application definition to allow for credential provisioning. An external application is mandatory.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, see *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

35.2.1.1.1 Mapping User Names to IM Addresses The `im.address.resolver.class` handles the resolver implementation used to map user names to IM addresses and IM addresses to user names. This implementation looks for IM addresses in the following places and order:

1. User Preferences - If the user has entered his or her IM address in the Presence service Preferences page, then the user's IM address is found in the user's preferences.
2. User Credentials - If an external application is configured, then an account field provides the user's IM address.
3. User Profiles - If the user has not supplied preferences and WebCenter Portal cannot fetch the IM address from the external application, then WebCenter Portal reads the IM address from LDAP (that is, the user's profile). The default LDAP property read is the `BUSINESS_EMAIL` attribute. Users can change this default with `im.address.profile.attribute`.

To use your own resolver implementation, extend from `IMPAddressResolver` class and implement two methods: `resolveAddress` and `resolveUsername`.

- The `resolveAddress` method takes in user name and returns the corresponding IM address.
- The `resolveUsername` method takes in the IM address and returns the corresponding user name.

To plug in the new resolver class, change the service property `im.address.resolver.class` from the default `oracle.webcenter.collab.rtc.IMPAddressResolverImpl` to your resolver implementation. Example 35–1 shows a sample `IMPAddressResolver` implementation, where the resolver appends the domain string `@example.com` to the

user name to construct the address and removes the same domain string from the address to construct the user name.

Example 35–1 Resolver Implementation

```
public class SampleAddressResolver extends IMPAddressResolver
{
  private String DOMAIN = "@example.com";

  public SampleAddressResolver()
  {
    super();
  }

  //Append DOMAIN to the username to construct the IM address
  public String resolveAddress(String username)
  {
    String imAddress = username;
    if(!imAddress.endsWith(DOMAIN))
    {
      imAddress = imAddress + DOMAIN;
    }

    return imAddress;
  }

  //Remove DOMAIN from the IM address to construct the username
  public String resolveUsername(String imAddress)
  {
    String username = imAddress;
    if(username.endsWith(DOMAIN))
    {
      int index = username.indexOf(DOMAIN);
      username = username.substring(0, index);
    }

    return username;
  }
}
```

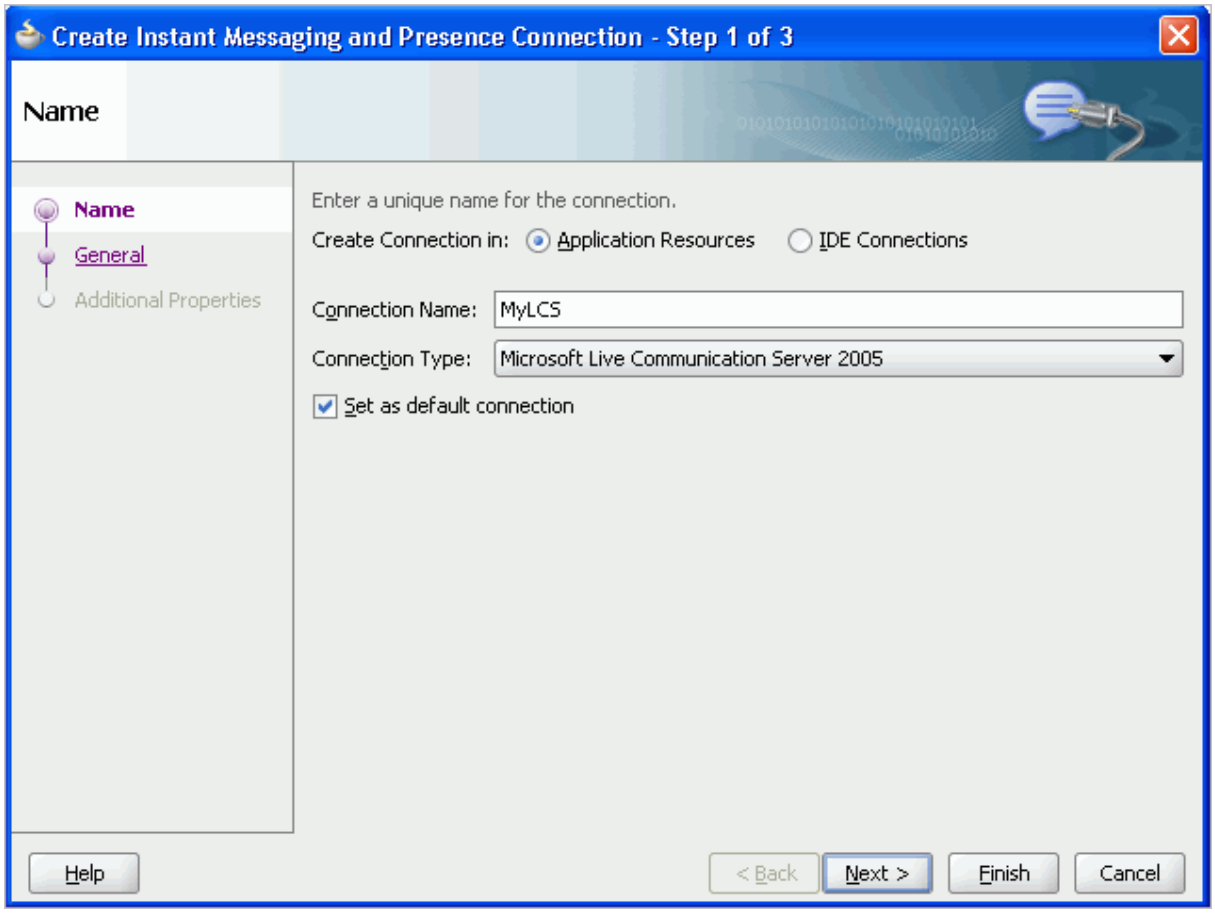
See Also: Section, "setIMPServiceProperty" in *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference*

35.2.1.2 How to Set Up Microsoft LCS Connections for the IMP Service

To set up the connection to the LCS presence server:

1. In Oracle JDeveloper, open the application in which to consume the Instant Messaging and Presence service.
2. In the Application Navigator, under Application Resources, right-click **Connections**, then select **Instant Messaging and Presence** from the list.
3. In the Create Instant Messaging and Presence connection dialog box, select to create the connection in **Application Resources**.

   A connection in Application Resources is available only for that application, while a connection in IDE connections is available for all applications you create. If you plan to use the connection in other applications, then select IDE connections to avoid having to re-create it.



4. On the **Name** page, for **Connection Name**, enter a unique name for your connection.

   No other connection should have the same name.

5. From the **Connection Type** list, select **Microsoft Live Communication Server 2005**.

6. Select the **Set as default connection** checkbox to use this as the default connection, as shown in Figure 35–3.

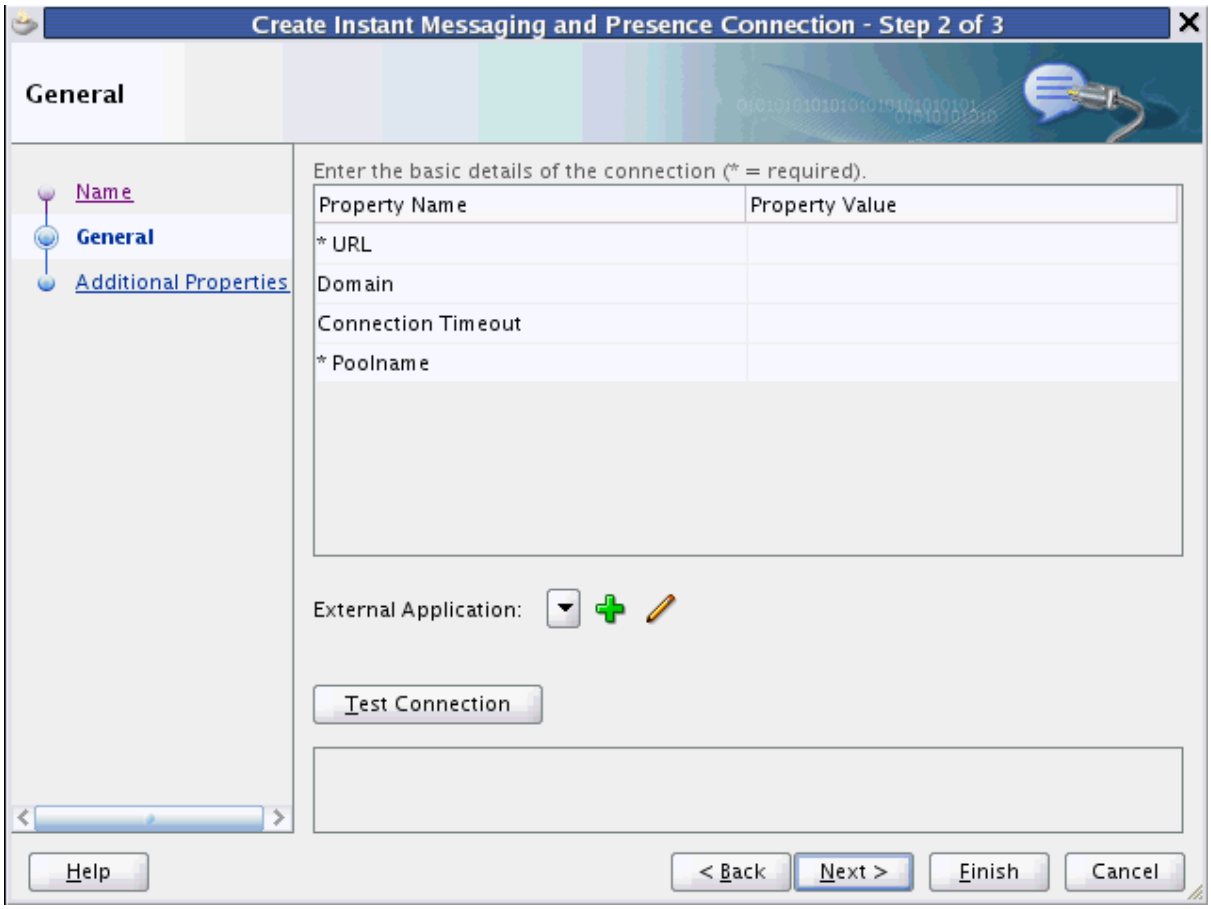


Figure 35–3 Create LCS Instant Messaging and Presence Connection, Step 1

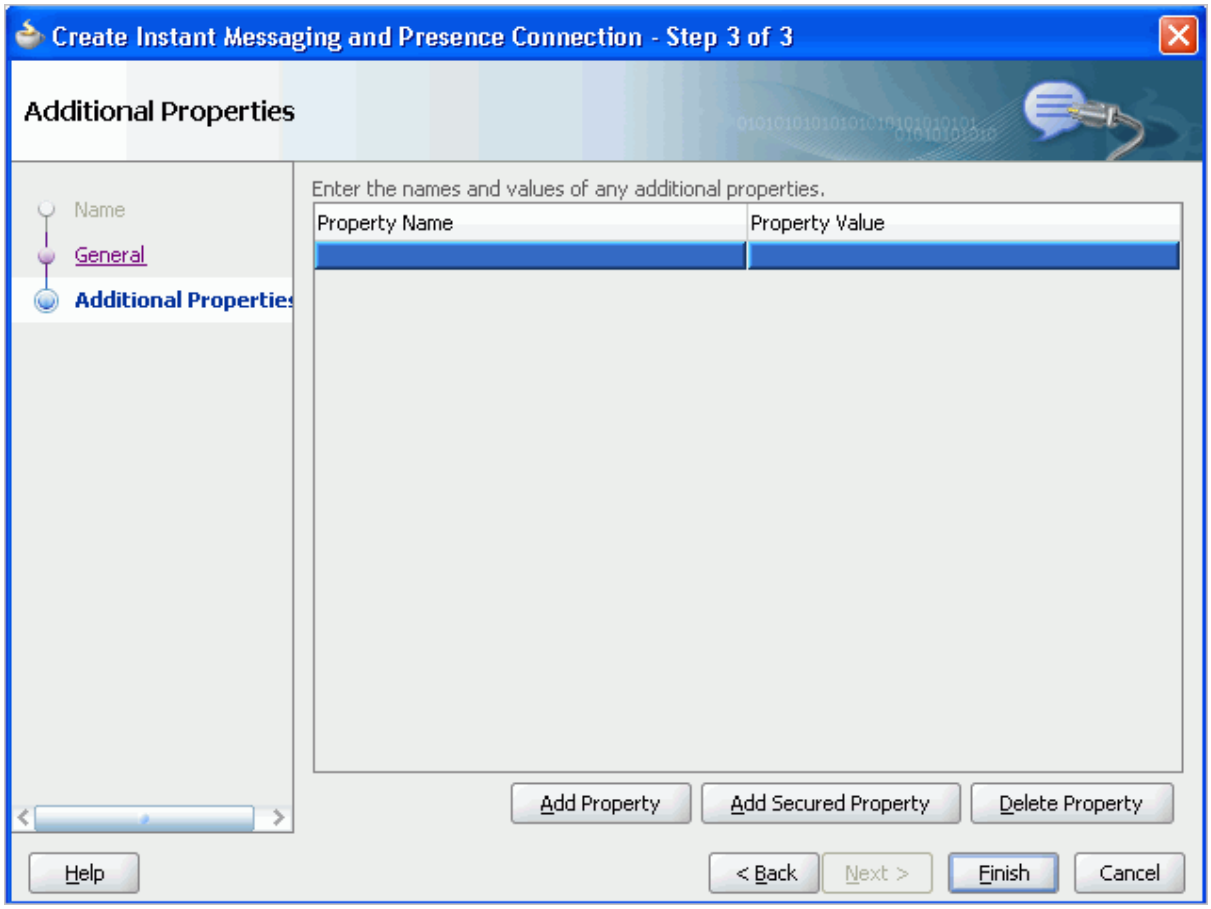
7. Click **Next**

8. On the **General** page (Figure 35–4), enter the information for your Microsoft LSC instance.

Figure 35–4 Create LCS Instant Messaging and Presence Connection, Step 2

For example:



- The `Url` could be `http://host:port/RTC` where RTC is the virtual directory name under which the server side module is deployed. (See the Microsoft Live Communications Server 2005 documentation for more information.)
- The `Domain` property is maintained for backward compatibility. It should be left blank.
- The `Connection Timeout` property is optional. It represents the time (in seconds) the service should wait for the server to respond while making the connection. If the presence server does not respond in the given time, then it aborts the connection and reports an error.
- For `PoolName`, enter the name of the pool under which Microsoft Communications Server components are deployed. (See the Microsoft Live Communications Server documentation for more information.)

9. On the same page, select an **External Application** to leverage the authentication mechanism (user names and passwords) on the presence server.

   For LCS connections, an external application is mandatory. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time they need information. For detailed information about configuring an external application for the IMP service, see Section 35.2.3, "Setting Security for the IMP Service."

10. Click **Test Connection** to confirm that the connection is good.
11. Click **Next** to create the connection.
12. On the **Additional Properties** page (Figure 35–5), you can optionally add parameter.s

Figure 35–5 Create LCS Instant Messaging and Presence Connection, Step 3

13. Click **Finish**.

You can see the new IM and presence connection under **Application Resources - Connections**.

35.2.1.3 How to Set Up Microsoft OCS and Microsoft Lync Connections for the IMP Service

To set up the connection to the Microsoft OCS or Microsoft Lync presence server:

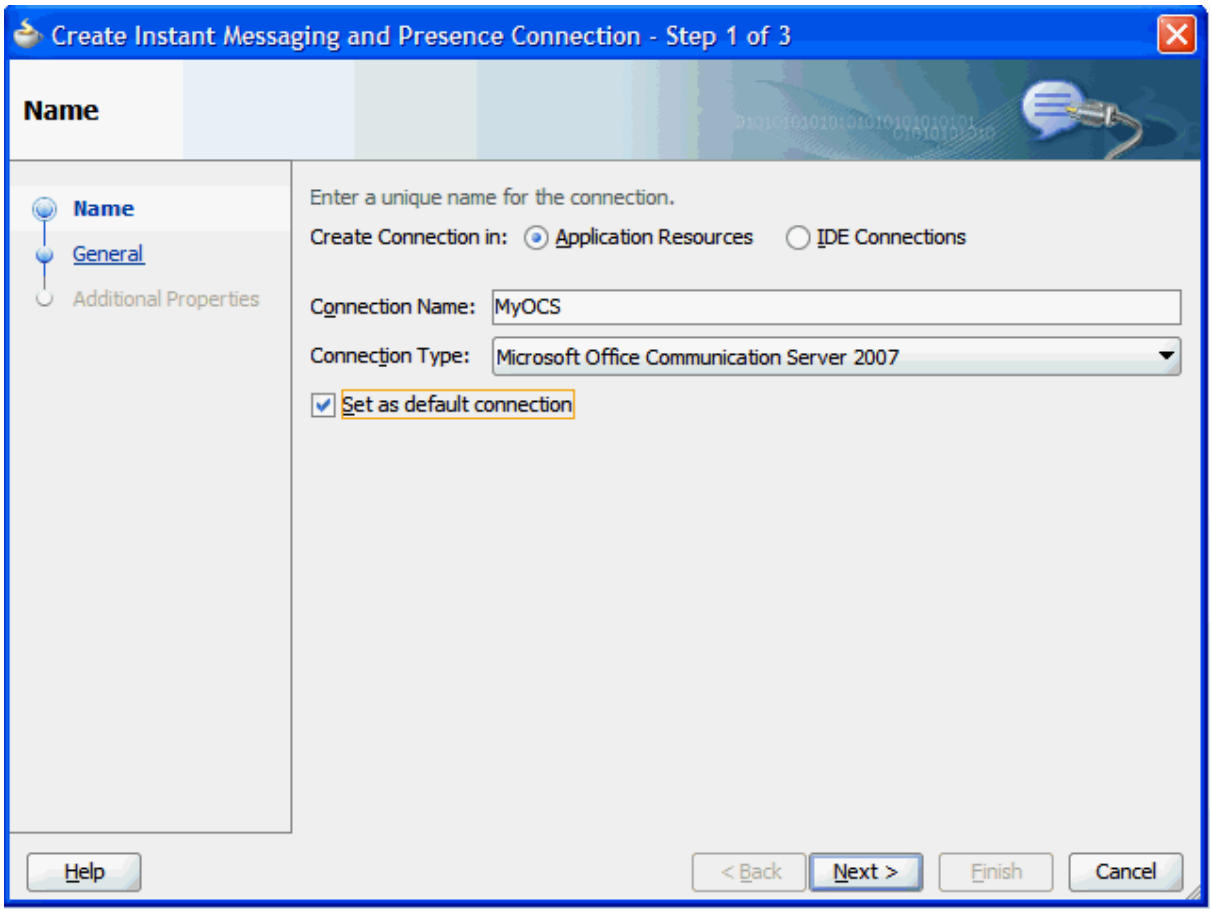
1. In Oracle JDeveloper, open the Framework application in which you plan to consume the Instant Messaging and Presence service.
2. In the Application Navigator, under Application Resources, right-click **Connections**, then select **Instant Messaging and Presence** from the list.
3. In the Create Instant Messaging and Presence connection dialog box, select to create the connection in **Application Resources**.

   A connection in Application Resources is available only for that application, while a connection in IDE connections is available for all applications you create. If you

plan to use the connection in other applications, then select IDE connections to avoid having to re-create it.

4. On the **Name** page, for **Connection Name**, enter a unique name for your connection.

   No other connection should have the same name.



5. From the **Connection Type** list, select **Microsoft Office Communications Server 2007**.

   Note: Microsoft Lync connections use the Microsoft Office Communications Server 2010 connection type.

6. Select the **Set as default connection** checkbox.

   The service requires that one connection be marked as the default connection, as shown in Figure 35–6.

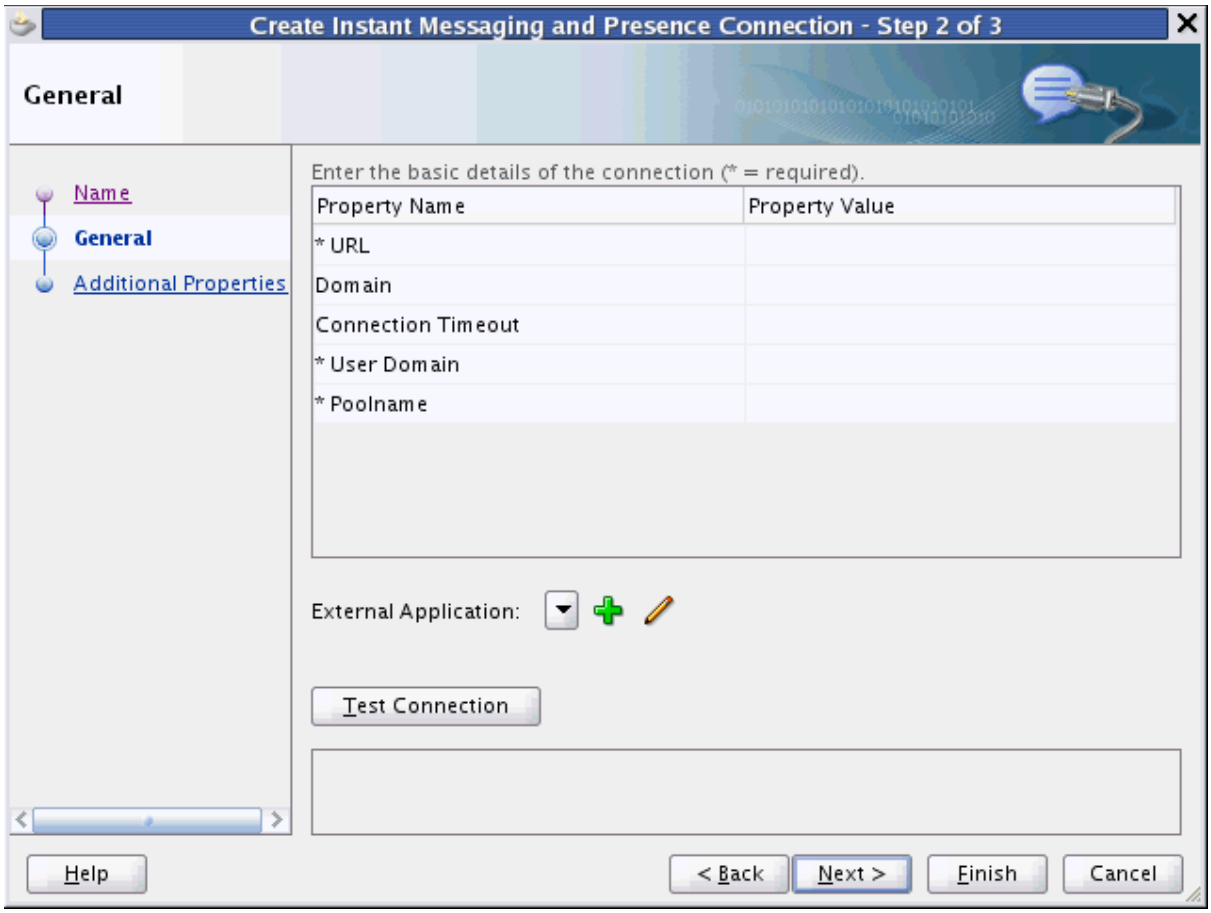


Figure 35–6 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 1

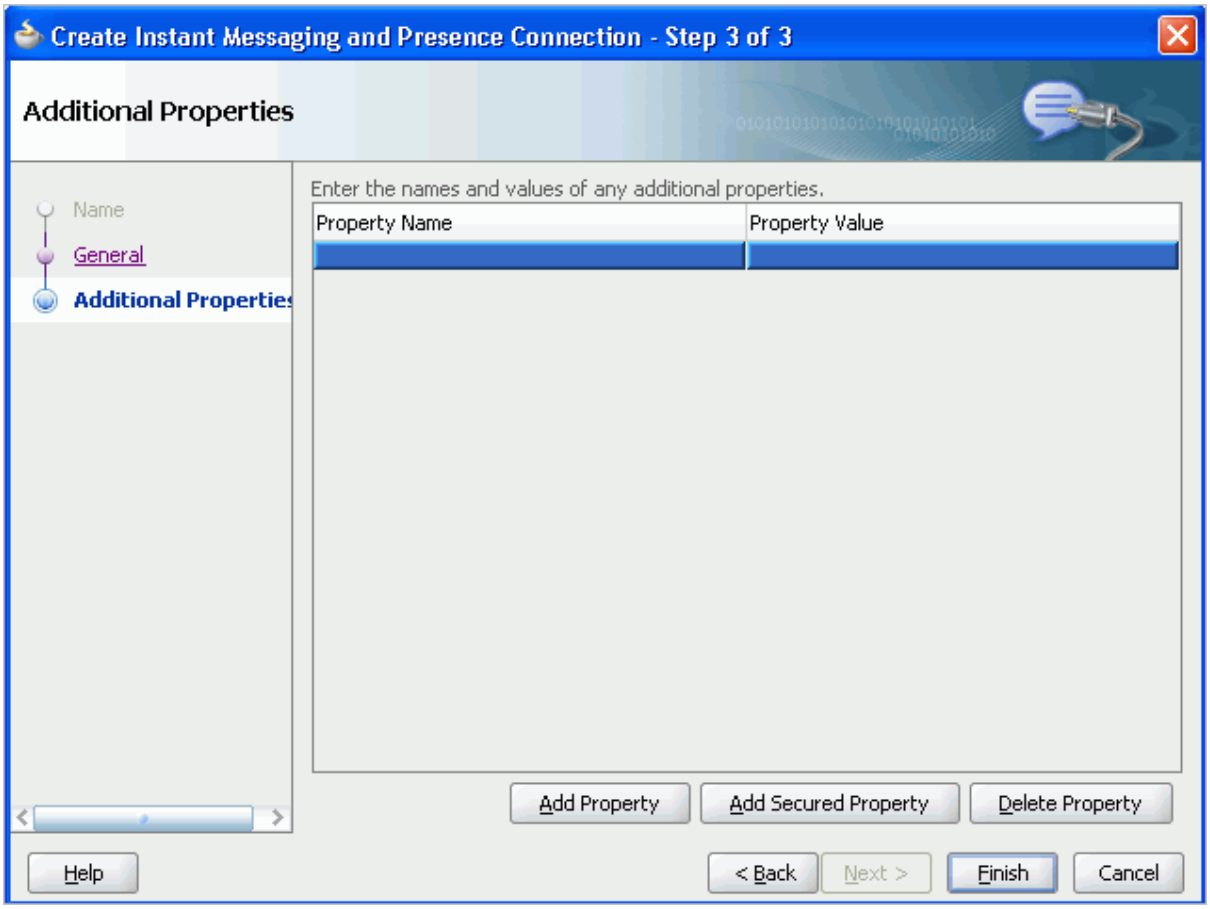
7. Click **Next**.

8. On the **General** page (Figure 35–7), enter the parameters for your Microsoft OCS or Microsoft Lync instance.

Figure 35–7 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 2

For example:

- The `URL` is the location of your Microsoft OCS or Lync instance. This could be `http://host:port/RTC` where RTC is the virtual directory name under which the server side module is deployed. (See the Microsoft documentation for more information.)
- The `Domain` property is maintained for backward compatibility. It should be left blank.
- The `Connection Timeout` property is optional. It represents the time (in seconds) the service should wait for the server to respond while making the connection. If the presence server does not respond in the given time, then it aborts the connection and reports an error.
- The `User Domain` is the Active Directory domain on Microsoft OCS or Lync. This parameter is mandatory.
- For `Poolname`, enter the name of the pool under which Microsoft Communications Server components are deployed. This parameter is mandatory. (See the Microsoft documentation for more information.)



9. On the same page, select an **External Application** to leverage the authentication mechanism (user names and passwords) on the presence server.

   For Microsoft OCS and Microsoft Lync connections, an external application is mandatory. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time they

need information. For detailed information about configuring an external application for the IMP service, see Section 35.2.3, "Setting Security for the IMP Service."

10. Click **Test Connection** to confirm that the connection is good.
11. Click **Next**.
12. On the **Additional Properties** page (Figure 35–5), you can optionally add parameters.

Figure 35–8 Create Microsoft OCS or Microsoft Lync IMP Connection, Step 3

13. Click **Finish**.

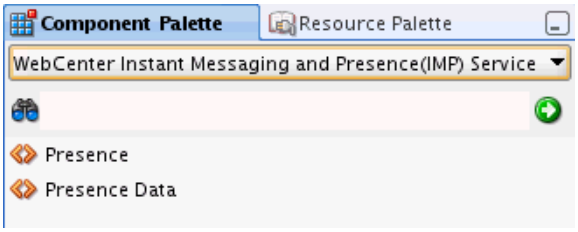
You can see the new IM and presence connection under **Application Resources - Connections**.

35.2.2 Adding the IMP Service at Design Time

This section explains a basic incorporation of the IMP service into your application. It includes the following subsections:

- Section 35.2.2.1, "IMP Service Task Flows"
- Section 35.2.2.2, "How to Add the IMP Service to your Application"

35.2.2.1 IMP Service Task Flows



The IMP service does not include any task flows.

35.2.2.2 How to Add the IMP Service to your Application

To add the IMP service to your Framework application:

1. Follow the steps described in Chapter 3, "Preparing Your Development Environment" to create a customizable page in your application.
2. Open the page on which you want to add the IMP service.
3. Ensure that you have configured your application to connect to the presence server. See Section 35.2.1, "Setting up Connections for the IMP Service."
4. In the Component Palette, drag and drop the **Presence** component to the page to add the Presence icon (Figure 35–9).

Figure 35–9 Component Palette - IMP Service Components

Use the **Presence** icon anywhere you want to display a user, for example, as the author of a discussion topic, the sender/recipient of a mail, or the owner of a document.

5. In the resulting dialog box, enter the user name of a user that exists in the back-end server that is linked to in the IM and Presence connection.

   You can add numerous presence components to the application page.

   For information about optional **Presence** component parameters, see Section 35.3.2, "Customizing IMP Views."

6. Click **Finish**.
7. From the Component Palette, drag and drop **Presence Data** to the end of the page (that is, before the `<af:document>` tag).

   This component does not have any attributes.

   The **Presence Data** component provides the status information for all **Presence** components on the page, such as online, offline, or busy. It verifies that all presence information corresponding to the user on the whole page shows consistent status information. Without this component, all users appear offline.

   Because the **Presence Data** component makes a call to the back-end server, for best performance, ensure that this is the last tag on the page. To avoid adding this tag to every page in your application, consider using a page template with **Presence Data** as the last component; that is, before the end of the `</af:form>` tag.

> **Note:** You can create new pages at runtime on which you can add components, such as forums, mail, or documents. Many components have **Presence** tags, but users do not have a handle to add the **Presence Data** tag to the page. To see presence on custom pages, you must manually add the **Presence Data** tag to the underlying template.

8. If **External Application** in IDE connections was selected when you created the connection, then drag and drop the **External Application - Change Password** task flow into your application from the Resource Palette or Component Palette.

   This task flow enables the end user to set the appropriate user name and password for the external application.

9. Save your project, and then run your page to a browser to see the Presence component.

   Figure 35–10 shows the runtime Presence component with the display name of user Monty Montasaurus111.

Figure 35–10 WebCenter Portal Presence Icon - Online

35.2.3 Setting Security for the IMP Service

The IMP service requires user identity. ADF security is configured by default if you created your application using the WebCenter Portal - Framework Application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."

Credentials are read from the external application (public credentials) and used to log on to the presence server. If you do not apply ADF security or if you do not have an external application configured, then users cannot authenticate and do not see any content at runtime.

> **Note:** The presence server and the Framework application should point to the same identity store. The identity store must be LDAP-based; that is, not file-based with `jazn-data.xml`.

To access the presence server, the IMP service can use an external application with dedicated user accounts.

Microsoft LCS, OCS, and Lync support external application connections. With a secured application, users get presence status. The Change Credentials option works as an alternative to using an external application. Logged-in users can click their own Presence context menu and select **Change Credentials**. Security should be on a private trusted network.

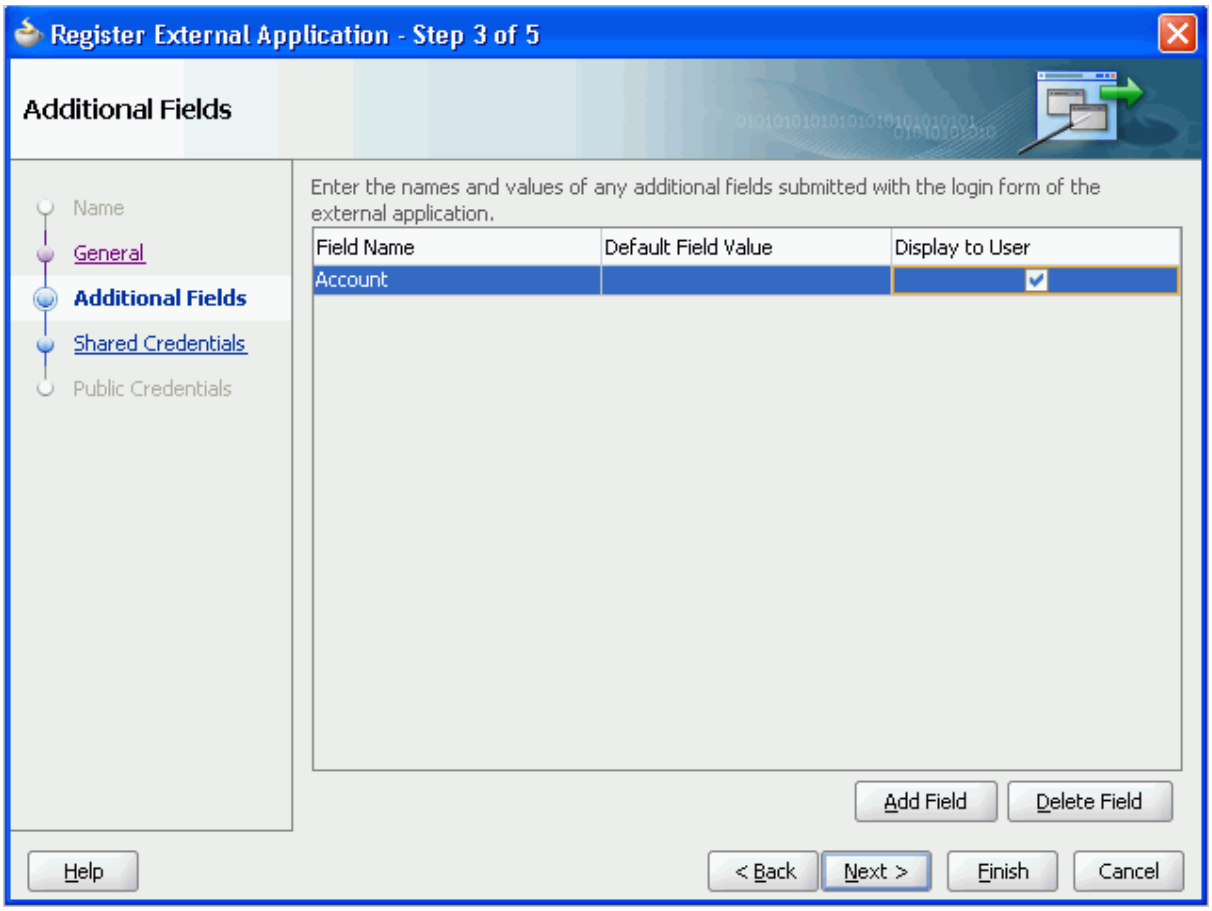
To use an external application for authentication:

1. On the General page of the Create Instant Messaging and Presence connection wizard, click the **+** icon next to External Application.

   This brings up the Register External Application wizard. The application maps the presence server user to the application user such that end users do not have to enter their user names and passwords each time.

   > **Note:** External application credential provisioning is built into the IMP connection. You do not need to drop **External Application - Change Password** task flow on a page.

2. On the Name page:



- For **Application Name**, enter a unique name to identify the application. This name must be unique within the Framework application, and among other connections as well. Note that you cannot edit this field afterward.
- For **Display Name**, enter a name for the application that end users see in the credential provisioning screens.

3. Click **Next**.
4. On the General page, leave the following properties with the default values.
   - **Login URL**
   - **User Name/ID Field Name**
   - **Password Field Name**
5. From the **Authentication Method** list, select **POST**. This submits login credentials within the body of a form. The external application for the IMP service requires this authentication method.
6. Click **Next**.
7. On the Additional Fields page:

   Click **Add Field**, and add an extra field with the name "Account." Make sure to select the **Display to User** checkbox, as shown in Figure 35–11.

   Note: The external application for the IMP service requires this additional field. It must be displayed to users.

Figure 35–11 Account Additional Field

8. The External Application service allows different types of credentials to be associated with a connection:
   - When shared credentials are specified, every *authenticated* user uses the same credentials to access the external application; that is, the user name and password you can define here. A single presence session is created for all logged-in users. This is not accessible to public users.
   - With public credentials, without authenticating your Framework application, you can view presence from a certain presence ID for all *unauthenticated* (public) users. Public credentials are used whenever an application is not secured or the user has not yet logged in. A single presence session is created for all public users.
   - With private credentials, each user must authenticate to an *individual* ID (that is, each application user must specify his own credentials). One presence session is created for each user.
9. Click **Finish** to have the external application use private credentials, or click **Next** to set up shared or public credentials.
10. *For Shared Credentials Only*: On the Shared Credentials page, ensure that **Specify Shared Credentials** is selected, then enter the shared user credentials and ID.
11. *For Public Credentials Only*: On the Public Credentials page, ensure that **Specify Public Credentials** is selected, then enter the user credentials and ID for public use.

12. Click **Finish** to register the external application.
13. In the IMP connection wizard, ensure that this newly-created external application connection for IMP is selected.

For information about using external applications, see Section 69.13, "Working with External Applications."

35.3 Advanced Information for the IMP Service

This section describes optional features available with the IMP service. It includes the following subsections:

- Section 35.3.1, "Enabling Network Presence"
- Section 35.3.2, "Customizing IMP Views"
- Section 35.3.3, "Troubleshooting the IMP Service"

35.3.1 Enabling Network Presence

When WebCenter Portal presence is not available (for example, if your enterprise uses a Jabber/XMPP presence server or has federated presence servers with users distributed across identity management systems), you can connect to a 3rd-party network presence service.

Out-of-the-box, WebCenter Portal supports Yahoo! Messenger on network presence. However, the network presence model can be extended to include other providers, such as ICQ.

This section includes the following subsections:

- Section 35.3.1.1, "Setting Up Yahoo! Messenger Presence"
- Section 35.3.1.2, "Setting Up Other Network Presence Providers"

35.3.1.1 Setting Up Yahoo! Messenger Presence

WebCenter Portal Framework allows end users to set their IM preferences to their Yahoo! Messenger presence. Portal developers enable this functionality by leveraging the `rtcPresenceHandler` bean.

Follow these steps to include Yahoo! Messenger presence in your Framework application.

1. On the Source tab for your JPSX page, add the user interface for users to enter their Yahoo! Messenger credentials: **Display Name** and **IM Address** input boxes and a **Save IM Preferences** button.

   Example 35–2 shows the two `af:inputText` components for users to enter Display Name and IM Address and an `af:commandButton` component for users to save the preferences.

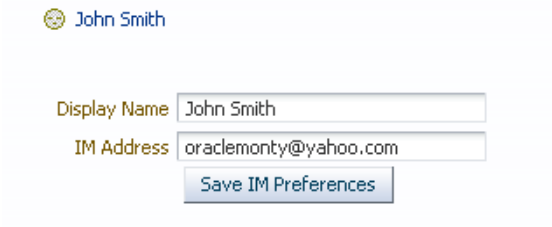
   Setting the `inputText` value with this EL sets the `displayName` and `imAddress` in the preferences bean. To save the values, users click the button, which invokes a method from the bean to save the preferences.

Example 35–2 User Interface for Yahoo! Messenger Presence

```
      <af:inputText label="Display Name"
value="#{rtcPreferenceHandler.displayName}" id="it1"/>
      <af:inputText label="IM Address"
value="#{rtcPreferenceHandler.imAddress}" id="it2"/>
```

```
                <af:commandButton text="Save IM Preferences" id="cb1"
            actionListener="#{rtcPreferenceHandler.savePreferences}"/>
```

Example 35–3 shows the full source code for the page, with the user interface included.



Example 35–3 Source Code for the Page with Yahoo Presence

```
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
          xmlns:f="http://java.sun.com/jsf/core"
          xmlns:h="http://java.sun.com/jsf/html"
          xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
          xmlns:rtc="http://xmlns.oracle.com/webcenter/collab/rtc">
  <jsp:directive.page contentType="text/html;charset=UTF-8"/>
  <f:view>
    <af:document id="d1">
      <af:form id="f1" usesUpload="true">
        <af:panelStretchLayout id="psl1">
          <f:facet name="bottom"/>
          <f:facet name="center">
            <af:panelGroupLayout layout="scroll"
                                 xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
                                 id="pgl1">
              <rtc:presence username="#{rtcPreferenceHandler.imAddress}"
displayName="#{rtcPreferenceHandler.displayName}" id="p1"/>
              <rtc:presenceData id="pd1"/>
              <af:inputText label="Display Name" value="#{rtcPreferenceHandler.displayName}"
id="it1"/>
              <af:inputText label="IM Address" value="#{rtcPreferenceHandler.imAddress}" id="it2"/>
              <af:commandButton text="Save IM Preferences" id="cb1"
                                actionListener="#{rtcPreferenceHandler.savePreferences}"/>

            </af:panelGroupLayout>
          </f:facet>
          <f:facet name="start">
            <af:spacer width="10" height="10" id="s1"/>
          </f:facet>
          <f:facet name="end">
            <af:spacer width="10" height="10" id="s2"/>
          </f:facet>
          <f:facet name="top"/>
        </af:panelStretchLayout>
      </af:form>
    </af:document>
  </f:view>
</jsp:root>
```

2. Run the JPSX page to see that now users can enter their Yahoo! Messenger credentials (Figure 35–12).

Figure 35–12 User Interface to Enter Yahoo! Messenger Credentials

Presence tags for that user shows their Yahoo presence, either online (Figure 35–13) or offline (Figure 35–14).

Figure 35–13 Yahoo Presence Icon - Online

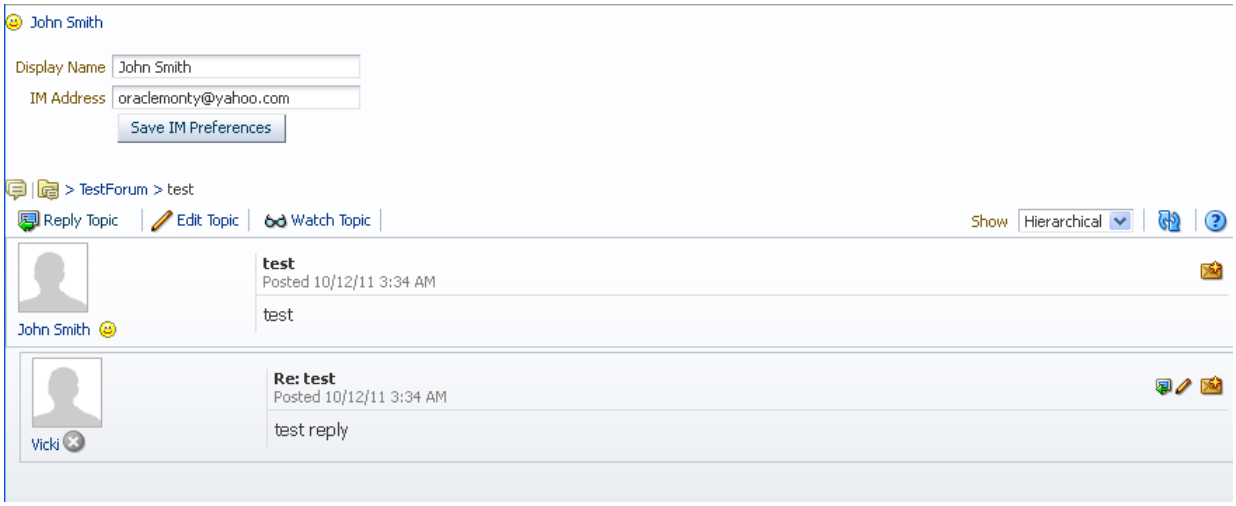


Figure 35–14 Yahoo Presence Icon - Offline

Figure 35–15 shows a sample page that includes the Discussion Forums task flow, where Yahoo! Messenger presence and WebCenter Portal presence are shown together.

Figure 35–15 Sample Page with WebCenter Portal Presence and Yahoo! Messenger Presence

35.3.1.2 Setting Up Other Network Presence Providers

To use a different network presence provider, deploy your application that contains the `PresenceNetworkAgent` implementation class for that service and an `imp-pna.config` file listing that implementation class into a jar file.

For example, suppose the new Presence Network Agent is called SamplePNA. You must create two files: the `Project1.SamplePNA` class file and the `imp-pna.config` file.

- `Project1.SamplePNA.java`: This class implements `oracle.webcenter.collab.rtc.PresenceNetworkAgent`. It must implement three methods:
  - `isSupported(PNAContext context)`: The method should return true if the PNA supports the user for which presence is requested. The `PNAContext` object supplied contains the user information. For example, if the PNA supports all IM addresses with the domain `example.com`, then it can get the imAddress from the `PNAContext` object and check for the domain `example.com`.
  - `getURL(PNAContext context)`: The method should return the fully qualified URL to reach to the user's Presence icon. Again, it gets the user information from the `PNAContext` object.
  - `getChatURI(PNAContext context)`: The method should return the browser compatible URI to invoke the chat client (for example, `sip:user@example.com`).

  Example 35–3 shows this SamplePNA class file.

Example 35–4 SamplePNA Class File

```
public class SamplePNA implements PresenceNetworkAgent
{
private String DOMAIN = "@example.com";

public SamplePNA()
{
super();
}

//Returns true if the imAddress ends with DOMAIN
public Boolean isSupported(PNAContext context)
{
String imAddress = context.getIMAddress();
if(imAddress.endsWith(DOMAIN))
{
return true;
}

return false;
}

//Returns the URL to the icon representing the current status of a user
public String getURL(PNAContext context)
{
String imAddress = context.getIMAddress();
Strung url = "http://www.example.com?address=" + imAddress;
return url;
}

//Returns the browser compatible chat uri to invoke the thick client
public String getChatURI(PNAContext context)
{
String imAddress = context.getIMAddress();
String chatURI = "sip:" + imAddress;
return chatURI;
}
}
```

- `META-INF/imp-pna.config`: This file lists the available `PNAAgent` classes. In this case, it contains only the following line:

  ```
  Project1.SamplePNA
  ```

See Chapter 56, "Extending the Spaces Application Using JDeveloper" for information on how to package your application and deploy it as a custom shared library (for example, in WebCenter Portal: Spaces).

Whenever a Presence tag is encountered with an IM address as *`user@example.com`*. The URL configured appears on the user interface as the Presence icon.

```
<rtc:presence username="user1@example.com" resolveAddress="false"/>
```

35.3.2 Customizing IMP Views

Table 35–1 lists the attributes supported by the **Presence** component. Only the `username` attribute is required; all other attributes are optional. You can update these attributes in the Property Inspector.

Table 35–1 Presence Component Description

Attribute	Description
`username`	The user whose presence information you want to add to the application page. This attribute is required.
`display`	How the component should display. Takes one of the following values: ■ `icon`: Display only the Presence icon; do not render the name. ■ `name`: Display the user name; do not display the Presence icon. ■ `both` (default): Display both the icon and the user name.
`displayName`	By default, the **Presence** component displays the user name. If the flag `get.display.name.from.user.profile` is set to `true` in `service-config.xml` *and* if this `displayName` attribute is not supplied, then the **Presence** component tries to look up a user's display name from the User Profile.
`iconPosition`	The position for the icon. Possible values are `begin` and `end`. The default value is `begin`.
`controlsEnabled`	A Boolean value that defines whether the component should provide rich interactions to the end user. If this attribute is set to `false`, then the Presence component does not do anything when clicked.
`id`	A unique identifier for the component on the page. The identifier must follow a subset of the syntax allowed in HTML: ■ Must not be a zero-length String. ■ First character must be an ASCII letter (A-Z, a-z) or an underscore ('_'). ■ Subsequent characters must be an ASCII letter or digit (A-Z, a-z, 0-9), an underscore ('_'), or a dash ('-').
`smallIcon`	A Boolean value that defines whether to use the small 12x12 icon set (`true`) or to use the default 16x16 icon set (`false`). The default value is `false`.
`rendered`	A Boolean value that defines whether to render this component. The default value is `true`.
`binding`	An EL reference to store the component instance on a bean. Use this to give programmatic access to a component from a backing bean or to move creation of the component to a backing bean.

Table 35–1 (Cont.) Presence Component Description

Attribute	Description
`inlineStyle`	The CSS styles to use for this component. Manually enter any style in compliance with CSS version 2.0 or later, or expand this node to specify style elements. This is intended for basic style changes.
`styleClass`	A CSS style class to use for this component.
`resolveToAddress`	A Boolean value that defines whether to resolve the supplied `username` to an IM address. The default value is `true`. However, if the supplied `username` is an IM address, then you can set this value to `false`, and the IMP service uses `username` as the IM address.

35.3.3 Troubleshooting the IMP Service

This section describes common problems and solutions for the IMP service.

Problem

The Presence icon is not visible in your Framework application.

Solution

Ensure that an IMP connection exists in your application and has been set as active.

Problem

Changes in the presence status of users are not visible in your Framework application.

Solution

For each logged-in user's session, the IMP service fetches the presence information from the presence server and stores it in the presence cache. For presence requests, the service returns the data from the cache until the cache expires. The default cache expiry period is 60 seconds.

To view the updated presence status, you can wait for the cache to expire and retrieve the latest presence status.

You can also change the cache expiry time by setting the `rtc.cache.time` service configuration property to the desired value (in seconds). Update `adf-config.xml` to include the highlighted entry, which shows the sample value as 30 seconds. Example 35–5 shows an example.

Example 35–5 Setting the rtc.cache.time Expiration Value in adf-config.xml

```
<adf-collaboration-config xmlns="http://xmlns.oracle.com/webcenter/collab/config">
<service-config serviceId="oracle.webcenter.collab.rtc">
<property name="rtc.cache.time" value="30"/></service-config>
</adf-collaboration-config>
```

Problem

A number of options, such as Send Instant Message, are not available in the context menu of the IMP service in your Framework application.

Solution

Ensure that IMP service is configured in your Framework application. Also, ensure the following settings for the various context menu options:

- **View Profile** option unavailable: Ensure that your application is secured.
- **Send Instant Message** option unavailable: Ensure that the IMP service is configured in the application.

Problem

You are unable to send a message from your Framework application. Clicking the **Send Instant Message** option returns an error.

Solution

Ensure that your SIP client is supported by the presence server and you have logged on as an authenticated user. The supported SIP client is Microsoft Communicator.

36

Integrating the Mail Service

This chapter explains how to integrate the Mail service in a WebCenter Portal: Framework application at design time.

For more information about managing and including mail, see:

- "Managing the Mail Service" in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*
- "Working with the Mail Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*

This chapter includes the following sections:

- Section 36.1, "Introduction to the Mail Service"
- Section 36.2, "Basic Configuration for the Mail Service"
- Section 36.3, "Advanced Information for the Mail Service"

> **Note:** The Mail service supports only the Inbox. No other folders (or moving of messages) are supported.

36.1 Introduction to the Mail Service

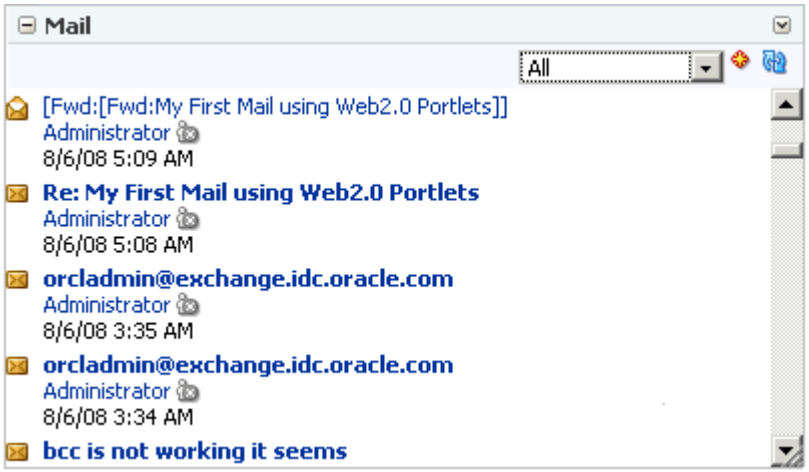
This section provides an overview of Mail service features and requirements. It includes the following subsections:

- Section 36.1.1, "Understanding the Mail Service"
- Section 36.1.2, "Requirements for the Mail Service"

36.1.1 Understanding the Mail Service

The Mail service enables users to access the inbox of a mail server that supports Internet Message Access Protocol4 (IMAP4) and Simple Mail Transfer Protocol (SMTP). Additionally, it enables users to compose a new mail message from within the application (with attachments) and delete, reply to, and forward messages.

The Mail service does not replace users' mail clients; it simply enables users to access and compose mail in a single, collaborative environment.



With the Mail service, you can do the following:

- Read a message by clicking the linked mail subject.
- View sender details (including date) by expanding the **From** field.

- Scroll down to see the other messages not in the view. You can navigate among the fetched messages as cached messages.
- Attach a file to a message by expanding the attachment section within the mail dialog and clicking **Attach**. Specify an attachment in the new dialog pop-up. Remove an attachment from the mail by clicking the **Remove Attachment** icon.
- Reply to a message by clicking the **Reply** or **Reply All** icon.
- Forward a message by clicking the **Forward** icon.
- Cancel an operation (for example, sending a mail) by clicking **Cancel**.

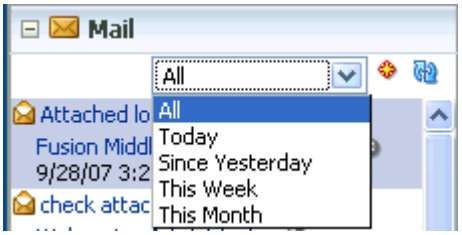


Figure 36–1 shows the Mail task flow at runtime. At the top of the view are three elements: a dropdown list that shows the number of mails to display (here, **All**), the **Compose** icon, and the **Refresh** icon. The **Refresh** icon provides a means of manually checking for new messages in the inbox.

Figure 36–1 Mail Service at Runtime

The dropdown list provides filters to focus the view on messages received today, messages received since yesterday, messages received this week, and messages received this month (Figure 36–2).

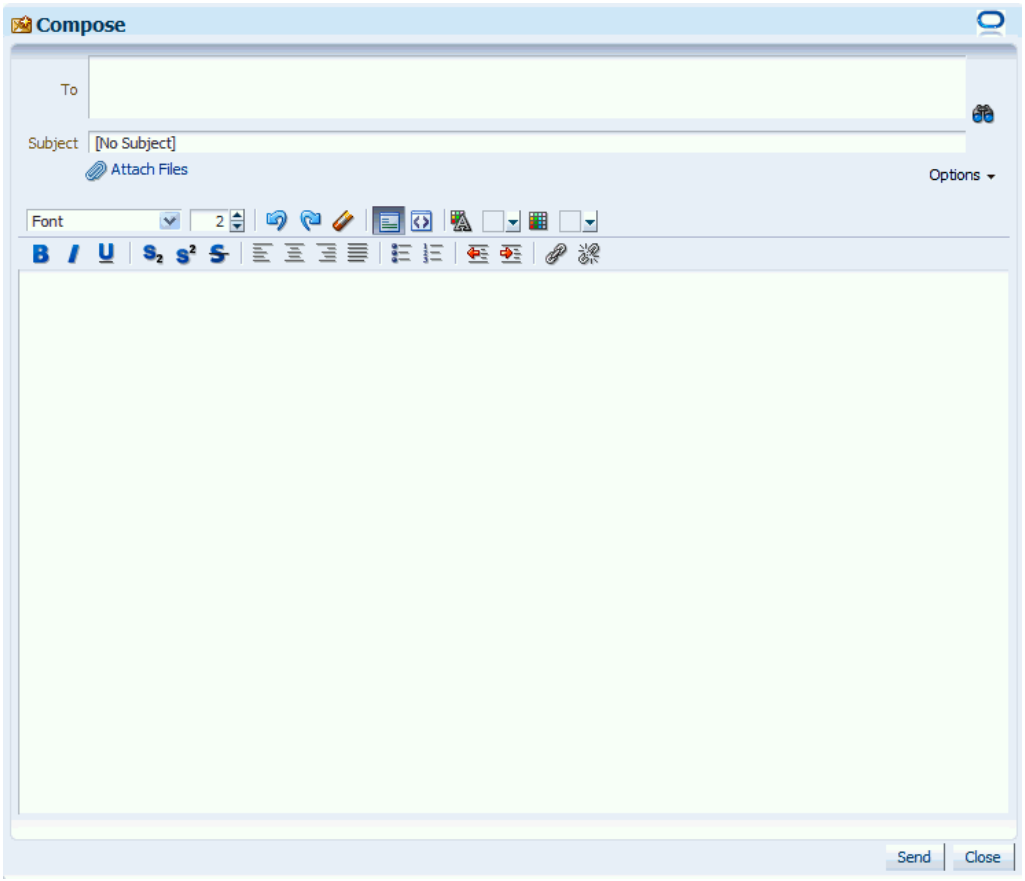

Figure 36–2 Message Filter

Note: By default, `All` displays the 50 most recent messages. For information on how to increase this amount, see Section 36.3.2, "Configuring the Number of Mails Displayed."

Click the **Compose** icon next to the dropdown list to compose a new message right from your application. Clicking this icon displays the Compose page, as shown in Figure 36–3.

Figure 36–3 Compose Mail

Use the **Search** icons to find mail addresses and contacts of users in the LDAP store that the Framework application uses. For any user not in the LDAP store, you must enter an explicit mail address.

For more information about the Mail service at runtime, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

36.1.2 Requirements for the Mail Service

The Mail service requires a mail server that supports IMAP4 and SMTP protocols.

In WebCenter Portal: Spaces, the Microsoft Exchange mail server is required for automatic creation of distribution lists when spaces are created. In a Framework application, this feature may not be desirable. To disable it, do not provide the LDAP (Active Directory) server details in the mail connection.

36.2 Basic Configuration for the Mail Service

This section describes the steps required for adding the Mail service to your application. It includes the following subsections:

- Section 36.2.1, "Configuration Roadmap - Mail Service"

- Section 36.2.2, "Setting up Connections for the Mail Service."
- Section 36.2.3, "Adding the Mail Service at Design Time"
- Section 36.2.4, "Setting Security for the Mail Service"

36.2.1 Configuration Roadmap - Mail Service

Use the roadmap in this section as a guide through the configuration process.

Figure 36–4 and Table 36–1 provide an overview of the prerequisites and tasks required to get the Mail service working in Framework applications.

Figure 36–4 Configuring the Mail Service for Framework Applications

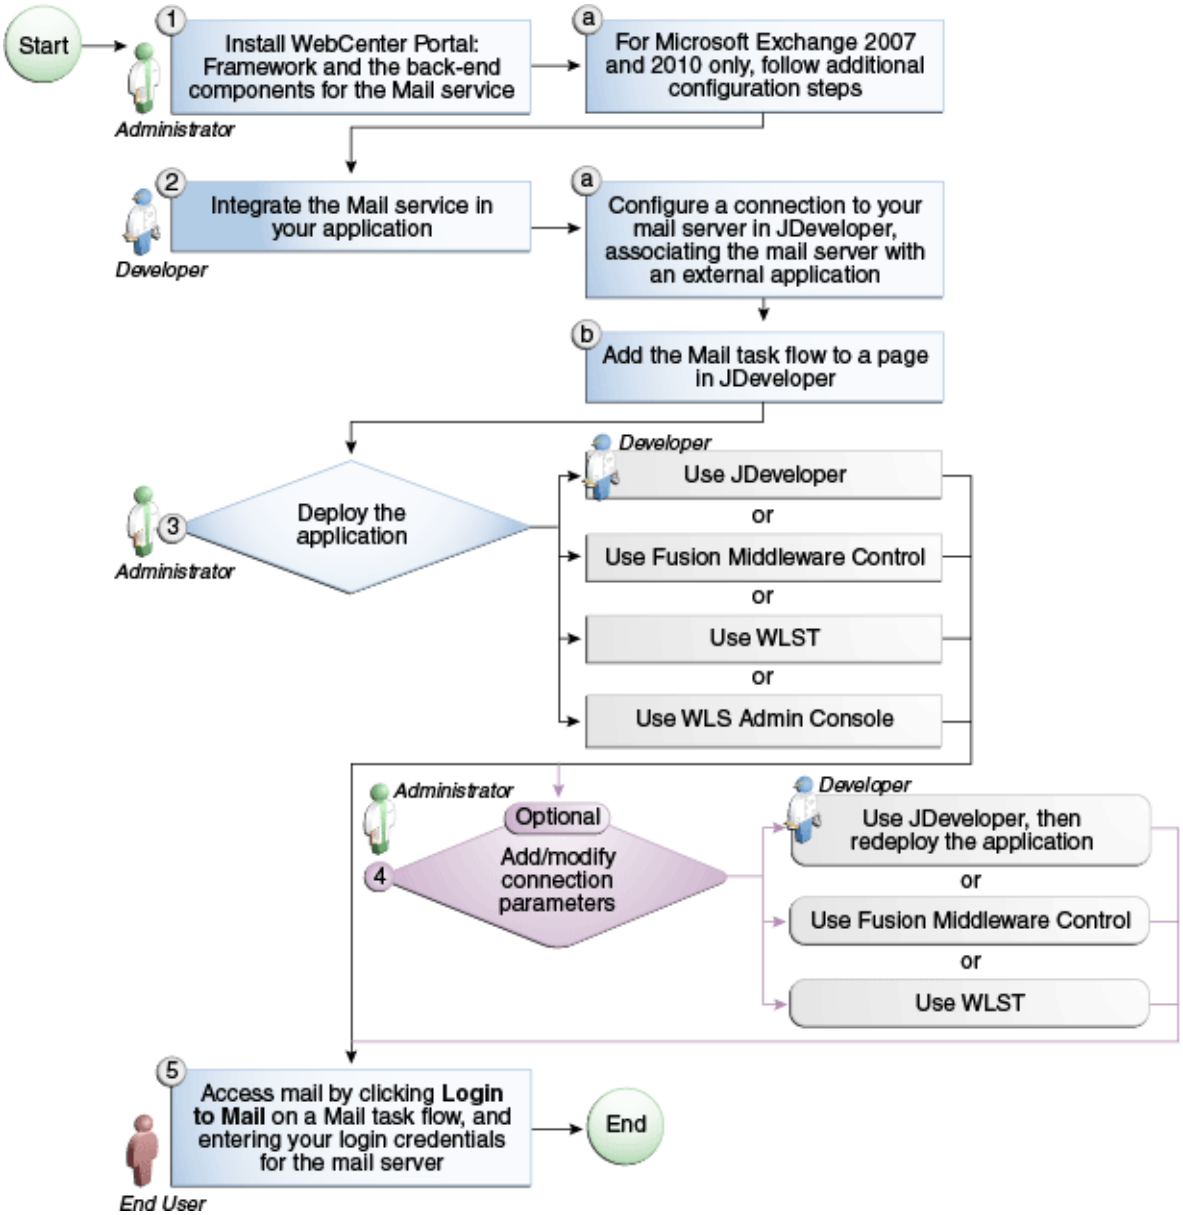

Table 36–1 Configuring the Mail Service for Framework Applications

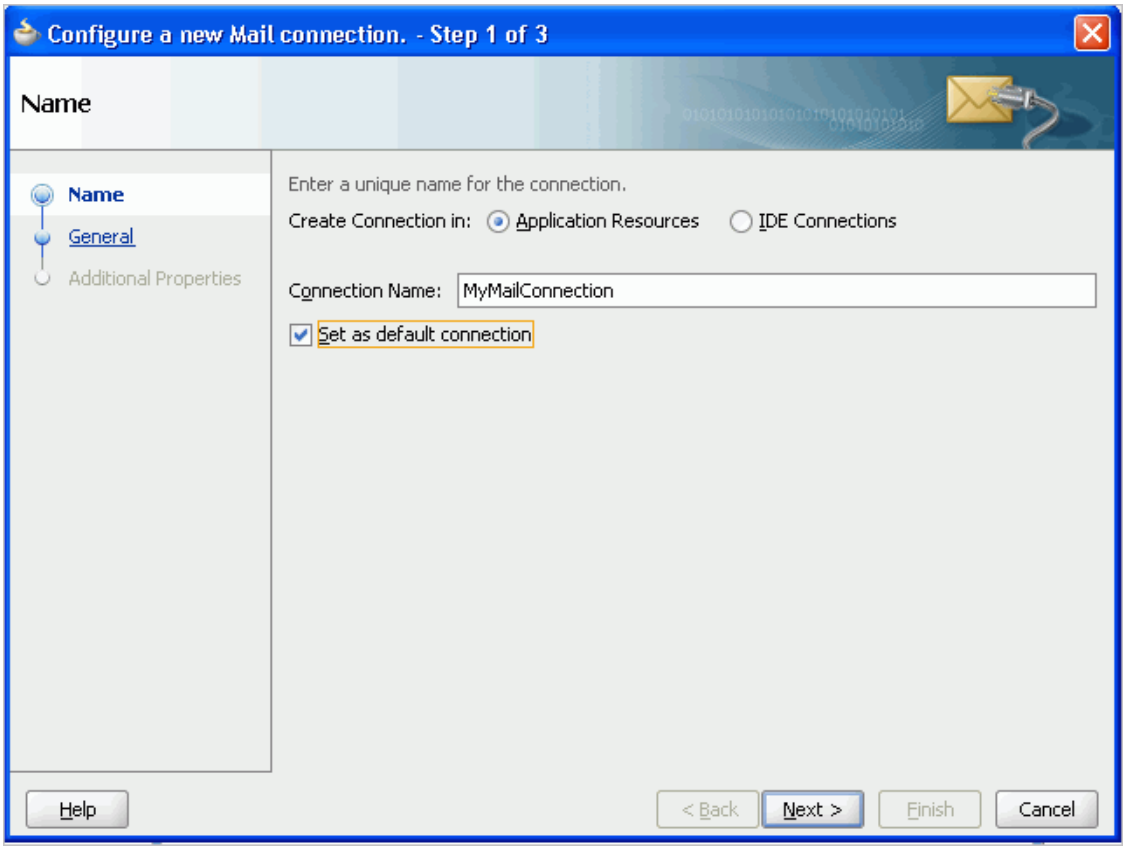
Actor	Task	Sub-task
Administrator	1. Install WebCenter Portal and the back-end components for the Mail service	1.a For Microsoft Exchange 2007 and 2010 only, follow additional configuration steps
Developer	2. Integrate the Mail service in your Framework application	2.a Configure a connection to your mail server in JDeveloper, associating the mail server with an external application
		2.b Add the Mail task flow to a page in JDeveloper
Developer or Administrator	3. Deploy the Framework application using one of the following tools: ■ JDeveloper (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator) ■ WLS Admin Control (Administrator)	
Developer or Administrator	4. (Optional) Add/modify connection parameters using one of the following tools: ■ JDeveloper, then redeploy the application (Developer) ■ Fusion Middleware Control (Administrator) ■ WLST (Administrator)	
End User	5. Access mail by clicking **Login to Mail** on a Mail task flow, and entering your login credentials for the mail server	

36.2.2 Setting up Connections for the Mail Service

Before you can use the Mail service, you must first set up the connection to your mail server. The Mail service supports any mail server based on IMAP4 and SMTP protocol.

> **Note:** While you can set up the connections to back-end servers at design time in Oracle JDeveloper, you can later add, delete, or modify connections in your deployed environment using Enterprise Manager Fusion Middleware Control. For more information, *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

To create a connection to your mail server from the application:



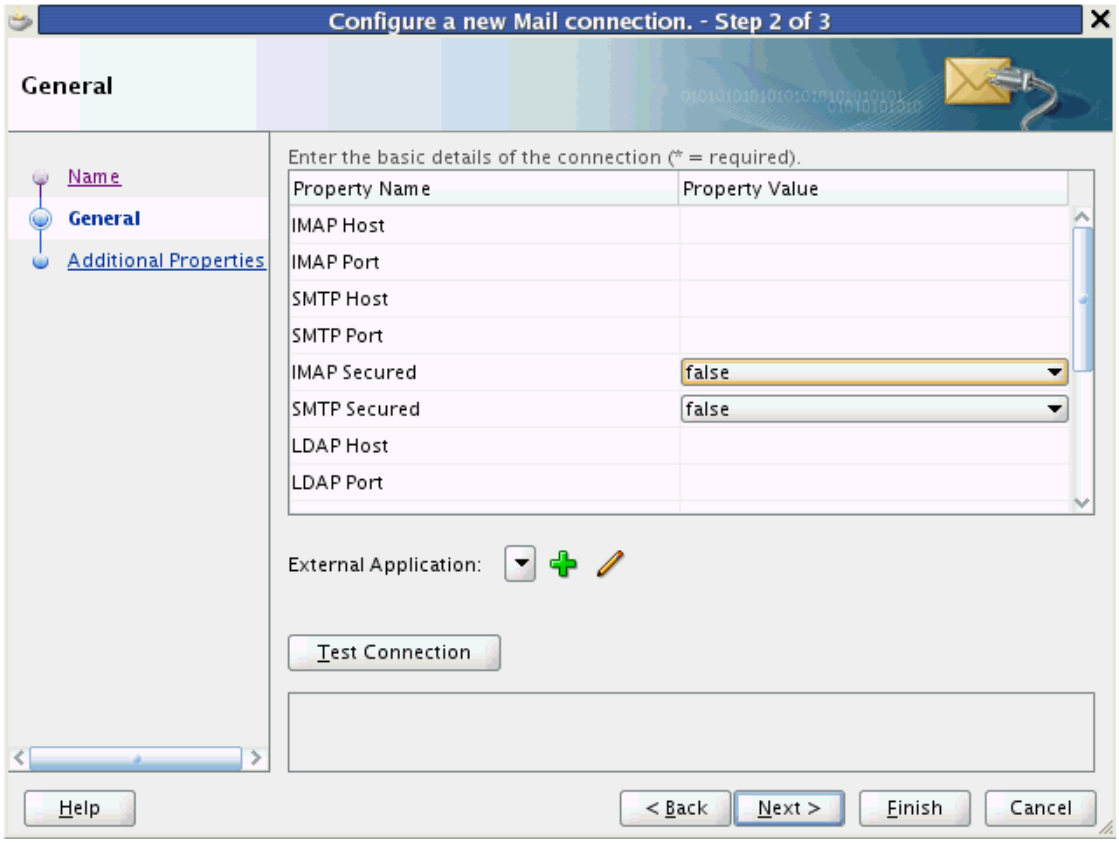
1. In Oracle JDeveloper, open the application in which to consume the Mail service.
2. In your application, under Application Resources, right-click **Connections**, then select **Mail** from the list.
3. Select to create the Mail service connection in **Application Resources**.

   A connection in Application Resources is available only for that application; while a connection in IDE Connections is available for all applications you create. If you

plan to use the connection in other applications, then select IDE Connections to avoid having to re-create it.

4. In the **Connection Name** field, enter a unique name for the connection.
5. When configuring a single mail account, select the **Set as default connection** checkbox to use this as the active connection (Figure 36–5).

Figure 36–5 Configure a New Mail Connection, Step 1



When configuring multiple mail accounts, you are not necessarily required to select this as the default connection. Keep in mind, however, that the service requires that one connection be marked as the default connection.

Note: After you create a connection as the default connection, you cannot edit it so that it is *not* the default. To use a different default connection, you must create a new connection and mark that as the default connection.

---

6. On the **General** page, enter values for the parameters (Figure 36–6).

Figure 36–6 Configure a New Mail Connection, Step 2

- `IMAP Host`: The location of your IMAP server
- `IMAP Port`: The IMAP server port number (default is -1)
- `SMTP Host`: The location of your SMTP server
- `SMTP Port`: The SMTP server port number (default is -1)
- `IMAP Secured`: Indicates (true/false) a secure SSL connection (default is false)
- `SMTP Secured`: Indicates (true/false) a secure SSL connection (default is false)
- `LDAP Host` and `LDAP Port`: These, and all other LDAP values, are required only if Microsoft Exchange is the mail server. For the Mail service to create distribution lists reliably, the WebCenter Portal: Spaces application should use the same Active Directory server as Microsoft Exchange.
- `Connection Timeout`: The connection timeout (in seconds).

7. Click **Test Connection** to check that the host and port are available.
8. You must select an existing external application or create a new external application to proceed:
   a. For **External Application**, click the **+** icon to open the Register External Application wizard

      The application maps the mail server user to the application user so that end users are not required to enter their user names and passwords each time.

For more information on external applications, see Section 69.13, "Working with External Applications."

Note: External application credential provisioning is built into the mail connection. You do not need to drop the **External Application - Change Password** task flow on a page.

---

b. On the Name page:

For **Application Name**, enter a unique name to identify the application. This name must be unique not only within the Framework application, but also among other connections. Note that you cannot edit this field afterward.

For **Display Name**, enter a name for the application that end users see in the credential provisioning screens.

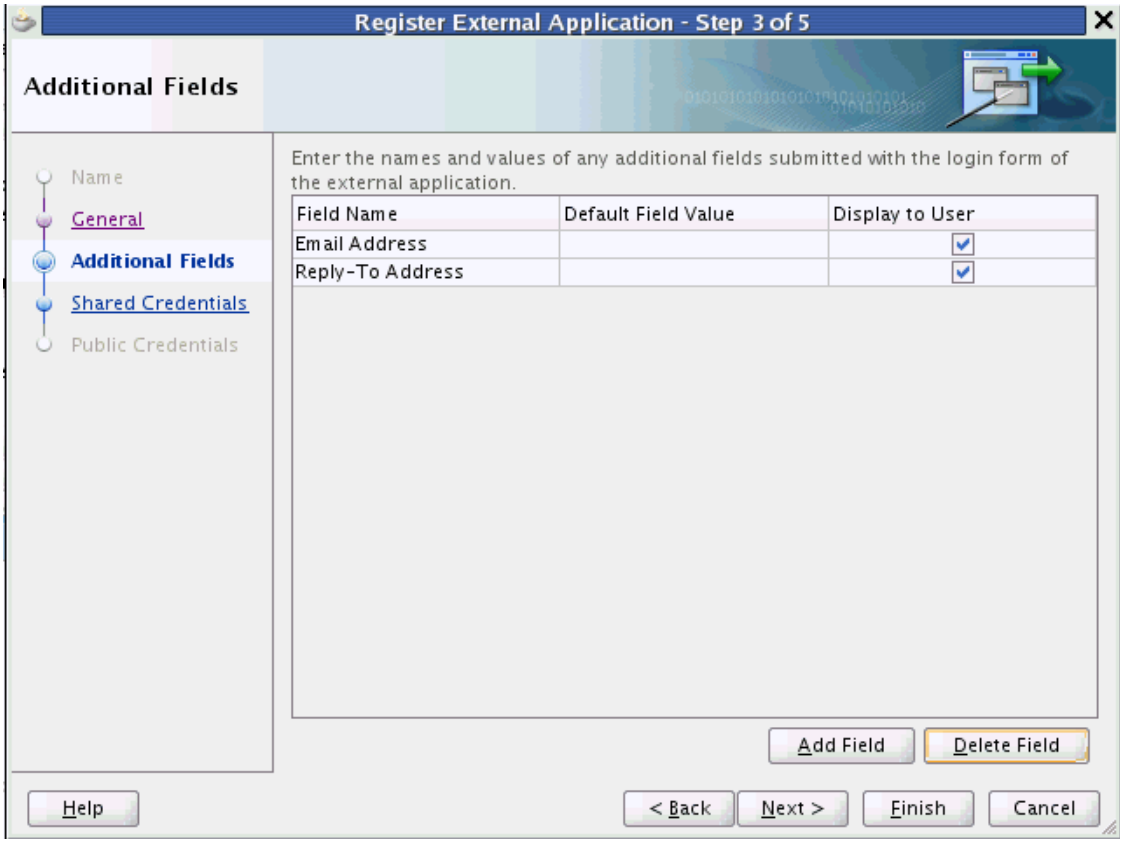
c. Click **Next**.

d. On the General page, you can *optionally* enter values if you want the external application for the Mail service to participate in Click Through Login.

For **Login URL**, enter the URL to which the HTML login page is submitted. View the HTML source of the application's login form to retrieve this URL.

For **User Name/ID Field Name**, enter the label that the application uses for the user name field, for example, User Name.

For **Password Field Name** field, enter the label that the application uses for the password field, for example Password.



From the **Authentication Method** list, select **POST**. This submits login credentials within the body of a form. The external application for the Mail service requires this authentication method.

e. Click **Next**.

f. On the Additional Fields page, click **Add Field**, and add an extra field with the name `Email Address`. This field captures the user's mail address, so that when the user sends mail, the sender address is this mail address. Select the **Display to User** checkbox.

Additionally, to specify that replies to the user's mail should go to different mail address than the `Email Address` field, click **Add Field** again, and add an extra field with the name `Reply-To Address`. Select the **Display to User** checkbox, as shown in Figure 36–7.

Figure 36–7 Email Address and Reply-To Additional Fields

Note: The external application for the Mail service requires the `Email Address` field, and it must be shown to users. Fields for `Display Name` and `Reply-To Address` also are leveraged when sending mail.

---

g. The External Application service allows different types of credentials to be associated with a connection.

When shared credentials are specified, every *authenticated* user uses the same credentials to access the external application; that is, the user name and password you define here.

With public credentials, without authenticating your Framework application, you can view mail from a certain mail ID for all *unauthenticated* (public) users. Public credentials are used whenever an application is not secured or the user has not yet logged in.

Note: Public credentials are required to send mail from a self-registration page.

With private credentials, each user must authenticate to an *individual* mail ID. That is, each application user must specify his own credentials.

h. Click **Finish** to have the external application use private credentials, or click **Next** to set up shared or public credentials.

i. *For Shared Credentials Only*: On the Shared Credentials page, ensure that **Specify Shared Credentials** is selected and then enter the shared user credentials and mail ID.

j. *For Public Credentials Only*: On the Public Credentials page, ensure that **Specify Public Credentials** is selected and then enter the user credentials and mail ID for public use.

k. Click **Finish** to register the external application.

9. Back on the Mail connection wizard, ensure that this newly-created external application connection for mail is selected.

10. Optionally, you can add LDAP parameter values for the Active Directory server to manage (WebCenter Portal: Spaces) space distribution lists.

    For detailed parameter information, see Table 36–2.

> **Note:** For WebCenter Portal: Spaces and the Mail service to share an identity management system for setting up space mailing lists, you must use Active Directory. For information about installing and configuring mail servers as the WebCenter Portal administrator, see *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*.

Table 36–2 LDAP Directory Server Configuration Parameters

Field	Description
LDAP Host	Enter the host name of the computer where the LDAP directory server is running.
LDAP Port	Enter the port on which the LDAP directory server listens.
LDAP Base DN	Enter the base distinguished name for the LDAP schema. For example, CN=Users,DC=oracle,DC=com.
LDAP Domain	Enter the domain to be appended to distribution list names. In WebCenter Portal: Spaces, for example, if the domain value is set to `oracle.com`, then the Finance Project space maintains a distribution list named `FinanceProject@oracle.com`.
LDAP Administrator User Name	Enter the user name of the LDAP directory server administrator. A valid user with privileges to make entries into the LDAP schema.
LDAP Administrator Password	Enter the password for the LDAP directory server administrator. The password is stored in a secured store.
LDAP Default User	Enter a comma-delimited list of user names to whom you want to grant moderator capabilities. These users become members of every space distribution list that is created. The users specified must exist in the base LDAP schema (specified in the `LDAP Base DN` field).
`ldap.secured`	Indicate whether a secured connection (SSL) is required between the Framework application and the LDAP directory server. If LDAP is configured to run in secure mode, then add this property (set to true/false) to use LDAP while creating distribution lists.

11. Click **Finish**.

You can see the new mail connection under **Application Resources - Connections**.

36.2.3 Adding the Mail Service at Design Time

This section explains a basic incorporation of the Mail service. It includes the following subsections:

- Section 36.2.3.1, "Mail Service Task Flows"
- Section 36.2.3.2, "How to Add the Mail Service to your Application"

36.2.3.1 Mail Service Task Flows

The Mail service includes one task flow: Mail. This task flow displays a mail inbox.

36.2.3.2 How to Add the Mail Service to your Application

To add the Mail service to your application:

1. Follow the steps described in Chapter 3, "Preparing Your Development Environment" to create a customizable page in your application.
2. Ensure that you have configured your application to connect to the mail server.
3. If you configured your external application for private or shared credentials, then the Framework application must be made secure using ADF security. ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."
4. Open the page on which to add the service.
5. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
6. Drag and drop the **Mail** task flow on to the page.
7. In the Create list, select **Region** to add the task flow to your page.
8. The resulting Edit Task Flow Binding dialog displays the optional `tabularView` parameter. If this parameter is set to `true`, then mail messages appear in a table, like an Inbox on any mail client. If this parameter is set to `false`, then mail messages render in a list view.

   Note: If you created a connection in IDE and not in the application, then the connection must be added to the application. For example, in the Resource Palette under IDE Connections, right-click the connection and select **Add to Application**.

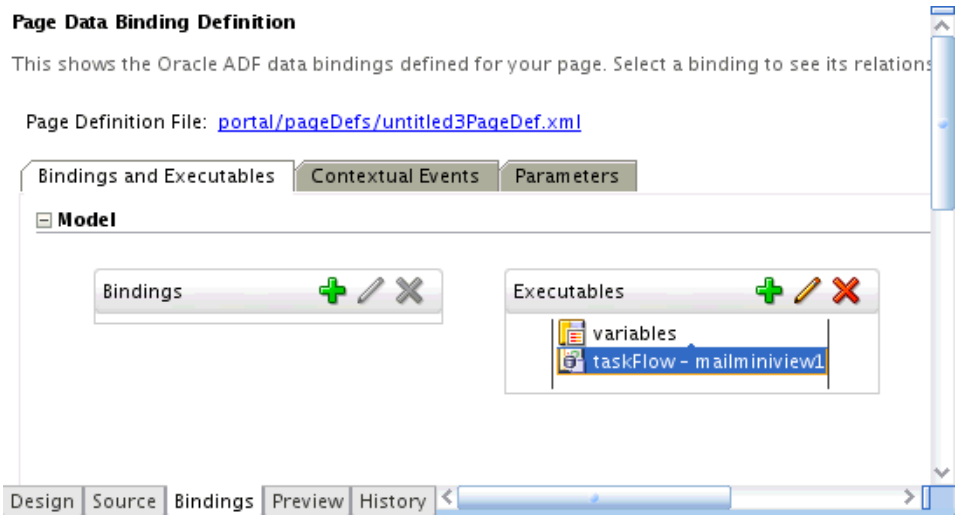
9. Save your page and run it to the browser.
10. When you run the page with the Mail task flow for the first time, you are prompted to enter external application mail credentials from within the Mail task flow.

    Enter the credentials, then click **Submit**.

Notes:

- All instances of the Mail task flow in an application run against the same mail server, and it serves no purpose to add multiple Mail task flow instances. This is true for all service task flows that require connections to back-end servers, such as task flows from the Discussions or Announcements services.
- After an application has been accessed with saved credentials, those credentials are persisted even after redeployment. To ignore saved credentials from previous deployments, edit `appUID` in `adf-config.xml` before redeploying the application. Edit the following value in bold to specify a modified value; for example, add 1 to the last value to update it as `WCApp1-1235`).

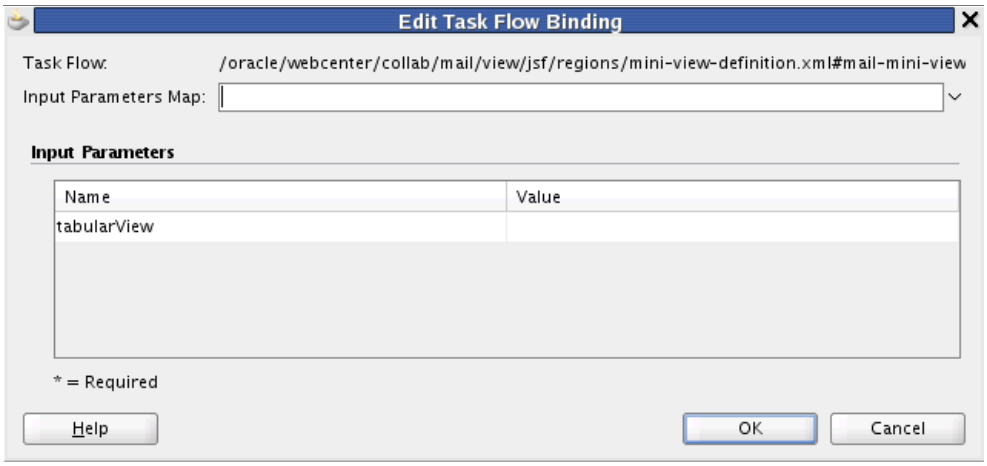
```
 <adf:adf-properties-child
xmlns="http://xmlns.oracle.com/adf/config/properties">
     <adf-property name="adfAppUID" value="WCApp1-1234"/>
 </adf:adf-properties-child>
```



36.2.3.3 How to Modify the Mail Service Task Flow Parameters

The Mail service task flow has an optional task flow binding parameter.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:



1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 36–8 shows an example of a Search task flow in the Executables section.

Figure 36–8 Page Data Binding Definition

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 36–9, revise the binding parameter values as required.

Figure 36–9 Edit Task Flow Binding Dialog for Mail Task Flow

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

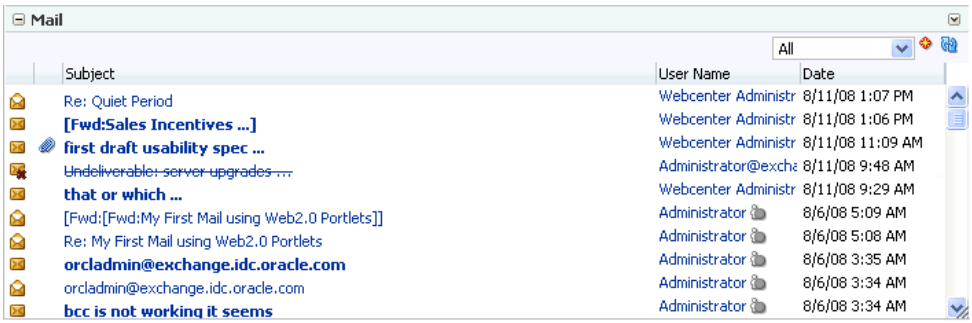


Table 36–3 describes the properties that are unique to the Mail service task flow.

Table 36–3 Mail Service Task Flow Parameters

Property	Description	Task Flow
`tabularView`	Using the EL value type, enter a value of true to display the information associated with a mail message, such as its subject, sender, and, date sent, in a tabular format. If this parameter is set to false, then mail messages render in a list view.	Mail

Figure 36–10 depicts the Mail task flow where the region parameter `tabularView` is set to true.

Figure 36–10 A Mail Task Flow where the Region Parameter Tabular Is Set to True

36.2.4 Setting Security for the Mail Service

The Mail service requires security to fetch mail for each logged-in user. ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."

The external application credentials for the user name used to log in to the application are fetched and used to log in to the mail server. The recommended approach is to have the mail server and the Framework application point to the same identity store.

> **Note:** Even if the Framework application and the mail server share the same identity store, the Mail service does not support identity propagation. Single sign-on functionality is enabled through the external application mechanism.

The Mail service works in a non-secured Framework application if, and only if, the external application connection is configured with public credentials. If you do not apply security, and if mail requires a login to access the content, then users are not able to authenticate and do not see any content at runtime.

For information about using external applications, see Section 69.13, "Working with External Applications."

36.3 Advanced Information for the Mail Service

This section describes optional features available with the Mail service. It includes the following subsections:

- Section 36.3.1, "Invoking the Mail Compose Page"
- Section 36.3.2, "Configuring the Number of Mails Displayed"
- Section 36.3.3, "Troubleshooting the Mail Service"

36.3.1 Invoking the Mail Compose Page

The **Mail Compose** page enables users to determine how they want to compose individual messages within the application.

Invoke the **Mail Compose** page directly with a navigation rule that directs the user to the full page (Example 36–1).

Example 36–1 Invoking the Mail Compose Page

```
/oracle/workplace/collab/mail/view/jsf/pages/ComposeView.jspx
```

When you cannot provision mail accounts for all users within a space but want to provide the ability for space members to send mails to other members, then specify a shared (public) mail connection with the `useConnection` parameter. (Specify the connection name as a region input parameter to the mail-service compose view.) The end user Mail Preferences does not display mail connections with shared credentials.

You can pass optional parameters to seed the compose message. For example, you can pass parameters to pre-populate fields like To, Cc, Bcc, From, Subject, and Content. Set parameters only for items you want to pre-populate. If you require an empty `ComposeView.jspx`, then no `setActionListener` is necessary. You must set all parameters on `pageFlowScope`.

Use the `scope` parameter to set the scope within which the compose view should be launched.

Use the `sendMailToGSMembers` parameter to select the option to send mail to all space members.

Example 36–2 shows some parameters for the Mail Compose page (`ComposeView.jspx`):

Example 36–2 Parameters of the Mail Compose Page

```
<af:commandLink text="Compose Mail" action="sendMail">

    <af:setActionListener from="#{'john.doe@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.toList']}"/>
    <af:setActionListener from="#{'Mail......'}"
to="#{pageFlowScope['collab.mail.compose.subject']}"/>
    <af:setActionListener from="#{'Mail Service'}"
to="#{pageFlowScope['collab.mail.compose.content']}"/>
    <af:setActionListener from="#{'ruby@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.ccList']}" />
    <af:setActionListener from="#{'ruby@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.bccList']}" />
    <af:setActionListener from="#{'monty@oracle.com'}"
to="#{pageFlowScope['collab.mail.compose.from']}" />
    <af:setActionListener from="#{'text/html'}"
to="#{pageFlowScope['collab.mail.compose.contentType']}" />
    <af:setActionListener from="Shared-mail-connection-name"
to="${pageFlowScope['collab.mail.compose.useConnectionName']}" />

</af:commandLink>
```

Example 36–3 shows how to hide the recipients fields (like **To**, **Cc** and **Bcc**) by setting the following action listener in `ComposeView.jspx`:

Example 36–3 Hiding Recipient Fields in the Mail Compose Page

```
    <af:setActionListener from="#{'false'}"
to="#{pageFlowScope['collab.mail.message.showrecipients']}" />
```

36.3.2 Configuring the Number of Mails Displayed

By default, the Mail service displays the 50 most recent mail messages from your Inbox folder. Providing that your mail server supports the increase in memory cache that fetching additional mail requires, the administrator can change this to a higher number in the `adf-config.xml` file.

Add the `mail.messages.fetch.size` property as shown in Example 36–4:

Example 36–4 Increasing the Number of Mails Displayed

```
<adf-collaboration-config xmlns="http://xmlns.oracle.com/webcenter/collab/config">

<service-config
serviceId="oracle.webcenter.collab.mail">
<property name="mail.messages.fetch.size" value="500"/>
</service-config>

</adf-collaboration-config>
```

Alternatively, your Fusion Middleware administrator can increase this value with the WLST command `setMailServiceProperty`. For more information, see *Oracle Fusion Middleware WebLogic Scripting Tool Command Reference*.

This change applies to all users; that is, following Example 36–4, all users see 500 recent mails in their Inbox in the Framework application. Increasing the number of

messages shown correspondingly increases the cache size on the Framework application. Take care to set this to a reasonable size.

36.3.3 Troubleshooting the Mail Service

This section describes common problems and solutions for the Mail service.

Problem

Users are not able to retrieve their mail messages or send mail messages from within the Framework application.

Solution

Ensure the following:

- Ensure that a Mail service connection exists in your application.
- Ensure the required Mail service connection is marked as the default connection.
- Ensure the mail server configured in the connection is up and running. You can try connecting from any other mail client to ensure that the connection details are correct.

Problem

The Mail service within your Framework application requires users to log in, but users are not able to authenticate and do not see any content at runtime. When users access the Mail service, it throws the ExtApp Authorization Exception.

Solution

The Mail service works in a non-secured Framework application if, and only if, the Mail connection is configured to use an external application connection with public credentials. If your application is running in non-secured mode, then ensure that you have configured public credentials for your external application.

If you want your Framework application to run in secure mode, then you must configure ADF security for your application.

Problem

When users receive mail in Framework applications, message content is shown as an attachment (named `content.html`) rather than within the message body. This can occur if the mail server is running Microsoft Exchange Server 2007 and the "*Update Rollup 3 for Microsoft Exchange Server 2007*" is not yet installed.

Solution

Mail server administrators must download and install "*Update Rollup 3 for Microsoft Exchange Server 2007*" which fixes this issue. For more information, see `http://support.microsoft.com/kb/930468`.

37

Integrating the Polls Service

This chapter explains how to integrate the Polls service into a WebCenter Portal: Framework application at design time. For more information about using polls, see "Working with the Polls Service" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

This chapter includes the following sections:

- Section 37.1, "Introduction to Polls"
- Section 37.2, "Basic Configuration for the Polls Service"
- Section 37.3, "Advanced Information for the Polls Service"

37.1 Introduction to Polls

The Polls service lets you create, edit, and take online polls on your application pages. Polls let you survey your audience (such as their opinions and their experience level), check whether they can recall important information, and gather feedback on the efficacy of presentations.

This section includes the following subsections:

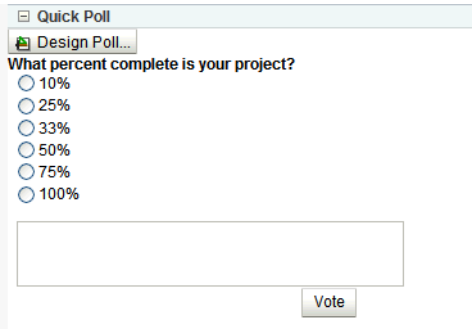
- Section 37.1.1, "Understanding the Polls Service"
- Section 37.1.2, "Requirements for Polls"
- Section 37.1.3, "What Happens at Runtime"

37.1.1 Understanding the Polls Service

In addition to taking available polls, the Polls service lets you do the following:

- Quickly create and publish polls.
- Customize an existing poll; for example, add or change questions, and publish (open) and close the poll.
- Take a specific or the most recently-published poll
- View poll results
- See the status of all polls and available actions for each poll, such as edit, delete, publish, analyze, and clear results.

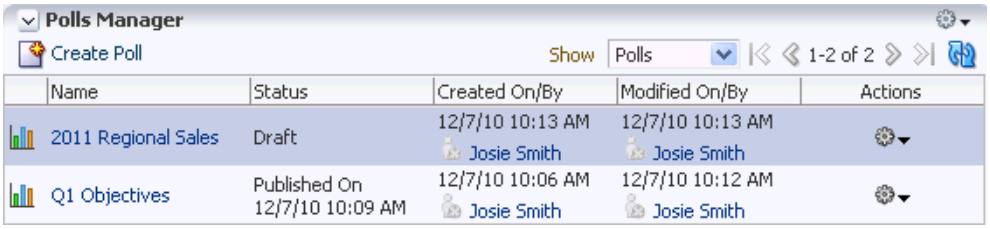
The Polls service is integrated with the Instant Messaging and Presence service in the Polls Manager.



37.1.2 Requirements for Polls

In a Framework application, the Polls service requires a connection to WebCenter Portal database schema. For details about setting up a database connection, see Section 7.2.2, "Setting Up a Database Connection."

37.1.3 What Happens at Runtime



At runtime, users can quickly create polls with just a name and a question. Figure 37–1 shows a sample quick poll.

Figure 37–1 Quick Poll

WebCenter Portal application administrators can access the Polls Manager, which lets you create polls with multiple questions or with templates. The Actions dropdown list lets continue designing the poll, publish the polls, analyze results, clear results, and delete the poll (Figure 37–2).

Figure 37–2 Polls Manager

Polls created through the Polls Manager must be published and open to be taken. Users cannot take unpublished or closed polls.

For more information about the service at runtime, see *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

37.2 Basic Configuration for the Polls Service

This section describes required steps for adding this service to your application. It includes the following subsections:

- Section 37.2.1, "Setting up Connections for the Polls Service"
- Section 37.2.2, "Adding the Polls Service at Design Time"
- Section 37.2.3, "Setting Security for Polls"

37.2.1 Setting up Connections for the Polls Service

The Polls service requires a connection to the database where the WebCenter Portal schema is installed. For details about setting up a database connection, see Section 7.2.2, "Setting Up a Database Connection."

37.2.2 Adding the Polls Service at Design Time

This section explains a basic incorporation of the Polls service. It includes the following sections:

- Section 37.2.2.1, "Polls Task Flows"
- Section 37.2.2.2, "How to Add the Quick Poll Task Flow to Your Page"
- Section 37.2.2.3, "How to Modify the Polls Service Task Flow Parameters"

37.2.2.1 Polls Task Flows

The Polls service includes the task flows described in Table 37–1.

Table 37–1 Polls Task Flows

Task Flow	Description
Poll - Quick Poll	This task flow displays a view that enables users to create one-question polls to be published immediately. Each quick poll needs its own Quick Poll task flow on the page.
Polls - Polls Manager	This task flow allows users to perform administrative operations on the polls. Any user who has access to this task flow can perform the administrative operations, such as edit or delete the poll.
Polls - Take Polls	This task flow displays the most recently-published available poll, unless it is set to a specific poll in the `pollId` parameter.
Polls - View Poll Results	This task flow displays the results of a poll as a graph for the supplied `pollId`. This task flow works only if `pollId` is supplied.

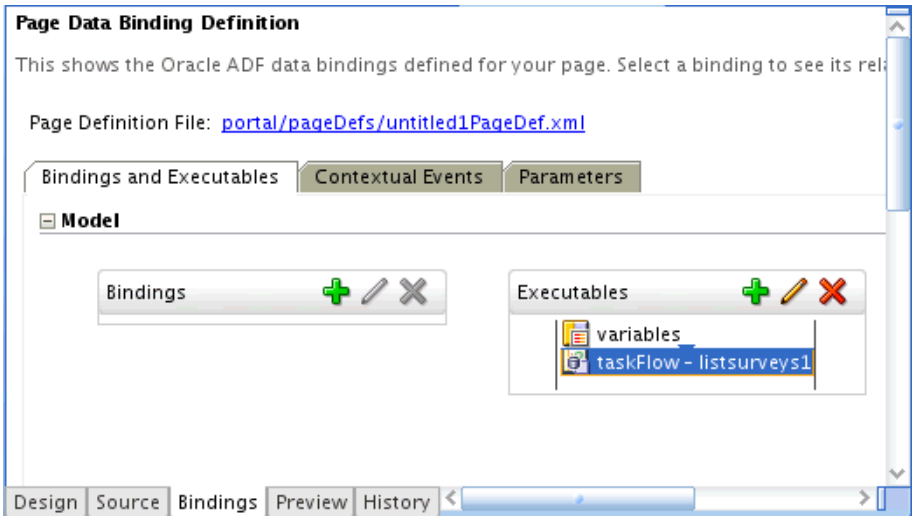
37.2.2.2 How to Add the Quick Poll Task Flow to Your Page

The Quick Poll task flow display polls and provides tools to create, edit, and delete polls. It also provides controls for determining when a poll when it expires. This task flow lets you present polls to end users where manage controls are not needed.

To add the Quick Poll task flow to your WebCenter Portal: Framework application:

1. Open the page on which you want to add the service.
2. In the Resource Palette, expand **My Catalogs**, **WebCenter Portal - Services Catalog**, and **Task Flows**.
3. Drag **Polls - Quick Poll** from the Resource Palette and drop it onto the page inside of the `af:form` `begin` and `end` tags.
4. When prompted, select **Region** as the way to create the task flow (and confirm with **Add Library**). This operation may take a moment to complete.
5. Click **OK**.
6. Save and run your page.

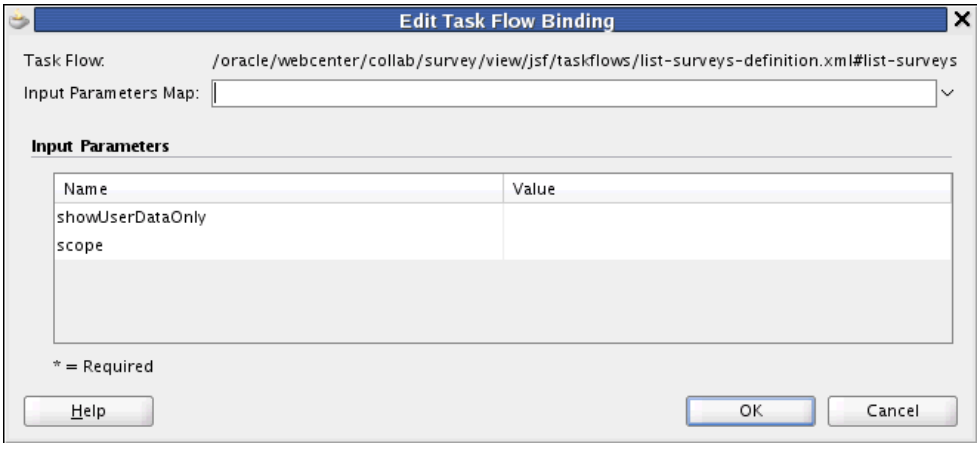
37.2.2.3 How to Modify the Polls Service Task Flow Parameters



The Polls service task flows have optional task flow binding parameters.

In addition to providing required values for successful task flow rendering, you can use task flow parameters to customize the appearance and behavior of a task flow instance. For example, you can use parameter values to set which poll to display.

You can adjust the parameter values when you drop the task flows onto a page or after you have placed a task flow on a page:



1. Navigate to the Edit Task Flow Binding dialog by clicking the **Bindings** tab at the bottom of the page (next to the **Source** tab).
2. Under **Executables**, you'll see the task flow you added. Figure 37–4 shows an example of a Search task flow in the Executables section.

Figure 37–3 Page Data Binding Definition

3. Select the task flow, and next to the Executables heading, click the **Edit selected element** (pencil) icon.
4. In the Edit Task Flow Binding dialog Figure 37–4, revise the binding parameter values as required.

Figure 37–4 Edit Task Flow Binding Dialog for Polls Manager Task Flow

5. When you are finished, click **OK.**
6. Save and run your page to see the results.

Table 37–2 describes the properties that are unique to the Polls task flows.

Table 37–2 Polls Service Task Flow Parameters

Property	Description
`scope`	The space name from which polls are to be fetched. If this is supplied, then polls of that particular space are shown. On the Home space, when this parameter is not supplied, it fetches polls from all spaces. This parameter appears in the properties for the Polls Manager task flow.
`showUserDataOnly`	This parameter determines whether to display all polls or only those polls created by the user. The default (No) is to show all polls. Set to Yes to display only those polls created by the user. If the `scope` parameter is specified, then this parameter works the same but within only that scope. This parameter appears in the properties for the Polls Manager task flow.
`pollId`	The poll to display. This parameter appears in the properties for the following task flows. ■ Take Polls ■ View Poll Results
`showInEditMode`	This parameter determines whether users can edit a quick poll. When a quick poll is in Edit mode, a Design Poll box for editing the poll appears. When a quick poll is not a Edit mode, the Design Poll box for editing is not visible. This parameter appears in the properties for the Quick Poll task flow.

37.2.3 Setting Security for Polls

The Polls service does not require security. Administrators control access to Polls task flows through the Resource Catalog, where they define the users and groups privileged to see polls. Security is driven by the page security on which the task flow exists or by the task flow permissions on that page. Any user who can see the task flow can edit the poll.

ADF security is configured by default if you created your application using WebCenter Portal's Framework application template. For information about configuring ADF security, see Section 69.3, "Configuring ADF Security."

37.3 Advanced Information for the Polls Service

This section describes optional features available with this service. It includes the following subsections:

- Section 37.3.1, "How to Add the Polls Manager Task Flow"
- Section 37.3.2, "How to Add the Take Polls Task Flow"
- Section 37.3.3, "How to Add the View Poll Results Task Flow"
- Section 37.3.4, "Using the Polls Service Data Controls"

37.3.1 How to Add the Polls Manager Task Flow

The Polls Manager task flow provides a complete view of polls and perform actions on them.

To add this to your Framework application, follow the same instructions that you did for the Polls Manager task flow in Section 37.2.2, "Adding the Polls Service at Design Time," but drag and drop Polls Manager onto the page.

37.3.2 How to Add the Take Polls Task Flow

This task flow displays published polls for users to take. It displays the most recently-published available poll, unless it is set to display a specific poll with the `pollId` parameter. After a user submits a response for that poll, it displays the next most recently-published poll.

To add this to your Framework application, follow the same instructions that you did for the Polls Manager task flow in Section 37.2.2, "Adding the Polls Service at Design Time," but drag and drop Polls - Take Polls onto the page.

37.3.3 How to Add the View Poll Results Task Flow

The View Poll Results task flow displays the results of a poll as a graph for the poll supplied with the required `pollId` parameter.

To add this task flow to your Framework application, follow the same instructions that you did for the Polls Manager task flow in Section 37.2.2, "Adding the Polls Service at Design Time," but drag and drop Polls - View Poll Results onto the page.

37.3.4 Using the Polls Service Data Controls

Use the Polls service data controls to build a customized user interface for polls with a Framework application or a custom task flow.

The Polls service includes two data controls to customize the user interface:

- Take Poll Data Control
- Polls Manager Data Control

37.3.4.1 Take Poll Data Control

The Take Poll data control contains the following methods:

- createResponse
- createResponseForLatestAvailablePoll
- getPublishedPolls
- getResults
- saveResponse

37.3.4.1.1 createResponse This method lets users respond to a particular poll. Table 37–3 describes the required parameters for this method.

Table 37–3 createResponse Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

37.3.4.1.2 createResponseForLatestAvailablePoll This method lets users respond to the most recently-published poll. It has no parameters.

37.3.4.1.3 getPublishedPolls Table 37–4 describes the required parameters for this method.

Table 37–4 getPublishedPolls Input Parameters

Parameter	Type	Description
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

37.3.4.1.4 getResults This method gets the poll results for a particular poll. Table 37–5 describes the required parameters for this method.

Table 37–5 getResults Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

37.3.4.1.5 saveResponse Table 37–6 describes the required parameters for this method.

Table 37–6 saveResponse Input Parameters

Parameter	Type	Description
`response`	Response	The response object acquired from the data control calls to `createResponse` or `createResponseForLatestAvailablePoll`.

37.3.4.2 Polls Manager Data Control

The Polls Manager data control contains the following methods:

- addQuestion
- addQuestion
- closePoll
- closePollAfterDate
- closePollAfterDays
- closePollAfterResponses
- createPoll
- deletePoll
- editPoll
- editPoll
- findPoll
- getPolls
- getPollsByUser
- getPollsByUserCount
- publishPoll
- publishPollOnDate

37.3.4.2.1 addQuestion This method creates polls with multiple choice questions. Table 37–7 describes the required parameters for this method.

Table 37–7 addQuestion Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`question`	String	The text of the question; for example, What is your favorite color?
`rowOptions`	String	Corresponding list of options for the question. This should be line-separated list of options.
`allowMultipleSelection`	Boolean	True to allow multiple options to be selected; false to allow only a single option selection.

37.3.4.2.2 addQuestion This method creates complex polls with matrix-type questions. Table 37–8 describes the required parameters for this method.

Table 37–8 addQuestion Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`questionType`	Question Type	Question type, either: ■ Matrix of choices (only one answer per row) ■ Matrix of choices (multiple answers per row)
`question`	String	The text of the question; for example, What is your favorite color?
`rowOptions`	String	Corresponding list of options for the question. This should be line-separated list of options.
`columnOptions`	String	Column options.
`isOptional`	Boolean	True if the question is optional (that is, users can ignore answering it); false if question is mandatory.
`commentLabel`	String	Enables a comment field for users to provide feedback or enter personalized text with their answers.
`commentFieldHeight`	Integer	Size for the comment field. To capture feedback, set this to 3; otherwise, set it to 1. This parameter value depends on the type of answer expected in the comment field.

37.3.4.2.3 closePoll This method closes a particular poll. Table 37–9 describes the required parameters for this method.

Table 37–9 closePoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

37.3.4.2.4 closePollAfterDate This method closes a poll on a specific date. Table 37–10 describes the required parameters for this method.

Table 37–10 closePollAfterDate Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`date`	Date	Date at which the poll should close.

37.3.4.2.5 closePollAfterDays This poll closes a poll at a set number of days after the poll is published. Table 37–11 describes the required parameters for this method.

Table 37–11 closePollAfterDays Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`days`	Integer	Number of days, after the publish date, at which the poll should close.

37.3.4.2.6 closePollAfterResponses This method closes as poll after a set number of responses have been collected. Table 37–12 describes the required parameters for this method.

Table 37–12 closePollAfterResponses Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`responses`	Integer	Number of responses at which the poll should close.

37.3.4.2.7 createPoll This method creates a quick poll. Table 37–13 describes the required parameters for this method.

Table 37–13 createPoll Input Parameters

Parameter	Type	Description
`name`	String	Name of the poll.
`description`	String	Description of the poll.

37.3.4.2.8 deletePoll This method deletes a particular poll. Table 37–14 describes the required parameters for this method.

Table 37–14 deletePoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

37.3.4.2.9 editPoll Table 37–15 describes the required parameters for this method.

Table 37–15 editPoll Input Parameters

Parameter	Type	Description
`pollInstance`	Poll	If a poll instance is directly edited, then that instance can be supplied for editing.

37.3.4.2.10 editPoll This method edits a particular poll. Table 37–16 describes the required parameters for this method.

Table 37–16 editPoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`name`	String	Name of the poll.
`description`	String	Description of the poll.

37.3.4.2.11 findPoll This method finds a particular poll. Table 37–17 describes the required parameters for this method.

Table 37–17 findPoll Input Parameters

Parameter	Type	Description
`id`	String	Poll instance ID

37.3.4.2.12 getPolls This method displays all polls, as defined in its parameters. Table 37–18 describes the required parameters for this method.

Table 37–18 getPolls Input Parameters

Parameter	Type	Description
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

37.3.4.2.13 getPollsByUser This method displays polls created by a particular user. Table 37–19 describes the required parameters for this method.

Table 37–19 getPollsByUser Input Parameters

Parameter	Type	Description
`createdBy`	String	User name of the person who created the poll.
`startIndex`	Integer	The index of the first matching result that should be included in the result set (0-n ... zero based). This is used for pagination.
`numResults`	Integer	The number or results to display.

37.3.4.2.14 getPollsByUserCount Table 37–20 describes the required parameters for this method.

Table 37–20 getPollsByUserCount Input Parameters

Parameter	Type	Description
`createdBy`	String	User name of the person who created the poll.

37.3.4.2.15 publishPoll This method publishes a particular poll. Table 37–21 describes the required parameters for this method.

Table 37–21 publishPoll Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.

37.3.4.2.16 publishPollOnDate This method publishes a poll on a specific date. Table 37–22 describes the required parameters for this method.

Table 37–22 publishPollOnDate Input Parameters

Parameter	Type	Description
`pollId`	String	The poll to display.
`date`	Date	Date at which the poll should be published.

Part VI

Working with the People Connections Service

This part provides comprehensive information about the People Connections service, including what it delivers and how to use it in aWebCenter portal application.

This part includes the following chapters:

- Chapter 38, "Introducing the People Connections Service"
- Chapter 39, "Basic Configuration for the People Connections Service"
- Chapter 40, "People Connections Task Flow Binding Parameters"
- Chapter 41, "Using People Connections Data Controls and Java APIs"
- Chapter 42, "People Connections Service REST APIs"

38

Introducing the People Connections Service

The People Connections service provides social networking tools for use in enhancing connection and communication within a project team and throughout an enterprise. It does this through a set of features that include:

- **Activity Stream** for viewing user activities generated through application or social networking actions.
- **Connections** for connecting to other application users to share information, comment on performance, exchange messages, and track activity
- **Feedback** for giving *ad hoc* performance feedback to other users
- **Message Board** for posting messages to other users
- **Profile** for entering personal contact information and viewing the contact information of other users
- **Publisher** for publishing status messages and posting files and links

This chapter describes the task flows associated with the People Connections service and provides some troubleshooting tips.

This chapter includes the following sections:

- Section 38.1, "Overview of the People Connections Service"
- Section 38.2, "Troubleshooting the People Connections Service"

38.1 Overview of the People Connections Service

The People Connections service provides social networking tools for creating, interacting with, and tracking the activities of one's connections. Its features enable users to manage their personal profiles, access the profiles of other users, provide *ad hoc* feedback, post messages, track activities, and connect with others.

In a production environment, an enterprise can leverage its back-end identity store as a means of providing People Connections with a population of potential connections. In a development environment, developers can add test-users to the `jazn-data.xml` file.

> **See Also:** For information about connecting to a back-end (LDAP) identity store for the production version of your application, see the chapter, "Managing Security," in the *Oracle Fusion Middleware Administrator's Guide for Oracle WebCenter Portal*. For information about creating test users in `jazn-data.xml`, see Section 24.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File."

This section provides an overview of the People Connections service. It includes the following subsections:

- Section 38.1.1, "People Connections Service Task Flows"
- Section 38.1.2, "People Connections Service Requirements"

38.1.1 People Connections Service Task Flows

The features of the People Connections service fall into five categories. Each category includes a set of task flows that expose People Connections features to your end users. Note that the Publisher task flow does not belong to these categories, but rather, works in concert with the Activity Stream.

This section introduces these categories. It includes the following subsections:

- Section 38.1.1.1, "Activity Stream"
- Section 38.1.1.3, "Feedback"
- Section 38.1.1.4, "Message Board"
- Section 38.1.1.2, "Connections"
- Section 38.1.1.5, "Profile"
- Section 38.1.1.6, "The Publisher Task Flow"

> **See Also:** For information about the People Connections service at runtime, see Part VIII, "Organizing Your Collaborative and Social Networking Environment," in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.
>
> For information about People Connections task flows, see Section 38.1.1, "People Connections Service Task Flows."

38.1.1.1 Activity Stream

The Activity Stream feature tracks the application activities of a user's connections. Table 38–1 lists the types of activities that may be tracked by the Activity Stream.

Table 38–1 Activities Tracked by Activity Stream

Service	Tracked Activities
Announcements	■ Create announcement ■ Edit announcement
Blogs	■ Create blog ■ Update blog
Connections	■ Invitations to connect ■ People are connected
Discussions	■ Create forum ■ Create topic ■ Reply to topic
Documents	■ Create document ■ Edit document ■ Add tag ■ Remove tag

Table 38–1 (Cont.) Activities Tracked by Activity Stream

Service	Tracked Activities
Events	■ Create an event ■ Edit an event
Feedback	■ Feedback left ■ Feedback received
Lists	■ Create a list ■ Add a row to a list ■ Edit a list row
Message Board	■ Message left ■ Message received
Pages	The following activities are tracked when they are performed within the service framework scope (for example, if a user creates pages under `/myapp/mypages/`, the page operations are not tracked): ■ Create page ■ Edit page ■ Delete page ■ Add tag
Profiles	■ Photo updated ■ Profile updated ■ Personal status note updated
Tagging	■ Add tag ■ Remove tag

Activity Stream compares somewhat to the Recent Activities service, which also tracks and reports on application activities (for more information, see Chapter 50, "Integrating the Recent Activities Service"). Both track the application activities of integrated services, though Activity Stream tracks a broader range of services. For example, Recent Activities tracks the Documents (including wikis and blogs), Announcements, Discussions, and Page services. Activity Stream tracks these services as well as People Connections. Recent Activities tracks activities no matter who performs the action. Activity Stream tracks activities performed by a user's connections and includes information about who performed the activity. Recent Activities does not include names.

The basic difference between these two services can be summarized as follows: Recent Activities provides an overview of what is happening in an application. Activity Stream provides an overview of what is happening with a user's connections.

The Publisher task flow works in concert with Activity Stream to provide content in the form of user messages. A message posted through the Publisher task flow is published to the Activity Streams of the user who entered it and that user's connections.

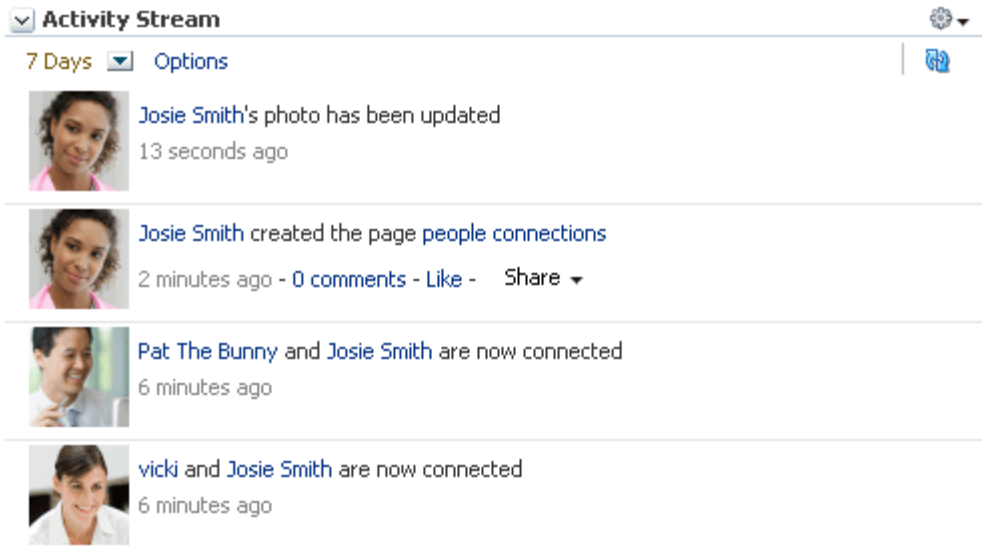
Activity Stream messages may include attachments, such as a file or a link. Depending on a file's mime type, Activity Stream allows for displaying a preview of such attachments. Activity Stream previews files through either a native web format or through UCM slide rendition. The previewer used depends on the mime type of the file to be previewed.

The mime types that use the native web format include:

- `image`
- `htm`
- `text`

The mime types that use UCM slide rendition include:

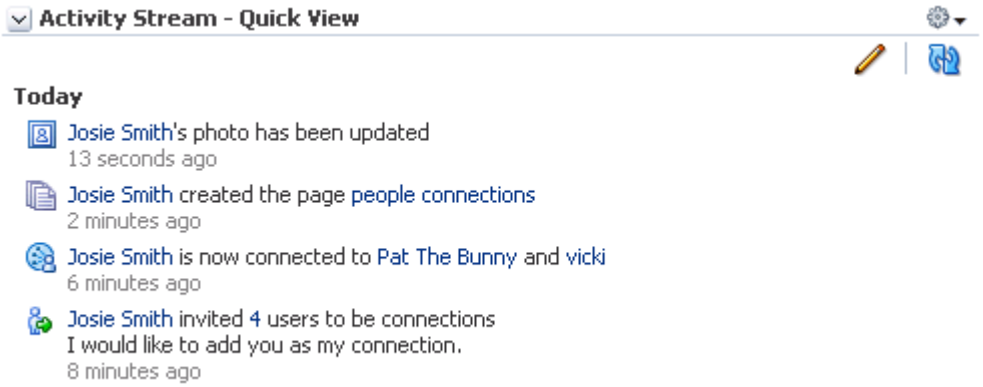
- `pdf`
- `powerpoint`
- `powerpnt`
- `pptx`



> **Note:** PDF file previews are available in Activity Stream when the mime type is `pdf`, `webContextRoot` is specified in the UCM connection, and the WebCenter Portal: Spaces application is accessed through an Oracle HTTP Server.

Note that the mime types shown in these bullet lists are the only mime types that are previewed. Other mime types appear as links. The mime types `docx` and `xlsx` are *not* previewed in Activity Stream. Note also that a parameter associated with an Activity Stream task flow instance can be set to omit file previews (for more information, see Section 40.2, "People Connections Task Flow Binding Parameters").

Two Activity Stream task flows are available through the Resource Palette:



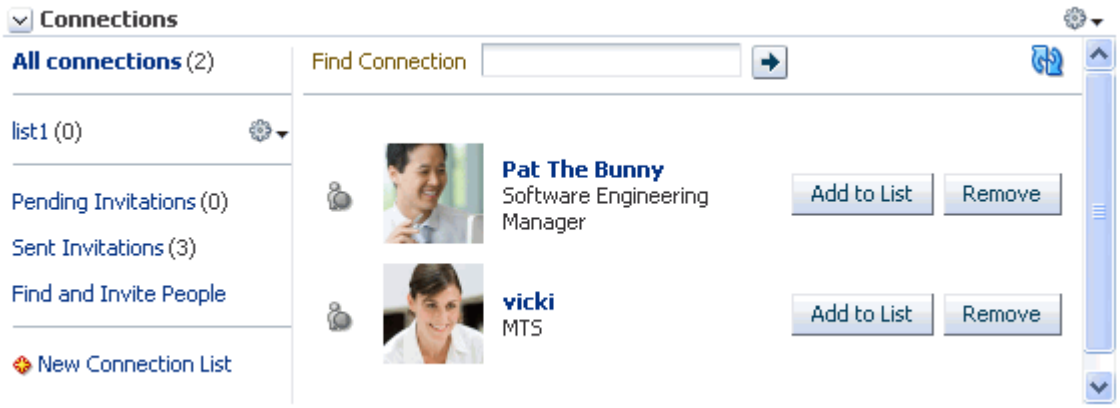
- Activity Stream—Provides users with the main view of the most recent activities of their connections (Figure 38–1).

Figure 38–1 Activity Stream Task Flow

- Activity Stream - Quick View—Provides users with a truncated view of streamed activities, where only the most recent of their connections' activities are shown. Users who want to see all activities can click a **More** link to navigate to the main view (Activity Stream) of the task flow (Figure 38–2).

Figure 38–2 Activity Stream - Quick View Task Flow

See Also: For information about Activity Stream task flows at runtime, see the section, "Working with Activity Stream Task Flows," in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.



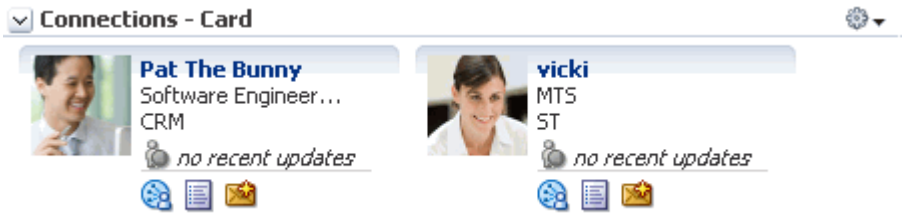
38.1.1.2 Connections

Connections provides users with a means of managing their own connections and viewing the connections of others. Use Connections to collect business friends and contacts into one or more smaller social groups. Use connections lists to manage the display of your connections.

Three Connections task flows are available through the Resource Palette:

- Connections—Provides users with a means of viewing and managing their connections, creating connections lists, and sending and responding to invitations to connect (Figure 38–3).

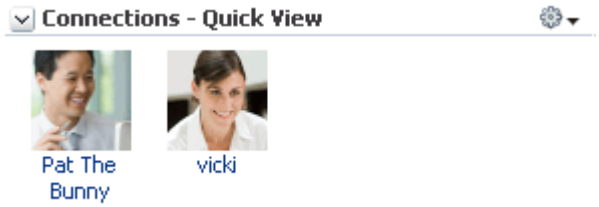
Figure 38–3 Connections Task Flow



- Connections - Card—Provides a choice of the following views:
  - `vcard` displays a connection's photo, job title, and status message.
  - `iconic` displays a connection's photo and user name.
  - `list` displays connections in a list, with each list row showing the profile photo, user name, job title, and an **Add to List** button.

– `tiled` renders the connection's personal Profile photo and shows the user name and job title beside the photo.

Tip: In all views, the name links to a summary view of the user's Profile.



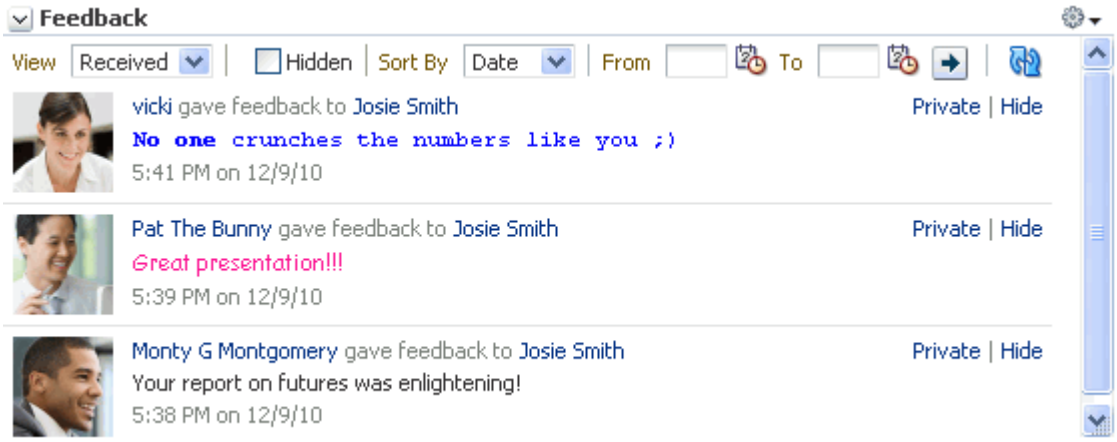
Select one of these views through task flow bindings (for more information, see Chapter 40, "People Connections Task Flow Binding Parameters") (Figure 38–4).

Figure 38–4 Connections - Card Task Flow

- Connections - Quick View—Provides users with a view of their connections' uploaded profile photos and a link to a summary view of their Profiles (Figure 38–5).

Figure 38–5 Connections - Quick View Task Flow

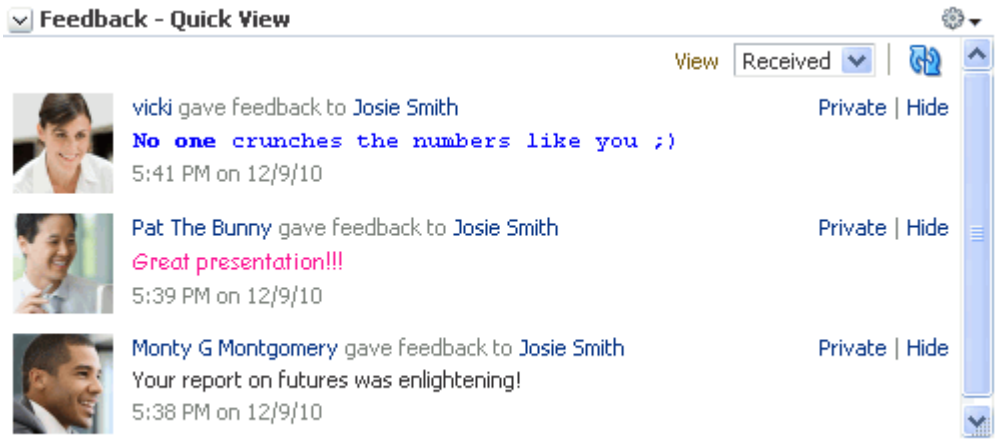
See Also: For information about Connections task flows at runtime, see the section, "Setting Up Your Social Network," in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.



38.1.1.3 Feedback

Feedback provides users with a means of viewing, posting, and managing feedback. By default, users can view feedback in their own Feedback views. Users can view and post feedback in other users' Feedback views.

Two Feedback task flows are available through the Resource Palette:



- Feedback—Provides users with the main view of the Feedback task flow. The main view contains controls for viewing, posting, sorting, and filtering Feedback—both given and received—and for hiding received Feedback (Figure 38–6).

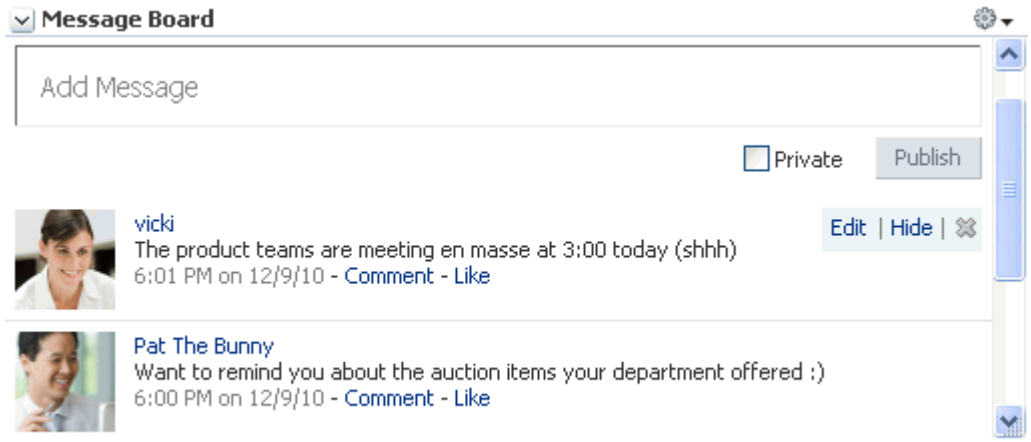
Figure 38–6 Feedback Task Flow

- Feedback - Quick View—Provides users with a truncated view of the Feedback task flow, where only the most recent posts are shown. When there are more posts than can be displayed in the initial view, users can click a **More** link to navigate to the main view of the Feedback task flow. When user `A` accesses user `B`'s view of Feedback - Quick View, user `A` additionally sees an **Add Feedback** option (Figure 38–7).

Figure 38–7 Feedback - Quick View Task Flow

See Also: For information about Feedback task flows at runtime, see the section, "Working with Feedback Task Flows," in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

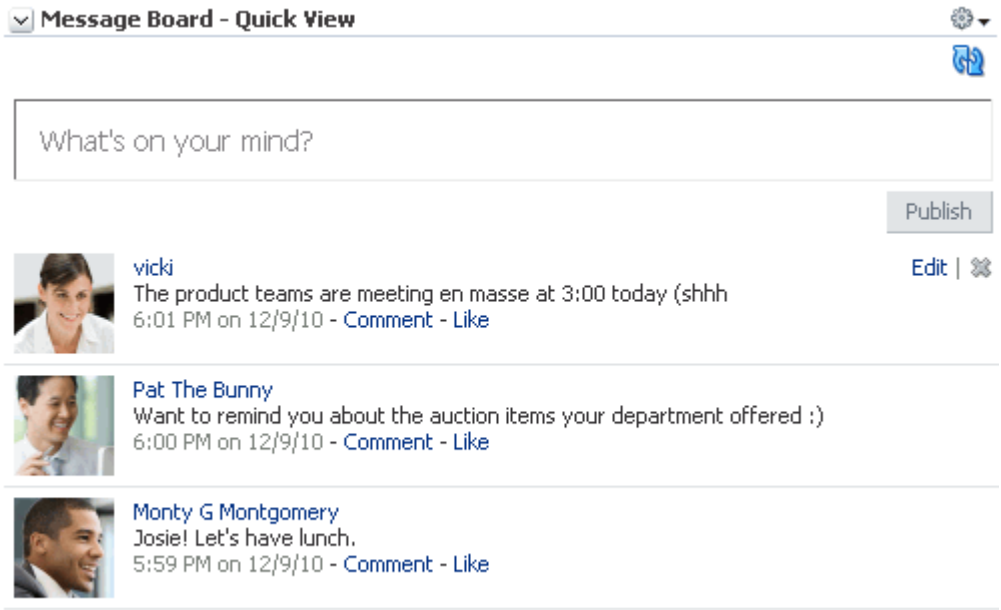
38.1.1.4 Message Board



Message Board provides a means of viewing and posting messages and attachments to Message Boards and Activity Streams.

Two Message Board task flows are available through the Resource Palette:

- Message Board—Message Board provides users with the main view of Message Board messages and a means of adding, viewing, updating, hiding, deleting, and



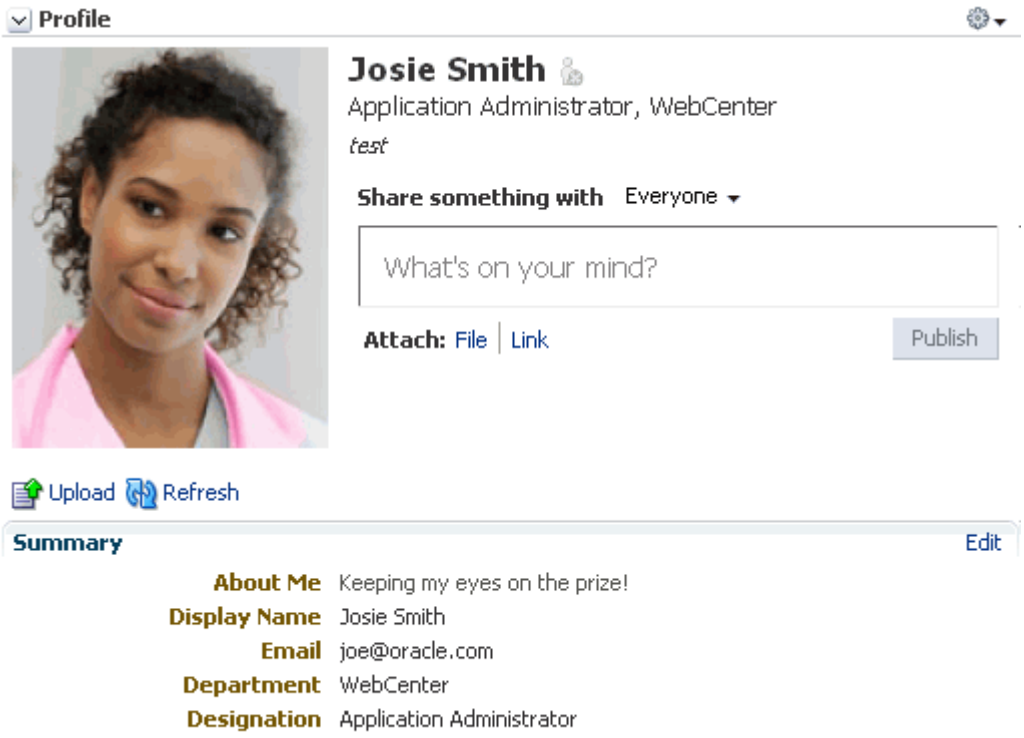
managing your view of messages, and for marking messages as private and sharing private messages (Figure 38–8).

Figure 38–8 Message Board Task Flow

- Message Board - Quick View—Provides users with a truncated view of Message Board messages and a means of adding, viewing, updating, hiding, and deleting messages, and for marking messages as private and sharing private messages. Users can click a **More** link to navigate to the Detailed View (Figure 38–9).

Figure 38–9 Message Board - Quick View Task Flow

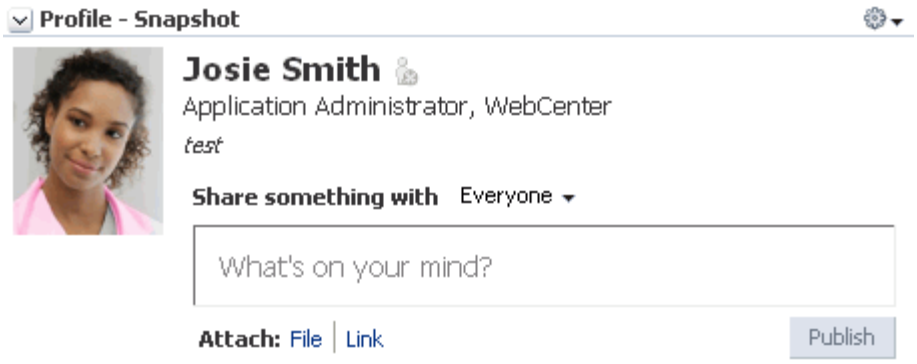
See Also: For information about Message Board task flows at runtime, see the section, "Working with Message Board Task Flows" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.



38.1.1.5 Profile

Profile provides users with a variety of views into their own and other users' personal profile information. Such information can include a user's email address, phone number, office location, department, manager, direct reports, and so on. Profile takes the bulk of its information from the back-end identity store that provides your WebCenter Portal application with its users. Additionally, Profile may offer opportunities for altering some of this information and for providing additional data not included in the identity store.

Three Profile task flow are available through the Resource Palette:



- Profile—Exposes a user's profile details, such as a user's email address, phone number, office location, department, manager, direct reports, and so on. It also exposes any personal image a user may have provided and the user's personal status message (Figure 38–10).

Figure 38–10 Profile Task Flow

- Profile - Snapshot—Exposes any personal image a user may have uploaded and provides a means of publishing messages, files, and links to a selected audience (Figure 38–11).

Figure 38–11 Profile - Snapshot Task Flow

Note: To enable users to upload anything to your ADF-based application at runtime, the page on which you have placed the upload task flow must have the `usesUpload` attribute set on the form. Additionally, for profile images, you must set the task flow binding parameter `photoUploadAllowed` to `true`. For more information, see the Note at the end of Section 39.2, "How to Add People Connections Task Flows to a Page," and see Chapter 40, "People Connections Task Flow Binding Parameters."

- Profile Gallery—Provides a summary view of each People Connections task flow. For example, it includes Activity Stream - Quick View, Connections - Quick View, and so on (Figure 38–12).

Figure 38–12 Profile Gallery Task Flow

See Also: For information about Profile task flows at runtime, see the section, "Viewing and Editing Personal Profiles" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

38.1.1.6 The Publisher Task Flow

The Publisher task flow works in concert with Activity Stream. Users enter content into Publisher, which is then published to the Activity Stream of the user who posted it as well as to the Activity Streams of that user's connections (Figure 38–13).

Figure 38–13 Publisher Task Flow

See Also: For information about the Publisher task flow at runtime, see the section, "Sharing Items, Files, and URLs Through the Publisher Task Flow" in the *Oracle Fusion Middleware User's Guide for Oracle WebCenter Portal: Spaces*.

38.1.2 People Connections Service Requirements

For a successful integration of People Connections with your WebCenter Portal: Framework application, ensure that the following steps have been taken:

1. Create a WebCenter Portal: Framework application (for more information, see Section 5.2, "Creating a Framework Application").
2. Set up the WebCenter schema, and create a database connection to it (for more information, see Chapter 7, "Preparing Your Application for WebCenter Portal Services").
3. Create a JSF (`.jspx`) page (for more information, see Section 5.3, "Adding Pages to a Portal").
4. Secure your application and create some test users (for more information, see Chapter 69, "Securing Your WebCenter Portal: Framework Application," and Section 24.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File").
5. Drag and drop a People Connections task flow onto your page (for more information, see Section 39.2, "How to Add People Connections Task Flows to a Page").
6. Provide required values for task flow bindings (for more information, see Chapter 40, "People Connections Task Flow Binding Parameters").
7. Run the page.
8. When required, provide the user name and password of a test user you created at Step 4.

38.2 Troubleshooting the People Connections Service

This section provides information to assist you in troubleshooting problems you may encounter while using the People Connections service.

People Connections task flows take up the full browser, even when empty

This problem may arise if you are using Internet Explorer, version 8 (IE8). In IE8, go to **Tools**, **Compatibility View Settings**. In the Compatibility View Settings dialog, clear the following check boxes:

- Display intranet sites in Compatibility View
- Display all websites in Compatibility View

New Profile Image is Not Shown

Changes to a Profile image may not be rendered immediately due to a stale WebCenter Database cache. Clicking the **Refresh** icon under the stale image will cause the image to update.

39

Basic Configuration for the People Connections Service

This chapter provides the required steps for adding the People Connections service to your WebCenter Portal: Framework application. It includes the following sections:

- Section 39.1, "How to Set Up a Database Connection for the People Connections Service"
- Section 39.2, "How to Add People Connections Task Flows to a Page"
- Section 39.3, "Setting Security for the People Connections Service"
- Section 39.4, "Establishing Site-Level Settings for People Connections Features"

39.1 How to Set Up a Database Connection for the People Connections Service

For information about setting up a database connection in support of Oracle WebCenter Portal: Services, see Section 7.2.2, "Setting Up a Database Connection."

39.2 How to Add People Connections Task Flows to a Page

This section describes how to add a People Connections task flow to an application page. The steps provided here are largely the same for all People Connections task flows. Differences are noted.

To add People Connections task flows to your WebCenter Portal: Framework application:

1. Prepare your application as described in Section 38.1.2, "People Connections Service Requirements."
2. Open the page on which to add a People Connections task flow.
3. In the Resource Palette, open **My Catalogs**, then **WebCenter Portal - Services Catalog**, then the **Task Flows** folder.
4. Drag and drop a task flow (for example, Connections - Quick View) onto the JSF (`.jspx`) page.
5. Select **Region** from the resulting context menu.

   It may ask whether you want to add the People Connections library to the project. Confirm by clicking **Add Library**.
6. In the Edit Task Flow Binding dialog, specify parameter values for the task flow.

For example, for Connections - Quick View, the parameter `userid` represents the name of the current user at runtime. You can specify an EL expression for the parameter that will evaluate to the currently logged-in user. For example, for `userid`, enter `#{securityContext.userName}`. For more information, see Chapter 40, "People Connections Task Flow Binding Parameters."

7. Click **OK**.

   The task flow is added to the page, and the ViewController project's libraries are configured to run the task flow.

8. Save and run your page to the browser.

Note: To enable users to upload anything to your ADF-based application at runtime, the page on which you have placed the task flow must have the `usesUpload` attribute set on the form. For example, to enable the upload of a document to the document library or a photo to a profile, add the following to the relevant page:

```
<af:form usesUpload="true">
  …
  <af:region value="#{bindings.profile1.regionModel}"/>
  …
</af:form>
```

Additionally, to enable the upload of a profile snapshot, the task flow binding parameter `photoUploadAllowed` must be set to `true`. For more information, see Chapter 40, "People Connections Task Flow Binding Parameters."

39.3 Setting Security for the People Connections Service

Because People Connections features are centered around users, application security must be set up for successful use of the service. Ideally, test users are also in place to enable you to interact in a meaningful way with each feature. Each feature in the People Connections service can be secured separately.

- ADF security is configured by default when you create your application using the WebCenter Portal Application template. For details about how to implement a basic security solution for your WebCenter Portal application, see Section 69.3, "Configuring ADF Security."
- To create test users, follow the steps outlined in Section 24.2.2, "How to Define Roles and Grant Privileges in the jazn-data.xml File."

  Once you have added test users, you can add additional user attributes, such as `business_email`, `title`, or `department`:

  1. Open the `jazn-data.xml` file.

     Tip: You will find the `jazn-data.xml` file in the Application Resources panel in the META-INF folder under Descriptors.

  2. Select the tab for **Source** at the bottom of the main content area.
  3. Inside the `<user>` node for a selected user, insert the following:

     ```
     <property name="[property-name]" value="[property-value]"/>
     ```

For example, to add `business_email` as `monty@domain.com` for the user `monty`, add:

```
<user>
     <name>monty</name>
     <display-name>monty</display-name>
     <credentials>{903}EfEepsY6I/TrKthpcmjJIsrlP36Ysr/j</credentials>
     <property name="business_email" value="monty@domain.com"/>
</user>
```

39.4 Establishing Site-Level Settings for People Connections Features

Two scripts are available to configure and revise People Connections site-level settings:

RCUHOME/rcu/integration/webcenter/sql/oracle/settings-insert.sql

RCUHOME/rcu/integration/webcenter/sql/oracle/settings-update.sql

The variable *RCUHOME* refers to your install location of the Resource Creation Utility (RCU). The RCU may be used in setting up the WebCenter schema and is packaged with the Oracle JDeveloper ship home. `RCUHOME` is the root folder where the RCU is installed.

This section describes the scripts and provides information about the types of settings they control. It includes the following subsections:

- Section 39.4.1, "Understanding the People Connections Site-Level Setting Scripts"
- Section 39.4.2, "Supported Site-Level Settings for People Connections Features"
- Section 39.4.3, "Example: Configuring Connections to Accept Invitations Automatically"

39.4.1 Understanding the People Connections Site-Level Setting Scripts

All site-level settings for People Connections features are stored in the WebCenter schema table `WC_PPL_COMMON_SETTING`. Out-of-the-box, this table does not contain any setting values. In the absence of values, the application assumes default values. To change the value of any setting, the setting must first be inserted into this table and then updated with the desired value. Two SQL scripts enable you to perform these steps in their proper sequence.

This section describes how to prepare and run the People Connections site-level settings scripts. It includes the following subsections:

- Section 39.4.1.1, "Preparing and Running settings-insert.sql"
- Section 39.4.1.2, "Preparing and Running settings-update.sql"

39.4.1.1 Preparing and Running settings-insert.sql

Before you can change People Connections site-level settings, you must run the `settings-insert.sql` script once. The script has `INSERT` statements for all supported settings. All `INSERT` statements are commented out by default. Before you run the script, you must prepare it by uncommenting all the settings you plan to change.

> **See Also:** For an example of the `settings-insert.sql` script in action, see Section 39.4.3, "Example: Configuring Connections to Accept Invitations Automatically."

To prepare and run the `settings-insert.sql` script:

1. Open the script in an editor.
2. For the settings you plan to change, uncomment the corresponding `INSERT` statement.

   Tip: To uncomment an `INSERT` statement, remove the leading double dash (--) on the lines the statement spans.

3. Once you have uncommented all the `INSERT` statements for the settings of interest, save and run the script.

   The uncommented settings are populated with default values.

   Note: You can run the `settings-insert.sql` script only once for a given set of settings on a given schema. If you must run it more than once—for example, if you must update a different set of settings—then the previously uncommented `INSERT` statements must be commented before you can run the script again. Otherwise, a SQL error is thrown during the re-execution of the `INSERT` statement.

39.4.1.2 Preparing and Running settings-update.sql

To change People Connections site-level settings, you must run the `settings-update.sql` script after you run `settings-insert.sql` once. The `settings-update.sql` script has `UPDATE` statements for all supported settings. All `UPDATE` statements are commented out by default.

You can run the `settings-update.sql` script as many times as required for a given set of settings on a given schema, provided you have run `settings-insert.sql` once for those settings.

See Also: For an example of the `settings-update.sql` script in action, see Section 39.4.3, "Example: Configuring Connections to Accept Invitations Automatically."

To prepare and run the `settings-update.sql` script:

1. Open the script in an editor.
2. For the settings you plan to change, uncomment the corresponding `UPDATE` statement.

   Tip: To uncomment an `INSERT` statement, remove the leading double dash (--) on the lines the statement spans.

3. For each uncommented statement, change the value of the `SETTING_KEY` column to the desired value.

   For information about settings and values, see Section 39.4.2, "Supported Site-Level Settings for People Connections Features."

4. Once you have revised all `UPDATE` statements of interest, save and run the script.

   The table `WC_PPL_COMMON_SETTING` is updated with the revised values.

5. If your WebCenter Portal: Framework application is running, restart it for the changes to take effect.

39.4.2 Supported Site-Level Settings for People Connections Features

This section lists and describes the supported site-level application settings for the People Connections service. It includes the following subsections:

- Section 39.4.2.1, "Activity Stream Site-Level Settings"
- Section 39.4.2.2, "Connections Site-Level Settings"
- Section 39.4.2.3, "Feedback Site-Level Settings"
- Section 39.4.2.4, "Message Board Site-Level Settings"
- Section 39.4.2.5, "Profile Site-Level Settings"

39.4.2.1 Activity Stream Site-Level Settings

Table 39–1 lists and describes the site-level settings for the People Connections service Activity Stream feature.

The service ID for Activity Stream is `oracle.webcenter.activitystreaming`. For a list of service IDs, see Table G–7.

Table 39–1 Site-Level Settings for Activity Stream

Setting Key	Description	Valid Site-Level Values
`accesscontrol.value.accessControlLevel`	Specifies who can view a user's Activity Stream.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`accesscontrol.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Activity Stream. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` `+`=TRUE `-`=FALSE

Table 39–1 (Cont.) Site-Level Settings for Activity Stream

Setting Key	Description	Valid Site-Level Values
`connectionsActivities.value`	Specifies whether the Home space activities of a user's connections are included in the user's Activity Stream. Users can override this setting on a task flow instance.	`NONE`, `ALL` `NONE`=No activities of the user's connections are shown. `ALL`=All activities of the user's connections are shown.
`groupSpaceActivities.value`	Specifies whether any space activities of a user's connections are included in the user's Activity Stream. Users can override this setting on a task flow instance.	`GSNONE`, `GSALL` `GSNONE`=No space activities are shown `GSALL`=Activities are shown for all of the spaces of which the user is a member and on which the user has view access.
`servicePublishedSettings[`*`serviceId`*`]`	Specifies whether to show activities published by the WebCenter service *`serviceId`* in a user's Activity Stream. A *`serviceId`* is the WebCenter service ID of any service that publishes activities. For a list of service IDs, see Table G–7. For example: `servicePublishedSettings[oracle.webcenter.community]` Users can override this setting on a task flow instance.	`+`, `-` `+`=TRUE `-`=FALSE

39.4.2.2 Connections Site-Level Settings

Table 39–2 lists and describes the site-level settings for the People Connections service Connections feature.

The service ID for Connections is `oracle.webcenter.peopleconnections.connections`. For a list of service IDs, see Table G–7.

Table 39–2 Site-Level Settings for Connections

Setting Key	Description	Valid Site-Level Values
`autoAcceptInvitations`	Specifies that connection invitations are accepted automatically by default. Individual users can override this application-level setting in their own view, provided the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE
`connectionsVisibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's Connections.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`connectionsVisibility.personalizable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Connections. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE

39.4.2.3 Feedback Site-Level Settings

Table 39–3 lists and describes the site-level settings for the People Connections service Feedback feature.

The service ID for Feedback is `oracle.webcenter.peopleconnections.kudos`. For a list of service IDs, see Table G–7.

Table 39–3 Site-Level Settings for Feedback

Setting Key	Description	Valid Site-Level Values
`visibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's received Feedback.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`visibility.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their received Feedback. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE
`addControl.accessControlSettings.accessControlLevel`	Specifies who can give Feedback to a user.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`addControl.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can give them Feedback. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE

Table 39–3 (Cont.) Site-Level Settings for Feedback

Setting Key	Description	Valid Site-Level Values
`miniViewRowCount.value`	Specifies the number of Feedback entries to show in a Feedback - Quick View task flow.	Positive integers
`miniViewRowCount.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for the number of entries to show in a Feedback - Quick View task flow. This setting is honored only when the application exposes the override control in a user preferences screen.	+, – +=TRUE –=FALSE
`postedUserActions.delete`	Specifies whether users are allowed to delete the Feedback they leave for other users.	+, – +=TRUE –=FALSE

39.4.2.4 Message Board Site-Level Settings

Table 39–4 lists and describes the site-level settings for the People Connections service Message Board feature.

The service ID for Message Board is `oracle.webcenter.peopleconnections.wall`. For a list of service IDs, see Table G–7.

Table 39–4 Site-Level Settings For Message Board

Setting Key	Description	Valid Site-Level Values
`visibility.accessControlSettings.accessControlLevel`	Specifies who can view a user's Message Board.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`visibility.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can view their Message Board. This setting is honored only when the application exposes the override control in a user preferences screen.	+, – +=TRUE –=FALSE
`addControl.accessControlSettings.accessControlLevel`	Specifies who can post to a user's Message Board.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`addControl.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for who can post to their Message Board. This setting is honored only when the application exposes the override control in a user preferences screen.	+, – +=TRUE –=FALSE
`miniViewRowCount.value`	Specifies the number of messages to show in a Message Board - Quick View task flow.	Positive integer

Table 39–4 (Cont.) Site-Level Settings For Message Board

Setting Key	Description	Valid Site-Level Values
`miniViewRowCount.endUserConfigurable`	Specifies whether individual users can override in their own application views the application-level setting for the number of messages to show in a Message Board - Quick View task flow. This setting is honored only when the application exposes the override control in a user preferences screen.	`+`, `-` +=TRUE -=FALSE
`postedUserActions.edit`	Specifies whether users are allowed to edit the messages they post on other users' Message Boards.	`+`, `-` +=TRUE -=FALSE
`postedUserActions.delete`	Specifies whether users are allowed to delete messages they post on other users' Message Boards.	`+`, `-` +=TRUE -=FALSE

39.4.2.5 Profile Site-Level Settings

Table 39–5 lists and describes the site-level settings for the People Connections service Profile feature.

The service ID for Profile is `oracle.webcenter.peopleconnections.profile`. For a list of service IDs, see Table G–7.

Table 39–5 Site-Level Settings for Profile

Setting Key	Description	Valid Site-Level Values
`general-profile-settings.logActivity`	Specifies whether profile updates, such as uploading a photo, updating personal status, changing profile attributes, should result in activities getting published in Activity Stream.	`true`, `false`
`general-profile-settings.personalWebVisibility`	Specifies who can view a user's Profile Gallery.	`SELF`, `CONNECTIONS`, `USERS` (that is, authenticated users), `PUBLIC`
`general-profile-settings.pwVisibilityPersonalizable`	Specifies whether individual users can override in their own views the application-level setting for who can view their Profile Gallery. This setting is honored only when the application exposes the override control in a user preferences screen.	`true`, `false`
`general-profile-settings.view.name.`*`profileSectionName`*`.access-control-level`	Specifies who can view the Profile section identified by *`profileSectionName`*. For example: `general-profile-settings.view.name.personalInfo.access-control-level` For more information, see Table 39–6, " Profile Section Names".	`SELF`, `USERS` (that is, authenticated users), `PUBLIC` **Note:** `CONNECTIONS` is not a valid value for this setting.

Table 39–5 (Cont.) Site-Level Settings for Profile

Setting Key	Description	Valid Site-Level Values
`general-profile-settings.view.name.profileSectionName.allow-personalize-visibility`	Specifies whether individual users can override in their own application views the application-level setting for who can view the Profile section identified by *`profileSectionName`* on their profile. This setting is honored only when the application exposes the override control in a user preferences screen. For more information, see Table 39–6, " Profile Section Names".	`true`, `false`
`general-profile-settings.view.name.profileSectionName.allow-user-edit`	Specifies whether users are allowed to edit the Profile section identified by *`profileSectionName`* on their own Profiles. For example: `general-profile-settings.view.name.personalInfo.allow-user-edit` For more information, see Table 39–6, " Profile Section Names".	`true`, `false`
`ootb-view-edit-settings.view.name.profileSectionName.profileFieldName.allow-edit`	Specifies whether users are allowed to update the field identified by *`profileFieldName`* when they edit the Profile section identified by *`profileSectionName`* on their own profile. For example: `ootb-view-edit-settings.view.name.personalInfo.homePhone.allow-edit` For more information, see Table 39–6, " Profile Section Names" and Table 39–7, " Profile Field Names".	`true`, `false`

Table 39–6 Profile Section Names

Section Name	Description
`basic`	Profile summary These details are discoverable in an application search.
`employee`	Employee detail
`businessContact`	Business contact information
`personalInfo`	Personal information

Table 39–7 Profile Field Names

Field Name	Description
`email`	Business email address
`displayName`	User display name
`Dept`	Office department

Table 39–7 (Cont.) Profile Field Names

Field Name	Description
title	Job title
phone	Business phone number
timeZone	Time zone
photo	User photo
persStatNote	Personal status message
description	About me
empType	Employee type
empNo	Employee number
prefLang	User's preferred language
organization	Employee's organization
expertise	Employee's expertise
fax	Fax number
mobile	Mobile/cell phone number
pager	Page number
street	Office address: street
city	Office address: city
state	Office address: state
poBox	Office address: P.O. box
poCode	Office address: ZIP/PIN/P.O. code
country	Office address: country
homeAdd	Home address
homePhone	Home phone number
dob	Date of birth
maidenName	Maiden name/surname before marriage
doh	Date of hire

39.4.3 Example: Configuring Connections to Accept Invitations Automatically

By default, when users send invitations to connect, recipients must explicitly accept them. Through site-level settings, the application administrator can configure the application to accept invitations automatically. This setting is identified by the key, `autoAcceptInvitations`, and the service ID, `oracle.webcenter.peopleconnections.connections`. To change the setting, the administrator performs the following steps:

1. Open the `settings-insert.sql` script and uncomment the following lines:

```
-- INSERT INTO WC_PPL_COMMON_SETTING (ID, APPLICATION_ID, SCOPE_ID, SERVICE_ID,
USER_ID, TASKFLOW_INST_ID, SETTING_KEY, SETTING_VALUE)
--   VALUES ('768e5d1f-a73d-41b4-819d-74be081e1de1', 'webcenter',
'defaultScope', 'oracle.webcenter.peopleconnections.connections', 'SYSTEM',
'SITE', 'autoAcceptInvitations', '-')
 -- ;
```

After modification, the lines appear as follows:

```
 INSERT INTO WC_PPL_COMMON_SETTING (ID, APPLICATION_ID, SCOPE_ID, SERVICE_ID,
USER_ID, TASKFLOW_INST_ID, SETTING_KEY, SETTING_VALUE)
   VALUES ('768e5d1f-a73d-41b4-819d-74be081e1de1', 'webcenter', 'defaultScope',
'oracle.webcenter.peopleconnections.connections', 'SYSTEM', 'SITE',
'autoAcceptInvitations', '-')
 ;
```

2. Save and run the script.
3. Open the `settings-update.sql` script and uncomment the following lines:

```
  -- UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='-'
  --   WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
  --   AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
SETTING_KEY='autoAcceptInvitations'
   -- ;
```

After the modification, the lines appear as follows:

```
   UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='-'
     WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
     AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
SETTING_KEY='autoAcceptInvitations'
    ;
```

4. Change the value of `SETTING_VALUE` to a plus sign (+).

   After modification, the lines appear as follows:

```
   UPDATE WC_PPL_COMMON_SETTING SET SETTING_VALUE='+'
     WHERE APPLICATION_ID='webcenter' AND SCOPE_ID='defaultScope' AND USER_
ID='SYSTEM' AND TASKFLOW_INST_ID='SITE'
     AND SERVICE_ID='oracle.webcenter.peopleconnections.connections' AND
SETTING_KEY='autoAcceptInvitations'
    ;
```

5. Save and run the script.
6. If your WebCenter Portal: Framework application is running, restart the application.

   After you restart, the setting takes effect. In this example, when a user invites another user to connect, the connection is created automatically.

See Also: For lists and descriptions of People Connections site-level settings, see Section 39.4.2, "Supported Site-Level Settings for People Connections Features."

40

People Connections Task Flow Binding Parameters

Each People Connections task flow has a set of required and optional task flow binding parameters. These provide a means of capturing information that is useful to the task flow's successful function. For example, all People Connections task flows provide a binding parameter for capturing the ID of the current runtime user. This value (typically `#{securityContext.userName}`) enables the task flow to return People Connections data that is relevant to the current user.

In addition to providing required values for successful task flow rendering, you can use task flow binding parameters to customize the appearance and behavior of a task flow instance. For example, you can use parameter values to determine whether headers and footers are rendered, the number of rows and columns of information to show, whether to apply a filter to returned data, and the like.

You can provide task flow binding parameter values when you drag and drop a task flow onto an application page. Doing so opens the Task Flow Bindings dialog (for more information, see Section 39.2, "How to Add People Connections Task Flows to a Page"). You can also adjust task flow binding parameter values after you have placed a task flow on a page.

This chapter describes how to revise task flow parameter values at design time and provides a table that lists and describes the binding parameters associated with People Connections task flows. It includes the following sections:

- Section 40.1, "How to Revise People Connections Task Flow Binding Parameters"
- Section 40.2, "People Connections Task Flow Binding Parameters"
- Section 40.3, "What You Should Know About the Activity Stream Advanced Query Option"

40.1 How to Revise People Connections Task Flow Binding Parameters

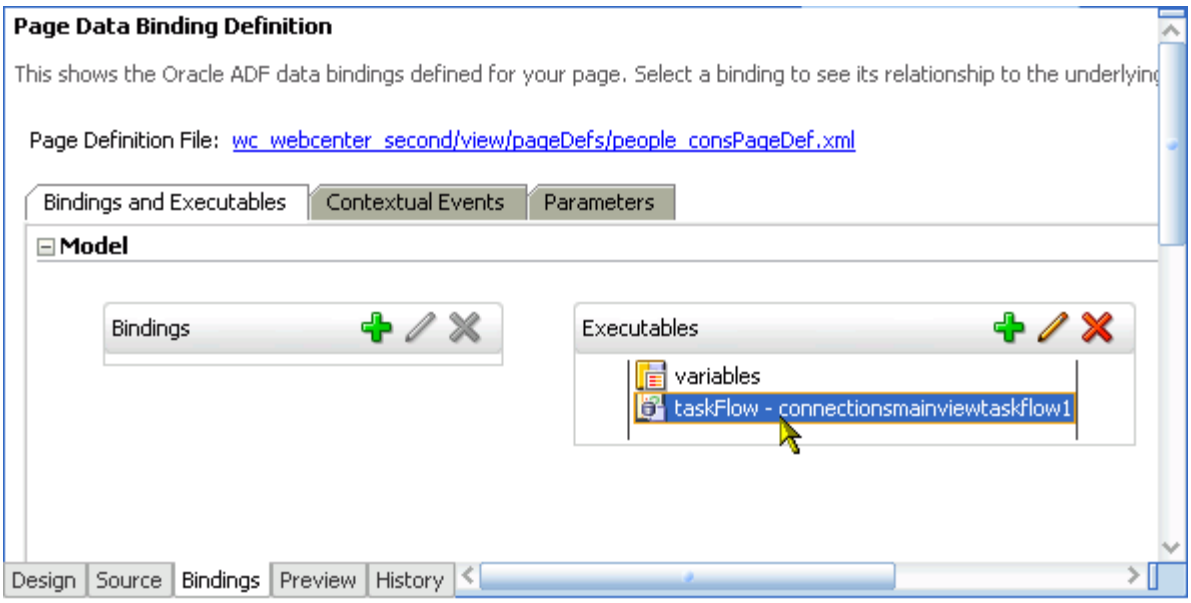
After you have added a task flow to a page, you may want to customize the instance by revising its binding parameter values. This section describes how to access the Edit Task Flow Binding dialog and change binding parameter values.

To access the Edit Task Flow Binding dialog:

1. Open the application page and set the view to bindings by clicking the **Bindings** tab at the bottom of the page.
2. Under **Executables**, double-click the task flow for which to revise task flow binding parameters (Figure 40–1) to open the Edit Task Flow Binding dialog (Figure 40–2).

Tip: Task flow names under **Executables** differ from names in design view. For example, Message Board task flows are instead referred to as *wall*, and Feedback task flows are instead referred to as *kudos*.

Figure 40–1 Bindings View of an Application Page



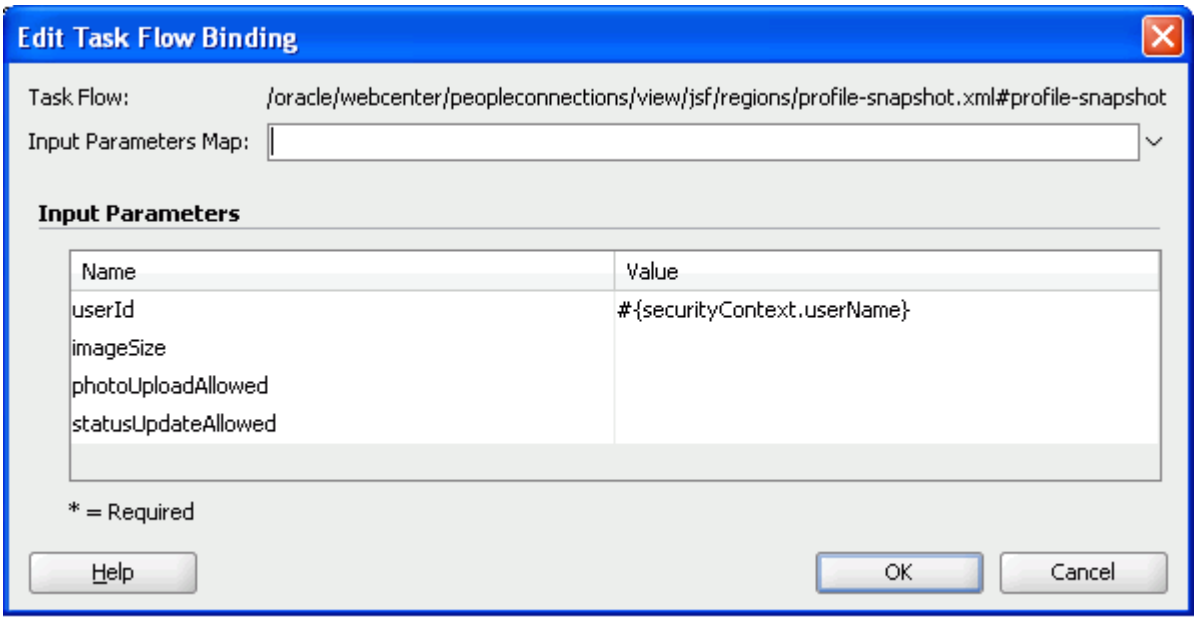


Figure 40–2 Edit Task Flow Binding Dialog

3. Revise binding parameter values (for more information, see Section 40.2, "People Connections Task Flow Binding Parameters").
4. Click **OK** to save your changes and exit the dialog.
5. Save and run your page to see the results.

40.2 People Connections Task Flow Binding Parameters

Table 40–1 lists and describes task flow binding parameters applicable to the People Connections service.

Table 40–1 People Connections Service Task Flow Binding Parameters

Parameter	Description
`__followEnforced`	A means of enforcing the follow logic when querying Activity Stream ■ Enter `#{true}` to establish that the user must follow the business object to access streamed activities, even when the object's activities are queried in an advance query clause. The default is true. ■ Enter `#{false}` to omit this requirement. The activities streamed for Fusion business objects are returned as far as required by the advanced query, no matter whether the user follows the objects. This parameter (for Fusion application business objects) is used in conjunction with the `advancedQuery` parameter. This parameter is associated with the Activity Stream task flow.
`__objectExtHandlerEnabled`	A means of using the object extension handler to process Fusion application business objects ■ Enter `#{true}` to use the object extension handler to process business objects. ■ Enter `#{false}` to omit using the object extension handler. False is the default. When you enter `#{true}`, then, before querying activities for the business objects, the Activity Stream uses the object extension handler to process the business objects. The handler checks whether the user has permission to access the business object. If the user does not have permission, the object is removed from the list, and, none activities are retrieved from this object. This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View
`__objects`	A comma separated list of objects for which to show activities Enter objects in the format `object-id;object-type;service-id`. Typically used only for followed objects. This parameter is associated with the Activity Stream task flow.
`__objectSecured`	A means of enforcing a security check on a Fusion application business object ■ Enter `#{true}` to enforce the security check. ■ Enter `#{false}` to omit the security check. False is the default. The security check is performed by the resource authorizer that is implemented by the Fusion application. If a user has no permission on a business object, the activities related to that business object are filtered out. This parameter is associated with the Activity Stream task flow. This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View
`advancedQuery`	A field for specifying a custom query to filter streamed items For more information, see Section 40.3, "What You Should Know About the Activity Stream Advanced Query Option." This parameter is associated with the Activity Stream task flow.

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`connectionListName`	The name of a connections list This parameter is associated with the task flow Connections - Card.
`currentView`	The view to display by default Valid values include: ▪ `connections`—(the default value) a list of connections ▪ `receivedInvitations`—a list of connections invitations you received ▪ `sentInvitations`—a list of connections invitations you sent ▪ `people`—a search field for finding people with whom to connect When users access the task flow instance, the view specified here is the first one they see. All selections, except `people`, provide controls for navigating to the application default view (`connections`). Selecting `people` provides search and select controls for inviting other users to connect. This parameter is associated with the Connections task flow.
`display_maxConnections`	The maximum number of connections to show in the task flow For example, enter `5` to specify that a maximum of five connections can appear in the task flow. A **More** link appears at the bottom of the task flow when there are more connections than the specified number of connections. Users click More to open the main view of the task flow where all connections are show. The value entered for this parameter is honored only when values for `display_numberOfRows` and `display_numberOfColumns` have not both been specified. If values for both of these parameters have been specified, then **Previous** and **Next** links appear when there are more connections than can fit into the specified numbers of rows and columns. This parameter is associated with the following task flows: ▪ Connections - Card ▪ Connections - Quick View
`display_numberOfColumns`	The number of columns to show in the task flow For example, in a Connections - Card task flow that shows six connections, a value of `2` means those connections are shown in two columns with three rows (see also `display_numberOfRows` and `display_maxConnections`). This parameter is associated with the following task flows: ▪ Connections - Card ▪ Connections - Quick View
`display_numberOfRows`	The number of rows to show in the task flow For example, in a Connections - Card task flow that shows six connections and a value of `2` for `display_numberOfColumns`, a value of `2` for this parameter means connections are shown in two columns with two rows. That is, four connections are shown. A **More** link appears at the bottom of the task flow when there are more connections than can be fit in the specified number of columns and rows. Users click More to open the main view of the task flow where all connections are shown. See also `display_maxConnections`. This parameter is associated with the following task flows: ▪ Connections - Card ▪ Connections - Quick View

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`display_profileFormat`	The default layout style for the task flow Enter one of the following: ■ `vcard`—displays a connection's photo and status message. ■ `iconic`—displays a connection's photo and user name. ■ `list`—displays connections in a list, with each list row showing the profile photo, user name (linked to a summary profile view), mail address, job title, status message, and actions icons and links. ■ `tiled`—renders the connection's personal Profile photo and shows the user name and job title beside the photo. In all layouts, the name links to a summary view of the user's Profile. This parameter is associated with the task flow Connections - Card.
`display_removalAllowed`	A means of showing or hiding the **Remove** action on the task flow Enter `true` to show the Remove action. Enter `false` to hide the Remove action. The default value (`true`) is applied if the input is invalid. This parameter is associated with the task flow Connections - Card.
`display_sortedBy`	The connections sort order Enter `LAST_ACTIVITY_TIME` to sort connections in descending date/time order. Leave this field blank to sort connections alphabetically by name. This parameter is associated with the task flow Connections - Card.
`displayCount`	The number of items to show in the task flow For example, enter `5` to specify that a maximum of five items can appear in the task flow. In quick views, a **More** link appears at the bottom of the task flow when there are more items than the specified number of items. Users click **More** to open the main view of the task flow where all items are accessible. In main views, **Previous** and **Next** links are shown. Users click these to page through entries. This parameter appears in the component properties for the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board ■ Message Board - Quick View
`displayMessageSize`	The number of characters to show for each feedback message Messages exceeding the specified value are truncated, and an ellipse (…) is appended to the end. This parameter is associated with the task flow Feedback - Quick View.
`editMode`	A means of enabling an edit mode on a Profile task flow instance Enter `#{true}` to enable an edit mode. Enter `#{false}` to disable it. This parameter is associated with the Profile task flow.

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`enableContextInfo`	A means of showing or omitting detailed information about the object in the current context (that is, in a popup or other contextual instrument) ■ Enter `#{true}` to enable Activity Stream to display the `af:contextInfo` component (a small, red dot). Users can click this dot to view object detail information. ■ Enter `#{false}` to omit object detail information. When this parameter is true and the `contextInfoTaskflowId` in the service definition is defined, the activity from the service displays the `af:contextInfo`. Otherwise, no context information is shown. This parameter is associated with the Activity Stream task flow.
`filterPattern`	A filter against task flow content For example, enter `pat` to show only those connections named *pat* (including *patrick* or *sripathy*). This parameter is associated with the task flow Connections - Card.
`fromDate`	The start date of a date range within which to show feedback messages Enter dates in the format `YYYY-MM-DD`. See also `toDate`. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board
`hideActions`	A means of hiding the actions normally associated with a Feedback or Message Board entry, such as Edit, Private, Hide, and Delete ■ Enter `#{true}` to hide actions associated with a Feedback or Message Board entry. ■ Enter `#{false}` to show such actions. When no value is entered, `false` is the default. This parameter appears in the component properties for the following task flows: ■ Feedback – Quick View ■ Message Board – Quick View
`hideAttach`	Specifies whether the **Attach: File | Link** option is shown or hidden ■ Check for `#{true}` to hide the **Attach: File | Link** option. ■ Clear for `#{false}` to show the **Attach: File | Link** option. This parameter is associated with the Publisher task flow.
`hideComments`	A means of showing or hiding the Comments feature on streamed activities Enter `true` to hide the Comments feature. Enter `false` to show it. This parameter is associated with the Activity Stream task flow
`hideConfigure`	A means of hiding the personalization option on the task flow instance This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`hideDocumentUploader`	A means of showing or hiding the Publisher task flow's document uploader Enter `#{true}` to hide the Publisher task flow's document uploader. Enter `#{false}` to show it. This parameter is associated with the Publisher task flow.
`hideFooter`	A means of showing or hiding the task flow footer The task flow footer contains the **More** link that appears at the bottom of a task flow when there are more items to show than can be accommodated in the current view. Hiding the footer hides the **More** link. Hiding the footer does not affect **Previous** and **Next** links that may also appear at the bottom of a task flow. Enter `true` to hide the footer. Enter `false` (default) to show the footer. This parameter is associated with the following task flows: ■ Activity Stream - Quick View ■ Connections - Card ■ Connections - Quick View ■ Feedback - Quick View ■ Message Board - Quick View
`hideGiven`	A means of showing or hiding feedback given to a user Enter true to allow the rendering of given feedback. Enter false to prohibit it. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View
`hideHeader`	A means of showing or hiding the task flow header Enter `true` to hide the task flow header. Enter `false` (default) to show the task flow header. This parameter is associated with the following task flows: ■ Activity Stream - Quick View ■ Connections - Quick View ■ Feedback ■ Feedback - Quick View ■ Message Board ■ Message Board - Quick View
`hideInlinePreview`	A means of allowing or omitting an inline preview of files attached to streamed activities Enter `true` to omit a file preview. Enter `false` to show it. This parameter is associated with the Activity Stream task flow.
`hideLike`	A means of showing or hiding the Like link on a streamed activity Enter true to hide the Like link. Enter false to show it. This parameter is associated with the Activity Stream task flow

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`hidePublisher`	A means of showing or hiding the message entry field and the upload file and URL controls (the Publisher) ■ Enter `#{true}` to disable the display of the message entry field in a given task flow instance. ■ Enter `#{false}` to allow the display of the message entry field in a given task flow instance. This parameter is associated with the following task flows: ■ Message Board ■ Message Board - Quick View
`hideScopePicker`	Specifies whether the **Share something with** option is shown or hidden ■ Check for `#{true}` to hide the **Share something with** option. ■ Clear for `#{false}` to show the Share something with option. This parameter is associated with the Publisher task flow.
`hintsTextKey`	Specifies the resource bundle class and message key for hint text Use the format `key[,RBClass]. __EMPTY__` as the predefined key for no hint text. This is the default value. This parameter is associated with the Publisher task flow.
`imageSize`	The display size of the profile photo Enter one of the following values: ■ `ORIGINAL` ■ `LARGE` ■ `MEDIUM` ■ `SMALL` This parameter is associated with the Profile - Snapshot task flow.
`isUpdateStatus`	A means of dedicating the task flow instance to updating the current user's Profile status message Enter `#{true}` to devote the task flow instance to updating user status messages. Enter `#{false}` to omit publishing messages to the current user's Profile status message. This parameter is associated with the Publisher task flow.
`keepOpenAfterPublish`	Specifies whether the text box remains active after a user clicks the **Publish** button ■ Enter `#{true}` to keep the text box open after a message is published. ■ Enter `#{false}` to close the text box after a message is published. This parameter is associated with the Publisher task flow.
`numberOfRows_list`	The number of rows to show when the Connections task flow instance is set to list view This parameter is associated with the Connections task flow.
`objectId`	The ID of an object to associate with a published message This parameter is associated with the Publisher task flow.
`objectType`	The type of an object to associate with a published message This parameter is associated with the Publisher task flow.

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`orgBreadCrumbsShown`	A means of showing or omitting organization breadcrumbs on a user profile that renders a management chain that is linked to each member up the chain Enter `#{true}` to show organizational breadcrumbs. Enter `#{false}` to omit them. This parameter is associated with the Profile - Snapshot task flow.
`pageSize`	The number of items to stream in a given task flow instance This parameter is associated with the following task flows: ■ Activity Stream ■ Activity Stream - Quick View
`pagination`	The form of pagination to use on a multipage stream ■ Enter `#{true}` to show Previous and Next links. ■ Enter `#{false}` hide to omit Previous and Next links. Instead, a more link is rendered, enabling users to navigate to a fuller view of the task flow where all streamed activities are shown. This parameter is associated with the Activity Stream task flow.
`photoUploadAllowed`	A means of allowing a photo upload from the profile screen Enter `true` (default) to allow users to upload a photo to their profile. Enter `false` to prevent users from uploading a photo. This parameter is associated with the task flow Profile - Snapshot.
`profileEditLinkShown`	A means of showing or omitting an Edit link on a Profile - Snapshot task flow Enter `#{true}` to show the Edit link. Enter `#{false}` to hide it. This parameter is associated with the Profile - Snapshot task flow.
`profileLaunchedOnSelection`	A means of launching a user Profile when the user name is clicked Enter `true` to launch a user Profile when the user name is clicked. Enter `false` to prevent launching a user Profile This parameter is associated with the task flow Connections - Card
`profileOnly`	A means of streaming activities only from user profiles ■ Enter `true` to stream only those activities associated with user profiles. ■ Enter `false` to stream other types of activities along with those associated with user profiles. This parameter is associated with the Activity Stream task flow.
`profileUserId`	ID of the user from whom to stream activity This parameter is associated with the Activity Steam - Quick View task flow.

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`resourceId`	The current user ID Enter `#{securityContext.userName}` to return the current user. This parameter is associated with the following task flows: ■ Activity Stream ■ Connections ■ Feedback ■ Message Board ■ Profile ■ Profile Gallery
`scopeId`	The ID of the scope to which to publish This property value assists in generating a link for use in navigating to the published object. It is not necessary to provide a value, unless you plan to do so using an EL expression. For information about EL expressions, seeAppendix G, "Expression Language Expressions." This parameter is associated with the Publisher task flow.
`sectionWiseEditEnabled`	A means of enabling or disabling section-by-section edit capability on the task flow ■ Enter `#{true}` to enable section-by-section editing. An **Edit** control is shown on each editable Profile section. ■ Enter `#{false}` to disable section-by-section editing. This parameter is associated with the Profile task flow.
`serviceCategories`	A field for entering a comma-separated list of names of services from which to stream activities Use this parameter to limit the display of streamed activities to only those associated with the specified service or services. Enter one or more service IDs, for example: `oracle.webcenter.collab.announcement, oracle.webcenter.collab.forum` For a list of valid service ID, see Table G–7, " Service IDs". Note that all listed service IDs cannot be used because all services do not stream items to the Activity Stream. For example, the RSS service does not stream any activities. This parameter is associated with the Activity Stream task flow.
`serviceId`	The service ID of the service to which the object associated with a published message belongs For a list of service IDs, see Table G–7, " Service IDs". This parameter is associated with the Publisher task flow.
`spaceName`	The space to which to publish messages If your application does not support spaces, do not provide a value for this parameter. This parameter is associated with the following task flows: ■ Message Board ■ Message Board - Quick View ■ Publisher

Table 40–1 (Cont.) People Connections Service Task Flow Binding Parameters

Parameter	Description
`spaces`	A comma-separated list of names or GUIDs of spaces from which to stream activities Use this parameter to limit the display of streamed activities to only those associated with the specified space or spaces. If your application does not support spaces, do not provide a value for this parameter. This parameter is associated with the Activity Stream task flow.
`statusUpdateAllowed`	A boolean value representing whether a control is available on the task flow for updating a profile status message Enter either `true` or `false`. This parameter appears in the component properties for the Profile - Snapshot task flow.
`toDate`	The end date of a date range within which to show feedback messages Enter dates in the format `YYYY-MM-DD`. See also `fromDate`. This parameter is associated with the following task flows: ■ Feedback ■ Feedback - Quick View ■ Message Board
`uploadDocumentOnly`	A means of limiting the Publisher task flow to its document upload feature Enter #{true} to limit the Publisher task flow to be only a document uploader. Enter `#{false}` to expose all Publisher features. This parameter is associated with the Publisher task flow.
`userId`	The current user ID Enter `#{securityContext.userName}` to return the current user. This parameter is associated with the following task flows: ■ Connections - Card ■ Connections - Quick View ■ Feedback - Quick View ■ Message Board - Quick View ■ Profile - Snapshot
`userName`	The name of the user to whom to publish messages This value is supplied by default. We recommend that you do not change the default value, `#{o_w_w_i_v_b_resourceViewerBean.username}`. This parameter is associated with the Publisher task flow.
`viaUser`	The user name of the person who provided the object the current user is sharing For example, John is sharing a document with everyone that Jane originally shared with him. In this case, Jane is the via user. This parameter is associated with the Publisher task flow.

40.3 What You Should Know About the Activity Stream Advanced Query Option

Use `Advanced Query` to create filters against streamed activities in an Activity Stream task flow. Create filters for user names, service IDs, and object details, such as a document's display name. You can use SQL syntax for parameter values. Additionally you can place EL expressions within the SQL.

You can construct queries against specific database objects, which are represented by aliases that are prefixed to the inquiry. Table 40–2 lists and describes the types of database objects against which you can construct a query and provides their alias prefixes.

> **See Also:** In many cases, you can use EL expressions to obtain the value you require for the supported fields and columns listed in Table 40–2. For more information, see Appendix G, "Expression Language Expressions."

Table 40–2 Supported Database Objects for Constructing a SQL WHERE Clause

Database Object	Alias Prefix	Supported Fields/Columns
ACTIVITY	AE	■ `SCOPE_ID`—The GUID of the scope (you can use an EL to return this value, for example, `#{serviceCtx.scope.GUID}`). ■ `SERVICE_ID`—The service ID of the service to track. See Table G–7 for a list of service IDs. ■ `ACTIVITY_TIME`—The time the activity occurs. Use the datetime format that is supported in the SQL or target database. You can also use Oracle database SQL constructs, such as `to_date()`. ■ `ACTIVITY_TYPE`—The type of activity to track For a list of valid activity type names, see Table 40–3.
ACTIVITY (ACTOR)	AD	`ACTOR_NAME`—The user name of the person performing the activity.
ACTIVITY (OBJECT)	OD	■ `SERVICE_ID`—The service ID of the service from which the tracked object issues. See Table G–7 for a list of service IDs. ■ `OBJECT_ID`—The GUID of the object. ■ `DISPLAY_NAME`—The object display name. ■ `OBJECT_TYPE`—The object type. Object type names for use with Advanced Query include: ■ `event` ■ `announcement` ■ `forum` ■ `topic` ■ `bookmark` ■ `list` ■ `page` ■ `blog` ■ `document` ■ `wiki`

Table 40–3 Activity Type Names for Advanced Query

Service	Activity Type Name
Events	▪ createEvent ▪ updateEvent
Announcements	▪ createAnnouncement ▪ updateAnnouncement
Discussions	▪ createForum ▪ createTopic ▪ replyTopic
Tags	▪ updateBookmark
Lists	▪ createList ▪ editList
Page	▪ createPage ▪ editPage
Documents	▪ create-blog ▪ update-blog ▪ create-document ▪ create-wiki ▪ update-document ▪ update-wiki
People Connections (Profile)	▪ updateStatus ▪ updateProfile ▪ updatePhoto
People Connections (Message Board)	▪ postScope ▪ postself ▪ post ▪ sharescope ▪ shareself ▪ share ▪ shareobjectscope ▪ shareobjectself ▪ shareobject ▪ updatescope ▪ updateself ▪ update
People Connections (Connections)	▪ connect ▪ inviteForConnection
People Connections (Feedback)	▪ post

The SQL string that is passed as the advanced query parameter complies with SQL standards. That is, it supports SQL constructs, such as `AND`, `OR`, `IN`, and the like. Note, however, that it does not support `INSERT`, `UPDATE`, `DELETE`, `SELECT`, `JOIN` constructs. The syntax of the advanced query must contain only the `WHERE` clause

portion of a SQL query. Because `SELECT` is not supported, the `WHERE` clause cannot have nested queries or subqueries.

The `Advanced Query` parameter also supports EL expressions, which can be embedded in the `WHERE` clause or used to generate the whole `WHERE` clause.

All the literals in the query must be escaped by prepending a backward slash (\); otherwise, such characters generate syntax errors (see Table 40–4 for examples).

Note that the advanced query `WHERE` clause is always `AND`'ed to the internal query that is generated by Activity Stream based on the current user, space membership, connection list, and the like. This is to prevent a user from viewing activities to which he or she does not have access.

Table 40–4 lists examples of advanced queries.

Table 40–4 Examples of Advanced Queries for Use with Activity Stream

Use Case	Query Syntax
Stream only document creation activities.	`AE.SERVICE_ID = \'oracle.webcenter.doclib\'`
Stream activities only from an object or current space.	`OD.OBJECT_ID = \'objectA\' OR AE.SCOPE_ID = \'#{serviceCtx.scope.GUID}\'`
Stream activities only about wikis created by the current user.	`OD.OBJECT_TYPE = \'Wiki\' AND AD.ACTOR_NAME = \'#{securityContext.userName}\'`
Stream activities for documents and discussions, but only create activities or all activities for the current user.	`(AE.SERVICE_ID IN (\'oracle.webcenter.doclib\', \'oracle.webcenter.collab.forum\') AND AE.ACTIVITY_TYPE IN (\'createDocument\', \'createTopic\')) OR AD.ACTOR_NAME = \'#{securityContext.userName}\'`

41

Using People Connections Data Controls and Java APIs

This chapter provides an overview of People Connections service data controls and Java APIs. It further provides details about each data control and how to add it to your project and a pointer to information about how to use data controls in a WebCenter Portal: Framework application.

This chapter includes the following sections:

- Section 41.1, "Using People Connections Data Controls"
- Section 41.2, "People Connections Service Java APIs"

41.1 Using People Connections Data Controls

The People Connections service provides data controls that enable you to create your own visualization of the People Connections functionality. This section provides an overview of the following data controls and lists and describes their supported methods, attributes, and classes:

- People Connections Management Data Control
- Kudos Service Data Control
- Profile Data Control

This section also includes the following subsections:

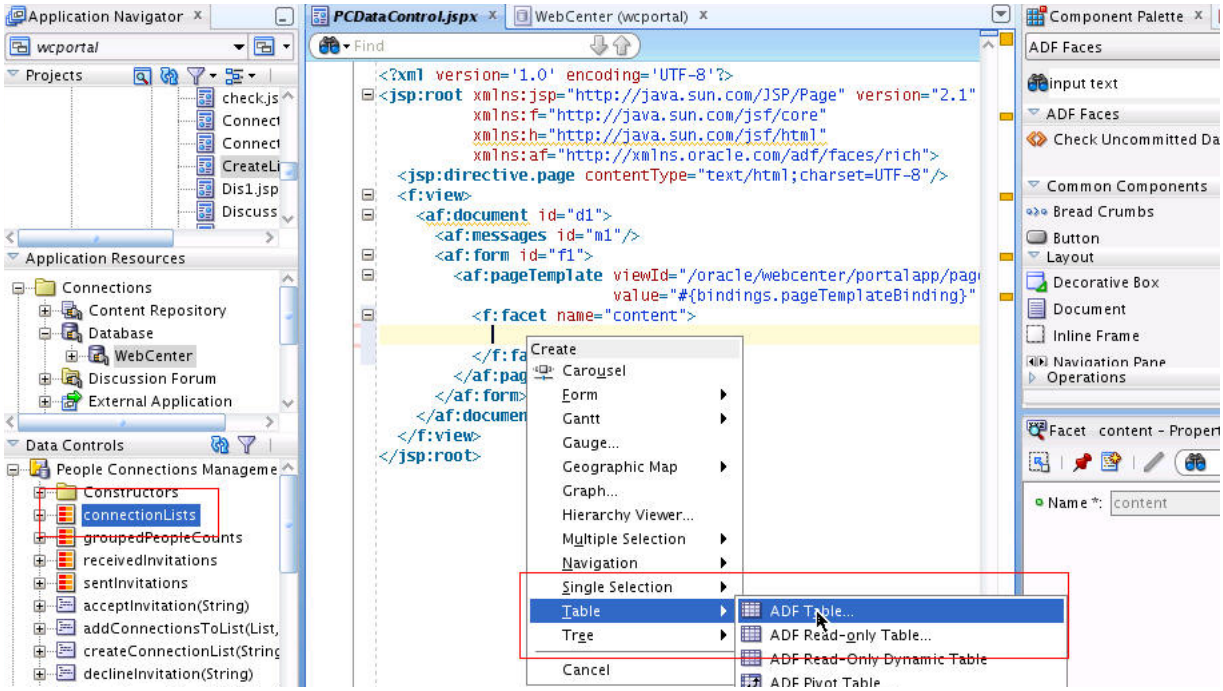
- Section 41.1.1, "Adding a Data Control to Your Project"
- Section 41.1.2, "Working with People Connections Management Data Control"
- Section 41.1.3, "Working with Profile Data Control"

41.1.1 Adding a Data Control to Your Project

You add a data control to your project by right-clicking it in the Resource Palette and selecting **Add to Project** from the resulting context menu. Once added, you can browse the data control's methods and attributes by expanding it in the Data Controls panel in the Application Navigator.

You add a data control to an application page by dragging it onto the page from the Data Controls panel. Once placed, a context menu opens with options for selecting the type of component to which to bind the data, such as a button or a text box.

To implement a People Connections Data Control:



1. Create a WebCenter Portal: Framework application in JDeveloper..

2. In your WebCenter portal application, navigate to **Resource Catalog** > **Services Catalog** > **Data Controls**.
3. Select a People Connection Data Control and right-click the control.
4. Click **Add to Project** in the context menu.

   The Data Controls appear in the Application Navigator Projects Data Controls folder.
5. Expand the Data Controls folder.

   On expanding, the Data Control objects and their corresponding Java methods appear.
6. Drag and drop the data control object on to the `.jspx` page and select the **ADF Table** option in the drop-down **Table** menu list, shown in Figure 41–1.

Figure 41–1 The Data Control Object Dragged and Dropped on to a .jspx Page With ADF Table Selected

7. To use the available Java methods, drag the methods to the .jspx page and select the **Method** item in the **Create** menu list, as shown in Figure 41–2, and bind it to the data in your project to achieve the desired functionality.

Figure 41–2 Dragging and Dropping Java Methods to the .jspx Page and Selecting Method in the Create Menu List

See Also: For more information about using data controls in a WebCenter Portal: Framework application, see Section 7.1.3, "Using WebCenter Portal Data Controls."

41.1.2 Working with People Connections Management Data Control

The People Connections Management Data Control provides methods for adding and managing connections and connections lists. The primary methods exposed include:

- connectionLists
- groupedPeopleCounts
- receivedInvitations
- sentInvitations
- acceptInvitation(String invitationId)
- addConnectionsToList(List userids, String listName)
- createConnectionList(String listName)
- declineInvitation(String invitationId)
- dropConnectionList(String listName)
- getConnectionList(String connectionListName)
- getConnections(String userid, String connectionListName, String filterPattern, String sortBy, int startIndex, int fetchSize)

- getNumberOfConnections(String userid, String connectionListName, String filterPattern)
- ignoreInvitation(String invitationId)
- inviteUserForConnection(String userid, String invitationMessage, Collection connectionListNames)
- isConnectionListModifiable(String listName)
- isConnectionPartOfUnmodifiableList(String connecteeGuid)
- removeConnection(String userid, boolean fromListOnly, String listName)
- searchUsers(String filterPattern, int startIndex, int fetchSize)
- updateConnectionListsMembership(String member, Collection addListIds, Collection removeListIds)

The subsections in this section list and describe the methods associated with the People Connections Management Data Control.

41.1.2.1 connectionLists

A collection of details about connections lists, including the list ID, name, localized name, number of members, whether or not the list is modifiable, and member user IDs. Table 41–1 lists and describes the attributes associated with this method.

Table 41–1 Attributes of the Method connectionLists

Attribute	Description
`id`	The connections lists IDs
`listName`	The names of connections lists
`localizedName`	The localized names of connections lists
`memberCount`	The number of members on each named connections list
`modifiable`	Information about whether a named connections list can be modified
`memberUserIds`	The user IDs of members on each named connections list

41.1.2.2 groupedPeopleCounts

The number of connections contained in each connections group.

41.1.2.3 receivedInvitations

A collection of details about a received invitation to connect, including when the invitation was sent and received, the invitation's GUID, the invitation message, and the user IDs of the user who sent the invitation and who received it. Table 41–2 lists and describes the attributes associated with this method.

Table 41–2 Attributes of the Method receivedInvitations

Attribute	Description
`dateFormattedAsReceived`	The date the invitation was received according to the recipient's time stamp
`dateFormattedAsSent`	The date the inviation was sent according to the sender's time stamp.
`id`	The GUID of the received invitation
`invitationMessage`	The invitation message

Table 41–2 (Cont.) Attributes of the Method receivedInvitations

Attribute	Description
inviteeUserid	The user ID of the person who received the invitation
invitorUserid	The user ID of the person who sent the invitation
sentDate	The date the invitation was sent according to the system time stamp

41.1.2.4 sentInvitations

A collection of details about a sent invitation to connect, including when the invitation was sent and received, the invitation's GUID, the invitation message, and the user IDs of the user who sent the invitation and who received it. lists and describes the attributes associated with this method. Table 41–3 lists and describes the attributes associated with this method.

Table 41–3 Attributes of the Method sentInvitations

Attribute	Description
dateFormattedAsReceived	The date the invitation was received according to the recipient's time stamp
dateFormattedAsSent	The date the inviation was sent according to the sender's time stamp
id	The unique GUID of the received invitation
invitationMessage	The invitation message
inviteeUserid	The user ID of the person who received the invitation
invitorUserid	The user ID of the person who sent the invitation
sentDate	The date the invitation was sent according to the system time stamp

41.1.2.5 acceptInvitation(String invitationId)

A method for accepting invitations to connect. Table 41–4 lists and describes the parameters associated with this method.

Table 41–4 Parameters of the Method acceptInvitations

Parameter	Description
invitationId	The GUID of the invitation to connect to be accepted

41.1.2.6 addConnectionsToList(List userids, String listName)

A method for adding identified users to a named connections list. Table 41–5 lists and describes the parameters associated with this method.

Table 41–5 Parameters of the Method addConnectionsToList

Parameter	Description
userids	The user names of the users to add to the named connections list
listName	The name of the connections list to which to add identified users

41.1.2.7 createConnectionList(String listName)

A method for creating a connections list. Table 41–6 lists and describes the parameters associated with this method.

Table 41–6 Parameters ofthe Method createConnectionList

Parameter	Description
`listName`	The name to give the new connections list

41.1.2.8 declineInvitation(String invitationId)

A method for declining an invitation to connect. Table 41–7 lists and describes the parameters associated with this method.

Table 41–7 Parameters of the Method declineInvitation

Parameter	Description
`invitationId`	The unique GUID of the declined invitation

41.1.2.9 dropConnectionList(String listName)

Method for deleting a connections list. Table 41–8 lists and describes the parameters associated with this method.

Table 41–8 Parameters of the Method dropConnectionList

Parameter	Description
`listName`	The name of the connections list to delete

41.1.2.10 getConnectionList(String connectionListName)

Returns an object that represents a Connections List. This object provides details about a connections list acquired for the given connection list name. Table 41–9 lists and describes the parameters associated with this method. Table 41–10 lists and describes the attributes associated with this method.

Table 41–9 Parameters of the Method getConnectionList

Parameter	Description
connectionListName	The name of the connections list for which to return the following attributes (see Table 41–10): ▪ `id` ▪ `listName` ▪ `localizedName` ▪ `memberCount` ▪ `modifiable` ▪ `memberUserIds`

Table 41–10 Attributes of the Method getConnectionList

Attribute	Description
`id`	The unique GUID of the connections list to return
`listName`	The name of the connections list to return
`localizedName`	The localized name of the connections list to return
`memberCount`	The number of members on the connections list to return
`modifiable`	An indicator of whether the returned connections list can be modified
`memberUserIds`	The user IDs of the members of a returned connections list

41.1.2.11 getConnections(String userid, String connectionListName, String filterPattern, String sortBy, int startIndex, int fetchSize)

Returns the `Connection` object, which provides details about the connection, including the connection's user ID, the connections lists on which the connection is a member, and details from a connection's profile. Table 41–11 lists and describes the parameters associated with this method. Table 41–12 lists and describes the attributes associated with this method.

Table 41–11 Parameters of the Method getConnections

Parameter	Description
`userid`	The user ID for each returned connection
`connectionListName`	The name of the connection list from which to obtain connections
`filterPattern`	A filter to use against returned connections, such as "co," which returns `condoleezza` as well as `nicole`
`sortBy`	The order by which to sort connections Enter `LAST_ACTIVITY_TIME` to sort connections in descending date/time order. Leave blank to sort alphabetically by name.
`startIndex`	The point from which to start fetching results This is used for pagination. For example, the search can return 50 matching records, and only 10 are needed, starting from 1. Set `startIndex` to 1 and `fetchSize` to 10.
`fetchSize`	The number of results to return (see `startIndex`)

Table 41–12 Attributes of the Method getConnections

Attribute	Description
`connecteeUserId`	The user ID of a connection
`connectionListsMembershipList`	The names of connections lists of which the connection is a member
`connecteeUserProfile`	The connectee's Profile details

41.1.2.12 getNumberOfConnections(String userid, String connectionListName, String filterPattern)

Returns the number of users (`int`) connected to the identified user. Table 41–13 lists and describes the parameters associated with this method. Table 41–14 lists and describes the attributes associated with this method.

Table 41–13 Parameters of the Method getNumberOfConnections

Parameter	Description
`userid`	The user ID for whom to return the number of connections
`connectionListName`	The name of the connection list from which to obtain a count
`filterPattern`	A filter to use against returned connections, such as "co," which returns `condoleezza` as well as `nicole`

Table 41–14 Attributes of the Method getNumberOfConnections

Attribute	Description
`Int`	The number of connections to return

41.1.2.13 ignoreInvitation(String invitationId)

Specifies that the invitation with the specified ID should be ignored. Table 41–15 lists and describes the parameters associated with this method.

Table 41–15 Parameters of the Method ignoreInvitation

Parameter	Description
`invitationId`	The GUID of the connection invitation to ignore

41.1.2.14 inviteUserForConnection(String userid, String invitationMessage, Collection connectionListNames)

A means of inviting the user with the specified user ID to connect. Includes the invitation message, such as, "I would like you to be my connection." Also includes one or more connection list names to which to add the invitee once the invitation is accepted. Table 41–16 lists and describes the parameters associated with this method.

Table 41–16 Parameters of the Method inviteUserForConnection

Parameter	Description
`userid`	User ID of the invitee
`invitationMessage`	Connection message, such as, "Let's connect!"
`connectionListNames`	The names of the connecitons lists to add the invitee to once the invitation is accepted

41.1.2.15 isConnectionListModifiable(String listName)

Returns true or false (`boolean`) as to whether the named connections list can be modified. Table 41–17 lists and describes the parameters associated with this method. Table 41–18 lists and describes the attributes associated with this method.

Table 41–17 Parameters of the Method isConnectionListModifiable

Parameter	Description
`listName`	The name of the connections list for which to determine whether it can be modified

Table 41–18 Attributes of the MethodisConnecitonListModifiable

Attribute	Description
`boolean`	True or false, depending on whether the named connections list can be modified

41.1.2.16 isConnectionPartOfUnmodifiableList(String connecteeGuid)

Returns true or false (boolean) as to whether the identified user is a member of a connections list that cannot be modified. Table 41–19 lists and describes the parameters associated with this method.

Table 41–19 Parameters of the Method isConnectionPartOfUnmodifiableList

Parameter	Description
`connecteeGuid`	The GUID of the connection for whom to determine whether this connection is a member of a connections list that cannot be modified

41.1.2.17 removeConnection(String userid, boolean fromListOnly, String listName)

A method for removing the identified connection either as a connection or from a connections list. Table 41–20 lists and describes the parameters associated with this method.

Table 41–20 Parameters of the Method removeConnection

Parameter	Description
`userid`	The user name of the connection to remove from the specified list
`fromListsOnly`	A flag (true or false) indicating whether to remove the user as a connection or remove the user only from the specified connections list
`listName`	The name of the connections list from which to remove the specified user

41.1.2.18 searchUsers(String filterPattern, int startIndex, int fetchSize)

Returns the object `Users`, which is a collection of details about returned users, including the user's relational attributes, GUID, and profile details. Table 41–21 lists and describes the parameters associated with this method. Table 41–22 lists and describes the attributes associated with this method.

Table 41–21 Parameters of the Method searchUsers

Parameter	Description
`filterPattern`	A filter to use against returned search terms, such as "co," which returns `condoleezza` as well as `nicole`
`startIndex`	The point from which to start fetching results This is used for pagination. For example, the search can return 50 matching records, and only 10 are needed, starting from 1. Set `startIndex` to 1 and `fetchSize` to 10.
`fetchSize`	The number of results to return (see `startIndex`)

Table 41–22 Attributes of the Method searchUsers

Attribute	Description
`relationalAttributes`	—
`userGuid`	The user's unique GUID
`userProfile`	The user's Profile details

41.1.2.19 updateConnectionListsMembership(String member, Collection addListIds, Collection removeListIds)

Provides a means of updating an identified connection's list membership by adding the connection to identified connections lists and removing the connection from identified connections lists. Table 41–23 lists and describes the parameters associated with this method.

Table 41–23 Parameters of the updateConnectionListsMembership Method

Parameter	Description
`member`	The user name of the member whose connections list membership to manage

Table 41–23 (Cont.) Parameters of the updateConnectionListsMembership Method

Parameter	Description
`addListIds`	The names of the connections lists to which to add the identified user
`removeListIds`	The names of the connections lists from which to remove the identified user

41.1.3 Working with Profile Data Control

The Profile Data Control provides methods for returning and updating Profile details.

The subsections in this section list and describe the methods associated with the Profile Data Control.

41.1.3.1 Method: getProfile(String userId)

A method for returning the `WCUserProfile` object, which is a collection of user Profile details. Table 41–24 lists and describes the parameters associated with this method.

Table 41–24 Parameters for the getProfile Method

Parameter	Description
`userID`	The ID of the user for whom to return Profile details

> **Tip:** To see the attributes associated with the `WCUserProfile` object, expand the `WCUserProfile` node under the `getProfile` method on the Data Controls panel in the Application Navigator.

41.1.3.2 Method: getProfileForUpdate(String userId)

A method for updating the `WCUserProfile` object, which is a collection of user Profile details. Table 41–25 lists and describes the parameters associated with this method.

Table 41–25 Parameters for the getProfileForUpdate Method

Parameter	Description
`userID`	The ID of the user for whom to update Profile details

> **Tip:** To see the attributes associated with the `WCUserProfile` object, expand the `WCUserProfile` node under the `getProfileForUpdate` method on the Data Controls panel in the Application Navigator.

41.2 People Connections Service Java APIs

The People Connections service has associated Java APIs that you can use to work with service features. These include:

- `oracle.webcenter.peopleconnections.connections`
- `oracle.webcenter.peopleconnections.wall`
- `oracle.webcenter.activitystreaming`

Look in *Oracle Fusion Middleware Java API Reference for Oracle WebCenter Portal* for more information

42

People Connections Service REST APIs

Oracle WebCenter Portal provides REST APIs to support the People Connections service. You can use the People Connections service REST APIs to perform the following actions:

- View a stream of your connections' activities in an activity stream
- Browse a profile or connections list
- Update profile status messages
- Create and delete connection lists
- Add and remove members from connection lists
- Create, read, and delete messages
- Read and delete feedback

This chapter describes the REST APIs associated with the People Connections service. It includes the following sections:

- Section 42.1, "Activity Stream REST APIs"
- Section 42.2, "Connections and Profile REST APIs"
- Section 42.3, "Feedback REST APIs"
- Section 42.4, "Message Board REST APIs"
- Section 42.5, "Creating an Invitation"

> **See Also:** For an introduction to the REST APIs, see Chapter 54, "Using Oracle WebCenter Portal REST APIs."

42.1 Activity Stream REST APIs

Use the Activity Stream REST APIs to browse user application activities in an activity stream. This section provides information about the REST APIs to use to perform this action. It includes the following subsections:

- Section 42.1.1, "Activity Stream Entry Point"
- Section 42.1.2, "Activity Stream Resource Type Taxonomy"
- Section 42.1.3, "Activity Stream Security Considerations"
- Section 42.1.4, "Activity Stream Resource Types"

Note: Because REST APIs can be configured in many different ways, it's possible that not all of a user's activities will be returned, allowing the REST client to customize how the Activity Stream behaves separately from the Webcenter Portal application.

42.1.1 Activity Stream Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. For the People Connections service, each feature has its own link element. For example, to find the entry point for the Activity Stream feature of the People Connections service, find the link elements with a `resourceType` of:

```
urn:oracle:webcenter:activities:stream
```

The corresponding `href` or `template` element provides the URI entry point, which retrieves application activities for the current user from the Activity Stream. The client sends HTTP requests to this entry point to work with the Activity Stream feature of the People Connections service.

See Also: For more information about the Resource Index, see Section 54.5.1, "The Resource Index."

For more information about resource types, see Section 54.5.2.1, "Resource Type."

42.1.2 Activity Stream Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.1.4, "Activity Stream Resource Types."

The resource type taxonomy for the Activity Stream feature of the People Connections service is:

```
urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:activity
```

42.1.3 Activity Stream Security Considerations

You must be logged in to the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

See Also: For general security considerations, see Section 54.8, "Security Considerations for WebCenter Portal REST APIs."

42.1.4 Activity Stream Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:activities:stream"
- "urn:oracle:webcenter:activities:activity"

urn:oracle:webcenter:activities:stream

The `stream` response contains URIs for use in retrieving activities from the Activity Stream.

You can retrieve the activities from a user's stream or activities from a user's connections' streams. To have even greater control over which activities to retrieve, use the activity stream query filter. With the query filter, you can:

- Specify the user to query
- Include the user's connections' activities in the results
- Include activities from spaces, including the Home space, in the results
- Restrict the results to activities from specific services

The options available to you depend on the path you take to get to the `stream` resource and the `rel` of the link that you use. For example, the activity stream query filter is available only from links with a `rel` attribute of `urn:oracle:webcenter:activities:stream`. If you access the activity stream query filter from the `person` resource, the `personGuid` parameter is prefilled.

Table 42–1 shows the activities returned depending on the `rel` element of the link.

Table 42–1 Activities Returned by stream

rel	Returns
`urn:oracle:webcenter:activities:stream:person`	Activities from the user's stream (*`GUID`*`/@self`)[1]
`urn:oracle:webcenter:activities:stream:connections`	Activities from the user's connections' streams (*`GUID`*`/@connections`)[1]
`urn:oracle:webcenter:activities:stream`	Activities determined by the activity stream query filter
`urn:oracle:webcenter:activities:stream:space`	Activities from the space activity stream
`urn:oracle:webcenter:activities:stream:list`	Activities from the space activity list

[1] *`GUID`* can be any valid user GUID or `@me`.

Navigation Paths to stream

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceIndex
   stream (rel="urn:oracle:webcenter:activities:stream:person" or
               "urn:oracle:webcenter:activities:stream")

resourceIndex
   person
      stream (rel="urn:oracle:webcenter:activities:stream:person" or
                  "urn:oracle:webcenter:activities:stream:connections" or
                  "urn:oracle:webcenter:activities:stream")

resourceIndex
   person
      list
         stream

resourceIndex
   space
```

```
      stream

stream
   activity
      param
         stream (rel="urn:oracle:webcenter:activities:stream:space")

personReference
   stream
```

Supported Methods for stream

The following method is supported by the `stream` resource:

- `GET`
  - **request—Parameters:**
    - `startIndex`, `itemsPerPage`

      See Also: For information about REST API parameters, such as `startIndex` and `itemsPerPage`, see "Common Request Query Parameters".

      The following additional parameters are available for the query filter URI:

      - `data` – Returns specified data only (for more information, see "Common Request Query Parameters"). For the stream resource, if you specify the constant `'data'` as the data parameter, all of the basic information about the resource is returned except "comments" and "likes" summaries. If you want to return comments or likes, specify the `data` parameter value `'commentsSummary'` or `'likesSummary'`.

      Note: You can specify multiple data values as a comma separated list. For example, `data=data, commentsSummary`.

      - `personGuid`—(Required) Retrieves activities from the stream for the specified user. **Valid values:** any valid user GUID or `@me`.
      - `serviceIds`—Retrieves activities only for the specified services. **Valid values:** An asterisk (*) returns all services. If null or empty, uses the user preference settings for service filters (from the settings link in the top bar).
      - `personal`—Includes the specified user's activities in the Home space. **Valid values:** `true` or `false`. **Default value:** `false`.
      - `connections`—Includes activities from the streams of the specified user's connections. **Valid values:** `true` or `false`. **Default value:** `false`.
      - `groupSpaces`—Includes activities from all spaces of which the specified user is a member. **Valid values:** `true` or `false`. **Default value:** `false`.
      - `connectionListIds` – A comma separated list of connection list names that specifies the connection lists used to show activities.
      - `groupSpaceGuids` – A comma separated list of space GUIDs used to show activities.

* `userGroupSpaceActivities` – Specifies whether or not to show the user's activities in their spaces. **Valid values:** `true` or `false`. **Default value:** `false`.
* `followedObjects` – Specifies whether or not to show all activities for followed objects that both the current user and the specified user follow. **Valid values:** `true` or `false`. **Default value:** `false`.
* `followedObjectsUserActivities` – Specifies whether or not to show the specified user's activities for followed objects that both the current user and the specified user follow. **Valid values:** `true` or `false`. **Default value:** `false`.
* `advancedQuery` – Specifies filters against streamed activities. Create filters for user names, service IDs, and object details, such as a document's display name.

Note: You must plug actual values into the `advancedQuery` parameter. You cannot pass EL expressions directly into the parameter. Typically, the REST API client handles an EL transformation manually and inserts the actual object data value into the REST URL. See the example below, and see also Section 40.3, "What You Should Know About the Activity Stream Advanced Query Option."

For example, the following URI returns activities from the current user's activity stream, for all services that the user has configured in their personal preference settings for service filters. It returns activities from the user's personal space and from the streams of the user's connections:

```
http://host:port/rest/api/activites?personal=true&connections=true&personGu
id=@me&token=token
```

The following URI returns only the user's personal profile and connections activities:

```
http://host:port/rest/api/activities?serviceIds=oracle.webcenter.peopleconn
ections.profile,oracle.webcenter.peopleconnections.connections&personal=
true&personGuid=@me&token=token
```

This next example illustrates how to use the `advancedQuery` parameter. As explained previously, you cannot pass an EL expression to `advancedQuery`. The REST API client must first obtain the actual data object value, and that value can then be passed to `advancedQuery`. For example, to filter activities for a particular space, you can pass the GUID of the space's scope to `advancedQuery`:

```
http://host:port/rest/api/activities?personGuid=@me&advancedQuery=AE.SCOPE_
ID%20%3D%20\%27s8bba98ff_4cbb_40b8_beee_296c916a23ed\%27&ttoken=token
```

where `s8bba98ff_4cbb_40b8_beee_296c916a23ed` is the GUID of the space. Note that the query string must be encoded with the appropriate escape codes. For a list of EL expressions that can be used to obtain values for `advancedQuery`, see Section 40.3, "What You Should Know About the Activity Stream Advanced Query Option."

– **response—Body:** 0 or more activities

Note: Because the `stream` resource includes activity items, the response may also return resource links for the objects referenced in the activity.

Resource Types Linked to From stream

Table 42–2 lists the resource types that the client can link to from the `stream` resource.

Table 42–2 Related Resource Types for stream

rel	resourceType
self urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
	urn:oracle:webcenter:activities:activity

urn:oracle:webcenter:activities:activity

The `activity` response contains the data for activities and URIs for use in retrieving all the data you need from an activity that is included in an Activity Stream.

Navigation Paths to activity

This section shows how the client can navigate through the hypermedia to access the `activity` resource:

```
resourceIndex
   stream
      activity

resourceIndex
   person
      stream
         activity

resourceIndex
   space
      stream
         activity
```

Supported Methods for activity

No methods are supported for `activity`. Activities are currently available only from the `stream` resource type.

Resource Types Linked to from activity

Table 42–3 lists the resource types that the client can link to from this resource.

Table 42–3 Related Resource Types for urn:oracle:webcenter:activities:activity

rel	resourceType
self	`urn:oracle:webcenter:activities:activity`
icon	`urn:oracle:webcenter:activities:activity:icon`

Read-only Elements for activity

Table 42–4 lists the read-only elements for the `activity` resource.

See Also: For information about `projection`, see "Common Request Query Parameters".

Note: The activity will also return a link to an activity icon in the links section of the response, if an icon is available. See urn:oracle:webcenter:activities:activity:icon.

Table 42–4 Read-Only Elements for activity

Element	Type	Description
`activityType`	String	Activity type Unique within the service. For example the Discussions service can return the `activityType` `createForum`.
`commentsCount`	String	If you specify `commentsSummary` in the data parameter, then the `commentsCount` parameter will be returned.
`createdDate`	Date (String)[1]	Date the activity was created.
`description`	String	The description of the activity.
`detail`	String	Detail information for the activity, if available. For example, this might return the contents of a message, the file name of a document, and the like. Similar to `detailURL`. Both, either, or neither can be used.
`detailURL`	String	Detail information for the activity, if available. Similar to `detail`. Both, either, or neither can be used.
`displayDescription`	String	A pre-formatted, internationalized description.
`displayMessage`	String	A pre-formatted, internationalized message (does not include template information).
`groupSpace`	groupSpaceReference	Information about the space in which the activity was performed **Note:** This reference is not present for activities that did not happen in a space (for example, activities that happened in the Home space). Also, because creation of a space happens in a personal space, that activity does not have this element either.
`id`	String	Unique ID of the message
`isSummary`	true or false	Indicates whether or not this activity is a summary of other activities.
`likesCount`	String	If you specify `likesSummary` in the data parameter, then the `likesCount` parameter will be returned.
`message`	String	Localized string for this activity This may contain replacement strings within curly braces ({}).

Table 42–4 (Cont.) Read-Only Elements for activity

Element	Type	Description
`permission`	PRIVATE SHARED PUBLIC	Permission level of this activity
`scope`	String	Scope of the activity This might return a space, like the Home space. For example, for a space, it returns a string similar to the following: `s8bba98ff_4cbb_40b8_beee_296c916a23ed`
`serviceId`	String	Unique ID of the service that created the activity **Note:** For a list of WebCenter Portal service IDs, see Table G–7, " Service IDs".
`templateParams`	urn:oracle:webcenter:activities:parameter	A list of `param` elements that capture data related to an activity. A key provided with each `templateParam` <param> element allows you to plug one or more data items into a parameterized activity message. See "Understanding the templateParams Element".
`custom`	Param	The custom parameter includes a `displayName`, `key`, and `type`, and may or may not have a URL.

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`. The `DATE` data type returns a Java standard date format, for example, `2009-08-21T14:43:11.0013-0700`, with `0700` representing the time zone.

Understanding the templateParams Element

Suppose you want to display the most recent messages for a user named Carl. You want to display information like this: "Carl created the space Customer Feedback". The `templateParams` elements helps you solve this problem.

The `templateParams` element is returned in objects of type `oracle:webcenter:activities:activity`. This element captures a lot of data related to an activity. For example, if a user creates a new space, the `templateParams` element for that activity captures information about the user and about the space. Keys are provided that allow you to perform string substitutions in a parameterized message string related to the activity.

For example, if the user creates a space, the returned activity object contains a `<message>` item that is parameterized like this:

```
<message>{actor[0]} has created the space {object[0]}</message>
```

By parsing the `templateParams` element for the activity, you can find the available keys that allow you to perform string substitutions as well as appropriate data to display, like the name of the user and the activity.

For a detailed example showing how you might code a UI using `templateParams` to display information about an activity, see Section 54.13.2, "Displaying Activity Stream Data."

The templateParams element also provides links to comments, likes, commentsSummary, and likesSummary objects, if they are requested using the data parameter. These links let you query for all the comments or likes for an object or post a new comment or like. The summary links returns the comments or likes count and several recent comments or likes. See also "Understanding Comments and Likes".

The links returned with the templateParams element vary depending on what kind of object is returned, like a user, document, space (GS), or custom object. For more information, see "urn:oracle:webcenter:activities:parameter".

> **Note:** The templateParams element can sometimes contain elements that are not directly referenced in the message.

If a rel link is marked "via," this means it is a link to the underlying REST object–for instance, the document not the parameter. If a rel link is marked "alternate" and type "text/html," it is a link to the HTML page for that object. Space (GS) objects include an activity stream link for spaces. Users have icon and activity stream links. Other objects can have an alt link to the tagged item, as well as the related tagged items list, if tagging is enabled for that object. If a regular object supports comments or likes, it can include the comments/commentsSummary and likes/likesSummary, as explained previously.

Understanding Comments and Likes

Likes and Comments only show up if they are requested using the data parameter. They do not appear by default. Comments are associated with the object referenced by the activity, not the activity itself. For example, if you edit a document, then the comments will be associated with the document, not the edit activity. This means that if you "like" the document, then the comments from editing it will also show up.

The links associated with comments and likes are:

- comments – The comments link lets you query for all the comments for an object. This link also lets you POST a new comment. For a comments POST, the text field is required.
- commentsSummary – The commentsSummary link returns the comments count and several recent comments.
- likes – The likes link lets you query for all the likes for an object. This link also lets you POST a new like. There are no required fields for a likes POST.
- likesSummary – The likesSummary link returns the likes count and the current user's like (if available).

> **Note:** Like objects themselves only support DELETE, not GET. The likesCount and commentsCount items return the number of likes or comments for the current object.

urn:oracle:webcenter:activities:parameter

The templateParams element returns a set of param elements. The param elements return data specific to the type of activity object returned. The possible types of param elements include:

- user – Returns the displayName, guid, id, key, primaryId, and type.

- `document` – Returns the `displayName`, `iconUrl`, `id`, `key`, `primaryId`, and `type`.
- `custom` – Returns `displayName`, `key`, and `type`, and may or may not have a URL.

A param can also be a variable reference or key of the general form `{prefix[index].variable}`.

urn:oracle:webcenter:activities:activity:icon

Use this resource type to get the icon of the activity, if available (`GET`).

Navigation Paths to activities:activity:icon

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   activities
      activity
         icon
```

Supported Methods for icon

The following methods are supported by this resource:

- `GET` – Returns the icon used for the named activity.

Resource Types Linked to from icon

Table 42–5 lists the resource types that the client can link to from this resource.

Table 42–5 Related Resource Types for urn:oracle:webcenter:activities:activity:icon

rel	resourceType
self	`urn:oracle:webcenter:activities:activity:icon`
urn:oracle:webcenter:parent	`urn:oracle:webcenter:activities:activity`

42.2 Connections and Profile REST APIs

Use the Connections and Profile REST APIs to browse a profile or a connections list, manage connections lists, add or remove connections, send invitations to connect, and update a profile status message.

This section provides information about the REST APIs to use to perform these actions. It includes the following subsections:

- Section 42.2.1, "Connections and Profile Entry Point"
- Section 42.2.2, "Connections and Profile Resource Type Taxonomy"
- Section 42.2.3, "Connections and Profile Security Considerations"
- Section 42.2.4, "Connections and Profile Resource Types"

42.2.1 Connections and Profile Entry Point

Each REST service has a link element within the Resource Index that provides the entry point for that service. For the People Connections service, each feature has its own link element. For example, to find the entry points for Connections and Profile

features of the People Connections service, find the link elements with a `resourceType` of:

`urn:oracle:webcenter:people` (returns the current user profile)

`urn:oracle:webcenter:people:person` (enables you to query for a user)

`urn:oracle:webcenter:people:invitations` (returns invitations sent or received by the current user)

Note: The `people:person` and `people:invitations` resource types have a `template` but not an `href`.

The corresponding `href` or `template` element provides the URI entry point, which returns a list of people (`people`) or an individual user (`people:person`). The client sends HTTP requests to this entry point to work with the Connections and Profile features of the People Connections service.

See Also: For more information about the Resource Index, see Section 54.5.1, "The Resource Index."

For more information about resource types, see Section 54.5.2.1, "Resource Type."

42.2.2 Connections and Profile Resource Type Taxonomy

When the client has identified the entry point, it can then navigate through the resource type taxonomy to perform the required operations. For more information about the individual resource types, see the appropriate section in Section 42.2.4, "Connections and Profile Resource Types."

The resource type taxonomy for the Connections and Profile features in the People Connections service is:

```
urn:oracle:webcenter:people
   urn:oracle:webcenter:people:person
   urn:oracle:webcenter:people:icon
   urn:oracle:webcenter:people:person:list
      urn:oracle:webcenter:people:person:listNames
      urn:oracle:webcenter:people:person:listName
      urn:oracle:webcenter:people:person:list:member
      urn:oracle:webcenter:people:person:status
   urn:oracle:webcenter:people:invitations
      urn:oracle:webcenter:people:invitation
```

42.2.3 Connections and Profile Security Considerations

You must be logged in to the REST service to access any of the People Connections REST APIs. After that, the underlying service handles permission checking and the like.

See Also: For general security considerations, see Section 54.8, "Security Considerations for WebCenter Portal REST APIs."

42.2.4 Connections and Profile Resource Types

This section provides you with all the information you need to know about each resource type. It includes the following subsections:

- "urn:oracle:webcenter:people"
- "urn:oracle:webcenter:people:person"
- "urn:oracle:webcenter:people:person:list"
- "urn:oracle:webcenter:people:person:listNames"
- "urn:oracle:webcenter:people:person:listName"
- "urn:oracle:webcenter:people:person:list:member"
- "urn:oracle:webcenter:people:person:status"
- "urn:oracle:webcenter:people:invitations"
- "urn:oracle:webcenter:people:invitation"

urn:oracle:webcenter:people

The `people` response contains URIs for use in retrieving the profile of one or more users.

Navigation Paths to people

This section shows how the client can navigate through the hypermedia to access the `people` resource:

```
resourceIndex
   people
```

Supported Methods for people

The following method is supported by the `people` resource:

- `GET`
  - **request—Parameters:**
    - `startIndex` – See "Common Request Query Parameters."
    - `itemsPerPage` – See "Common Request Query Parameters."
    - `projection` – See "Common Request Query Parameters."
    - `data` – The data parameter is a comma separated list that controls which data will be returned in the response. The predefined set `basic` is equivalent to `data=guid,id,displayName`. The predefined set `data` is a standard set that returns all the data for the user, but does not include `status`, `manager`, `reportees`, or `photos`. The full list of possible values includes the predefined sets `basic` and `data`, as well as the following individual data values: `guid`, `id`, `displayName`, `birthday`, `language`, `timeZone`, `name`, `addresses`, `organizations`, `workEmail`, `phoneNumbers`, `manager`, `reportees`, `photos`, and `status`.

      If you specify the constant `'data'` as the `data` parameter, all the basic information will be returned for the resource. If both the `projection` and `data` query string parameters are present, the `data` parameter will be used to determine which data to return.

      The `data` parameter can also take any of the following values comma-separated values to return the corresponding data: `guid`, `id`, `displayName`, `birthday`, `language`, `timeZone`, `name`, `addresses`, `organizations`,

workEmail, phoneNumbers, manager, reportees, photos, and/or status.

Note: The data parameter can accept a predefined set, a collection of values, or a mix of sets and values. For example, to get the basic data plus the user's birthday, you can specify data=basic,birthday.

* links – The links parameter is a comma-separated list that controls which links will be returned in the response. This parameter can accept predefined sets, individual data values, or a combination of predefined sets and individual data values. The predefined sets are basic, data, activitiesSet, connectionsSet, and feedbackSet. These predefined sets are described in "Predefined Sets for the links Parameter".

  The individual values for the links parameter are: person, profile, icon, status, messageBoard, activities, personActivities, connectionActivities, connections, listNames, invitation, givenFeedback, receivedFeedback, userGivenFeedback, manager, reportees, member.

  If both the projection and links query string parameters are present, the links parameter will be used to determine which links to return.

– **response—Body:** One or more person objects.

Predefined Sets for the links Parameter

The following items are predefined sets that can be returned in the links parameter. For example, if you specify links=basic, it is the equivalent of specifying data=person,profile,icon. You can also specify additional parameters as needed. For example, you could specify data=basic,birthday.

Note: Links that are not currently available will not be returned even if they are specified in the links parameter.

- basic – A standard set that returns the basic information for the profile and includes person, profile, and icon.
- data – A standard set that returns all the basic links for the response plus the connections list, status, and activity stream template.
- activitiesSet – Includes activities, personActivities, and connectionActivities.
- connectionsSet – Includes connections, listNames, and invitation.
- feedbackSet – Includes givenFeedback, receivedFeedback, and userGivenFeedback.

Resource Types Linked to from people

Table 42–6 lists the resource types that the client can link to from the people resource.

Table 42–6 Related Resource Types for people

rel	resourceType
urn:oracle:webcenter:people:icon	urn:oracle:webcenter:people:person

Table 42–6 (Cont.) Related Resource Types for people

rel	resourceType
urn:oracle:webcenter:people:person:list:connections	urn:oracle:webcenter:people:person:list
urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream:connections	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback
urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
self	urn:oracle:webcenter:people:person:status
urn:oracle:webcenter:people:person:list:list	urn:oracle:webcenter:people:person:list
self	urn:oracle:webcenter:people:person:listName
urn:oracle:webcenter:activities:stream:list	urn:oracle:webcenter:activities:stream

urn:oracle:webcenter:people:icon

Use this resource type to get the icon used for the named profile (`GET`).

Navigation Paths to people:icon

This section shows how the client can navigate through the hypermedia to access this resource:

```
resourceindex
   people
      icon
```

Supported Methods for icon

The following methods are supported by this resource:

- `GET` – Returns the icon used for the named profile.

> **Note:** This resource includes a template that lets you choose the size of the profile icon to use. The `size` template parameter can be set to `small`, `medium`, or `large`.

Resource Types Linked to from icon

Table 42–7 lists the resource types that the client can link to from this resource.

Table 42–7 Related Resource Types for urn:oracle:webcenter:people:icon

rel	resourceType
self	`urn:oracle:webcenter:people:icon`
urn:oracle:webcenter:parent	`urn:oracle:webcenter:people`

urn:oracle:webcenter:people:person

The `person` response contains profile data and the URIs for use in retrieving a user profile.

Navigation Paths to person

This section shows how the client can navigate through the hypermedia to access the `person` resource:

```
resourceIndex
   people

resourceIndex
   people
      person

resourceIndex
   person

author
   person

resourceIndex
   activities:stream
      person
```

Supported Methods for person

The following method is supported by the `person` resource:

- `GET`
  - **request—Parameters:** `q`

    To retrieve a specified person, the format of `q` is:

    ```
    q=[loginid:equals:username]
    Or
    q=[guid:equals:guid]
    Or
    q=[email:equals:email]
    ```

    Note: The parameter `q` is only on the `resourceIndex` template for `person`.

  - **response—Body:** `message`

    See Also: For information about the response `message`, see "Read-only Elements for person".

Read-only Elements for person

Table 42–8 lists the read-only elements for the `person` resource.

Note: The elements present in a `person` response depend on how the user repository is configured and the elements it supports. Additionally, several of the pieces of data represented in Table 42–8, such as `address`, `emails`, `photos`, `phoneNumbers`, and `organization`, can have multiple instances.

See Also: Some of the elements listed in Table 42–8 can be returned in predefined sets described in "Predefined Sets for the links Parameter".

Table 42–8 Read-Only Elements for person

Element	Type	Description
`guid`	String	Unique GUID of the person
`id`	String	Unique login ID of the person (that is, the user name, for example, pat_coi)
`displayName`	String	Display name of the person (the user's name, for example, Pat Coi). This may have the same value as `id`, depending on the repository configuration.
`birthday`	Date (String)[1]	Birth date of the person
`connected`	Boolean (String)1	Whether or not this person is connected to the current user
`language`	String	Preferred language of the person
`timeZone`	String	Time zone of the person
`name`	`name`	Name information for the person `name` is a portable contact type. For more information, see Section 54.10.2.1, "name Portable Contact Type."
`address`	`address`	Address information for the person address is a portable contact type. For more information, see Section 54.10.2.2, "address Portable Contact Type."
`emails`	`value`	Emails for the person `emails` is derived from the `value` portable contact type. For more information, see Section 54.10.2.4, "value Portable Contact Type."
`photos`	`value`	Profile photos for the person `photos` is derived from the `value` portable contact type. For more information, see Section 54.10.2.4, "value Portable Contact Type."
`phoneNumbers`	`value`	Phone numbers for the person `phoneNumber` is derived from the `value` portable contact type. For more information, see Section 54.10.2.4, "value Portable Contact Type."
`organizations`	`organization`	Organization information for the person organization is a portable contact type. For more information, see Section 54.10.2.3, "organization Portable Contact Type."

Table 42–8 (Cont.) Read-Only Elements for person

Element	Type	Description
`manager`	personReference	Manager of this person
`reportees`	personReference	Direct reports of this person
`status`	urn:oracle:webcenter:people:person:status	Person's profile status message

[1] Data types, such as `DATE` and `BOOLEAN`, are stored in the API as `STRING`.

Resource Types Linked to from person

Table 42–9 lists the resource types that the client can link to from the `person` resource.

Table 42–9 Related Resource Types for person

rel	resourceType
self	urn:oracle:webcenter:people:person
alternate	urn:oracle:webcenter:spaces:profile (HTML)
urn:oracle:webcenter:people:person:list:connections	urn:oracle:webcenter:people:person:list
	urn:oracle:webcenter:people:person:listNames
	urn:oracle:webcenter:people:person:status
urn:oracle:webcenter:activities:stream:person	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream:connections	urn:oracle:webcenter:activities:stream
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream
	urn:oracle:webcenter:messageBoard
urn:oracle:webcenter:feedback:all-given	urn:oracle:webcenter:feedback
urn:oracle:webcenter:feedback:all-received	urn:oracle:webcenter:feedback

urn:oracle:webcenter:people:person:list

The `list` response contains URIs for use in retrieving all the profiles on a connections list (`GET`), inviting a user to be a connection or adding a connection to a connections list (`POST`), and removing a connections list (`DELETE`).

Navigation Paths to list

This section shows how the client can navigate through the hypermedia to access the `list` resource:

```
resourceIndex
   person
      listNames
         list

resourceIndex
   person
      list (rel="urn:oracle:webcenter:people:person:list:connections")
```

Supported Methods for list

The following methods are supported by the `list` resource:

- `GET`
  - **request—Parameters:** `startIndex`, `itemsPerPage`, `projection`

See Also: For information about REST API parameters, such as `startIndex` and `itemsPerPage`, see "Common Request Query Parameters".

  - **response—Body:** 0 or more `person` items

- `POST`
  - **request—Body:** `member`
  - **response—Body:** `member`

    See Also: For information about `member` in the request and response elements, see "urn:oracle:webcenter:people:person:list:member".

- `DELETE`
  - **request**

Resource Types Linked to from list

Table 42–10 lists the resource types that the client can link to from the `list` resource.

Table 42–10 Related Resource Types for list

rel	resourceType
self urn:oracle:webcenter:people:person:list[1]	urn:oracle:webcenter:people:person:list
urn:oracle:webcenter:activities:stream	urn:oracle:webcenter:activities:stream
