# 1. Preface

## 1.1 Introduction

This manual is designed to help acquaint you with the Job scheduling process in Oracle FLEXCUBE.

## 1.2 Audience

This manual is intended for the following User/User Roles:

Role	Function
Back office data entry Clerks	Input functions for maintenance related to the interface.
Back office Managers/Officers	Authorization functions.

## 1.3 Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at <http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc>.

## 1.4 Acronyms and Abbreviations

Abbreviation	Description
System	Unless and otherwise specified, it shall always refer to Oracle FLEX-CUBE system

## 1.5 Organization

This manual is organized as follows:

Chapter	Description
Chapter 1	<i>About this Manual</i> gives information on the intended audience. It also lists the various chapters covered in this User Manual.
Chapter 2	<i>Job Scheduling</i> explains about the process of defining, scheduling, and maintaining Jobs within the module.
Chapter 3	<i>Function ID Glossary</i> has alphabetical listing of Function/Screen ID's used in the module with page references for quick navigation.

## 1.6 Glossary of Icons

This User Manual may refer to all or some of the following icons:

Icons	Function
-------	----------

	Exit
	Add row
	Delete row
	Option List

## 2. Job Scheduling

Job scheduling is the process where different tasks get executed at pre-determined time or when the right event happens. A job scheduler is a system that can be integrated with other software systems for the purpose of executing or notifying other software components when a pre-determined, scheduled time arrives. The two types of job schedulers used in Oracle FLEXCUBE FCJ architecture are as follows:

- Quartz - provides scheduler interface to enable operations such as scheduling and un-scheduling of jobs and starting, stopping, pausing the scheduler
- Flux - software component used for performing enterprise job scheduling

This chapter contains the following sections

- [Section 2.1, "Defining Jobs"](#)
- [Section 2.2, "Scheduling Jobs"](#)
- [Section 2.3, "Controlling Jobs"](#)
- [Section 2.4, "Notification Process"](#)
- [Section 2.5, "Viewing Notification Parameters"](#)
- [Section 2.6, "EMS Process with Scheduling Architecture"](#)
- [Section 2.7, "Approach"](#)

### 2.1 Defining Jobs

A job is a business activity which the system performs repeatedly on timely basis. Oracle FLEXCUBE enables you to define a job and schedule it using 'Job Maintenance' screen. You can invoke this screen by typing 'STDJOBMT' in the field at the top right corner of the Application tool bar and clicking on the adjoining arrow button.

The screenshot displays the 'Job Maintenance' application window, specifically the 'New' form. The form is organized into three main sections:

- Job Description:** Contains fields for Job Code (required), Job Description, Job Group, Job Type (dropdown), Max Number Instances (required), Scheduler, Trigger Type (dropdown), Scheduler Type (dropdown), Priority (dropdown), and Message Queue. A 'Validate' button is located below these fields.
- Job Details:** Contains fields for Cron Expression, Class Or Procedure, No of Submissions, Interval In Seconds, Trigger Listener (with an 'Active' checkbox), Ds Name (with 'Logging Required' and 'Veto Blocked Trigger' checkboxes), and Startup Mode (dropdown).
- Parameter Details:** Features a table with columns for Parameter Name, Data Type, and Parameter Value. It includes a 'Go' button and navigation arrows.

The bottom status bar includes fields for Maker, Date Time, Mod No, Record Status, Checker, Date Time, Authorization Status, and an 'Exit' button.

You can specify the following fields in this screen.

**Job Code**

Specify the unique code to identify the Job.

**Job Description**

Specify a brief description of what the job is supposed to do.

**Job Group**

Specify the job group name to represent the same group of jobs for identification.

**Job Type**

Select the type of job from the drop-down list. The following options are available for selection:

- PL/SQL
- JAVA

**Max Number Instances**

Specify the maximum number of instances that needs to be queued up.

**Example**

If a job runs for more than the duration defined, the next instance of the same job will be ready for processing. This parameter defines the job's behavior in such cases,

If you maintain the job as 'STATEFUL', then the number of such missed instances will be queued up so that it would start executing once this long running job ends. This field specifies the number of such job instances that needs to be queued up.

If you maintain the job as 'STATELESS', it indicates the number of threads that can be executed in parallel.

If you maintain the max number instances as '0',no instances are queued or parallel processed till the current running instance is completed.

**Scheduler**

Specify the name of the scheduler. The system defaults the name to 'SchedulerFactory'. However, you can modify this name. This signifies the scheduler name which is configured as part of infra.

**Trigger Type**

Select the type of the trigger from the drop-down list. The following options are available:

- Simple - Interval based jobs.(i.e., every one hour)
- Cron - Time based jobs.(i.e., Friday 4:30PM)

---

**Note**

When scheduler trigger type is set to 'CRON', and the parameter is 'TIMEZONE', then the system triggers the jobs based on the time zone set. If the 'TIMEZONE' property is not available, then the server time zone will be used to trigger the scheduler job.

---

**Scheduler Type**

Select the type of scheduler from the drop-down list. The following options are available:

- Quartz
- Flux

**Priority**

Select the priority on which the system should execute the jobs in the scheduler from the drop-down list. The following options are available.

- Normal
- High
- Low

If two jobs with different priorities fire at the same time, then system gives preference to the job with higher priority.

**Message Queue**

Specify the default JMS queue to which a job needs to send message. You can specify this only if the job has to send messages to JMS.

**Cron Expression**

Specify the corresponding Cron expression for a job with trigger type as 'Cron'. You need to do this to determine the time and interval of job firing.

**Class or Procedure**

Specify the Java class file name if job type is 'Java' or the PL/SQL procedure name if the job type is 'PL/SQL'. This denotes which java class or pl/sql procedure the system should call when a job fires.

**Number of Submissions**

Specify the number of times a job can fire before it is unscheduled from scheduler. This applies only to trigger types maintained as 'Simple'.

**Interval**

Specify the time interval between jobs. This applies only to trigger types maintained as 'Simple'.

**Trigger Listener**

Specify a java class as a trigger listener which will be notified of events such as before job fired, after job completed, misfired jobs.

**Active**

Check this box to set the job as active. The scheduler does not pick the inactive jobs for scheduling.

**Ds Name**

Specify the name of the database schema to which the job has to connect. This attribute is used in case of multi instance deployment of Oracle FLEXCUBE application.

**Logging Required**

Check this box to indicate that system should log each firing of job. This helps in logging the firing time of job and key log info as part of that firing. This also enables tracking of each job's firing times and helps in identifying miss-fired jobs.

**Startup Mode**

Specify start up mode of the job from the drop-down list. The following options are available:

- Auto - The job starts automatically when Oracle FLEXCUBE application starts
- Manual - You should start the job manually in job controller by resuming the job.

## **Parameter Details**

You can specify the job specific parameters, which are passed to job class or procedure at runtime. The following details are captured here:

### **Parameter Name**

Specify the name of the job parameter. The parameter name you specify here is passed to job class or procedure at run time.

### **Data Type**

Specify the data type of the parameter.

### **Parameter Value**

Specify the value of the parameter.

## **2.2 Scheduling Jobs**

All jobs for scheduling are stored in a static data store and each job is associated with a name indicating where the job has to execute. Jobs are created in the Application Server and are scheduled based on this data.

---

### **Note**

The job name should be unique across the schedulers available in the system.

---

When the application server starts, the job details from static data store will get cached. These cached jobs will then be scheduled using either the quartz or flux scheduler.

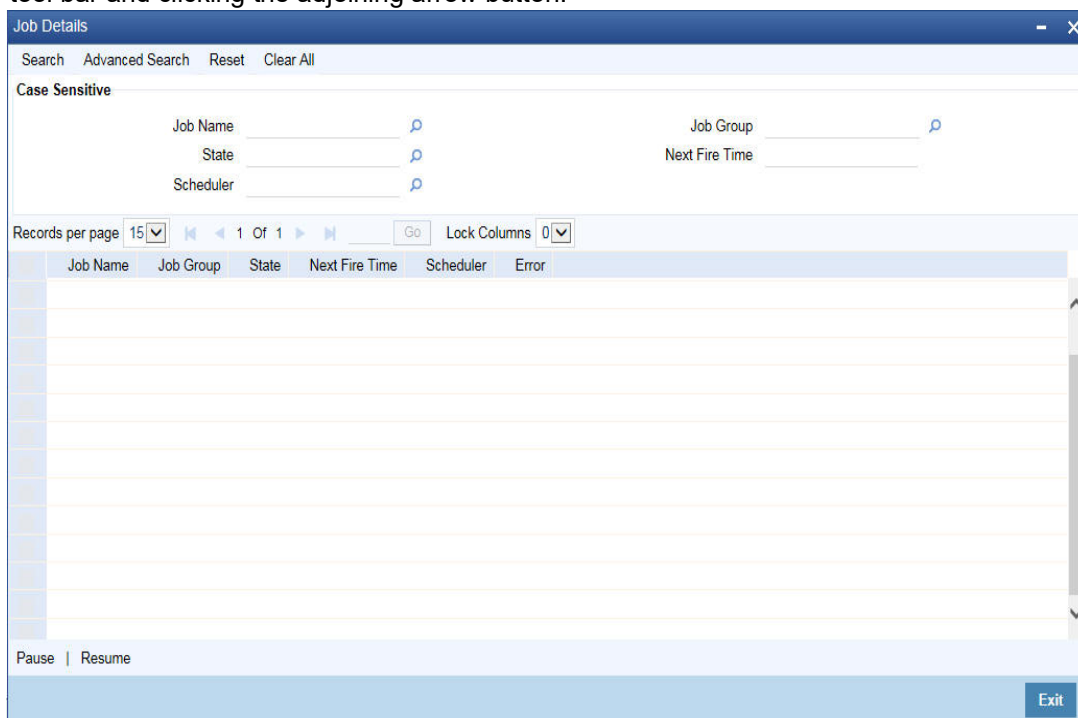

For example, the notification process can be handled by the job schedulers as follows:

1. When a contract is created in Oracle FLEXCUBE, a database level trigger acting on the contract main table inserts details like base table name, primary key fields, primary key values and branch code into a notification log table and sets the process status of the inserted record as 'U' (unprocessed).
2. The scheduled job polls the notification log table for unprocessed records and validates whether notification is required.
3. If notification is not required, then the process status is set to 'N' (not required) in notification log table.
4. If notification is required then notifications are sent to the respective destination and the process status of the record is changed to 'P' (Processed) in notification log table.

## **2.3 Controlling Jobs**

The details of jobs that are scheduled can be viewed using the 'Job Details' screen. In this screen you can pause or resume a job that has been scheduled. You can submit the records as a job for replication in the branch database through this screen. You can invoke the 'Job

Details' screen by typing 'SMSJBBRW' in the field at the top right corner of the Application tool bar and clicking the adjoining arrow button.

You can search for a scheduled job by specifying any of the following:

#### **Job Name**

Select the name of the job that you want to search for from the option list provided.

#### **State**

Select the state of the job you want to search for from the option list provided. The following options are possible for Quartz schedulers:

- Acquired
- Waiting
- Blocked
- Paused
- 

#### **Scheduler**

Select the scheduler to which the job you want to search for has been assigned.

#### **Job Group**

Select the group to which the job you want to search for belongs, from the option list provided.

#### **Next Fire Time**

Select the time when the job is scheduled to be run next.

Click 'Search' button to view the details related to the job. You can pause a job by selecting it and clicking the 'Pause' button.

You can resume a paused job by clicking 'Resume' button and the job is scheduled for its next fire time.

A job can take any of the following states.

- SCHEDULED -This indicates that the message is processed.
- NOT SCHEDULED -This indicates that the message processing is not scheduled.
- PAUSED - This indicates that the job is manually paused from executing.
- ERROR - A job trigger arrives at the 'Internal Server Error' state when the scheduler attempts to fire it, but cannot due to an error creating and executing its related job, hence pausing the job. Also, a job arrives at ERROR state for the following reasons.:
  - When the associated class for the job is not present in class path
  - If during setup, the queue has not been created, but a job has been created for that queue.
  - If call to the Scheduler EJB has failed.
  - If job related pooling tables are invalid.

---

**Note**

Each job is created with the location code maintained in the table `sttm_flexbranch_loc` runs for the respective branch location.

If a new branch is added to the bank for branch replication then the application should be restarted to add that particular branch in the 'Job Details' screen.

---

## 2.4 Notification Process

The notification process is in two layers. In the first layer the notification process as part of jobs in FCJ scheduler sends minimal data required for notification to an internal JMS queue. In the second layer the notification process as part of an MDB that listens on internal JMS queue builds final notifications and sends them to their intended destinations.

The Notification Process in Oracle FLEXCUBE using the jobs scheduler is as follows:

1. The trigger on the base table inserts key details into a static notification log table instead of Oracle AQ.
2. Once Job is triggered, a request is sent to EJB layer from job execution class and the notification log table is polled for unprocessed records.
3. Each unprocessed record is locked.
4. The record is verified against the notification maintenance and checked whether notification is to be sent or not.
5. If notification is to be sent, pre notification message xml is built and it is sent to internal `notify_queue`(JMS queue).
6. The job is then rescheduled to fire next time based on the previous execution.

The notification process in MDB is as follows:

1. The Notification MDB listens on the internal `notify` JMS queue.
2. On any message received, the MDB identifies which schema to connect using the JNDI name being present as part of the message xml.
3. Gateway notification processing package is called from MDB in order to build the actual notifications.
4. In MDB the notifications built is processed and sent to the destination specified in corresponding notification.
5. In case of any exception the whole transaction is rolled back.
6. If all notifications are successfully processed then transaction is committed.

The flow chart of notification process in scheduler:

The flow chart for notification process in MDB:

## 2.5 Viewing Notification Parameters

You can view and amend certain notification parameters in Oracle FLEXCUBE using 'Gateway Notification Maintenance' screen. You can invoke this screen by typing 'IFDNOTIF' in the field at the top right corner of the Application tool bar and clicking on the adjoining arrow button.

### Notification Code

The system displays a unique code to identify a notification.

### Description

The system displays a brief description of the notification. However, you can modify the description in this screen.

### Operation

Select the type of operation for the notification from the following.

- Insert - to indicate a new operation of notification function
- Update - To indicate a modification operation of notification

### Gateway Operation

Specify the gateway operation name to execute query for the mentioned service.

### Gateway Service

Specify the gateway service to be used to get the full screen response.

### IO Request Node

Specify the gateway IO request node to be used in querying operation.

### Specific Notification

Check this box to indicate the system to send specific notification. The system handles any deviation from generic notification process by creating specific triggers once you check this field.

### Full Screen Reply Required

Check this box to indicate that the full screen notification response has to be sent. Otherwise, the primary key response notification is sent.

### Head Office

Check this box to send notification only from head office.

## 2.6 EMS Process with Scheduling Architecture

### 2.6.1 EMS Process:

#### **Incoming EMS Process**

A job is scheduled to poll the incoming folder on timely basis. Once a message is received in the folder, the job picks the message and sends it to an internal JMS queue. An MDB listening on the queue will read the message and identifies the media and processes the message.

#### **Outgoing EMS Process**

A job is scheduled to poll the outgoing messages that are generated but not handed off. Each messages polled will be sent to an internal JMS queue.

A MDB, acting upon the internal JMS queue will pick the message from queue and sends the message to appropriate destination (Folder, or e-mail, or JMS queue).

## 2.7 Approach

The Outgoing EMS Process happens in two layers.

The EMS process as part of jobs in FCJ scheduler, polls the outgoing message table of FLEXCUBE for generated and un-send messages. The job then sends minimal data about the message to be handed off, to an internal JMS queue.

The EMS process as part of an MDB that listens on internal JMS queue to build final message and to send to their intended destinations.

The Incoming EMS Process happens in two layers.

The EMS process as part of jobs in FCJ scheduler, which polls the pre configured folder for messages and sends the messages read, to EMS internal queue.

The EMS process as part of an MDB, that listens on internal JMS queue identifies the message from queue and calls the incoming messages service package in backend to process the message. Additionally, the MDB can be made an independent unit to listen on external JMS to process incoming messages.

The Incoming EMS Process as part of jobs scheduler is as follows:

Once job is triggered, it polls for messages in a folder (Configured for incoming messages).

Each message is then sent to an internal JMS queue.

The job is then rescheduled to fire next time.

EMS processes in MDB are as follows:

An MDB that listens on the internal EMS incoming queue will receive the message.

The media details are identified and incoming message processing package in backend is called to process the message.

In case of any exception while processing, message will be sent to a deferred queue.

In case of messages directly arrive to JMS queue instead of a folder; the same MDB will be configured to listen on specific queue.

---
