| FAILED                                  | The port monitor was unable to start and remain running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |         |                                                                                                                        |          |                                                                                                                                   |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |
| STOPPING                                | The port monitor has been manually terminated but has not completed its shutdown procedure. STOPPING is an intermediate state on the way to NOTRUNNING.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |         |                                                                                                                        |          |                                                                                                                                   |          |                                                                                                                         |        |                                                          |          |                                                                                                                                                         |

**NOTRUNNING** The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal “not running” state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the `DISABLED` state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a `DISABLED` state as well as the `NOTRUNNING` state.

When a port monitor terminates, the SAC removes the `utmpx` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/pmtag/_sactab`.
- The number of times the port monitor has already been restarted.

**Security** `sac` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

```
sac session required pam_unix_session.so.1
```

If there are no entries for the `sac` service, then the entries for the "other" service will be used.

**Options** `-t sanity_interval` Sets the frequency (*sanity\_interval*) with which `sac` polls the port monitors on the system.

**Files** `/etc/saf/_sactab`  
`/etc/saf/_sysconfig`  
`/var/adm/utmpx`  
`/var/saf/_log`

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**Notes** The [pam\\_unix\(5\)](#) module is no longer supported. Similar functionality is provided by [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), [pam\\_passwd\\_auth\(5\)](#), [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), and [pam\\_unix\\_session\(5\)](#).

**Name** sacadm – service access controller administration

**Synopsis** sacadm -a -p *pmtag* -t *type* -c *cmd* -v *ver* [-f *dx*] [-n *count*]  
[-y *comment*] [-z *script*]

sacadm -r -p *pmtag*

sacadm -s -p *pmtag*

sacadm -k -p *pmtag*

sacadm -e -p *pmtag*

sacadm -d -p *pmtag*

sacadm -l [-p *pmtag* | -t *type*]

sacadm -L [-p *pmtag* | -t *type*]

sacadm -g -p *pmtag* [-z *script*]

sacadm -G [-z *script*]

sacadm -x [-p *pmtag*]

**Description** sacadm is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). sacadm performs the following functions:

- adds or removes a port monitor
- starts or stops a port monitor
- enables or disables a port monitor
- installs or replaces a per-system configuration script
- installs or replaces a per-port monitor configuration script
- prints requested port monitor information

Requests about the status of port monitors (-l and -L) and requests to print per-port monitor and per-system configuration scripts (-g and -G without the -z option) may be executed by any user on the system. Other sacadm commands may be executed only by the super-user.

**Options**

-a Add a port monitor. When adding a port monitor, sacadm creates the supporting directory structure in /etc/saf and /var/saf and adds an entry for the new port monitor to /etc/saf/\_sactab. The file \_sactab already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the -f option with the -x argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add port monitors.

-c *cmd* Execute the command string *cmd* to start a port monitor. The -c option may be used only with a -a. A -a option requires a -c.

- 
- d Disable the port monitor *pmtag*.
- e Enable the port monitor *pmtag*.
- f dx The -f option specifies one or both of the following two flags which are then included in the flags field of the `_sactab` entry for the new port monitor. If the -f option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A -f option with no following argument is illegal.
- d Do not enable the new port monitor.
- x Do not start the new port monitor.
- g The -g option is used to request output or to install or replace the per-port monitor configuration script `/etc/saf/pmtag/_config`. -g requires a -p option. The -g option with only a -p option prints the per-port monitor configuration script for port monitor *pmtag*. The -g option with a -p option and a -z option installs the file `script` as the per-port monitor configuration script for port monitor *pmtag*. Other combinations of options with -g are invalid.
- G The -G option is used to request output or to install or replace the per-system configuration script `/etc/saf/_sysconfig`. The -G option by itself prints the per-system configuration script. The -G option in combination with a -z option installs the file `script` as the per-system configuration script. Other combinations of options with a -G option are invalid.
- k Stop port monitor *pmtag*.
- l The -l option is used to request port monitor information. The -l by itself lists all port monitors on the system. The -l option in combination with the -p option lists only the port monitor specified by *pmtag*. A -l in combination with the -t option lists all port monitors of type *type*. Any other combination of options with the -l option is invalid.
- L The -L option is identical to the -l option except that the output appears in a condensed format.
- n *count* Set the restart count to *count*. If a restart count is not specified, count is set to 0. A count of 0 indicates that the port monitor is not to be restarted if it fails.
- p *pmtag* Specifies the tag associated with a port monitor.
- r Remove port monitor *pmtag*. `sacadm` removes the port monitor entry from `/etc/saf/_sactab`. If the removed port monitor is not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it SIGTERM to indicate that it should shut down. Note that the port monitor's directory structure remains intact.

- s Start a port monitor. The SAC starts the port monitor *pmtag*.
- t type Specifies the port monitor type.
- v ver Specifies the version number of the port monitor. This version number may be given as  
`-v 'pmspec -V'`  
where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `tttyadm` for `tttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.
- x The `-x` option by itself tells the SAC to read its database file (`_sactab`). The `-x` option with the `-p` option tells port monitor *pmtag* to read its administrative file.
- y comment Include *comment* in the `_sactab` entry for port monitor *pmtag*.
- z script Used with the `-g` and `-G` options to specify the name of a file that contains a configuration script. With the `-g` option, *script* is a per-port monitor configuration script; with `-G` it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` or `-G`). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` or `-G` with `-z`).

**Output** If successful, `sacadm` will exit with a status of 0. If `sacadm` fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (`-L`), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (`-l`) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is `#`.

**Examples** **EXAMPLE 1** A sample output of the `sacadm` command.

The following command line adds a port monitor. The port monitor tag is `npack`; its type is `listen`; if necessary, it will restart three times before failing; its administrative command is `nlsadmin`; and the configuration script to be read is in the file `script`:

```
sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v 'nlsadmin -V' -n 3 -z script
```

Remove a port monitor whose tag is `pmtag`:

```
sacadm -r -p pmtag
```

Start the port monitor whose tag is `pmtag`:

**EXAMPLE 1** A sample output of the `sacadm` command. *(Continued)*

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

**Files** `/etc/saf/_sactab`  
`/etc/saf/_sysconfig`  
`/etc/saf/pmtag/_config`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**Name** saf – Service Access Facility

**Description** The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.

Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the [sac\(1M\)](#) man page. The administrative levels and associated utilities are documented in the *System Administration Guide - Volume II*. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.

**Port Monitors** A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately.

A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.

A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.

**Port Management** The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.

Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.

**Activity Monitoring** The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

#### Other Port Monitor Functions

This section briefly describes other port monitor functions.

##### Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

##### Creating utmpx Entries

Port monitors are responsible for creating utmpx entries with the type field set to USER\_PROCESS for services they start. If this action has been specified, by using the -fu option in the pmadm command line that added the service, these utmpx entries may

### Port Monitor Process IDs and Lock Files

in turn be modified by the service. When the service terminates, the `utmpx` entry must be set to `DEAD_PROCESS`.

When a port monitor starts, it writes its process id into a file named `_pid` in the current directory and places an advisory lock on the file.

### Changing the Service Environment: Running

`doconfig(3NSL)` Before invoking the service designated in the port monitor administrative file, `_pmtab`, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function `doconfig(3NSL)`. Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.

### Terminating a Port Monitor

A port monitor must terminate itself gracefully on receipt of the signal `SIGTERM`. The termination sequence is the following:

1. The port monitor enters the stopping state; no further service requests are accepted.
2. Any attempt to re-enable the port monitor will be ignored.
3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping.
4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.

---

|                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SAF Files                            | This section briefly covers the files used by the SAF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| The Port Monitor Administrative File | <p>A port monitor's current directory contains an administrative file named <code>_pmtab</code>; <code>_pmtab</code> is maintained by the <code>pmadm</code> command in conjunction with a port monitor-specific administrative command.</p> <p>The port monitor administrative command for a listen port monitor is <code>nlsadmin(1M)</code>; the port monitor administrative command for <code>ttymon</code> is <code>ttyadm(1M)</code>. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.</p>                                                                                                                                                                                                                                                                   |
| Per-Service Configuration Files      | A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the <code>_pmtab</code> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Private Port Monitor Files           | A port monitor may create private files in the directory <code>/var/saf/tag</code> , where <code>tag</code> is the name of the port monitor. Examples of private files are log files or temporary files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| The SAC/Port Monitor Interface       | <p>The SAC creates two environment variables for each port monitor it starts: <code>PMTAG</code> and <code>ISTATE</code>.</p> <p>This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to <code>sac</code> messages. <code>ISTATE</code> is used to indicate to the port monitor what its initial internal state should be. <code>ISTATE</code> is set to "enabled" or "disabled" to indicate that the port monitor is to start in the enabled or disabled state respectively.</p> <p>The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open <code>_pmpipe</code>, in the current directory, to receive messages from the SAC and <code>./_sacpipe</code> to send return messages to the SAC.</p> |
| Message Formats                      | <p>This section describes the messages that may be sent from the SAC to a port monitor (<code>sac</code> messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.</p> <p><code>sac</code> Messages      The format of messages from the SAC is defined by the structure <code>sacmsg</code>:</p> <pre> struct sacmsg {     int sc_size; /* size of optional data portion */     char sc_type; /* type of message */ </pre>                                                                                                                                                                                                                                                                                                                                              |

```
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

```
SC_STATUS status request
SC_ENABLE enable message
SC_DISABLE disable message
SC_READDB message indicating that the port monitor's _pmtab file should be read
```

The `sc_size` field indicates the size of the optional data part of the message. See “Message Classes.” For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

Port Monitor Messages The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
 char pm_type; /* type of message */
 uchar_t pm_state; /* current state of port monitor */
 char pm_maxclass; /* maximum message class this port
 monitor understands */
 char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
 int pm_size; /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

```
PM_STATUS state information
PM_UNKNOWN negative acknowledgment
```

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

```
PM_STARTING starting
PM_ENABLED enabled
PM_DISABLED disabled
PM_STOPPING stopping
```

The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. `pm_size` indicates the size of the optional data part of the message. `pm_maxclass` is used to specify a message class. Both are discussed under

“Message Classes.” In Solaris, always set `pm_maxclass` to 1 and `sc_size` to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.

**Message Classes** The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the `pm_maxclass` field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of `pm_maxclass`. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set `pm_maxclass` to 1.

For any given port monitor, messages of class `pm_maxclass` and messages of all classes with values lower than `pm_maxclass` are valid. Thus, if the `pm_maxclass` field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. `pm_size` (an element of the `pmsg` structure) and `sc_size` (an element of the `sacmsg` structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both `sc_size` and `pm_size` to 0.

**Administrative Interface** This section discusses the port monitor administrative files available under the SAC.

**The SAC Administrative File `_sactab`** The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command `sacadm(1M)` with a `-a` option. `sacadm(1M)` is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.

**PMTAG** A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

**PMTYPE** The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. `ttymon` and `listen` are examples of valid port monitor types. The type designator is used to facilitate the administration of

groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

FLGS The flags that are currently defined are:

- d When started, do not enable the port monitor.
- x Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

RCNT The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

COMMAND A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

The Port Monitor  
Administrative File  
\_pmtab

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/pmtag`, where `pmtag` is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, `root`).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a `ttymon` port monitor, this will include the prompt string which is meaningful to `ttymon`). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttymax(1M)` command does this for `ttymon` and `nlsadmin(1M)` does it for `listen`. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FLGS       | Flags with the following meanings may currently be included in this field:<br><ul style="list-style-type: none"> <li>x Do not enable this port. By default the port is enabled.</li> <li>u Create a utmpx entry for this service. By default no utmpx entry is created for the service.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ID         | The identity under which the service is to be started. The identity has the form of a login name as it appears in <code>/etc/paswd</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| PMSPECIFIC | Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS-based pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| COMMENT    | A comment associated with the service entry. Port monitors may ignore the <i>u</i> flag if creating a utmpx entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmpx entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:<br><br><pre># VERSION=value</pre> <p>where <i>value</i> is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.</p> |

Monitor-Specific  
Administrative  
Command

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current

version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

#### The Port Monitor/Service Interface

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

##### New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3NSL)`.

##### Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

#### Port Monitor Requirements

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

##### Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open

- It cannot be a process group leader

- It has an entry in `/etc/utmpx` of type `LOGIN_PROCESS`

- An environment variable, `ISTATE`, is set to “enabled” or “disabled” to indicate the port monitor's correct initial state

- An environment variable, `PMTAG`, is set to the port monitor's assigned tag

- The directory that contains the port monitor's administrative files is its current directory

- The port monitor is able to create private files in the directory `/var/saf/tag`, where `tag` is the port monitor's tag

- The port monitor is running with user id 0 (root)

##### Important Files

Relative to its current directory, the following key files exist for a port monitor.

|                          |                                                                                                                                                                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_config</code>     | The port monitor's configuration script. The port monitor configuration script is run by the SAC. The SAC is started by <code>init(1M)</code> as a result of an entry in <code>/etc/inittab</code> that calls <code>sac(1M)</code> . |
| <code>_pid</code>        | The file into which the port monitor writes its process id.                                                                                                                                                                          |
| <code>_pmtab</code>      | The port monitor's administrative file. This file contains information about the ports and services for which the port monitor is responsible.                                                                                       |
| <code>_pmpipe</code>     | The FIFO through which the port monitor will receive messages from the SAC.                                                                                                                                                          |
| <code>svctag</code>      | The per-service configuration script for the service with the tag <code>svctag</code> .                                                                                                                                              |
| <code>../_sacpipe</code> | The FIFO through which the port monitor will send messages to <code>sac(1M)</code> .                                                                                                                                                 |

Port Monitor Responsibilities A port monitor is responsible for performing the following tasks in addition to its port monitor function:

- Write its process id into the file `_pid` and place an advisory lock on the file
- Terminate gracefully on receipt of the signal SIGTERM
- Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

- Create a `utmpx` entry if the requested service has the `u` flag set in `_pmtab`
- Port monitors may ignore this flag if creating a `utmpx` entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless `utmpx` entries have been created for them.
- Interpret the per-service configuration script for the requested service, if it exists, by calling the `doconfig(3NSL)` library routine

Configuration Files and Scripts The library routine `doconfig(3NSL)`, defined in `libnsl.so`, interprets the configuration scripts contained in the files `/etc/saf/_sysconfig` (the per-system configuration file), and `/etc/saf/pmtag/_config` (per-port monitor configuration files); and in `/etc/saf/pmtag/svctag` (per-service configuration files). Its syntax is:

```
#include <sac.h>
int doconfig (int fd, char *script, long rflag);
```

`script` is the name of the configuration script; `fd` is a file descriptor that designates the stream to which stream manipulation operations are to be applied; `rflag` is a bitmask that indicates the mode in which script is to be interpreted. `rflag` may take two values, `NORUN` and `NOASSIGN`,

which may be or'd. If *rflag* is zero, all commands in the configuration script are eligible to be interpreted. If *rflag* has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If *rflag* has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of -1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, `doconfig(3NSL)` is used to interpret a per-service configuration script.

```

. . .
 if ((i = doconfig (fd, svctag, 0)) != 0){
 error ("doconfig failed on line %d of script %s",i,svctag);
 }

```

#### The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3NSL)` manpage. When the SAC is started, it calls the `doconfig(3NSL)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

#### Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/pmtag/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

#### Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user.

Using the language described in the [doconfig\(3NSL\)](#) manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| The Configuration Language | <p>The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: <code>assign</code>, <code>push</code>, <code>pop</code>, <code>runwait</code>, and <code>run</code>. The comment character is <code>#</code>. Blank lines are not significant. No line in a command script may exceed 1024 characters.</p>                                                                                                                      |
|                            | <p><code>assign</code> <i>variable=value</i></p> <p>Used to define environment variables; <i>variable</i> is the name of the environment variable and <i>value</i> is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. <i>value</i> may be quoted. The quoting rules are those used by the shell for defining environment variables. <code>assign</code> will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.</p> |
|                            | <p><code>push</code> <i>module1[,module2, module3, ...]</i></p> <p>Used to push STREAMS modules onto the stream designated by <i>fd</i>; <i>module1</i> is the name of the first module to be pushed, <i>module2</i> is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.</p>                                        |
|                            | <p><code>pop</code> [<i>module</i>]</p> <p>Used to pop STREAMS modules off the designated stream. If <code>pop</code> is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If <i>module</i> is the special</p>                                                                                            |

keyword ALL, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

runwait command

The runwait command runs a command and waits for it to complete; command is the path name of the command to be run. The command is run with /bin/sh -c prepended to it; shell scripts may thus be executed from configuration scripts. The runwait command will fail if command cannot be found or cannot be executed, or if command exits with a nonzero status.

run command

The run command is identical to runwait except that it does not wait for command to complete; command is the path name of the command to be run. run will not fail unless it is unable to create a child process to execute the command. Although they are syntactically indistinguishable, some of the commands available to run and runwait are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The doconfig interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the [sh\(1\)](#) man page. The initial set of built-in commands is: cd, ulimit, umask.

Sample Port Monitor Code This example shows an example of a “null” port monitor that simply responds to messages from the SAC.

```
include <stdlib.h>
include <stdio.h>
include <unistd.h>
include <fcntl.h>
include <signal.h>
include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
```

```

 int argc;
 char *argv[];
{
 char *istate;
 strcpy(Tag, getenv("PMTAG"));
/*
* open up a log file in port monitor's private directory
*/
 sprintf(Scratch, "/var/saf/%s/log", Tag);
 Fp = fopen(Scratch, "a+");
 if (Fp == (FILE *)NULL)
 exit(1);
 log(Fp, "starting");
/*
* retrieve initial state (either "enabled" or "disabled") and set
* State accordingly
*/
 istate = getenv("ISTATE");
 sprintf(Scratch, "ISTATE is %s", istate);
 log(Fp, Scratch);
 if (!strcmp(istate, "enabled"))
 State = PM_ENABLED;
 else if (!strcmp(istate, "disabled"))
 State = PM_DISABLED;
 else {
 log(Fp, "invalid initial state");
 exit(1);
 }
 sprintf(Scratch, "PMTAG is %s", Tag);
 log(Fp, Scratch);
/*
* set up pid file and lock it to indicate that we are active
*/
 Tfp = fopen("_pid", "w");
 if (Tfp == (FILE *)NULL) {
 log(Fp, "couldn't open pid file");
 exit(1);
 }
 if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
 log(Fp, "pid file already locked");
 exit(1);
 }

 log(Fp, "locking file");
 if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
 log(Fp, "lock failed");
 exit(1);
 }

```

```
 }
 fprintf(Tfp, "%d", getpid());
 fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
 handlepoll();
 pause();
 fclose(Tfp);
 fclose(Fp);
}

handlepoll()
{
 int pfd; /* file descriptor for incoming pipe */
 int sfd; /* file descriptor for outgoing pipe */
 struct sacmsg sacmsg; /* incoming message */
 struct pmmsg pmmsg; /* outgoing message */
/*
 * open pipe for incoming messages from the sac
 */
 pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
 if (pfd < 0) {
 log(Fp, "_pmpipe open failed");
 exit(1);
 }
/*
 * open pipe for outgoing messages to the sac
 */
 sfd = open("../_sacpipe", O_WRONLY);
 if (sfd < 0) {
 log(Fp, "_sacpipe open failed");
 exit(1);
 }
/*
 * start to build a return message; we only support class 1 messages
 */
 strcpy(pmmsg.pm_tag, Tag);
 pmmsg.pm_size = 0;
 pmmsg.pm_maxclass = 1;
/*
 * keep responding to messages from the sac
 */
 for (;;) {
 if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
 log(Fp, "_pmpipe read failed");
 }
 }
}
```

```

 exit(1);
 }
/*
 * determine the message type and respond appropriately
 */
 switch (sacmsg.sc_type) {
 case SC_STATUS:
 log(Fp, "Got SC_STATUS message");
 pmmsg.pm_type = PM_STATUS;
 pmmsg.pm_state = State;
 break;
 case SC_ENABLE:
 /*note internal state change below*/
 log(Fp, "Got SC_ENABLE message");
 pmmsg.pm_type = PM_STATUS;
 State = PM_ENABLED;
 pmmsg.pm_state = State;
 break;
 case SC_DISABLE:
 /*note internal state change below*/
 log(Fp, "Got SC_DISABLE message");
 pmmsg.pm_type = PM_STATUS;
 State = PM_DISABLED;
 pmmsg.pm_state = State;
 break;
 case SC_READDB:
 /*
 * if this were a fully functional port
 * monitor it would read _pmtab here
 * and take appropriate action
 */
 log(Fp, "Got SC_READDB message");
 pmmsg.pm_type = PM_STATUS;
 pmmsg.pm_state = State;
 break;
 default:
 sprintf(Scratch, "Got unknown message <%d>",
 sacmsg.sc_type);
 log(Fp, Scratch);
 pmmsg.pm_type = PM_UNKNOWN;
 pmmsg.pm_state = State;
 break;
 }
/*
 * send back a response to the poll
 * indicating current state
 */

```

```

 if (write(sfd, &pmmsg, sizeof(pmmsg)) != sizeof(pmmsg))
 log(Fp, "sanity response failed");
 }
}
/*
 * general logging function
 */
log(fp, msg)
 FILE *fp;
 char *msg;
{
 fprintf(fp, "%d; %s\n", getpid(), msg);
 fflush(fp);
}

```

The sac.h Header File The following example shows the sac.h header file.

```

/* length in bytes of a utmpx id */
define IDLEN 4
/* wild character for utmpx ids */
define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
define PMTAGSIZE 14
/*
 * values for rflag in doconfig()
 */
/* don't allow assign operations */
define NOASSIGN 0x1

**Directory Structure** This section gives a description of the SAF files and directories.

|                                     |                                                                                                                                            |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/saf/_sysconfig</code>    | The per-system configuration script.                                                                                                       |
| <code>/etc/saf/_sactab</code>       | The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.                              |
| <code>/etc/saf/pmtag</code>         | The home directory for port monitor <i>pmtag</i> .                                                                                         |
| <code>/etc/saf/pmtag/_config</code> | The per-port monitor configuration script for port monitor <i>pmtag</i> .                                                                  |
| <code>/etc/saf/pmtag/_pmtab</code>  | Port monitor <i>pmtag</i> 's administrative file. Contains information about the services for which <i>pmtag</i> is responsible.           |
| <code>/etc/saf/pmtag/svctag</code>  | The file in which the per-service configuration script for service <i>svctag</i> (available through port monitor <i>pmtag</i> ) is placed. |
| <code>/etc/saf/pmtag/_pid</code>    | The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.                   |
| <code>/etc/saf/pmtag/_pmpipe</code> | The file in which the port monitor receives messages from the SAC and <code>./_sacpipe</code> and sends return messages to the SAC.        |
| <code>/var/saf/_log</code>          | The SAC's log file.                                                                                                                        |
| <code>/var/saf/pmtag</code>         | The directory for files created by port monitor <i>pmtag</i> , for example its log file.                                                   |

**List Of Commands** The following administrative commands relate to SAF.

`sacadm(1M)` port monitor administrative command  
`pmadm(1M)` service administration command

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

---

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsr         |

**See Also** `exec(1)`, `sh(1)`, `init(1M)`, `nlsadmin(1M)`, `pmadm(1M)`, `sac(1M)`, `sacadm(1M)`, `ttyadm(1M)`, `fork(2)`, `doconfig(3NSL)`, `attributes(5)`

**Name** sar, sa1, sa2, sadc – system activity report package

**Synopsis** /usr/lib/sa/sadc [*t n*] [*ofile*]

/usr/lib/sa/sa1 [*t n*]

/usr/lib/sa/sa2 [-aAbcdgkmpqruvwy] [-e *time*] [-f *filename*]  
[-i *sec*] [-s *time*]

**Description** System activity data can be accessed at the special request of a user (see [sar\(1\)](#)) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use [iostat\(1M\)](#), [sar\(1\)](#), or [vmstat\(1M\)](#).

sadc and two shell procedures, sa1 and sa2, are used to sample, save, and process this data.

sadc, the data collector, samples system data *n* times, with an interval of *t* seconds between samples, and writes in binary format to *ofile* or to standard output. The sampling interval *t* should be greater than 5 seconds; otherwise, the activity of sadc itself may affect the sample. If *t* and *n* are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the svc:/system/sar:default service writes the restart mark to the daily data file using the command entry:

```
su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa'date +%d"
```

The shell script sa1, a variant of sadc, is used to collect and store data in the binary file /var/adm/sa/sadd, where dd is the current day. The arguments *t* and *n* cause records to be written *n* times at an interval of *t* seconds, or once if omitted. The following entries in /var/spool/cron/crontabs/sys will produce records every 20 minutes during working hours and hourly otherwise:

```
0 * * * 0-6 /usr/lib/sa/sa1
20,40 8-17 * * 1-5 /usr/lib/sa/sa1
```

See [crontab\(1\)](#) for details.

The shell script sa2, a variant of sar, writes a daily report in the file /var/adm/sa/sardd. See the OPTIONS section in [sar\(1\)](#) for an explanation of the various options. The following entry in /var/spool/cron/crontabs/sys will report important activities hourly during the working day:

```
5 18 * * 1-5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

|              |                   |                   |

**See Also** [crontab\(1\)](#), [sag\(1\)](#), [sar\(1\)](#), [svcs\(1\)](#), [timex\(1\)](#), [iostat\(1M\)](#), [svcadm\(1M\)](#), [vmstat\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

*System Administration Guide: Advanced Administration*

**Notes** The `sar` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/sar
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** savecore – save a crash dump of the operating system

**Synopsis** /usr/bin/savecore [-Lvd] [-f *dumpfile*] [*directory*]

**Description** The savecore utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the dumpadm service each time the system boots.

savecore can be configured by [dumpadm\(1M\)](#) to save crash dump data in either a compressed or uncompressed format. For the compressed format, savecore saves the crash dump data in the file *directory/vmdump.N*, where *N* in the pathname is replaced by a number which increments by one each time savecore is run in *directory*. The compressed file can be uncompressed in a separate step using the *-f dumpfile* option. For the uncompressed format, savecore saves the crash dump data in the file *directory/vmcore.N* and the kernel's namelist in *directory/unix.N*.

Before writing out a crash dump, savecore reads a number from the file *directory/minfree*. This is the minimum number of kilobytes that must remain free on the file system containing *directory*. If after saving the crash dump the file system containing *directory* would have less free space the number of kilobytes specified in *minfree*, the crash dump is not saved. If the *minfree* file does not exist, savecore assumes a *minfree* value of 1 megabyte.

The savecore utility also logs a reboot message using facility LOG\_AUTH (see [syslog\(3C\)](#)). If the system crashed as a result of a panic, savecore logs the panic string too.

**Options** The following options are supported:

-d

Disregard dump header valid flag. Force savecore to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.

-f *dumpfile*

Save a crash dump from the specified file instead of from the system's current dump device. When given *directory/vmdump.N*, uncompress the file to *vmcore.N* and *unix.N*, where *N* is the same number as in the compressed name.

This option may also be useful if the information stored on the dump device has been copied to an on-disk file by means of the [dd\(1M\)](#) command.

-L

Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces savecore to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using [dumpadm\(1M\)](#).

savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.

-v

Verbose. Enables verbose error messages from savecore.

**Operands** The following operands are supported:

*directory*

Save the crash dump files to the specified directory. If *directory* is not specified, savecore saves the crash dump files to the default savecore *directory*, configured by [dumpadm\(1M\)](#).

- Files**
- *directory/vmcore.N*
  - *directory/unix.N*
  - *directory/bounds*
  - *directory/minfree*
  - */var/crash/`uname -n`* (default crash dump directory)

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | system/core-os  |

**See Also** [adb\(1\)](#), [mdb\(1\)](#), [svcs\(1\)](#), [dd\(1M\)](#), [dumpadm\(1M\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The system crash dump service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/dumpadm:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

If the dump device is also being used as a swap device, you must run savecore very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

When savecore creates a file it appends the suffix `.partial`. After the file is completed, it is renamed without the suffix. If files are found in the dump directory with this suffix, it means that either savecore is still busy, or that it was interrupted before completely writing the file. In the former case, use [ps\(1\)](#) to find the PID of the running savecore process and wait for it to complete. In the latter case, remove the partial file and recreate it by running `savecore -d`.

**Name** scadm – administer System Controller (SC)

**Synopsis** /usr/platform/*platform-name*/sbin/scadm *subcommand* [*option*]  
[*argument*] . . .

**Description** The scadm utility administers the System Controller (SC). This utility allows the host server to interact with the SC.

The scadm utility *must* be run as root.

The interface, output, and location in the directory hierarchy for scadm are uncommitted and might change.

*platform-name* is the name of the platform implementation. Use the uname -i command to identify the platform implementation. See [uname\(1\)](#).

The scadm utility has a number of subcommands. Some subcommands have specific options and arguments associated with them. See SUBCOMMANDS, OPTIONS, OPERANDS, and USAGE.

**SUBCOMMANDS** Subcommands immediately follow the scadm command on the command line, and are separated from the command by a SPACE.

The following subcommands are supported

**consolehistory** Display the SC's console log. The SC maintains a running log which captures all console output. This log is maintained as a first-in, first-out buffer: New console output may displace old console output if the buffer is full. By default, only the last eight kilobytes of the console log file are displayed.

The optional -a argument specifies that the entire console log file be displayed.

It is possible for the SC to fill this log more quickly than the consolehistory subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the consolehistory subcommand displays “scadm: lost <number> bytes of console log data” in the log output, to indicate that some data was lost.

The format for the consolehistory subcommand is:

```
scadm consolehistory [-a]
```

The consolehistory subcommand is not available on all platforms. If this command is used on a platform that does not support it, scadm prints this message:

```
scadm: command/option not supported
```

and exit with non-zero status.

---

|            | The format for the date subcommand is:                                                                                                                                                                                                                                                                                                                                         |
|            | <code>scadm date</code>                                                                                                                                                                                                                                                                                                                                                        |
| download   | Program the SC's firmware.                                                                                                                                                                                                                                                                                                                                                     |
|            | There are two parts to the firmware, the boot monitor and the main image.                                                                                                                                                                                                                                                                                                      |
|            | By default, The <code>scadm</code> command's download programs the main firmware image. The boot argument selects programming of the boot monitor.                                                                                                                                                                                                                             |
|            | The format for the download subcommand is:                                                                                                                                                                                                                                                                                                                                     |
|            | <code>scadm download [boot] file</code>                                                                                                                                                                                                                                                                                                                                        |
| fruhistory | Display the contents of the “field replacable unit” log maintained by the SC. By default, only the last eight kilobytes of the fru history log file are displayed. The data in contained this log contains snapshots of the SC's “showfru” command, taken whenever the system is reset, or a hot-plug event is detected by the SC.                                             |
|            | The optional <code>-a</code> argument specifies that the entire fru log file be displayed.                                                                                                                                                                                                                                                                                     |
|            | It is possible for the SC to fill this log more quickly than the <code>fruhistory</code> subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the <code>fruhistory</code> subcommand displays “scadm: lost <number> bytes of fru log data” in the log output, to indicate that some data was lost. |
|            | The format for the fruhistory subcommand is:                                                                                                                                                                                                                                                                                                                                   |
|            | <code>scadm fruhistory [-a]</code>                                                                                                                                                                                                                                                                                                                                             |
|            | The <code>fruhistory</code> subcommand is not available on all platforms. If this command is used on a platform which does not support it, <code>scadm</code> prints this message:                                                                                                                                                                                             |
|            | <code>scadm: command/option not supported</code>                                                                                                                                                                                                                                                                                                                               |
|            | and exit with non-zero status.                                                                                                                                                                                                                                                                                                                                                 |
| help       | Display a list of commands.                                                                                                                                                                                                                                                                                                                                                    |
|            | The format for the help subcommand is:                                                                                                                                                                                                                                                                                                                                         |
|            | <code>scadm help</code>                                                                                                                                                                                                                                                                                                                                                        |
| loghistory | Display the most recent entries in the SC event log. The optional <code>-a</code> argument causes the entire event log history to be displayed. The <code>-a</code>                                                                                                                                                                                                            |

argument is available only on platforms which support large log files. On platforms which do not support large log files, this flag has no additional effect.

It is possible for the SC to fill this log more quickly than the `loghistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `loghistory` subcommand displays “scadm: lost <number> events” in the log output, to indicate that some data was lost.

The format for the `loghistory` subcommand is:

```
scadm loghistory [-a]
```

**resetrsc** Reset the SC. There are two types of resets allowed, a hard reset and a soft reset. The hard reset is done by default. The soft reset can be selected by using the `-s` option.

The format for the `resetrsc` subcommand is:

```
scadm resetrsc [-s]
```

**send\_event** Manually send a text based event. The SC can forward the event to the SC event log. You can configure the `-c` option to send a critical warning to email, alert to logged in SC users, and `syslog`. Critical events are logged to [syslog\(3C\)](#). There is an 80 character limit to the length of the associated text message.

The format for the `send_event` subcommand is:

```
scadm send_event [-c] "message"
```

**set** Set SC configuration variables to a value.

Examples of SC configuration variables include: SC IP address `netsc_ipaddr` and SC Customer Information `sc_customerinfo`. See the output from the `scadm help` command for a complete list of SC configuration variables.

The format for the `set` subcommand is:

```
scadm set variable value
```

**show** Display the current SC configuration variable settings. If no variable is specified, `scadm` shows all variable settings.

The format for the `show` subcommand is:

```
scadm show [variable]
```

**shownetwork** Display the current network configuration parameters for SC.

| <code>version</code>      | Display the version numbers of the SC and its components.<br><br>The format for the <code>version</code> subcommand is:<br><code>scadm version [-v]</code>                                                                                                                                                      |

**Options** The `resetrsc`, `send_event`, and `version` subcommands have associated options. Options follow subcommands on the command line and are separated from the subcommand by a SPACE.

The `resetrsc` subcommand supports the following options:

- s Perform a soft reset instead of a hard reset. A hard reset physically resets the SC hardware. The SC software jumps to the boot firmware, simulating a reset, for a soft reset.

The `send_event` subcommand supports the following options:

- c Send a critical event. Without the -c, `send_event` sends a warning.

The `version` subcommand supports the following options:

- v Display a verbose output of version numbers and associated information.

The `consolehistory`, `fruhistory`, and `loghistory` subcommands support the following option:

- a Display the entire log. These subcommands normally display only the most recent log data. This flag causes them to display the entire log.

**Operands** The `download`, `send_event`, `set`, `show`, `useradd`, `userdel`, `userperm`, `usershow`, `userpassword`, and `userperm` subcommands have associated arguments (operands).

If the subcommand has an option, the arguments follow the option on the command line and is separated from the option by a SPACE. If the subcommand does not have an option, the arguments follow the subcommand on the command line and are separated from the subcommand by a SPACE. If there are more than one arguments, they are separated from each other by a SPACE.

The `download` subcommand supports the following arguments:

`boot` Program the boot monitor portion of the flash. The main portion of the flash is programmed without any arguments

`file` Specify *file* as the path to where the boot or main firmware image resides for download.

Examples of *file* are:

```
/usr/platform/platform_type/lib/image/alommainfw
```

or

```
/usr/platform/platform_type/lib/image/alombootfw
```

The `send_event` subcommand supports the following arguments:

`"message"` Describe event using the text contained in *message*. Enclose *message* in quotation marks.

The `set` subcommand supports the following arguments:

`variable` Set SC configuration *variable*.

`value` Set SC configuration variable to *value*.

The `show` subcommand supports the following arguments:

*variable*     Display the value of that particular variable.

The `useradd` subcommand supports the following arguments:

*username*     Add new SC account *username*.

The `userdel` subcommand supports the following arguments:

*username*     Remove SC account *username*.

The `userperm` subcommand supports the following arguments:

`-aucr`        Set permissions for SC user accounts. If no permissions are specified, all four permissions are disabled and read only access is assigned.

The following are the definitions for permissions:

`a`     Allow user to administer or change the SC configuration variables

`u`     Allow user to use the user commands to modify SC accounts

`c`     Allow user to connect to console.

`r`     Allow user to reset SC and to power on and off the host.

*username*     Change permissions on SC account *username*.

The `-usershow` subcommand supports the following arguments:

*username*     Display information on SC account *username*. If *username* is not specified, all accounts are displayed.

The `userpassword` subcommand supports the following arguments:

*username*     Set SC password for *username*.

The `userperm` subcommand supports the following arguments:

*username*     Change SC permissions for *username*.

### Examples **EXAMPLE 1** Displaying the SC's Date and Time

The following command displays the SC's date and time.

```
scadm date
```

### **EXAMPLE 2** Setting the SC's Configuration Variables

The following command sets the SC's configuration variable `netsc_ipaddr` to `192.168.1.2`:

```
scadm set netsc_ipaddr 192.168.1.2
```

**EXAMPLE 3** Displaying the Current SC's Configuration Settings:

The following command displays the current SC configuration settings:

```
scadm show
```

**EXAMPLE 4** Displaying the Current Settings for a Variable

The following command displays the current settings for the `sys_hostname` variable:

```
scadm show sys_hostname
```

**EXAMPLE 5** Sending a Text-Based Critical Event

The following command sends a critical event to the SC logs, alerts the current SC users, and sends an event to `syslog(3C)`:

```
scadm send_event -c "The UPS signaled a loss in power"
```

**EXAMPLE 6** Sending an Informational Text-Based Event

The following command sends a non-critical informational text based event to the SC event log:

```
scadm send_event "The disk is close to full capacity"
```

**EXAMPLE 7** Adding a User To the SC

The following command adds user `rscroot` to the SC:

```
scadm useradd rscroot
```

**EXAMPLE 8** Deleting a User From the SC

The following command deletes user `olduser` from the SC:

```
scadm userdel olduser
```

**EXAMPLE 9** Displaying User Details

The following command displays details of all user accounts:

```
scadm usershow
```

**EXAMPLE 10** Displaying Details for a Specific User

The following command displays details of user account `rscroot`:

```
scadm usershow rscroot
```

**EXAMPLE 11** Setting the User Permission Level

The following command sets the full permission level for user `rscroot` to `aucr`:

```
scadm userperm rscroot aucr
```

**EXAMPLE 12** Setting the User Permission Level

The following command sets only console access for user `newuser` to `c`:

```
scadm userperm newuser c
```

**EXAMPLE 13** Setting the User Permission Level

The following command sets the permission level for user `newuser` to read only access:

```
scadm userperm newuser
```

**EXAMPLE 14** Displaying the Current Network Parameters

The following command displays the current network configuration parameters for the SC:

```
scadm shownetwork
```

**EXAMPLE 15** Viewing the Consolehistory

The following command displays the the content console in the SC event log:

```
scadm consolehistory [-a]
```

**EXAMPLE 16** Viewing the Fruhistory

The following command displays the content of the “field replacable unit” in the SC event log:

```
scadm fruhistory [-a]
```

**EXAMPLE 17** Viewing the Loghistory

The following command displays the most recent entries in the SC event log:

```
scadm loghistory [-a]
```

**EXAMPLE 18** Displaying Verbose Information

The following command displays verbose version information on the SC and its components:

```
scadm version -v
```

**Exit Status** The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWkvm         |

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Evolving        |

**See Also** [uname\(1\)](#), [syslog\(3C\)](#), [attributes\(5\)](#)

**Name** sckmd – Sun cryptographic key management daemon

**Synopsis** /usr/platform/sun4u/lib/sckmd

**Description** sckmd is a server process that resides on a high-end system domain to maintain the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure communications between a Service Processor or System Controller (SC) and platform management software running within a domain. The [cvcd\(1M\)](#) and [dcs\(1M\)](#) daemons use these Security Associations. See [ipsec\(7P\)](#) for a description of Security Associations.

The sckmd daemon receives SAs from the Service Processor or SC and installs these SAs in a domain's Security Association Database (SADB) using [pf\\_key\(7P\)](#).

sckmd starts up at system boot time as an SMF service. The FMRI for the sckmd service is:

```
svc:/platform/sun4u/sckmd:default
```

A domain supports only one running sckmd process at a time.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                     |
|---------------------|-------------------------------------|
| Availability        | SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr |
| Interface Stability | Evolving                            |

**See Also** [cvcd\(1M\)](#), [dcs\(1M\)](#), [ipsecconf\(1M\)](#), [ipsecalgs\(1M\)](#), [attributes\(5\)](#), [ipsec\(7P\)](#), [ipsecah\(7P\)](#), [ipsecesp\(7P\)](#), [pf\\_key\(7P\)](#)

**Notes** The sckmd service is used only on Sun Fire high-end systems and the SPARC Enterprise Server family. It provides a mechanism for exchanging IPsec keys between a domain and its System Controller (SC) or Service Processor. These platforms use IPsec to secure the communications between the SC or Service Processor and certain platform-specific daemons in the domain. Such daemons currently include [cvcd\(1M\)](#) and [dcs\(1M\)](#).

The documentation for each platform that supports sckmd describes how to configure its use of IPsec for such communications. Also, the documentation for each specific application describes how to configure its security policies and IPsec options in a manner appropriate for the target platform. Refer to the platform- and application-specific documentation for detailed information.

**Name** sconadm – register system information

**Synopsis** /usr/sbin/sconadm register -a  
 [-e softwareUpdate | -E softwareUpdate]  
 [-h *hostname*] [-l *logfile*] [-N]  
 [-p *proxy\_host[:proxy\_port]*]  
 [-r *registration\_profile*] [-u *username*]  
 [-x *proxy\_username*]

/usr/sbin/sconadm proxy [-l *logfile*]  
 [-p *proxy\_host[:proxy\_port]*]  
 [-r *registration\_profile*] [-x *proxy\_username*]

**Description** The sconadm utility is a command-line version of the Basic Registration GUI. In the first form of the command in the SYNOPSIS, sconadm uses the register subcommand to register a host with a registration server. In the second form, sconadm uses the proxy subcommand to configure all of the components for software update to use an HTTP web proxy.

The parameters specified with -u, -e (or -E), -h, -p, and -x override values specified in your registration profile. A template for this profile, owned by root, with read-only permissions, is stored in /usr/lib/breg/data/RegistrationProfile.properties. See [registration\\_profile\(4\)](#).

For the proxy subcommand, the proxy password is stored in the RegistrationProfile.properties file, available if proxy authentication is needed. Storage in the profile prevents proxy passwords from being exposed as part of a listing of processes on a system.

**Options** The following options are supported:

|                                   |                                                                                                                 |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------|
| -a                                | Accept “Terms of Use and Binary Code License”. Absence of this option means that you do not accept the license. |
| -e softwareUpdate                 | Enable client to be managed at the Sun-hosted Update Connection Service.                                        |
| -E softwareUpdate                 | Disable client's ability to be managed at the Sun-hosted Update Connection Service.                             |
| -h <i>hostname</i>                | Hostname of the machine you want to register.                                                                   |
| -l <i>logfile</i>                 | Pathname of log file.                                                                                           |
| -N                                | Never register.                                                                                                 |
| -p <i>proxy_host[:proxy_port]</i> | Proxy host name and optional proxy port number.                                                                 |
| -r <i>registration_profile</i>    | Pathname to a registration profile.                                                                             |
| -u <i>username</i>                | User name (a Sun Online Account).                                                                               |
| -x <i>proxy_username</i>          | User name on the proxy host.                                                                                    |

**Examples** Unless specified otherwise, the commands below require root privileges or privileges equivalent to root. See [privileges\(5\)](#).

**EXAMPLE 1** Registering a New System

Assume a file `registrationprofile.properties` in `/tmp` that contains the following:

```
userName=user123
password=abc123
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To register a new system using the profile above, you enter:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

**EXAMPLE 2** Reregistering a System with a Different User

Assume a file `registrationprofile.properties` in `/tmp` with the contents shown below. Note the changed specification for `userName` and `password`.

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To reregister a new system using the profile above, you enter the same command you entered to register the system:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

**EXAMPLE 3** Reregistering a System, Adding a Sun Subscription Key

Modify `registrationprofile.properties` as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
```

**EXAMPLE 3** Reregistering a System, Adding a Sun Subscription Key (Continued)

```
proxyPort=
proxyUserName=
proxyPassword=
```

Run the command:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

**EXAMPLE 4** Reregistering and Enabling Access to all Update Connection Services

Modify `registrationprofile.properties` as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that `portalEnabled` is set to `false`. Run the command:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties \
-e softwareUpdate
```

**EXAMPLE 5** Never Registering

To never register a system, enter:

```
/usr/sbin/sconadm register -N
```

**EXAMPLE 6** Using a Proxy Server With Proxy Authentication

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

**EXAMPLE 6** Using a Proxy Server With Proxy Authentication *(Continued)*

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

**EXAMPLE 7** Changing Proxy Host Settings

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

Then, change the `proxyHostName` value by running the following command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties \
-p newproxy.mycompany.com
```

After the preceding command all proxies use `newproxy.mycompany.com`.

**EXAMPLE 8** Resetting a System Not to Use a Proxy

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that values for all proxy fields are null.

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

**Exit Status** 0 Success.

>0 An error occurred.

**Files** /usr/lib/breg/data/RegistrationProfile.properties  
Registration profile template.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWbrg         |
| Interface Stability | Stable          |

**See Also** [registration\\_profile\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#)

**Name** sdpadm – SDP system configuration administration

**Synopsis** /usr/sbin/sdpadm status | enable | disable

**Description** The sdpadm command is used to display the system state of the Sockets Direct Protocol (SDP) protocol. The sdpadm command can optionally be used to set the state of the SDP protocol. See [sdp\(7D\)](#).

By default the SDP protocol is disabled on the system. It can be enabled by using sdpadm enable.

**Options** The following subcommands are supported:

status      Displays the system status of the SDP protocol

enable      Enables the SDP protocol

disable     Disables the SDP protocol

**Usage** The required privileges to change the state of the SDP protocol are controlled by the network configuration policy. If a user does not have the correct privileges to set the SDP policy, sdpadm returns the current state of SDP without having changed the state.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWibsdpu     |

Infiniband Specification Volume 1 (<http://www.infinibandta.org>)

**Name** sendmail – send mail over the internet

**Synopsis** /usr/lib/sendmail [-Ac] [-Am] [-ba] [-bD] [-bd] [-bi] [-bl] [-bm] [-bp] [-bP] [-bs] [-bt] [-bv] [-B *type*] [-C *file*] [-D *logfile*] [-d *X*] [-F *fullname*] [-f *name*] [-G] [-h *N*] [-L *tag*] [-M *xvalue*] [-N *notifications*] [-n] [-O*option* =*value*] [-o *xvalue*] [-p *protocol*] [-Q [*reason*]] [-q [*time*]] [-q *Xstring*] [-R *ret*] [-r *name*] [-t] [-V *envid*] [-v] [-X *logfile*] [*address*]...

**Description** The sendmail utility sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.

sendmail is not intended as a user interface routine. Other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages.

With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.

Local addresses are looked up in the local [aliases\(4\)](#) file, or in a name service as defined by the [nsswitch.conf\(4\)](#) file, and aliased appropriately. In addition, if there is a .forward file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about .forward files.

Aliasing can be prevented by preceding the address with a backslash.

There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns *and* has exclusive write permission to the /etc/mail/aliases\* files.

If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a dead.letter file in the sender's home directory.

**Service Management** The sendmail service is managed by the service management facility, [smf\(5\)](#), under the service identifiers:

```
svc:/network/smtp:sendmail
svc:/network/sendmail-client:default
```

Administrative actions on these services, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The services' status can be queried using the [svcs\(1\)](#) command.

These are separate services rather than instances of the same service so that other services can properly express any dependencies. In particular, here are some guidelines about which service/instance should be depended on for which purposes:

- For a service that uses `sendmail` to send mail, an optional dependency on the service `svc:/network/sendmail-client` might be in order.
- For a service that needs to receive mail in general, but does not depend on `sendmail` being the particular SMTP receiver, a dependency on the service `svc:/network/smtp` might be in order.
- For a service that needs to interact with `sendmail` in particular, such as a `Milter`, a dependency on the instance `svc:/network/smtp:sendmail` might be in order.

For the last two, note the difference, as the latter has the `:"sendmail"` instance specification, whereas the former does not, thus representing the more general service.

#### Enabling Access to Remote Clients

On an unmodified system, access to `sendmail` by remote clients is enabled and disabled through the service management facility (see [smf\(5\)](#)). In particular, remote access is determined by the value of the `local_only` SMF property:

```
svc:/network/smtp:sendmail/config/local_only = true
```

A setting of `true`, as above, disallows remote access; `false` allows remote access. The default value is `true`.

The following example shows the sequence of SMF commands used to enable `sendmail` to allow access to remote systems:

```
svccfg -s svc:/network/smtp:sendmail setprop config/local_only = false
svcadm refresh svc:/network/smtp:sendmail
svcadm restart svc:/network/smtp:sendmail
```

See [svcadm\(1M\)](#) and [svccfg\(1M\)](#).

Note, however, on a system where any of the [sendmail\(4\)](#) files have been customized, setting this property might not have the intended effect. See [sendmail\(4\)](#) for details.

#### Automated Rebuilding of Configuration Files

See [sendmail\(4\)](#) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

#### Restricting Host Access

`sendmail` uses TCP Wrappers to restrict access to hosts. It uses the service name of `sendmail` for `hosts_access()`. For more information on TCP Wrappers, see [tcpd\(1M\)](#) and [hosts\\_access\(4\)](#) in the `SUNWtcpd` package. [tcpd\(1M\)](#) and [hosts\\_access\(4\)](#) are not part of the Solaris man pages.

#### Startup Options

The `/etc/default/sendmail` file stores startup options for `sendmail` so that the options are not removed when a host is upgraded. See also [sendmail\(4\)](#) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

You can use the following variables in the `/etc/default/sendmail` startup file:

**CLIENTOPTIONS=***string*

Selects additional options to be used with the client daemon, which looks in the client-only queue (`/var/spool/clientmqueue`) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable.

**CLIENTQUEUEINTERVAL=***#*

Similar to the `QUEUEINTERVAL` option, `CLIENTQUEUEINTERVAL` sets the time interval for mail queue runs. However, the `CLIENTQUEUEINTERVAL` option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, `/var/spool/clientmqueue`. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

**ETRN\_HOSTS=***string*

Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the [etrn\(1M\)](#) man page.

**MODE=***-bd*

Selects the mode to start `sendmail` with. Use the `-bd` option or leave it undefined.

**OPTIONS=***string*

Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

**QUEUEINTERVAL=***#*

Sets the interval for mail queue runs on the master daemon. *#* can be a positive integer that is followed by either *s* for seconds, *m* for minutes, *h* for hours, *d* for days, or *w* for weeks. The syntax is checked before `sendmail` is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and `sendmail` starts with a queue interval of 15 minutes.

**QUEUEOPTIONS=***p*

Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to *p*, which is the only setting available. Otherwise, this option is not set.

Mail Filter API `sendmail` supports a mail filter API called “milter”. For more information, see `/usr/include/libmilter/README` and <http://www.milter.org>

**Options** The following options are supported:

**-Ac**

Uses `submit.cf` even if the operation mode does not indicate an initial mail submission.

**-Am**

Uses `sendmail.cf` even if the operation mode indicates an initial mail submission.

- 
- ba  
Goes into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages are generated with a RETURN-LINEFEED at the end. Also, the From: and Sender: fields are examined for the name of the sender.
  - bd  
Runs as a daemon in the background, waiting for incoming SMTP connections.
  - bD  
Runs as a daemon in the foreground, waiting for incoming SMTP connections.
  - bi  
Initializes the [aliases\(4\)](#) database. Root must own *and* have exclusive write permission to the /etc/mail/aliases\* files for successful use of this option.
  - bl  
Runs as a daemon (like -bd) but accepts only loopback SMTP connections.
  - bm  
Delivers mail in the usual way (default).
  - bp  
Prints a summary of the mail queues.
  - bP  
Prints the number of entries in the queues. This option is only available with shared memory support.
  - bs  
Uses the SMTP protocol as described in RFC 2821. This flag implies all the operations of the -ba flag that are compatible with SMTP.
  - bt  
Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.
  - bv  
Verifies names only. Does not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.
  - B *type*  
Indicates body *type* (7BIT or 8BITMIME).
  - C *file*  
Uses alternate configuration file.
  - D *logfile*  
Send debugging output to the indicated log file instead of stdout.
  - d *X*  
Sets debugging value to *X*.

- f *name*  
Sets the name of the “from” person (that is, the sender of the mail).
- F *fullname*  
Sets the full name of the sender.
- G  
When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, `sendmail` might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. `sendmail` does not do any canonicalization in this mode.
- h *N*  
Sets the hop count to *N*. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.
- L *tag*  
Sets the identifier used in `syslog` messages to the supplied *tag*.
- M*xvalue*  
Sets macro *x* to the specified *value*.
- n  
Does not do aliasing.
- N *notifications*  
Tags all addresses being sent as wanting the indicated *notifications*, which consists of the word “NEVER” or a comma-separated list of “SUCCESS”, “FAILURE”, and “DELAY” for successful delivery, failure and a message that is stuck in a queue somewhere. The default is “FAILURE,DELAY”.
- o*xvalue*  
Sets option *x* to the specified *value*. Processing Options are described below.
- O*option=value*  
Sets *option* to the specified *value* (for long from names). Processing Options are described below.
- p *protocol*  
Sets the sending protocol. The *protocol* field can be in form *protocol: host* to set both the sending protocol and the sending host. For example: `-pUUCP: uunet` sets the sending *protocol* to UUCP and the sending host to uunet. Some existing programs use `-oM` to set the *r* and *s* macros; this is equivalent to using `-p`.
- q[*time*]  
Processes saved messages in the queue at given intervals. If *time* is omitted, processes the queue once. *time* is given as a tagged number, where *s* is seconds, *m* is minutes, *h* is hours, *d* is days, and *w* is weeks. For example, `-q1h30m` or `-q90m` would both set the timeout to one hour thirty minutes.

By default, sendmail runs in the background. This option can be used safely with `-bd`.

- `-qp [time-]`  
Similar to `-q[time]`, except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (*time*) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.
- `-qf`  
Processes saved messages in the queue once and does not `fork(2)`, but runs in the foreground.
- `-qG name`  
Processes jobs in queue group called *name* only.
- `-q[!]I substr`  
Limits processed jobs to those containing *substr* as a substring of the queue ID or not when `!` is specified.
- `-q[!]Q substr`  
Limits processed jobs to those quarantined jobs containing *substr* as a substring of the quarantine *reason* or not when `!` is specified.
- `-q[!]R substr`  
Limits processed jobs to those containing *substr* as a substring of one of the recipients or not when `!` is specified.
- `-q[!]S substr`  
Limits processed jobs to those containing *substr* as a substring of the sender or not when `!` is specified.
- `-Q[reason]`  
Quarantines a normal queue item with the given reason or unquarantines a quarantined queue item if no reason is given. This should only be used with some sort of item matching as described above.
- `-r name`  
An alternate and obsolete form of the `-f` flag.
- `-R ret`  
Identifies the information you want returned if the message bounces. *ret* can be HDRS for headers only or FULL for headers plus body.
- `-t`  
Reads message for recipients. `To:`, `Cc:`, and `Bcc:` lines are scanned for people to send to. The `Bcc:` line is deleted before transmission. Any addresses in the argument list is suppressed. The `NoRecipientAction` Processing Option can be used to change the behavior when no legal recipients are included in the message.

-v

Goes into verbose mode. Alias expansions are announced, and so forth.

-V *envid*

The indicated *envid* is passed with the envelope of the message and returned if the message bounces.

-X *logfile*

Logs all traffic in and out of sendmail in the indicated *logfile* for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

Processing Options There are a number of “random” options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

*Oxvalue*

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values t, T, f, or F; the default is TRUE), or a time interval.

The multiple character or long names use this syntax:

*O Longname=argument*

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below, the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

AliasFile (*Afile*)

Specifies possible alias files.

AliasWait (*a N*)

If set, waits up to *N* minutes for an “@:” entry to exist in the [aliases\(4\)](#) database before starting up. If it does not appear in *N* minutes, issues a warning. Defaults to 10 minutes.

AllowBogusHELO

Allows a HELO SMTP command that does not include a host name. By default this option is disabled.

BadRcptThrottle=*N*

If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleeps for one second after each rejected RCPT command.

BlankSub (*Bc*)

Sets the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to SPACE (that is, no change is made).

**CACertFile**

File containing one CA cert.

**CACertPath**

Path to directory with certs of CAs.

**CheckAliases (n)**

Validates the RHS of aliases when rebuilding the [aliases\(4\)](#) database.

**CheckpointInterval (CN)**

Checkpoints the queue every *N* (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

**ClassFactor (zfact)**

The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` are favored. Defaults to 1800.

**ClientCertFile**

File containing the cert of the client, that is, this cert is used when `sendmail` acts as client.

**ClientKeyFile**

File containing the private key belonging to the client cert.

**ClientPortOptions**

Sets client SMTP options. The options are key=value pairs. Known keys are:

**Addr Address Mask**

*Address Mask* defaults to `INADDR_ANY`. The address mask can be a numeric address in dot notation or a network name.

**Family**

Address family (defaults to `INET`).

**Listen**

Size of listen queue (defaults to 10).

**Port**

Name/number of listening port (defaults to `smtp`).

**RcvBufSize**

The size of the TCP/IP receive buffer.

**SndBufSize**

The size of the TCP/IP send buffer.

**Modifier**

Options (flags) for the daemon. Can be:

**h**

Uses name of interface for HELO command.

If `h` is set, the name corresponding to the outgoing interface address (whether chosen by means of the `Connection` parameter or the default) is used for the HELO/EHLO command.

#### `ColonOkInAddr`

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 “group” syntax. This option is on for version 5 and lower configuration files.

#### `ConnectionCacheSize (kN)`

The maximum number of open connections that are to be cached at a time. The default is 1. This delays closing the current connection until either this invocation of `sendmail` needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

#### `ConnectionCacheTimeout (Ktimeout)`

The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a cached connection, it always sends a NOOP (no operation) command to check the connection. If the NOOP command fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

#### `ConnectionRateThrottle`

The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or  $\leq 0$ , there is no limit.

#### `ConnectionRateWindowSize`

Define the length of the interval for which the number of incoming connections is maintained. The default is 60 seconds.

#### `ControlSocketName`

Name of the control socket for daemon management. A running `sendmail` daemon can be controlled through this Unix domain socket. Available commands are: `help`, `restart`, `shutdown`, and `status`. The `status` command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; `/var/spool/mqueue/.smcontrol` is recommended for the socket name.

#### `CRLFile`

File containing certificate revocation status, useful for X.509v3 authentication.

#### `DaemonPortOptions (Options)`

Sets server SMTP options. The options are *key=value* pairs. Known keys are:

##### Name

User-definable name for the daemon (defaults to “Daemon#”). Used for error messages and logging.

**Addr**

Address mask (defaults INADDR\_ANY).

The address mask may be a numeric address in dot notation or a network name.

**Family**

Address family (defaults to INET).

**InputMailFilters**

List of input mail filters for the daemon.

**Listen**

Size of listen queue (defaults to 10).

**Modifier**

Options (flags) for the daemon; can be a sequence (without any delimiters) of:

a

Requires authentication.

b

Binds to interface through which mail has been received.

c

Performs hostname canonification (.cf).

f

Requires fully qualified hostname (.cf).

h

Uses name of interface for HELO command.

u

Allows unqualified addresses (.cf).

C

Does not perform hostname canonification.

E

Disallows ETRN (see RFC 2476).

**Name**

User-definable name for the daemon (defaults to Daemon#). Used for error messages and logging.

**Port**

Name/number of listening port (defaults to smtp).

**ReceiveSize**

The size of the TCP/IP receive buffer.

**SendSize**

The size of the TCP/IP send buffer.

**children**

Maximum number of children per daemon. See `MaxDaemonChildren`.

**DeliveryMode**

Delivery mode per daemon. See `DeliveryMode`.

**refuseLA**

RefuseLA per daemon.

**delayLA**

DelayLA per daemon.

**queueLA**

QueueLA per daemon.

`sendmail` listens on a new socket for each occurrence of the `DaemonPortOptions` option in a configuration file.

**DataFileBufferSize**

Sets the threshold, in bytes, before a memory-based queue data file becomes disk-based. The default is 4096 bytes.

**DeadLetterDrop**

Defines the location of the system-wide dead.letter file, formerly hard-coded to `/var/tmp/dead.letter`. If this option is not set (the default), `sendmail` does not attempt to save to a system-wide dead.letter file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the `qf` file as it has in the past when the dead.letter file could not be opened.

**DefaultCharSet**

Sets the default character set to use when converting unlabeled 8 bit input to MIME.

**DefaultUser (*ggid*) or (*uid*)**

Sets the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to 1. The value can also be given as a symbolic group or user name.

**DelayLA=*LA***

When the system load average exceeds *LA*, `sendmail` sleeps for one second on most SMTP commands and before accepting connections.

**DeliverByMin=*time***

Sets minimum time for Deliver By SMTP Service Extension (RFC 2852). If 0, no time is listed, if less than 0, the extension is not offered, if greater than 0, it is listed as minimum time for the EHLO keyword DELIVERBY.

**DeliveryMode (*dx*)**

Delivers in mode *x*. Legal modes are:

**i**

Delivers interactively (synchronously).

**b**  
Delivers in background (asynchronously).

**d**  
Deferred mode. Database lookups are deferred until the actual queue run.

**q**  
Just queues the message (delivers during queue run).

Defaults to **b** if no option is specified, **i** if it is specified but given no argument (that is, **Od** is equivalent to **Odi**).

#### DHParameters

File containing the DH parameters.

#### DialDelay

If a connection fails, waits this many seconds and tries again. Zero means “do not retry”.

#### DontBlameSendmail

If set, overrides the file safety checks. This compromises system security and should not be used. See <http://www.sendmail.org/tips/dontBlameSendmail> for more information.

#### DontExpandCnames

If set, `$[ ... $]` lookups that do DNS-based lookups do not expand CNAME records.

#### DontInitGroups

If set, the `initgroups(3C)` routine is never invoked. If you set this, agents run on behalf of users only have their primary (`/etc/passwd`) group permissions.

#### DontProbeInterfaces

If set, `sendmail` does not insert the names and addresses of any local interfaces into the `=$w` class. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

#### DontPruneRoutes (R)

If set, does not prune route-addr syntax addresses to the minimum possible.

#### DoubleBounceAddress

If an error occurs when sending an error message, sends that “double bounce” error message to this address.

#### EightBitMode (8)

Uses 8-bit data handling. This option requires one of the following keys. The key can be selected by using just the first character, but using the full word is better for clarity.

##### mimify

Does any necessary conversion of 8BITIME to 7-bit.

##### pass

Passes unlabeled 8-bit input through as is.

**strict**

Rejects unlabeled 8-bit input.

**ErrorHeader** (*Efile/message*)

Appends error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or NULL, or if it names a file which does not exist or which is not readable, no message is printed.

**ErrorMode** (*ex*)

Disposes of errors using mode *x*. The values for *x* are:

**e**

Mails back errors and gives 0 exit status always.

**m**

Mails back errors.

**p**

Prints error messages (default).

**q**

No messages, just gives exit status.

**w**

Writes back errors (mail if user not logged in).

**FaLlbackMXhost** (*Vfallbackhost*)

If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

**FaLlBackSmartHost**

If specified, the *fallBackSmartHost* is used in a last-ditch effort for each host. This is intended to be used by sites with “fake internal DNS”. That is, a company whose DNS accurately reflects the world inside that company's domain but not outside.

**FastSplit**

If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache. To enforce initial sorting based on MX records set *FastSplit* to zero. If the mail is submitted directly from the command line, then the value also limits the number of processes to deliver the envelopes; if more envelopes are created they are only queued up and must be taken care of by a queue run. Since the default submission method is by way of SMTP (either from a MUA or by way of the Message Submission Program [MSP]), the value of *FastSplit* is seldom used to limit the number of processes to deliver the envelopes.

**ForkEachJob (Y)**

If set, delivers each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

**ForwardPath (Jpath)**

Sets the path for searching for users' .forward files. The default is \$Z/.forward. Some sites that use the automounter may prefer to change this to /var/forward/\$u to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; sendmail stops at the first file it can successfully and safely open. For example, /var/forward/\$u:\$Z/.forward searches first in /var/forward/*username* and then in *~username*/.forward (but only if the first file does not exist). Refer to the NOTES section for more information.

**HelloName=name**

Sets the name to be used for HELO/EHLO (instead of \$j).

**HelpFile (Hfile)**

Specifies the help file for SMTP.

**HoldExpensive (c)**

If an outgoing mailer is marked as being expensive, does not connect immediately.

**HostsFile**

Sets the file to use when doing “file” type access of host names.

**HostStatusDirectory**

If set, host status is kept on disk between sendmail runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

**IgnoreDots (i)**

Ignores dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

**LogLevel (Ln)**

Sets the default log level to *n*. Defaults to 9.

**(Mx value)**

Sets the macro *x* to *value*. This is intended only for use from the command line.

**MailboxDatabase**

Type of lookup to find information about local mail boxes, defaults to pw which uses [getpwnam\(3C\)](#). Other types can be introduced by adding them to the source code, see `libsm/mbdb.c` for details.

**MatchGECOS (G)**

Tries to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

**MaxDaemonChildren**

The maximum number of children the daemon permits. After this number, connections are rejected. If not set or  $\leq 0$ , there is no limit.

**MaxHopCount (hN)**

The maximum hop count. Messages that have been processed more than  $N$  times are assumed to be in a loop and are rejected. Defaults to 25.

**MaxMessageSize**

The maximum size of messages that are accepted (in bytes).

**MaxMimeHeaderLength= $M$ [/ $N$ ]**

Sets the maximum length of certain MIME header field values to  $M$  characters. For some of these headers which take parameters, the maximum length of each parameter is set to  $N$  if specified. If  $/N$  is not specified, one half of  $M$  is used. By default, these values are 0, meaning no checks are done.

**MaxNOOPCommands= $N$** 

Overrides the default of 20 for the number of useless commands.

**MaxQueueChildren= $N$** 

When set, this limits the number of concurrent queue runner processes to  $N$ . This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed **MaxQueueChildren** then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that **MaxQueueChildren** is not be exceeded, while the remaining queue groups are run later (in round robin order). See **MaxRunnersPerQueue**.

**MaxQueueRunSize**

If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

**MaxRunnersPerQueue= $N$** 

This sets the default maximum number of queue runners for queue groups. Up to  $N$  queue runners work in parallel on a queue group's messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the **Runners** option. The default is 1 when not set.

**MeToo (m)**

Sends to me too, even if I am in an alias expansion.

**MaxRecipientsPerMessage**

If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

**MinFreeBlocks** (*bN/M*)

Insists on at least *N* blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, `sendmail` gives a 452 response to the MAIL command. This invites the sender to try again later. The optional *M* is a maximum message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

**MinQueueAge**

Specifies the amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

**MustQuoteChars**

Specifies the characters to be quoted in a full name phrase. `&`, `;`, `\` `()` `[]` are quoted automatically.

**NiceQueueRun**

Specifies the priority of queue runners. See `nice(1)`.

**NoRecipientAction**

Sets action if there are no legal recipient files in the message. The legal values are:

**add-apparently-to**

Adds an `Apparently-to:` header with all the known recipients (which may expose blind recipients).

**add-bcc**

Adds an empty `Bcc:` header.

**add-to**

Adds a `To:` header with all the known recipients (which may expose blind recipients).

**add-to-undisclosed**

Adds a `To: undisclosed-recipients:` header.

**none**

Does nothing, that is, leaves the message as it is.

**OldStyleHeaders** (*o*)

Assumes that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

**OperatorChars** or *\$o*

Defines the list of characters that can be used to separate the components of an address into tokens.

**PidFile**

Specifies the filename of the pid file. The default is `/var/run/sendmail.pid`. The filename is macro-expanded before it is opened, and unlinked when `sendmail` exits.

**PostmasterCopy** (*Ppostmaster*)

If set, copies of error messages are sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

**PrivacyOptions** (*popt,opt,...*)

Sets privacy options. Privacy is really a misnomer; many of these options are just a way of insisting on stricter adherence to the SMTP protocol.

The *goaway* pseudo-flag sets all flags except *noreceipts*, *restrictmailq*, *restrictqrun*, *restrictexpand*, *noetrn*, and *nobodyreturn*. If *mailq* is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The *restrict-expand* pseudo-flag instructs sendmail to drop privileges when the *-bv* option is given by users who are neither root nor the *TrustedUser* so users cannot read private aliases, forwards, or *:include:* files. It adds the *NonRootSafeAddr* to the “*DontBlame-Sendmail*” option to prevent misleading unsafe address warnings. It also overrides the *-v* (verbose) command line option to prevent information leakage. Authentication Warnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using a non-standard queue directory.

The options can be selected from:

**authwarnings**

Puts *X-Authentication-Warning:* headers in messages.

**goaway**

Disallows essentially all SMTP status queries.

**needexpnhelo**

Insists on HELO or EHL0 command before EXPN.

**needmailhelo**

Insists on HELO or EHL0 command before MAIL.

**needvrfyhelo**

Insists on HELO or EHL0 command before VRFY.

**noactualrecipient**

Do not put an *X-Actual-Recipient* line in a DNS that reveals the actual account to which an address is mapped.

**noetrn**

Disallows ETRN entirely.

**noexpn**

Disallows EXPN entirely.

`noreceipts`

Prevents return receipts.

`nobodyreturn`

Does not return the body of a message with DSNs.

`novrfy`

Disallows VRFY entirely.

`public`

Allows open access.

`restrictexpand`

Restricts `-bv` and `-v` command line flags.

`restrictmailq`

Restricts `mailq` command.

`restrictqrun`

Restricts `-q` command line flag.

`ProcessTitlePrefix` *string*

Prefixes the process title shown on “`/usr/ucb/ps auxww`” listings with *string*. The string is macro processed.

`QueueDirectory` (*qdir*)

Uses the named *dir* as the queue directory.

`QueueFactor` (*qfactor*)

Uses *factor* as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (`x` flag) to determine the maximum message priority to be sent. Defaults to `600000`.

`QueueFileMode`=*mode*

Defaults permissions for queue files (octal). If not set, `sendmail` uses `0600` unless its real and effective uid are different in which case it uses `0644`.

`QueueLA` (*xLA*)

When the system load average exceeds *LA*, just queues messages (that is, does not try to send them). Defaults to eight times the number of processors online when `sendmail` starts.

`QueueSortOrder`=*algorithm*

Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are `host` (to order by the name of the first host name of the first recipient), `filename` (to order by the name of the queue file name), `time` (to order by the submission/creation time), `random` (to order randomly), `modification` (to order by the modification time of the `qf` file (older entries first)), `none` (to not order), and `priority` (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority

messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

**QueueTimeout** (*Trtime/wtime*)

Sets the queue timeout to *rtime*. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional *wtime* is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

**RandFile**

File containing random data (use prefix `file:`) or the name of the UNIX socket if EGD is used (use prefix `egd:`). Note that Solaris supports `random(7D)`, so this does not need to be specified.

**RecipientFactor** (*yfact*)

The indicated factor *fact* is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

**RefuseLA** (*XLA*)

When the system load average exceeds *LA*, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when `sendmail` starts.

**RejectLogInterval**

Log interval when refusing connections for this long (default: 3h).

**ResolverOptions** (*I*)

Tunes DNS lookups.

**RetryFactor** (*Zfact*)

The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

**RrtImpliesDsn**

If this option is set, a Return-Receipt-To: header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

**RunAsUser**

If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

**SafeFileEnvironment**

If set, sendmail does a chroot into this directory before writing files.

**SaveFromLine (f)**

Saves Unix-style From lines at the front of headers. Normally they are assumed redundant and discarded.

**SendMimeErrors (j)**

If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, sendmail does not return the DSN keyword in response to an EHLO and does not do Delivery Status Notification processing as described in RFC 1891.

**ServerCertFile**

File containing the cert of the server, that is, this cert is used when sendmail acts as server.

**ServerKeyFile**

File containing the private key belonging to the server cert.

**ServiceSwitchFile**

Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

**SevenBitInput (7)**

Strips input to seven bits for compatibility with old systems. This should not be necessary.

**SharedMemoryKey**

Specifies key to use for shared memory segment. If not set (or 0), shared memory is not be used. If this option is set, sendmail can share some data between different instances. For example, the number of entries in a queue directory or the available space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

**SharedMemoryKeyFile=*file***

If SharedMemoryKeyFile is set to -1, the automatically selected shared memory key will be stored in the specified file.

**SingleLineFromHeader**

If set, From: lines that have embedded newlines are unwrapped onto one line.

**SingleThreadDelivery**

If this option and the HostStatusDirectory option are both set, uses single thread deliveries to other hosts.

**SmtpgreetingMessage or \$e**

Specifies the initial SMTP greeting message.

**SoftBounce**

If set, issue temporary errors (4xy) instead of permanent errors (5xy). This can be useful during testing of a new configuration to avoid erroneous bouncing of mail.

**StatusFile** (*Sfile*)

Logs statistics in the named *file*. By default, this is `/etc/mail/sendmail.st`. As root, you must `touch(1)` this file to enable `mailstats(1)`.

**SuperSafe** (*s*)

This option can be set to `True`, `False`, `Interactive`, or `PostMilter`. If set to `True`, `sendmail` is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. `sendmail` always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to `True`. The `Interactive` value has been introduced in 8.12 and can be used together with `DeliveryMode=i`. It skips some synchronization calls which are effectively doubled in the code execution path for this mode. If set to `PostMilter`, `sendmail` defers synchronizing the queue file until any milters have signaled acceptance of the message. `PostMilter` is useful only when `sendmail` is running as an SMTP server; in all other situations it acts the same as `True`.

**TempFileMode** (*Fmode*)

Specifies the file mode for queue files.

**Timeout** (*rtimeouts*)

Timeout reads after time interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no *keyword=* part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

`acconnect`  
all connections for a single delivery attempt [0, unspecified]

`command`  
command read [1h, 5m]

`connect`  
initial connect [0, unspecified]

`control`  
complete control socket transaction [2m, none]

`datablock`  
data block read [1h, 3m]

`datafinal`  
reply to final . in data [1h, 10m]

`datainit`  
reply to DATA command [5m, 2m]

`fileopen`  
file open [60sec, none]

`helo`  
reply to HELO or EHLO command [5m, none]

---

`hoststatus`  
    `host retry` [30m, unspecified]

`iconnect`  
    first attempt to connect to a host [0, unspecified]

`ident`  
    IDENT protocol timeout [5s, none]

`initial`  
    wait for initial greeting message [5m, 5m]

`lhlo`  
    wait for reply to an LMTP LHLO command [2m, unspecified]

`mail`  
    reply to MAIL command [10m, 5m]

`misc`  
    reply to NOOP and VERB commands [2m, none]

`queuereturn`  
    undeliverable message returned [5d]

`queuwarn`  
    deferred warning [4h]

`quit`  
    reply to QUIT command [2m, none]

`rcpt`  
    reply to RCPT command [1h, 5m]

`resolver.retrans`  
    Resolver's retransmission time interval (in seconds) [varies]. Sets both  
    `Timeout.resolver.retrans.first` and `Timeout.resolver.retrans.normal`.

`resolver.retrans.first`  
    Resolver's retransmission time interval (in seconds) for the first attempt to deliver a  
    message [varies].

`resolver.retrans.normal`  
    Resolver's retransmission time interval (in seconds) for all look-ups except the first  
    delivery attempt [varies].

`resolver.retry`  
    Number of times to retransmit a resolver query [varies]. Sets both  
    `Timeout.resolver.retry.first` and `Timeout.resolver.retry.normal`.

`resolver.retry.first`  
    Number of times to retransmit a resolver query for the first attempt to deliver a message  
    [varies].

**resolver.retry.normal**

Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

**rset**

reply to RSET command [5m, none]

**starttls**

response to an SMTP STARTTLS command [1h]

**TimeZoneSpec (*tzinfo*)**

Sets the local time zone info to *tzinfo*, for example, "PST8PDT". Actually, if this is not set, the TZ environment variable is cleared (so the system default is used); if set but null, the user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

**TLSSrvOptions**

If this option is 'V', then no client verification is performed, that is, the server does not ask for a certificate.

**TrustedUser**

The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

**TryNullMXList (*w*)**

If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes `sendmail` to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.

**UnixFromLine or \$l**

The "From " line used when sending to files or programs.

**UnsafeGroupWrites**

If set, group-writable `:include:` and `.forward` files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.

**UseErrorsTo (*l*)**

If there is an `Errors-To:` header, sends error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes `sendmail` to violate RFC 1123. This option is not recommended and deprecated.

**UseMSP**

Uses as mail submission program, that is, allows group writable queue files if the group is the same as that of a `set-group-id sendmail` binary.

**UserDatabaseSpec (U)**

Defines the name and location of the file containing User Database information.

**Verbose (v)**

Runs in verbose mode. If this is set, sendmail adjusts the `HoldExpensive` and `DeliveryMode` options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The `Verbose` option should *never* be set in the configuration file; it is intended for command line use only.

**XscriptFileBufferSize**

Sets the threshold, in bytes, before a memory-based queue transcript file becomes disk-based. The default is 4096 bytes.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep sendmail from suppressing the blanks from between arguments.

If invoked as `newaliases`, sendmail rebuilds the alias database, so long as the `/etc/mail/aliases*` files are owned by root *and* root has exclusive write permission. If invoked as `mailq`, sendmail prints the contents of the mail queue.

**Operands** *address*

address of an intended recipient of the message being sent.

**Usage** See [largefile\(5\)](#) for the description of the behavior of sendmail when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Exit Status** sendmail returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

**EX\_OK**

Successful completion on all addresses.

**EX\_NOUSER**

User name not recognized.

**EX\_UNAVAILABLE**

Catchall. Necessary resources were not available.

**EX\_SYNTAX**

Syntax error in address.

**EX\_SOFTWARE**

Internal software error, including bad arguments.

**EX\_OSERR**

Temporary operating system error, such as “cannot fork”.

**EX\_NOHOST**

Host name not recognized.

**EX\_TEMPFAIL**

Message could not be sent immediately, but was queued.

**Environment Variables** No environment variables are used. However, sendmail's start-up script, invoked by [svcadm\(1M\)](#), reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, the start-up script parses this variable and invokes [etrn\(1M\)](#) appropriately. `ETRN_HOSTS` should be of the form:

```
"s1:c1.1,c1.2 s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of `server:client` where `client` can be one or more comma-separated names. The `:client` part is optional. `server` is the name of the server to prod; a mail queue run is requested for each `client` name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host `server`.

**Files** `dead.letter`

Unmailable text

`/etc/default/sendmail`

Contains default settings. You can override some of the settings by command line options.

`/etc/mail/aliases`

Mail aliases file (ASCII)

`/etc/mail/aliases.db`

Database of mail aliases (binary)

`/etc/mail/aliases.dir`

Database of mail aliases (binary)

`/etc/mail/aliases.pag`

Database of mail aliases (binary)

`/etc/mail/sendmail.cf`

Defines environment for sendmail

`/etc/mail/submit.cf`

Defines environment for MSP

`/etc/mail/trusted-users`

Lists users that are “trusted”, that is, able to set their envelope from address using `-f` without generating a warning message. Note that this file is consulted by the default `sendmail.cf`, but not by the default `submit.cf`, in which the line referring to `/etc/mail/trusted-users` is commented out. See [sendmail\(4\)](#) for instructions on making changes to `submit.cf` and `sendmail.cf`.

`/var/spool/clientmqueue/*`

Temporary files and queued mail

`/var/spool/mqueue/*`  
 Temporary files and queued mail

`~/ .forward`  
 List of recipients for forwarding messages

`/usr/include/libmilter/README`  
 Describes the steps needed to compile and run a filter

<http://www.sendmail.org>

<http://www.milter.org>

**Notes** The `sendmail` program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see [check-hostname\(1M\)](#)).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to `/etc/mail` and `/var/spool/mqueue` has been restricted.

Security restrictions have been placed users using `.forward` files to pipe mail to a program or redirect mail to a file. The default shell (as listed in `/etc/passwd`) of these users must be listed in `/etc/shells`. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on `.forward` and `:include:` files. These files and the directory structure that they are placed in cannot be group- or world-writable. See [check-permissions\(1M\)](#).

If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the `DontProbeInterfaces` option to enable delivery to those destinations. In its default startup behavior, `sendmail` probes each interface and adds an

interface's IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with `localhost` as the MX value. If this is not the result you want, enable `DontProbeInterfaces`.

**Name** setuname – change machine information

**Synopsis** setuname [-t] [-n *node*] [-s *name*]

**Description** The setuname utility changes the parameter value for the system name and node name. Each parameter can be changed using setuname and the appropriate option.

Either or both the -s and -n options must be given when invoking setuname.

The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.

**Options** The following options are supported:

- n *node* Changes the node name. *node* specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.
- s *name* Changes the system name. *name* specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.
- t Temporary change. No attempt will be made to create a permanent change.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [attributes\(5\)](#)

**Notes** setuname attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.

**Name** sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon

**Synopsis** sf880drd

**Description** The Sun Fire 880 Dynamic Reconfiguration daemon, `sf880drd`, is part of the PCI and system bus hotplug framework. `sf880drd` starts at boot time. It has no configuration options and does not report any system status.

`sf880drd` implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.

**Files** /usr/platform/SUNW,Sun-Fire-880/lib/sf880drd

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWsfdr.u      |

**See Also** [svcs\(1\)](#), [cfgadm\(1M\)](#), [cfgadm\\_pci\(1M\)](#), [cfgadm\\_sbd\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `sf880drd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/platform/sun4u/sf880drd
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** sftp-server – SFTP server subsystem

**Synopsis** /usr/lib/ssh/sftp-server

**Description** sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer.

sftp-server is a subsystem for sshd(1M) and must not be run directly. There are no options or config settings.

To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd\_config:

```
Subsystem sftp /usr/lib/ssh/sftp-server
```

See sshd\_config(4) for a description of the format and contents of that file.

There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Files** /usr/lib/ssh/sftp-server Server-side binary

**Attributes** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWsshdu       |
| Interface Stability | Evolving        |

**See Also** sftp(1), ssh(1), ssh-add(1), ssh-keygen(1), sshd(1M), sshd\_config(4), attributes(5)

To view license terms, attribution, and copyright for OpenSSH, the default path is /var/sadm/pkg/SUNWsshdr/install/copyright. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

**Author** Markus Friedl

**Name** share – make local resource available for mounting by remote systems

**Synopsis** share [-F *FSType*] [-o *specific\_options*] [-d *description*]  
[*pathname*]

**Description** The share command exports, or makes a resource available for mounting, through a remote file system of type *FSType*. If the option -F *FSType* is omitted, the first file system type listed in /etc/dfs/fstypes is used as default. For a description of NFS specific options, see [share\\_nfs\(1M\)](#). *pathname* is the pathname of the directory to be shared. When invoked with no arguments, share displays all shared file systems.

**Options**

|                               |                                                                                                                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -F <i>FSType</i>              | Specify the filesystem type.                                                                                                                                                       |
| -o <i>specific_options</i>    | The <i>specific_options</i> are used to control access of the shared resource. (See <a href="#">share_nfs(1M)</a> for the NFS specific options.) They may be any of the following: |
| rw                            | <i>pathname</i> is shared read/write to all clients. This is also the default behavior.                                                                                            |
| rw= <i>client[:client]...</i> | <i>pathname</i> is shared read/write only to the listed clients. No other systems can access <i>pathname</i> .                                                                     |
| ro                            | <i>pathname</i> is shared read-only to all clients.                                                                                                                                |
| ro= <i>client[:client]...</i> | <i>pathname</i> is shared read-only only to the listed clients. No other systems can access <i>pathname</i> .                                                                      |
|                               | Separate multiple options with commas. Separate multiple operands for an option with colons. See EXAMPLES.                                                                         |
| -d <i>description</i>         | The -d flag may be used to provide a description of the resource being shared.                                                                                                     |

**Examples** EXAMPLE 1 Sharing a Read-Only Filesystem

This line will share the /disk file system read-only at boot time.

```
share -F nfs -o ro /disk
```

EXAMPLE 2 Invoking Multiple Options

The following command shares the filesystem /export/manuals, with members of the netgroup having read-only access and users on the specified host having read-write access.

```
share -F nfs -o ro=netgroup_name,rw=host1:host2:host3 /export/manuals
```

**Files**

|                   |                                                    |
|-------------------|----------------------------------------------------|
| /etc/dfs/dfstab   | list of share commands to be executed at boot time |
| /etc/dfs/fstypes  | list of file system types, NFS by default          |
| /etc/dfs/sharetab | system record of shared file systems               |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [mountd\(1M\)](#), [nfsd\(1M\)](#), [share\\_nfs\(1M\)](#), [shareall\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

**Notes** Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the `share` command used to be invoked as [exportfs\(1B\)](#) or `/usr/sbin/exportfs`.

If `share` commands are invoked multiple times on the same filesystem, the last `share` invocation supersedes the previous—the options set by the last `share` command replace the old options. For example, if read-write permission was given to `usera` on `/somefs`, then to give read-write permission also to `userb` on `/somefs`:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

**Name** shareall, unshareall – share, unshare multiple resources

**Synopsis** shareall [-F *FSType* [,*FSType*]...] [-| *file*]  
unshareall [-F *FSType* [,*FSType*]...]

**Description** When used with no arguments, shareall shares all resources from *file*, which contains a list of share command lines. If the operand is a hyphen (-), then the share command lines are obtained from the standard input. Otherwise, if neither a *file* nor a hyphen is specified, then the file */etc/dfs/dfstab* is used as the default.

Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to -F.

unshareall unshares all currently shared resources. Without a -F flag, it unshares resources for all distributed file system types.

**Options** -F *FSType* Specify file system type. Defaults to the first entry in */etc/dfs/fstypes*.

**Files** */etc/dfs/dfstab*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [share\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

**Name** share\_nfs – make local NFS file systems available for mounting by remote systems

**Synopsis** share [-d *description*] [-F *nfs*] [-o *specific\_options*] *pathname*

**Description** The share utility makes local file systems available for mounting by remote systems. It starts the [nfsd\(1M\)](#) and [mountd\(1M\)](#) daemons if they are not already running.

If no argument is specified, then share displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.

**Options** The following options are supported:

-d *description*

Provide a comment that describes the file system to be shared.

-F *nfs*

Share NFS file system type.

-o *specific\_options*

Specify *specific\_options* in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If *specific\_options* is not specified, then by default sharing is read-write to all clients. *specific\_options* can be any combination of the following:

aclok

Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.

anon=*uid*

Set *uid* to be the effective user ID of unknown users. By default, unknown users are given the effective user ID UID\_NOBODY. If *uid* is set to -1, access is denied.

index=*file*

Load *file* rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.

log=*tag*

Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The tag is defined in `etc/nfs/nfslog.conf`. If no tag is specified, the default values associated with the *global* tag in `etc/nfs/nfslog.conf` is used. Support of NFS server logging is only available for NFS Version 2 and Version 3 requests.

nosub

Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the nosub option on server *foeey* then a NFS client cannot do:

```
mount -F nfs foeey:/export/home/mnt
```

NFS Version 4 does not use the MOUNT protocol. The nosub option only applies to NFS Version 2 and Version 3 requests.

**nosuid**

By default, clients are allowed to create files on the shared file system with the setuid or setgid mode enabled. Specifying nosuid causes the server file system to silently ignore any attempt to enable the setuid or setgid mode bits.

**public**

Moves the location of the public file handle from root (/) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the -ro=list and -rw=list options can be included with the public option.

**ro**

Sharing is read-only to all clients.

**ro=access\_list**

Sharing is read-only to the clients listed in *access\_list*; overrides the rw suboption for the clients specified. See *access\_list* below.

**root=access\_list**

Only root users from the hosts specified in *access\_list* have root access. See *access\_list* below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the anon=uid option described above). Netgroups can be used if the file system shared is using UNIX authentication (AUTH\_SYS).

**rw**

Sharing is read-write to all clients.

**rw=access\_list**

Sharing is read-write to the clients listed in *access\_list*; overrides the ro suboption for the clients specified. See *access\_list* below.

**sec=mode[:mode]. . .**

Sharing uses one or more of the specified security modes. The *mode* in the sec=mode option must be a node name supported on the client. If the sec= option is not specified, the default security mode used is AUTH\_SYS. Multiple sec= options can be specified on the command line, although each mode can appear only once. The security modes are defined in [nfssec\(5\)](#).

Each sec= option specifies modes that apply to any subsequent window=, rw, ro, rw=, ro= and root= options that are provided before another sec=option. Each additional sec= resets the security mode context, so that more window=, rw, ro, rw=, ro= and root= options can be supplied for additional modes.

**sec=*none***

If the option `sec=none` is specified when the client uses `AUTH_NONE`, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the `anon=uid` option for a description of how unauthenticated requests are handled.

**secure**

This option has been deprecated in favor of the `sec=dh` option.

**window=*value***

When sharing with `sec=dh`, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server allows. If a credential arrives with a life time larger than what is allowed, the NFS server rejects the request. The default value is 30000 seconds (8.3 hours).

*access\_list* The *access\_list* argument is a colon-separated list whose components may be any number of the following:

**hostname**

The name of a host. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname must be represented as a fully qualified DNS or LDAP name.

**netgroup**

A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.

**domain name suffix**

To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the `/etc/nsswitch.conf` must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,

```
NIS or NIS+ 172.16.45.9 --> "myhost"
```

and

```
DNS or LDAP 172.16.45.9 -->
 "myhost.mydomain.mycompany.com"
```

The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,

```
rw=.mydomain.mycompany.com
```

A single dot can be used to match a hostname with no suffix. For example,

```
rw=.
```

matches "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.

#### network

The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it is converted to a dotted address by `getnetbyname(3SOCKET)`. For example,

```
=@mynet
```

would be equivalent to:

```
=@172.16 or =@172.16.0.0
```

The network prefix assumes an octet-aligned netmask determined from the zeroth octet in the low-order part of the address up to and including the high-order octet, if you want to specify a single IP address (see below). In the case where network prefixes are not byte-aligned, the syntax allows a mask length to be specified explicitly following a slash (/) delimiter. For example,

```
=@theothernet/17 or =@172.16.132/22
```

...where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same @ notation described above, without a netmask specification. For example:

```
=@172.16.132.14
```

Multiple, individual IP addresses would be specified, for example, as:

```
root=@172.16.132.20:@172.16.134.20
```

A prefixed minus sign (-) denies access to that component of *access\_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

```
rw=-terra:engineering
```

denies access to terra but

```
rw=engineering:-terra
```

grants access to terra.

**Operands** The following operands are supported:

*pathname*

The pathname of the file system to be shared.

**Examples** EXAMPLE 1 Sharing A File System With Logging Enabled

The following example shows the /export file system shared with logging enabled:

```
example% share -o log /export
```

The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in /etc/nfs/nfslog.conf. The `nfslogd(1M)` daemon runs only if at least one file system entry in /etc/dfs/dfstab is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line does not start the `nfslogd(1M)`.

**Exit Status** The following exit values are returned:

0  
Successful completion.

>0  
An error occurred.

**Files** /etc/dfs/fstypes  
list of system types, NFS by default

/etc/dfs/sharetab  
system record of shared file systems

/etc/nfs/nfslogtab  
system record of logged file systems

/etc/nfs/nfslog.conf  
logging configuration file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnfsu        |

**See Also** [mount\(1M\)](#), [mountd\(1M\)](#), [nfsd\(1M\)](#), [nfslogd\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [getnetbyname\(3SOCKET\)](#), [nfslog.conf\(4\)](#), [netgroup\(4\)](#), [attributes\(5\)](#), [nfssec\(5\)](#)

**Notes** If the `sec=` option is presented at least once, all uses of the `window=`, `rw`, `ro`, `rw=`, `ro=` and `root=` options must come after the first `sec=` option. If the `sec=` option is not presented, then `sec=sys` is implied.

If one or more explicit `sec=` options are presented, `sys` must appear in one of the options mode lists for accessing using the AUTH\_SYS security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /var
```

grants read-write access to any host using AUTH\_SYS, but

```
share -F nfs -o sec=dh /var
```

grants no access to clients that use AUTH\_SYS.

Unlike previous implementations of share\_nfs, access checking for the window=, rw, ro, rw=, and ro= options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the ro= and rw= options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for hosta (albeit on each NFS request) to side-step the stronger controls of AUTH\_DES. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids AUTH\_DES only gets read-only access. In general, multiple security modes per share command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If rw=, and ro= options are specified in the same sec= clause, and a client is in both lists, the order of the two options determines the access the client gets. If client hosta is in two netgroups - group1 and group2 - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example hosta would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a sec= clause, both the ro and rw= options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the ro= and rw options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The ro= and rw= options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH\_SYS is guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH\_DES is guaranteed to work over any transport provider.

There are no interactions between the root= option and the rw, ro, rw=, and ro= options. Putting a host in the root list does not override the semantics of the other options. The access the host gets is the same as when the root= options is absent. For example, the following share command denies access to hostb:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following gives read-only permissions to hostb:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following gives read-write permissions to hostb:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) are shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following share command results in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

An NFS mount of server: `/export/foo` results in server: `/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file shares the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

The same command entered from the command line does not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The [mountd\(1M\)](#) and [nfsd\(1M\)](#) daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

The [mountd\(1M\)](#) process allows the processing of a path name that contains a symbolic link. This allows the processing of paths that are not themselves explicitly shared with `share_nfs`. For example, `/export/foo` might be a symbolic link that refers to `/export/bar` which has been specifically shared. When the client mounts `/export/foo` the `mountd` processing follows the symbolic link and responds with the `/export/bar`. The NFS Version 4 protocol does not use the `mountd` processing and the client's use of `/export/foo` does not work as it does with NFS Version 2 and Version 3 and the client receives an error when attempting to mount `/export/foo`.

**Name** showmount – show remote mounts

**Synopsis** /usr/sbin/showmount [-ade] [hostname]

**Description** showmount lists the clients that have remotely mounted a filesystem from *host*. This information is maintained by the [mountd\(1M\)](#) server on *host*, and is saved across crashes in the file `/etc/rmtab`. The default value for *host* is the value returned by [hostname\(1\)](#).

The showmount command does not display the names of NFS Version 4 clients.

**Options** -a Print all remote mounts in the format:

hostname : directory

where *hostname* is the name of the client, and *directory* is the root of the file system that has been mounted.

-d List directories that have been remotely mounted by clients.

-e Print the list of shared file systems.

**Files** /etc/rmtab

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWnfscu       |

**See Also** [hostname\(1\)](#), [mountd\(1M\)](#), [attributes\(5\)](#)

*Oracle Solaris 10 8/11 Installation Guide: Basic Installations*

**Bugs** If a client crashes, its entry will not be removed from the list of remote mounts on the server.

**Name** showrev – show machine, software revision, and patch revision information

**Synopsis** /usr/bin/showrev [-a] [-p | -p -R *root\_path*] [-w]  
[-c *command*] [-s *hostname*]

**Description** showrev displays revision information for the current hardware and software. With no arguments, showrev shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.

If a command is supplied with the -c option, showrev shows the PATH and LD\_LIBRARY\_PATH and finds out all the directories within the PATH that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.

**Options** The following options are supported:

- a Print all system revision information available. Window system and patch information are added.
  - c *command* Print the revision information about *command*.
  - p Print only the revision information about patches.
  - R *root\_path* Define the full path name of a directory to use as the *root\_path*. By specifying the root path, showrev retrieves the revision information about the patch from package system information files located under a directory tree starting at *root\_path*. The *root\_path* can be specified when retrieving installed patch information in a client from a server, for example, /export/root/client1.
- Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- s *hostname* Perform this operation on the specified *hostname*. The -s operation completes correctly only when *hostname* is running Solaris 2.5 or compatible versions.
  - w Print only the OpenWindows revision information.

**Output** Varies, based on flags passed. If no flags are passed, output similar to the following appears:

```

Hostname: system1
Hostid: 7233808e
Release: 5.10
Kernel architecture: sun4u
Application architecture: sparc
Hardware provider: Sun_Microsystems
Domain: a.network.COM
Kernel version: SunOS 5.10 generic

```

**Exit Status** The following error values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWadmc        |

**See Also** [arch\(1\)](#), [ldd\(1\)](#), [mcs\(1\)](#), [sum\(1\)](#), [patchadd\(1M\)](#), [attributes\(5\)](#)

**Bugs** For the -s option to work when `hostname` is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on `hostname`.

**Name** shutdown – shut down system, change system state

**Synopsis** /usr/sbin/shutdown [-y] [-g *grace-period*] [-i *init-state*]  
[*message*]

**Description** shutdown is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.

By default, shutdown brings the system to a state where only the console has access to the operating system. This state is called single-user.

Before starting to shut down daemons and killing processes, shutdown sends a warning message and, by default, a final message asking for confirmation. *message* is a string that is sent out following the standard warning message "The system will be shut down in . . ." If the string contains more than one word, it should be contained within single ( ' ) or double ( " ) quotation marks.

The warning message and the user provided *message* are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before shutdown begins. See EXAMPLES.

System state definitions are:

state 0 Stop the operating system.

state 1 State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.

state s, S State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.

state 5 Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The rc0 procedure is called to perform this task.

state 6 Stop the operating system and reboot to the state defined by the `initdefault` entry in `/etc/inittab`. The rc6 procedure is called to perform this task.

**Options** -y Pre-answer the confirmation question so the command can be run without user intervention.

-g *grace-period* Allow the super user to change the number of seconds from the 60-second default.

**-i *init-state*** If there are warnings, *init-state* specifies the state *init* is to be in. By default, system state 's' is used.

**Examples** EXAMPLE 1 Using shutdown

In the following example, shutdown is being executed on host *foo* and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "==== disk replacement ====="
Shutdown started. Tue Jun 7 14:51:40 PDT 1994

Broadcast Message from root (pts/1) on foo Tue Jun 7 14:51:41. . .
The system will be shut down in 2 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:52:41. . .
The system will be shut down in 1 minutes
==== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun 7 14:53:41. . .
The system will be shut down in 30 seconds
==== disk replacement =====
Do you want to continue? (y or n):
```

**Files** /etc/inittab controls process dispatching by *init*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**See Also** [boot\(1M\)](#), [halt\(1M\)](#), [init\(1M\)](#), [killall\(1M\)](#), [reboot\(1M\)](#), [ufsdump\(1M\)](#), [init.d\(4\)](#), [inittab\(4\)](#), [nologin\(4\)](#), [attributes\(5\)](#)

**Notes** When a system transitions down to the S or s state, the /etc/nologin file (see [nologin\(4\)](#)) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the /etc/rc2.d directory.

**Name** sldap – Service Location Protocol Daemon

**Synopsis** /usr/lib/inet/sldap [-f *configuration-file*]

**Description** The sldap daemon provides common server functionality for the Service Location Protocol (“SLP”) versions 1 and 2, as defined by IETF in *RFC 2165* and *RFC 2608*. SLP provides a scalable framework for the discovery and selection of network services.

sldap provides the following framework services:

|                                   |                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Directory Agent                   | This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. sldap does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained. |
| Service Agent Server              | All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, sldap is a service agent server.                                                                                                        |
| Passive Directory Agent Discovery | This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query sldap, obviating the need to perform discovery by means of multicast. By default, sldap performs this service.                                   |
| Proxy Registration                | This service can act as a proxy service agent for services that cannot register themselves. sldap reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.                                                                                                       |

All configuration options are available from the configuration file. sldap reads its configuration file upon startup.

Stop and start the sldap daemon using [svcadm\(1M\)](#). Use the command `svcadm enable network/slp` to start the sldap daemon. Use the command `svcadm disable network/slp` to stop it.

The file `/etc/inet/slp.conf` must exist before the slp service can start the daemon. Only the example file `/etc/inet/slp.conf.example` is present by default. To enable SLP, copy `/etc/inet/slp.conf.example` to `/etc/inet/slp.conf`.

**Options** The following options are supported:

`-f configuration-file` Specify an alternate configuration file

**Examples** **EXAMPLE 1** Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# svcadm disable network/slp
```

**EXAMPLE 2** Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# svcadm restart network/slp
```

**Files** `/etc/inet/slp.conf` The default configuration file

`slpd.reg` The proxy registration file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE    |
|---------------------|--------------------|
| Availability        | SUNWslpu, SUNWslpr |
| CSI                 | Enabled            |
| Interface Stability | Committed          |

**See Also** [svcs\(1\)](#), [svcadm\(1M\)](#), [slp\\_api\(3SLP\)](#), [slp.conf\(4\)](#), [slpd.reg\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [slp\(7P\)](#)

*System Administration Guide: Network Services*

Guttman, E., Perkins, C., Veizades, J., and Day, M., *RFC 2608, Service Location Protocol, Version 2*, The Internet Society, June 1999.

**Notes** The `slpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/slp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** smartcard – configure and administer a smart card

**Synopsis** smartcard -c admin [-a *application*] [*propertyname*]...  
 smartcard -c admin [-a *application*]  
     [-x { add|delete|modify } *propertyname=value*...]  
 smartcard -c admin -t service -j *classname* -x  
     { add|delete|modify}  
 smartcard -c admin -t terminal  
     { -j *classname* | -H *libraryname* } -d *device* -r *userfriendlyreadername* -n *readername* -x  
     { add|delete|modify }  
     [-R]  
 smartcard -c admin -t debug -j *classname* -l *level* -x  
     { add|delete|modify}  
 smartcard -c admin -t override -x { add|delete|modify} *propertyname=value*  
 smartcard -c admin -I -k *keytype* -i *filename*  
 smartcard -c admin -E -k *keytype* -o *filename*  
 smartcard -c load -A *aid* [-r *userfriendlyreadername*] -P *pin*  
     [-s *slot*] [-i *inputfile*] [-p *propfile*] [-v]  
     [*propertyname=value*]...  
 smartcard -c load -u -P *pin* [-A *aid*]  
     [-r *userfriendlyreadername*] [-s *slot*] [-v]  
 smartcard -c bin2capx -T *cardname* [-i *inputfile*]  
     [-o *outputfile*] [-p *propfile*] [-I *anothercapxfile*]  
     [-v] [*propertyname=value*]...  
 smartcard -c init -A *aid* [-r *readername*] [-s *slot*] -L  
 smartcard -c init -A *aid* [-r *readername*] -P *pin* [-s *slot*]  
     [*propertyname=value*]...  
 smartcard -c enable  
 smartcard -c disable

**Description** The smartcard utility is used for all configurations related to a smart card. It comprises the following subcommands:

1. Administration of OCF properties. (-c admin)

This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properties are:

```
defaultcard
default card for an application
```

```
defaultreader
 # default reader for an application
```

```
authmechanism
 # authentication mechanism
```

```
validcards
 # list of cards valid for an application
```

A complete listing can be obtained by using the smart card utility as described in the EXAMPLES section.

2. Loading and Unloading of applets from the smart card (-c load) and performing initial configuration of a non-Java card.

This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smart card. The applet is a Java class file that has been run through a converter to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the capx format. If no -r option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the smartcard -c admin command.

3. Converting card applets or properties to the capx format (-c bin2capx)

This subcommand is used to convert a Java card applet or properties into a new format called capx before downloading it onto the smart card. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

In the following example,

```
smartcard -c bin2capx -i cyberflex.bin \
-T CyberFlex aidto-000102030405060708090A0B0C0D0E0F fileID=2222 \
instanceID=2223 and more.
```

if no output file is specified, a default file with the name *input\_filename.capx* is created in the current directory. The mandatory -T option requires the user to specify the card name for which the capx file is being generated.

The following example

```
smartcard -c bin2capx -T IButton
```

tells the loader that the capx file contains the binary for IButton. A single capx file can hold binaries for multiple cards (1 per card.) Users can, for example, hold binary files for both CyberFlex and IButton in the same capx file as follows:

```
smartcard -c bin2capx -T IButton -i IButton.jib -o file.capx
```

In the following example,

```
smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \
-l file.capx -o file.capx
```

the `-l` option is used to provide an already-generated capx file. The output is directed to the same capx file, resulting in capx file holding binaries for both cards.

4. Personalizing a smart card (`-c init`)

This subcommand is used to set user-specific information required by an applet on a smart card. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cards.

5. Enabling and disabling the smart card desktop login (`-c {enable | disable}`)

**Options** The following options are supported:

`-a application`

Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then `ocf` is the default application.

`-A aid`

Specify a unique alphanumeric string that identifies the applet. The *aid* argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical *aid* already exists on the card, a load will result in an error.

`-c`

Specify subcommand name. Valid options are: `admin`, `load`, `bin2capx`, `init`, `enable`, and `disable`.

`-d device`

Specify device on which the reader is connected (for example, `/dev/cua/a`).

`-D`

Disable a system from using smart cards.

`-E`

Export the keys to a file.

`-H libraryname`

Specify the full path of the IFD handler library for the reader.

`-i filename`

Specify input file name.

`-I`

Import from a file.

`-j classname`

Specify fully-qualified class name.

`-k keytype`

Specify type of key (for example, `challenge_response`, `pki`.)

`-l`

Specify debug level (0–9), signifying level of debug information displayed.

- L  
List all properties configurable in an applet.
- n *readername*  
Specify reader name as required by the driver.
- o *filename*  
Specify output file name.
- p *propfile*  
Specify properties file name. This file could contain a list of property names and value pairs, in the format *propertyname=value*.
- P *pin*  
Specify pin used to validate to the card.
- r *userfriendlyreadername*  
Specify user-defined reader name where the card to be initialized is inserted.
- R  
Restart the ocf server.
- s *slot*  
Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.
- t  
Specify type of property being updated. The valid values are:
  - service  
Updating a card service provider details.
  - terminal  
Updating a card reader provider details.
  - debug  
OCF trace level.
  - override  
Override a system property of the same name.
- T *cardname*  
Specify card name.
- u  
Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.
- v  
Verbose mode ( displays helpful messages).

-x

Specify action to be taken. Valid values are: add, delete, or modify.

**Examples** EXAMPLE 1 Viewing the Values of All Properties

Enter the following command to view the values of all the properties that are set:

```
% smartcard -c admin
```

EXAMPLE 2 Viewing the Values of Specific Properties

Enter the following command to view the values of specific properties:

```
% smartcard -c admin language country
```

EXAMPLE 3 Adding a Card Service

Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

```
% smartcard -c admin -t service \
-j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

EXAMPLE 4 Adding a Reader

Enter the following command to add the IFD handler for the internal reader:

```
% smartcard -c admin -t terminal \
-H /usr/lib/smartcard/ifdh_scmi2c.so -x add \
-d /dev/scmi2c0 -r MyInternalReader -n SunISCRI
```

EXAMPLE 5 Deleting a Reader

Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```
% smartcard -c admin -t terminal -r SCM -x delete
```

EXAMPLE 6 Changing the Debug Level

Enter the following command to change the debug level for all of the `com.sun` package to 9:

```
% smartcard -c admin -t debug -j com.sun -l 9 -x modify
```

EXAMPLE 7 Setting the Default Card for an Application

Enter one of the following commands to set the default card for an application (`dtlogin`) to be CyberFlex.

If the property default card does not exist, enter the following command:

```
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:

**EXAMPLE 7** Setting the Default Card for an Application *(Continued)*

```
% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex
```

**EXAMPLE 8** Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

```
% smartcard -c admin -k challenge_response -E -o /tmp/mykeys
```

**EXAMPLE 9** Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

```
% smartcard -c admin -k challenge_response -I -i /tmp/mykeys
```

**EXAMPLE 10** Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into an SCM reader for the capx file supplied in the /usr/share/lib/smartcard directory:

```
% smartcard -c load -r SCM \
-i /usr/share/lib/smartcard/SolarisAuthApplet.capx
```

**EXAMPLE 11** Downloading an Applet Binary

Enter the following command to download an applet binary from some place other than the capx file supplied with Solaris 8 into an IButton (the aid and input file are mandatory, the remaining parameters are optional):

```
% smartcard -c load -A A000000062030400 -i newapplet.jib
```

**EXAMPLE 12** Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

```
% smartcard -c load -A newaid -i newapplet.bin \
fileID=2222 instanceID=3333 verifyKey=newKey \
MAC=newMAC heapsize=2000
```

**EXAMPLE 13** Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific aid, transport key, and initial pin:

```
% smartcard -c load -A A00000006203400 \
pin=242424246A617661 transportKey=4746584932567840
```

**EXAMPLE 14** Unloading an Applet from a Card

Enter the following command to unload an applet from iButton:

```
% smartcard -c load -u
```

**EXAMPLE 15** Displaying Usage of smartcard -c load

Enter the following command to display the usage of the smartcard -c load command:

```
% smartcard -c load
```

**EXAMPLE 16** Displaying All Configurable Parameters for an Applet

Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SCM reader:

```
% smartcard -c init -r SM -A 123456 -L
```

**EXAMPLE 17** Changing the PIN

Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the PIN for a PayFlex (non-Java) card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -P oldpin pin=newpin
```

**EXAMPLE 18** Displaying All Configurable Parameters for the SolarisAuthApplet.

Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -L
```

**EXAMPLE 19** Setting a Property to a Value on a smart card

Enter the following command to set properties called user to the value james and application to the value login on a card inserted into an SCM reader that has a pin testpin:

```
% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \
application=login user=james
```

**EXAMPLE 20** Converting an Applet for the CyberFlex Card into capx Format.

Enter the following command to convert an applet for the CyberFlex card into the capx format required for downloading the applet into the card:

```
% smartcard -c bin2capx \
-i /usr/share/lib/smartcard/SolarisAuthApplet.bin \
-T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12
```

**EXAMPLE 21** Converting an Applet for the IButton Card into capx Format

Enter the following command to convert an applet for the IButton card into the capx format required for downloading the applet into the button:

**EXAMPLE 21** Converting an Applet for the IButton Card into capx Format *(Continued)*

```
% smartcard -c bin2capx \
-i /usr/share/lib/smartcard/SolarisAuthApplet.jib \
-T IButton -o /home/CorporateCard.capx -v
```

**Exit Status** The following exit values are returned:

0  
Successful completion.

1  
An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWocf         |
| Interface Stability | Stable          |

**See Also** [ocfserv\(1M\)](#), [attributes\(5\)](#), [smartcard\(5\)](#)

**Notes** The command line options contain only alphanumeric input.

**Name** smatrrpop – populate security attribute databases in a name service

**Synopsis** smatrrpop [-c ] [-f] [-m] [-p *policy*] [-r] -s *scope* -t *scope*  
[-v] *database*

**Description** The smatrrpop command updates the [auth\\_attr\(4\)](#), [exec\\_attr\(4\)](#), [prof\\_attr\(4\)](#), and [user\\_attr\(4\)](#) role-based access control databases in a target NIS, NIS+, LDAP, or local /etc files name service from the corresponding databases in a source name service or files.

This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.

Any errors encountered while updating the target entry are reported to `stdout`, and the command continues with the next source database entry.

**Options** The following options are supported:

-c Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to `stdout`.

The target entry values are checked against entries in related databases:

- `auths` values — Each value must exist as the name of an authorization in the [auth\\_attr\(4\)](#) database.
- `profiles` values — Each value must exist as a name of a profile in the [prof\\_attr\(4\)](#) database.
- `roles` values — Each value must exist as the name of a role identity in the [user\\_attr\(4\)](#) database.
- For each [exec\\_attr\(4\)](#) entry in the source database, the name must exist as the name of a profile in the [prof\\_attr\(4\)](#) database.

-f Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.

-m For the `auths`, `profiles`, and `roles` attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:

- [prof\\_attr\(4\)](#) — the `auths` and `profiles` attribute values are merged.
- [user\\_attr\(4\)](#) — the `auths`, `profiles`, and `roles` attribute values are merged.
- [exec\\_attr\(4\)](#) — the `uid`, `gid`, `euid`, and `egid` values are merged.

- p *policy*** Specifies the value of the *policy* field in the `exec_attr(4)` database. Valid values are `suser` (standard Solaris superuser) and `tsol` (Trusted Solaris). If you specify this option, only the entries in the source `exec_attr` database with the specified *policy* are processed. If you omit this option, all entries in the source `exec_attr` database are processed.
- r** Specifies that role identities in the `user_attr(4)` database in the source name service are processed. If you omit this option, only the normal user entries in the `user_attr` source database are processed.
- s *scope*** Specifies the source name service or local file directory for database updates, using the following syntax:
- type:/server/domain*
- where *type* indicates the type of name service. Valid values for *type* are:
- `file` — local files
  - `nis` — NIS name service
  - `nisplus` — NIS+ name service
  - `ldap` — LDAP name service
- server* indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.
- domain* specifies the management domain name for the name service.
- You can use two special cases of *scope* values:
- To indicate the databases in the `/etc/security` local system directory, use the scope `file:/server`, where *server* is the name of the local system.
  - To load from databases in an arbitrary directory on the Solaris server, use the scope `file:/server/pathname`, where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.
- t *scope*** Specifies the target name service or local file directory for database updates, using the following syntax:
- type:/server/domain*
- where *type* indicates the type of name service. Valid values for *type* are:
- `file` — local files
  - `nis` — NIS name service
  - `nisplus` — NIS+ name service
  - `ldap` — LDAP name service
- server* indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

*domain* specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file:/server`, where *server* is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope `file:/server/pathname`, where where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

`-v` Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

**Operands** The following operands are supported:

*database* Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:

1. `auth_attr(4)`
2. `prof_attr(4)`
3. `exec_attr(4)`
4. `user_attr(4)`

**Examples** **EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.example.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

```
/usr/sadm/bin/smattrpop -s file:/hoosier \
-t nis:/hoosier/east.example.com all
```

**EXAMPLE 2** Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the `auth_attr` text format into the existing `auth_attr` database in the NIS+ domain, `east.example.com`. The command is executed on the NIS+ master server, `foobar`. Values from the source `auth_attr` file replace the corresponding field values in the NIS+ tables for each entry. A message is written to `stdout` for each entry processed. Database cross-checking is performed and any check error is written to `stdout`. A summary message indicating the number of entries processed and updated for the `auth_attr` database is written to `stdout`.

```
/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \
-t nisplus:/foobar/East.Sun.COM auth_attr
```

**Environment Variables** See [environ\(5\)](#) for a description of the JAVA\_HOME environment variable, which affects the execution of the smattrpop command. If this environment variable is not specified, the /usr/java location is used. See [smc\(1M\)](#).

**Exit Status** Any errors encountered while updating the target entry are reported to stdout. The following exit values are returned:

- 0 The specified tables were updated. Individual entries may have encountered checking errors.
- 1 A syntax error occurred in the command line.
- 2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

**Files**

- /etc/security/auth\_attr Authorization description database. See [auth\\_attr\(4\)](#).
- /etc/security/exec\_attr Execution profiles database. See [exec\\_attr\(4\)](#).
- /etc/security/prof\_attr Profile description database. See [prof\\_attr\(4\)](#).
- /etc/user\_attr Extended user attribute database. See [user\\_attr\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [smc\(1M\)](#), [smexec\(1M\)](#), [smprofile\(1M\)](#), [auth\\_attr\(4\)](#), [exec\\_attr\(4\)](#), [prof\\_attr\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** `smbios` – display the contents of a System Management BIOS image

**Synopsis** `smbios [-Be0sx] [-i id] [-t type] [-w file] [file]`

**Description** The `smbios` utility displays the contents of the System Management BIOS (SMBIOS) image exported by the current system or stored in a file. SMBIOS is an industry-standard mechanism for low-level system software to export hardware configuration information to higher-level system management software. The SMBIOS data format itself is defined by the Distributed Management Task Force (DMTF). Refer to <http://www.dmtf.org> for more information about SMBIOS and to obtain a copy of the SMBIOS specification and implementation guidelines.

The SMBIOS image consists of a table of structures, each describing some aspect of the system software or hardware configuration. By default, `smbios` displays the entire contents of the current SMBIOS image. If the `-s` option is specified, `smbios` displays a summary of the structures that are present in the image. If the `-w` option is specified, `smbios` writes a copy of the SMBIOS image to the specified file. `smbios` can then be applied to the resulting file to display its content.

`smbios` attempts to display each structure and its content in a human-readable fashion. If `smbios` does not recognize a structure's type or content, the raw hexadecimal data for the structure is displayed.

**Options** The following options are supported:

- B           Disable header validation for broken BIOSes.  
  
By default, `smbios` attempts to validate the SMBIOS header by verifying the anchor strings, header checksums, and version number. This option might be necessary when a BIOS has a non-compliant header.
- e           Display the contents of the SMBIOS entry point rather than the contents of the SMBIOS structure table.
- i *id*       Display only the specified structure, named by its integer *id*.
- O           Display obsolete structure types.  
  
By default, `smbios` elides output for structures whose type is marked as obsolete in the DMTF SMBIOS specification.
- s           Display only a summary listing of the structure identifiers and types, instead of the content of each selected structure.
- t *type*     Display only those structures whose type matches the specified integer type, as defined in the DMTF SMBIOS specification.
- w *file*     Write a copy of the SMBIOS image to the specified file and exit.

The SMBIOS entry point is written to the start of the file with its structure table address set to the file offset of the structure table, and a new entry point checksum is computed.

-x Display raw hexadecimal data for the selected structures in addition to human-readable output.

By default, hexadecimal data is only displayed if `smbios` cannot display human-readable output for the selected structures.

**Operands** The following operands are supported:

*file* Specifies an alternate SMBIOS image to display instead of the current system's SMBIOS image.

**Exit Status** The following exit values are returned:

- 0 Successful completion. All structures in the SMBIOS image were examined successfully.
- 1 A fatal error occurred, such as failure to open the specified file or device, or corruption in the image.
- 2 Invalid command-line options were specified.

**Files** `/dev/smbios` Kernel SMBIOS image device. This device special file is used to export a snapshot of the current system SMBIOS image.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | See below.      |

The command-line options are Evolving. The human-readable output is Unstable.

**See Also** [prtdiag\(1M\)](#), [attributes\(5\)](#), [smbios\(7D\)](#)

*System Management BIOS Reference Specification* (see <http://www.dmtf.org>)

**Notes** The implementation of a System Management BIOS image is entirely at the discretion of the system and BIOS vendors. Not all systems export an SMBIOS. The SMBIOS structure content varies widely between systems and BIOS vendors and frequently does not comply with the guidelines included in the specification. Some structure fields might not be filled in by the BIOS at all, and others might be filled in with non-conforming values.

**Name** smc – start the Solaris Management Console

**Synopsis** smc [ *subcommand*] [ *args*]

smc [ *subcommand*] [ *args*] -T *tool\_name*  
[ - - *tool\_args*]

**Description** The smc command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server.

The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it.

The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script.

For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the “Help” menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the smc edit command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select “Contents,” then “About the Solaris Management Console Editor,” then “To Create a Toolbox.”

**Subcommands** The smc *subcommands* are:

**open** The default subcommand for the Solaris Management Console is open. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line.

**edit** The edit subcommand will also launch the console, like the open subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.

**SMF Administration** The Solaris Management Console is implemented as a method that is managed by the service management facility (SMF) (see [smf\(5\)](#)), under the fault management resource identifier (FMRI):

```
svc:/application/management/wbem:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#).

The configuration properties of this service can be modified with `svccfg(1M)`.

Through `svcadm`, the Solaris Management Console supports the following actions:

- `start` Starts the CIM Object Manager (CIMOM) and Solaris Management Console server on the local host.
- `stop` Stops the CIMOM and Solaris Management Console server on the local host.
- `status` Gets the status of the CIMOM and Solaris Management Console server on the local host.

**Controlling Remote Access** The Solaris Management Console supports an SMF property that controls remote access to WBEM-based applications, which include the Solaris Management Console. The property, `options/tcp_listen`, has default value of `false`, which disallows remote access. The value `true` allows remote access. See **EXAMPLES**.

**Options** The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain` with the *domain* argument.

If *tool\_args* are specified, they must be preceded by the `--` option and separated from the double dashes by a space.

`--auth-data 13:file`

Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the `-u`, `-p`, `-r`, and `-l` options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of *file* is:

```
hostname=host name
username=user name
password=password for user name
rolename=role name
rolepassword=password for role name
```

Only one set of  
hostname-username-password-rolename-rolepassword

- may be specified in any one file. If the rolename is not specified, no role will be assumed.
- B** | - *--toolbox 13;toolbox*
- Loads the specified toolbox. *toolbox* can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,
- http://host\_name:port/ . . .**
- it must point to a *host\_name* and *port* on which an Solaris Management Console server is running. If you omit *port*, the default port, 898, is used. This option overrides the **-H** option.
- D** | - *--domain 13;domain*
- Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is *nis*, *nisplus*, *dns*, *ldap*, or *file*; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*) This option applies only to a single tool run in the terminal console.
- If you do not specify this option, the Solaris Management Console assumes the *file* default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
- h** | - *--help*
- Prints a usage statement about the *smc* command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter **-h** after the subcommand.
- H** | - *--hostname 13;host\_name:port*
- Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the **-B** option (see above), or set your console preferences to load a “home toolbox” by default.

|                                                  |                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-Jjava_option</code>                       | Specifies an option that can be passed directly to the Java runtime (see <code>java(1)</code> ). Do not enter a space between <code>-J</code> and the argument. This option is most useful for developers.                                                                                                                                                                                 |
| <code>-l   -rolepassword 13;role_password</code> | Specifies the password for the <code>role_name</code> . If you specify a <code>role_name</code> but do not specify a <code>role_password</code> , the system prompts you to supply a <code>role_password</code> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                 |
| <code>-p   -password 13;password</code>          | Specifies the password for the <code>user_name</code> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                         |
| <code>-r   -rolename 13;role_name</code>         | Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.                                                                                                                              |
| <code>-s   -silent</code>                        | Disables informational messages printed to the terminal.                                                                                                                                                                                                                                                                                                                                   |
| <code>-t</code>                                  | Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.                                                                                                                                                                                           |
| <code>-trust</code>                              | Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.                                                                                                                                                                                                                             |
| <code>-T   -tool 13;tool_name</code>             | Runs the tool with the Java class name that corresponds to <code>tool_name</code> . If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options <code>-H</code> and <code>-B</code> ). |

|                                                    |                                                                                                                                                                               |
|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-u   - --username <i>l3;user_name</i></code> | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                      |
| <code>-v   - --version</code>                      | Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the About box, available from the Help menu. |
| <code>-y   - --yes</code>                          | Answers yes to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.                  |

### Examples **EXAMPLE 1** Printing a Usage Statement

The following prints a usage statement about the `smc` command to the terminal window:

```
smc --help
```

### **EXAMPLE 2** Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to WBEM-based applications, including the Solaris Management Console.

```
svccfg -s svc:/application/management/wbem \
 setprop options/tcp_listen = true
svcadm refresh svc:/application/management/wbem
```

### **EXAMPLE 3** Passing an Option to Java

The following passes an option through to the Java VM, which sets the `com.example.boolean` system property to `true`. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

**Environment Variables** See [environ\(5\)](#) for a description of the following environment variable that affects the execution of the `smc` command:

`JAVA_HOME` If you do not specify this environment variable, your `PATH` is searched for a suitable `java`. Otherwise, the `/usr/j2se` location is used.

**Exit Status** The following exit values are returned. Other error codes may be returned if you specify a tool (using `-T tool_name`) that has its own error codes. See the documentation for the appropriate tool.

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmcc         |

**See Also** [auths\(1\)](#), [java\(1\)](#), [profiles\(1\)](#), [roles\(1\)](#), [smcconf\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [smf\(5\)](#), [X\(7\)](#)

**Name** smccompile – build class list and compile Solaris Management Console service beans for remote use

**Synopsis** /usr/sadm/bin/smccompile -c *beanname*

/usr/sadm/bin/smccompile -j tool | service [-n *altjarname*] *jarfile*

/usr/sadm/bin/smccompile -j library [-n *altjarname*] ALLTOOL | ALLSERVICE | ALL | *attachedBeanname*

**Description** The smccompile command is used by developers of tools, services, and libraries for the Solaris Management Console. For information regarding the Solaris Management Console, see [smc\(1M\)](#).

smccompile compiles service class files given by the bean name for use with the Solaris Management Console. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. Solaris Management Console requires running smccompile -c before creating service jar files, and smccompile -j after creating tool, service, and library jars.

smccompile, in conjunction with [smcregister\(1M\)](#), is intended to replace the smconf command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over smconf.

**Options** The following options are supported:

|                         |                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL                     | Specify that the library being registered to or unregistered from the repository is for use by all tools and services.                                                                                                                                                                                                                                                                          |
| ALLSERVICE              | Specify that the library being registered to or unregistered from the repository is for use by all services.                                                                                                                                                                                                                                                                                    |
| ALLTOOL                 | Specify that the library being registered to or unregistered from the repository is for use by all tools.                                                                                                                                                                                                                                                                                       |
| <i>attachedBeanname</i> | Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached. |
| <i>beanname</i>         | The full package path of the bean name to be compiled. An example bean name is: com.mycompany.myproduct.MyService.                                                                                                                                                                                                                                                                              |
| -c                      | Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run smccompile with this option before creating service type jar files.                                                                                                                            |

- `-j` Build a list of classes in text format, suitable as input to `smregister` for registration with the Solaris Management Console repository. The output is written to standard out and should be redirected to a file. You must run `smccompile` with this option after creating any tool, service, or library jar.
- `jarfile` Specify the full path to the jar file to be registered. The name must be in the form `beanname.jar`, where `beanname` is the package path to the bean. If it is not, an alternate name must be given in that form using the `-n` option.
- `-n altjarname` Rename the jarfile in the repository to `altjarname`. Typically, this is the full bean name. For example, if the jarfile was `MyTool.jar`, then `altjarname` might be `com.mycompany.myproduct.MyTool.jar`. It is recommended that an `altjarname` containing the full package path be used. You must use this same name when registering the jar with `smregister`.

### Examples **EXAMPLE 1** Compiling a Service

The following command takes a Solaris Management Console service and builds its proxy and stub classes to make the service usable by Solaris Management Console tools:

```
/usr/sadm/bin/smccompile -c com.mycompany.myproject.MyServiceImpl
```

### **EXAMPLE 2** Building a Class List for a Service

The following command builds the class list file (`classlist.txt`) for a service suitable for use with the `smregister(1M)` command:

```
/usr/sadm/bin/smccompile -j service \
-n com.mycompany.myproject.MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j service \
${HOME}/workarea/com.mycompany.myproject.MyServiceImpl.jar > classlist.txt
```

### **EXAMPLE 3** Building a Class List for a Tool

The following command builds the class list file (`classlist.txt`) for a tool suitable for use with the `smregister(1M)` command:

```
/usr/sadm/bin/smccompile -j tool \
-n com.mycompany.myproject.MyTool.jar \
${HOME}/workarea/MyTool.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

**EXAMPLE 3** Building a Class List for a Tool *(Continued)*

```
/usr/sadm/bin/smccompile -j tool \
 ${HOME}/workarea/com.mycompany.myproject.MyTool.jar > classlist.txt
```

**EXAMPLE 4** Building a Class List for a Library Attached to All Tools

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smregister(1M)` command, and is attached to all tools:

```
/usr/sadm/bin/smccompile -j library \
 -n com.mycompany.myproject.MyLibrary.jar \
 ALLTOOL ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
 ALLTOOL \
 ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

**EXAMPLE 5** Building a Class List for a Library Attached to a Specific Tool

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smregister(1M)` command, and is attached to a specific tool:

```
/usr/sadm/bin/smccompile -j library \
 -n com.mycompany.myproject.MyLibrary.jar \
 com.mycompany.myproject.MyTool.jar \
 ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
 com.mycompany.myproject.MyTool.jar \
 ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `smccompile`:

**JAVA\_HOME** If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWMc          |

**See Also** [smc\(1M\)](#), [smccomf\(1M\)](#), [smcregister\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** All standard shell quoting rules apply.

**Name** smccnf – configure the Solaris Management Console

**Synopsis** /usr/sadm/bin/smccnf [-h] [-v] toolbox [*action*] [*target*]  
                   [*parameters*] [*options*]  
                   /usr/sadm/bin/smccnf [-h] [-v] repository [*action*]  
                   [*target*] [*parameters*] [*options*]

**Description** The smccnf command configures the Solaris Management Console. See [smc\(1M\)](#). This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository.

Using smccnf to edit toolboxes is not as feature-rich as using the graphical editor in Solaris Management Console. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, smc edit. See [smc\(1M\)](#).

smcregister is intended to replace the smccnf command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over smccnf. See [smcregister\(1M\)](#), [smccompil\(1M\)](#), and the Solaris Management Console SDK Guide at [/usr/sadm/lib/smc/docs/sdkguide/index.html](#) for details.

**Options** The following options are supported:

- h Prints out a usage summary for the command.
- v Verbose option. Displays the debugging output at any time.

|                       |               |                                                                                                                                                                                                                                                                                     |
|-----------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| toolbox configuration | <i>action</i> | Legal values are:                                                                                                                                                                                                                                                                   |
|                       | add           | Adds a <i>target</i> to the toolbox. Specify the path to the toolbox using the <i>-B toolboxpath</i> option and, optionally, provide locale information with the <i>-L locale</i> option.                                                                                           |
|                       | remove        | Removes a <i>target</i> from the toolbox. Specify the path to the toolbox using the <i>-B toolboxpath</i> option and, as an alternative, provide locale information with the <i>-L locale</i> option.                                                                               |
|                       | create        | Creates a new toolbox with no tools in it. The only <i>target</i> recognized is toolbox.                                                                                                                                                                                            |
|                       | list          | Lists the contents of the toolbox. No <i>target</i> is recognized. If you specify a <i>parameter</i> , it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a <i>parameter</i> , the contents of the default toolbox are listed. |
|                       | <i>target</i> | Legal values are:                                                                                                                                                                                                                                                                   |

- tool** If the *action* is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.
- If the *action* is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you want to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox are removed.
- For the tool to appear in the console, the tool must also be registered in the repository. See the `repository configuration` section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.
- Removing a tool from a toolbox does not remove the tool from the server repository.
- tbxURL** If the *action* is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required *parameter* is the URL to the other toolbox.
- The properties of addition and removal are the same as for the `tool target`.
- toolbox** If the *action* is specified as `create`, this target creates a skeleton toolbox with no tools. The required *parameters* are: the toolbox name, description, and small and large icon paths. These must be followed by the `-B toolboxpath` and `-D scope` options.
- legacy** If the *action* is specified as `add` or `remove`, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required. The `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See `NOTES` for more information about legacy applications.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>folder</i>                | <p>If the <i>action</i> is specified as <i>add</i>, this target adds a folder to the toolbox. The required <i>parameters</i> are: the folder name, description, and small and large icon paths.</p> <p>If the <i>action</i> is specified as <i>remove</i>, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the <i>-F</i> option.</p> |
| <i>parameters</i>            | Specifies values that might be required, depending on the combination of <i>action</i> and <i>target</i> .                                                                                                                                                                                                                                                                                                                              |
| <i>options</i>               | Supported options for various <i>action</i> and <i>target</i> combinations for the toolbox configuration are:                                                                                                                                                                                                                                                                                                                           |
| <i>-A parameters</i>         | Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.                                                                                                                                                                                                                                                                                                                        |
| <i>-B toolboxpath</i>        | Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "This Computer".                                                                                                                                                                                                                                                                     |
| <i>-D scope</i>              | <p>Specifies the scope (domain) in which the tool should be run. The legal values for <i>scope</i> are <i>file</i>, <i>nis</i>, <i>nisplus</i>, <i>dns</i>, and <i>ldap</i>. This can also be specified for a folder or a toolbox.</p> <p>In the former case, all tools in that folder and its subfolders are run in that scope; in the latter, all tools in the toolbox are run in that scope.</p>                                     |
| <i>-E appPath</i>            | Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.                                                                                                                                                                                                                                                                                                                  |
| <i>-F folder</i>             | Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox.                                                                                                                                                                                                                                                                                                   |
| <i>-H [host_name][:port]</i> | Specifies the host and port from which a tool should be loaded. If <i>host_name</i> is not given, the default host is used. The default host is <i>localhost</i> , if the toolbox is loaded from the local file system, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server. If <i>:port</i> is not given, the default port will be used. If                                         |

this option is not given at all, both the default host and the default port are used.

- L *locale* Specifies the locale of the toolbox that is being modified. The default is the C locale.
- N *appName* Specifies the name of the legacy application being registered. This is the name that appears in the console. This option is available only for the legacy target.
- P *key:value* Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.
- T *appType* Specifies the legacy application type. Legal values are CLI, XAPP, or HTML. This option is available only for the legacy target.

**repository configuration** The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

**action** Legal values are:

- add** Adds information to the repository. If the -f option is given to add, the information overwrites any information of the same name already in the repository. If the -f option is not given, an error might be returned if the information is already in the repository.
- remove** Removes information from the repository.
- list** Lists the contents of the repository:
  - All registered tools
  - All registered services
  - All libraries attached to all tools
  - All libraries attached to all services
  - All libraries attached to all tools and services

**target** Legal values are:

- bean** If the *action* is specified as add, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required *parameter* is the path to the jar file that contains the bean to be added.

If the *action* is specified as remove, this target will remove a tool or service bean from the repository. The required *parameter* is the full Java classname of the desired bean.

- library** If the *action* is specified as `add`, this target adds a “library” jar file to a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the “pseudo-beans,” `ALL`, `ALLTOOL`, or `ALLSERVICE`, in which case the library is attached, respectively, to all beans, all tools, or all services in the repository.
- If the *action* is specified as `remove`, this target detaches a “library” jar file from a tool or service bean. The two required *parameters* are the full Java classname of the desired bean and the name of the jar file that is attached. As with the `add` action, the three “pseudo-beans” `ALL`, `ALLTOOL`, or `ALLSERVICE` can be used.
- property** If the *action* is specified as `add`, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,
- `-P key=value`
- Following this property list is a “pseudo-bean name,” *pseudoBeanName*, as defined for the `library` target, on which the properties are defined. Optionally, a library name can follow the “pseudo-bean” name, in which case the properties are defined on the library that is attached to the named bean.
- If the *action* is specified as `remove`, this target undefines a property on a tool or service. The key/value pairs, “pseudo-bean” name, and optional library are specified for the `add` action.

### Examples EXAMPLE 1 Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the command line interface (CLI) application, `/usr/bin/ls`, with arguments `-al -R`, giving it the name, `Directory Listing`:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

### EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, `New Folder`, the description, `This is a new folder`, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

```
/usr/sadm/bin/smcconf toolbox add folder "New Folder" \
"This is a new folder" folder_s.gif folder_l.gif \
-B /var/sadm/smc/toolboxes/smc/smc.tbx
```

**EXAMPLE 3** Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `HelloWorld.client>HelloTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it is run in the NIS domain, `syrix`, which is hosted by the machine, `temple`, and is retrieved from port 2112 on the machine from which the toolbox was loaded:

```
/usr/sadm/bin/smccnf toolbox add tool HelloWorld.client>HelloTool \
-D nis:/temple/syrix -H :2112
```

**EXAMPLE 4** Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `HelloWorld.jar` to the repository. The jar file contains information that the bean is a tool:

```
/usr/sadm/bin/smccnf repository add bean HelloWorld.jar
```

**EXAMPLE 5** Removing an Solaris Management Console Service from the repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely a convention; the repository knows whether a particular registered bean is a tool or a service:

```
/usr/sadm/bin/smccnf repository remove bean \
HelloWorld.server>HelloService
```

**EXAMPLE 6** Attaching a Library to a Tool

The following command adds the library jar file, `HelloWorld_fr.jar` (probably a French localized version of the `HelloTool`'s resources) to the bean, `HelloWorld.client>HelloTool`:

```
/usr/sadm/bin/smccnf repository add library \
HelloWorld.client>HelloTool HelloWorld_fr.jar
```

**EXAMPLE 7** Attaching a Library to all Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set that might be useful to any registered tools:

```
/usr/sadm/bin/smccnf repository add library ALLTOOL widgets.jar
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of the `smccnf` command:

- |                        |                                                                                                                                                                                                                                      |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>JAVA_HOME</code> | If you do not specify this environment variable, your <code>PATH</code> is searched for a suitable <code>java</code> . Otherwise, the <code>/usr/j2se</code> location is used.                                                       |
| <code>DISPLAY</code>   | If you do not set this environment variable, set it to null, or set it to an <code>X(7)</code> display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode. |

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmc          |

**See Also** [smc\(1M\)](#), [smccompile\(1M\)](#), [smcregister\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from “native” Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, `LegacyAppLauncher`, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

**Name** smcregister – configure the Solaris Management Console

**Synopsis** */usr/sadm/bin/smcregister [-h] tool [-n altjarname] jarfile classlistfile xmlfile*  
*/usr/sadm/bin/smcregister [-h] service [-n altjarname] jarfile classlistfile xmlfile*  
*[native\_lib\_list]*  
*/usr/sadm/bin/smcregister [-h] library [-n altjarname] jarfile classlistfile | none ALLTOOL | ALLSERVICE |*  
*/usr/sadm/bin/smcregister [-h] tool | service -u jarfile*  
*/usr/sadm/bin/smcregister [-h] library -u jarfile ALL | ALLTOOL | ALLSERVICE | Attachedbeanname*  
*/usr/sadm/bin/smcregister [-h] toolbox [-D] [action] [-f]*  
*[target] [parameters] [options]*  
*/usr/sadm/bin/smcregister [-h] property key value ALL | ALLTOOL | ALLSERVICE | Attachedbeanname*  
*/usr/sadm/bin/smcregister [-h] property -u key ALL | ALLTOOL | ALLSERVICE | Attachedbeanname*  
*/usr/sadm/bin/smcregister [-h] repository list*  
*/usr/sadm/bin/smcregister [-h] scripts regscript unregscript*

**Description** The `smcregister` command configures the Solaris Management Console. For information regarding the Solaris Management Console, see [smc\(1M\)](#). This command enables you to add to, remove from, and list the contents of toolboxes and the Solaris Management Console repository.

`smcregister` also allows you to register scripts to perform registrations and unregistrations. Typically, a package containing one or more tools or services posts tool and service registrations immediately after installation. On Solaris, this is by way of invocations of `smcregister` from within a package post-install script. Similarly, unregistrations would be posted from within a package pre-remove script. These are per-machine registrations - that is, registration requests must be posted on each machine on which the Solaris Management Console server will be running. However, due to the way that diskless clients are installed, registration requests cannot be made at install time. Therefore, packages should include and install registration and unregistration scripts, and then register these scripts during installation by way of the `scripts` subcommand. These scripts should contain tool, toolbox, service, library or property configurations in any of its forms as listed in this man page. While these scripts function very much like package post-install and pre-remove scripts, do not assume the normal package environment is available. However, `PATH` can assumed to be `/usr/sbin:/usr/bin`

Using `smcregister` to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, `smc edit`. See [smc\(1M\)](#).

`smregister` is intended to replace the `smconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smconf`.

**Options** The following options are supported:

|                       |                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                       | <code>-h</code>          | Prints out a usage summary for the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Scripts Configuration | <code>regscript</code>   | The full path of a script containing registration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is installed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                       | <code>unregscript</code> | The full path of a script containing unregistration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Toolbox Configuration | <code>action</code>      | Legal values are: <ul style="list-style-type: none"> <li><code>add</code> Adds a target to the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option.</li> <li><code>create</code> Creates a new toolbox with no tools in it. The only target recognized is <code>toolbox</code>.</li> <li><code>list</code> Lists the contents of the toolbox. No target is recognized. If you specify a parameter, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a parameter, the contents of the default toolbox are listed.</li> <li><code>remove</code> Removes a target from the toolbox. Specify the path to the toolbox using the <code>-B toolboxpath</code> option and, optionally, provide locale information with the <code>-L locale</code> option.</li> </ul> |
|                       | <code>-D</code>          | Defers execution of the <code>toolbox</code> command until the Solaris Management Console server is restarted. This is a convenient option for use in packaging scripts during install and un-install. Additionally, the command runs much faster than if run interactively (without <code>-D</code> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                       | <code>target</code>      | Legal values are: <ul style="list-style-type: none"> <li><code>folder</code> If the action is specified as <code>add</code>, this target adds a folder to the toolbox. There are four required parameters: the folder name, description, and small and large icon paths. If the action is specified as <code>remove</code>, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the <code>-F</code> option.</li> <li><code>legacy</code> If the action is specified as <code>add</code> or <code>remove</code>, this target adds or removes legacy applications (command line, X-windows, and</li> </ul>                                                                                                                                                                                                                                  |

web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required, and the `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See NOTES for more information about legacy applications.

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <code>tbxURL</code>     | If the action is specified as <code>add</code> or <code>remove</code> , this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox. The properties of addition and removal are the same as for the <code>tool</code> target.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>tool</code>       | If the action is specified as <code>add</code> , this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the <code>-F</code> option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder. If the action is specified as <code>remove</code> , this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you wish to remove. If you specify a folder name with the <code>-F</code> option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed. For the tool to show up in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded. Removing a tool from a toolbox does not remove the tool from the server repository. |
| <code>toolbox</code>    | If the action is specified as <code>create</code> , this target creates a skeleton toolbox with no tools. There are four required parameters: the toolbox name, description, and small and large icon paths. These must be followed by the <code>-B <i>toolboxpath</i></code> and <code>-D <i>scope</i></code> options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>parameters</code> | Specifies values that may be required depending on the combination of action and target.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>options</code>    | Supported options for various action and target combinations for the toolbox configuration are: <ul style="list-style-type: none"> <li><code>-A</code> Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

- 
- B Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, *This Computer*.
- D Specifies the scope (domain) in which the tool should be run. The legal values for scope are *file*, *nis*, *nispplus*, *dns*, and *ldap*. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.
- E Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.
- f If the -f option is given to add, the information will overwrite any information of the same name already in the toolbox. If the -f option is not given, an error may be returned if the information is already in the toolbox.
- F *folder* Specifies the full path of the container folder. If this option is not given, the default folder is the *root* folder of the toolbox.
- H [*host\_name*][:*port*] Specifies the host and port from which a tool should be loaded. If *host\_name* is not given, the default host (*localhost*, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If *port* is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.
- L *locale* Specifies the locale of the toolbox which is being modified. The default is the C locale.
- N *appName* Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the legacy target.

|                                          | ALL                                                                                                     | Specify that the library being registered to or unregistered from the repository is for use by all tools and services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                          | ALLSERVICE                                                                                              | Specify that the library being registered to or unregistered from the repository is for use by all services.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                          | ALLTOOL                                                                                                 | Specify that the library being registered to or unregistered from the repository is for use by all tools.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                                          | <i>attachedBeanname</i>                                                                                 | The name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as <i>altjarname</i> (if provided) or <i>jarfile</i> used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.                                                                                                                                                                                                                      |
|                                          | <i>classlistfile</i>                                                                                    | The classlist text file generated from the smccompile(1M) command.<br><br>Library registration does not require that a classlist file be specified. Instead, you can substitute the keyword none in place of the classlist path argument to smcregister, in which case one will be generated automatically. Generating the classlist automatically during server startup will cause the next server restart to take longer, so it is strongly suggested that developers always provide a classlist file with their libraries. Auto-generation is more appropriately used to register 3rd-party library jars. |
|                                          | <i>jarfile</i>                                                                                          | The full path to the jar file to be registered/unregistered. The name must be in the form <i>beanname.jar</i> , where <i>beanname</i> is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.                                                                                                                                                                                                                                                                                                                                                       |
|                                          | -n <i>altjarname</i>                                                                                    | Rename the jarfile in the repository to <i>altjarname</i> . This would typically be the full bean name. For example, if the jarfile was <i>MyTool.jar</i> , then <i>altjarname</i> might be <i>com.mycompany.myproduct.MyTool.jar</i> . It is recommended that an <i>altjarname</i> containing the full package path be used.                                                                                                                                                                                                                                                                                |

|                          |                        |                                                                                                                                                                                                                                                                                                                |
|--------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                          | <i>native_lib_list</i> | List of up to 4 native libraries that can be associated with a service bean.                                                                                                                                                                                                                                   |
|                          | -u                     | The operation will be to un-register the jar with the Solaris Management Console repository. The jarfile argument must be identical to the <i>altjarname</i> used to register the jar (if provided), or jarfile.                                                                                               |
|                          | xmlfile                | The xml descriptor file that describes this jarfile. Every tool or services must have one. See the Solaris Management Console SDK Guide located at <code>/usr/sadm/lib/smc/docs/sdkguide/index.html</code> .                                                                                                   |
| Repository Configuration |                        | The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.                                                                                                         |
|                          | list                   | Lists the contents of the repository: <ul style="list-style-type: none"> <li>▪ All registered tools</li> <li>▪ All registered services</li> <li>▪ All libraries attached to all tools</li> <li>▪ All libraries attached to all services</li> <li>▪ All libraries attached to all tools and services</li> </ul> |
| Property Configuration   |                        | See NOTES for more information about registration and unregistration of properties. If registering a property, this defines a property on a tool or service. Only one key value pair at a time can be registered.                                                                                              |
|                          | <i>beanname</i>        | The name of a registered jar on which the properties will be defined. Optionally, a library name may follow the bean name, in which case the properties are defined on the library that is attached to the named bean.                                                                                         |
|                          |                        | If unregistering a property, this undefines a property from a tool or service. Only one key value pair at a time can be registered. The key, <i>beanname</i> , and optional library are specified as for registering a property.                                                                               |

### Examples

**EXAMPLE 1** Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the Command Line Interface (CLI) application, `/usr/bin/ls` with arguments `-al -R`, giving it the name, Directory Listing:

```
/usr/sadm/bin/smregister toolbox add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

Use this variation to defer execution of this command until the Solaris Management Console server is restarted:

```
/usr/sadm/bin/smregister toolbox -D add legacy -N "Directory Listing" \
-T CLI -E /usr/bin/ls -A "-al -R"
```

**EXAMPLE 2** Adding a Folder to a Toolbox

The following command adds to the standard Management Tools toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, folder\_s.gif and folder\_l.gif:

```
/usr/sadm/bin/smcregister toolbox add folder "New Folder" \
 "This is a new folder" folder_s.gif folder_l.gif \
 -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

**EXAMPLE 3** Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is com.mycompany.myproject.client.MyTool (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, syrinx, which is hosted by the machine, temple, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
/usr/sadm/bin/smcregister toolbox add tool \
 com.mycompany.myproject.client.MyTool \
 -D nis:/temple/syrinx -H :2112
```

**EXAMPLE 4** Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in MyTool.jar to the repository. The xml file contains information about the tool. The classlist file would have been generated by smccompile -j:

```
/usr/sadm/bin/smcregister tool -n com.mycompany.myproject.client.MyTool.jar \
 ${HOME}/workarea/MyTool.jar \
 ${HOME}/workarea/MyTool_classlist.txt \
 ${HOME}/workarea/MyTool.xml
```

Use this variation to add an Solaris Management Console tool to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister tool \
 ${HOME}/workarea/com.mycompany.myproject.client.MyTool.jar \
 ${HOME}/workarea/MyTool_classlist.txt \
 ${HOME}/workarea/MyTool.xml
```

**EXAMPLE 5** Adding an Solaris Management Console Service to the Repository

The following command adds the Java bean found in MyServiceImpl.jar to the repository. The xml file contains information about the service. The classlist file would have been generated by smccompile -j. The extra proxy and stub classes included in the jar would have been generated by smccompile -c:

```
/usr/sadm/bin/smcregister service \
 -n com.mycompany.myproject.server.MyServiceImpl.jar \
 -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

**EXAMPLE 5** Adding an Solaris Management Console Service to the Repository *(Continued)*

```

${HOME}/workarea/MyServiceImpl.jar \
${HOME}/workarea/MyServiceImpl_classlist.txt \
${HOME}/workarea/MyServiceImpl.xml

```

Use this variation to add a Solaris Management Console service to the repository without specifying an alternate name:

```

/usr/sadm/bin/smregister service \
 ${HOME}/workarea/com.mycompany.myproject.server.MyServiceImpl.jar \
 ${HOME}/workarea/MyServiceImpl_classlist.txt \
 ${HOME}/workarea/MyServiceImpl.xml

```

**EXAMPLE 6** Removing an Solaris Management Console Tool From the Repository

The following command removes a Java tool bean from the repository:

```

/usr/sadm/bin/smregister tool \
 -u com.mycompany.myproject.client.MyTool.jar

```

**EXAMPLE 7** Removing an Solaris Management Console Service From the Repository

The following command removes a Java service bean from the repository:

```

/usr/sadm/bin/smregister service \
 -u com.mycompany.myproject.server.MyServiceImpl.jar

```

**EXAMPLE 8** Attaching a Library to a Specific Tool

The following command adds the library jar file, `MyTool_fr.jar` (probably a French localized version of the `MyTool`'s resources) to the bean, `com.mycompany.myproject.client.MyTool`:

```

/usr/sadm/bin/smregister library \
 -n MyTool_fr.jar \
 ${HOME}/workarea/MyTool_fr.jar \
 ${HOME}/workarea/MyTool_fr_classlist.txt \
 com.mycompany.myproject.client.MyTool

```

**EXAMPLE 9** Attaching a Library to All Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools. The classlist file would have been generated by `smccompile -j`.

```

/usr/sadm/bin/smregister library \
 ${HOME}/workarea/lib/widgets.jar \
 ${HOME}/workarea/lib/widgets_classlist.txt \
 ALLTOOL

```

Alternatively, to add a 3rd-party library jar to all tools, replace the classlist file with `none`:

**EXAMPLE 9** Attaching a Library to All Tools *(Continued)*

```
/usr/sadm/bin/smregister library \
 /opt/lib/XYZwidgets.jar none ALLTOOL
```

**EXAMPLE 10** Detaching a Library from All Tools

The following command removes the Java library bean from the repository:

```
/usr/sadm/bin/smregister library -u MyTool_fr.jar ALLTOOL
```

**EXAMPLE 11** Detaching a Library from a Specific Tool

The following command detaches the library jar file, MyTool\_fr.jar (probably a French localized version of the MyTool's resources) from the bean `com.mycompany.myproject.client.MyTool`, and removes it from the repository:

```
/usr/sadm/bin/smregister library -u MyTool_fr.jar \
 com.mycompany.myproject.client.MyTool
```

**EXAMPLE 12** Registering Scripts

The following command registers the following scripts containing registration and unregistration commands. `MyProduct_reg.sh` will be executed upon the next server restart after the file is installed by the owning package. `MyProduct_unreg.sh` will be executed upon the next server restart after the file is removed by the owning package:

```
/usr/sadm/bin/smregister scripts \
 /usr/sadm/lib/myProduct/MyProduct_reg.sh \
 /usr/sadm/lib/myProduct/MyProduct_unreg.sh
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `smregister`:

**JAVA\_HOME** If you do not specify this environment variable, your `PATH` is searched for a suitable `java`. Otherwise, the `/usr/j2se` location is used.

**Exit Status** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmc          |

**See Also** [smc\(1M\)](#), [smcconf\(1M\)](#), [smccompile\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from native Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, `LegacyAppLauncher`, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Registration and unregistration of tools, services, libraries, and properties do not take effect until the Solaris Management Console server is restarted. Run `/etc/init.d/init.wbem stop` followed by `/etc/init.d/init.wbem start`

**Name** smcron – manage jobs in the crontab database

**Synopsis** /usr/sadm/bin/smcron *subcommand* [ *auth\_args* ] - -  
[*subcommand\_args*]

**Description** The smcron command manages jobs in the [crontab\(1\)](#) database.

*subcommands* smcron *subcommands* are:

- add** Adds a job to the crontab(1) database. To add a job, the administrator must have the `solaris.jobs.user` authorization. To add a job to another user's crontab file, the administrator must have the `solaris.jobs.admin` authorization.
- delete** Deletes a job from the crontab(1) database. To delete a job, the administrator must have the `solaris.jobs.user` authorization. To delete a job from another user's crontab file, the administrator must have the `solaris.jobs.admin` authorization.
- list** Lists one or more jobs in the crontab(1) database. To list all jobs, the administrator must have the `solaris.jobs.user` authorization. To list a job in another user's crontab file, the administrator must have the `solaris.jobs.admin` authorization. No authorization is needed to list a user's own jobs.
- modify** Modifies a job in the crontab(1) database. To modify a job, the administrator must have the `solaris.jobs.user` authorization. To modify a job in another user's crontab file, the administrator must have the `solaris.jobs.admin` authorization.

**Options** The smcron authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smcron command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.

-D | - --domain *I3;domain* Specifies the default domain that you want to manage. smcron accepts only *file* for this option. *file* is also the default value.

|                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                     | The file default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                                                                                                                                                   |
| <code>-H   - --hostname 13;host_name:port</code>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smcron(1M) -B</a> option, or set your console preferences to load a “home toolbox” by default. |
| <code>-l   - --rolepassword 13;role_password</code> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                   |
| <code>-p   - --password 13;password</code>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                         |
| <code>-r   - --rolename 13;role_name</code>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-u   - --username 13;user_name</code>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                             |
| <code>- -</code>                                    | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the <code>- -</code> option.                                                                                                                                                                                                                                                                                                                                   |
| <i>subcommand_args</i>                              | For the time-related subcommands described below, <code>-m</code> , <code>-M</code> , <code>-t</code> , and <code>-w</code> , you can enter multiple arguments, separated only by commas. <code>smcron</code> will construct <code>crontab</code> entries appropriate for your arguments. See <a href="#">EXAMPLES</a> .                                                                                                                                                                             |
|                                                     | <i>Note:</i> Descriptions and other <code>arg</code> options that contain white spaces must be enclosed in double quotes.                                                                                                                                                                                                                                                                                                                                                                            |

- For subcommand `add`:

- c *command* Specifies the command that you want to run.
- h (Optional) Displays the command's usage statement.
- m *day\_of\_month* (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both -t and -m options, the job executes one day per month at the time specified by -t.
- M *month* (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both -t and -M options, the job executes during the specified month at the time specified by -t.
- n *name* Specifies the unique name of the job.
- o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.
- t *time\_of\_day* Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (-m, -M, or -w), the job executes every day at the time specified by -t. If you specify both -t and -w options, the job executes one day per week at the time specified by -t. If you specify both -t and -m options, the job executes one day per month at the time specified by -t. If you specify both -t and -M options, the job executes each day during the specified month at the time specified by -t.
- w *day\_of\_week* (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
  - 0=Sunday
  - 1=Monday
  - 2=Tuesday
  - 3=Wednesday
  - 4=Thursday
  - 5=Friday
  - 6=SaturdayIf you specify both -t and -w options, the job executes one day per week at the time specified by -t.

- For subcommand `delete`:

- h (Optional) Displays the command's usage statement.
- n *name* Specifies the unique name of the job.
- o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.

- For subcommand `list`:
  - f *n|s|v* (Optional) Specifies the format of the output. See EXAMPLES for examples of each output type.
    - *n* — Displays the data in native format, as it appears in the `crontab(1)` database.
    - *s* — Default format. Displays the data in summary format.
    - *v* — Displays the data in verbose format.
  - h (Optional) Displays the command's usage statement.
  - o *owner* (Optional) Lists all jobs for the specified owner (user name). If you do not specify this option, all jobs in the `crontab(1)` database are listed.
- For subcommand `modify`:
  - c *command* (Optional) Specifies the command that you want to run.
  - h (Optional) Displays the command's usage statement.
  - m *day\_of\_month* (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both -t and -m options, the job executes one day per month at the time specified by -t.
  - M *month* (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both -t and -M options, the job executes during the specified month at the time specified by -t.
  - n *name* Specifies the current unique name of the job.
  - N *new\_name* (Optional) Specifies the new unique name of the job.
  - o *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the -U option is assumed.
  - O *new\_owner* (Optional) Specifies the new owner of the job.
  - t *time\_of\_day* (Optional) Specifies the time (in *hh:mm*) that you want to execute the command. If no other time-related options are specified (-m, -M, or -w), then the job executes every day at the time specified by -t. If you specify both -t and -w options, the job executes one day per week at the time specified by -t. If you specify both -t and -m options, the job executes one day per month at the time specified by -t. If you specify both -t and -M, then the job executes each day during the specified month at the time specified by -t.
  - w *day\_of\_week* (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:
    - 0=Sunday

- 1=Monday
- 2=Tuesday
- 3=Wednesday
- 4=Thursday
- 5=Friday
- 6=Saturday

If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`.

#### Examples EXAMPLE 1 Adding a Job

The following adds a new job, owned by root, that removes the old log files from `/tmp` daily at 1:30 AM.

```
./smcron add -H myhost -u root -p mypassword -- -n "Remove old logs" \
-t 1:30 -c "rm /tmp/*.log" -o root
```

#### EXAMPLE 2 Deleting a Job

The following deletes the job Remove old logs owned by root:

```
./smcron delete -H myhost -u root -p mypassword -- \
-n "Remove old logs" -o root
```

#### EXAMPLE 3 Listing Jobs in Native Format

The following lists all jobs in native, or `crontab(1)`, format:

```
./smcron list -H myhost -u root -p mypassword -- -f n
MINUTE HOUR DATE MONTH DAY COMMAND

10 3 * * * /usr/sbin/logadm
15 3 * * 0 /usr/lib/fs/nfs/nfsfind
1 2 * * * [-x /usr/sbin/rtc] && /usr/sbin/rtc -c > /dev/null 2>&1
30 3 * * * [-x /usr/lib/gss/gsscred_clean] && /usr/lib/gss/gsscred_clean
```

#### EXAMPLE 4 Listing Jobs in Standard Format

The following lists all jobs owned by `lp` in standard format:

```
./smcron list -H myhost -u root -p mypassword -- -f s -o lp
NAME::OWNER::SCHEDULE::COMMAND

NoName_1765663371::lp:Weekly on Sundays at 3:13 AM::cd /var/lp/logs;
if [-f requests]; then if [-f requests.1]; then /bin/mv requests.1
requests.2; fi; /usr/bin/cp requests requests.1; > requests; fi
NoName_512822673::lp:Weekly on Sundays at 4:15 AM::cd /var/lp/logs;
if [-f lpsched]; then if [-f lpsched.1]; then /bin/mv lpsched.1
lpsched.2; fi; /usr/bin/cp lpsched lpsched.1; >lpsched; fi
```

**EXAMPLE 5** Listing jobs in verbose format

The following lists all jobs in verbose format:

```
./smcron list -H myhost -u root -p mypassword -- -f v
NAME::OWNER::SCHEDULE::NEXT_RUN::STATUS::COMMAND

NoName_1075488942::root::Advanced::::Finished on Feb 10 3:10 with code 1
::/etc/cron.d/logchecker
databackup::root::Weekly on Sundays at 3:10 AM::3/19/00 3:10 AM
::Finished on Sep 19 3:10::/usr/lib/newsyslog
runlog::root::Daily at 2:01 AM::3/14/00 2:01 AM::Finished on Feb 11
2:01 AM::/usr/sbin/rtc
```

**EXAMPLE 6** Changing a Job

The following modifies the job Remove old logs owned by root to execute daily at 2:00 AM:

```
./smcron modify -H myhost -u root -p mypassword -- -n "Remove old logs" \
-o root -t 2:00
```

**EXAMPLE 7** Specifying Multiple Time Arguments

smcron allows you to specify a range of times for all of its time-related subcommands, -m, -M, -t, and -w. For example, the following command:

```
smcron add -u root -p xxxx -- -n cronjob1 -w 1-4,5 \
-t 12:00,13:15,14:30 -c ls
```

...creates the following entry in crontab:

```
0,15,30 12,13,14 * * 1,2,3,4,6 ls #cronjob1
```

This job would run on Monday through Thursday and Saturday at the following times:

```
12:00 12:15 12:30
13:00 13:15 13:30
14:00 14:15 14:30
```

**Environment Variables** See [environ\(5\)](#) for a description of the JAVA\_HOME environment variable, which affects the execution of the smcron command. If this environment variable is not specified, the /usr/java location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [crontab\(1\)](#), [cron\(1M\)](#), [smc\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Notes** The timezone of the cron daemon sets the system-wide timezone for cron entries. This, in turn, is by set by default system-wide using `/etc/default/init`.

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

**Name** smcwebserver – manage the server for the Sun Web Console

**Synopsis** `/usr/sbin/smcwebserver subcommand options`

**Description** The `smcwebserver` utility manages the Sun Web Console server. Sun Web Console is a browser-based interface that performs systems management. System administrators can manage systems, devices and services from the console.

When the console webserver is running, you can view the console by opening a browser and pointing to:

`https://host:6789`

`host` is the machine where the console has been installed and the console server is running.

The `smcwebserver` service is managed by the service management facility (SMF) (see [smf\(5\)](#)), under the fault management resource identifier (FMRI):

`svc:/system/webconsole`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). `smcwebserver` can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with [svccfg\(1M\)](#).

`smcwebserver` supports an SMF property that controls remote access to the Sun Web Console server. The property, `options/tcp_listen`, has a default value of `false`, which disallows remote access. The value `true` allows remote access. See [EXAMPLES](#).

**Subcommands** The following subcommands are supported:

`disable` Disable automatic start or stop during system boot or shutdown. Until the administrator reruns the script with the `smcwebserver enable` subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:

```
/usr/sbin/smcwebserver [start | stop]
```

`enable` Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.

`restart` Stop and subsequently start the console webserver.

The format of the restart subcommand is:

```
restart [-U username]
```

`start` Start the console webserver.

The format of the start subcommand is:

```

 start [-U username]
stop Stop the console webserver.
status Display status of the console webserver.

 The format of the status subcommand is:

 status [-p]

```

**Options** The following options are supported:

```

-U username | --username username The user identity to run the server as. Once the
server has successfully started under the specified
identity, all subsequent starts will automatically be
done under that identity until you change it via this
option, or by changing the
com.sun.web.console.user configuration property
via the smreg(1M) command. The default is to run
the server under the noaccess identity.

-p | --parseable Display non-localized output suitable for
programmatically parsing. If the server is running, the
output will be:

running=yes

If the server is not running, the output will be:

running=no

-h | --help | -? Display the usage statement.

-V | --version Display console version information.

```

**Examples** EXAMPLE 1 Displaying the Usage Statement

The following command displays the smcwebserver usage statement:

```
% smcwebserver --help
```

EXAMPLE 2 Determining if the Server is Running

The following shell command will start the server if it is not already running.

```

ans='smcwebserver -p | grep running | cut -d"=" -f2'
if ["$ans" = "no"]; then
 smcwebserver start
fi

```

**EXAMPLE 3** Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to the Sun Web Console server.

```
svccfg -s svc:/system/webconsole \
 setprop options/tcp_listen = true
svcadm refresh svc:/system/webconsole
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of smcwebserver:

**JAVA\_HOME** If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, depending on the OS, the following default locations are used:

Solaris: /usr/j2se

Linux: /usr/java/j2sdk1.4\*

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWmcon        |
| Interface Stability | Stable          |

**See Also** [smreg\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [smf\(5\)](#)

**Name** smdiskless – manage diskless client support for a server

**Synopsis** /usr/sadm/bin/smdiskless *subcommand* [ *auth\_args*] - -  
[*subcommand\_args*]

**Description** The smdiskless command manages diskless client support for a server.

smdiskless *subcommands* are:

- add** Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a [sysidcfg\(4\)](#) formatted file as input. A future enhancement will allow specifying both a [sysidcfg\(4\)](#) formatted file and optional arguments, which will override the values in the [sysidcfg\(4\)](#) file.
- delete** Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the *os\_server* type.
- list** Lists existing diskless clients served by *os\_server*.
- modify** Modifies the specified attributes of the diskless client *os\_server*.

**Options** The smdiskless authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smdiskless command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain.

**Note** – smdiskless supports the --auth-data *file* option, which enables you to specify a file the console can read to collect authentication data. See [smc\(1M\)](#) for a description of this option.

-D | - --domain *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is *nis*, *nis+*, *dns*, *ldap*, or *file*; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*)

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                               | If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                           |
| -H   - --hostname <i>l3;host_name:port</i>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smc(1M)</a> -B option, or set your console preferences to load a “home toolbox” by default. |
| -l   - --rolepassword <i>l3;role_password</i> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                |
| -p   - --password <i>l3;password</i>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                      |
| -r   - --rolename <i>l3;role_name</i>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                                  |
| -u   - --username <i>l3;user_name</i>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                          |
| - -                                           | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.                                                                                                                                                                                                                                                                                                                                             |

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

■ For subcommand `add`:

- h (Optional) Displays the command's usage statement.
- i *IP\_address* Specifies the IP address for the host in the form of 172.16.200.1.
- e *ethernet\_addr* Specifies the Ethernet address.
- n *host* Specifies the client name.
- o *os\_server* (optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- x *os=platform* Specifies the operating system. The syntax for *platform* is as follows:  
*instruction\_set.implementation.Solaris\_version*  
where
  - *instruction\_set* is one of `sparc` or `i386`
  - *implementation* is the implementation architecture, that is, `i86pc` and `sun4u`.
  - *version* is the Solaris version number. The supported *version* numbers are 2.6, 2.7 (for Solaris 7), 8, 9, and 10. Examples are:  
`sparc.sun4u.Solaris_8`
- x *root=pathname* (Optional) Specifies the absolute path of the directory in which to create the root directory for diskless clients. The default (and recommended) *pathname* is `/export/root/client_name`.
- x *swap=pathname* (Optional) Specifies the absolute path of the directory in which to create the swap file for diskless clients. The default (and recommended) *pathname* is `/export/swap/client_name`.
- x *swapsize=size* (Optional) Specifies the size, in megabytes, of the swap file for diskless clients. The default swap size is 24M.
- x *dump=pathname* (Optional) Specifies the absolute path of the dump directory for diskless clients. The default (and recommended) *pathname* is `/export/dump/client_name`.
- x *dumpsize=size* (Optional) Specifies the size, in megabytes, of the dump file for diskless clients. The default swap size is 24M.
- x *pw=Y* (Optional) Prompts for the system's root password. The default is not to prompt.

The following options are used to configure workstations on first boot by `sysidtool(1M)`. They can either be specified on the command line, or in a `sysidcfg(4)` formatted file. *Note:* Use the `sysidcfg(4)` file to:

- Add a DNS client.
- Specify use of the LDAP name service.
- Specify a security policy.

The keywords and functions supported by `sysidtool` and `sysidcfg` vary among Solaris releases. Consult the man pages for your operating system release (`uname -r`) to determine the level of support available.

|                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-x tz=<i>timezone</i></code>                     | (Optional) Specifies the path of a timezone file, relative to <code>/usr/share/lib/zoneinfo</code> . The default is the server's timezone.                                                                                                                                                                                                                                                                                       |
| <code>-x ns=NIS   NIS+   NONE</code>                   | (Optional) Specifies the client's nameservice. This is one of <code>NIS</code> , <code>NIS+</code> , or <code>NONE</code> . Use a <code>sysidcfg(4)</code> file to specify DNS or LDAP. The default <code>ns</code> value is <code>NONE</code> , which results in the use of the <code>files</code> source in <code>nsswitch.conf</code> . See <code>nsswitch.conf(4)</code> for a description of the <code>files</code> source. |
| <code>-x nameserver=<i>hostname</i></code>             | (Optional) Specifies the nameserver's hostname. The default is the server's nameserver.                                                                                                                                                                                                                                                                                                                                          |
| <code>-x domain=<i>domain</i></code>                   | (Optional) Specifies the client's domain. The default is the server's domain.                                                                                                                                                                                                                                                                                                                                                    |
| <code>-x nameserver_ipaddress=<i>ip_address</i></code> | (Optional) Specifies the nameserver's IP address.                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-x netmask=<i>ip_address</i></code>              | (Optional) Specifies the client's IP address netmask. The default is the server's netmask.                                                                                                                                                                                                                                                                                                                                       |
| <code>-x locale=<i>locale</i></code>                   | (Optional) Specifies the client's system locale. The default is the C locale.                                                                                                                                                                                                                                                                                                                                                    |
| <code>-x terminal=<i>term</i></code>                   | (Optional) Specifies the workstation's terminal type, typically, <code>sun</code> or <code>xterms</code> .                                                                                                                                                                                                                                                                                                                       |
| <code>-x passwd=<i>root_password</i></code>            | (Optional) Specifies the system's root password. The default is no password.                                                                                                                                                                                                                                                                                                                                                     |
| <code>-x sysidcfg=<i>path_to_sysidcfg_file</i></code>  | (Optional) Specifies the file to be placed in the <code>/etc</code> directory of the diskless client. On first boot, <code>/etc/.UNCONFIGURED</code> exists and <code>sysidtool(1M)</code> will run. If a file called                                                                                                                                                                                                            |

/etc/sysidcfg exists, `sysidtool(1M)` reads this file and uses the information for system configuration.

- For subcommand `delete`:
  - h (Optional) Displays the command's usage statement.
  - n *host* Specifies the hostname of the diskless client to delete. This host is deleted from relevant tables and OS Services for this client are deleted.
  - o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.
- For subcommand `list`:
  - h (Optional) Displays the command's usage statement.
  - o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.
- For subcommand `modify`:
  - e *ethernet\_addr* Changes the specified diskless client's ethernet address to *ethernet\_addr*.
  - h (Optional) Displays the command's usage statement.
  - n *host* Specifies the host name of the diskless client to modify.
  - o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` -D option. This option is useful in the event that the name service server and the OS server are not the same machine.
  - x *tz=timezone* (Optional) Changes the specified diskless client's timezone.

### Examples EXAMPLE 1 Creating a new diskless client

The following command adds a new diskless client named `client1` which will run Solaris 10 on a `sun4u` machine:

```
example% /usr/sadm/bin/smdiskless add -- -i 172.16.200.1 \
-e 8:0:11:12:13:14 -n client1 -x os=sparc.sun4u.Solaris_10 \
-x root=/export/root/client1 -x swap=/export/swap/client1 \
-x swapsize=32 -x tz=US/Eastern -x locale=en_US
```

**EXAMPLE 2** Deleting an existing diskless client

The following command deletes the diskless client named `client1` from the OS server named `osserver`, where the OS server is using NIS+ and the NIS+ server is `nisplusservice`:

```
example% /usr/sadm/bin/smdiskless delete \
 -D nisplus:/nisplusservice/my.domain.com -- \
 -o osserver -n client1
```

**EXAMPLE 3** Listing the diskless clients served by a host

The following command lists the diskless clients running on the OS server, `osserver`:

```
example% /usr/sadm/bin/smdiskless list -D file:/osserver/osserver -- \
 -o osserver
```

**EXAMPLE 4** Modifying the attributes of the diskless client host

The following command modifies the ethernet address for the client named `client1` on the OS server, `osserver`, to be `8:0:11:12:13:15`:

```
example% /usr/sadm/bin/smdiskless modify -D file:/osserver/osserver -- \
 -o osserver -n client1 -e 8:0:11:12:13:15
```

**Environment Variables** See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smdiskless` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability  | SUNWdclnt      |

**See Also** [smc\(1M\)](#), [smoservice\(1M\)](#), [sysidtool\(1M\)](#), [nsswitch.conf\(4\)](#), [sysidcfg\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smexec – manage entries in the `exec_attr` database

**Synopsis** `/usr/sadm/bin/smexec subcommand [ auth_args ] - -`  
`[subcommand_args]`

**Description** The `smexec` command manages an entry in the `exec_attr(4)` database in the local `/etc` files name service or a NIS or NIS+ name service.

*subcommands* `smexec` *subcommands* are:

- `add` Adds a new entry to the `exec_attr(4)` database. To add an entry to the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.
- `delete` Deletes an entry from the `exec_attr(4)` database. To delete an entry from the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.
- `modify` Modifies an entry in the `exec_attr(4)` database. To modify an entry in the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.

**Options** The `smexec` authentication arguments, *auth\_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smexec` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the `- -` option.

*auth\_args* The *auth\_args* `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain` with the *domain* argument.

`-D | - --domain 13;domain` Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (Note: Do not use `nis+` for `nisplus`.)

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                               | If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                           |
| -H   - --hostname <i>l3;host_name:port</i>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smc(1M)</a> -B option, or set your console preferences to load a “home toolbox” by default. |
| -l   - --rolepassword <i>l3;role_password</i> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                |
| -p   - --password <i>l3;password</i>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                      |
| -r   - --rolename <i>l3;role_name</i>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                                  |
| -u   - --username <i>l3;user_name</i>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                          |
| - -                                           | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.                                                                                                                                                                                                                                                                                                                                             |

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).

■ For subcommand `add`:

- `-c command_path|CDE_action`
Specifies the full path to the command or CDE action associated with the new `exec_attr` entry. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.
- `-g egid`
(Optional) Specifies the effective group ID that executes with the command.
- `-G gid`
(Optional) Specifies the real group ID that executes with the command.
- `-h`
(Optional) Displays the command's usage statement.
- `-n profile_name`
Specifies the name of the profile associated with the new `exec_attr` entry.
- `-t type`
Specifies the type for the command. Currently, the only acceptable value for *type* is `cmd`.
- `-u uid`
(Optional) Specifies the effective user ID that executes with the command.
- `-U uid`
(Optional) Specifies the real user ID that executes with the command.
- `-M limit_privs`
Specifies the privilege name(s) to add to the new [exec\\_attr\(4\)](#) entry. The default is `all` for *limit* privilege.
- `-I inheritable_privs`
To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).  
Specifies the inheritable privilege name(s) to add to the new [exec\\_attr\(4\)](#) entry.

■ For subcommand `delete`:

- `-c command_path|CDE_action`
Specifies the full path to the command or CDE action associated with the `exec_attr` entry. Specifying a CDE action is available only if the system is

- configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.
- h (Optional) Displays the command's usage statement.
  - n *profile\_name* Specifies the name of the profile associated with the `exec_attr` entry.
  - t *type* Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
- For subcommand `modify`:
    - c *command\_path|CDE\_action* Specifies the full path to the command or CDE action associated with the `exec_attr` entry you want to modify. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.
    - g *egid* (Optional) Specifies the new effective group ID that executes with the command.
    - G *gid* (Optional) Specifies the new real group ID that executes with the command.
    - h (Optional) Displays the command's usage statement.
    - n *profile\_name* Specifies the name of the profile associated with the `exec_attr` entry.
    - t *type* Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.
    - u *euclid* (Optional) Specifies the new effective user ID that executes with the command.
    - U *uid* (Optional) Specifies the new real user ID that executes with the command.
    - M *limit\_privs* Specifies the privilege name(s) to modify in an `exec_attr(4)` entry. The default is `all` for *limit* privilege.  
  
To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
    - I *inheritable\_privs* Specifies the inheritable privilege name(s) to modify in an `exec_attr(4)` entry.

### Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B toolbox` option to specify a toolbox that contains support for Trusted Extensions. For example:

```
smexec -add -c <CDE action> -n "User Manager" \
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, `<server>` is the name of the machine running the Solaris Management Console. See [smc\(1M\)](#) for a description of the `-B` option.

### Examples

#### EXAMPLE 1 Creating an `exec_attr` Database Entry

The following creates a new `exec_attr` entry for the User Manager profile on the local file system. The entry type is `cmd` for the command `/usr/bin/cp`. The command has an effective user ID of `0` and an effective group ID of `0`.

```
./smexec add -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp -u 0 -g 0
```

#### EXAMPLE 2 Deleting an `exec_attr` Database Entry

The following example deletes an `exec_attr` database entry for the User Manager profile from the local file system. The entry designated for the command `/usr/bin/cp` is deleted.

```
./smexec delete -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp
```

#### EXAMPLE 3 Modifying an `exec_attr` Database Entry

The following modifies the attributes of the `exec_attr` database entry for the User Manager profile on the local file system. The `/usr/bin/cp` entry is modified to execute with the real user ID of `0` and the real group ID of `0`.

```
./smexec modify -H myhost -p mypasswd -u root -- -n "User Manager" \
-t cmd -c /usr/bin/cp -U 0 -G 0
```

### Environment Variables

See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smexec` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

### Exit Status

The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

### Files

The following file is used by the `smexec` command:

`/etc/security/exec_attr` Rights profiles database. See [exec\\_attr\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWmga         |
| Interface Stability | Evolving        |

**See Also** [smc\(1M\)](#), [exec\\_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smgroup – manage group entries

**Synopsis** /usr/sadm/bin/smgroup *subcommand* [ *auth\_args*] - -  
[*subcommand\_args*]

**Description** The smgroup command manages one or more group definitions in the group database for the appropriate files in the local /etc files name service or a NIS or NIS+ name service.

The following smgroup *subcommands* are supported

- add        Adds a new group entry. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.
- delete    Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.
- list       Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (:). To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.
- modify    Modifies a group entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

**Options** The smgroup authentication arguments, *auth\_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The smgroup command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain.

The following *auth\_args* are supported:

- D | - -domain *13;domain*        Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap` or `file`; *host\_name* is the name of the machine that serves the domain;

and *domain\_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - --hostname *13;host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the [smc\(1M\)](#) -B option, or set your console preferences to load a “home toolbox” by default.

-l | - --rolepassword *13;role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - --password *13;password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - --rolename *13;role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - --username *13;user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

*subcommand\_args* Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

The `add` subcommand supports the following *subcommand\_args*:

- `-g gid` (Optional) Specifies the group ID for the new group. The group ID must be a non-negative decimal integer with a maximum value of 2MB (2,147,483,647). Group IDs 0–99 are reserved for the system and should be used with care. If you do not specify a *gid*, the system automatically assigns the next available *gid*. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.
- `-h` (Optional) Displays the command's usage statement.
- `-m group_member1 -m group_member2 . . .` (Optional) Specifies the new members to add to the group.
- `-n group_name` Specifies the name of the new group. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

The `delete` subcommand supports the following *subcommand\_args*:

- `-h` (Optional) Displays the command's usage statement.
- `-n group_name` Specifies the name of the group you want to delete.

The `list` subcommand supports the following *subcommand\_args*:

- `-h` (Optional) Displays the command's usage statement.
- `-n group_name` (Optional) Specifies the name of the group you want to list. If you do not specify a group name, all groups are listed.

The `modify` subcommand supports the following *subcommand\_args*:

- `-h` (Optional) Displays the command's usage statement.

|                                                    |                                                                                                                                                                                               |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-m group_member1 -m group_member2 ...</code> | (Optional) Specifies the new members to add to the group. Note that <i>group_member</i> overwrites the existing member list in the group file.                                                |
| <code>-n group_name</code>                         | Specifies the name of the group you want to modify.                                                                                                                                           |
| <code>-N new_group</code>                          | (Optional) Specifies the new group name. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter. |

### Examples EXAMPLE 1 Creating a Test Group

The following creates the `test_group` group entry with a group ID of 123 and adds `test_member1` and `test_member2` to the group:

```
./smgroup add -H myhost -p mypasswd -u root -- -n test_group \
-m test_member1 -m test_member2 -g 123
```

### EXAMPLE 2 Deleting a Group

The following deletes `test_group`:

```
./smgroup delete -H myhost -p mypasswd -u root -- -n test_group
```

### EXAMPLE 3 Displaying All Groups

The following displays all groups in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root --
```

### EXAMPLE 4 Displaying a Group

The following displays the `group_1` data in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root -- -n group_1
```

### EXAMPLE 5 Renaming a Group

The following renames a group from `finance` to `accounting`:

```
./smgroup modify -H myhost -p mypasswd -u root -- \
-n finance -N accounting
```

**Environment Variables** See [environ\(5\)](#) for a description of the JAVA\_HOME environment variable, which affects the execution of the smgroup command. If this environment variable is not specified, the /usr/java location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the smgroup command:

/etc/group Group file. See [group\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [smc\(1M\)](#), [group\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

- 
- Name** smlog – manage and view WBEM log files
- Synopsis** /usr/sadm/bin/smLog *subcommand* [*auth\_args*] --  
[*subcommand\_args*]
- Description** The smlog command manages WBEM log files and allows a user to view WBEM log file records.
- Subcommands** The smlog command supports the following subcommands:
- backup Backs up the entries in the current WBEM log file. The backup command then creates a new log file and makes this log file the current log file.
  - delete Deletes an existing (backed up) WBEM log file.
  - list Lists the names of all the WBEM log files available for viewing.
  - view Allows the user to view the contents of the specified WBEM log file.
- Options** The smlog authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smlog command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.
- The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.
- auth\_args*** The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.
- D | - --domain *13;domain* Specifies the default domain that you want to manage. smlog accepts only *file* for this option. *file* is also the default value.
- The *file* default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
- H | - --hostname *13;host\_name:port* Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a

toolbox to load into the console. To override this behavior, use the `smc -B` option (see [smc\(1M\)](#)), or set your console preferences to load a “home toolbox” by default.

- l | - `rolepassword 13;role_password` Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p | - `password 13;password` Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r | - `rolename 13;role_name` Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u | - `username 13;user_name` Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- - This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

`subcommand_args` Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

The `backup` subcommand supports the following *subcommand\_args*:

- h Displays the command's usage statement.

This *subcommand\_arg* is optional.

The `delete` subcommand supports the following *subcommand\_args*:

- h Displays the command's usage statement.

This *subcommand\_arg* is optional.

- n *name* Specifies the name of the log file you want to delete.

The `list` subcommand supports the following *subcommand\_args*:

-h Displays the command's usage statement.

This *subcommand\_arg* is optional.

The view subcommand supports the following *subcommand\_args*:

-h Displays the command's usage statement.

This *subcommand\_arg* is optional.

-n *name* Specifies the name of the log file you want to view.

-v Displays the data in verbose format.

This *subcommand\_arg* is optional.

### Examples **EXAMPLE 1** Listing WBEM Log Files

The following command lists all available WBEM log files:

```
./smlog list -H myhost -p mypasswd -u root --
```

```
Log.01/03/2001.14:38:29
Log.01/04/2001.16:34:59
Log.01/08/2001.14:13:33
Log.01/11/2001.18:39:53
Log.01/12/2001.10:31:31
Log.12/21/2000.17:41:11
```

### **EXAMPLE 2** Displaying a WBEM Log File

The following command displays the contents of a log file:

```
./smlog view -H myhost -p mypasswd -u root -- -n Log.01/04/2001.16:34:59
```

| Date and Time      | Client    | User | Source            | Severity      | Category        |
|--------------------|-----------|------|-------------------|---------------|-----------------|
| 1/5/01 5:22:47 PM  | hostname1 | root | Solaris_OsService | Informational | Application log |
| No services found. |           |      |                   |               |                 |
| 1/5/01 5:21:46 PM  | hostname1 | root | Solaris_OsService | Informational | Application log |
| No services found. |           |      |                   |               |                 |

The smlog output wraps when it exceeds 80 characters.

**Environment Variables** See [environ\(5\)](#) for a description of the JAVA\_HOME environment variable, which affects the execution of the smlog command. If this environment variable is not specified, the /usr/java1.2 location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

0 Successful completion.

- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [smc\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smmaillist – manage email alias entries

**Synopsis** /usr/sadm/bin/smmaillist *subcommand* [ *auth\_args*] - -  
[*subcommand\_args*]

**Description** The smmaillist command manages one or more email alias entries for the appropriate files in the local /etc files name service or a NIS or NIS+ name service.

*subcommands* smmaillist *subcommands* are:

- add** Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.
- delete** Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete Postmaster or Mailer-Daemon aliases.
- list** Lists one or more email alias entries. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.
- modify** Modifies an email alias entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

**Options** The smmaillist authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smmaillist command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.

-D | - --domain *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (*Note:* Do not use `nis+` for `nisplus`.)

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                            | If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                           |
| <code>-H   - --hostname <i>l3;host_name:port</i></code>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smc(1M)</a> -B option, or set your console preferences to load a “home toolbox” by default. |
| <code>-l   - --rolepassword <i>l3;role_password</i></code> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                |
| <code>-p   - --password <i>l3;password</i></code>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                      |
| <code>-r   - --rolename <i>l3;role_name</i></code>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>-u   - --username <i>l3;user_name</i></code>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                          |
| <code>- -</code>                                           | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.                                                                                                                                                                                                                                                                                                                                             |

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:
  - `-a address1 -a address2...` (Optional) Specifies the new email address. See [sendmail\(1M\)](#).
  - `-h` (Optional) Displays the command's usage statement.
  - `-n alias_name` Specifies the name of the alias you want to add. See [sendmail\(1M\)](#).
- For subcommand `delete`:
  - `-h` (Optional) Displays the command's usage statement.
  - `-n alias_name` Specifies the alias you want to delete.
- For subcommand `list`:
  - `-h` (Optional) Displays the command's usage statement.
  - `-n alias_name` (Optional) Specifies the name of the alias you want to display. If you do not specify an alias, all aliases are listed.
- For subcommand `modify`:
  - `-a address1 -a address2...` (Optional) Specifies new email address(es) to replace the existing one(s). See [sendmail\(1M\)](#).
  - `-h` (Optional) Displays the command's usage statement.
  - `-n alias_name` (Optional) Specifies the name of the alias you want to modify.
  - `-N new_alias_name` Specifies the new alias name. Use only when renaming an alias. See [sendmail\(1M\)](#).

### Examples EXAMPLE 1 Creating an alias

The following creates the `coworkers` alias and adds the following member list: `bill@machine1`, `sue@machine2`, and `me@machine3` to the alias.

```
./smmaillist add -H myhost -p mypasswd -u root -- -n coworkers \
-a bill@machine1 -a sue@machine2 -a me@machine3
```

### EXAMPLE 2 Deleting a mail alias

The following deletes the `my_alias` alias:

```
./smmaillist delete -H myhost -p mypasswd -u root -- -n my_alias
```

### EXAMPLE 3 Displaying members of a mail alias

The following displays the list of members belonging to the `my_alias` alias:

```
./smmaillist list -H myhost -p mypasswd -u root -- -n my_alias
```

**EXAMPLE 4** Displaying members of all mail aliases

The following displays the list of members belonging to all mail aliases:

```
./smmaillist list -H myhost -p mypasswd -u root --
```

**EXAMPLE 5** Renaming a mail alias

The following renames the `current_name` mail alias to `new_name`:

```
./smmaillist modify -H myhost -p mypasswd -u root -- \
-n current_name -N new_name
```

**EXAMPLE 6** Redefining an address list

The following changes the recipients of the alias `my_alias` to `bill@machine1`. Any previous recipients are deleted from the alias.

```
./smmaillist modify -H myhost -p mypasswd -u root -- \
-n my_alias -a bill@machine1
```

**Environment Variables** See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smmaillist` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smmaillist` command:

- `/var/mail/aliases` Aliases for [sendmail\(1M\)](#). See [aliases\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [sendmail\(1M\)](#), [smc\(1M\)](#), [aliases\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smmultiuser – manage bulk operations on user accounts

**Synopsis** /usr/sadm/bin/smmultiuser *subcommand* [ *auth\_args*] - –  
[*subcommand\_args*]

**Description** The `smmultiuser` command allows bulk operations on user entries in the local `/etc` filesystem or a NIS or NIS+ name service, using either an input file or piped input. *Note:* Both input files and piped input contain a cleartext (non-encrypted) password for each new user entry.

*subcommands* smmultiuser *subcommands* are:

- add** Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.
- delete** Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.
- modify** Modifies existing user entries in the user account database. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. Here is the list of what can be modified using the `modify` subcommand:
  1. UserName (only under certain conditions; see Note 2 in NOTES).
  2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
  3. Description.
  4. Primary Group ID.
  5. Shell type.
  6. FullName.

**Options** The `smmultiuser` authentication arguments, *auth\_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smmultiuser` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the `- -` option.

*auth\_args* The valid *auth\_args* are `-D`, `-H`, `-l`, `-p`, `-r`, `- -trust`, and `-u`; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- -domain`.

`-D | - -domain l3;domain` Specifies the default domain that you want to manage. The syntax of *domain* is

*type*:/host\_name/domain\_name, where *type* is nis, nisplus, dns, ldap, or file; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - --hostname *l3;host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the [smc\(1M\)](#) -B option, or set your console preferences to load a “home toolbox” by default.

-l | - --rolepassword *l3;role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - --password *l3;password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - --rolename *l3;role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

- --trust

Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

If using piped input into any of the `smmultiuser` subcommands, it will now be necessary to use the `-t rust` option with the `-L logfile` option. See EXAMPLES.

`-u | -` `--username l3;user_name`

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- -`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- -` option.

*subcommand\_args* *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

`-h` (Optional) Displays the command's usage statement.

`-i input_file` Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i input_file` option, you must include a `piped_input` operand immediately before the command. See EXAMPLES.

`-L logfile` (Optional) Specifies the full pathname to the text file that stores the command's success/failure data. *Note:* This text file is an ASCII—formatted log file; it is different from and unrelated to the output of the normal logging mechanism that also occurs within the Log Viewer tool. The `-L logfile` option is used to dump additional logging information to a text file.

- For subcommand `delete`:

`-h` (Optional) Displays the command's usage statement.

`-i input_file` Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i input_file` option, you must include a `piped_input` operand immediately before the command. See EXAMPLES.

`-L logfile` (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

- For subcommand `modify`:

`-h` (Optional) Displays the command's usage statement.

- i *input\_file* Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i input_file` option, you must include a *piped\_input* operand immediately before the command. See EXAMPLES. *Note:* When modifying passwords, use the piped input, since it is more secure than keeping passwords in a file. See Note 1 in NOTES.
- L *logfile* (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

**Operands** The following operands are supported:

- piped\_input* You must include *piped\_input* if you do not specify an *input\_file*. Include the piped input immediately before the command. The piped input must follow the `/etc/passwd` file format. See EXAMPLES. *Note:* Use the `-t rust` option when using piped input with the `-L logfile` option to avoid the user prompt from the Security Alert Manager, which normally asks the user whether the log file should be created. Without the `-t rust` option, the piped input is improperly taken as the answer to the prompt before the user can answer “Y” or “N”, and the logging operation will probably fail.

**Examples** EXAMPLE 1 Creating multiple user accounts

The following reads in user account data from the `/tmp/foo` file and creates new user accounts on the local file system. The input file is formatted in the `/etc/passwd` format.

```
./smmultiuser add -H myhost -p mypasswd -u root -- -i /tmp/foo
```

EXAMPLE 2 Deleting multiple user accounts

The following reads in user account data from the `/tmp/foo` file and deletes the named user accounts from the local file system:

```
./smmultiuser delete -H myhost -p mypasswd -u root -- -i /tmp/foo
```

EXAMPLE 3 Creating a log file with piped input

The following example shows the use of the `smc(1M) -t rust` option that is required when creating a log file. It is applicable to the `delete` and `modify` subcommands also.

```
cat /tmp/users.txt | smmultiuser add --trust -- -L /tmp/mylog.txt
```

**Environment Variables** See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smpofile` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smprofile` command:

`/etc/passwd` Contains the file format to use for the `input_file` and `pipedReader`. See [passwd\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

**See Also** [smc\(1M\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

- Notes**
- The file format used by both the `add` and `modify` subcommands is the `/etc/passwd` format. But there is an allowance for a mutated version of this file format that contains an extra field at the end of each line to be used for the Full Name. If the extra field is appended to the end of each line, it will be used for the Full Name value, but if it is omitted, it will be assumed that no Full Name modification is being done. The extra field is separated with a colon (:), just like all the other fields.  
 Example of regulation `/etc/passwd` entry:  

```
rick2:x:101:10:description1:/home/rick2:/bin/sh
```

 Example of `/etc/passwd` variant entry:  

```
rick2:x:101:10:description1:/home/rick2:/bin/sh:Ricks_fullname
```
  - The modifies are all done based on lookups of the user name in the user tables. If a user name can not be found in this lookup, a secondary check will be made to see if the `uid` and `FullName` can be found in the user tables. If they are both found, assume that a user rename has occurred. If neither can be found, assume that the user account does not exist and cannot be modified.
  - If no password is supplied, assume that there is no change to the password information. If a password is being changed, it should be supplied in cleartext as piped input, although this is not required. The password can be supplied in the input file also. Once read in, the password will be changed accordingly.

**Name** smoservice – manage OS services

**Synopsis** /usr/sadm/bin/smoservice *subcommand* [ *auth\_args*] - -  
[*subcommand\_args*]

**Description** The smoservice command manages OS services.

smoservice *subcommands* are:

**add** Adds the specified OS services.

**delete** Deletes the specified OS services.

**list** Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.

**patch** Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.

**Options** The smoservice authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smoservice command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - -domain.

-D | - -domain *l3;domain*

Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is nis, nis+, dns, ldap, or file; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (Note: Do *not* use nis+ for nisplus.)

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                               | If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                           |
| -H   - --hostname <i>13;host_name:port</i>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smc(1M)</a> -B option, or set your console preferences to load a “home toolbox” by default. |
| -l   - --rolepassword <i>13;role_password</i> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                |
| -p   - --password <i>13;password</i>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                      |
| -r   - --rolename <i>13;role_name</i>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                                  |
| -u   - --username <i>13;user_name</i>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                          |
| - -                                           | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.                                                                                                                                                                                                                                                                                                                                             |

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

- h (Optional) Displays the command's usage statement.
- o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- x *mediapath=path* Specifies the full path to the Solaris CD image.
- x *platform=platform* Specifies the OS service to add. The instruction architecture, machine class, OS, and version are given in the form:  
  
*instruction\_set.machine\_class.Solaris\_os\_version*  
  
for example, `sparc.sun4m.Solaris_10`
- x *cluster=cluster* Specifies the Solaris cluster to install. For example, `SUNWCaLL`.
- x *locale=locale[locale, ...]* (Optional) Specifies the locales to install from the specified cluster. A comma-delimited list of locales can be specified.

- For subcommand `delete`:

- h (Optional) Displays the command's usage statement.
- o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.
- x *rmplatform=platform* Specifies the OS service to remove. The instruction architecture, machine class, OS, and version are given in the form:  
  
*instruction\_set.machine\_class.Solaris\_os\_version*  
  
for example, `sparc.all.Solaris_10`. *Note:* Only a machine class of `all` is supported.

- For subcommand `list`:

- h (Optional) Displays the command's usage statement.
- o *os\_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that

specified in the `smc(1M) -D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

■ For subcommand `patch`:

- a *patch\_directory/patch\_ID*
Adds the specified patch, *patch\_ID*, to the spool directory. *patch\_directory* specifies the source path of the patch to be spooled which includes the patchid directory name. Patches are spooled to `/export/diskless/Patches/`. If the patch being added obsoletes an existing patch in the spool, the obsolete patch is moved to the archive area, `/export/diskless/Patches/Archive` (to be restored if this new patch is ever removed).
- h
(Optional) Displays the command's usage statement.
- m
(Optional) Synchronizes spooled patches with offline copies of each diskless client OS service on the server. Spooled patches and applied patches are compared so that newly spooled patches can be installed and patches recently removed from the spool can be backed out. This option does not apply to patches directly to diskless client OS services or diskless clients; the `-u` option must be used to update the services and clients with the changes. Clients are not required to be down at this time, as all patching is done off line. *Note:* The server is fully available during this operation.
- P
Lists all currently spooled patches with an associated synopsis. The list is split up into sections detailing the patches for each OS and architecture in this format:

```
Solaris os_rel1 architecture1:
patchid Synopsis
patchid Synopsis
.....
Solaris os_rel1 architecture2:
patchid Synopsis
.....
```
- r *patchid*
Removes the specified patchid from the spool if it is not a requirement for any of the other patches in the spool. All archived patches that were obsoleted by the removed patch are restored to the spool.
- U
(Optional) Updates all diskless client OS services and diskless clients with any changes after synchronizing

patches with the `-m` option. Clients must be brought down during this operation. Once execution has completed, each client should be booted again.

### Examples EXAMPLE 1 Creating a new OS service

The following command adds an OS service for Solaris 10 for the sun4u machine class where the OS server is *not* using a name service:

```
example% /usr/sadm/bin/smosservice add -- \
-x mediapath=/net/imageserver/5.8/sparc \
-x platform=sparc.sun4u.Solaris_10 \
-x cluster=SUNWCXall -x locale=en_US
```

The following command adds an OS service for Solaris 10 for the sun4u machine class where the OS server is using NIS, the NIS server is `nisserver`, the OS server is `osserver`, and the port to which you connect on `osserver` is 898:

```
example% /usr/sadm/bin/smosservice add -D nis:/nisserver/my.domain.com -- \
-H ossserver:898 -- \
-x mediapath=/net/imageserver/5.8/sparc \
-x platform=sparc.sun4u.Solaris_10 \
-x cluster=SUNWCXall -x locale=en_US \
-o ossserver
```

In the preceding example, the OS service is placed in `/export` on `osserver`, while the `hosts.byaddr`, `ethers`, and `bootparams` maps are updated on the NIS server.

### EXAMPLE 2 Deleting an OS service

The following command deletes the OS service for Solaris 10 for the sun4u machine class where the OS server is using NIS, the NIS server is `nisserver`, and the OS server is `osserver`:

```
example% /usr/sadm/bin/smosservice delete\
-D nis:/nisserver/my.domain.com -- \
-x rmlplatform=sparc.all.Solaris_10 \
-o ossserver
```

### EXAMPLE 3 Listing installed OS services

The following command lists the OS services installed on the machine, `osserver`:

```
example% /usr/sadm/bin/smosservice list \
-D file:/osserver/osserver -- -o ossserver
```

**Environment Variables** See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smosservice` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdclnt       |

**See Also** [smc\(1M\)](#), [smdiskless\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smpatch – download, apply, and remove updates

**Synopsis** /usr/sbin/smpatch add -i *update-id* [*auth-opts*]  
 [-i *update-id*] ... [-d *update-dir*] [-b *BE\_name*]  
 [-n *system-name*] ... [-x *mlist=system-list-file*] [-V]

/usr/sbin/smpatch add -x *idlist=update-list-file*  
 [*auth-opts*]  
 [-d *update-dir*] [-n *system-name*] ...  
 [-b *BE\_name*] [-x *mlist=system-list-file*] [-V]

/usr/sbin/smpatch analyze [*auth-opts*] [-i *update-id*] ...  
 [-n *system-name*] ...  
 [-x *idlist=update-list-file*] [-V]

/usr/sbin/smpatch download [*auth-opts*] [-i *update-id*] ...  
 [-d *update-dir*] [-f] [-n *system-name*] ...

 [-d *update-dir*] [-n *system-name*] ... [-b *BE\_name*]  
 [-x *idlist=update-list-file*] [-V]

**Description** The smpatch command manages the update process on a single system or on multiple systems. Use this command to download, apply, and remove updates. Also, use the smpatch command to configure the update management environment for your system.

If you want to run the smpatch command in remote mode, your system must run at least the Developer Solaris Software Group of the Solaris 10 system.

The smpatch analyze command determines the updates that are appropriate for the systems you want to update. The smpatch command can download and apply updates that you specify

on the command line. Or, `smpatch` can download and apply updates based on an analysis of one or more systems. Use the `-i` option or the `-x idlist=` option to specify the particular updates.

All of the systems on which you want to apply updates must be running the same version of the Solaris Operating System, have the same hardware architecture, and have the same updates applied.

The list of updates that is generated by the analysis is based on all of the available updates from the Sun update server. No explicit information about your host system or its network configuration is transmitted to Sun. Only a request for the Sun update set is transmitted. The update set is scanned for updates that are appropriate for this host system, the results are displayed, and those updates are optionally downloaded.

`smpatch` supports the Live Upgrade feature of the Solaris operating system (see [live\\_upgrade\(5\)](#)). Through the `add`, `remove`, and `update` subcommands, described below, `smpatch` enables you to perform operations on a boot environment (BE). A BE is an operating system image, consisting of a particular set of operating system and application software packages.

The `smpatch` command supports the following subcommands:

#### `add`

Applies one or more updates to one or more systems. You must specify at least one update to apply. By default, updates are applied to the local system.

This subcommand attempts to apply *only* the updates you specify. If you specify an update that depends on another that has not been applied, the `add` command fails to apply the update you specified.

This subcommand does not apply updates based on the specified update policy. To apply updates based on the update policy, use the `update` subcommand.

Use the `-i` or `-x idlist=` option to specify the updates to apply. Note that all of the updates you specify, and those on which they depend, must exist in the download directory.

Use the `-n` or the `-x mlist=` option to specify the systems on which to apply updates.

Optionally use the `-d` option to specify an alternate download directory.

If the updates on which the specified updates depend are unavailable, run the `smpatch download` subcommand to obtain the updates you need.

When you use the `-b BE_name` option, the `add` subcommand applies a specified update to the BE `BE_name`, rather than to the currently running operating system. Upon successful installation of the update, `smpatch` activates `BE_name` (see [luactivate\(1M\)](#)) and informs you that you can, at that point, boot from `BE_name`.

#### `analyze`

Analyzes a system to generate a list of the appropriate updates.

After analyzing the system, use the `update` subcommand or the `download` and `add` subcommands to download and apply the updates to your systems.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

If you supply a list of one or more updates, the list is augmented with the updates on which those updates depend. The list is also put in an order suitable for applying updates.

The `smpatch analyze` command depends on network services that are not available while the system is in single-user mode.

#### download

Downloads updates from the Sun update server to a system. You can optionally specify which updates to download. You can also specify the name of a system and download the appropriate updates to that system.

Use the `-i` or `-x idList=` option to specify the updates to download.

Use the `-f` option to force the download of the exact update revision specified by `-i update-id`. If `-i update-id` does not specify a revision, the highest revision of the update is downloaded.

Use the `-t` option to download the README file for the update specified by `-i update-id`. If `-i update-id` does not specify a revision, the README file for the highest revision of the update is downloaded.

Use the `-n` option to analyze a remote system and to determine which updates to download. The updates, and those on which they depend, are downloaded from the Sun update server to the download directory of the system you specified.

The `smpatch download` command depends on network services that are not available while the system is in single-user mode.

#### get

Lists one or more of the `smpatch` configuration parameter values. See "Configuring Your Update Management Environment."

To see values for all parameters, run the `smpatch get` command with no arguments. The output shows an entry for all configuration parameters. Each entry appears on a line by itself. Each entry includes three fields: the parameter name, the value you have assigned it, and its default value. The fields are separated by one or more tab characters.

The following values have special meaning: `-` means that no value is set, `""` means that the value is the null string, `\-` means that the value is `-`, and `\"` means that the value is `""` (two double quotes).

In addition to these special values, these special characters might appear in the output: `\t` for a tab, `\n` for a newline, and `\\` for a backslash.

To see values for particular parameters, run the `smpatch get` command with one or more parameter names. The output lists one parameter value per line in the order in which the parameter names are specified on the command line.

#### messages

Displays messages from the message-of-the-day (MOTD) file. This file stores messages, some of which can be urgent, from Sun. By default, when there is a new message in this file, the message shown below is displayed in `stderr`:

```
You have new messages. To retrieve: smpatch messages [-a]
```

The preceding message appears at the top of any `smpatch analyze/download/update` reports. The `-a` option to the `messages` subcommand displays all messages. Without the `-a` option, only new (that is, as yet unread) messages are displayed.

The receiving of messages from the software update client is controlled by the property:

```
patchpro.report.motd.messages
```

When this property is enabled, the default condition, the client receives messages from Sun. To disable this property, enter:

```
smpatch set patchpro.report.motd.messages=false
```

#### order

Sorts a list of updates into an order that can be used to apply updates.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

Use the `-i` or `-x idlist=` option to specify the updates to order. Note that all of the updates you specify must exist in the download directory.

#### remove

Removes a single update from a single system.

Use the `-i` option to specify which update to remove. Do not use the `-x idlist=` option. Optionally, use the `-n` option to specify the name of a system. Do not use the `-x mlist=` option. By default, the update is removed from the local system.

If the update that you want to remove is required by one or more of the updates that have already been applied to the system, the update is not removed.

When you use the `-b BE_name` option, the `remove` subcommand removes a specified update from the BE `BE_name`, rather than from the currently running operating system.

#### set

Sets the values of one or more configuration parameters. Nothing is written to standard output or standard error when you set parameters, even if a parameter value you set is invalid. This command does not validate the values you set.

**unset**

Resets one or more configuration parameters to the default values. You must specify at least one configuration parameter.

**update**

Updates a single local or remote system by applying appropriate updates. This subcommand analyzes the system, then downloads the appropriate updates from the Sun update server to your system. After the availability of the updates has been confirmed, the updates are applied based on the update policy.

By default, standard updates and those that have `rebootafter` or `reconfigafter` properties are applied.

If an update does not meet the policy for applying updates, the update is not applied. Instead, the ID of the update is written to a file in the download directory. After the update ID is written to the file, `smpatch` continues to apply the other updates. Later, you can use `patchadd` to manually apply any updates listed in this file. The updates listed in the file are still in the download directory.

When you use the `-b BE_name` option, the `update` subcommand applies an update to the BE `BE_name`, rather than to the currently running operating system. Upon successful installation of the update, `smpatch` activates `BE_name` (see [luactivate\(1M\)](#)) and informs you that you can, at that point, boot from `BE_name`.

Installation instructions for updates that require special handling are included in the README file for each update.

The `smpatch update` command depends on network services that are not available while the system is in single-user mode.

**Using Local Mode or Remote Mode**

Starting with Solaris 9, the `smpatch` command is available in two modes: local mode and remote mode. *Local mode* can be run only on the local system and can be run by users who have the appropriate authorizations. This mode can be run while the system is in single-user mode. *Remote mode* can be used to perform tasks on remote systems and can be run by users or roles that have the appropriate authorizations.

By default, local mode is run. In local mode, the Solaris WBEM services are not used, and none of the authentication options or those options that refer to remote systems are available. The command in local mode runs faster than in remote mode.

If the Solaris WBEM services are running and you specify any of the remote or authentication options, the command in remote mode is used.

On Solaris 8 systems, the `smpatch` command only supports local mode operations.

**Specifying the Source of Updates** Your system must specify the source of updates to use. By default, you obtain updates from the Sun update server. However, you can also obtain updates from an update server on your intranet or from a local collection of updates on your system.

You must specify the URL that points to the collection of updates. By default, the Sun update server is the source of updates. The URL is:

```
https://getupdates.sun.com/solaris/
```

The URL must point to an update server or to a collection of updates that is available to the local system. The value of this URL cannot be null.

**Configuring Your Update Management Environment** You can use the `smpatch set` command to configure the update management environment for your system. Use these parameters:

```
patchpro.patchset
```

Name of the update set to use. The default name is `current`.

```
patchpro.download.directory
```

Path of the directory where downloaded updates are stored and from which updates are applied. The default location is `/var/sadm/spool`.

```
patchpro.backout.directory
```

Path of the directory where update backout data is saved. When an update is removed, the data is retrieved from this directory as well. By default, backout data is saved in the package directories.

```
patchpro.patch.source
```

URL that points to the collection of updates. The default URL is that of the Sun update server, `https://getupdates.sun.com/solaris/`.

```
patchpro.proxy.host
```

Host name of your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed.

```
patchpro.proxy.port
```

Port number used by your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed. The default port is `8080`.

```
patchpro.proxy.user
```

Your user name used by your web proxy for authentication.

```
patchpro.proxy.passwd
```

Password used by your web proxy for authentication.

```
patchpro.install.types
```

Your policy for applying updates. The value is a list of zero or more colon-separated update properties that are permitted to be applied by an update operation (`smpatch update`).

This policy *only* affects which updates are installed on your system. The policy does not affect which updates are downloaded.

By default, updates that have the `standard`, `rebootafter`, and `reconfigafter` properties can be applied. See “Setting an Update Policy.”

**Setting an Update Policy** Updates are classified as being standard or nonstandard. A *standard update* can be applied by `smpatch update`. Such an update is associated with the `standard` update property. `smpatch` applies standard updates immediately. These updates require no system restart. A *nonstandard update* has one of the following characteristics:

- An update that is associated with the `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, or `singleuser` properties. Such a nonstandard update can be applied automatically during a system shutdown if permitted by the policy.
- An update that is associated with the `interactive` property. Such an update cannot be applied by using automated installation mechanisms like `smpatch update`. When you attempt to apply one of these updates using `smpatch update`, the update will be downloaded but not installed. You must examine the update's README file and perform whatever manual steps it describes. Typically, you are instructed to apply the update manually using `patchadd` or `smpatch add`.

Use `smpatch set` to specify the types of updates that `smpatch` can additionally apply during an update operation. Such updates might include those that require a reboot and those that must be applied while the system is in single-user mode.

This policy only affects which updates are installed on your system. The policy does not affect which updates are downloaded.

Specify the types of updates that can be applied by using the following command:

```
smpatch set patchpro.install.types=update-property-list
```

*update-property-list* is a colon-separated list of one or more of the following update properties:

#### `interactive`

An update that cannot be applied by running the usual update management tools (`pprosv`, `smpatch`, or `patchadd`). Before this update is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the update's README file.

#### `rebootafter`

The effects of this update are not visible until after the system is rebooted.

#### `rebootimmediate`

When this update is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost.

#### `reconfigafter`

The effects of this update are not visible until after a reconfiguration reboot (`boot -r`). See the [boot\(1M\)](#) man page.

**reconfigimmediate**

When this update is applied, the system becomes unstable until the system gets a reconfiguration reboot (`boot -r`). An unstable system is one in which the behavior is unpredictable and data might be lost.

**singleuser**

Do not apply this update while the system is in multiuser mode. You must apply this update on a quiet system with no network traffic and with extremely restricted I/O activity.

**standard**

This update can be applied while the system is in multiuser mode. The effects of the update are visible as soon as it is applied unless the application being updated is running while the update is applied. In this case, the effects of the update are visible after the affected application is restarted.

**Options** The `smpatch` command supports two kinds of options: authentication options and subcommand options.

**Authentication Options** The `smpatch` authentication options, *auth-opts*, apply to all of the subcommands.

If no authentication options are specified, certain defaults are assumed and the user might be prompted for additional information, such as a password for authentication purposes.

These authentication options are only available if the Solaris Management Console and the Solaris WBEM services are available on the local system. If the WBEM services are not running on the local system, `smpatch` performs update operations on the local system only. You can also “force” the use of the local-mode `smpatch` command by using the `-L` option.

The single letter options can also be specified by their equivalent option words preceded by two hyphens. For example, you can specify either `-l` or `--rolepassword`.

The following authentication options are supported:

**-H** | `--hostname host-name:port`

Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify a host (*host-name:port*), the Solaris Management Console connects to the local host on port 898. You might still have to choose a toolbox to load into the console. To override this behavior, use the `smc -B` command, or set your console preferences to load a home toolbox by default.

**-L**

Forces the `smpatch` command to use local mode, which does not rely on Solaris WBEM services. On Solaris 8 systems, this option does not do anything.

This option is mutually exclusive with the other authentication options.

- l | --rolepassword *role-password*  
Specifies the password for *role-name*. If you specify *role-name* but do not specify *role-password*, you are prompted to supply *role-password*. Because passwords specified on the command line can be seen by any user on the system, this option is considered to be insecure.
- p | --password *password*  
Specifies the password for *user-name*. If you do not specify a password, you are prompted to supply one. Because passwords specified on the command line can be seen by any user on the system, this option is considered to be insecure.
- r | --rolename *role-name*  
Specifies a role name for authentication. If this option is not specified, no role is assumed.
- u | --username *user-name*  
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

Subcommand Options The following options pertain to the `smpatch` subcommands:

- b *BE\_name*  
Specifies the name of BE that is to be created and updated (for the `add` and `update` subcommands), or to be removed, for the `remove` subcommand.
- d *update-dir*  
Specifies an alternate download directory in which updates are downloaded and from which they are applied.  
  
The default download directory is `/var/sadm/spool`.  
  
The directory must be writable by root and be publicly readable.  
  
*update-dir* uses one of the following forms:
  - For remote mode, specify *host-name:/update-dir*, where */update-dir* is a fully qualified, shared directory.
  - For local mode, specify */update-dir*, which is a fully qualified, shared directory.  
This option is supported by the `add`, `download`, `order`, and `update` subcommands.
- f  
Forces the download of the exact update revision specified by `-i update-id`. If `-i update-id` does not specify a revision, the highest revision of the update is downloaded.  
  
This option is supported by the `download` subcommand.
- h  
Displays information about the command-line options for the specified subcommand. This option is mutually exclusive with all other options.

---

**-i *update-id***

Specifies the ID of an update.

You can specify more than one update ID by using the `-i` option for each update. You can also use the `-x idlist=` option to point to a list of update IDs.

When using the `remove` subcommand, you can specify exactly one update ID.

This option is supported by the `add`, `analyze`, `download`, `order`, `remove`, and `update` subcommands.

**-n *system-name***

Specifies the name of the system on which to manage updates.

When using the `add` subcommand, you can specify more than one system by using the `-n` option for each system. When using the `analyze`, `download`, `remove`, and `update` subcommands, you can only specify a single system.

To specify more than one system for the `smpatch add` command, use the `-x mlist=` option. This option enables you to specify a list of systems instead of using the `-n` option to specify each system. The `-n` option and the `-x mlist=` option are mutually exclusive.

If you do not specify this option, the system is assumed to be the one specified by the `-H` option.

This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified by this option.

This option is supported by the `add`, `analyze`, `download`, `get`, `order`, `remove`, `set`, `unset`, and `update` subcommands.

**-t**

Downloads the README file associated with the update specified by `-i update-id`. If `-i update-id` does not specify a revision, the README file for the highest revision of the update is downloaded.

This option is supported by the `download` subcommand.

**-V**

Displays version information for an `smpatch` subcommand.

**-x *idlist=update-list-file***

Specifies the name of a file, *update-list-file*, that contains a list of updates to download or apply.

Each update ID in the file must be terminated by a newline character. The file name you specify must be a full path name.

You can use the `-i` option to specify a list of update IDs.

This option is supported by the `add`, `analyze`, `download`, `order`, and `update` subcommands.

`-x mlist=system-list-file`

Specifies the name of a file, *system-list-file*, that contains a list of systems on which to manage updates.

Each system name must be terminated by a newline character. The file name you specify must be a full path name.

You can use the `-n` option to specify a list of systems instead of using the `-x mlist=` option. The `-n` option and the `-x mlist=` option are mutually exclusive.

This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified in *system-list-file*.

This option is supported by the `add` subcommand.

#### **Examples** EXAMPLE 1 Analyzing Your System to Obtain the List of Appropriate Updates for the Local System

```
smpatch analyze
```

Shows how to analyze your system to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to your system.

#### EXAMPLE 2 Analyzing Your System to Obtain the List of Appropriate Updates for Another System

```
smpatch analyze -n lab1
```

Shows how to analyze a different system, `lab1`, to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to that system.

#### EXAMPLE 3 Applying Updates to Multiple Systems

```
smpatch add -i 102893-01 -i 106895-09 -i 106527-05 \
-d fileserver:/files/updates/s10 -n lab1 -n lab2
```

Applies updates `102893-01`, `106895-09`, and `106527-05` to the systems `lab1` and `lab2`. The updates are located in the `/files/updates/s10` directory on the system named `fileserver`.

#### EXAMPLE 4 Applying Updates by Using an Update List File

```
smpatch add -x idlist=/tmp/update/update_file \
-d /net/fileserver/export/updatespool/Solaris10 -n lab1 -n lab2
```

Applies the updates specified in the file `/tmp/update/update_file` to the systems `lab1` and `lab2`. The updates are located in the NFS-mounted directory named `/net/fileserver/export/updatespool/Solaris10`.

**EXAMPLE 5** Applying Updates by Using an Update List File and a System List File

```
smpatch add -x idlist=/tmp/update/update_file \
-x mlist=/tmp/update/sys_file
```

Applies the updates listed in the file `/tmp/update/update_file` to the systems listed in the file `/tmp/update/sys_file`. The updates are located in the default `/var/sadm/spool` directory on the local system.

**EXAMPLE 6** Analyzing a System and Downloading Updates From the Sun Update Server

```
smpatch download -n lab1
```

Analyzes the `lab1` system and downloads the appropriate updates from the Sun update server to the download directory.

**EXAMPLE 7** Downloading Updates From the Sun Update Server

The command below downloads the `102893-01` and `106895-09` updates from the Sun update server to the `/files/updates/s10` directory.

```
smpatch download -i 102893-01 -i 106895-09 -d /files/updates/s10
```

**EXAMPLE 8** Downloading Specific Update Revisions From the Sun Update Server

The command below downloads the `102893-01` and `106895-02` updates from the Sun update server. The specific revisions are downloaded, not the highest available revision.

```
smpatch download -f -i 102893-01 -i 106895-02
```

**EXAMPLE 9** Downloading the Highest Available Update Revisions From the Sun Update Server

The command below downloads the `102893-01` and `106895-09` updates, which are the highest available revisions, from the Sun update server.

```
smpatch download -f -i 102893 -i 106895
```

**EXAMPLE 10** Downloading Update README Files From the Sun Update Server

The command below downloads the README files for updates `102893-01` and `106895-02`. Because update `102893` was specified without a revision number, the README file for the highest available update revision, `102893-01`, is downloaded from the Sun update server.

```
smpatch download -t -i 102893 -i 106895-02
```

**EXAMPLE 11** Listing All Configuration Parameter Values

```
smpatch get -p password
Loading Tool: com.sun.admin.patchmgr.cli.PatchMgrCli from mars
Login to mars as user root was successful.
Download of com.sun.admin.patchmgr.cli.PatchMgrCli from mars
was successful.
```

**EXAMPLE 11** Listing All Configuration Parameter Values (Continued)

On machine mars:

```

patchpro.backout.directory - ""
patchpro.download.directory - /var/sadm/spool
patchpro.install.types - rebootafter:reconfigafter:standard
patchpro.patch.source - https://getupdates.sun.com/solaris/
patchpro.patchset - current
patchpro.proxy.host - ""
patchpro.proxy.passwd **** *
patchpro.proxy.port - 8080
patchpro.proxy.user - ""
patchpro.sun.passwd **** *
patchpro.sun.user - ""

```

Lists the configuration settings for the system.

**EXAMPLE 12** Listing One or More Configuration Parameter Values

```

smpatch get -L patchpro.patch.source patchpro.download.directory
https://getupdates.sun.com/solaris/
/var/sadm/spool

```

Uses `smpatch` in local mode to list the values of the `patchpro.patch.source` and the `patchpro.download.directory` parameters.

**EXAMPLE 13** Reordering a List of Updates

```

smpatch order -x idlist=/tmp/plist

```

Reorders the update list called `/tmp/plist` in an order that is suitable for applying the updates.

**EXAMPLE 14** Removing an Update

```

smpatch remove -i 102893-01

```

Removes update `102893-01`.

**EXAMPLE 15** Specifying the Update Policy

The following command specifies the update policy.

```

smpatch set \
patchpro.install.types=standard:singleuser:reconfigafter:rebootafter

```

Specifies the update policy for your system. The following types of updates are allowed to be applied to your system:

- Standard updates
- Updates that must be applied in single-user mode

---

**EXAMPLE 15** Specifying the Update Policy *(Continued)*

- Updates that require that the system undergo a reconfiguration reboot after they have been applied
- Updates that require that the system undergo a reboot after they have been applied

**EXAMPLE 16** Changing the Download Directory Location

```
smpatch set patchpro.download.directory=/export/home/updates
```

**EXAMPLE 17** Specifying a Local Web Proxy

```
smpatch set patchpro.proxy.host=webaccess.corp.net.com \
patchpro.proxy.port=8080
```

Specifies the host name, `webaccess.corp.net.com`, and port, `8080`, of the local web proxy.

**EXAMPLE 18** Resetting a Configuration Parameter Value

```
smpatch unset patchpro.patch.source
```

Resets the value of the `patchpro.patch.source` parameter to its default value, which is the URL that points to the Sun update server.

**EXAMPLE 19** Updating Your System

```
smpatch update -L
```

Analyzes your local system, determines the appropriate updates, downloads those updates to the download directory, and applies those updates.

**EXAMPLE 20** Adding an Update to a BE

The following command adds a specific update to the BE `altboot`.

```
smpatch add -b altboot 111111-01
```

Following successful completion of this command, you can then boot from `altboot`.

**EXAMPLE 21** Updating a BE

The following command performs an update on the BE `altboot`.

```
smpatch update -b altboot
```

This command performs all of the usual analysis and dependency checking that occurs with any update command. Following successful completion of this command, you can then boot from `altboot`.

**EXAMPLE 22** Obtaining smpatch Version Number

The following command returns the version number for an `smpatch` subcommand.

EXAMPLE 22 Obtaining smpatch Version Number (Continued)

```
smpatch update -V
1.0.9
```

**Environment Variables** See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smpatch` command. The default value of this variable is `/usr/java`. See the `smc(1M)` man page.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See the `attributes(5)` man page for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|

*Sun Update Manager 1.0 Administration Guide*

**Name** smprofile – manage profiles in the prof\_attr and exec\_attr databases

**Synopsis** /usr/sadm/bin/smprofile *subcommand* [ *auth\_args* ] - -  
[*subcommand\_args*]

**Description** The smprofile command manages one or more profiles in the prof\_attr(4) or exec\_attr(4) databases in the local /etc files name service or a NIS or NIS+ name service.

*subcommands* smprofile *subcommands* are:

- add** Adds a new profile (right) to the prof\_attr(4) database. To add a profile, the administrator must have the solaris.profmgr.write authorization.
- delete** Deletes a profile from the prof\_attr(4) database, deletes all associated entries from the exec\_attr(4) database, and deletes the assigned profile from the user\_attr(4) database. To delete a profile, the administrator must have the solaris.profmgr.execattr.write and solaris.profmgr.write authorization.
- list** Lists one or more profiles from the prof\_attr(4) or exec\_attr(4) databases. To list a profile, the administrator must have the solaris.profmgr.read authorization.
- modify** Modifies a profile in the prof\_attr(4) database. To modify a profile, the administrator must have the solaris.profmgr.write authorization.

**Options** The smprofile authentication arguments, *auth\_args*, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The smprofile command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.

-D | - --domain *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is nis, nisplus, dns, ldap, or file; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (*Note:* Do not use nis+ for nisplus.)

|                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                            | If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.                                                                                                                                                                                        |
| <code>-H   - --hostname <i>l3;host_name:port</i></code>    | Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <code>smc(1M) -B</code> option, or set your console preferences to load a “home toolbox” by default. |
| <code>-l   - --rolepassword <i>l3;role_password</i></code> | Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                             |
| <code>-p   - --password <i>l3;password</i></code>          | Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.                                                                                                                                                                                                                                                   |
| <code>-r   - --rolename <i>l3;role_name</i></code>         | Specifies a role name for authentication. If you do not specify this option, no role is assumed.                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>-u   - --username <i>l3;user_name</i></code>         | Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.                                                                                                                                                                                                                                                                                                                                                       |
| <code>- -</code>                                           | This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the <code>- -</code> option.                                                                                                                                                                                                                                                                                                                             |

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add privileges to or modify privileges in a profile entry, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).

- For subcommand `add`:

- a *addauth1* -a *addauth2* ... (Optional) Specifies the authorization name(s) to add to the new profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding “grant” authorization. A “grant” authorization is one in which the lowest component of the authorization name is replaced by the word `grant`. For example, to grant some profile the `solaris.role.write` authorization, the administrator needs that authorization and also the `solaris.role.grant` authorization. For more information on granting authorizations, see [auth\\_attr\(4\)](#).
- d *description* Specifies the description of the new profile.
- h (Optional) Displays the command's usage statement.
- m *html\_help* Specifies the HTML help file name for the new profile. The help file name must be put in the `/usr/lib/help/profiles/locale/C` directory.
- n *name* Specifies the name of the new profile.
- p *addprof1* -p *addprof2* ... (Optional) Specifies the supplementary profile name(s) to add to the new profile.
- I *inherited\_privs* Specifies the inherited privilege name(s) to add to the new [prof\\_attr\(4\)](#) entry.

To add privileges to or modify privileges in a profile entry, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).

- For subcommand `delete`:

- h (Optional) Displays the command's usage statement.
- n *name* Specifies the name of the profile you want to delete.

- For subcommand `list`:

- h (Optional) Displays the command's usage statement.
- l (Optional) Displays the detailed output for each profile in a block of *key:value* pairs, followed by a blank line that delimits

each profile block. Each *key:value* pair is displayed on a separate line. All the attributes associated with a profile from the `prof_attr` and `exec_attr` databases are displayed. If you do not specify this option, only the specified profile name(s) and associated profile description(s) are displayed.

- n *name1* -n *name2* ... (Optional) Specifies the profile(s) that you want to display. If you do not specify a profile name, all profiles are displayed.
- For subcommand `modify`:
  - a *addauth1* -a *addauth2* ... (Optional) Specifies the authorization name(s) to add to the profile. The administrator must currently have been granted each of the specified authorizations and must have the ability to grant each of those authorizations to other users or roles. For more information on granting authorizations, see [auth\\_attr\(4\)](#).
  - d *description* (Optional) Specifies the new description of the profile.
  - h (Optional) Displays the command's usage statement.
  - m *html\_help* (Optional) Specifies the new HTML help file name of the profile. If you change this name, you must accordingly rename the help file name entered in the `/usr/lib/help/profiles/locale/C` directory.
  - n *name* Specifies the name of the profile you want to modify.
  - p *addprof1* -p *addprof2* ... (Optional) Specifies the supplementary profile name(s) to add to the profile. The administrator must have the `solaris.profmgr.assign` authorization to add any profile and the `solaris.profmgr.delegate` authorization to add any profile that has been assigned to the authenticated user.
  - q *delprof1* -q *delprof2* ... (Optional) Specifies the supplementary profile name(s) to delete from the profile. The administrator must have the `solaris.profmgr.assign` authorization to delete any profile and the `solaris.profmgr.delegate` authorization to delete any profile that has been assigned to the authenticated user.
  - r *delauth1* -r *delauth2* ... (Optional) Specifies the authorization name(s) to delete from the profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. For more information about "grant" authorizations, see the -a option description for the `add` subcommand above.

`-I inherited_privs`

Specifies the inherited privilege name(s) to modify in the `prof_attr(4)` entry.

To add privileges to or modify privileges in a profile entry, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

#### Examples EXAMPLE 1 Creating a new profile

The following creates a new User Manager profile on the local file system. The new profile description is Manage users and groups, and the authorizations assigned are `solaris.admin.usermgr.write` and `solaris.admin.usermgr.read`. The supplementary profile assigned is Operator. The help file name is `RtUserMgmt.html`.

```
./smprofile add -H myhost -p mypasswd -u root -- -n "User Manager" \
-d "Manage users and groups" -a solaris.admin.usermgr.write \
-a solaris.admin.usermgr.read -p Operator -m RtUserMgmt.html
```

#### EXAMPLE 2 Deleting a profile

The following deletes the User Manager profile from the local file system:

```
./smprofile delete -H myhost -p mypasswd -u root -- -n "User Manager"
```

#### EXAMPLE 3 Listing all profiles

The following lists all profiles and their associated profile descriptions on the local file system.

```
./smprofile list -H myhost -p mypasswd -u root --
```

#### EXAMPLE 4 Modifying a profile

The following modifies the User Manager profile on the local file system. The new profile description is Manage world, the new authorization assignment is `solaris.admin.usermgr.*` authorizations, and the new supplementary profile assignment is All. (The `-a` option argument must be enclosed in double quotes when the wildcard character (\*) is used.)

```
./smprofile modify -H myhost -p mypasswd -u root -- -n "User Manager" \
-d "Manage world" -a "solaris.admin.usermgr.*" -p All
```

**Environment Variables** See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smprofile` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smprofile` command:

`/etc/security/exec_attr` Rights profiles database. See [exec\\_attr\(4\)](#).

`/etc/security/prof_attr` Profile description database. See [prof\\_attr\(4\)](#).

`/etc/user_attr` Extended user attribute database. See [user\\_attr\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWmga         |

|                     |          |
|---------------------|----------|
| Interface Stability | Evolving |
|---------------------|----------|

**See Also** [smc\(1M\)](#), [auth\\_attr\(4\)](#), [exec\\_attr\(4\)](#), [prof\\_attr\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smreg – register objects for the Sun Web Console

**Synopsis** /usr/sbin/smreg [-h | --help] *subcommand options*

**Description** The smreg utility is a Command Line Interface (CLI) -based registration mechanism to manage the information in the console's registration databases. smreg adds management web applications, libraries, and configuration information to registration databases. It also validates an application's deployment descriptor to make sure it has certain required tags that enable the application to run in the console.

smreg has four subcommands: add, remove, check, and list.

**Subcommands** The following subcommands are supported:

add

Registers objects of a specified type. If the object is already registered, any new registration will replace the previous registration. The application registration descriptor `app.xml` is verified to ensure that meets some initial requirements.

The format of the add subcommand is:

add -a [-x *context*] *path*

add -d *path*

add -l [-L] [-n *lib\_name*] -s ALL | *app\_name path*

add -m -b *behavior* [-s *service*] -o *name=value ... module*

add -p [-c | -e] *name=value ...*

add -h

remove

Unregisters named objects.

The format of the remove subcommand is:

remove -a *app\_name* | *context*

remove -n *app\_name* | -d *path*

remove -l -s ALL | *app\_name lib\_name*

remove -m [-s *service*] *module*

remove -p [-c | -e] *name ...*

remove -h

check

Check an application.

The check subcommand parses the application's `web.xml` file to make sure that it has the *filter* and *filter-mapping* tags. The console requires these tags to run an application.

The required tags are as follows:

```
<filter>
 <filter-name>SessionManagerFilter</filter-name>
 <filter-class>
 com.sun.management.services.session.AppSessionManagerFilter
 </filter-class>
 <init-param>
 <param-name>ignore-paths</param-name>
 <param-value>
 images/*
 </param-value>
 </init-param>
</filter>
<filter-mapping>
 <filter-name>SessionManagerFilter</filter-name>
 <url-pattern>*/</url-pattern>
</filter-mapping>
```

Elements in the `web.xml` file must appear in a fixed order. For example, the *filter* tag must appear in the `web.xml` file before the *filter-mapping* tag. For more information, see the *Java Servlet Specifications 2.3*.

The `smreg check` subcommand parses the application's `web.xml` file, checking for the existence of these tags and for the correct tag content. That is, the embedded *filter-name* tag content must be `SessionManagerFilter`, and the *filter-class* tag content must be:

```
com.sun.management.services.session.AppSessionManagerFilter
```

If the tag content is not correct, the application will not be registered.

If the tags are not included in the application's `web.xml` file, the script prints to standard output a corrected version the `web.xml` file, with the tags embedded in the correct location. Because multiple *filter* tags are allowed in a file, `smreg` also includes the new tags as the first in a series.

The format for the check subcommand is:

```
check [-d] path
```

```
check -h
```

The `-d` is used strictly to maintain interface compatibility with 1.0-based application packages, and is otherwise ignored.

`list`

Prints list of registered objects.

The format of the list subcommand is:

```
list [-a | -l | -m | -p]
```

If no options are specified, then all registered objects are listed.

**Options** The following options are supported:

**-a | --application**

Object type is an application.

See *app\_name* under ARGUMENTS for more information on the name by which an application is registered.

**-b *behavior* | --behavior *behavior***

A flag value that controls behavior as authentication proceeds down the login module stack. See *behavior* under ARGUMENTS for more information on values allowed.

**-c *name=value ...* | --configuration *name=value ...***

When used with **-p**, this option specifies that the property arguments are server configuration properties. The *name=value* pairs are written to a datastore, to be read during the next server startup. Any property name can be created, but only those recognized by the server will have any effect.

**-d *path* | --directory *path***

This option is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

When used with the “add” subcommand, it has the same effect as “-a”.

When used with the “remove” subcommand, *path* is the path to the original installation location of the application. This path will be mapped to the registered *app\_name* so that the application can be unregistered using “smreg remove -a *app\_name*”. When used with the “check” subcommand, **-d** is ignored. The **-d** option is preserved strictly to maintain 1.0 interface compatibility.

**-e *name=value ...* | --environment *name=value ...***

When used with **-p**, this option specifies that the property arguments are server environment properties. The *name=value* pairs are placed into the server's environment during the next server startup. Any environment name can be created, and is available for use by any application.

**-h | -? | --help**

Displays command and subcommand usage information.

**-l | --library**

Object type is a library JAR file.

Library JAR files that are not installed in the same location as the application, or are not registered at the same time as the application (for example, localization JAR files), can be registered separately by using this option. See *lib\_name* under ARGUMENTS for more information on the name by which a library is registered.

A library can be registered with global scope so that it can be used by all applications, by specifying the `-s ALL` option. A library can be registered so that it may only be used by a specific application, by specifying the `-s app_name` option. If a library must be shared by more than one application but not globally, then a separate registration is required for each instance in which the library is to be shared.

`-L | --link`

Specifies to register the library JAR as a symbolic link rather than as a file copy. This option is ignored on operating systems which do not support symbolic links.

`-m | --module`

Object type is a login module.

`-n [app_name | lib_name] | --name [app_name | lib_name]`

When used with the “add -l” subcommand, specifies the name by which an application or library is known to the registration service.

When used with the “remove” subcommand, specifies the name by which an application is known to the registry service. “remove -n” is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

See *app\_name* under ARGUMENTS for more information on the name by which an application is registered.

See *lib\_name* under ARGUMENTS for more information on the name by which a library is registered.

`-o name=value ... | --option name=value ...`

Options specific to the login module implementation. The options are specified as *name=value* pairs, each preceded by the `-o` option. Values containing more than one word must be enclosed in double quotes (“”).

`-p | --properties`

Object type is properties. This option is specified for use with either `-c` (for configuration properties) or `-e` (for environment properties). If neither `-c` nor `-e` are specified, then `-c` is assumed.

See the PROPERTIES section for information on specific configuration properties that are useful to a system administrator.

`-s [ALL | app_name] | --scope [ALL | app_name]`

When used with `-l`, specifies the sharing scope for the library being registered. A scope of ALL makes the library available to all applications. A scope of *app\_name* makes the library available only to the application already registered as *app\_name*. See *app\_name* under ARGUMENTS for more information on the name by which an application is registered.

`-s service | --scope service`

When used with `-m`, specifies the login service scope for the module. If not specified, the default is ConsoleLogin, which is the web console's browser login service.

`-V | --version`

Display console version information.

`-x context | --context context`

The deployment context path for an application. This option is to be used to register applications built with the SDK version 2.1 or greater. If not provided and the application is unpacked, the context is the parent directory of the application's WEB-INF directory. This option is ignored when registering applications built with an SDK version prior to 2.1.

**Arguments** The subcommand arguments are:

<i>app_name</i>	The unique name of the registered application in the format of <i>pluginName_version</i> , where <i>pluginName</i> and <i>version</i> are tags extracted from the application's registration descriptor, <code>app.xml</code> . All subsequent references to the registered application must then be made by using this registered name.
<i>path</i>	When used with the “add -a”, “add -d”, or “remove -d” subcommands, the full directory path where the application has been installed.  When used with the check subcommand, if it is a directory then it is the full directory path where the application has been installed. If it is a file, then it is the path to a web.xml-compliant file.  When used with the “add -l” subcommand, the full path where the library JAR file is installed.
<i>behavior</i>	Specifies the authentication behavior. The possible values are: <code>required</code> , <code>requisite</code> , <code>sufficient</code> , or <code>optional</code> .
<i>lib_name</i>	The name by which a library JAR file is known to the registration service. By default, libraries will be registered using the basename of the path to the library. This default value can be overridden by using the <code>-n lib_name</code> option to register the object by using a globally unique name.
<i>module</i>	The fully-qualified class name of the module. For example: <code>com.sun.management.services.authentication.MyLoginModule</code>

**Properties** While the list of configuration properties is unlimited, certain properties that may be useful to a system administrator are mentioned here:

`session.timeout.value`

This is the time interval of no user activity after which the user will be prompted to log in again to continue. The default session timeout is 15 minutes. Setting the value to `-1` means there is no timeout. To set the session timeout to 5 minutes, run the following command:

```
smreg add -p -c session.timeout.value=5
```

### debug.trace.path

This is the directory where log files are created. The default is `/var/log/webconsole`. To set the directory to `/tmp/logs`, run the following command:

```
smreg add -p -c debug.trace.path=/tmp/logs
```

### java.home

This is the path to the Java Development Kit (JDK) that will be used to run the web server. The default is `/usr/j2se` on Solaris and `/usr/java/j2sdk1.4.2` on Linux. To set the path to `/usr/jdk142`, run the following command:

```
smreg add -p -c java.home=/usr/jdk142
```

### java.options

This contains the options for configuring the Java Virtual machine (JVM). The defaults are “`-server -XX:+BackgroundCompilation`”. To include setting the initial Java heap size to 64MB, run the following command:

```
smreg add -p -c java.options="-Xms64 \
-server -XX:+BackgroundCompilation"
```

## Examples EXAMPLE 1 Registering an unpacked Application

The following command registers an application which has been installed unpacked in `/opt/myCompany/myApp`:

```
smreg add -a /opt/myCompany/myApp
```

## EXAMPLE 2 Unregistering an Application

The following command unregisters an application previous registered with an *app\_name* of `com.myCompany.myApp_1.2`:

```
smreg remove -a com.myCompany.myApp_1.2
```

## EXAMPLE 3 Registering a Library JAR File with Global Scope

The following command registers `myLibrary.jar`, installed in `/opt/myCompany/MyApp`, as `com_myCompany_myLibrary.jar` for use by all applications:

```
smreg add -l -n com_myCompany_myLibrary.jar \
-s ALL /opt/myCompany/MyApp/myLibrary.jar
```

## EXAMPLE 4 Registering a Library JAR file with a Specific Application Scope

The following command registers `Utilities.jar`, installed in `/opt/SomeCompany/lib`, with the application already registered as `com.myCompany.myApp_1.2`:

```
smreg add -l -s com.myCompany.myApp_1.2 \
/opt/SomeCompany/lib/Utilities.jar
```

**EXAMPLE 5** Unregister a Library JAR File from Global Scope

The following command unregisters `com_myCompany_myLibrary.jar` from global scope so that it is not available to applications:

```
smreg remove -l -s ALL com_myCompany_myLibrary.jar
```

**EXAMPLE 6** Unregister a Library JAR File from a Specific Application Scope

The following command unregisters `Utilities.jar` so that it is not available to the registered application `com.myCompany.myApp_1.2`:

```
smreg remove -l -s com.myCompany.myApp_1.2 Utilities.jar
```

**EXAMPLE 7** Checking that Application's Deployment Descriptor Meets Sun Web Console Guidelines

Either of the following commands to check to see if the deployment descriptor located at `/opt/myCompany/myApp/WEB-INF/lib/web.xml` meets the Sun Web Console guideline:

```
smreg check /opt/myCompany/myApp
smreg check /opt/myCompany/myApp/WEB-INF/lib/web.xml
```

**EXAMPLE 8** Registering an Environment Property

The following command registers the environment property name `GREETING` with value "Hello World" and the name `FOO` with the value "bar" so that they appear in the server's environment and are available to any application:

```
smreg add -p -e GREETING="Hello World" FOO=bar
```

**EXAMPLE 9** Unregistering an Environment Property

The following command unregisters the environment property names `GREETING` and `FOO` so that they no longer appear in the server's environment and are not available to any application:

```
smreg remove -p -e GREETING FOO
```

**EXAMPLE 10** Registering a Login Module

The following command registers the module class `com.sun.management.services.authentication.myLoginModule` with "requisite" behavior and a `commandPath` argument:

```
smreg add -m -b requisite \
-o commandPath="/usr/lib/webconsole" \
com.sun.management.services.authentication.myLoginModule
```

**EXAMPLE 11** Unregistering a Login Module

The following command unregisters the module class `com.sun.management.services.authentication.myLoginModule`:

```
smreg remove -m com.sun.management.services.authentication.myLoginModule
```

**EXAMPLE 12** Print a List of All Registered Applications

```
smreg list -a
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Usage error: missing or malformed arguments.
- 2 An error occurred that prevents registration - either a console configuration problem, or badly-formatted `web.xml` or `app.xml`.
- 3 Unable to determine OS for this machine.
- 4 Detected OS for this machine is not supported.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcon
Interface Stability	Obsolete

**See Also** [smcwebserver\(1M\)](#), [attributes\(5\)](#)

**Name** smrole – manage roles and users in role accounts

**Synopsis** /usr/sadm/bin/smrole *subcommand* [ *auth\_args*] - -  
[*subcommand\_args*]

**Description** The smrole command manages roles and adds or deletes users in role accounts.

*subcommands* smrole *subcommands* are:

- add** Adds a new role entry. To add an entry, the administrator must have the `solaris.role.write` authorization.
- delete** Deletes one or more roles. To delete an entry, the administrator must have the `solaris.role.write` authorization.
- list** Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.
- modify** Adds or deletes users from a role account. To modify an entry, the administrator must have the `solaris.role.write` authorization.

**Options** The smrole authentication arguments, *auth\_args*, are derived from the [smc\(1M\)](#) arg set and are the same regardless of which subcommand you use. The smrole command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must come after the *auth\_args* and must be separated from them by the - - option.

*auth\_args* The *auth\_args* are -D, -H, -l, -p, -r, and -u are described below. They are all optional. These options are a subset of the full complement of supported options described in [smc\(1M\)](#).

If no *auth\_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.

-D | - --domain *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host\_name/domain\_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host\_name* is the name of the machine that serves the domain; and *domain\_name* is the name of the domain you want to manage. (*Note: Do not use nis+ for nisplus.*)

	If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
-H   - --hostname <i>13;host_name:port</i>	Specifies the <i>host_name</i> and <i>port</i> to which you want to connect. If you do not specify a <i>port</i> , the system connects to the default port, 898. If you do not specify <i>host_name:port</i> , the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the <a href="#">smc(1M)</a> -B option, or set your console preferences to load a “home toolbox” by default.
-l   - --rolepassword <i>13;role_password</i>	Specifies the password for the <i>role_name</i> . If you specify a <i>role_name</i> but do not specify a <i>role_password</i> , the system prompts you to supply a <i>role_password</i> . Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
-p   - --password <i>13;password</i>	Specifies the password for the <i>user_name</i> . If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
-r   - --rolename <i>13;role_name</i>	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
-u   - --username <i>13;user_name</i>	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- -	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - - option.

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).

■ For subcommand add:

- `-a adduser1 -a adduser2 ...`
(Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization.
- `-c comment`
(Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).
- `-d dir`
(Optional) Specifies the home directory of the new role, limited to 1024 characters.
- `-F full_name`
(Optional) Specifies the full, descriptive name of the role. The *full\_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
- `-G group1 -G group2 ...`
(Optional) Specifies the new role's supplementary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).
- `-h`
(Optional) Displays the command's usage statement.
- `-n rolename`
Specifies the name of the role you want to create.
- `-p addprof1 -p addprof2 ...`
(Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
- `-P password`
(Optional) Specifies the role's password. The *password* can contain up to eight characters. If you do not specify a password, the system prompts you for one. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password using the `-P` option, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. However, if you do not specify a password (and the system prompts you for one), the echo is turned off when you type in the password.

- 
- s *shell* (Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcsh` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
- u *uid* (Optional) Specifies the ID of the role you want to add. If you do not specify this option, the system assigns the next available unique ID greater than 100.
- x *autohome=Y|N* (Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/login name`.
- x *perm=home\_perm* (Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is `0775`.
- x *serv=homedir\_server* (Optional) If -D is `nis`, `nisplus`, or `ldap`, use this option to specify the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.
- M *limit\_privs* Specifies the privilege name(s) to add to the new `user_attr(4)` entry. The default is `all` for *limit* privilege.
- To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
- D *default\_privs* Specifies the default privilege name(s) to add to the new `user_attr(4)` entry.

The options to the `add` subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

- x *clear=clearanceval* (Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default, `admin_high`, is in effect. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- x *label=labelval* (Optional) Specifies the role's minimum label. *labelval* can be a string label or a

- 
- hex label. If this option is not specified, the default, `admin_low`, is in effect. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- `-x labelview=HIDE|SHOW` (Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is specified, `labelview=*shows1` will be recorded. If `HIDE` is specified, `labelview=*hides1` will be recorded. The asterisk portion can be replaced by “`internal`,” “`external`,” or “”(null). If this option is not specified, the default, `SHOW`, is in effect.
- `-x view=INTERNAL|EXTERNAL|DEFAULT` (Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default, `INTERNAL`, is in effect.
- For subcommand `delete`:
    - `-h` (Optional) Displays the command's usage statement.
    - `-n rolename1 -n rolename2...` Specifies the name of the role(s) you want to delete.
  - For subcommand `list`:
    - `-h` (Optional) Displays the command's usage statement.
    - `-l` (Optional) Displays the output for each user in a block of *key:value* pairs (for example, `user name: root`), followed by a blank line that delimits each user block. Each *key:value* pair is displayed on a separate line. The keys are: `autohome setup`, `comment`, `home directory`, `login shell`, `primary group`, `secondary groups`, `server`, `user ID (UID)`, and `user name`.
    - `-n role1 -n role2...` (Optional) Specifies the role(s) that you want to list. If you do not specify a role name, all roles are listed.
  - For subcommand `modify`:

- `-a adduser1 -a adduser2 ...` (Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization, or must have the `solaris.role.delegate` authorization and be a member of the role being modified.
- `-c comment` (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (:).
- `-d dir` (Optional) Specifies the home directory of the new role, limited to 1024 characters.
- `-F full_name` (Optional) Specifies the full, descriptive name of the role. The *full\_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full\_name* in double quotes.
- `-G group1 -G group2 ...` (Optional) Specifies the new role's secondary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).
- `-h` (Optional) Displays the command's usage statement.
- `-n rolename` Specifies the name of the role you want to modify.
- `-N new_rolename` (Optional) Specifies the new name of the role.
- `-p addprof1 -p addprof2 ...` (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
- `-P password` (Optional) Specifies the role's password. The *password* can contain up to eight characters. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
- `-q delprof1 -q delprof2 ...` (Optional) Specifies the profile(s) to delete from the role.
- `-r deluser1 -r deluser2 ...` (Optional) Specifies the user name(s) to delete from the role.

- `-s shell` (Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfsh` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
- `-x autohome=Y|N` (Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/login_name`.
- `-x perm=home_perm` (Optional) Sets the permissions on the role's home directory. `perm` is interpreted as an octal number, and the default is `0775`.
- `-M limit_privs` Specifies the privilege name(s) to modify in a `user_attr(4)` entry.
- To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
- `-D default_privs` Specifies the default privilege name(s) to modify in a `user_attr(4)` entry.

The options to the `modify` subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

- `-x clear=clearanceval` (Optional) Specifies the role's clearance. `clearanceval` can be a string value or a hex value. If this option is not specified, the default, `admin_high`, is in effect. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- `-x label=labelval` (Optional) Specifies the role's minimum label. `labelval` can be a string label or a hex label. If this option is not specified, the default, `admin_low`, is in effect. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- `-x labelview=HIDE|SHOW` (Optional) Specifies the second part of the `labelview key-value` pair. If `SHOW` is

specified, `labelview=*shows1` will be recorded. If `HIDE` is specified, `labelview=*hides1` will be recorded. The asterisk portion can be replaced by “internal,” “external,” or “”(null). If this option is not specified, the default, `SHOW`, is in effect.

`-x view=INTERNAL|EXTERNAL|DEFAULT`

(Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default, `INTERNAL`, is in effect.

Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B toolbox` option to specify a toolbox that contains support for Trusted Extensions. For example:

```
smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -x clear=clearanceval \
-B http://<server>/toolboxes/tso1_files.tbx
```

In the command above, `<server>` is the name of the machine running the Solaris Management Console. See [smc\(1M\)](#) for a description of the `-B` option.

### Examples EXAMPLE 1 Creating a Role Account

The following creates the `role1` account with a full name of `Engineering Admin` and a password of `abc123` on the local file system, and assigns `user1` and `user2` to the role. This role has Name Service Security and Audit Review rights. The system assigns the next available unique UID greater than 100.

```
./smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -a user1 -a user2 \
-p "Name Service Security" -p "Audit Review"
```

### EXAMPLE 2 Deleting Role Accounts

The following deletes the `role1` and `role2` accounts from the local file system.

```
./smrole delete -H myhost -p mypasswd -u root -- -n role1 -n role2
```

**EXAMPLE 3** Listing Role Accounts

The following lists all role accounts on the local file system in summary form.

```
./smrole list -H myhost -p mypasswd -u root --
```

**EXAMPLE 4** Modifying a Role Account

The following modifies the `role1` account so the role defaults to the Korn shell, includes the `user3` account, and does not include the `user2` account.

```
./smrole modify -H myhost -p mypasswd -u root -- -n role1 \
-s /bin/pfksh -a user3 -r user2
```

**Environment Variables** See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smrole` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smrole` command:

<code>/etc/aliases</code>	Mail aliases. See <a href="#">aliases(4)</a> .
<code>/etc/auto_home</code>	Automatic mount points. See <a href="#">automount(1M)</a> .
<code>/etc/group</code>	Group file. See <a href="#">group(4)</a> .
<code>/etc/passwd</code>	Password file. See <a href="#">passwd(4)</a> .
<code>/etc/security/policy.conf</code>	Configuration file for security policy. See <a href="#">policy.conf(4)</a> .
<code>/etc/shadow</code>	Shadow password file. See <a href="#">shadow(4)</a> .
<code>/etc/user_attr</code>	Extended user attribute database. See <a href="#">user_attr(4)</a> .

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga
Interface Stability	Evolving

**See Also** [automount\(1M\)](#), [smc\(1M\)](#), [aliases\(4\)](#), [group\(4\)](#), [passwd\(4\)](#), [policy.conf\(4\)](#), [shadow\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** smrsh – restricted shell for sendmail

**Synopsis** smrsh -c *command*

**Description** The smrsh program is intended as a replacement for the sh command in the prog mailer in [sendmail\(1M\)](#) configuration files. The smrsh program sharply limits commands that can be run using the |program syntax of sendmail. This improves overall system security. smrsh limits the set of programs that a programmer can execute, even if sendmail runs a program without going through an alias or forward file.

Briefly, smrsh limits programs to be in the directory /var/adm/sm.bin, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters: ,, <, >, |, ;, &, \$, \r (RETURN), or \n (NEWLINE) on the command line to prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to /usr/ucb/vacation, /usr/bin/vacation, /home/server/mydir/bin/vacation, and vacation all actually forward to /var/adm/sm.bin/vacation.

System administrators should be conservative about populating /var/adm/sm.bin. Reasonable additions are utilities such as [vacation\(1\)](#) and [procmail](#). Never include any shell or shell-like program (for example, perl) in the sm.bin directory. This does not restrict the use of shell or perl scrips in the sm.bin directory (using the #! syntax); it simply disallows the execution of arbitrary programs.

**Options** The following options are supported:

-c *command*     Where *command* is a valid command, executes *command*.

**Files** /var/adm/sm.bin     directory for restricted programs

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr, SUNWcsu

**See Also** [sendmail\(1M\)](#), [attributes\(5\)](#)

---

<b>Name</b>	smserialport – manage serial port						
<b>Synopsis</b>	<code>/usr/sadm/bin/smserialport <i>subcommand</i> [<i>auth_args</i>] -- [<i>subcommand_args</i>]</code>						
<b>Description</b>	The <code>smserialport</code> command manages serial ports.						
<b>Sub-commands</b>	The following <code>smserialport</code> sub-commands ( <i>subcommand</i> ) are supported: <ul style="list-style-type: none"> <li><code>configure</code>      Configures a serial port's basic settings for a device such as a terminal, modem or no connection.</li> <li><code>delete</code>            Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.</li> <li><code>list</code>                Lists all serial ports.</li> <li><code>modify</code>            Modifies a serial port's parameters.</li> </ul>						
<b>Options</b>	There are two kinds of options: authentication arguments ( <i>args</i> ) and sub-command arguments ( <i>subcommand_args</i> ).						
<b>Authentication Arguments</b>	<p>The <code>smserialport</code> authentication arguments, <i>args</i>, are derived from the <code>smc(1M)</code> argument set and are the same regardless of which sub-command you use.</p> <p>Valid <i>args</i> are <code>-D</code>, <code>-H</code>, <code>-l</code>, <code>-p</code>, <code>-r</code>, and <code>-u</code>; they are all optional. If no <i>args</i> are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes.</p> <p>The single letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either <code>-D</code> or <code>--domain</code>.</p> <p>Descriptions and other arg options that contain white spaces must be enclosed in double quotes.</p> <p>The following authentication arguments (<i>args</i>) are supported:</p> <table style="width: 100%; border: none;"> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-D   --domain <i>domain</i></code></td> <td>Specifies the default domain that you want to manage. <code>smserialport</code> accepts only the <i>file</i> value for this option. <i>file</i> is also the default value.</td> </tr> <tr> <td colspan="2" style="padding-top: 10px;">The <i>file</i> default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the <i>domain</i> for all other tools.</td> </tr> <tr> <td style="vertical-align: top; padding-right: 20px;"><code>-H   --hostname <i>host_name:port</i></code></td> <td>Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify</td> </tr> </table>	<code>-D   --domain <i>domain</i></code>	Specifies the default domain that you want to manage. <code>smserialport</code> accepts only the <i>file</i> value for this option. <i>file</i> is also the default value.	The <i>file</i> default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the <i>domain</i> for all other tools.		<code>-H   --hostname <i>host_name:port</i></code>	Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify
<code>-D   --domain <i>domain</i></code>	Specifies the default domain that you want to manage. <code>smserialport</code> accepts only the <i>file</i> value for this option. <i>file</i> is also the default value.						
The <i>file</i> default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the <i>domain</i> for all other tools.							
<code>-H   --hostname <i>host_name:port</i></code>	Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, 898. If you do not specify						

a host (*host\_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc -B` option, or set your console preferences to load a home toolbox by default.

- l | --rolepassword *role\_password* Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p | --password *password* Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Because passwords specified on the command line can be seen by any user on the system, this option is considered insecure.
- r | --rolename *role\_name* Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u | --username *user\_name* Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

Sub-command Arguments The sub-command specific options, *subcommand\_args*, must come after the *args* and must be separated from them by the -- option. Enclose descriptions and *arg* options that contain white space in double quotes.

`configure` The `configure` sub-command requires the following sub-command argument:

-n *port\_name* Specifies the name of the serial port to reconfigure.

The following sub-command arguments are optional for the `configure` sub-command:

-b *baudrate* Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and auto. The default is 9600.

---

	-c <i>comment</i>	Specifies a short comment description of the service. The default is a description of the requested device type.
	-h	Displays the command's usage statement.
	-l <i>login_prompt</i>	Specifies the login prompt. The default is <i>tty'port_name' login:.</i>
	-t <i>terminal_type</i>	Specifies the terminal type. The default is <i>vti925</i> .
	-x <i>device=device_name</i>	Specifies the device to be configured. Valid <i>device_names</i> are: <i>terminal</i> , <i>modemdialin</i> , <i>modemdialout</i> , <i>modemdialinout</i> or <i>initializeonly</i> for no connection. The default is <i>terminal</i> .
	-x <i>service=y   n</i>	Specifies the status of service, that is <i>y</i> for enabled or <i>n</i> for disabled. The default is <i>y</i> .
delete	The delete sub-command requires the following sub-command arguments:	
	-n <i>port_name</i>	Specifies the name of the serial port to be disabled.
	The following sub-command arguments are optional for the delete sub-command:	
	-h	Displays the command's usage statement.
list	The list sub-command does not require any sub-command arguments.	
	The following sub-command arguments are optional for the list sub-command:	
	-h	Displays the command's usage statement.
	-v	Displays the data in verbose format.
modify	The modify sub-command requires the following sub-command arguments:	
	-n <i>port_name</i>	Specifies the name of the serial port to modify.
	The following sub-command arguments are optional for the modify sub-command:	
	-b <i>baudrate</i>	Specifies the port baud rate. The supported baud rate are 38400, 19200, 9600, 4800, 2400, 1200, 300 and auto.
	-c <i>comment</i>	A short comment description of the service.
	-h	Displays the command usage statement.

- l *login\_prompt* Specifies the login prompt.
- t *terminal\_type* Specifies the terminal type.
- x *bidirectional=y | n* Specifies the bi-directional port flag, *y* for set or *n* for not set. When this flag is set, the line can be used in both directions.
- x *connect\_on\_carrier=y | n* Specifies if to connect on carrier, that is *y* or *n*.
- x *initialize\_only=y | n* Specifies if the service invocation. If *y* the service is invoked only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.
- x *service\_program=command* Specifies the full pathname of the service command to invoke when a connection request is received.
- x *service\_status=y | n* Specifies the status of service, that is *y* for enabled or *n* for disabled.
- x *software\_carrier=y | n* Specifies the carrier detection. *y* for software or *n* for hardware.
- x *timeout=timeout* Specifies the time to close a port if the open on the port succeeds, and no input data is received in *timeout* seconds. The supported *timeout* are never, 30, 60 and 90.

**Examples** EXAMPLE 1 Listing Serial Ports

The following example lists the serial ports:

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	9600	tvi925	ttyb login:	

EXAMPLE 2 Modifying Serial Ports

The following example contains two commands. The first command modifies serial port *b* for a baud rate of 4800, an *xterm* as terminal type, a *b*: for login prompt and a comment. The second command lists the ports.

```
example% ./smserialport modify -H myhost -u root -p mypassword -- \
-n b -b 4800 -t xterm -l b: -c "modified port b"
```

**EXAMPLE 2** Modifying Serial Ports (Continued)

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	4800	xterm	b:	modified port b

**EXAMPLE 3** Deleting a Serial Port

The following example contains two commands. The first command deletes serial port b. The second command lists the ports.

```
example% ./smserialport delete -H myhost -u root \
-p mypassword -- -n b
```

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	disabled	9600	tvi925	ttyb login:	

**EXAMPLE 4** Configuring a Serial Port

The following example contains two commands. The first command configures serial port b for a bi-directional modem. The second command lists the ports.

```
example% ./smserialport configure -H myhost -u root \
-p mypassword -- -n b -x device=modemdialinout
```

```
example% ./smserialport list -H myhost -u root -p mypassword --
```

Port	Service	Baud-Rate	Terminal-Type	Prompt	Comment
a	enabled	9600	xterm	as	welcome
b	enabled	9600	tvi925	ttyb login:	Modem - Dial In and Out

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `smserialport`: `JAVA_HOME`. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

**See Also** [tip\(1\)](#), [pmadm\(1M\)](#), [sacadm\(1M\)](#), [smc\(1M\)](#), [ttyadm\(1M\)](#), [ttymon\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#)

---

<b>Name</b>	smtnrhdb – manage entries in the tnrhdb database
<b>Synopsis</b>	<code>/usr/sadm/bin/smtnrhdb subcommand [auth_args] -- subcommand_args]</code>
<b>Description</b>	<p>The smt nrhdb command adds, modifies, deletes, and lists entries in the tnrhdb database.</p> <p>The tnrhdb database specifies which remote-host template to use for each host, including the local host, in the distributed system. If a host's IP address cannot be matched to some entry in the tnrhdb database, communication with the host is not permitted.</p> <p>The smt nrhdb command requires the Solaris Management Console to be initialized for the command to succeed (see <a href="#">smc(1M)</a>). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.</p>
Valid Host Addresses and Wildcards	<p>The trusted network software uses a network “longest prefix of matching bits” mechanism when looking for a host. The software looks first for the IP address of the host. If the software does not find this address, then the software falls back to searching for an IP address with the longest prefix of a matching bit pattern, and so on.</p> <p><b>Note</b> – The actual numeric value of the subnet address or other subnetting information on the system (for example, from the <a href="#">netmasks(4)</a> file) are not considered by this mechanism.</p> <p>Using the “longest prefix of matching bits” mechanism, an IPv4 address of 0.0.0.0 is a wildcard address with a prefix length of 0 and hence matches any IPv4 address. For more information about prefix lengths in IPv4 and IPv6 addresses, see <a href="#">System Administration Guide: IP Services</a>.</p> <p>The smt nrhdb command accepts a hostname, IP address, and wildcard address with an optional prefix as valid addresses. See <i>subcommand_args</i>, below, for the format of valid addresses.</p>
<b>Sub-commands</b>	<p>smt nrhdb <i>subcommands</i> are:</p> <p><b>add</b> Adds a new entry to the tnrhdb database. To add an entry, the administrator must have the <code>solaris.network.host.write</code> and <code>solaris.network.security.write</code> authorizations.</p> <p><b>delete</b> Deletes an entry from the tnrhdb database. To delete an entry, the administrator must have the <code>solaris.network.host.write</code> and <code>solaris.network.security.write</code> authorizations.</p> <p><b>list</b> Lists all entries in the tnrhdb database. To list an entry, the administrator must have the <code>solaris.network.host.read</code> and <code>solaris.network.security.read</code> authorizations.</p> <p><b>modify</b> Modifies an entry in the tnrhdb database. To modify an entry, the administrator must have the <code>solaris.network.host.write</code> and <code>solaris.network.security.write</code> authorizations.</p>

**Options** The `smtnrhdb` authentication arguments, *auth\_args*, are derived from the `smc` arg set. These arguments are the same regardless of which subcommand you use.

The subcommand-specific options, *subcommand\_args*, must be preceded by the `--` option.

*auth\_args* The valid *auth\_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

`-D` | `--domain` *domain*

Specifies the default domain that you want to manage. The syntax of *domain=type:/host\_name/domain\_name*, where *type* is `dns`, `ldap`, or `file`; *host\_name* is the name of the server; and *domain\_name* is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H` | `--hostname` *host\_name:port*

Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898.

`-l` | `--rolepassword` *role\_password*

Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `--password` *password*

Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `--rolename` *role\_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `--username` *user\_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

*subcommand\_args* Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

-h

Displays the command's usage statement.

-H *hostname*

Specifies the name of the host. For the list subcommand, the hostname argument is not specified. This is not required if the ipaddress subcommand argument is specified.

-i *ipaddress*

Specifies the IP address of the host. This is not required if the hostname subcommand argument is specified. This option is not valid with the -w option.

-n *templatename*

Specifies the name of an existing template.

-p *prefixlen*

Specifies the prefix length (in bits) of a wildcard representation of the IP address. The prefix is the left-most portion of the IP address. This option is valid only with the -w option. For example, when the value of -w *ipaddress-wildcard* is 192.168.0.0, a *prefixlen* value of 24 indicates that the wildcard matches all addresses on the 192.168.0 network. With a *prefixlen* of 32, the wildcard 192.168.0.0 matches all addresses on the 192.168.0.0 network.

-w *ipaddress-wildcard*

Specifies the IP address of the subnet using a wildcard.

- One of the following sets of arguments must be specified for subcommand `add`:

```
-H hostname -n templatename |
-i ipaddress -n templatename |
-w ipaddress-wildcard -n templatename [-p prefixlen] |
-h
```

- One of the following sets of arguments must be specified for subcommand `modify`:

```
-H hostname -n templatename |
-i ipaddress -n templatename |
-w ipaddress-wildcard -n templatename [-p prefixlen] |
-h
```

- One of the following sets of arguments must be specified for subcommand `delete`:

```
-H hostname |
-i ipaddress |
-w ipaddress-wildcard [-p prefixlen] |
-h
```

- The subcommand `list` takes the following argument:

```
-h
```

**Examples** EXAMPLE 1 Specifying the Template Name for a Wildcard IP Address

The admin role specifies the template name, `cipso_lan`, for a series of hosts that use the IP address wildcard `192.168.113.0` on the local file system. Since no authorization arguments were specified, the administrator connects to port 898 of the local host on the local server with the file domain type, which are the defaults. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnrhdb add -- -w 192.168.113.0 -n cipso_lan
```

## EXAMPLE 2 Deleting an Entry in the tnrhdb Database

The admin role connects to port 898 (which happens to be the default) of the LDAP server and deletes a host entry from the database by specifying its IP address, `192.168.113.8`. Since the domain was not specified, the file domain type and local server are used by default. The administrator is prompted for the admin password.

```
/usr/sadm/bin/smtnrhdb delete \
-D ldap:/example.domain -i 192.168.113.8
```

## EXAMPLE 3 Adding a Subnet to the tnrhdb Database

The following command adds all the addresses on the `192.168.55.0` subnet, from `192.168.55.1` to `192.168.55.255`, to the `tnrhdb` database:

```
/usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
-- -w 192.168.55.0 -n cipso
Authenticating as user: root
Type ?/ for help, pressing <enter> accepts the default denoted by []
Please enter a string value for: password ::
Loading Tool: com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
was successful.
```

## EXAMPLE 4 Adding Subnet 192.168.0 to the tnrhdb Database

The following command adds all the addresses on the `192.168.0` subnet, from `192.168.0.1` to `192.168.0.255` to the `tnrhdb` database. The prefix, `24`, indicates that the first 24 bits (`192.168.0`) are fixed. Only the final zero is a wildcard.

```
/usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
-- -w 192.168.0.0 -p 24 -n cipso

Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM was successful.
```

**Exit Status** The following exit values are returned:

- 0  
Successful completion.
- 1  
Invalid command syntax. A usage message displays.
- 2  
An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smtnrddb` command:

`/etc/security/tsol/tnrddb`  
Trusted network remote-host database.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmgts
Interface Stability	Committed

**See Also** [smc\(1M\)](#), [netmasks\(4\)](#), [attributes\(5\)](#)

*System Administration Guide: Security Services*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** smtnrhtp – manage entries in the trusted network template database

**Synopsis** /usr/sadm/bin/smtnrhtp *subcommand* [*auth\_args*] -- [*subcommand\_args*]

**Description** The smtnrhtp command adds, modifies, deletes, and lists entries in the tnrhtp database.

smtnrhtp *subcommands* are:

- add** Adds a new entry to the tnrhtp database. To add an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.
- modify** Modifies an entry in the tnrhtp database. To modify an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.
- delete** Deletes an entry from tnrhtp database. To delete an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.
- list** Lists entries in the tnrhtp database. To list an entry, the administrator must have the `solaris.network.security.read` authorizations.

**Options** The smtnrhtp authentication arguments, *auth\_args*, are derived from the smc argument set and are the same regardless of which subcommand you use. The smtnrhtp command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.

The subcommand-specific options, *subcommand\_args*, must be *preceded* by the -- option.

*auth\_args* The valid *auth\_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain.

-D | --domain *domain*

Specifies the default domain that you want to manage. The syntax of *domain=type:/host\_name/domain\_name*, where *type* is dns, ldap, or file; *host\_name* is the name of the server; and *domain\_name* is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

- H | --hostname *host\_name:port*  
 Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898.
- l | --rolepassword *role\_password*  
 Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p | --password *password*  
 Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r | --rolename *role\_name*  
 Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u | --username *user\_name*  
 Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

*subcommand\_args* Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

- h Displays the command's usage statement.
- n *templatename* Specifies the name of the template.
- t *hosttype* Specifies the host type of the new host. Valid values are `unlabeled` and `cipso`. The `cipso` host type is for hosts that use CIPSO (Common IP Security Options - Tag Type 1 only) to label packets.
- x *doi=doi-value* Specifies the DOI value (the domain of interpretation). In the case of the `unlabeled` host type, this is the domain of interpretation for the `def_label`.

The domain of interpretation defines the set of rules for translating between the external or internal representation of the security attributes and their network representation. When systems that are configured with Trusted Extensions software have the same `doi`, they share that set of rules. In the case of the `unlabeled` host type, these systems also share the same

interpretation for the default attributes that are assigned to the unlabeled templates that have that same `doi`.

- x `max=maximum-label` Specifies the maximum label. Together with `min`, this value specifies the label accreditation range for the remote hosts that use this template. Values can be a hex value or string (such as `admin_high`).
- x `min=minimum-label` Specifies the minimum label. Together with `max`, this value specifies the label accreditation range for the remote hosts that use this template. For gateway systems, `min` and `max` define the default range for forwarding labeled packets. The label range for routes is typically set by using a [route\(1M\)](#) subcommand with the `-secattr` option. When the label range for routes is not specified, the `min` to `max` range in the security template is used. Values can be a hex value or string (such as `admin_low`).
- x `label=default-label` Specifies the default label to be applied to incoming data from remote hosts that do not support these attributes. This option does not apply if `hosttype` is `cipso`. Values can be a hex value or string (such as `admin_low`).
- x `s1set=l1,l2,l3,l4` Specifies a set of sensitivity labels. For gateway systems, the labels in `s1set` are used for forwarding labeled packets. `s1set` is optional. You can specify up to four label values, separated by commas. Values can be a hex value or string (such as `admin_low`).

- One of the following sets of arguments must be specified for subcommand `add`:

```
-n template name (
 -t cipso [-x doi=doi-value -x min=minimum-label -x max=maximum-label -x
s1set=l1,l2,l3,l4] |
 -t unlabeled [-x doi=doi-value -x min=minimum-label -x max=maximum-label -x
label=default-label -x s1set=l1,l2,l3,l4] |
 -h
)
```

- One of the following sets of arguments must be specified for subcommand `modify`:

```
-n template name (
 -t cipso [-x doi=doi-value -x min=minimum-label -x max=maximum-label -x
s1set=l1,l2,l3,l4] |
 -t unlabeled [-x doi=doi-value -x min=minimum-label -x max=maximum-label -x
label=default-label -x s1set=l1,l2,l3,l4] |
 -h
)
```

)

If the host type is changed, all options for the new host type must be specified.

- One of the following sets of arguments must be specified for subcommand `delete`:

```
-n templatename |
-h
```

- The following argument can be specified for subcommand `list`:

```
-n templatename |
-h
```

### Examples **EXAMPLE 1** Adding a New Entry to the Network Template Database

The admin role connects to port 898 of the LDAP server and creates the `unlabeled_ntk` entry in the `tnrhttp` database. The new template is assigned a host type of `unlabeled`, a domain of interpretation of 1, minimum label of `public`, maximum label of `restricted`, and a default label of `needtoknow`. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnrhttp \
add -D ldap:directoryname -H servername:898 -- \
-n unlabeled_ntk -t unlabeled -x DOI=1 \
-x min=public -x max=restricted -x label="need to know"
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

**Files** The following files are used by the `smtnrhttp` command:

`/etc/security/tsol/tnrhttp` Trusted network remote-host templates.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmgts
Interface Stability	Committed

**See Also** [smc\(1M\)](#), [attributes\(5\)](#)

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Warnings** Changing a template while the network is up can change the security view of an undetermined number of hosts.

Allowing unlabeled hosts onto a Solaris Trusted Extensions network is a security risk. To avoid compromising the rest of your network, such hosts must be *trusted* in the sense that the administrator is certain that these unlabeled hosts will not be used to compromise the distributed system. These hosts should also be physically protected to restrict access to authorized individuals. If you cannot guarantee that an unlabeled host is physically secure from tampering, it and similar hosts should be isolated on a separate branch of the network.

If the security template is modified while the network is up, the changes do not take effect immediately unless `tnctl(1M)` is used to update the template entries. Otherwise, the changes take effect when next polled by the trusted network daemon, `tnsd(1M)`. Administrators are allowed to add new templates and modify attributes of existing templates while the network is up.

- Name** smtnzoncfg – manage entries in the zone configuration database for Trusted Extensions networking
- Synopsis** `/usr/sadm/bin/smtnzoncfg subcommand [auth_args] -- [subcommand_args]`
- Description** The smtnzoncfg command adds, modifies, deletes, and lists entries in the tnzoncfg database.
- smtnzoncfg *subcommands* are:
- add** Adds a new entry to the tnzoncfg database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.
  - modify** Modifies an entry in the tnzoncfg database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.
  - delete** Deletes an entry from the tnzoncfg database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.
  - list** Lists entries in the tnzoncfg database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.
- Options** The smtnzoncfg authentication arguments, *auth\_args*, are derived from the smc argument set and are the same regardless of which subcommand you use. The smtnzoncfg command requires the Solaris Management Console to be initialized for the command to succeed (see [smc\(1M\)](#)). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.
- The subcommand-specific options, *subcommand\_args*, must be *preceded* by the `--` option.
- auth\_args* The valid *auth\_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth\_args* are specified, certain defaults will be assumed and the user can be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.
- `-D | --domain domain`  
Specifies the default domain that you want to manage. The syntax of `domain=type:/host_name/domain_name`, where *type* is `dns`, `ldap`, or `file`; *host\_name* is the name of the server; and *domain\_name* is the name of the domain you want to manage.
- If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis. This option specifies the domain for all other tools.

- H | --hostname *host\_name:port*  
 Specifies the *host\_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host\_name:port*, the Solaris Management Console connects to the local host on port 898.
- l | --rolepassword *role\_password*  
 Specifies the password for the *role\_name*. If you specify a *role\_name* but do not specify a *role\_password*, the system prompts you to supply a *role\_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- p | --password *password*  
 Specifies the password for the *user\_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
- r | --rolename *role\_name*  
 Specifies a role name for authentication. If you do not specify this option, no role is assumed.
- u | --username *user\_name*  
 Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
- This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

*subcommand\_args* Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

- h  
 Displays the command's usage statement.
- n *zonename*  
 Specifies the zone name for the entry. This name is used when the zone is configured. See [zonecfg\(1M\)](#), under the -z *zonename* option, for the constraints on zone names. The specified zone name must be one of the configured zones on the system. The following command returns a list of configured zones:
- ```
/usr/sbin/zoneadm list -c
```
- l *label*
 Specifies the label for the zone. This field is used to label the zone when the zone is booted. Each zone must have a unique label.
- x *polycymatch=0|1*
 Specifies the policy match level for non-transport traffic. Only values of 0 (match the label) or 1 (be within the label range of the zone) are accepted.

ICMP packets that are received on the global zone IP address are accepted based on the label range of the global zone's security template if the global zone's *polycymatch* field is set to 1. When this field is set to 0 for a zone, the zone will not respond to an ICMP echo request from a host with a different label.

This subcommand argument is optional. If not specified, it will have a default value of 0.

`-x mlpzone=""|port/protocol`

Specifies the multilevel port configuration entry for zone-specific IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP zone values. This subcommand argument is optional.

An MLP is used to provide multilevel service in the global zone as well as in non-global zones. As an example of how a non-global zone can use an MLP, consider setting up two labeled zones, `internal` and `public`. The `internal` zone can access company networks; the `public` zone can access public internet but not the company's internal networks. For safe browsing, when a user in the `internal` zone wants to browse the Internet, the `internal` zone browser forwards the URL to the `public` zone, and the web content is then displayed in a `public` zone web browser. That way, if the download in `public` zone compromises the web browser, it cannot affect the company's internal network. To set this up, TCP port 8080 in the `public` zone is an MLP (8080/tcp), and the security template for the `public` zone has a label range from `PUBLIC` to `INTERNAL`.

`-x mlpshared=""|port/protocol`

Specifies the multilevel port configuration entry for shared IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP shared values. This subcommand argument is optional.

A shared IP address can reduce the total number of IP addresses that are needed on the system, especially when configuring a large number of zones. Unlike the case of the zone-specific IP address, when MLPs are declared on shared IP addresses, only the global zone can receive the incoming network traffic that is destined for the MLP.

- One of the following sets of arguments must be specified for subcommand `add`:

```
-n zonename -l label [-x polycymatch=policy-match-level \
-x mlpzone=port/protocol;... | \
-x mlpshared=port/protocol;... ]
-h
```

- One of the following sets of arguments must be specified for subcommand `modify`:

```
-n zonename [-l label] [-x polycymatch=policy-match-level \
-x mlpzone=port/protocol;... | \
-x mlpshared=port/protocol;... ]
-h
```

- One of the following arguments must be specified for subcommand `delete`:

```
-n zonename |
-h
```

- The following argument can be specified for subcommand `list`:

```
-n zonename |
-h
```

Examples

EXAMPLE 1 Adding a New Entry to the Zone Configuration Database

The admin role creates a new zone entry, `public`, with a label of `public`, a policy match level of 1, and a shared MLP port and protocol of 666 and TCP. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtntzonecfg add -- -n public -l public \
-x policymatch=1 -x mlpshared=666/tcp
```

EXAMPLE 2 Modifying an Entry in the Zone Configuration Database

The admin role changes the `public` entry in the `tnzonecfg` database to `needtoknow`. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtntzonecfg modify -- -n public -l needtoknow
```

EXAMPLE 3 Listing the Zone Configuration Database

The admin role lists the entries in the `tnzonecfg` database. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtntzonecfg list --
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.
- 2 An error occurred while executing the command. An error message displays.

Files The following files are used by the `smtntzonecfg` command:

`/etc/security/tsol/tnzonecfg` Trusted zone configuration database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWmgts |
| Interface Stability | Committed |

See Also [smc\(1M\)](#), [attributes\(5\)](#)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name smuser – manage user entries

Synopsis /usr/sadm/bin/smuser *subcommand* [*auth_args*] - -
[*subcommand_args*]

Description The smuser command manages one or more user entries in the local /etc filesystem or a NIS or NIS+ target name service.

subcommands smuser *subcommands* are:

- add** Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.
- delete** Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.
- list** Lists one more user entries from the appropriate files. To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.
- modify** Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

Options The smuser authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The smuser command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the - - option.

auth_args The valid *auth_args* are -D, -H, -l, -p, -r, and -u are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or - --domain with the *domain* argument.

-D | - --domain *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is nis, nisplus, dns, ldap, or file; *host_name* is

the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (Note: Do not use nis+ for nisplus.)

If you do not specify this option, the Solaris Management Console assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | - --hostname *13;host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port 898. You may still have to choose a toolbox to load into the console. To override this behavior, use the [smc\(1M\)](#) -B option, or set your console preferences to load a “home toolbox” by default.

-l | - --rolepassword *13;role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | - --password *13;password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | - --rolename *13;role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | - --username *13;user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

- -

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the - -

option.

subcommand_args *Note:* Descriptions and other arg options that contain whitespace must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).

- For subcommand `add`:

- c *comment* (Optional) Includes a short description of the login, which is typically the user's name. Consists of a string of up to 256 printable characters, excluding the colon (:).
- d *dir* (Optional) Specifies the home directory of the new user, limited to 1024 characters.
- e *ddmmyyyy* (Optional) Specifies the expiration date for a login. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (" ") to indicate that the login is always valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- f *inactive* (Optional) Specifies the maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. Enter zero to indicate that the login account is always active.
- F *full_name* (Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
- g *group* (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
- G *group1 -G group2 . . .* (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the -g and -G options are ignored.
- h (Optional) Displays the command's usage statement.
- n *login* Specifies the new user's login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

-
- P *password*** (Optional) Specifies up to an eight-character password assigned to the user account. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
- s *shell*** (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).
- t *template*** (Optional) Specifies a template, created using the User Manager tool, that contains a set of pre-defined user attributes. You may have entered a name service server in the template. However, when a user is actually added with this template, if a name service is unavailable, the user's local server will be used for both the Home Directory Server and Mail Server.
- u *uid*** (Optional) Specifies the user ID of the user you want to add. If you do not specify this option, the system assigns the next available unique user ID greater than 100.
- x *autohome=Y|N*** (Optional) Sets the home directory to automount if set to *Y*. The user's home directory path in the password entry is set to `/home/login name`.
- x *mail=mail_server*** (Optional) Specifies the host name of the user's mail server, and creates a mail file on the server. Users created in a local scope must have a mail server created on their local machines.
- x *perm=home_perm*** (Optional) Sets the permissions on the user's home directory. *perm* is interpreted as an octal number, and the default is `0775`.
- x *pwmax=days*** (Optional) Specifies the maximum number of days that the user's password is valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- x *pwmin=days*** (Optional) Specifies the minimum number of days between user password changes. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
- x *pwwarn=days*** (Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration prior to the password expiring. The administrator must have the `solaris.admin.usermgr.pswd` authorization.

- x *serv=homedir_server* (Optional) Specifies the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.
- M *limit_privs* Specifies the privilege name(s) to add to the new `user_attr(4)` entry. The default is `all` for limit privilege.
- To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
- D *default_privs* Specifies the default privilege name(s) to add to the new `user_attr(4)` entry.

The following options to the add subcommand are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

- x *clear=clearanceval* (Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- x *idlecmd=LOGOUT|LOCK* Specifies the command to execute if the system has been idled. If `LOGOUT` is specified, `idlecmd=logout` will be recorded in `user_attr`. If `LOCK` is specified, `idlecmd=lock` will be recorded in `user_attr`. If this option is not specified, the default is the `IDLECMD` in the `/etc/security/policy.conf` file.
- x *idletime=minutes* (Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid. This value is recorded in `user_attr` as `idletime=val`. If this option is not specified, the default is the `IDLETIME` in the `/etc/security/policy.conf` file.

-
- x label=*labelval* (Optional) Specifies the user's minimum label. *labelval* can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- x labelview=HIDE|SHOW (Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is specified, `labelview=*showsl` will be recorded. If `HIDE` is specified, `labelview=*hidesl` will be recorded. The asterisk portion can be replaced by "internal," "external," or ""(null). If this option is not specified, the default is the `LABELVIEW` in the `/etc/security/policy.conf` file.
- x lock=Y|N (Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in `user_attr` as `lock_after_retries`. If this option is not specified, the default is the `LOCK_AFTER_RETRIES` in the `/etc/security/policy.conf` file.
- x view=INTERNAL|EXTERNAL|DEFAULT (Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default action, that nothing gets recorded in `user_attr`, is in effect.
- For subcommand `delete`:
 - h (Optional) Displays the command's usage statement.
 - n *login1* Specifies the login name of the user you want to delete.

- n *login2* . . . (Optional) Specifies the additional login name(s) of the user(s) you want to delete.
- For subcommand *list*:
 - h (Optional) Displays the command's usage statement.
 - l Displays the output for each user in a block of *key:value* pairs (for example, *user name: root*) followed by a blank line to delimit each user block. Each *key:value* pair is displayed on a separate line. The keys are: *autohome setup*, *comment*, *days to warn*, *full name*, *home directory*, *home directory permissions*, *login shell*, *mail server*, *max days change*, *max days inactive*, *min days change*, *password expires*, *password type*, *primary group*, *rights*, *roles*, *secondary groups*, *server*, *user ID (UID)*, and *user name*.
 - n *login1* Specifies the login name of the user you want to list.
 - n *login2* . . . (Optional) Specifies the additional login name(s) of the user(s) you want to list.
- For subcommand *modify*:
 - a *addrole1* -a *addrole2* . . . (Optional) Specifies the role(s) to add to the user account. To assign a role to a user, the administrator must have the *solaris.role.assign* authorization or must have the *solaris.role.delegate* authorization and be a member of each of the roles specified.
 - c *comment* (Optional) Describes the changes you made to the user account. Consists of a string of up to 256 printable characters, excluding the colon (:).
 - d *description* (Optional) Specifies the user's home directory, limited to 1024 characters.
 - e *ddmmyyyy* (Optional) Specifies the expiration date for a login in a format appropriate to the locale. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (" ") to indicate that the login is always valid.
 - f *inactive* (Optional) Specifies the maximum number of days allowed between uses of a login ID before the ID is declared invalid. Normal values are positive integers. Specify zero to indicate that the login account is always active.
 - F *full_name* (Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can

- contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
- g *group* (Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
 - G *group1* -G *group2* ... (Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the -g and -G options are ignored.
 - h (Optional) Displays the command's usage statement.
 - n *name* Specifies the user's current login name.
 - N *new_name* (Optional) Specifies the user's new login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
 - p *addprof1* -p *addprof2* ... (Optional) Specifies the profile(s) to add to the user account. To assign a profile to a user, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
 - P *password* (Optional) Specifies up to an eight-character password assigned to the user account.

When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
 - q *delprof1* -q *delprof2* ... (Optional) Specifies the profile(s) to delete from the user account.
 - r *delrole1* -r *delrole2* ... (Optional) Specifies the role(s) to delete from the user account.
 - s *shell* (Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).l)
 - x *autohome*=Y|N (Optional) Sets up the home directory to automount if set to Y. The user's home directory path in the password entry is set to `/home/login name`.

- x *pwmax=days* (Optional) Specifies the maximum number of days that the user's password is valid.
- x *pwmin=days* (Optional) Specifies the minimum number of days between password changes.
- x *pwwarn=days* (Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration before the password expires.
- M *limit_privs* Specifies the privilege name(s) to modify in the [user_attr\(4\)](#) entry. The default is `all` for limit privilege.
- To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See [privileges\(5\)](#).
- D *default_privs* Specifies the default privilege name(s) to modify in the [user_attr\(4\)](#) entry.

The following options to the `modify` subcommand are available only if a system is configured with Solaris Trusted Extensions. See “Using Options that Require Solaris Trusted Extensions,” below.

- x *clear=clearanceval* (Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
- x *idlecmd=LOGOUT|LOCK* Specifies the command to execute if the system has been idled. If `LOGOUT` is specified, `idlecmd=logout` will be recorded in `user_attr`. If `LOCK` is specified, `idlecmd=lock` will be recorded in `user_attr`. If this option is not specified, the default is the `IDLECMD` in the `/etc/security/policy.conf` file.
- x *idletime=minutes* (Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid.

| | |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -x label= <i>labelval</i> | This value is recorded in <code>user_attr</code> as <code>idletime=val</code> . If this option is not specified, the default is the <code>IDLETIME</code> in the <code>/etc/security/policy.conf</code> file. |
| -x labelview=HIDE SHOW | (Optional) Specifies the user's minimum label. <i>labelval</i> can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the <code>solaris.admin.usermgr.labels</code> authorization. |
| -x lock=Y N | (Optional) Specifies the second part of the <code>labelview key-value</code> pair. If <code>SHOW</code> is specified, <code>labelview=*showsl</code> will be recorded. If <code>HIDE</code> is specified, <code>labelview=*hidesl</code> will be recorded. The asterisk portion can be replaced by "internal," "external," or ""(null). If this option is not specified, the default is the <code>LABELVIEW</code> in the <code>/etc/security/policy.conf</code> file. |
| -x view=INTERNAL EXTERNAL DEFAULT | (Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in <code>user_attr</code> as <code>lock_after_retries</code> . If this option is not specified, the default is the <code>LOCK_AFTER_RETRIES</code> in the <code>/etc/security/policy.conf</code> file.

(Optional) Specifies the label view type for the <code>labelview</code> in <code>user_attr</code> . If <code>INTERNAL</code> is specified, <code>labelview=internal</code> will be recorded; if <code>EXTERNAL</code> is specified, <code>labelview=external</code> will be recorded; if <code>DEFAULT</code> is specified, nothing will be recorded in <code>user_attr</code> . If this option is not specified, the default action, that nothing gets recorded in <code>user_attr</code> , is in effect. |

Using Options that
Require Solaris Trusted
Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B toolbox` option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smuser add -H myhost -p mypasswd -x idlecnd=LOGOUT \  
-B http://<server>/toolboxes/tso1_files.tbx
```

In the command above, `<server>` is the name of the machine running the Solaris Management Console. See [smc\(1M\)](#) for a description of the `-B` option.

Examples **EXAMPLE 1** Creating a New User Account

The following creates a new user account on the local file system. The account name is `user1`, and the full name is `Joe Smith`. The comment field verifies that the account is for Joe Smith. The system will assign the next available user ID greater than 100 to this account. There is no password set for this account, so when Joe Smith logs in for the first time, he will be prompted to enter a password.

```
./smuser add -H myhost -p mypasswd -u root -- -F "Joe Smith" \  
-n user1 -c "Joe's account"
```

EXAMPLE 2 Deleting a User Account

The following deletes the `user1` account from the local file system:

```
./smuser delete -H myhost -p mypasswd -u root -- -n user1
```

EXAMPLE 3 Listing All User Accounts

The following lists all user accounts on the local file system in summary form:

```
./smuser list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Modifying a User Account

The following modifies the `user1` account to default to a Korn shell, and assigns the account to the `qa_group` secondary group.

```
./smuser modify -H myhost -p mypasswd -u root -- -n user1 \  
-s /bin/ksh -G qa_group
```

Environment Variables See [environ\(5\)](#) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smuser` command. If this environment variable is not specified, the `/usr/java` location is used. See [smc\(1M\)](#).

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Invalid command syntax. A usage message displays.

Name snmpbulkget – communicate with a network entity using SNMP GETBULK requests

Synopsis snmpbulkget [*application options*] [*common options*] *oid*
[*oid*]...

Description The snmpbulkget utility is an SNMP application that uses the SNMP GETBULK operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. Each variable name must be entered in the format specified in [snmp_variables\(4\)](#).

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

Options The following options are supported:

- Cnum Set the non-repeaters field in the GETBULK PDU. This specifies the number of supplied variables that should not be iterated over. The default is 0.
- Crnum Set the max-repetitions field in the GETBULK PDU. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to this option, snmpbulkget takes the common options described in the [snmpcmd\(1M\)](#) manual page.

Examples **EXAMPLE 1** Retrieving Multiple Objects

The following snmpbulkget command retrieves the variable `system.sysDescr.0` (which is the lexicographically next object to `system`) and the first five objects in the `ifTable`:

```
# snmpbulkget -v2c -Cn1 -Cr5 -Os -c public zeus system ifTable
```

This command produces output such as the following:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
ifIndex.1 = INTEGER: 1
ifIndex.2 = INTEGER: 2
ifDescr.1 = STRING: "lo0"
[...]
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWsmcmd |
| Interface Stability | External |

Exit Status 0 Successful completion.

1 A usage syntax error. A usage message is displayed. Also used for timeout errors.

2 An error occurred while executing the command. An error message is displayed.

See Also [snmpcmd\(1M\)](#), [snmp_variables\(4\)](#), [attributes\(5\)](#)

RFC 1905

Notes As the name implies, `snmpbulkget` uses the SNMP GETBULK message, which is not available in SNMPv1.

Name snmpbulkwalk – communicate with a network entity using SNMP BULK requests

Synopsis /usr/sfw/bin/snmpbulkwalk [*application_options*]
[*common_options*] [*oid*]

Description The snmpbulkwalk utility is an SNMP application that uses SNMP GETBULK requests to query a network entity efficiently for a tree of information.

You can specify an object identifier (OID) on the command line. This OID identifies the portion of the object identifier space that will be searched using GETBULK requests. All variables in the subtree below the given OID are queried and their values returned. Each variable name is given in the format specified in [snmp_variables\(4\)](#). If no OID argument is present, snmpbulkwalk searches MIB-2.

If a network entity has an error processing the request packet, an error packet is returned and a message is displayed. The message helps to pinpoint the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message "End of MIB" is displayed.

Options The following options are supported:

- Cc Do not check whether the returned OIDs are increasing. Some agents (agents for Laser-Jet printers are an example) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause snmpbulkwalk to loop indefinitely. By default, snmpbulkwalk tries to detect this behavior and warns you when it hits an agent acting illegally. Use -Cc to turn off this behavior.
- Ci Include the given OID in the search range. Normally, snmpbulkwalk uses GETBULK requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. Use this option to include the OID specified on the command line in the printed results if it is a valid OID in the tree itself.
- Cnum Set the non-repeaters field in the GETBULK PDUs. This specifies the number of supplied variables that should not be iterated over. The default is 0.
- Cp Upon completion of the walk, display the number of variables found.
- Crnum Set the max-repetitions field in the GETBULK PDUs. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to these options, snmpbulkwalk takes the common options described in the [snmpcmd\(1M\)](#) manual page.

Examples EXAMPLE 1 Retrieving Variables Under system

The following command retrieves all of the variables under system:

```
# snmpbulkwalk -v2c -Os -c public zeus system
```

The return from `snmpbulkwalk` is as follows:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72
```

In contrast to `snmpwalk(1M)`, this information will be gathered in a single transaction with the agent, rather than one transaction per variable found. `snmpbulkwalk` is thus more efficient in terms of network utilization, which might be especially important when retrieving large tables.

Exit Status 0 Successful completion.

1 A usage syntax error. A usage message displays. Also used for timeout errors.

2 An error occurred while executing the command. An error message displays.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWsmcmd |
| Interface Stability | External |

See Also [snmpcmd\(1M\)](#), [snmpwalk\(1M\)](#), [snmp_variables\(4\)](#), [attributes\(5\)](#)

Notes As the name implies, `snmpbulkwalk` uses the SNMP GETBULK message, which is not available in SNMP v1.

Name snmpcmd – commands to communicate with a network entity using SNMP requests

Synopsis snmpcmd [*options*] *agent* [*parameters*]

Description This manual page describes the common options for the following SNMP commands:

- snmpbulkget(1M)
- snmpbulkwalk(1M)
- snmpdf(1M)
- snmpget(1M)
- snmpgetnext(1M)
- snmpnetstat(1M)
- snmpset(1M)
- snmptrap(1M)
- snmpusm(1M)
- snmpvacm(1M)
- snmpwalk(1M)

The command line applications use the SNMP protocol to communicate with an SNMP-capable network entity, an agent. Individual applications usually (but not invariably) take additional parameters that are given after the agent specification. These parameters are documented in the manual pages for each application.

Options The following options are supported:

- | | |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a <i>authProtocol</i> | Set the authentication protocol (MD5 SHA) used for authenticated SNMPv3 messages. Overrides the defAuthType token in the snmp.conf file. |
| A <i>authPassword</i> | Set the authentication pass phrase used for authenticated SNMPv3 messages. Overrides the defAuthPassphrase token in the snmp.conf file. Insecure to specify pass word phrases on the command line, see snmp.conf(4). |
| -c <i>community</i> | Set the community string for SNMPv1/v2c transactions. Overrides the defcommunity token in the snmp.conf file. |
| -d | Dump (in hexadecimal) the sent and received SNMP packets. |
| -D <i>token</i> [,...] | Turn on debugging output for the given <i>token</i> (s). Try ALL for extremely verbose output. |
| -e <i>engineID</i> | Set the authoritative (security) <i>engineID</i> used for SNMPv3 REQUEST messages. This is the engineID of the agent or proxy (for example, 800000020109840301). This value will be discovered if not supplied. |

-
- E *engineID* Set the context *engineID* used for SNMPv3 REQUEST messages scopedPdu. This is the *engineID* of the agent (for example, 800000020109840301). This will be the authoritative *engineID* if not specified.
- h, --help Display a brief usage message and then exit.
- H Display a list of configuration file directives understood by the command and then exit.
- I brRhu Specifies input parsing options. See INPUT OPTIONS below.
- l *secLevel* Set the securityLevel used for SNMPv3 messages (noAuthNoPriv|authNoPriv|authPriv). Appropriate pass phrase(s) must be provided when using any level higher than noAuthNoPriv. Overrides the defSecurityLevel token in the snmp.conf file.
- m *miblist* Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.
- The special keyword ALL is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with a period (.) will be parsed as if it were a MIB file.
- If the *miblist* has a leading plus sign (+), then the listed MIB modules are loaded in addition to MIB modules specified in the environment variable MIBS.
- If a *mibfile* token is specified in the snmp.conf file, the -m MIB option overrides the *mibfile* token.
- M *dirlist* Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.
- If *dirlist* has a leading plus sign (+), then the given directories are added to the list of MIB directories. Without the leading +, the given directory list overrides the list specified with the environment variable MIBDIRS. Note that the directories listed at the end of the list have precedence over directories at the beginning of the list.
- If no value is specified for the environment variable MIBDIRS, then the command will still search a default *mib* directory, after it searches the MIB directories specified on the -M option. The default directory is /etc/sma/snmp/mibs. To avoid having a default *mib* directory searched, set the MIBDIRS environment

variable to the empty string (""). Even if the default MIB directory is searched, the directories specified in the `-M` option have precedence in the search order over the default directory.

If the `-M` option is specified and either a `mibfile` or `mibdirs` token is also specified in the `snmp.conf` file, the directories in the `-M` option have precedence in the MIB search order, over the directories set with either the `mibdirs` token and the `mibfile` token.

- `-n contextName` Set the destination *contextName* used for SNMPv3 messages. The default *contextName* is the empty string (""). Overrides the `defContext` token in the `snmp.conf` file.
- `-O anEebqQfsSvXTuxUt` Specifies output printing options. See OUTPUT OPTIONS below.
- `-P cdeRuwW` Specifies MIB parsing options. See MIB PARSING OPTIONS below.
- `-r retries` Specifies the number of retries to be used in the requests. The default is 5.
- `-t timeout` Specifies the timeout in seconds between retries. The default is 1.
- `-u secName` Set the *securityName* used for authenticated SNMPv3 messages. Overrides the `defSecurityName` token in the `snmp.conf` file.
- `-v 1 | 2c | 3` Specifies the protocol version to use: 1 (RFCs 1155-1157), 2c (RFCs 1901-1908), or 3 (RFCs 2571-2574). The default is version 1. This option overrides the `defVersion` token in the `snmp.conf` file.
- `-V, --version` Display version information for the application and then exit.
- `-x privProtocol` Set the privacy protocol (DES) used for encrypted SNMPv3 messages.
- `-X privPassword` Set the privacy pass phrase used for encrypted SNMPv3 messages. Overrides the `defPrivPassphrase` token in the `snmp.conf` file. Note that it is insecure to specify password phrases on the command line. See [snmp.conf\(4\)](#).
- `-Z boots,time` Set the `engineBoots` and `engineTime` used for authenticated SNMPv3 messages. This will initialize the local notion of the agents *boots/time* with an authenticated value stored in the LCD. This value will be discovered if not supplied.

The string *agent* specifies the remote SNMP entity with which to communicate. The format of this parameter is defined in the AGENT SPECIFICATION section below.

Agent Specification The *agent* specification (see SYNOPSIS) takes the form:

```
[transport-specifier: ]transport-address
```

At its simplest, the *agent* specification consists of a hostname or an IPv4 address in the standard, "dotted quad" notation. In this case, communication will be attempted using UDP/IPv4 to port 161 of the given host. Otherwise, the *transport-address* part of the specification is parsed according to the following table:

```
<transport-specifier> <transport-address> format
udp                               hostname[ :port]
```

Note that *transport-specifier* strings are case-insensitive so that, for example, "tcp" and "TCP" are equivalent. Here are some examples, along with interpretations:

```
myhost:161
```

Perform query using UDP/IPv4 datagrams sent to myhost on port 161. The :161 is redundant here because that is the default SNMP port.

```
udp:myhost
```

Identical to the previous specification. The `udp:` is redundant here because UDP/IPv4 is the default transport.

MIB Parsing Options The Net-SNMP MIB parser mostly adheres to the Structure of Management Information (SMI). As that specification has changed through time, and in recognition of the diversity in compliance expressed in MIB files, additional options provide more flexibility in reading MIB files.

- Pw Show some warning messages in resolving the MIB files. Can be also set with the configuration token `mibWarningLevel`.
- PW Show additional warning messages. Can be also set with the configuration token `mibWarningLevel`.
- Pe Show MIB errors. Can be also set with the configuration token `showMibErrors`. An example of an error that would be shown is if an imported module is not found during MIB parsing.
- Pc Allow ASN.1 comment to extend to the end of the MIB source line (that is, disallow the use of two dashes (- -) to terminate comments). This overcomes some problems with manually maintained MIB files. Can be also set with the configuration token `strictCommentTerm`.

- Pd Toggles the default of whether or not to save the DESCRIPTIONs of the MIB objects when parsing. Since the default is to save the DESCRIPTIONs, specifying -Pd causes the DESCRIPTIONs not to be saved during MIB parsing. For example:

```
snmptranslate -Td -OS -IR system.sysDescr.0
```

will show a description, while:

```
snmptranslate -Td -OS -IR -Pd system.sysDescr.0
```

will not show a description. Collecting the DESCRIPTION information into the parsed hierarchy increases the memory used by the size of each DESCRIPTION clause.
- Pu Allow underline characters in symbols. Can be also set with the configuration token `mibAllowUnderline`.
- PR Replace MIB objects using the last read MIB file. The parser replaces MIB objects in its hierarchy whenever it sees a subidentifier and name match.

Caution – Setting this option might result in an incorrect hierarchy. Can be also set with the configuration token `mibReplaceWithLatest`.

Output Options Output display can be controlled by passing various parameters to the `-O` flag. The following examples demonstrate this feature.

The default output displays as follows:

```
snmpget -c public -v 1 localhost system.sysUpTime.0
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

- Oq Removes the equal sign and type information:

```
system.sysUpTime.0 1:15:09:27.63
```
- OQ Removes the type information:

```
system.sysUpTime.0 = 1:15:09:27.63
```
- Of Gives you the complete OID:

```
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime.0 = \
Timeticks: (14096763) 1 day, 15:09:27.63
```
- Os Deletes all but the last symbolic part of the OID:

```
sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```
- OS A variation on -Os that adds the name of the MIB that defined the object:

```
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

Starting with release 5.0, this is the default output format.
- Ou Displays the OID in the UCD-style (inherited from the original CMU code). That means removing a series of "standard" prefixes, if relevant, and breaking down the

OID into the displayable pieces. For example, the OID `vacmSecurityModel.0.3.119.101.115` is broken down by default and the string hidden in the OID is shown. The result would be: `vacmSecurityModel.0."test"`. The `-Ob` option disables this feature.

```
system.sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-On` Displays the OID numerically:

```
.1.3.6.1.2.1.1.3.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-Oe` Removes the symbolic labels from enumerations:

```
snmpget -c public -v 1 localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: forwarding(1)
snmpget -c public -v 1 -Oe localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: 1
```

`-Ob` When OIDs contain an index to a table, they are broken into the displayable pieces and shown to you. For example, the OID `vacmSecurityModel.0.3.119.101.115` is nicely broken down by default and the string hidden in the OID is shown to you as `vacmSecurityModel.0."wes"`. The `-Ob` option disables this feature and displays it as `vacmSecurityModel.0.3.119.101.115` once again.

`-OE` Modifies the index strings to include a backslash (`\`) to escape the quotes, to allow them to be reused in shell commands, such as `vacmSecurityModel.0.\"wes\"`

`-OX` Modifies the output of index OIDs to look more "program-like". Square brackets are placed around each index and the `DISPLAY-HINT` information and string conversions are used to format each index. If you take an entry from the `IPV6-MIB::ipv6RouteTable`, it is indexed with an IPv6 address and two integers, and if you are used to IPv6 addresses you know that decimal OIDs are not the preferred notation. Compare:

```
snmpgetnext -OS host IPV6-MIB:ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex.63.254.1.0.255.0.0.0.0.0.0.0.0.0.0.64.1 \
= INTEGER: 2
```

```
snmpgetnext -OSX host IPV6-MIB:ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex[3ffe:100:ff00:0:0:0:0:0][64][1] = INTEGER: 2
```

`-Oa` If a string-valued object definition does not include a display hint, then the library attempts to determine whether it is an ASCII or binary string, and displays the value accordingly. This flag bypasses this check, and displays all strings as ASCII. Note that this does not affect objects that do have a display hint.

`-Ox` This works similarly to `-Oa`, but displays strings as hexadecimal values.

`-OT` If hexadecimal code is displayed, this will also display any printable characters after the hexadecimal codes.

- Ov Output only the variable value, not the OID:

```
snmpget -c public -v 1 -Ov localhost ip.ipForwarding.0
INTEGER: forwarding(1)
```
- OU Do not display the UNITS suffix at the end of the value.
- Ot Output timeticks values as raw numbers:

```
system.sysUpTime.0 = 14096763
```

Note that most of these options can be turned on or off by default by tuning the `snmp.conf` file. See [snmp.conf\(4\)](#) for details.

Input Options The `-I` flag specifies various options that control how your input to the program is parsed. By default, unless one of the following flags is specified, all input parsing methods are used: First the OID is parsed in the normal way, then `-IR` is used, then `-Ib` is used. The use of one of the following flags forces a command to use only one method.

- IR Specifies random access lookup, so that if the entire OID path is not specified, it will search for a node in the MIB tree with the given name. Normally, you'd have to specify the `vacmSecurityModel` OID above as:

```
.iso.org.dod.internet.snmpV2.snmpModules.snmpVacmMIB.vacmMIBObjects.\
vacmSecurityToGroupTable.vacmSecurityToGroupEntry.vacmSecurityModel.0.\
"wes"
```

But the use of the `-IR` flag allows you to shorten that to `vacmSecurityModel.0."wes"`. This OID needs to be quoted to prevent the shell from swallowing the double quotes: But the use of the `-IR` flag allows you to shorten that to just `vacmSecurityModel.0."wes"`. This OID must be quoted to prevent the shell from swallowing the double quotes: `'vacmSecurityModel.0."wes"'`.

For more information, see the RANDOM ACCESS MIBS section, below.

- Ib Indicates that the expression you gave the command is a regular expression that should be used to search for the best match possible in the MIB tree. This would allow you to specify the `vacmSecurityModel` MIB node as something as generic as `vacmsecuritymodel` (since case-insensitive searches are done) or `vacm.\(**model`. Note that multiple matches are obviously possible (`.\(**` matches everything). The best result is calculated as the one that matches the closest to the beginning of the node name and the highest in the tree. A side effect of this option is that you cannot specify indexes or multiple nodes, because the period (`.`) is treated as part of the regular expression.
- Iu Use the traditional UCD-style input approach of assuming that OIDs are rooted at the `mib-2` point in the tree (unless they start with an explicit period (`.`)) If random access lookup is in effect (which is the default for most commands), then this will affect only

OIDs specified with a leading numeric subidentifier (and no initial period). Thus an input of `snmpcmd . . . 1` would refer to `iso` (from v5.0 onwards) while `snmpcmd -Iu . . . 1` would refer to `system`.

-Ir By default, indices into tables and values to be assigned to objects are checked against the range and type specified in the MIB. The `-Ir` flag disables this check. This flag is mostly useful when you are testing an agent. For normal operation, it is useful to get your requests checked before they are sent to the remote agent. The diagnostic that the library can provide is also much more precise.

-Ih By default, the library will use `DISPLAY-HINT` information when assigning values. This flag disables this behavior. The result is that, instead of:

```
snmpset localhost HOST-RESOURCES-MIB::hrSystemDate.0 = \
2002-12-10,2:4:6.8
```

you will have to write:

```
snmpset localhost HOST-RESOURCES-MIB::hrSystemDate.0 x \
"07 D2 0C 0A 02 04 06 08"
```

Random Access MIBs In previous releases of the UCD-SNMP package (and if using the `-Iu` option), an object identifier such as `system.sysDescr.0` is looked up in a single "well known" place, built into the SNMP library (or specified by the `P@PREFIX` environment variable). The standard place is `.iso.org.dod.internet.mgmt.mib-2`. The identifier can alternatively be a complete object identifier. This is designated by a leading "dot" if using UCD-input style, and is the first thing tried otherwise. To simplify the specification of object identifiers the library supports random access to the identifiers in the MIBs. This is requested by the `-IR` option to the SNMP applications. Additionally, `-Os` prints OIDs in this manner. Using this, `system.sysDescr.0` can also be entered as `sysDescr.0`.

To search only a single MIB for the identifier (if it appears in more than one), specify it as `SNMPv2-MIB:sysDescr.0`. Use `-OS` to print output OIDs in this manner; this is the default since v5.0. This notation also ensures that the specified MIB is loaded, that is, it need not be mentioned in the `-m` option (or `MIBS` environment variable).

| | | |
|------------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Environment Variables | P@PREFIX | The standard prefix for object identifiers (if using UCD-style output). Defaults to <code>.iso.org.dod.internet.mgmt.mib-2</code> . |
| | MIBS | The list of MIBs to load. Defaults to:

<code>SNMPv2-TC:SNMPv2-MIB:IF-MIB:IP-MIB:TCP-MIB:UDP-MIB:SNMP-VACM-MIB</code>

Overridden by the <code>-m</code> option. |
| | MIBDIRS | The list of directories to search for MIBs. Defaults to <code>/etc/sma/snmp/mibs</code> . Overridden by the <code>-m</code> option. |

Files /etc/sma/snmp/snmpd.conf Agent configuration file. See [snmpd.conf\(4\)](#).

~/ .snmp/snmp.conf

~/ .snmp/snmp.conf Application configuration files. See [snmp.conf\(4\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |

Name snmpconf – creates and modifies SNMP configuration files

Synopsis snmpconf
 snmpconf -g basic_setup
 snmpconf [*options*] [*file_to_create*]

Description The snmpconf utility is a simple script that walks you through setting up a configuration file, step-by-step. It works by asking you a series of questions. It creates the configuration file based on your responses.

In its default mode of operation, snmpconf prompts you with menus showing sections of the various configuration files it knows about. When you selects a section, a submenu is shown listing the descriptions of the tokens that can be created in that section. When a description is selected, you are prompted with questions that determine the specification of the selected token.

When you quit snmpconf, any configuration files that have been edited are saved to the local directory. snmpconf supplies comments in the configuration files for each change.

A particularly useful option is the -g switch, which walks you through a specific set of configuration questions. For an example, invoke:

```
# snmpconf -g basic_setup
```

This command walks you through an initial setup of the snmpd daemon.

Options The following options are supported:

- f Force overwriting existing files in the current directory without prompting the user.
- i When finished, install the files in the location where the global system commands expect to find them.
- p When finished, install the files into the user's home directory's .snmp subdirectory. Applications will search for configuration files in this location.
- I *directory* When finished, install the files into the directory *directory*.
- a Do not issue queries. Read in the various known configuration files and write them back out again. This has the effect of "auto-commenting" the configuration files for you.
- r all | none Read in either all or none of the found configuration files. Normally, snmpconf prompts you for which files you wish to read in.
- R *file,...* Read in a specific list of configuration files.
- g *groupname* Groups of configuration entries can be created that can be used to walk a user through a series of questions to create an initial configuration file. There are no menus to navigate, just a list of questions. The command:

- ```
snmpconf -g basic_setup
```
- provides a good example.
- G List all the known groups.
  - c *configdir* snmpconf uses a directory of configuration information to learn about the files and questions that it should be asking. This option tells the utility to use a different location for configuring itself.
  - q Run slightly more quietly than the default. Because this is an interactive program, this option is not recommended. It removes information from the output that might be helpful to you.
  - d Turn on copious debugging output.
  - D Add more (beyond -d) debugging output in the form of Perl variable dumps.

**Examples** EXAMPLE 1 Adding Comments to `snmpd.conf`

The following command reads in an `snmpd.conf` file and adds comments describing what each token does.

```
snmpconf -R /etc/sma/snmp/snmpd.conf -a -f snmpd.conf
```

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpd\(1M\)](#), [snmpd.conf\(4\)](#), [snmp\\_config\(4\)](#), [attributes\(5\)](#)

**Name** snmpd – daemon to respond to SNMP request packets

**Synopsis** /usr/sbin/snmpd [*options*] [*listening addresses*]

**Description** The snmpd daemon is an SNMP agent that binds to a port and awaits requests from SNMP management software. Upon receiving a request, it processes the request(s), collects the requested information, performs any requested operation(s), and, finally, returns information to the requester.

**Options** The following options are supported:

- a                   Log the source addresses of incoming requests.
  - A                   Append to the log file rather than truncating it.
  - c *file*            Read *file* as a configuration file.
  - C                   Do not read any configuration files except the one optionally specified by the -c option.
- Note that this behavior also covers the persistent configuration files. This can result in dynamically-assigned values being reset following an agent restart, unless the relevant persistent configuration files are explicitly loaded using the -c option.
- d                   Dump (in hexadecimal) the sent and received SNMP packets.
  - D[*token*[,...]]    Turn on debugging output for the given *token*(s). Without any tokens specified, this option defaults to printing all of the tokens (which is equivalent to the keyword ALL). Use ALL for extremely verbose output. Note that you must not put a space between the -D flag and the listed *tokens*.
  - f                   Do not fork() from the calling shell.
  - g *GID*             Change to the numerical group ID *GID* after opening listening sockets.
  - h, -help           Display a brief usage message and then exit.
  - H                   Display a list of configuration file directives understood by the agent and then exit.
  - I *-initlist*       This option specifies which modules you do (or do not) want to be initialized when the agent starts up. If the comma-separated *initlist* is preceded with an hyphen (-), it is the list of modules that you do not want to be started. Otherwise, *initlist* is the list of modules to be started.
- To obtain a list of compiled modules, run the agent with the arguments -Dmib\_init -H This command assumes you have debugging support compiled in.

- l [*file*] Log all output from the agent (including stdout and stderr) to *file*. If no filename is given, log to a default file set at compile time, normally `/var/log/snmpd.log`.
- L Do not open a log file. Send all messages to stderr instead.
- P *file* Save the process ID of the daemon in *file*.
- q Print simpler output for easier automated parsing.
- r Do not require root access to run the daemon. Specifically, do not exit if files accessible only to root (such as `/dev/kmem`) cannot be opened.
- s Use syslog for logging. See [syslogd\(1M\)](#)
- S d[0-7] Specifies the syslog facility to use when logging to syslog. d means LOG\_DAEMON and the integers 0 through 7 refer to LOG\_LOCAL0 through LOG\_LOCAL7. LOG\_DAEMON is the default.
- u *UID* Change to the user ID *UID* (which can be given in numerical or text form) after opening listening sockets.
- v --version Display version information for the agent and then exit.
- V Symbolically dump SNMP transactions.
- x *address* Listens for AgentX connections on *address* rather than on the default `/var/agentx/master`. The address can either be a Unix domain socket path or the address of a network interface. The format is the same as the format of listening addresses described below. Note that it is a possible security risk to expose the master agent listening address through TCP/UDP. See section 9 of RFC 2741 for more details.
- X Run as an AgentX subagent rather than as an SNMP master agent.

**Listening Addresses** By default, snmpd listens for incoming SNMP requests only on UDP port 161. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to the daemon. A listening address takes the form:

[<*transport-specifier*>:]<*transport-address*>

At its simplest, a listening address can consist of only a port number, in which case snmpd listens on that UDP port on all IPv4 interfaces. Otherwise, the <*transport-address*> part of the specification is parsed according to the following table:

< <i>transport-specifier</i> >	< <i>transport-address</i> > format
udp	<i>hostname</i> [: <i>port</i> ] or <i>IPv4-address</i> [: <i>port</i> ]
tcp	<i>hostname</i> [: <i>port</i> ] or <i>IPv4-address</i> [: <i>port</i> ]

<i>&lt;transport-specifier&gt;</i>	<i>&lt;transport-address&gt;</i> <b>format</b>
unix	<i>pathname</i>

Currently transports TCP/UDP over IPv4/IPv6 and unix domain sockets. Note that *<transport-specifier>* strings are case-insensitive so that, for example, `tcp` and `TCP` are equivalent. Below are some examples, with accompanying explanations.

<code>127.0.0.1:161</code>	Listen on UDP port 161, but only on the loopback interface. This prevents <code>snmpd</code> from being queried remotely. The <code>:161</code> is redundant because that is the default SNMP port.
<code>TCP:1161</code>	Listen on TCP port 1161 on all IPv4 interfaces.
<code>unix:/tmp/local-agent</code>	Listen on the Unix domain socket <code>/tmp/local-agent</code> .
<code>/tmp/local-agent</code>	Identical to the previous specification, because the Unix domain is the default transport if and only if the first character of <i>&lt;transport-address&gt;</i> is a slash ( <code>/</code> ).
<code>udp6:10161</code>	Listen on port 10161 on all IPv6 interfaces.

Note that not all the transport domains listed above will always be available. For example, hosts with no IPv6 support will not be able to use `udp6` transport addresses, and attempts to do so will result in the error “Error opening specified endpoint”.

**Files** `snmpd` checks for the existence of and parses the following files:

<code>snmp.conf</code>	Common configuration for the agent and applications. See <a href="#">snmp.conf(4)</a> for details.
<code>snmpd.local.conf</code>	Agent-specific configuration. See <a href="#">snmp.conf(4)</a> for details. These files are optional and can be used to configure access control, trap generation, subagent protocols, and other features.
	In addition to these two configuration files, the agent will read any files with the names <code>snmpd.conf</code> and <code>snmpd.local.conf</code> in a colon-separated path specified in the <code>SNMPCONFPATH</code> environment variable, the default location upon agent startup are <code>/etc/sma/snmp</code> and <code>/usr/local/share/snmp</code> .
<code>/etc/sma/snmp/mibs</code>	The agent loads all files in this directory as MIBs. It does not, however, load any file that begins with a dot ( <code>.</code> ) or descend into subdirectories.

<b>Exit Status</b> <code>0</code>	Successful completion.
<code>1</code>	A usage syntax error. A usage message is displayed. Also used for timeout errors.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmagt
Interface Stability	Stable

**See Also** [svcadm\(1M\)](#), [svccfg\(1M\)](#), [snmp.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** In addition to basic privileges, to run successfully, the agent requires PRIV\_NET\_PRIVADDR. See [privileges\(5\)](#).

The snmpd service is managed by the service management facility, [smf\(5\)](#), under the service identifiers:

```
svc:/application/management/sma
svc:/application/management/seaport
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

The service uses the solaris.smf.manage.sma privilege. If /etc/sma/snmp/snmpd.conf contains DISABLE=YES, then the service does not start and displays the message:

```
snmpd disabled by config file /etc/sma/snmp/snmpd.conf
```

**Name** snmpdelta – monitor deltas of integer valued SNMP variables

**Synopsis** /usr/sfw/bin/snmpdelta [*common options*] [-Cf] [-Ct] [-Cs] [-CS] [-Cm] [-CF *configfile*] [-Cl] [-Cp *period*] [-CP *peaks*] [-Ck] [-CT] [-Cv *vars/pkt*] *agent OID* [*OID*]. . .

**Description** The `snmpdelta` command monitors the specified integer-valued OIDs and reports changes over time.

The operand *agent* identifies a target SNMP agent, which is instrumented to monitor a given set of objects. At its simplest, the *agent* specification will consist of a hostname or an IPv4 address. With such an operand, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See [snmpcmd\(1M\)](#) for a full list of the possible formats for *agent*.

The operand *OID* is an object identifier that uniquely identifies the object type within a MIB. Multiple OIDs can be specified in a single `snmpdelta` command.

**Options** See [snmpcmd\(1M\)](#) for a list of *common options*. In addition to the *common options*, `snmpdelta` supports the options described below.

- Cf Do not fix errors and then retry the request. Without this option, if multiple OIDs have been specified for a single request and if the request for one or more of the OIDs fails, `snmpdelta` will retry the request so that data for OIDs apart from the ones that failed will still be returned. Specifying `-Cf` tells `snmpdelta` not to retry a request, even if there are multiple OIDs specified.
- Ct Determines time interval from the monitored entity.
- Cs Displays a timestamp.
- CS Generates a "sum count" in addition to the individual instance counts. The "sum count" is the total of all the individual deltas for each time period.
- Cm Displays the maximum value ever attained.
- CF *configfile* Tells `snmpdelta` to read its configuration from the specified file. This option allows the input to be set up in advance rather than having to be specified on the command line.
- Cl Tells `snmpdelta` to write its configuration to files whose names correspond to the MIB instances monitored. For example:  

```
% snmpdelta -c public -v 1 -Cl localhost ifInOctets.1
```

...will create a file `localhost-ifInOctets.1`.
- Cp Specifies the number of seconds between polling periods. Polling involves sending a request to the agent. The default polling period is one second.

- CP *peaks* Specifies the reporting period in number of polling periods. If this option is specified, `snmpdelta` polls the agent *peaks* number of times before reporting the results. The result reported includes the average value over the reporting period. In addition, the highest polled value within the reporting period is shown.
- Ck When the polling period (-Cp) is an increment of 60 seconds and the timestamp is displayed in the output (-Cs), then the default display shows the timestamp in the format *hh:mm mm/dd*. This option causes the timestamp format to be *hh:mm:ss mm/dd* (adding seconds).
- CT Display output in tabular form.
- Cv *vars/pkt* Specifies the maximum number of OIDs allowed to be packaged in a single PDU. Multiple PDUs can be created in a single request. The default value of variables per packet is 60. This option is useful if a request response results in an error because the request packet is too big.

#### Examples EXAMPLE 1 Obtaining Timestamped Output

The following command uses the -Cs option to timestamp output. This example assumes that there are at least three entries in your `ifTable`.

```
% snmpdelta -c public -v 1 -Cs localhost \
IF-MIB::ifInUcastPkts.3 IF-MIB::ifOutUcastPkts.3
```

```
[20:15:43 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:43 6/14] ifOutUcastPkts.3 /1 sec: 158
[20:15:44 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:44 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:46 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:46 6/14] ifOutUcastPkts.3 /1 sec: 158
[20:15:47 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:47 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:48 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:48 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:49 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:49 6/14] ifOutUcastPkts.3 /1 sec: 158
^C
```

#### EXAMPLE 2 Displaying Output in Tabular Form

The following command uses the -CT option to format output as a table. This example assumes that there are at least three entries in your `ifTable`.

```
% snmpdelta -c public -v 1 -Cs -CT localhost \
IF-MIB::ifInUcastPkts.3 IF-MIB::ifOutcastPkts.3 \
```

**EXAMPLE 2** Displaying Output in Tabular Form *(Continued)*

```
localhost ifInUcastPkts.3 ifOutUcastPkts.3
```

```
[20:15:59 6/14] 184.00 184.00
[20:16:00 6/14] 158.00 158.00
[20:16:01 6/14] 184.00 184.00
[20:16:02 6/14] 184.00 184.00
[20:16:03 6/14] 158.00 158.00
[20:16:04 6/14] 184.00 184.00
[20:16:05 6/14] 184.00 184.00
[20:16:06 6/14] 158.00 158.00
^C
```

**EXAMPLE 3** Sending Output to a File

The following example uses a number of options. This example assumes that there are at least four entries in your `ifTable`. Because the `-Cl` option is specified, the output is sent to a file and not to the screen.

```
% snmpdelta -c public -v 1 -Ct -Cs -CS -Cm -Cl -Cp 60 -CP 60 \
interlink.sw.net.cmu.edu .1.3.6.1.2.1.2.2.1.16.3 \
.1.3.6.1.2.1.2.2.1.16.4
```

**Exit Status** 0 Successful completion.

1 A usage syntax error. A usage message is displayed. Also used for timeout errors and for cases where an SNMP client session could not be opened.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmpdf – get a listing of disk space usage on a remote machine by means of SNMP

**Synopsis** /usr/sfw/bin/snmpdf [*common options*] [-Cu] *agent*

**Description** The snmpdf command is a networked version of the [df\(1M\)](#) command. It checks the disk space on the remote machine by examining the HOST-RESOURCES-MIB's hrStorageTable or the UCD-SNMP-MIB's dskTable. By default, the hrStorageTable is preferred, as it typically contains more information than the dskTable. However, the -Cu argument can be passed to snmpdf to force the usage of dskTable.

The *agent* operand identifies a target SNMP agent, which is instrumented to monitor specified objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host.

See the [snmpcmd\(1M\)](#) manual page for a full list of the possible formats for *agent*.

See the [snmpd.conf\(4\)](#) manual page for guidance on setting up dskTable using the disk directive in the snmpd.conf file.

**Options** The following options are supported:

*common options* See [snmpcmd\(1M\)](#) for a list of possible values for *common options*, as well as their descriptions.

-Cu Forces the command to use dskTable in UCD-SNMP-MIB instead of the default to determine the storage information. Generally, the default use of hrStorageTable in HOST-RESOURCES-MIB is preferred because it usually contains more information than dskTable.

**Examples** EXAMPLE 1 Obtaining Disk Usage of a Remote System

The following command returns a display of the disk usage of a remote system.

Description	size (kB)	Used	Available	Used%
/	7524587	2186910	5337677	29%
/proc	0	0	0	0%
/etc/mnttab	0	0	0	0%
/var/run	1223088	32	1223056	0%
/tmp	1289904	66848	1223056	5%
/cache	124330	2416	121914	1%
/vol	0	0	0	0%
Real Memory	524288	447456	76832	85%
Swap Space	1420296	195192	1225104	13%

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

---

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
  - 2 An error occurred while executing the command. An error message is displayed.

**See Also** [df\(1M\)](#), [snmpcmd\(1M\)](#), [snmp.conf\(4\)](#), [snmpd.conf\(4\)](#), [attributes\(5\)](#)

**Name** snmpdx – Sun Solstice Enterprise Master Agent

**Synopsis** `/usr/lib/snmp/snmpdx [-hy] [-a filename] [-c config-dir]  
[-d debug-level] [-i filename] [-m GROUP -m SPLIT]  
[-o filename] [-p port] [-r filename]`

**Description** The Master Agent, snmpdx, is the main component of Solstice Enterprise Agent (SEA) technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.

Upon invocation, snmpdx reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.

The Master Agent is invoked by the service management facility [smf\(5\)](#) at boot time if `svc:/application/management/snmpdx` is enabled (see NOTES) and contents of the resource configuration file `/etc/snmp/conf/snmpdx.rsrc` are non-trivial.

**Note** – The SMA (Systems Management Agent) is the default SNMP agent in the Solaris operating system. See [netsnmp\(5\)](#). snmpdx is Obsolete and may not be supported in a future release of Solaris.

**Options** The following options are supported:

- |                                  |                                                                                                                                                                                                                                                                                     |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-a filename</code>         | Specify the full path of the access control file used by the Master Agent. The default access control file is <code>/etc/snmp/conf/snmpdx.acl</code> .                                                                                                                              |
| <code>-c config-dir</code>       | Specify the full path of the directory containing the Master Agent configuration files. The default directory is <code>/etc/snmp/conf</code> .                                                                                                                                      |
| <code>-d debug-level</code>      | Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.                                                                                                                                    |
| <code>-h</code>                  | Help. Print the command line usage.                                                                                                                                                                                                                                                 |
| <code>-i filename</code>         | Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is <code>/var/snmp/snmpdx.st</code> . |
| <code>-m GROUP   -m SPLIT</code> | Specify the mode to use for forwarding of SNMP requests.                                                                                                                                                                                                                            |

**GROUP** Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at most, one send-request per agent.

**SPLIT** Each variable in the incoming request results in one send-request to each subagent.

The default is **GROUP**.

**-ofilename** Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is `/etc/snmp/conf/enterprises.oid`.

**-pport** Specify the port number. The default port number is 161.

**-rfilename** Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is `/etc/snmp/conf/snmpdx.rsrc`.

**-y** Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

<b>Files</b>	<code>/etc/snmp/conf/enterprises.oid</code>	Enterprise-name OID map
	<code>/etc/snmp/conf/snmpdx.acl</code>	Access control file
	<code>/etc/snmp/conf/snmpdx.rsrc</code>	Resource configuration file
	<code>/var/snmp/snmpdx.st</code>	Master Agent status file
	<code>/var/snmp/mib/snmpdx.mib</code>	Master Agent MIB file

**Exit Status** The following error values are returned:

`0` Successful completion.

non-zero An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsasnm
Interface Stability	Obsolete

**See Also** [attributes\(5\)](#), [netsnmp\(5\)](#), [smf\(5\)](#)

**Notes** The snmpdx service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/application/management/snmpdx
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** snmpget – communicate with a network entity using SNMP GET requests

**Synopsis** /usr/sfw/bin/snmpget [*common options*] [-Cf] *oid* [*oid*]...

**Description** The snmpget utility is an SNMP application that uses the SNMP GET request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in [snmp\\_variables\(4\)](#).

For example, the command:

```
snmpget -c public zeus system.sysDescr.0
```

retrieves the variable system.sysDescr.0:

```
system.sysDescr.0 = "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed. If there were other variables in the request that were correctly formed, the request will be resent without the bad variable.

**Options** The following option is supported:

-Cf If -Cf is not specified, some applications (including [snmpgetnext\(1M\)](#) and snmpget) attempt to fix errors returned by the agent that you were talking to and resend the request. The -Cf option suppresses this fix-and-resend feature.

Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires "all or nothing" types of requests. In the following example note that system.sysUpTime is an incomplete OID, because it requires the .0 index appended to it:

```
snmpget -v1 -Cf -c public localhost system.sysUpTime \
system.sysContact.0
Error in packet
Reason: (noSuchName) There is no such variable name in this MIB.
This name doesn't exist: system.sysUpTime
```

```
snmpget -v1 -c public localhost system.sysUpTime system.sysContact.0
Error in packet
Reason: (noSuchName) There is no such variable name in this MIB.
This name doesn't exist: system.sysUpTime
```

```
system.sysContact.0 = STRING: root@localhost
```

In addition to this option, snmpwalk takes the common options described in the [snmpcmd\(1M\)](#) manual page.

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
  - 2 An error occurred while executing the command. An error message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmpgetnext – communicate with a network entity using SNMP GETNEXT requests

**Synopsis** snmpgetnext [-Cf] [*common options*] *oid* [*oid*]...

**Description** The snmpgetnext utility is an SNMP application that uses the SNMP GETNEXT request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in [snmp\\_variables\(4\)](#). For each variable, the one that is lexicographically "next" in the remote entity's MIB is returned.

For example, the command:

```
snmpgetnext -c public zeus interfaces.ifTable.ifEntry.ifType.1
```

retrieves the variable `interfaces.ifTable.ifEntry.ifType.2`:

```
interfaces.ifTable.ifEntry.ifType.2 = softwareLoopback(24)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed.

**Options** The following options are supported:

-Cf If -Cf is not specified, some applications (including [snmpget\(1M\)](#) and snmpgetnext) attempt to fix errors returned by the agent that you were talking to and resend the request. The -Cf option suppresses this fix-and-resend feature.

Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires "all or nothing" types of requests.

In addition to this option, snmpgetnext takes the common options described in the [snmpcmd\(1M\)](#) manual page.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	SUNWsmcmd
Interface Stability	External

**Exit Status**

- 0 Successful completion.
- 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
- 2 An error occurred while executing the command. An error message is displayed.

**See Also** [snmpcmd\(1M\)](#), [snmpget\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmpnetstat – show network status using SNMP

**Synopsis** /usr/sfw/bin/snmpnetstat [*common options*] [-a] [-n] *agent*  
 /usr/sfw/sma\_snmp/bin/snmpnetstat [*common options*] [-iorns] *agent*  
 /usr/sfw/sma\_snmp/bin/snmpnetstat [*common options*] [-in]  
 [-I *interface*] *agent* [*interval*]  
 /usr/sfw/sma\_snmp/bin/snmpnetstat [*common options*] [-an]  
 [-s] [-P *protocol*] *agent*

**Description** The `snmpnetstat` command symbolically displays the values of various network-related information retrieved from a remote system using the SNMP protocol. There are a number of output formats, depending on the options for the information presented. Referring to the SYNOPSIS, above:

- The first form of the command displays a list of active sockets.
- The second form presents the values of other network-related information according to the option selected.
- The third form, with an interval specified, continuously displays the information regarding packet traffic on the configured network interfaces.
- The fourth form displays statistics about the named protocol.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor the given objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host. See [snmpcmd\(1M\)](#) for a full list of the possible formats for *agent*.

The version 1 and version 2c community specifies the community name for the transaction with the remote system.

**Options** The following options are supported:

- |                       |                                                                                                                                                                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>common options</i> | See <a href="#">snmpcmd(1M)</a> for a list of possible values for common options, as well as their descriptions.                                                                                                                                                           |
| -a                    | With the default display, show the state of all sockets. Normally, sockets used by server processes are not shown.                                                                                                                                                         |
| -i                    | Show the state of all of the network interfaces. The interface display provides a table of cumulative statistics regarding packets transferred, errors, and collisions. The network addresses of the interface and the maximum transmission unit (MTU) are also displayed. |
| -o                    | Show an abbreviated interface status, giving octets in place of packets. This is useful when observing virtual interfaces (such as Frame Relay circuits) on a router.                                                                                                      |

---

-I <i>interface</i>	Show information only about this interface; used with an interval as described below.
-n	Show network addresses as numbers. (Normally, <code>snmpnetstat</code> interprets addresses and attempts to display them symbolically). This option can be used with any of the display formats.
-P <i>protocol</i>	Show statistics about <i>protocol</i> , which is either a well-known name for a protocol or an alias for it. Some protocol names and aliases are listed in the file <code>/etc/protocols</code> or in a naming service. A null response typically means that there are no interesting numbers to report. The program will complain if <i>protocol</i> is unknown or if there is no statistics routine for it.
-s	Show per-protocol statistics. When used with the <code>-r</code> option, show routing statistics instead.
-r	Show the routing tables. When <code>-s</code> is also present, show per-protocol routing statistics instead of the routing tables.
<i>interval</i>	When <code>snmpnetstat</code> is invoked with an interval argument, it displays a running count of statistics related to network interfaces. <i>interval</i> is the number of seconds between reporting of statistics.

`snmpnetstat` supports the following types of display:

active sockets display (default)

The default display, for active sockets, shows the local and remote addresses, protocol, and the internal state of the protocol. Address formats are of the form *host.port* or *network.port* if a socket's address specifies a network but no specific host address. When known, the host and network addresses are displayed symbolically according to `/etc/hosts` and `/etc/networks`, respectively. If a symbolic name for an address is unknown, or if the `-n` option is specified, the address is printed numerically, according to the address family. For more information regarding the Internet "dot format," refer to [inet\(3SOCKET\)](#). Unspecified, or wildcard, addresses and ports appear as "`\ (**`".

interface display

The interface display provides a table of cumulative statistics regarding packets transferred, errors, and collisions. The network addresses of the interface and the maximum transmission unit (MTU) are also displayed.

## routing table display

The routing table display indicates the available routes and their status. Each route consists of a destination host or network and a gateway to use in forwarding packets. The flags field shows the state of the route (U if the route is up), whether the route is to a gateway (G), whether the route was created dynamically by a redirect (D), and whether the route has been modified by a redirect (M). Direct routes are created for each interface attached to the local host. The gateway field for such entries shows the address of the outgoing interface. The interface entry indicates the network interface used for the route.

## interface display with an interval

When `snmpnetstat` is invoked with an interval argument, it displays a running count of statistics related to network interfaces. This display consists of a column for the primary interface and a column summarizing information for all interfaces. The primary interface can be replaced with another interface with the `-I` option. The first line of each screen of information contains a summary since the system was last rebooted. Subsequent lines of output show values accumulated over the preceding interval.

## active sockets display for a single protocol

When a protocol is specified with the `-P` option, the information displayed is similar to that in the default display for active sockets, except the display is limited to the given protocol.

Note that figures `snmpnetstat` reports in the `Ipkts` column (part of the interface display) might differ from figures in the `Ipkts` column in `netstat(1M)`. `snmpnetstat` displays a total of unicast, multicast, and broadcast packets. `netstat` omits broadcast packets from its total.

**Examples** EXAMPLE 1 Displaying Active Sockets

The following is an example of `snmpnetstat`'s default display, which is to display active sockets.

```
% snmpnetstat -v 2c -c public -a testhost
```

```
Active Internet (tcp) Connections (including servers)
Proto Local Address Foreign Address (state)
```

**EXAMPLE 1** Displaying Active Sockets (Continued)

```

tcp *.echo *.* LISTEN
tcp *.discard *.* LISTEN
tcp *.daytime *.* LISTEN
tcp *.chargen *.* LISTEN
tcp *.ftp *.* LISTEN
tcp *.telnet *.* LISTEN
tcp *.smtp *.* LISTEN

```

## Active Internet (udp) Connections

Proto Local Address

```

udp *.echo
udp *.discard
udp *.daytime
udp *.chargen
udp *.time

```

```
% snmpnetstat -v 2c -c public -i testhost
```

Name	Mtu	Network	Address	Ipkts	Ierrs	Opkts	Oerrs	Queue
eri0	1500	10.6.9/24	testhost	170548881	245601	687976	0	0
lo0	8232	127	localhost	7530982	0	7530982	0	0

**EXAMPLE 2** Displaying Statistics for a Specific Protocol

The following example shows how `snmpnetstat` displays statistics for a specific protocol.

```
% snmpnetstat -v 2c -c public -P tcp testhost
```

## Active Internet (tcp) Connections

Proto Local Address Foreign Address (state)

```

tcp *.echo *.* LISTEN
tcp *.discard *.* LISTEN
tcp *.daytime *.* LISTEN
tcp *.chargen *.* LISTEN
tcp *.ftp *.* LISTEN
tcp *.telnet *.* LISTEN
tcp *.smtp *.* LISTEN

```

**Exit Status** 0 Successful completion.

1 A usage syntax error. A usage message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [iostat\(1M\)](#), [netstat\(1M\)](#), [snmpcmd\(1M\)](#), [vmstat\(1M\)](#), [attributes\(5\)](#)

**Name** snmpset – communicate with a network entity using SNMP SET requests

**Synopsis** snmpset [*common options*] *oid type value* [*oid type value*] . . .

**Description** The snmpset utility is an SNMP application that uses the SNMP SET request to set information on a network entity. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in [snmp\\_variables\(4\)](#).

The *type* is a single character, one of:

```
i INTEGER
u UNSIGNED
c COUNTER32
s STRING
x HEX STRING
d DECIMAL STRING
n NULLOBJ
o OBJID
t TIMETICKS
a IPADDRESS
b BITS
```

If you have the proper MIB file loaded, you can, in most cases, replace the type with an equal sign (=). For an object of type OCTET STRING this assumes a string such as the "s"-type notation. For other types, snmpset interprets the data in the way you would expect.

For example, the command:

```
snmpset -c private -v 1 test-hub system.sysContact.0 s dpz@noc.rutgers.edu
ip.ipforwarding.0 = 2
```

sets the variables `sysContact.0` and `ipForwarding.0`, as follows:

```
system.sysContact.0 = STRING: "dpz@noc.rutgers.edu"
ip.ipForwarding.0 = INTEGER: not-forwarding(2)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

**Options** snmpset takes the common options described in the [snmpcmd\(1M\)](#) manual page.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
  - 2 An error occurred while executing the command. An error message is displayed.

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmptable – obtain and display an SNMP table

**Synopsis** /usr/sfw/bin/snmptable [*common options*] [-Cb] [-CB] [-Cb] [-Ch] [-CH] [-Ci] [-Cf *string*] [-Cw *width*] [*agent*] [*table-oid*]

**Description** The snmptable command is an SNMP application that repeatedly uses the SNMP GETNEXT or GETBULK requests to query for information on a network entity. The operand *table-oid* must specify an SNMP table. Both numeric and symbolic (string) OIDs are supported.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the *agent* specification consists of a hostname or an IPv4 address. With such an address, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See [snmpcmd\(1M\)](#) for a full list of the possible formats for *agent*.

**Options** See [snmpcmd\(1M\)](#) for a list of *common options*. In addition to the *common options*, snmptable supports the options described below.

- Cb Display only a brief heading. Any common prefix of the table field names is not displayed.
- CB Use only GETNEXT, not GETBULK, requests to retrieve data.
- Cf *string* The string *string* is used to separate table columns. With this option, each table entry is printed in compact form, using only the specified string to separate the columns. This option can be useful if you intend to import the table into a database. Without this option, the table is displayed in vertically aligned columns.
- Ch Display only the column headings.
- CH Do not display the column headings or the table name. Only raw data is displayed.
- Ci Prepends the index of the entry to all printed lines.
- Cw *width* Specifies the width of the lines when the table is printed. If a line is longer than *width*, lines are truncated to fit within *width*.

**Examples** EXAMPLE 1 Retrieving an SNMP Table

The following commands retrieve two-column SNMP tables.

```
% snmptable -v 2c -c public localhost at.atTable
```

```
SNMP table: at.atTable RFC1213-MIB::atTable
atIfIndex atPhysAddress atNetAddress
1 8:0:20:20:0:ab 130.225.243.33
```

**EXAMPLE 1** Retrieving an SNMP Table (Continued)

```
% snmptable -v 2c -c public -Cf + localhost at.atTable
```

```
SNMP table: at.atTable
atIfIndex+atPhysAddress+atNetAddress
 1+8:0:20:20:0:ab+130.225.243.33
```

- Exit Status** 0 Successful completion.
- 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
- 2 An error occurred while executing the command. An error message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Bugs** The test for *table-oid* actually specifying a table is not perfect. Note also that the test requires the defining MIB file to be loaded.

**Name** snmpstat – communicate with a network entity using SNMP requests

**Synopsis** /usr/sfw/bin/snmpstat [*common options*] *agent*

**Description** snmpstat is a flexible SNMP application that can monitor and manage information on a network entity.

Invoking snmpstat invokes a command line interpreter that accepts commands. This interpreter enables you to send different types of SNMP requests to target agents.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the target host. See [snmpcmd\(1M\)](#) for a full list of the possible formats for *agent*.

After you invoke snmpstat, the command line interpreter prompts with:

Variable:

At this point you can enter one or more variable names, one per line. A blank line ends the parameter input and sends the request (variables entered) in a single packet to the remote entity. Each variable name is given in the format specified in [snmp\\_variables\(4\)](#). For example, the command:

```
snmpstat -c public -v 1 zeus
Variable: system.sysDescr.0
Variable:
```

...returns information about the request and reply packets, as well as the data:

```
requestid 0x5992478A errstat 0x0 errindex 0x0
system.sysDescr.0 = STRING: "Unix 4.3BSD"
```

The *errstat* value shows the error status code for the call. The possible values for *errstat* are in the header file `/usr/sfw/include/net-snmp/library/snmp.h`. The *errindex* value identifies the variable that has an error. Index values are assigned to all the variables entered at the `Variable:` prompt. The first value is assigned an index of 1.

Upon startup, the program defaults to sending a GET request packet. The type of request can be changed by typing one of the following commands at the `Variable:` prompt:

```
$G Send a GET request.
$N Send a GETNEXT request.
$S Send a SET request.
$B Send a GETBULK request. Note that GETBULK is not available in SNMPv1.
$I Send an inform request.
```

\$T Send an SNMPv2 trap request.

Other values that can be entered at the Variable: prompt are:

\$D Toggle the dumping of each sent and received packet.

\$QP Toggle a quicker, less verbose output form.

\$Q Quit the program.

The following are valid request types:

GET request When in "GET request" mode (\$G or default), you can enter an OID at the Variable: prompt. You can enter multiple OIDs, one per prompt. Enter a blank line to send the GET request.

GETNEXT request The "GETNEXT request" mode (\$N) is similar to the "GET request" mode, described above.

SET request When in the "SET request" mode (\$S), more information is requested by the prompt for each variable. The prompt:

Type [i|s|x|d|n|o|t|a]:

...requests the type of the variable be entered. Depending on the type of value you want to set, type one of the following:

- i integer
- u unsigned integer
- s octet string in ASCII
- x octet string in hex bytes, separated by whitespace
- d octet string as decimal bytes, separated by whitespace
- a IP address in dotted IP notation
- o object identifier
- n null
- t timeticks

At this point a value will be prompted for. To enter an integer value, just type the integer (in decimal). If it is a decimal string, type in whitespace-separated decimal numbers, one per byte of the string. Again, enter a blank line at the prompt for the variable name to send the packet.

GETBULK request The "GETBULK request" mode (\$B) is similar to the "SET request" mode. Note, however, that GETBULK is not available in SNMPv1.

Inform request	The "Inform request" mode (\$I) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the <i>agent</i> specified in the snmpptest command should correspond to the target snmptrapd agent.
SNMPv2 trap request	The "SNMPv2 trap request" mode (\$T) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the <i>agent</i> specified in the snmpptest command should correspond to the target snmptrapd agent.

**Options** snmpptest takes the common options described in the [snmpcmd\(1M\)](#).

**Examples** **EXAMPLE 1** Sending a GET Request for Two OIDs

The following is an example of sending a GET request for two OIDs:

```
% snmpptest -v 2c -c public testhost:161

Variable: system.sysDescr.0
Variable: system.sysContact.0
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD63 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysDescr.0 = STRING: SunOS testhost 5.9 Generic_112233-02 sun4u
SNMPv2-MIB::sysContact.0 = STRING: x1111
```

**EXAMPLE 2** Sending a GETNEXT Request

The following is an example of sending a GETNEXT request:

```
Variable: $N
Request type is Getnext Request
Variable: SNMPv2-MIB::sysORUpTime.1
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD64 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysORUpTime.2 = Timeticks: (6) 0:00:00.06
Variable:
```

**EXAMPLE 3** Sending a SET Request

The following is an example of sending a SET request:

```
Variable: $S
Request type is Set Request
Variable: system.sysLocation.0
Type [i|u|s|x|d|n|o|t|a]: s
Value: building 17
Variable:
Received Get Response from 128.2.56.220
```

**EXAMPLE 3** Sending a SET Request *(Continued)*

```
requestid 0x7D9FCD65 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysLocation.0 = STRING: building A
Variable:
```

**EXAMPLE 4** Sending a GETBULK Request

The following is an example of sending a GETBULK request:

```
Variable: $B
Request type is Bulk Request
Enter a blank line to terminate the list of non-repeaters
and to begin the repeating variables
Variable:
Now input the repeating variables
Variable: system.sysContact.0
Variable: system.sysLocation.0
Variable:
What repeat count? 2
Received Get Response from 128.2.56.220
requestid 0x2EA7942A errstat 0x0 errindex 0x0
SNMPv2-MIB::sysName.0 = STRING: testhost
SNMPv2-MIB::sysORLastChange.0 = Timeticks: (58) 0:00:00.58
SNMPv2-MIB::sysLocation.0 = STRING: bldg A
SNMPv2-MIB::sysORID.1 = OID: IF-MIB::ifMIB
Variable:
```

**EXAMPLE 5** Sending an Inform Request

The following is an example of sending an Inform request:

```
snmpptest -v 2c -c public snmptrapd_host:162
Variable: $I
Request type is Inform Request
(Are you sending to the right port?)
Variable: system.sysContact.0
Type [i|u|sIx|d|n|o|t|a]: s
Value: x12345
Variable:
Inform Acknowledged
Variable:
```

The snmptrapd\_host will show:

```
snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sysContact.0 = STRING: x12345
```

**EXAMPLE 6** Sending an SNMPv2 Trap Request

The following is an example of sending an SNMPv2 Trap request:

**EXAMPLE 6** Sending an SNMPv2 Trap Request (Continued)

```

snmpstat -v 2c -c public snmptrapd_host:162
Variable: $T
Request type is SNMPv2 Trap Request
(Are you sending to the right port?)
Variable: system.sysLocation.0
Type [i|u|s|x|d|n|o|t|a]: s
Value: building a
Variable:

The snmptrapd_host will show:

snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sys.0 = STRING:
building A

```

**Exit Status** 0 Successful completion.

1 A usage syntax error. A usage message is displayed. Also used for timeout errors.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmpget\(1M\)](#), [snmpset\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmptranslate – translate SNMP OID values into a more useful form

**Synopsis** /usr/sfw/bin/snmptranslate [-D *token*...] [-h] [-m *miblist*]  
[-M *dirlist*] [-T *transopts*] [*common options*] *OID*  
[*OID*]...

**Description** snmptranslate is an application that translates one or more SNMP object identifier values from their symbolic (text) forms into their numerical forms or vice-versa.

*OID* is either a numeric or text object identifier.

**Options** The following options are supported:

-D *token*[,...] Turn on debugging output for the specified *token*(s). Use ALL for extremely verbose output.

-h Display a brief usage message and then exit.

-m *miblist* Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.

The special keyword ALL is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with "." is parsed as if it were a MIB file.

-M *dirlist* Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.

-T *transopts* Provides control over the translation of the OID values. The following *transopts* are available:

-Td Display full details of the specified OID.

-Tp Display a graphical tree, rooted at the specified OID.

-Ta Dump the loaded MIB in a trivial form.

-Tl Dump a labeled form of all objects.

-To Dump a numeric form of all objects.

-Ts Dump a symbolic form of all objects.

-Tt Dump a tree form of the loaded MIBs (mostly useful for debugging).

-V Display version information for the application and then exit.

-w *width* Specifies the width of -Tp and -Td output. The default is very large.

In addition to the preceding options, `snmptranslate` takes the OID input (-I), MIB parsing (-M) and OID output (-O) options described in the INPUT OPTIONS, MIB PARSING OPTIONS and OUTPUT OPTIONS sections of `snmpcmd(1M)`.

### Examples EXAMPLE 1 Expanding sysDescr

The following command translates `sysDescr` to a more qualified form:

```
% snmptranslate -On -IR sysDescr

.1.3.6.1.2.1.1.1
```

The following command does further translation of `sysDescr`:

```
% snmptranslate -Onf -IR sysDescr

.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
```

Again, the following command does further translates `sysDescr`:

```
% snmptranslate -Td -IR -OS system.sysDescr

SNMPv2-MIB::sysDescr
sysDescr OBJECT-TYPE
-- FROM SNMPv2-MIB
-- TEXTUAL CONVENTION DisplayString
SYNTAX OCTET STRING (0..255)
DISPLAY-HINT "255a"
MAX-ACCESS read-only
STATUS current
DESCRIPTION "A textual description of the entity. This
value should include the full name and
version identification of the system's
hardware type, software operating-system,
and networking software."
::= { iso(1) org(3) dod(6) internet(1) mgmt(2) mib-2(1) system(1) 1 }
```

### EXAMPLE 2 Displaying a Tree

The following command displays the tree shown below:

```
% snmptranslate -Tp -IR -OS system

+--system(1)
|
+-- -R-- String sysDescr(1)
| Textual Convention: DisplayString
| Size: 0..255
+-- -R-- ObjID sysObjectID(2)
+-- -R-- TimeTicks sysUpTime(3)
```

**EXAMPLE 2** Displaying a Tree *(Continued)*

```

| |
| +-- sysUpTimeInstance(0)
|
+-- -RW- String sysContact(4)
| Textual Convention: DisplayString
| Size: 0..255
+-- -RW- String sysName(5)
| Textual Convention: DisplayString
| Size: 0..255
+-- -RW- String sysLocation(6)
| Textual Convention: DisplayString
| Size: 0..255
+-- -R-- INTEGER sysServices(7)
| Range: 0..127
+-- -R-- TimeTicks sysORLastChange(8)
| Textual Convention: TimeStamp
|
+--sysORTable(9)
|
+--sysOREntry(1)
| Index: sysORIndex(1)
|
+-- ---- INTEGER sysORIndex(1)
| Range: 1..2147483647
+-- -R-- ObjID sysORID(2)
+-- -R-- String sysORDescr(3)
| Textual Convention: DisplayString
| Size: 0..255
+-- -R-- TimeTicks sysORUpTime(4)
| Textual Convention: TimeStamp

```

**EXAMPLE 3** Dumping MIB Contents

The commands shown below produce the dumps that follow.

```

% snmptranslate -Ta | head

dump DEFINITIONS ::= BEGIN
org ::= { iso 3 }
dod ::= { org 6 }
internet ::= { dod 1 }
directory ::= { internet 1 }
mgmt ::= { internet 2 }
experimental ::= { internet 3 }
private ::= { internet 4 }

```

**EXAMPLE 3** Dumping MIB Contents (Continued)

```
security ::= { internet 5 }
snmpV2 ::= { internet 6 }
```

Here is use of the `-Tl` option:

```
% snmptranslate -Tl | head

.iso(1).org(3)
.iso(1).org(3).dod(6)
.iso(1).org(3).dod(6).internet(1)
.iso(1).org(3).dod(6).internet(1).directory(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysDescr(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysObjectID(2)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysUpTime(3)
```

Here is the use of the `-To` option:

```
% snmptranslate -To | head

.1.3
.1.3.6
.1.3.6.1
.1.3.6.1.1
.1.3.6.1.2
.1.3.6.1.2.1
.1.3.6.1.2.1.1
.1.3.6.1.2.1.1.1
.1.3.6.1.2.1.1.2
.1.3.6.1.2.1.1.3
```

Here is the use of the `-Ts` option:

```
% snmptranslate -Ts | head

.iso.org
.iso.org.dod
.iso.org.dod.internet
.iso.org.dod.internet.directory
.iso.org.dod.internet.mgmt
.iso.org.dod.internet.mgmt.mib-2
.iso.org.dod.internet.mgmt.mib-2.system
.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
.iso.org.dod.internet.mgmt.mib-2.system.sysObjectID
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime
```

**EXAMPLE 3** Dumping MIB Contents *(Continued)*

Here is the use of the `-Tt` option:

```
% snmptranslate -Tt | head

org(3) type=0
dod(6) type=0
 internet(1) type=0
 directory(1) type=0
 mgmt(2) type=0
 mib-2(1) type=0
 system(1) type=0
 sysDescr(1) type=2 tc=4 hint=255a
 sysObjectID(2) type=1
 sysUpTime(3) type=8
```

- Exit Status** 0 Successful completion.
- 1 A usage syntax error. A usage message is displayed. Also used for matching object errors, after which an error message is displayed.
- 2 An error occurred while executing the command. An error message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmptrap, snmpinform – send an SNMP trap to a manager

**Synopsis** `snmptrap -v 1 [common options] [-Ci] enterprise-oid agent generic-trap specific-trap uptime [oid type value]...`

`snmptrap -v {2c | 3} [common options] [-Ci] uptime trap-oid [oid type value]...`

`snmptrap -v {2c | 3} [common options] uptime trap-oid [oid type value]...`

**Description** The `snmptrap` utility is an SNMP application that uses the SNMP TRAP operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in [snmp\\_variables\(4\)](#).

When invoked as `snmpinform`, or when you specify the `-Ci` option to `snmptrap`, it sends an INFORM-PDU, expecting a response from the trap receiver, and retransmitting if required. Otherwise, it sends a TRAP-PDU or TRAP2-PDU.

If any of the required version 1 parameters—`enterprise-oid`, `agent`, and `uptime`—are specified as empty, they default to 1.3.6.1.4.1.3.1.1 (`enterprises.cmu.1.1`), `hostname`, and `host-uptime` respectively.

The *type* is a single character, one of:

```
i INTEGER
u UNSIGNED
c COUNTER32
s STRING
x HEX STRING
d DECIMAL STRING
n NULLOBJ
o OBJID
t TIMETICKS
a IPADDRESS
b BITS
```

For example, the following command sends a generic linkUp trap to manager, for interface 1:

```
snmptrap -v 1 -c public manager enterprises.spider test-hub 3 0 ''
interfaces.iftable.ifentry.ifindex.1 i 1
```

**Options** The following option is supported:

`-Ci` Sends an INFORM-PDU, as described above. Applies only to `snmptrap`. This option provides the equivalent function of `snmpinform`.

In addition to this option, `snmptrap` takes the common options described in the [snmpcmd\(1M\)](#) manual page.

**Exit Status** 0 Successful completion.

- 1 A usage syntax error. A usage message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**See Also** [snmpcmd\(1M\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmptrapd – receive and log SNMP trap messages

**Synopsis** /usr/sfw/sbin/snmptrapd [*options*] [*listening addresses*]

**Description** The snmptrapd utility is an SNMP application that receives and logs SNMP TRAP and INFORM messages.

The default is to listen on UDP port 162 on all IPv4 interfaces. Because 162 is a privileged port, snmptrapd must be run as root.

**Options** This command supports the following options:

- a Ignore authenticationFailure traps.
- c *file* Read *file* as a configuration file.
- C Do not read any configuration files except the one optionally specified by the -c option.
- d Dump (in hexadecimal) the sent and received SNMP packets.
- D *token*[,...] Turn on debugging output for the specified *token*(s). Use ALL for extremely verbose output.
- e Print event numbers (rising/falling alarm, and so forth).
- f Do not call fork() from the calling shell.
- F *format* When logging to standard output, use the format in the string *format*. See *Format Specifications* below for more details.
- h, --help Display a brief usage message and then exit.
- H Display a list of configuration file directives understood by the trap daemon and then exit.
- l d | 0-7 Specifies the [syslog\(3C\)](#) facility to use when logging to syslog. d means LOG\_DAEMON; 0 through 7 means LOG\_LOCAL0 through LOG\_LOCAL7. LOG\_LOCAL0 is the default.
- m *miblist* Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable MIBS.
- M *dirlist* Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable MIBDIRS.
- n Do not attempt to translate source addresses of incoming packets into host names.
- o *file* Log formatted incoming traps to *file*. Upon receipt of a SIGHUP, the daemon will close and reopen the log file. This feature is useful when rotating the log file with other utilities such as logrotate.

- P Print formatted incoming traps to `stderr`.
- s Log formatted incoming traps to `syslog(3C)`. These `syslog` messages are sent with a level of `LOG_WARNING` and facility as determined by the `-l` flag (`LOG_LOCAL0` by default). This is the default unless you use the `-o` or `-P` flag.
- u *file* Save the process ID of the trap daemon in *file*.
- v, --version Print version information for the trap daemon and then exit.

In addition to the preceding options, `snmptrapd` takes the same output formatting options as the other Net-SNMP commands. See the section *OUTPUT OPTIONS* in `snmpcmd(1M)`.

For extensibility and configuration information, see `snmptrapd.conf(4)`.

**Format Specifications** `snmptrapd` interprets format strings similarly to `printf(3C)`. It interprets the following formatting sequences:

- %% A literal percent sign(%).
- %t Decimal number of seconds since the operating system's epoch, as returned by `time(2)`.
- %y Current year on the local system.
- %m Current (numeric) month on the local system.
- %l Current day of month on the local system.
- %h Current hour on the local system.
- %j Current minute on the local system.
- %k Current second on the local system.
- %T The value of the `sysUpTime.0 varbind` in seconds.
- %Y The year field from the `sysUpTime.0 varbind`.
- %M The numeric month field from the `sysUpTime.0 varbind`.
- %L The day of month field from the `sysUpTime.0 varbind`.
- %H The hour field from the `sysUpTime.0 varbind`.
- %J The minute field from the `sysUpTime.0 varbind`.
- %K The seconds field from the `sysUpTime.0 varbind`.
- %a The contents of the `agent-addr` field of the PDU (v1 TRAPs only).
- %A The hostname corresponding to the contents of the `agent-addr` field of the PDU, if available. Otherwise the contents of the `agent-addr` field of the PDU (v1 TRAPs only).
- %b PDU source address (note that this is not necessarily an IPv4 address).

---

%B	PDU source hostname if available, otherwise PDU source address (which is not necessarily an IPv4 address).
%N	Enterprise string.
%w	Trap type (numeric, in decimal).
%W	Trap description.
%q	Trap sub-type (numeric, in decimal).
%P	Security information from the PDU (community name for v1/v2c, user and context for v3).
%v	List of trap's variable-bindings.

In addition to these values, you can also specify an optional field width and precision, just as in [printf\(3C\)](#), and a flag value. The following flags are valid:

- left justify
- 0 use leading zeros
- # use alternate form

The "use alternate form" flag changes the behavior of some format flags. Normally, the fields that display time information base it on the local timezone, but this flag tells them to use GMT instead. Also, the variable-binding list is normally a tab-separated list, but this flag changes it to a comma-separated one. The alternate form for the uptime is similar to "3 days, 0:14:34.65".

**Listening Addresses** By default, `snmptrapd` listens for incoming SNMP TRAP and INFORM packets on UDP port 162 on all IPv4 interfaces. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to `snmptrapd`. See [snmpd\(1M\)](#) for more information about the format of listening addresses.

### NOTIFICATION-LOG-MIB Support

As of Net-SNMP 5.0, the `snmptrapd` application supports the NOTIFICATION-LOG-MIB. It does this by opening an AgentX subagent connection to the master `snmpd` agent and registering the notification log tables. As long as the `snmpd` application is started first, it will attach itself to it. Thus you should be able to view the last recorded notifications by means of the `nMLogTable` and `nMLogVariableTable`. See [snmptrapd.conf\(4\)](#) and the `dontRetainLogs` token for turning off this support. See the NOTIFICATION-LOG-MIB for more details about the MIB itself.

### Examples

**EXAMPLE 1** Using `snmptrapd`

To get a message such as `14:03 TRAP3.1 from humpty.example.edu` you can use a command similar to:

```
snmptrapd -P -F "%02.2h:%02.2j TRAP%.%q from %A\n"
```

**EXAMPLE 1** Using snmptrapd (Continued)

If you want the same effect, but in GMT rather than local time, use:

```
snmptrapd -P -F "%#02.2h:%#02.2j TRAP%w.%q from %A\n"
```

**EXAMPLE 2** Viewing Traps on the Host on Which You Invoke snmptrapd

To view traps on the host from which you invoke snmptrapd, enter:

```
snmptrapd -P
```

The preceding command sends output to stdout rather than to a log file.

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmagt
Interface Stability	Stable

**See Also** [snmpcmd\(1M\)](#), [snmpd\(1M\)](#), [printf\(3C\)](#), [syslog\(3C\)](#), [snmptrapd.conf\(4\)](#), [snmp\\_variables\(4\)](#), [attributes\(5\)](#)

**Name** snmpusm – create and maintain SNMPv3 users on a remote entity

**Synopsis** snmpusm [*common options*] AGENT create user [*clonefrom-user*]  
 snmpusm [*common options*] AGENT delete user  
 snmpusm [*common options*] AGENT cloneFrom user clonefrom-user  
 snmpusm [*common options*] [-Co] [-Ca] [-Cx] AGENT passwd old-passphrase new-passphrase

**Description** The snmpusm utility is an SNMP application that can be used to do simple maintenance on an SNMP agent's User-based Security Module (USM) table. The user needs write access to the usmUserTable MIB table. You can create, delete, clone, and change the passphrase of users configured on a running SNMP agent.

The SNMPv3 USM specifications (see RFC 3414) dictate that users are created and maintained by adding and modifying rows to the usmUserTable MIB table. To create a new user you simply create the row using [snmpset\(1M\)](#). User's profiles contain private keys that are never transmitted over the wire in clear text, regardless of whether the administration requests are encrypted.

The secret key for a user is initially set by cloning another user in the table, so that a new user inherits the cloned user's secret key. A user can be cloned only once, however, after which they must be deleted and re-created to be re-cloned. The authentication and privacy security types are also inherited during this cloning (for example, MD5 vs. SHA1). To change the secret key for a user, you must know the user's old passphrase as well as the new one. The passwd subcommand of the snmpusm command requires both the new and the old passphrases be supplied. After cloning from the appropriate template, you should immediately change the new user's passphrase.

The Net-SNMP agent must first be initialized so that at least one user is setup in it before you can use this command to clone new ones. See the [snmpd.conf\(4\)](#) manual page for a description of the createUser configuration parameter.

Passphrases must be a minimum of eight characters in length.

**Options** See [snmpcmd\(1M\)](#) for a description of *common options*.

**Examples** Assume for our examples that the following VACM and USM configurations lines are in the snmpd.conf file for a Net-SNMP agent. These lines set up a default user named initial with the authentication passphrase setup\_passphrase. Establishing these parameters enables the initial setup of an agent.

```
VACM configuration entries
rwuser initial
The name of the new user that is going to be created
rwuser wes
USM configuration entries
createUser initial MD5 setup_passphrase DES
```

Note that the `initial` user's setup should be removed after creating a real user to whom you grant administrative privileges. The real user is `wes` in this example.

#### EXAMPLE 1 Creating a New User

The following command creates a new user, `wes`, which is cloned from `initial`. `wes` inherits that user's passphrase, `setup_passphrase`.

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create wes initial
```

#### EXAMPLE 2 Changing the User's Passphrase

After creating the user `wes` with the same passphrase as the user `initial`, we need to change his passphrase for `wes`. The following command changes it from `setup_passphrase`, which was inherited from `initial`, to `new_passphrase`.

```
snmpusm -v 3 -u wes -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost passwd setup_passphrase new_passphrase
```

#### EXAMPLE 3 Testing the New User

If the preceding commands were successful, the following command should perform an authenticated SNMPv3 GET request to the agent.

```
snmpget -v 3 -u wes -n "" -l authNoPriv -a MD5 -A new_passphrase \
localhost sysUpTime.0
```

Following a successful test, remove the VACM group `snmpd.conf` entry for the user `initial`. At this point, you have a valid user `wes` that you can use for future transactions.

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
  - 2 An error occurred while executing the command. An error message is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

RFC 3414

**Name** snmpvacm – perform maintenance on an SNMP agent's View-based Access Control Module (VACM) table

**Synopsis** /usr/sfw/bin/snmpvacm [*common options*] [*subcommand options*] AGENT subcommand subcommand-arg

**Description** snmpvacm is a SNMP application that can be used to do maintenance on an SNMP agent's View-based Access Control Module (VACM) table. The VACM table defines a set of services that can be used for checking access rights, that is, checking whether a specific type of access to a specific managed object is allowed. snmpvacm supports three types of entries--group, view, and access. The agent maintains these entries in memory and stores VACM groups, views, and access entries in the persistent configuration file upon agent shutdown.

**Subcommands** This section describes the snmpvacm subcommands.

**createSec2Group** Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

snmpvacm [*common options*] createSec2Group MODEL SECURITYNAME GROUPNAME

**MODEL** An integer greater than zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

- 1 reserved for SNMPv1
- 2 reserved for SNMPv2c
- 3 User-Based Security Model (USM)

**SECURITYNAME** A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a GROUPNAME.

**GROUPNAME** A string that identifies the group to which this table entry (the combination of securityModel and securityName) belongs.

**deleteSec2Group** Deletes SNMPv3 security to group name entries. The group entry to be deleted is indexed by the specified MODEL and SECURITYNAME.

snmpvacm [*common options*] deleteSec2Group MODEL SECURITYNAME

**MODEL** An integer greater than zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

- 1 reserved for SNMPv1

- 2 reserved for SNMPv2c
- 3 User-Based Security Model (USM)

**SECURITYNAME** A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a **GROUPNAME**.

**createView** Creates a MIB view. A MIB view is a family of view subtrees, which are pairings of OID subtree values with bit string mask values.

Each MIB view is defined by two sets of view subtrees, included in or excluded from the MIB view.

`snmpvacm [common options] [-Ce] createView NAME SUBTREE MASK`

**-Ce** An optional flag used when the MIB view type needs to be "excluded" from the MIB view. If not used, the type is defaulted to "included".

**NAME** The OID subtree which when combined with the corresponding instance of **MASK** defines a family of view subtrees.

**SUBTREE** The OID subtree which when combined with the corresponding instance of **MASK** defines a family of view subtrees.

**MASK** The bit mask, a hex string, which, in combination with the corresponding instance **SUBTREE**, defines a family of view subtrees.

The mask indicates which sub-identifiers of the associated subtree OID are significant to a particular MIB view instance.

**deleteView** Deletes a MIB view. A MIB view is a family of view subtrees. A view subtree is a pairing of an OID subtree value with a bit string mask value.

`snmpvacm [common options] deleteView NAME SUBTREE`

**NAME** A string representing a MIB view name that is associated to a subtree/mask pairing.

**SUBTREE** The OID subtree which, when combined with the corresponding instance of **MASK**, defines a family of view subtrees.

**createAccess** Creates SNMPv3 access configuration entries. These entries are used to store the access rights defined for the groups. Each entry is indexed by a

group name, a context prefix, a security model, and a security level. A group and view needs to be defined in order to make use of the access check.

```
snmpvacm [common options] createAccess GROUPNAME
[CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
CONTEXTMATCH READVIEWNAME WRITEVIEWNAME
NOTIFYVIEWNAME
```

GROUPNAME	The name of the group to which this access right applies.
CONTEXTPREFIX	<p>A string representing a contextName must match the value of the instance of this object exactly when CONTEXTMATCH is set to "exact" or partially when CONTEXTMATCH is set to "prefix".</p> <p>If not specified, the value reverts to the default, an empty string, "".</p>
SECURITYMODEL	An integer representing the securityModel that must be used in order to gain access to this access right.
SECURITYLEVEL	<p>An integer representing the minimum security level that must be used to gain access to this access right. A security level of noAuthNoPriv is less than authNoPriv and authNoPriv is less than authPriv.</p> <p>Integer values supported:</p> <ol style="list-style-type: none"> <li>1 noAuthNoPriv</li> <li>2 authNoPriv</li> <li>3 authPriv</li> </ol>
CONTEXTMATCH	<p>An integer whose value determines the type of match required. When set to "exact", the context name must exactly match the value in CONTEXTPREFIX. If set to "prefix", the context name must match the first few starting characters of the value in CONTEXTPREFIX.</p> <p>Integer values supported:</p> <ol style="list-style-type: none"> <li>1 exact</li> <li>2 prefix</li> </ol>

	READVIEWNAME	The authorized MIB view name used for read access. If the value is an empty string, then there is no active view configured for read access.
	WRITEVIEWNAME	The authorized MIB view name used for write access. If the value is an empty string, then there is no active view configured for write access.
	NOTIFYVIEWNAME	The authorized MIB view name used for notify access. If the value is an empty string, then there is no active view configured for notify access.
deleteAccess		Deletes SNMPv3 access configuration entries, given a group name, context prefix, security model, and security level.
		snmpvacm [common options] deleteAccess GROUPNAME [CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
	GROUPNAME	The name of the group to which this access right applies.
	CONTEXTPREFIX	A string representing a contextName must match the value of the instance of this object exactly when CONTEXTMATCH is set to "exact" or partially when CONTEXTMATCH is set to "prefix".
	SECURITYMODEL	An integer representing the securityModel that must be used to gain access to this access right.
	SECURITYLEVEL	An integer representing the minimum security level that must be used to gain access to this access right. A security level of noAuthNoPriv is less than authNoPriv and authNoPriv is less than authPriv.
		The following integer values are supported:
		1 noAuthNoPriv
		2 authNoPriv
		3 authPriv

**Examples** For the following examples, the user is my\_user and the password is my\_password. Use net-snmp-config to create the first user (my\_user). Then clone my\_user to configure another SNMPv3 user, my\_user\_2. See [snmpusm\(1M\)](#).

**EXAMPLE 1** Creating a VACM Group Entry  
Create a VACM group entry, as follows:

**EXAMPLE 1** Creating a VACM Group Entry *(Continued)*

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost createSec2Group
 3 my_user_2 my_group
```

Run [snmpwalk\(1M\)](#) to verify the group name was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost
 SNMP-VIEW-BASED-ACM-MIB::vacmGroupName
```

In addition to other configured VACM group entries, you will note an entry such as the following:

```
SNMP-VIEW-BASED-ACM-MIB::vacmGroupName.3."my_user_2" = STRING: my_group
```

**EXAMPLE 2** Creating a MIB View Entry

The command below creates a MIB view entry applicable only to the system group MIB.

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost createView
 my_view .1.3.6.1.2.1.1 FF
```

Run [snmpwalk\(1M\)](#) to verify the my\_view MIB view was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost
 SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyTable
```

In `snmpwalk` output, observe the lines, such as those below, related to the my\_view MIB view.

```
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyMask."my_view".2.1.3.6.1.2.1.1\
= Hex-STRING: FF
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyType."my_view".2.1.3.6.1.2.1.1\
= INTEGER: included(1)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStorageType.\
"my_view".2.1.3.6.1.2.1.1 = INTEGER: nonVolatile(3)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStatus.\
"my_view".2.1.3.6.1.2.1.1 = INTEGER: active(1)
```

**EXAMPLE 3** Creating an Access Entry

The command below creates an access entry using the following components:

- the "my\_group" entry created above
- an empty prefix string ("")
- the USM security model (3)
- the security level (3)

**EXAMPLE 3** Creating an Access Entry (Continued)

- the context match (1)
- the read view name ("my\_view")
- the write view name ("")
- the notify view name ("")

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost createAccess
 my_group "" 3 3 1 my_view "" ""
```

Run `snmpwalk(1M)` to verify the access entry was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
 my_password -x DES -X my_password localhost
 SNMP-VIEW-BASED-ACM-MIB::vacmAccessTable
```

```
SNMP-VIEW-BASED-ACM-MIB::vacmAccessContextMatch."my_group"."".3.authPriv\
= INTEGER: exact(1)
SNMP-VIEW-BASED-ACM-MIB::vacmAccessReadViewName."my_group"."".3.authPriv\
= STRING: my_view
SNMP-VIEW-BASED-ACM-MIB::vacmAccessWriteViewName."my_group"."".3.authPriv\
= STRING:
SNMP-VIEW-BASED-ACM-MIB::vacmAccessNotifyViewName."my_group"."".3.authPriv\
= STRING:
SNMP-VIEW-BASED-ACM-MIB::vacmAccessStorageType."my_group"."".3.authPriv\
= INTEGER: nonVolatile(3)
SNMP-VIEW-BASED-ACM-MIB::vacmAccessStatus."my_group"."".3.authPriv\
= INTEGER: active(1)
```

**EXAMPLE 4** Testing the Configuration

Test the preceding setup by verifying the access setup. You do this by accessing an object in the system group and another object outside this range. Note the use of the user name `my_user_2`.

```
snmpget -mALL -v 3 -u my_user_2 -l authPriv -a MD5
 -A my_password -x DES -X my_password localhost sysObjectID.0
```

At this point, when you to access an object outside the access range, the attempt fails with an appropriate error:

```
snmpgetnext -mALL -v 3 -u my_user_2 -l authPriv -a MD5
 -A my_password -x DES -X my_password localhost ifTable
```

```
RFC1213-MIB::ifTable = No more variables left in this MIB View (It is
 past the end of the MIB tree)
```

- Exit Status**
- 0 Successful completion.
  - 1 A usage syntax error. A usage message displays. Also used for time out errors.
  - 2 An error occurred while executing the command. An error message displays.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

*RFC 3415*

**Name** snmpwalk – communicate with a network entity using SNMP GETNEXT requests

**Synopsis** snmpwalk [*application options*] [*common options*] [*oid*]

**Description** The snmpwalk utility is an SNMP application that uses SNMP GETNEXT requests to query a network entity for a tree of information.

You can specify an object identifier (OID) on the command line. This OID specifies which portion of the object identifier space will be searched using GETNEXT requests. All variables in the subtree below the specified OID are queried and their values returned. Each variable name must be entered in the format specified in [snmp\\_variables\(4\)](#).

If no OID argument is present, snmpwalk searches MIB-2. If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message “End of MIB” is displayed.

**Options** The following options are supported:

- Cc Do not check whether the returned OIDs are increasing. Some agents (for example, agents for Laser-Jet printers) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause snmpwalk to loop indefinitely. By default, snmpwalk tries to detect this behavior and warns you when it encounters an agent acting illegally. Use -Cc to turn off this feature.
- Ci Include the given OID in the search range. Normally, snmpwalk uses GETNEXT requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. This option allows you to include the OID specified on the command line in the displayed results (assuming the OID is a valid OID in the tree).
- Cp Upon completion of the walk, display the number of variables found.

In addition to these options, snmpwalk takes the common options described in the [snmpcmd\(1M\)](#) manual page.

**Examples** EXAMPLE 1 Retrieving All of the Variables Under system

The following command retrieves all of the variables under system:

```
snmpwalk -Os -c public -v 1 zeus system
```

Output from this command will be similar to:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
```

**EXAMPLE 1** Retrieving All of the Variables Under system (Continued)

```
sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

**Exit Status**

- 0 Successful completion.
- 1 A usage syntax error. A usage message is displayed. Also used for timeout errors.
- 2 An error occurred while executing the command. An error message is displayed.

**Name** snmpXdmid – Sun Solstice Enterprise SNMP-DMI mapper subagent

**Synopsis** `/usr/lib/dmi/snmpXdmid -s hostname [-h] [-c config-dir]  
[-d debug-level]`

**Description** The `snmpXdmid` utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (`snmpdx(1M)`) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to `snmpdx`. By default, `snmpXdmid` also forwards the DMI indications as SNMP traps to `snmpdx`. The feature is configurable and can be disabled by setting `TRAP_FORWARD_TO_MAGENT=0` in the `snmpXdmid` configuration file, `snmpXdmid.conf`.

This subagent runs as a daemon in the system. The subagent uses a set of `.MAP` files located in `/var/dmi/map` to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, `miftomib`. They are read by `snmpXdmid` when a corresponding MIF file gets registered with the DMI Service Provider (`dmispd(1M)`).

**Note** – The SMA (Systems Management Agent) is the default SNMP agent in Solaris. See `sma_snmp(5)`. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

The `snmpXdmid.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are:

**WARNING\_TIMESTAMP**

Indication subscription expiration, warning time.

**EXPIRATION\_TIMESTAMP**

Indication subscription expiration timestamp.

**FAILURE\_THRESHOLD**

DMISP retries before dropping indication due to comm errors.

**TRAP\_FORWARD\_TO\_MAGENT**

0 Drop indication at the subagent level.

non-zero Forward indications as SNMP traps to `snmpdx`.

By default, the configuration file `snmpXdmid.conf` is located in the `/etc/dmi/conf` directory. You can specify an alternative directory with the `-c` option.

**Options** The following options are supported:

`-c config-dir` Specify the directory where `snmpXdmid.conf` file is located.

`-d debug-level` Debug. Levels from 1 to 5 are supported, giving various levels of debug information.

- 
- h Help. Print the command line usage.  
-s *hostname* Specify the host on which dmispd is running.

**Files** /etc/dmi/conf/snmpXdmi.conf DMI mapper configuration file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadmi
Interface Stability	Obsolete

**Name** snmpXwbemd – SNMP Adapter Subagent for WBEM

**Synopsis** /usr/sadm/lib/wbem/snmpXwbemd [-d] [-h] [-p *port*]

**Description** The snmpXwbemd daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package.

This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent [snmpdx\(1M\)](#) into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into a SNMP response, which it passes back to [snmpdx\(1M\)](#).

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.

**Options** The following options are supported:

- d Displays all debug information.
- h Displays help by printing the correct command line usage.
- p Specifies the port number to use.

**Operands** The following operand is supported:

*port* Specifies the port number you want to use.

**Examples** EXAMPLE 1 An Example of a 050SUNWwbcou.map File

This mapping file that Sun Microsystems provides contains definitions of objects, in this format:

```
#
#pragma ident "@(#)050SUNWwbcou.map 1.0 01/04/03 SMI"
#
Copyright (c) 2001 by Sun Microsystems, Inc.

**Name** snoop – capture and inspect network packets

**Synopsis** snoop [-aqrCDNPSvV] [-t [r | a | d]] [-c *maxcount*]  
 [-d *device*] [-i *filename*] [-n *filename*] [-o *filename*]  
 [-p *first* [, *last*]] [-s *snaplen*] [-x *offset* [, *length*]]  
 [*expression*]

**Description** snoop captures packets from the network and displays their contents. snoop uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file (which is *RFC 1761*-compliant) for later inspection.

snoop can display packets in a single-line summary form or in verbose multi-line forms. In summary form, with the exception of certain VLAN packets, only the data pertaining to the highest level protocol is displayed. If a packet has a VLAN header and its VLAN ID is non-zero, then snoop will show that the packet is VLAN tagged. For example, an NFS packet will have only NFS information displayed. Except for VLAN information under the condition just described, the underlying RPC, UDP, IP, and Ethernet frame information is suppressed, but can be displayed if either of the verbose options are chosen.

In the absence of a name service, such as LDAP or NIS, snoop displays host names as numeric IP addresses.

snoop requires an interactive interface.

- Options**
- C List the code generated from the filter expression for either the kernel packet filter, or snoop's own filter.
  - D Display number of packets dropped during capture on the summary line.
  - N Create an IP address-to-name file from a capture file. This must be set together with the -i option that names a capture file. The address-to-name file has the same name as the capture file with *.names* appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a *.names* file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.
  - P Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.
  - S Display size of the entire link layer frame in bytes on the summary line.
  - V Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For

instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through `grep` to extract packets of interest. For example, to view only RPC summary lines, enter the following: `example#`

**snoop -i rpc.cap -V | grep RPC**

-a

Listen to packets on `/dev/audio` (warning: can be noisy).

-c *maxcount*

Quit after capturing *maxcount* packets. Otherwise keep capturing until there is no disk space left or until interrupted with Control-C.

-d *device*

Receive packets from the network using the interface specified by *device*, for example, `eri0` or `hme0`. The program `netstat(1M)`, when invoked with the `-i` flag, lists all the interfaces that a machine has. Normally, `snoop` will automatically choose the first non-loopback interface it finds.

-i *filename*

Display packets previously captured in *filename*. Without this option, `snoop` reads packets from the network interface. If a *filename.names* file is present, it is automatically loaded into the `snoop` IP address-to-name mapping table (See `-N` flag).

-n *filename*

Use *filename* as an IP address-to-name mapping table. This file must have the same format as the `/etc/hosts` file (IP address followed by the hostname).

-o *filename*

Save captured packets in *filename* as they are captured. (This *filename* is referred to as the "capture file".) The format of the capture file is RFC 1761-compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file `/dev/null`.

-p *first* [ , *last* ]

Select one or more packets to be displayed from a capture file. The *first* packet in the file is packet number 1.

-q

When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.

-r

Do not resolve the IP address to the symbolic name. This prevents `snoop` from generating network traffic while capturing and displaying packets. However, if the `-n` option is used, and an address is found in the mapping file, its corresponding name will be used.

-s *snaplen*

Truncate each packet after *snaplen* bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means

less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a *snaplen* of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a *snaplen* of 80 bytes. NFS headers can be captured in 120 bytes.

**-t [ r | a | d ]**

Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in d (delta) format (the time since receiving the previous packet). Option a (absolute) gives wall-clock time. Option r (relative) gives time relative to the first packet displayed. This can be used with the -p option to display time relative to any selected packet.

**-v**

Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.

**-xoffset [ , length]**

Display packet data in hexadecimal and ASCII format. The *offset* and *length* values select a portion of the packet to be displayed. To display the whole packet, use an *offset* of 0. If a *length* value is not provided, the rest of the packet is displayed.

### **Operands** *expression*

Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, snoop generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to snoop. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or snoop. The kernel packet filter has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, snoop tries to split the filter and do as much filtering in the kernel as possible. The remaining filtering is done by the packet filter for snoop. The -C flag can be used to view generated code for either the packet filter for the kernel or the packet filter for snoop. If packets are read from a capture file using the -i option, only the packet filter for snoop is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to [Example 2](#) for information about setting up more efficient filters.

The primitives are:

**host** *hostname*

True if the source or destination address is that of *hostname*. The *hostname* argument may be a literal address. The keyword *host* may be omitted if the name does not conflict with the name of another expression primitive. For example, *pinky* selects packets transmitted to or received from the host *pinky*, whereas *pinky* and *dinky* selects packets exchanged between hosts *pinky* AND *dinky*.

The type of address used depends on the primitive which precedes the *host* primitive. The possible qualifiers are *inet*, *inet6*, *ether*, or *none*. These three primitives are discussed below. Having none of the primitives present is equivalent to “*inet* *host* *hostname* or *inet6* *host* *hostname*”. In other words, *snoop* tries to filter on all IP addresses associated with *hostname*.

**inet** or **inet6**

A qualifier that modifies the *host* primitive that follows. If it is *inet*, then *snoop* tries to filter on all IPv4 addresses returned from a name lookup. If it is *inet6*, *snoop* tries to filter on all IPv6 addresses returned from a name lookup.

**ipaddr**, **atalkaddr**, or **etheraddr**

Literal addresses, IP dotted, AppleTalk dotted, and Ethernet colon are recognized. For example,

- “172.16.40.13” matches all packets with that IP
- “2::9255:a00:20ff:fe73:6e35” matches all packets with that IPv6 address as source or destination;
- “65281.13” matches all packets with that AppleTalk address;
- “8:0:20:f:b1:51” matches all packets with the Ethernet address as source or destination.

An Ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the Ethernet address is *aa:0:45:23:52:44*, then specify it by add a leading zero to make it *0aa:0:45:23:52:44*.

**from** or **src**

A qualifier that modifies the following *host*, *net*, *ipaddr*, *atalkaddr*, *etheraddr*, *port* or *rpc* primitive to match just the source address, *port*, or *RPC* reply.

**to** or **dst**

A qualifier that modifies the following *host*, *net*, *ipaddr*, *atalkaddr*, *etheraddr*, *port* or *rpc* primitive to match just the destination address, *port*, or *RPC* call.

**ether**

A qualifier that modifies the following *host* primitive to resolve a name to an Ethernet address. Normally, IP address matching is performed. This option is not supported on media such as *IPoIB* (IP over *InfiniBand*).

**ethertype** *number*

True if the Ethernet type field has value *number*. If *number* is not 0x8100 (VLAN) and the packet is VLAN tagged, then the expression will match the encapsulated Ethernet type.

**ip, ip6, arp, rarp, pppoed, pppoes**

True if the packet is of the appropriate ethertype.

**vlan**

True if the packet has ethertype VLAN and the VLAN ID is not zero.

**vlan-id** *id*

True for packets of ethertype VLAN with the id *id*.

**pppoe**

True if the ethertype of the packet is either pppoed or pppoes.

**broadcast**

True if the packet is a broadcast packet. Equivalent to `ether[2:4] = 0xffffffff` for Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

**multicast**

True if the packet is a multicast packet. Equivalent to “`ether[0] & 1 = 1`” on Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

**bootp, dhcp**

True if the packet is an unfragmented IPv4 UDP packet with either a source port of BOOTPS (67) and a destination port of BOOTPC (68), or a source port of BOOTPC (68) and a destination of BOOTPS (67).

**dhcp6**

True if the packet is an unfragmented IPv6 UDP packet with either a source port of DHCPV6-SERVER (547) and a destination port of DHCPV6-CLIENT (546), or a source port of DHCPV6-CLIENT (546) and a destination of DHCPV6-SERVER (547).

**apple**

True if the packet is an Apple Ethertalk packet. Equivalent to “`ethertype 0x809b` or `ethertype 0x80f3`”.

**decnet**

True if the packet is a DECNET packet.

**greater** *length*

True if the packet is longer than *length*.

**less** *length*

True if the packet is shorter than *length*.

**udp, tcp, icmp, icmp6, ah, esp**

True if the IP or IPv6 protocol is of the appropriate type.

**net** *net*

True if either the IP source or destination address has a network number of *net*. The *from* or *to* qualifier may be used to select packets for which the network number occurs only in the source or destination address.

**port** *port*

True if either the source or destination port is *port*. The *port* may be either a port number or name from */etc/services*. The *tcp* or *udp* primitives may be used to select TCP or UDP ports only. The *from* or *to* qualifier may be used to select packets for which the *port* occurs only as the source or destination.

**rpc** *prog* [ , *vers* [ , *proc* ] ]

True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The *prog* may be either the name of an RPC protocol from */etc/rpc* or a program number. The *vers* and *proc* may be used to further qualify the program *version* and *procedure* number, for example, *rpc nfs, 2, 0* selects all calls and replies for the NFS null procedure. The *to* or *from* qualifier may be used to select either call or reply packets only.

**ldap**

True if the packet is an LDAP packet on port 389.

**gateway** *host*

True if the packet used *host* as a gateway, that is, the Ethernet source or destination address was for *host* but not the IP address. Equivalent to “*ether host host* and not *host host*”.

**nofrag**

True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to *ip[6:2] & 0x1fff = 0*.

**expr** *relop* *expr*

True if the relation holds, where *relop* is one of *>*, *<*, *>=*, *<=*, *=*, *!=*, and *expr* is an arithmetic expression composed of numbers, packet field selectors, the *length* primitive, and arithmetic operators *+*, *-*, *\**, *&*, *|*, *^*, and *%*. The arithmetic operators within *expr* are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

```
base[expr [: size]]
```

where *expr* evaluates the value of an offset into the packet from a *base* offset which may be *ether*, *ip*, *ip6*, *udp*, *tcp*, or *icmp*. The *size* value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

```
ether[0] & 1 = 1
```

is equivalent to *multicast*

```
ether[2:4] = 0xffffffff
```

is equivalent to broadcast.

```
ip[ip[0] & 0xf * 4 : 2] = 2049
```

is equivalent to `udp[0:2] = 2049`

```
ip[0] & 0xf > 5
```

selects IP packets with options.

```
ip[6:2] & 0x1fff = 0
```

eliminates IP fragments.

```
udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0
```

finds all packets with UDP checksums.

The length primitive may be used to obtain the length of the packet. For instance “length > 60” is equivalent to “greater 60”, and “ether[length - 1]” obtains the value of the last byte in a packet.

and

Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example “dinky pinky” is the same as “dinky AND pinky”.

or or ,

Perform a logical OR operation between two boolean values. A comma may be used instead, for example, “dinky , pinky” is the same as “dinky OR pinky”.

not or !

Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

s!p

True if the packet is an SLP packet.

sctp

True if the packet is an SCTP packet.

ospf

True if the packet is an OSPF packet.

### Examples EXAMPLE 1 Using the snoop Command

Capture all packets and display them as they are received:

```
example# snoop
```

Capture packets with host funky as either the source or destination and display them as they are received:

**EXAMPLE 1** Using the snoop Command *(Continued)*

```
example# snoop funky
```

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

```
example# snoop -o cap funky pinky
example# snoop -i cap -t r | more
```

To look at selected packets in another capture file:

```
example# snoop -i pkts -p 99,108
 99 0.0027 boutique -> sunroof NFS C GETATTR FH=8E6
100 0.0046 sunroof -> boutique NFS R GETATTR OK
101 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102 0.0102 marmot -> viper NFS C LOOKUP FH=561E screen.r.13.i386
103 0.0072 viper -> marmot NFS R LOOKUP No such file or directory
104 0.0085 bugbomb -> sunroof RLOGIN C PORT=1023 h
105 0.0005 kandinsky -> sparky RSTAT C Get Statistics
106 0.0004 beeblebrox -> sunroof NFS C GETATTR FH=0307
107 0.0021 sparky -> kandinsky RSTAT R
108 0.0073 office -> jeremiah NFS C READ FH=2584 at 40960 for 8192
```

To look at packet 101 in more detail:

```
example# snoop -i pkts -v -p101
ETHER: ----- Ether Header -----
ETHER:
ETHER: Packet 101 arrived at 16:09:53.59
ETHER: Packet size = 210 bytes
ETHER: Destination = 8:0:20:1:3d:94, Sun
ETHER: Source = 8:0:69:1:5f:e, Silicon Graphics
ETHER: Ethertype = 0800 (IP)
ETHER:
IP: ----- IP Header -----
IP:
IP: Version = 4, header length = 20 bytes
IP: Type of service = 00
IP: ..0. = routine

IP: 0.. = normal reliability
IP: Total length = 196 bytes
IP: Identification 19846
IP: Flags = 0X
IP: .0.. = may fragment
IP: ..0. = more fragments
IP: Fragment offset = 0 bytes
IP: Time to live = 255 seconds/hops
```

**EXAMPLE 1** Using the snoop Command (Continued)

```

IP: Protocol = 17 (UDP)
IP: Header checksum = 18DC
IP: Source address = 172.16.40.222, boutique
IP: Destination address = 172.16.40.200, sunroof
IP:
UDP: ----- UDP Header -----
UDP:
UDP: Source port = 1023
UDP: Destination port = 2049 (Sun RPC)
UDP: Length = 176
UDP: Checksum = 0
UDP:
RPC: ----- SUN RPC Header -----
RPC:
RPC: Transaction id = 665905
RPC: Type = 0 (Call)
RPC: RPC version = 2
RPC: Program = 100003 (NFS), version = 2, procedure = 1
RPC: Credentials: Flavor = 1 (Unix), len = 32 bytes
RPC: Time = 06-Mar-90 07:26:58
RPC: Hostname = boutique
RPC: Uid = 0, Gid = 1
RPC: Groups = 1
RPC: Verifier : Flavor = 0 (None), len = 0 bytes
RPC:
NFS: ----- SUN NFS -----
NFS:
NFS: Proc = 11 (Rename)
NFS: File handle = 000016430000000100080000305A1C47
NFS: 597A000000800002046314AFC450000
NFS: File name = MTra00192
NFS: File handle = 000016430000000100080000305A1C47
NFS: 597A000000800002046314AFC450000
NFS: File name = .nfs08
NFS:

```

To view just the NFS packets between sunroof and boutique:

```

example# snoop -i pkts rpc nfs and sunroof and boutique
1 0.0000 boutique -> sunroof NFS C GETATTR FH=8E6C
2 0.0046 sunroof -> boutique NFS R GETATTR OK
3 0.0080 boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08

```

To save these packets to a new capture file:

```

example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique

```

To view encapsulated packets, there will be an indicator of encapsulation:

**EXAMPLE 1** Using the snoop Command *(Continued)*

```
example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request (1 encap)
```

If -V is used on an encapsulated packet:

```
example# snoop -V ip-in-ip
sunroof -> boutique ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique IP D=172.16.40.222 S=172.16.40.200 LEN=104, ID=27497
sunroof -> boutique IP D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique ICMP Echo request
```

**EXAMPLE 2** Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: greater, less, port, rpc, nofrag, and relop. The presence of OR makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be OR'd.

To capture packets between funky and pinky of type tcp or udp on port 80:

```
example# snoop funky and pinky and port 80 and tcp or udp
```

Since the primitive port cannot be handled by the kernel filter, and there is also an OR in the expression, a more efficient way to filter is to move the OR to the end of the expression and to use parentheses to enforce the OR between tcp and udp:

```
example# snoop funky and pinky and (tcp or udp) and port 80
```

**Exit Status** 0 Successful completion.

1 An error occurred.

**Files** /dev/audio Symbolic link to the system's primary audio device.  
 /dev/null The null file.  
 /etc/hosts Host name database.  
 /etc/rpc RPC program number data base.  
 /etc/services Internet services and aliases.

**See Also** [netstat\(1M\)](#), [hosts\(4\)](#), [rpc\(4\)](#), [services\(4\)](#), [attributes\(5\)](#), [audio\(7I\)](#), [bufmod\(7M\)](#), [d\lpi\(7P\)](#), [pfmod\(7M\)](#), [tun\(7M\)](#)

Callaghan, B. and Gilligan, R. *RFC 1761, Snoop Version 2 Packet Capture File Format*. Network Working Group. February 1995.

**Warnings** The processing overhead is much higher for realtime packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the `-o` option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly if the captured packets are interpreted realtime. This processing load further increases if verbose options are used. Since heavy use of `snoop` may deny computing resources to other processes, it should not be used on production servers. Heavy use of `snoop` should be restricted to a dedicated computer.

`snoop` does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

`snoop` may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the `snaplen` (`-s` option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s Ethernet, do not set `snaplen` less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s Ethernet, `snaplen` should be 250 bytes or more.

`snoop` requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

**Name** soconfig – configure transport providers for use by sockets

**Synopsis** `/sbin/soconfig -f file`  
`/sbin/soconfig family type protocol [path]`

**Description** The `soconfig` utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the `socket(3SOCKET)` call are mapped to the name of a transport provider such as `/dev/tcp`. This utility can be used to add an additional mapping or remove a previous mapping.

The `init(1M)` utility uses `soconfig` with the `sock2path(4)` file during the booting sequence.

**Options** The following options are supported:

`-f file` Set up the `soconfig` configuration for each driver according to the information stored in `file`. A `soconfig` file consists of lines of at least the first three fields listed below, separated by spaces:

*family type protocol path*

These fields are described in the OPERANDS section below.

An example of `file` can be found in the EXAMPLES section below.

**Operands** The following operands are supported:

*family* The protocol family as listed in the `/usr/include/sys/socket.h` file, expressed as an integer.

*type* The socket type as listed in the `/usr/include/sys/socket.h` file, expressed as an integer.

*protocol* The protocol number as specified in the family-specific `include` file, expressed as an integer. For example, for `AF_INET` this number is specified in `/usr/include/netinet/in.h`. An unspecified protocol number is denoted with the value zero.

*path* The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.

**Examples** EXAMPLE 1 Using `soconfig`

The following example sets up `/dev/tcp` for family `AF_INET` and type `SOCK_STREAM`:

```
example# soconfig 2 2 0 /dev/tcp
```

The following is a sample file used with the `-f` option. Comment lines begin with a number sign (#):

**EXAMPLE 1** Using soconfig *(Continued)*

```

Family Type Protocol Path
 2 2 0 /dev/tcp
 2 2 6 /dev/tcp

 2 1 0 /dev/udp
 2 1 17 /dev/udp

 1 2 0 /dev/ticotsord
 1 1 0 /dev/ticlts

 2 4 0 /dev/rawip

```

**Files** /etc/sock2path file containing mappings from sockets to transport providers

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**See Also** [init\(1M\)](#), [sock2path\(4\)](#), [attributes\(5\)](#)

*Network Interface Guide*

**Name** soladdapp – add an application to the Solstice application registry

**Synopsis** /usr/snadm/bin/soladdapp [-r *registry*] -n *name* -i *icon* -e *executable*  
[*args*]

**Description** soladdapp adds an application to the Solstice application registry. After it is added, the application is displayed in the Solstice Launcher main window (see [solstice\(1M\)](#)).

**Options**

- r *registry* Define the full path name of the Solstice registry file.
- n *name* Define the name of the tool to be registered.
- i *icon* Define the full path name of the tool icon.
- e *executable* Define the full path name of the tool.
- args* Specify any arguments to use with the tool.

When executed without options, soladdapp uses /opt/SUNWadm/etc/.solstice\_registry (the default registry path).

**Return Values**

- 0 on success
- 1 on failure
- 2 if the registry is locked
- 3 if the entry is a duplicate.

**Examples** EXAMPLE 1 A sample display of the soladdapp command.

The following adds an application called Disk Manager to the Solstice application registry for display in the Solstice Launcher main window.

```
soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
-i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

**Files** /opt/SUNWadm/etc/.solstice\_registry The default registry path.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

**See Also** [soldelapp\(1M\)](#), [solstice\(1M\)](#), [attributes\(5\)](#)

**Notes** Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be added only using soladdapp.

**Name** soldelapp – remove an application from the Solstice application registry

**Synopsis** /usr/snadm/bin/soldelapp [-r *registry*] -n *name*

**Description** soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see [solstice\(1M\)](#)).

**Options** -r *registry* Define the full path name of the Solstice registry file.  
-n *name* Define the name of the tool to be removed.

When executed without options, soldelapp uses /opt/SUNWadm/etc/.solstice\_registry (the default registry path).

**Return Values**

0	on success
1	on failure
2	if the registry is locked
3	if <i>name</i> is not found in the registry
4	if the named registry or default registry is not found

**Examples** EXAMPLE 1 A sample display of the soldelapp command.

The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

```
soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
```

**Files** /opt/SUNWadm/etc/.solstice\_registry The default registry file.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

**See Also** [soladdapp\(1M\)](#), [solstice\(1M\)](#), [attributes\(5\)](#)

**Notes** Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be removed only using soldelapp.

**Name** solstice – access system administration tools with a graphical user interface

**Synopsis** /bin/solstice

**Description** solstice used on a system presents the Solstice Launcher, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

**Usage** The Solstice Launcher allows you to do the following tasks:

Launch applications	Use the Solstice Launcher to launch system administration tools.
Register applications	Use the Solstice Launcher to add and register applications locally with the launcher.
Remove applications	Use the Solstice Launcher to remove locally registered applications.
Customize application properties	Use the Solstice Launcher to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

**Files** /\$HOME/.solstice\_registry Local registry information.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

**See Also** [soladdapp\(1M\)](#), [soldeapp\(1M\)](#), [attributes\(5\)](#)

**Notes** The Solstice Launcher adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the Solstice Launcher. To register global applications for use by local and remote users, use the [soladdapp\(1M\)](#) command. To remove globally registered applications, use the [soldeapp\(1M\)](#) command.

**Name** spptun – PPP tunneling driver utility

**Synopsis** spptun plumb  
 spptun plumb *protocol device*  
 spptun unplumb *interface*  
 spptun query

**Description** The spptun utility is used to configure and query the Solaris PPP tunneling device driver, /dev/spptun. Currently, only PPP over Ethernet (PPPoE) is supported, so the plumb and unplumb arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the query option lists the plumbed interfaces.

The use of spptun to add interfaces is similar to the use of [ifconfig\(1M\)](#) to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).

The proper way to plumb interfaces for PPPoE is to list the interfaces, one per line, in the /etc/ppp/pppoe.if file.

<b>Usage</b> spptun plumb	When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the <i>protocol</i> argument below.
spptun plumb <i>protocol device</i>	This plumbs a new interface into the driver. The <i>protocol</i> parameter is pppoe for the PPP-carrying "Session Stage" connection or pppoe for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The <i>device</i> parameter is the path name of the Ethernet interface to use (use <a href="#">ifconfig(1M)</a> to list available devices). If the path begins with /dev/, then this portion may be omitted.
spptun unplumb <i>interface</i>	This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The <i>interface</i> parameter is the name of the interface as reported when the interface was plumbed.
spptun query	Displays the canonical names of all interfaces plumbed into the /dev/spptun device driver.

**Examples** **EXAMPLE 1** Setting up to Use PPPoE on hme0  
 Plumb the hme0 interface.

**EXAMPLE 1** Setting up to Use PPPoE on hme0 (Continued)

```
sppptun plumb pppoed hme0
hme0:pppoed
sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the hme0 interface.

```
sppptun unplumb hme0:pppoed
sppptun unplumb hme0:pppoe
```

**EXAMPLE 2** Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in `sppptun query`
do
 sppptun unplumb $intf
done
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 One or more errors occurred.

**Files**

- /etc/ppp/pppoe.if list of Ethernet interfaces to be plumbed at boot time
- /usr/sbin/sppptun executable command
- /dev/sppptun Solaris PPP tunneling device driver

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

**See Also** [pppd\(1M\)](#), [pppoe\(1M\)](#), [pppoed\(1M\)](#), [sppptun\(7M\)](#)

*RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE)*, Mamakos et al, February 1999

**Name** spray – spray packets

**Synopsis** /usr/sbin/spray [-c *count*] [-d *delay*] [-l *length*]  
[-t *nettype*] *host*

**Description** spray sends a one-way stream of packets to *host* using RPC, and reports how many were received, as well as the transfer rate. The *host* argument can be either a name or an Internet address.

spray is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. spray can report a large number of packets dropped when the drops were caused by spray sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

**Options**

- c *count* Specify how many packets to send. The default value of *count* is the number of packets required to make the total stream size 100000 bytes.
- d *delay* Specify how many microseconds to pause between sending each packet. The default is 0.
- l *length* The *length* parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of *length* are possible, and spray rounds up to the nearest possible value. When *length* is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the *length* field no longer has a simple correspondence to Ethernet packet size. The default value of *length* is 86 bytes, the size of the RPC and UDP headers.
- t *nettype* Specify class of transports. Defaults to netpath. See [rpc\(3NSL\)](#) for a description of supported classes.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

**See Also** [rpc\(3NSL\)](#), [attributes\(5\)](#)

**Name** sshd – secure shell daemon

**Synopsis** sshd [-deiqtD46] [-b *bits*] [-f *config\_file*]  
[-g *login\_grace\_time*] [-h *host\_key\_file*]  
[-k *key\_gen\_time*] [-p *port*] [-V *client\_protocol\_id*]

**Description** The sshd (Secure Shell daemon) is the daemon program for [ssh\(1\)](#). Together these programs replace `rlogin` and `rsh`, and provide secure encrypted communications between two untrusted hosts over an insecure network. The programs are intended to be as easy to install and use as possible.

sshd is the daemon that listens for connections from clients. It forks a new daemon for each incoming connection. The forked daemons handle key exchange, encryption, authentication, command execution, and data exchange.

This implementation of sshd supports both SSH protocol versions 1 and 2 simultaneously. Because of security weaknesses in the v1 protocol, sites should run only v2, if possible. In the default configuration, only protocol v2 is enabled for the server. To enable v1 and v2 simultaneously, see the instructions in [sshd\\_config\(4\)](#).

Support for v1 is provided to help sites with existing ssh v1 clients and servers to transition to v2. v1 might not be supported in a future release.

SSH Protocol Version 1 Each host has a host-specific RSA key (normally 1024 bits) used to identify the host. Additionally, when the daemon starts, it generates a server RSA key (normally 768 bits). This key is normally regenerated every hour if it has been used, and is never stored on disk.

Whenever a client connects the daemon responds with its public host and server keys. The client compares the RSA host key against its own database to verify that it has not changed. The client then generates a 256-bit random number. It encrypts this random number using both the host key and the server key, and sends the encrypted number to the server. Both sides then use this random number as a session key which is used to encrypt all further communications in the session. The rest of the session is encrypted using a conventional cipher, currently Blowfish or 3DES, with 3DES being used by default. The client selects the encryption algorithm to use from those offered by the server.

Next, the server and the client enter an authentication dialog. The client tries to authenticate itself using `.rhosts` authentication, `.rhosts` authentication combined with RSA host authentication, RSA challenge-response authentication, or password-based authentication.

Rhosts authentication is normally disabled because it is fundamentally insecure, but can be enabled in the server configuration file if desired. System security is not improved unless [rshd\(1M\)](#), [rlogind\(1M\)](#), [rexecd\(1M\)](#), and [rexed\(1M\)](#) are disabled (thus completely disabling [rlogin\(1\)](#) and [rsh\(1\)](#) into the machine).

**SSH Protocol Version 2** Version 2 works similarly to version 1: Each host has a host-specific DSA/RSA key. However, when the daemon starts, it does not generate a server key. Forward security is provided through a Diffie-Hellman key agreement. This key agreement results in a shared session key. The rest of the session is encrypted using a symmetric cipher, currently 128-bit AES, Blowfish, 3DES, or AES. The client selects the encryption algorithm to use from those offered by the server. Additionally, session integrity is provided through a cryptographic message authentication code (`hmac-sha1` or `hmac-md5`).

Protocol version 2 provides a public key based user authentication method (PubKeyAuthentication) GSS-API based user authentication, conventional password authentication, and a generic prompt/reply protocol for password-based authentication.

**Command Execution and Data Forwarding** If the client successfully authenticates itself, a dialog for preparing the session is entered. At this time the client can request things like allocating a pseudo-tty, forwarding X11 connections, forwarding TCP/IP connections, or forwarding the authentication agent connection over the secure channel.

Finally, the client either requests a shell or execution of a command. The sides then enter session mode. In this mode, either side may send data at any time, and such data is forwarded to/from the shell or command on the server side, and the user terminal on the client side.

When the user program terminates and all forwarded X11 and other connections have been closed, the server sends command exit status to the client, and both sides exit.

`sshd` can be configured using command-line options or the configuration file `/etc/ssh/ssh_config`, described in [ssh\\_config\(4\)](#). Command-line options override values specified in the configuration file.

`sshd` rereads its configuration file when it receives a hangup signal, `SIGHUP`, by executing itself with the name it was started as, that is, `/usr/lib/ssh/sshd`.

**Host Access Control** The `sshd` daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of `sshd` for `hosts_access()`. For more information on TCP Wrappers see [tcpd\(1M\)](#) and [hosts\\_access\(3\)](#) man pages, which are part of the `SUNWfman` package (they are not SunOS man pages). TCP wrappers binaries, including `libwrap`, are in `SUNWtcpd`, a required package for `SUNWsshdu`, the package containing `sshd`.

**Options** The options for `sshd` are as follows:

`-b bits`

Specifies the number of bits in the server key (the default is 768).

`-d`

Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple `-d` options increase the debugging level. Maximum is 3.

- e  
When this option is specified, `sshd` will send the output to standard error instead of to the system log.
- f *configuration\_file*  
Specifies the name of the configuration file. The default is `/etc/ssh/sshd_config`. `sshd` refuses to start if there is no configuration file.
- g *login\_grace\_time*  
Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.
- h *host\_key\_file*  
Specifies a file from which a host key is read. This option must be given if `sshd` is not run as root (as the normal host key files are normally not readable by anyone but root). The default is `/etc/ssh/ssh_host_key` for protocol version 1, and `/etc/ssh/ssh_host_rsa_key` and `/etc/ssh/ssh_host_dsa_key` for protocol version 2. It is possible to have multiple host key files for the different protocol versions and host key algorithms.
- i  
Specifies that `sshd` is being run from `inetd`. `sshd` is normally not run from `inetd` because it needs to generate the server key before it can respond to the client, and this may take tens of seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using `sshd` from `inetd` may be reasonable.
- k *key\_gen\_time*  
(SSHv1-specific) Specifies how often the server key is regenerated (the default is 3600 seconds, or one hour). The motivation for regenerating the key fairly often is that the key is not stored anywhere, and after about an hour, it becomes impossible to recover the key for decrypting intercepted communications even if the machine is cracked into or physically seized. A value of zero indicates that the key will never be regenerated.
- o *option*  
Can be used to specify options in the format used in the configuration file. This is useful for specifying options for which there are no separate command-line flags.
- p *port*  
Specifies the port on which the server listens for connections (the default is 22).
- q  
Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.
- t  
Test mode. Check only the validity of the configuration file and the sanity of the keys. This is useful for updating `sshd` reliably as configuration options might change.

-D  
When this option is specified `sshd` does not detach and does not become a daemon. This allows easy monitoring of `sshd`.

-4  
Forces `sshd` to use IPv4 addresses only.

-6  
Forces `sshd` to use IPv6 addresses only.

### Extended Description

`authorized_keys` File Format

The `$HOME/.ssh/authorized_keys` file lists the public keys that are permitted for RSA authentication in protocol version 1 and for public key authentication (PubkeyAuthentication) in protocol version 2. The `AuthorizedKeysFile` configuration option can be used to specify an alternative file.

Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments).

For each RSA key for protocol version 1, the file consists of the following space-separated fields:

*options bits exponent modulus comment*

For the public key for protocol version 2, the file consists of the following space-separated fields:

*options key-type base64-encoding-key comment*

For protocol version 2, *key-type* is one of `ssh-rsa` or `ssh-dsa`.

The options field is optional; its presence is determined by whether the line starts with a number. (The option field never starts with a number.) The bits, exponent, and modulus fields give the RSA key; the comment field is a convenient place for you to identify the key.

Lines in this file are usually several hundred bytes long (because of the size of the key modulus). You will find it very inconvenient to type them in; instead, copy the public key file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the `StrictModes` option of `sshd_config(4)`.

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

`from="pattern-list"`

Specifies that, in addition to public key authentication, the canonical name of the remote host must be present in the comma-separated list of patterns ('\*' and '?' serve as wildcards).

The list can also contain negated patterns by prefixing the patterns with '!'. If the canonical host name matches a negated pattern, the key is not accepted.

The purpose of this option is to give you the option of increasing security: public key authentication by itself does not trust the network or name servers or anything but the key. However, if someone manages to steal the key, possession of the key would permit the intruder to log in from anywhere in the world. This option makes using a stolen key more difficult, because name servers and routers would have to be compromised, in addition to just the key.

`command="command"`

Specifies that the *command* is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a pty if the client requests a pty; otherwise it is run without a tty. If an 8-bit clean channel is required, one must not request a pty or should specify `no-pty`. You can include a quote in the command by escaping it with a backslash. This option might be useful to restrict certain public keys from performing a specific operation. An example is a key that permits remote backups but nothing else. Note that the client can specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited from doing so. Also note that this option applies to shell, command, or subsystem execution.

`environment="NAME=value"`

Specifies that the string *NAME=value* is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted. Environment processing is disabled by default and is controlled via the `PermitUserEnvironment` option.

`no-port-forwarding`

Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the `command` option.

`no-X11-forwarding`

Forbids X11 forwarding when this key is used for authentication. Any X11 forward requests by the client will return an error.

`no-agent-forwarding`

Forbids authentication agent forwarding when this key is used for authentication.

`no-pty`

Prevents tty allocation (a request to allocate a pty will fail).

`permitopen="host:port"`

Limit local ssh -L port forwarding such that it can connect only to the specified host and port. IPv6 addresses can be specified with an alternative syntax: *host/port*. You can invoke multiple `permitopen` options, with each instance separated by a comma. No pattern matching is performed on the specified hostnames. They must be literal domains or addresses.

**ssh\_known\_hosts File Format** The `/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts` files contain host public keys for all known hosts. The global file should be prepared by the administrator (optional), and the per-user file is maintained automatically: whenever the user connects from an unknown host its key is added to the per-user file.

For the RSA key for protocol version 1, these files consist of the following space-separated fields:

```
hostnames bits exponent modulus comment
```

For the public key for protocol version 2, these files consist of the following space-separated fields:

```
hostnames key-type base64-encoding-key comment
```

For protocol version 2, *key-type* is one of `ssh-rsa` or `ssh-dsa`.

Hostnames is a comma-separated list of patterns (\* and ? act as wildcards); each pattern in turn is matched against the canonical host name (when authenticating a client) or against the user-supplied name (when authenticating a server). A pattern can also be preceded by ! to indicate negation: if the host name matches a negated pattern, it is not accepted (by that line) even if it matched another pattern on the line.

Alternately, hostnames can be stored in a hashed form, which hides host names and addresses should the file's contents be disclosed. Hashed hostnames start with a vertical bar (|) character. Only one hashed hostname can appear on a single line and none of the above negation or wildcard operators may be applied.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained, for example, from `/etc/ssh/ssh_host_rsa_key.pub`. The optional comment field continues to the end of the line, and is not used.

Lines starting with a hash mark (#) and empty lines are ignored as comments.

When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking `/etc/ssh/ssh_host_rsa_key.pub` and adding the host names at the front.

**Environment Variables** sshd sets the following environment variables for commands executed by ssh users:

**DISPLAY**

Indicates the location of the X11 server. It is automatically set by sshd to point to a value of the form `hostname:n`, where *hostname* indicates the host where the shell runs, and *n* is an integer greater than or equal to 1. ssh uses this special value to forward X11 connections

over the secure channel. Unless you have important reasons to do otherwise, you should not set `DISPLAY` explicitly, as that will render the X11 connection insecure and will require you to manually copy any required authorization cookies.

**HOME**

Set to the path of the user's home directory.

**LANG, LC\_ALL, LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, LC\_MONETARY, LC\_NUMERIC, LC\_TIME**

A locale setting. The locale defaults to that of `ssh` (usually the system-wide default locale), or is negotiated between the client and server during initial key exchange (as per RFC 4253).

Following initial key exchange, each of the variables can be overridden in the following sequence:

1. If a locale setting is set in a client's environment and that client supports "Environment Variable Passing" (see RFC 4254), then the setting will be passed over to the server side.
2. If the public key authentication method was used to authenticate the server and the `PermitUserEnvironment` variable in `ssh_config(4)` is set to `yes` on the server side, then the setting can be changed through the use of the `environment` option in the client's `AuthorizedKeysFile` file.
3. The setting can be change in the client's `~/.ssh/environment` file on the server.

See `PermitUserEnvironment` in `ssh_config(4)` as to when the `AuthorizedKeysFile` and `~/.ssh/environment` files are processed and used for setting the user environment.

**LOGNAME**

Synonym for `USER`. Set for compatibility with systems that use this variable.

**MAIL**

Set to point to the user's mailbox.

**SSH\_AUTH\_SOCK**

Indicates the path of a unix-domain socket used to communicate with the agent.

**SSH\_CONNECTION**

Identifies the client and server ends of the connection. The variable contains four space-separated values: client IP address, client port number, server IP address and server port number.

**SSH\_CLIENT**

Identifies the client end of the connection. The variable contains three space-separated values: client IP address, client port number, and server port number.

**SSH\_TTY**

Set to the name of the `tty` (path to the device) associated with the current shell or command. If the current session has no `tty`, this variable is not set.

**TZ**

Indicates the present timezone, if TIMEZONE is set in /etc/default/login or if TZ was set when the daemon was started.

**HZ**

If set in /etc/default/login, the daemon sets it to the same value.

**SHELL**

The user's shell, if ALTSHELL=YES in /etc/default/login.

**PATH**

Set to the value of PATH or SUPATH (see [login\(1\)](#)) in /etc/default/login, or, if not set, to /usr/bin:/bin.

**USER**

Set to the name of the user logging in.

Additionally, sshd reads \$HOME/.ssh/environment and adds lines of the format VARNAME=*value* to the environment.

**Examples** In the following examples, certain lines might wrap due to line length limits in your display. You should nevertheless consider the wrapped line as a single line.

**EXAMPLE 1** authorized\_key File Entries

The following are examples of authorized\_key file entries for protocol 1:

```
1024 33 12121...312314325 ylo@foo.bar
from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula
command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323 backup.hut.fi
```

**EXAMPLE 2** authorized\_key File Entries for Protocol 2

The following are examples of authorized\_key file entries for protocol 2:

```
ssh-rsa AAAAB3NzaC1y...EU88ovYKg4GfclWGCFYTuw8= ylo@foo.bar
from="*.niksula.hut.fi" ssh-rsa AAAAB3NzaC...uw8= ylo@niksula
command="dump /home",no-pty,no-port-forwarding ssh-rsa AA..8= backup.hut.fi
```

**EXAMPLE 3** ssh\_known\_hosts File Entries for Protocol 1

The following are examples of ssh\_known\_hosts file entries for protocol 1:

```
closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93 closenet.hut.fi
```

**EXAMPLE 4** ssh\_known\_hosts File Entries for Protocol 2

The following are examples of ssh\_known\_hosts file entries for protocol 2:

```
closenet,closenet.hut.fi,...,130.233.208.41 ssh-rsa AA..8= closenet.hut.fi
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Files** /etc/default/login

Contains defaults for several `sshd_config` parameters, environment variables, and other environmental factors.

The following parameters affect environment variables (see [login\(1\)](#) and descriptions of these variables, above):

- TIMEZONE
- HZ
- ALTSHELL
- PATH
- SUPATH

The following `/etc/default/login` parameters supply default values for corresponding [sshd\\_config\(4\)](#) parameters:

- CONSOLE (see `PermitRootLogin` in [sshd\\_config\(4\)](#))
- PASSREQ (see `PermitEmptyPasswords` in [sshd\\_config\(4\)](#))
- TIMEOUT (see `LoginGraceTime` in [sshd\\_config\(4\)](#))

The following `/etc/default/login` parameters:

- UMASK
- ULIMIT

...set the [umask\(2\)](#) and file size limit of, respectively, the shells and commands spawned by `sshd`.

Finally, two `/etc/default/login` parameters affect the maximum allowed login attempts per-connection using interactive user authentication methods (for example, `keyboard-interactive` but not `publickey`), as per [login\(1\)](#):

- RETRIES
- SYSLOG\_FAILED\_LOGINS

`/etc/ssh/sshd_config`

Contains configuration data for `sshd`. This file should be writable by root only, but it is recommended (though not necessary) that it be world-readable.

`/etc/ssh/ssh_host_key`

`/etc/ssh/ssh_host_dsa_key`

`/etc/ssh/ssh_host_rsa_key`

Contains the private part of the host key. This file should only be owned by root, readable only by root, and not accessible to others. `sshd` does not start if this file is group/world-accessible.

`/etc/ssh/ssh_host_key.pub`

`/etc/ssh/ssh_host_dsa_key.pub`

`/etc/ssh/ssh_host_rsa_key.pub`

Contains the public part of the host key. This file should be world-readable but writable only by root. Its contents should match the private part. This file is not used for encryption; it is provided only for the convenience of the user so its contents can be copied to known hosts files. These two files are created using [ssh-keygen\(1\)](#).

`/var/run/sshd.pid`

Contains the process ID of the sshd listening for connections. If there are several daemons running concurrently for different ports, this contains the pid of the one started last. The content of this file is not sensitive; it can be world-readable. You can use the `PidFile` keyword in `sshd_config` to specify a file other than `/var/run/sshd.pid`. See [sshd\\_config\(4\)](#).

`/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts`

These files are consulted when using `rhosts` with public key host authentication to check the public key of the host. The key must be listed in one of these files to be accepted. The client uses the same files to verify that the remote host is the one it intended to connect. These files should be writable only by root or the owner. `/etc/ssh/ssh_known_hosts` should be world-readable, and `$HOME/.ssh/known_hosts` can but need not be world-readable.

`/etc/nologin`

If this file exists, sshd refuses to let anyone except root log in. The contents of the file are displayed to anyone trying to log in, and non-root connections are refused. The file should be world-readable.

`$HOME/.ssh/authorized_keys`

Lists the public keys (RSA or DSA) that can be used to log into the user's account. This file must be readable by root. This might, on some machines, imply that it is world-readable if the user's home directory resides on an NFS volume. It is recommended that it not be accessible by others. The format of this file is described above. Users will place the contents of their `identity.pub`, `id_dsa.pub` and/or `id_rsa.pub` files into this file, as described in [ssh-keygen\(1\)](#).

`$HOME/.rhosts`

This file contains host-username pairs, separated by a space, one per line. The given user on the corresponding host is permitted to log in without password. The same file is used by `rlogind` and `rshd`. The file must be writable only by the user; it is recommended that it not be accessible by others. It is also possible to use `netgroups` in the file. Either host or user name may be of the form `+@groupname` to specify all hosts or all users in the group.

`$HOME/.shosts`

For ssh, this file is exactly the same as for `.rhosts`. However, this file is not used by `rlogin` and `rshd`, so using this permits access using SSH only.

#### `/etc/hosts.equiv`

This file is used during `rhosts` authentication. In its simplest form, this file contains host names, one per line. Users on these hosts are permitted to log in without a password, provided they have the same user name on both machines. The host name can also be followed by a user name; such users are permitted to log in as any user on this machine (except root). Additionally, the syntax `+@group` can be used to specify netgroups. Negated entries start with a hyphen (-).

If the client `host/user` is successfully matched in this file, login is automatically permitted, provided the client and server user names are the same. Additionally, successful RSA host authentication is normally required. This file must be writable only by root; it is recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in `hosts.equiv`. Beware that it really means that the named user(s) can log in as anybody, which includes `bin`, `daemon`, `adm`, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to `rsh/rlogin`.

#### `/etc/ssh/moduli`

A private file.

#### `/etc/ssh/shosts.equiv`

This file is processed exactly as `/etc/hosts.equiv`. However, this file might be useful in environments that want to run both `rsh/rlogin` and `ssh`.

#### `$HOME/.ssh/environment`

This file is read into the environment at login (if it exists). It can contain only empty lines, comment lines (that start with `#`), and assignment lines of the form `name=value`. The file should be writable only by the user; it need not be readable by anyone else. Environment processing is disabled by default and is controlled by means of the `PermitUserEnvironment` option.

#### `$HOME/.ssh/rc`

If this file exists, it is run with `/bin/sh` after reading the environment files but before starting the user's shell or command. If X11 spoofing is in use, this will receive the `proto` cookie pair in standard input (and `DISPLAY` in environment). This must call `xauth` in that case.

The primary purpose of `$HOME/.ssh/rc` is to run any initialization routines that might be needed before the user's home directory becomes accessible; AFS is a particular example of such an environment. If this file exists, it is run with `/bin/sh` after reading the environment files, but before starting the user's shell or command. It must not produce any output on `stdout`; `stderr` must be used instead. If X11 forwarding is in use, it will receive the `proto` cookie pair in its standard input and `DISPLAY` in its environment. The script must call `xauth` because `sshd` will not run `xauth` automatically to add X11 cookies.

This file will probably contain some initialization code followed by something similar to:

```

if read proto cookie && [-n "$DISPLAY"]
then
 if ['echo $DISPLAY | cut -c1-10' = 'localhost:']
 then
 # X11UseLocalhost=yes
 echo add unix:'echo $DISPLAY |
 cut -c11-' $proto $cookie
 else
 # X11UseLocalhost=no
 echo add $DISPLAY $proto $cookie
 fi | xauth -q -
fi

```

If this file does not exist, `/etc/ssh/sshrc` is run, and if that does not exist, `xauth` is used to store the cookie. `$HOME/.ssh/rc` should be writable only by the user, and need not be readable by anyone else.

#### `/etc/ssh/sshrc`

Similar to `$HOME/.ssh/rc`. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

**Security** `sshd` supports the use of several user authentication mechanisms: a public key system where keys are associated with users (through users' `authorized_keys` files), a public key system where keys are associated with hosts (see the `HostbasedAuthentication` configuration parameter), a GSS-API based method (see the `GssAuthentication` and `GssKeyEx` configuration parameters) and three initial authentication methods: `none`, `password`, and a generic prompt/reply protocol, `keyboard-interactive`.

`sshd` negotiates the use of the GSS-API with clients only if it has a GSS-API acceptor credential for the “host” service. This means that, for GSS-API based authentication, the server must have a Kerberos V keytab entry (see below) or the equivalent for any other GSS-API mechanism that might be installed.

In order for Kerberos authentication to work, a `host/<FQDN>` Kerberos principal must exist for each Fully Qualified Domain Name associated with the `in.sshd` server. Each of these `host/<FQDN>` principals must have a keytab entry in the `/etc/krb5/krb5.keytab` file on the `in.sshd` server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See [kadmin\(1M\)](#) or [gkadmin\(1M\)](#) for instructions on adding a principal to a `krb5.keytab` file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

GSS-API authorization is covered in [gss\\_auth\\_rules\(5\)](#).

sshd uses `pam(3PAM)` for the three initial authentication methods as well as for account management, session management, and password management for all authentication methods.

Specifically, sshd calls `pam_authenticate()` for the “none,” “password” and “keyboard-interactive” SSHv2 `userauth` types, as well as for the null and password authentication methods for SSHv1. Other SSHv2 authentication methods do not call `pam_authenticate()`. `pam_acct_mgmt()` is called for each authentication method that succeeds.

`pam_setcred()` and `pam_open_session()` are called when authentication succeeds and `pam_close_session()` is called when connections are closed.

`pam_open_session()` and `pam_close_session()` are also called when SSHv2 channels with `ptys` are opened and closed.

Each SSHv2 `userauth` type has its own PAM service name:

SSHv2 Userauth	PAM Service Name
none	sshd-none
password	sshd-password
keyboard-interactive	sshd-kbdint
pubkey	sshd-pubkey
hostbased	sshd-hostbased
gssapi-with-mic	sshd-gssapi
gssapi-keyex	sshd-gssapi

For SSHv1, `sshd -v1` is always used.

If `pam_acct_mgmt()` returns `PAM_NEW_AUTHTOK_REQD` (indicating that the user's authentication tokens have expired), then sshd forces the use of “keyboard-interactive” `userauth`, if version 2 of the protocol is in use. The “keyboard-interactive” `userauth` will call `pam_chauthtok()` if `pam_acct_mgmt()` once again returns `PAM_NEW_AUTHTOK_REQD`. By this means, administrators are able to control what authentication methods are allowed for SSHv2 on a per-user basis.

#### Setting up Host-based Authentication

To establish host-based authentication, you must perform the following steps:

- Configure the client.
- Configure the server.
- Publish known hosts.
- Make appropriate entries in `/etc/ssh/shosts.equiv` and `~/.shosts`.

These steps are expanded in the following paragraphs.

- On a client machine, in the system-wide client configuration file, `/etc/ssh/ssh_config`, you must have the entry:
 

```
HostbasedAuthentication yes
```

 See [ssh\\_config\(4\)](#) and [ssh-keysign\(1M\)](#).
- On the server, in the system-wide server configuration file, `/etc/ssh/sshd_config`, you must have the entry:
 

```
HostbasedAuthentication yes
```

 If per-user `.shost` files are to be allowed (see last step), in the same file, you must have:
 

```
IgnoreRhosts no
```

 See [sshd\\_config\(4\)](#) for a description of these keywords.
- To publish known hosts, you must have entries for the clients from which users will be allowed host-based authentication. Make these entries in either or both of the system-wide file (`/etc/ssh/ssh_known_hosts`) or the per-user file (`~/.ssh/known_hosts`).
- Note that `sshd` uses `.shosts`, not `.rhosts`. If you want the functionality provided by `.rhosts`, but do not want to use `rlogin` or `rsh` because of their security shortcomings, you can use `.shosts` in conjunction with `sshd`. To use this feature, make appropriate entries in `/etc/ssh/shosts.equiv` and `~/.shosts`, in the format specified in [rhosts\(4\)](#).
 

For the vast majority of network environments, `.shosts` is preferred over `.rhosts`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsshdu
Interface Stability	Evolving

The interface stability of `/etc/ssh/moduli` is Private.

**See Also** [login\(1\)](#), [scp\(1\)](#), [ssh\(1\)](#), [ssh-add\(1\)](#), [ssh-agent\(1\)](#), [ssh-keygen\(1\)](#), [svcs\(1\)](#), [gkadmin\(1M\)](#), [kadadmin\(1M\)](#), [sftp-server\(1M\)](#), [ssh-keysign\(1M\)](#), [svcadm\(1M\)](#), [pam\(3PAM\)](#), [rhosts\(4\)](#), [ssh\\_config\(4\)](#), [sshd\\_config\(4\)](#), [attributes\(5\)](#), [gss\\_auth\\_rules\(5\)](#), [kerberos\(5\)](#), [pam\\_roles\(5\)](#), [smf\(5\)](#)

*System Administration Guide: Security Services*

**Notes** The `sshd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/ssh:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

sshd always sets PAM\_RHOST and sets PAM\_AUSER in the case of host-based userauth. This behavior allows for remote logins to roles using host-based authentication. See [pam\\_roles\(5\)](#).

**Name** ssh-keysign – ssh helper program for host-based authentication

**Synopsis** ssh-keysign

**Description** ssh-keysign is used by [ssh\(1\)](#) to access the local host keys and generate the digital signature required during host-based authentication with SSH protocol version 2. This signature is of data that includes, among other items, the name of the client host and the name of the client user.

ssh-keysign is disabled by default and can be enabled only in the global client configuration file `/etc/ssh/ssh_config` by setting `HostbasedAuthentication` to `yes`.

ssh-keysign is not intended to be invoked by the user, but from `ssh`. See [ssh\(1\)](#) and [sshd\(1M\)](#) for more information about host-based authentication.

**Files** `/etc/ssh/ssh_config` Controls whether ssh-keysign is enabled.

`/etc/ssh/ssh_host_dsa_key`

`/etc/ssh/ssh_host_rsa_key`

These files contain the private parts of the host keys used to generate the digital signature. They should be owned by root, readable only by root, and not accessible to others. Because they are readable only by root, ssh-keysign must be set-uid root if host-based authentication is used.

**Security** ssh-keysign will not sign host-based authentication data under the following conditions:

- If the `HostbasedAuthentication` client configuration parameter is not set to `yes` in `/etc/ssh/ssh_config`. This setting cannot be overridden in users' `~/.ssh/ssh_config` files.
- If the client hostname and username in `/etc/ssh/ssh_config` do not match the canonical hostname of the client where `ssh-keysign` is invoked and the name of the user invoking `ssh-keysign`.

In spite of ssh-keysign's restrictions on the contents of the host-based authentication data, there remains the ability of users to use it as an avenue for obtaining the client's private host keys. For this reason host-based authentication is turned off by default.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsshu
Interface Stability	Evolving

**See Also** [ssh\(1\)](#), [sshd\(1M\)](#), [ssh\\_config\(4\)](#), [attributes\(5\)](#)

**Authors** Markus Friedl, markus@openbsd.org

**History** ssh-keysign first appeared in OpenBSD 3.2.

**Name** statd – network status monitor

**Synopsis** /usr/lib/nfs/statd

**Description** statd is an intermediate version of the status monitor. It interacts with [lockd\(1M\)](#) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.

statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.

lockd is started by [automountd\(1M\)](#), [mount\\_nfs\(1M\)](#), and [share\(1M\)](#) if NFS automounts are needed.

<b>Files</b> /var/statmon/sm	lists hosts and network addresses to be contacted after a reboot
/var/statmon/sm.bak	lists hosts and network addresses that could not be contacted after last reboot
/var/statmon/state	includes a number which changes during a reboot
/usr/include/rpcsvc/sm_inter.x	contains the rpcgen source code for the interface services provided by the statd daemon.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfsclu

**See Also** [svcs\(1\)](#), [automountd\(1M\)](#), [lockd\(1M\)](#), [mount\\_nfs\(1M\)](#), [share\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

*System Administration Guide: IP Services*

**Notes** The crash of a server is only detected upon its recovery.

The statd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

svc:/network/nfs/status

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

If it is disabled, it will be enabled by [mount\\_nfs\(1M\)](#), [share\\_nfs\(1M\)](#), and [automountd\(1M\)](#) unless its `application/auto_enable` property is set to `false`.

**Name** stclient – Service Tag Administration Program

**Synopsis** stclient -x [-r *root\_dir*]

```
stclient -a [-i instance_URN] -p product_name -e product_version
-t product_URN [-F parent_URN] -P product_parent
[-I product_defined_instance_id] -m product_vendor -A platform_arch
-z container -S source [-r root_dir]
```

```
stclient -u -i instance_URN -F parent_URN -I product_defined_instance_id
[-r root_dir]
```

```
stclient -d -i instance_URN [-r root_dir]
```

```
stclient -g -i instance_URN [-r root_dir]
```

```
stclient -f -t product_URN [-r root_dir]
```

```
stclient -h
```

```
stclient -v
```

**Description** The `stclient` command displays, finds, adds, updates and deletes records in the Service Tag registry. The registry is in the XML file `/var/sadm/servicetag/registry/servicetag.xml`, and contains the inventory of the product instances installed in the machine. Each record has a unique product instance identifier which is generated when the service tag is added in the registry. This product instance identifier is used as a key when finding, updating or deleting the service tag records. The extract option prints out the registry contents in XML format in stdout.

The `stclient` command also runs in interactive mode. This mode is invoked by running `stclient` without any parameters. A menu of all the available options are displayed, and the user is prompted to enter different parameters depending on the option chosen.

Any user can extract or get the contents of the registry, but only users with the appropriate privileges, the “`svctag`” user, or the creator of the service tag is authorized to update or delete a service tag record.

**Options** The following options are supported:

-p <i>product_name</i>	Sets the product name of the service tag to be added. For example, “ <code>stclient -p “Solaris 10 Operating System”</code> ” sets the product name to the “Solaris 10 Operating System”.
-e <i>product_version</i>	Sets the product version of the service tag to be added. For example, “ <code>stclient -r 5.10</code> ” sets the product version to “5.10”.
-t <i>product_URN</i>	Sets the Sun product unique identifier of the service tag to be added. For example, “ <code>stclient -t urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113</code> ” sets

- the Sun product unique identifier to “urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113”.
- i instance\_URN* Sets the product instance unique identifier of the service tag. For example, “stclient -i 3a444ab2-1dd2-11b2-a69d-830020782a6b” sets the product instance unique identifier to “3a444ab2-1dd2-11b2-a69d-830020782a6b”. This field may also be set when the service tag is added but is not typically used. The generation of the instance ID is normally left to the `stclient`.
- F product\_parent\_URN* Sets the Sun product unique identifier of parent product. For example, “stclient -F urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113” sets the Sun product unique identifier of parent product to “urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113”.
- P product\_parent* Sets the parent product of the service tag. For example, “stclient -P JES” sets the product parent to “JES”.
- I product\_defined\_instance\_id* Sets the product defined instance identifier. For example, “stclient -I ser:abc-klm-000-7190” sets the product defined instance identifier to “ser:abc-klm-000-7190”.
- m product\_vendor* Sets the vendor of the product. For example, “stclient -m Sun” sets the product vendor to “Sun”.
- A platform\_arch* Sets the platform architecture that the product is running on. For example, “stclient -A sparc” sets the platform architecture to “sparc”.
- z container* Sets the container that the product is running on. For example, “stclient -z “global zone”” sets the container to “global zone”.
- S source* Sets the source of this service tag, naming the entity that created it.
- r root\_dir* Sets the root directory where the command searches for the registry. The command searches `/var/sadm/servicetag/registry` by default. When this option is used, the command looks for the Registry in the specified root directory, (for example, “-r /home/user1” searches `/home/user1/var/sadm/servicetag`). This is typically used for testing.

## Operands

- Function Letters** The function portion of the key is specified by one of the following letters:
- x Extract. Extracts and prints the contents of the Service Tag registry in XML format. An alternate root directory may be specified for testing purposes.
  - a Add. Adds a service tag in the registry. A unique product instance identifier may be supplied and is automatically generated if not provided. This field is returned by the command. The required fields for add are product name, product version, product URN, product parent, vendor, platform architecture, container and source.
  - u Update. Updates a service tag in the registry using the product instance URN as the key. The parent URN and product defined instance id fields can be updated.
  - d Delete. Deletes a service tag in the registry using the product instance URN as the key.
  - E Extract Environment. Enumerates to standard output the environmental or “agent” information associated with the registered Service Tags on this system.
  - g Get. Gets and prints a service tag from the registry using the product instance URN as the key.
  - f Find. Finds and prints all the instance URNs of a given product URN.
  - h Help. Displays the command options.
  - v Version. Displays the version number of the command.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- > 0 An error occurred.

**Examples** **EXAMPLE 1** Adding a Service Tag in the Registry

To add a service tag, enter the following:

```
stclient -a -p "Java Enterprise Web Server 6.0" -e 6.0 \
-t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
-P Java Enterprise Server -m Sun -A sparc -z global -s patch
```

The screen displays the following:

```
Java Enterprise Web Server 6.0 6.0 added
Product instance URN=urn:st:7fc61914-1dd2-11b2-b992-830020782a6b
```

**EXAMPLE 2** Updating a Service Tag in the Registry

To update a service tag, enter the following:

**EXAMPLE 2** Updating a Service Tag in the Registry *(Continued)*

```
stclient -u -i 7fc61914-1dd2-11b2-b992-830020782a6b \
-I urn:st:product.defined.id
```

The screen displays the following:

```
Service tag updated
```

**EXAMPLE 3** Extracting a Service Tag Registry

To extract a service tag, enter the following:

```
stclient -x
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<registry urn="urn:uuid:1234ab-00e1-11b3-98737646873" version="1.0">
 <service_tag>
 .
 .
 .
 </service_tag>
</registry>
```

**EXAMPLE 4** Finding all product instances

To find all product instances, enter the following:

```
stclient -f -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
fc61914-1dd2-11b2-b992-830020782a6b
```

**EXAMPLE 5** Listing the Environmental Information

To list the environmental information associated with the registered Service Tags on this system, enter the following:

```
stclient -E
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent>
 <agent_urn>urn:st:af15ee62-0bb3-ef2d-fa96-85a11996cc71</agent_urn>
 .
 .
 .
 </system_info>
</agent>
```

---

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `stclient`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	SUNWservicetagu
Interface Stability	Committed

**See Also** [in.stdiscover\(1M\)](#), [in.stlisten\(1M\)](#)

**Name** stmsboot – administration program for the Solaris I/O multipathing feature

**Synopsis** /usr/sbin/stmsboot [[-D (fp | mpt | mpt\_sas | iscsi) ] -d | -e | -u]  
 | -L | -l *controller\_number*]

**Description** The Solaris I/O multipathing feature is a multipathing solution for storage devices that is part of the Solaris operating environment. This feature was formerly known as Sun StorEdge Traffic Manager (STMS) or MPxIO.

The stmsboot program is an administrative command to manage enumeration of multipath-capable devices with Solaris I/O multipathing. Solaris I/O multipathing-enabled devices are enumerated under `scsi_vhci(7D)`, providing multipathing capabilities. Solaris I/O multipathing-disabled devices are enumerated under the physical controller.

In the `/dev` and `/devices` trees, Solaris I/O multipathing-enabled devices receive new names that indicate that they are under Solaris I/O multipathing control. This means a device will have a different name from its original name (after enabling) when it is under Solaris I/O multipathing control. The stmsboot command automatically updates `/etc/vfstab` and dump configuration to reflect the device names changes when enabling or disabling Solaris I/O multipathing. One reboot is required for changes to take effect.

**Options** The following options are supported:

-e [ -E fp | mpt | mpt\_sas | iscsi ]

Enables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath-capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D)` or `mpt_sas(7D)`) controller ports. Following this enabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the enabling operation to ports attached using the specified driver.

-d [ -D fp | mpt | mpt\_sas | iscsi ]

Disables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath-capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D)` or `mpt_sas(7D)`) controller ports. Following this disabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the disabling operation to ports attached using the specified driver.

-u [ -D fp | mpt | mpt\_sas | iscsi ]

Updates `vfstab` and the dump configuration after you have manually modified the configuration to have Solaris I/O multipathing enabled or disabled on specific `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` controller ports. This option prompts you to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes.

-L

Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for multipath-enabled controller ports. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

-l *controller\_number*

Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for the specified controller. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Note that [mpt\\_sas\(7D\)](#) has MPxIO turned on by default. This means that when using the -L or -l option with -D [mpt\\_sas](#), `stmsboot` does not display any non-multipathed and multipathed device names.

**Usage** The primary function of `stmsboot` is to control the enabling and disabling of Solaris I/O multipathing on the host. The utility automatically updates [vfstab\(4\)](#) and [dumpadm\(1M\)](#) configuration to reflect device name changes. The system administrator is responsible for modifying application configuration (for example, backup software, DBMS, and so forth) to reflect updated device names.

The -L and -l options display the mapping between multipathed and non-multipathed device names. These options function only after changes to the Solaris I/O multipathing configuration have taken effect, that is, following the reboot after invoking `stmsboot -e`.

ZFS datasets, including ZFS root datasets, are correctly handled by `stmsboot`.

**Examples** EXAMPLE 1 Enabling Solaris I/O Multipathing

To enable Solaris I/O multipathing for all multipath-capable controllers, run:

```
stmsboot -e
```

To enable Solaris I/O multipathing on multipath-capable [mpt\(7D\)](#) controller ports, enter:

```
stmsboot -D mpt -e
```

To enable Solaris I/O multipathing on multipath-capable [mpt\\_sas\(7D\)](#) controller ports, enter:

```
stmsboot -D mpt_sas -e
```

To enable Solaris I/O Multipathing on multipath-capable fibre channel controller ports, enter:

```
stmsboot -D fp -e
```

To enable Solaris I/O Multipathing on multipath-capable iSCSI controller ports, enter:

```
stmsboot -D iscsi -e
```

**EXAMPLE 2** Disabling Solaris I/O Multipathing

To disable Solaris I/O multipathing on all multipath-capable controllers, enter:

```
stmsboot -d
```

To disable Solaris I/O multipathing on multipath-capable `mpt(7D)` controller ports, enter:

```
stmsboot -D mpt -d
```

To disable Solaris I/O multipathing on multipath-capable `mpt_sas(7D)` controller ports, enter:

```
stmsboot -D mpt_sas -d
```

To disable Solaris I/O multipathing on multipath-capable iSCSI controller ports, enter:

```
stmsboot -D iscsi -d
```

To disable Solaris I/O multipathing on multipath-capable fibre channel controller ports, enter:

```
stmsboot -D fp -d
```

**EXAMPLE 3** Enabling Solaris I/O Multipathing on Selected Ports

To enable Solaris I/O multipathing on specific fibre channel controller ports and disable the feature on others, manually edit the `/kernel/drv/fp.conf` file. (See `fp(7d)`.) The following command will update `vfstab(4)` and `dumpadm(1M)` configurations to reflect the changed device names:

```
stmsboot -u
```

A similar procedure involving the `/kernel/drv/mpt.conf` file should be followed for devices attached by means of the `mpt(7D)` driver. For devices attached by means of the `iscsi(7D)` driver, follow a similar procedure that uses the `/kernel/drv/iscsi.conf` file.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs, system/library
Interface Stability	Obsolete

**See Also** `dumpadm(1M)`, `fsck(1M)`, `mpathadm(1M)`, `ufsdump(1M)`, `zfs(1M)`, `zpool(1M)`, `ufsdump(4)`, `vfstab(4)`, `emlxs(7D)`, `fcpc(7D)`, `fp(7d)`, `iscsi(7D)`, `mpt(7D)`, `mpt_sas(7D)`, `qlc(7D)`, `scsi_vhci(7D)`

*Solaris SAN Configuration and Multipathing Guide* (see <http://docs.oracle.com>)

Consult a particular storage product's system administrator's guide and release notes for further information specific to that product.

**Notes** Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the `-e` and `-d` options replace `mpxio-disable` property entries with a global `mpxio-disable` entry in `fp.conf`.

Enabling Solaris I/O Multipathing on a Sun StorEdge Disk Array

The following applies to Sun StoreEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.

To place your Sun StorEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the `mp_support` of the subsystem must be set to `mpxio` mode. The preferred sequence is to change the subsystem's `mp_support` to `mpxio` mode, then run `stmsboot -e`. If Solaris I/O multipathing is already enabled but the subsystem's `mp_support` is not in `mpxio` mode, then change the `mp_support` to `mpxio` mode and run `stmsboot -u`.

Refer to the *Sun StorEdge Administrator's Guide* for your subsystem for more details.

Using `ufsdump`

The `ufsdump(1M)` command records details of filesystem dumps in `/etc/dumpdates` (see `ufsdump(4)`). Among other items, the entries contain device names. An effect of the “active” `stmsboot` options (`-e`, `-d`, and `-u`) is to change the device name of a storage device.

Because `stmsboot` does not modify `dumpdates`, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation `ufsdump` will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

Procedure to Use `stmsboot` in Conjunction with Sun Cluster

If possible, invoke `stmsboot -e` before installing Sun Cluster software. After executing `stmsboot`, install Sun Cluster software normally.

If Sun Cluster software is installed before executing `stmsboot`, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

```
stmsboot -e
```

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. `# /usr/cluster/bin/scdidadm -C`
2. `# /usr/cluster/bin/scdidadm -r`

The preceding commands update `did` mappings with new device names while preserving `did` instance numbers for disks that are connected to multiple cluster nodes. `did` instance numbers of the local disks might not be preserved. For this reason, the `did` disk names for local disks might change.

The remaining steps are required only if local `did` number changes require editing of `/etc/vfstab`. If such editing is not required, run `/usr/cluster/bin/scgdevs` from each node in the cluster to complete the procedure.

3. Update `/etc/vfstab` to reflect any new `did` disk names for your local disks.
4. Reboot the system.

To disable the Solaris multipathing feature, use `stmsboot -d` (instead of `stmsboot -e`), then follow the procedure above.

To view mappings between the old and new device names, run `stmsboot -L`. To view `did` device name mappings, run `/usr/cluster/bin/scdidadm -L`.

With active-passive storage arrays, it is possible that while your host is rebooting the array controller could failover the path that a particular target is using. In this scenario, [fsck\(1M\)](#) will fail to open the physical path listed in `/etc/vfstab`. The `svc:/system/filesystem/local:default` SMF service will transition to a maintenance state as a result. To rectify this, consult the documentation for your storage array to failback the path. The [mpathadm\(1M\)](#) can assist with determining the active and passive path(s).

**Limitations** On x86 platforms, the current Solaris release does not support disabling Solaris I/O multipathing of boot devices attached by means of fibre channel. Solaris I/O multipathing is always enabled for supported fibre channel-attached boot devices. Disabling Solaris I/O multipathing in this situation must be performed on a per-port basis. See [fp\(7d\)](#).

Executing `devfsadm -C` removes obsolete device entries that `stmsboot` relies on. This will prevent correct operation of the `-d` option for boot devices (regardless of platform type) and the `-L` option.

**Name** strace – print STREAMS trace messages

**Synopsis** strace [*mid sid level*]...

**Description** `strace` without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see [log\(7D\)](#)). If arguments are provided, they must be in triplets of the form *mid*, *sid*, *level*, where *mid* is a STREAMS module ID number, *sid* is a sub-ID number, and *level* is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token `all` may be used for any member to indicate no restriction for that attribute.

The format of each trace message output is:

```
<seq> <time> <ticks> <level> <flags> <mid> <sid> <text>
```

<seq> trace sequence number

<time> time of message in *hh:mm:ss*

<ticks> time of message in machine ticks since boot

<level> tracing priority level

<flags> E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)

<mid> module ID number of source

<sid> sub-ID number of source

<text> formatted text of the trace message

Once initiated, `strace` will continue to execute until terminated by the user.

**Examples** **EXAMPLE 1** A sample output of the `strace` command:

The following example outputs all trace messages from the module or driver whose module ID is 41:

```
strace 41 all all
```

The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:

```
strace 41 0 1 41 1 1 41 2 0
```

Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [attributes\(5\)](#), [log\(7D\)](#)

*STREAMS Programming Guide*

- Notes**
- There is no restriction to the number of `strace` processes opening the STREAMS log driver at a time.
  - The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the `strace` process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running `strace` will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the `strace` process. If trace messages are generated faster than the `strace` process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

**Name** strclean – STREAMS error logger cleanup program

**Synopsis** strclean [-a *age*] [-d *logdir*]

**Description** strclean is used to clean up the STREAMS error logger directory on a regular basis (for example, by using cron). By default, all files with names matching `error.*` in `/var/adm/streams` that have not been modified in the last three days are removed.

**Options** The following options are supported:

-a *age*        The maximum age in days for a log file can be changed using the -a option.

-d *logdir*     A directory other than `/var/adm/streams` can be specified using the -d option.

**Examples** EXAMPLE 1 A sample of using the strclean command.

This example has the same result as running strclean with no arguments:

```
example% strclean -d /var/adm/streams -a 3
```

**Files** /var/adm/streams/error.\*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [cron\(1M\)](#), [strerr\(1M\)](#), [attributes\(5\)](#)

*STREAMS Programming Guide*

**Notes** strclean is typically run from cron on a daily or weekly basis.

**Name** strerr – STREAMS error logger daemon

**Synopsis** strerr

**Description** strerr receives error log messages from the STREAMS-based log driver (see [log\(7D\)](#)) and appends them to a log file. The resultant error log files reside in the directory `/var/adm/streams`, and are named `error.mm-dd`, where *mm* is the month and *dd* is the day of the messages contained in each log file.

The format of an error log message is:

`<seq> <time> <ticks> <flags> <mid> <sid> <text>`

`<seq>` error sequence number

`<time>` time of message in hh:mm:ss

`<ticks>` time of message in machine ticks since boot priority level

`<flags>` T : the message was also sent to a tracing process F : indicates a fatal error N : send mail to the system administrator (hardcoded as root)

`<mid>` module ID number of source

`<sid>` sub-ID number of source

`<text>` formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS-based driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using `mail`. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, strerr continues to execute until terminated by the user. It is commonly executed asynchronously.

**Files** `/var/adm/streams/error.mm-dd` error log file.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [attributes\(5\)](#), [log\(7D\)](#)

*STREAMS Programming Guide*

**Notes** There is no restriction to the number of `strerr` processes opening the STREAMS-based log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

**Name** sttydefs – maintain line settings and hunt sequences for TTY ports

**Synopsis** /usr/sbin/sttydefs -a *ttylabel* [-b] [-f *final-flags*]  
          [-i *initial-flags*] [-n *nextlabel*]  
  
/usr/sbin/sttydefs -l [*ttylabel*]  
  
/usr/sbin/sttydefs -r *ttylabel*

**Description** sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the /etc/ttydefs file.

sttydefs with a -a or -r option may be invoked only by the super-user. sttydefs with -l may be invoked by any user on the system.

**Options** The following options are supported:

- a *ttylabel* Add a record to the `tttydefs` file, using *ttylabel* as its label. The following describes the effect of the -b, -n, -i, or -f options when used in conjunction with the -a option:
- b Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.
- f *final-flags* Specify the value to be used in the *final-flags* field in /etc/ttydefs. *final-flags* must be in a format recognized by the `stty` command. *final-flags* are the [termio\(7I\)](#) settings used by `ttymon` after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, `sttydefs` will set *final-flags* equal to the [termio\(7I\)](#) flags 9600 and sane.
- i *initial-flags* Specify the value to be used in the *initial-flags* field in /etc/ttydefs. *initial-flags* must be in a format recognized by the `stty` command. These flags are used by `ttymon` when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, `sttydefs` will set *initial-flags* equal to the [termio\(7I\)](#) flag 9600.
- n *nextlabel* Specify the value to be used in the *nextlabel* field in /etc/ttydefs. If this option is not specified, `sttydefs` will set *nextlabel* equal to *ttylabel*.
- l [*ttylabel*] If a *ttylabel* is specified, `sttydefs` displays the record from /etc/ttydefs whose TTY label matches the specified *ttylabel*. If no *ttylabel* is specified, `sttydefs` displays the entire contents of /etc/ttydefs. `sttydefs` verifies that each entry it displays is correct and that the entry's *nextlabel* field references an existing
- r *ttylabel* Remove any record in the `tttydefs` file that has *ttylabel* as its label.

**Output** If successful, `sttydefs` will exit with a status of 0. `sttydefs -l` will generate the requested information and send it to standard output.

**Examples** **EXAMPLE 1** A sample of `sttydefs` command.

The following command lists all the entries in the `ttydefs` file and prints an error message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```
example# sttydefs -l 9600
```

```

9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800

```

```
ttylabel: 9600
initial flags: 9600 hupcl erase ^h
final flags: 9600 sane ixany tab3 hupcl erase ^h
autobaud: no
nextlabel: 4800
```

The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

**Files** /etc/ttydefs

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [attributes\(5\)](#), [termio\(7I\)](#)

**Name** su – become superuser or another user

**Synopsis** su [-] [*username* [*arg...*]]

**Description** The su command allows one to become another user without logging off or to assume a role. The default user *name* is root (superuser).

To use su, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified *username*. Additionally, the new shell's project ID is set to the default project ID of the specified user. See [getprojent\(3PROJECT\)](#), [setproject\(3PROJECT\)](#). The new shell will be the shell specified in the shell field of *username*'s password file entry (see [passwd\(4\)](#)). If no shell is specified, `/usr/bin/sh` is used (see [sh\(1\)](#)). If superuser privilege is requested and the shell for the superuser cannot be invoked using [exec\(2\)](#), `/sbin/sh` is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.

Any additional arguments given on the command line are passed to the new shell. When using programs such as sh, an *arg* of the form `-c string` executes *string* using the shell and an *arg* of `-r` gives the user a restricted shell.

To create a login environment, the command “su -” does the following:

- In addition to what is already propagated, the LC\* and LANG environment variables from the specified user's environment are also propagated.
- Propagate TZ from the user's environment. If TZ is not found in the user's environment, su uses the TZ value from the TIMEZONE parameter found in `/etc/default/login`.
- Set MAIL to `/var/mail/new_user`.

If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of \$PATH, which is controlled by PATH and SUPATH in `/etc/default/su`.

All attempts to become another user using su are logged in the log file `/var/adm/sulog` (see [sulog\(4\)](#)).

**Security** su uses [pam\(3PAM\)](#) with the service name su for authentication, account management, and credential establishment.

**Examples** **EXAMPLE 1** Becoming User bin While Retaining Your Previously Exported Environment

To become user bin while retaining your previously exported environment, execute:

```
example% su bin
```

**EXAMPLE 2** Becoming User bin and Changing to bin's Login Environment

To become user `bin` but change the environment to what would be expected if `bin` had originally logged in, execute:

```
example% su - bin
```

**EXAMPLE 3** Executing command with user bin's Environment and Permissions

To execute command with the temporary environment and permissions of user `bin`, type:

```
example% su - bin -c "command args"
```

**Environment Variables**

Variables with `LD_` prefix are removed for security reasons. Thus, `su bin` will not retain previously exported variables with `LD_` prefix while becoming user `bin`.

If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of `su` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `su` behaves.

**LC\_CTYPE** Determines how `su` handles characters. When `LC_CTYPE` is set to a valid value, `su` can display and handle text and filenames containing valid characters for that locale. `su` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `su` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

**LC\_MESSAGES** Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

<b>Files</b>	<code>\$HOME/.profile</code>	user's login commands for <code>sh</code> and <code>ksh</code>
	<code>/etc/passwd</code>	system's password file
	<code>/etc/profile</code>	system-wide <code>sh</code> and <code>ksh</code> login commands
	<code>/var/adm/sulog</code>	log file
	<code>/etc/default/su</code>	the default parameters in this file are:
	<b>SULOG</b>	If defined, all attempts to <code>su</code> to another user are logged in the indicated file.
	<b>CONSOLE</b>	If defined, all attempts to <code>su</code> to root are logged on the console.

**PATH** Default path. (/usr/bin:)

**SUPATH** Default path for a user invoking su to root. (/usr/sbin:/usr/bin)

**SYSLOG** Determines whether the [syslog\(3C\)](#) LOG\_AUTH facility should be used to log all su attempts. LOG\_NOTICE messages are generated for su's to root, LOG\_INFO messages are generated for su's to other users, and LOG\_CRIT messages are generated for failed su attempts.

/etc/default/login the default parameters in this file are:

**TIMEZONE** Sets the TZ environment variable of the shell.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [csh\(1\)](#), [env\(1\)](#), [ksh\(1\)](#), [login\(1\)](#), [roles\(1\)](#), [sh\(1\)](#), [syslogd\(1M\)](#), [exec\(2\)](#), [getproject\(3PROJECT\)](#), [setproject\(3PROJECT\)](#), [pam\(3PAM\)](#), [pam\\_authenticate\(3PAM\)](#), [pam\\_acct\\_mgmt\(3PAM\)](#), [pam\\_setcred\(3PAM\)](#), [pam.conf\(4\)](#), [passwd\(4\)](#), [profile\(4\)](#), [sulog\(4\)](#), [syslog\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Name** sulogin – access single-user mode

**Synopsis** sulogin

**Description** The sulogin utility is automatically invoked by init when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke sulogin.

The sulogin utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See [consadm\(1m\)](#) and [msglog\(7D\)](#) for a description of how to configure a serial device to display the single-user login prompt.

**Files** /etc/default/sulogin      Default value can be set for the following flag:

PASSREQ      Determines if login requires a password. Default is PASSREQ=YES.

/etc/default/login      Default value can be set for the following flag:

SLEEPTIME      If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

Both [su\(1M\)](#) and [login\(1\)](#) are affected by the value of SLEEPTIME.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

**Name** suninstall – install the Solaris operating system

**Synopsis** suninstall

**Description** `install-solaris(1M)` is now the preferred command for starting and restarting the Solaris Installation program. It should be used instead of `suninstall`. `suninstall` is symbolically linked to `install-solaris`.

`suninstall` is a forms-based and graphical subsystem for installing the operating system.

`suninstall` exists only on the Solaris installation media (CD or DVD) and should only be invoked from there. Refer to the *Oracle Solaris 10 8/11 Installation Guide: Basic Installations* for more details.

`suninstall` allows installation of the operating system onto any standalone system. `suninstall` loads the software available on the installation media. Refer to the *Oracle Solaris 10 8/11 Installation Guide: Basic Installations* for disk space requirements.

**Usage** Refer to the *Oracle Solaris 10 8/11 Installation Guide: Basic Installations* for more information on the various menus and selections.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcdrom (Solaris installation media)

**See Also** `pkginfo(1)`, `install(1M)`, `install-solaris(1M)`, `pkgadd(1M)`, `attributes(5)`

*Oracle Solaris 10 8/11 Installation Guide: Basic Installations*

**Notes** It is advisable to exit `suninstall` by means of the exit options in the `suninstall` menus.

**Name** SUNWgfb\_config – fbconfig module for configuring Sun XVR-1000 Graphics Accelerator

**Synopsis** fbconfig [-dev *device-filename*]  
 [-active a | b | both | auto]  
 [-res *video-mode* [now | try] [noconfirm]]  
 [-file machine | system]  
 [-doublewide enable | disable | reverse]  
 [-doublehigh enable | disable | reverse]  
 [-multisample enable | disable | auto [static | dynamic]]  
 [-samples *samples-per-pixel*]  
 [-g *gamma-correction-value*] [-master a | b | input]  
 [-clearpixel0 | 255]

fbconfig [-dev *device-filename*] -stream a | b  
 [-port hd15 | dvid | svideo | auto]  
 [-res *video-mode* [now | try] [noconfirm]]  
 [-file machine | system]  
 [-offset *xoff-value* [*yoff-value*]]  
 [-slave [enable | disable] [internal | external]]

fbconfig [-dev *device-filename*] -defaults

fbconfig [-dev *device-filename*]  
 [-propt | -prconf | -res \?]

fbconfig [-help | -list]

**Description** SUNWgfb\_config is the Sun XVR-1000 Graphics Accelerator device dependent layer for [fbconfig\(1M\)](#). It configures the Sun XVR-1000 Graphics Accelerator and some of the X11 window system defaults. The device can drive two monitors, each with a unique video stream (called stream a and stream b).

The first form of SUNWgfb\_config shown in the synopsis above sets card options, which are options common to both stream a and stream b, and apply to the entire card.

The second form is used to set stream options, which are options specific to either stream a or stream b. The second form usage requires the -stream option to define which stream is affected.

Both the first form and the second form store the specified options in the `OWconfig` file. These options will be used to initialize the device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. For -res with now or try, -slave, -master, -port, and -g, the device will be immediately programmed.

The third form, which invokes the -defaults option, sets all card options and all stream options to their default values and saves these defaults in the `OWconfig` file.

The fourth form, which invokes the -prconf, -propt, and -res \? options, queries the device for status that is card-specific.

The fifth form, which invokes the `-help`, and `-list` options, provides instruction on using `SUNWgfb_config` and a list of available devices. Additionally for the fifth form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices requires multiple invocations of `SUNWgfb_config`.

Only Sun XVR-1000 Graphics Accelerator-specific options can be specified through `SUNWgfb_config`. The normal window system options for specifying default depth, default visual class, and so forth are still specified as device modifiers on the command line when the X server is started.

You can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. You can use the `-file` option to specify an alternate file. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

<b>General Options</b>	<code>-dev <i>device-filename</i></code>	Specifies the device's special file. The default is <code>/dev/fb</code> .
	<code>-file <i>machine system</i></code>	Specifies which <code>OWconfig</code> file to update. If <i>machine</i> is specified, the machine-specific <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree is updated. If <i>system</i> is specified, the global <code>OWconfig</code> file in the <code>/usr/openwin</code> directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is <i>machine</i> .
	<code>-res <i>video-mode</i>[<i>now   try</i>] [<i>noconfirm</i>]</code>	Specifies the video mode used to drive the monitor connected to the specified device. If <code>-res</code> is invoked with <i>now</i> or <i>try</i> , you must specify a <code>-stream</code> option or a device, such as <code>/dev/fbs/gfb0a</code> . If <code>-active</code> is set to both or <i>auto</i> , then both stream <i>video-mode</i> values will be modified.  The <i>video-mode</i> argument specifies resolution and timing information for the display (for example, <code>SUNW_STD_1280x1024x76</code> ). The naming convention for the <i>video-mode</i> specifier is:  <i>origin_type_widthxheightxrate</i>  The elements of the specifier are described as follows:

<i>origin</i>	This can be one of: <ul style="list-style-type: none"> <li>▪ SUNW, Sun derived resolution</li> <li>▪ VESA, Video Electronics Standards Association-derived resolution</li> <li>▪ other, other source</li> </ul>
<i>type</i>	This can be one of: <ul style="list-style-type: none"> <li>▪ STD, normal resolution, usable by most display devices</li> <li>▪ DIG, resolution tuned only for LCD flat panels</li> <li>▪ INT, interlaced</li> <li>▪ STEREO, stereo</li> </ul>
<i>width</i>	screen width in pixels
<i>height</i>	screen height in pixels
<i>rate</i>	vertical frequency of the screen refresh

Note that some video-modes supported by the device, might not be supported by the monitor. The list of video-modes supported by the device and the monitor can be obtained by running `SUNWgfb_config` with the `- res \?` option (the fourth form shown in the command synopsis above).

The `- res` option also accepts additional, optional arguments, listed below, immediately following the video mode specification. Either `now` or `try` (`try` subsumes `now`) and `noconfirm` can be present.

<i>now</i>	If present, not only is the video mode updated in the <code>OWconfig</code> file, but the device is immediately programmed to display this video mode. This is useful for changing the video mode before starting the window system.
------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Note** – It is recommended that you not use this suboption with `SUNWgfb_config` while the configured device is being used (for example, while running the window system). Unpredictable results can occur. To run `SUNWgfb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen do not change until the window system is exited and reentered. In addition, the system might not recognize changes in stereo mode.

`noconfirm` Using the `-res` option, the user can put the system into an unusable state, with no video output. To reduce the chance of this, the default behavior of `SUNWgfb_config` is to display a warning message and to ask the user whether to continue. The `noconfirm` bypasses this confirmation. This option is useful when `SUNWgfb_config` is being run from a shell script.

`try` If present, the specified video mode will be programmed on a trial basis. The user is asked to confirm the video mode by typing `y` within 10 seconds. Alternatively, the user can

terminate the trial before 10 seconds elapse by typing any character other than **y** or carriage return. Such input is considered a **no** and the previous video mode is restored. With a negative response, `SUNWgfb_config` does not change the video mode in the `OWconfig` file; other options specified still take effect. If a carriage return is typed, the user is asked (**y** or **n**) whether to keep the new video mode.

This sub-option should not be used with `SUNWgfb_config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWgfb_config` with the `try` sub-option, the window system should be brought down first.

`-defaults`

Resets all option values to their default values. Writes these values to the `OWconfig` file.

`-propt`

Displays the current values of all options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the `OWconfig` file after the call to `SUNWgfb_config` completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/gfb0 ---
OWconfig: machine
Active Streams: both
Samples Per Pixel: 2
Multisample Allocation Model: static
```

```

Multisample Mode: auto
Doublewide: disable
Gamma Correction Value: 2.22

--- OpenWindows Configuration for Stream a ---
Video Mode: SUNW_STD_1280x1024x76

--- OpenWindows Configuration for Stream b ---
Video Mode: VESA_STD_640x480x60

-prconf Displays the XVR-1000 hardware
 configuration. The following is an example
 display:

--- Hardware Configuration for /dev/fb (SUNWgfb0) ---
Type: Sun Graphics Accelerator
Part: 501-5865
Memory:
 MAJC: 32MB
 Texture: 256MB total
 3DRAM64: 5.0M pixels

Versions: FCode 1.14 MCode 0.19 MAJC 2.1 FBC3 3.0 XChip 2.0

Video Streams:
 Stream a
 Current resolution Setting: SUNW_STD_1280x1024x76
 Monitor/EDID data (13W3)
 Monitor Manufacturer: SUN
 Monitor Name: GDM-5410
 EDID: Version 1, Revision 2
 Stream b
 Current resolution Setting: VESA_STD_640x480x60
 Port: svideo

-help Displays a list of the SUNWgfb_config
 command line options, along with a brief
 explanation of each.

-res \? Displays list of defined video-mode names.

```

**Card Options**

```

-active a | b | both | auto
 Specifies which streams are enabled. both select both streams. The default is auto, which
 means whichever stream is chosen by the console.

-multisample enable | disable | auto [static | dynamic]
 The suboptions for -multisample are described as follows:
 disable No multisample is possible.

```

- enable      Multisample is possible but is selected on a per-application basis.
- auto        All Sun OpenGL applications are rendered using multisampling.
- static      Multisample allocation occurs at X startup/config load time. The config *samples-per-pixel* or *max* parameter specifies the depth that is pre-allocated.
- dynamic     OpenGL tasks allocate buffers themselves.
- samples *samples-per-pixel*  
 Specifies the number of samples/pixel to pre-allocate in static mode. Provides a hint to OpenGL in dynamic mode. The allowable choices for *samples-per-pixel* are 2, 3, 4, 5, 6, 8, 10, 16, and max. The default is max, which means to use the maximum number of samples that can be supported with the amount of memory available.
- doublewide enable | disable | reverse  
 This option makes it easy for you to combine both streams into one side-by-side virtual display. If you specify *enable*, stream a is to the left of stream b. If *reverse* is specified, stream b is to the left of stream b. Both will be the same resolution defined with the *-res* option. If you specify *disable*, only one stream will be enabled. *-doublewide* precludes *-doublehigh*.
- doublehigh enable | disable | reverse  
 This option makes it easy for you to combine both streams into one virtual display, with one monitor on a shelf above the other. If you specify *enable*, stream a is above stream b. If *reverse* is specified, stream b is above stream a. Both will be the same resolution defined with the *-res* option. If you specify *disable*, only one stream will be enabled. *-doublehigh* precludes *-doublewide*.
- g *gamma-correction value*  
 This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the *OWconfig* file for the next time the window system starts.
- master a | b | input  
 This option controls the setting frame pins on the stereo/sync connector on the device. It also controls which stream drives stereo glasses, which attach to the same connector.
- If a (the default) or b is selected, the card is setup to be a sync master, and the frame sync signal from the corresponding stream will be sent out this connector.
- If you select *input*, the card is setup to take its frame sync from another card through this connector. This sync can then be used to sync either or both streams by setting the stream-specific *-slave* option(s) to *external*.
- If stereo glasses are used, the a or b options select which stream is used for the sync signal to the glasses.

`-clearpixel 0 | 255`

Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

**Stream Options** `-stream a | b`

Specifies for which stream options will be set. It is a required option for each of the other options in this section. It is optional for `-res`. Only one `-stream` option can be specified.

`-port hd15 | dvid | svideo | auto`

Directs stream `b` to the appropriate output connector: `hd-15`, `dvid`, or `svideo`. If `auto`, then the output connector for stream `b` is selected by the console. Stream `a` is always output through the 13W3 connector.

`-offset xoff-value [yoff-value]`

Offsets the display of the stream (specified by `-stream`) relative to the adjoining edge of the other stream when `doublewide` or `doublehigh` is enabled. This can be used to cause an overlap.

*xoff-value*      Number of pixels offset in horizontal direction for the right-hand stream when `doublewide` is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges touch.

*yoff-value*      Number of pixels offset in vertical direction for the bottom stream when `doublehigh` is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

`-slave [enable | disable] [internal | external]`

This option allows you to specify the sync source for the specified stream. `internal` indicates that the sync source is the other stream of this device. `external` indicates the sync is taken from a source outside the device. If you use `external`, you also need to use the `card` option `-master input`.

**Defaults** For a given invocation of `SUNWgfb_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system is run, if an option has never been specified through `SUNWgfb_config`, a default value is used. The option defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fb</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>

---

-samples	max
-multisample	enable/dynamic
-clearpixel	255
-master	a
-slave	disable/external
-doublewide	not set
-g	2.22
-active	auto
-port	auto
-offset	0/0

---

The default for the - res option of none means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This provides compatibility for users who are used to specifying the device resolution through the PROM.

**Examples** EXAMPLE 1 Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 Hz:

```
example% fbconfig -stream a -res -SUNW_STD_1280x1024x76
```

**Files** /usr/lib/fbconfig/SUNWgfb\_config device special file

`[-multisample enable | disable | auto]`

`/usr/lib/fbconfig/SUNWifb_config [-propt] [prconf]`

`/usr/lib/fbconfig/SUNWifb_config [-help] [-res \?]`

**Description** SUNWifb\_config configures the Sun Expert3D Graphics Accelerator, Sun Expert3D-Lite, and Sun XVR-500 Graphics Accelerators, and some of the X11 window system defaults for the graphics accelerator.

The first form of SUNWifb\_config shown in the synopsis above stores the specified options in the OWconfig file. These options will be used to initialize the Sun Expert3D device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms of SUNWifb\_config, which invoke only the -prconf, -propt, -help, and -res \? options, do not update the OWconfig file. Additionally, for the third form of the command, all other options are ignored.

Options may be specified for only one Sun Expert3D device at a time. Specifying options for multiple Sun Expert3D devices requires multiple invocations of SUNWifb\_config.

Only options specific to the Sun Expert3D device can be specified through SUNWifb\_config. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line (see the Xsun(1) manual page in the [Open Windows Desktop Reference Manual](#)).

**Options** The following options are supported:

<code>-dev <i>device-filename</i></code>	Specifies the Sun Expert3D special file. The default is <code>/dev/fbs/ifb0</code> .
<code>-file<i>machine</i>   system</code>	Specifies which OWconfig file to update. If <i>machine</i> is specified, the machine-specific OWconfig file in the <code>/etc/openwin</code> directory tree is updated. If <i>system</i> is specified, the global OWconfig file in the <code>/usr/openwin</code> directory tree is updated. If the

- res *video-mode*

specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

Specifies the video mode used to drive the monitor connected to the specified Sun Expert3D device.

The format of these built-in video modes is:

*widthxheightxrate* where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. The s suffix of 960x680x112s and 960x680x108s means that these are stereo video modes. The i suffix of 640x480x60i and 768x575x50i designates interlaced video timing. If absent, non-interlaced timing will be used. As a convenience, - res also accepts formats with @ (at sign) in front of the refresh rate instead of x. For example: 1280x1024@76. Note that some video-modes supported by the Sun Expert3D device might not be supported by the monitor. The list of video-modes supported by the Sun Expert3D device and the monitor can be obtained by running SUNWifb\_config with the - res \? option (shown in the command synopsis above). The following is a list of all possible video-modes supported on the Sun Expert3D device:

1024x768x60  
1024x768x70  
1024x768x75  
1024x768x75  
1024x768x77

1920x1200x70  
1920x1200x75

#### Symbolic names

For convenience, some of the above video modes have symbolic names defined for them. Instead of the form *width x height x rate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name none is that when the window system is run the screen resolution will be the

video mode that is currently programmed in the device.

Name	Corresponding Video Mode
-----	
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
stereo	960x680x112s
ntsc	640x480x60i
pal	768x575x50i
none	(see text above)

now

The `res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of the following might be present.

If present, not only will the video mode be updated in the `OWconfig` file, but the Sun Expert3D device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

Note that it is inadvisable to use this suboption with `SUNWifb_config` while the configured device is being used (for example, while running the window system); unpredictable results might occur. To run `SUNWifb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system

session, the video mode will be changed immediately, but the width and height of the affected screen will not change until the window system is exited and reentered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

`noconfirm`

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `SUNWifb_config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `SUNWifb_config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `SUNWifb_config` is being run from a shell script.

`nocheck`

If present, the normal error checking based on the monitor sense code (described above) will be suspended. The video mode specified by the user

will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the Sun Expert3D device). Use of this option implies `noconfirm` as well.

`try`

If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or carriage return is considered a no and the previous video mode will be restored and `SUNWifb_config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with `SUNWifb_config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWifb_config` with the

try sub-option, the window system should be brought down first.

`-deflinear true | false`

The Sun Expert3D device possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun(1) `-defdepth` and `-defclass` options described in the *OpenWindows Desktop Reference Manual*). If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options will be chosen to be the default. This option cannot be used when the `-defoverlay` option is present, because the Sun Expert3D does not possess a linear overlay visual.

`-defoverlay true | false`

The Sun Expert3D device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the Sun Expert3D visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. If the value of this option is `true`, the overlay visual will be made the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `-defdepth` and `-defclass`, will be chosen as the default visual. See the Xsun(1) manual page in the *OpenWindows Desktop Reference Manual*. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun Expert3D device does not possess a linear overlay visual.

---

<code>-linearorder first   last</code>	If <code>first</code> , linear visuals will come before their non-linear counterparts on the X11 screen visual list for the Sun Expert3D screen. If <code>last</code> , the nonlinear visuals will come before the linear ones.
<code>-overlayorder first   last</code>	If <code>first</code> , the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the Sun Expert3D screen. If <code>last</code> , the non-overlay visual will come before the overlay one.
<code>-expvis enable   disable</code>	If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor, and so forth) can be found in the screen visual list.
<code>-slave enable   disable</code>	If enabled, the video for this frame buffer will be synced with the video of the display which is connected to it. For applications which support it buffers will also be swapped synchronously.
<code>-accum enable   disable</code>	If enabled, frame buffer memory is allocated for accelerated accumulation buffer for windows. If disabled, software accumulation buffering will be done for windows. Accelerated accumulation buffers for pBuffers are always available as memory allows.
<code>-g <i>gamma-correction_value</i></code>	This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by <code>XSolarisGetVisualGamma()</code> . See <code>XSolarisGetVisualGamma(3)</code> for a description of that function. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.
<code>-g file <i>gamma-correction_file</i></code>	This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values

should be in hexadecimal format and separated from each other by at least one space. Also, this file should provide 1024 such triplets. An example of this file is as follows.

```
0x00 0x00 0x000
0x01 0x01 0x001
0x02 0x02 0x002
...
...
0x3ff 0x3ff 0x3ff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note that, when gamma correction is being done using a user-specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

`-defaults`

Resets all option values to their default values.

`-propt`

Prints the current values of all Sun Expert3D options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWifb_config` completes. This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/ifb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Accum: Disabled (do not allocate an accumulation buffer)
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
 Overlay Visuals are last
OpenGL Visual Expansion: enabled
Gamma Correction Value: 2.22
Gamma Correction Table: Available
```

`-prconf`

Prints the Sun Expert3D hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/ifb0 ---
PROM Information: @(#)ifb.fth 1.25 99/10/12 SMI
```

EDID Data: Available - EDID version 1 revision 1  
 Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75,  
 1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s,  
 640x480x60  
 Current resolution setting: 1280x1024x76

`-help` Prints a list of the `SUNWifb_config` command-line options, along with a brief explanation of each.

`-samples 1 | 2 | 4 | 8 | 16` Requested number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resources exist for the request.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples after you specify the option `-multisample enable`.

The default is 16.

`-multisample enable | disable | auto` If set to `disable`, no multisample is possible. If set to `enable`, multisample is possible but is selected on a per-window basis using a library interface. If set to `auto`, all Sun OpenGL windows are rendered using multisampling.

Query the number of samples used with `-propt` (see above) or the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples if `-multisample` is set to `enable`.

The default is `disable`.

The `xglnfo` utility is shipped with the Sun OpenGL package, `SUNWglrt`. The man page for `xglnfo` is part of another Sun OpenGL package, `SUNWgl doc`.

**Defaults** For a given invocation of `SUNWifb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if a Sun Expert3D option has never been specified via `SUNWifb_config`, a default value is used. The option defaults are as follows:

Option	Default
-----	
<code>-dev</code>	<code>/dev/fbs/ifb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>

```

-defoverlay false
-linearorder last
-overlayorder last
-expvis enable
-slave disable
-accum enable
-g 2.22
-samples 16
-multisample disable

```

The default for the `-res` option of `none` means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This design choice provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX), this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun Expert3D video mode.

**Examples** EXAMPLE 1 Changing Monitor Resolution

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/lib/fbconfig/SUNWifb_config -res 1280x1024x76
```

 fbconfig [-help] [-res ?]

**Description** SUNWjfb\_config configures the Sun XVR-600 and XVR-1200 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-600 and XVR-1200.

You can specify options for only one device at a time. If you want to specify options for multiple devices, you must invoke the SUNWjfb\_config utility multiple times.

You can use the SUNWjfb\_config utility to specify Sun XVR-600 or XVR-1200 specific options. Use the normal window system options to specify default depth, default visual class and so forth. Specify these as device modifiers on the command line. See Xsun(1)

You can also specify which OWconfig file to update. By default, SUNWjfb\_config updates the machine-specific file in the /etc/openwin. You can specify an alternate file by using the -file option. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the SUNWjfb\_config program, which is owned by the root user, always runs with setuid root permission.

The first form of SUNWjfb\_config shown in the SYNOPSIS section stores the specified options in the OWconfig file. These options initialize the Sun XVR-600 and XVR-1200 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options, do not update the `OWconfig` file. Additionally, for the third form all other options are ignored.

**Options** The following options are supported:

`-accum enable | disable`

Enable or disable frame buffer memory. If enabled, frame buffer memory is allocated for the accelerated accumulation buffer for windows. If disabled, software accumulation buffering for windows is used. Accelerated accumulation buffers for pBuffers are always available as memory allows.

`-dev device-filename`

Specify the SunSun XVR-600 or XVR-1200 special file. The default is `/dev/fbs/jfb0`.

`-defaults`

Reset all option values except `-dev` to their default values.

This option sets the resolution override to `none` which implies the last video mode setting is preserved. If no monitor is attached, the video mode is set to `1152x900x66`.

`-deflinear true | false`

Both the Sun XVR-600 and XVR-1200 possess two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

If the value of this option is `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the `Xsun defdepth` and `defclass` options; see `Xsun(1)`). If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options is chosen as the default visual. This option cannot be used when the `-defoverlay` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.

`-defoverlay true | false`

Both the Sun XVR-600 and XVR-1200 provide an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, is chosen as the default visual. See `Xsun(1)`. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message is printed and the `-defoverlay` option is treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.

**-defdepth 8 | 24**

Set the depth (bits per pixel) on the device. Possible values for the `-defdepth` option are 8 or 24. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using `fbconfig`. The default is determined by the X Server `smf(5)` default depth property. You can query this property with the following command:

```
% /usr/sbin/svccfg -s svc:/application/x11/x11-server listprop \
'options/default_depth'
```

**-doublehigh enable | disable**

Configure the two outputs of the Sun XVR-1200 into one vertical virtual display. The default is `disable`.

This option is not applicable to the Sun XVR-600 device.

**-doublewide enable | disable**

Configure the two outputs of the Sun XVR-1200 into one horizontal virtual display. The default is `disable`.

This option is not applicable to the Sun XVR-600 device.

**-fake8 enable | disable**

Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. The default is `disable`.

**-file machine|system**

Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

**-g *gamma-correction value***

Change the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

**-gfile *gamma-correction file***

Load the gamma correction table from the file specified by *gamma-correction file*. You should format this file to provide the gamma correction values for R, G, and B channels on each line. Specify each value in hexadecimal format and separate it from another value by at least 1 space. The *gamma-correction file* file should provide 1024 such triplets.

You can load the gamma correction table with this option can while the window system is running. The new gamma correction affects all the window being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction

value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction file*:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...
...
0x3ff 0x3ff 0x3ff
```

**-help**

Print a list of the SUNWjfb\_config command line options, along with a brief explanation of each.

**-multisample available | disable | forceon**

If set to `disable`, no multisample is possible. If set to `available`, multisample is possible but is selected on a per-window basis using a library interface. If set to `forceon`, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with `-propt` or the `xglinfo(1)` utility. The `xglinfo` utility can return the number of multisamples if `-multisample` is set to enable. The default is `disable`.

**-offset *xval yval***

Adjust the position of the specified stream by the value specified. This option is only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the *xval* to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, use the *yval* to position the bottom stream. Negative is up (overlaps with top stream). The default is `[0, 0]`.

**-outputs swapped | direct**

If either `-doublewide` or `-doublehigh` are enabled, reverse the position of the two outputs relative to each other. The default is `direct`.

**-propt**

Print the current values of all Sun XVR-600 and XVR-1200 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they will be in the OWconfig file after the call to `SUNWjfb_config` completes.

This is a typical display:

```
fbconfig -dev jfb2 -propt

--- OpenWindows Configuration for /dev/fbs/jfb2 ---

OWconfig: machine
Video Mode: 1280x1024x60
Accum: Enabled (allocate an accumulation buffer if possible)

Multisample Information:
```

Multisample Mode: Disabled (multisample visuals  
will not be available)  
Samples Per Pixel: N/A (multisampling disabled)

Screen Information:  
DoubleWide: Disabled  
DoubleHigh: Disabled  
Output Configuration: Direct  
Offset/Overlap: [0, 0]

Visual Information:  
Default Visual: Non-Linear Normal Visual  
Visual Ordering: Linear Visuals are last  
Gamma Correction Value: 2.22  
Gamma Correction Table: Available  
Fake8 rendering: disabled

```

`-res video-mode [ now | try [ noconfirm | nocheck ] ]`

Specify the video mode of the monitor connected to the specified Sun XVR-600 or XVR-1200 device.

The `-res` option requires you to specify the video-mode. You can specify *video-mode* in the format of *widthxheightxrate* or as a symbolic name.

*widthxheightxrate*

Specify *video-mode* in the format of *widthxheightxrate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

You can use the *s* suffix to specify stereo video modes. The *s* suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes.

The `-res` option also accepts formats with `@` (at sign) in front of the refresh rate instead of *x*, (`280x1024@76`). Some video-modes, supported by Sun XVR-600 and XVR-1200, might not be supported by the monitor.

The list of video-modes supported by the Sun XVR-600 and XVR-1200 device and the monitor can be obtained by running `SUNWjfb_config` with the `-res ?` option. See SYNOPSIS.

### Symbolic Names

Some video modes have symbolic names defined for them. Instead of using the *widthxheightxrate* format, you can specify one of the symbolic names as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

<code>svga</code>	<code>1024x768x60</code>
<code>1152</code>	<code>1152x900x76</code>
<code>1280</code>	<code>1280x1024x76</code>
<code>stereo</code>	<code>960x680x112s</code>
<code>ntsc</code>	<code>640x480x60i</code>
<code>pal</code>	<code>768x575x50i</code>
<code>none</code>	Programmed video mode

The `-res` option accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

#### `now`

If present, updates the video mode to be updated in the `OWconfig` file. Programs the Sun XVR-600 or XVR-1200 device to display the video mode. This is useful for changing the video mode before starting the window system.

Do not use this suboption with `SUNWjfb_config` while the configured device is being used, for example, while running the window system. Unpredictable results can occur.

If you want to run `SUNWjfb_config` with the `now` suboption, first bring the window system down. If you use the `now` suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

#### `noconfirm`

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `SUNWjfb_config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `-noconfirm` option instructs `SUNWjfb_config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `SUNWjfb_config` is run from a shell script.

#### `nocheck`

If present, the normal error checking based on the monitor sense code is suspended. The video mode specified is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the Sun XVR-600 or XVR-1200 device. Use of this option implies `noconfirm`.

#### `try`

If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a `y` within 10 seconds. You can terminate the trial before 10 seconds by entering any character but `y` or RETURN.

Terminating the trial by entering a character other than `y` or RETURN restores the previous video mode. `SUNWjfb_config` does not change the video mode in the `OWconfig` file. Other specified options still take effect. If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption.

If you want to run `SUNWjfb_config` with the `now` suboption, first bring the window system down. If you use the `now` suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is strongly discouraged.

#### `-samples 1 | 4 | 8 | 16 | adaptive`

Request the number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resources exist for the request. If set to `adaptive`, variable multisampling is possible, with the minimum samples per pixel set to 2. Query the number of samples used with `-propt` or the `xglinfo(1)` utility. The `xglinfo` utility can return the number of multisamples after you specify the option `-multisample enable`. The default is 16.

`-slave disable | multiview | stereo | bnc`

Enable or disable a specific port. Specify `multiview` for the DB9 connector, `stereo` for the mini-DIN connector, or `bnc` for the bnc connector. Specify `disable` to disable a specific port. If set, the option is an exclusive slave instance in the Framelock Configuration Setup. The default is `disable`.

`multiview` and `bnc` are only applicable to the Sun XVR-1200 device.

**Defaults** For a given invocation of `SUNWjfb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if an option has never been specified by way of `SUNWjfb_config`, a default value is used. The options and their corresponding defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fbs/jfb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-linearorder</code>	<code>last</code>
<code>-slave</code>	<code>disable</code>
<code>-accum</code>	<code>enable</code>
<code>-g</code>	<code>2.22</code>
<code>-samples</code>	<code>16</code>
<code>-multisample</code>	<code>disable</code>
<code>-doublewide</code>	<code>disable</code>
<code>-doublehigh</code>	<code>disable</code>
<code>-outputs</code>	<code>direct</code>
<code>-offset</code>	<code>[0,0]</code>

The default for the `-res` option of `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. This means that the PROM ultimately determines the default video mode.

**Examples** **EXAMPLE 1** Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig -dev jfb0 -res 1280x1024x76
```

**Files** /dev/fbs/jfb*n*

Device special file for the XVR-600 or XVR-1200 high performance single screen

The Xsun(1) man page, which is not part of the SunOS man page collection.

**Name** SUNWkfb\_config – fbconfig module for configuring the Sun XVR-2500 Graphics Device

**Synopsis** /usr/lib/fbconfig/SUNWkfb\_config [-dev *device-filename*]  
 [-res *video-mode*] [-file *machine* | *system*]  
 [-deflinear *true* | *false*] [-defoverlay *true* | *false*]  
 [-deftransparent *true* | *false*]  
 [-slave *disable* | *multiview*]  
 [-g *gamma-correction-value*]  
 [-gfile *gamma-correction-file*]  
 [-doublewide *enable* | *disable*]  
 [-doublehigh *enable* | *disable*]  
 [-multisample *available* | *disable* | *forceon*]  
 [-samples *1* | *2* | *4* | *8* | *16* ] [-offset *xval yval*]  
 [-propt] [-prconf] [-defaults]  
  
 /usr/lib/fbconfig/SUNWkfb\_config [-propt] [-prconf]  
 /usr/lib/fbconfig/SUNWkfb\_config [-help] [-res ?]

**Description** SUNWkfb\_config configures the Sun XVR-2500 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-2500.

The first form of SUNWkfb\_config shown in the SYNOPSIS section stores the specified options in the OWconfig file. These options initialize the Sun XVR-2500 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the -prconf, -propt, -help, and -res ? options, do not update the OWconfig file. For the third form, all other options are ignored.

You can specify options for only one device at a time. If you want to specify options for multiple devices, invoke the SUNWkfb\_config utility multiple times.

Only the Sun XVR-2500 options can be specified through the SUNWkfb\_config utility. Use the normal window system options to specify default depth (see [svccfg\(1M\)](#)), default visual class and so forth. Specify these as device modifiers on the command line. See [Xsun\(1\)](#).

You can also specify which OWconfig file to update. By default, SUNWkfb\_config updates the machine-specific file in the /etc/openwin directory tree. Use the -file option to specify an alternate file. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the SUNWkfb\_config program, which is owned by the root user, always runs with setuid root permission.

**Options** The following options are supported:

`-defaults`

Resets all option values except `-dev` to their default values. This option sets the resolution override to `none` which implies that the last video mode setting is preserved. If no monitor is attached, the video mode is set to `1152x900x66`.

`-deflinear true | false`

This option selects the default X visual. The Sun XVR-2500 device supports two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not.

If the value of this option is `true`, the default visual is set to default depth 24 and the default class is `TrueColor` with gamma correction enabled. If `false`, a non-linear visual that satisfies the other default visual selection options, such as the default depth and default class, is chosen as the default visual. See `Xsun(1)`.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-defoverlay true | false`

This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit `PseudoColor` visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. The default depth is 8 bit and the default class is `PseudoColor`. If `false`, the `nonoverlay`

visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See Xsun(1).

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-deftransparent true | false`

This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals.

If the value of this option is `true`, the overlay visual used as the default is a transparent overlay visual. A visual with transparency supports a colormap with 255 colors and one transparent pixel. The default depth is 8 bit and the default class is PseudoColor. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See Xsun(1).

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-dev device-filename`

Specifies the SunXVR-2500 special file. The default is `/dev/fbs/kfb0`.

---

-doublehigh enable   disable	Configures the two outputs of the Sun XVR-2500 device into one vertical virtual display. The default is <code>disable</code> .
-doublewide enable   disable	Configures the two outputs of the Sun XVR-2500 device into one horizontal virtual display. The default is <code>disable</code> .
-file machine   system	Specifies which <code>OWconfig</code> file to update. If <i>machine</i> is specified, the machine-specific <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree is updated. If <i>system</i> is specified, the global <code>OWconfig</code> file in the <code>/usr/openwin</code> directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is <i>machine</i> .
-g <i>gamma-correction value</i>	Changes the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.
-g file <i>gamma-correction file</i>	Loads the gamma correction table from the file specified by <i>gamma-correction file</i> . Format this file to provide the gamma correction values for R, G, and B channels on each line. Specify each value in hexadecimal format, separated from another value by at least one space. The <i>gamma-correction file</i> should provide 1024 such triplets.  You can load the gamma correction table with this option while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction value is undefined. By default, the window system

assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction file*:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...
...
0x3ff 0x3ff 0x3ff
```

**-help**

Prints a list of the SUNWkfb\_config command line options, along with a brief explanation of each.

**-multisample available | disable | forceon**

If set to *disable*, no multisample is possible. If set to *available*, multisample is possible but is selected on a per-window basis using a library interface. If set to *forceon*, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with *-propt* or the *xglinf*(1) utility. The *xglinf* utility can return the number of multisamples if *-multisample* is set to *available*. The default is *disable*.

**-offset *xval yval***

Adjusts the position of the specified stream by the value specified. This option is only implemented in *-doublewide* and *-doublehigh* modes. For *-doublewide*, use the *xval* to position the rightmost stream. Negative is left (overlaps with the left stream). For *-doublehigh*, use the *yval* to position the bottom stream. Negative is up (overlaps with top stream). The default is [0, 0].

**-prconf**

Prints the Sun XVR-2500 hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/kfb2 ---
```

```
Type: XVR-2500
```

```
PROM Information: @(#) xvr2500.fth 14.106 05/08/15 SMI
```

## Monitor/Resolution Information:

```

Monitor Manufacturer: SUN
Product code: 1352
Serial #: 7225675
Manufacture date: 1997, week 51
Monitor dimensions: 48x31 cm
Monitor preferred resolution: 1920x1200x70
Separate sync supported: yes
Composite sync supported: yes
EDID: Version 1, Revision 1
Supported resolutions: 1920x1200x70, SUNW_STD_1600x1000x76,
SUNW_STD_1600x1000x66, SUNW_STD_1440x900x76, 1920x1080x70,
1600x900x76, 1600x900x66, 1440x810x76, 1280x720x76,
1920x1080x72, VESA_STD_720x400x70, VESA_STD_720x400x88,
VESA_STD_640x480x60, VESA_STD_640x480x67,
VESA_STD_800x600x56, VESA_STD_800x600x60,
VESA_STD_800x600x72, VESA_STD_800x600x75,
VESA_STD_1024x768x70, VESA_STD_1280x1024x75,
Current resolution setting: SUNW_STD_1280x1024x76

```

## Framelock Configuration:

```
Slave Mode: Disabled
```

```
-propt
```

Prints the current values of all Sun XVR-2500 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWkfb_config` completes.

This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/kfb2 ---
```

```
OWconfig: machine
Video Mode: SUNW_STD_1280x1024x76
```

## Multisample Information:

```

Multisample Mode: Disabled (multisample visuals
will not be available)
Samples Per Pixel: N/A (multisampling disabled)

```

## Screen Information:

```

DoubleWide: Disabled
DoubleHigh: Disabled
Offset/Overlap: [0, 0]

```

**Visual Information:**

Default Visual: Non-Linear Normal Visual

Gamma Correction Value: using gamma value 2.22

**-res *video-mode***

Specifies the video mode of the monitor connected to the specified Sun XVR-2500 device.

You must specify the video mode with the -res option. You can specify *video-mode* in the format of *widthxheightxrate* or as a symbolic name. The format of these built-in video modes is:

*widthxheightxrate*     *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

You can use the *s* suffix to specify stereo video modes. The *s* suffix of 960x680x112s and 960x680x108s means that these are stereo video modes.

As a convenience, the -res option also accepts formats with @ (at sign) in front of the refresh rate instead of *x*, as for example, 1280x1024@76. Some video-modes supported by the Sun XVR-2500 device may not be supported by the monitor.

You can obtain the list of video-modes supported by the Sun XVR-2500 device and the monitor by running `SUNWkfb_config` with the `- res ?` option. See SYNOPSIS.

### *Symbolic Names*

Some video modes have symbolic names defined for them. Instead of using the *widthxheightxrate* format, you can specify one of the symbolic names as the argument to the `- res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

Name	Corresponding Video Mode
<code>svga</code>	<code>1024x768x60</code>
<code>1152</code>	<code>1152x900x76</code>
<code>1280</code>	<code>1280x1024x76</code>
<code>stereo</code>	<code>960x680x112s</code>
<code>none</code>	(see text above)

`-samples 1 | 2 | 4 | 8 | 16`

Requests the number of samples to compute per display pixel. The requested number of samples per pixel is used if `-multisample` is not disabled and resources exist for the request. Query the number of samples used with `-propt` or the `xglnfo(1)` utility. The `xglnfo` utility can return the number of multisamples after you specify the option `-multisample` available. The default is 4.

`-slave disable | multiview`

If you set the `multiview` argument for the `-slave` option, the device synchronizes video with a master through the `multiview` ribbon cable. Both devices should be running the same resolution and the option should be issued when the window system is running. The default is `disable`.

**Defaults** For a given invocation of the `SUNWkfb_config` command line, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated and retains its previous value.

When the window system is run, if a Sun XVR-2500 option has never been specified by way of `SUNWkfb_config`, a default value is used. The options and their corresponding defaults are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fbs/kfb0</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-deflinear</code>	<code>false</code>
<code>-defoverlay</code>	<code>false</code>
<code>-deftransparent</code>	<code>false</code>
<code>-slave</code>	<code>disable</code>
<code>-g</code>	<code>2.22</code>
<code>-samples</code>	<code>4</code>
<code>-multisample</code>	<code>disable</code>

Option	Default
-doublewide	disable
-doublehigh	disable
-outputs	direct
-offset	[0,0]

The default for the -res option of none means that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

**Examples** EXAMPLE 1 Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig -dev kfb0 -res 1280x1024x76
```

**Files** /dev/fbs/kfbn Device special file for the XVR-2500 high performance single screen  
 /usr/sbin/kfbdaemon The kfb memory manager

**Name** SUNWnfb\_config – fbconfig module for configuring XVR-300 Graphics Accelerator

**Synopsis** fbconfig [-dev *device-filename*]  
           [-res *video-mode* [now | try] [noconfirm | nocheck]]  
           [-file machine | system] [-fake8 enable | disable]  
           [-doublewide enable | disable]  
           [-doublehigh enable | disable]  
           [-clone enable | disable] [-outputs swapped | direct]  
           [-depth 8 | 24] [-offset xval yval] [-defaults]  
  
 fbconfig [-propt] [-prconf]  
 fbconfig [-help] [-res ?]

**Description** SUNWnfb\_config is the XVR-300 device dependent layer for fbconfig. It configures the XVR-300 Graphics Accelerator and some of the X11 window system defaults for XVR-300. The XVR-300 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2).

The first form of SUNWnfb\_config shown in the SYNOPSIS section sets options for the XVR-300. This form stores the specified options in the OWconfig file. These options will be used to initialize the XVR-300 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots. For -res now, the XVR-300 device will be immediately programmed.

The second form, which invokes the -prconf and -propt options, queries the XVR-300 for status.

The third form, which invokes the -help and -res ? options, provides instruction on using SUNWnfb\_config. Additionally, for the third form all other options are ignored.

Options may be specified for only one XVR-300 device at a time. Specifying options for multiple XVR-300 devices requires multiple invocations of SUNWnfb\_config.

Only XVR-300-specific options can be specified through SUNWnfb\_config. The normal window system options for specifying default depth, default visual class and so forth can still be specified as device modifiers on the command line when the X Server is started. See the dtlogin(1) reference to Xservers File.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

**Options** -dev *device-filename*  
           Specifies the XVR-300 special file. The default is /dev/fb.

-file machine | system

Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created.

-res video-mode [now | try] [noconfirm | nocheck ]

Specifies the video mode used to drive the monitor connected to the specified XVR-300 device. Video modes are built-in.

*video-mode* Specifies resolution and timing information for the display (for example, 1280x1024x76). The format of the *video-mode* specifier is: *widthxheightxrate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, -res also accepts formats with @ preceding the refresh rate instead of x. For example, 1280x1024@76.

Symbolic names. For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to -res. The meaning of the symbolic name none is that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

Some video-modes supported by XVR-300 may not be supported by the monitor. The list of video-modes supported by the XVR-300 device and the monitor can be obtained by running SUNWnfb\_config with the -res ? option (the third form shown in the command SYNOPSIS section).

-res option arguments. The -res option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

*now* If present, not only will the video mode be updated in the OWconfig file, but the XVR-300 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this suboption with SUNWnfb\_config while the configured device is being used (for example, while running the window system) because unpredictable results may occur. To run SUNWnfb\_config with the now suboption, first bring the window system down. If the now suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the

window system is exited and reentered again. Consequently, this usage is discouraged.

`noconfirm` Using the `-res` option, the user could put the system into an unusable state, which has no video output. To reduce the chance of this, the default behavior of `SUNWnfb_config` is to print a warning message and to ask the user whether to continue. The `noconfirm` suboption bypasses this confirmation. This suboption is useful when `SUNWnfb_config` is being run from a shell script.

`nocheck` If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This suboption is useful if a different monitor is to be connected to the XVR-300 device. Use of this suboption implies `noconfirm` as well.

`try` If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing 'y' within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than 'y' or carriage return is considered a no and the previous video mode will be restored and `SUNWnfb_config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption (see the warning note on the `now` suboption).

`-doublewide enable | disable`

This option allows you to configure the two outputs of the Sun XVR-300 into one horizontal virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

`-doublehigh enable | disable`

This option allows you to configure the two outputs of the Sun XVR-300 into one vertical virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

`-clone enable | disable`

If this option is set to `enable`, the two outputs will display identically. Default is `disable`.

`-outputs swapped | direct`

If either `doublewide` or `doublehigh` is enabled, this option allows you to reverse the positions of the two outputs relative to each other. Default is `direct`.

-fake8 enable | disable

If enabled, simple 8 bit X windows will be rendered without a hardware colormap to reduce colormap flashing. Some performance reductions may be observed. Default is `disable`.

-depth 8 | 24

Sets the default depth for the window system to start with. Possible values are 8 or 24. Log out of the current window system session and log back in for the change to take effect. Any `defdepth` setting in the Xserver command line takes precedence over what is set using `fbconfig`. Default is 24. This option is only supported on Solaris 9. For Solaris 10 and above, use `/usr/sbin/svccfg` to configure depth.

-offset *xval yval*

Adjusts the position of the specified stream by the value specified. Currently only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, the *xval* is used to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, the *yval* is used to position the bottom stream. Negative is up (overlaps with top stream). Positive values are treated as 0. Default is [0, 0]

-defaults

Resets all option values to their default values.

-propt

Prints the current values of all XVR-300 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWnfb_config` completes. This is a typical display:

```
--- Graphics Configuration for /dev/fbs/nfb0 ---
```

```
OWconfig: machine
```

```
Video Mode: NONE
```

```
Screen Information:

VESA\_STD\_1024x768x75, VESA\_STD\_1280x1024x75, APPLE\_1152x870x75  
Current resolution setting: 1152x900x66

**-help**

Prints a list of the SUNWnfb\_config command line options, along with a brief explanation of each.

- res ?  
Prints list of defined *video-mode* names.

**Defaults** For a given invocation of a SUNWnfb\_config command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated and retains its previous value.

When the window system is run, if an XVR-300 option has never been specified via SUNWnfb\_config, a default value is used. The option defaults are as follows:

Option	Default
-dev	/dev/fb
-file	machine
-res	none
-fake8	disable
-doublewide	disable
-doublehigh	disable
-clone	disable
-outputs	direct
-offset	[0,0]

The default for the - res option of none means that when the window system is run, the screen resolution will be the video mode that is currently programmed in the XVR-300 PROM.

This provides compatibility for users who are used to specifying the device resolution through the XVR-300 PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default XVR-300 video mode.

**Examples** EXAMPLE 1 Switching the monitor type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% fbconfig -res 1280x1024x76
```

<b>Files</b>	/dev/fbs/nfbri	Device special file for XVR-300 single screen
	/dev/fbs/nfbria	Device special file for the XVR-300 first video out
	/dev/fbs/nfbrib	Device special file for the XVR-300 second video out
	/usr/lib/fbconfig/SUNWnfb_config	Device dependent configuration module

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfbcf
Interface Stability	Evolving

**See Also** [fbconfig\(1M\)](#), [attributes\(5\)](#), [nfb\(7D\)](#)

See the `dtlogin(1)` man page in the CDE man page collection. Also useful is the `XSun(1)` man page in the OpenWindows man page collection.

**Name** SUNWpfb\_config – fbconfig module for configuring the XVR-50 and the Sun XVR-100 Graphics Accelerator

**Synopsis** For XVR-50:

```
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
 [-res video-mode [now | try] [noconfirm | nocheck]]
 [-file machine | system]
 [-fake8 enable | disable]
 [-g enable | disable | gamma-value]
 [-defaults]
```

For Sun XVR-100:

```
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
 [-res video-mode [now | try] [noconfirm | nocheck]]
 [-file machine | system]
 [-fake8 enable | disable]
 [-g enable | disable | gamma-value]
 [-doublewide enable | disable]
 [-doublehigh enable | disable]
 [-outputs swapped | direct]
 [-depth 8 | 24]
 [-offset xval yval]
 [-defaults]
```

For Sun XVR-100 and XVR-50:

```
/usr/lib/fbconfig/SUNWpfb_config [-pt] [-prconf]
/usr/lib/fbconfig/SUNWpfb_config [-help] [-res \?]
```

**Description** SUNWpfb\_config is the XVR-50 and the Sun XVR-100 device dependent layer for [fbconfig\(1M\)](#). It configures the XVR-50 and the Sun XVR-100 Graphics Accelerator and some of the X11 window system defaults for the XVR-50 and Sun XVR-100. The Sun XVR-100 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2). The XVR-50 drives one video stream.

The first two forms of SUNWpfb\_config shown in the SYNOPSIS section sets options for the XVR-50 and the Sun XVR-100 devices. It stores the specified options in the `OWconfig` file. These options initialize the XVR-50 and the Sun XVR-100 devices the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. The XVR-50 and the Sun XVR-100 devices are immediately programmed if you specify the `-res now`.

The third form, which invokes the `-prconf` and `-propt` options, queries the XVR-50 and the Sun XVR-100 device for status.

The fourth form, which invokes the `-help`, and `-res \?` options, provides instruction on using SUNWpfb\_config. Additionally, for the fourth form all other options are ignored.

You can only specify options for only one XVR-50 or Sun XVR-100 device at a time. If you want to specify options for multiple XVR-50 or Sun XVR-100 devices, you must use multiple invocations of the `SUNWpfb_config` command.

You can only use `SUNWpfb_config` to specify XVR-50 or Sun XVR-100 specific options. You can use the normal window system options to specify the default depth, default visual class and so forth as device modifiers on the command line when the X Server is started. See `dtlogin(1)` for information regarding the `Xservers` File.

You can also specify the `OWconfig` file to update. The machine-specific file in the `/etc/openwin` directory tree is updated by default. You can use the `-file` option to specify an alternate file. For example, you can update the system-global `OWconfig` file in the `/usr/openwin` directory tree instead.

**Options** The following options are supported:

`-defaults`

Reset all option values to their default values.

`-depth 8 | 24`

Set the depth (bits per pixel) for the window system. Possible values for the `-depth` option are 8 or 24. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using `fbconfig`. The default is 8. This option is only available with Solaris 8 or Solaris 9.

`-dev device-filename`

Specify the XVR-50 or the Sun XVR-100 special file. The default is `/dev/fb`.

`-doublehigh enable | disable`

Configure the two outputs of the Sun XVR-100 into one vertical virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-doublewide enable | disable`

Configure the two outputs of the Sun XVR-100 into one horizontal virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-fake8 enable | disable`

Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-file machine|system`

Specifies which `OWconfig` file to update. If `machine` is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If `system` is specified, the

global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is `machine`.

`-g enable | disable | gamma-value`

This option allows you to change the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is 2.22. Any value less than zero is illegal.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-help`

Print a list of the `SUNWpfb_config` command line options, along with a brief explanation of each option.

`-offset xval yval`

Adjust the position of the secondary stream on the Sun XVR-100. This option is currently implemented only for the `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the `xval` to position the DVI stream, if `-outputs` are direct (VGA stream if `-outputs` are swapped). A negative value specifies the overlapped region with the primary stream. This is similar for `-doublehigh`, except the `yval` is used. Positive values are treated as 0. You must log out of the current window system session and log back in again for the change to take effect. The default is `[0, 0]`.

`-outputs swapped | direct`

Reverse the positions of the `-doublewide` or `-doublehigh` outputs relative to each other on the Sun XVR-100. You must log out of the current window system session and log back in again for the change to take effect. The default is `direct`.

`-propt`

Print the current values of all XVR-50 and Sun XVR-100 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they will be in the `OWconfig` file after the call to `SUNWpfb_config` completes.

This is a typical display for the Sun XVR-100:

```
--- Graphics Configuration for /dev/fbs/pfb0 ---
```

```
OWconfig: machine
Video Mode: not set
Depth: not set
```

```
Screen Information:
 Doublewide: Disable
 Doublehigh: Disable
 Offset/Overlap: [0.0]
```

```

Output Configuration: Direct
Fake8 Rendering: Disable
Gamma Configuration: Disable

```

**-prconf**

Print the XVR-50 and Sun XVR-100 hardware configuration.

This is a typical display:

```
--- Hardware Configuration for /dev/fbs/pfb0 ---
```

```
Type: XVR-100
ASIC: version 0x5159 REV : version 0x3000000
PROM: version 4.2
```

## Monitor/Resolution Information:

```
EDID Data: Not Available
Current resolution setting: 1152x900x66
```

## Depth Information:

```
Possible depths: 8, 24
Current depth: 8
```

**-res *video-mode* [ now | try [ noconfirm | nocheck ]]**

Specify the video mode that drives the monitor connected to the specified XVR-50 or Sun XVR-100 device.

Video modes are built-in. The **-res** option requires you to specify the video-mode. You can specify *video-mode* in the format of *widthxheightxrate* or as a symbolic name.

**video-mode** Specify *video-mode* in the format of *widthxheightxrate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. An example video mode specified in this format is 1280x1024x60.

The **-res** option also accepts formats with @ preceding the refresh rate instead of x (1280x1024@60).

**Symbolic Names**

Some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate* format, you can specify one of the symbolic names as the argument to the **-res** option. The meaning of the symbolic name “none” is that when the window system is run the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

Name	Corresponding Video Mode
svga	1024x768x60

1152	1152x900x76
1280	1280x1024x75
none	Programmed video mode

Some video-modes, supported by XVR-50 and Sun XVR-100, might not be supported by the monitor. Use the `-res \?` option to obtain the list of video-modes supported by the XVR-50 and Sun XVR-100 device and the monitor.

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

<code>nocheck</code>	If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the XVR-50 or the Sun XVR-100 device. Use of this option implies <code>noconfirm</code> as well.
<code>noconfirm</code>	You could put the system into an unusable state using the <code>-res</code> option, which has no video output. To reduce the chance of this, the default behavior of <code>SUNWpfb_config</code> is to print a warning message and to ask the user whether to continue. The <code>noconfirm</code> option bypasses this confirmation. This option is useful when you are running <code>SUNWpfb_config</code> from a shell script.
<code>now</code>	If present, updates the video mode in the <code>OWconfig</code> file and immediately programs the XVR-50 or Sun XVR-100 device to display this video mode. This is useful for changing the video mode before starting the window system.

Do not use this suboption with `SUNWpfb_config` while the configured device is being used (for example, while running the window system) as unpredictable results can occur.

If you want to run `SUNWpfb_config` with the `now` suboption, first bring the window system down, and executed from the console command line. If you use the `now` option within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

<code>try</code>	If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a <code>y</code> within 10 seconds. You can terminate the trial before 10 seconds by entering any character but <code>y</code> or <code>&lt;RETURN&gt;</code> .
------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

This sub-option should not be used with `SUNWpfbconfig` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWpfbconfig` with the `try` sub-option, the window system should be brought down first, and executed from the console command line.

`-res \?`

Print a list of defined *video-mode* names.

**Defaults** For a given invocation of `SUNWpfb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value.

When the window system is run, if a XVR-50 or Sun XVR-100 option has never been specified by `SUNWpfb_config`, a default value is used. The options and their corresponding defaults for a XVR-50 are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fb</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-fake8</code>	<code>disable</code>
<code>-g</code>	<code>disable</code>

The options and their corresponding defaults for a Sun XVR-100 are as follows:

Option	Default
<code>-dev</code>	<code>/dev/fb</code>
<code>-file</code>	<code>machine</code>
<code>-res</code>	<code>none</code>
<code>-fake8</code>	<code>disable</code>
<code>-g</code>	<code>disable</code>
<code>-depth</code>	<code>8 (Solaris 8 and Solaris 9)</code>
<code>-doublewide</code>	<code>disable</code>
<code>-doublehigh</code>	<code>disable</code>
<code>-outputs</code>	<code>direct</code>
<code>-offset</code>	<code>[0,0]</code>

The default for the `-res` option `none` means that when the window system is run, the screen resolution will be the video mode that is currently programmed in the XVR-50 or Sun XVR-100 PROM.

This provides compatibility for users who are used to specifying the device resolution through the XVR-50 or the Sun XVR-100 PROM. On some devices (e.g. GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default XVR-50 or Sun XVR-100 video mode.

**Examples** EXAMPLE 1 Switching the Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 60 Hz:

```
example% fbconfig -res 1280x1024x60
```

<b>Files</b>	/dev/fbs/pfb <i>n</i>	Device special file for XVR-50 or Sun XVR-100 single screen
	/dev/fbs/pfb <i>na</i>	Device special file for the Sun XVR-100 first video out
	/dev/fbs/pfb <i>nb</i>	Device special file for the Sun XVR-100 second video out
	/usr/lib/fbconfig/SUNWpfb_config	Device special file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

[sync [auto |tip | tri | slice]] [pol [auto | pos | neg]]]

**Description** SUNWzulu\_config is the Sun XVR-4000 Graphics Accelerator device-dependent layer for [fbconfig\(1M\)](#). It configures the Sun XVR-4000 Graphics Accelerator and some of the X11 window system defaults and some interactions with 3D-accelerated graphics (through OpenGL).

The first through third synopses, above, show the general form of a SUNWzulu\_config command. The fourth synopsis (with -res as the first option) shows card options. The fifth synopsis is for managed-area options. The sixth and last synopsis shows stream options. These option categories—card, managed-area, and streams—are used mainly to explain the SUNWzulu\_config functions. Where appropriate, you can use options of different types on the same command line.

The Sun XVR-4000 device can support one or two unique video streams (called *stream a* and *stream b*), each of which can drive a display device.

**Option Classes** The many options that fbconfig can select on the Sun XVR-4000 Graphics Accelerator are divided into the following categories:

general options                      Shared among different invocation forms or used for query without selecting device settings.

card options	Of the entire XVR-4000 Graphics Accelerator, shared between up to two video streams.
managed area options	Pertain to an area of the frame buffer managed by X and possibly shared between two video streams.
stream options	Specific to a video stream.

#### Device Usage and Invocation Forms

To use the device to provide a single X managed area with one video stream, use a stream-independent device argument (for example, `-dev zulu0`) without a trailing `a` or `b`. The device name (for example, `/dev/fb` or `/dev/fbs/zulu0`), without any trailing stream indicator should appear on the `Xsun` command line. Stream options will control `stream a` (the only stream used).

To enable two streams from a single X managed area (without needing X's `+xinerama` option), use the device name (for example, `-dev zulu0`) without any trailing `a` or `b`. Enable card option `-doublewide` or `-doublehigh`. Without using the `-stream` option, any stream options you specify are applied to both streams. Stream options can differ between the video streams if `fbconfig` is be run separately for each stream, using the `-stream a | b` option, as shown in EXAMPLES (second example), below.

To use the device's two streams as independent X screens, run `fbconfig` separately for each stream (`-dev zulu0a` and `-dev zulu0b`), as shown in EXAMPLES (third example). Card options `-doublehigh` and `-doublewide` are not available. The device names with trailing stream indicators (for example, `/dev/fbs/zulu0a` and `/dev/fbs/zulu0b`) must be added to the `Xsun` command line to use these independent X screens. The `-stream` option is not needed; the stream is implied by the stream-specific device name.

The `fbconfig` utility checks settings for the two stream devices to assure X can use them simultaneously. Therefore, you might need to use `fbconfig` to reduce resource consumption (for example, `-samples`) used by one stream's device (for example, `zulu0a`) before you can use `fbconfig` to increase consumption by the other stream's device (for example, `zulu0b`).

The first form of `SUNWzulu_config` shown in SYNOPSIS, above, stores the specified options in the `OWconfig` file associated with the device and (for stream options) the stream. These options are used to initialize the device the next time the window system is started on that device-filename. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. You can select the `OWconfig` file that is to be updated using the `-file` option. For `-jitter` and all stream options, the device will also be immediately programmed.

The second form, which invokes any of the `-prconf` and `-propt` options, queries the device for status that is card-specific.

The third form, which invokes the `-help`, `-list`, or `-res \?` options, provides instruction on using `SUNWzulu_config`, a list of available devices, or a list of available resolutions. When using this form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices (or multiple independent X managed areas or streams) requires multiple invocations of `fbconfig`.

Only Sun XVR-4000 Graphics Accelerator-specific options can be specified through `SUNWzulu_config`. Window system options for specifying default depth, default visual class, `-nobanner`, and so forth are still specified as device modifiers on the Xsun command line when the X server is started, probably in CDE's `Xservers` file. See the `Xsun(1)` man page in the OpenWindows man page collection and `/usr/dt/config/Xservers`.

**Options** This section is subdivided into general, card, managed area, and stream options.

- General Options**
- `-dev device-filename` Specifies the device's special file, such as `/dev/fbs/zulu0` or the basename such as `zulu0` as a shorthand. The default is `/dev/fb`. See "Device Usage and Invocation Forms," above.
  - `-file machine|system` Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.
  - `-defaults` Resets all option values to their default values, listed in the DEFAULTS section, below. For example, invoking `-defaults` on `zulu0`, `zulu0a`, or `zulu0b` will reset all card, managed area, and stream options for all these `zulu0` subdevices.
  - `-propt` Displays the current values of all options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the `OWconfig` file after the call to `SUNWzulu_config` completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/zulu0 ---
```

```
OWconfig File: machine
```

```
Card:
```

```
Double(wide/high): disable
Stream to Port Mapping: direct (Stream A to Port A; B to B)
Clearpixel Value: 255
```

```
Managed Area:
```

```

```

- help                    Displays a list of the SUNWzulu\_config command line options, along with a brief explanation of each.
- res \?                Displays list of defined video mode names supported by the XVR-4000 Graphics Accelerator and the display device.
- Card Options -doublewide enable | disable                    This option makes it easy for you to combine both streams into one side-by-side virtual display. When enabled with -outputs direct, stream a is to the left of stream b. Both streams will use the same video mode defined with the -res option. If you specify disable, only stream a will be enabled. Enabling -doublewide disables -doublehigh.
- doublehigh enable | disable                    This option makes it easy for you to combine both streams into one virtual display with one display device above the other. When enabled with -outputs direct, stream a is above stream b. Both streams will use the same video mode defined with the -res option. If you specify disable, only stream a will be enabled. Enabling -doublehigh disables -doublewide.
- outputs direct | swapped | streamA | streamB                    Controls the internal routing of video streams to output ports (that is, backplane 13W3 connectors). The choices are:

<code>direct</code>	Stream a to output port a, stream b to output port b
<code>swapped</code>	Stream a to output port b, stream b to output port a
<code>streamA</code>	Stream a to both output ports
<code>streamB</code>	Stream b to both output ports

The default is `direct`. `swapped` can be used to reverse the connectors when `-doublewide` or `-doublehigh` is enabled. The `streamA` and `streamB` arguments are incompatible with stream-specific device names (for example, `zulu0a` or `zulu0b`). When the `-res` option selects an S-video (NTSC or PAL composite) video mode, the `svideo` output port is automatically selected, sometimes overriding `-outputs` selection.

`-master a | b`

This option controls which stream drives the `FIELD` and `FRAME_OUT` pins on the device's stereo/sync connector. This pin can drive stereo shutter glasses, and allow another device to framelock to this device's output. The default is `a`.

Independent of this option, the `-slave` external option allows a stream to sync to another card by means of this connector's `FIELD_IN` pin.

`-clearpixel 0 | 255`

Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

Managed Area Options `-res video_mode`

The `video_mode` argument specifies resolution and timing information for the display (for example,

SUNW\_STD\_1280x1024x76). The naming convention for the video mode specifier is:

*origin\_type\_widthxheightxrate*

The elements of the specifier are described as follows:

<i>origin</i>	This can be one of:
SUNW	Sun-derived resolution
VESA	Video Electronics Standards Association-derived resolution
<i>other</i>	other source
<i>type</i>	This can be one or more of:
STD	normal resolution, usable by most display devices
DIG	resolution tuned only for LCD flat panels
INT	interlaced
STEREO	stereo
<i>width</i>	screen width in pixels
<i>height</i>	screen height in pixels
<i>rate</i>	vertical frequency of the screen refresh (in hertz, that is, video frames per second)

Note that some video modes supported by the XVR-4000 might not be supported by the display device. The list of video modes supported by the device and the display device can be obtained by running `SUNWzulu_config` with the `-res \?` option.

`-multisample available | disable | forceon`

The `-multisample` option controls whether a multisample buffer is allocated

by the window system and used by OpenGL applications. The suboptions are:

- |                        |                                                                                                                                                                                                                                                      |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>disable</code>   | No multisample rendering is possible. Only one sample per pixel is allocated, despite the <code>-samples</code> option value. Furthermore, display filtering is disabled.                                                                            |
| <code>available</code> | Multisample is possible but is selected on a per-application basis. (Each process may choose whether to multisample at the density allocated when the window system started, or not to multisample at all. Intermediate densities are not possible.) |
| <code>forceon</code>   | Sun OpenGL will use multisample rendering for all applications. There may be a minor performance penalty for rendering at higher sample densities.                                                                                                   |

Multisample allocation occurs when the window system starts up. This is the only allocation mode supported on the Sun XVR-4000 Graphics Accelerator.

`-samples samples-per-pixel`

Specifies the number of samples per pixel to allocate when multisample is not `disable`. Allowable choices are 1 to 16 or `max`, but a very high sample density can be allocated only at low resolution. Setting sample density to 1 is not equivalent to disabling multisampling; samples will still be subject to filtering and jitter. Sample resolutions (without frame rates) and their maximum sample densities follow.

Resolution	Maximum Density	Maximum Balanced Density
width by height	(single stream)	(one stream + another)
1920 by 1200	4 samples	2 + 2 samples
1600 by 1200	5 samples	3 + 2 samples
1600 by 1024	6 samples	3 + 3 samples
1280 by 1024	8 samples	4 + 4 samples
1152 by 900	9 samples	5 + 4 samples
1024 by 800	11 samples	5 + 5 samples
800 by 600	15 samples	7 + 7 samples
768 by 575	15 samples	7 + 7 samples
640 by 480	16 samples	9 + 9 samples

The default is max, which means to use the maximum number of samples that can be supported with the amount of memory available, possibly dependent on the video timing (horizontal frequency).

For dual independent streams, if the first stream used by the window system (typically, the first in the Xservers file) chooses max, it takes most of the memory and video resources. The second stream can then use only a low sample density. If it also chooses max, X automatically finds the highest sample density remaining, such as 1 or 2 samples per pixel. To assign sample density more evenly, set each stream's density explicitly. SUNWzulu\_config allows a combination of resolutions and sample densities only if they will coexist successfully. You might have to reduce one stream's sample density (or choose max) before you can increase the other stream's.

- jitter regular | random | permuted | auto

Indirectly determines the subpixel (X,Y) locations of the samples stored in the

sample buffer. (The sample density also affects the sample locations.) Choices are:

- |          |                                                                                                                                                                                                                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| regular  | Samples are regularly-spaced both vertically and horizontally. The sample locations repeat every pixel or two in X and Y.                                                                                                                                                                                   |
| random   | Samples are pseudo-randomly (irregularly) spaced within the pixel. The sample locations repeat every 2 pixels in X and Y.                                                                                                                                                                                   |
| permuted | Samples are pseudo-randomly spaced within the pixel, and also permuted (stirred) in hardware so that the sample locations repeat every 128 pixels in X and Y. At moderate to high sample density, this choice can improve visual quality. At low sample density, straight lines or edges can appear jagged. |
| auto     | Automatically selects the best jitter option for the current sample density. This is the default.                                                                                                                                                                                                           |

The same jitter selection must be used by OpenGL when rendering and by the display subsystem when refreshing the display from the sample buffer. The jitter value is changed immediately in hardware, but any multisamples already in the sample buffer were rendered using the prior jitter selection; that will look incorrect (for example, unstraight lines or edges) if the jitter selection is changed.

When a new OpenGL application starts up, it will render using the new jitter selection. (The window system need not be restarted.) The jitter value is also saved in the `OWconfig` file for the next time the window system starts.

Stream Options `-stream a | b`

Determines whether stream options will be set for stream a or stream b. The "Device Usage and Invocation Forms" section, above, describes the usage and the default. The `-stream` option is required only to set different stream options for the two video streams enabled using card option `-doublewide` or `-doublehigh`.

`-filter cylinder | gaussian | mitchell | catmull`

`-filter_file filter_filename`

There are two ways to configure filtering. The `-filter` option is the simpler. It selects from these predefined filters:

- |                       |                                                                                                                                                           |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cylinder</code> | Poorest visual quality, most like a box filter.                                                                                                           |
| <code>gaussian</code> | Blurriest; suitable for users who want to forgo detail to avoid all visible sampling artifacts.                                                           |
| <code>mitchell</code> | The best photo-realistic compromise between sharp detail and noticeable blurriness. This filter is the default.                                           |
| <code>catmull</code>  | The Catmull-Rom filter produces images a little sharper than Mitchell, but are more likely to have visible sampling artifacts, widely known as "jaggies". |

The `-filter_file` option allows a user to provide his own filter by producing a filter file and copying or linking it into the directory `/etc/openwin/server/etc/filters` or `/usr/openwin/server/etc/filters`. (Both directories are writable by super-user by default.) The `filter_filename` must not start with `/` or `./` nor contain the substring `././`, but can contain subdirectory components.

`fbconfig` and `X` search the directories above in the order listed. If the `filter_filename` is present and valid, the file takes precedence over a predefined filter.

The format of the file is a sequence of floating-point radius and weight values, each value separated by whitespace. Radius values must be monotonically increasing from 0. Weight values must be between -1.0 and +1.0, inclusive. Though more values can be present in the file, only values through radius 2.0 are used. Whitespace and comment lines prefixed with a hash mark (`#`) are ignored.

Example files contain the (irregular) radius values for which the device uses weight values. The file reader interpolates between existing values if the required radius is not present.

A valid filter option is changed immediately in hardware and saved in the `OWconfig` file for the next time the window system starts. However, when `multisample` is disabled, no filtering occurs.

`-offset xoff-value yoff-value`

Offsets the display of the stream (specified by `-stream`) relative to the adjoining edge of the other stream when `doublewide` or `doublehigh` is enabled. This can be used to cause an overlap.

*xoff-value*      Number of pixels offset in horizontal direction for the righthand stream when `doublewide` is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges abut.

*yoff-value*      Number of pixels offset in vertical direction for the bottom stream when `doublehigh` is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

`-g gamma-correction-value`

This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the `OWconfig` file for the next time the window system starts.

`-slave [enable | disable]`

`[frame-lock [internal | external] | genlock | bothlock ]`

This option allows you to enable a synchronization technique for the specified stream. Available techniques:

`frame-lock [internal | external]`      This provides "asynchronous frame reset": multiple streams all start a frame at roughly the same time. This allows stereo shutters to view the same eye's image from all the synchronized display devices. Using `frame-lock` requires the incoming synchronization signal have the same frame rate as the stream's video format.

When using `frame-lock` (or `bothlock`), you can also specify the synchronization source:

`internal`      Indicates that the sync source is the other stream of this device.

`external`      Indicates the sync is taken from a source outside the device. Using `external` requires a Frame Lock Cable (part number 530-2754) to be

connected. If `-slave enable` is used without specifying a technique, `frameLock external` is used.

`genlock` This provides pixel-accurate horizontal synchronization, which is important in some video mixing situations. Use of `genlock` requires a `genlock` cable. Use of `bothlock` is recommended, when possible. Certain video formats are incompatible with `genlock`.

`bothlock` This enables both `frameLock` and `genlock` techniques, and requires both `frameLock` (if `external`) and `genlock` cables.

`-genlock [defaults] [hphase  $\pm$ hphs][vphase  $\pm$ vphs]  
[sync [auto|tip|tri|slice]] [pol [auto|pos|neg]]`

When `-slave` is enabled and the `genlock` technique is selected, the selections chosen with the `-genlock` option determine `genlock` details. These details are used immediately by the hardware, and saved in the `OWconfig` file for future use. Note that they may no longer be desired after changing to a different video format.

`defaults` Reset all `genlock` details to their defaults.

`hphase  $\pm$ hphs` The horizontal phase allows a pixel offset between the external video format and the stream's output. It may be specified as an absolute integer ranging from 0 to the total number of pixel clocks in a horizontal period (active video plus blanked pixels). Or, if the *hphs* starts with a + or -, the value will be added to the current horizontal phase and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

`vphase  $\pm$ vphs` The vertical phase allows a scanline offset between the external video format and the stream's output. It can be specified as an absolute integer ranging from 0 to the total number of scanlines in a frame (active video plus blanked scanlines). Or, if the *vphs* starts with a + or -, the value will be added to the current vertical phase and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

`sync [auto|tip|slice|tri]` This option controls the details of input sync signal sampling, if necessary:

`auto` Sample the `genlock` input pulses as most appropriate for the (Sun) video format. This is

		the default, and should be used whenever the sync master is also a Sun video format.
	tip	Consider the sync to have occurred at the minimum signal value. This can be used with RS-170 (NTSC or PAL) or with TTL signals.
	slice	Consider the frame sync to have occurred halfway between the minimum and maximum value (sync tip and back porch "blank" levels). This can be used with RS-170 (NTSC or PAL) or with TTL signals.
	tri	Synchronize to a tri-level signal, used by HDTV analog formats.
pol [auto pos neg]		When the sync master is not a Sun video format, it might be necessary to choose which edge of the genlock input sync pulse should be used for genlock.
	auto	Choose rising or falling edge for sync pulse, whichever is most appropriate for the video format. This is the default, and should be used whenever the sync master is also a Sun video format.
	pos	Synchronize with a rising edge of a sync pulse.
	neg	Synchronize with a falling edge of a sync pulse.

**Defaults** For a given invocation of `SUNWzulu_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system starts, if an option has never been specified through `SUNWzulu_config`, a default value is used. The option defaults are as follows:

Option Class	Option	Default
General	-dev	/dev/fb
General	-file	machine (/etc/openwin/server/etc/OWconfig)
Card	-doublewide	disable
Card	-doublehigh	disable
Card	-master	a
Card	-outputs	direct
Card	-clearpixel	255
Managed Area	-res	SUNW_STD_1280x1024x76

Managed Area	-multisample	forceon
Managed Area	-samples	max
Managed Area	-jitter	auto
Stream	-offset	0,0
Stream	-filter	mitchell
Stream	-slave	disable/external/framelock
Stream	-genlock	hphase 0/vphase 0/auto/auto
Stream	-g	2.22

**Examples** EXAMPLE 1 Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 hertz:

```
% fbconfig -dev zulu0 -res SUNW_STD_1280x1024x76
```

## EXAMPLE 2 Using Two Side-by-side Monitors with One Large X Screen

The following example enables use of two side-by-side monitors to display together a single large shared X window system "screen" (frame buffer managed area):

```
% fbconfig -dev zulu0 -doublewide enable
```

If the wrong monitor is on the left, they can be swapped in software:

```
% fbconfig -dev zulu0 -outputs swapped
```

A stream option selects a Gaussian (blurry) filter for video stream b:

```
% fbconfig -dev zulu0 -stream b -filter gaussian
```

For the two examples above, the factory-installed `/usr/dt/config/Xservers` file is sufficient (if `/dev/fb` is a link to the Sun XVR-4000 Graphics Accelerator device). If an `/etc/dt/config/Xservers` file exists, for Example 1 or 2, the file would refer to device `zulu0` (not `zulu0a` or `zulu0b`):

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -dev /dev/fbs/zulu0
```

## EXAMPLE 3 Using Two Displays as Independent X Screens

The following example enables use of two displays, each with their own X window system managed frame buffer area and resolution. The larger resolution is not multisampled or filtered, so the smaller resolution will have more samples available to it.

```
% fbconfig -dev zulu0a -res SUNW_STD_1920x1200x75 -multisample disable
% fbconfig -dev zulu0b -res SUNW_STD_1280x1024x76 -samples max
```

In this example, and assuming the display device for stream b is to the right of that for stream a, the `/etc/dt/config/Xservers` file might contain (as one long line):

**EXAMPLE 3** Using Two Displays as Independent X Screens *(Continued)*

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -nobanner
-dev /dev/fbs/zulu0a -dev /dev/fbs/zulu0b right
```

**Files**

/dev/fb	default device file
/usr/lib/fbconfig/SUNWzulu_config	device configuration program
/etc/openwin/server/etc/filters/	root file system directory for filter files
/usr/openwin/server/etc/filters/	/usr file system directory for filter files

An administrator might also have to edit /etc/dt/config/Xservers.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzuluc

**Name** svcadm – manipulate service instances

**Synopsis** /usr/sbin/svcadm [-v] enable [-rst] {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] disable [-st] {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] restart {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] refresh {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] clear {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] mark [-It] *instance\_state*  
     {*FMRI* | *pattern*}...  
 /usr/sbin/svcadm [-v] milestone [-d] *milestone\_FMRI*

**Description** svcadm issues requests for actions on services executing within the service management facility (see [smf\(5\)](#)). Actions for a service are carried out by its assigned service restarter agent. The default service restarter is `svc.startd` (see [svc.startd\(1M\)](#)).

**Options** The following options are supported:

-v     Print actions verbosely to standard output.

## Subcommands

**Common Operations** The subcommands listed below are used during the typical administration of a service instance.

For subcommands taking one or more operands, if the operand specifies a service (instead of a service instance), and that service has only a single instance, svcadm operates on that instance. If an abbreviated *FMRI* (a fault management resource identifier) or pattern matches more than one service, a warning message is displayed and that operand is ignored. See [smf\(5\)](#).

In the case that the service has more than one instance, svcadm return a non-zero exit status.

`enable [-rst] {FMRI | pattern}...`     Enables the service instances specified by the operands. For each service instance, the assigned restarter will try to bring it to the online state. This action requires permission to modify the “general” property group of the service instance (see [smf\\_security\(5\)](#)).

If the -r option is specified, svcadm enables each service instance and recursively enables its dependencies.

If the -s option is specified, svcadm enables each service instance and then waits for each service instance to enter the online or degraded state. svcadm

will return early if it determines that the service cannot reach these states without administrator intervention.

If the `-t` option is specified, `svcadm` temporarily enables each service instance. Temporary enable only lasts until reboot. This action requires permission to modify the “restarter\_actions” property group of the service instance (see [smf\\_security\(5\)](#)). By default, enable is persistent across reboot.

`disable [-st] {FMRI | pattern}...`

Disables the service instance specified by the operands. For each service instance, the assigned restarter will try to bring it to the disabled state. This action requires permission to modify the “general” property group of the service instance (see [smf\\_security\(5\)](#)).

If the `-s` option is specified, `svcadm` disables each service instance and then waits for each service instance to enter the disabled state. `svcadm` will return early if it determines that the service cannot reach this state without administrator intervention.

If the `-t` option is specified, `svcadm` temporarily disables each service instance. Temporary disable only lasts until reboot. This action requires permission to modify the “restarter\_actions” property group of the service instance (see [smf\\_security\(5\)](#)). By default, `disable` is persistent across reboot.

`restart {FMRI | pattern}...`

Requests that the service instances specified by the operands be restarted. This action requires permission to modify the “restarter\_actions” property group of the service instance (see [smf\\_security\(5\)](#)).

This subcommand can restart only those services that are in the online or degraded states, as those states are defined in [smf\(5\)](#).

`refresh {FMRI | pattern}...`

For each service instance specified by the operands, requests that the assigned restarter update the service's running configuration snapshot with the values from the current configuration. Some of these values take effect immediately (for example, dependency changes). Other values do not take effect until the next service restart. See the restarter and service documentation for more information.

If the service is managed by `svc.startd(1M)`, the `refresh` method will be invoked if it exists to request the service reread its own configuration. For other restarters, see the restarter documentation.

This action requires permission to modify the “restarter\_actions” property group of the service instance (see `smf_security(5)`).

`clear {FMRI | pattern}...`

For each service instance specified by the operands, if the instance is in the maintenance state, signal to the assigned restarter that the service has been repaired. If the instance is in the degraded state, request that the assigned restarter take the service to the online state. This action requires permission to modify the “restarter\_actions” property group of the service instance (see `smf_security(5)`).

Exceptional Operations The following subcommands are used for service development and temporary administrative manipulation.

`mark [-It] instance_state {FMRI | pattern}...`

If `instance_state` is “maintenance”, then for each service specified by the operands, `svcadm` requests that the assigned restarter place the service in the maintenance state. See `svc.startd(1M)` and `inetd(1M)` for a detailed description of the actions taken for each restarter.

If `instance_state` is “degraded”, then for services specified by the operands in the online state, `svcadm` requests that the restarters assigned to the services move them into the degraded state.

If the `-I` option is specified, the request is flagged as immediate.

The `-t` option is only valid for maintenance requests. When this option is specified, the request is flagged as temporary, and its effect will only last until the next reboot.

`milestone [-d] milestone_FMRI`

If `milestone_FMRI` is the keyword “none”, all services other than the master restarter,

`svc:/system/svc/restarter:default`, will be temporarily disabled.

If `milestone_FMRI` is the keyword “all”, temporary enable and disable requests for all services will be nullified.

If `milestone_FMRI` is one of the following:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

then temporary enable and disable requests for the indicated service and all services it depends on (directly or indirectly) will be nullified. All other services will be temporarily disabled.

Changing the system's current milestone with the “milestone” subcommand will not change the current run level of the system. To change the system's run level, invoke `/sbin/init` directly.

This action requires permission to modify the “options\_ovr” property group of the `svc:/system/svc/restarter:default` service instance (see [smf\\_security\(5\)](#)).

The `-d` option immediately changes the milestone to the requested milestone, as above. Additionally, it makes the specified milestone the default boot milestone, which persists across reboot. The default milestone is defined by the `options/milestone` property on the master restarter,

```
svc:/system/svc/restarter:default.
```

If this property is absent, “all” is the default. This action requires permission to modify the “options” property group of the `svc:/system/svc/restarter:default` service instance (see [smf\\_security\(5\)](#)).

Operands The following operands are supported:

*FMRI* An *FMRI* that specifies one or more instances. *FMRI*s can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the *FMRI*:

```
svc:/network/smtp:sendmail
```

All the following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

While the following are invalid:

```
mail
network
network/smt
```

If the *FMRI* specifies a service, then the command applies to all instances of that service. Abbreviated forms of *FMRI*s are unstable, and should not be used in scripts or other permanent tools.

*pattern* A pattern that is matched against the *FMRI*s of service instances according to the “globbing” rules described by [fnmatch\(5\)](#). If the pattern does not begin with “svc:”, then “svc:” is prepended.

If an abbreviated *FMRI* or pattern matches more than one service, a warning message is displayed and that operand is ignored.

#### Examples EXAMPLE 1 Restarting a Service Instance

The following command restarts the NFS server. The full *FMRI* for the default service instance is: `svc:/network/nfs/server:default`

However, you can abbreviate the full *FMRI* as follows:

```
svcadm restart nfs/server
```

#### EXAMPLE 2 Disabling the Standard HTTP Server

The following command disables the standard HTTP server, using an abbreviated *FMRI*:

```
$ svcadm disable http
```

**EXAMPLE 3** Enabling an Instance and Its Dependent Instances

The following command enables the `foo:bar` instance, and all instances on which it depends:

```
$ svcadm enable -r foo:bar
```

**EXAMPLE 4** Synchronously enabling an instance

The following command enables the `foo:bar` instance. The command will not return until the instance comes online or `svcadm` determines it is not possible for the service to come online.

```
$ svcadm enable -s foo:bar
```

**EXAMPLE 5** Restricting and Restoring the Running Services

The following command restricts the running services to single user mode:

```
svcadm milestone milestone/single-user
```

The following command restores the running services:

```
svcadm milestone all
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred. One or more error messages are displayed on standard error.
- 2 Invalid command line options were specified.
- 3 `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service instance itself.
- 4 `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service's dependencies.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

**See Also** `svccprop(1)`, `svcs(1)`, `inetd(1M)`, `init(1M)`, `svccfg(1M)`, `svc.startd(1M)`, `libscf(3LIB)`, `contract(4)`, `attributes(5)`, `smf(5)`, `smf_security(5)`

**Notes** The amount of time `svcadm` will spend waiting for services and their dependencies to change state is implicitly limited by their method timeouts. For example, a service using the default restarter whose start method hangs will be transitioned to the maintenance state when its timeout expires. `svcadm` will then consider it impossible for this service to come online without administrator intervention.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.

- 
- Name** svccfg – import, export, and modify service configurations
- Synopsis** /usr/sbin/svccfg [-v] [-s *FMRI*]  
 /usr/sbin/svccfg [-v] [-s *FMRI*] *subcommand* [args]...  
 /usr/sbin/svccfg [-v] [-s *FMRI*] -f *command-file*
- Description** The `svccfg` command manipulates data in the service configuration repository. `svccfg` can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.
- Changes made to an existing service in the repository typically do not take effect for that service until the next time the service instance is refreshed. See the `refresh` subcommand on the [svcadm\(1M\)](#) man page for more details.
- Options** The following options are supported:
- f *command-file*  
 Reads and executes `svccfg` subcommands from *command-file*.
  - s *FMRI*  
 Selects the entity indicated by *FMRI* (a fault management resource identifier) before executing any subcommands. See [smf\(5\)](#).
  - v  
 Verbose.
- Subcommands** Subcommands are divided into the categories specified in the subsections that follow.
- All subcommands that accept *FMRI*s also accept abbreviated or globbed patterns. Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the *FMRI*:
- ```
svc:/network/smtp:sendmail
```
- All the following are valid abbreviations:
- ```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```
- While the following are invalid:
- ```
mail
network
network/smt
```
- Abbreviated forms of *FMRI*s are unstable, and should not be used in scripts or other permanent tools. If a pattern matches more than one instance or service, an error message is printed and no action is taken.

- General Subcommands
- end
 - exit
 - quit
 - Exits immediately.
 - repository *repfile*
 - Uses *repfile* as a repository. By default, `svccfg` uses the system repository.
 - Use repository only with files from the identical version of Solaris, including patches, that you are currently running. Do not use this subcommand with the system repository, `/etc/svc/repository.db`.
 - set [-v|-V]
 - Sets optional behavior. If no options are specified, set displays the options currently in effect.
 - v
 - Turns on verbose mode.
 - V
 - Turns off verbose mode.
- Service Profile Subcommands
- apply *file*
 - If *file* is a service profile, then service instances specified within the file are enabled or disabled according to it. See [smf\(5\)](#) for a description of service profiles. This command requires privileges to modify the “general/enabled” property of the service instances. See [smf_security\(5\)](#) for the privileges required to modify properties. If *file* is not a service profile, the subcommand fails.
 - extract [>*file*]
 - Prints a service profile which represents the enabled status of the service instances in the repository to standard output. The output may be redirected to a file.
- Service Manifest Subcommands
- archive
 - Dumps a full XML service description for all services, instances, and their persistent properties in the repository. This does not include transient properties such as service state, and is suitable for a relocatable repository backup.
 - export *service_FMRI* [>*file*]
 - The service description for the specified service and its instances is written to standard output or redirected to the given file. Dependencies with a boolean “external” property set to true are omitted in the belief that they were created on behalf of another service.
 - Without the `-a` option, property groups containing protected information (identified by the presence of the `read_authorization` property—see [smf_security\(5\)](#)) will be exported without their property values. When the `-a` option is specified, all values will be archived. An error results if there are insufficient privileges to read these values.

Note that `export` requires a service FMRI. If you specify an instance (including an abbreviation, such as `apache2` or `sendmail`, that specifies an instance), the command fails.

`import file`

If *file* is a service manifest, then the services and instances it specifies are imported into the repository. According to the file, dependencies may be created in other services. See [smf\(5\)](#) for a description of service manifests. See [smf_security\(5\)](#) for the privileges required to create and modify service configurations.

For existing services and instances, properties which have not changed since the last `import` snapshot was taken are upgraded to those specified by the manifest. Conflicts (properties which have been changed both in the repository and the manifest) are reported on the standard error stream. `svccfg` will never upgrade the “general/enabled” and “general/restarter” properties, since they represent administrator preference.

`inventory file`

If *file* is determined to be a service manifest, then the FMRI of the services and instances the *file* describes are printed. For each service, the FMRI of its instances are displayed before the FMRI of the service.

`validate file`

file is processed similarly to `import`, but no changes are made to the repository. If any errors are detected, `svccfg(1M)` exits with a nonzero exit status.

Entity Selection,
Modification, and
Navigation
Subcommands

An “entity” refers to a scope, service, or service instance.

`add name`

A new entity with the given name is created as a child of the current selection. See [smf_security\(5\)](#) for the privileges required to create entities.

`delete [-f] {name | fmri}`

The named child of the current selection or the entity specified by *fmri* is deleted. Attempts to delete service instances in the “online” or “degraded” state will fail unless the `-f` flag is specified. If a service or service instance has a “dependents” property group of type “framework”, then for each of its properties with type “astring” or “fmri”, if the property has a single value which names a service or service instance then the dependency property group in the indicated service or service instance with the same name as the property will be deleted. See [smf_security\(5\)](#) for the privileges required to delete service configurations.

`list [pattern]`

The child entities of the current selection whose names match the glob pattern *pattern* are displayed (see [fnmatch\(5\)](#)). ‘:properties’ is also listed for property-bearing entities, namely services and service instances.

`select {name | fmri}`

If the argument names a child of the current selection, it becomes the current selection. Otherwise, the argument is interpreted as an FMRI and the entity that the argument specifies becomes the current selection.

- `unselect`
The parent of the current selection becomes the current selection.
- Property Inspection and Modification Subcommands `addpg name type [flags]`
Adds a property group with the given *name* and type to the current selection. *flags* is a string of characters which designates the flags with which to create the property group. 'P' represents SCF_PG_FLAG_NONPERSISTENT (see `scf_service_add_pg(3SCF)`). See `smf_security(5)` for the privileges required to create property groups.
- `addpropvalue pg/name [type:] value`
Adds the given value to a property. If *type* is given and the property exists, then if *type* does not agree with the property's *type*, the subcommand fails. The values may be enclosed in double-quotes. String values containing double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. Nonexistent properties are created, in which case the *type* specifier must be present. See `scf_value_create(3SCF)` for a list of available property types. See `smf_security(5)` for the privileges required to modify properties.
- `delpg name`
Deletes the property group *name* of the current selection. See `smf_security(5)` for the privileges required to delete property groups.
- `delprop pg[/name]`
Deletes the named property group or property of the current selection. See `smf_security(5)` for the privileges required to delete properties.
- `delpropvalue pg/name globpattern`
Deletes all values matching the given *glob* pattern in the named property. Succeeds even if no values match. See `smf_security(5)` for the privileges required to modify properties.
- `editprop`
Comments of commands to reproduce the property groups and properties of the current selection are placed in a temporary file and the program named by the EDITOR environment variable is invoked to edit it. Upon completion, the commands in the temporary file are executed. The default editor is `vi(1)`. See `smf_security(5)` for the privileges required to create, modify, or delete properties.
- `listpg [pattern]`
Displays the names, types, and flags of property groups of the current selection. If an argument is given, it is taken as a glob pattern and only property groups with names which match the argument are listed.
- `listprop [pattern]`
Lists property groups and properties of the current selection. For property groups, names, types, and flags are listed. For properties, names (prepended by the property group name and a slash (/)), types, and values are listed. See `scf_value_create(3SCF)` for a list of available property types. If an argument is supplied it is taken as a glob pattern and only property groups and properties with names which match the argument are listed.

`setenv [-i | -s] [-m method_name] envvar value`

Sets a method environment variable for a service or instance by changing the “environment” property in the *method_name* property group, if that property group has type “method”. If *method_name* is not specified and the `-i` option is used, the “method_context” property group is used, if an instance is currently selected. If the `-s` option is used and a service is currently selected, its “method_context” property group is used. If the `-s` option is used and an instance is currently selected, the “method_context” property group of its parent is used. If neither the `-i` option nor the `-s` option is used, the “start” property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the “inetd_start” property group is not located, it is searched for in a similar manner.

Once the property is located, all values which begin with *envvar* followed by a “=” are removed, and the value “*envvar=value*” is added. See [smf_security\(5\)](#) for the privileges required to modify properties.

`setprop pg/name = [type:] value`
`setprop pg/name = [type:] ([values ...])`

Sets the *name* property of the *pg* property group of the current selection to the given values of type *type*. See [scf_value_create\(3SCF\)](#) for a list of available property types. If the property already exists and the *type* disagrees with the existing *type* on the property, the subcommand fails. Values may be enclosed in double-quotes. String values which contain double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. If the named property does not exist, it is created, as long as the type is specified. See [smf_security\(5\)](#) for the privileges required to create or modify properties.

`unsetenv [-i | -s] [-m method_name] envvar value`

Removes a method environment variable for a service or instance by changing the “environment” property in the *method_name* property group, if that property group has type “method”. If *method_name* is not specified and the `-i` option is used, the “method_context” property group is used, if an instance is currently selected. If the `-s` option is used and a service is currently selected, its “method_context” property group is used. If the `-s` option is used and an instance is currently selected, the “method_context” property group of its parent is used. If neither the `-i` option nor the `-s` option is used, the “start” property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the “inetd_start” property group is not located, it is searched for in a similar manner.

Once the property is located, all values which begin with *envvar* followed by “=” are removed. See [smf_security\(5\)](#) for the privileges required to modify properties.

revert [*snapshot*]

Reverts the properties of the currently selected instance and its service to those recorded in the named snapshot. If no argument is given, use the currently selected snapshot and deselect it on success. The changed property values can be made active via the `refresh` subcommand of `svcadm(1M)`. See `smf_security(5)` for the privileges required to change properties.

selectsnap [*name*]

Changes the current snapshot to the one named by *name*. If no *name* is specified, deselect the currently selected snapshot. Snapshots are read-only.

Examples EXAMPLE 1 Importing a Service Description

The following example imports a service description for the `seismic` service in the XML manifest specified on the command line.

```
# svccfg import /var/svc/manifest/site/seismic.xml
```

Note that the manifest must follow the format specified in `service_bundle(4)`.

EXAMPLE 2 Exporting a Service Description

To export a service description on the local system:

```
$ svccfg export dumpadm >/tmp/dump.xml
```

EXAMPLE 3 Deleting a Service Instance

To delete a service instance:

```
$ svccfg delete network/inetd-upgrade:default
```

EXAMPLE 4 Checking Properties in an Alternate Repository

To examine the state of a service's properties after loading an alternate repository, use the sequence of commands shown below. One might use such commands, for example, to determine whether a service was enabled in a particular repository backup.

```
# svccfg
svc:> repository /etc/svc/repository-boot
svc:> select telnet:default
svc:/network/telnet:default> listprop general/enabled
general/enabled boolean false
svc:/network/telnet:default> exit
```

EXAMPLE 5 Enabling Debugging

To modify `LD_PRELOAD` for a start method and enable the use of `libumem(3LIB)` with debugging features active:

```
$ svccfg -s system/service setenv LD_PRELOAD libumem.so
$ svccfg -s system/service setenv UMEM_DEBUG default
```

Environmental Variables EDITOR
The command to run when the `editprop` subcommand is used. The default editor is `vi(1)`.

Exit Status The following exit values are returned:

0

Successful execution.

1

One or more subcommands resulted in failure. Error messages are written to the standard error stream.

2

Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | See below. |

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

See Also [svcprop\(1\)](#), [svcs\(1\)](#), [svcadm\(1M\)](#), [svc.configd\(1M\)](#), [libscf\(3LIB\)](#), [libumem\(3LIB\)](#), [scf_service_add_pg\(3SCF\)](#), [scf_value_create\(3SCF\)](#), [contract\(4\)](#), [service_bundle\(4\)](#), [attributes\(5\)](#), [fnmatch\(5\)](#), [smf\(5\)](#), [smf_method\(5\)](#), [smf_security\(5\)](#)

Name `svc.configd` – Service Management Facility repository daemon

Synopsis `/lib/svc/bin/svc.configd`

Description `svc.configd` is the repository daemon for the Service Management Facility. `svc.configd` is invoked automatically during system startup, and restarted if any failures occur. `svc.configd` should never be invoked directly.

Interaction with `svc.configd` is by way of [libscf\(3LIB\)](#) and the command line tools: [svcs\(1\)](#), [svcprop\(1\)](#), [svcadm\(1M\)](#), and [svccfg\(1M\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsr |

See Also [svcs\(1\)](#), [svcprop\(1\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [libscf\(3LIB\)](#), [attributes\(5\)](#)

| | |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name | svc.startd – Service Management Facility master restarter |
| Synopsis | <pre>/lib/svc/bin/svc.startd svc:/system/svc/restarter:default</pre> |
| Description | <p>svc.startd is the master restarter daemon for Service Management Facility (SMF) and the default restarter for all services. svc.startd starts, stops, and restarts services based on administrative requests, system failures, or application failures.</p> <p>svc.startd maintains service state, as well as being responsible for managing faults in accordance with the dependencies of each service.</p> <p>svc.startd is invoked automatically during system startup. It is restarted if any failures occur. svc.startd should never be invoked directly.</p> <p>See smf_restarter(5) for information on configuration and behavior common to all restarters.</p> <p>svcs(1) reports status for all services managed by the Service Configuration Facility. svcadm(1M) allows manipulation of service instances with respect to the service's restarter.</p> |
| Environment Variables | <p>Environment variables with the “SMF_” prefix are reserved and may be overwritten.</p> <p>svc.startd supplies the “SMF_” environment variables specified in smf_method(5) to the method. PATH is set to “/usr/sbin:/usr/bin” by default. By default, all other environment variables supplied to svc.startd are those inherited from init(1M).</p> <p>Duplicate entries are reduced to a single entry. The value used is undefined. Environment entries that are not prefixed with “<name>=” are ignored.</p> |
| Restarter Options | <p>svc.startd is not configured by command line options. Instead, configuration is read from the service configuration repository. You can use svccfg(1M) to set all options and properties.</p> <p>The following configuration variables in the options property group are available to developers and administrators:</p> <p>boot_messages
 An <i>astring</i> (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to print to the console during boot. The supported message options include quiet and verbose. The quiet option prints minimal messages to console during boot. The verbose option prints a single message per service started to indicate success or failure. You can use the boot -m option to override the boot_messages setting at boot time. See kernel(1M).</p> <p>logging
 Control the level of global service logging for svc.startd. An <i>astring</i> (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to log to syslog (see syslog(3C) and svc.startd's global logfile,</p> |

`/var/svc/log/svc.startd.log`. The supported message options include `quiet`, `verbose`, and `debug`. The `quiet` option sends error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global logfile. The `verbose` option sends error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global logfile, and information about errors which do not require administrative intervention to `svc.startd`'s global logfile. A single message per service started is also sent to the console. The `debug` option sends `svc.startd` debug messages to `svc.startd`'s global logfile, error messages requiring administrative intervention to the console, `syslog` and `svc.startd`'s global logfile, and a single message per service started to the console.

milestone

An FMRI which determines the milestone used as the default boot level. Acceptable options include only the major milestones:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

or the special values `all` or `none`. `all` represents an idealized milestone that depends on every service. `none` is a special milestone where no services are running apart from the master `svc:/system/svc/restarter:default`. By default, `svc.startd` uses `all`, a synthetic milestone that depends on every service. If this property is specified, it overrides any `initdefault` setting in `inittab(4)`.

system/reconfigure

Indicates that a reconfiguration reboot has been requested. Services with actions that must key off of a reconfiguration reboot may check that this property exists and is set to 1 to confirm a reconfiguration boot has been requested.

This property is managed by `svc.startd` and should not be modified by the administrator.

Configuration errors, such as disabling `svc.startd` are logged by `syslog`, but ignored.

SERVICE STATES Services managed by `svc.startd` can appear in any of the states described in `smf(5)`. The state definitions are unmodified by this restarter.

SERVICE REPORTING In addition to any logging done by the managed service, `svc.startd` provides a common set of service reporting and logging mechanisms.

Reporting properties `svc.startd` updates a common set of properties on all services it manages. These properties are a common interface that can be used to take action based on service instance health. The `svcs(1)` command can be used to easily display these properties.

```
restarter/state
restarter/next_state
```

The current and next (if currently in transition) state for an instance.

restarter/auxiliary_state

A caption detailing additional information about the current instance state. The auxiliary state available for services managed by `svc.startd` is:

maintenance

```

    fault_threshold_reached
    stop_method_failed
    administrative_request

```

restarter/state_timestamp

The time when the current state was reached.

restarter/contract

The primary process contract ID, if any, that under which the service instance is executing.

Logs

By default, `svc.startd` provides logging of significant restarter actions for the service as well as method standard output and standard error file descriptors to `/var/svc/log/service:instance.log`. The level of logging to system global locations like `/var/svc/log/svc.startd.log` and `syslog` is controlled by the `options/logging` property.

SERVICE DEFINITION When developing or configuring a service managed by `svc.startd`, a common set of properties are used to affect the interaction between the service instance and the restarter.

Methods

The general form of methods for the fork/exec model provided by `svc.startd` are presented in [smf_method\(5\)](#). The following methods are supported as required or optional by services managed by `svc.startd`.

refresh Reload any appropriate configuration parameters from the repository or `config` file, without interrupting service. This is often implemented using `SIGHUP` for system daemons. If the service is unable to recognize configuration changes without a restart, no refresh method is provided.

This method is optional.

start Start the service. Return success only after the application is available to consumers. Fail if a conflicting instance is already running, or if the service is unable to start.

This method is required.

stop Stop the service. In some cases, the stop method can be invoked when some or all of the service has already been stopped. Only return an error if the service is not entirely stopped on method return.

This method is required.

If the service does not need to take any action in a required method, it must specify the `: true` token for that method.

`svc.startd` honors any method context specified for the service or any specific method. The method expansion tokens described in [smf_method\(5\)](#) are available for use in all methods invoked by `svc.startd`.

Properties

An overview of the general properties is available in [smf\(5\)](#). The specific way in which these general properties interacts with `svc.startd` follows:

`general/enabled`

If `enabled` is set to `true`, the restarter attempts to start the service once all its dependencies are satisfied. If set to `false`, the service remains in the disabled state, not running.

`general/restarter`

If this FMRI property is empty or set to `svc:/system/svc/restarter:default`, the service is managed by `svc.startd`. Otherwise, the restarter specified is responsible (once it is available) for managing the service.

`general/single_instance`

If `single_instance` is set to `true`, `svc.startd` only allows one instance of this service to transition to online or degraded at any time.

Additionally, `svc.startd` managed services can define the optional properties listed below in the `startd` property group.

`startd/duration`

The `duration` property defines the service's model. It can be set to `transient`, `child` also known as “wait” model services, or `contract` (the default).

`startd/ignore_error`

The `ignore_error` property, if set, specifies a comma-separated list of ignored events. Legitimate string values in that list are `core` and `signal`. The default is to restart on all errors.

`startd/need_session`

The `need_session` property, if set to `true`, indicates that the instance should be launched in its own session. The default is not to do so.

`startd/utmpx_prefix`

The `utmpx_prefix` string property defines that the instance requires a valid `utmpx` entry prior to start method execution. The default is not to create a `utmpx` entry.

SERVICE FAILURE `svc.startd` assumes that a method has failed if it returns a non-zero exit code or if fails to complete before the timeout specified expires. If `$SMF_EXIT_ERR_CONFIG` or `$SMF_EXIT_ERR_FATAL` is returned, `svc.startd` immediately places the service in the

maintenance state. For all other failures, `svc.startd` places the service in the offline state. If a service is offline and its dependencies are satisfied, `svc.startd` tries again to start the service (see [smf\(5\)](#)).

If a contract or transient service does not return from its start method before its defined timeout elapses, `svc.startd` sends a SIGKILL to the method, and returns the service to the offline state.

If five failures happen in a row and the service is restarting with a rate greater than one in ten minutes, `svc.startd` places the service in the maintenance state.

The conditions of service failure are defined by a combination of the service model (defined by the `startd/duration` property) and the value of the `startd/ignore_error` property.

A contract model service fails if any of the following conditions occur:

- all processes in the service exit
- any processes in the service produce a core dump
- a process outside the service sends a service process a fatal signal (for example, an administrator terminates a service process with the `kill` command)

The last two conditions may be ignored by the service by specifying `core` and/or `signal` in `startd/ignore_error`.

Defining a service as transient means that `svc.startd` does not track processes for that service. Thus, the potential faults described for contract model services are not considered failures for transient services. A transient service only enters the maintenance state if one of the method failure conditions occurs.

“wait” model services are restarted whenever the child process associated with the service exits. A child process that exits is not considered an error for “wait” model services, and repeated failures do not lead to a transition to maintenance state.

LEGACY SERVICES `svc.startd` continues to provide support for services invoked during the startup run level transitions. Each `/etc/rc?.d` directory is processed after all managed services which constitute the equivalent run level milestone have transitioned to the online state. Standard `init` scripts placed in the `/etc/rc?.d` directories are run in the order of their sequence numbers.

The milestone to run-level mapping is:

| | |
|------------------------------------------|--------------------------------------|
| <code>milestone/single-user</code> | Single-user (5) |
| <code>milestone/multi-user</code> | Multi-user (2) |
| <code>milestone/multi-user-server</code> | Multi-user with network services (3) |

Additionally, `svc.startd` gives these legacy services visibility in SMF by inserting an instance per script into the repository. These legacy instances are visible using standard SMF interfaces such as [svcs\(1\)](#), always appear in the LEGACY-RUN state, cannot be modified, and can not be specified as dependencies of other services. The initial start time of the legacy service is captured as a convenience for the administrator.

- Files**
- `/var/svc/log` Directory where `svc.startd` stores log files.
 - `/etc/svc/volatile` Directory where `svc.startd` stores log files in early stages of boot, before `/var` is mounted read-write.

Example EXAMPLE 1 Turning on Verbose Logging

To turn on verbose logging, type the following:

```
# /usr/sbin/svccfg -s system/svc/restarter:default
svc:/system/svc/restarter:default> addpg options application
svc:/system/svc/restarter:default> setprop options/logging = \
astring: verbose
svc:/system/svc/restarter:default> exit
```

This request will take effect on the next restart of `svc.startd`.

Name swap – swap administrative interface

Synopsis /usr/sbin/swap -a *swapname* [*swaplow*] [*swaplen*]
 /usr/sbin/swap -d *swapname* [*swaplow*]
 /usr/sbin/swap -l
 /usr/sbin/swap -s

Description The swap utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.

Options The following options are supported:

-a *swapname* [*swaplow*] [*swaplen*]

Add the specified swap area. This option can only be used by the superuser or by one who has assumed the Primary Administrator role. *swapname* is the name of the swap area or regular file. For example, on system running a UFS root file system, specify a slice, such as /dev/dsk/c0t0d0s1, or a regular file for a swap area. On a system running a ZFS file system, specify a ZFS volume, such as /dev/zvol/dsk/rpool/swap, for a swap area. Using a regular file for swap is not supported on a ZFS file system. In addition, you cannot use the same ZFS volume for both the swap area and a dump device when the system is running a ZFS root file system.

swaplow is the offset in 512-byte blocks into the file where the swap area should begin. *swaplen* is the desired length of the swap area in 512-byte blocks. The value of *swaplen* can not be less than 16. For example, if *n* blocks are specified, then (*n*-1) blocks would be the actual swap length. *swaplen* must be at least one page in length. The size of a page of memory can be determined by using the `pagesize` command. See [pagesize\(1\)](#). Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 pagesize bytes. The size of a page of memory is machine-dependent.

swaplow + *swaplen* must be less than or equal to the size of the swap file. If *swaplen* is not specified, an area will be added starting at *swaplow* and extending to the end of the designated file. If neither *swaplow* nor *swaplen* are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the /sbin/swapadd script. This script adds all swap areas which have been specified in the /etc/vfstab file; for the syntax of these specifications, see [vfstab\(4\)](#).

To use an NFS or local file system *swapname*, you should first create a file using [mkfile\(1M\)](#). A local file system swap file can now be added to the running system by just running the swap -a command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:

1. Add the following line to /etc/dfs/dfstab:

```
share -F nfs -o \
  rw=clientname, root=clientname path-to-swap-file
```

2. Run `shareall(1M)`.
3. Have the client add the following line to `/etc/vfstab`:

```
server:path-to-swap-file - local-path-to-swap-file nfs \
- - - local-path-to-swap-file - - swap - - -
```

4. Have the client run `mount`:
5. The client can then run `swap -a` to add the swap space:

```
# swap -a local-path-to-swap-file
```

`-d swapname`

Delete the specified swap area. This option can only be used by the super-user. *swapname* is the name of the swap file: for example, `/dev/dsk/c0t0d0s1` or a regular file. *swaplow* is the offset in 512-byte blocks into the swap area to be deleted. If *swaplow* is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

`-l`

List the status of all the swap areas. The output has five columns:

`path`

The path name for the swap area.

`dev`

The major/minor device number in decimal if it is a block special device; zeroes otherwise.

`swaplo`

The *swaplow* value for the area in 512-byte blocks.

`blocks`

The *swapplen* value for the area in 512-byte blocks.

`free`

The number of 512-byte blocks in this area that are not currently allocated.

The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If `swap -l` is run while *swapname* is in the process of being deleted (by `swap -d`), the string INDEL will appear in a sixth column of the swap stats.

`-s`

Print summary information about total swap space usage and availability:

`allocated`

The total amount of swap space in bytes currently allocated for use as backing store.

reserved

The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.

used

The total amount of swap space in bytes that is either allocated or reserved.

available

The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the `-l` option, as well swap space in the form of physical memory.

Usage On the 32-bit operating system, only the first 2 Gbytes `-l` are used for swap devices greater than or equal to 2 Gbytes in size. On the 64-bit operating system, a block device larger than 2 Gbytes can be fully utilized for swap up to $2^{63} - 1$ bytes.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of swap: `LC_CTYPE` and `LC_MESSAGE`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Notes For information about setting up a swap area with ZFS, see the *ZFS Administration Guide*.

Warnings No check is done to determine if a swap area being added overlaps with an existing file system.

Name sync – update the super block

Synopsis sync

Description sync executes the sync system primitive. If the system is to be stopped, sync must be called to ensure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See [sync\(2\)](#) for details.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [sync\(2\)](#), [attributes\(5\)](#)

Name syncinit – set serial line interface operating parameters

Synopsis /usr/sbin/syncinit *device*
 [[*baud_rate*] | [*keyword=value*,]... | [*single-word option*]]

Description The syncinit utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, syncinit reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

Options Options to syncinit normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, loop= and loopback= are equivalent.

The following options are supported:

| Keyword | Value | Effect |
|---------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| loop | yes | Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud. |
| | no | Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc. |
| echo | yes | Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test. |
| | no | Disable auto-echo mode. |
| nrzi | yes | Set the port to operate with NRZI data encoding. |
| | no | Set the port to operate with NRZ data encoding. |
| txc | txc | Transmit clock source will be the TxC signal (pin 15). |
| | rxc | Transmit clock source will be the RxC signal (pin 17). |
| | baud | Transmit clock source will be the internal baud rate generator. |
| | pll | Transmit clock source will be the output of the DPLL circuit. |

| | | |
|-------|----------------|----------------------------------------------------------------|
| rx | rx | Receive clock source will be the Rx signal (pin 17). |
| | tx | Receive clock source will be the Tx signal (pin 15). |
| | baud | Receive clock source will be the internal baud rate generator. |
| | pll | Receive clock source will be the output of the DPLL circuit. |
| speed | <i>integer</i> | Set the baud rate to <i>integer</i> bits per second. |

There are also several single-word options that set one or more parameters at a time:

| | |
|----------|-------------------------|
| Keyword | Equivalent to Options: |
| external | txc=txc rxc=rx loop=no |
| sender | txc=baud rxc=rx loop=no |
| internal | txc=pll rxc=pll loop=no |
| stop | speed=0 |

Examples EXAMPLE 1 Using syncinit

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rx
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [syncloop\(1M\)](#), [syncstat\(1M\)](#), [Intro\(2\)](#), [ioctl\(2\)](#), [attributes\(5\)](#), [zsh\(7D\)](#)

Diagnostics *device* missing minor device number The name *device* does not end in a decimal number that can be used as a minor device number.

bad speed: *arg*

The string *arg* that accompanied the speed= option could not be interpreted as a decimal integer.

Bad arg: *arg*

The string *arg* did not make sense as an option.

ioctl failure code = *errno*

An `ioctl(2)` system call failed. The meaning of the value of *errno* may be found in [Intro\(2\)](#).

Warnings Do not use syncinit on an active serial link, unless needed to resolve an error condition. Do not use this command casually or without being aware of the consequences.

Name syncloop – synchronous serial loopback test program

Synopsis /usr/sbin/syncloop [-cdlstv] *device*

Description The syncloop command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, syncloop opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the *device* argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, syncloop proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, syncloop attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an exhorting message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

```
CRC errors   Aborts   Overruns   Underruns   In<-Drops-> Out
           0         0         0         0         0         0
```

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

Options The options for syncloop are described in the following table:

| Option | Parameter | Default | Description |
|--------|----------------------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -c | <i>packet_count</i> | 100 | Specifies the number of packets to be sent in the multiple-packet phase. |
| -d | <i>hex_data_byte</i> | <i>random</i> | Specifies that each packet will be filled with bytes with the value of <i>hex_data_byte</i> . |
| -l | <i>packet_length</i> | 100 | Specifies the length of each packet in bytes. |
| -s | <i>line_speed</i> | 9600 | Bit rate in bits per second. |
| -v | | | Sets verbose mode. If data errors occur, the expected and received data is displayed. |
| -t | <i>test_type</i> | <i>none</i> | A number, from 1 to 4, that specifies which test to perform. The values for <i>test_type</i> are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the syncinit(1M) command. |

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t *test_type* option, syncloop prompts for it.

Examples EXAMPLE 1 A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [syncinit\(1M\)](#), [syncstat\(1M\)](#), [attributes\(5\)](#), [zsh\(7D\)](#)

- Diagnostics**
- device* missing minor device number The name *device* does not end in a decimal number that can be used as a minor device number.
- invalid packet length: *nnn* The packet length was specified to be less than zero or greater than 4096.
- poll: nothing to read
- poll: nothing to read or write. The [poll\(2\)](#) system call indicates that there is no input pending and/or that output would be blocked if attempted.
- len *xxx* should be *yyy* The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.
- nnn* packets lost in outbound queueing
- nnn* packets lost in inbound queueing A discrepancy has been found between the number of packets sent by `syncloop` and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.
- Warnings** To allow its tests to run properly, as well as prevent disturbance of normal operations, `syncloop` should only be run on a port that is not being used for any other purpose at that time.

Name syncstat – report driver statistics from a synchronous serial link

Synopsis /usr/sbin/syncstat [-c] *device* [*interval*]

Description The syncstat command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.

The *device* argument is the name of the serial device as it appears in the /dev directory. For example, zsh0 specifies the first on-board serial device.

The following is a breakdown of syncstat output:

| | |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| speed | The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem. |
| ipkts | The total number of input packets. |
| opkts | The total number of output packets. |
| undrun | The number of transmitter underrun errors. |
| ovrun | The number of receiver overrun errors. |
| abort | The number of aborted received frames. |
| crc | The number of received frames with CRC errors. |
| isize | The average size (in bytes) of input packets. |
| osize | The average size (in bytes) of output packets. |

Options -c Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

interval syncstat samples the statistics every *interval* seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

Examples EXAMPLE 1 Sample output from the syncstat command:

```
example# syncstat zsh0
```

```
speed ipkts opkts undrun ovrrun abort crc isize osize
9600 15716 17121 0 0 1 3 98 89
```

```
example# syncstat -c zsh0
```

```
speed ipkts opkts undrun ovrrun abort crc isize osize
9600 0 0 0 0 0 0 0 0
```

In the following sample output a new line of output is generated every five seconds:

```
example# syncstat zsh0 5
```

```
ipkts opkts undrun ovrrun abort crc iutil outil
12 10 0 0 0 0 5% 4%
22 60 0 0 0 0 3% 90%
36 14 0 0 0 1 51% 2%
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [syncinit\(1M\)](#), [syncloop\(1M\)](#), [attributes\(5\)](#), [zsh\(7D\)](#)

| | |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Diagnosics bad interval: <i>arg</i> | The argument <i>arg</i> is expected to be an interval and could not be understood. |
| <i>device</i> missing minor device number | The name <i>device</i> does not end in a decimal number that can be used as a minor device number. |
| baud rate not set | The <i>interval</i> option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics. |

Warnings Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as

cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

Name sysdef – output system definition

Synopsis /usr/sbin/sysdef [-i] [-n *namelist*]
/usr/sbin/sysdef [-h] [-d] [-i] [-D]

Description The sysdef utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.

It generates the output by analyzing the named bootable operating system file (*namelist*) and extracting the configuration information from it.

The default system *namelist* is /dev/kmem.

Options

- i Prints the configuration information from /dev/kmem. This is the default and only needs to be specified if the configuration information from both /dev/kmem and the system file specified with the “-n *namelist*” option is needed.
- n *namelist* Specifies a *namelist* other than the default (/dev/kmem). The *namelist* specified must be a valid bootable operating system.
- h Prints the identifier of the current host in hexadecimal. If sysdef -h is executed within a non-global zone and the zone emulates a host identifier, then the zone's host identifier is printed. This numeric value is not guaranteed to be unique.
- d The output includes the configuration of system peripherals formatted as a device tree.
- D For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.

Examples EXAMPLE 1 Sample output format

The following example displays the format of the sysdef -d output:

```
example% sysdef -d

Name syseventadm – sysevent event specification administration

Synopsis syseventadm add [-R *rootdir*] [-v *vendor*] [-p *publisher*]
 [-c *class*] [-s *subclass*] [-u *username*] *path* [*args*]
 syseventadm remove [-R *rootdir*] [-v *vendor*] [-p *publisher*]
 [-c *class*] [-s *subclass*] [-u *username*] [*path* [*args*]]
 syseventadm list [-R *rootdir*] [-v *vendor*] [-p *publisher*]
 [-c *class*] [-s *subclass*] [-u *username*] [*path* [*args*]]
 syseventadm restart

Description The syseventadm command is an administrative front-end to add, remove and list sysevent event handlers. You can also restart the sysevent daemon by use of the restart command. syseventadm can only be run by root.

The syseventadm add command adds a handler for a sysevent event specified by at least one of vendor, publisher or class. If *class* is specified, it may be qualified with a *sub-class*. Only the values specified for *vendor*, *publisher*, *class* and *sub-class* when adding the handler are matched against sysevent events to determine if the specification matches the event and the handler should be run. *path* is the full pathname of the command to be run in response to matching events, with optional arguments (*args*). If *username* is specified, the command is invoked as user *username*, otherwise as root.

The syseventadm remove command removes handlers for matching sysevent event specifications. Event specifications may be matched by specifying at least one of *vendor*, *publisher*, *class*, *username* or *path*. If *class* is specified, it may be qualified with a *sub-class*. Any of *vendor*, *publisher*, *class*, *sub-class*, *username*, *path* or *args* not specified match the corresponding fields of all events. Handlers for all matching specifications are removed.

The syseventadm list command lists the handlers for matching sysevent event specifications using the same match criteria as the remove command but without the requirement that at least one of *vendor*, *publisher*, *class*, *username* or *path* be specified. With no match criteria, all specifications are listed. The list command output format is: [vendor=*vendor*] [publisher=*publisher*] [class=*class*] [subclass=*subclass*] [username=*username*] *path* [*args*] where each of *class*, *sub-class*, *vendor*, *publisher* and *username* is listed only if part of the match criteria for the listed specification.

The syseventadm restart command informs the syseventd daemon to reread the sysevent registry after a change has been made by adding or removing one or more sysevent handler specifications.

Argument Macro Substitution The sysevent handling facility provides extensive macro capability for constructing the command line arguments to be executed in response to an event. Macro expansion applies only to the command line *args* specified for an event handler, with macros expanded with data from the event itself. Pre-defined macros are provided for the event *class*, *subclass*, *publisher* and *vendor* information. Macros not matching one of the pre-defined macro names cause the

attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the \$ character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by \${ and }. A \ before the \$ causes macro expansion not to occur.

| | |
|--------------------|-----------------------------------------|
| <i>\$class</i> | The class string defining the event |
| <i>\$publisher</i> | The publisher string defining the event |
| <i>\$sequence</i> | The sequence number of the event. |
| <i>\$subclass</i> | The subclass string defining the event |
| <i>\$timestamp</i> | The timestamp of the event. |
| <i>\$vendor</i> | The vendor string defining the event |

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (DATA_TYPE_INT16, DATA_TYPE_INT32 and DATA_TYPE_INT64) are expanded as decimal digits.

Attributes with unsigned data types (DATA_TYPE_BYTE, DATA_TYPE_UINT16, DATA_TYPE_UINT32, DATA_TYPE_UINT64 and DATA_TYPE_HTTPTIME) are expanded as hexadecimal digits with a 0x prefix.

Attributes with string data type (DATA_TYPE_STRING) are expanded with the string data. The data is not quoted. If it is desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

Options The `add`, `list` and `remove` subcommands support the following options:

| | |
|---------------------------|--------------------------------------------------|
| <code>-c class</code> | Specify the event class, <i>class</i> . |
| <code>-p publisher</code> | Specify the event publisher, <i>publisher</i> . |
| <code>-R rootdir</code> | Specify an alternate root path, <i>rootdir</i> . |

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system,

might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

- s *subclass* Specify the event subclass, *subclass*.
- u *username* Specify the username (*username*) to invoke the command.
- v *vendor* Specify the vendor (*vendor*) that defines the event. Events defined by third-party software should specify the company's stock symbol as *vendor*. Sun-defined events use SUNW.

Operands The `add`, `list` and `remove` subcommands support the following options:

- args* Command arguments
- path* Full path of command to be run in response to event

Examples EXAMPLE 1 Adding an Event Handler

The following example adds an event handler for an event defined by vendor MYCO (“My Company”), class EC_ENV and sub-class ESC_ENV_TEMP. The command to be run is `/opt/MYCOenv/bin/ec_env_temp`, with arguments being the class name, sub-class name and pathname derived from the event attributes. The \$ characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on \$ALROOT.

```
# syseventadm add -R \${ALROOT} -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
/opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 2 Removing an Event Handler

The following example removes the event handler added in Example 1.

```
# syseventadm remove -R \${ALROOT} -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
/opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 3 Listing Event Handlers

The following example lists all event handlers for events of class EC_ENV, subclass ESC_ENV_TEMP, as defined by vendor MYCO:

```
# syseventadm list -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
vendor=MYCO class=EC_ENV subclass=ESC_ENV_TEMP \
/opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

EXAMPLE 4 Listing Event Handlers

The following example lists all event handlers defined by vendor VRTS.

```
# syseventadm list -v VRTS
```

EXAMPLE 5 Removing Event Handlers

The following example removes all event handlers defined by vendor VRTS, and restarts service.

```
# syseventadm remove -v VRTS
# syseventadm restart
```

EXAMPLE 6 Listing All Event Handlers Specified to Run a Command

The following example lists all event handlers specified to run the command `/opt/MYCOenv/bin/ec_env_temp`:

```
# syseventadm list /opt/MYCOenv/bin/ec_env_temp
```

EXAMPLE 7 Removing Event Handlers and Restarting Service

The following example removes all event handlers specified to run the command `/opt/MYCOenv/bin/ec_env_temp`, and restarts service:

```
# syseventadm remove /opt/MYCOenv/bin/ec_env_temp
# syseventadm restart
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 No matching event specification found (remove or list commands only).
- 2 Incorrect command usage.
- 3 Permission denied.
- 4 Command failed.
- 5 Out of memory.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [syseventd\(1M\)](#), [sysevent_post_event\(3SYSEVENT\)](#), [attributes\(5\)](#), [ddi_log_sysevent\(9F\)](#)

Notes To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's `postinstall` script. The event handler can then be removed by running `syseventadm` from the package's `preremove` script using the same arguments as when added.

Name syseventconfd – kernel system event command invocation daemon

Synopsis /usr/lib/sysevent/syseventconfd [-r *rootdir*]

Description syseventconfd is the user-level daemon that invokes user-level commands in response to kernel system events received from [syseventd\(1M\)](#).

Options The following options are supported:

-r *rootdir* Cause syseventconfd to use an alternate root path when creating its door. The root path must match the root path used to invoke syseventd.

Files /etc/sysevent/syseventconfd_event_service
syseventconfd event service door file

/usr/lib/sysevent/modules/sysevent_conf_mod.so
syseventd loadable module (SLM) managing sysevent.conf files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syseventd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The syseventconfd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name syseventd – kernel system event notification daemon

Synopsis /usr/lib/sysevent/syseventd [-d *debug_level*] [-r *rootdir*]

Description syseventd is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to propagate the event to all interested end event subscribers.

Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt.

Upon successful delivery of the event buffer to all interested event subscribers, syseventd frees the event buffer from the kernel event queue.

Options The following options are supported:

-d *debug_level* Enable debug mode. Messages are printed to the invoking user's terminal.

-r *rootdir* Cause syseventd to use an alternate root path when creating its door and lock files. Modules continue to be loaded from the standard module directories.

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Files /etc/sysevent/syseventd_daemon.lock
daemon lock file

/etc/sysevent/sysevent_door
kernel to syseventd door file

/usr/lib/sysevent/modules
SLM directory repository

/usr/platform/`uname -i`/lib/sysevent/modules
SLM directory repository

/usr/platform/`uname -m`/lib/sysevent/modules
SLM directory repository

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syseventconfd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The syseventd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name sysidconfig – execute system configuration applications, or define set of system configuration applications

Synopsis sysidconfig [-lv] [-a *application*] [-b *basedir*]
[-r *application*]

Description Invoked without any options, the `sysidconfig` program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, `-c`. This flag will cause the system configuration application to perform its configuration function. Without options, `sysidconfig` should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot.

All applications on the list will be executed, if possible. All activity taken by the `sysidconfig` program is logged in the `sysidconfig` log file, `/var/log/sysidconfig.log`. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time.

Executed with the `-l`, `-a`, or `-r` options, the `sysidconfig` program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running `sysidconfig` with options is the only way to view or manipulate the list. Only the super-user can execute the `sysidconfig` program with options.

The `-b` and `-v` options change the behavior of `sysidconfig`, and can be used with or without the list manipulation options discussed above. The `-b basedir` option is used to specify a reference root directory other than the default, `/`. The `-v` option duplicates the log file output on `stdout`.

By default, no SPARC based applications exist on this list. However, the x86 based systems are delivered with one application, `kdmconfig(1M)`, on the list. `kdmconfig` is not delivered on SPARC based systems.

This application is an extension of the `sysidtool(1M)` suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via `sysidconfig -a`.

This program is referenced, but not fully described, in the `sysidtool(1M)` manual page.

Options The valid options are:

`-a application` Add the named application to the list of defined applications. When next invoked without arguments, `sysidconfig` will run this newly added application after all previously defined applications. *application* must be a fully qualified path name that is not currently on the list of applications to execute.

- b *basedir*** Specify an alternate base directory (/ is defined as the default base directory if no other is specified). The specified directory is used as the root directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in /var/log, relative to the specified *basedir*. In the log file, the *basedir* is not noted. This means, for example, that if the super-user on a diskless client's server executes:
- ```
sysidconfig -b /export/root/client -a /sbin/someapp
```
- then the diskless client *client* would have /sbin/someapp executed upon reconfigure/reboot. The diskless client's log file would note that /sbin/someapp was added, not /export/root/client/sbin/someapp.
- Note** – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- l** List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.
- r *application*** Remove the named application from the list of defined applications. *application* must be a fully qualified path name and it must be on the existing list of applications to execute.
- v** Verbose mode. This option echoes all information sent to the log file to stdout. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

**Return Values** The sysidconfig program will return 0 if it completes successfully.

When executed with the -r or -a options, error conditions or warnings will be reported on stderr. If the requested action completes successfully, an exit code of 0 will be returned.

- Errors**
- EPERM** The program was executed by a user other than the super-user.
  - EINVAL** Option -l, -a, or -r was passed and the action could not be completed successfully.

**Files** /var/log/sysidconfig.log sysidconfig log file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmap

**See Also** [sys-unconfig\(1M\)](#), [sysidtool\(1M\)](#), [attributes\(5\)](#)

x86 Only [kdmconfig\(1M\)](#)

**Diagnostics** When run without options, a log of the `sysidconfig` program's activity can be found in `/var/log/sysidconfig.log`. This file contains a timestamp log of each program executed, its resulting `stderr` output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.

- 
- Name** sysidtool, sysidnet, sysidns, sysidsys, sysidroot, sysidpm, sysidnfs4, sysidkbd – system configuration
- Synopsis** /usr/sbin/sysidnet  
 /usr/sbin/sysidns  
 /usr/sbin/sysidsys  
 /usr/sbin/sysidroot  
 /usr/sbin/sysidpm  
 /usr/sbin/sysidnfs4  
 /usr/sbin/sysidkbd
- Description** sysidtool is a suite of programs that configure a new system, or one that has been unconfigured with [sys-unconfig\(1M\)](#). The sysidtool programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured.
- These programs have no effect except at such times, and should never be run manually.
- The sysidtool programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. The following list shows the available commands and the information for which each of the commands lists.
- sysidnet:** network configuration  
 Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.
- sysidns:** name service configuration  
 Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network. Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)
- sysidsys:** miscellaneous system configuration  
 Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.
- sysidroot:** control superuser information  
 Machine's root password.
- sysidpm:** power management configuration  
 Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.
- sysidnfs4:** NFSv4 domain configuration  
 Domain name to be used by NFSv4 client(s) and server(s) to transmit user and group id's as strings of the general form “[user|group]@domain”.

**sysidkbd:** keyboard layout configuration

The corresponding keytable is loaded into the kernel according to the configured keyboard layout.

**sysidconfig:** host- or platform-specific configuration

This command controls specification and execution of custom configuration applications that can be specified for a particular host or a particular platform. See [sysidconfig\(1M\)](#).

The **sysidtool** programs attempt to obtain system configuration information from various name service databases, for example, NIS, or from the [sysidcfg\(4\)](#) file, and you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the [sysidcfg\(4\)](#) file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See *Oracle Solaris 10 8/11 Installation Guide: Basic Installations* for more details about how to preconfigure the system configuration information.

The machine's configuration information is set up in its `/etc` and `/var` files.

If a system has more than one network interface, you can use **sysidtool** to configure all interfaces on the system.

You cannot use the name service databases or the [sysidcfg\(4\)](#) file to suppress the Power Management configuration prompt. However, you can suppress it by creating either the `/autoshtutdown` or `/noautoshtutdown` file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The `/autoshtutdown` or `/noautoshtutdown` files are removed by **sysidpm** before it exits.

If you have non-global zones installed and the `nfs4_domain` keyword exists in the [sysidcfg](#) file, the first boot of a non-global zone sets the domain. Otherwise, the Solaris interactive installation program comes up and you are prompted to provide a domain name before the boot process completes. See [sysidcfg\(4\)](#) and *Oracle Solaris 10 8/11 Installation Guide: Custom JumpStart and Advanced Installations*.

**sysidkbd** prompts for the keyboards with `zero-bCountryCode` and then sets the keyboard layout string in the `/etc/default/keyboard` file. If the **sysidkbd** gets the valid keyboard layout string, the string will be set into the entry "LAYOUT=" in the file.

**Files** `/etc/.UNCONFIGURED`  
`/etc/nodename`  
`/etc/hostname.??[0-9]`  
`/etc/default/init`  
`/etc/defaultdomain`  
  
`/etc/passwd` password file. See [passwd\(4\)](#).

/etc/shadow shadow password file. See [shadow\(4\)](#).

/etc/inet/hosts

/etc/inet/netmasks

/var/nis/NIS\_COLD\_START

/var/yp/aliases

/var/yp/binding/\*/ypservers

/etc/.sysIDtool.state

/etc/power.conf Power Management configuration file. See [power.conf\(4\)](#).

/etc/.PM\_RECONFIGURE If this file is present during system reboot, the sysidpm program is run. This file is removed by sysidpm.

/etc/.NFS4inst\_state.domain

/etc/default/kdb

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmap, SUNWpmu

**See Also** [powerd\(1M\)](#), [sys-unconfig\(1M\)](#), [sysidconfig\(1M\)](#), [passwd\(4\)](#), [power.conf\(4\)](#), [shadow\(4\)](#), [sysidcfg\(4\)](#), [attributes\(5\)](#)

*Oracle Solaris 10 8/11 Installation Guide: Custom JumpStart and Advanced Installations*

**Notes** NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit <http://www.sun.com/directory/nisplus/transition.html>.

**Name** syslogd – log system messages

**Synopsis** /usr/sbin/syslogd [-d] [-f *configfile*] [-m *markinterval*]  
[-p *path*] [-t | -T]

**Description** syslogd reads and forwards system messages to the appropriate log files or users, depending upon the priority of a message and the system facility from which it originates. The configuration file /etc/syslog.conf (see [syslog.conf\(4\)](#)) controls where messages are forwarded. syslogd logs a mark (timestamp) message every *markinterval* minutes (default 20) at priority LOG\_INFO to the facility whose name is given as mark in the syslog.conf file.

A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <sys/syslog.h>.

syslogd reads from the STREAMS log driver, /dev/log, and from any transport provider specified in /etc/netconfig, /etc/net/transport/hosts, and /etc/net/transport/services.

syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see [signal.h\(3HEAD\)](#)), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal.

As it starts up, syslogd creates the file /var/run/syslog.pid, if possible, containing its process identifier (PID).

If message ID generation is enabled (see [log\(7D\)](#)), each message will be preceded by an identifier in the following format: [ ID *msgid facility . priority* ]. *msgid* is the message's numeric identifier described in [msgid\(1M\)](#). *facility* and *priority* are described in [syslog.conf\(4\)](#). [ ID 123456 kern.notice ] is an example of an identifier when message ID generation is enabled.

If the message originated in a loadable kernel module or driver, the kernel module's name (for example, ufs) will be displayed instead of unix. See EXAMPLES for sample output from syslogd with and without message ID generation enabled.

In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See [Examples](#).

The /etc/default/syslogd file contains the following default parameter settings, which are in effect if neither the -t nor -T option is selected. See FILES.

The recommended way to allow or disallow message logging is through the use of the service management facility ([smf\(5\)](#)) property:

```
svc:/system/system-log/config/log_from_remote
```

This property specifies whether remote messages are logged. log\_from\_remote=true is equivalent to the -t command-line option and false is equivalent to the -T command-line option. The default value for -log\_from\_remote is false. See NOTES, below.

**LOG\_FROM\_REMOTE**

Specifies whether remote messages are logged. LOG\_FROM\_REMOTE=NO is equivalent to the -t command-line option. The default value for LOG\_FROM\_REMOTE is YES.

**Options** The following options are supported:

- d  
Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should *not* be used in the system start-up scripts, as this will cause the system to hang at the point where syslogd is started.
- f *configfile*  
Specify an alternate configuration file.
- m *markinterval*  
Specify an interval, in minutes, between mark messages.
- p *path*  
Specify an alternative log device name. The default is /dev/log.
- T  
Enable the syslogd UDP port to turn on logging of remote messages. This is the default behavior. See [Files](#).
- t  
Disable the syslogd UDP port to turn off logging of remote messages. See [Files](#).

**Examples** **EXAMPLE 1** syslogd Output Without Message ID Generation Enabled

The following example shows the output from syslogd when message ID generation *is not* enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

**EXAMPLE 2** syslogd Output with ID generation Enabled

The following example shows the output from syslogd when message ID generation *is* enabled. The message ID is displayed when writing to log file/var/adm/messages.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice]
 alloc /: file system full
```

**EXAMPLE 3** syslogd Output with ID Generation Enabled

The following example shows the output from syslogd when message ID generation *is* enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```

**EXAMPLE 4** Enabling Acceptance of UDP Messages from Remote Systems

The following commands enable `syslogd` to accept entries from remote systems.

```
svccfg -s svc:/system/system-log setprop config/log_from_remote = true
svcadm restart svc:/system/system-log
```

- Files**
- `/etc/syslog.conf`  
Configuration file
  - `/var/run/syslog.pid`  
Process ID
  - `/etc/default/syslogd`  
Contains default settings. You can override some of the settings by command-line options.
  - `/dev/log`  
STREAMS log driver
  - `/etc/netconfig`  
Transport providers available on the system
  - `/etc/net/transport/hosts`  
Network hosts for each transport
  - `/etc/net/transport/services`  
Network services for each transport

Availability	SUNWcsu

**See Also** [logger\(1\)](#), [svcs\(1\)](#), [msgidd\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [signal.h\(3HEAD\)](#), [smf\(5\)](#), [log\(7D\)](#)

**Notes** The mark message is a system time stamp, and so it is only defined for the system on which `syslogd` is running. It can not be forwarded to other systems.

When `syslogd` receives a HUP signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, `syslogd` discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and `syslogd` cannot complete reconfiguration, `syslogd` sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by `syslogd` (especially console windows) is run in the system default locale (which is `syslogd`'s locale). If

this advice is not followed, it is possible for a sys log message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

The `syslogd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/system-log:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

When `syslogd` is started by means of [svcadm\(1M\)](#), if a value is specified for `LOG_FROM_REMOTE` in the `/etc/defaults/syslogd` file, the SMF property `svc:/system/system-log/config/log_from_remote` is set to correspond to the `LOG_FROM_REMOTE` value and the `/etc/default/syslogd` file is modified to replace the `LOG_FROM_REMOTE` specification with the following comment:

```
LOG_FROM_REMOTE is now set using svccfg(1m), see syslogd(1m).
```

If neither `LOG_FROM_REMOTE` nor `svc:/system/system-log/config/log_from_remote` are defined, the default is to log remote messages.

On installation, the initial value of `svc:/system/system-log/config/log_from_remote` is `false`.

**Name** sys-unconfig – undo a system's configuration

**Synopsis** /usr/sbin/sys-unconfig

**Description** The `sys-unconfig` command is used to restore a system's configuration to an “as-manufactured” state, ready to be reconfigured again. The system's configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the [sysidnet\(1M\)](#), [sysidns\(1M\)](#), and [sysidsys\(1M\)](#) programs run at boot. See [sysidtool\(1M\)](#).

`sys-unconfig` does the following:

- Saves current `/etc/inet/hosts` file information in `/etc/inet/hosts.saved`.
- If the current `/etc/vfstab` file contains NFS mount entries, saves the `/etc/vfstab` file to `/etc/vfstab.orig`.
- Restores the default `/etc/inet/hosts` file.
- Removes the default hostname in `/etc/hostname.interface` files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command `ifconfig -a`. The `/etc/hostname.interface` files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (`lo0`), will be removed.
- Removes the default domainname in `/etc/defaultdomain`.
- Restores the timezone to PST8PDT in `/etc/TIMEZONE`.
- Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured.
- Removes the file `/etc/inet/netmasks`.
- Removes the file `/etc/defaultrouter`.
- Removes the password set for root in `/etc/shadow`.
- Removes the file `/etc/.rootkey`.
- Executes all system configuration applications. These applications are defined by prior executions of a `sysidconfig -a application`. (See [sysidconfig\(1M\)](#)). When `sys-unconfig` is run, all system configuration applications are passed one argument, `-u`.
- Removes the file `/etc/resolv.conf`.
- Removes the file `/etc/sysidcfg`.
- Disables LDAP by removing `/var/ldap/ldap_client_cache`, `/var/ldap/ldap_client_file`, `/var/ldap/ldap_client_cred`, and `/var/ldap/cachemgr.log`.
- Regenerates keys for [sshd\(1M\)](#).

When `sys-unconfig` is finished, it performs a system shutdown. `sys-unconfig` is a potentially dangerous utility and can only be run by the super user.

<b>Files</b>	<code>/etc/default/init</code>	process control initialization
	<code>/etc/defaultdomain</code>	determines host's domain name
	<code>/etc/defaultrouter</code>	specifies an IPv4 host's default router
	<code>/etc/hostname.<i>interface</i></code>	identifies symbolic host name associated with network interface <i>interface</i>
	<code>/etc/inet/hosts</code>	host name database
	<code>/etc/inet/netmasks</code>	network mask database
	<code>/etc/nodename</code>	local source for system name
	<code>/etc/.rootkey</code>	super-user's secret key
	<code>/etc/shadow</code>	shadow password file
	<code>/etc/sysidcfg</code>	system identification configuration file for diskless booting
	<code>/etc/vfstab</code>	virtual file system table
	<code>/var/nis/NIS_COLD_START</code>	list of NIS+ servers that serve a host's default domain
	<code>/var/yp/binding/*/ypservers</code>	identifies NIS servers to which the client is allowed to bind

**Notes** `sys-unconfig` is not available on diskless clients.

**Name** tapes – creates /dev entries for tape drives attached to the system

**Synopsis** /usr/sbin/tapes [-r *root\_dir*]

**Description** [devfsadm\(1M\)](#) is now the preferred command for /dev and /devices and should be used instead of tapes.

tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:

1. The /dev/rmt directory is searched for a /dev/rmt/*n* entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.
2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.
3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive.

tapes does not remove links to non-existent devices; these must be removed by hand.

tapes is run each time a reconfiguration-boot is performed, or when [add\\_drv\(1M\)](#) is executed.

**Notice to Driver Writers** [tapes\(1M\)](#) considers all devices with the node type DDI\_NT\_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [ *l,m,h,c,u* ][ *b* ][ *n* ].

The first character set is used to specify the tape density of the device, and are named low (*l*), medium (*m*), high (*h*), compressed (*c*), and ultra (*u*). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where *l* means 800 BPI, *m* means 1600 BPI, and *h* means 6250 BPI, whereas 4mm DAT tapes defines *l* as standard format, and *m*, *h*, *c* and *u* as compressed format. Drivers may choose to implement any or all of these format types.

During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. *b* instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.

*n* or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See [mtio\(7I\)](#).

The minor number for tape devices should be created by encoding the device's instance number using the tape macro `MTMINOR` and `ORing` in the proper combination of density, BSD behavior, and no-rewind flags. See [mtio\(7I\)](#).

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string `DDI_NT_TAPE` when calling [ddi\\_create\\_minor\\_node\(9F\)](#).

**Options** The following options are supported:

`-r root_dir` Causes tapes to presume that the `/dev/rmt` directory tree is found under `root_dir`, not directly under `/`.

**Errors** If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

**Examples** **EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's `attach()` Function

This example demonstrates creating tape device nodes from within the `xktape` driver's [attach\(9E\)](#) function.

```
#include <sys/mtio.h>
struct tape_minor_info {
 char *minor_name;
 int minor_mode;
};
/*
 * create all combinations of logical tapes
 */
static struct tape_minor_info example_tape[] = {
 {"", 0}, /* default tape */
 {"l", MT_DENSITY1},
 {"lb", MT_DENSITY1 | MT_BSD},
 {"lbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
 {"m", MT_DENSITY2},
 {"mb", MT_DENSITY2 | MT_BSD},
 {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
 {"h", MT_DENSITY3},
 {"hb", MT_DENSITY3 | MT_BSD},
 {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
 {"c", MT_DENSITY4},
 {"cb", MT_DENSITY4 | MT_BSD},
 {"cbn", MT_DENSITY4 | MT_BSD | MT_NOREWIND},
 {NULL, 0},
};
```

**EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's `attach()` Function *(Continued)*

```

int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
 int instance;
 struct tape_minor_info *mdp;
 /* other stuff in attach... */
 instance = ddi_get_instance(dip);

 for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
 ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
 (MTMINOR(instance)| mdp->minor_mode), DDI_NT_TAPE, 0);
 }
}

```

Installing the `xktape` driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```

ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isp@4
crw-rw-rw- 1 root sys 33,136 Aug 29 00:02 xktape@4,0:
crw-rw-rw- 1 root sys 33,200 Aug 29 00:02 xktape@4,0:b

### *Writing Device Drivers*

**Bugs** tapes silently ignores malformed minor device names.

**Name** taskstat – prints ASET tasks status

**Synopsis** /usr/aset/util/taskstat [-d *aset\_dir*]

**Description** taskstat is located in the /usr/aset/util directory. /usr/aset is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the aset -d command or the ASETDIR environment variable. See [aset\(1M\)](#). Because aset dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. taskstat prints the status of the tasks, listing those that are completed and those that are still executing.

The ASET reports, which are located in the /usr/aset/reports directory (see the -d option), are not complete until all the tasks finish executing.

**Options** -d *aset\_dir* Specify the working directory for ASET. By default, this directory is /usr/aset. With this option, the reports directory will be located under *aset\_dir*.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*System Administration Guide: Basic Administration*

## REFERENCE

### System Administration Commands - Part 3

**Name** th\_define – create fault injection test harness error specifications

**Synopsis** th\_define [-n *name* -i *instance*] -P *path*] [-a *acc\_types*]  
 [-r *reg\_number*] [-l *offset* [*length*]]  
 [-c *count* [*failcount*]] [-o *operator* [*operand*]]  
 [-f *acc\_chk*] [-w *max\_wait\_period* [*report\_interval*]]

or

th\_define [-n *name* -i *instance*] -P *path*]  
 [-a *log* [*acc\_types*] [-r *reg\_number*] [-l *offset* [*length*]]]  
 [-c *count* [*failcount*]] [-s *collect\_time*] [-p *policy*]  
 [-x *flags*] [-C *comment\_string*]  
 [-e *fixup\_script* [*args*]]

or

th\_define [-h]

**Description** The th\_define utility provides an interface to the bus\_ops fault injection bofi device driver for defining error injection specifications (referred to as errdefs). An errdef corresponds to a specification of how to corrupt a device driver's accesses to its hardware. The command line arguments determine the precise nature of the fault to be injected. If the supplied arguments define a consistent errdef, the th\_define process will store the errdef with the bofi driver and suspend itself until the criteria given by the errdef become satisfied (in practice, this will occur when the access counts go to zero).

You use the th\_manage(1M) command with the start option to activate the resulting errdef. The effect of th\_manage with the start option is that the bofi driver acts upon the errdef by matching the number of hardware accesses—specified in *count*, that are of the type specified in *acc\_types*, made by instance number *instance*—of the driver whose name is *name*, (or by the driver instance specified by *path*) to the register set (or DMA handle) specified by *reg\_number*, that lie within the range *offset* to *offset* + *length* from the beginning of the register set or DMA handle. It then applies *operator* and *operand* to the next *failcount* matching accesses.

If *acc\_types* includes log, th\_define runs in automatic test script generation mode, and a set of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current directory with the name <*driver*>.test.<*id*> (for example, glm.test.978177106). A separate, executable script is generated for each access handle that matches the logging criteria. The log of accesses is placed at the top of each script as a record of the session. If the current directory is not writable, file output is written to standard output. The base name of each test file is the driver name, and the extension is a number that discriminates between different access handles. A control script (with the same name as the created test directory) is generated that will run all the test scripts sequentially.

Executing the scripts will install, and then activate, the resulting error definitions. Error definitions are activated sequentially and the driver instance under test is taken offline and brought back online before each test (refer to the -e option for more information). By default, logging applies to all PIO accesses, all interrupts, and all DMA accesses to and from areas

mapped for both reading and writing. You can constrain logging by specifying additional *acc\_types*, *reg\_number*, *offset* and *length*. Logging will continue for *count* matching accesses, with an optional time limit of *collect\_time* seconds.

Either the *-n* or *-P* option must be provided. The other options are optional. If an option (other than *-a*) is specified multiple times, only the final value for the option is used. If an option is not specified, its associated value is set to an appropriate default, which will provide maximal error coverage as described below.

**Options** The following options are available:

<i>-n name</i>	Specify the name of the driver to test. (String)
<i>-i instance</i>	Test only the specified driver instance ( <i>-1</i> matches all instances of driver). (Numeric)
<i>-P path</i>	Specify the full device path of the driver to test. (String)
<i>-r reg_number</i>	Test only the given register set or DMA handle ( <i>-1</i> matches all register sets and DMA handles). (Numeric)
<i>-a acc_types</i>	Only the specified access types will be matched. Valid values for the <i>acc_types</i> argument are <i>log</i> , <i>pio</i> , <i>pio_r</i> , <i>pio_w</i> , <i>dma</i> , <i>dma_r</i> , <i>dma_w</i> and <i>intr</i> . Multiple access types, separated by spaces, can be specified. The default is to match all hardware accesses.  If <i>acc_types</i> is set to <i>log</i> , logging will match all PIO accesses, interrupts and DMA accesses to and from areas mapped for both reading and writing. <i>log</i> can be combined with other <i>acc_types</i> , in which case the matching condition for logging will be restricted to the specified additional <i>acc_types</i> . Note that <i>dma_r</i> will match only DMA handles mapped for reading only; <i>dma_w</i> will match only DMA handles mapped for writing only; <i>dma</i> will match only DMA handles mapped for both reading and writing.
<i>-l offset [length]</i>	Constrain the range of qualifying accesses. The <i>offset</i> and <i>length</i> arguments indicate that any access of the type specified with the <i>-a</i> option, to the register set or DMA handle specified with the <i>-r</i> option, lie at least <i>offset</i> bytes into the register set or DMA handle and at most <i>offset + length</i>

-c *count* [*failcount*]

bytes into it. The default for *offset* is 0. The default for *length* is the maximum value that can be placed in an `offset_t` C data type (see `types.h`). Negative values are converted into unsigned quantities. Thus, `th_define -l 0 -1` is maximal.

Wait for *count* number of matching accesses, then apply an operator and operand (see the `-o` option) to the next *failcount* number of matching accesses. If the access type (see the `-a` option) includes logging, the number of logged accesses is given by  $count + failcount - 1$ . The `-1` is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if *failcount* and *operator* are nonzero and if the access type includes logging and any of the other access types (`pio`, `dma` and `intr`) See the description of access types in the definition of the `-a` option, above.

When the *count* and *failcount* fields reach zero, the status of the `errdef` is reported to standard output. When all active `errdefs` created by the `th_define` process complete, the process exits. If *acc\_types* includes `log`, *count* determines how many accesses to log. If *count* is not specified, a default value is used. If *failcount* is set in this mode, it will simply increase the number of accesses logged by a further  $failcount - 1$ .

-o *operator* [*operand*]

For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of *operator*:

- EQ     *operand* is returned to the driver.
- OR     *operand* is bitwise ORed with the real value.
- AND    *operand* is bitwise ANDed with the real value.
- XOR    *operand* is bitwise XORed with the real value.

For PIO write accesses, the following operator is allowed:

**NO** Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the `ddi_getX()`, `ddi_putX()`, `ddi_rep_getX()` and `ddi_rep_putX()` routines (where *X* is 8, 16, 32 or 64). Accesses made using `ddi_getX()` and `ddi_putX()` are treated as a single access, whereas an access made using the `ddi_rep_*(9F)` routines are broken down into their respective number of accesses, as given by the *repcount* parameter to these DDI calls. If the access is performed via a DMA handle, *operator* and *value* are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

**DELAY** After *count* accesses (see the `-c` option), delay delivery of the next *failcount* number of interrupts for *operand* number of microseconds.

**LOSE** After *count* number of interrupts, fail to deliver the next *failcount* number of real interrupts to the driver.

**EXTRA** After *count* number of interrupts, start delivering *operand* number of extra interrupts for the next *failcount* number of real interrupts.

The default value for *operand* and *operator* is to corrupt the data access by flipping each bit (XOR with -1).

`-f acc_chk`

If the *acc\_chk* parameter is set to 1 or `pio`, then the driver's calls to `ddi_check_acc_handle(9F)` return `DDI_FAILURE` when the access count goes to 1. If the *acc\_chk* parameter is set to 2 or `dma`, then the driver's calls to `ddi_check_dma_handle(9F)` return `DDI_FAILURE` when the access count goes to 1.

- w max\_wait\_period [report\_interval]* Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for *max\_wait\_period* seconds, the test will be aborted. If *report\_interval* is set to a nonzero value, the current status of the error definition is reported to standard output every *report\_interval* seconds. The default value is zero. The status of the errdef is reported in parsable format (eight fields, each separated by a colon (: ) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):
- ft:mt:ac:fc:chk:ec:s:"message"* which are defined as follows:
- |                  |                                                                                                                         |
|------------------|-------------------------------------------------------------------------------------------------------------------------|
| <i>ft</i>        | The UTC time when the fault was injected.                                                                               |
| <i>mt</i>        | The UTC time when the driver reported the fault.                                                                        |
| <i>ac</i>        | The number of remaining non-faulting accesses.                                                                          |
| <i>fc</i>        | The number of remaining faulting accesses.                                                                              |
| <i>chk</i>       | The value of the <i>acc_chk</i> field of the errdef.                                                                    |
| <i>ec</i>        | The number of fault reports issued by the driver against this errdef ( <i>mt</i> holds the time of the initial report). |
| <i>s</i>         | The severity level reported by the driver.                                                                              |
| <i>"message"</i> | Textual reason why the driver has reported a fault.                                                                     |
- h* Display the command usage string.
- s collect\_time* If *acc\_types* is given with the *-a* option and includes *log*, the errdef will log accesses for *collect\_time* seconds (the default is to log until the log becomes full). Note that, if the errdef

specification matches multiple driver handles, multiple logging errdefs are registered with the `bofi` driver and logging terminates when all logs become full or when `collect_time` expires or when the associated errdefs are cleared. The current state of the log can be checked with the `th_manage(1M)` command, using the `broadcast` parameter. A log can be terminated by running `th_manage(1M)` with the `clear_errdefs` option or by sending a SIGALRM signal to the `th_define` process. See `alarm(2)` for the semantics of SIGALRM.

`-p policy`

Applicable when the `acc_types` option includes `log`. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

- Use `rare` to bias error definitions toward rare accesses (default).
- Use `operator` to produce a separate error definition for each operator type (default).
- Use `common` to bias error definitions toward common accesses.
- Use `median` to bias error definitions toward median accesses.
- Use `maximal` to produce multiple error definitions for duplicate accesses.
- Use `unbiased` to create unbiased error definitions.
- Use `onebyte`, `twobyte`, `fourbyte`, or `eightbyte` to select errdefs corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the `-xr` option is enforced in order to ensure that `ddi_rep_*()` calls are decomposed into *multiple single accesses*).
- Use `multibyte` to create error definitions for multibyte accesses performed using `ddi_rep_get*()` and `ddi_rep_put*()`.

Policies can be combined by adding together these options. See the NOTES section for further information.

*-x flags*

Applicable when the *acc\_types* option includes *log*. The *flags* parameter modifies the way in which the *bofi* driver logs accesses. It is specified as a string containing any combination of the following letters:

- w Continuous logging (that is, the log will wrap when full).
- t Timestamp each log entry (access times are in seconds).
- r Log repeated I/O as individual accesses (for example, a `ddi_rep_get16(9F)` call which has a *repcount* of *N* is logged *N* times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the *repcount*).

*-C comment\_string*

Applicable when the *acc\_types* option includes *log*. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.

*-e fixup\_script [args]*

Applicable when the *acc\_types* option includes *log*. The output of a logging *errdefs* is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault-free state. The executable *fixup\_script* will be called twice with the set of optional *args*— once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

DRIVER_PATH	Identifies the device path of the instance.
DRIVER_INSTANCE	Identifies the instance number of the device.

DRIVER_UNCONFIGURE	Has the value 1 when the instance is about to be taken offline.
DRIVER_CONFIGURE	Has the value 1 when the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example configured, error free and servicing a workload). A minimal script for a network driver could be:

```
#!/bin/ksh

driver=xyznetdriver
ifnum=${driver}$DRIVER_INSTANCE

if [[$DRIVER_CONFIGURE = 1]]; then
 ifconfig $ifnum plumb
 ifconfig $ifnum ...
 ifworkload start $ifnum
elif [[$DRIVER_UNCONFIGURE = 1]]; then
 ifworkload stop $ifnum
 ifconfig $ifnum down
 ifconfig $ifnum unplumb
fi
exit $?
```

The `-e` option must be the last option on the command line.

If the `-a log` option is selected but the `-e` option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

## Examples

Examples of Error Definitions `th_define -n foo -i 1 -a log`

Logs all accesses to all handles used by instance 1 of the `foo` driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -a log pio
```

Logs PIO accesses to each PIO handle used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

Logs all accesses to all handles used by instance 1 of the foo driver while running the workload defined in the fixup script `fixup` with arguments `arg` and `-now`. Then generates a set of test scripts to inject appropriate errdefs while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a *median* number of times with respect to frequency of access to I/O addresses.

```
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the `se` driver to its command status register, thereby returning status busy.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. This is of course a no-op.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the foo driver to return 0x70003.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND
0xffffffffffffefff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```

Prevents the next physical I/O write access to any register in any register set of instance 3 of the foo driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

Causes 0x7 to be ORed into each long long in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the foo driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR 0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first long long of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the foo driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each long long in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the foo driver. Subsequent calls in the driver to `ddi_check_dma_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND 0xffffffffffffefff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first long long of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the foo driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the foo driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the foo driver to be delayed by 1024 microseconds.

**Notes** The policy option in the `th_define -p` syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

**Bytewise Policies** These select particular I/O transfer sizes. Specifying a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.

onebyte	Create errdefs for one byte accesses ( <code>ddi_get8()</code> )
twobyte	Create errdefs for two byte accesses ( <code>ddi_get16()</code> )
fourbyte	Create errdefs for four byte accesses ( <code>ddi_get32()</code> )
eightbyte	Create errdefs for eight byte accesses ( <code>ddi_get64()</code> )
multibyte	Create errdefs for repeated byte accesses ( <code>ddi_rep_get*()</code> )

**Frequency of Access Policies** The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let *maxa* and *mina* be the number of times these locations were accessed, and *mean* the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

$$(mean - mina) / 3 + mina$$

times. Similarly for the definition of common accesses:

$$maxa - (maxa - mean) / 3$$

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

rare	Create errdefs for locations that are rarely accessed.
common	Create errdefs for locations that are commonly accessed.
median	Create errdefs for locations that are accessed a median frequency.

**Policies for Minimizing errdefs** If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

maximal	Create multiple errdefs for locations that are repeatedly accessed.
unbiased	Create a single errdef for locations that are repeatedly accessed.
operators	For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the operators policy so that a separate errdef is created for each of the possible corruption operators.

**See Also** [kill\(1\)](#), [th\\_manage\(1M\)](#), [alarm\(2\)](#), [ddi\\_check\\_acc\\_handle\(9F\)](#), [ddi\\_check\\_dma\\_handle\(9F\)](#)

**Name** th\_manage – manage the fault injection test harness

**Synopsis** th\_manage *name instance command*

th\_manage *path command*

**Description** th\_manage applies the action specified by *command* to the instance specified by *instance* of the driver specified by *name* (or the driver instance specified by *path*). The driver instance must be running fault injection specifications (errdefs) defined by [th\\_define\(1M\)](#).

th\_manage supports several commands that operate on the driver instance specified by *name* and *instance* (or *path*). The commands are:

broadcast	Awaken all th_define processes, causing them to display their current status and exit if the errdef is now defunct (that is, if <i>count</i> , <i>failcount</i> , and <i>acc_chk</i> are all zero).
clear_acc_chk	Awaken all th_define processes. If <i>count</i> and <i>failcount</i> are already zero, then set <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.
clear_errdefs	Awaken all th_define processes. <i>count</i> , <i>failcount</i> and <i>acc_chk</i> are all set to zero so that all th_define commands exit once they have displayed their status.
clear_errors	Awaken all th_define processes. If <i>count</i> is already zero, set <i>failcount</i> and <i>acc_chk</i> to zero, so that th_define exits once it has displayed its status.
get_handles	List all the access handles.
start	Begin or resume execution of all errdefs.
stop	Suspend all errdefs for this <i>name</i> and <i>instance</i> (or <i>path</i> ).

**Examples** EXAMPLE 1 Useful Commands

To begin the tests, enter:

```
th_manage foo 0 start
```

To check the status of the errdefs, enter:

```
th_manage foo 0 broadcast
```

This causes each th\_define process to print out its current status.

If the driver has reported a fatal error, you can take the driver offline using `libdevice`, clear the error condition by entering:

```
th_manage foo 0 clear_acc_chk
```

EXAMPLE 1 Useful Commands *(Continued)*

or

```
th_manage foo 0 clear_errors
```

and bring the driver online again using libdevice.

To terminate testing, enter:

```
th_manage foo 0 clear_errdefs
```

**See Also** [th\\_define\(1M\)](#)

**Name** tic – terminfo compiler

**Synopsis** tic [-v [*n*]] [-c] *file*

**Description** The command `tic` translates a terminfo file from the source format into the compiled format. The results are placed in the directory `/usr/share/lib/terminfo`. The compiled format is necessary for use with the library routines in [curses\(3CURSES\)](#).

If the environment variable `TERMINFO` is set, the compiled results are placed there instead of `/usr/share/lib/terminfo`.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

**Options** The following options are supported:

- c Specifies to check only *file* for errors. Errors in use= links are not detected.
- v[*n*] Specify that (verbose) output be written to standard error trace information showing `tic`'s progress. The optional integer *n* is a number from 1 to 10, indicating the desired level of detail of information. If *n* is omitted, the default level is 1. If *n* is specified and greater than 1, the level of detail is increased.

**Operands** *file* Contains one or more terminfo terminal descriptions in source format [see [terminfo\(4\)](#)]. Each description in the file describes the capabilities of a particular terminal. When a `use=entry-name` field is discovered in a terminal entry currently being compiled, `tic` reads in the binary from `/usr/share/lib/terminfo` to complete the entry. (Entries created from *file* will be used first. If the environment variable `TERMINFO` is set, that directory is searched instead of `/usr/share/lib/terminfo`.) `tic` duplicates the capabilities in *entry-name* for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

**Files** `/usr/share/lib/terminfo/??/*` Compiled terminal description database

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [captainfo\(1M\)](#), [infocmp\(1M\)](#), [curses\(3CURSES\)](#), [terminfo\(4\)](#), [attributes\(5\)](#)

**Notes** When an entry, for example, `entry_name_1`, contains a `use=entry_name_2` field, any canceled capabilities in `entry_name_2` must also appear in `entry_name_1` before `use=` for these capabilities to be canceled in `entry_name_1`.

**Name** tnchkdb – check file syntax of trusted network databases

**Synopsis** /usr/sbin/tnchkdb [-h *path*] [-t *path*] [-z *path*]

**Description** tnchkdb checks the syntax of the tnrhttp, tnrhdb, and tnzonecfg databases. By default, the *path* for each file is:

- /etc/security/tsol/tnrhttp
- /etc/security/tsol/tnrhdb
- /etc/security/tsol/tnzonecfg

You can specify an alternate path for any or all of the files by specifying that path on the command line by using the -h (tnrhdb), -t (tnrhttp) and -z (tnzonecfg) options. The options are useful when testing a set of modified files before installing the files as new system databases.

All three database files are checked for integrity. tnchkdb returns an exit status of 0 if all of the files are syntactically and, to the extent possible, semantically correct. If one or more files have errors, then an exit status of 1 is returned. If there are command line problems, such as an unreadable file, an exit status of 2 is returned. Errors are written to standard error.

To avoid cascading errors, when there are errors in tnrhttp, the template names in tnrhdb are not validated.

tnchkdb can be run at any label, but the standard /etc/security/tsol files are visible only in the global zone.

- Options**
- h [*path*] Check *path* for proper tnrhdb syntax. If *path* is not specified, then check /etc/security/tsol/tnrhdb.
  - t [*path*] Check *path* for proper tnrhttp syntax. If *path* is not specified, then check /etc/security/tsol/tnrhttp.
  - z [*path*] Check *path* for proper tnzonecfg syntax. If *path* is not specified, then check /etc/security/tsol/tnzonecfg.

**Examples** EXAMPLE 1 Sample Error Message

The tnchkdb command checks for CIPSO errors. In this example, the admin\_low template has an incorrect value of ADMIN\_HIGH for its default label.

```
tnchkdb
checking /etc/security/tsol/tnrhttp ...
tnchkdb: def_label classification 7fff is invalid for cipso labels:
line 14 entry admin_low
tnchkdb: def_label compartments 241-256 must be zero for cipso labels:
line 14 entry admin_low
checking /etc/security/tsol/tnrhdb ...
checking /etc/security/tsol/tnzonecfg ...
```

**Files** /etc/security/tsoL/tnrhdb Trusted network remote-host database

“How to Check the Syntax of Trusted Network Databases” in *Trusted Extensions Administrator’s Procedures*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

It is possible to have inconsistent but valid configurations of `tnrhtp` and `tnrhdb` when LDAP is used to supply missing templates.

**Name** tnctl – configure Trusted Extensions network parameters

**Synopsis** /usr/sbin/tnctl [-dfv] [-h *host* [/prefix] [:*template*]]  
[-m *zone:mlp:shared-mlp*][-t *template* [:*key=val* [:*key=val*]]]  
[-HTz] *file*]

**Description** tnctl provides an interface to manipulate trusted network parameters in the Solaris kernel.

As part of Solaris Trusted Extensions initialization, tnctl is run in the global zone by an smf(5) script during system boot. The tnctl command is not intended to be used during normal system administration. Instead, if a local trusted networking database file is modified without using the Solaris Management Console, the administrator first issues tnchkdb(1M) to check the syntax, and then refreshes the kernel copy with this command:

```
svcadm restart svc:/network/tnctl
```

See WARNINGS about the risks of changing remote host and template information on a running system.

**Options** -d

Delete matching entries from the kernel. The default is to add new entries.

When deleting MLPs, the MLP range must match exactly. MLPs are specified in the form:

```
port[-port]/protocol
```

Where *port* can be a number in the range 1 to 65535, or any known service (see services(4)), and *protocol* can be a number in the range 1 to 255, or any known protocol (see protocols(4)).

-f

Flush all kernel entries before loading the entries that are specified on the command line. The flush does not take place unless at least one entry parsed successfully.

-v

Turn on verbose mode.

-h *host*[/*prefix*][:*template*]

Update the kernel remote-host cache on the local host for the specified *host* or, if a template name is given, change the kernel's cache to use the specified *template*. If *prefix* is not specified, then an implied prefix length is determined according to the rules used for interpreting the tn rhdb. If -d is specified, then a template name cannot be specified.

-m *zone:mlp:shared-mlp*

Modify the kernel's multilevel port (MLP) configuration cache for the specified *zone*. *zone* specifies the zone to be updated. *mlp* and *shared-mlp* specify the MLPs for the zone-specific and shared IP addresses. The *shared-mlp* field is effective in the global zone only.

- t *template*[*key=val*;*key=val*]  
Update the kernel template cache for *template* or, if a list of *key=val* pairs is given, change the kernel's cache to use the specified entry. If -d is specified, then *key=val* pairs cannot be specified.
- T *file*  
Load all template entries in *file* into the kernel cache.
- H *file*  
Load all remote host entries in *file* into the kernel cache.
- z *file*  
Load just the global zone's MLPs from *file* into the kernel cache. To reload MLPs for a non-global zone, reboot the zone:  
  
# **zoneadm -z non-global zone reboot**

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

  - /etc/security/tsol/tnrhtp Trusted network remote-host templates
  - /etc/security/tsol/tnzonecfg Trusted zone configuration database
  - /etc/nsswitch.conf Configuration file for the name service switch

**See Also** [svcs\(1\)](#), [svcadm\(1M\)](#), [tninfo\(1M\)](#), [tnd\(1M\)](#), [tnchkdb\(1M\)](#), [zoneadm\(1M\)](#), [nsswitch.conf\(4\)](#), [protocols\(4\)](#), [services\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

“How to Synchronize the Kernel Cache With Trusted Network Databases” in *Trusted Extensions Administrator's Procedures*

**Warnings** Changing a template while the network is up can change the security view of an undetermined number of hosts.

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The `tnctl` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/tnctl
```

The service's status can be queried by using [svcs\(1\)](#). Administrative actions on this service, such as refreshing the kernel cache, can be performed using [svcadm\(1M\)](#), as in:

```
svcadm refresh svc:/network/tnctl
```

- Name** tnd – trusted network daemon
- Synopsis** `/usr/sbin/tnd [-p poll-interval]`
- Description** The tnd (trusted network daemon) initializes the kernel with trusted network databases and also reloads the databases on demand from an LDAP server and local files. tnd follows the order specified in the `nsswitch.conf(4)` file when loading configuration databases. tnd is started at the beginning of the boot process.
- tnd loads two databases into the kernel: the remote host database, `tnrhdb` and the remote-host template database, `tnrhtp`. These databases and their effect on the trusted network are described in their respective man pages. When the associated LDAP database or local databases are changed, tnd also updates the local kernel cache at the predetermined interval.
- If a local trusted networking database file is modified, the administrator should run `tnchkdb(1M)` to check the syntax, and should also run `svcadm refresh svc:/network/tnd` to initiate an immediate database scan by tnd.
- tnd is intended to be started from an `smf(5)` script and to run in the global zone. The following signals cause specific `svcadm` actions:
- SIGHUP** Causes `svcadm refresh svc:/network/tnd` to be run.
- Initiates a rescan of the local and LDAP `tnrhdb` and `tnrhtp` databases. tnd updates the kernel database with any changes found.
- SIGTERM** Causes `svcadm disable svc:/network/tnd` to be run.
- Terminates the tnd daemon. No changes are made to the kernel database.
- Running tnd in debug mode is determined by the value of the following service management facility (SMF) property:
- ```
tnd/debug_level = 0
```
- A value of 0, as above, prevents debug information from being collected; 1 turns on debugging. The default value is 0. Debug output is sent to the `/var/tsxol/tndlog` log file.
- Options** `-p poll-interval` Set poll interval to *poll-interval* seconds. The default *poll-interval* is 1800 seconds (30 minutes).
- Examples** **EXAMPLE 1** Changing the Poll Interval
- The following command changes the polling interval to one hour, and puts this interval in the SMF repository. At the next boot, the tnd poll interval will be one hour.
- ```
svccfg -s network/tnd setprop tnd/poll_interval=3600
```
- The following command changes the polling interval, but does not update the repository. At the next boot, the tnd poll interval remains the default, 30 minutes.

EXAMPLE 1 Changing the Poll Interval *(Continued)*

```
tnd -p 3600
```

“How to Synchronize the Kernel Cache With Trusted Network Databases” in *Trusted Extensions Administrator’s Procedures*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The tnd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/tnd
```

The service’s status can be queried by using [svcs\(1\)](#). Administrative actions on this service, such as requests to restart the daemon, can be performed using [svcadm\(1M\)](#), as in:

```
svcadm restart svc:/network/tnd
```

**Name** tninfo – print kernel-level network information and statistics

**Synopsis** /usr/sbin/tninfo [-h *hostname*] [-m *zone-name*] [-t *template*]

**Description** tninfo provides an interface to retrieve and display kernel-level network information and statistics.

**Options**

- h *hostname* Display the security structure for the specified host in the remote-host cache. The output should reflect what is specified in the tn rhdb database.
- m *zone-name* Display the MLP configuration associated with the specified zone. The output should reflect what is specified in the tnzonecfg database.
- t *template* Display the structure associated with the specified *template*. The output should reflect what is specified in the tn rhtp database.

**Examples** EXAMPLE 1 Displaying Remote Host Structures Cached in the Kernel

This example shows the remote host structures cached in the kernel. The output reflects the definition in the tn rhdb database.

```
tninfo -h machine1
 IP address= 192.168.8.61
 Template = cipso
```

EXAMPLE 2 Displaying Multilevel Ports for the Global Zone

This example shows the kernel-cached MLPs for the global zone. The output reflects the definition in the tnzonecfg database, plus any dynamically allocated MLPs. private indicates zone-specific MLPs.

```
tninfo -m global
private:23/tcp;111/tcp;111/udp;515/tcp;2049/tcp;6000-6003/tcp;
 32812/tcp;36698/ip;38634/tcp;64365/ip
shared: 6000-6003/tcp
```

EXAMPLE 3 Displaying the cipso Template Definition

This example shows the kernel-cached cipso template definition. The output reflects the definition in the tn rhtp database.

```
tninfo -t cipso
=====
Remote Host Template Table Entries:

template: cipso
host_type: CIPSO
doi: 1
min_sl: ADMIN_LOW
hex: ADMIN_LOW
max_sl: ADMIN_HIGH
```

**EXAMPLE 3** Displaying the cipso Template Definition *(Continued)*

hex: ADMIN\_HIGH

**Files** /etc/security/tsol/tnrhdb Trusted network remote-host database  
 /etc/security/tsol/tnrhtp Trusted network remote-host templates  
 /etc/security/tsol/tnzonecfg Trusted zone configuration database

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

“How to Synchronize the Kernel Cache With Trusted Network Databases” in *Trusted Extensions Administrator’s Procedures*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** `tracert` – print the route packets take to network host

**Synopsis** `tracert [-adFIlnSvx] [-A addr_family] [-c traffic_class]  
 [-f first_hop] [-g gateway [-g gateway...] | -r]  
 [-i iface] [-L flow_label] [-m max_hop]  
 [-P pause_sec] [-p port] [-Q max_timeout]  
 [-q nqueries] [-s src_addr] [-t tos] [-w wait_time] host  
 [packetlen]`

**Description** The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility `tracert` traces the route that an IP packet follows to another internet host.

The `tracert` utility utilizes the both the IPv4 and IPv6 protocols. Use the `-A` option to override the default behavior. `tracert` uses the IPv4 protocol *tll* (time to live) field or the IPv6 field *hop limit*. It attempts to elicit an ICMP or ICMP6 `TIME_EXCEEDED` response from each *gateway* along the path, and a `PORT_UNREACHABLE` (or `ECHO_REPLY` if `-I` is used) response from the destination host. It starts by sending probes with a *tll* or *hop limit* of 1 and increases by 1 until it either gets to the host, or it hits the maximum *max\_hop*. The default maximum *max\_hop* is 30 hops, but this can be set by the `-m` option.

Three probes are sent at each *tll* (*hop limit*) setting, and a line is printed showing the *tll* (*hop limit*), the hostname and the address of the gateway, and the *rtt* (round trip time) of each probe. The number of probes may be specifically set using the `-q` option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, an asterisk (\*) is displayed for that probe. The `-w` option may be used to set the timeout interval. Other possible annotations that may appear after the time are:

!  
 the *tll* (*hop limit*) value in the received packet is <= 1.

!H  
 host unreachable.

!X  
 communication administratively prohibited.

<!N>  
 ICMP (ICMP6) unreachable code N.

The following annotations appear only for IPv4:

!F  
 fragmentation needed. This should never occur. If this is seen, the associated gateway is broken.

!N  
 network unreachable.

!P  
protocol unreachable.

!S  
source route failed. It is likely that the gateway does not support source routing.

!T  
unreachable for the specified tos (type-of-service).

!U  
source host isolated or precedence problem.

The following annotations appear only for IPv6:

!A  
host unreachable for a reason other than lack of an entry in the routing table.

!B  
packet too big.

!E  
destination is not a neighbor.

!R  
unrecognized next header.

If almost all the probes result in some kind of unreachable code, then `tracert` gives up and exits.

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the `-p` option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All integer arguments to `tracert` can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as 256 or `0x100`.

#### Options -A *addr\_family*

Specify the address family of the target host. *addr\_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `tracert` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `traceroute` will use the IPv4 address associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `traceroute` will use the IPv6 address that is associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit.

- a  
Probe all of the addresses of a multi-homed destination. The output looks like `traceroute` has been run once for each IP address of the destination. If this option is used together with `-A`, `traceroute` probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a SIGINT, or exit `traceroute` by sending a SIGQUIT signal. See [signal\(3C\)](#)
- c *traffic\_class*  
Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of *traffic\_class* set in the probe packet. This option is valid only on IPv6.
- d  
Set the `SO_DEBUG` socket option.
- F  
Set the “don't fragment” bit. This option is valid only on IPv4. When specified from within a shared-IP zone, this option has no effect as the “don't fragment” bit is always set in this case.
- f *first\_hop*  
Set the starting *tll* (*hop limit*) value to *first\_hop*, to override the default value 1. `traceroute` skips processing for those intermediate gateways which are less than *first\_hop* hops away.
- g *gateway*  
Specify a loose source route *gateway*. The user can specify more than one *gateway* by using `-g` for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the `-r` option.  
  
Only users with the `{PRIV_NET_RAWACCESS}` privilege can specify a loose source route with this option.
- I  
Use ICMP (ICMP6) ECHO instead of UDP datagrams.
- i *iface*  
For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The `-s` option is also another way to do this.

For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, `eri0`, `hme0`.

**-L *flow\_label***

Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

**-l**

Print the value of the *t**tl* (*hop limit*) field in each packet received.

**-m *max\_hop***

Set the maximum *t**tl* (*hop limit*) used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

**-n**

Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

**-P *pause\_sec***

Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, `tracert` sends the next probe as soon as it has received a reply. Note that *pause\_sec* is a real number.

**-p *port***

Set the base UDP *port* number used in probes. The default is 33434. `tracert` hopes that nothing is listening on UDP *ports* ( $\text{base} + (\text{nhops} - 1) * \text{nqueries}$ ) to  $(\text{base} + (\text{nhops} * \text{nqueries}) - 1)$  at the destination host, so that an ICMP (ICMP6) `PORT_UNREACHABLE` message will be returned to terminate the route tracing. If something is listening on a *port* in the default range, this option can be used to select an unused *port* range. *nhops* is defined as the number of hops between the source and the destination.

**-Q *max\_timeout***

Stop probing this hop after *max\_timeout* consecutive timeouts are detected. The default value is 5. Useful in combination with the `-q` option if you have specified a large *nqueries* probe count.

**-q *nqueries***

Set the desired number of probe queries. The default is 3.

**-r**

Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See [in . `routed\(1M\)`](#). You cannot use this option if the `-g` option is used.

**-S**

Display a summary of how many probes were not answered for each hop.

**-s *src\_addr***

Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address `tracert` picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the `-i` option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

**-t *tos***

Set the *tos*(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the *tos* value set in the probe packet. This option is valid only on IPv4.

**-v**

Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than `TIME_EXCEEDED` and `UNREACHABLE` are listed as well.

**-w *waittime***

Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.

**-x**

Prevent `tracert` from calculating checksums. Checksums are usually required for the last hop when using ICMP `ECHO` probes. This option is valid only on IPv4. See the `-I` option.

When specified from within a shared-IP zone, this option has no effect as the checksum is always calculated by the operating system in this case.

**Operands** The following operands are supported:

***host***

The network host.

**Examples** **EXAMPLE 1** Sample Output From the `tracert` Utility

Some sample output from the `tracert` utility might be:

```
istanbul% tracert london
tracert: Warning: london has multiple addresses; \
 using 4::114:a00:20ff:ab3d:83ed
tracert: Warning: Multiple interfaces found; \
 using 4::56:a00:20ff:fe93:8dde @ eri0:2
tracert to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \
 60 byte packets
1 frbl dg7c-86 (4::56:a00:20ff:fe1f:65a1) 1.786 ms 1.544 ms 1.719 ms
```

**EXAMPLE 1** Sample Output From the `tracert` Utility (Continued)

```

2 frblgdg7b-77 (4::255:0:0:c0a8:517) 2.587 ms 3.001 ms 2.988 ms
3 london (4::114:a00:20ff:ab3d:83ed) 3.122 ms 2.744 ms 3.356 ms

```

The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, `tracert` uses IPv6 address of the destination host.

**EXAMPLE 2** Using the `tracert` Utility For a Host Which has Only IPv4 Addresses

In the following examples, `tracert` is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore `tracert` uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

```

istanbul% tracert sanfrancisco
tracert: Warning: Multiple interfaces found; using 172.31.86.247 @eri0
tracert to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
1 frblgdg7c-86 (172.31.86.1) 1.516 ms 1.283 ms 1.362 ms
2 bldg1a-001 (172.31.1.211) 2.277 ms 1.773 ms 2.186 ms
3 bldg4-bldg1 (172.30.4.42) 1.978 ms 1.986 ms 13.996 ms
4 bldg6-bldg4 (172.30.4.49) 2.655 ms 3.042 ms 2.344 ms
5 ferblgdg11a-001 (172.29.1.236) 2.636 ms 3.432 ms 3.830 ms
6 frblgdg12b-153 (172.29.153.72) 3.452 ms 3.146 ms 2.962 ms
7 sanfrancisco (172.29.64.39) 3.430 ms 3.312 ms 3.451 ms

```

**EXAMPLE 3** Using the `tracert` Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the `-g` option. The `-I` option makes `tracert` send ICMP ECHO probes to the host sanfrancisco. The `-i` options sets the source address to the IP address configured on the interface `qe0`.

```

istanbul% tracert -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
tracert to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
1 frblgdg7c-86 (172.31.86.1) 2.012 ms
2 flrblgdg7u (172.31.17.131) 4.960 ms
3 cairo (192.168.163.175) 4.894 ms
4 flrblgdg7u (172.31.17.131) 3.475 ms
5 frblgdg7c-017 (172.31.17.83) 4.126 ms
6 paris (172.31.86.31) 4.086 ms
7 frblgdg7b-82 (172.31.82.1) 6.454 ms
8 bldg1a-001 (172.31.1.211) 6.541 ms
9 bldg6-bldg4 (172.30.4.49) 6.518 ms
10 ferblgdg11a-001 (172.29.1.236) 9.108 ms
11 frblgdg12b-153 (172.29.153.72) 9.634 ms
12 sanfrancisco (172.29.64.39) 14.631 ms

```

**Exit Status** The following exit values are returned:

0  
Successful operation.

>0  
An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [netstat\(1M\)](#), [signal\(3C\)](#), [ping\(1M\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [zones\(5\)](#)

**Warnings** This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use `tracert(1M)` during normal operations or from automated scripts.

**Name** trapstat – report trap statistics

**Synopsis** /usr/sbin/trapstat [-t | -T | -e *entry*]  
 [-C *processor\_set\_id* | -c *cpulist*] [-P] [-a]  
 [-r *rate*] [ [*interval* [*count*]] | *command* | [*args*]]  
 /usr/sbin/trapstat -l

**Description** The trapstat utility gathers and displays run-time trap statistics on UltraSPARC-based systems. The default output is a table of trap types and CPU IDs, with each row of the table denoting a trap type and each column of the table denoting a CPU. If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width; if standard output is not a terminal, the table contains at most six columns of data. By default, data is gathered and displayed for all CPUs; if the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is gathered and displayed can be optionally specified with the -c or -C option.

Unless the -r option or the -a option is specified, the value displayed in each entry of the table corresponds to the number of traps per second. If the -r option is specified, the value corresponds to the number of traps over the interval implied by the specified sampling rate; if the -a option is specified, the value corresponds to the accumulated number of traps since the invocation of trapstat.

By default, trapstat displays data once per second, and runs indefinitely; both of these behaviors can be optionally controlled with the *interval* and *count* parameters, respectively. The *interval* is specified in seconds; the *count* indicates the number of intervals to be executed before exiting. Alternatively, *command* can be specified, in which case trapstat executes the provided command and continues to run until the command exits. A positive integer is assumed to be an *interval*; if the desired *command* cannot be distinguished from an integer, the full path of *command* must be specified.

UltraSPARC I (obsolete), II, and III handle translation lookaside buffer (TLB) misses by trapping to the operating system. TLB miss traps can be a significant component of overall system performance for some workloads; the -t option provides in-depth information on these traps. When run with this option, trapstat displays both the rate of TLB miss traps and the percentage of time spent processing those traps. Additionally, TLB misses that hit in the translation storage buffer (TSB) are differentiated from TLB misses that further miss in the TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be quickly filled; it is discussed in detail in the *UltraSPARC II User's Manual*.) The TLB and TSB miss information is further broken down into user- and kernel-mode misses.

Workloads with working sets that exceed the TLB reach may spend a significant amount of time missing in the TLB. To accommodate such workloads, the operating system supports multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the number of TLB misses. To provide insight into the relationship between page size and TLB miss rate, trapstat optionally provides in-depth TLB miss information broken down by page size using the -T option. The information provided by the -T option is a superset of that provided by the -t option; only one of -t and -T can be specified.

**Options** The following options are supported:

- a Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.
- c *cpulist* Enables trapstat only on the CPUs specified by *cpulist*.  
  
*cpulist* can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4,5,6 or 4,6-8).
- C *processor\_set\_id* Enables trapstat only on the CPUs in the processor set specified by *processor\_set\_id*.  
  
trapstat modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, trapstat modifies its output to include the added CPU; if a CPU is removed from the set, trapstat modifies its output to exclude the removed CPU. At most one processor set can be specified.
- e *entrylist* Enables trapstat only for the trap table entry or entries specified by *entrylist*. A trap table entry can be specified by trap number or by trap name (for example, the level-10 trap can be specified as 74, 0x4A, 0x4a, or level-10).  
  
*entrylist* can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, trapstat prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in *The SPARC Architecture Manual, Version 9* and the *Sun Microelectronics UltraSPARC II User's Manual*. If the parsable option (-P) is specified in addition to the -e option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; exant fields will remain unchanged.

- l Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the *entrylist* parameter for the -e argument. If the parsable option (-P) is specified in addition to the -l option, the format of the data is as follows:

Field	Contents
1	Trap number in hexadecimal
2	Trap number in decimal
3	Trap name
Remaining	Trap description

- P Generates parsable output. When run without other data gathering modifying options (that is, -e, -t or -T), trapstat's the parsable output has the following format:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

- r *rate* Explicitly sets the sampling rate to be *rate* samples per second. If this option is specified, trapstat's output changes from a traps-per-second to traps-per-sampling-interval.
- t Enables TLB statistics.

A table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs,

with each CPU consuming two rows: one row for user-mode events (denoted with u) and one row for kernel-mode events (denoted with k). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (-P) is specified in addition to the -t option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode (k denotes kernel, u denotes user)
4	I-TLB misses
5	Percentage of time in I-TLB miss handler
6	I-TSB misses
7	Percentage of time in I-TSB miss handler
8	D-TLB misses
9	Percentage of time in D-TLB miss handler
10	D-TSB misses
11	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

-T

Enables TLB statistics, with page size information. As with the -t option, a table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with u) and one set for kernel-level events (denoted with k). Each set, in turn, contains as many rows as

there are page sizes supported (see [getpagesizes\(3C\)](#)). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (-P) is specified in addition to the -T option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode k denotes kernel, u denotes user)
4	Page size, in decimal
5	I-TLB misses
6	Percentage of time in I-TLB miss handler
7	I-TSB misses
8	Percentage of time in I-TSB miss handler
9	D-TLB misses
10	Percentage of time in D-TLB miss handler
11	D-TSB misses
12	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

### Examples EXAMPLE 1 Using trapstat Without Options

When run without options, trapstat displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

```
example# trapstat
vct name | cpu0 cpu1 cpu4 cpu5 cpu8 cpu9
-----+-----
 24 cleanwin | 6446 4837 6368 2153 2623 1321
 41 level-1 | 100 0 0 0 1 0
```

## EXAMPLE 1 Using trapstat Without Options (Continued)

44 level-4		0	1	1	1	0	0

**EXAMPLE 2** Using trapset with CPU Filtering

The `-c` option can be used to limit the CPUs on which `trapstat` is enabled. This example limits CPU 1 and CPUs 12 through 15.

example# **trapstat -c 1,12-15**

vct	name		cpu1	cpu12	cpu13	cpu14	cpu15

**EXAMPLE 3** Using trapstat with TLB Statistics

The `-t` option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# trapstat -t
cpu m | itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 0 u | 2571 0.3 0 0.0 | 10802 1.3 0 0.0 | 1.6
 0 k | 0 0.0 0 0.0 | 106420 13.4 184 0.1 |13.6
-----+-----+-----+-----+-----+-----+-----+
 1 u | 3069 0.3 0 0.0 | 10983 1.2 100 0.0 | 1.6
 1 k | 27 0.0 0 0.0 | 106974 12.6 19 0.0 |12.7
-----+-----+-----+-----+-----+-----+-----+
 2 u | 3033 0.3 0 0.0 | 11045 1.2 105 0.0 | 1.6
 2 k | 43 0.0 0 0.0 | 107842 12.7 108 0.0 |12.8
-----+-----+-----+-----+-----+-----+-----+
 3 u | 2924 0.3 0 0.0 | 10380 1.2 121 0.0 | 1.6
 3 k | 54 0.0 0 0.0 | 102682 12.2 16 0.0 |12.2
-----+-----+-----+-----+-----+-----+-----+
 4 u | 3064 0.3 0 0.0 | 10832 1.2 120 0.0 | 1.6
 4 k | 31 0.0 0 0.0 | 107977 13.0 236 0.1 |13.1
=====+=====+=====+=====+=====+=====+=====+=====+=====+=====
ttl | 14816 0.3 0 0.0 | 585937 14.1 1009 0.0 |14.5
```

**EXAMPLE 4** Using trapstat with TLB Statistics and Page Size Information

By specifying the `-T` option, trapstat shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

```
example# trapstat -T -c 0
cpu m size| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
 0 u 8k| 1300 0.1 15 0.0 | 104897 7.9 90 0.0 | 8.0
 0 u 64k| 0 0.0 0 0.0 | 29935 2.3 7 0.0 | 2.3
 0 u 512k| 0 0.0 0 0.0 | 3569 0.2 2 0.0 | 0.2
 0 u 4m| 0 0.0 0 0.0 | 233 0.0 2 0.0 | 0.0
-----+-----+-----+-----+-----+-----+-----+-----+
 0 k 8k| 13 0.0 0 0.0 | 71733 6.5 110 0.0 | 6.5
 0 k 64k| 0 0.0 0 0.0 | 0 0.0 0 0.0 | 0.0
 0 k 512k| 0 0.0 0 0.0 | 0 0.0 206 0.1 | 0.1
 0 k 4m| 0 0.0 0 0.0 | 0 0.0 0 0.0 | 0.0
=====+=====+=====+=====+=====+=====+=====+=====+=====+=====
ttl | 1313 0.1 15 0.0 | 210367 17.1 417 0.2 |17.5
```

**EXAMPLE 5** Using trapstat with Entry Filtering

By specifying the `-e` option, trapstat displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the `dtlb-prot` and `syscall-32` traps on CPUs 12 through 15:

```
example# trapstat -e dtlb-prot,syscall-32 -c 12-15
vct name | cpu12 cpu13 cpu14 cpu15
-----+-----
 6c dtlb-prot | 817 754 1018 560
 108 syscall-32 | 1426 1647 2186 1142

vct name | cpu12 cpu13 cpu14 cpu15
-----+-----
 6c dtlb-prot | 1085 996 800 707
 108 syscall-32 | 2578 2167 1638 1452
```

**EXAMPLE 6** Using trapstat with a Higher Sampling Rate

The following example uses the `-r` option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the `-P` option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

```
example# trapstat -e level-10 -P -r 1000
1070400 0 4a level-10 0
2048600 0 4a level-10 0
3030400 0 4a level-10 1
4035800 0 4a level-10 0
5027200 0 4a level-10 0
6027200 0 4a level-10 0
7027400 0 4a level-10 0
8028200 0 4a level-10 0
9026400 0 4a level-10 0
10029600 0 4a level-10 0
11028600 0 4a level-10 0
12024000 0 4a level-10 0
13028400 0 4a level-10 1
14031200 0 4a level-10 0
15027200 0 4a level-10 0
16027600 0 4a level-10 0
17025000 0 4a level-10 0
18026000 0 4a level-10 0
19027800 0 4a level-10 0
20025600 0 4a level-10 0
21025200 0 4a level-10 0
22025000 0 4a level-10 0
```

**EXAMPLE 6** Using trapstat with a Higher Sampling Rate (Continued)

```
23035400 0 4a level-10 1
24027400 0 4a level-10 0
25026000 0 4a level-10 0
26027000 0 4a level-10 0
```

*Sun Microelectronics UltraSPARC II User's Manual*, January 1997, STP1031,

*The SPARC Architecture Manual, Version 9*, 1994, Prentice-Hall.

**Notes** When enabled, trapstat induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

Option	Approximate probe effect
default	3-5% per trap
-e	3-5% per specified trap
-t, -T	40-45% per TLB miss trap hitting in the TSB, 25-30% per TLB miss trap missing in the TSB

These probe effects are *per trap* not for the system as a whole. For example, running trapstat with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running trapstat with the -t or -T option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the -t or -T option, trapstat accounts for its probe effect when calculating the %tim fields. This assures that the %tim fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of trapstat.

While the *%tim* fields include the explicit cost of executing the TLB miss handler, they do *not* include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high *%tim* values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run `trapstat`.

Due to the limitation of the underlying statistics gathering methodology, only one instance of `trapstat` can run at a time.

**Name** ttyadm – format and output port monitor-specific information

**Synopsis** /usr/sbin/ttyadm [-b] [-c] [-h] [-I] [-r *count*] [-i *msg*]  
 [-m *modules*] [-p *prompt*] [-t *timeout*] [-S y | n]  
 [-T *termtype*] -d *device* -l *ttlabel* -s *service*

/usr/sbin/ttyadm -V

**Description** The `ttyadm` command is an administrative command that formats `ttymon(1M)`-specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller's administrative commands, `sacadm(1M)` and `pmadm(1M)`. `ttyadm` provides a means of presenting formatted port monitor-specific (`ttymon`-specific) data to these commands.

**Options** The following options are supported:

- b Set the “bi-directional port” flag. When this flag is set, the line can be used in both directions. `ttymon` will allow users to connect to the service associated with the port, but if the port is free, `uucico(1M)`, `cu(1C)`, or `ct(1C)` can use it for dialing out.
- c Set the connect-on-carrier flag for the port. If the `-c` flag is set, `ttymon` will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).
- d *device* *device* is the full pathname of the device file for the TTY port.
- h Set the hangup flag for the port. If the `-h` flag is not set, `ttymon` will force a hangup on the line by setting the speed to 0 before setting the speed to the default or specified value.
- i *message* Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the `ttymon` monitoring the port is disabled.
- I Initialize only. If the `-I` option is used, `ttymon` will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.
- l *ttlabel* Specify which *ttlabel* in the `/etc/ttydefs` file to use as the starting point when searching for the proper baud rate.
- m *modules* Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. *modules* must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.
- p *prompt* Specify the prompt message, for example, “login:”.

- r *count*      When the -r option is invoked, `ttymon` will wait until it receives data from the port before it displays a prompt. If *count* is 0, `ttymon` will wait until it receives any character. If *count* is greater than 0, `ttymon` will wait until *count* newlines have been received.
- s *service*    *service* is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes (" ").
- S y|n          Set the software carrier value. y will turn software carrier on. n will turn software carrier off.
- t *timeout*    Specify that `ttymon` should close a port if the open on the port succeeds, and no input data is received in *timeout* seconds.
- T *termtype*   Set the terminal type. The TERM environment variable will be set to *termtype*.
- V              Display the version number of the current `/usr/lib/saf/ttymon` command.

**Output** If successful, `tttyadm` will generate the requested information, write it to standard output, and exit with a status of 0. If `tttyadm` is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and `ttymon` will exit with a non-zero status.

**Files** `/etc/ttydefs`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*System Administration Guide: Basic Administration*

**Name** ttymon – port monitor for terminal ports

**Synopsis** /usr/lib/saf/ttymon

```
/usr/lib/saf/ttymon -g [-d device] [-h] [-t timeout]
[-l ttylabel] [-p prompt] [-m modules] [-T termtype]
```

**Description** ttymon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, ttymon is configured to run under the Service Access Controller, [sac\(1M\)](#), as part of the Service Access Facility (SAF). It is configured using the [sacadm\(1M\)](#) command. Each instance of ttymon can monitor multiple ports. The ports monitored by an instance of ttymon are specified in the port monitor's administrative file. The administrative file is configured using the [pmadm\(1M\)](#) and [ttyadm\(1M\)](#) commands. When an instance of ttymon is invoked by the sac command, it starts to monitor its ports. For each port, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See [logindevperm\(4\)](#).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the [sttydefs\(1M\)](#) command. Default line disciplines on ports are usually set up by the [autopush\(1M\)](#) command of the Autopush Facility.

ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon interprets the per-service configuration file for the port, if one exists, creates a utmpx entry if required (see [utmpx\(4\)](#)), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, ttymon cleans up the utmpx entry, if one exists, and returns the port to its initial state.

If *autobaud* is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by *autobaud* are 110, 1200, 2400, 4800, and 9600.

If a port is configured as a bidirectional port, ttymon will allow users to connect to a service, and, if the port is free, will allow [uucico\(1M\)](#), [cu\(1C\)](#), or [ct\(1C\)](#) to use it for dialing out. If a port is bidirectional, ttymon will wait to read a character before it prints a prompt.

If the *connect-on-carrier* flag is set for a port, ttymon will immediately invoke the port's associated service when a connection request is received. The prompt message will not be sent.

If a port is disabled, ttymon will not start any service on that port. If a disabled message is specified, ttymon will send out the disabled message when a connection request is received. If ttymon is disabled, all ports under that instance of ttymon will also be disabled.

**Service Invocation** The service `ttymon` invokes for a port is specified in the `ttymon` administrative file. `ttymon` will scan the character string giving the service to be invoked for this port, looking for a `%d` or a `%%` two-character sequence. If `%d` is found, `ttymon` will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If `%%` is found, they will be replaced by a single `%`. When the service is invoked, file descriptor 0, 1, and 2 are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with `ttymon`. Two environment variables, `HOME` and `TTYPROMPT`, are added to the service's environment by `ttymon`. `HOME` is set to the home directory of the user name under which the service is invoked. `TTYPROMPT` is set to the prompt string configured for the service on the port. This is provided so that a service invoked by `ttymon` has a means of determining if a prompt was actually issued by `ttymon` and, if so, what that prompt actually was.

See [ttyadm\(1M\)](#) for options that can be set for ports monitored by `ttymon` under the Service Access Controller.

**System Console Invocation** The invocation of `ttymon` on the system console is managed under [smf\(5\)](#) by the service `svc:/system/console-login`. It provides a number of properties within the property group `ttymon` to control the invocation, as follows:

NAME	TYPE	TTYMON OPTION
device	cstring	[-d device]
nohangup	boolean	[-h]
label	cstring	[-l label]
modules	cstring	[-m module1,module2]
prompt	cstring	[-p prompt]
timeout	count	[-t timeout]
terminal_type	cstring	[-T termttype]

If any value is the empty string or an integer set to zero, then the option is not passed to the `ttymon` invocation. The `-g` option is always specified for this invocation. The `-d` option always defaults to `/dev/console` if it is not set.

See [EXAMPLES](#).

**Security** `ttymon` uses [pam\(3PAM\)](#) for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with entries for `ttymon` using the UNIX session management module.

```
ttymon session required /usr/lib/security/pam_unix_session.so.1
```

If there are no entries for the `ttymon` service, then the entries for the "other" service will be used.

**Options** The following options are supported:

- g                   A special invocation of `ttymon` is provided with the `-g` option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to `login` service, but that cannot be pre-configured under the SAC. The following combinations of options can be used with `-g`:
- ddevice*           *device* is the full path name of the port to which `ttymon` is to attach. If this option is not specified, file descriptor `0` must be set up by the invoking process to a TTY port.
- h                   If the `-h` flag is not set, `ttymon` will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.
- \ttylabel*         *ttylabel* is a link to a speed and TTY definition in the `ttdefs` file. This definition tells `ttymon` at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.
- mmodules*         When initializing the port, `ttymon` will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.
- pprompt*           Allows the user to specify a prompt string. The default prompt is `Login:.`
- ttimeout*          Specifies that `ttymon` should exit if no one types anything in *timeout* seconds after the prompt is sent.
- Ttermtype*         Sets the TERM environment variable to *termtype*.

**Examples** EXAMPLE 1 Setting the Terminal Type

The following example sets the value of the terminal type (`-T`) option for the system console `ttymon` invocation:

```
svccfg -s svc:/system/console-login setprop \
 ttymon/terminal_type = "xterm"
svcadm refresh svc:/system/console-login:default
```

**Environment Variables** If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of `ttymon` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `ttymon` behaves.

**LC\_CTYPE** Determines how `ttymon` handles characters. When `LC_CTYPE` is set to a valid value, `ttymon` can display and handle text and filenames containing valid characters for that locale. `ttymon` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `ttymon` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

**Files** `/etc/logindevperm`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability	See below.

The command-line syntax is Stable. The SMF properties are Evolving.

**See Also** [ct\(1C\)](#), [cu\(1C\)](#), [autopush\(1M\)](#), [pmadm\(1M\)](#), [sac\(1M\)](#), [sacadm\(1M\)](#), [sttydefs\(1M\)](#), [ttyadm\(1M\)](#), [uucico\(1M\)](#), [pam\(3PAM\)](#), [logindevperm\(4\)](#), [pam.conf\(4\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), [pam\\_passwd\\_auth\(5\)](#), [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), [pam\\_unix\\_session\(5\)](#), [smf\(5\)](#)

*System Administration Guide: Basic Administration*

**Notes** If a port is monitored by more than one `ttymon`, it is possible for the `ttymons` to send out prompt messages in such a way that they compete for input.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam\\_authtok\\_check\(5\)](#), [pam\\_authtok\\_get\(5\)](#), [pam\\_authtok\\_store\(5\)](#), [pam\\_dhkeys\(5\)](#), [pam\\_passwd\\_auth\(5\)](#), [pam\\_unix\\_account\(5\)](#), [pam\\_unix\\_auth\(5\)](#), and [pam\\_unix\\_session\(5\)](#).

**Name** tunefs – tune an existing UFS file system

**Synopsis** tunefs [-a *maxcontig*] [-d *rotdelay*] [-e *maxbpg*]  
 [-m *minfree*] [-o *space* | *time*] *special* | *filesystem*

**Description** tunefs is designed to change the dynamic parameters of a file system that affect the layout policies. When using tunefs with *filesystem*, *filesystem* must be in /etc/vfstab. The parameters that can be changed are indicated by the options given below.

**Options** The following options are supported:

- a *maxcontig*** The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows:  

$$\text{maxcontig} = \text{disk drive maximum transfer size} / \text{disk block size}$$
 If the disk drive's maximum transfer size cannot be determined, the default value for *maxcontig* is calculated from kernel parameters as follows:  
 If *maxphys* is less than *ufs\_maxmaxphys*, which is 1 Mbyte, then *maxcontig* is set to *maxphys*. Otherwise, *maxcontig* is set to *ufs\_maxmaxphys*.  
 You can set *maxcontig* to any positive integer value.  
 The actual value will be the lesser of what has been specified and what the hardware supports.
- d *rotdelay*** This parameter is obsolete as of the Solaris 10 release. The value is always set to 0, regardless of the input value.
- e *maxbpg*** Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group.  
 The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.
- m *minfree*** Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to 0. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. *Note:* If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.

-o *space* | *time*     The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

Generally, you should optimize for time unless the file system is over 90% full.

**Usage** See [largefile\(5\)](#) for the description of the behavior of tunefs when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** txzonemgr – Trusted Extensions Zone Manager Configuration Utility

**Synopsis** /usr/sbin/txzonemgr

**Description** The txzonemgr shell script provides a simple menu-based GUI wizard for creating, installing, initializing, and booting labeled zones on a system where Trusted Extensions is enabled. The script provides contextual menus with appropriate choices.

txzonemgr is run by roles granted in the Zone Management Rights Profile, or by root in the global zone. It takes no options and returns no values.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Command Interface Stability	Committed
Interactive Dialogue	Not an Interface

**See Also** [zenity\(1\)](#), [ifconfig\(1M\)](#), [zoneadm\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [zones\(5\)](#)

*Solaris Trusted Extensions Administrator's Procedures*

**Notes** If administering zones from JDS, use txzonemgr rather than CDE actions.

txzonemgr uses the zenity command. For details, see the zenity(1) man page.

**Name** tzreload – notify timezone update

**Synopsis** /usr/sbin/tzreload [-a]

**Description** The `tzreload` command notifies active (running) processes to reread timezone information. The timezone information is cached in each process, absent a `tzreload` command, is never reread until a process is restarted. In response to a `tzreload` command, active processes reread the current timezone information at the next call to `ctime(3C)` and `mktime(3C)`. By default, the `tzreload` notification is sent to the processes within the current zone.

In addition to notifying active processes, the `tzreload` command also notifies `cron(1M)`, to reinitialize the job scheduler with the new timezone information.

**Options** The following options are supported:

-a  
Notify processes in all zones.

**Files** /usr/share/lib/zoneinfo  
Standard zone information directory.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [cron\(1M\)](#), [zdump\(1M\)](#), [zic\(1M\)](#), [zoneadm\(1M\)](#), [ctime\(3C\)](#), [mktime\(3C\)](#), [attributes\(5\)](#)

`rpc.cmsd(1M)`, part of the CDE man page set.

**Notes** Although `tzreload` reinitializes [cron\(1M\)](#), applications that are affected by timezone changes still need to be restarted or reinitialized if they do not reread the new timezone information before timezone changes take place.

**Name** tzselect – select a time zone

**Synopsis** /usr/bin/tzselect

**Description** The tzselect program asks you a series of questions about the current location and outputs the resulting time zone description to standard output. The output is suitable as a value for the TZ environment variable.

All user interaction is through standard input and standard error.

**Options** The tzselect command has no options.

**Exit Status** The following exit values are returned:

0 Timezone information was successfully obtained.

>0 An error occurred.

**Files** /usr/share/lib/zoneinfo directory containing timezone data files

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** uadmin – administrative control

**Synopsis** `/usr/sbin/uadmin cmd fcn [mdep]`  
`/sbin/uadmin cmd fcn [mdep]`

**Description** The `uadmin` command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both the *cmd* (command) and *fcn* (function) arguments are converted to integers and passed to the `uadmin` system call. The optional *mdep* (machine dependent) argument is only available for the *cmd* values of 1 (A\_REBOOT), 2 (A\_SHUTDOWN), or 5 (A\_DUMP). For any other *cmd* value, no *mdep* command-line argument is allowed.

When passing an *mdep* value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example:

```
uadmin 1 1 "-s kernel/unix"
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [halt\(1M\)](#), [reboot\(1M\)](#), [uadmin\(2\)](#), [attributes\(5\)](#)

**Warnings** Shutting down or halting the system by means of `uadmin` does not update the boot archive. Avoid using this command after

- editing of files such as `/etc/system`
- installing new driver binaries or kernel binaries
- updating existing driver binaries or kernel binaries.

Use [reboot\(1M\)](#) or [halt\(1M\)](#) instead.

**Name** ucodeadm – update processor microcode

**Synopsis** `/usr/sbin/ucodeadm -v`  
`/usr/sbin/ucodeadm -u microcode-text-file`  
`/usr/sbin/ucodeadm -i [-R path] microcode-text-file`

**Description** The ucodeadm utility can be used to report running microcode revision on the processors, update microcode, or install microcode on the target system to be used during the boot process.

The *microcode-text-file* can be obtained from processor vendors.

**Options**

<code>-v</code>	Report microcode revision.
<code>-u <i>microcode-text-file</i></code>	Update microcode on all cross-call interrupt ready processors.
<code>-i <i>microcode-text-file</i></code>	Install microcode files on target system to be used during the next boot cycle. The text file name must have the vendor name prefix, such as “intel” or “amd”.

By default the microcode files will be installed at:

`/platform/i86pc/ucode/$VENDORSTR/`

where VENDORSTR is either “GenuineIntel” or “AuthenticAMD”.

`-R alternate path` Install *microcode* path in the *alternate path*.

**Examples** EXAMPLE 1 Reporting the Microcode Revision

The following example displays the microcode revision that is currently running:

```
ucodeadm -v
```

EXAMPLE 2 Updating the Processor Microcode

The following example updates the processor microcode to `intel-ucode.txt`:

```
ucodeadm -u intel-ucode.txt
```

EXAMPLE 3 Installing the Microcode on the Target System

The following example installs the microcode on the target system, `/export/ucode-path`:

```
ucodeadm -i -R /export/ucode-path intel-ucode.txt
```

If an alternate path is used when installing the microcode on the target system, the installed microcode file is not used on the next boot cycle.

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [psradm\(1M\)](#), [psrinfo\(1M\)](#), [attributes\(5\)](#)

**Name** ufsdump – incremental file system dump

**Synopsis** /usr/sbin/ufsdump [*options*] [*arguments*] *files\_to\_dump*

**Description** ufsdump backs up all files specified by *files\_to\_dump* (usually either a whole file system or files within a file system changed after a certain date) to magnetic tape, diskette, or disk file.

The ufsdump command can only be used on unmounted file systems, or those mounted read-only. Attempting to dump a mounted, read-write file system might result in a system disruption or the inability to restore files from the dump. Consider using the [fssnap\(1M\)](#) command to create a file system snapshot if you need a point-in-time image of a file system that is mounted.

If a filesystem was mounted with the logging option, it is strongly recommended that you run ufsdump as the root user. Running the command as a non-root user might result in the creation of an inconsistent dump.

*options* is a single string of one-letter ufsdump options.

*arguments* may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.

*files\_to\_dump* is required and must be the last argument on the command line. See OPERANDS for more information.

With most devices ufsdump can automatically detect the end-of-media. Consequently, the *d*, *s*, and *t* options are not necessary for multi-volume dumps, unless ufsdump does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the *restore* command.

**Options** The following options are supported:

*0-9*

The “dump level.” All files specified by *files\_to\_dump* that have been modified since the last ufsdump at a lower dump level are copied to the *dump\_file* destination (normally a magnetic tape device). For instance, if a “level 2” dump was done on Monday, followed by a “level 4” dump on Tuesday, a subsequent “level 3” dump on Wednesday would contain all files modified or added since the “level 2” (Monday) backup. A “level 0” dump copies the entire file system to the *dump\_file*.

*a archive\_file*

Archive file. Archive a dump table-of-contents in the specified *archive\_file* to be used by [ufsrestore\(1M\)](#) to determine whether a file is in the dump file that is being restored.

*b factor*

Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge

tapes (`c` option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with [tar\(1\)](#).

**c**

Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since `ufsdump` can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is *not* specified, `ufsdump` will slightly miscalculate the size of the tape. If the `b`, `d`, `s` or `t` options are specified with this option, their values will override the defaults set by this option.

**d bpi**

Tape density. Not normally required, as `ufsdump` can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the `c` option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:

1/2 inch tape  
6250 BPI

1/4 inch cartridge

1000 BPI The tape densities and other options are documented in the [st\(7D\)](#) man page.

**D**

Diskette. Dump to diskette.

**f dump\_file**

Dump file. Use *dump\_file* as the file to dump to, instead of `/dev/rmt/0`. If *dump\_file* is specified as `-`, dump to standard output.

If the name of the file is of the form *machine:device*, the dump is done from the specified machine over the network using [rmt\(1M\)](#). Since `ufsdump` is normally run by root, the name of the local machine must appear in the `.rhosts` file of the remote machine. If the file is specified as *user@machine:device*, `ufsdump` will attempt to execute as the specified user on the remote machine. The specified user must have a `.rhosts` file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

**l**

Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

**L** *string*

Sets the tape label to *string*, instead of the default none. *string* may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the ufsdump tape format, and bears no resemblance to IBM or ANSI-standard tape labels.

**n**

Notify all operators in the sys group that ufsdump requires attention by sending messages to their terminals, in a manner similar to that used by the [wall\(1M\)](#) command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running ufsdump is logged in.

**N** *device\_name*

Use *device\_name* when recording information in /etc/dumpdates (see the u option) and when comparing against information in /etc/dumpdates for incremental dumps. The *device\_name* provided can contain no white space as defined in [scanf\(3C\)](#) and is case-sensitive.

**o**

Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.

**s** *size*

Specify the *size* of the volume being dumped to. Not normally required, as ufsdump can detect end-of-media. When the specified size is reached, ufsdump waits for you to change the volume. ufsdump interprets the specified size as the length in feet for tapes and cartridges, and as the number of 1024-byte blocks for diskettes. The values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the c option, for cartridge devices, and the D option for diskettes:

1/2 inch tape

2300 feet

60-Mbyte 1/4 inch cartridge

425 feet

150-Mbyte 1/4 inch cartridge

700 feet

diskette

1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad block information.)

**S** Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.

**t** *tracks*

Specify the number of tracks for a cartridge tape. Not normally required, as `ufsdump` can detect end-of-media. The default is 9 tracks. The `t` option is not compatible with the `D` option. Values for Sun-supported tape devices are:

60-Mbyte 1/4 inch cartridge

9 tracks

150-Mbyte 1/4 inch cartridge

18 tracks

**T** *time\_wait*[hms]

Sets the amount of time to wait for an `autoload` command to complete. This option is ignored unless the `l` option has also been specified. The default time period to wait is two minutes. Specify time units with a trailing `h` (for hours), `m` (for minutes), or `s` (for seconds). The default unit is minutes.

**u**

Update the dump record. Add an entry to the file `/etc/dumpdates`, for each file system successfully dumped that includes the file system name (or *device\_name* as specified with the `N` option), date, and dump level.

**v**

Verify. After each tape or diskette is written, verify the contents of the media against the source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system *must* be unmounted. This option cannot be used to verify a dump to standard output.

**w**

Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files `/etc/dumpdates` and `/etc/vfstab`. When the `w` option is used, all other options are ignored. After reporting, `ufsdump` exits immediately.

**W**

Warning with highlight. Similar to the `w` option, except that the `W` option includes all file systems that appear in `/etc/dumpdates`, along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.

**Operands** The following operand is supported:

*files\_to\_dump*

Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, `/dev/rdsk/c0t3d0s6`). Incremental dumps (levels 1 to 9) of files changed

after a certain date only apply to a whole file system. Alternatively, *files\_to\_dump* can identify individual files or directories. All named directories that may be examined by the user running `ufsdump`, as well as any explicitly-named files, are dumped. This dump is equivalent to a level 0 dump of the indicated portions of the filesystem, except that `/etc/dumpdates` is not updated even if the `-u` option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where `ufsdump` is being run.

*files\_to\_dump* is required and must be the last argument on the command line.

If no *options* are given, the default is `9uf /dev/rmt/0 files_to_dump`.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `ufsdump` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** EXAMPLE 1 Using `ufsdump`

The following command makes a full dump of a root file system on `c0t3d0`, on a 150-MByte cartridge tape unit 0:

```
example# ufsdump 0cfu /dev/rmt/0 /dev/rdisk/c0t3d0s0
```

The following command makes and verifies an incremental dump at level 5 of the `usr` partition of `c0t3d0`, on a 1/2 inch reel tape unit 1, :

```
example# ufsdump 5fuv /dev/rmt/1 /dev/rdisk/c0t3d0s6
```

**Exit Status** While running, `ufsdump` emits many verbose messages. `ufsdump` returns the following exit values:

- 0 Normal exit.
- 1 Startup errors encountered.
- 3 Abort – no checkpoint attempted.

**Files** `/dev/rmt/0`  
 default unit to dump to

`/etc/dumpdates`  
 dump date record

`/etc/group`  
 to find group `sys`

`/etc/hosts`  
 to gain access to remote system with drive

/etc/vfstab  
list of file systems

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

**See Also** [cpio\(1\)](#), [tar\(1\)](#), [dd\(1M\)](#), [devnm\(1M\)](#), [fssnap\(1M\)](#), [prtvtoc\(1M\)](#), [rmt\(1M\)](#), [shutdown\(1M\)](#), [ufsrestore\(1M\)](#), [volcopy\(1M\)](#), [wall\(1M\)](#), [scanf\(3C\)](#), [ufsdump\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [st\(7D\)](#)

**Notes**

**Read Errors** Fewer than 32 read errors on the file system are ignored.

**Process Per Reel** Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

**Operator Intervention** `ufsdump` requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the `n` option, `ufsdump` interacts with the operator on `ufsdump`'s control terminal at times when `ufsdump` can no longer proceed, or if something is grossly wrong. All questions `ufsdump` poses *must* be answered by typing yes or no, as appropriate.

Since backing up a disk can involve a lot of time and effort, `ufsdump` checkpoints at the start of each volume. If writing that volume fails for some reason, `ufsdump` will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

**Suggested Dump Schedule** It is vital to perform full, “level 0”, dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using [shutdown\(1M\)](#). While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

---

	Sun	Mon	Tue	Wed	Thu	Fri
Week 1:	Full	5	5	5	5	3
Week 2:		5	5	5	5	3
Week 3:		5	5	5	5	3
Week 4:		5	5	5	5	3

Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day's incremental dump.

**Process Priority of ufsdump** ufsdump uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a `nice` (process priority) of `-5` or better will likely make ufsdump run *slower* instead of faster.

**Overlapping Partitions** Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places `root` on slice 0, `swap` on slice 1, `/opt` on slice 5 and `/usr` on slice 6.

It should be emphasized that ufsdump dumps one ufs file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing ufsdump on slice 2 with the intent of dumping the entire disk would instead dump only the root file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

**Bugs** The `/etc/vfstab` file does not allow the desired frequency of backup for file systems to be specified (as `/etc/fstab` did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.

**Name** ufsrestore – incremental file system restore

**Synopsis** /usr/sbin/ufsrestore *i* | *r* | *R* | *t* | *x* [abdfhlmostvyLT]  
 [*archive\_file*] [*factor*] [*dumpfile*] [*n*] [*label*]  
 [*timeout*] [*filename*]...

**Description** The `ufsrestore` utility restores files from backup media created with the `ufsdump` command. `ufsrestore`'s actions are controlled by the *key* argument. The *key* is exactly one *function letter* (*i*, *r*, *R*, *t*, or *x*) and zero or more *function modifiers* (letters). The *key* string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the *key* string.

*filename* arguments which appear on the command line, or as arguments to an interactive command, are treated as shell `glob` patterns by the *x* and *t* functions; any files or directories matching the patterns are selected. The metacharacters `*`, `?`, and `[ ]` must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.

The temporary files `rstdir*` and `rstmode*` are placed in `/tmp` by default. If the environment variable `TMPDIR` is defined with a non-empty value, that location is used instead of `/tmp`.

## Options

**Function Letters** You must specify one (and only one) of the function letters listed below. Note that *i*, *x*, and *r* are intended to restore files into an empty directory. The *R* function is intended for restoring into a populated directory.

- i* Interactive. After reading in the directory information from the media, `ufsrestore` invokes a shell-like interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. Restoration has the same semantics as *x* (see below). See *Interactive Commands*, below, for a description of available commands.
- r* Recursive. Starting with an empty directory and a level 0 dump, the *r* function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, `restoresymtable`) is also included. Several `ufsrestore` runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the *r* function restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with `newfs(1M)`), if the file system contains files not on the backup media, they are preserved.
- R* Resume restoring. If an *r*-mode `ufsrestore` was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to *r*.

- t Table of contents. List each *filename* that appears on the media. If no *filename* argument is given, the root directory is listed. This results in a list of all files on the media, unless the *h* function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the *a* function modifier is used. The *a* function modifier is mutually exclusive with the *x* and *r* function letters.
- x Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.

If the *filename* argument matches a directory whose contents were written onto the media, and the *h* modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible).

If you omit the *filename* argument or specify *.*, the root directory is extracted. This results in the entire tape being extracted, unless the *h* modifier is in effect. *.* With the *x* function, existing files are overwritten and *ufs restore* displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences.

Use the *x* option to restore partial file system dumps, as they are (by definition) not entire file systems.

Function Modifiers	<i>a archive_file</i>	Read the table of contents from <i>archive_file</i> instead of the media. This function modifier can be used in combination with the <i>t</i> , <i>i</i> , or <i>x</i> function letters, making it possible to check whether files are on the media without having to mount the media. When used with the <i>x</i> and interactive ( <i>i</i> ) function letters, it prompts for the volume containing the file(s) before extracting them.
	<i>b factor</i>	Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.
	<i>c</i>	Convert the contents of the media in 4.1BSD format to the new <i>ufs</i> file system format.
	<i>d</i>	Debug. Turn on debugging output.
	<i>f dump_file</i>	Use <i>dump_file</i> instead of <i>/dev/rmt/0</i> as the file to restore from. Typically <i>dump_file</i> specifies a tape or diskette drive. If <i>dump_file</i> is specified as <i>'-'</i> , <i>ufs restore</i> reads from the standard input. This allows <i>ufsdump(1M)</i> and <i>ufs restore</i> to be used in a pipeline to copy a file system:

```
example# ufsdump 0f - /dev/rdisk/c0t0d0s7 \
| (cd /home;ufsrestore xf -)
```

If the name of the file is of the form *machine:device*, the restore is done from the specified machine over the network using *rmt(1M)*. Since *ufsrestore* is normally run by root, the name of the local machine must appear in the */ .rhosts* file of the remote machine. If the file is specified as *user@machine:device*, *ufsrestore* will attempt to execute as the specified user on the remote machine. The specified user must have a *.rhosts* file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

- h** Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.
- l** Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the *T* function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
- L label** The label that should appear in the header of the dump file. If the labels do not match, *ufsrestore* issues a diagnostic and exits. The tape label is specific to the *ufsdump* tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
- m** Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.
- o** Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.
- s n** Skip to the *n*th file when there are multiple dump files on the same tape. For example, the command:
- ```
example# ufsrestore xfs /dev/rmt/0hn 5
```
- would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what “*s n*” value is specified.

If “*s n*” is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward *n*-1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

- T timeout [hms] Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.
- v Verbose. `ufs restore` displays the name and inode number of each file it restores, preceded by its file type.
- y Do not ask whether to abort the restore in the event of tape errors. `ufs restore` tries to skip over the bad tape block(s) and continue as best it can.

Interactive Commands `ufs restore` enters interactive mode when invoked with the i function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

- add [*filename*] Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the h modifier is in effect).
- cd *directory* Change to *directory* (within the dump file).
- delete [*filename*] Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the h modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.
- extract Extract all files on the extraction list from the dump media. `ufs restore` asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If “*s n*” is given on the command line, volume 1 will automatically be positioned to file *n* when it is read.
- help Display a summary of the available commands.
- ls [*directory*] List files in *directory* or the current directory, represented by a ‘.’ (period). Directories are appended with a ‘/’ (slash). Entries marked for extraction are prefixed with a ‘*’ (asterisk). If the verbose option is in effect, inode numbers are also listed.

| | |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| marked [<i>directory</i>] | Like <code>ls</code> , except only files marked for extraction are listed. |
| pager | Toggle the pagination of the output from the <code>ls</code> and <code>marked</code> commands. The pager used is that defined by the <code>PAGER</code> environment variable, or <code>more(1)</code> if that envvar is not defined. The <code>PAGER</code> envvar may include white-space-separated arguments for the pagination program. |
| pwd | Print the full pathname of the current working directory. |
| quit | <code>ufsrestore</code> exits immediately, even if the extraction list is not empty. |
| setmodes | Prompts: set owner/mode for '.' (period). Type <code>y</code> for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type <code>n</code> for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped. |
| setpager <i>command</i> | Sets the command to use for paginating output instead of the default or that inherited from the environment. The <i>command</i> string may include arguments in addition to the command itself. |
| verbose | Toggle the status of the <code>v</code> modifier. While <code>v</code> is in effect, the <code>ls</code> command lists the inode numbers of all entries, and <code>ufsrestore</code> displays information about each file as it is extracted. |
| what | Display the dump header on the media. |

Operands The following operands are supported.

filename Specifies the pathname of files (or directories) to be restored to disk. Unless the `h` function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. *filename* is associated with either the `x` or `t` function letters, and must come last.

Usage See [largefile\(5\)](#) for the description of the behavior of `ufsrestore` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred. Verbose messages are displayed.

Environment Variables `PAGER` The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is [more\(1\)](#).

TMPDIR Selects the directory for temporary files. Defaults to /tmp if not defined in the environment.

Files

- /dev/rmt/0 the default tape drive
- \$TMPDIR/rstdir* file containing directories on the tape
- \$TMPDIR/rstmode* owner, mode, and timestamps for directories
- ./restoresymtable information passed between incremental restores

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [more\(1\)](#), [mkfs\(1M\)](#), [mount\(1M\)](#), [rmt\(1M\)](#), [ufsdump\(1M\)](#), [ufsdump\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Diagnostics ufsrestore complains about bad option characters.

Read errors result in complaints. If *y* has been specified, or the user responds *y*, ufsrestore will attempt to continue.

If the dump extends over more than one tape, ufsrestore asks the user to change tapes. If the *x* or *i* function letter has been specified, ufsrestore also asks which volume the user wishes to mount. If the *s* modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by ufsrestore. Most checks are self-explanatory or can “never happen”. Common errors are given below.

Converting to new file system format

A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape

The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the *r* function.

expected next file *inumber*, got *inumber*

A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low

When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

Incremental tape too high

When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument

Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring

Tape read error while skipping over inode inumber

Tape read error while trying to resynchronize

A tape read error has occurred

If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

resync ufsrestore, skipped *num*

After a tape read error, `ufsrestore` may have to resynchronize itself. This message lists the number of blocks that were skipped over.

Incorrect tape label. Expected 'foo', got 'bar'.

The `L` option was specified, and its value did not match what was recorded in the header of the dump file.

Notes `ufsrestore` can get confused when doing incremental restores from dump tapes that were made on active file systems.

A level 0 dump must be done after a full restore. Because `ufsrestore` runs in user mode, it has no control over inode allocation. This means that `ufsrestore` repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

- Name** unshare – make local resource unavailable for mounting by remote systems
- Synopsis** unshare [-F *FSType*] [-o *specific_options*]
[*pathname* | *resourcename*]
- Description** The unshare command makes a shared local resource unavailable as file system type *FSType*. If the option -F*FSType* is omitted, then the first file system type listed in file */etc/dfs/fstypes* will be used as the default. *Specific_options*, as well as the semantics of *resourcename*, are specific to particular distributed file systems.
- Options** -F *FSType* Specify the file system type.
-o *specific_options* Specify options specific to the file system provided by the -F option.
- Files** */etc/dfs/fstypes*
/etc/dfs/sharetab
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [share\(1M\)](#), [shareall\(1M\)](#), [attributes\(5\)](#)

Notes If *pathname* or *resourcename* is not found in the shared information, an error message will be sent to standard error.

When an unshare command completes successfully, a client mounting a file system specified in that unshare command no longer has access to that file system.

Name unshare_nfs – make local NFS file systems unavailable for mounting by remote systems

Synopsis unshare [-F nfs] *pathname*

Description The unshare command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the *FSType* in the file `/etc/dfs/sharetab`.

Options The following options are supported:

-F This option may be omitted if NFS is the first file system type listed in the file `/etc/dfs/fstypes`.

Files `/etc/dfs/fstypes`
`/etc/dfs/sharetab`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWnfssu |

See Also [nfsd\(1M\)](#), [share\(1M\)](#), [attributes\(5\)](#)

Notes If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following unshare command will result in `/export/bar` as the unshared pathname (and not `/export/foo`):

```
example# unshare -F nfs /export/foo
```

For file systems that are accessed by NFS Version 4 clients, once the unshare is complete, all NFS Version 4 state (open files and file locks) are released and unrecoverable by the clients. If the intent is to share the file system after some administrative action, the NFS daemon (`nfsd`) should first be stopped and then the file system unshared. After the administrative action is complete, the file system would then be shared and the NFS daemon restarted. See [nfsd\(1M\)](#)

Name update_drv – modify device driver attributes

Synopsis update_drv [-f | -v] *driver_module*

```
update_drv [-b basedir] [-f | -v] -a [-m 'permission' ]
           [-i 'identify-name' ] [-P 'privilege' ] [-p 'policy' ] driver_module
```

```
update_drv [-b basedir] [-f | -v] -d [-m 'permission' ]
           [-i 'identify-name' ] [-P 'privilege' ] [-p 'policy' ] driver_module
```

Description The update_drv command informs the system about attribute changes to an installed device driver. It can be used to re-read the [driver.conf\(4\)](#) file, or to add, modify, or delete a driver's minor node permissions or aliases.

Without options, update_drv reloads the driver.conf file.

Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or hotplug of the device.

Upon successfully updating the permissions, only the new driver minor nodes get created with the modified set of file permissions. Existing driver minor nodes do not get modified.

Options The following options are supported:

-a *permission, aliases, privilege* or *policy* entry.

With the -a option specified, a permission entry (using the -m option), or a driver's aliases entry (using the -i option), a device privilege (using the -P option) or a device policy (using the -p option), can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.

The -a and -d options are mutually exclusive.

-b *basedir* Installs or modifies the driver on the system with a root directory of basedir rather than installing on the system executing update_drv.

Note – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-d *permission, aliases, privilege* or *policy* entry.

The -m *permission*, -i *identify-name*, -P *privilege* or the -p *policy* option needs to be specified with the -d option.

The -d and -a options are mutually exclusive.

- If the entry doesn't exist `update_drv` returns an error.
- f Force the system to reread the `driver.conf` file even if the driver module cannot be unloaded. See NOTES section for details.
 - i '*identify-name*' A white-space separated list of aliases for the driver. If -a or -d option is not specified then this option is ignored. The *identify-name* string is mandatory. If all aliases need to be removed, `rem_drv(1M)` is recommended.
 - m '*permission*' Specify a white-space separated list of file system permissions for the device node of the device driver. If -a or -d option is not specified then, this option is ignored. The permission string is mandatory.
 - p '*policy*' With the -a option, policy is a white-space separated list of complete device policies. For the -d option, policy is a white space separated list of minor device specifications. The minor device specifications are matched exactly against the entries in `/etc/security/device_policy`, that is., no wildcard matching is performed.
 - P '*privilege*' With the -a option, privilege is a comma separated list of additional driver privileges. For the -d option, privilege is a single privilege. The privileges are added to or removed from the `/etc/security/extra_privs` file.
 - v Verbose.

Examples EXAMPLE 1 Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the existing minor permissions entry of the `clone` driver:

```
example# update_drv -a -m 'llc1 777 joe staff' clone
```

EXAMPLE 2 Removing All Minor Permissions Entries

The following command removes all minor permission entries of the `usbprn` driver, the USB printer driver:

```
example# update_drv -d -m '* 0666 root sys' usbprn
```

EXAMPLE 3 Adding a Driver Aliases Entry

The following command adds a driver aliases entry of the `ugen` driver with the identity string of `usb459,20`:

```
example# update_drv -a -i '"usb459,20"' ugen
```

EXAMPLE 4 Re-reading the driver.conf File For the ohci Driver

The following command re-reads the driver.conf(4) file.

```
example# update_drv ohci
```

EXAMPLE 5 Requiring a Self-defined Privilege to Open a tcp Socket

The following command requires a self-defined privilege to open a tcp socket:

```
example# update_drv -a -P net_tcp -p \
    'write_priv_set=net_tcp read_priv_set=net_tcp' tcp
```

EXAMPLE 6 Establishing a Path-oriented Alias

The following command establishes a path-oriented alias to force a specific driver, qlt, to be used for a particular device path:

```
example# update_drv -a -i '/pci@8,600000/SUNW,qlc@4' qlt
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [add_drv\(1M\)](#), [modunload\(1M\)](#), [rem_drv\(1M\)](#), [driver.conf\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#)

Notes If -a or -d options are specified, update_drv does not re-read the driver.conf file.

A forced update of the driver.conf file reloads the driver.conf file without reloading the driver binary module. In this case, devices which can not be detached reference driver global properties from the old driver.conf file, while the remaining driver instances reference global properties in the new driver.conf file.

It is possible to add an alias, which changes the driver binding of a device already being managed by a different driver. A force update with the -a option tries to bind to the new driver and report error if it cannot. If you specify more than one of the -m, -i, -P or -p options, a force flag tries to modify aliases or permissions. This is done even if the other operation fails and vice-versa. A force update with the -d option tries to delete entries and report the error if it cannot.

Name updatehome – update the home directory copy and link files for the current label

Synopsis /usr/bin/updatehome [-cirs]

Description updatehome reads the user's minimum-label copy and link-control files (`.copy_files` and `.link_files`). These files contain a list of files to be copied and symbolically linked from the user's minimum-label home directory to the user's home directory at the current label.

The Solaris Trusted Extensions `dt session` program performs an `updatehome` whenever a newly labeled workspace is created so that the user's favorite files are available for use. For example, the user probably wants a symbolic link to such files as `.profile`, `.login`, `.cshrc`, `.exrc`, `.mailrc`, and `~/bin`. The `updatehome` command provides a convenient mechanism for accomplishing this symlink. The user can add files to those to be copied (`.copy_files`) and to those to be symbolically linked (`.link_files`).

- Options**
- c Replace existing home-directory copies at the current label. The default is to skip over existing copies.
 - i Ignore errors encountered. The default aborts on error.
 - r Replace existing home-directory copies or symbolic links at the current label. This option implies options -c and -s. The default is to skip over existing copies or symbolic links.
 - s Replace existing home-directory symbolic links at the current label. The default is to skip over existing symbolic links.

Exit Status Upon success, `updatehome` returns 0. Upon failure, `updatehome` returns 1 and writes diagnostic messages to standard error.

Examples EXAMPLE 1 A Sample `.copy_files` File

The files that are listed in `.copy_files` can be modified at every user's label.

```
.cshrc
.mailrc
.mozilla/bookmarks.html
```

EXAMPLE 2 A Sample `.link_files` File

The files that are listed in `.link_files` can be modified at the lowest label. The changes propagate to the other labels that are available to the user.

```
~/bin
.mozilla/preferences
.xrc
.rhosts
```

EXAMPLE 3 Updating the Linked and Copied Files

The `.copy_files` and `.link_files` were updated by the user at the minimum label. At a higher label, the user refreshes the copies and the links. No privileges are required to run the command.

```
% updatehome -r
```

Files `$HOME/.copy_files` List of files to be copied
`$HOME/.link_files` List of files to be symbolically linked

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name updatemanager – start the Sun Update Manager application

Synopsis updatemanager

Description The updatemanager command starts the Sun Update Manager application. The Sun Update Manager is a graphical user interface (GUI) that you can use to manage updates and patches on your Solaris system.

For more information about using this application, see the *Sun Update Manager 1.0 Administration Guide* in the *Sun Update Connection, System Edition Collection* on docs.sun.com.

You can also manage updates and patches on the command line by using the smpatch command. See the [smpatch\(1M\)](#) man page.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWupdatemgru |
| Interface Stability | Unstable |

See Also [smpatch\(1M\)](#), [attributes\(5\)](#)

-
- Name** updatemedia – modify Solaris media with patches and packages
- Synopsis** `/usr/bin/updatemedia -d media-root [-v] [-o iso] [-l label]
pkg_or_patch [pkg_or_patch ...]`
- Description** The updatemedia utility takes a list of patches and packages as input and updates the install miniroot in *media-root* (the root directory of an on-disk image of a Solaris installation media) to include the specified patches and packages. These patches and packages are also placed in a subdirectory called DU under the Solaris install image. For example:
- ```
media-root/Solaris_10/DU
```
- When booting a system from the updated media, the patches and packages will be part of the booted Solaris image. They will also be applied to the target system being installed at the end of the installation process.
- If `-o` is specified, a bootable ISO image is created in the file `media.iso` that contains the Solaris install media. The ISO image can then be burned onto a CD/DVD with utilities such as `cdw(1)` or `cdrecord(1)`. (The latter is not a SunOS man page.)
- Options** The following options are supported:
- `-d media-root`  
 Top-level directory of on-disk image of Solaris installation media. This option must be specified.
  - `-o iso`  
 Create a Solaris ISO image of *media-root*.
  - `-l label`  
 Label/volume name of the ISO image (if `-o` option is specified). If `-o` is not specified, the name of Solaris directory under *media-root*, for example, `Solaris_10`, will be used.
  - `-v`  
 Verbose. Multiple `-v` options increase verbosity.
- Operands** The following operands are supported:
- `pkg_or_patch [pkg_or_patch ...]`  
 One or more patches or packages (you can have both patches and packages in a single command) with which the Solaris installation media *media-root* will be updated.
- Examples** **EXAMPLE 1** Updating a Solaris Install Image with Patch and Package
- The following command updates the Solaris install image in `s10u1` by adding patch `123456-07` and package `SUNWfoo`.
- ```
# /usr/bin/updatemedia -d s10u1 SUNWfoo 123456-07
```

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | Committed |

See Also [cdrw\(1\)](#), [mkbootmedia\(1M\)](#), [attributes\(5\)](#)

[mkisofs\(8\)](#), (`/usr/share/man/man8/mkisofs.8`), in the SUNWfsman package (not a SunOS man page)

Name useradd – administer a new user login on the system

Synopsis useradd [-c *comment*] [-d *dir*] [-e *expire*] [-f *inactive*]
 [-g *group*] [-G *group* [, *group*...]] [-m [-k *skel_dir*]]
 [-u *uid* [-o]] [-s *shell*] [-A *authorization* [,*authorization*...]]
 [-P *profile* [,*profile*...]] [-R *role* [,*role*...]]
 [-p *projname*] [-K *key=value*] *login*

useradd -D [-b *base_dir*] [-e *expire*] [-f *inactive*]
 [-g *group*] [-A *authorization* [,*authorization*...]]
 [-P *profile* [,*profile*...]] [-R *role* [,*role*...]]
 [-p *projname*] [-K *key=value*]

Description useradd adds a new user to the `/etc/passwd` and `/etc/shadow` and `/etc/user_attr` files. The -A and -P options respectively assign authorizations and profiles to the user. The -R option assigns roles to a user. The -p option associates a project with a user. The -K option adds a *key=value* pair to `/etc/user_attr` for the user. Multiple *key=value* pairs may be added with multiple -K options.

useradd also creates supplementary group memberships for the user (-G option) and creates the home directory (-m option) for the user if requested. The new login remains locked until the `passwd(1)` command is executed.

Specifying useradd -D with the -g, -b, -f, -e, -A, -P, -p, -R, or -K option (or any combination of these options) sets the default values for the respective fields. See the -D option, below. Subsequent useradd commands without the -D option use these arguments.

The system file entries created with this command have a limit of 2048 characters per line. Specifying long arguments to several options can exceed this limit.

useradd requires that usernames be in the format described in `passwd(4)`. A warning message is displayed if these restrictions are not met. See `passwd(4)` for the requirements for usernames.

Options The following options are supported:

-A *authorization*

One or more comma separated authorizations defined in `auth_attr(4)`. Only a user or role who has grant rights to the authorization can assign it to an account.

-b *base_dir*

The default base directory for the system if -d *dir* is not specified. *base_dir* is concatenated with the account name to define the home directory. If the -m option is not used, *base_dir* must exist.

-c *comment*

Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

-d *dir*

The home directory of the new user. It defaults to *base_dir/account_name*, where *base_dir* is the base directory for new login home directories and *account_name* is the new login name.

-D

Display the default values for group, base_dir, skel_dir, shell, inactive, expire, proj, projname and key=value pairs. When used with the -g, -b, -f, -e, -A, -P, -p, -R, or -K options, the -D option sets the default values for the specified fields. The default values are:

| | |
|------------------------------------------------------------|------------------|
| group | other (GID of 1) |
| base_dir | /home |
| skel_dir | /etc/skel |
| shell | /bin/sh |
| inactive | 0 |
| expire | null |
| auths | null |
| profiles | null |
| proj | 3 |
| projname | default |
| key=value (pairs defined in user_attr(4)) | not present |
| roles | null |

-e *expire*

Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See [getdate\(3C\)](#).

If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or "October 6, 1990". A null value (" ") defeats the status of the expired date. This option is useful for creating temporary logins.

-f *inactive*

The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-
- g *group*
An existing group's integer ID or character-string name. Without the -D option, it defines the new user's primary group membership and defaults to the default group. You can reset this default value by invoking `useradd -D -g group`. GIDs 0-99 are reserved for allocation by the Solaris Operating System.
 - G *group*
An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between *group* with the -g and -G options are ignored. No more than `NGROUPS_MAX` groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.
 - K *key=value*
A *key=value* pair to add to the user's attributes. Multiple -K options may be used to add multiple *key=value* pairs. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A, -P, -R, -p). See [user_attr\(4\)](#) for a list of valid *key=value* pairs. The "type" key is not a valid key for this option. Keys may not be repeated.
 - k *skel_dir*
A directory that contains skeleton information (such as `.profile`) that can be copied into a new user's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.
 - m
Create the new user's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the user's primary group.
 - o
This option allows a UID to be duplicated (non-unique).
 - P *profile*
One or more comma-separated execution profiles defined in [prof_attr\(4\)](#).
 - p *projname*
Name of the project with which the added user is associated. See the *projname* field as defined in [project\(4\)](#).
 - R *role*
One or more comma-separated execution profiles defined in [user_attr\(4\)](#). Roles cannot be assigned to other roles.
 - s *shell*
Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/sh` as the default. The value of *shell* must be a valid executable file.

-u *uid*

The UID of the new user. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. UIDs 0-99 are reserved for allocation by the Solaris Operating System.

Files /etc/datemsk
 /etc/passwd
 /etc/shadow
 /etc/group
 /etc/skel
 /usr/include/limits.h
 /etc/user_attr

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | Evolving |

See Also [passwd\(1\)](#), [profiles\(1\)](#), [roles\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [logins\(1M\)](#), [pwck\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [getdate\(3C\)](#), [auth_attr\(4\)](#), [passwd\(4\)](#), [prof_attr\(4\)](#), [project\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Diagnostics In case of an error, useradd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the *uid* specified with the -u option is not unique:

UX: useradd: ERROR: uid *uid* is already in use. Choose another.

The following indicates that the *group* specified with the -g option is already in use:

UX: useradd: ERROR: group *group* does not exist. Choose another.

The following indicates that the *uid* specified with the -u option is in the range of reserved UIDs (from 0-99):

UX: useradd: WARNING: uid *uid* is reserved.

The following indicates that the *uid* specified with the `-u` option exceeds MAXUID as defined in `<sys/param.h>`:

UX: useradd: ERROR: uid *uid* is too big. Choose another.

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:

UX: useradd: ERROR: Cannot update system files - login cannot be created.

Notes The `useradd` utility adds definitions to only the local `/etc/group`, `etc/passwd`, `/etc/passwd`, `/etc/shadow`, `/etc/project`, and `/etc/user_attr` files. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `useradd` cannot change information supplied by the network name service. However `useradd` will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.

Name userdel – delete a user's login from the system

Synopsis userdel [-r] *login*

Description The userdel utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.

Options The following options are supported:

-r Remove the user's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

Operands The following operands are supported:

login An existing login name to be deleted.

Exit Status The following exit values are returned:

0 Successful completion.
 2 Invalid command syntax. A usage message for the userdel command is displayed.
 6 The account to be removed does not exist.
 8 The account to be removed is in use.
 10 Cannot update the /etc/group or /etc/user_attr file but the login is removed from the /etc/passwd file.
 12 Cannot remove or otherwise modify the home directory.

Files

| | |
|----------------|------------------------------------------------------------------------|
| /etc/passwd | system password file |
| /etc/shadow | system file contain users' encrypted passwords and related information |
| /etc/group | system file containing group definitions |
| /etc/user_attr | system file containing additional user attributes |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [auths\(1\)](#), [passwd\(1\)](#), [profiles\(1\)](#), [roles\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [logins\(1M\)](#), [roleadd\(1M\)](#), [rolemod\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [passwd\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Notes The userdel utility only deletes an account definition that is in the local /etc/group, /etc/passwd, /etc/shadow, and /etc/user_attr file. file. If a network name service such as NIS or NIS+ is being used to supplement the local /etc/passwd file with additional entries, userdel cannot change information supplied by the network name service.

Name usermod – modify a user's login information on the system

Synopsis usermod [-u *uid* [-o]] [-g *group*] [-G *group* [, *group*...]]
[-d *dir* [-m]] [-s *shell*] [-c *comment*] [-\ *new_name*]
[-f *inactive*] [-e *expire*]
[-A *authorization* [, *authorization*]]
[-P *profile* [, *profile*]] [-R *role* [, *role*]]
[-K *key=value*] *login*

Description The usermod utility modifies a user's login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options might exceed this limit.

Options The following options are supported:

-A *authorization*

One or more comma separated authorizations as defined in [auth_attr\(4\)](#). Only a user or role who has grant rights to the *authorization* can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

-c *comment*

Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

-d *dir*

Specify the new home directory of the user. It defaults to `base_dir/login`, where *base_dir* is the base directory for new login home directories, and `login` is the new login.

-e *expire*

Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datensk`. See [getdate\(3C\)](#).

For example, you may enter `10/6/90` or `October 6, 1990`. A value of `''` defeats the status of the expired date.

-f *inactive*

Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

-g *group*

Specify an existing group's integer ID or character-string name. It redefines the user's primary group membership.

- G *group***
Specify an existing group's integer "ID" or character string name. It redefines the user's supplementary group membership. Duplicates between *group* with the `-g` and `-G` options are ignored. No more than `NGROUPS_UMAX` groups may be specified as defined in `<param.h>`.
- K *key=value***
Replace existing or add to a user's *key=value* pair attributes. Multiple `-K` options can be used to replace or add multiple *key=value* pairs. However, keys must not be repeated. The generic `-K` option with the appropriate key can be used instead of the specific implied key options (`-A`, `-P`, `-R`, `-p`). See [user_attr\(4\)](#) for a list of valid *keys*. Values for these keys are usually found in man pages or other sources related to those keys. For example, see [project\(4\)](#) for guidance on values for the `project` key. Use the command [ppriv\(1\)](#) with the `-v` and `-l` options for a list of values for the keys `defaultpriv` and `limitpriv`.
- The keyword type can be specified with the value `role` or the value `normal`. When using the value `role`, the account changes from a normal user to a role; using the value `normal` keeps the account a normal user.
- As a `role` account, no roles (`-R` or *roles=value*) can be present.
- l *new_logname***
Specify the new login name for the user. See [passwd\(4\)](#) for the requirements for usernames.
- m**
Move the user's home directory to the new directory specified with the `-d` option. If the directory already exists, it must have permissions `read/write/execute` by *group*, where *group* is the user's primary group.
- o**
This option allows the specified UID to be duplicated (non-unique).
- P *profile***
One or more comma-separated rights profiles defined in [prof_attr\(4\)](#). This replaces any existing profile setting in [user_attr\(4\)](#). If an empty profile list is specified, the existing setting is removed.
- R *role***
One or more comma-separated roles (see [roleadd\(1M\)](#)). This replaces any existing role setting. If no role list is specified, the existing setting is removed.
- s *shell***
Specify the full pathname of the program that is used as the user's shell on login. The value of *shell* must be a valid executable file.
- u *uid***
Specify a new UID for the user. It must be a non-negative decimal integer less than `MAXUID` as defined in `<param.h>`. The UID associated with the user's home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using [chown\(1\)](#).

Operands The following operands are supported:

login

An existing login name to be modified.

Examples **EXAMPLE 1** Assigning Privileges to a User

The following command adds the privilege that affects high resolution times to a user's initial, inheritable set of privileges.

```
# usermod -K defaultpriv=basic,proc_clock_highres jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,proc_clock_highres
```

EXAMPLE 2 Removing a Privilege from a User's Limit Set

The following command removes the privilege that allows the specified user to create hard links to directories and to unlink directories.

```
# usermod -K limitpriv=all,!sys_linkdir jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,limitpriv=all,!sys_linkdir
```

EXAMPLE 3 Removing a Privilege from a User's Basic Set

The following command removes the privilege that allows the specified user to examine processes outside the user's session.

```
# usermod -K defaultpriv=basic,!proc_session jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,!proc_session;limitpriv=all
```

EXAMPLE 4 Assigning a Role to a User

The following command assigns a role to a user. The role must have been created prior to this command, either through use of the Solaris Management Console GUI or through [roleadd\(1M\)](#).

```
# usermod -R mailadm jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;roles=mailadm;defaultpriv=basic;limitpriv=all
```

EXAMPLE 5 Removing All Profiles from a User

The following command removes all profiles that were granted to a user directly. The user will still have any rights profiles that are granted by means of the `PROFS_GRANTED` key in [policy.conf\(4\)](#).

EXAMPLE 5 Removing All Profiles from a User (Continued)

```
# usermod -P "" jdoe
```

Exit Status In case of an error, usermod prints an error message and exits with one of the following values:

- 2
The command syntax was invalid. A usage message for the usermod command is displayed.
- 3
An invalid argument was provided to an option.
- 4
The *uid* given with the *-u* option is already in use.
- 5
The password files contain an error. [pwconv\(1M\)](#) can be used to correct possible errors. See [passwd\(4\)](#).
- 6
The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8
The login to be modified is in use.
- 9
The *new_logname* is already in use.
- 10
Cannot update the */etc/group* or */etc/user_attr* file. Other update requests will be implemented.
- 11
Insufficient space to move the home directory (*-m* option). Other update requests will be implemented.
- 12
Unable to complete the move of the home directory to the new home directory.

Files

- /etc/group*
system file containing group definitions
- /etc/datemsk*
system file of date formats
- /etc/passwd*
system password file
- /etc/shadow*
system file containing users' encrypted passwords and related information

`/etc/user_attr`

system file containing additional user and role attributes

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | Committed |

See Also [chown\(1\)](#), [passwd\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [logins\(1M\)](#), [pwconv\(1M\)](#), [roleadd\(1M\)](#), [roledel\(1M\)](#), [rolemod\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [getdate\(3C\)](#), [auth_attr\(4\)](#), [passwd\(4\)](#), [policy.conf\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Notes The `usermod` utility modifies `passwd` definitions only in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `usermod` cannot change information supplied by the network nameservice. However `usermod` will verify the uniqueness of user name and user ID against the external nameservice.

The `usermod` utility uses the `/etc/datemsk` file, available with `SUNWaccr`, for date formatting.

-
- Name** utmpd – utmpx monitoring daemon
- Synopsis** utmpd [-debug]
- Description** The utmpd daemon monitors the /var/adm/utmpx file. See [utmpx\(4\)](#) (and [utmp\(4\)](#) for historical information).
- utmpd receives requests from [pututxline\(3C\)](#) by way of a named pipe. It maintains a table of processes and uses [poll\(2\)](#) on /proc files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmpx entry from /var/adm/utmpx. If the process' utmpx entry has not been removed, utmpd removes the entry. By periodically scanning the /var/adm/utmpx file, utmpd also monitors processes that are not in its table.
- Options** -debug
Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.
- Exit Status** The following exit values are returned:
- 0
Successful completion.
 - >0
An error occurred.
- Files** /etc/default/utmpd
You can set default values for the flags listed below. For example: SCAN_PERIOD=600
- SCAN_PERIOD
The number of seconds that utmpd sleeps between checks of /proc to see if monitored processes are still alive. The default is 300.
- MAX_FDS
The maximum number of processes that utmpd attempts to monitor. The default value is 4096.
- WTMPX_UPDATE_FREQ
The number of seconds that utmpd sleeps between read accesses of the wtmpx file. The wtmpx file's last access time is used by [init\(1M\)](#) on reboot to determine when the operating system became unavailable. The default is 60.
- /var/adm/utmpx
File containing user and accounting information for commands such as [who\(1\)](#), [write\(1\)](#), and [login\(1\)](#).
- /proc
Directory containing files for processes whose utmpx entries are being monitored.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [svcs\(1\)](#), [init\(1M\)](#), [svcadm\(1M\)](#), [poll\(2\)](#), [pututxline\(3C\)](#), [proc\(4\)](#), [utmp\(4\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes If the filesystem holding `/var/adm/wtmpx` is mounted with options which inhibit or defer access time updates, an unknown amount of error will be introduced into the `utmp DOWN_TIME` record's timestamp in the event of an uncontrolled shutdown (for example, a crash or loss of power). Controlled shutdowns will update the modify time of `/var/adm/wtmpx`, which will be used on the next boot to determine when the previous shutdown occurred, regardless of access time deferral or inhibition.

The `utmpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/utmp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name uucpcheck – check the uucp directories and permissions file

Synopsis /usr/lib/uucp/uucpcheck [-v] [-x *debug-level*]

Description uucpcheck checks for the presence of the uucp system required files and directories. uucpcheck also does error checking of the Permissions file (/etc/uucp/Permissions).

uucpcheck is executed during package installation. uucpcheck can only be used by the super-user or uucp.

Options The following options are supported:

- v Give a detailed (verbose) explanation of how the uucp programs will interpret the Permissions file.
- x *debug-level* Produce debugging output on the standard output. *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files /etc/uucp/Devices
 /etc/uucp/Limits
 /etc/uucp/Permissions
 /etc/uucp/Systems
 /var/spool/locks/*
 /var/spool/uucp/*
 /var/spool/uucppublic/*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWbnuu |

See Also [uucp\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [uucico\(1M\)](#), [uusched\(1M\)](#), [attributes\(5\)](#)

Bugs The program does not check file/directory modes or some errors in the Permissions file such as duplicate login or machine name.

Name uucico – file transport program for the uucp system

Synopsis /usr/lib/uucp/uucico [-f] [-c *type*] [-d *spool-directory*]
[-i *interface*] [-r *role-number*] [-s *system-name*]
[-x *debug-level*]

Description uucico is the file transport program for uucp work file transfers.

Options The following options are supported:

- | | |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f | This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the /etc/uucp/Limits file. |
| -c <i>type</i> | The first field in the Devices file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network. |
| -d <i>spool-directory</i> | This option specifies the directory <i>spool-directory</i> that contains the uucp work files to be transferred. The default spool directory is /var/spool/uucp. |
| -i <i>interface</i> | This option defines the <i>interface</i> used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write). |
| -r <i>role-number</i> | The <i>role-number</i> 1 is used for master mode. <i>role-number</i> 0 is used for slave mode (default). When uucico is started by a program or cron, <i>role-number</i> 1 should be used for master mode. |
| -s <i>system-name</i> | The -s option defines the remote system (<i>system-name</i>) that uucico will try to contact. It is required when the role is master; <i>system-name</i> must be defined in the Systems file. |
| -x <i>debug-level</i> | Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uused scheduler, for debugging purposes, and can be started manually. For example, the shell Outry starts uucico with debugging turned on. The <i>debug-level</i> is a number between 0 and 9. Higher numbers give more detailed debugging information. |

Files /etc/uucp/Devconfig

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWbnuu |

See Also [uucp\(1C\)](#), [uustat\(1C\)](#), [uux\(1C\)](#), [Uutry\(1M\)](#), [cron\(1M\)](#), [uusched\(1M\)](#), [attributes\(5\)](#)

Name uucleanup – uucp spool directory clean-up

Synopsis /usr/lib/uucp/uucleanup [-Ctime] [-Dtime] [-mstring]
[-otime] [-ssystem] [-Wtime] [-xdebug-level] [-Xtime]

Description uucleanup will scan the spool directories for old files and take appropriate action to remove them in a useful way:

- Inform the requester of send/receive requests for systems that can not be reached.
- Return undeliverable mail to the sender.
- Deliver rnews files addressed to the local system.
- Remove all other files.

In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: uucleanup will process as if all option times were specified to the default values unless time is specifically set.

This program is typically started by the shell uudemond.cleanup, which should be started by cron(1M).

| | | |
|----------------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Options | -Ctime | Remove any C. files greater or equal to time days old and send appropriate information to the requester (default 7 days). |
| | -Dtime | Remove any D. files greater or equal to time days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days). |
| | -mstring | Include string in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem". |
| | -otime | Delete other files whose age is more than time days (default 2 days). |
| | -ssystem | Execute for system spool directory only. |
| | -Wtime | Any C. files equal to time days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the JOBID, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day). |
| | -xdebug-level | Produce debugging output on standard output. debug-level is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.) |
| | -Xtime | Any X. files greater or equal to time days old will be removed. The D. files are probably not present (if they were, the X. could get executed). But if there are D. files, they will be taken care of by D. processing (default 2 days). |

Name uusched – uucp file transport program scheduler

Synopsis /usr/lib/uucp/uusched [-u *debug-level*] [-x *debug-level*]

Description uusched is the [uucp\(1C\)](#) file transport scheduler. It is usually started by the daemon *uudemon.hour* that is started by [cron\(1M\)](#) from an entry in user uucp's crontab file:

```
11,41 * * * * /etc/uucp/uucp/uudemon.hour
```

Options The options are for debugging purposes only. *debug-level* is a number between 0 and 9. Higher numbers give more detailed debugging information:

The following options are supported:

-u *debug-level* Passes the -u *debug-level* option [uucico\(1M\)](#) as -x *debug-level*.

-x *debug-level* Outputs debugging messages from uusched.

Name Uutry, uutry – attempt to contact remote system with debugging on

Synopsis /usr/lib/uucp/Uutry [-r] [-c *type*] [-x *debug-level*] *system-name*

Description Uutry is a shell script that is used to invoke [uucico\(1M\)](#) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file */tmp/system-name*.

Options The following options are supported:

- r This option overrides the retry time that is set in file */var/uucp/.Status/system-name*.
- c *type* The first field in the Devices file is the "Type" field. The -c option forces uucico to use only entries in the "Type" field that match the user-specified type. The specified type is usually the name of a local area network.
- x *debug-level* *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Name uuxqt – execute remote command requests

Synopsis /usr/lib/uucp/uuxqt [-s *system*] [-x *debug-level*]

Description uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.

There are two environment variables that are set before the uuxqt command is executed:

- UU_MACHINE is the machine that sent the job (the previous one).
- UU_USER is the user that sent the job.

These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.

Options The following options are supported:

- s *system* Specifies the remote *system* name.
- x *debug-level* *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files /etc/uucp/Limits

Name virtinfo – virtualization domain information

Synopsis virtinfo [-acdpstu]

Description The `virtinfo` utility provides virtualization information returned by `libv12n(3LIB)` about the current domain. When options are specified, symbols that represent one or more virtualization domain characteristics are written to standard output. If no options are specified, `virtinfo` shows only the virtualization domain type.

Options The `virtinfo` command supports the following options:

- a Shows all information that is currently available from the system.
- c Shows the network node name of the control domain. This name is identical to the string shown by running the `uname -n` command on the control domain.
- d Shows the domain name for this virtual domain.
- p Shows information in a parseable format.

The parseable output for Logical Domains (LDoms) has the following format:

```
VERSION 1.0
DOMAINROLE | impl=LDoms | control={true|false} |
            io={true|false} | service={true|false} |
            root={true|false}
DOMAINNAME | name=domain-name
DOMAINUUID | uuid=uuid
DOMAINCONTROL | name=control-domain-nodename
DOMAINCHASSIS | serialno=serial-no
```

- s Shows the platform serial number.
- t Shows the domain type.

The domain type for Logical Domains is a string of one or more of the following blank-separated values:

| | |
|---------|----------------------|
| LDoms | LDoms implementation |
| control | Control domain |
| guest | Guest domain |
| I/O | I/O domain |
| service | Service domain |
| root | Root I/O domain |

Note that the `control` and `guest` values are mutually exclusive.

-u Shows the universally unique identifier (UUID) of the domain. See the [libuuid\(3LIB\)](#) man page.

Exit Status The following exit values are returned:

0 Successful completion.
>0 An error occurred.

Examples **EXAMPLE 1** Viewing Default Information

The following example shows the default information about the domain:

```
$ virtinfo
Domain role: LDoms control I/O service root
```

The current domain is the control domain, which is also an I/O domain, the service domain and a root I/O domain.

EXAMPLE 2 Viewing All Information

The following example shows all available information about the domain:

```
$ virtinfo -a
Domain role: LDoms control I/O service root
Domain name: primary
Domain UUID: 8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
Control domain: san-t2k-6
Chassis serial#: 0704RB0280
```

EXAMPLE 3 Viewing All Information In a Parsable Format

The following example shows all available information about the domain in a parsable format:

```
$ virtinfo -ap
VERSION 1.0
DOMAINROLE|impl=LDoms|control=true|io=true|service=true|root=true
DOMAINNAME|name=primary
DOMAINUUID|uuid=8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
DOMAINCONTROL|name=san-t2k-6
DOMAINCHASSIS|serialno=0704RB0280
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | Uncommitted |

See Also [libuuid\(3LIB\)](#), [libv12n\(3LIB\)](#)

Name vmstat – report virtual memory statistics

Synopsis vmstat [-cipqsS] [*disks*] [*interval* [*count*]]

Description vmstat reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity.

On MP (multi-processor) systems, vmstat averages the number of CPUs into the output. For per-processor statistics, see [mpstat\(1M\)](#).

vmstat only supports statistics for certain devices. For more general system statistics, use [sar\(1\)](#), [iostat\(1M\)](#), or [sar\(1M\)](#).

Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the vmstat output, in one of the following forms:

```
<<device added: sd0>>  
<<device removed: sd0>>  
<<processors added: 1, 3>>  
<<processors removed: 1, 3>>
```

See *System Administration Guide: Advanced Administration* for device naming conventions for disks.

Options The following options are supported:

- c Report cache flushing statistics. This option is obsolete, and no longer meaningful. This option might be removed in a future version of Solaris.
- i Report the number of interrupts per device. *count* and *interval* does not apply to the -i option.
- p Report paging activity in details. This option will display the following, respectively:
 - epl Executable page-ins.
 - epo Executable page-outs.
 - epf Executable page-frees.
 - api Anonymous page-ins.
 - apo Anonymous page-outs.
 - apf Anonymous page-frees.
 - fpi File system page-ins.
 - fpo File system page-outs.

fpf File system page-frees.

When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone's pool.

- q Suppress messages related to state changes.
- s Display the total number of various system events since boot. *count* and *interval* does not apply to the -s option.
- S Report on swapping rather than paging activity. This option will change two fields in *vmstat*'s "paging" display: rather than the "re" and "mf" fields, *vmstat* will report "si" (swap-ins) and "so" (swap-outs).

Operands The following operands are supported:

- count* Specifies the number of times that the statistics are repeated. *count* does not apply to the -i and -s options.
- disks* Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are *id*, *sd*, *xd*, or *xy*, followed by a number (for example, *sd2*, *xd0*, and so forth).
- interval* Specifies the last number of seconds over which *vmstat* summarizes activity. This number of seconds repeats forever. *interval* does not apply to the -i and -s options.

Examples EXAMPLE 1 Using *vmstat*

The following command displays a summary of what the system is doing every five seconds.

```
example% vmstat 5
```

```

kthr  memory          page          disk          faults          cpu

EXAMPLE 1 Using `vmstat` (Continued)

| | |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kthr</code> | Report the number of kernel threads in each of the three following states: <ul style="list-style-type: none"> <code>r</code> the number of kernel threads in run queue <code>b</code> the number of blocked kernel threads that are waiting for resources I/O, paging, and so forth <code>w</code> the number of swapped out lightweight processes (LWPs) that are waiting for processing resources to finish. |
| <code>memory</code> | Report on usage of virtual and real memory. <ul style="list-style-type: none"> <code>swap</code> available swap space (Kbytes) <code>free</code> size of the free list (Kbytes) |
| <code>page</code> | Report information about page faults and paging activity. The information on each of the following activities is given in units per second. <ul style="list-style-type: none"> <code>re</code> page reclaims — but see the <code>-S</code> option for how this field is modified. <code>mf</code> minor faults — but see the <code>-S</code> option for how this field is modified. <code>pi</code> kilobytes paged in <code>po</code> kilobytes paged out <code>fr</code> kilobytes freed <code>de</code> anticipated short-term memory shortfall (Kbytes) <code>sr</code> pages scanned by clock algorithm <p>When executed in a zone and if the pools facility is active, all of the above (except for “<code>de</code>”) only report activity on the processors in the processor set of the zone's pool.</p> |
| <code>disk</code> | Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (<code>s</code> = SCSI, <code>i</code> = IPI, and so forth); the number is the logical unit number. |
| <code>faults</code> | Report the trap/interrupt rates (per second). <ul style="list-style-type: none"> <code>in</code> interrupts <code>sy</code> system calls <code>cs</code> CPU context switches <p>When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone's pool.</p> |

EXAMPLE 1 Using vmstat (Continued)

cpu Give a breakdown of percentage usage of CPU time. On MP systems, this is an average across all processors.

us user time

sy system time

id idle time

When executed in a zone and if the pools facility is active, all of the above only report activity on the processors in the processor set of the zone's pool.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | See below. |

Invocation is evolving. Human readable output is unstable.

See Also [sar\(1\)](#), [iostat\(1M\)](#), [mpstat\(1M\)](#), [sar\(1M\)](#), [attributes\(5\)](#)

System Administration Guide: Basic Administration

System Administration Guide: Advanced Administration

Notes The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

The -c option (Report cache flushing statistics) is not supported in this release.

Name vntsd – virtual network terminal server daemon for Logical Domains

Synopsis /usr/lib/ldoms/vntsd

Description The vntsd daemon is a server that supports connections to the Logical Domains (LDDoms) console by using `telnet(1)`. When a telnet session starts, vntsd sends telnet options to the client indicating a willingness to remotely echo characters and to suppress go ahead.

Consoles are organized into groups by the LDDoms Manager. Each console group is assigned a unique group name and TCP port number. vntsd uses the group's port number to export access to the consoles within that group. To establish a connection with a console or console group, a user starts a `telnet(1)` session with the corresponding group's port number.

Depending on the number of consoles within that group, vntsd does one of two things:

- If there is only one console in the group, vntsd connects a session to that LDDoms console.
- If there are multiple consoles in the group, vntsd prompts the user to select the console to which they would like to connect, as shown in “Multiple-Console Options,” below.

For each console, vntsd provides write access only to the first user connecting to the console. Subsequent users connecting to the console are allowed only to read from the console and wait for write access. When the first user disconnects, write privileges are transferred to the next user waiting in the queue. If a user who does not have write privileges attempts to write to a console, the vntsd displays the following message:

```
You do not have write access
```

A user who has no write access can acquire write access forcibly by using the `~w` special console command, described in “Special Console Commands,” below.

vntsd can be invoked only with superuser privileges or by someone in the Primary Administrator role.

Options The options for vntsd are divided into multiple-console options and console commands.

Multiple-Console Options The options listed below are supported when there are multiple LDDoms consoles in a group. The syntax for the use of these options is:

```
<hostname>-vnts-<group-name>: <option>
```

For example:

```
myhost-vnts-salesgroup: h
```

The `h` option invokes help, as described below.

```
h
```

Display the following help text:

```
h -- this help
l -- list of consoles
q -- quit
c{id}, n{name} -- connect to console of domain {id} or domain name
```

l

List all consoles in the group. For example:

| DOMAIN ID | DOMAIN NAME | DOMAIN STATE |
|-----------|-------------|--------------|
| 0 | ldg1 | onLine |
| 1 | ldg2 | connected |
| ... | ... | ... |

The two domain states and their meanings are:

onLine

No one is connected to the console.

connected

At least one user is already connected to the console.

q

Disconnect from vntsd.

c{id}, n{name}

Connect to specified console. Upon connection, the following message is displayed:

```
Connecting to console <domain-name> in group <group-name>
Press ~? for control options ....
```

Special Console Commands

A tilde (~) appearing as the first character of a line is an escape signal that directs vntsd to perform a special console command. The tilde-tilde (~~) sequence outputs a tilde. In conjunction with the initial tilde, vntsd accepts the following special console commands:

~.

Disconnect from the console or console group.

~w

Force write access to the console.

~p

Disconnect from this console, and connect to the console that precedes this console in the list of consoles.

~n

Disconnect from this console, and connect to the console that follows this console in the list of consoles.

~#

Send break.

~^B

Send alternate break.

~?

Display vntsd help, as follows:

```

~# - Send break
~^B - Send alternate break
~. - Exit from this console
~w - Force write access
~n - Console next
~p - Console previous
~? - Help

```

Files /usr/lib/ldoms/vntsd
Binary executable vntsd file.

/usr/lib/ldoms/vntsd.xml
Service management facility ([smf\(5\)](#)) manifest file for vntsd.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWldoms |
| Interface Stability | Evolving |

See Also [telnet\(1\)](#), [svccfg\(1M\)](#), [usermod\(1M\)](#), [auth_attr\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The vntsd is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/ldoms/vntsd
```

You can change the following properties using the [svccfg\(1M\)](#) command:

vntsd/vcc_device

Set an instance of the virtual console concentrator (vcc) driver to which vntsd is connected.

vntsd/listen_addr

Set the IP address to which vntsd listens, using the following syntax:

```
vntsd/listen_addr:"xxx.xxx.xxx.xxx"
```

...where *xxx.xxx.xxx.xxx* is a valid IP address. The default value of this property is to listen on IP address 127.0.0.1. Users can connect to a guest console over a network if the value is set to the IP address of the control domain.

Note – Enabling network access to a console has security implications. Any user can connect to a console and for this reason it is disabled by default.

vntsd/timeout_minutes

Set timeout in minutes. vntsd will timeout (close) telnet connection if there is no activity (input or output) on the console. The default value is 0, which disables timeout.

vntsd/authorization

Enable the authorization checking of users and roles for the domain console or consoles that are being accessed. The default value of this property is `false` to maintain backward compatibility. To enable authorization checking, use the `svccfg(1M)` command to set the property value to `true`. While this option is enabled, `vntsd` listens and accepts connections on `localhost`. If the `listen_addr` property specifies an alternate IP address when this option is enabled, `vntsd` ignores the alternate IP address and continues to listen on `localhost`. Connections that are initiated from other hosts will also fail. Authorizations are available to access all consoles or console groups, or to access specific consoles or console groups. When the `vntsd` service is enabled, the following authorization is added to the authorization description database, `auth_attr(4)`:

```
solaris.vntsd.consoles::Access All LDoms Guest Consoles::
```

Add any fine-grained authorizations based on the name of the console group. For example, if the name of the console group to be authorized is `ldg1`, add the following entry to the `auth_attr(4)` file:

```
solaris.vntsd.console-ldg1::Access Specific LDoms Guest Console::
```

By default, the authorization to access all consoles is assigned to the root user or role. The Primary Administrator (`superuser`) can use the `usermod(1M)` command to assign the required authorization or authorizations to other users or roles.

The following example gives user `user1` the authorization to access all domain consoles:

```
# usermod -A "solaris.vntsd.consoles" user1
```

The following example gives user `user1` the authorization to access the console group named `ldg1`:

```
# usermod -A "solaris.vntsd.console-ldg1" user1
```

Name volcopy – make an image copy of file system

Synopsis volcopy [-F *FSType*] [-V] [*generic_options*]
[-o *FSType-specific_options*] *operands*

Description volcopy makes a literal copy of the file system. This command may not be supported for all *FSTypes*.

Options The following options are supported:

-F *FSType* Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by matching the *operands* with an entry in the table. Otherwise, the default file system type specified in `/etc/default/fs` will be used.

-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from `/etc/vfstab`. This option should be used to verify and validate the command line.

generic_options Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

-a Require the operator to respond “yes” or “no” instead of simply waiting ten seconds before the copy is made.

-s (Default) Invoke the DEL if wrong verification sequence.

-o *FSType-specific_options* Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

Operands The following operands are supported:

operands generally include the device and volume names and are file system specific. A detailed description of the *operands* can be found on the *FSType*-specific man pages of volcopy.

Exit Status The following exit values are returned:

0 Successful file system copy

1 An error has occurred.

- Files** /etc/vfstab list of default parameters for each file system
- /etc/default/fs default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs.
- LOCAL: The default partition for a command if no *FSType* is specified.

See Also [labelit\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#) Manual pages for the *FSType*-specific modules of volcopy.

Name volcopy_ufs – make an image copy of a ufs file system

Synopsis volcopy [-F ufs] [*generic_options*] *fsname srcdevice volname1 destdevice volname2*

Description volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.

Options The following option is supported:

generic_options options supported by the generic volcopy command. See [volcopy\(1M\)](#).

Operands The following operands are supported:

fsname represents the mount point (for example, root, u1, etc.) of the file system being copied.

srcdevice or *destdevice* the disk partition specified using the raw device (for example, /dev/rdisk/cld0s8, /dev/rdisk/cld1s8, etc.).

srcdevice and *volname1* the device and physical volume from which the copy of the file system is being extracted.

destdevice and *volname2* the target device and physical volume.

fsname and *volname* are limited to six or fewer characters and recorded in the superblock. *volname* may be '-' to use the existing volume name.

Exit Status The following exit values are returned:

0 Successful file system copy.

non-zero An error has occurred.

Files /var/adm/filesave.log a record of file systems/volumes copied

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [cpio\(1\)](#), [dd\(1M\)](#), [labelit\(1M\)](#), [volcopy\(1M\)](#), [attributes\(5\)](#), [ufs\(7FS\)](#)

Notes volcopy does not support copying to tape devices. Use [dd\(1M\)](#) for copying to and from tape devices.

Name vold – Volume Management daemon to manage removable media devices

Synopsis /usr/sbin/vold [-n] [-t] [-v] [-f *config-file*] [-l *log-file*]
[-d *root-dir*] [-L *debug-level*]

Description The Volume Management daemon, vold, creates and maintains a file system image rooted at *root-dir* that contains symbolic names for removable media devices. These devices include CD-R, CD-RW, floppies, DVD, and USB and 1394 mass storage devices. The default *root-dir* is set to /vol if no directory is specified by the -d option.

vold reads the /etc/vold.conf configuration file upon startup. If the configuration file is modified later, vold must be told to reread the /etc/vold.conf file. Accomplish this rereading by entering:

```
example# svcadm refresh volfs
```

To tell vold to clean up and exit, enter:

```
example# svcadm disable volfs
```

To reenable:

```
example# svcadm enable volfs
```

To specify options (see OPTIONS):

```
example# svccfg
svc:> select volfs
svc:/system/filesystem/volfs> listprop vold/*
vold/config_file          astring
vold/log_debuglevel       count    0
vold/log_file             astring
vold/log_nfs_trace        boolean  false
vold/log_verbose          boolean  false
vold/never_writeback_label boolean  false
vold/root_dir             astring
svc:/system/filesystem/volfs> setprop vold/never_writeback_label=true
svc:/system/filesystem/volfs> exit
```

```
# svcadm disable volfs
```

```
# svcadm enable volfs
```

vold is hotplug-aware for USB and 1394 mass storage devices, thus there is no need for stopping and restarting vold. It is recommended to [eject\(1\)](#) the “media” before hot-removing a device. The eject command unmounts any filesystems mounted from the media, making it safe to remove the device. (Note that all USB and 1394 devices, regardless of whether they contain removable media, are treated like removable media devices).

Options The following options are supported:

- n Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE.
- t Dump NFS trace information to the log file. The default setting is FALSE.
- v Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file).
- d *root-dir* Specify an alternate root directory. The default location is `/vol`. Setting this will also cause other Volume Management utilities to use this as the default root directory.
- f *config-file* Specify an alternate configuration file. The default file is `/etc/vold.conf`.
- l *log-file* Specify an alternate log file. The default log file is `/var/adm/vold.log`.
- L *debug-level* Change the level (verbosity) of debug messages sent to the log file. The range is 0 to 99 where 0 is nothing and 99 is everything. The default level is 0.

Environment Variables vold sets the following environment variables to aid programs which are called when events such as `insert`, `notify`, and `eject` occur:

- VOLUME_ACTION Event that caused this program to be executed.
- VOLUME_PATH Pathname of the matched *regex* from the `vold.conf` file.
- VOLUME_DEVICE Device (in `/vol/dev`) that applies to the media.
- VOLUME_NAME Name of the volume in question.
- VOLUME_USER User ID of the user causing the event to occur.
- VOLUME_SYMNAME Symbolic name of a device containing the volume.
- VOLUME_MEDIATYPE Name of the type of media (CD-ROM, floppy or rmdisk)

- Files**
- `/etc/vold.conf` Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
 - `/usr/lib/vold/*.so.1` Shared objects called by Volume Management daemon when certain actions occur.
 - `/var/adm/vold.log` the default log file location (see the `-l` option for a description).
 - `/vol` the default Volume Management root directory.

System Administration Guide: Basic Administration

Notes The Volume Management daemon and associated commands might not be included in a future Solaris release.

Name wall – write to all users

Synopsis /usr/sbin/wall [-a] [-g *grpname*] [*filename*]

Description wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:

```
Broadcast Message from . . .
```

If *filename* is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, -a will send the message even to such pseudo-terminals.

It is used to warn all users, typically prior to shutting down the system.

The sender must be superuser to override any protections the users may have invoked See [mesg\(1\)](#).

wall runs `setgid()` to the group ID `tty`, in order to have write permissions on other user's terminals. See [setuid\(2\)](#).

wall will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a "^" followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.

Options The following options are supported:

- a Broadcast message to the console and pseudo-terminals.
- g *grpname* Broadcast to the users in a specified group only, per the group database (see [group\(4\)](#)).

Environment Variables If the `LC_*` variables (`LC_CTYPE`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) are not set in the environment, the operational behavior of wall for each corresponding locale category is determined by the value of the `LANG` environment variable. See [environ\(5\)](#). If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how wall behaves.

Files /dev/tty*

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [msg\(1\)](#), [write\(1\)](#), [setuid\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#)

Notes `wall` displays "Cannot send to . . ." when the open on a user's tty file fails.

Name wanboot_keygen – create and display client and server keys for WAN booting

Synopsis /usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=3des
 /usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=aes
 /usr/lib/inet/wanboot/keygen -m
 /usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=sha1
 /usr/lib/inet/wanboot/keygen -d -m
 /usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=*keytype*

Description The keygen utility has three purposes:

- Using the -c flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys.
- Using the -m flag, to generate and store a “master” HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A.
- Using the -d flag along with either the -c or -m flag to indicate the key repository, to display a key of type specified by *keytype*, which must be one of 3des, aes, or sha1.

The net and cid arguments are used to identify a specific client. Both arguments are optional. If the cid option is not provided, the key being created or displayed will have a per-network scope. If the net option is not provided, then the key will have a global scope. Default net and code values are used to derive an HMAC SHA-1 key if the values are not provided by the user.

Options The following options are supported:

- c Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with -o.
- d Display a key of type specified by *keytype*, which must be one of 3des, aes, or sha1. Use -d with -m or with -c and -o.
- m Generate and store a “master” HMAC SHA-1 key for WAN install.
- o Specifies the WANboot client and/or keytype.

Examples EXAMPLE 1 Generate a Master HMAC SHA-1 Key

```
# keygen -m
```

EXAMPLE 2 Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

```
# keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
# keygen -d -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
```

EXAMPLE 3 Generate and Display a 3DES Key with a Per-Network Scope

```
# keygen -c -o net=172.16.174.0,type=3des
# keygen -d -o net=172.16.174.0,type=3des
```

Exit Status 0 Successful operation.

>0 An error occurred.

Name wanboot_keymgmt – insert and extract keys

Synopsis /usr/lib/inet/wanboot/keymgmt -i -k *key_file* -s *keystore* -o type=*keytype*
 /usr/lib/inet/wanboot/keymgmt -x -f *outfile* -s *keystore* -o type=*keytype*

Description The keymgmt utility has two purposes:

- To take a raw key, stored in *key_file*, and insert it in the repository specified by *keystore*.
- To extract a key of a specified type from the repository specified by *keystore*, depositing it in *outfile*.

outfile will be created if it does not already exist. The type of key being added or extracted is specified by *keytype* and may have one of four values: 3des, aes, rsa, or sha1 (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.

Arguments The following arguments are supported:

- i Used in conjunction with -k to insert a raw key in *keystore*.
- f *outfile* Used to specify a file to receive an extracted key.
- k *key_file* Used in conjunction with -i to specify the file in which a raw key is stored. This key will be inserted in *keystore*.
- o type=*keytype* Specifies the type of key being inserted or extracted. Must be one of 3des, aes, rsa, or sha1.
- s *keystore* Specifies a repository in which a key will be inserted or from which a key will be extracted.
- x Used in conjunction with -f to extract a key of a specified type and deposit it in *outfile*.

Exit Status 0 Successful operation.
 >0 An error occurred.

ITU-T Recommendation X.208

Name wanboot_p12split – split a PKCS #12 file into separate certificate and key files

Synopsis `/usr/lib/inet/wanboot/p12split -i p12file -c out_cert -k out_key
[-t out_trust -l id -v]`

Description The `p12split` utility extracts a certificate and private key from the repository specified by `p12file`, depositing the certificate in `out_cert` and the key in `out_key`. If supplied, the `-l` option specifies the value for the `LocalKeyId` that will be used in the new certificate and key files. `p12split` can optionally extract a trust certificate into the `out_trust` file if the `-t` option is specified. Use the `-v` option to get a verbose description of the split displayed to standard output.

Options The following arguments and options are supported:

- `-c out_cert` Specifies a repository that receives a extracted certificate.
- `-i p12file` Specifies a repository from which a certificate and private key is extracted.
- `-k out_key` Specifies a repository that receives a extracted private key.
- `-l id` Specifies the value for the `LocalKeyId` that will be used in the new certificate and key files.
- `-t out_trust` Specifies a file for receiving an extracted trust certificate.
- `-v` Displays a verbose description of the split to sdtout.

Exit Status `0` Successful operation.
`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWwbsup |
| Interface Stability | Unstable |

Name wanbootutil – manage keys and certificates for WAN booting

Synopsis wanbootutil [keygen] [*option_specific_arguments*]
 wanbootutil [keymgmt] [*option_specific_arguments*]
 wanbootutil [p12split] [*option_specific_arguments*]

Description The wanbootutil command creates and manages WANboot encryption and hashing keys and manipulates PKCS #12 files for use by WAN boot.

wanbootutil has three subcommands, each covered in a separate man page:

[wanboot_keygen\(1M\)](#) Generates encryption and hashing keys.

[wanboot_keymgmt\(1M\)](#) Inserts and extracts keys from WAN boot key repositories.

[wanboot_p12split\(1M\)](#) Splits a PKCS #12 file into separate certificate and key files for use by WAN boot.

Options The options supported for wanbootutil are the use of keygen, keymgmt, or p12split. The options for these subcommands are described in their respective man pages.

Examples **EXAMPLE 1** Generate a 3DES Client Key
 # wanbootutil keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=3des

EXAMPLE 2 Insert an RSA Private Client Key
 wanbootutil keymgmt -i -k keyfile \
 -s /etc/netboot/172.16.174.0/010003BA0E6A36/keystore -o type=rsa

EXAMPLE 3 Split a PKCS #12 File into Certificate and Key Components
 # wanbootutil p12split -i p12file -c out_cert -k out_key

Exit Status 0 Successful operation.
 non-zero An error occurred. Writes an appropriate error message to standard error.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWwbsup |
| Interface Stability | Obsolete |

Name wbemadmin – start Sun WBEM User Manager

Synopsis /usr/sadm/bin/wbemadmin

Description The `wbemadmin` utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The `wbemadmin` utility allows you to perform the following tasks:

| | |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Manage user access rights | Use the <code>wbemadmin</code> utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system. |
| Manage namespace access rights | Use the <code>wbemadmin</code> utility to add, delete, or modify access rights for all users to a namespace. |

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the `root\security` namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- `root\cimv2` — Contains the default CIM classes that represent objects on your system.
- `root\security` — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- **Read Only** — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- **Read/Write** — Allows full read, write, and delete access to all CIM classes and instances.
- **Write** — Allows write and delete, but not read access to all CIM classes and instances.
- **None** — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the `wbemadmin` dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The `wbemadmin` security administration tool updates the following Java classes in the `root\security` namespace:

- `Solaris_UserAcl` — Updated when access rights are granted or changed for a user.
- `Solaris_namespaceAcl` — Updated when access rights are granted or changed for a namespace.

Usage The `wbemadmin` utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The `wbemadmin` utility terminates with exit status 0.

Warning The `root\security` namespace stores access privileges. If you grant other users access to the `root\security` namespace, those users can grant themselves or other users rights to all other namespaces.

Name `wbemconfig` – convert a JavaSpaces datastore to the newer Reliable Log datastore format

Synopsis `/usr/sadm/lib/wbem/wbemconfig convert`

Description A Reliable Log directory is created that contains the converted data. This directory is named `/var/sadm/wbem/logr`.

The `convert` argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the `init.wbem stop` command. Otherwise your data may be corrupted.

This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the `mofcomp` command on the MOF files containing the class definitions.

Because the `wbemconfig convert` command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the `wbemconfig convert` command is completed, you can change to any version of the JVM you want.

To see what version of the JVM you are running, issue the `java -version` command.

Options The following options are supported:

`convert` Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWwbcou |

See Also [init.wbem\(1M\)](#), [wbemadmin\(1M\)](#), [wbemlogviewer\(1M\)](#), [mofcomp\(1M\)](#), [attributes\(5\)](#)

Name wbemlogviewer – start WBEM Log Viewer

Synopsis /usr/sadm/bin/wbemlogviewer

Description The `wbemlogviewer` utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the `root\cimv2` namespace to view and maintain log files. Namespaces are described in [wbemadmin\(1M\)](#).

Log events can have three severity levels.

- Errors
- Warnings
- Informational

The WBEM log file is created in the `/var/sadm/wbem/log` directory, with the name `wbem_log`. The first time the log file is backed up, it is renamed `wbem_log.1`, and a new `wbem_log` file is created. Each succeeding time the `wbem_log` file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed *if* the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files.

The log file is renamed with a `.1` file extension and saved when one of the following two conditions occur:

- The current file reaches the specified file size limit.
- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.
- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.
- A user chooses Action->Back Up Now in the Log Viewer application.

Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.

Usage The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.

The WBEM Log Viewer allows you to perform the following tasks:

View the logs

Set properties of log files Click Action->Log File Settings to specify log file parameters and the log file directory.

Back up a log file Click Action->Back Up Now to back up and close the current log file and start a new log file.

- Open historical log files Click Action->Open Log File to open a backed-up log file.
- Delete an old log file Open the file and then click Action->Delete Log File. You can only delete backed-up log files.
- View log record details Double-click a log entry or click View->Log Entry Details to display the details of a log record.
- Sort the logs Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

Exit Status The `wbemlogviewer` utility terminates with exit status 0.

Files `/var/sadm/wbem/log/wbem_log` WBEM log file

- Name** wadmin – manage the configuration of the Sun Java Web Console
- Synopsis** `/usr/sbin/wadmin subcommand options`
`/usr/sbin/wadmin [-h|--help]`
`/usr/sbin/wadmin [-V|--version]`
- Description** wadmin is a Command Line Interface (CLI) — based tool for managing the configuration of the Sun Java Web Console.
- Subcommands** The following subcommands are supported:
- add** The wadmin `add` subcommand adds a new shared jar file, a new JAAS login module, or a new shared service property to the console configuration. An optional identifier may be specified; if omitted, the identifier is derived from the resource name. The resource is added when the console is next started.
- The format of the `add` subcommand is:
- ```
add -l -a appname [-n id] jarpath
add -m -a appname [-n id] -b behavior -s service [-o name=value] classname
add -p -a appname name=value [... name=value]
```
- deploy** The wadmin `deploy` subcommand deploys the specified web application into the console's web server instance. Applications are deployed directly from their installation directories.
- The format of the `deploy` subcommand is:
- ```
deploy [-D] -a appname -x context app_path
```
- disable** The wadmin `disable` subcommand disables access to the specified web application in the console's web server instance.
- The format of the `disable` subcommand is:
- ```
disable -x context
```
- enable** The wadmin `enable` subcommand enables access to the specified web application in the console's web server instance.
- The format of the `enable` subcommand is:
- ```
enable -x context
```
- list** The wadmin `list` subcommand lists the resources currently configured for the console; including deployed web applications, shared jar files, login modules, and shared service properties. If no option is specified, all resources are listed.

The format of the `list` subcommand is:

```
list [-a] [-d] [-l] [-m] [-p]
```

`password` The `wadmin password` subcommand manages the administrator and security keystore passwords for the console. Keystore passwords should not be changed while the console is running.

The format of the `password` subcommand is:

```
password [-a] [-k] [-t]
```

```
password -f password_file
```

`reload` The `wadmin reload` subcommand unloads the specified web application from the console's web server instance and reloads the application from its original installation directory.

The format of the `reload` subcommand is:

```
reload -x context
```

`remove` The `wadmin remove` subcommand removes a shared jar file, a login module, or a shared service property from the console configuration. The resource may be specified by its identifier or by its full jarpath or classname. The resource is removed when the console is next started.

The format of the `remove` subcommand is:

```
remove -l -a appname [-n id] jarpath
```

```
remove -m -a appname [-n id] classname
```

```
remove -p -a appname property [...]
```

`undeploy` The `wadmin undeploy` subcommand undeploys the specified web application from the console's web server instance.

The format of the `undeploy` subcommand is:

```
undeploy [-D] -a appname -x context
```

Options The following options are supported:

`-h` | `--help` | `-?` Display runtime help.

`-V` | `--version` Display console version information.

`-D` | `--defer` When used with the `deploy` and `undeploy` subcommands, defers the deployment or undeployment until the next console restart.

The operation is deferred by simply adding or removing the corresponding resource registration notification file. If `defer` is not specified, a runtime deployment or undeployment is performed, so that the application becomes available or unavailable in the running console. If the console instance is not currently running, the operation is automatically deferred.

| | |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-a</code> <code>--adminpassword</code> | Specify that the administrator password should be changed, when used with <code>password</code> subcommand. You are prompted for a new password, which must be 8 to 32 characters. |
| <code>-a</code> <code>--application</code> | Specify the application name, when used with subcommands other than <code>password</code> subcommand. |
| <code>-d</code> <code>--detail</code> | Specify that configuration details of each resource should be displayed. |
| <code>-f</code> | Specify the fully qualified path name to a file containing one or more password property values. See the description of the <code>password_file</code> argument. |
| <code>-k</code> <code>--keypassword</code> | Specify that the keystore password should be changed. You are prompted for a new password, which must be 8 to 32 characters. |
| <code>-l</code> <code>--library</code> | Specify that the resource is a shared jar file. |
| <code>-m</code> <code>--module</code> | Specify that the resource is a JAAS login module. |
| <code>-n</code> <code>--name</code> | Specify the short-hand identifier name for the resource. If omitted, the identifier name is derived from the full resource name. |
| <code>-o</code> <code>--option</code> | Specify the name and value of a login module option property, separated by the equals character. |
| <code>-p</code> <code>--property</code> | Specify that the resource is one or more shared service properties. |
| <code>-s</code> <code>--service</code> | Specify the name of the JAAS login service definition. If omitted, the default console login service definition is assumed. |
| <code>-t</code> <code>--trustpassword</code> | Specify that the truststore password should be changed. You are prompted for a new password, which must be 8 to 32 characters. |
| <code>-x</code> <code>--context</code> | Specify the web application context path name under which the application is deployed. |

| | | |
|------------------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Arguments | <i>app_path</i> | The fully qualified file system path to the web application installation directory. |
| | <i>appname</i> | The application name. The name must be unique among all web applications registered with the console. It is also used as the name of the subdirectory under the console's pre-registration directory which contains |

| | |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | all the resource registration notification files for that application. Typically, the application package name, plugin identifier, or context path name is specified for the application name. |
| <i>behavior</i> | The JAAS login module control flag behavior. Must be one of “optional”, “required”, “requisite”, or “sufficient”. |
| <i>classname</i> | The fully qualified Java package class name of the JAAS login module. The specified class must be included in a shared jar file added to the console. |
| <i>context</i> | The web application context path name under which the application is deployed. With the .reg suffix, the context forms the file name of the registration notification file for that application. |
| <i>id</i> | The short-hand identifier name for a jar file or login module resource to be added or removed. The identifier name must be unique among the resources shared for a given application name. With the .reg suffix, it forms the file name of the registration notification file for that resource. |
| <i>jarpath</i> | The fully qualified file system path to the jar file resource. When the resource is added to the console, its path is included in the classpath of the console's shared class loader. |
| <i>option</i> | The JAAS login module option property name. |
| <i>property</i> | The shared service property name. |
| <i>password_file</i> | The fully qualified path to a password text file that contains the new administrator, keystore, and truststore passwords in property file format. The administrator password is specified using the “adminpassword” property. The keystore password is specified using the “keypassword” property. The truststore password is specified using the “trustpasswd” property. At least one password property must be contained in the password file. |
| <i>value</i> | The login module option or shared service property value. If the value contains white space, it must be quoted. |

Examples The following command adds a jar file to be shared in the console:

```
wcadmin add -l -a myapp_1.0 -n wbem /usr/sadm/lib/wbem.jar
```

The following command deploys a new web application:

```
wcadmin deploy -a myapp_1.0 -x myapp /opt/SUNWmyapp/myapp
```

The following command reloads an existing web application:

```
wcadmin reload -x myapp
```

The following command undeploys a web application at the next server restart:

```
wadmin undeploy -D -a myapp_1.0 -x myapp
```

The following command lists all the deployed web applications in the console. If the status field is “running”, the web application is available. If the status field is “stopped”, the web application is disabled and is not available. If all web applications are “stopped”, this typically indicates the console web server instance is not running.

```
wadmin list -a
```

The following command removes a shared jar file:

```
wadmin remove -l -a myapp_1.0 -n wben
```

The following command changes passwords that are specified in a file:

```
wadmin password -f /home/mydir/console-passwords
```

Exit Status The following exit values are returned:

- 0 Subcommand succeeded without error
- 1 Usage error: missing or malformed arguments
- 2 Fatal error: subcommand failed with one or more errors

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name whodo – who is doing what

Synopsis /usr/sbin/whodo [-h] [-l] [*user*]

Description The whodo command produces formatted and dated output from information in the /var/adm/utmpx and /proc/pid files.

The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.

If *user* is specified, output is restricted to all sessions pertaining to that user.

Options The following options are supported:

- h Suppress the heading.
- l Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in *hours:minutes*), the idle time — that is, the time since the user last typed anything (in *hours:minutes*), the CPU time used by all processes and their children on that terminal (in *minutes:seconds*), the CPU time used by the currently active processes (in *minutes:seconds*), and the name and arguments of the current process.

Examples EXAMPLE 1 Using the whodo Command

The command:

```
example% whodo
```

produces a display like this:

```
Tue Mar 12 15:48:03 1985
bailey
tty09   mcn      8:51
      tty09  28158    0:29 sh

tty52   bdr      15:23
      tty52  21688    0:05 sh
      tty52  22788    0:01 whodo
      tty52  22017    0:03 vi
      tty52  22549    0:01 sh

xt162   lee      10:20
      tty08   6748    0:01 layers
      xt162   6751    0:01 sh
      xt163   6761    0:05 sh
      tty08   6536    0:05 sh
```

Environment Variables If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of [tar\(1\)](#) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the C (U.S. style) locale determines how whodo behaves.

| | |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LC_CTYPE | Determines how whodo handles characters. When LC_CTYPE is set to a valid value, whodo can display and handle text and filenames containing valid characters for that locale. The whodo command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. whodo can also handle EUC characters of 1, 2, or more column widths. In the C locale, only characters from ISO 8859-1 are valid. |
| LC_MESSAGES | Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the C locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English). |
| LC_TIME | Determines how whodo handles date and time formats. In the C locale, date and time handling follow the U.S. rules. |

Exit Status The following exit values are returned:

| | |
|----------|------------------------|
| 0 | Successful completion. |
| non-zero | An error occurred. |

| | | |
|--------------|----------------|--------------------------------------------|
| Files | /etc/passwd | System password file |
| | /var/adm/utmpx | User access and administration information |
| | /proc/pid | PID information for individual users |

Name wraacct – write extended accounting records for active processes and tasks

Synopsis `/usr/sbin/wraacct -i id_list [-t record_type]`
`{process | task}`

Description The wraacct utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a *record_type* option is also supported, allowing the administrator to request the writing of:

- an interval record, which reflects task usage since a previous interval record (or since task creation if there is no interval record), or
- a partial record, which reflects usage since task creation.

Options The following options are supported:

- `-i id_list` Select the IDs of the tasks or processes to write records for. Specify *id_list* as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.
- `-t record_type` Select type of record to write for the selected task or process. For tasks, *record_type* can be `partial` or `interval`. `partial` is the default type, and the only type available for process records.

Operands The following operands are supported:

- `process` Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.
- `task` Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.

Examples EXAMPLE 1 Writing a Partial Record

Write a partial record for all active sendmail processes.

```
# /usr/sbin/wraacct -i "pgrep sendmail" process
```

EXAMPLE 2 Writing an Interval Record

Write an interval record for the task with ID 182.

```
# /usr/sbin/wraacct -t interval -i 182 task
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command line options were specified.

3 Pertinent components of extended accounting facility are not active.

Files /var/adm/exacct/task

/var/adm/exacct/proc Extended accounting data files.

Name wrsmconf – manage WCI RSM controller configurations

Synopsis /usr/platform/sun4u/sbin/wrsmconf create -c *controller_id* -f *config_file*

wrsmconf initial -f *config_file* [-c *controller_id*]

wrsmconf remove [-c *controller_id*]

wrsmconf topology [-c *controller_id*]

wrsmconf dump -c *controller_id* -f *config_file*

Description wrsmconf provides a means to create, install, retrieve, and remove configurations for WCI remote shared memory (RSM) controllers.

Options The following options are supported:

create -c *controller_id* -f *config_file*

Create a set of per-node configurations for the specified controller and store them to the file *config_file*. The created file contains a per-node configuration for each node specified in the input for the specified controller. The file has a checksum on it and cannot be modified directly. This file can be used in a `wrsmconf initial` call on each node to install the node's configuration into the local driver.

A list of nodes and WCI devices connected to those nodes is read from standard input. For each connected pair of links, specify the nodename (uname -n), safari port id, and link number on both sides of the connection. The format of the information looks like this:

```
<nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno>
<nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno>
```

This interface is intended for installing configurations for testing (such as for SunVTS). Only direct-connect, non-striped configurations for 1 to 3 nodes can be specified. FM node ids and RSM hardware addresses are assigned to the specified nodes contiguously and in order starting from 0.

initial -f *config_file* [-c *controller_id*]

Install the configuration for the local node stored in the file *config_file* into the driver as the initial configuration for the specified controller. This command fails under the following circumstances:

- If *controller_id* is specified and the configuration in the file is not for the specified controller.
- If the file does not contain a valid configuration for the local node or if the checksum in the file shows it has been modified.
- If a configuration has already been installed for the controller. If this happens, use `wrsmsconf remove` to remove the existing configuration.

`remove [-c controller_id]`

Disable communication through the installed configuration for all controllers or the specified controller and remove the configuration(s) from the driver.

`topology -c controller_id`

For each installed controller (or for the specified controller), print to stdout the set of nodes this controller is configured to reach, including the nodename, FM node id, and RSM hardware address for each node. The following is example output:

| FM Node ID | Node Name | Controller Instance | Controller HW Addr |
|------------|-----------|---------------------|--------------------|
| 0 | hpc00 | 0 | 101 |
| 0 | hpc00 | 1 | 333 |
| 1 | hpc01 | 0 | 102 |
| 1 | hpc01 | 1 | 54 |
| 1 | hpc01 | 2 | 34 |
| 2 | hpc03 | 0 | 103 |
| 2 | hpc03 | 1 | 103 |
| 2 | hpc03 | 2 | 103 |

`dump -c controller-id -f config_file`

Fetch the installed configuration for the specified controller from the driver and store it into the file *config_file* along with a checksum to protect the data. This configuration can later be installed with the command `wrsmsconf install`.

Exit Status This command returns 0 on successful completion, and a non-zero value if an error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWwrsm |

See Also [kstat\(1M\)](#), [wrsmstat\(1M\)](#), [attributes\(5\)](#)

- Name** wrsmstat – report WCI RSM driver statistics
- Synopsis** /usr/platform/sun4u/sbin/wrsmstat controller
 [-c *controller_id*]
- wrsmstat wrsm [-i *wrsm_instance_num*] [-v]
- wrsmstat route [-c *controller_id*]
 [-h *node_hostname*]
- wrsmstat set [-i *wrsm_instance_num*] -c *cmmu* -s *start* -e *end*
- Description** The wrsmstat command provides statistics on remote shared memory (RSM) controllers, routes to nodes, and WCI interfaces managed by the WCI RSM driver (*wrsm*). It also provides an interface for setting extended performance counter control registers that constrain the wrsm counters available through [busstat\(1M\)](#).

Options The following options are supported:

controller [-c *controller_id*]

Displays information describing the state of the specified controller, or of all controllers if none is specified. The following is sample output:

```
$ wrsmstat controller -c 5 Controller 5 ----- Controller state: up Local RSM
Hardware address: 0x4 Exported segments: 0 # published: 0 # connections: 0 total bound
memory: 0 Imported segments: 0 Send Queues: 0 Registered Handlers: 0 Assigned WCIs: 4
Available WCIs: 2
```

wrsm [-i *wrsm_instance_num*] [-v]

Displays information describing the state of the specified RSM WCI, or of all RSM WCIs if none is specified. The following is sample output:

```
$ wrsmstat wrsm -i 2
WCI instance 2
-----
Portid: 5
Controller ID: 0
Config Version: 5
Link Error Shutdown Trigger: 40000
Link #0 is not present.
Link #1
  Link Enabled: yes
  Link State: up
  Remote RSM HW addr: 1
  Remote wnode ID: 1
  Remote link num: 1
  Remote WCI port ID: 3
  Error takedowns: 0
  Bad Config takedowns: 0
  Failed bringups: 0
```

```

    Total link errors: 0
    Maximum link errors: 0
    Average link errors: 0
    Auto shutdown enabled: yes
Link #2 is not present.

```

If you specify the `-v` option, the following additional information is displayed:

```

Cluster Error Count:      0
Uncorrectable SRAM ECC error:  no
Maximum SRAM ECC errors:  0
Average SRAM ECC errors:  0

```

`route [-c controller_id] [-h nodename]`

Displays the route to the specified node through the specified controller. If no node is specified, displays the routes to all nodes. If no controller is specified, displays the specified node's route through all controllers. If neither is specified, displays the routes to all nodes through all controllers. The following is sample output:

```

$ wrsmstat -c 3 -h fred
Controller 3 - Route to fred
-----
Config Version: 1
FM node id: 0x345543
RSM hardware address: 0x9
Route Changes: 3
Route Type: Passthrough
Number of WCIs: 2
Stripes: 4
WCI #0
  Port ID: 3
  Instance: 0
  Num of hops: 2
  Num of links: 2
    link# 1, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2
WCI #1
  Port ID: 13
  Instance: 1
  Num of hops: 2
  Num of links: 2
    link# 0, first hop RSM HW addr: 0x4
    link# 2, first hop RSM HW addr: 0x2

```

`set [-i wrsm_instance_num] -c cmmu -s <start> -e <end>`

For the specified WCI (or for each RSM WCI if none specified), configure the specified range of CMMU entries so that transactions through them are counted by `wrsm busstats` and `ksstats`. Each call will cause transactions to be counted through the new ranges of `cmmu` entries in addition to the previously specified ranges. To count transactions through all CMMUs, specify a start value of 0 and end value of 0. To clear all ranges (and not count

transactions through any cmmu entries), specify a start value of 0 and end value of -1.

Exit Status This command returns 0 on successful completion, and a non-zero value if an error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWwrm |

Name xntpd – Network Time Protocol daemon

Synopsis /usr/lib/inet/xntpd [-aAbdm] [-c *conffile*] [-e *authdelay*]
[-f *driftfile*] [-k *keyfile*] [-l *logfile*] [-p *pidfile*]
[-r *broadcastdelay*] [-s *statsdir*] [-t *trustedkey*]
[-v *variable*] [-V *variable*]

Description xntpd is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. xntpd is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by *RFC 1305*. It also retains compatibility with version 1 and 2 servers as defined by *RFC 1059* and *RFC 1119*, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source.

Ordinarily, xntpd reads its configuration from a configuration file at startup time. The default configuration file name is `/etc/inet/ntp.conf`, although this may be overridden from the command line. It is also possible to specify a working, although limited, xntpd configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when xntpd is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the [ntpq\(1M\)](#) program, various internal xntpd variables can be displayed and configuration options altered while the daemon is running.

The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.

Options The following command line arguments are understood by xntpd. See Configuration Commands for a more complete functional description:

- a Run in authentication mode.
- A Disable authentication mode.
- b Listen for broadcast NTP and sync to this if available.
- c *conffile* Specify an alternate configuration file.
- d Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.
- e *authdelay* Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.
- f *driftfile* Specify the location of the drift file.

| | |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -k <i>keyfile</i> | Specify the location of the file which contains the NTP authentication keys. |
| -l <i>logfile</i> | Specify a log file instead of logging to syslog. |
| -m | Listen for multicast messages and synchronize to them if available (requires multicast kernel). |
| -p <i>pidfile</i> | Specify the name of the file to record the daemon's process id. |
| -r <i>broadcast</i> | Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds). |
| -s <i>statsdir</i> | Specify the directory to be used for creating statistics files. |
| -t <i>trustedkey</i> | Add a key number to the trusted key list. |
| -v <i>variable</i> | Add a system variable. |
| -V <i>variable</i> | Add a system variable listed by default. |

Usage xntpd's configuration file format is similar to other Unix configuration files. Comments begin with a '#' character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted–decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

Configuration Commands In the following descriptions, optional arguments are delimited by '[]', while alternatives are separated by '|'. The first three commands specify various time servers to be used and time services to be provided.

`peer host_address [key #] [version #] [prefer]` Specifies that the local server is to operate in “symmetric active” mode with the remote server *host_address* named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The `peer` command, and the `server` and `broadcast` commands that follow, can take the following arguments:

| | |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| key | Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included. |
| version | Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default. |
| prefer | Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts. |

`server host_address [key #] [version fl#]
[prefer] [mode fl#] server`

Specifies that the local server is to operate in “client” mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.

`broadcast host_address [key #] [version #] [ttl #]`

Specifies that the local server is to operate in “broadcast” mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see `broadcastclient` or `multicastclient` commands elsewhere in this document. In

broadcast mode the *host_address* is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network, 224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

`ttl` Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

`broadcastclient`

Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the “broadcastclient” mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

`multicastclient`

[*IP address . . .*] Used in the same way as the `broadcastclient` command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s).

`driftfile filename`

If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

```
enable
auth | bclient | pll | monitor | stats [...]
disable
auth | bclient | pll | monitor | stats
[...]
```

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.

| Flag | Default | Description |
|---------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| auth | disable | Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier. |
| bclient | disable | Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. default for this flag is disable (off). |
| pll | enable | Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients. |
| monitor | disable | Enables the monitoring facility (see elsewhere). |
| stats | enable | Enables statistics facility filegen (see Monitoring Commands below). |

slewalways [yes|no]

Force xntpd to always slew the time.

Authentication
Commands

keys *filename* Specifies the name of a file which contains the encryption keys and key identifiers used by xntpd when operating in authenticated mode. The format of this file is described later in this document.

trustedkey # [# . . .] Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The

authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key 0 is fixed and globally known. If meaningful authentication is to be performed, the 0 key should not be trusted.

`controlkey #` Specifies the key identifier to use with the `ntpq(1M)` program, which is useful to diagnose and repair problems that affect `xntpd` operation. The operation of the `ntpq` program and `xntpd` conform to those specified in *RFC 1305*. Requests from a remote `ntpq` program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no `controlkey` command is included in the configuration file, or if the keys don't match. These requests are ignored.

Access Control Commands `restrict address [mask numeric_mask] [flag] [. . .]`
`xntpd` implements a general purpose address-and-mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted-quad format, the text string "default", with no mask option, may be used to indicate the default entry.

In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server.

One or more of the following flags may be specified:

| | |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ignore</code> | Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to. |
| <code>noquery</code> | Ignore all NTP mode 7 packets (i.e., information queries and configuration requests) from the source. Time service is not affected. |

| | |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>nomodify</code> | Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted. |
| <code>notrap</code> | Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs. |
| <code>lowpriotrap</code> | Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps. |
| <code>noserve</code> | Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted. |
| <code>nopeer</code> | Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners. |
| <code>notrust</code> | Treat these hosts normally in other respects, but never use them as synchronization sources. |
| <code>limited</code> | These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers to the IP notion of net (class A, class B, class C, etc.). Only the first <i>client_limit</i> hosts that have shown up at the server and that have been active during the last <i>client_limit_period</i> seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. “Private”, “control”, and “broadcast” packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of xntpd. Thus, monitoring is active as long as there is a restriction entry with the <code>limited</code> flag. The default value for <i>client_limit</i> is 3. The default value for <i>client_limit_period</i> is 3600 seconds. Currently both variables are not runtime configurable. |
| <code>ntpport</code> | This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard |

NTP UDP port (123). Both `ntpport` and `non-ntpport` may be specified. The `ntpport` is considered more specific and is sorted later in the list.

Default restriction list entries, with the flags, `ignore`, `ntpport`, for each of the local host's interface addresses are inserted into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with `xntpd` as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

| | |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>clientlimit limit</code> | Sets <code>client_limit</code> to <code>limit</code> ; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server. |
| <code>clientperiod period</code> | Sets <code>client_limit_period</code> ; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction. |

Monitoring Commands `statsdir /directory path/`

Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) filegen filename prefix to be modified for file generation sets used for handling statistics logs (see `filegen` statement below).

`statistics name...`

Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its *name*, a sample line of data, and an explanation of each field:

`loopstats` enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named "loopstats":

```
48773 10847.650 0.0001307 17.3478 2
```

| Field No. | Description |
|-----------|-------------|
|-----------|-------------|

| | |
|---|--------------------------------|
| 1 | The date (Modified Julian day) |
|---|--------------------------------|

| | |
|---|---------------------------------------------------|
| 2 | The time (seconds and fraction past UTC midnight) |
|---|---------------------------------------------------|

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3 | Time offset in seconds |
| 4 | Frequency offset in parts-per-million |
| 5 | Time constant of the clock-discipline algorithm at each update of the clock |
| peerstats | enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats": |
| | <pre>48773 10847.650 127.127.4.1 9714 -0.001605 \ 0.00000 0.00142</pre> |

| Field No. | Description |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The date (Modified Julian Day) |
| 2 | The time (seconds and fraction past UTC midnight) |
| 3 | The peer address in dotted-quad notation |
| 4 | peer status. The status field is encoded in hex in the format described in Appendix B.2.2 of the NTP specification, <i>RFC 1305</i> . |
| 5 | Offset in seconds |
| 6 | Delay in seconds |
| 7 | Dispersion in seconds |
| clockstats | enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats": |
| | <pre>49213 525.624 127.127.4.1 93 226 \ 00:08:29.606 D</pre> |

| Field No. | Description |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | The date (Modified Julian Day) |
| 2 | The time (seconds and fraction past UTC midnight) |
| 3 | The clock address in dotted-quad notation |
| 4 | The last timecode received from the clock in decoded ASCII format, where meaningful |
| | In some clock drivers a good deal of additional information can be gathered and displayed as well. |
| | Statistic files are managed using file generation sets (see <code>filegen</code> below). The information obtained by enabling statistics recording allows analysis |

of temporal properties of a xntpd server. It is usually only useful to primary servers or maybe main campus servers.

```
filegen name [ file filename ] [ type typename ][ flag flagval ]
[ link | nolink ] [ enable | disable ]
```

Configures setting of generation file set *name*. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The type given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of xntpd. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

- prefix* This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with “loopstats” and “peerstats” filegens can be configured using the `statsdir` statement explained above.
- filename* This string is directly concatenated to the *prefix* mentioned above (no intervening ‘/’ (slash)). This can be modified using the `file` argument to the `filegen` statement. No ‘.’ elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by *prefix*.
- suffix* This part reflects individual elements of a file set. It is generated according to the type of a file set as explained below.

A file generation set is characterized by its type. The following types are supported:

- none* The file set is actually a single plain file.
- pid* One element of file set is used per incarnation of a xntpd server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different xntpd server incarnations. The set member filename is built by appending a ‘.’ (dot) to concatenated *prefix* and *filename* strings, and appending the decimal representation of the process id of the xntpd server process.
- day* One file generation set element is created per day. The term *day* is based on UTC. A day is defined as the period between 00:00 and 24:00 UTC. The file set member suffix consists of a ‘.’ (dot) and a day specification in the form, *YYYYMMDD*. *YYYY* is a 4 digit year number (e.g., 1992). *MM* is a two digit month number. *DD* is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, *PrefixFilename.19921210*.

| | |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| week | Any file set member contains data related to a certain week of a year. The term <i>week</i> is defined by computing “day of year” modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter ‘W’, and a two digit week number. For example, information from January, 5th 1992 would end up in a file with suffix “.1992W1”. |
| month | One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month. |
| year | One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number. |
| age | This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter ‘a’, and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period. |

Information is only written to a file generation set when this set is enabled. Output is prevented by specifying, `disabled`.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying `link` and disabled using `no link`. If `link` is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter, ‘C’, and the pid of the xntpd server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

Miscellaneous
Commands

`broadcastdelay` *seconds*

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for *seconds*. When this command is not used, the default is 0.004 seconds.

`trap` *host_address* [`port` *port_number*]
[`interface` *interface_address*]

Configures a trap receiver at the given *host_address* and *port_number* for sending

messages with the specified local *interface_address*. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with the source address of the local interface the message is sent through. On a multi-homed host, the interface used may change with routing changes.

C information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that no messages are lost when the server is started.

`setvar variable [default]`

This command adds an additional system variable. Variables like this can be used to distribute additional information such as the access policy. If the variable of the form, *variable_name=value* is followed by the *default* keyword, the variable will be listed as one of the default system variables (see the [ntpq\(1M\)](#) command). Additional variables serve informational purposes only. They can be listed; but they are not related to the protocol. The known protocol variables always override any variables defined via the `setvar` mechanism.

Three special variables contain the names of all variable of the same group. *sys_var_list* holds the names of all system variables. *peer_var_list* holds the names of all peer variables. And *clock_var_list* hold the names of the reference clock variables.

`monitor [yes | no]`
`authenticate [yes | no]`

These commands have been superseded by the `enable` and `disable` commands. They are listed here for historical purposes.

`logconfig configkeyword`

Controls the amount of output written to syslog or the logfile. By default all output is turned on. *configkeyword* is formed by concatenating the message class with the event class. It is permissible to use the prefix, `all`, instead of a message class. A message class may also be

followed by the keyword, `all`, meaning to enable/disable all of the respective message class. All *configkeywords* can be prefixed with the symbols, '=', '+' and '-'. Here, '=' sets the `syslogmask`, '+' adds messages, and '-' removes messages. Syslog messages can be controlled in four classes: *sys*, *peer*, *clock*, *sync*. Within these classes four types of messages can be controlled. Each is described below, along with its `configkeyword`:

| Configkeyword | Message type |
|-------------------------|---------------------------------------------------------------------------------------------|
| <code>info</code> | Informational messages control configuration information. |
| <code>events</code> | Event messages control logging of events (reachability, synchronization, alarm conditions). |
| <code>statistics</code> | Statistical messages control statistical output. |
| <code>status</code> | Status messages describe mainly the synchronization status. |

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of `xntp` and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.

Authentication Key File Format The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in xntpd using the DES or MD5 algorithms to compute a digital signature, or message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). xntpd reads its keys from a file specified using the -k command line option or the keys statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, *keyno type key*. Here, *keyno* is a positive integer, *type* is a single character which defines the format the key is given in, and *key* is the key itself.

The *key* may be given in one of several different formats, controlled by the *type* character. The different key types, and corresponding formats, are described below:

Key: S

Format: A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key, in standard format, would be given as: 01010101010101.

Key: N

Format: A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: 8080808080808080.

Key: A

Format: A 1-to-8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string. Zeroes are added on the right when necessary to form a full width 56 bit key.

Key: M

Format : A 1–to–8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support xntpd has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, xntpd treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form *127.127.t.u* where *t* is an integer denoting the clock type and *u* indicates the type-specific unit number. Reference clocks are configured using a *server* statement in the configuration file where the *host_address* is the clock address. The *key*, *version* and *ttl* options are not used for reference clock support. Some reference clocks require a *mode* option to further specify their operation. The *prefer* option can be useful to persuade the server to cherish a reference clock with somewhat more enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in *restrict* statements, although such use would normally be considered strange.

Reference clock support provides the *fudge* command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is,

```
fudge 127.127.t.u [ time1 secs ] [ time2 secs ] \
    [ stratum int ] [ refid int ] \
    [ flag1 0|1 ] [ flag2 0|1 ] [ flag3 0|1 ] [ flag4 0|1 ]
```

with options described as follows:

time1

time2

Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, *time1* is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.

stratum

Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.

refid

Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.

flag1
flag2
flag3
flag4

Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, *flag3* invokes the TIOCSPPS ioctl, while *flag4* is used to enable recording verbose monitoring data to the clockstats file configured with the `filegen` command.

Ordinarily, the stratum of a reference clock is zero, by default. Since the `xntpd` daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The `stratum` option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The `refid` option is used for this purpose. Except where noted, these options apply to all clock drivers.

`xntpd` on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo-clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the README file in the `./doc` directory of the `xntp3` program distribution. The clock drivers, and the addresses used to configure them, are described in the file, `README.refclocks`, in the `doc` directory of the current program distribution.

Variables Most variables used by the NTP protocol can be examined with `ntpq` (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These variables are either created with the `setvar` directive or the leap warning variables. The leap warning bits that can be set in the `leapwarning` variable (up to one month ahead). Both, the `leapwarning` and in the `leapindication` variable, have a slightly different encoding than the usual leap bits interpretation:

`00` The daemon passes the leap bits of its synchronization source (usual mode of operation).

`01/10` A leap second is added/deleted (operator forced leap second).

`11` Leap information from the synchronization source is ignored (thus LEAP_NOWARNING is passed on).

Files

| | |
|-----------------------------------|----------------------------------------|
| <code>/etc/inet/ntp.conf</code> | Default name of the configuration file |
| <code>/etc/ntp/ntp.drift</code> | Conventional name of the drift file |
| <code>/etc/inet/ntp.keys</code> | Conventional name of the key file |
| <code>/etc/inet/ntp.server</code> | Sample server configuration file |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWntpu |

See Also [svcs\(1\)](#), [ntpdate\(1M\)](#), [ntpq\(1M\)](#), [ntptrace\(1M\)](#), [svcadm\(1M\)](#), [xntpd\(1M\)](#), [rename\(2\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The xntpd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/ntp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name xntpd – special NTP query program

Synopsis xntpd [-i\l\ps] [-c *command*] [*host*] [...]

Description xntpd queries the xntpd daemon about its current state and requests changes in that state. You can run xntpd in interactive mode or in controlled using command line arguments.

Extensive state and statistics information is available through the xntpd interface. In addition, nearly all the configuration options which can be specified at start up using xntpd's configuration file may also be specified at run time using xntpd.

If one or more request options is included on the command line when xntpd is executed, each of the requests is sent to the NTP servers running on each of the hosts given as command line arguments, or on the local host by default. If no request options are given, xntpd attempts to read commands from the standard input and execute these on the NTP server running on the first host specified on the command line, again defaulting to the local host when no other host is specified. xntpd prompts for commands if the standard input is a terminal device.

xntpd uses NTP mode 7 packets to communicate with the NTP server, and can be used to query any compatible server on the network which permits it. As NTP is a UDP protocol, this communication is somewhat unreliable, especially over large distances. xntpd does not attempt to re-transmit requests, and times requests out if the remote host is not heard from within a suitable timeout time.

The operation of xntpd is specific to the particular implementation of the xntpd daemon. You can expect xntpd to work only with this and maybe some previous versions of the daemon. Requests from a remote xntpd program that affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier.

Options xntpd reads interactive format commands from the standard input. If you specify the -c, -l, -p or -s option, the specified queries are sent to the hosts immediately.

The following command line options are supported:

-c *command* - . . . Add *command* to the list of commands to execute on the specified hosts. *command* is interpreted as an interactive format command.

Multiple -c options may be specified.

-i Force xntpd to operate in interactive mode.

Prompts are written to the standard output. Commands are read from the standard input.

-l Obtain a list of peers which are known to the servers.

This option is equivalent to -c listpeers. See listpeers in Control Message Commands.

- n Output all host addresses in dotted-quad numeric format rather than converting to the canonical host names.
- p Print a list of the peers known to the server as well as a summary of their state.

This option is equivalent to -c peers. See peers in Control Message Commands.
- s Print a list of the peers known to the server as well as a summary of their state, but in a slightly different format than the -p option. This option is equivalent to -c dmpeers. See dmpeers in Control Message Commands.

Operands The following operands are supported:

Usage

Interactive Commands The interactive commands consist of a keyword (*command_keyword*) followed by zero to four arguments. You need to enter only enough characters of the *command_keyword* to uniquely identify it. The output of an interactive command is sent to the standard output by default. You can send the output of an interactive command to a file by appending a <, followed by a file name, to the command line.

A number of interactive format commands are executed entirely within the xntpd program itself and do not result in NTP mode.

The following interactive commands are supported:

- ? [*command_keyword*] Without an argument, print a list of ntpq command keywords. If *command_keyword* is specified, print function and usage information about the *command_keyword*.
- delay *milliseconds* Specify a time interval to add to timestamps included in requests which require authentication.

This enables (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Because the server no longer requires timestamps in authenticated requests, this command may be obsolete.
- help [*command_keyword*] Without an argument, print a list of ntpq command keywords. If *command_keyword* is specified, print function and usage information about the *command_keyword*.
- host *hostname* Set the host (*hostname*) to which future queries are sent. Specify *hostname* as a host name or a numeric address.

| | |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hostnames [yes no] | <p>Print hostnames or numeric addresses in information displays.</p> <p>Specify <i>yes</i> to print host names. Specify <i>no</i> to print numeric addresses.</p> <p>The default is <i>yes</i>, unless the <i>-n</i> command line option is specified.</p> |
| keyid <i>keyid</i> | <p>Enable specification of a key number (<i>keyid</i>) to authenticate configuration requests. <i>keyid</i> must correspond to a key number the server has been configured to use for this purpose.</p> |
| passwd | <p>Allow the user to specify a password at the command line to authenticate configuration requests.</p> <p>The password is not displayed, and must correspond to the key configured for use by the NTP server for this purpose. If the password does not correspond to the key configured for use by the NTP server, requests are not successful.</p> |
| quit | <p>Exit <i>xntpd</i>.</p> |
| timeout <i>milliseconds</i> | <p>Specify a timeout period for responses to server queries.</p> <p>The default is approximately <i>8000</i> milliseconds. As <i>xntpd</i> retries each query once after a timeout, the total waiting time for a timeout is twice the timeout value set.</p> |
| Control Message Commands | <p>Query commands result in NTP mode 7 packets containing requests for information being sent to the server. These control message commands are read-only commands in that they make no modification of the server configuration state.</p> <p>The following control message commands are supported:</p> |
| clkbug | <p>Obtain debugging information for a reference clock driver. This information is provided only by some clock drivers.</p> |
| clockinfo <i>clock_peer_address</i> [...] | <p>Obtain and print information concerning a peer clock.</p> <p>The values obtained provide information on the setting of fudge factors and other clock performance information.</p> |
| dmpeers | <p>Obtain a list of peers for which the sserver is maintaining state, along with a summary of that state.</p> |

| | |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p>The peer summary list is identical to the output of the <code>peers</code> command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A <code>.</code> indicates that this peer was cast off in the falseticker detection, while a <code>+</code> indicates that the peer made it through. A <code>*</code> denotes the peer with which the server is currently synchronizing.</p> |
| <code>iostats</code> | <p>Print statistics counters maintained in the input-output module.</p> |
| <code>kerninfo</code> | <p>Obtain and print kernel phase-lock loop operating parameters.</p> <p>This information is available only if the kernel has been specially modified for a precision timekeeping function.</p> |
| <code>listpeers</code> | <p>Obtain and print a brief list of the peers for which the server is maintaining state.</p> <p>These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchronization candidates.</p> |
| <code>loopinfo [oneline multiline]</code> | <p>Print the values of selected loop filter variables.</p> <p>The loop filter is the part of NTP which deals with adjusting the local system clock.</p> <p>The <code>oneline</code> and <code>multiline</code> options specify the format in which this information is printed. <code>multiline</code> is the default.</p> <p>The <code>offset</code> is the last offset given to the loop filter by the packet processing code. The <code>frequency</code> is the frequency error of the local clock in parts-per-million (ppm). The <code>time_const</code> controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The <code>watchdog</code> timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter.</p> |
| <code>memstats</code> | <p>Print statistics counters related to memory allocation code.</p> |

| | |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| monlist [version] | Obtain and print traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified. |
| peers | <p>Obtain a list of peers for which the server is maintaining state, along with a summary of that state.</p> <p>The following summary information is included:</p> <ul style="list-style-type: none">▪ Address of the remote peer.▪ Local interface address. If a local address has yet to be determined it is 0.0.0.0.▪ Stratum of the remote peer. A stratum of 16 indicates the remote peer is unsynchronized.▪ Polling interval, in seconds.▪ Reachability register, in octal.▪ Current estimated delay, offset and dispersion of the peer, in seconds.▪ Mode in which the peer entry is operating. <p>This is represented by the character in the left margin. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchronizing to.</p> <ul style="list-style-type: none">▪ Host. <p>This field may contain a host name, an IP address, a reference clock implementation name with its parameter or REFCLK (implementation number, parameter). On hostnames no only IP-addresses is displayed.</p> |
| pstats <i>peer_address</i> [...] | Show the per-peer statistic counters associated with the specified peers. |
| reslist | <p>Obtain and print the server's restriction list.</p> <p>Generally, this list is printed in sorted order.</p> |

| | |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| showpeer <i>peer_address</i> [...] | Show a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification. |
| sysinfo | Print a variety of system state variables that are related to the local server. |
| | The output from <code>sysinfo</code> is described in NTP Version 3 specification, RFC-1305. All except the last four lines are described in the NTP Version 3 specification, RFC-1305. |
| | The <code>system flags</code> show various system flags, some of which can be set and cleared by the <code>enable</code> and <code>disable</code> configuration commands, respectively. These are the <code>auth</code> , <code>bclient</code> , <code>monitor</code> , <code>pll</code> , <code>pps</code> and <code>stats</code> flags. See the <code>xntpd</code> documentation for the meaning of these flags. There are two additional flags which are read only, the <code>kernel_pll</code> and <code>kernel_pps</code> . These flags indicate the synchronization status when the precision time kernel modifications are in use. The <code>kernel_pll</code> indicates that the local clock is being disciplined by the kernel, while the <code>kernel_pps</code> indicates the kernel discipline is provided by the PPS signal. The <code>stability</code> is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value initially decreases from as high as 500 ppm to a nominal value in the range .01 to 0.1 ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the kernel variable <code>tick</code> may be incorrect. The <code>broadcastdelay</code> shows the default broadcast delay, as set by the <code>broadcastdelay</code> configuration command. The <code>authdelay</code> shows the default authentication delay, as set by the <code>authdelay</code> configuration command. |
| sysstats | Print statistics counters maintained in the protocol module. |
| timerstats | Print statistics counters maintained in the timer/event queue support code. |
| Runtime Configuration Requests | The server authenticates all requests that cause state changes in the server. The server uses a configured NTP key to accomplish this. This facility can also be disabled by the server by not configuring a key). |

You must make the key number and the corresponding key known to xntpd. Use the `keyid` or `passwd` commands to do so.

The `passwd` command prompts users for a password to use as the encryption key. It also prompts automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication provides verification that the requester has permission to make such changes. It also gives an extra degree of protection against transmission errors.

Authenticated requests always include a time stamp in the packet data. The time stamp is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If the time stamps differ by more than a small amount the request is rejected.

Time stamps are rejected for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts.

While the reconfiguration facility works well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it works very poorly for more distant hosts. If reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the run time reconfiguration facility should provide an adequate level of security.

The following commands make authenticated requests.

`addpeer peer_address [keyid] [version] [prefer]`

Add a configured peer association at the given address and operating in symmetric active mode. An existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate.

If the optional *keyid* is a non-zero integer, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the *keyid* is 0 or omitted, no authentication is done.

Specify *version* as 1, 2 or 3. The default is 3.

The *prefer* keyword indicates a preferred peer. This keyword is used primarily for clock synchronisation if possible. The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronisation so is the PPS signal.

`addserver peer_address [keyid] [version] [prefer]`

Identical to the `addpeer` command, except that the operating mode is client.

`addtrap [address [port] [interface]`

Set a trap for asynchronous messages.

authinfo

Return information concerning the authentication module, including known keys and counts of encryptions and decryptions which have been done.

broadcast *peer_address* [*keyid*] [*version*] [*prefer*]

Identical to the `addpeer` command, except that the operating mode is `broadcast`. In this case a valid key identifier and key are required. The `peer_address` parameter can be the broadcast address of the local network or a multicast group address assigned to NTP. If a multicast address, a multicast-capable kernel is required.

clrtrap [*address* [*port*] [*interface*]

Clear a trap for asynchronous messages.

delrestrict *address mask* [*ntpport*]

Delete the matching entry from the restrict list.

fudge *peer_address* [*time1*] [*time2*] [*stratum*] [*refid*]

Provide a way to set certain data for a reference clock.

readkeys

Cause the current set of authentication keys to be purged and a new set to be obtained by re-reading the keys file. The keys file must have been specified in the `xntpd` configuration file. This enables encryption keys to be changed without restarting the server.

restrict *address mask flag* [*flag*]

This command operates in the same way as the `restrict` configuration file commands of `xntpd`.

reset

Clear the statistics counters in various modules of the server.

traps

Display the traps set in the server.

trustkey *keyid* [...]**untrustkey** *keyid* [...]

These commands operate in the same way as the `trustedkey` and `untrustedkey` configuration file commands of `xntpd`.

unconfig *peer_address* [...]

Cause the configured bit to be removed from the specified peers. In many cases this causes the peer association to be deleted. When appropriate, however, the association may persist in an unconfigured mode if the remote peer is willing to continue on in this fashion.

unrestrict *address mask flag* [*flag*]

Unrestrict the matching entry from the restrict list.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Name ypbind – NIS binder process

Synopsis /usr/lib/netsvc/yp/ypbind [-broadcast | -ypset | -ypsetme]

Description NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in [ypclnt\(3NSL\)](#). Administrative tools are described in [ypinit\(1M\)](#), [ypwhich\(1\)](#), and [ypset\(1M\)](#). Tools to see the contents of NIS maps are described in [ypcat\(1\)](#), and [ypmatch\(1\)](#).

ypbind is a daemon process that is activated at system startup time from the `svc:/network/nis/client:default` service. By default, it is invoked as `ypbind -broadcast`. ypbind runs on all client machines that are set up to use NIS. See [sysidtool\(1M\)](#). The function of ypbind is to remember information that lets all NIS client processes on a node communicate with some NIS server process. ypbind must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. If the NIS server is a NIS+ server in NIS (YP) compatibility mode, see the NOTES section of the [ypfiles\(4\)](#) man page for more information.

The information ypbind remembers is called a *binding* — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the `-broadcast` option, the ypbind process broadcasts on the net trying to find an NIS server, either a `ypserv` process serving the domain or an `rpc.nisd` process in “YP-compatibility mode” serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the `-broadcast` option, ypbind process steps through the list of NIS servers that was created by `ypinit -c` for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in the `/etc/hosts` file along with their IP addresses. Once a domain is bound by ypbind, that same binding is given to every client process on the node. The ypbind process on the local node or a remote node may be queried for the binding of a particular domain by using the [ypwhich\(1\)](#) command.

If ypbind is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, ypbind will try to bind to another NIS server using the process described above. ypbind also accepts requests to set its binding for a particular domain. The request is usually generated by the [ypset\(1M\)](#) command. In order for `ypset` to work, ypbind must have been invoked with flags `-ypset` or `-ypsetme`.

Options `-broadcast` Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to ypbind with no options in earlier Sun releases and is recommended for ease of use.

- ypset Allow users from any remote machine to change the binding by means of the ypset command. By default, no one can change the binding. This option is insecure.
- ypsetme Only allow root on the local machine to change the binding to a desired server by means of the ypset command. ypbind can verify the caller is indeed a root user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

Files /var/yp/binding/ypdomain/ypservers
 /etc/inet/hosts

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWnisu |

See Also [svcs\(1\)](#), [ypcat\(1\)](#), [ypmatch\(1\)](#), [ypwhich\(1\)](#), [ifconfig\(1M\)](#), [rpc.nisd\(1M\)](#), [svcadm\(1M\)](#), [ypinit\(1M\)](#), [ypset\(1M\)](#), [ypclnt\(3NSL\)](#), [hosts\(4\)](#), [ypfiles\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes ypbind supports multiple domains. The ypbind process can maintain bindings to several domains and their servers, the default domain is the one specified by the [domainname\(1M\)](#) command at startup time.

The -broadcast option works only on the UDP transport. It is insecure since it trusts “any” machine on the net that responds to the broadcast request and poses itself as an NIS server.

The ypbind service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nis/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name ypinit – set up NIS client

Synopsis /usr/sbin/ypinit [-c] [-m] [-s *master_server*]

Description ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if [ypbind\(1M\)](#) is started with the `-broadcast` option (it is invoked with this option from the `svc:/network/nis/client:default` service).

Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.

ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers must be listed in the `/etc/hosts` file along with its IP address. ypinit stores the list in file `/var/yp/binding/domain/ypservers`. This file is used by ypbind when run without the `-broadcast` option.

Options

- `-c` Set up a ypclient system.
- `-m` Build a master ypserver data base.
- `-s master_server` Slave data base. *master_server* must be the same master configured in the YP maps and returned by the `ypwhich -m` command.

Files `/etc/hosts`
`/var/yp/binding/domain/ypservers`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWnisu |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [ypbind\(1M\)](#), [sysinfo\(2\)](#), [hosts\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The NIS client service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

`svc:/network/nis/client:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Bugs ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the `SI_SRPC_DOMAIN` command to [sysinfo\(2\)](#). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.

Name ypmake – rebuild NIS database

Synopsis `cd /var/yp ; make [map]`

Description The file called `Makefile` in `/var/yp` is used by [make\(1S\)](#) to build the Network Information Service (NIS) database. With no arguments, `make` creates dbm databases for any NIS maps that are out-of-date, and then executes [yppush\(1M\)](#) to notify slave databases that there has been a change.

If you supply a *map* on the command line, `make` will update that map only. Typing `make passwd` will create and `yppush` the password database (assuming it is out of date). Likewise, `make ipnodes` and `make networks` will create and `yppush` the `ipnodes` and `network` files, `$(INETDIR)/ipnodes` and `$(DIR)/networks`.

There are four special variables used by `make`: `DIR`, which gives the directory of the source files; `NOPUSH`, which when non-null inhibits doing a `yppush` of the new database files; `INETDIR`, which gives the directory of the `ipnodes` source file; and `DOM`, which is used to construct a domain other than the master's default domain. The default for `DIR` is `/etc`, and the default for `INETDIR` is `/etc/inet`. The default for `NOPUSH` is the null string.

Refer to [ypfiles\(4\)](#) and [ypserv\(1M\)](#) for an overview of the NIS service.

If a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`, is present, the NIS server components run in N2L mode. In N2L mode, the server components use a new set of map files with an LDAP-prefix, based on the LDAP DIT. In N2L mode, authoritative NIS information is obtained from the DIT. The NIS source files and `ypmake` have no role, and they should not be used. If `ypmake` is accidentally run, then the server components will detect this, and will log a warning message. For additional information, see [ypfiles\(4\)](#).

Files

| | |
|------------------------------|-----------------------------------------------|
| <code>/var/yp</code> | Directory containing NIS configuration files. |
| <code>/etc/inet/hosts</code> | System hosts file. |
| <code>/etc</code> | Default directory for source files. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWypu |
| Interface Stability | Evolving |

See Also [make\(1S\)](#), [NIS+\(1\)](#), [makedbm\(1M\)](#), [rpc.nisd\(1M\)](#), [ypbind\(1M\)](#), [yppush\(1M\)](#), [ypserv\(1M\)](#), [ypclnt\(3NSL\)](#), [NISLDAPmapping\(4\)](#), [ypfiles\(4\)](#), [ypserv\(4\)](#)

Notes The NIS makefile is only used when running the [ypserv\(1M\)](#) server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see [rpc.nisd\(1M\)](#); this makefile is not relevant. See [ypfiles\(4\)](#) for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

Name ypmap2src – convert NIS maps to NIS source files

Synopsis /usr/lib/netsvc/yp/ypmap2src [-t]
 [[-c *custom-map-name*]]... [-d *domain*] -o *output-directory*
 [[*source-file*]]...

Description Use the ypmap2src utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of [ypmake\(1M\)](#).

The primary use for ypmap2src is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The ypmap2src utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available.

Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended.

The ypmap2src utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by ypmake and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred.

Per entry comment fields, from existing source files, are not merged into source files generated by ypmap2src. If a user wishes N2L to maintain comment information, then the NISLDAPmapping configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files.

When ypmap2src is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.

Handling Custom Maps ypmap2src only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the ypmap2src script.

Options ypmap2src supports the following options:

- c Specifies that *custom-map-name* should be converted to a source file by running `makedbm -u` on it. This is a short cut so that simple custom maps can be handled without editing ypmap2src.
- d *domain-name* Specifies the domain to convert. The *domain-name* can be a fully qualified file path, such as `/var/yp/a.b.c`, or just a domain name, `a.b.c`. In the latter case, ypmap2src looks in `/var/yp` for the domain directory.

- o *dest*** Specifies the destination directory for the converted files. A directory other than /etc should be specified. The maps generated are copied to the correct location, /etc, /etc/security or other source directory, as appropriate.
- t** Specifies that traditional NIS maps, without N2L's LDAP_ prefix, should be converted. By default, maps with the LDAP_ prefix are converted.

Operands ypmmap2src supports the following operands:

- source-file*** Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files specified by the -c option, are converted.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Name yppoll – return current version of a NIS map at a NIS server host

Synopsis /usr/sbin/yppoll [-d *ypdomain*] [-h *host*] *mapname*

Description The yppoll command asks a ypserv() process what the order number is, and which host is the master NIS server for the named map.

Options -d *ypdomain* Use *ypdomain* instead of the default domain.
-h *host* Ask the ypserv process at *host* about the map parameters. If *host* is not specified, the NIS server for the local host is used. That is, the default host is the one returned by [ypwhich\(1\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWnisu |

See Also [ypwhich\(1\)](#), [ypfiles\(4\)](#), [attributes\(5\)](#)

Name yppush – force propagation of changed NIS map

Synopsis /usr/lib/netsvc/yp/yppush [-v] [-h *host*] [-d *domain*]
[-p *#parallel-xfrs*] *mapname*

Description yppush copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the Makefile in /var/yp after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS ypservers map within the *domain*. Keys within the ypservers map are the ASCII names of the machines on which the NIS servers run.

A “transfer map” request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program that actually moves the map) to call back the yppush. When the attempt has completed (successfully or not), and the transfer agent has sent yppush a status message, the results can be printed to stdout. Messages are also printed when a transfer is not possible, for instance, when the request message is undeliverable, or when the timeout period on responses has expired.

Refer to [ypfiles\(4\)](#) and [ypserv\(1M\)](#) for an overview of the NIS service.

Options The following options are supported:

-d *domain* Specifies a *domain*.
 -h *host* Propagates only to the named *host*.
 -p *#parallel-xfrs* Allows the specified number of map transfers to occur in parallel.
 -v Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.

Files /var/yp Directory where NIS configuration files reside.
 /var/yp/*domain*/ypservers. {*dir*, *pag* } Map containing list of NIS servers to bind to when running in server mode.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE |
|---------------|-----------------|
| Availability | SUNWypu |

See Also [ypserv\(1M\)](#), [ypxfr\(1M\)](#), [ypfiles\(4\)](#), [attributes\(5\)](#)

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

Bugs In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an “old-style” message has been sent. The system administrator should later check to see that the transfer has actually taken place.

Name ypserv, ypxfrd – NIS server and binder processes

Synopsis /usr/lib/netsvc/yp/ypserv [-dv] [-i | -I] [-r | -R]
/usr/lib/netsvc/yp/ypxfrd

Description The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See [ndbm\(3C\)](#). These files are described in [ypfiles\(4\)](#). The processes are /usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind, the NIS binder. The programmatic interface to the NIS service is described in [ypclnt\(3NSL\)](#). Administrative tools are described in [yppoll\(1M\)](#), [yppush\(1M\)](#), [ypset\(1M\)](#), [ypxfr\(1M\)](#), and [ypwhich\(1\)](#). Tools to see the contents of NIS maps are described in [ypcat\(1\)](#), and [ypmatch\(1\)](#). Database generation and maintenance tools are described in [ypinit\(1M\)](#), [ypmake\(1M\)](#), and [makedbm\(1M\)](#).

The ypserv utility is a daemon process typically activated at system startup from `svc:/network/nis/server:default`. Alternatively, you can, as the root user, start NIS services using [ypstart\(1M\)](#) from the command-line. ypserv runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the [ypstop\(1M\)](#) command.

The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, be sure ypxfrd is running on the master server. See /usr/lib/netsvc/yp/ypstart. ypxfr attempts to use ypxfrd first. If that fails, it prints a warning, then uses the older transfer method.

The ypserv daemon's primary function is to look up information in its local database of NIS maps.

The operations performed by ypserv are defined for the implementor by the *YP Protocol Specification*, and for the programmer by the header file `<rpcsvc/yp_prot.h>`.

Communication to and from ypserv is by means of RPC calls. Lookup functions are described in [ypclnt\(3NSL\)](#), and are supplied as C-callable functions in the [libnsl\(3LIB\)](#) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: [yp_match\(3NSL\)](#), [yp_first\(3NSL\)](#), [yp_next\(3NSL\)](#), and [yp_all\(3NSL\)](#). The [yp_match](#) operation takes a key, and returns the associated value. The [yp_first](#) operation returns the first key-value pair from the map, and [yp_next](#) can be used to enumerate the remainder. [yp_all](#) ships the entire map to the requester as the response to a single RPC request.

A number of special keys in the DBM files can alter the way in which ypserv operates. The keys of interest are:

| | |
|----------------|---------------------------------------------------------------------------------------------------------------------------|
| YP_INTERDOMAIN | The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files. |
|----------------|---------------------------------------------------------------------------------------------------------------------------|

| | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| YP_SECURE | This key causes ypserv to answer only questions coming from clients on reserved ports. |
| YP_MULTI_hostname | This is a special key in the form, YP_MULTI_hostname addr1,...,addrN. A client looking for hostname receives the closest address. |

Two other functions supply information about the map, rather than map entries: [yp_order\(3NSL\)](#), and [yp_master\(3NSL\)](#). In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with [makedbm\(1M\)](#), however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include `do_you_serve_this_domain?`, `transfer_map`, and `reinitialize_internal_state`.

On start up, ypserv checks for the existence of the NIS to LDAP (N2L) configuration file `/var/yp/NISLDAPmapping`. If it is present then a master server starts in N2L mode. If the file is not present it starts in “traditional” (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an LDAP_ prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and [ypmake\(1M\)](#) are not used.

It is possible that [ypmake\(1M\)](#) can be accidentally run in N2L mode. If the occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting [yppush\(1M\)](#) operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. ypserv keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call yppush directly instead of ypmake.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When ypserv is started, a warning will be logged.
2. When a NIS read access is made and the TTL entry has expired, a warning is logged. Information that is returned from the cache has not been updated.
3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If `ypxfrd` is running in N2L mode and is asked to transfer a map, `ypxfrd` first checks whether the map is out of date. If the map is out of date, `ypxfrd` initiates an update from the DIT. `ypxfrd` cannot wait for the update to complete. If `ypxfrd` waited, the client end `ypxfr` operation could time out. To prevent `ypxfrd` from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent `ypxfrd` operations.

Options

- `ypserv -d` The NIS service should go to the DNS for more host information. This requires the existence of a correct `/etc/resolv.conf` file pointing to a DNS server. This option turns on DNS forwarding regardless of whether or not the `YP_INTERDOMAIN` flag is set in the hosts maps. See [makedbm\(1M\)](#). In the absence of an `/etc/resolv.conf` file, `ypserv` complains, but ignores the `-d` option.
- `-i` If in N2L mode, initialize the NIS related parts of the DIT based on the current, non LDAP_ prefixed, map files. The LDAP_ prefixed maps are not created or updated. If you require that LDAP_ prefixed maps be updated or created, then use the `-ir` option.
- The `-i` option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.
- `-I` Identical to `-i`, except that any missing domain and container objects are created.
- `-r` If in N2L mode, then refresh the LDAP_ prefixed map files based on the contents of the DIT.
- `-ir` If both `-i` and `-r` are specified in N2L mode, then the DIT will first be initialized from the current non LDAP_ prefixed map files. A new set of LDAP_ prefixed maps will then be generated from the contents of the DIT. A new set of LDAP_ prefixed maps is required when moving from traditional NIS to N2L mode NIS.
- `-Ir` Identical to `-ir`, except that any missing domain and container objects are created.
- `-v` Operate in the verbose mode, printing diagnostic messages to `stderr`.

When run with the `-i`, `-r`, `-I`, `-ir` or `-Ir` options, the `ypserv` command runs in the foreground and exits once map initialization has been completed. Once the `ypserv` command exits, the user knows the maps are ready and can restart `ypserv` and the other `yp` daemons by running [ypstart\(1M\)](#).

If there is a requirement to initialize the DIT from the NIS source files, which may have been modified since the maps were last remade, run `ypmake` before running `ypserv -i` or `ypserv -ir`. `ypmake` regenerated old style NIS maps. Then `ypserv -ir` dumps them into the DIT. When the `-ir` option is used, the LDAP_ prefix maps are also generated or updated. Since these maps will be more recent than the old style maps, `ypmake` will not be reported as erroneous when it is run.

- Files** `/var/yp/securenets` Defines the hosts and networks that are granted access to information in the served domain. It is read at startup time by both `ypserv` and `ypxfrd`.

| | |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/var/yp/ypserv.log</code> | If the <code>/var/yp/ypserv.log</code> file exists when <code>ypserv</code> starts up, log information is written to it when error conditions arise. |
| <code>/var/yp/binding/domainname/ypservers</code> | Lists the NIS server hosts that <code>ypbind</code> can bind to. |

Network Interface Guide

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes `ypserv` supports multiple domains. The `ypserv` process determines the domains it serves by looking for directories of the same name in the directory `/var/yp`. It replies to all broadcasts requesting `yp` service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

NIS uses `ndbm()` files to store maps. Therefore, it is subject to the 1024 byte limitations described in the `USAGE` and `NOTES` sections of the [ndbm\(3C\)](#) man page.

The NIS server service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name ypset – point ypbind at a particular server

Synopsis /usr/sbin/ypset [-d *ypdomain*] [-h *host*] *server*

Description In order to run ypset, ypbind must be initiated with the `–ypset` or `–ypsetme` options. See [ypbind\(1M\)](#). ypset tells ypbind to get NIS services for the specified *ypdomain* from the ypserv process running on *server*. If *server* is down, or is not running ypserv, this might not be discovered until an NIS client process tries to obtain a binding for the domain. At this point, the binding set by ypset is tested by ypbind. If the binding is invalid, ypbind attempts to rebind for the same domain.

ypset is useful for binding a client node that is not on a broadcast net, or is on a broadcast net that is not running an NIS server host. It is also useful for debugging NIS client applications, for instance, where an NIS map exists only at a single NIS server host.

Where several hosts on the local net are supplying NIS services, ypbind can rebind to another host, even while you attempt to find out if the ypset operation succeeded. For example, if you enter the ypset command below, you might get the subsequent response from ypwhich:

```
example% ypset host1
example% ypwhich
host2
```

The sequence shown above is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when host1 does not respond to ypbind because it is not running ypserv (or is overloaded), and host2, running ypserv, obtains the binding.

server indicates which NIS server to bind to, and must be specified as a name or an IP address. This works only if the node has a current valid binding for the domain in question and ypbind has been set to allow use of ypset. In most cases, *server* should be specified as an IP address.

ypset tries to bind over a connectionless transport. The NIS library call, `yp_all()`, uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by ypset.

Refer to [ypfiles\(4\)](#) for an overview of the NIS name service.

Options `-d ypdomain` Use *ypdomain*, instead of the default domain.
`-h host` Set ypbind's binding on *host*, instead of locally. Specify *host* as a name.

Name ypstart, yptest – Start and stop NIS services

Synopsis /usr/lib/netsvc/yp/ypstart
/usr/lib/netsvc/yp/yptest

Description The ypstart command is used to start the Network Information Service (NIS). After the host has been configured using the [ypinit\(1M\)](#) command, ypstart automatically determines the NIS status of the machine and starts the appropriate daemons.

The yptest command is used to stop the Network Information Service (NIS).

System Administration Guide: Basic Administration

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

Name ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host

Synopsis /usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C *tid prog server*]
 [-d *ypdomain*] [-h *host*] [-s *ypdomain*] *mapname*

Description The ypxfr command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory /var/yp/*ypdomain* (this directory must already exist; *ypdomain* is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real *name*.

If run interactively, ypxfr writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file /var/yp/ypxfr.log exists, it appends all its output to that file. Since ypxfr is most often run from the privileged user's crontab file, or by ypserv, the log file can retain a record of what was attempted, and what the results were.

For consistency between servers, ypxfr should be run periodically for every map in the NIS data base. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A [crontab\(1\)](#) entry can be used to automatically perform periodic updates. Rather than having a separate crontab entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in /usr/sbin/yp: ypxfr_1perday, ypxfr_2perday, and ypxfr_1perhour.

Refer to [ypfiles\(4\)](#) for an overview of the NIS name service.

Options

- c Do not send a “Clear current map” request to the local ypserv process. Use this flag if ypserv is not running locally at the time you are running ypxfr. Otherwise, ypxfr complains that it cannot communicate with the local ypserv, and the transfer fails.
- f Force the transfer to occur even if the version at the master is not more recent than the local version.
- C *tid prog server* This option is for use *only* by ypserv. When ypserv starts ypxfr, it specifies that ypxfr should call back a yppush process at the host *server*, registered as program number *prog*, and waiting for a response to transaction *tid*.
- d *ypdomain* Specify a domain other than the default domain.
- h *host* Get the map from *host*, regardless of the master. If *host* is not specified, ypxfr asks the NIS service for the name of the master, and tries to get the map from there. *host* must be a valid host name.

`-s ypdomain` Specify a source domain from which to transfer a map that should be the same across domains.

Name zdb – ZFS debugger

Synopsis zdb *pool*

Description The zdb command is used by support engineers to diagnose failures and gather statistics. Since the ZFS file system is always consistent on disk and is self-repairing, zdb should only be run under the direction by a support engineer.

If no arguments are specified, zdb, performs basic consistency checks on the pool and associated datasets, and report any problems detected.

Any options supported by this command are internal to Sun and subject to change at any time.

Exit Status The following exit values are returned:

- 0 The pool is consistent.
- 1 An error was detected.
- 2 Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWzfsu |
| Interface Stability | Unstable |

See Also [zfs\(1M\)](#), [zpool\(1M\)](#), [attributes\(5\)](#)

Name zdump – time zone dumper

Synopsis zdump [*--version*] [-v] [-c [*loyear*,*hiyear*] [*zonename*]]...

Description The zdump command prints the current time for each time zone (*zonename*) listed on the command line. Specify *zonename* as the name of the time zone database file relative to `/usr/share/lib/zoneinfo`.

Specifying an invalid time zone (*zonename*) to zdump does not return an error, rather zdump uses GMT0. This is consistent with the behavior of the library calls; zdump reflects the same behavior of the time routines in `libc`. See [ctime\(3C\)](#) and [mktime\(3C\)](#).

Options The following options are supported:

- version* Outputs version information and exits.
- v* Displays the entire contents of the time zone database file for *zonename*. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See [mktime\(3C\)](#) and [ctime\(3C\)](#) for information regarding time value (`time_t`). Each line of output ends with `isdst=1` if the given time is Daylight Saving Time, or `isdst=0` otherwise.
- c [*loyear*,*hiyear*]* Cuts off the verbose output near the start of the given year(s). By default, the program cuts off verbose output near the start of the years -500 and 2500.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files `/usr/share/lib/zoneinfo` Standard zone information directory

```

Description The `zfs` command configures ZFS datasets within a ZFS storage pool, as described in [zpool\(1M\)](#). A dataset is identified by a unique path within the ZFS namespace. For example:

```
pool/{filesystem,volume,snapshot}
```

where the maximum length of a dataset name is `MAXNAMELEN` (256 bytes).

A dataset can be one of the following:

file system

A ZFS dataset of type `filesystem` can be mounted within the standard system namespace and behaves like other file systems. While ZFS file systems are designed to be POSIX compliant, known issues exist that prevent compliance in some cases. Applications that depend on standards conformance might fail due to nonstandard behavior when checking file system free space.

volume

A logical volume exported as a raw or block device. This type of dataset should only be used under special circumstances. File systems are typically used in most environments.

snapshot

A read-only version of a file system or volume at a given point in time. It is specified as *filesystem@name* or *volume@name*.

ZFS File System Hierarchy A ZFS storage pool is a logical collection of devices that provide space for datasets. A storage pool is also the root of the ZFS file system hierarchy.

The root of the pool can be accessed as a file system, such as mounting and unmounting, taking snapshots, and setting properties. The physical storage characteristics, however, are managed by the `zpool(1M)` command.

See `zpool(1M)` for more information on creating and administering pools.

Snapshots A snapshot is a read-only copy of a file system or volume. Snapshots can be created extremely quickly, and initially consume no additional space within the pool. As data within the active dataset changes, the snapshot consumes more data than would otherwise be shared with the active dataset.

Snapshots can have arbitrary names. Snapshots of volumes can be cloned or rolled back, but cannot be accessed independently.

File system snapshots can be accessed under the `.zfs/snapshot` directory in the root of the file system. Snapshots are automatically mounted on demand and may be unmounted at regular intervals. The visibility of the `.zfs` directory can be controlled by the `snapdir` property.

Clones A clone is a writable volume or file system whose initial contents are the same as another dataset. As with snapshots, creating a clone is nearly instantaneous, and initially consumes no additional space.

Clones can only be created from a snapshot. When a snapshot is cloned, it creates an implicit dependency between the parent and child. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as a clone exists. The `origin` property exposes this dependency, and the `destroy` command lists any such dependencies, if they exist.

The clone parent-child dependency relationship can be reversed by using the `promote` subcommand. This causes the “origin” file system to become a clone of the specified file system, which makes it possible to destroy the file system that the clone was created from.

Mount Points Creating a ZFS file system is a simple operation, so the number of file systems per system is likely to be numerous. To cope with this, ZFS automatically manages mounting and unmounting file systems without the need to edit the `/etc/vfstab` file. All automatically managed file systems are mounted by ZFS at boot time.

By default, file systems are mounted under */path*, where *path* is the name of the file system in the ZFS namespace. Directories are created and destroyed as needed.

A file system can also have a mount point set in the `mountpoint` property. This directory is created as needed, and ZFS automatically mounts the file system when the `zfs mount -a` command is invoked (without editing `/etc/vfstab`). The `mountpoint` property can be inherited, so if `pool/home` has a mount point of `/export/stuff`, then `pool/home/user` automatically inherits a mount point of `/export/stuff/user`.

A file system can be mounted temporarily at a location other than the file system's persistent mount point by specifying the `-o mountpoint=value` option to the `zfs mount` command. This is only permitted for file systems with non-legacy mount points.

A file system `mountpoint` property of `none` prevents the file system from being mounted.

If needed, ZFS file systems can also be managed with traditional tools (`mount`, `umount`, `/etc/vfstab`). If a file system's mount point is set to `legacy`, ZFS makes no attempt to manage the file system, and the administrator is responsible for mounting and unmounting the file system.

Zones A ZFS file system can be added to a non-global zone by using the `zonecfg add fs` subcommand. A ZFS file system that is added to a non-global zone must have its `mountpoint` property set to `legacy`.

The physical properties of an added file system are controlled by the global administrator. However, the zone administrator can create, modify, or destroy files within the added file system, depending on how the file system is mounted.

A dataset can also be delegated to a non-global zone by using the `zonecfg add dataset` subcommand. You cannot delegate a dataset to one zone and the children of the same dataset to another zone. The zone administrator can change properties of the dataset or any of its children. However, the quota property is controlled by the global administrator.

A ZFS volume can be added as a device to a non-global zone by using the `zonecfg add device` subcommand. However, its physical properties can be modified only by the global administrator.

For more information about `zonecfg` syntax, see [zonecfg\(1M\)](#).

After a dataset is delegated to a non-global zone, the `zoned` property is automatically set. A zoned file system can only be mounted in the global zone by use of a temporary `mountpoint` property (see “Temporary Mount Point Properties”).

The global administrator can forcibly clear the `zoned` property, though this should be done with extreme care. The global administrator should verify that all the mount points are acceptable before clearing the property.

Native Properties Properties are divided into two types, native properties and user-defined (or “user”) properties. Native properties either export internal statistics or control ZFS behavior. In addition, native properties are either editable or read-only. User properties have no effect on ZFS behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see the “User Properties” section, below.

Every dataset has a set of properties that export statistics about the dataset as well as control various behaviors. Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The values of numeric properties can be specified using human-readable suffixes (for example, k, KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal) specifications:

1536M, 1.5g, 1.50GB

The values of non-numeric properties are case sensitive and must be lowercase, except for `mountpoint`, `sharenfs`, and `sharesmb`.

The following native properties consist of read-only statistics about the dataset. These properties can be neither set, nor inherited. Native properties apply to all dataset types unless otherwise noted.

`available`

The amount of space available to the dataset and all its children, assuming that there is no other activity in the pool. Because space is shared within a pool, availability can be limited by any number of factors, including physical pool size, quotas, reservations, or other datasets within the pool.

This property can also be referred to by its shortened column name, `avail`.

`compressratio`

The compression ratio achieved for this dataset, expressed as a multiplier. Compression can be turned on by running: `zfs set compression=on dataset`. The default value is `off`.

`creation`

The time this dataset was created.

`defer_destroy`

This property is `on` if the snapshot has been marked for deferred destroy by using the `zfs destroy -d` command. Otherwise, the property is `off`.

`groupused@group`

The amount of space consumed by the specified group in this dataset. Space is charged to the group of each file, as displayed by `ls -l`. See the `userused@user` property for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the `groupused` privilege with `zfs allow`, can access all groups' usage.

mounted

For file systems, indicates whether the file system is currently mounted. This property can be either yes or no.

origin

For cloned file systems or volumes, the snapshot from which the clone was created. The origin cannot be destroyed (even with the `-r` or `-f` options) so long as a clone exists.

referenced

The amount of data that is accessible by this dataset, which may or may not be shared with other datasets in the pool. When a snapshot or clone is created, it initially references the same amount of space as the file system or snapshot it was created from, since its contents are identical.

This property can also be referred to by its shortened column name, `refer`.

type

The type of dataset: `filesystem`, `volume`, or `snapshot`.

used

The amount of space consumed by this dataset and all its descendents. This is the value that is checked against this dataset's quota and reservation. The space used does not include this dataset's reservation, but does take into account `refreservation` (through `usedbyrefreservation`) and the reservations of any descendent datasets (through `usedbychildren`). The amount of space that a dataset consumes from its parent, as well as the amount of space that are freed if this dataset is recursively destroyed, is the greater of its space used and its reservation.

When snapshots (see the “Snapshots” section) are created, their space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, space that was previously shared becomes unique to the snapshot, and counted in the snapshot's space used. Additionally, deleting snapshots can increase the amount of space unique to (and used by) other snapshots.

The amount of space used, available, or referenced does not take into account pending changes. Pending changes are generally accounted for within a few seconds. Committing a change to a disk using `fsync(3C)` or `O_SYNC` does not necessarily guarantee that the space usage information is updated immediately.

usedby*

The `usedby*` properties decompose the `used` properties into the various reasons that space is used. Specifically, `used = usedbychildren + usedbydataset + usedbyrefreservation + usedbysnapshots`. These properties are only available for datasets created on `zpool` version 13 pools.

usedbychildren

The amount of space used by children of this dataset, which would be freed if all the dataset's children were destroyed.

usedbydataset

The amount of space used by this dataset itself, which would be freed if the dataset were destroyed (after first removing any `refreservation` and destroying any necessary snapshots or descendents).

usedbyrefreservation

The amount of space used by a `refreservation` set on this dataset, which would be freed if the `refreservation` was removed.

Space accounted for by this property represents potential consumption by future writes, reserved in advance to prevent write allocation failures in this dataset. This can include unwritten data, space currently shared with snapshots, and compression savings for volumes (which may be lost when replaced with less compressible data). When allocations for later writes increase `usedbydataset` or `usedbysnapshots`, `usedbyrefreservation` will decrease accordingly.

usedbysnapshots

The amount of space consumed by snapshots of this dataset. In particular, it is the amount of space that would be freed if all of this dataset's snapshots were destroyed. Note that this is not simply the sum of the snapshots' `used` properties because space can be shared by multiple snapshots.

userused@user

The amount of space consumed by the specified user in this dataset. Space is charged to the owner of each file, as displayed by `ls -l`. The amount of space charged is displayed by `du` and `ls -s`. See the `zfs userspace` subcommand for more information.

Unprivileged users can access only their own space usage. The root user, or a user who has been granted the `userused` privilege with `zfs allow`, can access everyone's usage.

The `userused@...` properties are not displayed by `zfs get all`. The user's name must be appended after the `@` symbol, using one of the following forms:

- *POSIX name* (for example, `joe`)
- *POSIX numeric ID* (for example, `789`)
- *SID name* (for example, `joe.smith@mydomain`)
- *SID numeric ID* (for example, `S-1-123-456-789`)

userrefs

This property is set to the number of user holds on this snapshot. User holds are set by using the `zfs hold` command.

volblocksize=*blocksize*

For volumes, specifies the block size of the volume. The `blocksize` cannot be changed once the volume has been written, so it should be set at volume creation time. The default `blocksize` for volumes is 8 KBs. Any power of 2 from 512 bytes to 1 MB is valid.

This property can also be referred to by its shortened column name, `volblock`.

The following native properties can be used to change the behavior of a ZFS dataset.

`aclmode=discard | mask | passthrough |`

Controls how an ACL is modified during `chmod(2)`. A file system with an `aclmode` property of `discard` (the default) deletes all ACL entries that do not represent the mode of the file. An `aclmode` property of `mask` reduces user or group permissions. The permissions are reduced so that they are no greater than the group permission bits, unless it is a user entry that has the same UID as the owner of the file or directory. In this case, the ACL permissions are reduced so that they are no greater than owner permission bits. The `mask` value also preserves the ACL across mode changes (without an explicit ACL set [by means of `chmod(1)`] between the mode changes). A file system with an `aclmode` property of `passthrough` indicates that no changes will be made to the ACL other than generating the necessary ACL entries to represent the new mode of the file or directory.

`aclinherit=discard | noallow | restricted | passthrough | passthrough-x`

Controls how ACL entries are inherited when files and directories are created. A file system with an `aclinherit` property of `discard` does not inherit any ACL entries. A file system with an `aclinherit` property value of `noallow` only inherits inheritable ACL entries that specify deny permissions. The property value `restricted` (the default) removes the `write_acl` and `write_owner` permissions when the ACL entry is inherited. A file system with an `aclinherit` property value of `passthrough` inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. A file system with an `aclinherit` property value of `passthrough-x` has the same meaning as `passthrough`, except that all ACEs inherit the execute permission only if the file creation mode also requests the execute bit.

When the property value is set to `passthrough`, files are created with a mode determined by the inheritable ACEs. If no inheritable ACEs exist that affect the mode, then the mode is set in accordance to the requested mode from the application.

`atime=on | off`

Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and other similar utilities. The default value is `on`.

`canmount=on | off | noauto`

If this property is set to `off`, the file system cannot be mounted, and is ignored by `zfs mount -a`. Setting this property to `off` is similar to setting the `mountpoint` property to `none`, except that the dataset still has a normal `mountpoint` property, which can be inherited. Setting this property to `off` allows datasets to be used solely as a mechanism to inherit properties. One example of setting `canmount=off` is to have two datasets with the same `mountpoint`, so that the children of both datasets appear in the same directory, but might have different inherited characteristics.

When the `noauto` option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the `zfs mount -a` command or unmounted by the `zfs unmount -a` command.

This property is not inherited.

`checksum=on | off | fletcher2, | fletcher4 | sha256`

Controls the checksum used to verify data integrity. The default value is `on`, which automatically selects an appropriate algorithm (currently, `fletcher4`, but this may change in future releases). The value `off` disables integrity checking on user data. Disabling checksums is *NOT* a recommended practice.

Changing this property affects only newly-written data.

`compression=on | off | lzjb | gzip | gzip-N | zle`

Controls the compression algorithm used for this dataset. The `lzjb` compression algorithm is optimized for performance while providing decent data compression. Setting compression to `on` uses the `lzjb` compression algorithm. The `gzip` compression algorithm uses the same compression as the `gzip(1)` command. You can specify the `gzip` level by using the value `gzip-N` where `N` is an integer from 1 (fastest) to 9 (best compression ratio). Currently, `gzip` is equivalent to `gzip-6` (which is also the default for `gzip(1)`).

This property can also be referred to by its shortened column name `compress`. Changing this property affects only newly-written data.

`copies=1 | 2 | 3`

Controls the number of copies of data stored for this dataset. These copies are in addition to any redundancy provided by the pool, for example, mirroring or RAID-Z. The copies are stored on different disks, if possible. The space used by multiple copies is charged to the associated file and dataset, changing the used property and counting against quotas and reservations.

Changing this property only affects newly-written data. Therefore, set this property at file system creation time by using the `-o copies=N` option.

`devices=on | off`

Controls whether device nodes can be opened on this file system. The default value is `on`.

`exec=on | off`

Controls whether processes can be executed from within this file system. The default value is `on`.

`groupquota@group=size | none`

Limits the amount of space consumed by the specified group. Group space consumption is identified by the `userquota@user` property.

Unprivileged users can access only their own groups' space usage. The root user, or a user who has been granted the `groupquota` privilege with `zfs allow`, can get and set all groups' quotas.

`logbias=latency|throughput`

Provides a hint to ZFS about handling of synchronous requests in this dataset. If `logbias` is set to `latency` (the default), ZFS uses the pool's log devices (if configured) to handle the requests at low latency. If `logbias` is set to `throughput`, ZFS does not use the configured pool log devices. Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources.

`mountpoint=path|none|legacy`

Controls the mount point used for this file system. See the “Mount Points” section for more information on how this property is used.

When the `mountpoint` property is changed for a file system, the file system and any children that inherit the mount point are unmounted. If the new value is `legacy`, then they remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously `legacy` or `none`, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location.

`nbmand=on|off`

Controls whether the file system should be mounted with `nbmand` (Non Blocking mandatory locks). This is used for SMB clients. Changes to this property only take effect when the file system is unmounted and remounted. See [mount\(1M\)](#) for more information on `nbmand` mounts.

`primarycache=all|none|metadata`

Controls what is cached in the primary cache (ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`.

`quota=size|none`

Limits the amount of space a dataset and its descendents can consume. This property enforces a hard limit on the amount of space used. This includes all space consumed by descendents, including file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor's quota, but rather imposes an additional limit.

Quotas cannot be set on volumes, as the `volsize` property acts as an implicit quota.

`readonly=on|off`

Controls whether this dataset can be modified. The default value is `off`.

This property can also be referred to by its shortened column name, `rdonly`.

recordsize=*size*

Specifies a suggested block size for files in the file system. This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically tunes block sizes according to internal algorithms optimized for typical access patterns.

For databases that create very large files but access them in small random chunks, these algorithms may be suboptimal. Specifying a `recordsize` greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged, and may adversely affect performance.

The default `recordsize` is 128 KB. The size specified must be a power of two greater than or equal to 512 and less than or equal to 1 MB.

Changing the file system's `recordsize` affects only files created afterward; existing files and received data are unaffected.

This property can also be referred to by its shortened column name, `recsize`.

refquota=*size* | none

Limits the amount of space a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include space used by descendents, including file systems and snapshots.

refreservation=*size* | none

The minimum amount of space guaranteed to a dataset, not including its descendents.

When the `usedbydataset` space is below this value, the dataset is treated as if it were taking up the amount of space specified by `refreservation`. The `usedbyrefreservation` figure represents this extra space, adding to the total used space charged to the dataset, and in turn consuming from the parent datasets' usage, quotas, and reservations. This protects the dataset from overcommitment of pool resources, by ensuring that space for future writes is reserved in advance.

Space shared with snapshots can later be replaced with new data, and the snapshot represents a commitment to keep both copies. If `refreservation` is set, `usedbyrefreservation` must be increased to the full size of `refreservation` when taking a new snapshot, accounting for this commitment. If there is insufficient space available to the dataset for this increase, snapshot creation will be denied.

This property can also be referred to by its shortened column name, `refreserv`.

reservation=*size* | none

The minimum amount of space guaranteed to a dataset and its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by its reservation. Reservations are accounted for in the parent datasets' space used, and count against the parent datasets' quotas and reservations.

This property can also be referred to by its shortened column name, `reserv`.

`rstchown=on | off`

Indicates whether the file system restricts users from giving away their files by means of [chown\(1\)](#) or the [chown\(2\)](#) system call. The default is to restrict chown. When `rstchown` is `off` then `chown` will act as if the user has the `PRIV_FILE_CHOWN_SELF` privilege.

`secondarycache=all | none | metadata`

Controls what is cached in the secondary cache (L2ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`.

`setuid=on | off`

Controls whether the set-UID bit is respected for the file system. The default value is `on`.

`sharesmb=on | off | opts`

Controls whether the file system is shared by using the Solaris SMB service, and what options are to be used. A file system with the `sharesmb` property set to `off` is managed through traditional tools such as [share_nfs\(1M\)](#). Otherwise, the file system is automatically shared and unshared with the `zfs share` and `zfs unshare` commands.

Because SMB shares requires a resource name, a unique resource name is constructed from the dataset name. The constructed name is a copy of the dataset name except that the characters in the dataset name, which would be illegal in the resource name, are replaced with underscore (`_`) characters. A pseudo property “name” is also supported that allows you to replace the data set name with a specified name. The specified name is then used to replace the prefix dataset in the case of inheritance. For example, if the dataset `data/home/john` is set to `name=john`, then `data/home/john` has a resource name of `john`. If a child dataset of `data/home/john/backups`, it has a resource name of `john_backups`.

When SMB shares are created, the SMB share name appears as an entry in the `.zfs/shares` directory. You can use the `ls` or `chmod` command to display the share-level ACLs on the entries in this directory.

When the `sharesmb` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously set to `off`, or if they were shared before the property was changed. If the new property is set to `off`, the file systems are unshared.

Note – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`sharenfs=on | off | opts`

Controls whether the dataset is shared by using the NFS protocol. If the property is set to `on`, the `zfs share` command is invoked with no options. You can specify a comma-separated list of options as the contents of this property. See the [EXAMPLES](#) section. You can also share a ZFS file system by using the `zfs share` command. Setting the `sharenfs` property or using the `zfs share` command is preferred over using the legacy [share\(1M\)](#) command.

When the `sharenfs` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously `off`, or if they were shared before the property was changed. If the new property is `off`, the file systems are unshared.

`snapdir=hidden | visible`

Controls whether the `.zfs` directory is hidden or visible in the root of the file system as discussed in the “Snapshots” section. The default value is `hidden`.

`sync=standard | always | disabled`

Determines the degree to which file system transactions are synchronized. This property can be set when a dataset is created, or dynamically, and will take effect immediately. `sync` can have one of the following settings:

`standard`

The default option. Synchronous file system transactions are written to the intent log and then all devices written are flushed to ensure the data is stable (that is, not cached by device controllers).

`always`

Every file system transaction would be written and flushed to stable storage. This setting should be used only where extreme caution is required, as there is a significant performance penalty.

`disabled`

Synchronous requests are disabled. File system transactions commit to stable storage only on the next DMU transaction group commit, which might be after many seconds. This setting gives the highest performance. However, it is very dangerous as ZFS would be ignoring the synchronous transaction demands of applications such as databases or NFS. Furthermore, when this setting is in effect for the currently active root or `/var` filesystem, out-of-spec behavior, application data loss, and increased vulnerability to replay attacks can result. Administrators should only use this option only when these risks are understood.

`userquota@user=size | none`

Limits the amount of space consumed by the specified user. Similar to the `refquota` property, the `userquota` space calculation does not include space that is used by descendent datasets, such as snapshots and clones. User space consumption is identified by the `userspace@user` property.

Enforcement of user quotas may be delayed by several seconds. This delay means that a user might exceed her quota before the system notices that she is over quota. The system would then begin to refuse additional writes with the `EDQUOT` error message. See the `zfs userspace` subcommand for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the `userquota` privilege with `zfs allow`, can get and set everyone's quota.

This property is not available on volumes, on file systems before version 4, or on pools before version 15. The `userquota@...` properties are not displayed by `zfs get all`. The user's name must be appended after the `@` symbol, using one of the following forms:

- *POSIX name* (for example, `joe`)
- *POSIX numeric ID* (for example, `789`)
- *SID name* (for example, `joe.smith@mydomain`)
- *SID numeric ID* (for example, `S-1-123-456-789`)

`version=1 | 2 | current`

The on-disk version of this file system, which is independent of the pool version. This property can only be set to later supported versions. See the `zfs upgrade` command.

`volsize=size`

Specifies the logical size of the volume. By default, creating a volume establishes a `refreservation` that is a somewhat larger than the actual logical volume size, to account for ZFS metadata overhead. Any changes to `volsize` are reflected in an equivalent change to the `refreservation`. The `volsize` can only be set to a multiple of `volblocksize`, and cannot be zero.

The `refreservation` is set on the volume to prevent unexpected behavior for consumers. Without the reservation, the volume could run out of space, resulting in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while it is in use (particularly when shrinking the size). Extreme care should be used when adjusting the volume size.

Though not recommended, a sparse volume (also known as *thin provisioning*) can be created by specifying the `-s` option to the `zfs create -V` command. A sparse volume is a volume where the reservation is less than the volume size. Consequently, writes to a sparse volume can fail with `ENOSPC` when the pool is low on space. For a sparse volume, changes to `volsize` are not reflected in the reservation.

`vscan=on | off`

Controls whether regular files should be scanned for viruses when a file is opened and closed. In addition to enabling this property, the virus scan service must also be enabled for virus scanning to occur. The default value is `off`.

`xattr=on | off`

Controls whether extended attributes are enabled for this file system. The default value is `on`.

`zoned=on | off`

Controls whether the dataset is managed from a non-global zone. See the “Zones” section for more information. The default value is `off`.

The following three properties cannot be changed after the file system is created, and therefore, should be set when the file system is created. If the properties are not set with the `zfs create` or `zpool create` commands, these properties are inherited from the parent

dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

`casesensitivity=sensitive | insensitive | mixed`

Indicates whether the file name matching algorithm used by the file system should be case-sensitive, case-insensitive, or allow a combination of both styles of matching. The default value for the `casesensitivity` property is `mixed`. Traditionally, UNIX and POSIX file systems have case-sensitive file names.

The `mixed` value for the `casesensitivity` property indicates that the file system can support requests for both case-sensitive and case-insensitive matching behavior. Currently, case-insensitive matching behavior on a file system that supports mixed behavior is limited to the Solaris SMB server product. For more information about the `mixed` value behavior, see the *Oracle Solaris ZFS Administration Guide*.

Note – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`normalization = none | formC | formD | formKC | formKD`

Indicates whether the file system should perform a unicode normalization of file names whenever two file names are compared, and which normalization algorithm should be used. File names are always stored unmodified, names are normalized as part of any comparison process. If this property is set to a legal value other than `none`, and the `utf8only` property was left unspecified, the `utf8only` property is automatically set to `on`. The default value of the `normalization` property is `none`. This property cannot be changed after the file system is created.

Note – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`utf8only=on | off`

Indicates whether the file system should reject file names that include characters that are not present in the UTF-8 character code set. If this property is explicitly set to `off`, the normalization property must either not be explicitly set or be set to `none`. The default value for the `utf8only` property is `off`. This property cannot be changed after the file system is created.

Note – This SMB-related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

Temporary Mount Point Properties When a ZFS file system is mounted, either through the legacy `mount(1M)` command for legacy mounts or the `zfs mount` command, its mount options are set according to its properties. The correlation between properties and mount options is as follows:

| PROPERTY | MOUNT OPTION |
|-----------------------|--------------------------------|
| <code>devices</code> | <code>devices/nodevices</code> |
| <code>exec</code> | <code>exec/noexec</code> |
| <code>readonly</code> | <code>ro/rw</code> |

| | |
|----------|---------------------|
| setuid | setuid/nosetuid |
| xattr | xattr/noxattr |
| rstchown | rstchown/norstchown |

In addition, these options can be set on a per-mount basis using the `-o` option, without affecting the property that is stored on disk. The values specified on the command line override the values stored in the dataset. The `-nosuid` option is an alias for `nodevices,nosetuid`. These properties are reported as *temporary* by the `zfs get` command. For properties other than `mountpoint`, if the properties are changed while the dataset is mounted, the new setting overrides any temporary settings. The `mountpoint` property cannot be changed while a temporary `mountpoint` property is in effect (that is, while the dataset is mounted at a temporary location).

User Properties In addition to the standard native properties, ZFS supports arbitrary user properties. User properties have no effect on ZFS behavior, but applications or administrators can use them to annotate datasets (file systems, volumes, and snapshots).

User property names must contain a colon (`:`) character to distinguish them from native properties. They may contain lowercase letters, numbers, and the following punctuation characters: colon (`:`), dash (`-`), period (`.`), and underscore (`_`). The expected convention is that the property name is divided into two portions such as *module:property*, but this namespace is not enforced by ZFS. User property names can be at most 256 characters, and cannot begin with a dash (`-`).

When making programmatic use of user properties, it is strongly suggested to use a reversed DNS domain name for the *module* component of property names to reduce the chance that two independently-developed packages use the same property name for different purposes.

The values of user properties are arbitrary strings, are always inherited, and are never validated. All of the commands that operate on properties (`zfs list`, `zfs get`, `zfs set`, and so forth) can be used to manipulate both native properties and user properties. Use the `zfs inherit` command to clear a user property. If the property is not defined in any parent dataset, it is removed entirely. Property values are limited to 1024 characters.

ZFS Volumes as Swap or Dump Devices During an initial installation or a live upgrade from a UFS file system, a swap device and dump device are created on ZFS volumes in the ZFS root pool. The default swap device varies based on the amount of the system's physical memory. The size of the dump device depends on the kernel's requirements at installation time. Separate ZFS volumes must be used for the swap area and dump devices. Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

If you need to change your swap area or dump device after the system is installed or upgraded, use the `swap(1M)` and `dumpadm(1M)` commands. If you need to change the size of your swap area or dump device, see the *Oracle Solaris ZFS Administration Guide*

Subcommands All subcommands that modify state are logged persistently to the pool in their original form.

`zfs ?`

Displays a help message.

`zfs help subcommand | help property property | permission`

Displays `zfs` subcommand usage information. You can display help for a specific subcommand, property, or delegated permission. If you display help for a specific subcommand or property, the subcommand syntax or property value is displayed. Using `zfs help` without any arguments displays a complete list of `zfs` subcommands.

`zfs create [-p] [-o property=value] ... filesystem`

Creates a new ZFS file system. The file system is automatically mounted according to the `mountpoint` property inherited from the parent.

`-p`

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target filesystem already exists, the operation completes successfully.

`-o property=value`

Sets the specified property as if the command `zfs set property=value` was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

`zfs create [-ps] [-b blocksize] [-o property=value] ... -V size volume`

Creates a volume of the given size. The volume is exported as a block device in `/dev/zvol/{dsk, rdsk}/path`, where *path* is the name of the volume in the ZFS namespace. The size represents the logical size as exported by the device. By default, a reservation of equal size is created.

size is automatically rounded up to the nearest 128 Kbytes to ensure that the volume has an integral number of blocks regardless of *blocksize*.

`-p`

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target filesystem already exists, the operation completes successfully.

`-s`

Creates a sparse volume with no reservation. See `volsize` in the Native Properties section for more information about sparse volumes.

`-o property=value`

Sets the specified property as if the `zfs set property=value` command was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

`-b blocksize`

Equivalent to `-o volblocksize=blocksize`. If this option is specified in conjunction with `-o volblocksize`, the resulting behavior is undefined.

`zfs destroy [-rRf] filesystem|volume`

Destroys the given dataset. By default, the command unshares any file systems that are currently shared, unmounts any file systems that are currently mounted, and refuses to destroy a dataset that has active dependents (children or clones).

`-r`

Recursively destroy all children.

`-R`

Recursively destroy all dependents, including cloned file systems outside the target hierarchy.

`-f`

Force an unmount of any file systems using the `umount -f` command. This option has no effect on non-file systems or unmounted file systems.

Extreme care should be taken when applying either the `-r` or the `-f` options, as they can destroy large portions of a pool and cause unexpected behavior for mounted file systems in use.

`zfs destroy [-rRd] snapshot`

The given snapshot is destroyed immediately if and only if the `zfs destroy` command without the `-d` option would have destroyed it. Such immediate destruction would occur, for example, if the snapshot had no clones and the user-initiated reference count were zero.

If the snapshot does not qualify for immediate destruction, it is marked for deferred deletion. In this state, it exists as a usable, visible snapshot until both of the preconditions listed above are met, at which point it is destroyed.

`-d`

Defer snapshot deletion.

`-r`

Destroy (or mark for deferred deletion) all snapshots with this name in descendent file systems.

`-R`

Recursively destroy all dependents.

`zfs snapshot [-r] [-o property=value] ... filesystem@snapname|volume@snapname`

Creates a snapshot with the given name. All previous modifications by successful system calls to the file system are part of the snapshot. `zfs snap` can be used as an alias for `zfs snapshot`. See the “Snapshots” section for details.

`-r`

Recursively create snapshots of all descendent datasets. Snapshots are taken atomically, so that all recursive snapshots correspond to the same moment in time.

`-o property=value`

Sets the specified property; see `zfs create` for details.

`zfs rollback [-rRf] snapshot`

Roll back the given dataset to a previous snapshot. When a dataset is rolled back, all data that has changed since the snapshot is discarded, and the dataset reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to do so, all intermediate snapshots must be destroyed by specifying the `-r` option.

The `-rR` options do not recursively destroy the child snapshots of a recursive snapshot.

Only the top-level recursive snapshot is destroyed by either of these options. To completely roll back a recursive snapshot, you must rollback the individual child snapshots.

`-r`

Recursively destroy any snapshots more recent than the one specified.

`-R`

Recursively destroy any more recent snapshots, as well as any clones of those snapshots.

`-f`

Used with the `-R` option to force an unmount of any clone file systems that are to be destroyed.

`zfs clone [-p] [-o property=value] ... snapshot filesystem|volume`

Creates a clone of the given snapshot. See the “Clones” section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

`-p`

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. If the target file system or volume already exists, the operation completes successfully.

`-o property=value`

Sets the specified property; see `zfs create` for details.

zfs promote *clone-filesystem*

Promotes a clone file system to no longer be dependent on its *origin* snapshot. This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The `rename` subcommand can be used to rename any conflicting snapshots.

zfs rename *filesystem|volume|snapshot****filesystem|volume|snapshot*****zfs rename [-p] *filesystem|volume filesystem|volume***

Renames the given dataset. The new target can be located anywhere in the ZFS hierarchy, with the exception of snapshots. Snapshots can only be renamed within the parent file system or volume. When renaming a snapshot, the parent file system of the snapshot does not need to be specified as part of the second argument. Renamed file systems can inherit new mount points, in which case they are unmounted and remounted at the new mount point.

-p

Creates all the nonexistent parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent.

zfs rename -r *snapshot snapshot*

Recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset that can be renamed recursively.

zfs list [-r|-d *depth*] [-H] [-o *property*[,...]] [-t *type*[,...]] [-s *property*] ... [-S *property*] ... [*filesystem|volume|snapshot*] ...

Lists the property information for the given datasets in tabular form. If specified, you can list property information by the absolute pathname or the relative pathname. By default, all file systems and volumes are displayed. Snapshots are displayed if the `listsnapshots` property is on (the default is on). The following fields are displayed, `name, used, available, referenced, mountpoint`.

-H

Used for scripting mode. Do not print headers and separate fields by a single tab instead of arbitrary white space.

-r

Recursively display any children of the dataset on the command line.

-d *depth*

Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of 1 will display only the dataset and its direct children.

-o *property*

A comma-separated list of properties to display. The property must be:

- One of the properties described in the “Native Properties” section
- A user property
- The value name to display the dataset name
- The value space to display space usage properties on file systems and volumes. This is a shortcut for specifying the syntax:

```
-o name,avail,used,usedsnap,usedds,usedrefreserv,\
usedchild -t filesystem,volume
```

-s *property*

A property for sorting the output by column in ascending order based on the value of the property. The property must be one of the properties described in the “Properties” section, or the special value name to sort by the dataset name. Multiple properties can be specified at one time using multiple *-s* property options. Multiple *-s* options are evaluated from left to right in decreasing order of importance.

The following is a list of sorting criteria:

- Numeric types sort in numeric order.
- String types sort in alphabetical order.
- Types inappropriate for a row sort that row to the literal bottom, regardless of the specified ordering.
- If no sorting options are specified the existing behavior of `zfs list` is preserved.

-S *property*

Same as the *-s* option, but sorts by property in descending order.

-t *type*

A comma-separated list of types to display, where *type* is one of `filesystem`, `snapshot`, `volume`, or `all`. For example, specifying *-t snapshot* displays only snapshots. The following aliases can be used in place of the type specifiers: `fs` (`filesystem`), `snap` (`snapshot`), and `vol` (`volume`).

`zfs set [-r] property=value filesystem|volume|snapshot ...`

Sets the property to the given value for each dataset. Only some properties can be edited. See the “Properties” section for more information on what properties can be set and acceptable values. Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively). User properties can be set on snapshots. For more information, see the “User Properties” section.

-r

Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

`zfs get [-rHP|-d depth] [-o all | field[,...]] [-s source[,...]] all | property[,...]
filesystem|volume|snapshot ...`

Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

| | |
|----------|-----------------------------------------------------------------------------------|
| name | Dataset name |
| property | Property name |
| value | Property value |
| source | Property source. Can either be local, default, temporary, inherited, or none (-). |

All columns except the RECEIVED column are displayed by default; specify particular or all columns, using the -o option. This command takes a comma-separated list of properties as described in the “Native Properties” and “User Properties” sections.

The special value `all` can be used to display all properties that apply to the given dataset's type (filesystem, volume, or snapshot).

-r

Recursively display properties for any children.

-d *depth*

Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of 1 will display only the dataset and its direct children.

-H

Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

-o *field*

Set of fields to display. One or more of:

name, property, value, received, source

Present multiple fields as a comma-separated list. The default value is:

name, property, value, source

The keyword `all` specifies all sources.

-s *source*

A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:

local, default, inherited, temporary, received, none

The default value is all sources.

-p
Display numbers in parseable (exact) values.

`zfs inherit [-rS] property filesystem|volume|snapshot ...`

Clears the specified property, causing it to be inherited from an ancestor. If no ancestor has the property set, then the default value is used. See the “Properties” section for a listing of default values, and details on which properties can be inherited.

-r
Recursively inherit the given property for all children.

-S
Revert to the received property value, if any. If the property does not have a received value, the behavior of `zfs inherit -S` is the same as `zfs inherit` without `-S`. If the property does have a received value, `zfs inherit` masks the received value with the inherited value until `zfs inherit -S` reverts to the received value.

`zfs upgrade`

Identifies a file system version, which determines available file system features in the currently running software release. You can continue to use older file system versions, but some features might not be available. A file system can be upgraded by using the `zfs upgrade -a` command. You will not be able to access a file system of a later version on a system that runs an earlier software version.

`zfs upgrade [-v]`

Displays ZFS file system versions that are supported by the current software. The current ZFS file system versions and all previously supported versions are displayed, along with an explanation of the features provided with each version.

`zfs upgrade [-r] [-V version] [-a | filesystem]`

Upgrades file systems to a new, on-disk version. Upgrading a file system means that it will no longer be accessible on a system running an older software version. A `zfs send` stream that is generated from a new file system snapshot cannot be accessed on a system that runs an older software version.

In general, the file system version is independent of the pool version. See [zpool\(1M\)](#) for information on the `zpool upgrade` command.

In some cases, the file system version and the pool version are interrelated and the pool version must be upgraded before the file system version can be upgraded.

-a
Upgrade all file systems on all imported pools.

filesystem
Upgrade the specified file system.

-r
Upgrade the specified file system and all descendent file systems

-V *version*

Upgrade to the specified *version*. If the **-V** flag is not specified, this command upgrades to the most recent version. This option can only be used to increase the version number, and only up to the most recent version supported by this software.

zfs userspace [-hniHp] [-o *field*[,...]] [-s*S field*]... [-t *type* [...]] *filesystem* | *snapshot*
 Displays space consumed by, and quotas on, each user in the specified filesystem or snapshot. This corresponds to the `userused@user` and `userquota@user` properties.

-h

Displays syntax help message and exit.

-n

Displays numeric ID instead of user/group name.

-H

Does not print headers, use tab-delimited output.

-p

Uses exact (parseable) numeric output.

-o *field*[,...]

Displays only the specified fields from the following set, `type`, `name`, `used`, `quota`. The default is to display all fields.

-s *field*

Sorts output by the specified field. The `s` and `S` flags may be specified multiple times to sort first by one field, then by another. The default is `-s type -s name`.

-S *field*

Sorts by this field in reverse order. See `-s`.

-t *type*[,...]

Displays only the specified types from the following set, `all`, `posixuser`, `smbuser`, `posixgroup`, `smbgroup`.

The default is `-t posixuser, smbuser`

The default can be changed to include group types.

-i

Translates SID to POSIX ID. The POSIX ID may be ephemeral if no mapping exists. Normal POSIX interfaces (for example, `stat(2)`, `ls -l`) perform this translation, so the `-i` option allows the output from `zfs userspace` to be compared directly with those utilities. However, `-i` may lead to confusion if some files were created by an SMB user before a SMB-to-POSIX name mapping was established. In such a case, some files are owned by the SMB entity and some by the POSIX entity. However, the `-i` option will report that the POSIX entity has the total usage and quota for both.

zfs groupspace [-niHp] [-o *field*[,...]] [-sS *field*]... [-t *type* [...]] *filesystem* | *snapshot*

Displays space consumed by, and quotas on, each group in the specified filesystem or snapshot. This subcommand is identical to **zfs userspace**, except that the default types to display are -t *posixgroup*, *smbgroup*.

-

zfs mount

Displays all ZFS file systems currently mounted.

zfs mount [-v0] [-o *options*] -a | *filesystem*

Mounts ZFS file systems. Invoked automatically as part of the boot process.

-o *options*

An optional, comma-separated list of mount options to use temporarily for the duration of the mount. See the “Temporary Mount Point Properties” section for details.

-O

Perform an overlay mount. See [mount\(1M\)](#) for more information.

-v

Report mount progress.

-a

Mount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem

Mount the specified filesystem.

zfs unmount [-f] -a | *filesystem*|*mountpoint*

Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process.

-f

Forcefully unmount the file system, even if it is currently in use.

-a

Unmount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|*mountpoint*

Unmount the specified filesystem. The command can also be given a path to a ZFS file system mount point on the system.

zfs share -a | *filesystem*

Shares ZFS file systems that have the *sharenfs* or *sharesmb* property set. Sharing a file system with the NFS or SMB protocol means that the file system data is available over the network. ZFS file systems that have the *sharenfs* or *sharesmb* property set are automatically shared when a system is booted.

-a
Shares all ZFS file systems that have the `sharenfs` or `sharesmb` property set and according to the share property values.

filesystem

Shares the specified file system that has the `sharenfs` or `sharesmb` property set and according to the share property values.

`zfs unshare -a | filesystem|mountpoint`

Unshares all ZFS file systems that have the `sharenfs` or `sharesmb` property set.

-a

Unshare all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|*mountpoint*

Unshare the specified filesystem. The command can also be given a path to a ZFS file system shared on the system.

`zfs send [-Rbpv] [-iI] snapshot snapshot`

`zfs send -r [-bcpv] [-i] snapshot snapshot`

Creates a stream representation of the second *snapshot*, which is written to standard output. The output can be redirected to a file or to a different system (for example, using [ssh\(1\)](#)). By default, a full stream is generated.

-b

Sends only received property values whether or not they are overridden by local settings, but only if the dataset has ever been received. Use this option when you want `zfs receive` to restore received properties backed up on the sent dataset and to avoid sending local settings that may have nothing to do with the source dataset, but only with how the data is backed up.

-c

Creates a self-contained stream. A self-contained stream is one that is not dependent on any datasets not included in the stream package. Valid only with the `-r` option. If used with the `-i` option, the stream is dependent on the snapshot specified as an argument to the that option.

See the “ZFS Streams” section of the ZFS Administration Guide for details.

-i *snapshot*

Generates an incremental stream from the first *snapshot* to the second *snapshot*. The incremental source (the first *snapshot*) can be specified as the last component of the snapshot name (for example, the part after the `@`), and it is assumed to be from the same file system as the second *snapshot*.

If the destination is a clone, the source may be the origin snapshot, which must be fully specified (for example, `pool/fs@origin`, not just `@origin`).

-I snapshot

Generates a stream package that sends all intermediary snapshots from the first snapshot to the second snapshot. For example, `-I @a fs@d` is similar to `-i @a fs@b`; `-i @b fs@c`; `-i @c fs@d`. The incremental source snapshot may be specified as with the `-i` option.

-R

Generates a replication stream package that replicates the specified file system, and all descendent file systems, up to the named snapshot. When received, all properties, snapshots, descendent file systems, and clones are preserved.

If the `-i` or `-I` flags are used in conjunction with the `-R` flag, an incremental replication stream is generated. The current values of properties, and current snapshot and file system names are set when the stream is received. If the `-F` flag is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed.

-r

Generates a recursive stream package. A recursive stream package contains a series of full and/or incremental streams. When received, all properties and descendent file systems are preserved. Unlike with the replication stream packages generated with the `-R` flag, intermediate snapshots are not preserved unless the intermediate snapshot is the origin of a clone that is included in the stream.

If the `-i` option is used in conjunction with the `-r` option, an incremental recursive stream is generated. The current values of properties as well as current snapshot and file system names are set when the stream is received. If the `-F` option is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed. The `-I` option cannot be used in conjunction with the `-r` option.

When combined with the `-c` option, a self-contained recursive stream package is created. If both the `-c` and `-i` options are used, file systems and volumes that do not have the snapshot specified with the `-i` option are sent as self-contained streams.

See the “ZFS Streams” section of the *ZFS Administration Guide* to understand how a recursive stream package differs from a replication stream package.

-p

Sends properties.

-v

Displays verbose information about the stream package generated.

The format of the stream is committed. You will be able to receive your streams on future versions of ZFS.

```
zfs receive [-vnFu] [[-o property=value] | [-x property]] ... filesystem|volume|snapshot
zfs receive [-vnFu] [[-o property=value] | [-x property]] ... [-d | -e] filesystem
```

Creates a snapshot whose contents are as specified in the stream provided on standard input. If a full stream is received, then a new file system is created as well. Streams are created using the `zfs send` subcommand, which by default creates a full stream. `zfs recv` can be used as an alias for `zfs receive`.

If an incremental stream is received, then the destination file system must already exist, and its most recent snapshot must match the incremental stream's source. For `zvol`s, the destination device link is destroyed and recreated, which means the `zvol` cannot be accessed during the receive operation.

When a snapshot replication package stream that is generated by using the `zfs send -R` command is received, any snapshots that do not exist on the sending location are destroyed by using the `zfs destroy -d` command. If `-o property=value` or `-x property` is specified, it applies to the effective value of the property throughout the entire subtree of replicated datasets. Effective property values may be set or inherited, depending on the property and whether the dataset is the topmost in the replicated subtree. Received properties are retained in spite of being overridden and may be restored with `zfs inherit -rS` or `zfs send -Rb`.

The name of the snapshot (and file system, if a full stream is received) that this subcommand creates depends on the argument type and the `-d` or `-e` option.

If the argument is a snapshot name, the specified *snapshot* is created. If the argument is a file system or volume name, a snapshot with the same name as the sent snapshot is created within the specified *filesystem* or *volume*. If the `-d` or `-e` option is specified, the snapshot name is determined by appending the sent snapshot's name to the specified filesystem. If the `-d` option is specified, all but the pool name of the sent snapshot path is appended (for example, `b/c@1` appended from sent snapshot `a/b/c@1`), and if the `-e` option is specified, only the tail of the sent snapshot path is appended (for example, `c@1` appended from sent snapshot `a/b/c@1`). In the case of `-d`, any file systems needed to replicate the path of the sent snapshot are created within the specified file system.

`-d`

Uses all but the first element of the sent snapshot path (all but the pool name) to determine the name of the new snapshot as described in the paragraph above.

`-e`

Uses the last element of the sent snapshot path to determine the name of the new snapshot as described in the paragraph above.

`-F`

Forces a rollback of the file system to the most recent snapshot before performing the receive operation. If receiving an incremental replication stream (for example, one generated by `zfs send -R -[iI]`), destroy snapshots and file systems that do not exist on the sending side.

- n
Do not actually receive the stream. This can be useful in conjunction with the -v option to verify the name the receive operation would use.
- o *property=value*
Sets the specified property as if the command `zfs set property=value` is invoked at the same time the received dataset is created from the non-incremental send stream or updated from the incremental send stream. Any editable ZFS property can also be set at receive time. Set-once properties bound to the received data, such as `normalization` and `casesensitivity`, cannot be set at receive time even when the datasets are newly created by `zfs receive`. Multiple -o options can be specified. An error results if the same property is specified in multiple -o or -x options.
- u
File system that is associated with the received stream is not mounted.
- v
Prints verbose information about the stream and the time required to perform the receive operation.
- x *property*
Ensures that the effective value of the specified property after the receive is unaffected by the value of that property in the send stream (if any), as if the property had been excluded from the send stream. If the specified property is not present in the send stream, this option does nothing. If a received property needs to be overridden, the effective value can be set or inherited, depending on the property. In the case of an incremental update, -x leaves any existing local setting or explicit inheritance unchanged (since the received property is already overridden). All -o restrictions apply equally to -x.

`zfs allow filesystem | volume`

Delegates ZFS administration permissions for the specified file system to non-privileged users. See the other forms of `zfs allow` for more information.

`zfs allow [-ldug] everyone|user|group[,...] perm|@setname[,...] filesystem | volume`

`zfs allow [-ld] -e perm|@setname[,...] filesystem | volume`

Delegates ZFS administration permission for the file systems to non-privileged users.

`[-ug] everyone|user|group[,...]`

Specifies to whom the permissions are delegated. Multiple entities can be specified as a comma-separated list. If neither of the -ug options are specified, then the argument is interpreted preferentially as the keyword `everyone`, then as a user name, and lastly as a group name. To specify a user or group named “everyone”, use the -u or -g options. To specify a group with the same name as a user, use the -g options.

`[-e] perm|@setname[,...]`

Specifies that the permissions be delegated to everyone. Multiple permissions may be specified as a comma-separated list. Permission names are the same as ZFS

subcommand and property names. See the property list below. Property set names, which begin with an at sign (@), may be specified. See the -s form below for details.

`[-ld] filesystem|volume`

Specifies where the permissions are delegated. If neither of the -ld options are specified, or both are, then the permissions are allowed for the file system or volume, and all of its descendants. If only the -l option is used, then is allowed “locally” only for the specified file system. If only the -d option is used, then is allowed only for the descendent file systems.

Permissions are generally the ability to use a ZFS subcommand or change a ZFS property. The following permissions are available:

```
# zfs help permissions
```

The following delegated permissions are supported:

| NAME | TYPE | NOTES |
|------------|------------|--------------------------------------------------------------------------------------------------------------------|
| allow | subcommand | Must also have the permission that is being allowed |
| clone | subcommand | Must also have the 'create' ability and 'mount' ability in the origin file system |
| create | subcommand | Must also have the 'mount' ability |
| destroy | subcommand | Must also have the 'mount' ability |
| diff | subcommand | Allows lookup of paths within a dataset, given an object number. Ordinary users need this in order to use zfs diff |
| hold | subcommand | Allows adding a user hold to a snapshot |
| mount | subcommand | Allows mount/umount of ZFS datasets |
| promote | subcommand | Must also have the 'mount' and 'promote' ability in the origin file system |
| receive | subcommand | Must also have the 'mount' and 'create' ability |
| release | subcommand | Allows releasing a user hold which might destroy the snapshot |
| rename | subcommand | Must also have the 'mount' and 'create' ability in the new parent |
| rollback | subcommand | Allows rolling back datasets to previously-taken snapshots |
| send | subcommand | Allows sending of snapshots |
| share | subcommand | Allows sharing file systems over NFS or SMB protocols |
| snapshot | subcommand | Allows taking of snapshots |
| groupquota | other | Allows accessing any groupquota@... property |
| groupused | other | Allows reading any groupused@... property |
| userprop | other | Allows changing any user property |
| userquota | other | Allows accessing any userquota@... |

| | | |
|----------|-------|------------------------------------------|
| | | property |
| userused | other | Allows reading any userused@... property |

The following properties can have delegated permissions applied:

| | | | |
|-----------------|---------------|----------------|----------------|
| aclinherit | aclmode | atime | canmount |
| casesensitivity | checksum | compression | copies |
| devices | exec | logbias | mountpoint |
| nbmand | normalization | primarycache | quota |
| readonly | recordsize | refquota | refreservation |
| reservation | rstchown | secondarycache | setuid |
| shareiscsi | sharenfs | sharesmb | snappdir |
| sync | utf8only | version | volblocksize |
| volsize | vscan | xattr | zoned |

`zfs allow -c perm@setname[,...] filesystem|volume`

Sets create time permissions. These permissions are granted (locally) to the creator of any newly-created descendent file system.

`zfs allow -s @setname perm@setname[,...] filesystem|volume`

Defines or adds permissions to a permission set. The set can be used by other `zfs allow` commands for the specified file system and its descendents. Sets are evaluated dynamically, so changes to a set are immediately reflected. Permission sets follow the same naming restrictions as ZFS file systems, but the name must begin with an at (@) sign, and can be no more than 64 characters long.

`zfs unallow [-rldug] everyone|user|group[,...] [perm@setname[, ...]] filesystem|volume`

`zfs unallow [-rld] -e [perm@setname [...]] filesystem|volume`

`zfs unallow [-r] -c [perm@setname[,...]]`

`filesystem|volume`

Removes permissions that were granted with the `zfs allow` command. No permissions are explicitly denied, so other permissions granted are still in effect. For example, if the permission is granted by an ancestor. If no permissions are specified, then all permissions for the specified *user*, *group*, or *everyone* are removed. Specifying *everyone* (or using the `-e` option) only removes the permissions that were granted to everyone, not all permissions for every user and group. See the `zfs allow` command for a description of the `-ldugec` options.

`-r`

Recursively remove the permissions from this file system and all descendents.

`zfs unallow [-r] -s @setname [perm@setname[,...]]`

`filesystem|volume`

Removes permissions from a permission set. If no permissions are specified, then all permissions are removed, thus removing the set entirely.

`zfs hold [-r] tag snapshot...`

Adds a single reference, named with the *tag* argument, to the specified snapshot or snapshots. Each snapshot has its own tag namespace, and tags must be unique within that space.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the `zfs destroy` command return EBUSY.

-r

Specifies that a hold with the given tag is applied recursively to the snapshots of all descendent file systems.

`zfs holds [-r] snapshot...`

Lists all existing user references for the given snapshot or snapshots.

-r

Lists the holds that are set on the named descendent snapshots, in addition to listing the holds on the named snapshot.

`zfs release [-r] tag snapshot...`

Removes a single reference, named with the *tag* argument, from the specified snapshot or snapshots. The tag must already exist for each snapshot.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the `zfs destroy` command return EBUSY.

-r

Recursively releases a hold with the given tag on the snapshots of all descendent file systems.

`zfs diff [-FHte] [-o field] ... snapshot snapshot | filesystem`

`zfs diff -E[-FHT] -o field ... snapshot | filesystem`

Gives a high-level description of the differences between a snapshot and a descendent dataset. The descendent can be either a snapshot of the dataset or the current dataset.

If a single snapshot is specified, then differences between that snapshot and the current dataset are given.

For each file that has undergone a change between the original snapshot and the descendent, the type of change is described along with the name of the file. In the case of a rename, both the old and new names are shown. Whitespace characters, backslash characters, and other non-printable or non-7-bit ASCII characters found in file names are displayed as a backslash character followed by the three-digit octal representation of the byte value.

If the `-t` option is specified, the first column of output from the command is the file's `st_ctim` value. For deleted files, this is the final `st_ctim` in the earlier snapshot.

The type of change follows any timestamp displayed, and is described with a single character:

- + Indicates the file was added in the later dataset.
- Indicates the file was removed in the later dataset.
- M Indicates the file was modified in the later dataset.

R Indicates the file was renamed in the later dataset.

If the `-F` option is specified, the next column of output is a single character describing the type of the file. The mappings are:

F regular file
/ directory
B block device
> door
| FIFO
@ symbolic link
P event portal
= socket

If the modification involved a change in the link count of a non-directory file, the change is expressed as a delta within parentheses on the modification line. If the file was renamed, the old name is separated from the new with the string “->”.

If the `-H` option is selected, easier-to-parse output is produced. Fields are separated by a single tab, and no arrow string (`->`) is placed between the old and new names of a rename. No guarantees are made on the spacing between fields of non `-H` output.

If the `-e` option is selected, then all files added or modified between the two snapshots are enumerated and no deleted files are displayed. The change type always reports as `+` regardless of the type of modification.

If the `-E` option is selected, then differences are given as if from an empty snapshot to the specified snapshot or dataset.

If the `-o` field option is selected, then only selected fields are displayed. Each line starts with the standard fields requested by the `-F` and `-t` options, followed by the fields requested in successive `-o` options. As with the `-H` option, all fields are separated by a single tab. The allowable field names include:

| | |
|-------------|--------------------------------------------------------|
| object | The number printed by <code>ls -li</code> for the file |
| parent | The number printed by <code>ls -li</code> for the file |
| size | The file size as displayed by <code>ls -s</code> |
| links | The number of links to the file |
| linkschange | The change in the number of links to the file |
| name | The name of the file |

| | |
|----------------------|------------------------------------------------------------------------------------------------|
| <code>oldname</code> | The name of the file before the rename, or <code>-</code> (hyphen) if the file was not renamed |
| <code>user</code> | The owner name of the file as displayed by <code>ls</code> |
| <code>group</code> | The group name of the file as displayed by <code>ls</code> |
| <code>ctime</code> | The timestamp when the file's metadata was last modified |
| <code>mtime</code> | The timestamp when the file was last modified |
| <code>atime</code> | The timestamp when a file was last accessed |
| <code>ctime</code> | The timestamp when a file was created |

Unless they already have the `{PRIV_SYS_CONFIG}` or `{PRIV_SYS_MOUNT}` privilege, users must be granted the `diff` permission with `zfs allow` to use this subcommand.

Examples EXAMPLE 1 Creating a ZFS File System Hierarchy

The following commands create a file system named `pool/home` and a file system named `pool/home/bob`. The mount point `/export/home` is set for the parent file system, and is automatically inherited by the child file system.

```
# zfs create pool/home
# zfs set mountpoint=/export/home pool/home
# zfs create pool/home/bob
```

EXAMPLE 2 Creating a ZFS Snapshot

The following command creates a snapshot named `yesterday`. This snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of the `pool/home/bob` file system.

```
# zfs snapshot pool/home/bob@yesterday
```

EXAMPLE 3 Creating and Destroying Multiple Snapshots

The following command creates snapshots named `yesterday` of `pool/home` and all of its descendent file systems. Each snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of its file system. The second command destroys the newly created snapshots.

```
# zfs snapshot -r pool/home@yesterday
# zfs destroy -r pool/home@yesterday
```

EXAMPLE 4 Disabling and Enabling File System Compression

The following command disables the `compression` property for all file systems under `pool/home`. The next command explicitly enables compression for `pool/home/anne`.

```
# zfs set compression=off pool/home
# zfs set compression=on pool/home/anne
```

EXAMPLE 5 Listing ZFS Datasets

The following command lists all active file systems and volumes in the system. Snapshots are displayed if the `listsnapshots` property is on. The default is on. See [zpool\(1M\)](#) for more information on pool properties.

```
# zfs list
NAME                                USED  AVAIL  REFER  MOUNTPOINT
pool                                450K  457G   18K    /pool
pool/home                           315K  457G   21K    /export/home
pool/home/anne                       18K  457G   18K    /export/home/anne
pool/home/bob                        276K  457G  276K    /export/home/bob
```

EXAMPLE 6 Setting a Quota on a ZFS File System

The following command sets a quota of 30 GB for `pool/home/bob`.

```
# zfs set quota=30G pool/home/bob
```

EXAMPLE 7 Listing ZFS Properties

The following command lists all properties for `pool/home/bob`.

```
# zfs get all pool/home/bob
NAME          PROPERTY          VALUE          SOURCE
pool/home/bob type              filesystem     -
pool/home/bob creation          Wed Jun  6 15:16 2012 -
pool/home/bob used              31K            -
pool/home/bob available         30.0G          -
pool/home/bob referenced        31K            -
pool/home/bob compressratio    1.00x          -
pool/home/bob mounted            yes            -
pool/home/bob quota              30G            local
pool/home/bob reservation        none           default
pool/home/bob recordsize      128K           default
pool/home/bob mountpoint        /pool/home/bob default
pool/home/bob sharenfs          off            default
pool/home/bob checksum          on             default
pool/home/bob compression        on             local
pool/home/bob atime            on             default
pool/home/bob devices          on             default
pool/home/bob exec              on             default
pool/home/bob setuid            on             default
pool/home/bob readonly         off            default
pool/home/bob zoned             off            default
pool/home/bob snapdir          hidden         default
pool/home/bob aclmode          discard        default
pool/home/bob aclinherit        restricted     default
pool/home/bob canmount          on             default
pool/home/bob shareiscsi        off            default
```

EXAMPLE 7 Listing ZFS Properties (Continued)

| | | | |
|---------------|----------------------|----------|---------|
| pool/home/bob | xattr | on | default |
| pool/home/bob | copies | 1 | default |
| pool/home/bob | version | 5 | - |
| pool/home/bob | utf8only | off | - |
| pool/home/bob | normalization | none | - |
| pool/home/bob | casesensitivity | mixed | - |
| pool/home/bob | vscan | off | default |
| pool/home/bob | nbmand | off | default |
| pool/home/bob | sharesmb | off | default |
| pool/home/bob | refquota | none | default |
| pool/home/bob | refreservation | none | default |
| pool/home/bob | primarycache | all | default |
| pool/home/bob | secondarycache | all | default |
| pool/home/bob | usedbysnapshots | 0 | - |
| pool/home/bob | usedbydataset | 31K | - |
| pool/home/bob | usedbychildren | 0 | - |
| pool/home/bob | usedbyrefreservation | 0 | - |
| pool/home/bob | logbias | latency | default |
| pool/home/bob | sync | standard | default |
| pool/home/bob | rekeydate | - | default |
| pool/home/bob | rstchown | on | default |

The following command gets a single property value.

```
# zfs get -H -o value compression pool/home/bob
on
```

The following command lists all properties with local settings for pool/home/bob.

```
# zfs get -r -s local -o name,property,value all pool/home/bob
NAME          PROPERTY      VALUE
pool/home/bob quota         30G
pool/home/bob compression   on
```

EXAMPLE 8 Rolling Back a ZFS File System

The following command reverts the contents of pool/home/anne to the snapshot named yesterday, deleting all intermediate snapshots.

```
# zfs rollback -r pool/home/anne@yesterday
```

EXAMPLE 9 Creating a ZFS Clone

The following command creates a writable file system whose initial contents are the same as pool/home/bob@yesterday.

```
# zfs clone pool/home/bob@yesterday pool/clone
```

EXAMPLE 10 Promoting a ZFS Clone

The following commands illustrate how to test out changes to a file system, and then replace the original file system with the changed one, using clones, clone promotion, and renaming:

```
# zfs create pool/project/production
  populate /pool/project/production with data
# zfs snapshot pool/project/production@today
# zfs clone pool/project/production@today pool/project/beta
  make changes to /pool/project/beta and test them
# zfs promote pool/project/beta
# zfs rename pool/project/production pool/project/legacy
# zfs rename pool/project/beta pool/project/production
  once the legacy version is no longer needed, it can be destroyed
# zfs destroy pool/project/legacy
```

EXAMPLE 11 Inheriting ZFS Properties

The following command causes `pool/home/bob` and `pool/home/anne` to inherit the checksum property from their parent.

```
# zfs inherit checksum pool/home/bob pool/home/anne
```

EXAMPLE 12 Remotely Replicating ZFS Data

The following commands send a full stream and then an incremental stream to a remote machine, restoring them into `poolB/received/fs@a` and `poolB/received/fs@b`, respectively. `poolB` must contain the file system `poolB/received`, and must not initially contain `poolB/received/fs`.

```
# zfs send pool/fs@a | \
  ssh host zfs receive poolB/received/fs@a
# zfs send -i a pool/fs@b | ssh host \
  zfs receive poolB/received/fs
```

EXAMPLE 13 Using the `zfs receive -d` Option

The following command sends a full stream of `poolA/fsA/fsB@snap` to a remote machine, receiving it into `poolB/received/fsA/fsB@snap`. The `fsA/fsB@snap` portion of the received snapshot's name is determined from the name of the sent snapshot. `poolB` must contain the file system `poolB/received`. If `poolB/received/fsA` does not exist, it is created as an empty file system.

```
# zfs send poolA/fsA/fsB@snap | \
  ssh host zfs receive -d poolB/received
```

EXAMPLE 14 Setting User Properties

The following example sets the user-defined `com.example:department` property for a dataset.

```
# zfs set com.example:department=12345 tank/accounting
```

EXAMPLE 15 Performing a Rolling Snapshot

The following example shows how to maintain a history of snapshots with a consistent naming scheme. To keep a week's worth of snapshots, the user destroys the oldest snapshot, renames the remaining snapshots, and then creates a new snapshot, as follows:

```
# zfs destroy -r pool/users@7daysago
# zfs rename -r pool/users@6daysago @7daysago
# zfs rename -r pool/users@5daysago @6daysago
# zfs rename -r pool/users@4daysago @5daysago
# zfs rename -r pool/users@3daysago @4daysago
# zfs rename -r pool/users@2daysago @3daysago
# zfs rename -r pool/users@yesterday @2daysago
# zfs rename -r pool/users@today @yesterday
# zfs snapshot -r pool/users@today
```

EXAMPLE 16 Setting sharenfs Property Options on a ZFS File System

The following example shows how to share a file system with nosuid access. In this case, single quotes are not needed for the share property value because a single share option is included.

```
# zfs set sharenfs=nosuid tank/shares
```

The following commands show how to set sharenfs property options to enable rw access for a set of IP addresses and to enable root access for system neo on the tank/home file system. In this case, single quotes are required for multiple options.

```
# zfs set sharenfs='rw=@123.123.0.0/16,root=neo' tank/home
```

If you are using DNS for host name resolution, specify the fully qualified hostname.

EXAMPLE 17 Delegating ZFS Administration Permissions on a ZFS Dataset

The following example shows how to set permissions so that user anne can create, destroy, mount, and take snapshots on pool/home/anne. The permissions on pool/home/anne are also displayed.

```
# zfs allow anne create,destroy,mount,snapshot pool/home/anne
# zfs allow pool/home/anne
---- Permissions on pool/home/anne -----
Local+Descendent permissions:
    user anne create,destroy,mount,snapshot
```

Because the pool/home/anne mount point permission is set to 755 by default, user anne will be unable to mount file systems under pool/home/anne. Set an ACL similar to the following syntax to provide mount point access:

```
# chmod A+user:anne:add_subdirectory:allow /pool/home/anne
```

EXAMPLE 18 Delegating Create Time Permissions on a ZFS Dataset

The following example shows how to grant anyone in the group `staff` to create file systems in `pool/home`. This syntax also allows staff members to destroy their own file systems, but not destroy anyone else's file system. The permissions on `pool/home` are also displayed.

```
# zfs allow staff create,mount pool/home
# zfs allow -c destroy pool/home
# zfs allow pool/home
---- Permissions on pool/home -----
Create time permissions:
    destroy
Local+Descendent permissions:
    group staff create,mount
```

EXAMPLE 19 Defining and Granting a Permission Set on a ZFS Dataset

The following example shows how to define and grant a permission set on the `pool/home` file system. The permissions on `pool/home` are also displayed.

```
# zfs allow -s @pset create,destroy,snapshot,mount pool/home
# zfs allow staff @pset pool/home
# zfs allow pool/home
---- Permissions on pool/home -----
Permission sets:
    @pset create,destroy,mount,snapshot
Create time permissions:
    destroy
Local+Descendent permissions:
    group staff @pset,create,mount
```

EXAMPLE 20 Delegating Property Permissions on a ZFS Dataset

The following example shows how to grant the ability to set quotas and reservations on the `tank/users` file system. The permissions on `tank/users` are also displayed.

```
# zfs allow mark quota,reservation tank/users
# zfs allow tank/users
---- Permissions on tank/users -----
Local+Descendent permissions:
    user mark quota,reservation

mark% zfs set quota=10G tank/users/tim
mark% zfs get quota tank/users/tim
NAME          PROPERTY  VALUE  SOURCE
tank/users/tim quota     10G   local
```

EXAMPLE 21 Removing ZFS Delegated Permissions on a ZFS Dataset

The following example shows how to remove the snapshot permission from the @pset permission set for the staff group on the pool/home file system. The permissions on pool/home are also displayed.

```
# zfs unallow -s @pset snapshot pool/home
# zfs allow pool/home
---- Permissions on pool/home -----
Permission sets:
    @pset create,destroy,mount
Create time permissions:
    destroy
Local+Descendent permissions:
    group staff @pset,create,mount
```

EXAMPLE 22 Displaying ZFS Snapshot Differences

The following command shows the output from a zfs diff command with the -F and -t options.

```
# zfs diff -Ft myfiles@snap1
1269962501.206726811 M / /myfiles/
1269962444.207369955 M F /myfiles/link_to_me (+1)
1269962499.207519034 R /myfiles/rename_me -> /myfiles/renamed
1269962431.813566720 - F /myfiles/delete_me
1269962518.666905544 + F /myfiles/new_file
1269962501.393099817 + | /myfiles/new_pipe
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
An error occurred.
- 2
Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | system/file-system/zfs |
| Interface Stability | Committed |

See Also [chown\(1\)](#), [pktool\(1\)](#), [ssh\(1\)](#), [mount\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [zonecfg\(1M\)](#), [zpool\(1M\)](#), [chmod\(2\)](#), [chown\(2\)](#), [stat\(2\)](#), [write\(2\)](#), [fsync\(3C\)](#), [dfstab\(4\)](#), [attributes\(5\)](#)

See the [gzip\(1\)](#) man page, which is not part of the SunOS man page collection.

For information about using the ZFS web-based management tool and other ZFS features, see the *Oracle Solaris ZFS Administration Guide*.

Notes A file described as modified by the `diff` subcommand might have been modified in multiple ways. Any action that causes a change in the `st_ctim` (see [stat\(2\)](#)) is a basis for reporting a modification.

Name zic – time zone compiler

Synopsis zic [*--version*] [*-s*] [*-v*] [*-l localtime*] [*-p posixrules*]
 [*-d directory*] [*-y yearistype*] [*filename*]...

Description zic reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a *filename* is '-', the standard input is read.

Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.

Rule A rule line has the form:

For example:

```
Rule  NAME  FROM  TO  TYPE  IN  ON      AT  SAVE  LETTER/S
```

The fields that make up a rule line are:

```
Rule  USA   1969  1973  -  Apr  lastSun  2:00  1:00  D
```

NAME Gives the (arbitrary) name of the set of rules this rule is part of.

FROM Gives the first year in which the rule applies. The word *minimum* (or an abbreviation) means the minimum year with a representable time value. The word *maximum* (or an abbreviation) means the maximum year with a representable time value.

TO Gives the final year in which the rule applies. In addition to *minimum* and *maximum* (as above), the word *only* (or an abbreviation) can be used to repeat the value of the **FROM** field.

TYPE Gives the type of year in which the rule applies. If **TYPE** is:

- '-' The rule applies in all years between **FROM** and **TO**, inclusive.
- uspres* The rule applies in U.S. Presidential election years.
- nonpres* The rule applies in years other than U.S. Presidential election years.
- even* The rule applies to even-numbered years.
- odd* The rule applies to odd-numbered years.

If **TYPE** is something else, then zic will attempt to execute the command *yearistype year type*

to check the type of a year: an exit status of 0 means that the year is of the given type; an exit status of 1 means that the year is not of the given type. The `year is type` command is not currently provided in the Solaris environment.

- IN** Names the month in which the rule takes effect. Month names can be abbreviated.
- ON** Gives the day on which the rule takes effect. Recognized forms include:
- 5 the fifth day of the month
 - lastSun The last Sunday in the month
 - lastMon The last Monday in the month
 - Sun>=8 First Sunday on or after the eighth
 - Sun<=25 Last Sunday on or before the 25th
- Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the ON field.
- AT** Gives the time of day at which the rule takes effect. Recognized forms include:
- 2 Time in hours
 - 2:00 Time in hours and minutes
 - 15:00 24-hour format time (for times after noon)
 - 1:28:14 Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.
- Any of these forms can be followed by the letter `w` if the given time is local “wall clock” time; `s` if the given time is local “standard” time; or `u` (or `g` or `z`) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.
- SAVE** Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the AT field (without the `w` and `s` suffixes).
- LETTER/S** Gives the “variable part” (for example, the “S” or “D” in “EST” or “EDT” of time zone abbreviations to be used when this rule is in effect. If this field is ‘-’, the variable part is null.

Zone A zone line has the form:

```
Zone NAME           GMTOFF RULES/SAVE   FORMAT [UNTIL]
```

For example:

```
Zone Australia/SouthWest 9:30 - CST 1992 Mar 15 12:00
                        8:30 Aus  CST
```

The fields that make up a zone line are:

| | |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME | The name of the time zone. This is the name used in creating the time conversion information file for the zone. |
| GMTOFF | The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC. |
| RULES/SAVE | The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '-', then standard time always applies in the time zone. |
| FORMAT | The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations. |
| UNTIL | The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified. |

The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns.

The next line must be a "continuation" line. This line has the same form as a zone line except that the string "Zone" and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link A link line has the form:

```
Link LINK-FROM LINK-TO
```

For example:

```
Link Europe/Istanbul Asia/Istanbul
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.

Except for continuation lines, lines can appear in any order in the input.

- Options**
- v** *version* Outputs version information and exits.
 - d** *directory* Creates time conversion information files in the directory *directory* rather than in the standard directory `/usr/share/lib/zoneinfo`.
 - l** *localtime* Uses the given time zone as local time *localtime*. `zic` acts as if the file contained a link line of the form:

Link *localtime* localtime
 - p** *posixrules* Uses the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. `zic` acts as if the input contained a link line of the form:

Link *posixrules* posixrules

This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.
 - s** Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

This option is obsolete and may be removed in a future release.
 - v** Complains if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. UTC, January 1, 1970, to 3:14:07 a.m. UTC, January 19, 2038). This option also complains if a time of 24:00 (which cannot be handled by pre-1998 versions of `zic`) appears in the input.
 - y** *yearistype* Uses the given command *yearistype* rather than `yearistype` when checking year types (see Rules under DESCRIPTION).

Operands *filename* A file containing input lines that specify the time conversion information files to be created. If a *filename* is '-', the standard input is read.

Files `/usr/share/lib/zoneinfo` Standard directory used for created files
`/usr/share/lib/zoneinfo/src` Directory containing source files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | Committed* |

* The -s option is obsolete.

See Also [time\(1\)](#), [zdump\(1M\)](#), [ctime\(3C\)](#), [mktime\(3C\)](#), [attributes\(5\)](#)

Notes For areas with more than two types of local time, you might need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

If the current *timezone* file is edited and compiled using the “zic” command, the changes will only be reflected in any new processes that are running. The most accurate way to reflect the changes for the whole system would be a reboot.

Name zoneadm – administer zones

Synopsis zoneadm -z *zonename* [-u *uuid-match*] *subcommand*
[*subcommand_options*]
zoneadm [-R *root*] [-z *zonename*] [-u *uuid-match*] *list*
[*list_options*]
zoneadm [-R *root*] -z *zonename* [-u *uuid-match*] *mark incomplete*

Description The zoneadm utility is used to administer system zones. A zone is an application container that is maintained by the operating system runtime.

Security Once a process has been placed in a zone other than zone 0, the process or any of its children cannot change zones.

Options The following options are supported:

-R *root*

Specify an alternate root (boot environment). This option can only be used in conjunction with the “list” and “mark” subcommands.

-u *uuid-match*

Unique identifier for a zone, as assigned by [libuuid\(3LIB\)](#). If this option is present and the argument is a non-empty string, then the zone matching the UUID is selected instead of the one named by the -z option, if such a zone is present.

-z *zonename*

String identifier for a zone.

Subcommands Subcommands which can result in destructive actions or loss of work have a -F flag to force the action. If input is from a terminal device, the user is prompted if such a command is given without the -F flag; otherwise, if such a command is given without the -F flag, the action is disallowed, with a diagnostic message written to standard error. If a zone installation or uninstallation is interrupted, the zone is left in the incomplete state. Use `uninstall` to reset such a zone back to the configured state.

The following subcommands are supported:

`attach [-u | -U] [-b patchid]... [-F] [-n path] [brand-specific options]`

The `attach` subcommand takes a zone that has been detached from one system and attaches the zone onto a new system. Therefore, it is advised (though not required) that the `detach` subcommand should be run before the “attach” takes place. Once you have the new zone in the configured state, use the `attach` subcommand to set up the zone root instead of installing the zone as a new zone.

For native zones, zoneadm checks package and patch levels on the machine to which the zone is to be attached. If the packages/patches that the zone depends on from the global zone are different (have different revision numbers) from the dependent packages/patches on the source machine, zoneadm reports these conflicts and does not perform the attach. If

the destination system has only newer dependent packages/patches (higher revision numbers) than those on the source system, you can use the `-u` or `-U` options. The `-u` option updates the minimum number of packages within the attached zone to match the higher-revision packages and patches that exist on the new system. The `-U` option updates all packages in the attached zone that are also installed in the global zone. With `-u` or `-U`, as in the default behavior, `zoneadm` does not perform an attach if outdated packages/patches are found on the target system.

For native zones, one or more `-b` options can be used to specify a patch ID for a patch installed in the zone. These patches will be backed out before the zone is attached or, if `-u` was also specified, updated. If multiple `-b` options are specified, the patches will be removed in the order that they appear on the command line. Patches should be backed out in the reverse order in which they were installed.

The `-F` option can be used to force the zone into the “installed” state with no validation. This option should be used with care since it can leave the zone in an unsupported state if it was moved from a source system to a target system that is unable to properly host the zone. The `-n` option can be used to perform a “dry run” of the `attach` subcommand. It uses the output of the “`detach -n`” subcommand as input and is useful to identify any conflicting issues, such as the network device being incompatible, and can also determine whether the host is capable of supporting the zone. The path can be “`-`”, to read the input from standard input.

The zone's brand may include additional options that govern how the zone will be attached. See [brands\(5\)](#) for specific brand information.

The zone being attached must first be configured using the `zonecfg` (see [zonecfg\(1M\)](#)) command. This does not apply when running “`attach -n`”.

Use the following command to attach a zone:

```
# zoneadm -z my-zone attach
```

Use the following command to attach and update a zone:

```
# zoneadm -z my-zone attach -u (or -U)
```

In the absence of `-n` (as above), the source zone must be halted before this subcommand can be used.

`-n path`

Read the zone manifest and verify that the target machine has the correct configuration to host the zone without actually performing an attach. The zone on the target system does not have to be configured on the new host before doing a trial-run attach.

`-u or -U`

Update the attached zone as described above.

`boot [- - boot_options]`

Boot (or activate) the specified zones.

The following *boot_options* are supported:

`-i altinit`

Select an alternative executable to be the primordial Process. *altinit* is a valid path to an executable. The default primordial process is `init(1M)`.

`-m smf_options`

The *smf_options* include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

Message options determine the type and amount of messages that `smf(5)` displays during boot. Service options determine the services which are used to boot the system. See `kernel(1M)` for a listing of the `-m` suboptions.

`-s`

Boots only to milestone `svc:/milestone/single-user:default`. This milestone is equivalent to init level `s`. See `svc.startd(1M)` and `init(1M)`.

`clone [-m copy] [-s zfs_snapshot] source_zone`

Install a zone by copying an existing installed zone. This subcommand is an alternative way to install the zone.

`-m copy`

Force the clone to be a copy, even if a “ZFS clone” is possible.

`-s zfs_snapshot`

Specify the name of a ZFS snapshot to use as the source of the clone. The *snapshot* must be a *snapshot* of the source zone taken from a previous “zoneadm clone” installation.

The source zone must be halted before this subcommand can be used.

`detach [-n]`

Detach the specified zone. Detaching a zone is the first step in moving a zone from one system to another. The full procedure to migrate a zone is that the zone is detached, the *zonepath* directory is moved to the new host, and then the zone is attached on the new host. Once the zone is detached, it is left in the configured state. If you try to install or clone to a configured zone that has been detached, you will receive an error message and the `install` or `clone` subcommand will not be allowed to proceed. The `-n` option can be used to perform a “dry run” of the `detach` subcommand. This generates the information needed for running the “`attach -n`” subcommand, which is useful to identify any conflicting issues, such as the network device being incompatible or if the host is capable of supporting the zone. The information is sent to standard output and can be saved to a file or piped to the “`attach -n`” subcommand.

Use the following command to detach a zone:

```
# zoneadm -z my-zone detach
```

Unless the `-n` option is used, the source zone must be halted before this subcommand can be used.

`-n`

Generate a zone manifest on a running zone without actually detaching the zone. The state of the zone on the originating system is not changed. The zone manifest is sent to `stdout`. The global administrator can direct this output to a file or pipe it to a remote command to be immediately validated on the target host.

`halt`

Halt the specified zones. `halt` bypasses running the shutdown scripts inside the zone. It also removes run time resources of the zone.

Use:

```
zlogin zone shutdown
```

to cleanly shutdown the zone by running the shutdown scripts.

`help` [*subcommand*]

Display general help. If you specify *subcommand*, displays help on *subcommand*.

`install` [`-x nodataset`] [*brand-specific options*]

Install the specified zone on the system. This subcommand automatically attempts to verify first. It refuses to install if the verify step fails. See the `verify` subcommand.

The zone's brand may include additional options that govern how the software will be installed in the zone. See [brands\(5\)](#) for specific brand information.

`-x nodataset`

Do not create a ZFS file system.

`list` [*list_options*]

Display the name of the current zones, or the specified zone if indicated.

By default, all running zones are listed. If you use this subcommand with the `zoneadm -z zonename` option, it lists only the specified zone, regardless of its state. In this case, the `-i` and `-c` options are disallowed.

If neither the `-i` or `-c` options are given, all running zones are listed.

The following *list_options* are supported:

`-c`

Display all configured zones. This option overrides the `-i` option.

`-i`

Expand the display to all installed zones.

`-p`

Request machine parsable output. The output format is a list of lines, one per zone, with colon-delimited fields. These fields are:

zoneid:zonename:state:zonepath:uuid:brand:ip-type

If the *zonepath* contains embedded colons, they can be escaped by a backslash (“\:”), which is parsable by using the shell `read(1)` function with the environmental variable `IFS`. The *uuid* value is assigned by `libuuid(3LIB)` when the zone is installed, and is useful for identifying the same zone when present (or renamed) on alternate boot environments. Any software that parses the output of the “`zoneadm list -p`” command must be able to handle any fields that may be added in the future.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

`-v`

Display verbose information, including zone name, id, current state, root directory, brand type, ip-type, and options.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

`mark incomplete`

Change the state of an installed zone to “incomplete.” This command may be useful in cases where administrative changes on the system have rendered a zone unusable or inconsistent. This change cannot be undone (except by uninstalling the zone).

`move new_zonepath`

Move the *zonepath* to *new_zonepath*. The zone must be halted before this subcommand can be used. The *new_zonepath* must be a local file system and normal restrictions for *zonepath* apply.

`ready`

Prepares a zone for running applications but does not start any user processes in the zone.

`reboot`

Restart the zones. This is equivalent to a `halt` boot sequence. This subcommand fails if the specified zones are not active.

`uninstall [-F]`

Uninstall the specified zone from the system. Use this subcommand with caution. It removes all of the files under the *zonepath* of the zone in question. You can use the `-F` flag to force the action.

`verify`

Check to make sure the configuration of the specified zone can safely be installed on the machine. Following is a break-down of the checks by resource/property type:

`zonepath`

zonepath and its parent directory exist and are owned by root with appropriate modes. The appropriate modes are that *zonepath* is `700`, its parent is not `group` or `world-writable` and so forth. *zonepath* is not over an NFS mount. A sub-directory of the *zonepath* named “`root`” does not exist.

If `zonepath` does not exist, the `verify` does not fail, but merely warns that a subsequent install will attempt to create it with proper permissions. A `verify` subsequent to that might fail should anything go wrong.

`zonepath` cannot be a symbolic link.

fs

Any `fs` resources have their `type` value checked. An error is reported if the value is one of `proc`, `mntfs`, `autofs`, `cachefs`, or `nfs` or the filesystem does not have an associated mount binary at `/usr/lib/fs/<fstype>/mount`.

It is an error for the `directory` to be a relative path.

It is an error for the path specified by `raw` to be a relative path or if there is no `fsck` binary for a given filesystem type at `/usr/lib/fs/<fstype>/fsck`. It is also an error if a corresponding `fsck` binary exists but a `raw` path is not specified.

net

All physical network interfaces exist. All network address resources are one of:

- a valid IPv4 address, optionally followed by “/” and a prefix length;
- a valid IPv6 address, which must be followed by “/” and a prefix length;
- a host name which resolves to an IPv4 address.

Note that hostnames that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, both the physical and address properties must be set. For an exclusive-IP zone, the physical property must be set and the address property cannot be set.

rctl

It also verifies that any defined resource control values are valid on the current machine. This means that the privilege level is `privileged`, the limit is lower than the currently defined system value, and that the defined action agrees with the actions that are valid for the given resource control.

Examples EXAMPLE 1 Using the `-m` Option

The following command illustrates the use of the `-m` option.

```
# zoneadm boot -- -m verbose
```

EXAMPLE 2 Using the `-i` Option

The following command illustrates the use of the `-i` option.

```
# zoneadm boot -- -i /sbin/init
```

EXAMPLE 3 Using the -s Option

The following command illustrates the use of the -s option.

```
# zoneadm boot -- -s
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
An error occurred.
- 2
Invalid usage.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/zones |
| Interface Stability | Committed |

See Also [read\(1\)](#), [svcs\(1\)](#), [zlogin\(1\)](#), [zonename\(1\)](#), [init\(1M\)](#), [kernel\(1M\)](#), [svcadm\(1M\)](#), [svc.startd\(1M\)](#), [zonecfg\(1M\)](#), [libuuid\(3LIB\)](#), [attributes\(5\)](#), [brands\(5\)](#), [native\(5\)](#), [smf\(5\)](#), [zones\(5\)](#)

Notes The [zones\(5\)](#) service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

The act of installing a new non-global zone is a fresh installation of the Solaris operating system. A new installation of Solaris must not require interaction with the user (that is, it must be “hands off”). Because of this, packages installed in the global zone and all non-global zones cannot contain request scripts (see [pkgask\(1M\)](#)). If a package did have a request script, then the creation of a non-global zone could not be done without user intervention. Any package that contains a request script is added to the global zone only. See [pkgadd\(1M\)](#).

Name zoneadmd – zone administration daemon

Synopsis /usr/lib/zones/zoneadmd

Description zoneadmd is a system daemon that is started when the system needs to manage a particular zone. Because each instance of the zoneadmd daemon manages a particular zone, it is not unexpected to see multiple zoneadmd daemons running.

This daemon is started automatically by the zone management software and should not be invoked directly. The daemon shuts down automatically when no longer in use. It does not constitute a programming interface, but is classified as a private interface.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability | SUNWzoneu |
| Interface Stability | Private |

See Also [svcs\(1\)](#), [zlogin\(1\)](#), [svcadm\(1M\)](#), [zoneadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#), [zones\(5\)](#)

Notes The [zones\(5\)](#) service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name zonecfg – set up zone configuration

Synopsis zonecfg -z *zonename*
zonecfg -z *zonename subcommand*
zonecfg -z *zonename -f command_file*
zonecfg help

Description The zonecfg utility creates and modifies the configuration of a zone. Zone configuration consists of a number of resources and properties.

To simplify the user interface, zonecfg uses the concept of a scope. The default scope is global.

The following synopsis of the zonecfg command is for interactive usage:

```
zonecfg -z zonename subcommand
```

Parameters changed through zonecfg do not affect a running zone. The zone must be rebooted for the changes to take effect.

In addition to creating and modifying a zone, the zonecfg utility can also be used to persistently specify the resource management settings for the global zone.

In the following text, “rctl” is used as an abbreviation for “resource control”. See [resource_controls\(5\)](#).

Every zone is configured with an associated brand. The brand determines the user-level environment used within the zone, as well as various behaviors for the zone when it is installed, boots, or is shutdown. Once a zone has been installed the brand cannot be changed. The default brand is determined by the installed distribution in the global zone. Some brands do not support all of the zonecfg properties and resources. See the brand-specific man page for more details on each brand. For an overview of brands, see the [brands\(5\)](#) man page.

Resources The following resource types are supported:

attr

Generic attribute.

capped-cpu

Limits for CPU usage.

capped-memory

Limits for physical, swap, and locked memory.

dataset

ZFS dataset.

dedicated-cpu

Subset of the system's processors dedicated to this zone while it is running.

device

Device.

fs

file-system

inherit-pkg-dir

Directory inherited from the global zone. Used for sparse root zones (see the discussion of “Sparse and Whole Root Non-Global Zones,” below). Software packages whose contents have been transferred into that directory are inherited in read-only mode by the non-global zone and the non-global zone's packaging database is updated to reflect those packages. Such resources are not modifiable or removable once a zone has been installed with zoneadm.

net

Network interface.

rctl

Resource control.

Sparse and Whole Root
Non-Global Zones

In the administration of zones, it is useful to distinguish between the global zone and non-global zones. Within non-global zones, there are two zone root file system models: sparse and whole root. The sparse root zone model optimizes the sharing of objects. The whole root zone model provides the maximum configurability. Note that not all brands support the sparse zone model.

Sparse Root Zones

Non-global zones that have `inherit-pkg-dir` resources are called sparse root zones.

The sparse root zone model optimizes the sharing of objects in the following ways:

- Only a subset of the packages installed in the global zone are installed directly into the non-global zone.
- Read-only loopback file systems, identified as `inherit-pkg-dir` resources, are used to gain access to other files.

In this model, all packages appear to be installed in the non-global zone. Packages that do not deliver content into read-only loopback mount file systems are fully installed. There is no need to install content delivered into read-only loopback mounted file systems since that content is inherited (and visible) from the global zone.

- As a general guideline, a zone requires about 100 megabytes of free disk space per zone when the global zone has been installed with all of the standard Solaris packages.
- By default, any additional packages installed in the global zone also populate the non-global zones. The amount of disk space required might be increased accordingly, depending on whether the additional packages deliver files that reside in the `inherit-pkg-dir` resource space.

An additional 40 megabytes of RAM per zone are suggested, but not required on a machine with sufficient swap space.

A sparse zone inherits the following directories:

```
/lib
/platform
/sbin
/usr
```

Although `zonecfg` allows you to remove one of these as an inherited directory, you should not do so. You should either follow the whole-root model or the sparse model; a subset of the sparse model is not tested and you might encounter unexpected problems.

Adding an additional `inherit-pkg-dir` directory, such as `/opt`, to a sparse root zone is acceptable.

Whole Root Zones

The whole root zone model provides the maximum configurability. All of the required and any selected optional Solaris packages are installed into the private file systems of the zone. The advantages of this model include the capability for global administrators to customize their zones file system layout. This would be done, for example, to add arbitrary unbundled or third-party packages.

The disk requirements for this model are determined by the disk space used by the packages currently installed in the global zone.

Note – If you create a sparse root zone that contains the following `inherit-pkg-dir` directories, you must remove these directories from the non-global zone's configuration before the zone is installed to have a whole root zone:

- `/lib`
- `/platform`
- `/sbin`
- `/usr`

Properties Each resource type has one or more properties. There are also some global properties, that is, properties of the configuration as a whole, rather than of some particular resource.

The following properties are supported:

```
(global)
  zonename

(global)
  zonename

(global)
  autoboot
```

(global)
bootargs

(global)
pool

(global)
limitpriv

(global)
brand

(global)
cpu-shares

(global)
hostid

(global)
max-lwps

(global)
max-msg-ids

(global)
max-sem-ids

(global)
max-shm-ids

(global)
max-shm-memory

(global)
scheduling-class

fs
dir, special, raw, type, options

inherit-pkg-dir
dir

net
address, physical, defrouter

device
match

rctl
name, value

attr
name, type, value

dataset
name

dedicated-cpu
ncpus, importance

capped-memory
physical, swap, locked

capped-cpu
ncpus

As for the property values which are paired with these names, they are either simple, complex, or lists. The type allowed is property-specific. Simple values are strings, optionally enclosed within quotation marks. Complex values have the syntax:

```
(<name>=<value>, <name>=<value>, ...)
```

where each *<value>* is simple, and the *<name>* strings are unique within a given property. Lists have the syntax:

```
[<value>, ...]
```

where each *<value>* is either simple or complex. A list of a single value (either simple or complex) is equivalent to specifying that value without the list syntax. That is, “foo” is equivalent to “[foo]”. A list can be empty (denoted by “[]”).

In interpreting property values, zonecfg accepts regular expressions as specified in [fnmatch\(5\)](#). See EXAMPLES.

The property types are described as follows:

global: zonename
The name of the zone.

global: zonepath
Path to zone's file system.

global: autoboot
Boolean indicating that a zone should be booted automatically at system boot. Note that if the zones service is disabled, the zone will not autoboot, regardless of the setting of this property. You enable the zones service with a `svcadm` command, such as:

```
# svcadm enable svc:/system/zones:default
```

Replace `enable` with `disable` to disable the zones service. See [svcadm\(1M\)](#).

global: bootargs
Arguments (options) to be passed to the zone bootup, unless options are supplied to the “zoneadm boot” command, in which case those take precedence. The valid arguments are described in [zoneadm\(1M\)](#).

global: pool

Name of the resource pool that this zone must be bound to when booted. This property is incompatible with the `dedicated-cpu` resource.

global: limitpriv

The maximum set of privileges any process in this zone can obtain. The property should consist of a comma-separated privilege set specification as described in [priv_str_to_set\(3C\)](#). Privileges can be excluded from the resulting set by preceding their names with a dash (-) or an exclamation point (!). The special privilege string “zone” is not supported in this context. If the special string “default” occurs as the first token in the property, it expands into a safe set of privileges that preserve the resource and security isolation described in [zones\(5\)](#). A missing or empty property is equivalent to this same set of safe privileges.

The system administrator must take extreme care when configuring privileges for a zone. Some privileges cannot be excluded through this mechanism as they are required in order to boot a zone. In addition, there are certain privileges which cannot be given to a zone as doing so would allow processes inside a zone to unduly affect processes in other zones. [zoneadm\(1M\)](#) indicates when an invalid privilege has been added or removed from a zone’s privilege set when an attempt is made to either “boot” or “ready” the zone.

See [privileges\(5\)](#) for a description of privileges. The command “`ppriv -l`” (see [ppriv\(1\)](#)) produces a list of all Solaris privileges. You can specify privileges as they are displayed by `ppriv`. In [privileges\(5\)](#), privileges are listed in the form `PRIV_privilege_name`. For example, the privilege `sys_time`, as you would specify it in this property, is listed in [privileges\(5\)](#) as `PRIV_SYS_TIME`.

global: brand

The zone’s brand type.

global: ip-type

A zone can either share the IP instance with the global zone, which is the default, or have its own exclusive instance of IP.

This property takes the values `shared` and `exclusive`.

global: hostid

A zone can emulate a 32-bit host identifier to ease system consolidation. A zone’s `hostid` property is empty by default, meaning that the zone does not emulate a host identifier. Zone host identifiers must be hexadecimal values between 0 and FFFFFFFE. A `0x` or `0X` prefix is optional. Both uppercase and lowercase hexadecimal digits are acceptable.

fs: dir, special, raw, type, options

Values needed to determine how, where, and so forth to mount file systems. See [mount\(1M\)](#), [mount\(2\)](#), [fsck\(1M\)](#), and [vfstab\(4\)](#).

inherit-pkg-dir: dir

The directory path.

net: address, physical, defrouter

The network address and physical interface name of the network interface. The network address is one of:

- a valid IPv4 address, optionally followed by “/” and a prefix length;
- a valid IPv6 address, which must be followed by “/” and a prefix length;
- a host name which resolves to an IPv4 address.

Note that host names that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

The value for the optional default router is specified similarly to the network address except that it must not be followed by a / (slash) and a network prefix length. To enable correct use of the `def router` functionality, the zones that use the property must be on a different subnet from the subnet on which the global zone resides. Also, each zone (or set of zones) that uses a different `def router` setting must be on a different subnet.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, you must set both the physical and address properties; setting the default router is optional. The interface specified in the physical property must be plumbed in the global zone prior to booting the non-global zone. However, if the interface is not used by the global zone, it should be configured down in the global zone, and the default router for the interface should be specified here.

For an exclusive-IP zone, the physical property must be set and the address and default router properties cannot be set. Note that a single datalink cannot be shared among multiple exclusive-IP zones.

device: match

Device name to match.

rctl: name, value

The name and *priv/limit/action* triple of a resource control. See [prctl\(1\)](#) and [rctladm\(1M\)](#). The preferred way to set rctl values is to use the global property name associated with a specific rctl.

attr: name, type, value

The name, type and value of a generic attribute. The type must be one of `int`, `uint`, `boolean` or `string`, and the value must be of that type. `uint` means unsigned, that is, a non-negative integer.

dataset: name

The name of a ZFS dataset to be accessed from within the zone. See [zfs\(1M\)](#).

global: cpu-shares

The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This property is incompatible with the `dedicated-cpu` resource. This property is the preferred way to set the zone.`cpu-shares` rctl.

global: max-lwps

The maximum number of LWPs simultaneously available to this zone. This property is the preferred way to set the zone `.max-lwps` rctl.

global: max-msg-ids

The maximum number of message queue IDs allowed for this zone. This property is the preferred way to set the zone `.max-msg-ids` rctl.

global: max-sem-ids

The maximum number of semaphore IDs allowed for this zone. This property is the preferred way to set the zone `.max-sem-ids` rctl.

global: max-shm-ids

The maximum number of shared memory IDs allowed for this zone. This property is the preferred way to set the zone `.max-shm-ids` rctl.

global: max-shm-memory

The maximum amount of shared memory allowed for this zone. This property is the preferred way to set the zone `.max-shm-memory` rctl. A scale (K, M, G, T) can be applied to the value for this number (for example, 1M is one megabyte).

global: scheduling-class

Specifies the scheduling class used for processes running in a zone. When this property is not specified, the scheduling class is established as follows:

- If the `cpu-shares` property or equivalent rctl is set, the scheduling class FSS is used.
- If neither `cpu-shares` nor the equivalent rctl is set and the zone's `pool` property references a pool that has a default scheduling class, that class is used.
- Under any other conditions, the system default scheduling class is used.

dedicated-cpu: ncpus, importance

The number of CPUs that should be assigned for this zone's exclusive use. The zone will create a pool and processor set when it boots. See [pooladm\(1M\)](#) and [poolcfg\(1M\)](#) for more information on resource pools. The `ncpu` property can specify a single value or a range (for example, 1-4) of processors. The `importance` property is optional; if set, it will specify the `pset.importance` value for use by [poold\(1M\)](#). If this resource is used, there must be enough free processors to allocate to this zone when it boots or the zone will not boot. The processors assigned to this zone will not be available for the use of the global zone or other zones. This resource is incompatible with both the `pool` and `cpu-shares` properties. Only a single instance of this resource can be added to the zone.

capped-memory: physical, swap, locked

The caps on the memory that can be used by this zone. A scale (K, M, G, T) can be applied to the value for each of these numbers (for example, 1M is one megabyte). Each of these properties is optional but at least one property must be set when adding this resource. Only a single instance of this resource can be added to the zone. The `physical` property sets the `max-rss` for this zone. This will be enforced by [rcapd\(1M\)](#) running in the global zone. The

swap property is the preferred way to set the zone .max - swap rctl. The locked property is the preferred way to set the zone .max - locked -memory rctl.

capped -cpu: ncpus

Sets a limit on the amount of CPU time that can be used by a zone. The unit used translates to the percentage of a single CPU that can be used by all user threads in a zone, expressed as a fraction (for example, .75) or a mixed number (whole number and fraction, for example, 1.25). An ncpu value of 1 means 100% of a CPU, a value of 1.25 means 125%, .75 mean 75%, and so forth. When projects within a capped zone have their own caps, the minimum value takes precedence.

The capped -cpu property is an alias for zone .cpu -cap resource control and is related to the zone .cpu -cap resource control. See [resource_controls\(5\)](#).

The following table summarizes resources, property-names, and types:

| resource | property-name | type |
|-----------------|------------------|-----------------|
| (global) | zonename | simple |
| (global) | zonepath | simple |
| (global) | autoboot | simple |
| (global) | bootargs | simple |
| (global) | pool | simple |
| (global) | limitpriv | simple |
| (global) | brand | simple |
| (global) | ip-type | simple |
| (global) | hostid | simple |
| (global) | cpu-shares | simple |
| (global) | max-lwps | simple |
| (global) | max-msg-ids | simple |
| (global) | max-sem-ids | simple |
| (global) | max-shm-ids | simple |
| (global) | max-shm-memory | simple |
| (global) | scheduling-class | simple |
| fs | dir | simple |
| | special | simple |
| | raw | simple |
| | type | simple |
| | options | list of simple |
| inherit-pkg-dir | dir | simple |
| net | address | simple |
| | physical | simple |
| device | match | simple |
| rctl | name | simple |
| | value | list of complex |
| attr | name | simple |
| | type | simple |
| | value | simple |
| dataset | name | simple |
| dedicated-cpu | ncpus | simple or range |

| | | |
|---------------|------------|-------------------|
| | importance | simple |
| capped-memory | physical | simple with scale |
| | swap | simple with scale |
| | locked | simple with scale |
| capped-cpu | ncpus | simple |

To further specify things, the breakdown of the complex property “value” of the “rctl” resource type, it consists of three name/value pairs, the names being “priv”, “limit” and “action”, each of which takes a simple value. The “name” property of an “attr” resource is syntactically restricted in a fashion similar but not identical to zone names: it must begin with an alphanumeric, and can contain alphanumerics plus the hyphen (-), underscore (_), and dot (.) characters. Attribute names beginning with “zone” are reserved for use by the system. Finally, the “autoboot” global property must have a value of “true” or “false”.

Using Kernel Statistics to Monitor CPU Caps

Using the kernel statistics (`kstat(3KSTAT)`) module caps, the system maintains information for all capped projects and zones. You can access this information by reading kernel statistics (`kstat(3KSTAT)`), specifying caps as the `kstat` module name. The following command displays kernel statistics for all active CPU caps:

```
# kstat caps : '/cpucaps/'
```

A `kstat(1M)` command running in a zone displays only CPU caps relevant for that zone and for projects in that zone. See EXAMPLES.

The following are cap-related arguments for use with `kstat(1M)`:

`caps`

The `kstat` module.

`project_caps` or `zone_caps`

`kstat` class, for use with the `kstat -c` option.

`cpucaps_project_id` or `cpucaps_zone_id`

`kstat` name, for use with the `kstat -n` option. *id* is the project or zone identifier.

The following fields are displayed in response to a `kstat(1M)` command requesting statistics for all CPU caps.

`module`

In this usage of `kstat`, this field will have the value `caps`.

`name`

As described above, `cpucaps_project_id` or `cpucaps_zone_id`

`above_sec`

Total time, in seconds, spent above the cap.

`below_sec`

Total time, in seconds, spent below the cap.

`maxusage`

Maximum observed CPU usage.

`nwait`

Number of threads on cap wait queue.

`usage`

Current aggregated CPU usage for all threads belonging to a capped project or zone, in terms of a percentage of a single CPU.

`value`

The cap value, in terms of a percentage of a single CPU.

`zonename`

Name of the zone for which statistics are displayed.

See EXAMPLES for sample output from a `kstat` command.

Options The following options are supported:

`-f command_file`

Specify the name of zonecfg command file. *command_file* is a text file of zonecfg subcommands, one per line.

`-z zonename`

Specify the name of a zone. Zone names are case sensitive. Zone names must begin with an alphanumeric character and can contain alphanumeric characters, the underscore (`_`) the hyphen (`-`), and the dot (`.`). The name `global` and all names beginning with `SUNW` are reserved and cannot be used.

Subcommands You can use the `add` and `select` subcommands to select a specific resource, at which point the scope changes to that resource. The `end` and `cancel` subcommands are used to complete the resource specification, at which time the scope is reverted back to `global`. Certain subcommands, such as `add`, `remove` and `set`, have different semantics in each scope.

zonecfg supports a semicolon-separated list of subcommands. For example:

```
# zonecfg -z myzone "add net; set physical=myvnic; end"
```

Subcommands which can result in destructive actions or loss of work have an `-F` option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a command is given without the `-F` option otherwise, if such a command is given without the `-F` option, the action is disallowed, with a diagnostic message written to standard error.

The following subcommands are supported:

`add resource-type` (global scope)

`add property-name property-value` (resource scope)

In the global scope, begin the specification for a given resource type. The scope is changed to that resource type.

In the resource scope, add a property of the given name with the given value. The syntax for property values varies with different property types. In general, it is a simple value or a list of simple values enclosed in square brackets, separated by commas ([foo, bar, baz]). See PROPERTIES.

cancel

End the resource specification and reset scope to global. Abandons any partially specified resources. `cancel` is only applicable in the resource scope.

clear *property-name*

Clear the value for the property.

commit

Commit the current configuration from memory to stable storage. The configuration must be committed to be used by `zoneadm`. Until the in-memory configuration is committed, you can remove changes with the `revert` subcommand. The `commit` operation is attempted automatically upon completion of a `zoncfg` session. Since a configuration must be correct to be committed, this operation automatically does a verify.

create [-F] [-a *path* |-b | -t *template*]

Create an in-memory configuration for the specified zone. Use `create` to begin to configure a new zone. See `commit` for saving this to stable storage.

If you are overwriting an existing configuration, specify the `-F` option to force the action. Specify the `-t template` option to create a configuration identical to *template*, where *template* is the name of a configured zone.

Use the `-a path` option to facilitate configuring a detached zone on a new host. The *path* parameter is the `zonpath` location of a detached zone that has been moved on to this new host. Once the detached zone is configured, it should be installed using the “`zoneadm attach`” command (see [zoneadm\(1M\)](#)). All validation of the new zone happens during the `attach` process, not during zone configuration.

Use the `-b` option to create a blank configuration. Without arguments, `create` applies the Sun default settings.

delete [-F]

Delete the specified configuration from memory and stable storage. This action is instantaneous, no `commit` is necessary. A deleted configuration cannot be reverted.

Specify the `-F` option to force the action.

end

End the resource specification. This subcommand is only applicable in the resource scope. `zoncfg` checks to make sure the current resource is completely specified. If so, it is added to the in-memory configuration (see `commit` for saving this to stable storage) and the scope reverts to global. If the specification is incomplete, it issues an appropriate error message.

export [-f *output-file*]

Print configuration to standard output. Use the -f option to print the configuration to *output-file*. This option produces output in a form suitable for use in a command file.

help [usage] [*subcommand*] [syntax] [*command-name*]

Print general help or help about given topic.

info zonename | zonepath | autoboot | brand | pool | limitpriv

info [*resource-type* [*property-name=property-value*]*]

Display information about the current configuration. If *resource-type* is specified, displays only information about resources of the relevant type. If any *property-name* value pairs are specified, displays only information about resources meeting the given criteria. In the resource scope, any arguments are ignored, and info displays information about the resource which is currently being added or modified.

remove *resource-type*{*property-name=property-value*}(global scope)

In the global scope, removes the specified resource. The [] syntax means 0 or more of whatever is inside the square braces. If you want only to remove a single instance of the resource, you must specify enough property name-value pairs for the resource to be uniquely identified. If no property name-value pairs are specified, all instances will be removed. If there is more than one pair is specified, a confirmation is required, unless you use the -F option.

select *resource-type* {*property-name=property-value*}

Select the resource of the given type which matches the given *property-name property-value* pair criteria, for modification. This subcommand is applicable only in the global scope. The scope is changed to that resource type. The {} syntax means 1 or more of whatever is inside the curly braces. You must specify enough *property-name property-value* pairs for the resource to be uniquely identified.

set *property-name=property-value*

Set a given property name to the given value. Some properties (for example, zonename and zonepath) are global while others are resource-specific. This subcommand is applicable in both the global and resource scopes.

verify

Verify the current configuration for correctness:

- All resources have all of their required properties specified.
- A zonepath is specified.

revert [-F]

Revert the configuration back to the last committed state. The -F option can be used to force the action.

exit [-F]

Exit the zonecfg session. A commit is automatically attempted if needed. You can also use an EOF character to exit zonecfg. The -F option can be used to force the action.

Examples EXAMPLE 1 Creating the Environment for a New Zone

In the following example, zonecfg creates the environment for a new zone. /usr/local is loopback mounted from the global zone into /opt/local. /opt/sfw is loopback mounted from the global zone, three logical network interfaces are added, and a limit on the number of fair-share scheduler (FSS) CPU shares for a zone is set using the rctl resource type. The example also shows how to select a given resource for modification.

```
example# zonecfg -z myzone3
my-zone3: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:myzone3> create
zonecfg:myzone3> set zonepath=/export/home/my-zone3
zonecfg:myzone3> set autoboot=true
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/usr/local
zonecfg:myzone3:fs> set special=/opt/local
zonecfg:myzone3:fs> set type=lofs
zonecfg:myzone3:fs> add options [ro,nodevices]
zonecfg:myzone3:fs> end
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/mnt
zonecfg:myzone3:fs> set special=/dev/dsk/c0t0d0s7
zonecfg:myzone3:fs> set raw=/dev/rdisk/c0t0d0s7
zonecfg:myzone3:fs> set type=ufs
zonecfg:myzone3:fs> end
zonecfg:myzone3> add inherit-pkg-dir
zonecfg:myzone3:inherit-pkg-dir> set dir=/opt/sfw
zonecfg:myzone3:inherit-pkg-dir> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.0.1/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.1.2/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.2.3/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:my-zone3> set cpu-shares=5
zonecfg:my-zone3> add capped-memory
zonecfg:my-zone3:capped-memory> set physical=50m
zonecfg:my-zone3:capped-memory> set swap=100m
zonecfg:my-zone3:capped-memory> end
zonecfg:myzone3> exit
```

EXAMPLE 2 Creating a Non-Native Zone

The following example creates a new Linux zone:

```
example# zonecfg -z lxzone
lxzone: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:lxzone> create -t SUNWlx
zonecfg:lxzone> set zonepath=/export/zones/lxzone
zonecfg:lxzone> set autoboot=true
zonecfg:lxzone> exit
```

EXAMPLE 3 Creating an Exclusive-IP Zone

The following example creates a zone that is granted exclusive access to bge1 and bge33000 and that is isolated at the IP layer from the other zones configured on the system.

The IP addresses and routing is configured inside the new zone using [sysidtool\(1M\)](#).

```
example# zonecfg -z excl
excl: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:excl> create
zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> set ip-type=exclusive
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge1
zonecfg:excl:net> end
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge33000
zonecfg:excl:net> end
zonecfg:excl> exit
```

EXAMPLE 4 Associating a Zone with a Resource Pool

The following example shows how to associate an existing zone with an existing resource pool:

```
example# zonecfg -z myzone
zonecfg:myzone> set pool=mypool
zonecfg:myzone> exit
```

For more information about resource pools, see [pooladm\(1M\)](#) and [poolcfg\(1M\)](#).

EXAMPLE 5 Changing the Name of a Zone

The following example shows how to change the name of an existing zone:

```
example# zonecfg -z myzone
zonecfg:myzone> set zonename=myzone2
zonecfg:myzone2> exit
```

EXAMPLE 6 Changing the Privilege Set of a Zone

The following example shows how to change the set of privileges an existing zone's processes will be limited to the next time the zone is booted. In this particular case, the privilege set will be the standard safe set of privileges a zone normally has along with the privilege to change the system date and time:

```
example# zonecfg -z myzone
zonecfg:myzone> set limitpriv="default,sys_time"
zonecfg:myzone2> exit
```

EXAMPLE 7 Setting the zone.cpu-shares Property for the Global Zone

The following command sets the zone.cpu-shares property for the global zone:

```
example# zonecfg -z global
zonecfg:global> set cpu-shares=5
zonecfg:global> exit
```

EXAMPLE 8 Using Pattern Matching

The following commands illustrate zonecfg support for pattern matching. In the zone flexlm, enter:

```
zonecfg:flexlm> add device
zonecfg:flexlm:device> set match="/dev/cua/a00[2-5]"
zonecfg:flexlm:device> end
```

In the global zone, enter:

```
global# ls /dev/cua
a    a000 a001 a002 a003 a004 a005 a006 a007 b
```

In the zone flexlm, enter:

```
flexlm# ls /dev/cua
a002 a003 a004 a005
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs

The following sequence uses the zonecfg command to set the CPU cap for a zone to three CPUs.

```
zonecfg:myzone> add capped-cpu
zonecfg:myzone>capped-cpu> set ncpus=3
zonecfg:myzone>capped-cpu>capped-cpu> end
```

The preceding sequence, which uses the capped-cpu property, is equivalent to the following sequence, which makes use of the zone.cpu-cap resource control.

```
zonecfg:myzone> add rctl
zonecfg:myzone:rctl> set name=zone.cpu-cap
zonecfg:myzone:rctl> add value (priv=privileged,limit=300,action=none)
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs *(Continued)*

```
zonecfg:myzone:rctl> end
```

EXAMPLE 10 Using `kstat` to Monitor CPU Caps

The following command displays information about all CPU caps.

```
# kstat -n /cpucaps/
module: caps                instance: 0
name:  cpucaps_project_0    class:   project_caps
      above_sec             0
      below_sec             2157
      crtime                 821.048183159
      maxusage               2
      nwait                  0
      snaptime               235885.637253027
      usage                  0
      value                  18446743151372347932
      zonename               global

module: caps                instance: 0
name:  cpucaps_project_1    class:   project_caps
      above_sec             0
      below_sec             0
      crtime                 225339.192787265
      maxusage               5
      nwait                  0
      snaptime               235885.637591677
      usage                  5
      value                  18446743151372347932
      zonename               global

module: caps                instance: 0
name:  cpucaps_project_201  class:   project_caps
      above_sec             0
      below_sec             235105
      crtime                 780.37961782
      maxusage               100
      nwait                  0
      snaptime               235885.637789687
      usage                  43
      value                  100
      zonename               global

module: caps                instance: 0
name:  cpucaps_project_202  class:   project_caps
      above_sec             0
      below_sec             235094
```

EXAMPLE 10 Using kstat to Monitor CPU Caps (Continued)

```

    zonename            test_001

```

EXAMPLE 11 Displaying CPU Caps for a Specific Zone or Project

Using the `kstat -c` and `-i` options, you can display CPU caps for a specific zone or project, as below. The first command produces a display for a specific project, the second for the same project within zone 1.

```

# kstat -c project_caps

# kstat -c project_caps -i 1

```

Exit Status The following exit values are returned:

```

0
    Successful completion.

1
    An error occurred.

2
    Invalid usage.

```

Notes All character data used by zonecfg must be in US-ASCII encoding.

Name zonep2vchk – check a global zone's configuration for physical to virtual migration into non-global zone

Synopsis zonep2vchk -V

zonep2vchk [-T *release*] -c

zonep2vchk [-T *release*] [-P] [-b] [-s path[,path...]] [-S *file*]
 [-r {*time*}(h|m|s)] [-x] [-e *execname*[,*execname*...]]
 [-E *file*]

Description The zonep2vchk utility is used to evaluate a global zone's configuration before the process of physical-to-virtual (p2v) migration into a non-global zone.

The p2v process involves archiving a global zone (source), and then installing a non-global zone (target) using that archive.

zonep2vchk serves two functions. First, it can be used to report issues on the source which might prevent a successful p2v migration. Second, it can output a template zonecfg, which can be used to assist in configuring the non-global zone target.

zonep2vchk can be executed on a Solaris 10 or later global zone. To execute on Solaris 10, copy the zonep2vchk utility to the Solaris 10 source global zone.

Security The zonep2vchk utility must be run with an effective user id of zero. It interrogates the configuration state of a variety of Solaris subsystems.

Options The following options are supported:

-V

Display the command version and exit.

-T *release*

Specify the target release. The defaults are:

| Global Zone | Default Target |
|-------------|----------------|
| Solaris 10 | S10 |
| Solaris 11 | S11 |

Any configuration files generated by zonep2vchk will be applicable to the target release. See -c below.

When run on Solaris 10, a target release of S11 can be specified, which will check for p2v into a Solaris 10 Branded zone.

When the target is S10, it is assumed that a shared stack will be used. Any issues that will require an exclusive IP stack will be reported.

When the target is S11, it is assumed that an exclusive IP stack will be used.

If a particular feature in use by the global zone requires a particular patch/update level of the target to function, this information will be printed in the zonep2vchk output.

- P
Generate machine-parseable output. See the section “Parseable Output Format” below.
- c
Display a template zone configuration on stdout in the form of `zonecfg(1M) export` output. This configuration will contain resource limits and network configuration based on the source host’s physical resources and networking configuration.
- b
Perform basic checks. This will check the global zone for issues that could prevent a successful p2v. This is the default behavior if none of -b, -c, -s, -S, -r, -x are specified.
- r{time} (h|m|s)
Perform runtime checks for the specified duration. This will analyze the currently executing processes in the global zone, and report issues that could prevent successful execution inside a non-global zone. Issues reported reflect actions made by the processes during the time in which zonep2vchk was executing.
- x
Perform runtime checks (as with -r) until SIGINT is received, such as is delivered by Ctrl-C from most shells.
- e *execname*[,*execname*...]
When performing runtime analysis (-r, -x), limit inspected programs to those matching the specified list of *execnames*. The *execname* is the name of process, as returned by `ps -o comm`. It is not necessary for named processes to exist when zonep2vchk is invoked. Any matching processes created while zonep2vchk is running will be inspected.
- E *file*
Similar to -e, but reads the list of *execnames* from *file*, one per line.
- s *path*[,*path*...]
Perform static binary analysis on the files or directories specified. This will inspect ELF binaries for system and library calls that might affect function inside a zone. Directories will be recursed, and non-ELF files will be ignored.
- S *file*
Similar to -s, but reads the path list from *file*, one per line.

Parseable Output Format

zonep2vchk will output a single line of parseable output for each issue detected. The line format is:

```
category:issue:field1:[field2: . . .]
```

Each field is delimited by a colon (:). Colon characters escaped with a backslash (\:) should not be treated as field delimiters.

Multiple instances of the same issue can be reported, each with fields describing the particular instance of the issue.

Below the existing categories and issues are defined. Future versions of zonep2vchk might include additional categories and issues. Existing issues might have new fields added after the existing fields for existing issues.

headerCategory The header category lists information about the source, target, and zonep2vchk version. The issues in this category are:

version

The version of the zonep2vchk command.

Field1: The version of the zonep2vchk command.

source

Information about the source system.

Field1: The nodename of the source system.

Field2: The /etc/release version of the source system.

Field3: The kernel version of the source system.

Field4: The platform of the source system.

target

Information about the specified target of the p2v check.

Field1: The Solaris version of the target.

Field2: The brand type that would be used on the target.

Field3: The ip-type of the expected zone on the target.

footerCategory The footer category lists final summary information. The issues in this category are:

issues

A summary of the number of issues found.

Field1: The number of issues detected.

incompatibleCategory The incompatible category represents issues that will not function in a non-global zone. The issues in this category are:

etcssystem

An /etc/system tunable exists. These tunables do not function inside a zone. The /etc/system tunable can be transferred to the target global zone, but it will affect the entire system, including all zones and the global zone. If there is an alternate tunable that can be configured from within the zone, this tunable is described.

Field1:

The /etc/system tunable setting.

Field2:

One of:

| | |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| noalternate | There is no alternate tunable from within a non-global zone. |
| obsolete | The tunable is obsolete on the target. It no longer serves any function. |
| replaced | The tunable has been replaced on the target. The replacement is configured in the global zone, and described by fields 3 and 4. |
| alternate | An alternate tunable exists. This tunable can be configured from within a non-global zone. The tunable is described by fields 3 and 4. |
| noinfo | zonep2vchk is not knowledgeable of the tunable. Tunable likely has no alternate inside a zone. |

Field3:

Type of alternate/replacement tunable.

Field4:

Description of alternate/replacement tunable.

be

More than one boot environment exists. Only the active boot environment will be transferable to the non-global zone.

Field1: The name of the non-active boot environment.

unsupported

A feature is enabled that will not function in a zone.

Field1: mobileip The mobile IP agent, which does not function in a zone, is configured. See [mipagent\(1M\)](#) for details.

nfs (S10 sources only)

The system is sharing a filesystem by means of NFS. Native zones on Solaris 10 and Solaris 10 zones on Solaris 11 cannot share by means of NFS.

Field1: Path of file system being shared.

smb

The system is sharing a filesystem by means of in-kernel smb/cifs. Zones cannot share filesystems by means of SMB.

Field1: Path of file system being shared.

pkg

A package delivering software known not to work in a zone is installed.

Field1: Name of the package.

iscsi-target

The system is exporting an iSCSI target. Zones cannot export iSCSI targets.

Field1: Name of the iSCSI target.

fcoe-target

The system has configured an FCOE target. Zones cannot configure FCOE targets.

Field1: Ethernet device used.

Field2: WWN of the FCOE target.

fc-target

The system has configured an Fiberchannel target. Zones cannot configure Fiberchannel targets.

Field1: WWN of the Fiberchannel target.

npiv

The system has configured a virtual NPIV HBA. Zones cannot configure virtual HBAs.

Field1: Physical WWN hosting the virtual HBA.

Field2: Virtual WWN.

scsi

The system has configured an SCSI block device. Zones cannot configure scsi block devices.

Field1: Object configured as a SCSI device.

svcnotallowed

A service is enabled that will not function in a zone.

Field1: Name of the service.

resourcepool

A Solaris resource pool is configured. Zones cannot configure resource pools.

Field1: Name of the pool.

pset

A processor set is configured. Zones cannot configure processor sets.

Field1: Processor set ID.

Field2: List of CPU IDs in the processor set.

zones

Zones are configured. A zone cannot host zones. Any zones will not exist in the target non-global zone after p2v. Zones can be migrated separately using the `detach/attach` features in [zoneadm\(1M\)](#).

Field1: Name of the zone.

Field2: State of the zone.

lofi (Solaris 10 targets only)

A lofi device is configured. A zone cannot configure lofi devices.

Field1: Name of the lofi device.

Field2: Path of the file backing the device.

`syscall` (generated by `-s` and `-f`)

A binary makes a system or library call that cannot be made from a zone.

Field1: Name of the the binary file.

Field2: Name of the system or library call.

`syscallargs` (generated by `-s` and `-f`)

A binary makes a system or library call that cannot be made from a zone if called with certain arguments.

Field1: Name of the system or library call.

See regular output (no `-P`) for details on disallowed arguments.

`lib` (generated by `-s` and `-f`)

A binary links with a library that cannot be used inside a zone.

Field1: Name of the binary file.

Field2: Name of the disallowed library.

`privnotallowed` (generated by `-r` and `-x`)

A privilege is used by a process that cannot be added to a zone.

Field1: Name of the process.

Field2: Name of the privilege.

`devnotallowed` (generated by `-r` and `-x`)

A device is opened by a process that cannot be added to a zone.

Field1: Name of the process.

Field2: Name of the device.

configuration Category The `configuration` category represents issues that will require a configuration setting to allow the issue to function inside the non-global zone. This could be a [zonecfg\(1M\)](#) configuration setting, a configuration change in the global zone, or both.

The issues in this category are:

`datalink`

A `datalink` feature is configured that cannot be configured from within a zone. The `datalink` feature must be configured in the global zone, and if necessary, delegated to the zone using `zonecfg add anet` (Solaris 11 only) or `zonecfg add net`.

Field1: Name of the `datalink` feature. One of:

`aggr` Aggregation.

| | |
|------------------------|----------------------------------------|
| <code>ibiface</code> | Infiniband interface. |
| <code>ibpart</code> | Infiniband partition. |
| <code>vnic</code> | Virtual NIC. |
| <code>etherstub</code> | Ethernet stub. |
| <code>bridge</code> | A bridge instance. |
| <code>secobj</code> | A wireless WPA or WEB security object. |

Field2: Datalink object name.

`dhcp-server` (Solaris 10 targets only)

The host is a DHCP server. To provide DHCP service, a zone must have `ip-type=exclusive`, or have the the privilege `net_rawaccess` and the device `/dev/ip`. Note that this will allow a shared stack zone to read and write raw IP packets on the network, similar to an exclusive stack zone or global zone.

Field1: FMRI of the DHCP server service.

`ntp-client`

An NTP client service is enabled. This service updates the system clock. Since all zones share the same system clock, this service is disabled automatically during `p2v`. If it is desired that the zone update the system clock on the target host, the zone will need the privilege `sys_time`, and the service will need to be enabled inside the zone after `p2v`.

Field1: FMRI of the client service.

`driverconf`

A networking device contains configuration settings in its `.conf` file. Zones cannot configure drivers. The driver must be configured in the global zone. Some network driver settings might be configurable using [dladm\(1M\)](#) instead of editing a driver configuration file.

Field1: Path of the configuration file.

`ifname` (Solaris 10 targets only)

An existing configuration file will be impacted by the change of a network device name. For example, an `/etc/hostname.bge0` file will be impacted if the network device given to the target non-global zone is not `bge0`.

Field1: Path of the impacted file.

`iscsi-initiator`

The system is accessing an iSCSI target as a client. Zones cannot access iSCSI targets. The global zone must be the iSCSI initiator. The device can then be added to the zone using `zonecfg add device`.

Field1: iSCSI target being accessed.

fcoe-initiator

The system has an FCOE initiator configured. A zone cannot configure an FCOE initiator. The global zone must configure the FCOE initiator, and make the SCSI target devices available to the zone using `zonecfg add fs` or `zonecfg add device`.

Field1: Ethernet network device.

Field2: WWN of the initiator.

fc-initiator

The system has an HBA Fiberchannel port online. A zone cannot access a Fiberchannel target. The target must be accessed from the global zone and made available to the zone.

Field1: Fiberchannel HBA port WWN.

linkprop

Datalink properties are configured. A zone cannot configure datalink properties. They must be configured from the global zone.

Field1: Name of the datalink.

Field2: Property name

Field3: Property value.

ndd

Tunables that cannot be configured by a zone have been configured using `ndd`. These tunables must be configured from the global zone.

Field1: File or script setting the tunable.

Field2: Driver being tuned.

Field3: Tunable parameter.

dynaddr

One or more dynamically assigned IP addresses are configured on a network interface. These addresses are not supported with shared-IP zones. These IP addresses could change as a result of MAC address changes. You may need to modify this system's address information on the DHCP server and on the DNS, LDAP, or NIS name servers.

Field1 can be one of:

| | |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>dhcp</code> | Configured DHCP address. In this case, <i>Field2</i> is the name of the interface configured for DHCP. |
| <code>v6autoconf</code> | IPv6 stateless address configuration is enabled. In this case, <i>Field2</i> is the name of the interface with IPv6 auto configuration. |
| <code>rarp</code> (Solaris 10 source only) | Reverse ARP assigned address is enabled. In this case, <i>Field2</i> is the name of the interface with reverse ARP |

enabled.

`patch` (Solaris 10 source with Solaris 11+ target only)

A patch is required before p2v into a non-global zone.

Field1: The patch required.

`physif` (Solaris 10 targets only)

A physical interface exists on the source system that will have to be replaced with a dedicated physical or VLAN interface on the destination system if migrating to an exclusive-IP zone.

Field1: Name of the interface on the source system.

`sched`

The system is configured with a default scheduling class. The default scheduling class of a non-global zone can be configured using the `zonecfg set scheduler` property. This will be provided in the `-c` output.

Field1: The configured default scheduling class.

`sharedip` (Solaris 10 targets only)

If migrating to a shared-IP zone, the following networking features will need to be configured from the global zone on behalf of the zone.

Field1 can be one of:

| | |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ipmpgroup</code> | An IPMP group is configured. If IPMP is required, it must be configured from the global zone. In this case, <i>Field2</i> is the IPMP group name. |
| <code>vni</code> | A virtual network interface is configured. These must be configured from the global zone. In this case, <i>Field2</i> is the VNI interface name. |
| <code>v4forwarding</code>
<code>v6forwarding</code> | IP forwarding (v4 or v6) is configured on an interface. In this case, <i>Field2</i> is the interface with IP forwarding configured. |
| <code>staticroute</code> | Static routes are configured. Static routes must be configured from the global zone. |

`exclusiveonly` (Solaris 10 targets only)

A networking feature is configured that is not supported for use with shared-IP zones. The feature will work without modification in exclusive-IP zones.

Field1:

`iptun` A IPv4, IPv6, or 6to4 tunnel interface has been plumbed.

Field2: Name of the tunnel interface.

sharedonly

A networking feature is configured that is not supported in an exclusive-IP zone. When migrating to a shared-IP zone, the feature must be configured in the global zone to support communication.

Field1:

cgtp A Carrier Grade Transport Protocol interface has been plumbed.

Field2: Name of the CGTP interface.

netdevalloc

A networking feature requires its underlying device be allocated to the zone with the `zonecfg(1M) add device` command. This feature is not supported with shared-IP zones.

Field1: Can be :

ppp Point-to-Point Protocol (PPP). PPP configuration files exist under `/etc/ppp`. The underlying device that needs to be allocated to the zone is either a serial port or, in the case of pppoe, an Ethernet physical or VNIC interface.

svcexlip (Solaris 10 targets only)

A service is enabled that will require an exclusive-IP zone.

Field1: Name of the service FMRI.

svcprio

A service is enabled that will require additional privileges be added to the zone using the `zonecfg(1M) limitpriv` property.

Field1: FMRI of the service.

Field2: List of the privileges required by the service.

svm

A Solaris Volume Manager metadvice is configured. Metadevices must be configured in the global zone, and made available to the non-global zone using `zonecfg(1M) add device, add fs, or add dataset`.

Field1: Name of the metadvice.

ramdisk

A ramdisk device is configured. A zone cannot configure ramdisk devices.

Field1: Ramdisk device path.

vfstab

A filesystem mount is configured by means of `/etc/vfstab`. The filesystem must be migrated to the target global zone and made available to the non-global zone.

Field1: Device being mounted.

Field2: Mountpoint.

zpool

The system has additional zpools configured. These zpools must be migrated to the target global zone, and made available to the zone using `zonectfg add dataset` or `zonectfg add fs`.

Field1: Name of the pool.

privexclip (Solaris 10 targets only)

A process used a privilege that requires and exclusive-IP stack. See [zonectfg\(1M\)](#) for a description of the `ip`-type property.

Field1: Name of the process.

Field2: Privilege used.

devexclip (Solaris 10 targets only)

A process opened a device that requires an exclusive IP stack. See [zonectfg\(1M\)](#) for a description of the `ip`-type property.

Field1: Name of the process.

Field2: Name of the device.

privoptioanal

A process used a privilege that requires additional privilege be added to the target non-global zone. See [zonectfg\(1M\)](#) for a description of the `limitpriv` property.

Field1: Name of the process.

Field2: Privilege used.

devoptional

A process opened a device that is not available in a zone by default. See [zonectfg\(1M\)](#) for a description of the `add device` resource.

Field1: Name of the process.

Field2: Path of the device.

syscallpriv (generated by -s and -f)

A binary makes a system or library call that might require additional privilege be added to the target non-global zone. See [zonectfg\(1M\)](#) for a description of the `limitpriv` property. See the non-parseable output for details concerning the system or library call.

Field1: Path of the binary

Field2: Name of the system call.

`syscalllexclip` (generated by `-s` and `-f`)

A binary makes a system or library call that might require an exclusive-ip stack. See [zonecfg\(1M\)](#) for a description of the `ip-type` property. See the non-parseable output for details concerning the system or library call.

Field1: Path of the binary

Field2: Name of the system call.

Examples **EXAMPLE 1** Performing Static Binary Analysis

The following command performs static analysis on all ELF binaries in two application directory trees:

```
# zonep2vchk -s /opt/myapplication,/usr/local
```

EXAMPLE 2 Generating a Template for the Target Zone

The following command will generate a template zone configuration for Solaris 11 when run on a Solaris 10 global zone.

```
# zonep2vchk T S11 -c
```

EXAMPLE 3 Analyzing Running Applications for a Period

The following command will analyze the process named `myapplication` for one hour and report any activity that might not function in a zone.

```
# zonep2vchk -s 1h -e myapplication
```

EXAMPLE 4 Performing Basic Checks

The following command will analyze the global zone for configuration and Solaris features in use that might not function in a zone. Each discovered issue will be reported as a single line of parseable output.

```
# zonep2vchk -bP
```

Exit Status The following exit values are returned:

- 0
Successful completion, no issues detected.
- 1
An internal error occurred.
- 2
Invalid usage.
- 3
One or more issues were detected.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/zones |
| Interface Stability | See below |

Command invocation and parseable output is Committed. Human readable output (default output) is Uncommitted.

See Also [dladm\(1M\)](#), [mipagent\(1M\)](#), [zoneadm\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [zones\(5\)](#)

Notes The static (-s and -f) checks make use of the [elfdump\(1\)](#) utility, which is delivered by the following package:

Solaris 11 developer/base-developer-utilities

Solaris 10 SUNWbtool

The runtime (-r) checks make use of the [dtrace\(1M\)](#) utility, which is delivered by the following package:

Solaris 11 system/dtrace

Solaris 10 SUNWdtrc

Name zpool – configures ZFS storage pools

Synopsis zpool [-?]

```

zpool help subcommand | help property property
zpool add [-fn] pool vdev ...
zpool attach [-f] pool device new_device
zpool clear [-F [-n]] pool [device]
zpool create [-fn] [-o property=value] ... [-O file-system-property=value]
    ... [-m mountpoint] [-R root] pool vdev ...
zpool destroy [-f] pool
zpool detach pool device

zpool upgrade
zpool upgrade -v

```

```
zpool upgrade [-V version] -a | pool ...
```

Description The `zpool` command configures ZFS storage pools. A storage pool is a collection of devices that provides physical storage and data replication for ZFS datasets.

All datasets within a storage pool share the same space. See [zfs\(1M\)](#) for information on managing datasets.

Virtual Devices (vdevs) A *virtual device* describes a single device or a collection of devices organized according to certain performance and fault characteristics. The following virtual devices are supported:

disk

A block device, typically located under `/dev/dsk`. ZFS can use individual slices or partitions, though the recommended mode of operation is to use whole disks. A disk can be specified by a full path, or it can be a shorthand name (the relative portion of the path under `/dev/dsk`). A whole disk can be specified by omitting the slice or partition designation. When given a whole disk, ZFS automatically labels the disk, if necessary.

file

A regular file. The use of files as a backing store is strongly discouraged. It is designed primarily for experimental purposes, as the fault tolerance of a file is only as good as the file system of which it is a part. A file must be specified by a full path.

mirror

A mirror of two or more devices. Data is replicated in an identical fashion across all components of a mirror. A mirror with N disks of size X can hold X bytes and can withstand $(N-1)$ devices failing before data integrity is compromised.

raidz

raidz1

raidz2

raidz3

A variation on RAID-5 that allows for better distribution of parity and eliminates the RAID-5 write hole (in which data and parity become inconsistent after a power loss). Data and parity is striped across all disks within a `raidz` group.

A `raidz` group can have single-, double-, or triple parity, meaning that the `raidz` group can sustain one, two, or three failures, respectively, without losing any data. The `raidz1 vdev` type specifies a single-parity `raidz` group; the `raidz2 vdev` type specifies a double-parity `raidz` group; and the `raidz3 vdev` type specifies a triple-parity `raidz` group. The `raidz vdev` type is an alias for `raidz1`.

A `raidz` group with N disks of size X with P parity disks can hold approximately $(N-P)*X$ bytes and can withstand P device(s) failing before data integrity is compromised. The minimum number of devices in a `raidz` group is one more than the number of parity disks. The recommended number is between 3 and 9 to help increase performance.

spare

A special pseudo-*vdev* which keeps track of available hot spares for a pool. For more information, see the “Hot Spares” section.

log

A separate-intent log device. If more than one log device is specified, then writes are load-balanced between devices. Log devices can be mirrored. However, *raidz vdev* types are not supported for the intent log. For more information, see the “Intent Log” section.

cache

A device used to cache storage pool data. A cache device cannot be configured as a mirror or *raidz* group. For more information, see the “Cache Devices” section.

Virtual devices cannot be nested, so a mirror or *raidz* virtual device can only contain files or disks. Mirrors of mirrors (or other combinations) are not allowed.

A pool can have any number of virtual devices at the top of the configuration (known as *root vdevs*). Data is dynamically distributed across all top-level devices to balance data among devices. As new virtual devices are added, ZFS automatically places data on the newly available devices.

Virtual devices are specified one at a time on the command line, separated by whitespace. The keywords *mirror* and *raidz* are used to distinguish where a group ends and another begins. For example, the following creates two root *vdevs*, each a mirror of two disks:

```
# zpool create mypool mirror c0t0d0 c0t1d0 mirror c1t0d0 c1t1d0
```

Pool or Device Failure and Recovery

ZFS supports a rich set of mechanisms for handling device failure and data corruption. All metadata and data is checksummed, and ZFS automatically repairs bad data from a good copy when corruption is detected.

In order to take advantage of these features, a pool must make use of some form of redundancy, using either mirrored or *raidz* groups. While ZFS supports running in a non-redundant configuration, where each root *vdev* is simply a disk or file, this is strongly discouraged. A single case of bit corruption can render some or all of your data unavailable.

A pool's health status is described by one of four states:

ONLINE

A pool that has all devices operating normally.

DEGRADED

A pool with one or more failed devices, but the data is still available due to a redundant configuration.

FAULTED

A pool with corrupted metadata, or one or more faulted devices, and insufficient replicas to continue functioning.

SUSPENDED

A pool that is waiting for device connectivity to be restored. A suspended pool remains in the wait state until the device issue is resolved.

The health of the top-level *vdev*, such as mirror or raidz device, is potentially impacted by the state of its associated *vdevs*, or component devices. A top-level *vdev* or component device is in one of the following states:

DEGRADED

One or more top-level *vdevs* is in the degraded state because one or more component devices are offline. Sufficient replicas exist to continue functioning.

One or more component devices is in the degraded or faulted state, but sufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The number of checksum errors exceeds acceptable levels and the device is degraded as an indication that something may be wrong. ZFS continues to use the device as necessary.
- The number of I/O errors exceeds acceptable levels. The device could not be marked as faulted because there are insufficient replicas to continue functioning.

FAULTED

One or more top-level *vdevs* is in the faulted state because one or more component devices are offline. Insufficient replicas exist to continue functioning.

One or more component devices is in the faulted state, and insufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The device could be opened, but the contents did not match expected values.
- The number of I/O errors exceeds acceptable levels and the device is faulted to prevent further use of the device.

OFFLINE

The device was explicitly taken offline by the `zpool offline` command.

ONLINE

The device is online and functioning.

REMOVED

The device was physically removed while the system was running. Device removal detection is hardware-dependent and may not be supported on all platforms.

UNAVAIL

The device could not be opened. If a pool is imported when a device was unavailable, then the device will be identified by a unique identifier instead of its path since the path was never correct in the first place.

If a device is removed and later reattached to the system, ZFS attempts to put the device online automatically. Device attach detection is hardware-dependent and might not be supported on all platforms.

Hot Spares ZFS allows devices to be associated with pools as *hot spares*. These devices are not actively used in the pool, but when an active device fails, it is automatically replaced by a hot spare. To create a pool with hot spares, specify a `spa revedev` with any number of devices. For example,

```
# zpool create pool mirror c0d0 c1d0 spare c2d0 c3d0
```

Spares can be added with the `zpool add` command and removed with the `zpool remove` command. Once a spare replacement is initiated, a new spare *vdev* is created within the configuration that will remain there until the original device is replaced. At this point, the hot spare becomes available again if another device fails.

If the original failed device is physically replaced, brought back online, or the errors are cleared, either through an FMA event or by using the `zpool online` command or `zpool clear` command, and the state of the original device becomes healthy, the INUSE spare device will become AVAIL again.

Spares cannot replace log devices.

Intent Log The ZFS Intent Log (ZIL) satisfies POSIX requirements for synchronous transactions. For instance, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use `fsync()` to ensure data stability. By default, the intent log is allocated from blocks within the main pool. However, it might be possible to get better performance using separate intent log devices such as NVRAM or a dedicated disk. For example:

```
# zpool create pool c0d0 c1d0 log c2d0
```

Multiple log devices can also be specified, and they can be mirrored. See the EXAMPLES section for an example of mirroring multiple log devices.

Log devices can be added, replaced, attached, detached, and imported, and exported as part of the larger pool. Mirrored log devices can be removed by specifying the top-level mirror for the log.

Cache Devices Devices can be added to a storage pool as *cache devices*. These devices provide an additional layer of caching between main memory and disk. For read-heavy workloads, where the working set size is much larger than what can be cached in main memory, using cache devices allow much more of this working set to be served from low latency media. Using cache devices provides the greatest performance improvement for random read-workloads of mostly static content.

To create a pool with cache devices, specify a `cache vdev` with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a raidz configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or raidz configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

- Processes** Each imported pool has an associated process, named `zpool -poolname`. The threads in this process are the pool's I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provides visibility into the CPU utilization of the system's storage pools. The existence of this process is an unstable interface.
- Properties** Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

allocated

Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, `alloc`.

capacity

Percentage of pool space used. This property can also be referred to by its shortened column name, `cap`.

free

Number of blocks within the pool that are not allocated.

guid

A unique identifier for the pool.

health

The current health of the pool. Health can be `ONLINE`, `DEGRADED`, or `FAULTED`, or `SUSPENDED`.

size

Total size of the storage pool.

These space usage properties report actual physical space available to the storage pool. The physical space can be different from the total amount of space that any contained datasets can actually use. The amount of space used in a raidz configuration depends on the characteristics of the data being written. In addition, ZFS reserves some space for internal accounting that the `zfs(1M)` command takes into account, but the `zpool` command does not. For non-full pools of a reasonable size, these effects should be invisible. For small pools, or pools that are close to being completely full, these discrepancies may become more noticeable.

The following property can be set at creation time and import time:

altroot

Alternate root directory. If set, this directory is prepended to any mount points within the pool. This can be used when examining an unknown pool where the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid.

`altroot` is not a persistent property. It is valid only while the system is up. Setting `altroot` defaults to using `cachefile=none`, though this may be overridden using an explicit setting.

The following property can be set at import time:

`readonly=on | off`

Controls whether the pool can be modified. When enabled, any synchronous data that exists only in the intent log is not accessible until the pool is imported in read-write mode.

Importing a pool in read-only mode has the following limitations:

- Attempts to set additional pool properties during the import are ignored.
- All file system mounts are converted to include the read-only (`ro`) mount option.

A pool that has been imported in read-only mode can be restored to read-write mode by exporting and importing the pool.

The following properties can be set at creation time and import time, and later changed with the `zpool set` command:

`autoexpand=on | off`

Controls automatic pool expansion when a larger device is added or attached to the pool or when a larger device replaces a smaller device in the pool. If set to `on`, the pool will be resized according to the size of the expanded device. If the device is part of a mirror or `raidz` then all devices within that `mirror/raidz` group must be expanded before the new space is made available to the pool. The default behavior is `off`. This property can also be referred to by its shortened column name, `expand`.

`autoreplace=on | off`

Controls automatic device replacement. If set to `off`, device replacement must be initiated by the administrator by using the `zpool replace` command. If set to `on`, any new device, found in the same physical location as a device that previously belonged to the pool, is automatically formatted and replaced. The default behavior is `off`. This property can also be referred to by its shortened column name, `replace`.

`bootfs=pool/dataset`

Identifies the default bootable dataset for the root pool. This property is expected to be set mainly by the installation and upgrade programs.

`cachefile=path | none`

Controls the location of where the pool configuration is cached. Discovering all pools on system startup requires a cached copy of the configuration data that is stored on the root file system. All pools in this cache are automatically imported when the system boots. Some environments, such as install and clustering, need to cache this information in a different location so that pools are not automatically imported. Setting this property caches the pool configuration in a different location that can later be imported with `zpool import -c`. Setting it to the special value `none` creates a temporary pool that is never cached, and the special value `''` (empty string) uses the default location.

Multiple pools can share the same cache file. Because the kernel destroys and recreates this file when pools are added and removed, care should be taken when attempting to access this file. When the last pool using a `cache file` is exported or destroyed, the file is removed.

`delegation=on | off`

Controls whether a non-privileged user is granted access based on the dataset permissions defined on the dataset. See [zfs\(1M\)](#) for more information on ZFS delegated administration.

`failmode=wait | continue | panic`

Controls the system behavior in the event of catastrophic pool failure. This condition is typically a result of a loss of connectivity to the underlying storage device(s) or a failure of all devices within the pool. The behavior of such an event is determined as follows:

`wait`

Blocks all I/O access to the pool until the device connectivity is recovered and the errors are cleared. A pool remains in the wait state until the device issue is resolved. This is the default behavior.

`continue`

Returns EIO to any new write I/O requests but allows reads to any of the remaining healthy devices. Any write requests that have yet to be committed to disk would be blocked.

`panic`

Prints out a message to the console and generates a system crash dump.

`listsnapshots=on | off`

Controls whether snapshot information associated with this pool is displayed when `zfs list` is run without the `-t` option. The default value is on.

`version=version`

The current on-disk version of the pool. This can be increased, but never decreased. The preferred method of updating pools is with the `zpool upgrade` command, though this property can be used when a specific version is needed for backwards compatibility. This property can be any number between 1 and the current version reported by `zpool upgrade -v`.

Subcommands All subcommands that modify state are logged persistently to the pool in their original form.

The `zpool` command provides subcommands to create and destroy storage pools, add capacity to storage pools, and provide information about the storage pools. The following subcommands are supported:

`zpool -?`

Displays a help message.

`zpool help subcommand | help property property`

Displays `zpool` subcommand usage information. You can display help for a specific subcommand or property. If you display help for a specific subcommand or property, the

command syntax or property value is displayed. Using `zpool help` without any arguments displays a complete list of `zpool` subcommands.

`zpool add [-fn] pool vdev ...`

Adds the specified virtual devices to the given pool. The *vdev* specification is described in the “Virtual Devices” section. The behavior of the `-f` option, and the device checks performed are described in the `zpool create` subcommand.

`-f`

Forces use of *vdevs*, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

`-n`

Displays the configuration that would be used without actually adding the *vdevs*. The actual pool creation can still fail due to insufficient privileges or device sharing.

Do not add a disk that is currently configured as a quorum device to a ZFS storage pool. After a disk is in the pool, that disk can then be configured as a quorum device.

`zpool attach [-f] pool device new_device`

Attaches *new_device* to an existing `zpool` device. The existing device cannot be part of a `raidz` configuration. If *device* is not currently part of a mirrored configuration, *device* automatically transforms into a two-way mirror of *device* and *new_device*. If *device* is part of a two-way mirror, attaching *new_device* creates a three-way mirror, and so on. In either case, *new_device* begins to resilver immediately.

`-f`

Forces use of *new_device*, even if its appears to be in use. Not all devices can be overridden in this manner.

`zpool clear [-F [-n]] pool [device] ...`

Clears device errors in a pool. If no arguments are specified, all device errors within the pool are cleared. If one or more devices is specified, only those errors associated with the specified device or devices are cleared.

`-F`

Initiates recovery mode for an unopenable pool. Attempts to discard the last few transactions in the pool to return it to an openable state. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost.

`-n`

Used in combination with the `-F` flag. Check whether discarding transactions would make the pool openable, but do not actually discard any transactions.

`zpool create [-fn] [-o property=value] ... [-o file-system-property=value] ... [-m mountpoint] [-R root] pool vdev ...`

Creates a new storage pool containing the virtual devices specified on the command line. The pool name must begin with a letter, and can only contain alphanumeric characters as

well as underscore (`_`), dash (`-`), and period (`.`). The pool names `mirror`, `raidz`, `spare`, and `log` are reserved, as are names beginning with the pattern `c[0-9]`. The `vdev` specification is described in the “Virtual Devices” section.

The command verifies that each device specified is accessible and not currently in use by another subsystem. There are some uses, such as being currently mounted, or specified as the dedicated dump device, that prevents a device from ever being used by ZFS. Other uses, such as having a preexisting UFS file system, can be overridden with the `-f` option.

The command also checks that the replication strategy for the pool is consistent. An attempt to combine redundant and non-redundant storage in a single pool, or to mix disks and files, results in an error unless `-f` is specified. The use of differently sized devices within a single `raidz` or `mirror` group is also flagged as an error unless `-f` is specified.

Unless the `-R` option is specified, the default mount point is `/pool`. The mount point must not exist or must be empty, or else the root dataset cannot be mounted. This can be overridden with the `-m` option.

`-f`

Forces use of `vdevs`, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

`-n`

Displays the configuration that would be used without actually creating the pool. The actual pool creation can still fail due to insufficient privileges or if a device is currently in use.

`-o property=value [-o property=value] ...`

Sets the given pool properties. See the “Properties” section for a list of valid properties that can be set.

`-O file-system-property=value`

`[-O file-system-property=value] ...`

Sets the specified properties for the pool's top-level file system. See the “Properties” section of [zfs\(1M\)](#) for a list of valid properties that can be set.

`-R root`

Equivalent to `-o cachefile=none, altroot=root`

`-m mountpoint`

Sets the mount point for the pool's top-level file system. The default mount point is `/pool` or `altroot/pool` if `altroot` is specified. The mount point must be an absolute path, `legacy`, or `none`. For more information on dataset mount points, see [zfs\(1M\)](#).

`zpool destroy [-f] pool`

Destroys the given pool, freeing up any devices for other use. This command tries to unmount any active datasets before destroying the pool.

-f

Forces any active datasets contained within the pool to be unmounted.

`zpool detach pool device`

Detaches *device* from a mirror. The operation is refused if there are no other valid replicas of the data.

`zpool export [-f] pool ...`

Exports the given pools from the system. All devices are marked as exported, but are still considered in use by other subsystems. The devices can be moved between systems (even those of different endianness) and imported as long as a sufficient number of devices are present.

Before exporting the pool, all datasets within the pool are unmounted.

For pools to be portable, you must give the `zpool` command whole disks, not just slices, so that ZFS can label the disks with portable EFI labels. Otherwise, disk drivers on platforms of different endianness will not recognize the disks.

-f

Forcefully unmount all datasets, using the `umount -f` command.

`zpool get all | property[,...] pool ...`

Retrieves the given list of properties (or all properties if `all` is used) for the specified storage pool(s). These properties are displayed with the following fields:

| | |
|-----------------------|-----------------------------------------------|
| <code>name</code> | Name of storage pool |
| <code>property</code> | Property name |
| <code>value</code> | Property value |
| <code>source</code> | Property source, either 'default' or 'local'. |

See the “Properties” section for more information on the available pool properties.

`zpool history [-il] [pool] ...`

Displays the command history of the specified pools or all pools if no pool is specified.

-i

Displays internally logged ZFS events in addition to user initiated events.

-l

Displays log records in long format, which in addition to standard format includes, the user name, the hostname, and the zone in which the operation was performed.

`zpool import [-d path ...] [-D]`

`zpool import [-d path ...] [-c cachefile] [-F [-n]]pool | id`

Lists pools available to import. If the `-d` option is not specified, this command searches for devices in `/dev/dsk`. The `-d` option can be specified multiple times, and all directories and device paths are searched. If the device appears to be part of an exported pool, this command displays a summary of the pool with the name of the pool, a numeric identifier,

as well as the *vdev* layout and current health of the device for each device or file. Pools that were previously destroyed with the `zpool destroy` command, are not listed unless the `-D` option is specified.

The numeric identifier is unique, and can be used instead of the pool name when multiple exported pools of the same name are available.

`-c cachefile`

Reads configuration from the given *cachefile* that was created with the “*cachefile*” pool property. This *cachefile* is used instead of searching for devices.

`-d dir`

Searches for devices or files in *path*, where *path* can be a directory or a device path. The `-d` option can be specified multiple times.

`-D`

Lists destroyed pools only.

`zpool import [-o mntopts] [-o property=value] ... [-d path ...] [-c cachefile] [-D] [-f] [-m] [-N] [-R root] [-F [-n]] -a`

Imports all pools found in the search directories. Identical to the previous command, except that all pools with a sufficient number of devices available are imported. Pools that were previously destroyed with the `zpool destroy` command, are not imported unless the `-D` option is specified.

`-o mntopts`

Comma-separated list of mount options to use when mounting datasets within the pool. See [zfs\(1M\)](#) for a description of dataset properties and mount options.

`-o property=value`

Sets the specified property on the imported pool. See the “Properties” section for more information on the available pool properties.

`-c cachefile`

Reads configuration from the given *cachefile* that was created with the *cachefile* pool property. This *cachefile* is used instead of searching for devices.

`-d path`

Searches for devices or files in *path*. The `-d` option can be specified multiple times. This option is incompatible with the `-c` option.

`-D`

Imports destroyed pools only. The `-f` option is also required.

`-f`

Forces import, even if the pool appears to be potentially active.

`-F`

Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by

using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

- a
Searches for and imports all pools found.
- m
Allows a pool to import when a log device is missing.
- R *root*
Sets the *cache file* property to none and the *altroot* property to *root*.
- N
Imports the pool without mounting any file systems.
- n
Used with the -F recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the -F option, above.

```
zpool import [-o mntopts] [-o property=value] ... [-d path ... | -c cache file] [-D] [-f] [-m] [-R root] [-F [-n]] pool | id [newpool]
```

Imports a specific pool. A pool can be identified by its name or the numeric identifier. If *newpool* is specified, the pool is imported using the persistent name *newpool*. Otherwise, it is imported with the same name as its exported name. Do not import a root pool with a new name. Otherwise, the system might not boot.

If a device is removed from a system without running `zpool export` first, the device appears as potentially active. It cannot be determined if this was a failed export, or whether the device is really in use from another host. To import a pool in this state, the -f option is required.

- o *mntopts*
Comma-separated list of mount options to use when mounting datasets within the pool. See [zfs\(1M\)](#) for a description of dataset properties and mount options.
- o *property=value*
Sets the specified property on the imported pool. See the “Properties” section for more information on the available pool properties.
- c *cache file*
Reads configuration from the given *cache file* that was created with the *cache file* pool property. This *cache file* is used instead of searching for devices.
- d *path*
Searches for devices or files in *path*. The -d option can be specified multiple times. This option is incompatible with the -c option.
- D
Imports destroyed pool. The -f option is also required.

- f
Forces import, even if the pool appears to be potentially active.
- F
Recovery mode for a non-importable pool. Attempts to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.
- R *root*
Sets the `cache file` property to `none` and the `altroot` property to `root`.
- N
Imports the pool without mounting any file systems.
- n
Used with the `-F` recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the `-F` option, above.
- m
Allows a pool to import when a log device is missing.

`zpool iostat [-T d|u] [-v] [pool] ... [interval[count]]`

Displays I/O statistics for the given pools. When given an interval, the statistics are printed every *interval* seconds until `Ctrl-C` is pressed. If no *pools* are specified, statistics for every pool in the system is shown. If *count* is specified, the command exits after *count* reports are printed.

-T d|u
Display a time stamp.

Specify `d` for standard date format. See [date\(1\)](#). Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#).

-v
Verbose statistics. Reports usage statistics for individual *vdevs* within the pool, in addition to the pool-wide statistics.

`zpool list [-H] [-o props[,...]] [-T d|u] [pool] ...`

Lists the given pools along with a health status and space usage. When given no arguments, all pools in the system are listed.

When given an interval, the status and space usage are displayed every *interval* seconds until `Ctrl-C` is entered. If *count* is specified, the command exits after *count* reports are displayed.

-H
Scripted mode. Do not display headers, and separate fields by a single tab instead of arbitrary space.

-o *props*

Comma-separated list of properties to display. See the “Properties” section for a list of valid properties. The default list is `name, size, allocated, free, capacity, health, altroot`.

-T *d|u*

Display a time stamp.

Specify *d* for standard date format. See [date\(1\)](#). Specify *u* for a printed representation of the internal representation of time. See [time\(2\)](#).

`zpool offline [-t] pool device ...`

Takes the specified physical device offline. While the *device* is offline, no attempt is made to read or write to the device.

This command is not applicable to spares or cache devices.

-t

Temporary. Upon reboot, the specified physical device reverts to its previous state.

`zpool online [-e] pool device...`

Brings the specified physical device online.

This command is not applicable to spares or cache devices.

-e

Expand the device to use all available space. If the device is part of a mirror or `raidz` then all devices must be expanded before the new space will become available to the pool.

`zpool remove pool device ...`

Removes the specified device from the pool. This command currently only supports removing hot spares, cache, and log devices. A mirrored log device can be removed by specifying the top-level mirror for the log. Non-log devices that are part of a mirrored configuration can be removed using the `zpool detach` command. Non-redundant and `raidz` devices cannot be removed from a pool.

`zpool replace [-f] pool old_device [new_device]`

Replaces *old_device* with *new_device*. This is equivalent to attaching *new_device*, waiting for it to resilver, and then detaching *old_device*.

The size of *new_device* must be greater than or equal to the minimum size of all the devices in a mirror or `raidz` configuration.

new_device is required if the pool is not redundant. If *new_device* is not specified, it defaults to *old_device*. This form of replacement is useful after an existing disk has failed and has been physically replaced. In this case, the new disk may have the same `/dev/dsk` path as the old device, even though it is actually a different disk. ZFS recognizes this.

In `zpool status` output, the *old_device* is shown under the word `replacing` with the string `/old` appended to it. Once the resilver completes, both the `replacing` and the *old_device* are automatically removed. If the new device fails before the resilver completes and a third device is installed in its place, then both failed devices will show up with `/old` appended, and the resilver starts over again. After the resilver completes, both `/old` devices are removed along with the word `replacing`.

-f

Forces use of *new_device*, even if it appears to be in use. Not all devices can be overridden in this manner.

`zpool scrub [-s] pool ...`

Begins a scrub. The scrub examines all data in the specified pools to verify that it checksums correctly. For replicated (mirror or raidz) devices, ZFS automatically repairs any damage discovered during the scrub. The “`zpool status`” command reports the progress of the scrub and summarizes the results of the scrub upon completion.

Scrubbing and resilvering are very similar operations. The difference is that resilvering only examines data that ZFS knows to be out of date (for example, when attaching a new device to a mirror or replacing an existing device), whereas scrubbing examines all data to discover silent errors due to hardware faults or disk failure.

Because scrubbing and resilvering are I/O-intensive operations, ZFS allows only one at a time. If a scrub is already in progress, a subsequent `zpool scrub` returns an error, with the advice to use `zpool scrub -s` to cancel the current scrub. If a resilver is in progress, ZFS does not allow a scrub to be started until the resilver completes.

-s

Stop scrubbing.

`zpool set property=value pool`

Sets the given property on the specified pool. See the “Properties” section for more information on what properties can be set and acceptable values.

`zpool split [-R altroot] [-n] [-o mntopts] [-o property=value] pool newpool [device ...]`

Splits off one disk from each mirrored top-level *vdev* in a pool and creates a new pool from the split-off disks. The original pool must be made up of one or more mirrors and must not be in the process of resilvering. The `split` subcommand chooses the last device in each mirror *vdev* unless overridden by a device specification on the command line.

When using a *device* argument, `split` includes the specified device(s) in a new pool and, should any devices remain unspecified, assigns the last device in each mirror *vdev* to that pool, as it does normally. If you are uncertain about the outcome of a `split` command, use the `-n` (“dry-run”) option to ensure your command will have the effect you intend.

-R *altroot*

Automatically import the newly created pool after splitting, using the specified *altroot* parameter for the new pool's alternate root. See the `altroot` description in the “Properties” section, above.

-n

Displays the configuration that would be created without actually splitting the pool. The actual pool split could still fail due to insufficient privileges or device status.

-o *mntopts*

Comma-separated list of mount options to use when mounting datasets within the pool. See `zfs(1M)` for a description of dataset properties and mount options. Valid only in conjunction with the `-R` option.

-o *property=value*

Sets the specified property on the new pool. See the “Properties” section, above, for more information on the available pool properties.

`zpool status [-xv] [-T d|u] [pool] ... [interval [count]]`

Displays the detailed health status for the given pools. If no *pool* is specified, then the status of each pool in the system is displayed. For more information on pool and device health, see the “Device Failure and Recovery” section.

When given an interval, the status and space usage are displayed every *interval* seconds until Ctrl-C is entered. If *count* is specified, the command exits after *count* reports are displayed.

If a scrub or resilver is in progress, this command reports the percentage done and the estimated time to completion. Both of these are only approximate, because the amount of data in the pool and the other workloads on the system can change.

-x

Only display status for pools that are exhibiting errors or are otherwise unavailable.

-v

Displays verbose data error information, printing out a complete list of all data errors since the last complete pool scrub.

-T d|u

Display a time stamp.

Specify `d` for standard date format. See `date(1)`. Specify `u` for a printed representation of the internal representation of time. See `time(2)`.

`zpool upgrade`

Identifies a pool's on-disk version, which determines available pool features in the currently running software release. You can continue to use older pool versions, but some

features might not be available. A pool can be upgraded by using the `zpool upgrade -a` command. You will not be able to access a pool of a later version on a system that runs an earlier software version.

`zpool upgrade -v`

Displays ZFS pool versions supported by the current software. The current ZFS pool versions and all previous supported versions are displayed, along with an explanation of the features provided with each version.

`zpool upgrade [-V version] -a | pool ...`

Upgrades the specified pool to the latest on-disk version. If this command reveals that a pool is out-of-date, the pool can subsequently be upgraded using the `zpool upgrade -a` command. A pool that is upgraded will not be accessible on a system that runs an earlier software release.

`-a`

Upgrades all pools.

`-V version`

Upgrade to the specified version, which must be higher than the current version. If the `-V` flag is not specified, the pool is upgraded to the most recent version.

Examples EXAMPLE 1 Creating a RAID-Z Storage Pool

The following command creates a pool with a single raidz root *vdev* that consists of six disks.

```
# zpool create tank raidz c0t0d0 c0t1d0 c0t2d0 c0t3d0 c0t4d0 c0t5d0
```

EXAMPLE 2 Creating a Mirrored Storage Pool

The following command creates a pool with two mirrors, where each mirror contains two disks.

```
# zpool create tank mirror c0t0d0 c0t1d0 mirror c0t2d0 c0t3d0
```

EXAMPLE 3 Adding a Mirror to a ZFS Storage Pool

The following command adds two mirrored disks to the pool `tank`, assuming the pool is already made up of two-way mirrors. The additional space is immediately available to any datasets within the pool.

```
# zpool add tank mirror c1t0d0 c1t1d0
```

EXAMPLE 4 Listing Available ZFS Storage Pools

The following command lists all available pools on the system.

```
# zpool list
NAME      SIZE  ALLOC   FREE   CAP  HEALTH  ALTROOT
pool     136G   109M   136G    0%  ONLINE  -
rpool    67.5G  12.6G  54.9G   18%  ONLINE  -
```

EXAMPLE 5 Listing All Properties for a Pool

The following command lists all the properties for a pool.

```
% zpool get all pool
NAME PROPERTY      VALUE      SOURCE
pool  size           68G       -
pool  capacity       0%        -
pool  altroot        -         default
pool  health          ONLINE    -
pool  guid           17810032335006077463 default
pool  version         29        default
pool  bootfs         -         default
pool  delegation     on         default
pool  autoreplace    off        default
pool  cachefile      -         default
pool  failmode       wait      default
pool  listsnapshots  on         default
pool  autoexpand     off        default
pool  free           68.0G    -
pool  allocated     130K     -
pool  readonly      off       -
```

EXAMPLE 6 Destroying a ZFS Storage Pool

The following command destroys the pool tank and any datasets contained within.

```
# zpool destroy -f tank
```

EXAMPLE 7 Exporting a ZFS Storage Pool

The following command exports the devices in pool tank so that they can be relocated or later imported.

```
# zpool export tank
```

EXAMPLE 8 Importing a ZFS Storage Pool

The following command displays available pools, and then imports the pool tank for use on the system.

The results from this command are similar to the following:

```
# zpool import
pool: tank
   id: 7678868315469843843
  state: ONLINE
action: The pool can be imported using its name or numeric identifier.
config:

        tank ONLINE
        mirror-0 ONLINE
```

EXAMPLE 8 Importing a ZFS Storage Pool *(Continued)*

```
c1t2d0 ONLINE
c1t3d0 ONLINE
```

```
# zpool import tank
```

EXAMPLE 9 Upgrading All ZFS Storage Pools to the Current Version

The following command upgrades all ZFS Storage pools to the current version of the software.

```
# zpool upgrade -a
```

This system is currently running ZFS pool version 29.

All pools are formatted using this version.

EXAMPLE 10 Managing Hot Spares

The following command creates a new pool with an available hot spare:

```
# zpool create tank mirror c0t0d0 c0t1d0 spare c0t2d0
```

If one of the disks were to fail, the pool would be reduced to the degraded state. The failed device can be replaced using the following command:

```
# zpool replace tank c0t0d0 c0t3d0
```

After the device has been resilvered, the spare is automatically detached and is made available should another device fail. The hot spare can be permanently removed from the pool using the following command:

```
# zpool remove tank c0t2d0
```

EXAMPLE 11 Creating a ZFS Pool with Separate Mirrored Log Devices

The following command creates a ZFS storage pool consisting of two, two-way mirrors and mirrored log devices:

```
# zpool create pool mirror c0d0 c1d0 mirror c2d0 c3d0 log mirror \
    c4d0 c5d0
```

EXAMPLE 12 Adding Cache Devices to a ZFS Pool

The following command adds two disks for use as cache devices to a ZFS storage pool:

```
# zpool add pool cache c2d0 c3d0
```

Once added, the cache devices gradually fill with content from main memory. Depending on the size of your cache devices, it could take over an hour for them to fill. Capacity and reads can be monitored using the `iostat` option as follows:

```
# zpool iostat -v pool 5
```

EXAMPLE 13 Removing a Mirrored Log Device

The following example shows how to remove the mirrored log device `mirror-2` in the pool `tank`.

```
pool: tank
state: ONLINE
scrub: none requested
config:

    NAME          STATE        READ WRITE CKSUM
    tank          ONLINE      0     0     0
      mirror-0    ONLINE      0     0     0
        c6t0d0    ONLINE      0     0     0
        c6t1d0    ONLINE      0     0     0
      mirror-1    ONLINE      0     0     0
        c6t2d0    ONLINE      0     0     0
        c6t3d0    ONLINE      0     0     0
    logs
      mirror-2    ONLINE      0     0     0
        c4t0d0    ONLINE      0     0     0
        c4t1d0    ONLINE      0     0     0

# zpool remove tank mirror-2
```

EXAMPLE 14 Recovering a Faulted ZFS Pool

If a pool is faulted but recoverable, a message indicating this state is provided by `zpool status` if the pool was cached (see `cache file` above), or as part of the error output from a failed `zpool import` of the pool.

Recover a cached pool with the `zpool clear` command:

```
# zpool clear -F data
Pool data returned to its state as of Thu Jun 07 10:50:35 2012.
Discarded approximately 29 seconds of transactions.
```

If the pool configuration was not cached, use `zpool import` with the recovery mode flag:

```
# zpool import -F data
Pool data returned to its state as of Thu Jun 07 10:50:35 2012.
Discarded approximately 29 seconds of transactions.
```

EXAMPLE 15 Importing a ZFS Pool with a Missing Log Device

The following examples illustrate attempts to import a pool with a missing log device. The `-m` option is used to complete the import operation.

Additional devices are known to be part of this pool, though their exact configuration cannot be determined.

EXAMPLE 15 Importing a ZFS Pool with a Missing Log Device (Continued)

```
# zpool import tank
The devices below are missing, use -m to import the pool anyway:
    c5t0d0 [log]

cannot import 'tank': one or more devices is currently unavailable

# zpool import -m tank
# zpool status tank
    pool: tank
    state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas
exist for
    the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
    see: http://www.sun.com/msg/ZFS-8000-2Q
    scan: none requested
config:

        NAME                STATE      READ WRITE CKSUM
        tank                 DEGRADED   0     0     0
            c7t0d0           ONLINE     0     0     0
        logs
            1693927398582730352 UNAVAIL    0     0     0 was
/dev/dsk/c5t0d0
```

errors: No known data errors

The following example shows how to import a pool with a missing *mirrored* log device.

```
# zpool import tank
The devices below are missing, use ?-m? to import the pool anyway:
mirror-1 [log]
c5t0d0
c5t1d0

# zpool import -m tank

# zpool status tank
    pool: tank
    state: DEGRADED
status: One or more devices could not be opened. Sufficient replicas
exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
    see: http://www.sun.com/msg/ZFS-8000-2Q
    scan: none requested
config:
```

EXAMPLE 15 Importing a ZFS Pool with a Missing Log Device *(Continued)*

```

NAME                STATE    READ WRITE CKSUM
tank                DEGRADED  0    0    0
  c7t0d0            ONLINE    0    0    0
  logs
    mirror-1        UNAVAIL    0    0    0
insufficient replicas
  46385995713041169 UNAVAIL    0    0    0 was
/dev/dsk/c5t0d0
  13821442324672734438 UNAVAIL    0    0    0 was
/dev/dsk/c5t1d0

errors: No known data errors

```

EXAMPLE 16 Importing a Pool By a Specific Path

The following command imports the pool tank by identifying the pool's specific device paths, /dev/dsk/c9t9d9 and /dev/dsk/c9t9d8, in this example.

```
# zpool import -d /dev/dsk/c9t9d9s0 /dev/dsk/c9t9d8s0 tank
```

An existing limitation is that even though this pool is comprised of whole disks, the command must include the specific device's slice identifier.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | system/file-system/zfs |
| Interface Stability | Committed |

Name zuludaemon – load microcode for Sun XVR-4000 Graphics Accelerator device

Synopsis /usr/sbin/zuludaemon [-dev *zulu_device*]

Description The zuludaemon is a daemon, started and stopped from a script in `/etc/init.d`, that loads the microcode and provides other support functions for the Sun XVR-4000 Graphics Accelerator device. Do not kill this process. This daemon is essential to the [zulu\(7d\)](#) driver.

The zuludaemon process is not configurable.

Options -dev *zulu_device* name of the Sun XVR-4000 Graphics Accelerator device

Files /usr/sbin/zuludaemon daemon executable

/usr/lib/zulu.unicode file containing microcode used by zuludaemon

/etc/init.d/zulunit startup/kill script for zuludaemon

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWzuluc |
