News ....................................................................................................................... xlix

   New and Changed Features for Release 12 (11.12.x.0.0) .......................................... xlix
   Other Significant Changes in this Document for Release 12 (11.12.x.0.0) ................. xlix

1 Get Started with Oracle Fusion Applications

   1.1 Overview of Fusion Technologies .................................................................. 1-1

2 Set Up Your Development Environment

   2.1 Introduction to the Development Environment ............................................... 2-1
      2.1.1 Shared Environment ................................................................................ 2-2
      2.1.2 Personal Environment ............................................................................ 2-3
   2.2 Set Up the JDeveloper-based Personal Environment ........................................ 2-4
      2.2.1 Before You Begin .................................................................................... 2-4
      2.2.2 How to Use the Oracle Fusion Domain Wizard ....................................... 2-17
      2.2.3 How to Start Integrated WebLogic Server ............................................. 2-40
   2.3 Improve Shared and Personal Environments Performance ............................... 2-42
      2.3.1 How to Create the OWSM_MDS Schema ............................................... 2-42
      2.3.2 How to Use Alternate Database Schemas ............................................... 2-49
      2.3.3 How to Set Up the Personal Environment for Standalone WebLogic Server ... 2-50
   2.4 Use Deployment Profiles Settings ................................................................... 2-60
      2.4.1 How to Use Service Deployments .......................................................... 2-61
      2.4.2 How to Update the Standard ................................................................. 2-61
   2.5 Configure the Oracle Enterprise Scheduler (ESS) ............................................. 2-62
      2.5.1 How to Provision the Runtime Environment .......................................... 2-62
      2.5.2 How to Create Supporting Database Schema ......................................... 2-63
## 2.6 Test Your Installation

2.7 Use Best Practices for Setting Up the Development Environment

2.7.1 How to Implement Best Practices for JDeveloper

2.7.2 How to Refresh the Oracle ADF Library Dependencies Library

2.7.3 How to Manage OutOfMemory Exceptions (PermGen)

2.7.4 How to Work with Oracle ADF Libraries at Design Time

## 3 Set Up Your JDeveloper Application Workspace and Projects

3.1 Using Technology Scopes

3.2 Provisioning the Application Workspace

3.3 Add Necessary Libraries to Your Data Model Project

3.4 Add the Applications Core Tag Library to Your User Interface Project

3.5 Integrating Oracle Fusion Middleware Extensions for Applications (Applications Core)

3.5.1 What You May Need to Know About Setup UIs in Oracle Fusion Functional Setup Manager

3.5.2 How to Integrate Setup UIs into Functional Setup Manager

3.6 Creating or Updating a Database Connection

3.7 Adding the Search Navigation Tab to the Overview Editor for Oracle Enterprise Crawl and Search Framework (ECSF)

3.7.1 How to Add the Search Navigation Tab to the Overview Editor

3.7.2 What Happens When You Add the Search Navigation Tab to the Overview Editor

3.8 Overriding the Default Resource Bundle

3.9 Implementing Oracle Enterprise Scheduler Service Workspace and Deployment

3.9.1 How to Create the SuperEss Project

3.9.2 How to Build the EAR/MAR Profiles

3.10 Implementing Oracle Application Development Framework UI Workspace and Projects

3.10.1 How to Set Up Your Web Project

3.10.2 How to Create the SuperEss Project in the ADF UI Workspace

3.10.3 How to Deploy Your Web Project

## 4 Get Started with Business Services

4.1 Introduction to Implementing Business Logic

4.1.1 About Entity Objects

4.1.2 About View Objects

4.1.3 About Application Modules

4.2 Understanding Validators

4.3 Understanding List of Values (LOV)

4.4 Understanding Batch Processing

4.5 Understanding Extensibility and Reusability

4.6 Understanding Services

4.7 About Using the Declarative Approach

15.1.3 How Crawling Is Done................................................................. 15-5
15.1.4 How Attachments Are Shown.................................................. 15-10
15.1.5 How Attachments Are Opened............................................... 15-10
15.1.6 How to Implement Attachments Search................................. 15-11
15.2 Implementing Recent Items .......................................................... 15-13
  15.2.1 How to Choose Labels for Task Flows................................. 15-13
  15.2.2 How to Call Sub Flows.......................................................... 15-13
  15.2.3 How to Enable a Sub Flow to Be Bookmarked in Recent Items...... 15-15
  15.2.4 How to Use Additional Capabilities of the Recent Items openSubTask API........ 15-21
  15.2.5 How to Implement Data Security for Recent Items and Favorites ............... 15-22
  15.2.6 Known Issues......................................................................... 15-22
15.3 Implementing the Watchlist.......................................................... 15-22
  15.3.1 Watchlist Data Model Effects .................................................. 15-24
  15.3.2 Watchlist Physical Data Model Entities..................................... 15-24
  15.3.3 Supported Watchlist Items...................................................... 15-28
  15.3.4 How to Use the Watchlist....................................................... 15-31
15.4 Implementing Group Spaces.......................................................... 15-42
  15.4.1 How to Implement Group Spaces............................................ 15-43
  15.4.2 Overview of Group Spaces Functionality............................... 15-43
  15.4.3 How to Pass a Chromeless Template...................................... 15-44
15.5 Implementing Activity Streams and Business Events...................... 15-44
  15.5.1 Introduction to WebCenter Portal Activities........................... 15-44
  15.5.2 How to Publish Business Events to Activities.......................... 15-45
  15.5.3 How to Publish Activities Using a Programmatic API.................. 15-45
  15.5.4 How to Implement Activity Streams........................................ 15-49
  15.5.5 How to Define Activities........................................................ 15-52
  15.5.6 How to Implement Comments and Likes.................................. 15-57
  15.5.7 How to Implement Follow for an Object................................... 15-57
  15.5.8 How to Render Contextual Actions in Activity Streams............. 15-59
15.6 Implementing the Oracle Fusion Applications Search Results UI........ 15-60
  15.6.1 How to Disable Oracle Fusion Applications Search.................. 15-60
  15.6.2 How to Use Basic Search...................................................... 15-61
  15.6.3 How to Control the Look and Feel of Search........................... 15-69
  15.6.4 Introduction to the Crawled Objects Project............................ 15-82
  15.6.5 How to Implement Tags in Oracle Fusion Applications Search......... 15-83
  15.6.6 How to Use the Actionable Results API with Oracle Fusion Applications Search 15-87
  15.6.7 How to Integrate Non-Applications Data into Oracle Fusion Applications Search 15-99
15.7 Implementing Auto-suggest......................................................... 15-100
  15.7.1 How to Implement fnd:searchSuggestBehavior......................... 15-107
  15.7.2 How to Implement a Custom Suggestion Group......................... 15-110
  15.7.3 How to Implement fnd:searchSuggestBehavior in Global Search........... 15-112
  15.7.4 How to Implement Dynamic UI Support for searchSuggestBehavior ....... 15-114
15.8 Attachments in Global Search....................................................... 15-125
15.8.1 Crawl Functionality ...................................................................................................... 15-125
15.8.2 Show Attachments ........................................................................................................ 15-130
15.8.3 Open Attachments ........................................................................................................ 15-130
15.8.4 Implement the Attachment Plugin ............................................................................. 15-131
15.9 Support Global Search Alternate Words for the Cloud ...................................................... 15-132
15.9.1 Look Up the SES Endpoint (ECSF APIs) .................................................................... 15-134
15.9.2 SES Web Service Calls ................................................................................................. 15-135
15.9.3 Alternate Words Error Messages ................................................................................ 15-137
15.10 Implement List Search .................................................................................................... 15-137
15.10.1 How to Implement List Search at Design Time ....................................................... 15-144

16 Implement Additional Functions in the UI Shell

16.1 Introducing the Navigate API .............................................................................................. 16-1
16.1.1 How to Use the Navigate API Data Control Method .................................................. 16-2
16.1.2 How to Implement Navigation Across Web Applications ........................................... 16-8
16.2 Warning of Pending Changes in the UI Shell .................................................................... 16-8
16.2.1 How to Implement Warning of Pending Changes ...................................................... 16-9
16.2.2 How to Suppress Warning of Pending Changes ....................................................... 16-10
16.3 Implementing the Oracle Fusion Home Page UI ................................................................. 16-10
16.3.1 Supported Behavior .................................................................................................... 16-11
16.3.2 How to Create a Home Page ....................................................................................... 16-11
16.3.3 Getting the URL ........................................................................................................... 16-12
16.4 Using the Single Object Context Workarea ....................................................................... 16-12
16.4.1 Implementation Notes ................................................................................................ 16-13
16.5 Implementing the Third-Party Component Area ............................................................... 16-15
16.5.1 How to Implement the ThirdPartyComponentArea Facet Developer ............................ 16-15
16.6 Developing an Activity Guide Client Application with the UI Shell ................................. 16-16
16.6.1 How to Develop an Activity Guide Client Application Using Oracle UI Shell ............. 16-16
16.6.2 How to add a task flow to the Oracle UI Shell client application ............................... 16-20
16.6.3 How to Secure the Activity Guide Oracle UI Shell Client Application ........................ 16-23
16.7 Implementing Touch Device Support in the UI Shell .......................................................... 16-24
16.8 Implementing the Translation Editor ................................................................................. 16-25
16.8.1 How to Implement the Translation Editor .................................................................. 16-27
16.8.2 How to Add the Translation Editor to Existing Application Tables During Design Time ................................................................. 16-31
16.8.3 How to Add the Translation Editor to New Application Tables During Design Time ................................. 16-33
16.8.4 Handle Multi-Language Data Entry ............................................................................ 16-33
16.9 About the Create Page Wizard .......................................................................................... 16-51
16.9.1 How to Complete the Create Page Wizard ................................................................. 16-51
16.10 Troubleshooting UI Shell Issues ..................................................................................... 16-53
16.10.1 ApplSession Is Not Created ...................................................................................... 16-53
16.10.2 Navigator Shows a Little White Box .......................................................................... 16-54
17 Implement UIs in JDeveloper with Application Tables, Trees and Tree Tables

17.1 Implementing Applications Tables ................................................................. 17-1
  17.1.1 Understanding Applications Tables Facets and Properties ....................... 17-2
  17.1.2 How to Create an Applications Table ....................................................... 17-11
  17.1.3 Introduction to Selected Elements in the Table Property Inspector ............... 17-23
  17.1.4 How to Modify Applications Table Components and Properties ............... 17-26

17.2 Implementing the Applications Tree ............................................................... 17-28
  17.2.1 How to Add an Applications Tree to Your Page .......................................... 17-28

17.3 Implementing Applications Tree Tables ......................................................... 17-41
  17.3.1 How to Add an Applications Tree Table ..................................................... 17-50

17.4 Using the Custom Wizard with Applications Popups ......................................... 17-56
  17.4.1 Creating a Popup .......................................................................................... 17-57
  17.4.2 How to Modify Popup Components and Properties ...................................... 17-63

18 Implement Applications Panels, Master-Detail, Hover, and Dialog Details

18.1 Implementing Applications Panels .................................................................. 18-1
  18.1.1 Overview of Applications Panel Components .............................................. 18-1
  18.1.2 How to Create an Applications Panel ......................................................... 18-11
  18.1.3 How to Modify Applications Panels Components and Properties ............... 18-19

18.2 Implementing the Simple Panel ....................................................................... 18-21
  18.2.1 How to Implement the Simple Panel ............................................................. 18-29
  18.2.2 How to Add Simple Panel at Design Time ................................................... 18-30

18.3 Implementing Applications Master-Detail ....................................................... 18-44
  18.3.1 Component Structure and Functions ............................................................ 18-44
  18.3.2 Introduction to Master-Detail Components ............................................... 18-45
  18.3.3 How to Create a Master-Detail ................................................................. 18-46
  18.3.4 Master-Detail Guidelines for Creating New Records ................................... 18-55
  18.3.5 How to Modify Master-Detail Components and Properties ......................... 18-56

18.4 Implementing Hover ....................................................................................... 18-56

18.5 Implementing Applications Dialog Details ...................................................... 18-59
  18.5.1 How to Add Applications Dialog Details to Your Page ............................... 18-59

19 Implement Attachments

19.1 Introduction to Attachment Components ....................................................... 19-1
  19.1.1 About the Attachment Views Component ............................................... 19-2
  19.1.2 About the Attachment Link Component ............................................... 19-8
  19.1.3 About the Attachment Component ........................................................... 19-10
  19.1.4 About the Attachments Carousel ............................................................ 19-15

19.2 About Creating Attachments ......................................................................... 19-16
  19.2.1 Performing Prerequisite Tasks ................................................................. 19-16
  19.2.2 Understanding Content Repository Prerequisites ..................................... 19-19
19.2.3 About Setting Up Your Model Project for Attachments................................. 19-20
19.2.4 How to Create Attachment View Links............................................................... 19-21
19.2.5 What Happens When You Create an Attachment View Link............................. 19-39
19.2.6 About Deleting the Business Object ................................................................. 19-40
19.2.7 About Assigning Categories to the Attachment Entity........................................ 19-41
19.2.8 How to Create an Attachments Field, Attachments Table, Attachments Carousel,
or Attachment Views.............................................................................................................. 19-41
19.2.9 What Happens When You Implement Attachments ............................................ 19-42
19.2.10 How to Create an Attachments Column in an Applications Table .................... 19-43
19.2.11 How to Create an Attachments Column in an Existing Applications Table........ 19-44
19.2.12 About Setting Up Required Properties ............................................................. 19-44
19.2.13 What Happens at Runtime................................................................................. 19-45
19.2.14 How to Update Page Bindings for the Attachment Views Component................ 19-45
19.3 About Displaying Attachments for Multiple Entities in the Same Table................ 19-46
19.3.1 About Configuring the Attachments Component to Display Attachments for
Multiple Entities....................................................................................................................... 19-48
19.4 About Configuring Attachments Component Properties........................................ 19-50
19.4.1 About Using FUSE ................................................................................................. 19-50
19.5 About Working with Attachments Programmatically............................................ 19-51
19.5.1 About Creating New Attachment Types ............................................................... 19-52
19.5.2 About Retrieving Attachments............................................................................. 19-55
19.5.3 About Using Attachment Utilities........................................................................ 19-56
19.5.4 About Managing Attachments HTTP Sessions.................................................... 19-57
19.5.5 About Creating Third-Party Attachments............................................................ 19-57
19.5.6 About Implementing Attachments with PL/SQL.................................................. 19-59
19.6 About Setting Up Miscellaneous Attachments Features......................................... 19-62
19.6.1 About Custom Actions for the Attachments Component..................................... 19-62
19.6.2 About Custom Actions for the Attachment Views and Attachment Link
Component.............................................................................................................................. 19-63
19.6.3 About Approvals..................................................................................................... 19-64
19.6.4 About Redlining.................................................................................................... 19-65
19.7 About Integrating Attachments Task Flows into Oracle Fusion Functional Setup
Manager................................................................................................................................. 19-67
19.8 About Securing Attachments................................................................................ 19-68
19.8.1 About Entity Instance-Level Security................................................................. 19-68
19.8.2 About Attachment Category Data Security.......................................................... 19-69
19.8.3 About File Sharing ............................................................................................... 19-70
19.8.4 About File Format Filtering.................................................................................. 19-70
19.8.5 About Attachments SaaS..................................................................................... 19-71
19.9 Understanding How to Use Attachments (Runtime)............................................... 19-71
19.9.1 About Using Attachments File-Level Security..................................................... 19-71
19.9.2 About Updating Attachments............................................................................... 19-72
19.9.3 How to Check Out and Check In File Attachments.............................................. 19-75
Organize Hierarchical Data with Tree Structures

20.1 Introduction to Trees
  20.1.1 Understanding Tree Structures, Trees, and Tree Versions
  20.2 About Configuring the Trees Application Launch Page
    20.2.1 How to Create the Launch Page
  20.3 Working with Tree Structures
    20.3.1 About Managing Tree Structure Data Sources
    20.3.2 About Specifying Data Source Parameters
    20.3.3 About Using the Search Field
    20.3.4 About Using the Search Field
    20.3.5 How to Create a Tree Structure
    20.3.6 How to Duplicate a Tree Structure
    20.3.7 How to Edit a Tree Structure
    20.3.8 How to Delete a Tree Structure
  20.4 Working with Trees
    20.4.1 How to Search for a Tree
    20.4.2 How to Create a Tree
    20.4.3 How to Duplicate a Tree
    20.4.4 How to Edit a Tree
    20.4.5 How to Delete a Tree
  20.5 Working with Tree Versions
    20.5.1 How to Create a Tree Version
    20.5.2 About Adding Tree Nodes to a Tree Version
    20.5.3 How to Create a Record for a Data Source
    20.5.4 How to Duplicate a Tree Version
    20.5.5 How to Edit a Tree Version
    20.5.6 About Performing CRUD Operations on Tree Nodes Using APIs
    20.5.7 About Performing Sub-tree Node Operations Using PL/SQL APIs
    20.5.8 How to Set Tree Version Status
    20.5.9 About Auditing Trees and Tree Versions
    20.5.10 About Flattening Rows and Columns
  20.6 Manage Labels in the Generic Label Data Source
    20.6.1 How to Search for a Label
    20.6.2 How to Create a Label
    20.6.3 How to Edit a Label
    20.6.4 How to Delete a Label
  20.7 About Using the Applications Hierarchy Component to Develop Applications
    20.7.1 How to Create a Tree Application
    20.7.2 How to Create a Tree Table Application
    20.7.3 How to Sort Hierarchies
24.6 Create and Configuring Extensible Flexfield View Objects ......................................................... 24-20
24.6.1 How to Create and Configure Extensible Flexfield View Objects ............................................. 24-20
24.7 Defining and Registering Extensible Flexfields ............................................................................. 24-23
24.7.1 How to Register Extensible Flexfields ....................................................................................... 24-23
24.8 Creating Extensible Flexfield Business Components ................................................................. 24-28
24.8.1 How to Create Business Components For an Extensible Flexfield’s Usage ......................... 24-30
24.9 Employ an Extensible Flexfield on a User Interface Page ............................................................ 24-33
24.9.1 How to Expose an Extensible Flexfield Usage as a Single Task Flow for Multiple Contexts ........................................................................................................................................ 24-34
24.9.2 How to Expose the Complete Set of an Extensible Flexfield’s Usages, Logical Pages, and Associated Contexts .................................................................................................................... 24-36
24.9.3 How to Expose One Extensible Flexfield Context .................................................................... 24-39
24.9.4 How to Expose Extensible Flexfield Attributes in a Table ...................................................... 24-41
24.10 Incorporating Extensible Flexfields into a Search Form .............................................................. 24-43
24.10.1 How to Incorporate an Extensible Flexfield into a Search Form ............................................ 24-43
24.11 Preparing Extensible Flexfield Business Components for Oracle Business Intelligence ............ 24-44
24.11.1 How to Enable an Extensible Flexfield for Oracle Business Intelligence .............................. 24-45
24.11.2 How to Flatten the Extensible Flexfield Model for a Business Intelligence-Enabled Extensible Flexfield ................................................................................................................. 24-45
24.12 Integrating Extensible Flexfields with Business Intelligence Publisher ........................................ 24-47
24.13 Loading Seed Data ....................................................................................................................... 24-48
24.14 Customize the Extensible Flexfield Modelers ............................................................................. 24-48
24.14.1 How to Customize the Runtime Business Component Modeler for Extensible Flexfields .......... 24-48
24.14.2 How to Customize the Runtime User Interface Modeler for Extensible Flexfields ................. 24-50
24.15 Testing Flexfields .......................................................................................................................... 24-54
24.16 Making Extensible Flexfields Available to Web Services ............................................................ 24-54
24.16.1 How to Make an Extensible Flexfield Available to Web Services ........................................ 24-54
24.17 Access Information About Extensible Flexfield Business Components .................................... 24-56
24.17.1 How to Access Information About Extensible Flexfield Business Components ................ 24-56
24.18 Use the Advanced Features of Extensible Flexfields .................................................................... 24-58
24.18.1 How to Support Interface Loading of Extensible Flexfield Data .............................................. 24-58
24.18.2 How to Support Parallel Sets of Extensible Flexfield Artifacts for Different Uses .................. 24-60

25 Use Key Flexfields

25.1 Introduction to Key Flexfields ....................................................................................................... 25-1
25.1.1 Benefits of Key Flexfields ........................................................................................................ 25-1
25.1.2 How Key Flexfields Are Modeled in Oracle Application Development Framework .......... 25-2
25.1.3 Secondary Usage Feature ........................................................................................................ 25-2
25.1.4 Participant Roles ...................................................................................................................... 25-3
25.1.5 Complete the Key Flexfield Development Process ................................................................... 25-3
25.2 Complete the Producer Tasks for Key Flexfields

<table>
<thead>
<tr>
<th>Section</th>
<th>Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>25.2.1 How to Develop Key Flexfields</td>
<td>25-8</td>

</tr>
</tbody>
</table>
26.4.9   How to Use an API to Apply XML Filters ................................................................. 26-64
26.4.10  How to Remove Code-Combination Filters from Your Application............... 26-66
26.4.11  How to Remove Filters from the Filter Repository .................................................. 26-66

27   Test and Deploy Flexfields

27.1   Introduction to Testing and Deploying Flexfields.................................................... 27-1
27.2   Deploy and Run the Flexfield Configuration User Interface .................................... 27-2
  27.2.1  How to Deploy and Run the ApplCore Setup Application to Integrated WebLogic
          Server ......................................................................................................................... 27-2
27.3   Configure Flexfields ................................................................................................. 27-4
  27.3.1  How to Configure Flexfields for Testing ............................................................. 27-4
27.4   Test Flexfields ........................................................................................................... 27-5
  27.4.1  Test Flexfields from Oracle JDeveloper .............................................................. 27-5
  27.4.2  Test Flexfields from Integrated WebLogic Server ............................................... 27-7
27.5   Deploy Flexfields in a Standalone WebLogic Server Environment ....................... 27-10
  27.5.1  How to Package a Flexfield Application for Deployment .................................... 27-10
  27.5.2  How to Deploy a Flexfield Application ................................................................. 27-11
27.6   Use the WLST Flexfield Commands to Deploy Flexfields...................................... 27-16
  27.6.1  How to Prepare Your Environment to Use the WLST Flexfield Commands ...... 27-17
  27.6.2  How to Prepare Your Environment to Use the deployFlexForApp Command ... 27-17
27.7   Regenerate Flexfield Business Components Programmatically ............................ 27-18
27.8   Integrate Flexfield Task Flows into Oracle Fusion Functional Setup Manager.......... 27-19
27.9   Export Flexfield Business Components .................................................................. 27-22

28   Get Started with Oracle Enterprise Crawl and Search Framework

28.1   Introduction to Using Oracle Enterprise Crawl and Search Framework ............... 28-1
  28.1.1  Understanding the ECSF Architecture ................................................................. 28-1
28.2   Setting Up and Running ECSF Command Line Administration Utility ............... 28-5
  28.2.1  Set Up the ECSF Command Line Administration Utility .................................. 28-5
  28.2.2  Run the ECSF Command Line Administration Utility ....................................... 28-6
  28.2.3  About Making Searchable Objects Accessible to the ECSF Command Line
          Administration Utility .................................................................................................. 28-6
  28.2.4  About Setting the Class Path ............................................................................... 28-7
  28.2.5  About Setting the Connection Information ......................................................... 28-9
  28.2.6  About Manually Connecting to the Oracle Fusion Applications Database ....... 28-11
  28.2.7  How to Provide the Path of the JPS Config File .................................................. 28-12
  28.2.8  About Configuring the Log Settings ................................................................... 28-13
  28.2.9  About Automating the ECSF Command Line Administration Utility ............ 28-13
28.3   Set Up Oracle Enterprise Manager and Discovering ECSF ................................. 28-14
  28.3.1  How to Register the ECSF Runtime MBean to the Integrated WebLogic Server .. 28-14
  28.3.2  About Installing Oracle Enterprise Manager ..................................................... 28-16
  28.3.3  How to Discover ECSF in Oracle Enterprise Manager ...................................... 28-16
  28.3.4  About Adding Users to the Administrators Group .............................................. 28-17
31.2 About Validating the Search Metadata .......................................................... 31-1
  31.2.1 How to Validate Search Metadata .......................................................... 31-2
31.3 Testing Searchable Objects Through a Web Browser ........................................ 31-2
  31.3.1 Perform Prerequisite Steps....................................................................... 31-2
  31.3.2 How to Run the ECSF Feed Servlet ......................................................... 31-3
  31.3.3 How to Test the Config Feed ...................................................................... 31-4
  31.3.4 How to Test the Control Feed ..................................................................... 31-5
  31.3.5 How to Test the Data Feed ......................................................................... 31-6
  31.3.6 How to Reset the State of the Feeds.......................................................... 31-7

32 Deploy and Crawl Searchable Objects
  32.1 Introduction to Deploying and Crawling Searchable Objects ......................... 32-1
  32.2 Deploy Searchable Objects and Dependencies................................................ 32-1
    32.2.1 About Deploying the ECSF Shared Library to Oracle WebLogic Server ...... 32-1
    32.2.2 How to Create an Application................................................................. 32-3
    32.2.3 How to Change the Application Name and Context Root of the View-Controller Project ................................................................. 32-4
    32.2.4 How to Modify the Run Configuration of the View-Controller Project ..... 32-4
    32.2.5 About Adding the ECSF Runtime Server Library and Required Java Archive Files to the Model and View-Controller Projects ................................................. 32-7
    32.2.6 About Deploying the ECSF Application.................................................. 32-8
  32.3 About Crawling Searchable Objects ............................................................... 32-8
    32.3.1 How to Verify the Crawl........................................................................... 32-8

33 Advanced Topics for ECSF
  33.1 Introduction to Advanced Topics for ECSF...................................................... 33-1
  33.2 About Enabling Search on Fusion File Attachments....................................... 33-1
    33.2.1 How to Make File Attachments Crawlable ............................................. 33-2
  33.3 About Enabling Search on WebCenter Tags.................................................... 33-2
    33.3.1 How to Enable Search on WebCenter Portal Tags .................................. 33-5
    33.3.2 How to Customize Search on WebCenter Portal Tags ......................... 33-6
    33.3.3 How to Add Tags to Indexable Documents ............................................. 33-6
    33.3.4 About Adding Tags for Querying.............................................................. 33-7
    33.3.5 About Modifying Tags in Indexable Documents..................................... 33-8
    33.3.6 About Registering Change Listeners......................................................... 33-8
  33.4 About Enabling Search on Tree-Structure-based Source Systems .................... 33-9
    33.4.1 How to Enable Search on Tree-Structure-Based Source Systems .......... 33-11
    33.4.2 How to Crawl Tree Structures................................................................. 33-11
    33.4.3 About Integrating Search Functionality for Tree Structures.................... 33-21
  33.5 About Managing Recent Searches................................................................... 33-27
    33.5.1 About Using the RecentSearchManager API ......................................... 33-28
    33.5.2 Understanding How Recent Searches Are Processed............................. 33-29
  33.6 Set Up Federated Search.................................................................................. 33-31
33.6.1 How to Create the SearchDB Connection on Oracle WebLogic Server Instance... 33-32
33.6.2 How to Update the Application Deployment Profile with the Target Directory for
Searchable Objects .................................................................................................................. 33-32
33.6.3 About Updating the Application to Reference the ECSF Service Shared Library. 33-33
33.6.4 How to Add the ECSF Runtime Library ................................................................. 33-33
33.6.5 About Setting the System Parameter for Web Service............................................ 33-34
33.6.6 About Packaging and Deploying the Search Application........................................ 33-34
33.6.7 About Updating the Search Application with New Searchable Objects or
Dependences .......................................................................................................................... 33-35
33.6.8 How to Set Up the ECSF Client Application for Federation................................. 33-35
33.6.9 About Setting the SearchContext Scope to GLOBAL.............................................. 33-38
33.6.10 About Integrating Federation Across Oracle Fusion Applications Product
Families ................................................................................................................................. 33-39
33.7 About Federating Oracle SES Instances ...................................................................... 33-39
33.8 About Raising Change Events Synchronously ............................................................ 33-41
33.9 About Using the External ECSF Web Service for Integration..................................... 33-41
33.9.1 About Web Service Methods .................................................................................... 33-41
33.9.2 About ECSF Web Service WSDL and XSD ............................................................... 33-42
33.9.3 About Web Service Request XSDs and XMLs.......................................................... 33-48
33.9.4 Understanding Web Service Response XSDs .......................................................... 33-55
33.9.5 About Invoking the ECSF Web Service................................................................. 33-65
33.10 About Implementing Coherence Cache for Search ..................................................... 33-70
33.10.1 About Implement Cache Coherence for Search....................................................... 33-71
33.11 About Localizing ECSF Artifacts.................................................................................. 33-71
33.11.1 How to Translate Strings in Groovy Expressions...................................................... 33-71
33.11.2 About Localizing facet Display Names .................................................................... 33-74
33.11.3 About Localizing Crawl Management Display Names.......................................... 33-78
33.11.4 About Localizing Crawlable Dynamic Content ...................................................... 33-78
33.11.5 About Localizing Crawlable Template Content ...................................................... 33-78
33.11.6 About Determining Locale ..................................................................................... 33-80
33.12 About Using ECSF Diagnostics .................................................................................. 33-80
33.12.1 Query Tests ............................................................................................................... 33-81
33.12.2 About Crawl Tests .................................................................................................... 33-83
33.12.3 About Environment and Configuration Information Tests .................................... 33-84
33.12.4 About Security Tests ............................................................................................... 33-85
33.13 About Troubleshooting ECSF .................................................................................... 33-87
33.13.1 Understand Common Problems and Solutions ....................................................... 33-87
33.13.2 About Diagnosing ECSF Problems ........................................................................ 33-93

34 Initiate a SOA Composite from an Oracle ADF Web Application

34.1 Introduction to the Recommended Design Pattern..................................................... 34-1
34.2 Other Approaches ....................................................................................................... 34-3
34.3 Example ....................................................................................................................... 34-3
36.6 Verifying the Deployment
36.7 Troubleshooting the Use Case
36.8 What You May Need to Know About Orchestrating ADF Business Components Services

37 Manipulate Back-End Data from a SOA Composite
37.1 Introduction to the Recommended Design Pattern
37.2 Example
37.3 How to Manipulate Data from a BPEL Process Service Component
37.4 Securing the Design Pattern
37.5 Verifying the Deployment
37.6 Troubleshooting the Use Case
37.7 What You May Need to Know About Manipulating Back-end Data from a SOA Composite
    37.7.1 When Entity Variables Flush Changes Back to ADF Business Components
    37.7.2 Support for XPath Operations
    37.7.3 Invoking an ADF Business Components Service and Entity Variables in the Same BPEL Process Service Component

38 Access a PL/SQL Service from a SOA Composite
38.1 Introduction to the Recommended Design Pattern
38.2 Other Approaches
38.3 Example
38.4 How to Invoke a PL/SQL Stored Procedure from a SOA Composite Application
38.5 Securing the Design Pattern
38.6 Verifying the Deployment

39 Invoke Custom Java Code from a SOA Composite
39.1 Introduction to the Recommended Design Pattern
39.2 Other Approaches
39.3 Example
39.4 How to Invoke a Java Class from a SOA Composite Application
39.5 Securing the Design Pattern
39.6 Verifying the Deployment
39.7 Troubleshooting the Use Case
39.8 What You May Need to Know About Invoking Custom Java Code from a SOA Composite

40 Manage Tasks from an Oracle ADF Application
40.1 Introduction to the Recommended Pattern
40.2 Other Approaches
40.3 Example
40.4 How to Manage a Human Task Flow from an ADF Application
40.5 Other Approaches .......................................................................................................................... 40-5
40.6 Securing the Design Pattern ............................................................................................................. 40-6
40.7 Verifying the Deployment .................................................................................................................. 40-7
40.8 Troubleshoot the Use Case ................................................................................................................ 40-8
  40.8.1 Worklist Notification Locale Does Not Honor the Regional Applications Session Setting .. 40-8
  40.8.2 Task Does Not Display in Worklist Application ................................................................. 40-8
  40.8.3 Task Details Do Not Display in the ADF Task Flow .............................................................. 40-9
  40.8.4 Logging ....................................................................................................................................... 40-10
40.9 What You May Need to Know About Managing Tasks from an ADF Application ................. 40-11

41 Work with Data from a Remote ADF Business Components Service

41.1 Introduction to the Recommended Design Pattern ...................................................................... 41-1
41.2 Potential Approaches ....................................................................................................................... 41-1
41.3 Example ........................................................................................................................................ 41-2
41.4 How to Create Service-Based Entity Objects and View Objects .................................................... 41-2
41.5 Securing the Design Pattern ........................................................................................................... 41-3
41.6 Verifying the Deployment ............................................................................................................... 41-3
41.7 Troubleshooting the Use Case ......................................................................................................... 41-3
41.8 Understanding the Transactional Behavior of Service-Based Entity Objects and View Objects ......... 41-3
41.9 Known Issues and Workarounds .................................................................................................... 41-4

42 Invokie an Asynchronous Service from a SOA Composite

42.1 Introduction to the Recommended Design Pattern ...................................................................... 42-1
42.2 Other Approaches ............................................................................................................................. 42-2
42.3 Example ........................................................................................................................................ 42-2
42.4 How to Invoke a SOA Composite Application from Within a SOA Composite Application ......... 42-3
  42.4.1 Define a New Web Service Reference ..................................................................................... 42-3
  42.4.2 Wiring the BPEL Process to the New Web Service Reference ............................................... 42-4
  42.4.3 Invoke the Asynchronous Web Service from the BPEL Flow ................................................. 42-6
  42.4.4 What Happens When You Invoke an Asynchronous Service from within a SOA Composite Application .............................................................................................................. 42-12
  42.4.5 What Happens at Runtime: How an Asynchronous Service is Invoked from within a SOA Composite Application .............................................................................................................. 42-12
42.5 Securing the Design Pattern ........................................................................................................... 42-12
42.6 Verifying the Deployment ............................................................................................................... 42-12
42.7 Troubleshoot the Use Case ............................................................................................................... 42-13
  42.7.1 Deployment .............................................................................................................................. 42-13
  42.7.2 Runtime ..................................................................................................................................... 42-13
42.8 What You May Need to Know About Invoking an Asynchronous Service from Another SOA Composite ............................................................................................................................... 42-13
43  Synchronously Invoking an ADF Business Components Service from an Oracle ADF Application

43.1  Introduction to the Recommended Design Pattern
43.2  Potential Approaches
43.3  Example
43.4  How to Invoke an ADF Business Components Service from an Oracle ADF Application
43.5  Securing the Design Pattern
43.6  Verifying the Deployment

44  Implement an Asynchronous Service Initiation with Dynamic UI Update

44.1  Introduction to the Recommended Design Pattern
44.2  Potential Approaches
44.3  Example
44.4  How to Implement an Asynchronous Service Initiation with Dynamic UI Update
44.4.1  Writing the Active Data Handler
44.4.2  Building the Supporting Active Data Entry Classes
44.4.3  Register the Active Data Collection Model with the Oracle ADF UI Page
44.4.4  Register the Component Managed JavaBean for Supporting Method Actions
44.4.5  Reference the Managed JavaBean in the Page UI
44.4.6  Create the Data Model and Add Application Module Methods
44.4.7  Create a SOA Composite that Subscribes to the Published Event
44.4.8  Construct a BPEL Process to Perform Asynchronous Work
44.4.9  Invoking the ADF Business Components Service
44.5  Securing the Design Pattern
44.6  Verifying the Deployment
44.7  Troubleshooting the Use Case
44.8  What You May Need to Know About Initiating an Asynchronous Service with Dynamic UI Update
44.9  Known Issues and Workarounds

45  Manage Tasks Programmatically

45.1  Introduction to the Recommended Design Pattern
45.2  Potential Approaches
45.3  Example
45.4  Manage Human Workflow Tasks from a Java Application
45.4.1  How to Connect to the Task Service/Task Query Service
45.4.2  How to Use the Single Server Task Service API
45.4.3  How to Use the Single Server Task Query Service API
45.4.4  How to Use the Federated Server Task Query Service API
45.4.5  How to Query and Traverse Federated and Non-federated Query Result Sets
45.5  Other Approaches
45.6  Securing the Design Pattern
47.6 Verify the Deployment
47.6.1 How to Verify the Deployment of the XFamilyPub Composite
47.6.2 How to Verify the Deployment of the XFamilySub Composite
47.7 Troubleshoot the Use Case
47.7.1 Privileges to FUSION_RUNTIME
47.7.2 Aqueue enabled for Enqueuing and Dequeuing
47.7.3 AQ_INVALID_QUEUE_TYPE

48 Use Oracle Enterprise Scheduler to Invoke an Asynchronous Service
48.1 Introduction
48.2 Alternative Approaches
48.3 Example
48.4 Invoking an Asynchronous ADF Business Components Service from an Oracle Enterprise Scheduler Java Job
48.5 Securing the Design Pattern
48.6 Verifying the Design Pattern
48.7 Troubleshooting the Use Case
48.8 What You May Need to Know About the Design Pattern

49 Get Started with Security
49.1 Introduction to Securing Oracle Fusion Applications
49.1.1 Architecture
49.1.2 Authentication
49.1.3 Authorization
49.2 Authentication Techniques and Best Practices
49.2.1 API Support for Authentication
49.2.2 Expression Language Support for Authentication
49.2.3 Non-browser Based Login
49.3 Authorization Techniques and Best Practices
49.3.1 Function Security
49.3.2 Data Security
49.4 Learning More About Technologies Used to Secure Oracle Fusion Applications

50 Implement Oracle Fusion Data Security
50.1 Introduction to Oracle Fusion Data Security
50.1.1 Terminology
50.1.2 Integrating Oracle Fusion Data Security with Oracle Platform Security Services (OPSS)
50.1.3 Integrating Data Security Task Flows into Oracle Fusion Functional Setup Manager
50.1.4 Integrating Oracle Fusion Data Security with User Sessions
50.1.5 Integrating Oracle Fusion Data Security with Virtual Private Database (VPD)
50.2 Managing Data Security Artifacts in the Oracle Fusion Data Security Policy Tables
50.2.1 How to Get Started Managing Data Security ................................................................. 50-8
50.2.2 What You May Need to Know About Administering Oracle Fusion Data Security Policy Tables .................................................................................................................................................... 50-9
50.3 Integrating with ADF Business Components .................................................................... 50-9
  50.3.1 How to Configure the ADF Data Model Project ......................................................... 50-10
  50.3.2 How to Secure Rows for Read, Update and Delete Access ........................................ 50-11
  50.3.3 How to Secure Rows for Custom Operations and Specific View Objects .................. 50-11
  50.3.4 What You May Need to Know About Naming Actions .............................................. 50-14
  50.3.5 What You May Need to Know About Column-Level Security .................................. 50-14
  50.3.6 What You May Need to Know About Translatable Entity Objects ............................. 50-14
  50.3.7 What Happens at Runtime: How Oracle Fusion Data Security Filters View Instance Rows .......................................................................................................................................................................................... 50-15
  50.3.8 How to Perform Authorization Checks for Custom Operations ............................... 50-15
  50.3.9 How to Test Permissions Using Expression Language Expressions in the User Interface ............................................................................................................................................ 50-16
50.4 Use Oracle Fusion Data Security to Grant Access to Secured Business Objects .............. 50-18
  50.4.1 How to Create Data Security Policies for Custom Business Objects ......................... 50-20
  50.4.2 How to Use Parameterized Conditions When Securing a Business Object ................ 50-25
  50.4.3 How to Create Test Users in JDeveloper .................................................................... 50-28
  50.4.4 What You May Need to Know About Creating Application Roles ............................ 50-28
50.5 Getting Security Information from the Application User Session Context ....................... 50-29
  50.5.1 How to Use the DataSecurityAM API to Get Session Context Information ................ 50-29
  50.5.2 How to Use the PL/SQL Data Security API to Check User Privileges ....................... 50-30
50.6 Understanding Data Security Performance Best Practices ............................................. 50-32
50.7 Validating Data Security with Diagnostic Scripts ................................................................ 50-33
  50.7.1 How to Validate Data Security Configuration with Diagnostic Scripts ..................... 50-34
  50.7.2 How to Validate Applications Context ....................................................................... 50-35
50.8 Integrating with Data Security Task Flows ...................................................................... 50-37
  50.8.1 About Integrating the Data Security Task Flows into Your Application .................... 50-37
  50.8.2 How to Configure Data Security Task Flows to Display in the Primary Window .......... 50-41
  50.8.3 How to Configure the Object Instance Task Flow to Display in a Dialog ................... 50-47
  50.8.4 How to Grant the Data Security Task Flows Access to the Application Policy Store .......................................................................................................................................................................................... 50-53
  50.8.5 How to Grant the End User Access to the Data Security Task Flows .......................... 50-53
  50.8.6 How to Map the Application to an Existing Application Stripe ............................... 50-54

51 Implement Application User Sessions .................................................................................. 51-1
  51.1 Introduction to Application User Sessions ....................................................................... 51-1
  51.2 Configuring Your Project to Use Application User Sessions ......................................... 51-2
    51.2.1 How to Configure Your Project to Use Application User Sessions ........................ 51-2
    51.2.2 How to Configure the ADF Business Component Browser ..................................... 51-3
    51.2.3 How to Use the ApplSession Logger for Troubleshooting ...................................... 51-3
    51.2.4 What Happens at Runtime: How the Application User Session is Used ................ 51-4
## Design and Secure View Objects for Oracle Business Intelligence Applications

### 62.1 Introduction to View Objects for Oracle Business Intelligence Applications

- About Entity Object Guidelines
- About Association Guidelines
- About View Object Guidelines
- Understanding View Links Guidelines
- Understanding View Criteria Guidelines

### 62.2 Understanding General Design Guidelines

- About Entity Object Guidelines
- About Association Guidelines
- About View Object Guidelines
- Understanding View Links Guidelines
- Understanding View Criteria Guidelines

### 62.3 Understanding Oracle Business Intelligence Design Patterns

- Understanding Flattened View Objects
- Understanding Fact-Dimension Relationships
- Understanding Self Referencing Entities (Self-Joins)
- Understanding Business Intelligence Filters
- Understanding Translations
- Understanding Date Effectivity

### 62.4 About Designing and Securing Fact View Objects

- About Designing Fact View Objects
- About Securing Fact View Objects

### 62.5 About Designing and Securing Dimension View Objects

- Overview of Designing Dimension View Objects
- About Designing Business Unit Dimensions
- About Securing Dimension View Objects
- About Using Multi-Valued Dimension Attributes
- About Using Junk Dimensions and Mini Dimensions
- About Using Secured and Unsecured Dimension View Objects

### 62.6 About Designing Date Dimensions

- About Using the Gregorian Calendar
- About Using the Fiscal Calendar
- About Using the Projects Calendar
- About Using Timestamp Columns
- About Using Role-Playing Date Dimensions

### 62.7 About Designing Lookups as Dimensions

- About Securing Data on Lookups

### 62.8 About Designing and Securing Tree Data

- About Designing a Column-Flattened View Object for Oracle Business Intelligence
- About Customizing the FND Table Structure and Indexes
- About Using Declarative SQL Mode to Design View Objects for Oracle Business Intelligence Applications
- Guidelines for ATG-Registration and BICVO Generation
- Guidelines for Hierarchy Depth and Conformance
62.8.6 About Securing ADF Business Components View Objects for Trees .......................... 62-28
62.9 About Supporting Flexfields for Oracle Business Intelligence ....................................... 62-30
62.10 About Supporting SetID ...................................................................................................... 62-31
  62.10.1 How to Expose the SetID Attribute for Set-Enabled Lookups .................................. 62-31
  62.10.2 How to Expose the SetID Attribute for Set-Enabled Reference Tables .................. 62-31
62.11 About Supporting Multi-Currency ..................................................................................... 62-32

63 Implement ADF Desktop Integration
  63.1 Oracle Application Development Framework Desktop Integration Standards and Guidelines ................................................................. 63-1
    63.1.1 How to Structure the ADF Desktop Integration Directories ................................ 63-2
    63.1.2 How to Name Your ADF Desktop Integration Files ........................................... 63-3
    63.1.3 How to Implement the Dialog Attributes Declarative Component .................... 63-4
  63.2 Skinning Excel ADF Desktop Integration Workbooks ....................................................... 63-6
  63.3 Configure the WebLogic Server Frontend ........................................................................ 63-6

64 Create Customizable Applications
  64.1 Introduction to Creating Customizable Applications ............................................................. 64-1
  64.2 Prepare an Application for Customizations .................................................................... 64-2
    64.2.1 How to Set Project Properties to Enable User and Seeded Customizations ........ 64-3
    64.2.2 How to Configure the Persistence Change Manager ............................................ 64-4
    64.2.3 How to Enable Translations of Customized Strings .............................................. 64-6
    64.2.4 How to Add Composer Technology Scope to Your Project ................................. 64-7
    64.2.5 How to Enable the User Customization of the UI Shell Template ....................... 64-7
    64.2.6 How to Create a Database Connection at the IDE Level ..................................... 64-9
  64.3 Enable Runtime Customization of Pages and Components ............................................. 64-9
    64.3.1 How to Enable Pages for Runtime Customization .............................................. 64-12
    64.3.2 How to Enable End-User Personalizations for a Page .......................................... 64-14
    64.3.3 How to Restrict Customization of a Page, Page Fragment, or Component .......... 64-14
    64.3.4 How to Control the Editing of Components in Page Composer ......................... 64-15
    64.3.5 How to Authorize the Runtime Customization of Pages and Task Flows ............ 64-17
    64.3.6 How to Persist Implicit Runtime Customizations ................................................. 64-18

65 Work with Extensions to Oracle Enterprise Scheduler
  65.1 Introduction to Oracle Enterprise Scheduler Extensions .................................................. 65-2
  65.2 Understanding Standards and Guidelines ...................................................................... 65-2
  65.3 About Creating and Implementing a Scheduled Job in Oracle JDeveloper .................... 65-2
    65.3.1 How to Create and Implement a Scheduled Job in JDeveloper .......................... 65-3
    65.3.2 What Happens When You Create and Implement a Scheduled Job in JDeveloper 65-3
    65.3.3 What Happens at Runtime: How a Scheduled Job Is Created and Implemented in JDeveloper ........................................................................ 65-3
  65.4 About Creating a Job Definition ....................................................................................... 65-4
    65.4.1 Understanding Job Definitions and Job Types ..................................................... 65-4

Abstract

Documentation for external Oracle Fusion Applications developers that describes Oracle Fusion Middleware components, installing JDeveloper, deploying applications on WebLogic Server (WLS), using Applications Core Technology (ApplCore), customization, security, Flexfields, developing web applications with the UI Shell page template and patterns, Enterprise Crawl and Search (ECSF), database schema deployment, seed data, and use cases.
Welcome to the *Oracle Fusion Applications Developer’s Guide!* This guide describes the Oracle Middleware Extensions for Applications for developing Oracle Fusion Applications using the Oracle Fusion Middleware components. This guide includes guidelines on how to set up your development environment and build, test, and deploy Oracle Fusion Applications. It includes specific feature details needed by developers when using the Oracle Middleware Extensions to create applications.

In this user guide, the nomenclature “11.12.x.0.0”, where “x” is a number, is used to indicate the release and patch releases for which the guide is applicable. When using this document, be sure to replace “x” with the number of the release that is being used.

**Audience**

This document is intended for Oracle Fusion Applications Developers and assumes familiarity with:

- Java and SQL
- Java EE, Java Servlets, and JavaServer Pages
- Oracle Application Development Framework
- Oracle JDeveloper

**Documentation Accessibility**

**Access to Oracle Support**

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info) or visit [http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs](http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs) if you are hearing impaired.

# Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
The following topics introduce the new and changed features of the Oracle Fusion Applications Developer’s Guide Release 12 (11.12.x.0.0) and other significant changes that are described in this guide, and provides pointers to additional information.

New and Changed Features for Release 12 (11.12.x.0.0)

The Oracle Fusion Applications Developer’s Guide Release 12 (11.12.x.0.0) includes the following new and changed features for this document.

- The nomenclature “11.12.x.0.0”, where “x” is a number, is used to indicate the release and patch releases for which the guide is applicable.
- The Implementing Attachments chapter has been extensively reorganized and updated.
- A new subsection, About Configuring the Attachment Link Component UI, has been added to the Configuring Attachments Components Properties section.

Other Significant Changes in this Document for Release 12 (11.12.x.0.0)

For Release 12 (11.12.x.0.0), this guide has been updated in several ways. Following are the sections that have been added or changed.

- Implementing Search Functions in the UI Shell has received numerous updates.
1. Get Started with Oracle Fusion Applications

This chapter describes how to design and build your Oracle Fusion Applications using Oracle standards and guidelines. It includes an overview of Oracle Fusion technologies and using Oracle Application Development Framework (ADF) functional patterns.

This chapter includes this section:

• Overview of Fusion Technologies

1.1 Overview of Fusion Technologies

Oracle Fusion web applications are a set of business-related applications developed with the help of various technologies. This section describes the various technologies with which an Oracle Fusion web application developer works when developing the applications.

The following is a list of the various categories of technologies that, as an Oracle Fusion web application developer, you will encounter. This section does not go into the details about why the specified technologies have been chosen, the main intention is to give you an overview of the various technologies that are used to develop Oracle Fusion web applications.

• User interface (UI) technologies
• Model technologies
• Backend technologies
• Orchestration technologies
• Security
• Customization-related technologies
• Metadata services
• General middle-tier technologies
• Application server technologies

UI Technologies

Technologies that are used to create user interfaces fall into this category. The technologies that must be used in Oracle Fusion to create these user interfaces are:

• ADF Faces Rich Client:
  The ADF Faces rich client technology is used to create browser-based user interfaces. It provides a set of UI components, which can be dragged and dropped...
to create UIs. Among these ADF components are other components called the data visualization tools, which are a set of rich interactive components that provide graphical and tabular capabilities for visualizing and analyzing data.

For more information about ADF Faces, see the Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework guide.

For more information about ADF Faces rich client components, see the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide.

• ADF Desktop Integration:
This technology is used to create interfaces accessed through Microsoft Excel.

For more information about ADF Desktop Integration, see the Oracle Fusion Middleware Developing Applications with Oracle ADF Desktop Integration guide.

• ADF Mobile:
Oracle ADF Mobile helps developers build and extend enterprise applications for iOS and Android from a single code base. Based on a hybrid mobile architecture, ADF Mobile supports access to native device services, enables offline applications and protects enterprise investments from future technology shifts.

For more information about Oracle ADF Mobile, see the Oracle Fusion Middleware Developing Oracle ADF Mobile Browser Applications guide.

Model Technologies
Technologies that are used to represent the business logic and the data on which the business logic is based fall into this category. The UI technologies discussed previously can be based on any model technology such as Enterprise JavaBeans (EJB), Oracle Toplink, and so on. In Oracle Fusion, ADF Business Components is the model technology that is used in all applications.

Backend Technologies
These technologies are the set of storage technologies that are used to store the transactional and relational data. The primary technologies used in Oracle Fusion to store and retrieve data are:

• Oracle Database: This is used to store and retrieve all transactional and reference data.
  For more information see the Oracle Database Administrator’s Guide.

• Oracle Enterprise Scheduler: This is used to manage multi-dimensional data. Essbase provides adaptable data storage mechanisms for specific types of analytic and performance management applications. It is used to manage multi-dimensional data.

Orchestration Technologies
These are the technologies that are used in the service-oriented architecture (SOA) world. The primary purpose of these technologies is to assemble various services together to provide comprehensive functionality.

In Oracle Fusion, many product applications provide their functionality in the form of web services. Oracle Application Server BPEL Process Manager is used to assemble these web services together to provide end-to-end functionality.
For more information about SOA, see the *Developing SOA Applications with Oracle SOA Suite* guide.

**Security**

Security is an integral part of all of the technologies previously mentioned. The technology used to provide security for Oracle Fusion Applications is Oracle Platform Security Services (OPSS).

For more information about OPSS, see the *Oracle Fusion Middleware Oracle Platform Security Services (OPSS) & Oracle Authorization Policy Manager (OAPM) Frequently Asked Questions*.

**Customization-Related Technologies**

Customization-related technologies give customers the tools they need to customize the artifacts that developers have created. For example, the customer requires more information on the Invoices Entry UI that the developer created. They want to customize the UI by adding this extra information. To perform this type of customization, Metadata Services (MDS) technology is used.

Another level of customization, which is used to customize the UI pages at runtime, is called Design Time at Runtime (DTRT) customization. This type of customization is performed using the WebCenter technologies. (This uses Oracle Metadata Services (MDS) internally.)

**Additional Technologies**

In addition to the technologies previously discussed, there are many others that Oracle Fusion web application developers may encounter. These include:

- **Oracle Enterprise Scheduler Service**: Oracle Enterprise Scheduler Service provides the ability to run different Job Types, including: Java, PL/SQL, and Binary Scripts, distributed across the nodes in an Oracle Application Server Cluster. Oracle Enterprise Scheduler Service runs these jobs securely, with high availability and scalability, with load balancing and provides monitoring and management through Oracle Enterprise Manager Fusion Middleware Control.

  For more information about Oracle Enterprise Scheduler Service, see the *Developing Applications for Oracle Enterprise Scheduler* guide.

- **Oracle Enterprise Crawl and Search Framework (ECSF)**: ECSF helps expose application context information on business objects to enable full-text transactional search.

  For more information about Oracle Enterprise Crawl and Search Framework, see *Getting Started with Oracle Enterprise Crawl and Search Framework*.

- **Oracle Business Rules (OBR)**: Oracle Business Rules enable dynamic decisions at runtime allowing you to automate policies, computations, and reasoning while separating rule logic from underlying application code. This allows more agile rule maintenance and empowers business analysts with the ability to modify rule logic without programmer assistance and without interrupting business processes.

  For more information about Oracle Business Rules, see the *Designing Business Rules with Oracle Business Process Management* guide.
• **Oracle Data Integrator (ODI):** Oracle Data Integrator is a comprehensive data integration platform that covers all data integration requirements - from high-volume, high-performance batches, to event-driven, trickle-feed integration processes, to SOA-enabled data services.

For more information about Oracle Data Integrator, see the *Oracle Fusion Middleware Developing Integration Projects with Oracle Data Integrator* guide.
This chapter describes how to configure and test your development environment. It includes the steps for setting up your JDeveloper environment and Oracle Application Development Framework (Oracle ADF) installation, running and deploying applications on Integrated WebLogic Server, and the basic steps for setting up your Oracle SOA Suite development environment.

This chapter includes these sections:

- Introduction to the Development Environment
- Setting Up the JDeveloper-based Personal Environment
- Improving Shared and Personal Environments Performance
- Using Deployment Profiles Settings
- Configuring the Oracle Enterprise Scheduler (ESS)
- Testing Your Installation
- Using Best Practices for Setting Up the Development Environment

### 2.1 Introduction to the Development Environment

**Note:**

Although JDeveloper works well in a 32-bit environment, this chapter assumes that you are using a 64-bit operating system and a 64-bit JDK.

If you do need to create and run Standalone WebLogic Server on a local PC, such as when doing SOA work, then the operating system must be 64-bit. The MW_HOME directory that is installed contains several Oracle Homes and the Oracle Business Intelligence installation is 64-bit only.

Also, a 32-bit operating system is limited to accessing 4GB of RAM. 8GB of RAM is preferred.

Oracle Fusion Applications provisioning involves installing, patching, configuring, and deploying all the enterprise components. At the end of the provisioning process, the system will be operational. An application administrator will be able to log in to the application and begin the process of configuring the functional (application specific) components.

On-site, the administrator uses eDelivery or the DVD media to kick-start the provisioning processes to create the test environment and the production environment. These environments are completely isolated from one another and set
up in an identical manner. There is no reuse of, for example, the database from the production environment in the test environment, or reuse of the Identity Store across the environments.

These environments need to be extremely stable and should not be affected by development projects. Typical development projects include creating new customizations for existing Oracle Fusion applications, developing new in-house Oracle Fusion applications, and extending Oracle Fusion applications with additional functionality. These development projects will typically involve a team of developers that needs to reuse certain parts, but still needs the isolation to run, test, and debug without affecting other team members.

As a developer, you will work with one development environment that has two parts:

- **Shared environment**
  This fully-provisioned Oracle Fusion Applications environment includes the database and LDAP. It also can host the instance of WebLogic Server if you require SOA for your customization work. The shared environment usually is designated as the Test environment.

- **Personal environment**
  This is the JDeveloper instance and an instance of Integrated WebLogic Server that can run on your local desktop or laptop. You still would connect to the database and LDAP instances on the shared environment.

---

**Note:**

To use Integrated WebLogic Server, the connection to a database and an LDAP server is required. The database needs all the correct schemas for Oracle Fusion applications and a properly-seeded LDAP.

The Personal environment also can have a standalone MW_HOME and WebLogic Server domain, such as:

- **standalone:** Only the AdminServer where you can run and deploy ADF applications.
- **adminsoa:** AdminServer plus SOA managed server.
- **adminall:** AdminServer configured for a standalone domain and a SOA managed server.
- **adminadfess:** AdminServer configured for standalone domain and an ESS managed server.

The shared environment plus the personal environment form the complete development environment.

### 2.1.1 Shared Environment

The shared environment is a fully-provisioned Oracle Fusion Applications environment to be shared among multiple developers. It normally will be set up by an administrator using the provisioning framework. This environment normally is set up on a machine that is more powerful than the normal developer’s machine, which often is a laptop.
Developers would obtain the EAR files to be customized from the filesystem from this environment.

The database, WebLogic Servers and common services provided by this environment would be used by the developers’ applications.

When it is provisioned, the shared environment contains:

- Database
- Oracle Middleware Home
- WebLogic Server domains
- Identity Store and Policy Store

Properties and features of the shared environment include:

- The shared environment can be accessed from the personal environment (see Personal Environment) so developers can reach the installation directory that normally is called MW_HOME.

- The exploded EAR directory in Middleware home can be opened from JDeveloper and a workspace can be created. The exploded EARs in Middleware home have the connections.xml and adf-config.xml files set up correctly to point to the correct database and other deployed applications in the shared environment.

- The LDAP and OPSS credentials in the personal environment point to the Identity Store and the Policy Store in the shared environment.

- WebLogic Server domains run in the shared environment and Oracle Fusion applications are deployed to those domains.

  The shared environment is a completely-provisioned Oracle Fusion Applications instance.

For more information about provisioning an environment, see "Provisioning a New Applications Environment" in the Installation Guide, and the Oracle Fusion Applications release notes.

2.1.2 Personal Environment

Each developer has a personal environment that uses the database, Middleware home, and the Identity and Policy stores from the shared environment. The shared environment is made available by using NFS mount or a mapped drive in the personal environment. In this environment, developers can use JDeveloper to run, test, and debug their changes. If network sharing is not an option, exploded EAR files can be copied to a local directory of the personal environment.

The personal environment consists of two parts:

- The JDeveloper-based environment that is created by installing JDeveloper, extension bundles and patches.
- The environment for Standalone WebLogic Server that is created using scripts and installer files.

Manually Deploying the oracle.apps.common.resource Shared Library

When an Integrated or a Standalone WebLogic Server instance has been launched, you will need to use the WebLogic Server Console to deploy
oracle.apps.common.resource.ear as a shared library using
oracle.apps.common.resource as the name. The file is located in the APPLTOP/
fusionapps/applications/com/deploy/ path of the fully-provisioned Oracle Fusion
Applications installation on the central server. See Managing Integrated WebLogic
Server.

If you forget to deploy that shared library, you will get an error when you try to run
any Oracle Fusion application in your Integrated or Standalone WebLogic Server
because they all have dependencies on this shared library.

## 2.2 Set Up the JDeveloper-based Personal Environment

You assemble this environment on your machine by performing these steps in this order:

- Install JDeveloper
- Install Extension Bundles
- Apply patches

Using JDeveloper and the Oracle Fusion Domain wizard, you can create the
fusion_apps_wls.properties file and a credential store. You will enter the host,
port, and other details for the database and Identity Store from the shared
environment. Eventually, the wizard will do the following:

- Create DefaultDomain.
- Extend DefaultDomain with WebLogic Server templates so that the shared
  libraries are added to the CLASSPATH and the system properties are set.
- Configure DefaultDomain with datasources and the Identity Store that are
  available in the shared environment.

DefaultDomain is run as part of Integrated WebLogic Server from within JDeveloper.
To create customizations for a shipped Oracle Fusion application, you can use
JDeveloper to point to the exploded EAR directory of the application in the shared
environment's Middleware home. A customization workspace will be created in
JDeveloper with the adf-config.xml file being modified such that the Metadata
Service (MDS) metadata store points to the filesystem. However, the DefaultDomain is
configured with the ApplicationDB datasource that points to the fusion runtime
schema that is installed in the database from the shared environment. Since the MDS
namespace has been altered while incorporating the exploded EAR directory, the
customizations that are created on the filesystem are picked up when the application is
run within Integrated WebLogic Server.

## 2.2.1 Before You Begin

Before you can use JDeveloper, there are several things you need to do.

### 2.2.1.1 Remove the SCIM Process

**Note:**

This step is not applicable if you are running a Windows environment.
If you are using your own workstation, you probably have a process called SCIM (Smart Common Input Method) running. SCIM is an input method platform used for multilingual work.

This process may prevent you from entering a password in the Oracle Fusion Domain wizard or anywhere a JPasswordField occurs. If it does interfere with your work, you can remove SCIM from your system by executing this command.

```
sudo yum remove scim
```

If you do not want to remove it completely, you can just kill the processes by executing the following command. However, if you just kill the processes instead of removing SCIM, you must kill them each time you reboot your system.

```
ps -ef | grep -i scim
```

You then can kill -9 all those processes.

### 2.2.1.2 Increase Open File Limit on Linux Machines

This system configuration change is required on Linux machines to increase the open file limit and resolve several JDeveloper, WebLogic Server and other "Too many files" errors when doing a build.

1. Add these two instructions to the `/etc/security/limits.conf` file:

   * soft nofile 8192
   * hard nofile 8192

   Note the leading asterisk (*).

2. Restart the machine to have these values take effect.

3. To check whether the settings took effect, change to a bash shell and run this command.

   ```
   [userid@blah ~]  bash
   bash-3.1$ > ulimit -n
   8192
   ```

### 2.2.1.3 Installing JDeveloper

Use the Oracle eDelivery system, download the Oracle JDeveloper 11g and Oracle Application Development Framework 11g and Oracle Fusion Applications Companion ZIP files that are appropriate for your operating system. Make sure to follow the instructions in the Readme file (click Readme at the top of the page).

**Note:**

*Always* use the Oracle eDelivery system. *Do not* download a random version from Oracle Technology Network (OTN).

Your administrator should make the contents of the ZIP files available on a shared directory. We strongly recommend that the administrator make the contents of the Oracle Fusion Applications Companion ZIP file available on a shared directory.
Follow these two basic steps to install JDeveloper.

- If you have not already done so, you must download and install the 64-bit JDK. To avoid the possibility of script errors, do not install to a directory location containing spaces, such as Program Files.

When installing JDeveloper, you will select the 64-bit JDK location you just installed.

If a 32-bit JDK was already installed and used, you must delete the old %MW_HOME% installation and the system directory in %JDEV_USER_HOME% before reinstalling JDeveloper and the Oracle Fusion Applications extensions updates.

- Install JDeveloper from the top level of the directory into which you extracted the ZIP files you downloaded from Oracle eDelivery.

For Windows, you can use the jdevstudioxxxxxinstall.exe installer (where xxxx is the version number). For Linux, you can use the jdevstudioxxxxxinstall.bin installer. If you decide to use the generic jdevstudioxxxxxinstall.jar installer, you must first install JDK 6 Update 24 from the Oracle Technology Network and then install JDeveloper using the generic installer.

The installation will let you specify the directory into which to install JDeveloper. To avoid possible errors when the installation scripts run, do not include any spaces in the path. This installation directory is referred to as MW_HOME.

When you have started JDeveloper, you will need to install the extension bundles from the fusion_apps_extensions directory in the location in which you extracted the Oracle Fusion Applications Companion files. See Adding Customization Extension Bundles to the jdev.conf File and Setting Up the JDeveloper-based Development Environment.

Related Links
The following document provides additional information related to subjects discussed in this section:

- For more installation information, see the Installing Oracle JDeveloper.

2.2.1.4 Add Customization Extension Bundles to the jdev.conf File

You must set this option before starting to customize an application if your application contains product-specific customization classes.
In $MW_HOME/jdeveloper/jdev/bin, open the jdev.conf file in a text editor and add this line:

```
AddVMOption -Dide.extension.extra.search.path /path/to/customization/bundles/directory1:/path/to/customization/bundles/directory2
```

where `-Dide.extension.extra.search.path /path/to/customization/bundles/directory1:/path/to/customization/bundles/directory2` is the fully-qualified path or paths to the directory or directories in which the JAR files containing the product-specific customization classes are located. Paths already exist as part of the provisioned environment.

- Check your adf-config.xml file to see if you are including any customization classes other than the ones described in "Personalizations Are Also Handled by the Customization Engine in MDS" in the Extensibility Guide for Developers and EnterpriseCC, which is deprecated. Those are your product-specific customization classes.

Example 2-1 shows customization class entries in the adf-config.xml file.

In Example 2-1, these two customization classes are outside the list:

```
<customization-class name="oracle.apps.hcm.common.core.HcmCountryCC"/>
<customization-class name="oracle.apps.hcm.common.core.HcmOrganizationCC"/>
```

- If you do have such product specific customization classes, you must modify your jdev.conf file to include the JAR files containing such customization classes. These JAR files have an Ext* prefix and are found under the application's APP_INF/lib directory.

- To find the path to such JAR files, contact your system administrator who can use these steps to locate APP_INF/lib/Ext*.jar:
  - Look under APP-INF/lib under the exploded EAR for all JAR files that start with Ext.
  - Find the JAR files that contain the product specific customization classes. These classes can be found in the adf-config file. If the product-specific customization class cannot be found in any of the JAR files under APP_INF/lib/Ext*.jar, look at all JAR files under the EarContents.

Example 2-1 Customization Class Entries in the adf-config.xml File

```
<cust-config>
  <match path="/*/">
    <customization-class name="oracle.apps.fnd.applcore.customization.GlobalCC"/>
    <customization-class name="oracle.apps.fnd.applcore.customization.SiteCC"/>
    <customization-class name="oracle.apps.fnd.applcore.customization.ProductCC"/>
    <customization-class name="oracle.apps.fnd.applcore.customization.EnterpriseCC"/>
    <customization-class name="oracle.apps.hcm.common.core.HcmCountryCC"/>
    <customization-class name="oracle.apps.hcm.common.core.HcmOrganizationCC"/>
    <customization-class name="oracle.apps.fnd.applcore.customization.UserCC"/>
  </match>
</cust-config>
```

2.2.1.5 Set Up the JDeveloper-based Development Environment

Follow these steps to create a development environment based on Integrated WebLogic Server:
1. From a command prompt, run `python -V` to see if you have Python 2.7.x on your machine. If you do not, install Python version 2.7.x. To avoid errors, do not install Python version 3.x. You can download Python from https://www.python.org.

2. Set these environment variables.

   **Note:**
   In many cases, it is convenient to have these in a script that is used to start JDeveloper. This is specially useful when you want to have different work directories for separate projects.

   **csh commands:**
   ```
   setenv PATH /path/to/python/bin:$PATH
   setenv HOME /path/to/user_dir (Important: If this variable is not set, the FADevConfigure.py script, which is called while creating an Oracle Fusion domain in JDeveloper, will fail.)
   setenv MW_HOME /path/to/JDeveloper/installation/directory
   setenv JAVA_HOME path/to/installed/64-bit/jdk (Important: A 32-bit JDK is installed into $MW_HOME when you install JDeveloper. If you are running the recommended 64-bit operating system, you will need to install a 64-bit JDK and set the JAVA_HOME variable to it.)
   setenv PATH $JAVA_HOME/bin:$PATH
   setenv JDEV_USER_HOME /path/to/a/directory (Optional) setenv FADEV_VERBOSE true
   setenv USER_MEM_ARGS "-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000"
   ```

   **bash commands:**
   ```
   export PATH=/path/to/python/bin:$PATH
   export HOME=/path/to/user_dir (Important: If this variable is not set, the FADevConfigure.py script, which is called while creating an Oracle Fusion domain in JDeveloper, will fail.)
   export MW_HOME=/path/to/JDeveloper/installation/directory
   export JAVA_HOME=path/to/installed/64-bit/jdk (Important: A 32-bit JDK is installed into $MW_HOME when you install JDeveloper. If you are running the recommended 64-bit operating system, you will need to install a 64-bit JDK and set the JAVA_HOME variable to it.)
   export PATH=$JAVA_HOME/bin:$PATH
   export JDEV_USER_HOME=/path/to/a/directory (Optional) export FADEV_VERBOSE=true
   export USER_MEM_ARGS="-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000"
   ```

   **Windows command prompt commands:**
   ```
   set HOME=path\to\user_dir (Important: If this variable is not set, the FADevConfigure.py script, that is called while creating an Oracle Fusion domain in JDeveloper, will fail. In Windows 7, HOME typically is c:\users\userid, such as c:\users\herbie.)
   set MW_HOME=path\to\JDeveloper\installation\directory (Important: The path must not contain spaces.)
   set JAVA_HOME=path\to\installed\64-bit\jdk (Important: A 32-bit JDK is installed into $MW_HOME when you install JDeveloper. If you are running the recommended 64-bit operating system, you will need to install a 64-bit JDK and set the JAVA_HOME variable to it. You can download a 64-bit JDK from the Oracle"

set PATH=%JAVA_HOME%\bin;%PATH%
set JDEV_USER_HOME=\path\to\a\directory (Important: The path must not contain spaces.)
set USER_MEM_ARGS=-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000
(Optional) set FADEV_VERBOSE=true

3. Change directory to $MW_HOME/jdeveloper/jdev/bin.

4. Open the jdev.conf file in a text editor and add this line:

   AddVMOption -Djdev.wlst.env.vars=HOME,JDEV_USER_HOME

   JDeveloper checks the environment before running Oracle WebLogic Scripting Tool or starting Oracle WebLogic Server. The domain creation scripts require access to certain environment variables. jdev.wlst.env.vars allows these environment variables to be accessed.

   Note that the HOME variable exists by default in Linux systems but must be set explicitly in Windows systems. See "Windows command prompt commands" in Step 2.

   If necessary, add other options from Table 2-1.

   Save and close the jdev.conf file.

---

</tbody>
</table>

5. Start JDeveloper.
   
   **Linux**
   
   jdev &
   
   **Windows**
   
   jdeveloper.exe
   
   If you need more details about the JDeveloper startup, you can use the *verbose* command line argument, such as:
   
   jdev -verbose
   
   When prompted, select the **Default Role**, as shown in Figure 2-1.

**Figure 2-1 Selecting the Default Role**
Because you will need to select a different role later, you should make sure you select the **Always prompt for role selection on startup** option.

The JDeveloper environment can be tailored based on the role you select. The modified environment removes unneeded items from JDeveloper, including menus, preferences, New Gallery, and even individual fields on dialogs. The JDeveloper role you select determines which technologies and options are available to you as you work in JDeveloper.

Table 2-2 provides a brief explanation of the available roles.

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Role</td>
<td>This role allows you general access to all of JDeveloper’s features without role-specific customizations. The other roles provide important <em>shaping</em> features that are not included in the Default Role. Some of these will be available once the Oracle Fusion Applications Extensions have been added to the IDE.</td>
</tr>
<tr>
<td>Oracle Fusion Applications Administrator Customization</td>
<td>This is the main customization role for Oracle Fusion Applications customers. <strong>Important:</strong> You <em>must</em> use this Role for customizing SOA Composites.</td>
</tr>
<tr>
<td>Oracle Fusion Applications Developer</td>
<td>This is for Oracle Fusion Applications developers to use to build new applications.</td>
</tr>
<tr>
<td>Database Edition</td>
<td>This gives you access to just the core database development tools.</td>
</tr>
<tr>
<td>Java EE Edition</td>
<td>This includes only features for core Java EE development.</td>
</tr>
<tr>
<td>Java Edition</td>
<td>This includes only features for core Java development.</td>
</tr>
<tr>
<td>BPM Process Analyst</td>
<td>Configures the product for a BPM Business Analyst.</td>
</tr>
<tr>
<td>Customization Developer</td>
<td>Configures the product for customizing metadata.</td>
</tr>
<tr>
<td>Oracle Fusion Applications Customization</td>
<td>Configures JDeveloper for customizing metadata for Oracle Fusion Applications developers.</td>
</tr>
</tbody>
</table>

Click **OK**. As JDeveloper loads, the **Migrate User Settings** prompt may display. If it does and you are not sure whether to migrate settings, you should click **No**.

6. Install the **Fusion Apps Development Environment** extension bundle, an all-encompassing JDeveloper bundle that is specific for Oracle Fusion Applications. To install the bundle:

   a. Select **Help > Check for Updates**.

   b. Click **Next** past the Welcome dialog.

   c. If the Proxy Setup dialog displays, enter the applicable information for your situation, as shown in **Figure 2-2**.
Figure 2-2 Completing the Proxy Setup Dialog

Ignore any error messages that might be displayed when you click the Test Proxy button.

d. Click OK. The Source dialog, shown in Figure 2-3, displays.

Figure 2-3 Available Update Centers

Unselect any marked Update Centers.

e. Click Add to display the Update Center dialog, shown in Figure 2-4.
g. Enter a name for the new Update Center, such as Oracle Fusion Applications Update Center.

h. Click **Browse** to locate and select the `fusion_apps_update_center.xml` file, as shown in Figure 2-5. The location of this file is on the Oracle Fusion Applications Companion 11g (11.1.1.7.1) disk in the `fusion_apps_extensions` directory, or on a shared directory provided by the administrator.

![Figure 2-5 Browsing for the Update File](image)

i. Click **Open**.

j. Click **OK**.

k. Select the newly-defined Update Center, as shown in Figure 2-6.

![Figure 2-6 Selecting the New Update Center](image)

Note that only the new Update Center should be selected.
l. Click Next to display the Updates dialog, shown in Figure 2-7. Note that, initially, no updates will be selected.

**Figure 2-7 Selecting the Updates**

![Figure 2-7 Selecting the Updates](image)

m. Select the Fusion Apps Development Environment extension bundle. The other bundles automatically will be selected.

n. Click Next to display the Download dialog and start the download, as shown in Figure 2-8.

**Figure 2-8 Downloading the Updates**

![Figure 2-8 Downloading the Updates](image)

When the download finishes, the Summary dialog, similar to that shown in Figure 2-9, displays automatically.
Click **Finish**. If you are using JDeveloper on a Linux system, the Confirm Exit prompt shown in Figure 2-10 displays.

Click **Yes** to exit JDeveloper.

**Note:** If you are using JDeveloper on Windows the prompt will ask if you want to restart JDeveloper. If you click **Yes**, JDeveloper is automatically restarted.

7. Restart JDeveloper, selecting either the **Oracle Fusion Applications Developer** role or the **Oracle Fusion Applications Administrator Customization** role, as shown in Figure 2-11. The restart results in installing the extension bundles that were downloaded.
If you do not have an administrator-supplied `fusion_apps_wls.properties` file in the default location, you will be prompted to configure WebLogic Server (launch the Oracle Fusion Domain wizard) as shown in Figure 2-12. Click Yes. See How to Use the Oracle Fusion Domain Wizard.

**Note:**

If you do not have access to a database and LDAP server, click No. Integrated WebLogic Server requires access to a valid database and LDAP server.

Note that if you do have an administrator-supplied `fusion_apps_wls.properties` file, the administrator also must supply the entire `o.jdevimpl.rescat2` folder from his `$JDEV_USER_HOME/system11.1.1.xx.yy.zz` folder. See Distributing the `fusion_apps_wls.properties` and `cwallet.sso` Files.

**Figure 2-12  WebLogic Server Not Configured Prompt**

When JDeveloper and Oracle WebLogic Server are properly installed and configured, the environment should have all the components in the correct locations. You should be able to create new, or customize existing, Oracle Fusion applications.

### 2.2.1.6 Use the OWSM_MDS Schema

The administrator has to make sure a database includes the Oracle Web Services Manager_Metadata Service (OWSM_MDS) schema. Typically, and particularly in a test environment and a production environment, this schema is in the Oracle Identity Manager (IDM) database. The administrator probably will not provide the shared environment schema connections because the schema would be locked down. The administrator should install a new MDS schema somewhere and provide that connection.

There are two options for how a developer can use the OWSM_MDS schema.

- The recommended method is for the administrator to use the Oracle Fusion Applications Repository Creation Utility to create the MDS schema, described in Creating the OWSM_MDS Schema, in the database in the shared environment. The schema name must have a prefix of **owsm**. This will create a schema named OWSM_MDS. Developers, then, will not need to do anything else to use the schema.

- The developers have to provide the connect string and other details of the owsm_mds schema available in the central IDM or LDAP while creating the properties file. This requires that an administrator provide the IDM database details. These are the host, port, userid, password, and SID. Figure 2-13 shows how the wizard’s Database dialog will be completed.
2.2.1.7 Distribute the fusion_apps_wls.properties and cwallet.sso Files

Instead of each developer creating the properties file and the credential store using the Oracle Fusion Domain wizard, the administrator can create them once and distribute them to the entire development team. The administrator can use the wizard and enter the property values, which include connect strings to the database and to the Identity Store. These values are captured in the fusion_apps_wls.properties file and the passwords are stored in an encrypted form using the credential store. Both the fusion_apps_wls.properties file and the cwallet.sso file, which is the credential store, are created in the o.jdevimpl.rescat2 sub-folder under the $JDEV_USER_HOME/system11.1.1.7.xx.yy.zz folder. The administrator can distribute the entire o.jdevimpl.rescat2 sub-folder to the development team. The developers can install JDeveloper and install the bundles. The developers then can copy the entire o.jdevimpl.rescat2 sub-folder under their own $JDEV_USER_HOME/system11.1.1.7.xx.yy.zz folder. This way, the administrator can enforce uniformity and the developers will not have to go through the wizard to create the properties file.

Now, if developers need to use their own SOAINFRA or MDS_SOA schemas, they can manually launch the wizard and provide connect strings specifically for those schemas.

Note:

Although the Oracle Fusion Domain wizard includes additional properties for Standalone WebLogic Server, the same fusion_apps_wls.properties and cwallet.sso files are used for both Integrated WebLogic Server and Standalone WebLogic Server creation and configuration.

2.2.2 How to Use the Oracle Fusion Domain Wizard

The wizard helps you to create and update a fusion_apps_wls.properties file and a cwallet.sso file that are used to set up the Oracle WebLogic Server domain for Oracle Fusion Applications development. The wizard incorporates two main paths: one for configuring an Integrated WebLogic Server domain (in which JDeveloper manages the server) and one for setting up a remote Standalone WebLogic Server domain.

In the case of Integrated WebLogic Server, completion of the wizard will create the domain. For Standalone WebLogic Server, you will have to create the domain from the command line, using a Python script and the fusion_apps_wls.properties and cwallet.sso files that were populated using the wizard.

The wizard can be run multiple times to change properties in the fusion_apps_wls.properties file. If certain critical properties are changed, the
domain will have to be re-created. This will be done automatically for the Integrated
WebLogic Server domain, but will be a manual step for a Standalone WebLogic Server
domain.

The wizard can be launched automatically or manually. It will be launched
automatically under either of these conditions:

- The \texttt{fusion\_apps\_wls.properties} file is not found when JDeveloper starts.
The name of the file defaults to \texttt{fusion\_apps\_wls.properties}, and the
location defaults to the \texttt{system1.1.xx.yy.zz/o.jdevimpl.rescat2}
directory.

- The \texttt{fusion\_apps\_wls.properties} file is not found when you select to \textbf{Run}
an application from JDeveloper, or you select to \textbf{Start Server Instance} from
JDeveloper.

To start the wizard manually from within JDeveloper:

- Select \textbf{View} > \textbf{Application Server Navigator}.

- Expand the \textbf{Application Servers} node.

- Right-click \textbf{IntegratedWebLogicServer} and select the \textbf{Configure Fusion Domain}
option, as shown in \textbf{Figure 2-14}.

\textbf{Figure 2-14} \hspace{1cm} \textbf{Manually Starting the Oracle Fusion Domain Wizard}

The properties that can be captured in the wizard are shown in Table 2-3. The
properties are defined under section headers that are surrounded by [square brackets],
for example:

\begin{verbatim}
[domain]
domainType=adminall
\end{verbatim}
<table>
<thead>
<tr>
<th>Property Name</th>
<th>Standalone/Integrated</th>
<th>Required</th>
<th>Default</th>
<th>Comments</th>
</tr>
</thead>
</table>
| domainType    | Standalone             | Yes      | standalone | Valid values are:  
|               |                        |          |          | **adfess**: Admin server only for Oracle ADF and ESS  
|               |                        |          |          | **adminsoa**: Admin server (EM) and SOA managed server  
|               |                        |          |          | **adminall**: Combination of standalone and adminsoa (Oracle ADF, ESS, SOA)  
|               |                        |          |          | **adminessadf**: Admin server for Oracle ADF and ESS managed server  
|               |                        |          |          | **standalone**: Default setting. This is an admin server only; not a managed server. |
| domainName    | Standalone             | Yes      | fusion_domain | This can be any name. It is used only for Standalone Weblogic Server. |
| domainDir     | Standalone             | Yes      |          | The location in the file system in which the domain will be created. To avoid possible errors during script execution, the directory name should not include spaces.  
|               |                        |          |          | If it is not specified, the domain will be created in the default location which is $MW_HOME/user_projects/<domain_name>. |
| installerLocation | Standalone          | Yes      |          | Location of the Oracle Fusion Applications installer files. These usually are located on a central server, rather than on each developer's system. Ask your administrator for the location. |
| listenPort    | Standalone             | Yes      | Default based on Standalone or Integrated. Default is 7011 for Standalone WebLogic Server. |
| soaPort       | Standalone             | Yes, only when domainType is adminsoa/adminall. |          | Needed for adminsoa and adminall.  
<p>|               |                        |          |          | As this is on their own machines, developers choose the values. |
| essPort       | Standalone             | Yes, only when domainType is adminess. |          | As this is on their own machines, developers choose the values. |
| wlName        | Both                   | Yes      | weblogic |          |</p>

| opssHost      | Standalone            | No       |         | Optional separate OPSS store. This is a string value similar to: opsshost\name\yourcompany.com. For Integrated WebLogic Server, the DefaultDomain uses the XML-based Policy Store (such as system-jazn-data.xml). For Standalone WebLogic Server, if undefined, the standalone domain defaults to the XML-based Policy Store (such as system-jazn-data.xml). For information and directions on how to migrate the OPSS policy store using the migrateSecurityStore.py OPSS script, see:  
• "Migrating the OPSS Security Store" and "Migrating with the Script migrateSecurityStore" in the Oracle Fusion Middleware Applications Security Guide.  
• "Extracting Data from an OID Store to a File" in the Administrator’s Guide. |
| opssPort      | Standalone            | No       |         | Example: 3061 |
| opssUser      | Standalone            | No       |         | Example: cn=wlsproxyuser |
| opssPass      | Standalone            | No       |         | Important: In the UI, the password will display as the standard "*****" mask. The password is not saved in the fusion\apps_wls.properties file. It is encrypted and saved in the cwallet.sso file maintained in the system11.1.1.xx.yy.zz/o.jdevimpl.rescat2/ directory. |
| opssSSLEnabled| Standalone            | No       | false   | true or false |
| jpsRootContext| Standalone            | No       |         | Text field  
Example: cn=FADevPolicies |
| biHostPort    | Standalone            | No       |         | Oracle Business Intelligence will only be supported in the Standalone WebLogic Server environment. Specify a port to point to the BI server. This generates a BIP configuration file that gets added to the domain home. The template then adds the location of the configuration file as a system property to be set when Oracle WebLogic Server is started. |

2.2.2.1 Creating the Properties File for Default Integrated Server

Note:
The wizard requires considerable information about the network and various servers, such as LDAP and database. In normal situations, the administrator will disseminate his entire o.jdevimpl.rescat2 folder from his $JDEV_USER_HOME/system11.1.1.xx.yy.zz folder to developers who will copy the folder into the correct directory. See Distributing the fusion_apps_wls.properties and cwallet.sso Files.

If the fusion_apps_wls.properties file is not found when you start JDeveloper, the prompt shown in Figure 2-12 displays. You also can start the wizard manually. Click Yes to launch the wizard and display the Usage page, as shown in Figure 2-15.
Figure 2-15  Selecting Domain Usage

- **Default Integrated Server**
  Select this option, the default, to configure and create a server that will be controlled by JDeveloper. This is the normal choice for development work. When the wizard finishes, an Integrated WebLogic Server domain will be created and can be used to run and test your applications.

- **Standalone Server**
  Selecting this option only creates or updates the fusion_apps_wls.properties and cwallet.sso files. See Completing the Oracle Fusion Domain Wizard for Standalone Server for the dialogs that are specific to creating the fusion_apps_wls.properties file for a Standalone WebLogic Server domain. Creating a Standalone WebLogic Server domain must be done from the command line.

- **Messages**
  A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

Further wizard pages depend on the selected Usage. The flow for the **Default Integrated Server** selection is covered first. The flow for the **Standalone Server** selection is covered in Completing the Oracle Fusion Domain Wizard for Standalone Server.

When you select the **Default Integrated Server** Usage option and click **Next**, the Domain dialog, shown in Figure 2-16, displays.
If the `fusion_apps_wls.properties` file already exists and is in place, the fields will show the values that are in the file.

- **WebLogic User Name**
  This value defaults to `weblogic`. Change it if necessary.

- **WebLogic Password / Confirm Password**
  The password requires at least one numeral. There is no default, and you must supply the password. Note that the password is not stored in the `fusion_apps_wls.properties` file. It is encrypted and stored in the `cwallet.sso` file.

- **Fusion Family Name**
  This name is used during Java Message Service queue creation; and as the SOA cluster name when creating an instance of Standalone Weblogic Server. The value should match the product you are customizing.

- **Messages**
  A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

Click **Next** to display the Database dialog, shown in **Figure 2-17**.
If the `fusion_apps_wls.properties` file already exists and is in place, the fields will show the values that are in the file.

**Note:** If you do not have access to a database, click **Cancel**.
Note:

- Values entered in the wizard are not validated, so the connection details must be validated outside the wizard.

- If a credential that is listed in the Database dialog does not have the same password as the corresponding schema name itself, you must provide the password using the fields to the right of the credential list.

- If the credential that is listed in the Database dialog has to be mapped to a schema other than the default schema, you should provide the appropriate schema name and password using the fields to the right of the credential list. For example, the OWSM MDS credential is mapped to the owsm_mds schema by default. But, if it has to be mapped to the hcm_fusion_mds_soa schema, you can choose the OWSM MDS credential from the list and then enter hcm_fusion_mds_soa in the Username field and specify the password in the Password field on the right. Again, the Connect String field can be left blank if the schema is in the same database.

- If each of the credentials in the Database dialog have the same password as the corresponding schema name, you only need to enter values in the Fusion Database field in the host:port:SID format.

- Make sure you have entered valid database connection details or your WebLogic Servers will not start. The ApplicationDB data source that is configured using these values is configured to support global transaction type Logging Last Resource. If the database is not available when you try to start WebLogic Server, it will fail with a message similar to:

  Server failed. Reason: JTAExceptions:119002A logging last resource failed during initialization. The server cannot boot unless all configured logging last resources (LLRs) initialize

- Fusion Database User
  This schema name comes from the database installation. fusion_runtime is a recommended standard name.

- Fusion Database Password
  Enter the password. You probably will need to get this from an administrator if the cwallet.sso file was not provided to you. (Passwords are encrypted and stored in that file.)

- Fusion Database
  Enter the host, port, and the SID information using a colon (:) delimiter, such as a.your.company.com:1234:xyzzyon. You probably will need to get this from an administrator if the fusion_apps_wls.properties file was not prepared for you.

- Credential Type List
  Several credentials are supplied with Oracle Fusion Applications and are included in the fusion_apps_wls.properties file. When you click a credential, the three fields to the right will display the default values. The Password field will
remain blank because any passwords are encrypted and stored in the
cwallet.sso file.

If OWSM_MDS is selected, and the administrator has chosen to open up the IDM
database in which the schema already exists, you will need to enter all the
necessary information in this dialog. However, if the administrator has created the
OWSM_MDS schema in the transaction database, you may not need to enter any
data here. For more information about the owsm_mds schema, see Creating the
OWSM_MDS Schema.

You can change the default values of almost all the credentials, if necessary.

- **User Name**
  
  This field corresponds to the Fusion Database User field.

- **Password**
  
  This field corresponds to the Fusion Database Password field.

- **Connect String**
  
  This field corresponds to the Fusion Database field.

- **Messages**

  A message is displayed in this field if any errors occur in the definition. These
  errors must be corrected before you continue.

Click **Next** to display the Security dialog, shown in Figure 2-18.

**Figure 2-18 Configuring Security for Integrated Domain Server**

If the fusion_apps_wls.properties file already exists and is in place, the fields
will show the values that are in the file.
Note: If you do not have access to an LDAP server, click Cancel.

- **LDAP Server**
  This field cannot be edited directly. Click the edit icon to display the Edit LDAP Server dialog shown in Figure 2-19.

*Figure 2-19 Editing the LDAP Server*

- **Host**
  Enter the name of your LDAP host, such as `ldap_server.your_company.com`.

- **Port**
  Enter the port number, such as `1066`.

- **Principal**
  This is the internal LDAP user name by which you connect to LDAP, such as `cn=wlsproxyuser`.

- **Password**
  Enter the password used by the Principal. The password will be encrypted and stored in the `cwallet.sso` file, and not in the `fusion_apps_wls.properties` file.

- **SSL Enabled**
  This value defaults to LDAP (not checked). Select this check box if you want to use LDAPS.

- **User Base DN**
  Enter the User DN based your LDAP. A sample User DN resembles `cn=users,dc=us,dc=your_company,dc=com`.
  The DN (Distinguished Name) is the LDAP attribute that uniquely defines an object. Each DN must have a unique name and location.
  The components include `cn=common name, ou=organizational unit, and dc=domain content`. DC often is listed with two entries, `dc=cp` and `dc=com`.

- **Group Base DN**
  Enter the Group DN based your LDAP. A sample Group DN resembles `cn=groups,dc=us,dc=your_company,dc=com`.
• **Messages**

A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

Click **Next** to display the Finish dialog shown in **Figure 2-20**.

**Figure 2-20  Finishing the Integrated Domain**

- **Click Finish to save the properties in the following file**

  This value cannot be edited. The field simply shows the name of the `fusion_apps_wls.properties` file and the directory in which it will be created or updated.

- **Create the Domain Now**

  This defaults to Yes (checked). When selected and you click **Finish**, the Integrated WebLogic Server domain will be created so you can test your applications by selecting one of the JDeveloper **Run** options.

  **Note:**

  Creating the domain involves a great deal of background work to correctly set up the environment. This process can take several minutes.

2.2.2.2 **Complete the Oracle Fusion Domain Wizard for Standalone Server**

When you select the Standalone Server Usage option and click **Next**, the Domain dialog, shown in **Figure 2-21**, displays.
Figure 2-21 Configure the Standalone Domain

If the fusion_apps_wls.properties file already exists and is in place, the fields will show the values that are in the file.

Note:

If an administrator has not created the fusion_apps_wls.properties file for you, with this information, you will need to get most of this information from an administrator.

- **Domain Type**
  This is the type of domain you wish to create. It can be:
  
  - **adfess**: Configured for Oracle ADF and Oracle Enterprise Scheduler technologies.
  
  - **adminsoa**: Creates an Oracle SOA Suite domain with an AdminServer with Oracle Enterprise Manager Fusion Middleware Control deployed, and a managed server, named soa_server1, where SOA composites are deployed and run.
  
  - **adminall**: A combination of standalone and Oracle SOA Suite, AdminServer for Oracle ADF/Oracle Enterprise Scheduler and managed server soa_server1 for Oracle SOA Suite.
  
  - **adminessadf**: Admin server for Oracle ADF and Oracle Enterprise Scheduler Service (ESS) managed server.

- **Domain Name**
The name of your domain. If you have more than one domain, you need to change this value and the domainDir value.

Follow these steps if you are using a Linux operating system:

- Create a new fusion_apps_wls.properties file with domainName=Domain1 and domainDir=$MW_HOME/user_projects/Domain1.

- When the properties file has been created, copy fusion_apps_wls.properties to fusion_apps_wls_Domain1.properties in the $JDEV_USER_HOME/system11.1.1.*/o.jdevimpl.rescat2 directory.

- Run FADevCreateDomain.py -p $JDEV_USER_HOME/system11.1.1.*/o.jdevimpl.rescat2/fusion_apps_wls_Domain1.properties to create Domain1.

- Edit fusion_apps_wls.properties and change domainName=Domain2 and domainDir=$MW_HOME/user_projects/Domain2.

- Copy fusion_apps_wls.properties to fusion_apps_wls_Domain2.properties in the $JDEV_USER_HOME/system11.1.1.*/o.jdevimpl.rescat2 directory.

- Run FADevCreateDomain.py -p $JDEV_USER_HOME/system11.1.1.*/o.jdevimpl.rescat2/fusion_apps_wls_Domain2.properties to create Domain2.

You now have two properties files in the o.jdevimpl.rescat2 folder and two domains.

Follow these steps if you are using a Windows operating system:

- Create a new fusion_apps_wls.properties file with domainName=Domain1 and domainDir=%MW_HOME%\user_projects\Domain1.

- cd %JDEV_USER_HOME%\system11.1.1.*\o.jdevimpl.rescat2

- copy fusion_apps_wls.properties fusion_apps_wls_Domain1.properties

- Run FADevCreateDomain.py -p %JDEV_USER_HOME%\system11.1.1.*\o.jdevimpl.rescat2\fusion_apps_wls_Domain1.properties to create Domain1.

- Edit fusion_apps_wls.properties and change domainName=Domain2 and domainDir=%MW_HOME%\user_projects\Domain2.

- cd %JDEV_USER_HOME%\system11.1.1.*\o.jdevimpl.rescat2

- copy fusion_apps_wls.properties fusion_apps_wls_Domain2.properties

- Run FADevCreateDomain.py -p %JDEV_USER_HOME%\system11.1.1.*\o.jdevimpl.rescat2\fusion_apps_wls_Domain2.properties to create Domain2.
You now have two properties files in the o.jdevimpl.rescat2 folder and two domains.

- **Installer Location**
  This is the location of the Oracle Fusion Applications installer files, usually on a central server.

- **Domain Location**
  The location in the file system in which the domain will be created.
  If it is not specified, it will be created in the default location, which is $MW_HOME/user_projects/<domain_name>.
  This can be changed by setting the domainDir property in the fusion_apps_wls.properties file. If you have more than one domain, you need to change this value. See the description of domainName.

- **Listen Port**
  Listen Port is the adminserver listen-port you want to use.

- **SOA Port**
  This field, which displays only if the Domain Type is adminall or adminsoa, is the port number for your Oracle SOA Suite managed server (soa_server1) if you are using Oracle SOA Suite. If you are not using Oracle SOA Suite, you can leave this blank.

- **BI Host Port**
  This is the host:port where the BI Publisher server is running. The format for the value for this field is hostname:port, such as my.domain.com:9999. You may need to get this value from your administrator.

- **WebLogic User Name**
  This value defaults to weblogic. Change it if necessary.

- **WebLogic Password / Confirm Password**
  The password requires at least one numeral. There is no default, and you must supply the password. Note that the password is not stored in the fusion_apps_wls.properties file. It is encrypted and stored in the cwallet.sso file.

- **Fusion Family Name**
  This name is used during Java Message Service queue creation; and as the SOA cluster name when creating an instance of Standalone Weblogic Server. The value should match the product you are customizing.

- **Messages**
  A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

Click **Next** to display the Database dialog, shown in Figure 2-22
If the `fusion_apps_wls.properties` file already exists and is in place, the fields will show the values that are in the file.

**Note:** If you do not have access to a database, click **Cancel**.

**Note:**

- Values entered in the wizard are *not* validated, so the connection details *must* be validated outside the wizard.

- If a credential that is listed in the Database dialog does not have the same password as the corresponding schema name itself, you *must* provide the password using the fields to the right of the credential list.

- If the credential that is listed in the Database dialog has to be mapped to a schema other than the default schema, you should provide the appropriate schema name and password using the fields to the right of the credential list. For example, the OWSM MDS credential is mapped to the `owsm_mds` schema by default. But, if it has to be mapped to the `hcm_fusion_mds_soa` schema, you can choose the OWSM MDS credential from the list and then enter `hcm_fusion_mds_soa` in the Username field and specify the password in the Password field on the right. Again, the Connect String field can be left blank if the schema is in the same database.

- If each of the credentials in the Database dialog have the same password as the corresponding schema name, you only need to enter values in the Fusion Database field in the `host:port:SID` format.
• **Fusion Database User**
  This schema name comes from the database installation. A recommended standard name is `fusion_runtime`.

• **Fusion Database Password**
  Enter the password. You probably will need to get this from an administrator if the `cwallet.sso` file was not provided to you. (Passwords are encrypted and stored in that file.)

• **Fusion Database**
  Enter the host, port, and the SID information using a colon (:) delimiter, such as `a.your.company.com:1234:xyzzyon`. You probably will need to get this from an administrator if the `fusion_apps_wls.properties` file was not prepared for you.

• **Credential Type List**
  Several credentials are supplied with Oracle Fusion Applications and are included in the `fusion_apps_wls.properties` file. When you click a credential, the three fields to the right will display the default values. The Password field will remain blank because any passwords are encrypted and stored in the `cwallet.sso` file.

  If OWSM_MDS is selected, and the administrator has chosen to open up the IDM database in which the schema already exists, you will need to enter all the necessary information in this dialog. However, if the administrator has created the OWSM_MDS schema in the transaction database, you may not need to enter any data here. For more information about the `owsm_mds` schema, see `Creating the OWSM_MDS Schema`.

  You can change the default values of almost all the credentials, if necessary.

  – **User Name**
    This field corresponds to the Fusion Database User field.

  – **Password**
    This field corresponds to the Fusion Database Password field.

  – **Connect String**
    This field corresponds to the Fusion Database field.

• **Messages**
  A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

Click **Next** to display the Security dialog shown in Figure 2-23.
Figure 2-23 Configuring Security for Standalone Server

If the `fusion_apps_wls.properties` file already exists and is in place, the fields will show the values that are in the file.

**Note**: If you do not have access to an LDAP server, click **Cancel**.

- **LDAP Server**
  
  This field cannot be edited directly. Click the edit icon to display the Edit LDAP Server dialog shown in Figure 2-24.

Figure 2-24 Editing the LDAP Server

- **Host**
  
  Enter the name of your LDAP host, such as `ldap_server.your_company.com`.

- **Port**
Enter the port number, such as 1066.

- **Principal**
  This is the internal LDAP user name by which you connect to LDAP, such as cn=wlsproxyuser.

- **Password**
  Enter the password used by the Principal. The password will be encrypted and stored in the cwallet.sso file, and not in the fusion_apps_wls.properties file.

- **SSL Enabled**
  This value defaults to LDAP (not checked). Select this check box if you want to use LDAPS.

- **User Base DN**
  Enter the User DN based your LDAP. A sample User DN resembles cn=users,dc=us,dc=your_company,dc=com.
  
  The DN (Distinguished Name) is the LDAP attribute that uniquely defines an object. Each DN must have a unique name and location.
  
  The components include cn=common name, ou=organizational unit, and dc=domain content. DC often is listed with two entries, dc=cp and dc=com.

- **Group Base DN**
  Enter the Group DN based your LDAP. A sample Group DN resembles cn=groups,dc=us,dc=your_company,dc=com.

- **OPSS Server**
  Defining the Oracle Platform Security Services (OPSS) Server is optional. Define this if its policy store is in a different location than your LDAP policy store. If OPSS-related properties are not specified, the domain is configured to use the XML-based Policy Store, such as system-jazn-data.xml.
  
  For information and directions on how to migrate the OPSS policy store using the migrateSecurityStore.py OPSS script, see:
  
  
  - "Extracting Data from an OID Store to a File" in the Administrator’s Guide.
– **Host**
  Enter the name of your LDAP host, such as `ldap_server.your_company.com`.

– **Port**
  Enter the port number, such as `1066`.

– **Principal**
  This is the internal LDAP user name by which you connect to LDAP, such as `cn=wlsproxyuser1`.

– **Password**
  Enter the password used by the Principal. The password will be encrypted and stored in the `cwallet.sso` file, and not in the `fusion_apps_wls.properties` file.

– **SSL Enabled**
  This value defaults to not enabled. Select this check box if you want to enable SSL.

– **JPS Root Context**
  Enter the JPS Root Distinguished Name, which is the top-level (outermost) node that contains OPSS data in an LDAP directory, such as `cn=FAPolicies`.

Click **Next** to display the Finish dialog shown in **Figure 2-26**.

**Figure 2-26**  **Finishing the Standalone Domain Configuration**

- Click **Finish** to save the properties in the following file.
This value cannot be edited. The field simply shows the name of the fusion_apps_wls.properties file and the directory in which it will be created or updated.

- To create the domain ...

This value cannot be edited. The field simply shows the directory in which the script file will be created, and the name of the script file, FADevCreateDomain.py, you will need to run at the command line. See Creating a Domain for Standalone WebLogic Server.

- Messages

A message is displayed in this field if any errors occur in the definition. These errors must be corrected before you continue.

2.2.3 How to Start Integrated WebLogic Server

You can start Integrated WebLogic Server before running or deploying any applications. If you run an application without having already started Oracle WebLogic Server, JDeveloper will start it.

2.2.3.1 Start Integrated WebLogic Server

There are two ways to start Integrated WebLogic Server.

- Right-click and run a page from a project. If the server is not running, it will be started.
- From the JDeveloper main menu, select Run > Start Server Instance, as shown in Figure 2-27.

Figure 2-27  Start Server Using Start Server Instance

2.2.3.2 Stop Integrated WebLogic Server and the Application

To stop Integrated WebLogic Server or the application from either the Integrated Server window or from the JDeveloper menu bar, click the red stop button and select
either the IntegratedWebLogicServer or the connection option, as shown in Figure 2-28.

Figure 2-28 Stopping Integrated WebLogic Server or the Application

If you select the connection option, the application will be undeployed and the server will remain running.

If you select the IntegratedWebLogicServer option, the deployed application will be undeployed and the server shut down. Wait for the application to be undeployed and the server to stop.

If the shutdown of Integrated WebLogic Server did not respond or shut down the server, click the red shutdown button again to kill the process, as shown in Figure 2-29.

Figure 2-29 Forcing Shutdown of Integrated WebLogic Server

If you still do not see the Process Exited message when you terminate Integrated WebLogic Server, you will have to manually kill the process.

To manually kill the process from Linux, follow these steps:

1. From a terminal window, execute this command.
   
   ```bash
   /usr/sbin/lsof -i -P | grep 7101
   ```

   **Note:**

   7101 is the default Integrated WebLogic Server port. It may be different.

2. Kill the process. For instance, if the process is 15846, you would execute this command:
   
   ```bash
   kill -9 15846
   ```

To manually kill the process from Windows, follow these steps:

1. Start the Windows Task Manager.
2. Click the Processes tab if it is not already active.
3. Click the Image Name column heading to place the processes in an alphabetical order.
4. Locate and select the java.exe process.
2.2.3.3 Manage Integrated WebLogic Server

The WebLogic Server Console is deployed by default and can be accessed to manage Integrated WebLogic Server. To access the WebLogic Server Console, enter the following URL in your web browser: http://<hostname.domainname>:<port>/console, such as http://localhost:7101/console.

2.3 Improve Shared and Personal Environments Performance

This section presents three situations whose security or performance can be improved:

- Creating a local OWSM_MDS Schema
- Using alternate database schemas
- Running Standalone WebLogic Server from the personal environment

2.3.1 How to Create the OWSM_MDS Schema

This step is optional and depends on how the environment is set up and the type of security that is required.

The mds-owsm datasource must be correctly configured to point to an MDS schema. In the production environment, this schema would be in the LDAP infrastructure database.

To configure the datasource, you need to know the schema password. The recommendation is for the administrator to create a new MDS schema and give developers the password for it.
2.3.1.1 Creating the OWSM_MDS Schema

This section provides detailed snapshots on how to create the OWSM_MDS schema using the Oracle Fusion Applications Repository Creation Utility.

In a production environment, the OWSM_MDS schema is in the IDM database. The IDM is typically locked down so information such as schema passwords are not handed out. But, to configure the domain, the schema and the password are required to set up the mds-owsm datasource. The starter transaction database does not contain the OWSM_MDS schema. This is correct and the base template to create the starter transaction database should not be changed to include it. To avoid widely disseminating the schema password of the IDM database, an extra MDS should be added to the development’s transaction database using the Oracle Fusion Applications Repository Creation Utility with a prefix of OWSM.

You do not have to do anything else apart from adding this schema. The schema will be correctly populated when your domain starts, if it does not already contain the correct data.

There may be several Oracle Fusion Applications Repository Creation Utilities available. To provision Oracle Fusion Applications, you will have created an installer repository. In this repository, you will see the following:

```
installers/
  fmw_rcu/
    linux/
      rcuHome.zip
    windows/
      rcuHome.zip
  biapps_rcu/
  fmw_rcu/
```

Copy the appropriate ZIP file to your system from the installers/fmw_rcu directory.

When you get the ZIP file to your machine, follow these steps:

**Linux system**

```
% mkdir fa_rcu
% cd fa_rcu
% cp /from_zip_file_location/rcuHome.zip .
% unzip rcuHome.zip
% cd bin
% ./rcu
```

**Windows system**

```
md fa_rcu
cd fa_rcu
copy \from_zip_file_location\rcuHome.zip .
unzip rcuHome.zip
\path_to_rcu_utility\rcu
```

The Oracle Fusion Applications Repository Creation Utility starts and displays the Create Repository dialog, shown in Figure 2-32.
Select **Create** and click **Next** to display the Database Connection Details dialog, shown in Figure 2-33.

**Figure 2-33  Creating the Database Connection**
Enter your database connection details and click **Next** to display the Checking Global Prerequisites dialog, shown in **Figure 2-34**.

![Figure 2-34 Checking Global Prerequisites](image)

Click **OK** to display the Select Components dialog, shown in **Figure 2-35**.

![Figure 2-35 Selecting Components](image)

Select **Create a new Prefix** and enter OWSM as the name.

Expand **AS Common Schemas** and select Metadata Services.

Click **Next** to display the Checking Component Prerequisites dialog, shown in **Figure 2-36**.
Click **OK** to display the Schema Passwords dialog, shown in **Figure 2-37**.

Select **Use same passwords for all schemas** and enter the password for the OWSM_MDS schema in the **Password** and **Confirm Password** fields.

Click **Next** to display the Map Tablespaces dialog, shown in **Figure 2-38**.
In the **Default Tablespace** field, select FUSION_TS_TOOLS.

In the **Temp Tablespace** field, select either FUSION_TEMP or TEMP3.

Click **Next** to display the Validating and Creating Tablespaces dialog, shown in Figure 2-39.

**Figure 2-39  Validating Created Tablespaces**

Click **OK** to display the Summary dialog, shown in Figure 2-40.
Verify the information and click **Create**.

When the operation has completed successfully, the Completion Summary dialog, shown in Figure 2-41, displays.
The OWSM_MDS schema now can be used to configure the mds_owsm datasource in the domain.

2.3.2 How to Use Alternate Database Schemas

The main reason to use an alternate database is to improve performance. For instance, if the main database is remote, you can improve performance by installing the dehydration store, EDN, MDS and OrasDPM on your local machine.

To use an alternate database schema, follow these steps.

1. Create the required database schemas, as shown in Example 2-2.

   ![Image of Completion Summary]

   Click Close.

   The OWSM_MDS schema now can be used to configure the mds_owsm datasource in the domain.

   **Note:**
   These steps need the number of processes in the database to be set to at least 200. If needed, log in as sysdba, run this command, and restart the database.

   ```sql
   alter system set processes=200 scope=SPFILE;
   ```

2. Drop the Repository, as shown in Example 2-3. Enter the SYS password when prompted.

   If the -silent switch is omitted, a wizard will be launched. It will ask you to enter the same values as shown in Example 2-2.

3. Recreate the Repository, as shown in Example 2-4. Enter the SYS password when prompted.
Note:
You will need to supply passwords for the different users. You will have to remember all the passwords because you will need them when you configure the DataSources.

Example 2-2  Creating database schemas
Follow these steps if you are using a Linux operating system:

```bash
cd $RCU_SHIPHOMELOC/bin
DB_HOST=localhost
DB_PORT=1521
DB_SID=XE
CONNECT_STRING=$DB_HOST:$DB_PORT:$DB_SID
```

Follow these steps if you are using a Windows operating system:

```bash
cd %RCU_SHIPHOMELOC%\bin
set DB_HOST=localhost
set DB_PORT=1521
set DB_SID=XE
set CONNECT_STRING=%DB_HOST%:%DB_PORT%:%DB_SID%
```

Example 2-3  Dropping the repository
Run this command if you are using a Linux operating system:

```bash
./rcu -silent -dropRepository -connectString $CONNECT_STRING -dbUser sys -dbRole sysdba -lockSchemas false -schemaPrefix SH -component SOAINFRA -component MDS - component ORASDPM -component BAM
```

Run this command if you are using a Windows operating system:

```bash
rcu.bat -silent -dropRepository -connectString %CONNECT_STRING% -dbUser sys -dbRole sysdba -lockSchemas false -schemaPrefix SH -component SOAINFRA -component MDS - component ORASDPM -component BAM
```

Example 2-4  Recreating the repository
Run this command if you are using a Linux operating system:

```bash
./rcu -silent -createRepository -connectString $CONNECT_STRING -dbUser sys -dbRole sysdba -lockSchemas false -schemaPrefix SH -component SOAINFRA -component MDS - component ORASDPM -component BAM
```

Run this command if you are using a Windows operating system:

```bash
rcu.bat -silent -createRepository -connectString %CONNECT_STRING% -dbUser sys - dbRole sysdba -lockSchemas false -schemaPrefix SH -component SOAINFRA -component MDS - component ORASDPM -component BAM
```

2.3.3 How to Set Up the Personal Environment for Standalone WebLogic Server
Following the steps in this section will give you a portable working environment without needing access to the full environment until you are ready to deploy and unit test.

While the JDeveloper-based environment with Integrated WebLogic Server is useful in creating and validating customizations to the Oracle ADF artifacts, it cannot be used to validate SOA customizations. Anything that relies upon SOA infrastructure for
development (such as BPM and ESS) will need the standalone environment in the following situations:

- Rapid testing of development before publishing to the full development environment.
- Remote access using either dial-up or VPN proves either to be too slow or unstable to connect to the full environment for successful deployment will benefit from the standalone environment installed locally on the developer's machine (64bit required).

To create this environment, you run Python scripts that are part of the JDeveloper-based environment and the repository of installer files that are used to create the shared environment. You first will have to create the JDeveloper-based environment, create or update the `fusion_apps_wls.properties` file, and then execute the scripts that are packaged with the `fa_dev_bundle.zip` extension bundle to create the standalone environment. One of the inputs to the Python script is the location of the repository that contains the installer files. You can use the Oracle Fusion Domain wizard from the JDeveloper-based environment to update the `fusion_apps_wls.properties` file such that it can be used in the standalone environment. So, the same properties file can be used to create both the JDeveloper-based environment and the standalone environment.

When the Python scripts are executed, they automatically do the following:

- Create a lightweight `MW_HOME` directory that is a subset of the Middleware home that is available in the shared environment.
- Create a Standalone WebLogic Server domain with an AdminServer and a ManagedServer.
- Use the `domainType` defined in the `fusion_apps_wls.properties` file to apply appropriate WebLogic Server templates and set up system properties for Oracle Fusion applications.
- Configure the domain with the data sources and the Identity Store that are available in the shared environment.
- Configure the domain to either point to the LDAP-based Policy Store in the shared environment or a local XML-based Policy Store.

Typically in this environment, you have to deploy the exploded EAR directory of the application from the Middleware home of the shared environment using the WebLogic Server Console. Consequently, the `adf-config.xml` descriptor contains an MDS metadata store that points to the database in the shared environment and the customizations are picked up from the MDS repository. If you have created customizations on the filesystem using the JDeveloper-based environment, you should import those customizations to the MDS schema in the database that is running as part of the shared environment to test and validate them. When you import the customizations to the repository and database in the shared environment, it will affect all the developers who are using the shared environment. You will be able to test and validate the customizations by exercising all the applications that have a touch-point with the customized application, to ensure that things outside the application are working as expected.

Because Standalone WebLogic Server for SOA points to a separate SOAINFRA MDS schema, the customizations need to be exported and imported into the shared environment when they are successfully tested by developers.
See "Managing the Metadata Repository" in the *Administering Oracle Fusion Middleware*.

Even though the Standalone WebLogic Server domain that is created as part of this environment is used to deploy the application from the same APPL_TOP and is configured to point to the same data sources, the Identity Store, and the Policy Store, as the domains that are part of the shared environment, you have the flexibility in setting up the domain that is part of the standalone environment in a way that it can work on a laptop or desktop without requiring excess resources. The domains that are created in the shared environment by the provisioning processes have one AdminServer and three ManagedServers. But, the domain in the standalone environment has just one AdminServer and one ManagedServer. You can decide whether to target SOA or ESS or various technologies at the ManagedServer based on the project.

**2.3.3.1 Create a Domain for Standalone WebLogic Server**

Installer files are used to create and run Standalone WebLogic Server domains. You may need to obtain the files from an administrator.

---

**Note:**

- The installer repository on Windows *must* be a local or a mapped drive.
- Windows and Linux operating systems *must* be 64-bit.
- You are using the 64-bit version of the JDK.

---

This install also allows Oracle SOA Suite developers to create their domains without extra installs or steps.

**2.3.3.1.1 How to Create a Special SOAINFRA Schema**

If you are creating a SOA customization, a special SOAINFRA schema that is in the database in the shared environment may need to be created so your work does not interfere with the normal database.

Because the existing composites reference Web Service Description Language (WSDL) and schemas in MDS, when new SOAINFRA and MDS_SOA schemas are created for the standalone environment, all the WSDLs and schemas needed by the composites to be customized need to be exported from the shared MDS_SOA and imported into the new standalone MDS_SOA schema.

See "Managing the Metadata Repository" in the *Administering Oracle Fusion Middleware*.

**2.3.3.1.2 How to Set Up the Environment for Standalone WebLogic Server**

Follow these steps to create a Standalone WebLogic Server environment. These steps assume that you already have downloaded and installed JDeveloper and the Fusion Apps Development Environment extension bundle.

1. If you have not already done so, download and install the 64-bit JDK, preferably not to a directory location containing spaces, such as \Program Files.

   When installing JDeveloper, you will select the 64-bit JDK location you just installed.
If a 32-bit JDK already was installed and used, you must delete the old %MW_HOME% installation and the system directory in %JDEV_USER_HOME% before reinstalling JDeveloper and the Oracle Fusion Applications extensions updates.

If you are using Windows XP and encounter issues running Integrated Weblogic Server, you will need to change to the 64-bit version of Windows 7.

2. You will need installer files from the provisioned environment. The site administrator should make the installer files available. When the system administrator downloaded the Oracle Fusion Applications DVDs and unzipped them, the installer files were placed in the installers directory that now contains numerous sub-directories. A directory listing looks similar to Figure 2-42.

![Figure 2-42  Installer Directory of a Provisioned Environment](image)

If you are not able to access a provisioned environment on a server, you will need to copy these directories (defined in the FADevInstallMwHome.py script file) and their contents from the installation disk to the installerLocation described in Table 2-3. (If you do not have the disk, you will need to download the entire 60GB Oracle Fusion Applications package from eDelivery.)

- atgpf
- biappsshiphome
- bishiphome (if included on the release)
- odi
- soa
- wc
- weblogic
- jdk

This subset of the entire installation package is approximately 20GB in size, with biappsshiphome using approximately 10GB.
Caution:
The installers directory is platform-specific. So if your production environment is Linux and you want to install Standalone WebLogic Server on a Windows machine, you will need to get the subset of installers from a Windows Oracle Fusion Applications download.

3. Update the properties file that was created for Integrated WebLogic Server so that it can be used to create Standalone WebLogic Server:

- In the Integrated WebLogic Server environment you already created, start JDeveloper, select the Oracle Fusion Applications Developer role, and launch the Oracle Fusion Domain wizard, as described in How to Use the Oracle Fusion Domain Wizard.

- Select the Standalone Server option on the wizard’s Usage dialog. Selecting this option creates or updates the fusion_apps_wls.properties and cwallet.sso files.

- On the Domain dialog, set Installer Location to the directory that the administrator has provided. See Step 2.

  Set Domain Location appropriately, such as /path_to_domain/FAStandaloneDomain. Make sure that the directory name you enter does not exist.

4. Create the Standalone WebLogic Server environment:

- Set these environment variables:

  csh commands:

  ```
  setenv MW_HOME /path_to/FAStandalone_MW_HOME
  setenv JDEV_MW_HOME /path/to/JDeveloper/install_directory
  setenv ANT_HOME $JDEV_MW_HOME/jdeveloper/ant
  setenv JAVA_HOME /path/to/JDK/installation/directory
  ```

  bash commands:

  ```
  export MW_HOME=/path_to/FAStandalone_MW_HOME.
  export JDEV_MW_HOME=/path/to/JDeveloper/install_directory
  export ANT_HOME=$JDEV_MW_HOME/jdeveloper/ant
  export JAVA_HOME=/path/to/installed/JDK
  ```

  Windows command prompt commands:

  ```
  set MW_HOME=%path_to\FAStandalone_MW_HOME
  set JDEV_MW_HOME=%path\to\JDeveloper\install_directory
  set ANT_HOME=%JDEV_MW_HOME%\jdeveloper\ant
  set JAVA_HOME=C:\JDK\install\directory
  ```

- `mkdir /path_to/FAStandaloneWork`

- `[for *nix only] chmod +x $JDEV_MW_HOME/jdeveloper/fadev/bin/* .py`

- `[Windows]`

  ```
  %JDEV_MW_HOME%\jdeveloper\fadev\bin\FADevInstallMwHome.py
  -m %MW_HOME%
  -i \path\to\installer_files
  ```
• Create a lightweight \texttt{MW\textunderscore HOME} directory by running the \texttt{FADevInstallMwHome.py} script. This script is installed when you install the Fusion Apps Development Environment extension bundle, described in Step 6 of \textit{Setting Up the JDeveloper-based Development Environment}. Note that the options have been placed on separate lines for clarity. When you run the script, all must be on the same line.

Run this command if you are using a Linux operating system:

```bash
$JDEV\_MW\_HOME/jdeveloper/fadev/bin/FADevInstallMwHome.py
-m $MW\_HOME
-i /path/to/installer\_files
-w /path/to/stagingdirectory
-v
```

Run this command if you are using a Windows operating system:

```bash
%JDEV\_MW\_HOME%\jdeveloper\fadev\bin\FADevInstallMwHome.py
-m %MW\_HOME%
-i C:\path\to\installer\_files
-w C:\path\to\stagingdirectory
-v
```

• \texttt{-m <mw\_home>}: Use an \texttt{MW\_HOME} directory other than the default, for an initial install or after it has already been created.

• \texttt{-i}: The location of the installer files. This setting is required only for a Standalone WebLogic Server domain and overrides the installerLocation setting in the properties file.

• \texttt{-w}: Set the working/staging directory for log and other temporary files.

• \texttt{-r}: Reinstall the \texttt{MW\_HOME} directory. Note that this will remove all items in the existing \texttt{MW\_HOME} directory.

• \texttt{-v}: Turn on verbose mode.

5. Patch the \texttt{MW\_HOME} directory.

For the standalone domain creation to succeed, you must patch these directories in the standalone \texttt{MW\_HOME} directory using the patches from the installer repository before executing the script to create the standalone domain. Otherwise, the standalone domain creation will not be complete and trying to deploy Oracle Fusion applications to the standalone domain will result in issues.

• atgpf

• biappsshiphome

• bishiphome (if included on the release)

• odi

• soa

• webcenter

• oracle_common
• Smart Update for Oracle Weblogic Server

Follow these steps to patch the directories in the standalone MW_HOME directory using all the opatches that are in the repository. The example uses the atgpf directory. Except for the Smart Update for Oracle Weblogic Server, replace atgpf in the opatch command with the names of the other directories, such as odi and soa.

Linux system

% setenv ORACLE_HOME $MW_HOME/atgpf
% setenv ATGPF_ORACLE_HOME $ORACLE_HOME
% setenv JHOME $MW_HOME/jdk6 [Note: Must be a 64-bit JDK.]
% setenv INV_LOC $ORACLE_HOME/oraInst.loc
% setenv PATH $ORACLE_HOME/OPatch:$PATH

% opatch napply <installer_repository_location>/installers/atgpf/patch -jdk $JHOME -invPtrLoc $INV_LOC

Repeat, substituting the names of the other directories in place of atgpf.

For the Smart Update, first change to the bsu directory:

% cd installation_directory/utils/bsu

Then use a command similar to the following, which installs the patch IRZ2 from the patch download directory that has been established for the current system:

% bsu -prod_dir=Oracle/Middleware/wlserver_10.3 -patchlist=IRZ2 -verbose -install

When executed, the preceding command displays the following output showing that the patch was successfully applied:

Checking for conflicts.
No conflict(s) detected

Starting installation of Patch ID: IRZ2
Installing /Oracle/Middleware/download-dir/IRZ2.jar
Result: Success

Windows system

c:\> set ORACLE_HOME=%MW_HOME%\atgpf
c:\> set ATGPF_ORACLE_HOME=%ORACLE_HOME%
c:\> set JHOME=%MW_HOME%\jdk6 [Note: Must be a 64-bit JDK.]
c:\> set PATH=%ORACLE_HOME%\OPatch;%PATH%

opatch napply <installer_repository_location>\installers\atgpf\patch -jdk %JHOME%

where -jdk is the location of the JDK under Oracle Fusion Middleware home.

[Note: For Windows, do not specify the invPtrLoc command-line argument.]

Repeat, substituting the names of the other directories in place of atgpf.

For the Smart Update, first change to the bsu directory:

cd c:\installation_directory\utils\bsu

Then use a command similar to the following, which installs the patch IRZ2 from the patch download directory that has been established for the current system:

bsu -prod_dir=c:\Oracle\Middleware\wlserver_10.3 -patchlist=IRZ2 -verbose -install
6. Create, extend and configure the Standalone WebLogic Server domain by running the FADevCreateDomain.py script. Note that the options have been placed on separate lines for clarity. When you run the script, all must be on the same line.

Run this command if you are using a Linux operating system:

```
$JDEV_MW_HOME/jdeveloper/fadev/bin/FADevCreateDomain.py
-r $MW_HOME
-p $JDEV_MW_HOME/jdeveloper/system11.1.1.7.xx.yy.zz/o.jdevimpl.rescat2/
fusion_apps_wls.properties
-i /path/to/installer_files
-w /path_to/FAStandaloneWork -v
```

Run this command if you are using a Windows operating system:

```
%JDEV_MW_HOME%\jdeveloper\fadev\bin\FADevCreateDomain.py
-r %MW_HOME%
-p %JDEV_MW_HOME%\jdeveloper\system11.1.1.7.xx.yy.zz\o.jdevimpl.rescat2\fusion_apps_wls.properties
-i \path\to\installer_files
-w \path_to\FAStandaloneWork
-v
```

**Example 2-5  FADevInstallMwHome.py Options**

Valid options are:
- **-m** : MW_HOME (standalone - will be created if it does not exist)
- **-i** : Installer location (the provisioning repository)
- **-w** : Working/staging directory. Used for response files, unzip installers
  Defaults to the current directory
- **-r** : reinstall MW_HOME
- **-v** : verbose

**Example 2-6  FADevCreateDomain.py Options**

- **-p** : property file
- **-m** : MW_HOME (standalone - will be created if does not exist)
- **-i** : installer location (Provisioning repository)
  overrides installerLocation in the properties file
- **-w** : working/staging directory for log and other temp files
- **-v** : verbose

**Example 2-7  FADevCreateDomain.py options**

If you execute FADevCreateDomain.py -help, the help shown in Example 2-6 will be displayed.

- **-p** <properties file>: Use a different fusion_apps_wls.properties file to configure the domain.
- **-m** <mw_home>: Use an MW_HOME directory other than the default, for an initial install or after it has already been created.
- **-i**: The location of the installer files. This setting is required only for a Standalone WebLogic Server domain and overrides the installerLocation setting in the properties file.
- **-w**: Set the working/staging directory for log and other temporary files.
- **-v**: Turn on verbose mode.
2.3.3.1.3 How to Fix Domain Creation Errors

These three causes of a domain creation error are easily corrected:

- The domain creation may fail in FADevCreateDomain.py related to the properties file such as:

  Creating domain for Fusion Applications Development ...
  ... checkWorkingDir
  ... checkPropFile
  Traceback (most recent call last):
  File "C:\Oracle\Middleware\jdeveloper\fadev\bin\FADevCreateDomain.py", line 546, in <module>
  checkPropFile()
  File "C:\Oracle\Middleware\jdeveloper\fadev\bin\FADevCreateDomain.py", line 146, in checkPropFile
  defaultPropFile= os.path.join(os.getenv('HOME'),'fusion_apps_wls.properties')
  File "C:\Python27\Lib\ntpath.py", line 96, in join
  assert len(path) > 0
  TypeError: object of type 'NoneType' has no len()

  For an Integrated WebLogic Server domain, this is caused by a Python installation issue. The suggested fix is to uninstall and re-install Python.
  For a Standalone WebLogic Server domain, the fix is to set the HOME environment variable. The recommended setting is to the user's home directory.

- The domain creation fails with:

  File "C:\Oracle\Middleware\jdeveloper\fadev\bin\FADevFusionAppsDomain.py", line 1754, in targetSharedLibraries
  KeyError: oracle.appstrace.model

  There is a synchronization issue between the domain creation scripts and templates used. This can be fixed by adding the entries tagged with "WORKAROUND" in the FADevFusionAppsDomain.py:

  'oracle.appltest.diagfwk.executor':14,   # ess-soa-adf
  'oracle.appstrace.model':2,              # WORKAROUND
  'oracle.appstrace.webapp':2,             # WORKAROUND
  'oracle.bi.adf.model.slib':15,           # ess-soa-adf-admin

- The domain creation can fail with:

  com.oracle.cie.domain.script.jython.WLSTException:
  com.oracle.cie.domain.script.jython.WLSTException:
  Error: unable to parse "template-info.xml" from template jar
  "c:\standalone\oracle_common\common\templates\applications\oracle.clickhistory_template_11.1.1.jar"

  Check whether the oracle.clickhistory_template_11.1.1.jar file exists. If it does not exist, copy it from JDEV_HOME to the standalone home:

  C:\Oracle>copy \oracle\Middleware\oracle_common\common\templates\applications\oracle.clickhistory_template_11.1.1.jar \standalone\oracle_common\common\templates\applications

2.3.3.1.4 How to Test the Server

To test the server:
1. Start the server using a command line command similar to:

[Windows]
C:\standalone\fusion_domain\bin\startWebLogic.cmd

[*nix]
/standalone/fusion_domain/bin/startWebLogic.sh

2. Once started, it can be accessed from a web browser, using a URL similar to:

http://1.23.45.678:7011/console

2.3.3.1.5 How to Manage the Standalone WebLogic Server Lifecycle

There will be times when you want to change the properties in fusion_apps_wls.properties, or point to a different Identity Store, or you may want to delete the domain and start from scratch. To do these, you will have to stop the running server, remove the domain directory, edit the properties file using the wizard, and recreate the domain. Follow these steps to accomplish the tasks. Remember to change any example directory names to the names you have used.

1. Stop the server

When you stop the server, use the same shell that was used to create the domain and execute these commands:

From Linux

<path_to_stopManagedWeblogic.sh>/stopManagedWeblogic.sh

If the script does not succeed, you will need to kill the process:

ps
kill -9 <pid_of_startWebLogic.sh> <pid_of_java>

From Windows

<path_to_stopManagedWeblogic.cmd>\stopManagedWeblogic.cmd

If you had started the ManagedServer, you should kill it, too.

2. Remove the domain

You may want to start over by removing the domain. Execute the following commands in a shell window:

rm -rf /path/to/FAStandaloneDomain
rm -rf /path/to/FAStandaloneWork/*

Execute these commands from a command prompt if you are using a Windows operating system:

rmdir /S /Q \path\to\FAStandaloneDomain
rmdir /S /Q \path\to\FAStandaloneWork/*

3. Edit the fusion_apps_wls.properties file

There may be times when you have to use a different Identity Store or modify some properties. In such an event, restart JDeveloper and follow these steps:
• Manually launch the Oracle Fusion Domain wizard. See How to Use the Oracle Fusion Domain Wizard.

• Right-click the Integrated Servers node and select the Configure Fusion Domain... option.

• Select the Standalone Server option from the first wizard dialog.

• Continue through the wizard, changing the property values as necessary.

4. Recreate the domain

To do so, execute these commands. Note that the options have been placed on separate lines for clarity. When you run the FADevCreateDomain.py script, all must be on the same line.

Run these commands if you are using a Linux operating system:

```bash
rm -rf /path/to/FAStandaloneDomain
rm -rf /path/to/FAStandaloneWork/*
$JDEV_MW_HOME/jdeveloper/fadev/bin/FADevCreateDomain.py
    -m $MW_HOME
    -p $JDEV_MW_HOME/jdeveloper/system11.1.1.7.xx.xx.xx/o.jdevimpl.rescat2/fusion_apps_wls.properties
    -i /path/to/Repository/installers
    -w /path/to/FAStandaloneWork -v
```

Run these commands if you are using a Windows operating system:

```bash
rmdir /S /Q \path\to\FAStandaloneDomain
rmdir /S /Q \path\to\FAStandaloneWork/*
%JDEV_MW_HOME%\jdeveloper\fadev\bin\FADevCreateDomain.py
    -m %MW_HOME%
    -p %JDEV_MW_HOME%\jdeveloper\system11.1.1.7.xx.xx.xx\o.jdevimpl.rescat2\fusion_apps_wls.properties
    -i \path\to\Repository\installers
    -w \path\to\FAStandaloneWork
    -v
```

2.4 Use Deployment Profiles Settings

When creating an Oracle ADF library deployment profile, you can include connection information. When a project attaches that Oracle ADF library, the connection information is merged with its own connection information. This provides runtime consistency. The Oracle ADF library, by including the connection information, can ensure that all of the resources that it needs (the connections) are properly propagated to the consumers.

When creating an Oracle ADF library deployment profile, the default is to include all connection details for every connection in the connections.xml, which is a workspace level file. Subsequently, when the Oracle ADF library is attached to a project, all of the connections are merged with the connections.xml for that project's workspace. This causes a proliferation of the connections across Oracle Fusion Applications. While the propagation of the connections is desirable, it is propagating much more than is really needed.

**Example of Connections Propagation**

A Financials project creates an Oracle ADF library with the defaults. All of the connection information for that Financials workspace is included in the Oracle ADF
library. HCM picks up that Oracle ADF library. HCM’s workspace now contains all connections that HCM needs, and all of the connections from the Financials workspace. If the defaults are retained, all of HCM’s projects contain connection information from Financials plus HCM. If CRM picks up any of those HCM Oracle ADF libraries, it merges the connection information into the CRM workspace; which now contains all of Financials plus HCM plus CRM.

2.4.1 How to Use Service Deployments

A project that contains an Oracle ADF Business Components-based service can have two purposes. The Oracle ADF Business Components code can be invoked as a service or it can be used as a regular Oracle ADF Business Components object. Oracle ADF provides two different deployment profiles to handle each of these cases.

For the service scenario, the BC Service Profile creates two JAR files. One is the **Common** one that contains information that is needed by the service invoker (Web Service Description Language (WSDL), XML schema definition (XSD), Service Interface). The **MiddleTier** one is an Enterprise JavaBeans (EJB) JAR file that contains the actual implementation.

For use as an Oracle ADF Business Components object, consumers must get an Oracle ADF library. That is the only way the Oracle ADF Business Components objects are exposed to consumers in the Oracle ADF Business Components design time wizards. Oracle ADF library also has no option for filtering, so it includes all the artifacts from the project including the WSDL, XSD, and Service Interface. Additionally, the Oracle ADF library includes the connection information for invoking the service. Because of this, developers inherit extra connection information if they want to use a service-enabled application module, not as a service, but as an application module.

**Common** must be an Oracle ADF library because consumers of this need a connection entry to be injected into the consumers’ `connections.xml` file. This does not happen with ordinary JAR files.

2.4.2 How to Update the Standard

All Oracle ADF library deployment profiles should be updated to selectively include connections that are important to that one project. Common scenarios include:

- **Data Model Project**
  - ApplicationDB database connection
  - ApplicationsRepository, if you use Attachments
  - Service connections for any ServiceFactory invocations
  - Essbase
- **User interface project**
  - Portlet producers
  - Web Service Data Control connections

In the **Edit ADF Library JAR Deployment Profile Properties** dialog, choose to include **Connection Name Only**, as shown in **Figure 2-43**
2.5 Configure the Oracle Enterprise Scheduler (ESS)

If you have elected to use Standalone WebLogic Server for Oracle Fusion Applications ESS development, you will need to perform the tasks in this section.

For information about using the Oracle Enterprise Scheduler, see the Developing Applications for Oracle Enterprise Scheduler.

**Note:**

The ESS and Fusion schema *must* be located in the same database and *must* be linked to each other.

Provisioning should set up all the required synonyms and grants between the schema. The FUSION schema has views, such as ESS_REQUEST_HISTORY, that are linked to the ESS schema. To validate that some linking is in place, check to see if the view works. (Although this is not a complete check of all links, it will fail if no linking has been established.)

2.5.1 How to Provision the Runtime Environment

*How to Set Up the Personal Environment for Standalone WebLogic Server* shows how to configure the fusion_apps_wls.properties file and run the FADevConfigDomain.py script to stage and deploy the necessary infrastructure. For Oracle Enterprise Scheduler, you must ensure that you have configured the `domainType` property in the `fusion_apps_wls.properties` file to `standalone`, `adminall` or `adminessadf`. Example 2-8 shows correctly configured Oracle Enterprise Scheduler database and schema information, and ESS-related settings.

After provisioning the runtime, you should create the supporting database schema before starting the managed servers which is covered in *How to Create Supporting Database Schema.*
Example 2-8  Sample Showing Correctly-Configured Oracle ESS Database and Schema Information, and ESS-related Settings

[domain]
domainType=adminessadf
domainName=fusion_domain
listenPort=7011
soaPort=7012
wlName=weblogic
wlPassword=password
...
[wlsconfig]
fusionDbHost=host.example.com
fusionDbPort=1522
fusionDbSid=fusiondbsid
...
# leave oraessDbHost, oraessDbPort, oraessDbSid blank if using fusion database
oraessDbHost=
oraessDbPort=
oraessDbSid=
oraessDbUser=oraess_dbuser
oraessDbPassword=password
#
essMdsDbHost=
essMdsDbPort=
essMdsDbSid=
essMdsDbUser=fusion_mds_ess
essMdsDbPassword=password

2.5.2 How to Create Supporting Database Schema

There are two approaches to creating the database schema: using the Oracle Fusion Applications Repository Creation Utility or creating the schema using SQL scripts. The latter allows greater flexibility in the naming of the schema and user, but requires use of SQL*Plus.

For pre-requisite steps and configuration of the Oracle Enterprise Scheduler schema using the Oracle Fusion Applications Repository Creation Utility, see How to Use Alternate Database Schemas. Example 2-9 shows how to configure the Oracle Enterprise Scheduler schema using the Oracle Fusion Applications Repository Creation Utility schema.

Alternatively, creating the schema by running scripts in SQL*Plus can be performed as shown in Example 2-10

---

**Note:**

You should determine the appropriate TEMP tablespace by reviewing the entries in dba_tablespaces before attempting to run these scripts.

---

Example 2-9  Configuring Oracle Enterprise Scheduler Schema Using the Oracle Fusion Applications Repository Creation Utility Schema

Run these commands if you are using a Linux operating system:

```bash
cd $RCU_SHIPHOMELOC/bin
DB_HOST=localhost
DB_PORT=1521
DB_SID=XE
```
CONNECT_STRING=$DB_HOST:$DB_PORT:$DB_SID

./rcu -silent -createRepository -connectString $CONNECT_STRING -dbUser sys -dbRole sysdba -lockSchemas false -schemaPrefix D8B2 -component ESS

Run these commands if you are using a Windows operating system:

cd %RCU_SHIPHOMELOC%\bin
set DB_HOST=localhost
set DB_PORT=1521
set DB_SID=XE
set CONNECT_STRING=%DB_HOST%:%DB_PORT%:%DB_SID%

rcu.bat -silent -createRepository -connectString %CONNECT_STRING% -dbUser sys -dbRole sysdba -lockSchemas false -schemaPrefix D8B2 -component ESS

Example 2-10 Using SQL*Plus Scripts to Create Schema

cd $MW_HOME/rcu/rcu/integration/ess/sql
sqlplus sys/manager as sysdba;
@createuser_ess_oracle.sql oraess_d8b2 oraess_d8b2 SYSTEM TEMP;
connect oraess_d8b2/oraess_d8b2
@createschema_ess_oracle.sql  oraess_d8b2

2.5.2.1 Post-Installation Checks

Perform these steps to make sure the ESS installation was successful.

2.5.2.1.1 Verifying the Temp Directory Location and Write Permissions

The ESSAPP (also known as the ESS Base application) is the deployed infrastructure that supports the deployment of the product team Oracle Enterprise Scheduler applications, known as hosted applications. By default, this application writes all request log and output to a directory path known as the \userFileDir\, which is configured in the \ess.xml\ file.

The ESS application defaults to file persistence mode and writes all the request log and output to a directory path known as the RequestFileDirectory, which is configured in the ESSAPP connections.xml file. By default, the temp directory will point to /tmp/ess/requestFileDirectory. Ensure that the directory exists and, if not, create it as the user who will start the ESS managed server.

2.5.2.1.2 Verifying ESS Artifacts Deployment Targets

Make sure ESS datasources and shared libraries are targeted to clusters and managed servers. Stop and Start WebLogic Servers as needed.

2.5.2.1.3 Checking ESS Health

Run ESS Health checks by accessing these links:

- Checking health of an ESS Node: http://<hostName>:<port>/EssHealthCheck/checkHealth.jsp
- Checking health of an ESS Cluster: http://<hostName>:<port>/EssHealthCheck/diagnoseHealth.jsp
2.6 Test Your Installation

To test your JDeveloper and Oracle ADF installation, perform the following steps to create both a data model project and a user interface project, create an ApplicationDB database connection, and create and run a simple page.

1. In JDeveloper, select the Application Navigator menu, then select New Application to open the Create Application wizard. See Figure 2-44.

**Figure 2-44  Naming Your Application**

![Create Fusion Web Application (ADF) - Step 1 of 5](image)

**Tip:**
The name of the wizard changes according to the application template that is selected.

2. Complete the following:
   - **Application Name:** Enter `Setuptest`
   - **Application Package Prefix:** Enter `oracle.apps.test`
   - **Application Template:** Choose `Fusion Web Application (ADF)`

3. Click Next to access the Name Your ADF-Model Project dialog. See Figure 2-45.

**Note:**
The system automatically will create data model and user interface projects for you. The default names for these projects that JDeveloper provides are `Model` and `ViewController`.

You can enter a new name for your data model project or you can keep the default name `Model`. 
Figure 2-45  Naming Your Oracle ADF Model Project

The Project Technologies are automatically selected based on the application template that was chosen. You can select additional technologies if required.

4. Click **Next** to access the Configure Java Settings for the ADF-Model dialog. This dialog displays the Java settings for your data model project. See Figure 2-46.

Figure 2-46  Configuring Java Settings for the ADF Model
5. Click Next to access the Name Your ADF ViewController Project dialog.

You can enter a new name for your user interface project or you can keep the default name ViewController. See Figure 2-47.

**Figure 2-47 Naming Your Oracle ADF User Interface Project**

![Create Fusion Web Application (ADF) - Step 4 of 5](Image)

**Note:**

The Project Technologies are automatically selected based on the application template that was chosen. You can select additional technologies if required.

6. Click Next to access the Configure Java Settings for the ViewController... dialog.

This dialog displays the Java settings for your user interface project. See Figure 2-48.
Click **Finish** to create your new application.

7. Add the **Applications Core, Applications Core (Attachments Model), Topology Manager, Functional Setup Model, BC4J Service Runtime**, and **Java EE 1.5** libraries to the data model project. See **Adding Necessary Libraries to Your Data Model Project**.

8. Add the **Applications Core (ViewController)** tag library to the user interface project. See **Adding the Applications Core Tag Library to Your User Interface Project**.

9. Add this option to the Model project's Run options:

   ```
   -Doracle.jdbc.createDescriptorUseCurrentSchemaForSchemaName=true
   ```

   **Note:** Setting this JVM parameter helps avoid an error caused by the username for the current schema being set to “fusion” instead of “fusion_runtime” Setting the username to “fusion” results in incorrect data type associations. This parameter sets the username back to “fusion_runtime.”

   To add the option:

   - Right-click the Model project and select **Project Properties**.
   - Select **Run/Debug/Profile**.
   - In the Run Configurations list, select **Default** and click **Edit**.
   - Select **Launch Settings**.
     As shown in **Figure 2-49**, enter the option string in the Java Options field.
• Click OK.
• Click OK.

10. The ApplicationDB database connection is created automatically when the Applications Core library is attached to the model project. However, you will need to adjust the values that are defined in the connection to reflect the database you want to use. See Creating or Updating a Database Connection. For this example, enter these connection details:

   **Connection Type:** Choose Oracle (JDBC)

   **Username / Password:** Enter the username and password for your team’s Fusion_Runtime database schema.

   **Deploy Password:** Select this option.

   **Host Name:** Enter the host name, such as my.host.com

   **JDBC Port:** Enter the port number for your database.

   **SID:** Enter the database name, such as mydb.

11. Choose Application Navigator > Model. Right-click and choose New from the menu to open the New Gallery.

12. Choose the Business Tier > ADF Business Components category. Select the Business Components from Tables item to launch the Create Business Components from Tables wizard. See Figure 2-50.
13. Complete the following to create your entity object:

a. **Filter Types**: Select only *Tables* to narrow your search for schema objects.

b. **Filter Name**: Enter a filter, such as `%EMP%` to narrow your search to tables.

c. **Query**: Click this button to perform your search.

---

**Note:**
The results of your search displays in the *Available* column.

---

d. Choose the required object, such as *FND_DEMO_EMP* and click > to shuttle it over to the *Selected* column.

e. Click Next to go to the next step in the wizard.

14. Choose the required entity object located in the *Available* column and click > to shuttle it over to the *Selected* column. See Figure 2-51.
15. Click Finish to create your updatable view object and to close the Business Objects wizard.

16. Ensure that your application module configuration is using JDBC data source.
   
   This is required for your application module to run on the WebLogic Server.

   To update your application module configuration:
   
   **a.** Go to the Application Navigator and select your application module. Right-click and select Configurations from the menu.
   
   **b.** Choose the configuration <AM Name>Local, then choose Edit.
   
   **c.** Change the Connection Type to JDBC DataSource and Datasource Name to java:comp/env/jdbc/ApplicationDBDS. Click OK.

17. Validate your model with the Business Component Tester to make sure that the ApplicationDBDS data source has been configured for the Integrated WebLogic Server environment.

   In the Navigator tree, right-click the application module and select Run, as shown in Figure 2-52.

**Figure 2-51  Create Business Components from Tables — Updatable View Objects**

![Create Business Components from Tables - Step 2 of 6](image)

**Figure 2-52  Running the Application Module**

![Running the Application Module](image)
If your installation is set up correctly, a dialog similar to that shown in Figure 2-53 displays. If an error message displays, you will need to re-check that the previous steps have been performed correctly.

**Figure 2-53  Application Module in Business Component Browser**

In this example, right-click FndDemoEmpView1 and select *Show* to display data, as shown in Figure 2-54.

**Figure 2-54  Showing Data in the Business Component Browser**

18. Choose *Application Navigator > ViewController*. Right-click and select *New* from the menu to open the New Gallery.

19. Choose the *Web Tier > JSF* category. Select the *JSF Page* item and click *OK* to open the Create JSF Page dialog.

20. Complete the following:
   - **File Name**: Enter *Setup.jsp*
   - Select to create jspx file.
   - Click *OK*.

21. Go to the Data Controls panel and drag the collection onto the open *Setup.jspx* window. See Figure 2-55.
22. Select to create Forms > ADF read-only from the context menu that displays. See Figure 2-56.

23. Remove some of the rows that are displayed in the opened dialog so that your page only lists a few fields. Select the Include Navigation Controls checkbox and click OK. See Figure 2-57.
24. Click the Run button located on the toolbar to run your page.

**Note:**

Make sure the URL uses the full host name. For instance, if the displayed URL is `http://127.0.0.1:7101/AppICoreCRMDemo/faces/Region6UIShellPage`, you should edit it manually so it appears similar to `http://myhost.name.com:7101/AppICoreCRMDemo/faces/Region6UIShellPage`.

When your page is displayed, you can use the buttons that appear at the bottom of your page to view next and previous employees.

### 2.7 Use Best Practices for Setting Up the Development Environment

Implementing these best practices when using JDeveloper will significantly reduce problems.

#### 2.7.1 How to Implement Best Practices for JDeveloper

These recommendations are specific to improving the performance of JDeveloper.

**Increase the Number of Lines in the Log Message Window**

The default of 3000 lines generally is insufficient for Oracle Fusion applications, and important errors and exceptions may be removed too quickly. The solution is to increase the number of lines, such as to 30000. Whenever you create a new view and run JDeveloper for the first time, increase the limit. Open **Tools > Preferences > Environment > Log** and edit the **Maximum Log Lines** setting.
Running JDeveloper in Verbose Mode

You can run JDeveloper in its default non-verbose mode, or in its verbose mode.

- **jdev**: The default non-verbose mode limits the amount of information displayed to the console. This helps you focus on the important information being displayed.

- **jdev -v**: The verbose mode displays all the information to your console. Although this information is not useful for everyday workflow, when something goes wrong, more information can help you debug your problem.

Increase the minimum / maximum heap size for JDeveloper (and other Java parameters)

This is specifically about increasing the heap size for JDeveloper, since JDeveloper itself is a Java executable and runs in its own Java Virtual Machine (JVM). This will not affect Integrated WebLogic Server; for that you set USER_MEM_ARGS, since it's a separate process and therefore a separate JVM.

To change the values for minimum and maximum Java heap, modify the corresponding parameters in `$jdev_install/ide/bin/ide.conf`.

Other parameters can be set in `$jdev_install/jdev/bin/jdev.conf`.

Do not set Xms or Xmx in the `jdev.conf` file because it will just result in duplicating the parameter on the command line because it already is set in the `ide.conf` file. You can add any other parameter than is not already passed on the command line in this file, using the same format as the existing parameters.

Enable the JDeveloper Java heap meter

You can enable the JDeveloper heap monitor (that is, the heap, permgen, and dustbin icon that forces garbage collection on the status bar of the main jdev window). Add this line to the `$jdev_install/jdev/bin/jdev.conf` file.

```
AddVMOption -DMainWindow.MemoryMonitorOn=true
```

The heap monitor shows the current size of the heap; not necessarily the maximum size. The heap is created at the specified minimum size. When additional space is required, and if garbage collection cannot free up enough space, the heap size is increased. If the heap reaches its maximum and there still is not enough space after garbage collection, an OutOfMemoryException is thrown.

2.7.2 How to Refresh the Oracle ADF Library Dependencies Library

The Oracle ADF Library Dependencies library is refreshed by doing the Refresh ADF Library Dependencies.

- There is a new library file per project in the project directory. This file will only exist if the project has unresolved deployment dependencies required by the directly-imported Oracle ADF JAR files in the project.

- The file should be added to the project source-controlled file set.

- The file should be included in all transactions where it was updated during the design time.

- If a runtime exception, such as No Def Found or No Class Def Found occurs, the project menu command to refresh the Oracle ADF Library Dependencies is
necessary to update the file. This could happen because of updated lower-level dependency changes outside of the design time session.

2.7.3 How to Manage OutOfMemory Exceptions (PermGen)

When you use Integrated WebLogic Server, make sure the USER_MEM_ARGS environment variable is set before starting JDeveloper.

USER_MEM_ARGS=-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000

- The csh command is:
  `setenv USER_MEM_ARGS "-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000"`

- The bash command is:
  `export USER_MEM_ARGS="-Xms256m -Xmx1024m -XX:MaxPermSize=512m -XX:CompileThreshold=8000"

Verify that it is set correctly.

```
$ env | grep USER_MEM_ARGS
```

$USER_MEM_ARGS is read by the WebLogic Server startup scripts, and is used to override the default JVM memory settings. If using the default MaxPermSize=256M, you will regularly get OutOfMemoryExceptions due to exhausted permGen. Setting permGen higher doesn’t completely fix the problem, but it does mean you can work longer before deployment fails with a permGen-related OutOfMemoryException.

In the JDeveloper message log window, you will see this line when Integrated WebLogic Server is started. Make sure it reflects the overridden values defined in $USER_MEM_ARGS.

`JAVA Memory arguments: -Xms256M -Xmx1024M -XX:CompileThreshold=8000 -XX:PermSize=64M -XX:MaxPermSize=512M`

Remember that overriding the Java memory arguments is a balancing act, and if you set them too high for your machine resources, either JDeveloper or WebLogic Server may fail to start, may hang, or may fail with a resource-related exception. For example, setting XX:MaxPermSize=1024m may be too high. If you experience problems after increasing the permanent generation size, try unsetting $USER_MEM_ARGS to see if it could be the cause.

Example exceptions

```
java.lang.OutOfMemoryError: PermGen space
at java.lang.ClassLoader.defineClass1(Native Method)
at java.lang.ClassLoader.defineClass(ClassLoader.java:621)
at java.security.SecureClassLoader.defineClass(SecureClassLoader.java:124)
at weblogic.utils.classloaders.GenericClassLoader.defineClass(GenericClassLoader.java:344)
Truncated. see log file for complete stacktrace
```

Sometimes deployment just becomes very slow before it eventually fails.

When you hit OutOfMemoryExceptions, if you then try and close Integrated WebLogic Server, the first attempt may fail because it is in a bad state. If you try a second time, JDeveloper now does a `kill -9`, which should clear it. You should no longer need to kill WebLogic Server by manually issuing the kill command from another terminal session. However, if you ever do need to, try identifying the WebLogic Server process. This command assumes that you are using the default port 7101.
If you have another instance of WebLogic Server running, and the port is already in use, JDeveloper will use another port. Also, you may have changed the port in fusion_apps_wls.properties.

This command lists the Java processes with the full command line, which should help you to identify the WebLogic Server process.

```
$ ps -elf | grep java | grep <userid>
```

### 2.7.4 How to Work with Oracle ADF Libraries at Design Time

Every data model or user interface project should have an Oracle ADF library deployment profile. Service projects are the exception.

Oracle ADF libraries should be added to your project using the Resource Catalog by creating a File connection. From there, you can right-click any of the libraries and select **Add to Project**. Then all Oracle ADF libraries get managed under a Library called **ADF Libraries**. Mixing and matching different methods of adding Oracle ADF libraries can cause them to appear under different Libraries and sometimes under multiple libraries. That makes it hard to manage.

All references to components contained in Oracle ADF libraries are resolved when the workspace is loaded in JDeveloper. If a reference to a component or Java class in an Oracle ADF library cannot be resolved because, for instance, it does not exist or is incompatible with the existing reference, you probably will receive a compilation error.

Closing and restarting JDeveloper with a workspace open does not refresh the references to Oracle ADF libraries. Closing the workspace, and re-opening it does.

If you have a specific project selected in the JDeveloper navigator pane, select View > **Refresh ADF Library Dependencies** for *.jpr* to refresh the references to Oracle ADF libraries.

When you make any changes to the components in a project, where the components are being referenced as an Oracle ADF library by your user interface project, you need to redeploy the Oracle ADF library and refresh the Oracle ADF library dependencies for your user interface project. The same applies to one model project referencing from another model project.

If you are developing or debugging code in a data model project while running the referencing user interface project to test it, it may be easier to add the model project as a build output dependency, so you do not have to go through the cycle of redeploying the Oracle ADF library or refreshing Oracle ADF library references each time you make a change.
Set Up Your JDeveloper Application Workspace and Projects

This chapter describes how to set up your JDeveloper application workspace and projects, add libraries to projects, integrate Oracle Fusion Middleware extensions, create a database connection, implement Oracle Enterprise Crawl and Search (ECSF), and deploy Oracle SOA Suite.

Whenever you create new projects, you must first create an application using the Fusion Web Application (Oracle ADF) template. The system will then automatically create the data model and user interface projects for you. The default names that JDeveloper provides for these projects are Model and ViewController.

After your projects have been created, you must manually add the Applications Core library to the data model project and the Applications Core Tag library to the user interface project.

This chapter discusses:
- Using Technology Scopes
- Provisioning the Application Workspace
- Adding Necessary Libraries to Your Data Model Project
- Adding the Applications Core Tag Library to Your User Interface Project
- Integrating () Setup UIs
- Creating or Updating a Database Connection
- Adding the Search Navigation Tab to the Overview Editor for (ECSF)
- Overriding the Default Resource Bundle
- Implementing Oracle Enterprise Scheduler Service Workspace and Deployment
- Implementing Oracle Application Development Framework UI Workspace and Projects

3.1 Using Technology Scopes

Technology scopes are attributes on the project that can be used to identify the different technologies used for that particular project. These attributes are used only within JDeveloper to assist you as you work. With technology scopes, the choices presented to you in the New Gallery and in the menus and palettes are filtered so that you see only those items that are most relevant to you as you work. Technology scopes have no effect on the data in the project itself.

The JDeveloper online Help has more information.
3.2 Provisioning the Application Workspace

The application’s Enterprise Archive (EAR) will be available for developers to pick up when creating a custom application workspace. An EAR is a Java EE archive file that is used in deploying applications on a Java EE application server. Framework applications are deployed using both a generic EAR file, which contains the application and the respective runtime customization, and a targeted EAR file, which contains only the application for deployment to the application server. An administrator that provisions the environment will be responsible for providing developers with the following:

- EAR locations for the various applications.
- jazn-data for the various applications.
- LDAP/credential store that the developer can set up for authentication.

In addition, the Oracle Fusion Applications Customization Application Wizard will create a complete development environment for customizing existing Oracle Fusion applications. See the online Help in the wizard, and “Using Oracle JDeveloper for Customizations” in the Extensibility Guide for Developers.

3.3 Add Necessary Libraries to Your Data Model Project

Use these directions to add the Applications Core, Applications Core (Attachments Model), Topology Manager, Functional Setup Model, BC4J Service Runtime, Java EE 1.5, and Java EE 1.5 API libraries to the data model project. The default name, provided by JDeveloper, for this project is Model.

To add the necessary libraries to a data model project:

1. Choose Application Navigator > Model project. Right-click and choose Project Properties from the menu.

2. Choose the Libraries and Classpath category. Click Add Library to open the Add Library dialog.

3. Select the Applications Core, Applications Core (Attachments Model), Topology Manager, Functional Setup Model, BC4J Service Runtime, Java EE 1.5, and Java EE 1.5 API libraries from the list of available libraries. Click OK to save your selection and close the Add Library dialog.

The libraries are now displayed in the Classpath Entries region of the Libraries and Classpath dialog, as shown here.
4. Click OK to save your changes.

3.4 Add the Applications Core Tag Library to Your User Interface Project

Use these directions to add the Applications Core Tag Library to the user interface project. The default name provided by JDeveloper for this project is ViewController.

To add the Applications Core Tag library to the user interface project:

1. Choose Application Navigator > ViewController project. Right-click and choose Project Properties from the menu.

2. Choose the JSP Tag Libraries category. Go to the Distributed libraries folder and click Add to open the Add Library dialog.

3. Select the Applications Core (ViewController) 11.1.1.0.0 tag library from the list of available libraries. Click OK to save your selection and close the Add Library dialog.

The Applications Core (ViewController) 11.1.1.0.0 is now displayed under the Distributed libraries folder on the JSP Tag Libraries dialog, as shown in Figure 3-2.
4. Click **OK** to save your changes.

5. Choose **Application Navigator > ViewController** project. Right-click and choose **Project Properties** from the menu.

Choose the **Dependencies** category and select the **Model.jpr**.

---

**Note:**

Even if you are only using the user interface project you must still initialize the data model project as they are dependent on each other.

---

6. Click **OK** to save your changes and close the Project Properties dialog.

### 3.5 Integrating Oracle Fusion Middleware Extensions for Applications (Applications Core) Setup UIs

The most common use of Applications Core setup UIs is through Oracle Fusion Functional Setup Manager tasks that invoke the UIs running on the Applications Core Setup Java EE application. Applications Core setup UIs are part of the Applications Core (Setup UI) shared library, which is hosted centrally in the Applications Core Setup Java EE application. Consequently, developers typically will not need to include the shared library in their own Java EE applications.

#### 3.5.1 What You May Need to Know About Setup UIs in Oracle Fusion Functional Setup Manager

Every Oracle Fusion application registers ADF task flows with the Functional Setup Manager, which provides a single, unified user interface that allows implementers and administrators to configure all applications by creating set up data.
For example, a Human Resources application can register setup activities such as "Create Employees" and "Manage Employee Tree Structure." For more information, see the Oracle Fusion Functional Setup Manager User's Guide.

To make these task flows available to developers, implementers or administrators, a developer integrates the desired Applications Core setup UI task flows with Functional Setup Manager. For information about specific task flows, see:

- About Integrating Messages Task Flows into
- About Integrating SetID Task Flows into
- About Integrating Lookups Task Flows into
- About Integrating Document Sequence Task Flows into
- About Integrating Attachments Task Flows into
- Integrating Flexfield Task Flows into
- About Integrating Profiles Task Flows into

The most common use of setup UIs is through Oracle Fusion Functional Setup Manager tasks. This is true even for product-specific tasks that invoke the task flows with parameters that restrict the results to a single object or set of objects.

### 3.5.2 How to Integrate Setup UIs into Functional Setup Manager

To determine your requirements, familiarize yourself with these three scenarios and decide which one best fits your needs. The first two patterns are the typical use cases. The third is for approved exceptions only.

- **Scenario 1** is a generic setup task that invokes a setup task flow running in the Applications Core Setup Java EE application. For example, you want to give your product administrator roles access to the generic Manage Descriptive Flexfields setup task.

- **Scenario 2** is a product team-specific setup task that invokes a setup task flow running in the Applications Core Setup Java EE application and passes in product-specific parameters to restrict the objects to only those relevant to this specific task. For example, you want to give your product administrator roles access to a Manage GL Descriptive Flexfields setup task that launches the Manage Descriptive Flexfields setup UI for descriptive flexfields belonging to the GL module only.

- **Scenario 3** is a product team-specific setup task that invokes a setup task flow running in the product team's own Java EE application. This scenario is for approved exceptions only. For example, you plan to embed the setup UI within another UI in your own product team's Java EE application. For instance, the Manage Item Categories UI in Product Information Management (PIM) embeds the Manage Extensible Flexfields setup UI.

Follow the instructions in Table 3-1 that are relevant to your scenario to integrate Applications Core setup UIs into Functional Setup Manager.
Table 3-1  Instructions for Each Scenario

<table>
<thead>
<tr>
<th>Step</th>
<th>Scenario 1</th>
<th>Scenario 2</th>
<th>Scenario 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Follow Functional Setup Manager guidelines to create product-specific setup tasks in the Application Design Repository. Tailor the behavior of the setup UI by passing allowed values to the task flow parameters. Decide what Applications Core setup UI task flows that you want to incorporate and locate the chapter (see What You May Need to Know About Setup UIs in Oracle Fusion ) that describes each task flow and its parameter values.</td>
<td>X</td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>Product teams should set the value of the Enterprise Application field (in the Application Design Repository) to the appropriate Java EE application for any of their product-specific Functional Setup Manager tasks that use Applications Core setup task flows. Typically, this should be set to the Applications Core Setup Java EE application.</td>
<td>X</td>
<td>X</td>

<tr>
<td>Ensure product team roles inherit the appropriate Applications Core duty role. The duty roles support securing the setup tasks so only authorized users have access.</td>
<td>X</td>
<td>X</td>
<td>X</td>
</tr>
<tr>
<td>If you intend to integrate a product-team specific setup UI and it will run in your product team's own Java EE application, your application will need to include the Applications Core shared library.</td>
<td></td>
<td></td>
<td>X</td>
</tr>
<tr>
<td>For any of the duty roles and their associated privileges that your application inherits, include permissions for those privileges in your application's jazn-data.xml file. Permissions make it possible to grant authorized users access to your setup tasks.</td>
<td></td>
<td></td>
<td>X</td>
</tr>
</tbody>
</table>

3.6 Creating or Updating a Database Connection

A connection to a valid database is necessary to run most, if not all, applications.

When you have added the libraries as described in Adding Necessary Libraries to Your Data Model Project and Adding the Applications Core Tag Library to Your User Interface Project to your project, the connections for the ApplicationDB, ApplicationAuditDB, and AppMasterDB databases will have been created. You just need to update them to have the connection information for your actual environment.

To create or update a database connection:

1. In JDeveloper, choose Application Resources > Connections. Right-click and choose New Connection > Database from the menu.

2. Add or update the following connection details for the ApplicationDB connection name as shown in Figure 3-3.
Figure 3-3 Create Database Connection Dialog

Connection Name: The value for the connection name must be ApplicationDB.

Connection Type: Choose Oracle (JDBC).

Username and Password: Enter the database username and password.

Deploy Password: Select this checkbox.

Host Name: This is the default host name if the database is on the same machine as JDeveloper. If the database is on another machine, type the name (or IP address) of the computer where the database is located.

JDBC Port: This is the default value for the port used to access the database. If you do not know this value, check with your database administrator.

SID: This is the default value for the SID that is used to connect to the database. If you do not know this value, check with your database administrator.

3. Click Test Connection. (Database listener Port). If the database is available and the connection details are correct, the message Success! is displayed. If not, review and correct the information that you entered.

4. Click OK. The connection now appears below the Application Resources Connections folder as shown in Figure 3-4.
3.7 Adding the Search Navigation Tab to the Overview Editor for Oracle Enterprise Crawl and Search Framework (ECSF)

ECSF provides developers a set of tools and a framework to quickly and efficiently integrate Oracle Secure Enterprise Search (SES) into enterprise applications to expose business objects for full text search.

Developers use ECSF to integrate search functionality in Oracle Fusion applications by defining searchable objects and searchable attributes. Defining searchable objects and searchable attributes enables the corresponding view objects and view object attributes for search, and creates the necessary metadata for ECSF. However, before you can define searchable objects and searchable attributes, you must add the Search navigation tab to the overview editor in JDeveloper.

For more information about defining searchable objects, see Creating Searchable Objects.

3.7.1 How to Add the Search Navigation Tab to the Overview Editor

To add the Search navigation tab to the overview editor in JDeveloper, download the JDeveloper extension for ECSF.

To download the JDeveloper extension for ECSF:

1. Launch JDeveloper.

Note:

If you have trouble initializing Java Virtual Machine (JVM), launch JDeveloper by entering jdeveloper.exe -J-Xmx125m at a command prompt.

2. In JDeveloper, choose Check for Updates from the Help menu.
3. In the Check for Updates dialog, click Next.
4. In the Source tab, select the Search Update Centers radio button, then select the Internal Automatic Updates checkbox.
5. Click Next, then select the ECSF Design Time Extension checkbox.
6. Click Next, then click Finish.
7. When prompted to restart JDeveloper, click Yes.
3.7.2 What Happens When You Add the Search Navigation Tab to the Overview Editor

When the Search navigation tab is added, the oracle.ecsf.dt.jar file appears in the oracle_home/jdev/extensions directory and the following files appear in the oracle_home/ecsf/lib directory:

- ecsfSchema.sql
- ecsfSysView.sql
- search_admin_wsclient.jar
- ecsf.jar
- ecsf-dt_bundle.zip
- search_client.jar
- ecsfSeedData.sql

The Search navigation tab appears in the overview editor of JDeveloper, as shown in Figure 29-3.

Use the Search navigation tab to configure the search-related properties.

For more information, see Creating Searchable Objects.

3.8 Overriding the Default Resource Bundle

In an Oracle Fusion application, strings are not hard-coded; they are placed in resource bundles. An application can have multiple resource bundles.

However, you may need to change a specific string in all places where that string appears without having to change it on a per-instance (page/ADF BC object) basis. For instance, you may need to change "worker" to "employee," "activity" to "task," or "expenditure" to "cost." The method to use is the override resource bundle.

In the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide, see:

- Internationalizing and Localizing Pages for information about setting up resource bundles.
- How to Define Custom Validator and Converter Messages for All Instances of a Component for general instructions on overriding a resource bundle.

This bundle is specified in the adf-config.xml file and is created at runtime. For Oracle Fusion applications, there are two important points:

- This file must be named FusionAppsOverrideBundle.xlf
- Although an application can have multiple resource bundles, it can have only one override resource bundle.

3.9 Implementing Oracle Enterprise Scheduler Service Workspace and Deployment

Oracle Enterprise Scheduler Service applications, also known as Oracle Enterprise Scheduler Service hosting applications, are deployed to an Oracle Enterprise...
Scheduler Service-configured runtime or cluster that has been pre-deployed with the base ESSAPP infrastructure Java EE application. Following standards, Oracle Enterprise Scheduler Service workspaces exist one per product family and are responsible for containing these supporting projects:

- Oracle Enterprise Scheduler Service projects for containing Job, Job Set, Incompatibility and Schedule Metadata as well as source files for any Java Job implementation.
- ADF data model projects for containing Parameter view object business components.
- ADF user interface projects for containing Parameter task flows.
- Optional servlet or UI task flow projects for development-time testing.
- SuperEss consolidating the Enterprise JavaBeans deployment descriptors for the entire Oracle Enterprise Scheduler Service hosting application. See How to Create the SuperEss Project in the ADF UI Workspace.

**Note:**
All the projects in an Oracle Enterprise Scheduler Service application, regardless of their content type, should have an ADF Business Components Shared Library deployment profile.

A typical Oracle Enterprise Scheduler Service workspace structure resembles Figure 3-5.

*Figure 3-5   Typical Oracle Enterprise Scheduler Service Workspace Structure in JDeveloper*
3.9.1 How to Create the SuperEss Project

In Oracle Fusion Applications, all Oracle Enterprise Scheduler Service workspaces must contain a SuperEss project that contains the EJB deployment descriptors to register the hosted application with the ESSAPP base application, and to register both the MetadataService and RuntimeService EJBs. This technique avoids having multiple projects with conflicting deployment descriptors in a single deployment archive (EAR).

RuntimeService and MetadataService beans are hosted by the ADF UI application and the Oracle Enterprise Scheduler Service hosting application.

If you are creating a new Oracle Enterprise Scheduler Service workspace or your Oracle Enterprise Scheduler Service workspace does not already have a SuperEss project, create one using these steps:

1. In JDeveloper, create the SuperEss project by creating a new Generic Project named SuperEss.
2. In the project properties, create a new EJB-JAR deployment profile.
3. In the File Groups Properties, click New to create a new file group.
4. Name it and set the directory path of both to src/META-INF.
5. In the source directory, create the src/META-INF directory. Create the ejb-jar.xml and weblogic-ejb.jar.xml files. See "Building a Combined Oracle Enterprise Scheduler Application" in the Developing Applications for Oracle Enterprise Scheduler. Save the files in the src/META-INF directory.

After completing these steps, the SuperEss project will be complete. Follow How to Build the EAR/MAR Profiles to build the EAR/MAR deployment profiles. An EAR (Enterprise Archive) is a Java EE archive file that is used in deploying applications on a Java EE application server. Framework applications are deployed using both a generic EAR file, which contains the application and the respective runtime customization, and a targeted EAR file, which contains only the application for deployment to the application server. A MAR (Metadata Archive) is a compressed archive of selected metadata used to deploy metadata content to the MDS Repository.

3.9.2 How to Build the EAR/MAR Profiles

Oracle Enterprise Scheduler Service-hosted applications are built into EAR files and deployed as Java EE applications. The EAR archive must contain the SuperEss EJB JAR, the MAR archive containing all Oracle Enterprise Scheduler Service metadata, and all the Job and Job-related classfiles using JARs in the APP-INF/lib directory. Follow these steps to create the appropriate deployment profiles.

3.9.2.1 Deploying a Project-level Metadata Archive (MAR)

**Note:**

Oracle Enterprise Scheduler Service is used in the instructions because it is the primary, but not only, use case.

To simplify patching of Oracle Enterprise Scheduler Service metadata artifacts and align with code-level patching, it is essential to have project-level deployment artifacts.
To support this requirement, EARs with multiple MAR files can be deployed. This section describes what must be done to properly build Oracle Enterprise Scheduler Service workspaces to support project-level MARs.

3.9.2.1.1 How to Enable Your Application Workspace for Project-level MAR Deployment

In contrast to standard MAR deployment, in which a single .mar file is created as a metadata aggregate from contributors defined from one or more projects in the application workspace, this approach focuses on the creation of a JAR-based deployment profile in each project where the target file is named with a .mar extension. The resultant .mar files are then deployed into the application workspace’s jlib folder, which is added to the top-level directory of the EAR by the EAR deployment profile.

Follow these steps to implement the project-level MAR deployment.

1. Prepare the Application Workspace EAR deployment profile.
   a. Open your Oracle Enterprise Scheduler Service Workspace in JDeveloper.
   b. Open the Application Properties, select the Deployment panel, choose your application’s EAR deployment profile and click Edit.
      These steps will need to be repeated if you have multiple EAR deployments for development or test purposes.
   c. Select File Groups and click New to create a new file group. Leave the type as Packaging and name this group MAR Group.
   d. Leave the remaining values at their defaults and click OK.
   e. Select the Contributors heading beneath the new MAR Group file group and click Add.
   f. Browse to find the application workspace-level jlib directory and click OK.
   g. In the Filters heading beneath the MAR Group, remove all the filters and add these two rules so they display in this order:
      Include *.mar
      Exclude *.*

2. Prepare each metadata project JAR(MAR) deployment profile.
   These steps will need to be repeated if you have multiple projects containing Oracle Enterprise Scheduler Service metadata.
   a. Select the Oracle Enterprise Scheduler Service metadata containing project and open the project properties.
   b. Select the Deployment panel and click New.
   c. If necessary, select the JAR File archive type and provide a meaningful profile name, such as <ProjectName>_MAR.
   d. In the JAR Options panel, change the JAR File destination to point to the application workspace-level jlib directory, and change the file’s .jar extension to .mar.
   e. Select File Groups > Project Output > Contributors and de-select Project Output Directory and Project Dependencies.
3. Complete the Application Workspace EAR deployment profile.
These steps will need to be repeated if you have multiple EAR deployments for test or development purposes.

a. Open the Application Properties.
b. Select the Deployment panel and choose the EAR deployment profile for your application.
c. In the MAR Group file group, select Filters and ensure that all of your project level MAR archives are selected.
d. Select the Application Assembly heading and de-select the application workspace-level MAR profile.
e. Click OK.
f. Select the Profile Dependencies in the left-hand side.
g. Check the boxes for each of the new JAR-based MAR profiles.
h. Click OK.
i. Deploy as EAR and verify.

3.9.2.2 Build the EAR Profile

The EAR profile pulls together all of the previously-created EJB and MAR profiles to build the Oracle Enterprise Scheduler Service-hosted application. All the Oracle Enterprise Scheduler Service workspace projects should have ADF library JAR deployment profiles, and those with Job-supporting implementation classes should be deployed to a directory that can be added to the Oracle Enterprise Scheduler Service EAR’s contributor list.

To create the EAR profile, follow these steps:

1. Open the Application Properties and select the Deployment panel.
2. Click New to create a new deployment, choose EAR File as the profile type, and provide a unique name.
3. In the Application Assembly, choose the SuperESS EJB-JAR profile and nothing else.
4. Select the File Groups menu entry and click New, giving the name APP-INF/lib and assigning the target directory to ess workspace root path/jlib.
5. Under the APP-INF/lib File Group’s contributors, add the directory that holds all of the Job-supporting Implementation classes (not data model projects with ADF Business Components for parameter view objects or parameter task flows).
6. Select the File Groups menu entry and click New, giving the name MAR Group and leave the target directory empty. Under the MAR Group’s contributors, add the directory that holds all the project level mar files (such as Ess/jlib).

7. Click OK.

Note that the EAR profile should contain only the SuperEss EJB JAR, the MAR, and the JAR files for the Job implementation classes. The Oracle Enterprise Scheduler Service hosting application’s EAR file must not contain JARs, descriptors or other artifacts for UI, data model or services functionality. Should your application contain projects with servlet or UI task flows for development testing, they must be bundled into a separate, UI-specific, set of EAR/MAR deployment profiles.

3.9.2.3 Deploy an Oracle Enterprise Scheduler Service Hosting Application

When deploying an Oracle Enterprise Scheduler Service hosting application, the target managed server must have the ESSAPP base application pre-deployed and configured to run against a working Oracle Enterprise Scheduler Service database schema. A database schema is a named collection of objects, such as tables, views, clusters, procedures, packages, attributes, object classes, and their corresponding matching rules, which are associated with a particular user.

For deployment from JDeveloper, you will need to create an Application Server connection in the JDeveloper resources palette before or as part of the deployment activity using the New Connection feature. When your Oracle Enterprise Scheduler Service application is ready for deployment, including all requisite project and application-level profiles, you can initiate deployment by following these steps:

1. Click Deploy > <ear profile name> from the Application menu.

2. Choose Deploy to Application Server and click Next.

3. If no application servers are defined, or the one to which you wish to deploy is not defined, click Add an Application Server. Otherwise, select the server. Do not click Next yet.

4. De-select the Deploy to all server instances in the domain option, because certain libraries needed for deployment of the Oracle Enterprise Scheduler Service hosting application will not be targeted to all the managed servers, and deployment will fail.

5. Click Next.

6. Choose the appropriate managed server and click Next.

7. Click Finish to begin deployment.

JDeveloper will build the EJB JAR and the MAR, and bundle those archives, along with the JAR files, in the APP-INF/lib contributor location. This packaged archive will be sent to the managed server for deployment. During deployment, the Oracle Enterprise Scheduler Service hosting application will register itself through the ESSAPP base application using the ESSAppEndpoint descriptor in your ejb-jar.xml file.

When deployment is finished, jobs can be submitted programmatically or through the Oracle Enterprise Scheduler Service UI submission task flows. These methods are documented in the Developing Applications for Oracle Enterprise Scheduler guide.
3.10 Implementing Oracle Application Development Framework UI Workspace and Projects

Before you can deploy your web project, you need to complete several preliminary steps. These include setting up your web project and configuring your user interface project; creating the SuperESS project; creating the appropriate deployment profiles; and creating and setting up Oracle WebLogic Server.

3.10.1 How to Set Up Your Web Project

When you choose the Oracle Fusion Applications Developer role when starting JDeveloper, many settings default automatically for you. However, there are still certain options that you need to set manually to configure your project.

This section discusses the specific options that need to be set manually to configure your user interface project. The default name for the project that JDeveloper provides is ViewController.

3.10.1.1 Configure Your User Interface Project

This section describes how to configure your user interface project in JDeveloper.

To configure your user interface project:

1. Choose Application Navigator > ViewController project. Right-click and choose Project Properties from the menu.

2. Choose the Project Source Paths category to display the Project Source Paths dialog.

3. In the Default Package field, enter the name of your default package, as shown in Figure 3-6.

Figure 3-6  Project Properties — Project Source Paths Dialog
Many objects are generated automatically and are stored in the default package.

4. Choose the **ADFm Sources** category from the Project Source Paths hierarchy to display the Project Source Paths: ADFm Sources dialog, as shown in Figure 3-7.

**Figure 3-7  Project Properties — Project Source Paths: ADFm Sources Dialog**

The location for all the ADF Metadata sources is the location that is entered in the **ADFm Source Directory** field. You should not have to change the default location.

5. Choose the **Web Application** category from the Project Source Paths hierarchy to display the Project Source Paths: Web Application dialog, as shown in Figure 3-8.
The location for all the HTML content is the location that is entered in the **HTML Root Directory** field. You should not have to change the default location.

6. Choose the **ADF Model** category to display the ADF Model dialog, as shown in Figure 3-9.

The location of the page definition files is based on a combination of the **PageDef sub-package** value, the default package location, and the ADFm Sources directory.

7. Choose the **Deployment** category to display the Deployment dialog.
8. Select **New** to open the Create Deployment Profile dialog, as shown in **Figure 3-10**.

*Figure 3-10*  **Project Properties — Deployment — Create Deployment Profile Dialog**

9. Choose **ADF Library Jar File** from the **Archive Type** list.

   Enter the **Name** as `Adf<projName>` in accordance with the Package Structure and Naming Standards.

10. Click **OK** to save the new deployment profile and close the Create Deployment Profile dialog.

    **Note:**

    The new deployment profile is now listed on the Deployment dialog.

11. Choose the **JSP Tag Libraries** category to display the JSP Tag Libraries dialog, as shown in **Figure 3-11**.
Verify that you have the following tag libraries listed under the **Distributed libraries** folder:

- Applications Core (ViewController) 11.1.1.0.0
- Trinidad HTML Components 1.2

**Note:**

You may have to include additional tag libraries for other features, such as Data Visualization Tools (DVT) and WebCenter. For more information about adding tag libraries to your user interface project, see [Adding the Applications Core Tag Library to Your User Interface Project.](#)

12. Choose the **Libraries and Classpath** category to display the Libraries and Classpath dialog, as shown in Figure 3-12.
Verify that the libraries listed in Figure 3-12 have been attached to your user interface project. As with tag libraries, you may have to add additional libraries.

**Important:** The Applications Core library *must* be included to make the page's design tab visual, instead of showing nesting boxes of XML elements. To add the Applications Core library:

- Click Add Library.
- In the Add Library list, select the Applications Core entry, as shown in Figure 3-13 and click **OK**.

- Verify that the Applications Core library now is included in the Libraries and Classpath list, as shown in Figure 3-14.
13. Choose the Resource Bundle category to display the Resource Bundle dialog, as shown in Figure 3-15.

**Figure 3-15  Project Properties — Resource Bundle Dialog**

Verify that the Resource Bundle Type is set to Xliff.

**Note:**

The default settings will be correct when you start JDeveloper using the Oracle Fusion Applications Developer role.

14. Choose the Technology Scope category to display the Technology Scope dialog, as shown in Figure 3-16.
Verify that the technology scopes that are selected in Figure 3-16 are selected for your project.

Note:
This selection is limited to what is available, by default, in the New Gallery. To see other types of objects, choose All technologies from the New Gallery.

3.10.2 How to Create the SuperEss Project in the ADF UI Workspace

Follow the steps in How to Create the SuperEss Project. The differences are that the ejb-jar.xml file will have no ESSAppEndpoint MDB and the weblogic-ejb.jar.xml file will be empty.

3.10.3 How to Deploy Your Web Project

Deployment is the process of packaging application files and artifacts and transferring them to a target application server to be run. During application development using JDeveloper, developers can test the application using Integrated WebLogic Server that is built into the JDeveloper installation, or they can use JDeveloper to directly deploy to a standalone application server.

After the application has been developed, administrators can deploy it to production application servers.
Note:

This section assumes that you are deploying a web project to Standalone WebLogic Server. Creating deployment profiles is not necessary if you are running the project in Integrated WebLogic Server from within JDeveloper. In this case, JDeveloper, behind the scenes, creates an in-memory deployment profile.

For other deployment options, see Deployment Techniques for Development or Production Environments in the Developing Fusion Web Applications with Oracle Application Development Framework.

To deploy the web project to Standalone Weblogic Server, you must:

- Create a Web Archive (WAR) deployment profile. This file is used in deploying applications on a Java EE application server. WAR files encapsulate in a single module all of the components necessary to run an application. WAR files typically contain an application’s servlet, JSP, and JSF JSP components. To create the WAR deployment profile, see How to Create Deployment Profiles in the Developing Fusion Web Applications with Oracle Application Development Framework.

- When you have defined the WAR, create an EAR deployment profile that includes the WAR profile, for the application. To create an EAR deployment profile, see Creating an Application-Level EAR Deployment Profile in the Developing Fusion Web Applications with Oracle Application Development Framework.

- Create, if necessary, and prepare the standalone application server for deployment. To run ADF applications, you must install the standalone application server with the ADF runtime. You can include the ADF runtime during a new application server installation or you can install the ADF runtime into an existing application server installation.

- Deploy the application using one of these methods:
  - Oracle Enterprise Manager Fusion Middleware Control
  - WebLogic Scripting Tool (WLST) commands (see Deployment Commands in the WLST Command Reference for WebLogic Server) or WebSphere Application Server (wsadmin) commands
  - Command scripts and Ant scripts
  - Oracle WebLogic Administration Console or IBM WebSphere Administrative Console
Get Started with Business Services

This chapter provides an overview of ADF Business Components, validators, list of values (LOVs), and data types. It also discusses migrating PL/SQL to Java, batch processing, and extensibility and reusability. Also included is an overview of services.

This chapter includes the following sections:

• Introduction to Implementing Business Logic
• Understanding Validators
• Understanding List of Values (LOV)
• Understanding Batch Processing
• Understanding Extensibility and Reusability
• Understanding Services
• About Using the Declarative Approach

4.1 Introduction to Implementing Business Logic

The core business logic is implemented in one or more business components that are provided in ADF Business Components. Entity objects, view objects, and application modules are the key business components that are discussed in this section.

4.1.1 About Entity Objects

An entity object represents a row in a database table. It encapsulates the business logic and database storage details of your business entities. It simplifies modifying its data by handling Data Manipulation Language (DML) operations automatically. There are two general classifications of business logic that are placed on the entity object:

• Standard business and validation logic
• Specialized business functions

4.1.1.1 Standard Business and Validation Logic

An entity has a life cycle; customized business rules can be added to an entity object at various places to be executed in different phases of its life cycle.

The entity object should contain all logic that is invoked during entity object life cycle events. This comprises logic for create, initDefaults, all validation (including attribute validation, entity validation and cross entity validation), DML, and so on. In other words, the entity object encapsulates the rules that ensure the entity object is created and remains in a valid state.
Note:
All logic existing in one entity object Java class not required. It's valid for the entity object to call utility classes for code modularity purposes.

If a business rule can be defined declaratively, you should always use the declarative approach. For example, if an attribute has a constant default value, then you should specify it in the Entity Object wizard rather than coding it. You should also first consider using declarative validators for your validation logic, which is explained in Understanding Validators.

The life cycle of an entity object begins with being created as a new entity object or fetched from the database as an unmodified entity object. The entity object can then be modified or removed. Only new, modified, or removed entity objects are in the transaction pending change list and are posted to the database when the transaction is committed.

For more information about the key events in the entity objects life cycle and where you can add entity object business logic programmatically, see the Introduction to Programmatic Business Rules section in the "Implementing Validation and Business Rules Programmatically" chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.

4.1.1.2 Specialized Business Functions
The entity object is the core business object that is used to encapsulate task-level business logic. It is shared by both user interfaces (UIs) and services. Core business functions and tasks should be placed on the entity object as custom methods for maximum reusability. Corresponding methods on the view object and application modules should delegate to these functions on the entity object. Examples of business functions are approvePurchaseOrder and hireApplicant. Internally, these custom methods can be implemented using Java or may invoke legacy PL/SQL.

Custom business functions that are not invoked during entity object life cycle events should be placed in either the entity object or model application module. Generally these are the custom business functions that are required by the UI and Service application module.

4.1.2 About View Objects
A view object represents a SQL query and also collaborates with entity objects to consistently validate and save the changes when end users modify data in the UI. The relationships between view objects are captured using view links. View objects are used to present your business data for the specific needs of a given application scenario or task, and generally don't contain business logic.

However, view objects may have additional attributes that do not exist in the underlying entity objects, which are used to store some calculated values. Usually you define different view objects for supporting services and UIs:

- Service view object: Represents an outfacing business object and contains only the attributes in the business object. For example, it contains the foreign key ID attribute such as SupplierID, but it does not contain foreign key reference attributes such as SupplierName.
• **UI view object**: This view object may contain additional UI flags and calculated attributes that are used for a particular UI. In addition, the UI view object may join to other tables for additional foreign key attribute references.

**Note:**
A service view object must be versioned to support service versioning. However, there is no versioning requirement for an internal UI view object.

### 4.1.3 About Application Modules

An application module encapsulates an active data model and the business functions for a logical unit of work related to an end-user task. The active data model is defined as a collection of view object instances.

The methods on the application module are used to encapsulate task-level business logic, although these methods should delegate to the methods on entity objects whenever possible. If you have an option to put your business logic either on an entity object or an application module, then you should always put it on the entity object. This is because the entity object owns the business object and also for better reusability. The task-level validations that span multiple related parent-child entities, such as purchase order header and lines, should be put on the parent entity. It is also important that the entity object should not trust the incoming data and always perform all validations.

Application modules can be used to support UIs or define services. Usually you want to have two separate application modules for the two different purposes because:

• **UI application modules** may contain additional view objects and context values that are only required for a particular UI, but not needed by a business service.

• **Application modules** that define public services are versioned, but internal UI application modules are not.

UI application modules and service application modules share the underlying entity objects as shown in Figure 4-1. A UI application module can also call a service.

![UI Application Module and Service Application Module](image.png)

#### 4.2 Understanding Validators

In Fusion, you should use validators to implement the validation logic. Validators are added declaratively, which provides visibility and personalizability to customers as well as the benefit of being easy to use and maintain. Validation view objects can be attached to entity objects declaratively as view accessors, which can then be used in declarative validators.
For more information about how to use validators and Groovy (a Java-like scripting language), see Defining Defaulting and Derivation Logic.

### 4.3 Understanding List of Values (LOV)

List of Values (LOV) is the mechanism to specify a list of valid values for an attribute in a view object. There are basically two parts involved when a LOV is defined: the base object and the LOV object. The base object is a view object, which contains the attribute whose list of valid values need to be defined, such as a PurchaseOrder view object containing a BuyerId attribute. The LOV object is a normal view object that contains the list of valid values, such as a Buyer view object containing all the valid buyers. You should use the view object design time wizard to add a List Value on the BuyerId attribute to associate with the Buyer view object.

In Fusion, the LOV metadata is defined on the server using ADF Business Components, and this drives and defaults the UI controls to automatically render the LOV bound items accordingly when you define a page, such as LOV and poplist controls.

It's important to define the LOV and entity validators to share the same view object instance to avoid redundant database round-trips for validation. To achieve this, you should add the LOV view object as a view accessor in the entity object, and use the view accessor to define entity level validators. The same view accessor is available at the view object level and is needed to define the LOV. When the user picks up a row from LOV on the UI, the row is placed on the LOV view object cache. The entity object validation then hits the cache instead of going against the database. A LOV/validation view object can also be defined as a global data source that is shared among all the users.

For more information, see the “Sharing Application Module View Instances” chapter, in the Developing Fusion Web Applications with Oracle Application Development Framework.

### 4.4 Understanding Batch Processing

Depending on the use case, different approaches should be considered to achieve the best performance.

For the use case of complicated bulk processing, such as very high volume or multiple step processing, a combination of multiple techniques must considered. For example, ADF Business Components, C, PL/SQL, SOA, Oracle Enterprise Scheduler (ESS), and so on.

For the other use cases, such as integration with third parties or data migration, if the data volume is low to medium, then ADF Business Components service is necessary. Internally, a combination of interface table and PL/SQL can be used to handle large amount of data, complicated processing, and validation logic. The inbound data is loaded into an interface table through a service and then the PL/SQL API is executed to process the data.

---

**Note:**

You should still provide services for all objects, and double code the high performance alternatives when necessary.
4.5 Understanding Extensibility and Reusability

Fusion web applications are extensible applications, which can be tailored to fit the business practices specific to a customer, locale or an industry. Adaptation through Business Editor enables you to extend Oracle applications declaratively, which satisfies most of the extensibility requirements. You can also use the programmatic extensibility feature to address additional use cases.

4.6 Understanding Services

A service is a set of operations defined by an interface that can be used by other components. In Fusion, applications use both ADF Business Components services and SOA services. ADF Business Components services should be created to manage business objects and SOA services are for orchestration and business processes.

In Fusion, you make your data and business logic available via UIs and services. For more information about services, see Developing Services.

4.7 About Using the Declarative Approach

When building your model objects, you should use the declarative approach whenever possible. For example, when defining your view objects, use declarative SQL mode whenever possible, base your view objects on entity objects, and use view criteria.

4.7.1 About Defining View Objects Using the Declarative Approach

When you define your view objects, use declarative SQL mode wherever possible. The next option is to use normal SQL mode.

When building your view objects, use declarative SQL mode wherever possible. Reasons for not using declarative SQL include:

- You have a complicated query and the WHERE clause cannot be implemented using view criteria.
- Your query includes derived attributes that cannot be implemented as calculated attributes based on a SQL expression.

If you are unable to use declarative SQL mode, you should try and use normal SQL mode, which gives you full control over the WHERE clause. Only use expert mode if other modes do not work. However, you should still base the view object on an entity object when the query supports it.

Non-expert mode view objects are metadata based and more declarative instead of SQL based. The declarative approach gives you benefits such as:

- Increased development productivity:
  - Proven experience from PeopleSoft and Siebel.
  - Removes the requirement for you to tune each view object.
- Easier to perform dependency and impact analysis.
- Can be extended more robustly.
Declarative SQL mode is recommended because it is an even more declarative approach to defining the view object than normal mode.

- The runtime query optimization feature is enabled only when you use declarative SQL mode. ADF Business Components makes runtime changes to the SQL based on usage such as column pruning to improve performance.
- Declarative SQL optimization means you can consider creating view objects that can be reused in multiple UIs without impacting runtime performance.

For more information about how to set the SQL mode, see the Working with View Objects in Declarative SQL Mode section of the "Defining SQL Queries Using View Objects" chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.

4.7.1.1 About Using Entity Object Based View Objects

All view objects (including read-only view objects) should be based on entity objects unless:

- Entity object based view objects are not supported for the SQL statement you are using, for example:
  - Union
  - Select Distinct
  - Group By
- Your data doesn’t come from the database. For example, the data comes from external files.

Even if you have to use expert mode view object, you should still base your view object on top of entity objects because:

- The attributes from the entity object are still declaratively defined so that you can partially benefit from the declarative approach.
- Multiple view objects based on the same entity object can automatically see updates made by any one of them.
- Updated reference information is reflected when foreign key attribute values are changed.
- Metadata, (UI hints, associations, and other attributes), are automatically propagated up to the view objects from entity objects.
- New row management, such as view link consistency, only works with an entity object-based view object.
- findByKey doesn’t work for view objects with no entity usage unless you turn on the key management at the view object level (and this will add significant resources and CPU time). The findByKey method is a frequently invoked by any operation that involves setting the current row, such as clicking a row on an ADF Faces rich client table:
  - findByKey does not find the matching view row in the view object cache if the key management is not enabled.
findByKey adds the row fetched from the database into view object cache even if the view object already has the same row in cache if the key management is not enabled.

- Updatable view objects must be based on entity objects so that view objects can coordinate with the underlying entity objects to perform DML.

4.7.1.2 About Utilizing View Criteria

Instead of directly setting the WHERE clause, use declarative named view criteria whenever possible. Named criteria can be re-used in the UI and in the service interface. Also, it supports customization better and is required for declarative SQL mode.

In parallel, always use named bind parameters. Define the named bind parameters during design time if possible. Otherwise, add the named bind parameters programmatically. Named bind parameters are much easier to understand and manage than the indexed bind parameters so therefore, the code is easier to develop and maintain. If the same bind parameter appear multiple times in the WHERE clause, you only need to bind it once.
Service-oriented development is based on the concept of services. It is the realization of business functionality via software that customers can use to compose new business applications by using existing services in the context of new or modified business processes. This chapter describes how you should design and develop the services to make them useful for both Oracle Fusion Applications and for customers. It also covers how the services are consumed.

This chapter contains the following sections:

- Introduction to Services
- Designing the Service Interface
- About Developing Services
- About Invoking Services

### 5.1 Introduction to Services

A service is defined in terms of its interface, which is the way the service is exposed to the outside world. The service interface includes a set of operations the service supports, a set of parameters (defining data required for interaction with the service), and communication protocol used for data transfer and actual service invocation. Grouping of the methods in the service interface is defined by business functionality of the service.

Services have the following characteristics:

- Business-driven
- Coarse-grained
- Process-centric
- Stateless invocation
- Loosely coupled
- Distributed
- Standards-based

In Oracle Fusion, applications use both ADF Business Components services and service-oriented architecture (SOA) services. ADF Business Components services should be created to manage business objects and SOA services are for orchestration and business processes. SOA services use business object services to encapsulate business processes as illustrated in Figure 5-1:
This chapter focuses on business object services that are implemented using ADF Business Components services.

In Oracle Fusion, you make business objects and related business logic available via user interfaces (UIs) and services. A single general-purpose service can satisfy multiple use cases such as:

- Programmatic application programming interface (API) calls required by external customers, cross-pillar integration, or third-party integration.
- Business Process Execution Language (BPEL) process flows and composite applications
- Business-to-business (B2B) integration through standardized documents
- Foreign UI technologies such as Microsoft .NET framework
- XML-based reporting
- Desktop applications such as Excel and Access

5.2 Designing the Service Interface

A service is a public interface, and it requires careful design to make it useful. For ADF Business Components services, on which this chapter focuses, the purpose of these services is managing business objects, including the generic lifecycle of the objects (create/update/delete/query), and special actions that can be applied to the objects.

Therefore, designing these services will start from identifying the business objects, continue with identifying service operations on business objects, and grouping the operations into services. Exceptions, warnings, or informational messages need to be defined for each operation and service as part of the service interface design process.

5.2.1 About Identifying Business Objects

Identify which business objects that you want to expose from the service interface.

5.2.1.1 About Business Object Attributes

The shape of the business object is very important. You need to include all the attributes that represent the objects, but exclude anything that is of no business value.

The business object must contain the following attributes:
• Primary key attributes, including the system generated surrogate keys when defined.
• Attributes that are of business value to the consumer. This will include most attributes of the physical tables.

5.2.2 Identifying Service Operations on the Business Objects

The service operations are the actions that can be performed on business objects, such as create and delete.

5.2.2.1 Types of Operations

Standard operations and Custom operations are the two types of service operations that are supported by ADF Business Components service.

Standard Operations

The primary purpose of standard service operations is to locate a business object and handle its persistence. This includes storage, manipulation and retrieval of data, locking, transaction management, business rule validation, and bulk processing. ADF Business Components auto-generates the following groups of standard service operations:

• CRUD (Create, Read, Update, Delete) Operations:
  - get<businessObjectName>: get a single business object by primary key.
  - create<businessObjectName>: create a single business object.
  - update<businessObjectName>: update a single business object.
  - delete<businessObjectName>: delete a single business object by primary key.
  - merge<businessObjectName>: update a business object if exists, otherwise create new one.

• Find Operation:
  - find<businessObjectName>: find and return a list of business objects by find criteria.

• Bulk Processing Operations:
  - process<businessObjectName>: process a list of business objects via a CRUD command.
  - processCS<businessObjectName>: process a list of business objects via a change summary.

• Control Hints Operations:
  - List<AttrCtrlHints>
  - getDfltCtrlHints(String viewName, String localeName): takes the view object name and a locale and returns the base UI hints for that locale.
Custom Operations

Custom service operations encapsulate complex business rules and may coordinate execution of two or more data-centric operations within one atomic transaction.

5.2.2.2 About Business-Object Operations

All core business functions should be exposed in services. When developing a list of business object operations, consider the entire application life cycle from creation to deletion. Also, consider potential use cases that are required by others. Typically, the functionality exposed from UI should be achievable from services. For example, the following list includes many of the operations associated with requisitions and purchase orders:

- **Operations associated with Requisitions:**
  - create
  - merge
  - update
  - delete requisition
  - delete requisition line
  - delete requisition distribution
  - copy requisition
  - get requisition
  - cancel
  - approve (including all approval states such as approve, reject, and pre-approve)
  - view approval history

- **Operations associated with Purchase Order:**
  - create
  - delete purchase order
  - delete purchase order line
  - delete purchase order shipment
  - delete purchase order distribution
  - copy purchase order
  - merge
  - update (change)
  - acknowledge
  - get purchase order
  - cancel purchase order
- cancel purchase order line
- approve (including all approval states)
- view approval history
- close

Typically, you should include all the standard operations, although the delete operation should only be included if supported by the business object.

Custom operations must be coarse-grained and must reflect a business task to be carried out. activateCustomerParty, suspendOrder, and closeServiceRequest are some examples.

### 5.2.2.3 General Guidelines for Defining Service Operations

There are general guidelines you must follow when defining service operations.

**Be generic where it makes sense**

Since most Oracle Fusion services serve multiple use cases as listed in *About Business-Object Operations*, services should not be designed narrowly for only one use case at the exclusion of others. Instead, services should be designed from the start to be general purpose and contain APIs that can serve the widest use cases. This is especially important to consider for common business functions that are initially required for the UI or to meet enhancement requests from other products. It should be the conceptual essence of the use case that drives the interface, not the fine-grained specifics of one consumer. A consumer can be seen as a representative of a specific use case, but the provider should always apply well-measured foresight when defining the interface details. Creating general purpose APIs from the beginning will:

- Prevent method explosion as other similar use cases are requested.
- Increase reuse by multiple use case.

For example:

There is a requirement to return a person’s name based on `personId`. To satisfy that requirement, you might want to create an operation such as:

```java
public String getPersonName(Long personId)
```

However, it is likely that this service will soon be adopted by more consumers, which will require other attributes of a person. In this example, it makes sense to return the person object instead of just the name into the first specification of the service interface, such as:

```java
public Person getPerson(Long personId)
```

**Leverage standards wherever possible**

When there is an existing industry standard that can be applied to your service, leveraging the standard is definitely recommended to avoid costly negotiation of proprietary interfaces.

However, in many situations either no standard exists or the standard does not optimally support your business need. In this case you should make the interface as generic as possible for your given group of consumers. This will make sure that the interface stays stable as more consumers adopt it, while being highly useful for your given business processes. With good strategic planning it is possible to define generic interfaces for a defined subset of stakeholders.
Service operation granularity

Because it is possible to call services across a network, the service operations should be generally coarse-grained. That is, a service operation should wrap a substantial body of application logic, delivering value that justifies the latency cost of a network request. Similarly, services should expose coarse-grained operations. Rather than expose many operations that each manipulate small amounts of state, services should expose fewer operations that allow a single request to perform a complete function.

Compensating service operations

For operations that involve data manipulation, a clear strategy for compensation must be defined. Services are frequently distributed remotely and there is no central transaction coordinator with sufficient control over all resources. This is inherent in Simple Object Access Protocol (SOAP), which is predominantly used in the web services space and therefore, a two-phase commit protocol cannot be enforced. Also, two-phase commit implies resource locking, which may lead to scalability and availability issues if locks are held for longer periods.

To allow for service operations to be undone, in certain business scenarios it may be possible to offer compensating service operations. These operations are used to revert the system back to the state before the original operation was invoked. Providers and consumers must agree on the conditions under which an original operation can be undone and what information is required to achieve the compensating effect.

In most cases, the decision to provide a compensating operation is primarily functional. It might technically be possible to delete an existing purchase order, but functionally it is only correct to cancel it after it has been submitted for approval. Not all operations should, by default, be paired with a compensating operation. Compensating operations should be provided only if the business process demands that the system can be rolled back into the original state.

If it is not possible to provide a compensating operation, you should strive to make the service operations truly accomplishable (idempotent). Making the operations idempotent means that the operation can be invoked multiple times with the same payload but still the result will be the same with no undesirable effects. If neither providing compensating service operations nor making the service operations idempotent is feasible, processes should be designed in such a way that the service operation would never be called more than once under any circumstances for a specific request.

Service operation parameters

Each service operation can have zero or more parameters. Each parameter can be a primitive type (String, Date, and so on), a complex type represented as a Service Data Object (SDO), or a List of a primitive type or SDO. Complex types can in turn contain nested complex types.

- Long Parameter List or Complex Types?

You should consider using complex types in a service operation instead of using a long list of individual parameters unless the parameter list can be reduced to a short list of simple types (3-5).

For example:

A service operation `updatePerson()` takes a compound complex type of `Person`, which includes several individual attributes such as `BirthDate`, a collection of `PersonName`, and a collection of `PersonAddress`, and so on. The reasons are:
- Taking a list of individual parameters leads to a not so clean operation signature:

- Adding an optional attribute on a complex type doesn’t break compatibility, but adding a new parameter in a method does.

- In the `updatePerson` example, if the person’s email address must be updated, the operation that takes a `Person` can stay unchanged.

- **Complex Types or Primary Keys?**

  As an alternative to complex types, business object Primary Keys can be used in operation signatures in certain cases.

  Auto-generated data-centric standard operations, such as create, update, delete, merge, and Bulk Processing take complex business object types as parameters. Auto-generated `get()` takes primary keys.

  Custom methods may take business object primary keys or developer key as parameters, when the key attribute is used to look up the business object, such as `terminateEmployee`. Complex business object documents should be passed primarily to the data-centric custom methods: `validatePerson()`, `promoteEmployee()`, `formatPersonAddress()`, and so on.

**Example 5-1  Service Operation on a List of Parameters**

```java
void updatePerson (Date BirthDate, PersonName[] Names, PersonAddress[] Addresses);
```

### 5.2.3 How to Identify Services

A service is a grouping of operations. Often this grouping is by the business object it maintains, which is especially true for the CRUD operations. In most cases, one service per business object provides a more manageable hierarchy. For example, the business object `Person` could be offering all operations that can be performed on it as a service called `PersonService`.

After you have identified your services and what business object(s) they include, the list(s) of the corresponding operations that were identified in About Business-Object Operations provide the list of candidate methods for each service.

Services from other products that may compliment this list are not included. For example, a `SupplierService` and `InvoiceService` provide detailed information about suppliers and invoices respectively. The procurement services should identify only who the supplier is in various transactions and provide information on procurement-specific supplier data such as, supplier price, quality and on-time delivery performance. It should not provide core supplier operations like creating, updating, deleting, and so on because that is the responsibility of the `SupplierService`.

It’s important that the Oracle Fusion services compliment one other. Therefore, after you’ve identified your working list of services, coordinate with related products to ensure that you have not duplicated efforts or created confusing and conflicting APIs. Also, communicate any expectations that you have of their services.

### 5.2.4 About Defining Service Exceptions and Information

Services might throw exceptions or warnings when there is issue of processing inbound request. Sometimes it is desirable to return informational messages along with the response. It is an important step to define when to return exceptions,
warnings, and informational messages, and what messages should be returned. This is especially true for the bulk processing operations with partial failure.

5.2.4.1 Defining Service Exceptions

After the required criteria for successful execution of a service operation is agreed upon, all stakeholders must then define a complete set of error conditions. You must define which exceptions can happen and which information should be reported back to the consumer due to an exception. Exception processing should be consistently implemented across all operations in the application. If one operation throws an exception while another returns an empty collection, the consumers perceive the services as unstable and unpredictable. The reported exception should contain as much information as possible so that the consumers can pinpoint the problem easily.

All service operations are delegated to the underlying ADF Business Components objects and their methods. As a service provider, you just need to implement your validation logic and business rules in your server side objects, define appropriate error messages declaratively, or throw appropriate JboExceptions programmatically.

Oracle ADF has one generic exception or fault to handle all ADF Business Components exceptions. Whenever an exception is thrown from the underlying ADF Business Components object for one of the service standard or custom methods, the exception is thrown as a Service Exception, which contains all of the information available from the original thrown exception. This also includes support for bundled exceptions.

5.2.4.2 Defining Partial Failure and Bulk Processing

Services can support partial failure during bulk processing of data, which can be very useful. For example, if the client loads a large amount of data using batch load applications, the occurrence of one or more failures does not prevent the continued posting of other unrelated data.

During design of your services, you need to decide whether partial failure should be enabled for a business object including details. For example, a purchase order business object includes a header, lines for each header, and shipments for each line. The partial failure switch is set on each level including header, line, and shipment. Usually the top level object should allow partial failure, but the decision on the detail level depends on whether it make sense to simply skip that object if it fails. You must ask yourself the question: “Does it make sense to still post the other lines and the header if one line fails?” In some cases, you may need to preserve the integrity of the business object and not allow the object to be posted with partially populated children.

Caution:

The partial failure mode is only used in the processXXX API and this API also uses a runtime partial failure flag in the ProcessControl parameter. This means the partial failure feature is only enabled when both the design time flag and the runtime flag are enabled.

5.2.4.3 Defining Informational Messages

Informational messages are not exceptions and won’t affect the current transaction. However, these messages may be useful to the clients. For example, you may want to know when the system automatically transfers money from your saving account to your checking account because there may not enough funds in your checking account when your check is cashed out.
The service provider needs to define a complete list of informational messages as well as the conditions that these messages should be returned.

5.3 About Developing Services

After you design the service interface, you now must implement those services.

Note:
This is from the service provider perspective.

For more information see “Implementing Business Services with Application Modules” in Developing Fusion Web Applications with Oracle Application Development Framework.

5.3.1 About Creating Service Data Objects

In Oracle Fusion, service data objects (SDOs) are used to expose business objects in services. SDO is an industry standard, and it provides a unifying API and architecture that allows SOA applications handle data from heterogeneous sources, including relational databases, Web services, and enterprise information systems. Oracle has implemented it based on the SDO specification.

Each SDO must be backed by a view object. Hence, you don’t create the standalone SDO. Instead, you always start with a view object, and service-enable the view object using the "Generate Service Data Object Class" option in the view object wizard’s Java panel to create SDO.

This implies that you might need to create transient view object when there is no corresponding entity object. For example, you want to use a SDO to capture parameters when number of parameters is big.

5.3.1.1 SDO Attributes

When you create the view object, make sure the attributes are properly defined. See About Business Object Attributes for information about what attributes should be included in SDO. You can hide view object attribute from SDO if you need to by navigating to the attribute editor and de-selecting the SDO Property checkbox.

Note:
If a view object extends another one, then the subtype SDO cannot hide or unhide an attribute that is defined in the base SDO.

The SDO attribute name is derived from the view object attribute name, and you cannot override it.

5.3.1.1.1 Ensure Attribute Type Consistency

In general, the SDO attribute type is defaulted from the view object attribute, and you can just use the default value. However, the following types are exceptions:

- Boolean type
- AmountType
• MeasureType

**Boolean Type:**

A SDO attribute in boolean domain (only have true/false value) must be of Boolean type.

Oracle ADF provides a feature that maps between the view object attribute String type and the SDO attribute Boolean type. This feature will allow you to continue using String in the view object attribute, but use Boolean in SDO.

To expose a Boolean domain view object attribute of String type as Boolean type in SDO, do the following:

1. Determine the possible values of the attribute. Since it is of Boolean domain, there are only two possible values: **Y/N, T/F, or 1/0**.

2. If needed, create a property set. This property set is used to indicate how Oracle ADF should convert between String and Boolean. Oracle ADF provides property sets for Y/N or T/F or 1/0. If the possible values are not Y/N or T/F or 1/0, then you will need to create a property set. Navigate to the **New Object Gallery**, and select **Property Sets** under **ADF Business Components**.

3. Navigate to the Source view and add the following element as a child of the Domain element:

   ```xml
   <Domain>
     ....
     <Properties>
       <SchemaBasedProperties>
         <BooleanValueMapping>
           <ValueMapping JavaStringValue="true" StorageValue="A"/>
           <ValueMapping JavaStringValue="false" StorageValue="I"/>
         </BooleanValueMapping>
       </SchemaBasedProperties>
     </Properties>
   </Domain>
   
   This example assumes that the possible values are "A" and "T", where "A" means true and "T" means false. You should replace these values with your own.

4. Specify the property set for the attribute. If the view object attribute is entity-object based, then go to the entity object. Otherwise, go to the view object. Navigate to the Source view and, in the corresponding Attribute or ViewAttribute section, add the **TypeValueMapPropertySet** attribute. For example:

   ```xml
   <Attribute
     Name="_Flag"
     ....
     TypeValueMapPropertySet="oracle.jbo.valuemaps.BooleanYNPropertySet">
   ....
   </Attribute>
   
   If your attribute is of Y/N domain, then use
   oracle.jbo.valuemaps.BooleanYNPropertySet as the property set. If it is of T/F domain, then use oracle.jbo.valuemaps.BooleanTFPropertySet. If it is of 1/0 domain, then use oracle.jbo.valuemaps.Boolean10PropertySet. Otherwise, you will need to use your own property set, which you created in the previous step.

5. Navigate to **View Object wizard > Java > Generate Service Data Object Class** and generate or regenerate the SDO.
AmountType:

An SDO attribute storing a price or amount could use the AmountType datatype. Examples are 100 USD or 35.3 RMB. A number and a currency code are always present in this type of attribute. AmountType is a complex type and defined as:

```xml
<xsd:complexType name="AmountType">
  <xsd:simpleContent>
    <xsd:extension base="xsd:decimal">
      <xsd:attribute name="currencyCode" type="xsd:normalizedString" use="optional"/>
    </xsd:extension>
  </xsd:simpleContent>
</xsd:complexType>
```

Therefore, a SalePrice attribute of 100 USD will be represented in xml as:

```xml
<SalePrice currencyCode="USD">100</SalePrice>
```

To use the AmountType, two attributes in view objects must be present: One for the number/amount itself, and the other for the currency code. To use the AmountType, do the following:

1. Navigate to View Object wizard >Attributes and select the specified Price or Amount attribute. Then, click Edit.

2. In the View Attribute panel, select AmountType as the XSD Type.

3. In the corresponding CurrencyCode field, choose the attribute that is used to determine the currency code. If the currency is not defined in the current view object and derived from another place, first create a transient attribute and add logic to populate the transient attribute value, for example, via a Groovy expression. For the transient currency code, override the setter method of the ViewRowImpl class, and validate that the new value is the same as the source attribute. For example, if you have a currency code defined at the parent level, then the transient currency code attribute at the child level should be always the same as the parent level currency code value.

4. Keep the currency code in the SDO payload. In another words, always expose the currency code attribute in SDO, and don’t disable "SDO Property". This will allow the consumer to change the currency code even if the price/amount is not present.

   During runtime, if the payload contains conflicting currency codes, then an exception will be thrown from Oracle ADF. For example, an exception will be thrown if the service payload is something like the following:

   ```xml
   <SalePrice currencyCode="USD">100</SalePrice>
   <ListPrice currencyCode="RMB">100</SalePrice>
   ```

   Instead, both SalePrice and ListPrice should contain same value for the currencyCode attribute:

   ```xml
   <SalePrice currencyCode="USD">100</SalePrice>
   <ListPrice currencyCode="USD">100</SalePrice>
   ```

   Or the currencyCode is specified in one element and omitted from the other:

   ```xml
   <SalePrice currencyCode="USD">100</SalePrice>
   <ListPrice>100</ListPrice>
   ```

MeasureType:
An SDO attribute storing a quantity could use the MeasureType data type. Examples of quantities are: 10 meters or 105.3 pounds. Two things are always associated with a quantity: A number and a unit of measure. MeasureType is a complex type and defined as the following:

```xml
<xsd:complexType name="MeasureType">
  <xsd:simpleContent>
    <xsd:extension base="xsd:decimal">
      <xsd:attribute name="unitCode" type="xsd:normalizedString" use="optional"/>
    </xsd:extension>
  </xsd:simpleContent>
</xsd:complexType>
```

Therefore, a Length attribute of 10 meters will be represented in XML as:

```xml
<Length unitCode="meter">10</Length>
```

In a view object, there are two attributes related to this one quantity: The number attribute and the unit of measure attribute. To define the attribute as MeasureType, do the following:

1. Navigate to **View Object wizard** > **Attributes** and select the specified Quantity attribute. Then, click **Edit**.
2. In the **View Attribute** panel, select MeasureType as the XSD Type.
3. In the corresponding unitCode field, choose the attribute that is used to determine the unit of measure. If the unit of measure is derived from another place, create a transient attribute and add logic to populate the transient attribute value, for example, via a Groovy expression. For the transient currency code, override the setter method of the **ViewRowImpl** class, and validate that the new value is the same as the source attribute.
4. Keep the unit of measure attribute in the SDO. In another words, always expose the unit of measure attribute in SDO, and don't disable "SDO Property". This will allow consumers to change the unit of measure even if the quantity itself is not present.

As with AmountType, an exception is thrown by Oracle ADF if the payload contains conflicting unit codes.

### 5.3.1.2 Parent-Child Relationships

For parent-child relationships, you should define two view objects, one for the parent and one for the child, and then define a view link between them. You must also have the destination accessor generated so that the service framework is unable to query or post the child along with the parent.

For composite object, you should create a composite association between the parent entity object and the child entity object, and base the view link on the association. However, in cases where composite associations cannot be defined you must add a custom property, `SERVICE_PROCESS_CHILDREN=true`, to the entity association or view link. This allows for the child objects to be processed along with the parent object (in `createXXX`, `updateXXX`, `mergeXXX`, `deleteXXX`, and `processXXX`). Reasons for cases where composite associations cannot be defined include:

- A child has multiple parents but the relationship is really composite.

When there is an entity association and the association has the destination accessor generated, then you should add the custom property in the association. When an
association doesn’t exist such as flexfield or the association doesn’t have the destination accessor generated, then you must add the same property to the view link.

5.3.1.3 About Enabling Partial Failure

The default setting for partial failure is not enabled. To enable partial failure, add the PARTIAL_FAILURE_ALLOWED custom property on the view object and set the value to true.

To determine if you should enable partial failure, see Defining Partial Failure and Bulk Processing.

5.3.1.4 About Enabling Support Warnings

There is a design time flag to indicate whether the informational messages are enabled or not for each view object and service data object. The default setting for this flag is off, and you need to go to the view object editor’s Java tab and select the Support Warnings field.

---

**Note:**

Signatures of the service operations that ADF Business Components generate vary depending on this Support Warnings flag. If you change this flag in a future release, your service will no longer be backward compatible. In addition, when partial failure is on, the exceptions are not thrown from the service invocation. Instead, the exceptions are reported as warnings, and the caller can only receive these warnings if the Support Warnings flag on the service view object is turned on. Therefore, you must turn on the Support Warnings flag for the top-level service data objects that are exposed directly in the process methods.

---

For the purchase order header, line, and shipment example, if your service includes the processPurchaseOrders API that takes a list of purchase order headers, then you must enable Support Warnings in the purchase order header view object. If your service also includes the processLines API that takes a list of purchase order lines, then you also need to enable Support Warnings in the line view object. For the other detail level service data objects, you should take a more proactive approach and define your business object as supporting informational messages if you think you will need this feature in the future.

5.3.1.5 Defining a List of Values (LOV) to Resolve Foreign Key ID

Except the services that are only consumable only within Fusion Applications, not only the foreign key ID attributes but also the foreign alternate key attributes should be added to the SDO, when the foreign key ID is a surrogate key. In many cases, it is desirable to include developer key attributes for foreign keys. For example, an employee service is used to process employees, and the employee has a department associated with it. The department has a DepartmentId (surrogate primary key) attribute and a DepartmentName (developer key) attribute.

When the consumer constructs the inbound payload, the consumer could choose to provide DepartmentId or DepartmentName or both. If only DepartmentName is provided, then logic needs to exist to resolve DepartmentId based on the name. If both name and id are provided, then validation must be provided to make sure the two matches. An LOV can be defined to resolve foreign key ID based on foreign alternate key attributes.
An LOV is defined at attribute level, but it can be configured to be driven by multiple attributes. When an LOV is driven by multiple attributes, the LOV query will use all the driven attributes in the where clause. Service framework doesn’t call individual setters, instead, it calls `setAttributeValues()` method in the `ViewRowImpl` class, which takes a list of attribute names and a second list of attribute values. LOVs will be fired after the attribute values are populated. So, if a foreign key has a composite alternate key, it will still work since the LOV fires after all the alternate key attributes are set.

When an attribute from a reference entity object is included in a view object, the attribute is read-only. However, if there is an LOV defined on the attribute, then the attribute is updateable in the sense that the attribute value can be used to drive the LOV.

The following are several scenarios and the steps you must perform for each of them.

**5.3.1.5.1 Scenario 1**

Single attribute Foreign Key and single attribute Alternate Key (Example: PersonVO has DeptId and Dname. DeptId is the foreign key ID, and Dname is the foreign alternate key).

An LOV should be defined on the alternate key attribute, with the foreign key ID as a derived attribute.

1. Create PersonVO based on PersonEO and a reference DeptEO. The foreign alternate key (Dname) from the reference EO is included in the PersonVO.
2. Define the LOV view object (DeptVVO).
3. Define a view accessor on PersonEO/PersonVO pointing to DeptVVO.
4. Define an LOV on the foreign alternate key (Dname) using the above view accessor, and configure the LOV to populate the foreign key ID (DeptId) as the derived attribute.

**5.3.1.5.2 Scenario 2**

Single attribute Foreign Key and multiple attribute Alternate Key (Example: PersonVO has OrganizationId as foreign key id, and OrganizationName+BusinessGroupName as the composite alternate key).

Each alternate key attribute needs to have an LOV defined, and each LOV should have all the alternate key attributes as the driving attribute and the foreign key ID as the derived attribute.

1. Create PersonVO based on PersonEO and a reference OrganizationEO and another reference BusinessGroupEO. The foreign alternate key (OrganizationName and BusinessGroupName) from the reference entity objects are included in the PersonVO.
2. Define the LOV view object (OrganizationVVO).
3. Define a view accessor on PersonEO/PersonVO pointing to OrganizationVVO.
4. Define an LOV on each of the foreign alternate key attributes (OrganizationName and BusinessGroupName) using the above view accessor, and configure the LOV to populate the foreign key ID (OrganizationId) as a derived attribute.
5. Modify `PersonVO.xml` to make the LOVs driven by all the foreign alternate key attributes. For example:
5.3.1.5.3 Scenario 3

Single attribute Foreign Key and multiple attribute Alternate Key and one of the alternate key attributes is another foreign key (Example: PersonVO has BirthOfCountry as foreign key id, and BirthOfCity as another foreign key ID. BirthOfCity has BirthOfCountry+CityName as a composite alternate key).

The first foreign key (BirthOfCountry) must be resolved first, either based on #1 or #2. Then the second alternate key should filter by the first alternate).

1. Create PersonVO based on PersonEO and a reference EO CountryEO and another reference EO CityEO. CountryName from CountryEO and CityName from CityEO should be included. CityName should be listed after CountryName in the PersonVO.

2. Define an LOV view object based on CountryEO.

3. Define an LOV view object based on CityEO. Define a view criteria to filter by CountryId.

4. Define a view accessor on PersonEO/PersonVO pointing to CountryVVO.

5. Define a view accessor on PersonEO/PersonVO pointing to CityVVO, and bind CountryId to BirthOfCountry.

6. Define an LOV on CountryName using CountryVVO view accessor, with BirthOfCountry as a derived attribute from CountryId from CountryVVO.

7. Define an LOV on CityName using CityVVO view accessor, with BirthOfCity as a derived attribute from CityId from CityVVO.

5.3.1.5.4 Scenario 4

Composite foreign key.

Each foreign key ID will be dealt with individually. For example, the foreign key id is OrgId+SourceId, then orgId and SourceId should be resolved based on solution in #1 or #2 or #3 separately. Then a validator must be defined to make sure combination of OrgId and SourceId is valid. This has the assumption that each individual attribute are a primary key itself.
5.3.2 Overview of Creating Services

The service interface is generated from an Oracle ADF application module. Go to the Service Interface tab in the Application Module wizard to expose the service interface for an application module.

5.3.2.1 What You May Need to Know About Design Time

This section discusses what happens during design time with application modules and the runtime object.

No Service Data Object in the Application Module

The custom methods in the Application Module do not take Data Object or a Data Object list as parameters. Instead, the Application Module's custom methods take ViewRowImpl/AttributeList or a list of ViewRowImpl/AttributeList as parameters. When you publish these methods in the service interface, ADF Business Components service will convert these to Data Object or a list of Data Object in the service interface during design time, and then performs conversion between Data Object and ViewRowImpl/AttributeList during runtime.

Return Object

The informational messages (and warnings) are reported as part of the return object. ADF Business Components generates appropriate wrappers as the return objects when necessary, and the wrappers contain the actual method return as well as the informational messages. Table 5-1 lists some examples:

<table>
<thead>
<tr>
<th>Table 5-1</th>
<th>Return Objects Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Operation without Informational Messages (Support Warnings Flag is off)</strong></td>
<td><strong>Operation with Informational Messages (Support Warnings Flag is on)</strong></td>
</tr>
<tr>
<td>List&lt;Person&gt; processPerson(String op, List&lt;Person&gt; persons, ProcessControl ctrl)</td>
<td>PersonResult processPerson(String op, List&lt;Person&gt; persons, ProcessControl ctrl)</td>
</tr>
<tr>
<td>Person createPerson(Person person)</td>
<td>PersonResult createPerson(Person person)</td>
</tr>
<tr>
<td>void terminateEmployee(BigDecimal empId)</td>
<td>ServiceMessage terminateEmployee(BigDecimal empId)</td>
</tr>
<tr>
<td>String getApplicationName(BigDecimal applicationId)</td>
<td>StringResult getApplicationName(BigDecimal applicationId)</td>
</tr>
</tbody>
</table>

If the Support Warnings design time flag is off, no informational messages are returned (the first column in the above table). If the flag is on (the second column in the above table), then:
• `getXXX` returns the original object
• `create, update, mergeXXX, findXXX, and processXXX` returns the wrapper object that contains a list of the original object and a list of information messages
• `deleteXXX` returns the informational message
• Each custom method can be configured individually about whether to return informational messages

Note:
Note that `ServiceMessage` is created by the framework based on the warning or errors thrown during service execution. When you develop your service, you don’t throw `ServiceMessage`. Instead, you throw `JboException` or `ApplcoreException`. See About Defining Service Exceptions and Information for information about error and informational messages.

Find Operation
When you include the standard operations in a service interface, you can enable the generic find operation, or select a view criteria and expose a find operation that uses the view criteria.

Oracle ADF has a default list of operators (such as =, contains, and so on) that can be used in the find operation. You can enable more custom operators or disable an operator in the default list.

5.3.3 How to Generate Synchronous and Asynchronous Service Methods

Each service method can be exposed as both synchronous version and asynchronous version.

To generate synchronous and asynchronous services methods, do the following:

1. Go to the Application Module Design Time wizard.
2. Choose the Service Interface tab.
3. Choose the Service Interface category. See Figure 5-2.

Figure 5-2 Edit Service Interface Dialog

4. Select Generate Asynchronous Web Service Methods. Click OK.
5. Save your changes.
5.3.4 About Exposing Flexfields

Flexfields are used as extension points. If your object has a flexfield defined, then you might want to consider including the flexfield in the service interface so that your customer can utilize flexfields through web service.

See the following sections for information about how to expose the flexfields in a service interface:

- Publishing Descriptive Flexfields as Web Services
- Making Extensible Flexfields Available to Web Services
- How to Publish Key Flexfield Application Modules as Web Services

5.3.5 About Enabling Security

You need to enable security on your service to make sure only the granted people can invoke the service.

5.3.5.1 Authentication

An authentication policy determines how the caller proves its identity. A simple case could be user name and a password in clear text, which is simple but not very secure. Or a token can be generated by an identity provider and then passed to the service provider.

See Securing Web Services Use Cases for information about the different authentication policies supported. Once a security policy is chosen, you need to add it as an annotation in your xxxServiceImpl class. For example:

```java
@SecurityPolicy( { "oracle/wss11_saml_or_username_token_with_message_protection_service_policy"})
@CallbackSecurityPolicy("oracle/wss11_saml_token_with_message_protection_client_policy")
```

5.3.5.2 Enable Authorization

Authorization determines who can invoke a service operation. To enable authorization, do the following:

1. Add ServicePermissionCheckInterceptor as one of the EJB interceptors in your xxxServiceImpl class. The result will be similar to this:

```java
@Interceptors({ServiceContextInterceptor.class,
               ServicePermissionCheckInterceptor.class})
```

**Note:**

ADF Business Components service is implemented with EJB, and the EJB interceptor is used here to authorize before any service operation can be invoked.

2. Grant access to the service operations to desired roles in jazn-data.xml:
   a. Add a web service resource type.
Navigate to Application Resources >Descriptors/META-INF/jazn-data.xml, click the Resource Grants tab, and then add a new resource type. This is shown in Figure 5-3.

**Figure 5-3  Create Resource Type**

![Create Resource Type](image)

The following xml snippet in **jazn-data.xml** will be generated:

```xml
<resource-type>
    <name>WebserviceResourceType</name>
    <display-name>WebserviceResourceType</display-name>
    <description>Webservice Resource</description>
    <matcher-class>oracle.wsm.security.WSFunctionPermission</matcher-class>
    <actions-delimiter>,'</actions-delimiter>
    <actions>invoke</actions>
</resource-type>
```

b. Add a resource, as shown in Figure 5-4.

- Add the privilege and specify which role can access the resource defined above.
- Click Entitlement Grants in **jazn-data.xml**.
- Create a new entitlement or edit an existing one.
- Add the newly created resource.
- Choose the action.
c. Add JpsInterceptor in ejb-jar.xml.

Note:

In the previous steps, the authorization is granted to the application roles. The application roles are computed using JpsInterceptor. Without the JpsInterceptor setting in ejb-jar.xml, the application roles won’t be computed and authorization will fail.

- Navigate to service project > Application Sources > META-INF.ejb-jar.xml and add the following code snippet:

```xml
<ejb-jar...>
  ...
  <interceptors>
    <interceptor>
      <interceptor-class>oracle.security.jps.ee.ejb.JpsInterceptor</interceptor-class>
      <env-entry>
        <env-entry-name>application.name</env-entry-name>
        <env-entry-type>java.lang.String</env-entry-type>
        <env-entry-value><application_name></env-entry-value>
        <injection-target>
          <injection-target-class>oracle.security.jps.ee.ejb.JpsInterceptor</injection-target-class>
          <injection-target-name>application_name</injection-target-name>
        </injection-target>
      </env-entry>
    </interceptor>
  </interceptors>
  ...
</ejb-jar>
Replace *application_name* with your application name, which is defined under `policy-store/applications/application/name` element in your `jazn-data.xml`.

d. Specify the applicationid in `weblogic-application.xml`:

```xml
<application-param>
  <param-name>jps.policystore.applicationid</param-name>
  <param-value><application_name></param-value>
</application-param>
```

Replace *application_name* with the application name you used in Step 2.c.

### 5.3.6 About Using the Java Transaction API

Java Transaction API (JTA) is used to handle ADF Business Components transactions.

#### 5.3.6.1 Specify the Data Source

JTA manages distributed transactions across multiple resources. However, the resources must participate in global transaction to be part of the JTA. All the ADF Business Components services must use ApplicationServiceDBDS as the data source, and must not use ApplicationDBDS. ApplicationDBDS doesn't participate global transaction. ApplicationServiceDBDS supports global transaction using Oracle WebLogic Server Emulate Two-Phase Commit emulation.

To specify the data source used by the service, do the following:

1. Click the **Configuration** tab of Application Module wizard, then choose the configuration with type "SI", as shown in Figure 5-5.
2. Select the appropriate data source for your service.

If you don’t see the data source in the dropdown list, you will need to create the database connection first.

3. Navigate to `ejb-jar.xml` and add ApplicationServiceDBDS as the `resource-ref`:

   ```xml
   <ejb-jar ...>
   <enterprise-beans>
   <session>
   <ejb-name>.....</ejb-name>
   <resource-ref>
   <res-ref-name>jdbc/ApplicationDBDS</res-ref-name>
   <res-type>javax.sql.DataSource</res-type>
   <res-auth>Container</res-auth>
   </resource-ref>
   <resource-ref>
   <res-ref-name>jdbc/ApplicationServiceDBDS</res-ref-name>
   <res-type>javax.sql.DataSource</res-type>
   <res-auth>Container</res-auth>
   </resource-ref>
   ....
   ```

Related Links
The following document provides additional information related to subjects discussed in this section:

- For more information about data sources, see "JDBC Data Source Transaction Options" in Administering JDBC Data Sources for Oracle WebLogic Server.

### 5.3.6.2 About Transaction Attributes

ADF Business Components service is implemented as a stateless session bean. Transaction attributes can be specified at the class level or method level, and these attributes determine the JTA behavior.

### 5.3.7 About Deploying Services

The service can be deployed to an integrated or standalone Oracle WebLogic Server service.

To deploy to an integrated Oracle WebLogic Server, right-click the xxxServiceImpl class, and then select **Run** from the context menu.

To deploy to the standalone Oracle WebLogic Server, create a Business Component Service Interface profile. The window is shown in

**Figure 5-6  Create Deployment Profile**

![Create Deployment Profile](image)

This profile is a compound profile and includes two child profiles: Common (JAR File) and MiddleTier (EJB Jar File). The Common profile includes the service interface. This .jar file will be required by the consumer when the consumer uses ServiceFactory to invoke the service. (See Using Service Factory for more information.) The MiddleTier .jar file contains the service implementation. MiddleTier profile has a dependency on the common profile.

Include the MiddleTier profile in your application’s ear profile (Ear Deployment Profile >Application Assembly) so that the service will be included in the application ear file. Do not include the Common profile in the ear profile’s Application Assembly. The Common profile will be included via profile dependency.

**Note:**

Do not include connections.xml in the common .jar file. There cannot be more than one connections.xml in one application, otherwise whatever shows up first in the classpath will be picked up, and this one might not be the right one. To prevent that, the service interface common profile cannot include connections.xml.
5.3.7.1 About Service Context Root

When the service is deployed, the service can be accessed through a service end point URL, such as http://localhost:7101/mycontext/MyService. Note that the context root of a service is defined at the service project (Project properties >Java EE Application > Java EE Web Context Root, shown in Figure 5-7).

Figure 5-7 Project Properties

5.3.8 About Testing Services

You can test the service only after it has been deployed.

5.3.8.1 Understanding What to Test

An ADF Business Components service is based on ADF Business Components. These components should have been already tested with junit, such as the defaulting and validation logic, queries, and other business logic. One commonly asked question is: Why should I test my service since my underlying application module/view object has been tested already? The ADF Business Components service testing is not a duplicate test of the ADF Business Components testing. Instead, the focus should be on the service layer and what is not covered in the ADF Business Components testing.

Areas that are not covered in the ADF Business Components testing are the following:

- Security: ADF Business Components service is authenticated and authorized at the service layer, not the business components object layer.

- Exception: The exception will come back as soap fault instead of JboException. You should check it has all the details that you expected.

However, you do not need to repeat the tests that have been done in ADF Business Components testing:
• Data security is defined at the business components object layer, so you do not need to repeat the data security testing at service layer.

• You need to test each service method, but you do not need to test all permutations of inbound parameters. Therefore, you probably just need to test a success case and a couple of typical failure cases for each of your service methods.

The following is a list of items that you should validate during the service testing (both the synchronous and asynchronous versions).

• If the service is running
• If the service is responding within a reasonable amount time
• For all service methods:
  – Successful cases: Verify the response. You might also want to do a query after a post to check the data is indeed committed.
  – Failure cases: Verify the fault comes back, and with the expected content.
  – Security: Test both authentication and authorization.

5.3.8.2 Understanding How to Test

For ad-hoc testing, use the browser test page, HTTP Analyzer, or Oracle Enterprise Manager.

• Web service test page

In a web browser, access the service endpoint URL. The service end point URL follows the format of http://host:port/context_root/service_name. When the service is deployed to integrated Oracle WebLogic Server, the service endpoint URL is printed out in the Oracle JDeveloper console.

After you open up the web service test page, you can enter the inbound parameters from the UI and submit the service request. For the service that is secured with GPA, you will need to expand the WS-Security element, and provide the user name and password there. For service that is secured with oracle/wss11_saml_or_username_token_with_message_protection_service_policy, you cannot invoke it from the web service test page.

• HTTP Analyzer

You can access HTTP Analyzer within Oracle JDeveloper by navigating to Tools > HTTP Analyzer, and then clicking on "Create New Request". You then can follow the UI to invoke a service. Similarly, it doesn’t really handle service secured with oracle/wss11_saml_or_username_token_with_message_protection_service_policy.

• Oracle Enterprise Manager

Use Oracle Enterprise Manager to invoke a service. For more information, see the Oracle Fusion Middleware Administering Web Services guide.

For unit testing, you should write unit test code.

http://globaldc.oracle.com/perl/twiki/view/FusionSharedTools/ApplicationsTestFramework
5.4 About Invoking Services

All ADF Business Components services have both synchronous and asynchronous versions for the same method. The service consumer must decide which version of the service method to use.

A service method can be invoked synchronously if all of the following conditions are met:

- The invoked method takes a simple payload, such as a single document or a fixed number of documents (including parent and children).
- The invoked method is expected to be finished in real time and takes no longer than a few seconds.

The consumer should consider invoking the method asynchronously if one of the following conditions is met:

- The method takes a flexible number of documents, such as a list of service data objects.
- The method may be long-running.

5.4.1 Invoking a Synchronous Service

You can invoke a synchronous service using service factory, service-based entity object and view object, Java API for XML Web Services (JAX-WS) client, or from SOA.

5.4.1.1 Using Service Factory

If you need to invoke a synchronous service from a Java client, including an ADF Business Components component, UI, or Oracle Enterprise Scheduler, then using a service factory is recommended.

- It is easier to write a service client using service factory than using JAX-WS.
- The consumer side doesn’t need to generate or maintain the source control of the proxy code.
- If the service is co-located, the service invocation is more performant because it does not invoke XML serialization and de-serialization.

To invoke a service using service factory, do the following:

1. Identify the common.jar file provided by the service provider team.
   Service factory requires that the service interface common.jar file be in the classpath of the consumer. (See About Deploying Services for information service deployment.) Subsequently, the consumer needs to identify the name of the common.jar file first from the provider team, and include it in the classpath.

2. Retrieve the service endpoint information from the connections.xml file.
   Service Factory can be used to invoke a service via Remote Method Invocation (RMI) or Simple Object Access Protocol (SOAP). RMI can only be used within one domain, for example, receivables application invokes a service deployed in ledger application. RMI cannot be used across an Oracle WebLogic Server domain due to security constraint. For the cross Oracle WebLogic Server domain service
invocation, such as when receivables invokes a service hosted in Oracle Fusion Human Capital Management, SOAP must be used.

Service Factory uses ADF Connection Architecture to retrieve the service endpoint information from connections.xml. It creates a dynamic proxy to the remote service using the designated protocol in connections.xml.

The following is a sample entry in connections.xml using RMI:

```xml
<Reference name="{http://xmlns.oracle.com/apps/sample/dtsvc/}WorkerService" className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
        <StringRefAddr addrType="serviceInterfaceName">
            <Contents>oracle.apps.sample.dtsvc.WorkerService</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceEndpointProvider">
            <Contents>ADFBC</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="jndiName">
            <Contents>WorkerServiceBean#oracle.apps.sample.dtsvc.WorkerService</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceSchemaName">
            <Contents>WorkerService.xsd</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceSchemaLocation">
            <Contents>oracle/apps/sample/dtsvc/</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="jndiFactoryInitial">
            <Contents>weblogic.jndi.WLInitialContextFactory</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="jndiProviderURL">
            <Contents>t3://localhost:7202</Contents>
        </StringRefAddr>
    </RefAddresses>
</Reference>
```

In the example, the serviceEndpointProvider is ADF Business Components, which indicates that it is a RMI invocation.

You need to replace the code in bold with the service that you plan to invoke. Table 5-2 lists the appropriate values:

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference/name</td>
<td>The service qualified name. It follows the format of {&lt;targetNamespace&gt;}&lt;name&gt;. The targetNamespace and name can be found in the wsdl file of the service to be invoked.</td>
<td>({<a href="http://xmlns.oracle.com/apps/sample/dtsvc/%7DWorkerService">http://xmlns.oracle.com/apps/sample/dtsvc/}WorkerService</a>)</td>
</tr>
</tbody>
</table>
### Table 5-2 (Cont.) Service Property Values

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Value</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>serviceInterfaceName</td>
<td>This is the service interface name. You can get it from the service interface java class in the common .jar file.</td>
<td>oracle.apps.sample.dtsvc.WorkerService</td>
</tr>
<tr>
<td>jndiName</td>
<td>This is the EJB bean name. ADF Business Components service is implemented by EJB. It follows the format of &lt;ServiceName&gt;Bean#&lt;ServiceInterfaceName&gt;</td>
<td>WorkerServiceBean#oracle.apps.sample.dtsvc.WorkerService</td>
</tr>
<tr>
<td>serviceSchemaName</td>
<td>The ADF Business Components service always has a schema file generated for the service. It follows the format of &lt;ServiceName&gt;.xsd.</td>
<td>WorkerService.xsd</td>
</tr>
<tr>
<td>serviceSchemaLocation</td>
<td>The path of the service schema. It is basically the service interface package path.</td>
<td>oracle/apps/sample/dtsvc/</td>
</tr>
<tr>
<td>jndiProviderUrl</td>
<td>The host name and port number where the service is deployed. This is not needed during design time, but apparently required during runtime. This value will be tokenized during packaging and be &quot;replaced&quot; with the server URL during provisioning.</td>
<td>t3://localhost:7202</td>
</tr>
</tbody>
</table>

For a SOAP invocation, two entries are required in connections.xml: a ServiceFactory entry and a web service connection entry. The first entry is very similar to the RMI entry except for the following:

- The serviceEndPointProvider value is SOAP.
- A webServiceConnectionName entry, which is used to link to the second entry, is included. That is, the value of webServiceConnectionName must be the name of the second connection.
- There are no jndiFactoryInitial or jndiProviderUrl properties.
Example 5-2 and Example 5-3 show the two entries in connections.xml using SOAP.

The second connection is a standard web service connection. To generate the web service connection entry in connections.xml, do the following:

a. Create a web service proxy. (See "Creating a Web Service Proxy Class to Programatically Access the Service" in Developing Fusion Web Applications with Oracle Application Development Framework, for more information.)

b. Create a web service connection. (See "How to Create a New Web Service Connection" in Developing Fusion Web Applications with Oracle Application Development Framework for more information.)

c. Remove the web service proxy code.

---

**Note:**

The connections.xml file in source control contains the concrete web service endpoint URL. This URL can be used for testing in integrated Oracle WebLogic Server. As part of the ear generation, these URLs will be looked up and replaced with abstract tokens. These tokens will again be replaced when application is installed at customer site with the customer's server URL.

There is a ServiceRepository.xml file that contains the list of services produced by Oracle Fusion Applications. The token replacement during ear generation uses this file to look up and replace the concrete URL with abstract tokens.

---

3. Secure the service.

For RMI invocation, only identity propagation is supported. Subsequently, there is nothing more that you need or can configure.

For SOAP invocation, remember that the client-side security policy is driven by the server-side security policy, and the client-side policy must match the server-side policy. In most cases, you can utilize GPA, which uses wss10_saml_token_client_policy and propagates the identity from the caller to the service. The following cases require the use of LPA:

- The service is protected by message protection policy. Usually, this service is an external service that can be accessed outside the Fusion Applications firewall. In this case, you will need to add the security policy in the web service connection of the connections.xml. For example:

```xml
<Reference name="HrServiceConnection" 
className="oracle.adf.model.connection.webservice.impl.WebServiceConnectionImpl" xmlns="">
  <Factory 
className="oracle.adf.model.connection.webservice.api.WebServiceConnectionFactory"/>
  <RefAddresses>
    <XmlRefAddr addrType="WebServiceConnection"> 
      <Contents> 
        <wsconnection ......> 
          <model ......>
            <service ......>
              <port ......> 
                <policy-references xmlns="http://oracle.com/af"/>
```
The following are the client-side policies that you can use to invoke a service protected by message protection policy:

- wss_username_token_over_ssl_client_policy
- wss_saml_token_bearer_over_ssl_client_policy
- wss11_username_token_with_message_protection_client_policy
- wss11_saml_token_with_message_protection_client_policy
- wss_http_token_over_ssl_client_policy

- Identity switch is required. If the service must be invoked with a different user (usually using appid), then you need to specify LPA:

```xml
<call-properties xmlns="http://oracle.com/adf">
  <call-property id="csf-key" xmlns=""/>
</call-properties>

<soap ...

Replace system1-key with the csf-key holding the application identity user name and password required by the user case. The actual application identities and their corresponding csf-keys are centrally provided.

If the service is protected by message protection policy, then use oracle/wss11_username_token_with_message_protection_client_policy.

4. Invoke the service.

Write your client code to invoke the service. For example,

```java
OrganizationService svc = (OrganizationService) ServiceFactory.getServiceProxy(OrganizationService.NAME);
DataFactory datafactory = ServiceFactory.getDataFactory(svc);
List orgs = new ArrayList(2);
Org org1 = (Org) datafactory.create(Org.class);
org1.setOrgName("OrgName");
org1.setName("TranslatedName");
org1.setDescription("Your org Description"); //... and set more attributes
orgs.add(org1);
svc.processOrganization("Merge", orgs, null);
```
SDOs based on polymorphic view objects don’t have Java classes generated. To create these SDOs, use the generic DataObject class:

```java
import commonj.sdo.DataObject;

DataObject emp = datafactory.create("http://xmlns.oracle.com/apps/fooService/", "Bar");
emp.set("Empno", new Long(8080));
emp.set("Ename", "Oliver");
emp.set("Job", "MANAGER");
```

**Note:**
You will need to add "BC4J Service Client" library to your client project.

5. Perform runtime control for the query.

The standard `find` method API provides control over the query behavior.

- **Partial Attribute**
  By default, the find operation returns all the attributes including all details. When you only need some attributes, you should set the partial attributes on the `FindCriteria` parameter of the `find` method. Do this in the following situations:
  - SDO contains LOB, which can be very expensive to retrieve and transfer.
  - SDO contains details that are not needed, such as translations. Querying detail is also expensive.

**Note:**
The standard `getXXX` function doesn’t take a `FindCriteria`, so this function always returns everything. You should use `findXXX` to trim your return attributes.

The following example shows how to set the partial attributes to include only `Dname`, `Loc` from `Dept`, and exclude `Empno` from `Emp`:

```java
FindCriteria fc = (FindCriteria)datafactory.create(FindCriteria.class);
List l = new ArrayList();
l.add("Dname");
l.add("Loc");
l.add("Emp");
fc.setFindAttribute(l);
List cfcl = new ArrayList();
ChildFindCriteria cfc =
    (ChildFindCriteria)datafactory.create(ChildFindCriteria.class);
cfc.setChildAttrName("Emp");
List cl = new ArrayList();
cl.add("Empno");
cfc.setFindAttribute(cl);
cfc.setExcludeAttribute(true);
cfcl.add(cfc);
f.setChildFindCriteria(cfcl);
DeptResult res = svc.findDept(fc, null);
```
The following example shows how to set the partial attributes to exclude PurchaseOrderLine from PurchaseOrder:

```java
FindCriteria fc = (FindCriteria)datafactory.create(FindCriteria.class);
List l = new ArrayList();
fc.setExcludeAttribute(true);
l.add("PurchaseOrderLine");
fcc.setFindAttribute(l);
PurchaseOrderResult res = svc.findPurchaseOrder(fc, null);
```

**Filter**

The find API allows you to specify the WHERE clause of your query. The WHERE clause can be set on any level of the SDO. The following example shows how to retrieve only the departments with a department number greater than 10 and child employees whose names start with 'A':

```java
FindCriteria fc = (FindCriteria)datafactory.create(FindCriteria.class);
//create the view criteria item
List value = new ArrayList();
value.add(new Integer(10));
ViewCriteriaItem vci = (ViewCriteriaItem)datafactory.create(ViewCriteriaItem.class);
vci.setValue(value);
vci.setAttribute("Deptno");
List<ViewCriteriaItem> items = new ArrayList(1);
items.add(vci);
//create view criteria row
ViewCriteriaRow vcr = (ViewCriteriaRow)
datafactory.create(ViewCriteriaRow.class);
vcr.setItem(items);
//create the view criteria
List group = new ArrayList();
group.add(vcr);
ViewCriteria vc = (ViewCriteria)datafactory.create(ViewCriteria.class);
vc.setGroup(group);
//set filter
fc.setFilter(vc);
```

List cfc1 = new ArrayList();
//create the child find criteria
ChildFindCriteria cfc = (ChildFindCriteria)datafactory.create(ChildFindCriteria.class);
cfc.setChildAttrName("Emp");
//create the child view criteira
ViewCriteria cvc = (ViewCriteria)datafactory.create(ViewCriteria.class);
cfc.setFilter(cvc);
//create the view criteria item
List cvalue = new ArrayList();
cvalue.add("A%");
ViewCriteriaItem cvci = (ViewCriteriaItem)datafactory.create(ViewCriteriaItem.class);
cvci.setValue(value);
cvci.setAttribute("Dname");
cvci.setOperator("LIKE");
List<ViewCriteriaItem> citems = new ArrayList(1);
citems.add(cvci);
//create child view criteria row
ViewCriteriaRow cvcr = (ViewCriteriaRow)
datafactory.create(ViewCriteriaRow.class);
cvcr.setItem(citems);
List cgroup = new ArrayList();
cgroup.add(cvcr);
cvc.setGroup(cgroup);

DeptResult dres = svc.findDept(fc, null);

You also can query the parents with the children that satisfy certain criteria. For example, use the following to retrieve the departments with employees whose salary is greater than $10,000:

//create the view criteria item on the employees
List nvalue = new ArrayList();
nvalue.add(new BigDecimal(10000));
ViewCriteriaItem nvci = (ViewCriteriaItem)datafactory.create(ViewCriteriaItem.class);
vci.setValue(nvalue);
vci.setAttribute("Salary");
vci.setOperation(">");
List<ViewCriteriaItem> nitems = new ArrayList(1);
nitems.add(nvci);
//create view criteria row
ViewCriteriaRow nvcr = (ViewCriteriaRow)
datafactory.create(ViewCriteriaRow.class);
nvcr.setItem(nitems);
//create the nested view criteria
List ngroup = new ArrayList();
group.add(nvcr);
ViewCriteria nvc = (ViewCriteria)datafactory.create(ViewCriteria.class);
nvc.setGroup(ngroup);

//create the view criteria item on the department
ViewCriteriaItem vci = (ViewCriteriaItem)datafactory.create(ViewCriteriaItem.class);
vci.setAttribute("Emp");
vci.setNested(nvc);
List<ViewCriteriaItem> items = new ArrayList(1);
items.add(vci);
//create view criteria row
ViewCriteriaRow vcr = (ViewCriteriaRow)
datafactory.create(ViewCriteriaRow.class);
vcr.setItem(items);
//create view criteria on department
ViewCriteria vc = (ViewCriteria)datafactory.create(ViewCriteria.class);
group = new ArrayList()
group.add(vcr);
vcr.setGroup(group);
//set filter
FindCriteria fc = (FindCriteria)datafactory.create(FindCriteria.class);
fcs.setFilter(vc);

DeptResult dres = svc.findDept(fc, null);

• Paging

If you know that your query might return a large amount of data, you should make multiple service invocations, and use FetchSize and FetchIndex to control the amount of the data that you want to retrieve.

The following example shows how to retrieve only the second employee and the employee's department:

FindCriteria fc = (FindCriteria)datafactory.create(FindCriteria.class);
List cfcl = new ArrayList();
ChildFindCriteria cfc =
(ChildFindCriteria)datafactory.create(ChildFindCriteria.class);
cfc.setChildAttrName("Emp");
cfc.setFetchStart(1);
cfc.setFetchSize(1);
cfcl.add(cfc);
fc.setChildFindCriteria(cfcl);
DeptResult dres = svc.findDept(fc, null);

6. Perform runtime control for post.

The process API provides a bulk operation that can handle multiple SDOs simultaneously.

- Return mode
  Use ReturnMode on ProcessControl to specify whether you want to return a list of SDOs with all attributes, or with primary key attributes, or return nothing in processXXX method. You should only return the primary key or nothing, unless you need the full SDO returned for further processing.

- Exception return mode
  When an error occurs, the returned error message can contain just the primary key of the failure SDO, or all attributes of the failure SDO. You can specify which behavior you want using the ExceptionReturnMode attribute of the ProcessControl parameter in the processXXX method.

- Partial failure
  For bulk load, it often makes more sense to commit as many records as possible, and report the problematic data. By default, either all SDOs go through or none goes through in processXXX method. However, you can call setPartialFailureAllowed on ProcessControl and pass that ProcessControl to the processXXX method. This will turn on the partial failure feature.

7. Handle exceptions.

All ADF Business Components services throw ServiceException. ServiceException contains FaultInfo, and FaultInfo stores the error messages. (Based on JAX-WS 2.0, exceptions thrown from service operations need to have a property named "FaultInfo").

@WebFault(name="ServiceErrorMessage", targetNamespace="http://xmlns.oracle.com/adf/svc/errors/",
          faultBean="#oracle.jbo.service.errors.ServiceErrorMessage")
public class ServiceException extends RuntimeException
{
    public ServiceErrorMessage getFaultInfo()...
    public void setFaultInfo(ServiceErrorMessage faultInfo)...
}

The ServiceErrorMessage can contain one or more child error messages, and each child can contain its own children. Basically it is a tree hierarchy. You could consider ServiceErrorMessage as a counterpart of the JboException at the service layer.
The ServiceErrorMessage has a few subclasses including ServiceAttrValErrorMessage, ServiceRowValErrorMessage, and ServiceDMLErrorMessage. Their counterparts in ADF Business Components are AttrValException, RowValException, and DMLException. Note that ServiceException is an Exception, but all other classes above including ServiceMessage, ServiceErrorMessage, ServiceAttrValErrorMessage, ServiceRowValErrorMessage, and ServiceDMLErrorMessage are not exceptions.

As the consumer of a service, if you call a service and need to take different actions based on the exceptions, you might need to walk through the message tree structure.

The following is a simple example that walks through the message and converts to JboException:

```java
public static RuntimeException convertServiceException(ServiceException ex) {
    return convertToRuntimeException(ex.getFaultInfo());
}

public static RuntimeException convertToRuntimeException(ServiceMessage svcMsg) {
    RuntimeException ret = null;
    String msgStr = svcMsg.getMessage();
    List d = svcMsg.getDetail();
    Throwable[] details = null;
    if(d != null && !d.isEmpty()) {
        details = new Throwable[d.size()];
        for(int i=0; i<d.size(); i++) {
            Object obj = d.get(i);
            if(obj instanceof ServiceMessage)
                details[i] = convertToRuntimeException((ServiceMessage)obj));
            else if(obj instanceof Throwable)
                details[i] = (Throwable) obj;
            else
                details[i] = new Throwable(obj.toString());
        }
    }
    if(svcMsg instanceof ServiceErrorMessage) {
        JboException ex = new JboException(msgStr);
        ex.setExceptions(details);
        ret = ex;
    }
    else {
        JboWarning w = new JboWarning(msgStr);
        w.setDetails(details);
        ret = w;
    }
    return ret;
}
```

8. Create informational messages.

Informational messages are not exceptions, and won’t stop service from committing the current transaction. However, these information might be very useful to the clients. For example, you might want to know when there is not enough money in your checking account and have the system automatically transfer some from your savings account.
The service provides decides whether a service will possibly return informational messages or not. If so, the informational message will be part of the return, as shown below:

```java
public EmployeeResult processEmployee(String changeOperation,
    List<Employee> employee,
    ProcessControl processControl) throws
ServiceException;
```

As the service consumer, you should retrieve the informational message from the return and perform appropriate actions such as converting it to `JboException` and displaying it in the UI. An example might be:

```java
ProcessControl pc = (ProcessControl)datafactory.create(ProcessControl.class);
pc.setPartialFailureAllowed(true);
EmployeeResult res = svc.processEmployee("Create", list, pc);
if(res != null) {
    List msgs = res.getMessage();
    if(svcMsgs != null && !svcMsgs.isEmpty()) {
        Exception[] exceptions = new Exception[svcMsgs.size()];
        for(int i=0; i<exceptions.length; i++)
            exceptions[i] = convertToRuntimeException(svcMsgs.get(i));
        JboException ex = new JboException(....., exceptions); //create a bundled
            exception with the service errors as detail
        }
    throw ex;
}
```

For more information about invoking a service using service factory, see
Synchronously Invoking an ADF Business Components Service from an Application.

Example 5-2 Entry 1

```xml
<Reference name="[http://xmlns.oracle.com/apps/sample/hrService/]HrService" 
className="oracle.jbo.client.svc.Service" xmlns="">
    <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
    <RefAddresses>
        <StringRefAddr addrType="serviceInterfaceName">
            <Contents>oracle.apps.sample.hrService.HrService</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceEndpointProvider">
            <Contents>SOAP</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="webServiceConnectionName">
            <Contents>HrServiceConnection</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceSchemaName">
            <Contents>HrService.xsd</Contents>
        </StringRefAddr>
        <StringRefAddr addrType="serviceSchemaLocation">
            <Contents>oracle/apps/sample/hrService/</Contents>
        </StringRefAddr>
    </RefAddresses>
</Reference>
```
Example 5-3 Entry 2

<Reference name="HrServiceConnection"
className="oracle.adf.model.connection.webservice.impl.WebServiceConnectionImpl"
xmlns=""">
  <Factory
className="oracle.adf.model.connection.webservice.api.WebServiceConnectionFactory"/>
  <RefAddresses>
    <XmlRefAddr addrType="WebServiceConnection">
      <Contents>
        <wsconnection description="http://rws65094fwks:7202/MySampleSvc/HrService?WSDL" service="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
          <model name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService" xmlns="http://oracle.com/ws/model">
            <service name="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
              <port name="HrServiceSoapHttpPort" binding="{http://xmlns.oracle.com/apps/sample/hrService/}HrServiceSoapHttp" portType="{http://xmlns.oracle.com/apps/sample/hrService/}HrService">
                <policy-references xmlns="http://oracle.com/adf">
                  <policy-reference category="security" uri="oracle/wss11_saml_token_with_message_protection_client_policy" enabled="true" id="oracle/wss11_saml_token_with_message_protection_client_policy" xmlns=""/>
                </policy-references>
                <soap addressUrl="http://rws65094fwks:7202/MySampleSvc/HrService" xmlns="http://schemas.xmlsoap.org/wsdl/soap/"/>
              </port>
            </service>
          </model>
        </wsconnection>
      </Contents>
    </XmlRefAddr>
  </RefAddresses>
</Reference>

5.4.1.2 About Using Service-Based Entity Object and View Object

When you need to work with output from a service in the format of an ADF Business Components component, such as rendering the data in a UI table or creating a view link to it, then you should consider using service-based entity objects and view objects.

For more information about working with data from a remote ADF Business Components service, see Working with Data from a Remote ADF Business Components Service.

5.4.1.3 About Using the JAX-WS Client

Generally, you should not use JAX-WS or Java APIs for XML-Based Remote Procedure Call (JAX-RPC) client to access an ADF Business Components service. You can use JAX-WS to access BPEL or a third-party service.

See "Creating a Web Service Proxy Class to Programmatically Access the Service" in Developing Fusion Web Applications with Oracle Application Development Framework for information about how to create a JAX-WS proxy.

In summary, you need to do the following

- Create the JAX-WS proxy client.
  
  Navigate to New Gallery > Business Tier > Web Services > Web Service Proxy to create proxy clients.
Note:

Perform the steps as listed when using the web proxy wizard to create the JAX-WS proxy client, with the following exceptions:

- At the "Select Web Service Description" screen, deselect the **Copy WSDL into Project** checkbox.
- At the "Specify Default Mapping Options" screen, deselect the **Generate As Async** checkbox.

For the proxy code, it is recommended to have proxy in the package structure, such as `oracle.apps.<lbaTop>.<lbaCore>.<xyzService>.proxy`. It is recommended to generate the type in the "type" subpackage.

- Create a web service connection.

  The proxy generated in previous step hard coded the service end point. To externalize the end point to `connections.xml`, you need to right-click on the generated proxy object, and choose **Create Web Service Connection**. In the Edit Web Service Connection dialog, provide the appropriate information, but don’t provide any value for user name or password.

  This will create a connection entry in `connections.xml`. This entry can be changed during deployment.

  You can attach different security policies in the `connections.xml` file, as described in the Using Service Factory.

- Develop client-side code. For example:

  ```java
  ADFContext aDFContext = ADFContext.getCurrent();
  WebServiceConnection con = (WebServiceConnection)aDFContext.getConnectionsContext().lookup("YourConnectionNameHere");
  YourService svc = con.getJaxWSPort(YourService.class);
  //invoke your service below
  ```

5.4.1.4 About Using SOA

When you invoke an ADF Business Components service from BPEL, you usually use the asynchronous version unless you are sure the service satisfies the synchronous invocation condition that was discussed previously.

For more information, see Common Service Use Cases and Design Patterns.
Caution:
Web Service data control is an anti-pattern that is not allowed. Instead, build ADF Business Components components and bind these components to the UI. If you are trying to invoke an ADF Business Components service, then you can use service-enabled entity objects and view objects.

For more information, see the "How to Service-Enable Individual View Objects" section in the "Integrating Service-Enabled Application Modules" chapter of the *Developing Fusion Web Applications with Oracle Application Development Framework*.

PL/SQL calling Web Service is also an anti-pattern that is not allowed because of security issues.

5.4.2 Understanding How to Invoke an Asynchronous Service

In general, BPEL is used to invoke an asynchronous service. If you need to invoke an ADF Business Components service from Java that does not meet the synchronous condition, then you must use one of the following alternate approaches:

**Asynchronous Invocation (The caller-side must wait for response)**

- **If the caller is ADF UI**: The UI must raise an event, which is received by a mediator. The mediator invokes a BPEL process that invokes the asynchronous service and then invokes a second service after receiving the callback. The second service is responsible for notifying the UI side that the process has completed and then the UI uses the Active Data Service to refresh the UI.

  For information about how to enable the UI for dynamic update via Active Data Service, see Implementing an Asynchronous Service Initiation with Dynamic UI Update.

- **If the caller is Oracle Enterprise Scheduler Service**: Oracle Enterprise Scheduler Service Java Jobs can invoke the asynchronous service via a JAX-WS proxy, but must set the asynchronous callback service to that of the Oracle Enterprise Scheduler Service Web Service. During this time, the Job’s status will be Running and when the asynchronous callback comes through the Oracle Enterprise Scheduler Service Web Service callback port, the Job code will be notified with the response and can Complete.

**One-way Invocation (The caller fires and forgets)**

- The caller must raise an event, which is received by a mediator. The mediator invokes a BPEL process, which invokes the asynchronous service. A callback is received from the asynchronous service.
Define Defaulting and Derivation Logic

This chapter describes how to define your defaulting and derivation logic, how to use Groovy (a Java-like scripting language), and how to use Oracle Application Development Framework (Oracle ADF) validators and convertor hints instead of using messages.

This chapter includes the following sections:

- Understanding Entity Object Defaulting and Derivation Logic
- About Using Groovy Scripting Language
- Using Validators and Convertor Hints

6.1 Understanding Entity Object Defaulting and Derivation Logic

Defaulting logic means assigning attribute values when a row or entity object is first created or refreshed. (The logic is not re-applied when the entity object is changed.) Defaulting is achieved either declaratively in the default field of the attribute or programmatically by adding code to the EOImpl.

Derivation logic means assigning attribute values when some other attributes have changed. Derivation is achieved either declaratively in the default field of the transient attribute or by using a validator, or programmatically by adding code to the EOImpl.

Figure 6-1, illustrates what you need to consider when determining whether to implement defaulting or derivation logic.
When implementing defaulting or derivation logic, you should also consider the following factors:

- Always assign a valid value to an attribute.
  You should know what the valid values are and there is no reason why you would want to assign invalid values. The end users do not set these values and would have no idea why they would be invalid.
- Always use `initDefaultExpressionAttribute` for calculations that cross containerships. Use `initDefault` for literal or statically computed values.
- Instead of writing code in one of the triggering points during validation or the posting cycle to achieve derivation logic, you can use a method validator or an expression validator.
  When you want the derivation logic to be customizable, the validator approach is preferable. When using this approach the validation result should always be `true` because this is not really a validation logic. You should also make sure that the attribute avoids an infinite loop due to validation.
- You can call either `setAttribute(setter)` or `populateAttribute` to assign the default or derived value to an attribute.
  When you call `setAttribute(setter)`, the logic in the setter is fired and the validation logic is also executed. This does not happen when you call `populateAttribute`.
  In most cases, using `populateAttribute` is sufficient because you should always assign a valid value and therefore do not need to fire validation logic.
However, you may want to call the setter if there is additional logic such as cascading derivation in the setter.

**Tip:**
When you call `setAttribute(setter)` make sure that you do not cause an infinite loop. This may happen due to the attribute and the entity becoming invalid and causing the validation logic to refire.

- You can call `beforeCommit` as well as `setAttribute(setter), validateEntity, and prepareForDML` if your derivation logic involves multiple entities that are not composite.

  For composite object, you can just put your logic either in `validateEntity` or `prepareForDML` of the parent `EOImpl`.

- Oracle ADF handles the propagation of the foreign key ID if there is an association between two entities. This is where the association is defined from the parent entity object to the child entity object, and when the detail entity object is created from the association accessor of the parent entity object. For example:

  ```java
  Row parentRow = ....RowIterator ri = (RowIterator)parentRow.getAttribute("<childEOAccessorName>";
  Row childRow = ri.createRow();
  ```

  Similarly, if there is a view link between two view objects, the framework also handles the foreign key propagation when the child view row is created via the view link accessor of the parent view row.

- List of Values (LOVs) also perform derivation. However, this is at the view object level and you should not place business logic (including derivation) at this level.

  A LOV should only be used on the user interface (UI) to show a list of valid values or as a service to derive the foreign key ID based on the foreign alternate key.

### 6.2 About Using Groovy Scripting Language

ADF Business Components now provide integrated support for Groovy (a Java-like scripting language), which is dynamically compiled and evaluated at run-time. Because it is dynamically compiled, Groovy script can be stored inline in the XML and is eligible for customization. Groovy also supports object access via dot-separated notation, which means you can now use syntax such as `empno` instead of `getAttribute(EMPNO)`.

You can embed Groovy script into various declarative areas, including:

- **Validation** - Use a Groovy script that returns `true` or `false` for declarative validation.
- **Validation Error Messages** - Use Groovy expressions to substitute the tokens in the error message.
- **Bind Variables** - Define the value for a bind variable using a Groovy script expression.
- **View Accessor Bind Variable Values** - Supply bind variable values in a view accessor using Groovy script.
- **Attributes** - Base a transient attribute on a Groovy script. (Currently no UI support).
• **Attribute Default Values** - Define a default value expression on an attribute using Groovy script. (Currently no UI support).

• **Variables** - Define a variable on an entity whose value is computed using Groovy script. (Currently no UI support).

### 6.2.1 About Keywords and Available Names

As with the original Script implementation, the current object is passed into the script as "this" object. Therefore, to refer to any attribute inside the current object simply use the attribute name. For example, in an attribute or validator expression for an entity, to refer to an attribute named `Ename`, the script may say `return Ename`.

There is one top-level reserved name, `adf`, which is used to get to objects that the framework makes available to the Groovy script. Currently, these objects are:

- `ADFContext` (`adf.context`)
- Object on which the expression is being applied (`adf.object`)
- Error handler that lets the validator generate exceptions or warnings (`adf.error`)

All other names come from the context in which the script is applied:

- **Variable** - gets the Variable, `structureDef` in which it is contained via `getStructureDef` method on `VariableImpl`.

- **Transient Attribute** - gets the Entity or ViewRow as its context so that all attributes in the entity are accessible by name. Any method on the entity may be invoked by directly calling the entity method as if you were writing a method in the entity subclass.

  **Tip:**
  
  Only public methods on the entity are available to call.

  You also need to call the method using the "object" keyword, such as `adf.object.createUnqualifiedRowSet()`. The "object" keyword is equivalent to the "this" keyword in Java. Without it, in transient expressions, the method is assumed to exist on the script object itself, which it does not.

- **Validator** - gets the Validator context `JboValidatorContext` merged with the Entity on which the validator is applied. This is done so that you can use:
  - `newValue` and `oldValue` to get to the values being validated
  - `sourceRow` to get to the Entity or ViewRow on which the validator is applied
  - All attribute names in the Entity or ViewRow as top-level names

### 6.2.2 About Scripting Logic

Groovy scripting logic is similar to Expression Language (EL) because you can use a "." separated path to get to a value inside an object. Note that if a Java object implements Map, only the map lookup is performed instead of the bean style property lookup. However, for Maps that extend `JboAbstractMap` you get the same EL behavior, which is map first followed by bean lookup. This is due to the implementation of `get` in `JboAbstractMap`. 
Consider the following information:

- All Java methods, language constructs, and Groovy language constructs are available in the script.

- Aggregates are implemented by calling `sum(expr)`, `count(expr)`, or `avg(expr)` on a `RowSet` object where `expr` can be any Groovy expression that returns a numeric value or number domain.

- The `defaultRowSet` reserved keyword has been removed. The method `EntityImpl.createUnqualifiedRowSet()` replaces `EntityImpl.getDefaultRowSet()` and can be accessed like any other public method in `EntityImpl`.

- Use the return keyword as you would in Java to return a value. That is, unless it is a single-line expression where the return is assumed to be the result of the expression itself. For example, "Sal + Comm" or "Sal > 0".

- Do not use `{}` to surround the entire script because Groovy interprets `{` to be the beginning of a Closure object.

- Any object that implements `oracle.jbo.Row`, `oracle.jbo.RowSet`, or `oracle.jbo.ExprValueSupplier` is wrapped into a Groovy `Expando` object. This is to extend the properties available for those objects to beyond the bean properties and also as a way to avoid introspection for most used names.

### 6.2.3 Groovy Expression Examples

The following are some examples of Groovy.

#### 6.2.3.1 Querying Based on the Current Locale

Instead of using the following SQL to achieve this:

```sql
SELECT C.ISO_COUNTRY_CODE, C.COUNTRY_NAME
FROM COUNTRY_CODES C
WHERE LANGUAGE = SYS_CONTEXT('USERENV', 'LANG')
ORDER BY C.COUNTRY_NAME
```

Create a bind variable and base its default value on the `adf.context.locale.language` expression:

#### 6.2.3.2 Error Message Tokens

To get the attribute new value and label:

```text
Error Message: ProductID_Rule_0

Errors: Product Identifier (prod) is an invalid value for (label).

Error Message Expressions

<table>
<thead>
<tr>
<th>Index</th>
<th>Expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>prod</td>
<td>newVal</td>
</tr>
<tr>
<td>label</td>
<td>source.ProductID Label</td>
</tr>
</tbody>
</table>
```
The above example uses the following two Groovy expressions:

```
newValue  // This works because an attribute level validator has been created.
source.hints.ProductId.label

and

source.structureDef.name" of type "+sourceFullName
```

### 6.2.3.3 Expression Validators

**Example 6-1** is an example of an Object graph, custom error, and a warning:

**Example 6-2** is an example of how to average a collection.

**Example 6-3** is an example of a built-in or custom method call on the sourceObject of this validator (sourceObject being the Entity on which this validator is being run). isAttributeChanged(String) is a public method on the EntityImpl.

**Example 6-4** is an example of getting to oldValue / newValue of an attribute on which this validator is applied:

**Example 6-5** is an example of accessing the Entity state relative to the database and relative to the last post operation.

Use adf.object.entityState or adf.object.postState.

To get the old value of an attribute (this works in the context of a transient Entity Object attribute):

**Example 6-6** is an example of the WHRxle construct as well as calling an accessor (Emp):

**Example 6-1    Object Graph, Custom Error, and a Warning**

```
if (EmpSal >= 5000)
{
  // If EmpSal is greater than a property value set on the custom
  // properties on the root AM
  // raise a custom exception else raise a custom warning
  if (EmpSal > source.DBTransaction.rootApplicationModule.propertiesMap.salHigh)
  {
    adf.error.raise("ExcGreaterThanApplicationLimit");
  }
  else
  {
    adf.error.warn("WarnGreaterThan5000");
  }
}
else if (EmpSal <= 1000)
{
  adf.error.raise("ExcTooLow");
}
return true;
```

**Example 6-2    Averaging a Collection**

```
attribute Number EmpSal : SAL
|
expressionValidator(expression =
  "newValue <= source.createUnqualifiedRowSet().avg("EmpSal") * 1.2");
```
Example 6-3  Built-in or Custom method Call

```java
if (source.isAttributeChanged("EmpSal") || source.isAttributeChanged("EmpComm")) {
    return true;
} return false;
```

Example 6-4  Getting to Old Value and New Value of an Attribute

```java
return (oldValue == null || newValue < oldValue * 1.2);
```

Example 6-5  Getting the Old Value of a Transient Entity Object Attribute

```java
index = object.getStructureDef().getAttributeIndexOf("Salary");
return object.getAttribute(index, oracle.jbo.server.EntityImpl.ORIGINAL_VERSION);
```

Example 6-6  While Construct and Calling an Accessor

```java
emps = Emp;
boolean alreadyfound = false;
emps.reset();
while (emps.hasNext()) {
    if (emps.next().Job == "CLERK") {
        if (alreadyfound) {
            adfError.raise("alreadyfound");
        }
        alreadyfound = true;
    }
}
return true;
```

6.2.3.4 Attribute Defaulting and Calculation

Example 6-7, Example 6-8, and Example 6-9 are examples of a simple transient attribute, how to sum or count a collection, and how to create a complex calculation of a bind variable value.

Example 6-10 is of an entity-attribute XML fragment where a transient expression is used to provide a default value for that attribute. This expression is evaluated before the protected `create` method of the entity is called. Example 6-11 is an example of an attribute defaulting with a transient attribute calculation expression.

Example 6-7  Simple Transient Attribute

```java
attribute transient Integer YearSal {
    transientexpression = "EmpSal * 12";
}
```

Example 6-8  Sum or Count a Collection

```java
attribute transient Integer TotalSal {
    transientexpression = "object.createUnqualifiedRowSet().sum("EmpSal")";
}
attribute transient Integer TotalCount {
    transientexpression = "object.createUnqualifiedRowSet().count("EmpSal")";
}
```
Example 6-9  Complex Calculation of a Bind Variable Value

```groovy
query EmpView
{
  entity Emp EmpUsage \*;
  where "SAL > :avgSal"
  orderby "1"
  bindingstyle "OracleName"

  variables
  {
    Double avgSal
    kind (where)
    {
      transientexpression
      {
        totSal = 0;
        empCount =0;
        fullVO = structureDef.getApplicationModule().createViewObject("_AvgSal",
          testp.kava.VO7.si33mt.EmpAllView);
        empCount = 0;
        while (fullVO.hasNext())
        {
          row = fullVO.next();
          sal = row.EmpSal; totalSal = totSal + sal; empCount = empCount + 1;
        }
        fullVO.remove();
        if (empCount > 0)
        {
          return (int)(totalSal / empCount);
        }
        else
        {
          return 0;
        }
      }
    }
  }
}
```

Example 6-10  Attribute Value Defaulting

```groovy
<Attribute
  Name="EmpComm"
  ColumnName="COMM"
  Type="oracle.jbo.domain.Number"
  ColumnType="NUMBER"
  SQLType="NUMERIC"
  TableName="EMP">
  <TransientExpression><![CDATA[
    if (EmpSal == null)
    {
      return null;
    }
    if (EmpDeptNum == null)
    {
      return 0;
    }
    if (EmpDeptNum > 40)
    {
      return 500;
    }
  ]]>]]>
</Attribute>
```
Example 6-11    Attribute Defaulting with a Transient Attribute Calculation Expression

```xml
<ViewAttribute
    Name="Total"
    IsUpdateable="false"
    AttrLoad="Each"
    IsSelected="false"
    IsPersistent="false"
    PrecisionRule="false"
    Type="java.lang.String"
    ColumnType="VARCHAR2"
    AliasName="View_ATTR"
    SQLType="VARCHAR">
    <TransientExpression>
        <![CDATA[
        if (Sal != null && Comm != null)
        {
            return Sal + Comm;
        }
        else
        {
            return Sal;
        }
        ]]>
    </TransientExpression>
</ViewAttribute>
```

6.2.4 About Defining Expressions at Design Time

An expression for an attribute can be defined using either the Attribute Editor (see Figure 6-2) or the Expression Editor (see Figure 6-3).

Figure 6-2    Entity Object — Attribute Editor

If you want to define a string literal instead of a Groovy expression, select Literal as the Value Type and enter the value as "My Literal Value".
To access the Expression Editor, click the **Edit** button located next to the **Value** text box.

**Note:**

Recalculate Expression is used to determine whether the expression must be recalculated as changes are made during run-time. The Recalculate option is hidden for persistent attributes. This is because Persistent attribute values are always updateable by the user and therefore, the expression of the attribute should only act as a default expression so recalculation is not necessary. For non-persistent attributes, the user can choose to always recalculate, never recalculate, or decide if recalculation is needed based on the evaluation of the recalculate expression.

6.3 Using Oracle ADF Validators and Convertor Hints

An Oracle ADF validator is appropriate for simple data entry errors that the user can easily correct immediately, on the same UI. In some situations, you should consider using these validators or converter hints instead of using messages.

However, errors such as those that require you to leave the UI to fix, require administrator intervention or an incident report to be filed, should be a Message Dictionary message instead.

**Caution:**

Oracle ADF validators and converter hints can only be used with messages stored in the Strings resource bundles. They cannot be used for messages stored in the Message Dictionary.
To ensure that the user has supplied the correct sort of value or a value in a valid range, input fields can be validated using an Oracle ADF validator. Values may be converted by a converter, for example to convert a string of input characters into a value of some other type such as a date or color.

To validate or convert an input value, you add the input component to the page and then add a validator or converter to that field. Each validator and converter has some messages associated with it:

- **Hints** to display to the user details of what sort of value they need to enter.
- **Error messages** to display if the user enters an invalid value.

For an individual component, you can explain the error to a user in terms relating to that specific input component by overriding the hints or by adding or overriding a detailed error message.

### 6.3.1 Override an Oracle ADF Validator or Converter Message with New Text

You may not see any messages when you follow these steps to select the Application Messages resource bundle:

1. In JDeveloper, select the af validator tag in the UI page.
2. Open the Property Inspector.
3. Select the message attribute.
4. Select the text resource.
5. Select the Application Messages resource bundle.

In this case, you may need to override the default message from the validator. To do so, follow the procedure in "Displaying Hints and Error Messages for Validation and Conversion" in the *Developing Web User Interfaces with Oracle ADF Faces*. 

Define Defaulting and Derivation Logic 6-11
7

Define and Use Message Dictionary Messages

This chapter provides a detailed overview of Message Dictionary messages and discusses how to use them in Oracle Fusion Applications.

This chapter contains the following sections:

- Introduction to Message Dictionary Messages
- Understanding Message Types
- Understanding Message Content
- About Grouping Messages by Category and Severity
- Understanding Incidents and Diagnostic Logs with Message Dictionary
- Using Message Dictionary Messages in Oracle ADF Java Code
- About Associating Message Dictionary Messages with Oracle ADF Validation Rules
- About Raising Error Messages Programmatically in PL/SQL
- About Diagnosing Generic System Error Messages
- About Formatting Message Dictionary Messages for Display in Oracle ADF Applications
- About Integrating Messages Task Flows into

7.1 Introduction to Message Dictionary Messages

The Message Dictionary stores translatable Error and Warning messages for Oracle Fusion Applications. These types of messages provide information about business rule errors, such as missing or incorrect data, and how to resolve them, warn about the consequences of intended actions, inform about the status of an application, page, or business object, and indicate that processes and actions are performing or are completed.

All other messages, except the strings and messages that need to be accessed by C or PL/SQL programs, can be stored in resource bundles (resource bundles only can be accessed by Java programs). The strings and messages that need to be accessed by C or PL/SQL programs can be stored in the Message Dictionary as Information and UI String messages. Resource bundles also can be used to store job output or log file messages for Oracle Enterprise Scheduler (ESS) Java programs and test output messages for Java Diagnostic Testing Framework tests.
The Error, Warning, Information, and UI String message types are described in detail in Understanding Message Types.

**Note:**
Because the messages are stored in Application Object Library FND_MESSAGE_% tables, these types of messages are sometimes referred to as FND messages.

By using the messages in the Message Dictionary, you can define standard messages that you can use in all your applications, provide consistency for messages within and across all your applications, define flexible messages, and change or translate the text of your messages without regenerating or recompiling your application code.

**Note:**
Non-message strings, such as labels, report headings, and message fragments are typically stored in Oracle Application Development Framework (ADF) resource bundles. However, because Oracle ADF resource bundles only can be accessed by Java programs, you can store these types of strings in the Message Dictionary if C or PL/SQL programs need to access them.

Message Dictionary messages are composed of several message components, which enable you to author different messages for different audiences, such as the end user or help desk personnel, and for different conditions, such as when an action must be performed before the user can continue. For more information, see About Message Components.

Messages can be displayed to the UI and written to logs and incidents. Incidents are collections of information about system errors for which end users might require assistance from help desk personnel. An incident contains information about the state of the system at the time the problem occurred. Help desk personnel can use incidents to supply internal support personnel or Oracle support personnel with information about problems that need to be resolved.

You can set up a Message Dictionary message such that an incident and an associated log entry are created automatically. This is referred to as implicit incident creation. For information on how to generate incidents and log entries from Message Dictionary messages, see Understanding Incidents and Diagnostic Logs with Message Dictionary. For information about how incidents and log entries can be used, see the following chapters in the Administrator’s Guide:

- "Troubleshooting Oracle Fusion Applications Using Incidents, Logs, QuickTrace, and Diagnostic Tests"
- "Understanding Oracle Fusion Applications Incidents and Log Files"

### 7.1.1 Creating and Reviewing Messages

Use the Manage Messages task in the application’s Setup and Maintenance work area to create and maintain Message Dictionary messages. For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.

Oracle Fusion applications provide some common messages in the Message Dictionary with message names that begin with FND_CMN_. Do not modify or replace these messages.

7.2 Understanding Message Types

All messages must have a message type. The message type indicates which message components are applicable, determines whether implicit logging and incident creation occurs, and determines the logging level if the message is logged. For information about message components, see About Message Components. For information about logging and incident creation, see Understanding Incidents and Diagnostic Logs with Message Dictionary. For information about the standard log settings and about logging profile options see the "Default System Log Settings" section in the Administrator’s Guide.

The valid values for message types are fixed and therefore cannot be customized.

**Error Messages**

Use the Error message type for messages that alert the user to data inaccuracies when completing a field, submitting or saving a page, navigating from the page, or when an application or unknown failure occurs. An error message requires attention or correction before the user can continue with their task.

**Warning Messages**

Use the Warning message type for messages that inform users about an application condition or a situation that might require their decision before they can continue. Warning messages describe the reason for the warning and potential consequence of the selected or intended action by users. The warning requires the attention of users, and a standard question might be posed with the warning, or the warning can take the form of a statement.

**Information Messages**

The Information message type is intended for the following types of strings:

- Non-error and non-warning text and messages that are accessed by C or PL/SQL code or are used by Oracle Enterprise Scheduler (ESS) statuses or log files. Because C and PL/SQL programs cannot access Java-based resource bundles, these strings must be stored in the Message Dictionary.

  An example of such a string is the completion text for an ESS program or process.

- Strings that are written to ESS job log or output files, as shown in Figure 7-1. These strings are used to provide a text record about request processing execution, failures, and so on.
Figure 7-1  Processing Request Output Log File

Strings for information level diagnostic logging.

You can choose to use the Information message type in one of two ways:

- Use the Information message type for all non-error and non-warning messages.
- Use the Information message type to store complete messages and use the UI String message type, which is described in the next section, to store fragments. For example, if your messages must pass a review process, you might choose to use the UI String message type for messages that do not need to conform to message guidelines.

UI String Messages

Use the UI String message type for non-error and non-warning strings that need to be stored in the Message Dictionary but are not complete messages, such as prompts, titles, or translated fragments. For example, "Upload Process Parameters." Note that UI String messages are processed exactly as Information messages.

7.3 Understanding Message Content

Messages must have unique message names. Although message numbers are not required, you should use them for error messages to make it easier for users to identify the precise error in logs, and to enable users to find more information about the error in various help sources, including those in different languages.

Translation Notes are required for many messages. You are encouraged to write a complete description that describes the use case for all of your messages.

Different combinations of information are provided depending on the nature of the message and the intended audience, such as end user or help desk personnel. This is accomplished using message components.

Tokens are also an important part of messages. Tokens are the programmatic parts of message text that allow the substitution of other text or values into the message at runtime. They are used as a way to include variable information in the same message. In Oracle Fusion Applications, tokens are used for dates, numbers, and specific types of text.

7.3.1 About Message Names

Every message must have a unique name. You should include a unique prefix that makes it easier to find your custom messages and that helps to avoid name conflicts with non-custom messages. Names that begin with FND_CMN_ are reserved for Oracle Fusion Applications common messages.
7.3.2 About Message Numbers

A unique and persistent message number can be included with each message. The message range 10,000,000 to 10,999,999 has been allocated for customers' own messages.

When displayed, the number takes the format of (Application Shortname-Number). For example:

Descriptive flexfields do not support unit of measure enabled segments. (FND-2774)

If the message does not have a message number, the formatted number is not displayed.

7.3.3 About Translation Notes

A translation note (message context) is a descriptive note to developers, translators, and message customizers describing where and how the message is used. The note is not translated and cannot contain tokens. It is never displayed to end users or help desk personnel. The maximum size of this field is 4000 characters.

7.3.4 About Message Components

Message components enable you to define messages for different audiences and address additional information needs. All messages require a value for the Message Text component, the other components are optional.

Both help desk personnel and end users see the message text and cause components. For the other components, you can use the Message Mode profile option, which has a code of FND_MESSAGE_MODE, to configure whether the end user or help desk personnel (or both) see each type of component. For example, you can set the profile option to enable a particular user to see the Message Admin Detail component. You use the Manage Administrator Profile Values task in the Oracle Fusion Applications Setup and Maintenance work area to set the Message Mode profile option to Administrator or User at the Site, Product, and User levels.

Note:

Incidents contain all message components. For more information about incidents, see Understanding Incidents and Diagnostic Logs with Message Dictionary.

Message Text

Message text is required. This is a brief statement of the operation attempted and the problem that consequently occurred, or information that the user needs to know. The text is included in log and incident creation messages. The content in this field is customizable and the text can contain tokens. The maximum field size for messages stored in the Message Dictionary is 240 characters.

If the entire message, after tokens have been substituted, exceeds the 240 character limit, the message text is truncated. To allow room for expansion in other languages, the US version of any translated column should be no more than 70% of the maximum possible length. (For example, 240 character short text becomes 160 characters in US).
Caution:

Tokens are just values substituted into the message at runtime. Tokens must come from a translated source unless it is a number, seed data, technical information, or a name that is not translated. Extreme care must be taken with tokens when substituting translatable data. You must make sure that it makes sense at run-time.

For more information, see About Tokens.

The text appears in bold at the top of the message window region. In addition, the message text is the only message component displayed in limited real estate UIs, such as pagers and phones. Therefore, the message text should be clear enough to be understood alone when used in this context. This is a required field for all message types.

Message User Detail

This is a more detailed explanation of the problem identified in the short message and its audience is the end user. This field includes the details that are appropriate and meaningful to the end user and should outline exactly what caused the error to occur. For example, in the case of an incident creation error message, this field can be used to provide the user with information about the type of error. The content in this field is customizable and the text can contain numerous tokens. The maximum field size is 4000 characters.

The text appears in normal letters just below the short message. This field is optional.

Message Admin Detail

Message Admin Detail text provides a detailed explanation of the problem identified in the short message. This information is never seen by the end user. This field is for technical details that are not meaningful to an end user. The content in this field is customizable and the text can contain numerous tokens. The maximum field size is 4000 characters.

For errors that require help desk processing, you must use this component, and it must contain information to assist the help desk personnel to resolve the issue, such as the technical background.

Message Cause

The message cause text provides for the end user a concise explanation of why the error occurred. It lists reasons for the failure such as a prerequisite that is not met, incorrect inputs, an anticipated but incorrect action, and so on. The content in this field is customizable and the text can contain numerous tokens. The maximum field size is 4000 characters.

The word Cause (in bold) is prefixed automatically to the beginning of the cause text. This text appears below the user detail, if available. This component is optional and is only applicable for messages of type Error and Warning. The components Cause and User Action are mutually required, meaning if you enter one you must enter both.

Message User Action

This component is for messages that state the action that the user must perform to continue and complete the task. This is intended for and seen by the end user. The content in this field is customizable and the text can contain tokens. The maximum field size is 4000 characters.
The word **Action** (in bold) is prefixed automatically to the beginning of the action text. This text appears below the cause text. This component is optional and is only applicable for messages of type Error and Warning.

**Message Admin Action**

Message Admin Action messages state the action that must be performed to resolve the error condition. This should contain the information that the help desk personnel requires to resolve the error. The content in this component is customizable and the text can contain tokens. The maximum field size is 4000 characters.

The word **Action**: (in bold) is prefixed automatically to the beginning of the action text. This text appears below the cause text and is only applicable for messages of type Error and Warning. This component is only enabled if Cause and User Action are entered. If this is NULL and User Action information is available, then the User Action information is displayed.

### 7.3.5 About Tokens

Tokens are identified in the message text by their use of curly braces and all uppercase letters. The token values are supplied at runtime by the code that raises the message. For example, the following token `{MATURITY_DATE}` is replaced by a date when the user receives the error message on their screen:

"Enter an effective date that is the same as or later than `{MATURITY_DATE}`".

Becomes:

"Enter an effective date that is the same as or later than 25-APR-2010".

---

**Note:**

Tokens have the following requirements:

- They **must** use curly braces and all uppercase letters.
- They generally must be text, not numbers.
- They cannot contain any spaces, but can contain an underscore.

### 7.4 About Grouping Messages by Category and Severity

You can group messages by category and by severity. These groups are used to define logging and incident policies. Otherwise, category and severity have no affect. Category and severity values do not appear in logging entries, incidents, or the UI.

- **Message Category**: This is a more generic attribute that is used to group messages. For example, all the messages that relate to one functionality, such as a concurrent program, can be grouped together into one category.

  This is an optional field, but it must have a value to enable implicit incident creation.

  Message categories are defined by lookups (of type extensible) so that they can be customized by an administrator. The maximum size of this field is 30 characters. The following are seeded values, but you can add more if required.
**Product** - This value refers to issues concerning product functionality, setup and maintenance. Such messages are typically intended for functional administrators or product super users.

**System** - This value refers to issues concerning the system, database, technology stack, and so on. Such messages are typically intended for technical users such as system administrators or database administrators.

**Security** - This value refers to issues concerning permissions, access, compliance, passwords, and so on. Such messages are typically intended for security administrators.

- **Message Severity**: This grouping attribute is not generic and indicates the severity of the message. You must set the severity to *High* to enable implicit incident creation for the message. The following are seeded values, but you can add more if required.
  - *High* - This value can be used for serious messages that completely stop the progress of an important business process or affect a large user community, and require help-desk personnel’s attention.
  - *Medium* - This value can be used for less severe and more isolated messages.
  - *Low* - This value can be used when it is unclear whether the message has a negative impact on end users or business processes.

Valid message severity values are defined by lookups (of type extensible) so that they can be customized by an administrator. The maximum size of this field is 30 characters.

### 7.5 Understanding Incidents and Diagnostic Logs with Message Dictionary

Incidents are collections of information about system errors for which the customer might require assistance from help desk personnel. An incident contains information about the state of the system at the time the problem occurred. Help desk personnel can monitor and respond to incidents and send them to Oracle if further assistance is necessary. For information about how incidents and log entries can be used, see the following chapters in the *Administrator’s Guide*:

- "Troubleshooting Oracle Fusion Applications Using Incidents, Logs, QuickTrace, and Diagnostic Tests"
- "Understanding Oracle Fusion Applications Incidents and Log Files"

Implicit incident creation and logging occurs when the Message Dictionary message is retrieved in PL/SQL and C code, or when it is formatted in Java code, and the message has the following settings:

- Logging enabled (*loggable_alertable*): *Y*
- Message type: *ERROR*
- Message Category: not null
- Message severity: For incident creation, it must be *HIGH*. For logging, it must be not null.
Note:

Implicit incident creation occurs when logging is enabled. Implicit logging only occurs if the SEVERE log level or more logging are enabled.

Use the Message Dictionary APIs to retrieve a Message Dictionary message. The PL/SQL methods are in the FND_MESSAGE package and the Java methods are in the messageService package. For C code, use the methods in the fddutl package.

For Java code, implicit incident creation and logging occurs for qualifying messages when the appropriate formatting methods are called from the MessageServiceAMImpl class and the MessageServiceAM interface, such as the getUserXML(), formatMap(), formatUserTextMap(), or formatAdminTextMap() methods. See the MessageServiceAM and MessageServiceImpl Javadoc for information about which methods to call for implicit logging. Implicit incident creation and logging also occur when exceptions are created using the ApplcoreException classes.

When implicit logging and incident creation occurs, additional information is appended to the message, as follows:

- If the incident is created in the middle tier using Java, a Business Process Execution Language (BPEL) process, or C, the following note is appended:
  
  An application error has occurred. Your help desk was notified. For more information your help desk may refer to incident {incident number}, {application server name}, {application server domain name}.

- If the incident is created in the database tier using PL/SQL, the following note is appended:

  An application error has occurred. Your help desk was notified. For more information your help desk may refer to incident {incident number_SID}, {database server name}, {database instance name}.

To learn more about the information that is included with incidents and associated log entries, see the How the Diagnostic Framework Works section in the Administering Oracle Fusion Middleware.

### 7.6 Using Message Dictionary Messages in Oracle ADF Java Code

You can use messages in the Message Dictionary in Java code to raise exceptions using Oracle Fusion Middleware Extensions for Applications exception classes. You can also retrieve the message text programmatically.

#### 7.6.1 About Raising Exceptions Using Oracle Fusion Middleware Extensions for Applications Exception Classes

Exceptions from messages in the Message Dictionary should be raised using wrapper classes that are provided in the oracle.apps.fnd.applcore.message package. Wrappers that are provided correspond to the most commonly used Oracle ADF exception classes. See Table 7-1.
Table 7-1  Oracle ADF Exception Classes vs. Message Dictionary Classes

<table>
<thead>
<tr>
<th>Exception Class</th>
<th>Message Dictionary Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>JboException</td>
<td>oracle.apps.fnd.applcore.messages.ApplcoreException</td>
</tr>
<tr>
<td>RowValException</td>
<td>oracle.apps.fnd.applcore.messages.ApplcoreRowValException</td>
</tr>
<tr>
<td>AttrValException</td>
<td>oracle.apps.fnd.applcore.messages.ApplcoreAttrValException</td>
</tr>
</tbody>
</table>

In each of these classes, the message name is expected to be passed in the format: 
APP_NAME:::MESSAGE_NAME (application short name, followed by exactly 3 colons, followed by the message name). For example: "FND:::FND_CMN_POSITIVE".

Message tokens passed to most Message Dictionary Java APIs are expected to be supplied as Map<String, Object> or as an array of alternating String/Object pairs. With either style, the String is the name of the message token and the following Object is an object representing the value of that token. The type of the Object is expected to match the type of the token as shown in Table 7-2.

Table 7-2  Message Tokens and Data Types

<table>
<thead>
<tr>
<th>Token Type</th>
<th>Token Value Object Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>NUMBER</td>
<td>java.math.BigDecimal</td>
</tr>
<tr>
<td>DATE</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>

Exceptions that are raised using JboException or one of its subclasses with a severity level of SEVERITY_ERROR, which is the default, or any java.lang.RuntimeException, are treated as system errors, and the following occurs:

- The error message is replaced with a generic message, such as "An application error occurred. Your help desk was informed"
- An incident is created for the system error
- A stack trace is written to the log file for the system error

If you do not want the JboException to be treated as a system error, do one of the following:

- Convert the exception type to ApplcoreException
- Set the severity level to other than SEVERITY_ERROR, such as SEVERITY_RECOVERABLE_ERROR.

Tip:
If you need to see the original error message, you can run the application with the -DAFERROR_MODE=debug parameter, as described in About Diagnosing Generic System Error Messages.
You should use the wrappers wherever possible. However, it is possible to also use
native Oracle ADF exceptions directly if there isn’t a wrapper that exactly suits your
needs. If you do this, you must specify the FndMapResourceBundle resource bundle
class, and format tokens correctly.

Example 7-1 shows sample code that raises an ApplcoreException exception.
Example 7-2 shows an example of raising ApplcoreRowValException exception.
Use of the ApplcoreAttrValException exception is shown in Example 7-3.
Example 7-4 illustrates how to throw a native JBOException.

To display more than one application error message, such as a series of validation
error messages, bundle the exceptions and throw the bundled exceptions, as shown in
Example 7-5. The exceptions in the bundle must be only application error exceptions,
such as ApplcoreException, JboException with
SEVERITY_RECOVERABLE_ERROR, or ValidationException. If you include any
system error exceptions in the bundle, such as NullPointerException, the bundle
is processed as a system error. For example, if you include a RuntimeException
exception in the bundle, you cannot display the bundled exception error messages in a
popup dialog, because it will be processed as a system error.

Example 7-1 ApplcoreException

```java
import oracle.apps.fnd.applcore.messages.ApplcoreException;

// Construct and populate HashMap with token values
Map<String, Object> tokens = new HashMap<String, Object>();
tokens.put("TEXT_TOKEN", "text token value");
tokens.put("NUMBER_TOKEN", new BigDecimal(10));
Calendar cal = Calendar.getInstance();
cal.set(1999, Calendar.DECEMBER, 31, 0, 0, 0);
tokens.put("DATE_TOKEN", new Timestamp(cal.getTimeInMillis()));
throw new ApplcoreException("MYAPP:::MY_MESSAGE_NAME", tokens);
```

Example 7-2 ApplcoreRowValException

```java
import oracle.apps.fnd.applcore.messages.ApplcoreRowValException;

// Construct and populate HashMap with token values
Map<String, Object> tokens = new HashMap<String, Object>();
tokens.put("TEXT_TOKEN", "text token value");
tokens.put("NUMBER_TOKEN", new BigDecimal(10));
Calendar cal = Calendar.getInstance();
cal.set(1999, Calendar.DECEMBER, 31, 0, 0, 0);
tokens.put("DATE_TOKEN", new Timestamp(cal.getTimeInMillis()));
Key key = new Key(new Object[]{"Primary Key"});
ApplcoreRowValException ex = new ApplcoreRowValException("MYAPP:::MY_MESSAGE_NAME", "MyEODefName", key, tokens);
```

Example 7-3 ApplcoreAttrValException

```java
import oracle.apps.fnd.applcore.messages.ApplcoreAttrValException;

// Construct and populate HashMap with token values
Map<String, Object> tokens = new HashMap<String, Object>();
tokens.put("TEXT_TOKEN", "text token value");
tokens.put("NUMBER_TOKEN", new BigDecimal(10));
Calendar cal = Calendar.getInstance();
cal.set(1999, Calendar.DECEMBER, 31, 0, 0, 0);
```
Example 7-4  Native JBOException

```java
import oracle.apps.fnd.applcore.messages.ApplcoreException;

// Construct and populate HashMap with token values
Map<String, Object> tokens = new HashMap<String, Object>;
tokens.put("TEXT_TOKEN", "text token value");
tokens.put("NUMBER_TOKEN", new BigDecimal(10));
Calendar cal = Calendar.getInstance();
cal.set(1999, Calendar.DECEMBER, 31, 0, 0, 0); tokens.put("DATE_TOKEN", new Timestamp(cal.getTimeInMillis()));

JboException ex = new JboException(FndMessagesUtil.getFndMapResourceBundleDef(),
"MYAPP:::MY_MESSAGE_NAME", null);
ex.setErrorParametersMap(tokens);
throw ex;
```

Example 7-5  Throwing Bundled Exceptions

```java
ApplcoreException error1 =
new ApplcoreException("PON:::PON_NEG_REQ_TOTAL_WEIGHT_ERROR");
ApplcoreException error2 =
new ApplcoreException("PON:::PON_KNOCKOUT_CRITERIA_ERROR");

ApplcoreException[] details = {error1, error2};
ValidationException errorBundle = new ValidationException("");
errorBundle.setExceptions(details);
throw errorBundle;
```

7.6.2 About Retrieving Message Text Programmatically

You can use static methods in the `oracle.apps.fnd.applcore.messages.Message` class to retrieve translated, token substituted message text without raising exceptions. APIs are provided to retrieve the fully formatted text of the user message, the administrator message, or to retrieve the parts of the message (short message, cause, action, and so on) individually, as shown in Example 7-6.

Example 7-6  Retrieving Messages

```java
// Construct and populate HashMap with token values
Map<String, Object> tokens = new HashMap<String, Object>();
tokens.put("TEXT_TOKEN", "text token value");
tokens.put("NUMBER_TOKEN", new BigDecimal(10));
Calendar cal = Calendar.getInstance();
cal.set(1999, Calendar.DECEMBER, 31, 0, 0, 0); tokens.put("DATE_TOKEN", new Timestamp(cal.getTimeInMillis()));

// Get the token substituted message short text.
String shortText = Message.getShortText("MYAPP", "MY_MESSAGE", tokens);

// Get the token substituted full user message, in plain text format.
String userText = Message.getUserText("MYAPP", "MY_MESSAGE", tokens);

// Get the token substituted full user message, in HTML format.
String userHTML = Message.getUserHTML("MYAPP", "MY_MESSAGE", tokens);
```
7.7 About Associating Message Dictionary Messages with Oracle ADF Validation Rules

The easiest way to create and manage validation rules is through declarative validation rules. Declarative validation rules are defined using the overview editor for the entity object, and when created, are stored in the entity object’s XML file. These are known as declarative validation rules on entity objects.

For information about defining validation rules on entity objects, see the Defining Validation and Business Rules Declaratively chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.

Oracle ADF provides built-in declarative validation rules that satisfy many of your needs. You can also base validation on a Groovy expression, as described in About Using Groovy Scripting Language.

When you add a validation rule, you supply an appropriate error message. You can also define how validation is triggered and set the severity level.

These messages can contain named message tokens for retrieving and displaying context sensitive values.

Tip:

When raising exceptions with the ADF Business Components validation rules, the tokens must be formatted as \{TOKEN_NAME\} and not (TOKEN_NAME).

7.7.1 How to Associate Error Messages with Oracle ADF Entity Object Validation Rules

To associate an error message with your validation rule, do the following:

1. Go to the Failure Handling tab of your declarative validation rule when you have finished defining your rule. In the Validation Failure Severity field, Select Error.

2. Click Select Message to open the Select Text Resource dialog. Choose Application Messages from the Resource Picker dropdown list.

3. Use the Search area to filter your search results. For example, enter FND_VIEW in the search text area to filter your results to messages whose key begins with FND_VIEW.

Note:

You can search for messages only by the message key. All other types of searches have been disabled. Also notice from the results that message keys are prepended with the application short name.

4. Select the required error message from the list of results. The Select Text Resource dialog closes and the selected error message displays in the Failure Message Text area on the Failure Handling tab.
5. If your message contains tokens, bind them to Groovy expressions to retrieve context sensitive values. Groovy script is a Java-like scripting language. For more information about Groovy script, see About Using Groovy Scripting Language.

A validation rule's error message can contain embedded expressions that are resolved by the server at runtime. To access this feature, simply enter a named token delimited by curly braces (for example, \{TOKEN_NAME\} or \{ERRORPARAM\}) in the error message text where you want the result of the Groovy expression to appear.

The Token Message Expressions table at the bottom of the dialog displays a row that allows you to enter a Groovy expression for the token. Figure 7-2 shows the failure message for a validation rule in the PaymentOptionEO entity object that contains message tokens.

![Figure 7-2 Using Message Tokens in a Failure Message](image)

Declarative validation is different from programmatic validation, which is stored in an entity object's Java file. For more information about programmatic validation, see the Implementing Validation and Business Rules Programatically chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.
7.8 About Raising Error Messages Programmatically in PL/SQL

Because they make calls to the database, both PL/SQL and C code require that the message is stored in the Message Dictionary. PL/SQL and C code cannot reference Java-based resource bundles. You can use PL/SQL to:

- Raise exceptions in PL/SQL programmatically using messages from the Message Dictionary
- Retrieve those errors when PL/SQL is called from Java
- Retrieve the message from the stack

7.8.1 About Raising Exceptions Programmatically in PL/SQL

There are three packages that you can use to handle errors in PL/SQL using messages in the Message Dictionary:

- **FND_MESSAGE**: This package includes basic APIs to set messages on the error stack, set tokens, retrieve token substituted message text, and so on.
- **APP_EXCEPTION**: This package includes utilities to raise SQL exceptions with messages in the Message Dictionary as the exception text.
- **FND_MSG_PUB**: This package includes utilities to set messages on the error stack. In Oracle Fusion Applications, the error stack also exists natively in the FND_MESSAGE package; this package is primarily used for backward compatibility with existing code. PL/SQL code that in EBS was primarily called from Framework usually uses this method.

For more information about these packages, see the package headers.

7.8.2 About Raising Errors in PL/SQL

The **FND_MESSAGE** PL/SQL package allows you to set one message and its tokens, as shown in Example 7-7. It also allows you to set multiple messages in the stack by explicitly pushing the current message onto the stack, as shown in Example 7-8. When you need to retrieve the message from the stack, an explicit `pop()` is required, as shown in Example 7-9.

**Example 7-7  Getting Message and its Tokens**

```sql
-- setting INVALID_USER as the current message
fnd_message.set.name('FND', 'INVALID_USER');
-- setting token value for NAME
fnd_message.set_token('NAME', '<USER>');
..........
-- get the current translated and token substituted message
-- then clear the message
msg := fnd_message.get;
```

**Example 7-8  Receiving a Message Record and Clearing Message**

```sql
-- setting INVALID_USER as the current message
fnd_message.set.name('FND', 'INVALID_USER');
-- setting token value for NAME
fnd_message.set_token('NAME', '<USER>');
..........
-- receive a message record which contains everything about the
```
-- current message. The record contains message number, message category
-- message severity and translated and token substituted message text, 
-- translated and token substituted user message, user action, ...
-- Getting message record for current message will NOT clear the message
msg_rec := fnd_message.get_message_record;
-- clear the message
fnd_message.clear;

Example 7-9    Retrieving message from the Stack

-- setting INVALID_USER as the current message
fnd_message.set_name('FND', 'INVALID_USER');
-- setting value for token NAME for INVALID_USER message
fnd_message.set_token('NAME', 'TESTUSER');
-- saving the current message onto stack
fnd_message.push;
-- setting LOGIN_FAILED as the current message
fnd_message.set_name('FND', 'LOGIN_FAILED');
-- saving the current message onto stack
fnd_message.push;
.......
-- poping one message out of stack and set it as the current message
fnd_message.pop;
-- get the translated and token subsituted LOGIN_FAILED message
-- then clear the current message
msg := fnd_message.get;
-- poping one message out of stack and set it as the current message
fnd_message.pop;
-- get the translated and token subsituted INVALID_USER message
-- then clear the message
msg := fnd_message.get;

7.8.3 About Retrieving Errors when PL/SQL is Called from Java

You can use the OAExceptionUtil.CheckErrors() API to check for error messages after calling PL/SQL from Java. The CheckErrors() API looks for errors on both the new FND_MESSAGE and FND_MSG_PUB stacks, raises a bundled exception for each error found on both stacks, and then clears both PL/SQL error stacks.

Where the call to OAExceptionUtil.CheckErrors() depends on which style of error handling your PL/SQL code uses:

- If your PL/SQL code uses FND_MESSAGE with FND_MSG_PUB, then errors will be left on the PL/SQL error stack without raising any exceptions. The call to OAExceptionUtil should go immediately after the PL/SQL call.

- If your PL/SQL code uses APP_EXCEPTION.RAISE_EXCEPTION, or FND_MESSAGE.RAISE, then errors will cause SQL exceptions to be raised. The call to OAExceptionUtil.CheckErrors() should be in a SQLException catch block.

- If you do not know what style of error handling your PL/SQL code uses, or there could be a mixture of both, then you should include calls to OAExceptionUtils.CheckError() in both places, as shown in Example 7-10.

Example 7-10    Calls to OAExceptionUtils.CheckError() — Unknown Error Handling Style

import oracle.apps.fnd.applcore.common.OAExceptionUtils;
...

7-16 Oracle Fusion Applications Developer's Guide
7.9 About Diagnosing Generic System Error Messages

If you see an error message similar to one the following messages, it is because a system error was raised and the original error message was replaced with a generic message:

An application error occurred. Your help desk was informed.

An application error occurred. See the incident log for more information.

When you receive these types of errors, you can look at the log file entry to find the original error message.

Note:

When generic errors are raised, you will see oracle.apps.fnd.applcore.messages.ExceptionHandlerUtil class information at the top of the call stack. This is the code that is replaced the unhandled exception with the generic error and should not be mistaken for the original error from the Message Dictionary.

You can also set one of the following debug options to allow you to see the error more directly, without having to view the log file entry:

- -DAFERROR_MODE=debug: Causes the original error to be displayed in the UI
- -DAFLOG_ECHOED=true: Sends logging output to the console, as well as the log file

For information about finding the cause of an error and its corrective action and for information about viewing and managing log files, see the following chapters in the Administrator’s Guide:
7.10 About Formatting Message Dictionary Messages for Display in Oracle ADF Applications

When raising an exception or attribute validation error by retrieving a message from the Message Dictionary using a resource bundle interface, the exception message returns in XML format.

You can convert XML formatted messages to HTML or plain text for display in Oracle ADF applications, as shown in Figure 7-3.

Figure 7-3  Error Message Example

This can be done in one of two ways:

- Programmatically
- By configuring the error format handler in the DataBindings.cpx file

7.10.1 About Programmatically Converting XML Messages

When directly handling Oracle Fusion Applications resource bundle exceptions in Java code, you can convert XML messages to HTML or plain text using utility APIs. The utility APIs are found in oracle.apps.fnd.appcore.messages.model.util.Util.

Sample code is shown in Example 7-11.

Example 7-11  Converting XML Messages to HTML or Plain Text

```java
Exception exception = new ApplcoreException("FND:::MY_TEST_MESSAGE");

// Retrieve the HTML short message
String htmlShort = Util.formatHTMLMessage(exception);

// Retrieve the HTML message details.
String htmlDetails = (Util.formatHTMLDetailMessage(exception)).getHTMLText();

// Retrieve the plain text message details
String textDetails = (Util.formatHTMLDetailMessage(exception)).getText();

// Retrieve the full plain text message
String textMsg = Util.formatTextMessage(exception);
```
7.10.2 How to Convert XML Messages by Configuring the Error Format Handler

You can convert XML messages to HTML or plain text by configuring the error format handler in the `DataBindings.cpx` file.

To convert XML messages to HTML, do the following:

1. Under the user interface project, open the `DataBindings.cpx` file.

   Tip:
   JDeveloper names the user interface project `ViewController` by default.

2. In the Property Inspector, set the **ErrorHandlerClass** field to the value shown in Example 7-12 and Figure 7-4.

   **Figure 7-4** Setting the Value of the **ErrorHandlerClass** Field in the Property Inspector

   ![Property Inspector screenshot]

   **Example 7-12** The Value of the **ErrorHandlerClass** Field

   `oracle.apps.fnd.applcore.messages.MessageFormatHandler`

7.11 About Integrating Messages Task Flows into Oracle Fusion Functional Setup Manager

Every Oracle Fusion application registers task flows with a product called Oracle Fusion Functional Setup Manager. These task flows are available from the application’s Setup and Maintenance work area and enable customers and implementers to set up and configure business processes and products.

For information about implementing your specific product family, do the following:

1. Access the `Oracle Fusion Applications` library.

2. See the Implementing Common Features guides for your product family.

Function Security controls your privileges to a specific task flow, and users who do not have the required privilege cannot view the task flow. For more information about
how to implement function security privileges and roles, see Implementing Function Security.

Table 7-3 lists the task flows and their parameters.

**Table 7-3  Messages Task Flows and Parameters**

<table>
<thead>
<tr>
<th>Task Flow Name</th>
<th>Task Flow XML</th>
<th>Parameters Passed</th>
<th>Behavior</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Messages</td>
<td>/WEB-INF/oracle/apps/fnd/applcore/messages/ui/flow/ManageMessagesTF.xm#ManageMessagesTF</td>
<td>mode='search' [moduleType] [moduleName] [applicationId] [pageTitle]</td>
<td>Search mode launches the search page, with optional parameters to restrict to a particular module.</td>
<td>NA.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>mode='edit' messageName applicationId [pageTitle]</td>
<td>Edit mode launches the edit page for a particular message. The messageName and applicationId parameters are mandatory as they specify the message to edit.</td>
<td></td>
</tr>
</tbody>
</table>

About Integrating Messages Task Flows into Oracle Fusion Functional Setup Manager
This chapter describes how to share reference data across organizations by using setIDs to partition the data into different sets of values. Each organization can then maintain its data in a common table, using a set of values specific to that organization.

This chapter includes the following sections:

- Introduction to SetIDs
- About Implementing SetID on Entity Objects
- About Integrating SetID Task Flows into

8.1 Introduction to SetIDs

Different organizations within a single company often need to use different sets of reference data to serve the same purpose. For example, the job codes for one country might be different from the job codes for another country. Different Oracle Fusion Applications customers should be able to make their own decisions about how to define the job codes, and be able to define a separate set for each organizational section of the enterprise. They should also be able to define a common set or sets and instruct the system which set is required by which organizations. For example, job codes for software engineers might be MTS, SMTS, PMTS; job codes for managers might be M1, M2, M3. SetIDs enable them to accomplish this easily.

For information about set-enabling lookups, see Implementing Lookups.

SetID Implementation

After you have completed the development process as discussed in this chapter, and delivered your application with the ability to use set-enabled reference data, application implementers and administrators must then be able to define and maintain reference data sets and set assignments that are appropriate to the organization which will use the application. They can accomplish these tasks using the Manage Reference Data Sets and Manage Reference Data Set Assignments applications, respectively.

You make these setup applications available to implementers and administrators by incorporating their task flows into Oracle Functional Setup Manager. For more information, see About Integrating SetID Task Flows into.

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.
8.1.1 About Partitioning by SetID

SetIDs enable you to share a set of reference data across many organizations. Sharing reference data is a method of limiting the set of available values to those that are appropriate for a validated attribute. Some benefits of this include:

- The list of values for a field in a user interface is reduced
- An attribute passed into an API is validated against the limited set of values

The end goal is to save customers some effort in maintaining reference data by enabling it to be shared between different parts of the organization that implements applications. Reference data should not need to be maintained in multiple places at multiple times. Reference data is data in tables that you do not regard as transactional and high volume; for example, payment terms that can be used on a customer invoice.

By dividing the reference data into partitions appropriate to the organizational entities that will use the data, setIDs enable you to share control table information and processing options among business units. The goal is to minimize redundant data and system maintenance tasks. For example, you can define a group of common job codes that are shared between several business units. Each business unit that shares the job codes is assigned the same setID for that record group.

SetIDs can be thought of as a striping technology to partition referenced data. All shared reference tables can be striped with a setID column to enable partitions (or sets). This does not require you to change the tables’ primary keys.

With partitioning, a customer can choose to have reference data sets specific to each organizational unit mapped one-to-one, or have several different organizational units use the same set of reference data. Customers, rather than development, will have the choice in determining what level of sharing or exclusivity they would like to maintain in the reference data.

A setID is the means by which applications can filter reference data into subsets when they are referenced by different transactional entities. The filtering is driven, indirectly, by contextual values available in the referring transactional entity.

8.1.2 About SetID Determinant Types

Use of the shared data partitions is facilitated by a context setting called the determinant, which is usually a column on the referring transactional entity. The purpose of the determinant is to identify an organizational subset; you use it to specify which reference data is valid for use in a given business context. The determinant is the value of a transactional column that is one of several designated determinant types. If at least one column of the transactional table is a setID determinant type, data sharing may make sense for the transaction.

For example, different business units may use the same office supply vendor, but have different requirements for which supplies can be purchased. The determinant type and value provide part of the criteria for selecting the appropriate office supply reference data set.

In addition to the presence of a determinant on the transactional entity, the data that you want to reference must be set-enabled as described later in this documentation.

The setID determinant type can be one of the following existing fields:

- **Asset Book** — A book that contains assets belonging to a business unit or ledger. It holds information about the asset’s acquisition, depreciation, and retirement. An
asset may be assigned to one or more books; for example, the corporate, tax and budget books.

- **Business Unit** — This roughly corresponds to a department or organization. For example, Virgin might have an airline, a store, and a recording label as different business units.

- **Cost Organization** — A cost organization groups inventory organizations within a legal entity to achieve the following:
  - Establish the cost accounting policies for the inventory organizations.
  - Support cost accounting reporting.
  - Allow the definition of defaults.
  - Allow multiple inventory organizations to share cost calculation.
  - Restrict role access to costing data.

Cost organization will likely map into a company's enterprise structure as a cost department.

- **Project Unit** — A logical organization within a company created to ensure and enforce consistent project management practices.

- **Reference Data Set** — For cases where shared reference data has references to other shared reference entities.

### Some Criteria for Selecting a Determinant Type

To help decide what determinant type to use for a given application, consider the following:

- If you cannot change the reference data for different parts of a deploying enterprise, the reference data is global and partitioning is not required.

  Examples of data suitable for partitioning include (but are not limited to) units of measure, currency codes, country codes, or anything else governed by a standard.

- If the values for the reference data will be decided by the general manager, the best reference data set determinant is likely to be the **Business Unit**.

For more information about setID determinant types, see [How to Annotate Transactional Entity Objects for SetID](#).

### 8.1.3 Understanding SetID Machinery

SetID Machinery is the collection of Applications Core Technology software elements that act in concert to facilitate the use of setIDs to partition, access and maintain reference data. At a high level, the machinery is comprised of:

- SetID configuration tables
- SetID metadata for business objects and extensions to ADF Business Components middleware
- SetID design-time extensions
- SetID summary tables
The following sections introduce the elements of setID machinery and the ways in which they can be used to implement data sharing.

### 8.1.3.1 About Partitioning Patterns

There are three setID partitioning patterns. Choose one of these patterns based on your business requirements:

- **Row striping** *(ROWSTRIPE)* — This is the simplest pattern, and the default. In this pattern the SET_ID column is just a striping column, and is not part of the set of unique keys for the table. You can filter as follows:

  ```sql
  WHERE SET_ID = :1
  ```

- **Row striping with common rows** *(COMMON)* — This is the same as the row striping pattern, with the addition of a COMMON partition. You filter as follows:

  ```sql
  WHERE SET_ID IN (:1, 0)
  ```

  **Note:**
  The set with setID of 0 is seeded as the common set. This set will be available for assignment only if you select **Row Striping With Common Rows** for the reference entity.

- **SetID subscription** *(SUBSCRIPTION)* — The drawback of the first two patterns is that if reference data must be in two different partitions (other than the common one), it has to be copied and placed in both sets. To avoid that, a setID subscription table can be introduced and used to list which sets include each row. This will allow the same reference data to be in two different sets without the need to copy the data for each set. You join your reference entity with the setID subscription table and filter as follows:

  ```sql
  SET_ID: WHERE PARENT.PK1=SUBSCRIPTION.PK1 AND SUBSCRIPTION.SET_ID = :1
  ```

For more information about partitioning patterns, see [How to Annotate Reference Entity Objects for Sharing](#).

### 8.1.3.2 About Reference Groups

In addition to tables, other sources of reference data such as lookup types and views can also be shared using setIDs. These are all generically referred to as **reference entities**. Reference entities are generally considered to be setup data, and they may be implementing business policies and legal rules. Reference entities in your application are grouped into logical units called **reference groups**, based on the functional area and the partitioning requirements they have in common. For example, all tables and views that define Sales Order Type details might be part of the same reference group.

Figure 8-1 illustrates an example of a Worker Assignment transaction table with two set-enabled references: a reference to Salary Codes with partitions determined by Business Unit, and another reference to Labor Agreement with partitions determined by Cost Organization.
8.1.3.3 About Set Configuration Tables

There are five types of set configuration tables:

- Sets
- Reference groups
- SetID assignments
- Reference entities

Sets Table

The sets table, FND_SETID_SETS, lists all of the sets defined for Oracle Applications, plus any new sets that you define. It includes the columns SET_ID and SET_NAME, which enable you to select the proper SET_CODE.

Sets listed in this table include:

- The two default seeded sets, COMMON and ENTERPRISE.
- Default sets that map to existing transaction data, created as an upgrade to Applications Unlimited.
- New sets created by customers, to implement set-enabled reference entities specific to their organizations.

Reference Groups Table

The reference groups table, FND_SETID_REFERENCE_GROUPS_B, captures the default determinant type for all reference entities in each group. This table uses the primary key of REFERENCE_GROUP_NAME. It also includes the APPLICATION_ID column, which is used for filtering and managing ownership.
The available reference groups defined in the reference groups table will be populated before you start creating entity objects. Reference group definitions are owned by the application that owns the reference entities in that group. Application development teams are ultimately responsible for defining and delivering reference groups.

**Note:**

Only reference entities that might be referenced as setID targets need to be captured here; this is not intended to be an exhaustive inventory of all tables in the applications. For more information about reference groups, see About Reference Groups.

---

**SetID Assignments Table**

A transactional entity may have multiple sets of reference data that are treated in the same manner. For this reason, reference data sets are assigned to a reference group, then the setID assignment is configured for each determinant value, determinant type, and reference group.

The setID assignments table, FND_SETID_ASSIGNMENTS, records which set to use in every reference table for every determinant value. It is a SQL-joinable entity that can be used to convert available context information into a setIDentifier suitable for filtering rows from referenced entities. The context information serves as the table’s primary keys:

- REFERENCE_GROUP_NAME
- DETERMINANT_TYPE
- DETERMINANT_VALUE

Based on these keys, you can determine a setID.

**Note:**

Although development may seed this table with default values, it will be accessed by customers to implement set-enabled reference entities specific to their organizations.

---

**Reference Entities Table**

The reference entities table, FND_SETID_REFERENCE_ENTITIES, contains the list of all setID enabled non-lookup reference entities. The SET_ID_PATTERN column indicates which setID pattern is being used by each reference entity. If the value of this field is SUBSCRIBE (setID subscription), the column SET_ID_CHILD_TABLE will be populated with the setID subscription table name.

**Note:**

For customers, this table is read-only.

---

**8.1.3.4 About SetID PL/SQL Utilities**

The setID PL/SQL utilities are APIs that include the following packages:
Fnd_setid_sets_pkg package
This package contains table handlers for fnd_setid_sets table.

Fnd_setid_assignments package
This package contains table handlers for fnd_setid_assignments table.

Fnd_setid_reference_groups package
This package contains table handlers for fnd_setid_reference_groups table.

Fnd_setid_ref_entities_pkg package
This package contains table handlers for fnd_setid_reference_entities table.

Fnd_setid_set_groups package
This package contains table handlers for fnd_setid_set_groups and fnd_setid_set_group_members tables.

Fnd_setid_utility package
This package contains the following utilities:

• isValid

```java
/**
 * Returns true if the given parameters are valid, false if not.
 * @param referenceGroupName The reference group name
 * @param setIdDeterminantType The determinant type which could be: BU, RR, LE...
 * @param setIdDeterminantValue The determinant value.
 * @param setId The setid value.
 * @return true or false.
 */
function isValid(X_REFERENCE_GROUP_NAME in varchar2,
                 X_DETERMINANT_TYPE in varchar2,
                 X_DETERMINANT_VALUE in varchar2,
                 X_SET_ID in number) return boolean;
```

• getSetId

```java
/**
 * Returns the set ID corresponding to the specified determinant value, type,
 * and reference group name. This method implements an LRU cache to speed
 * up the lookup.
 * @param setIdDeterminantValue The determinant value
 * @param setIdDeterminantType The determinant type which could be: BU, RR, LE...
 * @param referenceGroupName the reference group name.
 * @return the corresponding set ID value.
 */
function getSetId(X_REFERENCE_GROUP_NAME in varchar2,
                  X_DETERMINANT_TYPE in varchar2,
                  X_DETERMINANT_VALUE in varchar2) return number;
```

• getReferenceGroupName

```java
/**
 * Returns the reference group name based on a given reference entity name.
 * @param referenceEntityName The name of the table to obtain
 * the reference group for
 */
```
8.2 About Implementing SetID on Entity Objects

You define the following information to implement shared (that is, set-enabled) reference entities:

- On the reference entities to be shared:
  - You provide the shared reference entity group name.
  - You specify which setID pattern to use: row striping, row striping with common rows, or setID subscription.
  - In the case of the setID subscription pattern, you specify the subscription table name.
  - You make sure the attribute corresponding to setID is named SetId, and specify the determinant type as SET.
  - You make sure that any view objects built on the reference entity include the SetId attribute.

For more information about setID partitioning patterns, see About Partitioning Patterns.

- On the transactional entities that will use the shared reference data:
  - You build entity associations to all shared reference entities.
  - You specify which attributes are determinants by specifying the determinant type.
  - On foreign keys that point to shared reference entities, you indicate which determinant attribute drives the set of that reference entity.

Before you begin:

Following are the activities that you should complete before you engage in set-enabling references or lookups:

- Determine which reference entities you want to partition for sharing, and set-enable them by adding a SET_ID column.

- Generate ADF Business Components entity objects for your set-enabled reference entities and transactional entities. Make sure that your entity objects extend from
Oracle Applications base classes (if available) under
\texttt{oracle.apps.fnd.applcore.oaext.model}.

For more information, see the "Creating a Business Domain Layer Using Entity Objects" chapter in the \textit{Developing Fusion Web Applications with Oracle Application Development Framework}.

- Generate ADF Business Components entity associations for all of your entity objects.

  The following setID metadata will be saved in ADF Business Components metadata as properties:
  - The reference group name of reference entities.
  - The setID pattern used by each shared reference entity.
  - The determinant attributes and their types in a transactional entity.
  - The determinant on the transactional entity that controls the setID of a shared reference entity.

- The setID-related database tables and views should be available as described in \textit{About Set Configuration Tables}.

- Ensure that setID seed metadata has been configured as follows:
  - The Reference Groups have been defined by teams and approved through the SetID Design Intent Repository process, then seeded in the standard reference groups table.
  - All set-enabled lookup types have been identified and approved through the SetID Design Intent Repository process, and then properly seeded in the standard lookup types table.

For more information, see \textit{Understanding SetID Machinery}.

\section*{8.2.1 How to Annotate Reference Entity Objects for Sharing}

\textbf{Note:}

These annotations are required only for \textit{set-enabled} non-lookup reference entities. Lookup references and set-enabled lookup references use a predefined lookups pattern; the reference group name is retrieved directly from database by the lookup code and the view application ID that are set on the foreign key reference of the transactional reference.

After building an entity object for a shared reference entity, you annotate the entity object.

To annotate the reference entity object, do the following:

1. Double-click the entity object to access its properties, as shown in \textit{Figure 8-2}.
2. In the Applications section of the Property Inspector, specify the name of the setID reference group to which the entity object belongs.

   For more information, see About Reference Groups.

3. Specify the setID pattern that the reference entity should use. There are three setID partitioning patterns. Choose one of these patterns based on your business requirements:
   
   • Row Striping (this is the default value)
   • Striping With Common Rows
   • Subscription

   When you select the SUBSCRIPTION pattern, the SetID Reference Table Pattern field appears. Specify the subscription table to use.

   **Caution:**

   The primary key columns of the setID subscription table must be named the same as those in the reference entity, and the setID column must be named SET_ID.

   For more information about these options, see About Partitioning Patterns.

4. In the entity object attributes, ensure that the entity object setID attribute that corresponds to the SET_ID database column is named SetId, as shown in Figure 8-3.
Caution:

If you cannot use the SET_ID column as your setID attribute, you must ensure that the attribute you use is named SetId, even if the database column is named differently. This applies to both entity objects and view objects.

8.2.2 Guidelines for Building Entity Associations for All Foreign References

After building an entity object for a transactional entity, you must create entity associations for all foreign references, including FND lookups. Because SET_ID must not be part of the primary key for any shared reference table (except FND_LOOKUP_VALUES), there is nothing unusual about associations for shared references.

Follow these guidelines when creating the associations:

- Make sure a destination accessor is generated for the association. ADF Business Components will not honor the association if you do not generate a destination accessor.
- Because these reference entities are non-composite, you should not generate source accessors.

8.2.3 How to Annotate Transactional Entity Objects for SetID

After you create entity associations for foreign references, you annotate the transactional entity object.

To annotate the transactional entity object, do the following:

1. Double-click the entity object to access its properties, as shown in Figure 8-4.
2. In the Applications section of the Property Inspector, designate which attributes are setID determinants for the table. For more information, see About SetID Determinant Types.

For every attribute that you want to use as a setID determinant, specify the corresponding determinant type.

To access setID determinant types programatically, use the following codes:

### Table 8-1  SetID Determinant Type Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Determinant Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>AB</td>
<td>Asset Book</td>
</tr>
<tr>
<td>BU</td>
<td>Business Unit</td>
</tr>
<tr>
<td>CST</td>
<td>Cost Organization</td>
</tr>
<tr>
<td>PU</td>
<td>Project Unit</td>
</tr>
<tr>
<td>SET</td>
<td>Reference Data Set</td>
</tr>
</tbody>
</table>

**Note:**

- The attribute you need to use as a determinant might not exist on the parent record where its value can be retrieved from some context. In that case, you must create a transient attribute to represent the determinant, set the **SetId Determinant Type** property for it, then override the getter method of the transient attribute to get the value from wherever it has been stored.

- After a SetId Determinant code is defined, you can change the code in the EO.xml file.

3. For foreign keys that are setID enabled, specify the determinant attribute that drives each foreign key reference, as shown in Figure 8-5.

The default value of the setID determinant attribute is the default determinant type of the reference entity group targeted by the association that is defined for the foreign key.
Note:
If the determinant value is not directly available on the transaction table, you must create a transient attribute to model it, and ensure that the attribute is correctly populated.

Figure 8-5  SetID Determinant Attribute for a Foreign Key

Caution:
If the reference data has a composite key, you must specify the SetId Determinant Attribute property for the first attribute of the composite key.

8.2.4 About Defining View Accessors for Shared Reference Entities
Create a view accessor from the transaction entity to the reference entity.

8.2.5 How to Define a Key Exists Validator for Shared Reference Entities
The key exists validator will include the mapping of the foreign key attributes in the transactional entity to the corresponding attributes in the reference view accessor.
Caution:

If an attribute in your transactional entity was defined with null values allowed, the validator that you create will skip that attribute, and the end user will receive no indication of any problem. To ensure that the attribute is validated, you must edit the attribute and select the Mandatory checkbox in the attribute properties.

To define a keys exists validator, do the following:

1. Open the entity object for editing.
2. On the Attributes tab, select the foreign key attribute and add a validation rule. The Edit Validation Rule page appears, as shown in Figure 8-6.
3. At the top of the page, select a rule type of Key Exists.

Figure 8-6    Foreign Reference Validation Rule Definition

4. On the Rule Definition tab, select ViewAccessor as the validation target type.
5. Select the entity object lookup code attribute on the left-hand list, and the corresponding view accessor validation target lookup code attribute on the right-hand list.
6. Click Add to include the attribute pair on the mapping list.
7. Select the Validation Execution tab, as shown in Figure 8-7.
Because the validation should be executed every time the determinant value changes, it should be specified as a triggering attribute.

**Figure 8-7  Foreign Reference Validation Triggering Attributes**

![Edit Validation Rule for: WorkerAssignmentsID]

- **Validation Level**
  - The rule can be executed once at the transaction level for all entities, or at the entity level.
  - **Execute at Entity Level**
  - **Defer execution to Transaction Level**

- **Conditional Execution**
  - To execute this rule only when certain conditions are true, provide a boolean expression.
  - When no condition is provided, this rule always executes.

- **Triggering Attributes**
  - Execute only if one of the selected attributes has been changed.

<table>
<thead>
<tr>
<th>Available Attributes</th>
<th>Selected Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>AssignmentId</td>
<td></td>
</tr>
<tr>
<td>AssignmentName</td>
<td></td>
</tr>
<tr>
<td>BusinessUnit</td>
<td></td>
</tr>
<tr>
<td>EmploymentCategory</td>
<td></td>
</tr>
<tr>
<td>License</td>
<td></td>
</tr>
<tr>
<td>RequirementsRegion</td>
<td></td>
</tr>
</tbody>
</table>

---

**Note:**

The foreign key attributes that were mapped on the Rule Definition tab are by default added as triggering attributes.

8. In the Triggering Attributes section, select the determinant attribute from the left-hand list and shuttle it to the right-hand list.

9. Optionally, on the Failure Handling tab, specify a failure error message.

10. Click **OK** to create the key exists validator.

### 8.2.6 How to Create a Transient SetID Attribute

To create a transient setID attribute, do the following:

1. Create a new transient setID attribute to map to the SetId attribute on the reference entity, as shown in **Figure 8-8**.
2. Set the Type to Long.

3. Deselect the Persistent checkbox.

4. In the Updatable section, select Never, then click OK to create the transient attribute.

5. On the Java tab, generate or edit a Java class for the transaction entity object.

6. Because the setID value is computed at runtime based on the values of the reference group name, determinant type and determinant value, you must modify the transaction entity object's Java code to return the setID value at runtime.

Open the transactional EOImpl class and edit the getter method of your transient setID attribute to pass in the corresponding foreign key attribute name. For example:

```java
/** This method gets the attribute value for TransientSetIdAttr, using the alias name TransientSetIdAttr. */
public Long getTransientSetIdAttr() {
    return this.getSetId("SalaryCode");
    //"SalaryCode" is the foreign key attribute name on the WorkerAssignments transactional entity
}
```

In this example, you open the WorkerAssignmentsImpl.java class and edit getTransientSetIdAttr() to pass in the attribute name "SalaryCode" so its value will be returned at runtime.

**8.2.7 How to Create LOVs for Shared Reference Entities**

ADF Business Components supports defining LOVs at the attribute level in view objects.

To build a lookups LOV for a set-enabled reference entity:
1. Create an LOV on the foreign key attribute in the attribute wizard.

   The default LOV name is typically kept as \texttt{LOV\_attribute\_name}, as shown in Figure 8-9.

   \textbf{Figure 8-9} \hspace{1em} \textit{LOV Definition for a Set-Enabled Reference Entity}

2. Choose a view accessor from the list of available view accessors.

   Typically you will choose the same view accessor which was defined for the underlying entity object and used for the Key Exists validator.

3. Select an attribute from the view accessor to validate against, and ADF Business Components will automatically add that attribute to the list of return values.

4. Optionally, you can specify additional attributes to be returned to the master row when an LOV entry is selected.

5. Optionally, you can customize the LOVs UI hints by clicking \texttt{Edit List UI Hints} to access the List UI Hints dialog.

8.3 \textbf{About Integrating SetID Task Flows into Oracle Fusion Functional Setup Manager}

Every application registers task flows with a product called \textit{Oracle Fusion Functional Setup Manager}. Functional Setup Manager provides a single, unified user interface that enables implementers and administrators to configure all multiple applications by defining custom configuration templates or tasks based on their business needs.

The Functional Setup Manager UI enables customers and implementers to select the business processes or products that they want to implement. For example, an HR application can register setup activities like "Create Employees" and "Manage Employee Tree Structure" with Functional Setup Manager.
There is an application task flow for managing reference data sets, and one for managing reference data set assignments. To make these task flows available to application developers, implementers or administrators, you can register the appropriate task flow with Functional Setup Manager, using the parameters listed for each task flow in Table 8-2.

### Table 8-2  SetID Task Flows and Parameters

<table>
<thead>
<tr>
<th>Task Flow Name</th>
<th>Task Flow XML</th>
<th>Parameters Passed</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Reference Data Sets</td>

For information about implementing your specific product family, do the following:

2. See the Implementing Common Features guides for your product family.
This chapter describes the Oracle Fusion Middleware extensions for Oracle Applications base classes that extend the features of standard ADF Business Components classes.

The chapter includes the following sections:

- Introduction to Extensions for Oracle Applications Base Classes
- Understanding Multi-Language Support Features
- About Using WHO Column Features
- About Using PL/SQL-Based Entities
- About Accessing FND Services
- About Using Unique ID
- About Using Data Security
- About Using Document Sequencing

9.1 Introduction to Oracle Fusion Middleware Extensions for Oracle Applications Base Classes

Oracle Fusion Middleware extensions for Oracle Applications base classes provide additional features that are not part of the standard ADF Business Components core entity objects, view objects, and application modules.

The Oracle Fusion Middleware extensions support the following standard Oracle Applications features:

- TL (translatable) table
- WHO column
- PL/SQL entity
- FND services
- Unique ID
- Data security
- Document sequencing
The base classes extend ADF Business Components Entity, EntityDef, ViewObject, ViewRow, and ApplicationModule implementation classes.

The base classes provided by Oracle Fusion Middleware extensions are the following:

- OAApplicationModuleImpl
- OAEntityImpl
- OAEntityDefImpl
- OAVLObjectImpl
- OAViewRowImpl
- OAViewCriteriaAdapter

They are found in oracle.apps.fnd.applcore.oaext.model.package and extend the JBO classes with the same name (but without the OA prefix) in oracle.jbo.server.package.

In Oracle JDeveloper, selecting the Oracle Fusion Applications Developer role automatically sets the Oracle Fusion Middleware extensions for Oracle Applications base classes as the default classes for ADF Business Components objects. The base classes become available when you add the Applications Core library. For more information, see Set Up Your Development Environment.

9.2 Understanding Multi-Language Support Features

Multi-language support (MLS) gives Oracle the ability to ship its products in multiple languages by setting standards and guidelines for translation.

In JDeveloper, multi-language entities are those that maintain one or more translated attributes and require the storage of all relevant translations of these attributes. Such entities have a base table that has attributes that are not translated and do not vary by language (such as codes and IDs) and a TL table that has, in addition to the base table primary key, the translatable attributes for that entity (such as Display Name, and Application Name). Figure 9-1 illustrates this concept.

**Figure 9-1  Multi-Language Entity Tables**

For each row in the base table, there will be as many rows in the translation table as there are installed languages. The translation table's primary key is made up of the foreign key to the base table and a language column, which may be viewed as a foreign key to the FND_LANGUAGES table.

The translation table is fully populated. This means that rows for all installed languages are inserted even if the actual translations for these languages are not yet available. The logic, which maintains multi-language entities, is responsible for ensuring that the translation rows are inserted, updated, or deleted as required to meet the "fully populated" requirement. Translations, which have not been supplied, must be defaulted from one of the available translations. As updates occur to supply missing translations, the default values will be converted to true translations.

Since applications are run in a single language for any given user session, a convenient view is provided for the multi-language entities, which joins the base table and translation table and filters translations to the runtime language. This is the Multi-
language View. This view uses the userenv('LANG') expression to select the correct translation based on the session language, which usually comes from the NLS_LANG environment variable.

The following extensions support TL tables:

- OAEntityImpl
- OAViewRowImpl

As a developer, you can use multi-language extensions to deal with only one entity that contains both translatable and non-translatable attributes, instead of having to deal with two entities, one for the base table and one for the translation table.

Whenever an entity is created, the extensions ensure that the TL entities are also created for every installed language in the environment.

Whenever an insert is made into the base table or the table is updated, the same operations must also be performed on the corresponding TL table. Behind the scenes, the extensions override the appropriate ADF Business Components methods, such as create() and setAttribute(), to ensure that the TL table is populated correctly.

The extensions also enable you to work with only one ADF Business Components entity object at runtime for a multi-language database entity, and shield you from the two underlying tables (base and multi-language) that hold the data. You will see no inherent difference between a multi-language entity and a standard one. In addition, the extensions allow you to define an entity as multi-language in a JDeveloper design time environment, and provide any additional metadata for such that entity.

9.2.1 About Using Utility APIs

In addition, the following utility APIs are provided in OAEntityImpl:

- public boolean isTranslatable () - Returns true if this entity is a translatable entity.
- public boolean isTranslated () - Returns true if there is at least one translated language other than the base language for this entity.
- public String [] getTranslatedLanguages () - Returns an array of Language codes for which actual translations exist. The list always returns the base language as one of the translated languages. A record is considered translated if the LANGUAGE and SOURCE_LANG columns are equal.

The same set of APIs also will be provided on the OAViewRowImpl object, since it also would have the same characteristics of a row.

9.2.2 How to Create a Multi-Language ADF Business Components Entity Object

Creating a multi-language ADF Business Components entity object consists of four tasks:

- Creating an Entity Object for a _TL Table
- Creating an Entity Object for a Base Table
- Associating the _VL View and _TL Table Entity Objects
- Creating a View Object That Uses a Translatable Entity
9.2.2.1 Creating an Entity Object for a _TL Table

To create an entity object for translatable (_TL) tables, perform the following procedure.

Note:
This procedure does not apply to a _VL view. For information about creating an entity object for a _VL view, see Creating an Entity Object for a Base Table.

1. Name the entity `<Entity>TranslationEO`.
   For example, for a table named FND_ITEMS_DEMO_TL, you can name the entity `ItemsDemoTranslationEO`.

2. Include all of the table's attributes.
   Make sure the attribute for the LANGUAGE column is named `Language`, and the attribute for the SOURCE_LANG column is named `SourceLang`.
   If your TL table columns for LANGUAGE and SOURCE_LANG are named differently, it is important that you still name the attributes `Language` and `SourceLang`.

3. Identify the table's primary keys, including the LANGUAGE column.

4. Verify that this extends `OAEntityImpl` like any other entity object.

5. Add whatever validation logic you need for this entity and its attributes.
   The translatable values are unlikely to need any special validation.

Overriding the default attribute behavior:
By default, all the attributes in the _TL table will be considered translatable if they are:
- not a primary key attribute
- not an entity accessor
- one of the following types: VARCHAR, CHAR, FIXED_CHAR, LONGVARCHAR, CLOB

Note:
`SourceLang` and `Language` are special attributes and are handled by Oracle Fusion Middleware Extensions for Applications.

9.2.2.2 Creating an Entity Object for a Base Table

To create an entity object for a base table, perform the following procedure.

1. Name the entity object.
   Use the regular entity object naming convention. For example, for the FND_ITEMS_DEMO table, the corresponding entity would be named `ItemsDemoEO`. The entity should be based on the _VL view.
2. Include all columns except the RowId pseudo-column in the view.

3. Identify your primary keys as you normally would.

4. Set the entity-level Oracle Fusion Middleware Extensions for Applications schema-based ADF Business Components property named fnd:OA_BASE_TABLE with a value that names the true base table of your translatable entity.

For example, for the FND_ITEMS_DEMO_VL view, this value would be set to FND_ITEMS_DEMO_B.

You could use the entity Property Inspector to set this property, as shown in Figure 9-2.

**Figure 9-2  Entity Property Inspector**

Oracle Fusion Middleware Extensions for Applications automatically overrides the entity’s doDML() method to ensure that all inserts, updates, and deletes are actually performed on the base table identified by this property. All reads will be done against the _VL view.

9.2.2.3 Associate the _VL View and _TL Table Entity Objects

To create the association between the _VL view and _TL table entity objects, perform the following procedure.

1. Follow the standard association object naming convention that describes the entity relationships. For example, ItemsToTranslation.

2. In the Structure window, choose the entity object. In this case, it is ItemsToTranslation.
3. In the Overview window, choose the **Relationship** option.

4. Designate the association as a **Composition Association** with a 1:* cardinality, as shown in Figure 9-3.

**Figure 9-3 Composition Association**

When you select **Composition Association**, be sure to uncheck **Implement Cascade Delete** and **Cascade Update Key Attributes** if they are selected.

5. Select the base entity as the source and the _TL entity as the destination.

Since the Applications Core OAEntityImpl class overrides the `remove()` method on the EntityImpl class to handle Translation rows deletion, **Cascade Delete** is not required.

6. Configure **Source Accessor** and **Destination Accessor**, as shown in Figure 9-4.

**Note:**

Ensure that the **Source Accessor** has been created prior to performing Step 6.
9.2.2.4 Create a View Object That Uses a Translatable Entity

When creating the view objects that will access your translatable tables, keep in mind the following:

- Always use the base entity object created for the _VL view. For example, `ItemsDemoEO`.
- Do not use the _Translation entity object `ItemsDemoTranslationEO` directly. For the purpose of any code that needs to access your translatable entity, you should treat the base entity object as the only entity object. Coordination between the base and Translation entities is handled automatically and the Translation entity should remain "invisible". Otherwise, you can treat your base entity object like any other entity object.

For a _TL table with no corresponding _B table:

There may be a rare case where you have a _TL table and _VL view and no _B table, because all of the attributes are translatable. If this occurs, do the following:

1. Define the base entity on the database view _VL.
2. Set the Applications Core schema-based property `fnd:OA_BASE_TABLE` to be the _VL view name.
3. Override `doDML()` for the base entity to do nothing. This is going to be a virtual entity that does not have an underlying database table.
4. Create the translation entity object and the composite association between the base entity and the translation entity as you would in the regular scenario.
The Translation EO in this scenario alone must also include the non-translatable attributes because the base entity’s doDML() does nothing. If the translation entity does not include non-translatable attributes, you might get exceptions saying the attribute is not populated.

5. Mark all the non-translatable columns in the _TL entity, i.e., non-string fields and non-primary keys, as explicitly translatable by setting OA Translatable to true in the Applications section of the Property Inspector, as shown in Figure 9-5.

Figure 9-5   OA Translatable Setting

By default, only string fields (VARCHAR2 and its variants) are identified as translatable automatically by the parent. Primary key changes on the entity are also handled automatically by the framework. This means any numeric, date, or other data type attributes that are not primary key need to have the OA Translatable property set explicitly to true.

There is a slight downside to this approach as non-translatable columns (like numbers and dates), technically, are being marked as translatable. However, this approach is required in order to ensure attributes set on the base entity are propagated to the TL entity; otherwise, you will get an “attribute not populated” exception. This is needed because the base entity is virtual and the doDML() method on the base entity is empty.

9.2.2.5 What You Need to Know About Overrides

If you happen to override the create(AttributeList attributeList) method on your entity, do not forget to call super.create(attributeList) in the override method before invoking custom code. This is true in all scenarios.
9.3 About Using WHO Column Features

The WHO feature reports information about who created or updated rows in Oracle Applications tables. Oracle Applications upgrade technology relies on WHO information to detect and preserve customizations. ADF Business Components provides the ability to track the creation of an entity or the changes made to one.

The OAEntityImpl populates the WHO columns automatically. In addition to the standard history columns supported by ADF Business Components, the extension provides support for Last Update Login field.

All WHO columns are updated based on the current User Session. Table 9-1 lists the WHO columns and their descriptions.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Type</th>
<th>Null?</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATED_BY</td>
<td>VARCHAR2(64)</td>
<td>NOT NULL</td>
<td>Keeps track of which user created each row.</td>
</tr>
<tr>
<td>CREATION_DATE</td>
<td>DATE</td>
<td>NOT NULL</td>
<td>Stores the date on which each row was created.</td>
</tr>
<tr>
<td>LAST_UPDATED_BY</td>
<td>VARCHAR2(64)</td>
<td>NOT NULL</td>
<td>Keeps track of who last updated each row.</td>
</tr>
<tr>
<td>LAST_UPDATE_DATE</td>
<td>DATE</td>
<td>NOT NULL</td>
<td>Stores the date on which each row was last updated.</td>
</tr>
<tr>
<td>LAST_UPDATE_LOGIN</td>
<td>VARCHAR2(32)</td>
<td></td>
<td>Stores the Session ID of the user who last updated the row.</td>
</tr>
</tbody>
</table>

9.3.1 How to Use the Extension

In order for Oracle Fusion Middleware Extensions for Applications to populate your WHO columns automatically, do the following:

1. Ensure that your WHO column attributes are of the appropriate History Column type by using the Entity Attribute Wizard, as shown in Figure 9-6.
In the example entity, the WHO column **LastUpdateDate** is identified as a **modified on History Column** type.

2. Identify the following attributes as indicated:
   - **LastUpdatedBy** - modified by
   - **CreationDate** - created on
   - **CreatedBy** - created by

3. Ensure that the **LAST_UPDATE_DATE** and **CREATION_DATE** WHO columns have the Type as Timestamp (java.sql.Timestamp), as shown in Figure 9-7.
9.3.2 What Happens with WHO Column at Design Time and Runtime

WHO column features provide the following design time and runtime support:

- The extension supports the LAST_UPDATE_LOGIN column and ensures that the other columns are populated correctly.

- The LAST_UPDATED_BY and CREATED_BY columns are populated with a value based on the user name, and not with the user GUID, a user ID, or a session ID. To obtain the value to populate these columns in PL/SQL, use FND_GLOBAL.WHO_USER_NAME. In Java, the CreatedBy and LastUpdatedBy attributes will normally be populated automatically with the correct value by the base classes, or you can also obtain the value from OAEntityImpl.getWhoUser().

- History is provided for the Session ID of the user who last updated the row.

- Proper shaping in the Oracle Fusion Applications Developer role to make this history available.

9.4 About Using PL/SQL-Based Entities

PL/SQL entities are those that depend on PL/SQL packages to handle their Data Manipulation Language (DML) operations (insert, delete, update, and lock). Since Oracle Applications has a large amount of their business logic in PL/SQL and a lot of teams still use it, they need a mechanism that will allow them to use their PL/SQL code when building ADF Business Components entities. The Oracle Fusion Middleware extensions provide the following:

- A way to identify a PL/SQL entity using a custom property

- TL table support and the ability to override the appropriate DML operation
9.4.1 About Using APIs to Facilitate DML Operations

In addition, the following APIs are provided in the OAEntityImpl class to facilitate the insert, update, and delete DML operations in PL/SQL:

- protected void insertRow();
- protected void updateRow();
- protected void deleteRow();

The default implementations of these methods delegate to super.doDML(operation), which will result in SQL insert/update/delete being called for the entity.

9.4.2 How to Use the Extensions

A PL/SQL-based entity object provides an object representation of the data from a table or view and routes the DML operations to stored procedures in the database.

To identify an entity as a PL/SQL one, a custom attribute, OA_PLSQL_ENTITY, must be set to Y (Yes). This allows the framework to identify this entity as PL/SQL based. Do the following:

1. From the Applications window, choose an entity object.
2. In the Structure window, highlight the entity object.
3. From the Property Inspector tab, choose the Applications option.
4. Under PL/SQL, select Y from the OA PLSQL Entity dropdown menu, as shown in Figure 9-8.
5. Override the following methods for its DML operations and provide JDBC calls when applicable:
   - void insertRow();
   - void updateRow();
   - void deleteRow();

   Use the PL/SQL entity objects only if you have legacy PL/SQL code that maintains all your transactions and validations. If you are working on a new product and/or do not have a lot of PL/SQL legacy code, Applications Core recommends the use of Java entity objects over PL/SQL entity objects.

6. Call your PL/SQL insert, update, or delete procedure in your void insertRow();, void updateRow();, or void deleteRow(); method without calling super().

7. Create a callable statement to invoke your PL/SQL method.

8. Validate your attributes. You can do this in either of two places:
   - In your insertRow() or updateRow() methods: Perform your validation in Java in either of these two methods, or in PL/SQL stored procedures called from the methods.
   - In your validateEntity() method: If validations are done in a separate stored procedure in PL/SQL, you can call that stored procedure in this method.
9.4.3 What Happens with PL/SQL Entities at Design Time and Runtime

The extensions provide the following design time and runtime support:

- Provides the ability to identify PL/SQL-based entities.
- Invokes PL/SQL for DML operations.

9.5 About Accessing FND Services

Oracle Fusion Middleware extensions for Oracle Applications provide the following services:

- Profile
- Lookup
- Message
- Language
- Application
- Taxonomy
- Data Security
- Attachments

Oracle Fusion Middleware extensions provide an easy way to access these services and to invoke them. Typically, the services are provided as application modules. An application module serves as a container for the various view objects and provides business-service-specific functionality.

The services listed above are provided as a service-specific application module. For example, Profile functionality is made available in ProfileService.

Access to these services is provided as a getFNDNestedService (String service) method in the OAApplicationModuleImpl class. The OAApplicationModuleImpl extension is used to support access to the services.

See About Using the Extension, for implementation information.

9.5.1 About Using the Extension

The code in Example 9-1 shows how to provide access to an FND service. In this case, it is ProfileService.

OAConstants exposes the various service names as a constant.

Note that the getFNDNestedService () is just a utility method that looks up the rootAM and checks to see if an instance of the requested service already exists in the rootAM as a nested AM. If one exists, it will return it; if it does not, it will instantiate a new AM for that service that will be nested inside the rootAM and return it.

Example 9-1 Accessing an FND Service

ProfileService profileService = (ProfileService) myAM.getFNDNestedService (OAConstants.PROFILE_SERVICE);
// now call profile specific methods on the ProfileService AM
String appsServletAgent = profileService.getProfile("APPS_SERVLET_AGENT");
9.6 About Using Unique ID

In order to avoid primary key collision issues when synchronizing with disconnected clients, Oracle Applications standards require that an ADF Business Components entity object's primary key be populated with a Unique ID.

Oracle Fusion Middleware extensions support Unique ID by allowing an entity attribute to be populated with a globally unique value. The Fusion Unique ID Generator provided by ADF Business Components does this. The Unique ID can be used to populate an entity attribute of the BigDecimal and Long data types. The Unique IDs generated are of the BigDecimal type and meet certain criteria for uniqueness across database instances.

---

**Note:**

The database table column data type that corresponds to the entity attribute requiring a Unique ID must be large enough to hold the uniquely generated value. Typically, it should be of type NUMBER (18). NUMBER (15) may not be sufficient to hold the uniquely generated values.

In addition, Oracle Applications coding standards require that the entity attribute populated with a Unique ID be of type Long.

---

9.6.1 About Using the Extension

Oracle Fusion Middleware extensions provide both design time and runtime support for Unique ID.

9.6.2 What Happens with Unique ID at Design Time

At design time, Oracle Fusion Middleware extensions provide the ability to identify if an entity attribute needs a globally Unique ID. This is accomplished by setting Application Unique ID to true in the entity attribute's Property Inspector section, as shown in Figure 9-9.
9.6.3 What Happens with Unique ID at Runtime

Based on the design time setting, the framework populates the entity attribute with a globally unique value at runtime. This is accomplished by setting the following transient expression on the entity attribute's definition:

```java
oracle.jbo.server.uniqueid.UniqueIdHelper.getUniqueId(adf.object.unwrapObject());
```

9.7 About Using Data Security

Any custom view criteria adapter created by a product team will need to extend the `OAViewCriteriaAdapter` class in order for Data Security to work correctly.

By setting custom ADF Business Components properties at runtime, the `OAApplicationModuleImpl` class establishes the `OAViewCriteriaAdapter` class as the standard view criteria adapter for the ADF Business Components container.

9.7.1 How to Use the Extension

Product teams can do the following to create and use a custom view criteria adapter:

1. Extend `OAViewCriteriaAdapter` and invoke super methods for use cases not handled by the custom view criteria adapter.

2. Set the custom view criteria adapter by invoking the `setViewCriteriaAdapter()` method in the `create()` method of the custom `ViewObjectImpl` class.

3. Set the custom view criteria adapter on the `ViewObject`. 
9.8 About Using Document Sequencing

Document sequencing is a way to uniquely identify all business documents and business events belonging to a legal entity.

Document-sequence numbering has many country-specific requirements. It is a legal requirement in many EMEA, Asia Pacific, and Latin American countries. In the United States and the United Kingdom, it is used for internal control purposes and for financial-statement and other audits.

For more information about ADF Business Components integration of this feature provided by Oracle Fusion Middleware extensions, see Setting Up Document Sequences.
This chapter discusses how to use lookups for providing lists of values (LOVs) for application end users to select from, and for performing validation of newly entered data. It also discusses how to share lookup data across organizations by using setIDs to partition the data into different sets of LOVs. Each organization can then maintain its lookups in a common table, using LOVs specific to that organization.

This chapter includes the following sections:

- Introduction to Lookups
- About Preparing Entities and Views for Lookups
- About Referencing Lookups
- About Defining Validators for Lookups
- Annotating Lookup Code Reference Attributes for Set-Enabled Lookups
- About Integrating Lookups Task Flows into

10.1 Introduction to Lookups

Lookups in applications are used to represent a set of codes and their translated meanings. For example, a product team might store the values ‘Y’ and ‘N’ in a column in a table, but when displaying those values they would want to display "Yes" or "No" (or their translated equivalents) instead. Each set of related codes is identified as a lookup type. There are many different examples of these across multiple applications.

Lookups Implementation

When you have completed the development process as discussed in this chapter and have delivered your application with the ability to use lookups, application implementers and administrators must then be able to define and maintain lookups that are appropriate to the organization that will use the application. They can accomplish these tasks using the Manage Standard Lookups, Manage Set-Enabled Lookups and Manage Common Lookups applications.

You make these setup applications available to implementers and administrators by incorporating their task flows into Oracle Fusion Functional Setup Manager. For more information, see About Integrating Lookups Task Flows into.

10.1.1 Overview of Lookups

Lookups are codes that are defined in the global FND_LOOKUP_VALUES table, which is striped into multiple virtual tables using a VIEW_APPLICATION_ID column. Each of these virtual tables is thus identified as a view application. Each view application is exposed as a database view, and all have separate ADF Business Components. It is the responsibility of the team who owns a particular view
application to provide both the database view and the necessary ADF Business Components objects. Only these view definitions, and any validation code supporting them, should access the underlying lookups tables directly. All other code that references lookups should always go through the database views and their supporting ADF Business Components objects, never directly referencing either the lookups tables or their base classes.

Note:
If you have a custom view application, you need to prepare a custom lookup view. For more information, see How to Prepare Custom Lookup Views.

Lookup codes are identified in an application by the following keys:

- A lookup view, which defines a distinct set of lookup types.
  Each lookup view is accessed through its own view, and may have different attributes or different validation, almost as if it were a separate table.

- A lookup type, which is a string identifier of a type that groups certain codes together; for example, COLORS.
  Within each lookup type, multiple lookup codes can be defined. Example 10-1 shows sample code for defining multiple lookup codes.

- A lookup code, which is a string identifier for a code within a type; for example, RED.

- A set or setID (for set-enabled lookups), which identifies the reference data set to which the lookup code belongs.
  For more information about setIDs, see Managing Reference Data with SetIDs.

The FND_LOOKUP_TYPES table defines the lookup types available.

Note:
When you register a lookup view application, you set a SET_ENABLED flag to indicate that the lookup view is set enabled. For this to be valid, every lookup type within that lookup view must have a reference group defined. The reference group is part of the lookup definition, and was defined when the lookup was defined. How that happens is beyond the scope of this documentation.

A reference to a non set-enabled lookup can be implemented exactly like any other foreign key reference, by specifying the lookup type in the view criteria. For set enabled lookups, you must specify the following additional properties, but only to add the indirection through the setID metadata:

- Indicate the view application ID and lookup type for lookup code attributes.
- Indicate the determinant attribute and determinant type, if the lookup type is set-enabled.

The use of setID metadata allows for the use of generic lookup entity objects, because the lookup type is automatically bound based on the metadata that you provide.
### Example 10-1   Defining Multiple Lookup Codes

View Application = 0 (FND_LOOKUPS)
- Lookup Type = COLORS "Colors"
  - Lookup Code = RED "Red"
  - Lookup Code = YELLOW "Yellow"
  - Lookup Code = GREEN "Green"

View Application = 3 (FND_COMMON_LOOKUPS)
- Lookup Type = COLORS "Colors"
  - Lookup Code = MAGENTA "Magenta"
  - Lookup Code = CHARTREUSE "Chartreuse"
  - Lookup Code = AQUAMARINE "Aquamarine"

### 10.1.2 About Standard, Set-Enabled, and Common Lookup Views

All lookups business objects exist in the `publicEntity` subpackage of the `oracle.apps.fnd.appcore.lookups.model` package. They can be imported into any Oracle JDeveloper application through `Lookups-Model.jar`. They are as follows:

**Lookup Types**

- **Entity Object:** `LookupTypePEO`
- **View Object:** `LookupTypePVO`
- **Base Table/View:** `FND_LOOKUP_TYPES_VL`

Each lookup type defines a set of lookup codes, and describes the intended usage of that set of codes. Note the `FND_LOOKUP_TYPES_VL` table and ADF Business Components objects are only meaningful when a `VIEW_APPLICATION_ID` is specified to choose the view application. You should never use either the table or the view without supplying the `VIEW_APPLICATION_ID`.

Product teams that own a view application must expose a pre-defined view for lookup types, exposing only the lookup types appropriate to their view application.

---

**Note:**

Product teams that own a view application also are responsible for providing the service, the loader, the UI, and the database view.

---

If your product has no special validation requirements, you can place your lookups in one of the central lookup views such as `FND_LOOKUPS`. However, if you define your own view application, you must supply a database view to match it.

**Lookup Values**

- **Entity Object:** `LookupValuePEO`
- **View Object:** none
- **Base Table/View:** `FND_LOOKUP_VALUES_VL`

The `FND_LOOKUP_VALUES_B` table (along with `FND_LOOKUP_VALUES_TL`) is the primary table that stores all the different lookup codes.

The `FND_LOOKUP_VALUES_VL` view is extended by the views in the three following listings (`FND_LOOKUPS`, `FND_COMMON_LOOKUPS`, and `FND_SETID_LOOKUPS`). If you want to define your own product specific lookups, you should extend this view as
well. This object contains the subset of columns that are expected to be common to all views that extend from this, with any additional columns required being added on an as-needed basis.

These objects should only be referenced by lookup view application owners when defining their own views and ADF Business Components objects. All other references should go through the objects created for that lookup view. The three standard ones that Oracle ships are FND lookups, common lookups, and setID lookups. If other products have lookup views, you should use the entity objects and view objects provided for them by the owning team.

(FND) Lookups

- **Entity Object**: LookupPEO
- **View Object**: LookupPVO
- **Base Table/View**: FND_LOOKUPS

The naming of the lookup objects can get confusing; the Lookups object is intended to refer specifically to FND lookups. The Lookup Values object in the previous listing is the generic object. The FND_LOOKUPS view is primarily used to store FND-specific lookup values but is also used to store lookup values that are common across multiple applications. For example, the "Yes/No" example given in the overview might be used by multiple product teams, so to avoid duplication that code can be stored centrally in FND_LOOKUPS.

This view extends from the FND_LOOKUP_VALUES_VL view, but only selects rows that have VIEW_APPLICATION_ID = 0 and SET_ID = 0.

Common Lookups

- **Entity Object**: CommonLookupPEO
- **View Object**: CommonLookupPVO
- **Base Table/View**: FND_COMMON_LOOKUPS

**Note:**

This view also was used to store lookup codes that were common to multiple applications, but it now exists only for backward compatibility.

This view extends from the FND_LOOKUP_VALUES_VL view, but only selects rows that have VIEW_APPLICATION_ID = 3 and SET_ID = 0.

SetID Lookups

- **Entity Object**: SetIdLookupPEO
- **View Object**: SetIdLookupPVO
- **Base Table/View**: FND_SETID_LOOKUPS

This view is used to store lookup codes that are set-enabled. The meanings corresponding to the given lookup code will vary depending on the value of the setID determinant.

This view extends from the FND_LOOKUP_VALUES_VL view, but only selects rows that have VIEW_APPLICATION_ID = 2.
10.1.3 About Lookup Customization Levels

Customization levels are defined on lookup types and can be used to enforce pre-defined data security policies that restrict how and by whom lookup types and their codes can be edited.

Valid values for CUSTOMIZATION_LEVEL are defined in the standard lookup type 'CUSTOMIZATION_LEVEL'. Table 10-1 lists these values.

Table 10-1    CUSTOMIZATION_LEVEL Lookup Codes

<table>
<thead>
<tr>
<th>Lookup Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>U</td>
<td>User</td>
</tr>
<tr>
<td>E</td>
<td>Extensible</td>
</tr>
<tr>
<td>S</td>
<td>System</td>
</tr>
</tbody>
</table>

10.1.3.1 What Happens to Customization Levels at Runtime

At runtime, the customization levels are interpreted as follows:

**User**
- Insertion of new codes is allowed
- Updating of start date, end date, and enabled fields is allowed
- Deletion of codes is allowed
- Updating of tag is allowed

**Extensible**
- Deletion of lookup type is **not** allowed
- Insertion of new codes is allowed
- Updating of start date, end date, enabled fields, and tag is allowed **only** if the code is not 'seed data'
- Deletion of codes is allowed **only** if the code is not 'seed data'
- Updating of module is **not** allowed

**System**
- Deletion of lookup type is **not** allowed
- Insertion of new codes is **not** allowed
- Updating of start date, end date, and enabled fields is **not** allowed
- Deletion of codes is **not** allowed
- Updating of tag is **not** allowed
- Updating of module is **not** allowed
In each of these scenarios, 'seed data' means LAST_UPDATED_BY = 'SEED_DATA_FROM_APPLICATION'. Also, to allow seed data to be edited, these rules are not enforced if the current user is 'SEED_DATA_FROM_APPLICATION'.

10.2 About Preparing Entities and Views for Lookups

It is expected that the owner of a lookup view will produce entity objects and view objects based on the entity objects for standard lookups database objects; for example, HR_LOOKUPS, GL_LOOKUPS, OE_LOOKUPS and so on. These view objects will typically be used for lookup validation as well as LOVs. If you put your lookups in the standard lookup views, you do not have to define anything, but simply reference the objects that are already provided.

Additionally, multiple ViewCriteria may be exposed on the lookups view object to take care of date ranging the lookup by supplying bind parameters for start and end active dates.

For a description of lookups tables and views provided by Oracle Fusion Middleware Extensions for Applications and their corresponding public business objects, see About Standard_Set-Enabled_ and Common Lookup Views.

10.2.1 How to Prepare Custom Lookup Views

If you have a simple lookup with no special requirements, you are free to define it in the centrally provided lookup views. You do not have to create your own lookup view just because you have lookups. However, if you have special validation requirements that are not satisfied by the central lookup views, you might want to create a private lookup view. If you do choose to create your own lookup view, you must take responsibility for the additional work required to support your lookup view as described in the following sections.

In preparing lookup views, you must perform several decision-based tasks.

To prepare lookup views, do the following:

1. Decide whether you really need a private lookup view.

   If you have no need for special attributes, special validation, or a private namespace for lookup types, you can use one of the centrally defined lookup views (FND_LOOKUPS, FND_COMMON_LOOKUPS, and FND_SETID_LOOKUPS). All of these lookup views are available for any product to use. If none of the central views meet your needs, you may define your own.

   **Note:**
   
   If you are using any of the three central lookup types (FND_LOOKUPS, FND_COMMON_LOOKUPS, and FND_SETID_LOOKUPS), you can skip the rest of this section.

   Lookup views are owned by applications (as determined by the view_application_id). There can be only one lookup view per view_application_id. It is up to the owner of the lookup view to make the view available for other applications to use, or to designate the lookup view as private.

2. Decide whether your lookup view should be set enabled.
If so, you must expose set_id as part of the "primary key" of your lookup view, and all references to it will have to include, either directly or indirectly, the set_id to use.

3. Define a database view to expose the lookup types included in your lookup view.

At a minimum your view must select from the base FND_LOOKUP_TYPES_VL view, expose the internal name and the display name, and include "where VIEW_APPLICATION_ID = my_application_id" in the where clause. In addition, if your view is set enabled, the lookup types view must include the REFERENCE_GROUP_NAME column. You are free to join additional tables, add additional attributes, or add additional filters to the where clause as desired. A template for the view might be:

```sql
select LOOKUP_TYPE,
       MEANING, DISPLAY_NAME,
       REFERENCE_GROUP_NAME, /* Only if set enabled */
... from FND_LOOKUP_TYPES_VL
where VIEW_APPLICATION_ID = my_application_id
and ...
```

4. Define a database view to expose the lookup codes included in your lookup view.

At a minimum your view must select from the base FND_LOOKUP_VALUES_VL view, expose the lookup type, the lookup code internal name, and the lookup code display name, and include "where VIEW_APPLICATION_ID = my_application_id" in the where clause. In addition, if your view is set enabled, the lookup values view must include the SET_ID column as part of the primary key. You are free to join additional tables, add additional attributes, or add additional filters to the where clause as desired. A template for the view might be:

```sql
select LOOKUP_TYPE,
       LOOKUP_CODE,
       SET_ID, /* Only if set enabled */
       MEANING,
... from FND_LOOKUP_VALUES_VL
where VIEW_APPLICATION_ID = my_application_id
and SET_ID = 0 /* Only if not set enabled */
and ...
```

5. Register your lookup view application and database views.

All view applications and the views used to reference them must be registered in the FND_LOOKUP_VIEWS metadata table. To register your lookup views, write a SQL script that calls the FND_LOOKUPS_UTIL.REGISTER_LOOKUP_VIEWS PL/SQL API. For example:

```sql
begin
  fnd_lookups_util.register_lookup_views(
    p_view_application_short_name => 'FND',
    p_set_enabled => 'N',
    p_lookup_type_view => 'FND_STANDARD_LOOKUP_TYPES',
    p_lookup_code_view => 'FND_LOOKUPS');
end;
```

This script registers required seed data, and must be run on every database instance.
6. Create ADF Business Components objects for your lookup view.

Each lookup view should have a separate entity object and view object (or PEO and PVO) for both lookup types and lookup codes, extending from the base entity object and view object provided for FND_LOOKUP_TYPES and FND_LOOKUP_VALUES.

For more information, see About Standard Set-Enabled and Common Lookup Views.

10.3 About Referencing Lookups

You must create view accessors for all lookups data sources (FND_COMMON_LOOKUPS, FND_SETID_LOOKUPS, HR_LOOKUPS, and so on) that are referenced in the entity object.

10.3.1 How to Reference Lookups

Lookups that are referenced in the entity object must have view accessors.

To reference lookups, do the following:

1. Import the lookups standard view objects into your project and make sure they can be referenced.

2. Open the entity object for editing.

3. On the View Accessors tab, add a view accessor. The View Accessors page appears.

4. Select a view object from the left-hand list and shuttle it to the right-hand list, then specify an accessor name.

5. Select the new view accessor and click Edit. The Edit View Accessor page appears.

6. Select the view criteria to use (if available), specify an order-by, and provide the bind parameter value.

---

**Note:**

All set-enabled view accessors are row sensitive (the determinant on the master or transactional row affects the query); therefore the **Row-level bind values exist** check box must always be selected for set-enabled view accessors. For example, view accessors to FND_SETID_LOOKUPS (set-enabled lookups cases) must have **Row-level bind values exist** selected because the setID value may change row by row and affect the validation result. Hence, the ViewAccessor Row Set will need to be refreshed row by row.

7. Click **OK** twice to finish creating the view accessor.

10.4 About Defining Validators for Lookups

You must create a validator for every foreign reference in an entity object. For set-enabled reference entities, the validator must be created at the entity object level, not at the attribute level, because it has dependencies on other attribute values such as the setID determinant attribute.

The type of validator to use depends on the expected size of the rowset for a given lookup type:
For a lookup definition where the rowset returned for a lookup type or lookup code is expected to be less than approximately 100 rows, use a list validator. See How to Define a List Validator.

For a lookup definition where the rowset returned for a lookup type or lookup code is expected to significantly exceed 100 rows, use a key exists validator. See About Defining a Key Exists Validator.

**Caution:**

If an attribute in your transactional entity was defined with null values allowed, the validator that you create will skip that attribute, and the end user will receive no indication of any problem. To ensure that the attribute is validated, you must edit the attribute and select the Mandatory checkbox in the attribute properties.

### 10.4.1 How to Define a List Validator

You define a list validator for lookup definitions where the rowset returned for a lookup type or lookup code is expected to be less than 100 rows.

To define a list validator, do the following:

1. Open the entity object for editing.

2. On the Validators tab, add a validation rule for the entity. The Edit Validation Rule page appears, as shown in Figure 10-1.

3. At the top of the page, select a Rule Type of List.
4. On the Rule Definition tab, do the following:

   a. Select the foreign reference column that is the lookup code (for example, SalaryCode) as the attribute.

   b. Select In as the operator.

   c. Select View Accessor Attribute as the list type.

5. From the Select View Accessor Attribute list, select LookupCode as the view accessor validation target lookup code attribute.

6. Select the Validation Execution tab, as shown in Figure 10-2.

   Because the validation should be executed every time the determinant value changes, it should be specified as a triggering attribute.
Figure 10-2  Lookups List Validator Execution

Note:
The foreign key attributes that were mapped on the Rule Definition tab are by default added as triggering attributes.

7. In the Triggering Attributes section, select the determinant attribute from the left-hand list and shuttle it to the right-hand list.

8. Optionally, on the Failure Handling tab, specify a failure error message.

9. Click OK to create the list validator for this lookup.

10.4.2 About Defining a Key Exists Validator

The key exists validator will include the mapping of the foreign key attributes in the transactional entity to the corresponding attributes in the reference view accessor. There must be a foreign key attribute on the transactional entity for each primary key attribute on the reference entity. First, you must provide missing foreign key attributes in the form of transient attributes. Next, you can create the validator that uses those attributes.

10.4.2.1 How to Define a Transient Lookup Type

Do the following:

1. Open the transactional entity object for editing.
2. Create a new transient lookup type attribute to map to the LookupType attribute on the reference entity, as shown in Figure 10-3.

**Figure 10-3  New Transient Lookup Type Entity Attribute**

3. Set the **Type** to **String**.

4. Set the **Value Type** to **Expression**, and provide a constant value for the attribute.

5. Deselect the **Persistent** checkbox.

6. In the **Updatable** section, select **Never**, then click **OK** to create the transient attribute.

**10.4.2.2 How to Define a Key Exists Validator**

Do the following:

1. On the Validators tab, add a validation rule for the transactional entity. The Edit Validation Rule page appears, as shown in Figure 10-4.

2. At the top of the page, select a Rule Type of **Key Exists**.
3. On the Rule Definition tab, select a **Validation Target Type** of View Accessor.

4. Select the entity object lookup code attribute on the left-hand list, and the corresponding view accessor validation target lookup code attribute on the right-hand list.

   Click **Add** to include the attribute pair on the mapping list.

5. Select the entity object transient lookup type attribute on the left-hand list, and the corresponding view accessor validation target lookup type attribute on the right-hand list.

   Click **Add** to include the attribute pair on the mapping list.

6. Select the entity object transient setID attribute on the left-hand list, and the corresponding view accessor validation target setID attribute on the right-hand list.

   Click **Add** to include the attribute pair on the mapping list.

7. Select the Validation Execution tab, as shown in Figure 10-5.

   Because the validation should be executed every time the determinant value changes, it should be specified as a triggering attribute.
8. In the Triggering Attributes section, select the determinant attribute from the left-hand list and shuttle it to the right-hand list.

9. Optionally, on the Failure Handling tab, specify a Failure Message.

10. Click OK to generate the key exists validator for this lookup. Then, save your project.

10.5 Annotate Lookup Code Reference Attributes for Set-Enabled Lookups

These properties are used only for set-enabled lookups, and only to do setID indirection. The setID lookup type LOV will show only those lookup types that are defined in your specified view application ID.

Do the following to annotate lookup code reference attributes:

1. Edit your set-enabled transaction table entity object.

2. Annotate each lookup code reference with setID machinery metadata, as shown in Figure 10-6.
To specify an attribute for use as a lookup code reference, select the attribute in the entity object editor. On the Applications tab of the Property Inspector.

- For a set-enabled lookup type, specify which determinant attribute on the entity object drives the setID of this lookup reference.

- For a set-enabled foreign key, you should also specify the setID determinant attribute that drives the foreign key reference.

3. Specify the **SetID View Application Id** and **SetId LookUp Type** properties.

### 10.6 About Integrating Lookups Task Flows into Oracle Fusion Functional Setup Manager

Every Oracle application registers task flows with a product called *Oracle Fusion Functional Setup Manager*. Functional Setup Manager provides a single, unified user interface that enables implementers and administrators to configure all multiple applications by defining custom configuration templates or tasks based on their business needs.

The Functional Setup Manager UI enables customers and implementers to select the business processes or products that they want to implement. For example, an HR application can register setup activities like "Create Employees" and "Manage Employee Tree Structure" with Functional Setup Manager.

There are application task flows for managing common lookups, set-enabled lookups, and standard lookups. To make these task flows available to application developers,
implementers or administrators, you can register the appropriate task flow with Functional Setup Manager, using the parameters listed for each task flow in Table 10-2. These taskflows can be used to manage lookups in the centrally defined lookup views (FND_LOOKUPS, FND_COMMON_LOOKUPS, and FND_SETID_LOOKUPS). All other lookup views (and any associated taskflows) are owned by applications (as determined by the VIEW_APPLICATION_ID). Contact the owning application for instructions on managing lookups in their lookup views.

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.

2. See the Implementing Common Features guides for your product family.
This chapter describes how to set up document sequences, which uniquely number documents, provide proof of completeness, and create audit trails.

This chapter contains the following sections:

- **Introduction to Document Sequences**
- **About Defining Document Sequence Categories**
- **About Assigning a Document Sequence**
- **About Striping Document Sequence Assignments**
- **About Defining a Document Sequence Audit Table**
- **About Enabling Document Sequences in ADF Business Components**
- **About Managing PL/SQL APIs**
- **About Integrating Document Sequence Task Flows into**

### 11.1 Introduction to Document Sequences

A document sequence uniquely numbers documents generated by an Oracle Fusion application. Using Oracle Fusion applications, you initiate a transaction by entering data through a form and generating a document, for example, an invoice. A document sequence generates an audit trail that identifies the application that created the transaction, for example, Oracle Receivables, and the original document that was generated, for example, invoice number 1234.

Document sequences can provide proof of completeness. For example, document sequences can be used to account for every transaction, even transactions that fail. Document sequences generate audit data, so even if documents are deleted, their audit records remain.

Document sequences can also provide an audit trail. For example, a document sequence can provide an audit trail from the general ledger into the subsidiary ledger, and to the document that originally affected the account balance.

There are three types of document sequence numbering:

- **Automatic** - Assigns a unique number to each document as it is generated. Automatic numbering is sequential by date and time of creation.

- **Gapless** - Automatically generates a unique number for each document, but ensures that the document was successfully generated before assigning the number. With gapless numbering, no sequence numbers are lost due to incomplete or failed document creation.
For gapless numbering, you also have the option of validating the transaction date. Validating the transaction date ensures that the sequence numbers and transaction dates are "chronologically correlated", that is, lower sequence numbers have been issued to earlier transaction dates. You enable this option on the Manage Document Sequence user interface.

**Note:**
It is recommend that you choose this type only when gapless numbering is essential, as it may affect the performance of your system.

- **Manual** - Requires a user to assign a unique number to each document before it is generated. With manual numbering, numerical ordering and completeness is not enforced. Users can skip or omit numbers when entering the sequence value.

Table 11-1 defines document-sequence terminology.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Document Sequences</td>
<td>Document sequences are owned by a product and can be assigned to categories that belong to the same product as the sequence. Sequences can be automatic, manual, or gapless, and are effective within a date range.</td>
</tr>
<tr>
<td>Document Sequence Categories</td>
<td>A document sequence category belongs to a table, which is owned by a product. Document sequence categories are entered with either the System Administrator form (Payables and Cash Management) or product forms (General Ledger and Receivables).</td>
</tr>
<tr>
<td>Sequence Assignments</td>
<td>The user assigns a sequence for each category. The assignments are owned by determinant type and determinant value and are effective within a date range.</td>
</tr>
</tbody>
</table>

11.2 About Defining Document Sequence Categories

Document sequence categories organize documents into logical groups.

- A document sequence category is one of the rules you use to define which documents a sequence assigns numbers to.

- You can separately number each document sequence category by assigning a different sequence to each category.

A document sequence category identifies the database table that stores documents resulting from transactions your users enter. When you assign a sequence to a category, the sequence numbers the documents that are stored in a particular table.

11.3 About Assigning a Document Sequence

Before you can assign a sequence to number documents, you must define which documents are to be numbered.

Defining a sequence is different from assigning a sequence to a series of documents.

- A sequence's definition determines whether a document's number is automatically generated or manually entered by the user.
• A sequence’s assignment, that is, the documents a sequence is assigned to, is defined in the Sequence Assignments form.

11.4 About Striping Document Sequence Assignments

Document sequences can optionally be given a determinant type when defined. This determinant type specifies the context "dimension" that will be used to stripe assignments of this document sequence. If a determinant type has been specified, then each assignment of this document sequence must include a particular value (or "determinant value") for this context. At runtime, only those document sequence assignments with a determinant value matching the current value for this dimension in the user's session context will be visible. If no determinant type is defined, then all assignments are considered global and are always visible.

Table 11-2 shows the possible values for the determinant type.

Table 11-2 Determinant Type Values

<table>
<thead>
<tr>
<th>Determinant Type Code</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>LEDGER</td>
<td>Ledger</td>
</tr>
<tr>
<td>LE</td>
<td>Legal Entity</td>
</tr>
<tr>
<td>BU</td>
<td>Business Unit</td>
</tr>
</tbody>
</table>

For example, if a document sequence is defined with determinant type of "Ledger", then each assignment of this document sequence must include a particular Ledger value. At runtime, only assignments that match the current Ledger value will be visible.

11.5 About Defining a Document Sequence Audit Table

Each time a C or PL/SQL call is made to request the next document sequence value, this audit data is inserted into the corresponding product team’s document sequence audit table.

Product teams using FND Document Sequence need to create an audit table with a name whose format is `application_short_name_DOC_SEQUENCE_AUDIT`, where `application_short_name` is the name of the application. For example, "AR_DOC_SEQUENCE_AUDIT."

The audit table must contain the columns and types shown in Table 11-3.

Table 11-3 Audit Table Columns and Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOC_SEQUENCE_ID</td>
<td>NOT NULL</td>
<td>NUMBER(18)</td>
</tr>
<tr>
<td>DOC_SEQUENCE_VALUE</td>
<td>NOT NULL</td>
<td>NUMBER(15)</td>
</tr>
<tr>
<td>DOC_SEQUENCE_ASSIGNMENT_ID</td>
<td>NOT NULL</td>
<td>NUMBER(18)</td>
</tr>
<tr>
<td>CREATION_DATE</td>
<td>NOT NULL</td>
<td>TIMESTAMP(6)</td>
</tr>
<tr>
<td>CREATED_BY</td>
<td>NOT NULL</td>
<td>VARCHAR2(64 CHAR)</td>
</tr>
</tbody>
</table>
**Table 11-3 (Cont.) Audit Table Columns and Types**

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>LAST_UPDATE_DATE</td>
<td>NOT NULL</td>
<td>TIMESTAMP(6)</td>
</tr>
<tr>
<td>LAST_UPDATED_BY</td>
<td>NOT NULL</td>
<td>VARCHAR2(64 CHAR)</td>
</tr>
<tr>
<td>LAST_UPDATE_LOGIN</td>
<td></td>
<td>VARCHAR2(32 CHAR)</td>
</tr>
<tr>
<td>ENTERPRISE_ID</td>
<td>NOT NULL</td>
<td>NUMBER(18)</td>
</tr>
</tbody>
</table>

**Note:**

Document sequence auditing is optional. If the AUDIT_TABLE_NAME attribute is null (that is, if the "Audit" checkbox has been unselected in the user interface), audit data will not be inserted at runtime.

---

**11.6 About Enabling Document Sequences in ADF Business Components**

This section focuses on ADF Business Components integration of document sequences provided by Fusion Middleware extensions for Oracle Applications base classes.

**11.6.1 About Using the Document-Sequence Extension**

The document sequence is generated and validated in the `postChanges()` method of the `OAEntityImpl` class. In automatic mode, it is generated by calling the public API `Long getDocSequence(Long appId, String categoryCode, Long sobId, String methodCode, TimestamptxnDate, Long seqVal, String suppressWarn, String suppressError)` in the `OAEntityImpl` class. In manual mode, it is validated by calling `public void validateDocSequence(Long appId, String categoryCode, Long sobId, String methodCode, Timestamp txnDate, Long seqVal, String suppressWarn, String suppressError)` in the same class.

You do not need to do anything to get the default behavior of generation and validation of a document sequence. However, if you require some special behavior, such as additional validation or adding an additional prefix or suffix, you can override these methods.

The Javadoc for the key methods in `OAEntityImpl` is shown in **Example 11-1**.

**Example 11-1 Javadoc for OAEntityImpl**

```java
/**
 * Override of EntityImpl.postChanges() to handle document sequencing.
 * If an entity attribute has been identified that it should be populated
 * using a document sequence (in the Applications Property Inspector panel),
 * then at this point in the entity life cycle, we will populate the attribute
 * with a document sequence based on the inputs, provided the sequence method
 * is automatic. If the document sequence is manual, we will validate the
 * document sequence.
 * See parent class for complete documentation
 * @param e this Entity Object's transaction event.
 * @see #validateDocSequence
 * @see #getDocSequence
 * @see EntityImpl#postChanges
 */
```
public void postChanges(TransactionEvent e){...}

/**
 * Will populate the entity attribute with a document sequence in Automatic mode, based on the schema based properties being set on the attribute using Applications Property Inspector in the Entity Attribute editor in JDev for
 * fnd:DOC_SEQUENCE (Document Sequence),
 * fnd:DOC_SEQ_APPLICATION_ID (Application Id),
 * fnd:DOC_SEQ_METHOD_CODE (Method Code),
 * fnd:DOC_SEQ_CATEGORY_CODE (Category Code),
 * fnd:DOC_SEQ_DETERMINANT_VALUE (Ledger Id),
 * fnd:DOC_SEQ_DETERMINANT_TYPE
 * fnd:DOC_SEQ_TXN_DATE (Transaction Date)
 * Application Id, Method Code, Category Code, Ledger Id and Transaction Code,
 * should be populated with valid Groovy expressions.
 * The Groovy expressions when evaluated should return a Long for Application Id,
 * and Ledger Id, String for Method Code and Category Code, Timestamp for Transaction Date fields.
 * This method will be invoked by postChanges() method on the entity, when posting the data to the database.
 * Override this if you want a different behavior/way of populating the document sequence.
 * @param appId Application Id
 * @param categoryCode Document Sequence Category Code
 * @param sobId Ledger Id to use for this Document Sequence.
 * @param methodCode Document sequence Method Code (Automatic ("A"), Manual ("M") or null for both modes).
 * @param txndateDocument Transaction Date
 * @param seqVal Document Sequence Value to use in Manual Mode
 * @param suppressWarn Suppress warning (Y/N/null)
 * @param suppressError Suppress Error (valid values are Y/N/null)
 * @return Document Sequence Value
 * @see #postChanges
 */

public Long getDocSequence(Long appId, String categoryCode, Long sobId, String methodCode, Timestamp txnDate, Long seqVal, String suppressWarn, String suppressError)
{
...

/**
 * Will validate the entity attribute with a document sequence value to use in Manual mode, based on the schema based properties being set on the attribute using Applications Property Inspector in the Entity Attribute editor in JDev for
 * fnd:DOC_SEQUENCE (Document Sequence),
 * fnd:DOC_SEQ_APPLICATION_ID (Application Id),
 * fnd:DOC_SEQ_METHOD_CODE (Method Code),
 * fnd:DOC_SEQ_CATEGORY_CODE (Category Code),
 * fnd:DOC_SEQ_DETERMINANT_VALUE (Ledger Id),
 * fnd:DOC_SEQ_DETERMINANT_TYPE
 * fnd:DOC_SEQ_TXN_DATE (Transaction Date)
 * Application Id, Method Code, Category Code, Ledger Id and Transaction Code,
 * should be populated with valid Groovy expressions.
 * The Groovy expressions when evaluated should return a Long for Application Id,
 * and Ledger Id, String for Method Code and Category Code, Timestamp for Transaction Date fields.
 */
* This method will be invoked by postChanges() method on the entity, when
* posting the data to the database.
* 
* Exception will be raised if document sequence value validation fails.
* 
* Override this if you want a different behavior/way of validating the document
* sequence.
* 
* @param appId Application Id
* @param categoryCode Document Sequence Category Code
* @param detType Determinant Type
* @param sobId Ledger Id to use for this Document Sequence.
* @param methodCode Document sequence Method Code (Automatic ("A"), Manual
* ("M") or null for both modes).
* @param txnDate Document Transaction Date
* @param seqVal Document Sequence Value in Manual Mode
* @param suppressWarn Suppress warning (Y/N/null)
* @param suppressError Suppress Error (valid values are Y/N/null)
* @see #postChanges
* /
public void validateDocSequence(Long appId, String categoryCode, Long sobId,
String methodCode, Timestamp txnDate, Long seqVal, String suppressWarn, String
suppressError)
{...}

11.6.1.1 What Happens with Document Sequences at Design Time

Oracle Fusion Middleware extensions provide the ability to identify if an entity
attribute needs a document sequence. This is accomplished by setting Document
Sequence to true in the entity attribute's Property Inspector window, as shown in
Figure 11-1.

Figure 11-1  Property Inspector: Document Sequence
By default, the entity attribute property is not set because it is not a document sequence field.

Fusion Middleware extensions also capture the additional metadata (as Groovy expressions) needed to generate a document sequence. Table 11-4 lists the metadata fields in the Property Inspector window and their descriptions.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Id</td>
<td>The application ID. The Groovy expression should return an object of type Long.</td>
</tr>
<tr>
<td>Category Code</td>
<td>The document sequence category code. The Groovy expression should return an object of type String.</td>
</tr>
<tr>
<td>Method Code</td>
<td>The document sequence method code. Select from the following: &quot;A&quot; (Automatic), &quot;M&quot; (Manual), or null (both modes). The Groovy expression should return an object of type String.</td>
</tr>
<tr>
<td>Determinant Type</td>
<td>The determinant type to use for this document sequence. The Groovy expression should return an object of type String.</td>
</tr>
<tr>
<td>Determinant Value</td>
<td>The determinant value to use for this document sequence. The Groovy expression should return an object of type Long.</td>
</tr>
<tr>
<td>Transaction Date</td>
<td>The document transaction date. The Groovy expression should return an object of type Timestamp.</td>
</tr>
</tbody>
</table>

11.6.1.2 What Happens with Document Sequences at Runtime

Based on the design time setting and additional metadata, Fusion Middleware extensions invoke document sequencing APIs and populate the attribute with a document sequence (in automatic mode) and validate the document sequence (in manual mode) in the postChanges() phase of the entity in ADF Business Components lifecycle. Document sequence processing is done at this phase so that the document sequence generation can be delayed as much as possible when in automatic mode. This is to avoid the potential wasting of document sequence if generated earlier.

If Document Sequence is not set or is set to false, nothing is done. If Document Sequence is set to true, Fusion Middleware extensions populate the entity attribute with a document sequence value if the method code is automatic.

This is accomplished by doing the following.

- Evaluating the Groovy expressions corresponding to the additional required metadata
- Invoking the document sequence PL/SQL APIs to do one of the following:
  - Generate a document sequence value when invoked in automatic mode
  - Validate the document sequence value when invoked in manual mode

11.7 About Managing PL/SQL APIs

Document sequence public PL/SQL APIs can be found in the FND_SEQNUM package. The package can be used to retrieve information about document sequences and assignments, create new document sequences or assignments, and to verify or retrieve the next sequence value for a particular document sequence assignment.
Sample APIs are shown in the examples that follow. For complete documentation, see comments in the package header.

**Example 11-2 Define a New Document Sequence**

```plsql
declare
    ret number;
begin
    -- Define a new document sequence
    ret := fnd_seqnum.define_doc_seq(
        app_id      => 222,               -- Application ID
        docseq_name => 'MY_DOC_SEQUENCE', -- Unique Doc_Seq Name
        docseq_type => 'A',               -- Sequence Type
        ('A'=automatic,'G'=gapless,'M'=manual)
        msg_flag    => 'Y',               -- Message Flag
        init_value  => 1,                 -- Initial sequence value
        start_date  => sysdate,           -- Effective Start date
        end_date    => null,              -- Effective End date
        det_type    => 'BU');             -- Determinant Type value
    if (ret <> FND_SEQNUM.SEQSUCC) then
        dbms_output.put_line('Fail: '||to_char(ret));
    end if;
end;
```

**Example 11-3 Retrieve the Next Sequence Value for an Automatic Sequence**

```plsql
declare
    ret number;
    docseq_val number;
    docseq_id number;
begin
    -- Retrieve the next sequence value for an Automatic sequence
    ret := fnd_seqnum.get_seq_val(
        app_id      => 222,               -- Application ID
        cat_code    => 'MY_CAT',          -- Category code
        sob_id      => 12345,             -- Determinant value
        met_code    => 'A',               -- Method Code ('A'=automatic/batch, 'M'=manual)
        trx_date    => sysdate,           -- Transaction date
        seq_val     => docseq_val,        -- Doc Seq value (output value for automatic)
        docseq_id   => docseq_id);        -- Doc Seq ID (output)
    if (ret <> FND_SEQNUM.SEQSUCC) then
        dbms_output.put_line('Fail: '||to_char(ret));
    else
        dbms_output.put_line('Next sequence value is '||to_char(docseq_val));
    end if;
end;
```

**Example 11-4 Verify a Sequence Value for a Manual Sequence**

```plsql
declare
    ret number;
    docseq_val number;
    docseq_id number;
begin
    -- Verify a sequence value for a Manual sequence
    docseq_val := 54321;
    ret := fnd_seqnum.get_seq_val(
        app_id      => 222,               -- Application ID
        cat_code    => 'MY_CAT',          -- Category code
        sob_id      => 12345,             -- Determinant value
        docseq_val  => docseq_val,        -- Doc Seq value (output value for automatic)
        docseq_id   => docseq_id);        -- Doc Seq ID (output)
end;
```
Example 11-5  Add Determinant Type

```sql
function define_doc_seq (app_id in number, mod_id in varchar2, docseq_name in fnd_document_sequences.name%TYPE, docseq_type in fnd_document_sequences.type%TYPE, msg_flag in fnd_document_sequences.message_flag%TYPE, init_value in fnd_document_sequences.initial_value%TYPE, p_startDate in date, p_endDate in date default NULL, det_type in fnd_document_sequences.determinant_type%TYPE default NULL, p_audit in boolean default true) return number;
```

Example 11-6  Enable Transaction Date Validation

```sql
function get_seq_val_date_enforced (app_id in number, cat_code in varchar2, det_type in varchar2, sob_id in number, met_code in char, trx_date in date, seq_val in out nocopy number, docseq_id out nocopy number, latest_date_used out date, suppress_error in char default 'N', suppress_warn in char default 'N') return number;
```

11.8 About Integrating Document Sequence Task Flows into Oracle Fusion Functional Setup Manager

Every Oracle application registers task flows with a product called Oracle Fusion Functional Setup Manager. Functional Setup Manager provides a single, unified user interface that allows customers and implementers to configure all Oracle applications by defining custom configuration templates or tasks based on their business needs.

The Functional Setup Manager UI enables customers and implementers to select the business processes or products that they want to implement. For example, an Accounts Payable application can register a setup activity like "Create Invoice" with Functional Setup Manager. After you define a category, for example, "Invoices," in the Categories task flow, document sequence task flows then provide the mechanism that
allows you to define a sequence and specify its properties. You then can assign the sequence to the "Invoices" category in the Assignments region in the same flow.

Table 11-5 lists the task flows and their parameters.

| Table 11-5  Task Flow Parameters |
|-----------------|-----------------|-----------------|-----------------|-----------------|
| Task Flow Name  | Task Flow XML   | Parameters Passed | Behavior                  | Comments               |
| Manage Document Sequence Categories | /WEB-INF/oracle/apps/fnd/applcore/docseq/ui/flow/ManageDocSeqCategoriesTF.xm#ManageDocSeqCategoriesTF | mode='search' [moduleType] [moduleKey] mode='edit' applicationId code [pageTitle] | Allows you to create and edit document sequence categories. Search mode allows you to search and edit categories. The moduleType and moduleKey parameters are optional, and if passed restrict the categories that can be queried and edited. Edit mode allows you to query and edit a single category. The applicationId and code parameters are required, and specify the category to edit. | Search and edit document sequence categories. |
| Manage Document Sequences | /WEB-INF/oracle/apps/fnd/applcore/docseq/ui/flow/ManageDocSequencesTF.xml#ManageDocSequencesTF | mode='search' [moduleType] [moduleKey] mode='edit' name [pageTitle] | Allows you to search and edit document sequences, and assignments of those sequences. Search mode allows you to query and edit sequences. The moduleType and moduleKey parameters are optional; if passed they restrict the sequences that can be queried. Edit mode allows you to edit a single document sequence and its assignments. The name parameter is required, and specifies the sequence to edit. | Search and edit document sequences (and the assignments belonging to a sequence). |

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.
This chapter describes how to implement Audit Reports in Oracle Fusion Applications.

This chapter contains the following sections:

- **Introduction to Audit Reports**
- **Implementing Audit Reports in the Framework**
- **Using Audit Reports**

### 12.1 Introduction to Audit Reports

Audit Reports creates a history of the changes that have been made to data in Oracle Fusion Applications. Audit Reports includes information such as what operation was performed on an item, when it was performed, and how the value was changed. The audit information is logged without any interaction from the end user.

The auditing solution brings together multiple underlying auditing frameworks, such as Oracle Fusion Middleware auditing that is based on an Oracle Platform Security Services (OPSS) framework, and Oracle Fusion Applications auditing that is based on an Oracle Fusion Middleware Extensions for Applications framework. The OPSS framework captures audit information through events that applications raise during their processing. The Applications Core framework creates a "shadow" table to record all operations on the base table.

### 12.2 Implement Audit Reports in the Oracle Fusion Applications Framework

Database auditing involves observing a database to be aware of the actions of database users. Audit setup provides a user interface mechanism for administrators to choose and select the objects and the specific attributes that need to be audited. When an object has been set to be audited using the audit setup user interface, any Data Manipulation Language (DML) actions on this object, that is, its underlying database schema objects, are captured and stored for reporting purposes.

The Audit Setup UI page is a task flow that is made available through the Oracle Fusion Middleware Extensions for Applications library. This task flow is available in Functional Setup Manager and can be included in an application that is accessible by the administrator. The UI consists of an Applications Tree Table that holds the structure of the auditable application modules, the children application modules, if present, and all the auditable view objects and their children. The administrator selects the view object on which to start auditing and in the applications table components below the tree table, the administrator chooses to add the attributes that need to be audited.
You also can set up the Fusion Middleware auditing as described in How to Set Up Auditing.

Metadata

Two database schema tables, FND_AUDIT_WEBAPP_AM and FND_AUDIT_ATTRIBUTES, hold metadata information that is required for Auditing.

- FND_AUDIT_WEBAPP_AM captures the list of application modules for an application.

<table>
<thead>
<tr>
<th>WEBAPP</th>
<th>APPLICATION_MODULE</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR2(80)</td>
<td>VARCHAR2(240)</td>
</tr>
</tbody>
</table>

- FND_AUDIT_ATTRIBUTES table data is populated during runtime when view objects are configured using the Audit Setup UI. This is an internal table and should not be changed.

<table>
<thead>
<tr>
<th>WEBAPP</th>
<th>VIEW_OBJE</th>
<th>VIEW_ATRI</th>
<th>ENABLED_F</th>
<th>TABLE_NAME</th>
<th>COLUMN_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR2(80)</td>
<td>VARCHAR2(240)</td>
<td>VARCHAR2(80)</td>
<td>VARCHAR2(1)</td>
<td>VARCHAR2(30)</td>
<td>VARCHAR2(30)</td>
</tr>
</tbody>
</table>

12.2.1 How to Set Metadata

This section covers the steps needed to populate and define metadata needed to run the Audit task flows.

To populate and define metadata:

1. Make sure every application has the webApp defined and set. This is done by populating the Oracle Fusion Applications Functional Core (ASK) deployment tables. These tables are populated at deployment time through Oracle Fusion Functional Setup Manager tasks.

   The webApp value is your MODULE_SHORT_NAME from the ASK_MODULES table.

2. Determine, for a given module, what are the applications modules that are to be registered in the metadata table (fnd_audit_webapp_am) for audit purposes.

   You can use the AuditServiceAM to register these applications modules. This service allows data to be extracted and uploaded.

   To use the AuditServiceAM, follow these steps:

   - Right-click your Model project.
   - Select Seed Date > Import/Export.
   - Select AuditServiceAM in the wizard that is displayed. If it is not available, make sure to import it to your project.
   - Click OK.

   If you do not have access to, or know how to use the AuditServiceAM, you can run this SQL example (using appropriate values).
describe fnd_audit_webapp_am;
insert into fnd_audit_webapp_am values ('ApplCoreCRMDemo', 'oracle.apps.fnd.appcore.crmdemo.model.CrmDemoAM', sysdate, 'pjl', sysdate, 'pjl', 'pjl', 1);
commit;
select * from fnd_audit_webapp_am;

3. Enable Audit on the Base Table.

You need to create a shadow table for each base table that is being audited. To create the shadow table:

- Open the .table file in JDeveloper.
- Right-click this object and select Properties.
- In the wizard that is displayed, select User Properties.
- In the list that is displayed on the right, scroll down to select the property Enable Audit and set its value to Y, as shown in Figure 12-1.

Figure 12-1 Setting Audit on a Table

- Save your changes.
- A new .table file will be created. This table will have an underscore (_) at the end of the name.
- Check in this new file.

Note: If your base table is enabled for multi tenant, make the same changes for the shadow table.

4. Set the Shadow Table Name on the entity object.

When a shadow table has been created, set this name on your base table EO.xml file as a schema-based property.

Property Name - "FND_AUDIT_TABLENAME"
Property Value - Shadow table name created in step 4.

<Properties>
  <SchemaBasedProperties>
5. Determine which business objects of each application module may be audited. When the business objects are identified, set a non-translatable schema-based property, named FND_AUDIT_ENABLED, on it with Name="Auditable" and Value="Y". Only when this property is set will the business object be shown in the Audit Setup UI for auditing. This follows an opt-in policy.

6. Determine which attributes of each business object you do want to audit and which ones you do not want to audit. By default:

- Attributes with a schema-based property called FND_AUDIT_ATTR_ENABLED and Value="false" will not be shown in the attribute selection dialog (see Figure 12-4).

- Attributes that are history columns are not shown (for example: Created By, Creation Date, Last Updated By)

- Attributes with a schema-based property called FND_AUDIT_ATTR_ENABLED and Value="true" are on by default if the view object is audited. In the attribute selection dialog (see Figure 12-4), these attributes will be displayed on the right (selected) side of the shuttle.

- If no value is set, the attribute will be available for selection in the attribute selection dialog (see Figure 12-4).
7. Define user-friendly names for application modules, business objects and attributes.

To have a user-friendly display name for all application modules, business objects and attribute names, the label property for each must be set. For application modules and business objects, you should add a tooltip, since the tooltip will be shown in the Audit Setup UI and also will give the administrator further information on the business objects and application module. The label and tooltip are available as properties.

The following shows an example for a view object:

```xml
<Properties>
    <SchemaBasedProperties>
        <fnd:FND_AUDIT_ENABLED Value="true"/>
    </SchemaBasedProperties>
    <LABEL ResId="ViewObjectVO_LABEL"/>
    <TOOLTIP ResId="ViewObjectVO_TOOLTIP"/>
</Properties>
</viewAttribute>
```

The following shows an example for an attribute. Set the Label property under the UI Hints in the property inspector for an attribute.

```xml
<ViewAttribute
    Name="TableName"
    PrecisionRule="true"
    EntityAttrName="TableName"
    EntityUsage="FndAuditAttributesEO"
    AliasName="TABLE_NAME">
    <Properties>
        <SchemaBasedProperties>
            <LABEL ResId="TableName_LABEL"/>
        </SchemaBasedProperties>
    </Properties>
</ViewAttribute>
```

8. Enable a User Key.

The User Key is the value that will appear in the Description field in the Audit Reports. See Figure 12-5.

If you need to be able to search based on a key other than the primary key of the view object, then you need to set a schema-based property called FND_AUDIT_USER_KEY on this attribute. This attribute must have a unique value.
and the new property should be set on only one attribute that is not the primary key. If you have a multi-part key, then you should use the one that is the most important as the User Key, and use the context name/value pairs for the others. Although end users may not be able to search down to just one item, they can see the context values to determine the ones in which they are interested.

```xml
<ViewAttribute
    Name="TableName"
    IsUnique="true"
    IsNotNull="true"
    PrecisionRule="true"
    EntityAttrName="TableName"
    EntityUsage="FndTablesEO"
    AliasName="TABLE_NAME">
  <Properties>
    <SchemaBasedProperties>
      <fnd:FND_AUDIT_USER_KEY Value="true"/>
    </SchemaBasedProperties>
  </Properties>
</ViewAttribute>
```

9. Configure lookups on the User Key attribute.

Foreign Key lookup can be configured on the User Key attribute. To do so, configure the User Key attribute and then configure the Foreign Key lookup. In addition, the annotation listed below needs to be mentioned at View Object level to derive the User Key from the lookup value (while a Description search is performed).

The user key can be something other than a straight value. This is accomplished by allowing more tags to be used with the `FND_AUDIT_USER_KEY` tag:

```xml
  <fnd:FND_AUDIT_USER_KEY Value="true"/>
  <fnd:FND_AUDIT_FK_VIEWOBJECT Value=" "/>
  <fnd:FND_AUDIT_FK_DISPLAYATTR Value=" "/>
  <fnd:FND_AUDIT_FK_WHEREATTR Value=" "/>
  <fnd:FND_AUDIT_FK_WHEREATTR_ADDL Value=" "/>
  <fnd:FND_AUDIT_VALUE_ADDL Value=" "/>
  <fnd:FND_AUDIT_USERKEY_LKP_COND Value=" "/> <!-- This attribute must be used if the FK tags are used. -->
```

Example

Assume the `PersonId` attribute is defined as the User Key and the Foreign Key lookup is defined on the User Key:

```xml
  <fnd:FND_AUDIT_USER_KEY Value="true"/>
  <fnd:FND_AUDIT_FK_VIEWOBJECT Value="abc.PersonVO"/>
  <fnd:FND_AUDIT_FK_DISPLAYATTR Value="PersonName"/>
  <fnd:FND_AUDIT_FK_WHEREATTR Value="PersonId"/>
  <fnd:FND_AUDIT_USERKEY_LKP_COND Value="SELECT PERSON_ID FROM PERSONS WHERE PERSON_NAME LIKE ?"/>
```

10. Configure custom objects.

For custom business objects, identify the application module to which the custom business objects belong and add this to the metadata table as defined in step 5. Define the `FND_AUDIT_ENABLED` property as shown in step 4 on the custom
business objects. If entity objects also are generated at a customer instance, set the property mentioned in step 4.

11. If needed, configure the attribute lookup based on the FND_LOOKUPS table.

For columns that show raw data of lookup codes instead of the meaning (such as "A034" instead of "washing machine"), you can specify annotation across the attribute specifying its lookup type. Audit Report internally queries the FND_LOOKUPS table for that lookup_type to show the column meaning. The schema-based property to use is FND_AUDIT_LOOKUP_TYPE as shown below:

```xml
<ViewAttribute
  Name="ProblemDescription" IsNotNull="true" PrecisionRule="true" EntityAttrName="ProblemDescription"
  EntityUsage="ServiceRequestsEO" AliasName="PROBLEM_DESCRIPTION">&#160;&#160;
  <Properties>
    <SchemaBasedProperties>
      <fnd:FND_AUDIT_LOOKUP_TYPE Value="AHL_PLANNING_VISIT_TYPE"/>
    </SchemaBasedProperties>
  </Properties>
</ViewAttribute>
```

12. If needed, configure context descriptive attributes to show context attributes that define the context of a changed record.

A maximum of 3 context descriptive attributes can be defined for a given view object. If context attributes were defined for both parent and child view objects, the report will show parent context information for parent records, and child context information for child records.

Each context attribute must be defined with an annotation similar to that shown in the example but that has FND_AUDIT_CONTEXT2 and FND_AUDIT_CONTEXT3 as its prefix.

If you need an additional WHERE condition to derive the context attribute value, you can use the _ADDL annotations, as shown in the example.

```xml
<ViewObject ...>
  <Properties>
    <CustomProperties>
      <Property Name="AUDIT_CONTEXT1_VIEWOBJECT" Value=""/> <!--fully qualified view object name, optional for same view -->
      <Property Name="AUDIT_CONTEXT1_DISPLAYATTR" Value=""/> <!--attribute of lookup view to display-->
      <Property Name="AUDIT_CONTEXT1_WHEREATTR" Value=""/> <!--attribute of lookup view to apply WHERE condition-->
      <Property Name="AUDIT_CONTEXT1_WHEREATTR_ADDL" Value=""/> <!--attribute of base view for WHERE condition key-->
      <!-- composite key specification - start-->
      <Property Name="AUDIT_CONTEXT1_WHEREATTR_ADDL" Value=""/> <!--attribute of lookup view to apply additional WHERE condition-->
      <!-- either <Property Name="AUDIT_CONTEXT1_VALUE_ADDL" Value=""/> <!-- for hardcoded value-->
      or <Property Name="AUDIT_CONTEXT1_KEYATTR_ADDL" Value=""/> <!-- attribute of base view for additional key-->
      <!-- composite key specification - end-->
    </CustomProperties>
  </Properties>
</ViewObject>
```
Example Use Case

You want to specify Product as one of the context attributes for the Revenue view objects. But Product is composed of a composite key: InventoryItemId and InventoryOrgId.

The specification will appear similar to:

```xml
<ViewObject name="Revenue"...>
  <Properties>
    <CustomProperties>
      <Property Name="AUDIT_CONTEXT1_VIEWOBJECT" Value="com.oracle...
EgpSystemItemsVO"/>
      <Property Name="AUDIT_CONTEXT1_DISPLAYATTR" Value="Description"/>
      <Property Name="AUDITCONTEXT1_WHEREATTR" Value="InventoryOrgId"/>
      <!-- composite key specification - start-->
      <Property Name="AUDITCONTEXT1_WHEREATTR_ADDL" Value="InventoryItemId"/>
      <Property Name="AUDITCONTEXT1_KEYATTR_ADDL" Value="InventoryItemId"/>
      <!-- for additional key attr -->
      <!-- composite key specification - end-->
    </CustomProperties>
  </Properties>
</ViewObject>
```

The SQL statement that will be generated will be:

```sql
SELECT Description from <table used by EgpSystemItemsVO> where (InventoryOrgId = Revenue.InventoryOrgId) AND (InventoryItemId = Revenue.InventoryItemId)
```

13. If needed, configure attribute lookup based on Foreign Key tables.

This works the same as Configure Attribute Lookup Based on the FND_LOOKUPS table, but is not limited to the FND_LOOKUPS table.

```xml
<ViewObject ...
  <ViewAttribute
    Name="OWNER"IsNotNull="true"PrecisionRule="true"EntityAttrName="Owner"EntityUsage="ServiceRequestsEO"AliasName="Owner">
    <Properties>
      <SchemaBasedProperties>
        <fnd:FND_AUDIT_FK_VIEWOBJECT Value=""/>
        <fnd:FND_AUDIT_FK_DISPLAYATTR Value=""/>
        <fnd:FND_AUDIT_FK_WHEREATTR Value=""/>
      </SchemaBasedProperties>
    </Properties>
</ViewAttribute>
</ViewObject>
```

14. If needed, define View Criteria on Business Objects to filter the display of view objects. For instance, a table might be shared by three applications, and you need to filter based on only one of the applications.

Simple query-based View Criteria:

```xml
<ViewObject ...
  <Properties>
    <SchemaBasedProperties>
      <fnd:FND_AUDIT_VIEWCRITERIA_DBOBJECT Value=""/>
    </Properties>
</ViewObject>
```
Complex query-based View Criteria:

15. If needed, force writing attributes to the Shadow Table.

The `FND_AUDIT_FORCE_WRITE` property co-exists with the normal audit properties.

Product teams may want to write certain attributes to the shadow table all the time, even if the attribute is not enabled for auditing. This could be because Virtual Private Datasource policy is set up on the attribute, or the attribute participated in a WHERE condition. This sample code shows how to enable force writing of the attributes:

```
<ViewAttribute
    Name="TableName"
    IsUnique="true"
    IsNotNull="true"
    PrecisionRule="true"
    EntityAttrName="TableName"
    EntityUsage="FndTablesEO"
    AliasName="TABLE_NAME">
    <Properties>
        <SchemaBasedProperties>
            <fnd:FND_AUDIT_FORCE_WRITE Value="true"/>
        </SchemaBasedProperties>
    </Properties>
</ViewAttribute>
```

- If the property value is set to "true," and the attribute is not enabled for audit, it will not appear in the audit reports (unless it also is defined as the user key, context attribute, and so on).

- If the property value is set to "true," and the attribute is enabled for audit, it will only appear when the value changes.

```
<Properties>
    <SchemaBasedProperties>
        <fnd:FND_AUDIT_FORCE_WRITE Value="true"/>
    </SchemaBasedProperties>
</Properties>
```

Note that when a search is conducted on a view object, then the search result will include rows from even the child view objects.
16. If needed, exclude a view object from a search in the Audit Report.

The Audit Reports UI contains a search query panel in which a user can select a particular Product from the Product LOV and then filter the search further by selecting a view object from the Business Object LOV.

The fnd:FND_AUDIT_REPORT_EXCLUDE audit annotation provides the ability to exclude a particular view object from the Business Object LOV, even if it may be marked as auditable. This is required for use cases in which a view object without the context of its parent will not make sense, so developers can expose the parent object and hide the children.

```
<ViewObject
xmlns="http://xmlns.oracle.com/bc4j"
xmlns:fnd="http://xmlns.oracle.com/apps/entityview"
...
</Properties>
</ViewObject>
```

17. If needed, configure custom display names for Context attribute names.

The custom display name of the Context attribute name in an Audit Report can be configured by using the annotation fnd:FND_AUDIT_CONTEXT1_LABEL_ID. The value provided to this annotation must be a resource ID in the resource bundle of the view object in which these context annotations are defined. If the annotation is not used, then the display name of the context view attribute itself is displayed in the Audit Report.

```
<ViewObject ...
<Properties>
  <SchemaBasedProperties>
    <fnd:FND_AUDIT_CONTEXT1_VIEWOBJECT Value=""/>
    <fnd:FND_AUDIT_CONTEXT1_DISPLAYATTR Value=""/>
    <fnd:FND_AUDIT_CONTEXT1_WHEREATTR Value=""/>
    <fnd:FND_AUDIT_CONTEXT1_KEYATTR Value=""/>
    <fnd:FND_AUDIT_CONTEXT1_LABEL_ID Value=""/>
  </SchemaBasedProperties>
</Properties>
</ViewObject>
```

The custom display name can be configured to each Context attribute by using the FND_AUDIT_CONTEXT2_LABEL_ID and FND_AUDIT_CONTEXT3_LABEL_ID annotations.

18. If needed, configure lookups on the User Key attribute.

A Foreign Key lookup can be configured on a User Key attribute. Configure a User Key attribute as described in step 8. Then configure a Foreign Key lookup as described in step 13. Include this annotation at the view object level to derive a User Key from the lookup value while a Description search is performed.

```
<ViewObject ...
<Properties>
  <SchemaBasedProperties>
    ....
  </Properties>
</ViewObject>
```
Example

Assume that the PersonId attribute is defined as a User Key, and Foreign Key lookup is defined on the User Key, as shown here:

```xml
<viewObject ...>
<properties>
    <schemaBasedProperties>
        ....
        <fnd:FND_AUDIT_USERKEY_LKP_COND Value="SELECT PERSON_ID FROM PERSONS WHERE PERSON_NAME LIKE ?"/>
    </schemaBasedProperties>
</properties>
</viewObject>
```

19. If needed, you can hide a view object under an application module in the Audit Setup UI

If the view object contains the audit annotation `<fnd:FND_AUDIT_ENABLED Value="true"/>`, it will be displayed in the Setup UI. However, there are cases in which the view object that is owned by a different team is present under the application module and the user is not interested in seeing it under the application module in the Setup UI.

For example, when Oracle Fusion CRM creates custom objects, it also creates an Attachment object as its child, by default. However, they do not want to see the Attachment object in the Setup UI. Since the Attachment view object is an FND object and is not owned by Oracle Fusion CRM, there is no way for them to remove the `fnd:FND_AUDIT_ENABLED` annotation from it.

The annotation shown here can be specified in the application module which is registered for audit in the `fnd_audit_webapp_am` table. The user is expected to provide a comma-separated list of all view object names that is present in the Data Model of the application module and needs to be hidden in the Audit Setup UI. With this, in place the listed view objects and their children, if any, will be hidden.

```xml
<appModule ...>
    <properties>
        ...
        <customProperties>
            <property Name="fnd:FND_AUDIT_SETUP_HIDE_VIEWOBJECT_LIST" Value = 'oracle.apps.fnd.applcore.audit.setup.view.FndTablespacesVO'/>
        </customProperties>
    </properties>
</appModule>
```

20. If needed, support audit-specific Data Security view criteria in a view object
Audit considers the Data Security privilege for Business Object instances when specified in application modules (using view criteria in the format of FNDDS_privilegeNameobjectName_objectAlias) or if specified at the Entity level by enabling the "read" privilege in the Security section.

If, for any reason, this cannot be done, audit supports the annotation shown here that allows the Data Security privilege to be specified in the view object. Audit History will consider this view object-level privilege as first priority.

```xml
<ViewObject ...
  <Properties>
    <SchemaBasedProperties>
      ....
      <fnd:FND_AUDIT_DS_VIEWCRITERIA
        Value="FNDDS__read__FND_CRM_CASES__QRLT,FNDDS__read__FND_CRM_CASES__CasesEO"/>
    </SchemaBasedProperties>
  </Properties>
</ViewObject>
```

21. If needed, there is audit support for PL/SQL-based Data Manipulation Language (DML) operations

Audit maintains a history of changes done to business objects in Oracle Fusion Applications.

During business transaction flows based on ADF Business Components, audited attribute values are stored in shadow tables. Audit automatically extends product transactions without needing to change product team code or business flows. For transaction flows using PL/SQL, data is not automatically saved to the shadow table. The changes shown here must be made in the PL/SQL procedures that write to the base tables.

**API Signature**

```
-- Type tr_data will contain data for only one of the variables based on the column's data type.
-- If the column is varchar, varchar2_value needs to be set.

TYPE tr_data IS RECORD(
  varchar2_value VARCHAR2(4000),
  number_value NUMBER,
  date_value DATE,
  timestamp_value TIMESTAMP);

TYPE tr_column_data IS RECORD(
  column_name VARCHAR2(30),
  column_type VARCHAR2(30),
  old_data tr_data,
  new_data tr_data);

TYPE tt_columns_data is table of tr_column_data INDEX BY BINARY_INTEGER;

-- get_audited_columns function returns the list of columns enabled for auditing for the passed in base table.
-- Parameters
-- p_base_table_name - pass the base table name on which the DML Operation occurred
```

FUNCTION get_audited_columns (p_base_table_name IN VARCHAR2) RETURN
  tt_column_names;

-------------------------------------------------------------------------------
-- Create_Audit_Row method writes to the audit shadow table
-- Parameters
-- p_base_table_name- pass the base table name on which the DML Operation occurred
-- p_event_type     - pass "INSERT", "UPDATE", or "DELETE" based on the DML
  operation on base table
-- p_audit_data     - pass a table structure with each row(tr_column_data) contain the column,
  its type and old and new value. All the columns returned from get_audited_columns needs to be passed.
-- Additionally all the who columns (created_by, creation_date, last_update_date, last_updated_by, last_update_login needs to be passed. In case of INSERT, only new data needs to be passed and in case of DELETE, only old data. In case of UPDATE, pass both the old and new value even for attributes that are not changed.
----------------------------------------------------------------------------------

-----------------------------------------------------------------------------

PROCEDURE create_audit_row(
  p_base_table_name IN VARCHAR2,
  p_event_type IN VARCHAR2,
  p_audit_data IN tt_columns_data);

Coding Steps

• Check if the table is enabled for Auditing

  FND_AUDIT_UTIL.is_table_audited(
    p_base_table_name in varchar2(30)  // input parameter - base table name
  ) return varchar2(5)               // returns "true" or "false"

  If the API returns false, do nothing.

• If the table is audited and the DML type is INSERT for the base table, call the
  PL/SQL API, passing in all the values as new values.

    declare
      tt FND_AUDIT_UTIL.tt_columns_data;
      p_base_table_name varchar2(30);

    begin
      p_base_table_name := 'FND_LOOKUP_TYPES';
      if (FND_AUDIT_UTIL.is_table_audited(p_base_table_name) = 'false') then
        return;
      end if;

      tt(1).column_name := 'CUSTOMIZATION_LEVEL';
      tt(1).column_type := 'VARCHAR2';
      tt(1).new_data.varchar2_value := 'U';

      tt(2).column_name := 'ENTERPRISE_ID';
      tt(2).column_type := 'NUMBER';
      tt(2).new_data.NUMBER_value := '0';

      tt(3).column_name := 'LOOKUP_TYPE';
      tt(3).column_type := 'VARCHAR2';
      tt(3).new_data.varchar2_value := 'TEST11';
FND_AUDIT_UTIL.CREATE_AUDIT_ROW(
   p_base_table_name,
   'INSERT',
   tt);
end;

• If the table is audited and the DML type is UPDATE, call the PL/SQL API to get a list of audit-enabled attributes.

```
TYPE tt_column_names  IS TABLE OF VARCHAR2(30) INDEX BY BINARY_INTEGER;
FND_AUDIT_UTIL.get_audited_columns(
   p_base_table_name in varchar2(30)  // input parameter - base table name
) return tt_column_names
```

If any column that is updated in the current transaction is in the list returned from get_audited_columns, get the value for all the other columns in the table and call the PL/SQL API. Note that you need to pass in values (old and new) for all the columns returned from the get_audited_columns() function, and also for all the who columns, even if the values have not changed.

```
declare
   tt FND_AUDIT_UTIL.tt_columns_data;
   p_base_table_name varchar2(30);
   col_list  FND_AUDIT_UTIL.tt_column_names;
   l_col_change_found varchar2(30);
begin
   p_base_table_name := 'FND_LOOKUP_TYPES';
   l_col_change_found := 'false';
   if (FND_AUDIT_UTIL.is_table_audited(p_base_table_name) = 'false') then
      return;
   end if;
   col_list := FND_AUDIT_UTIL.get_audited_columns(p_base_table_name);
```
-- assuming here that only customization_level has changed
FOR i IN 1 .. col_list.count LOOP
  IF (col_list(i) = 'CUSTOMIZATION_LEVEL') THEN
    l_col_change_found := 'true';
  END IF;
END LOOP;

-- if you don't have all the values, query the rest of the values from your
base table
-- then pass the same value for old and new value.
-- if the old or new value is blank, audit code will assume that the value
has been cleared out.

if (l_col_change_found :='true') THEN
  tt(1).column_name := 'CUSTOMIZATION_LEVEL';
  tt(1).column_type := 'VARCHAR2';
  tt(1).old_data.varchar2_value := 'U';
  tt(1).new_data.varchar2_value := 'S';
  tt(2).column_name := 'ENTERPRISE_ID';
  tt(2).column_type := 'NUMBER';
  tt(2).old_data.NUMBER_value := '0';
  tt(2).new_data.NUMBER_value := '0';
  tt(3).column_name := 'LOOKUP_TYPE';
  tt(3).column_type := 'VARCHAR2';
  tt(3).old_data.varchar2_value := 'TEST11';
  tt(3).new_data.varchar2_value := 'TEST11';
  tt(4).column_name := 'MODULE_ID';
  tt(4).column_type := 'VARCHAR2';
  tt(4).old_data.varchar2_value := '40B3FA7250D19380E040449823C67A1A';
  tt(4).new_data.varchar2_value := '40B3FA7250D19380E040449823C67A1A';
  tt(5).column_name := 'VIEW_APPLICATION_ID';
  tt(5).column_type := 'NUMBER';
  tt(5).old_data.NUMBER_value := '0';
  tt(5).new_data.NUMBER_value := '0';
  tt(6).column_name := 'CREATED_BY';
  tt(6).column_type := 'VARCHAR2';
  tt(6).old_data.varchar2_value := 'ADMIN';
  tt(6).new_data.varchar2_value := 'ADMIN';
  tt(7).column_name := 'LAST_UPDATED_BY';
  tt(7).column_type := 'VARCHAR2';
  tt(7).old_data.varchar2_value := 'ADMIN';
  tt(7).new_data.varchar2_value := 'APPLICATION_ADMINISTRATOR';
  tt(8).column_name := 'CREATION_DATE';
  tt(8).column_type := 'TIMESTAMP';
  tt(8).old_data.timestamp_value := sysdate -10;
  tt(8).new_data.timestamp_value := sysdate-10;
  tt(9).column_name := 'LAST_UPDATE_DATE';
  tt(9).column_type := 'TIMESTAMP';
  tt(9).old_data.timestamp_value := sysdate -10;
  tt(9).new_data.timestamp_value := sysdate;

FND_AUDIT_UTIL.CREATE_AUDIT_ROW(
  p_base_table_name,
• If the table is audited and the DML type is DELETE for the base table, call PL/SQL API, passing in all the values (as old values) from the base table.

```sql
DECLARE
    tt FND_AUDIT_UTIL.tt_columns_data;
    p_base_table_name varchar2(30);
BEGIN
    p_base_table_name := 'FND_LOOKUP_TYPES';
    IF (FND_AUDIT_UTIL.is_table_audited(p_base_table_name) = 'false') THEN
        RETURN;
    END IF;

    tt(1).column_name := 'CUSTOMIZATION_LEVEL';
    tt(1).column_type := 'VARCHAR2';
    tt(1).old_data.varchar2_value := 'S';

    tt(2).column_name := 'ENTERPRISE_ID';
    tt(2).column_type := 'NUMBER';
    tt(2).old_data.NUMBER_value := '0';

    tt(3).column_name := 'LOOKUP_TYPE';
    tt(3).column_type := 'VARCHAR2';
    tt(3).old_data.varchar2_value := 'TEST11';

    tt(4).column_name := 'MODULE_ID';
    tt(4).column_type := 'VARCHAR2';
    tt(4).old_data.varchar2_value := '40B3FA7250D19380E040449823C67A1A';

    tt(5).column_name := 'VIEW_APPLICATION_ID';
    tt(5).column_type := 'NUMBER';
    tt(5).old_data.NUMBER_value := '0';

    tt(6).column_name := 'CREATED_BY';
    tt(6).column_type := 'VARCHAR2';
    tt(6).old_data.varchar2_value := 'ADMIN';

    tt(7).column_name := 'LAST_UPDATED_BY';
    tt(7).column_type := 'VARCHAR2';
    tt(7).old_data.varchar2_value := 'APPLICATION_ADMINISTRATOR';

    tt(8).column_name := 'CREATION_DATE';
    tt(8).column_type := 'TIMESTAMP';
    tt(8).old_data.timestamp_value := sysdate -10;

    tt(9).column_name := 'LAST_UPDATE_DATE';
    tt(9).column_type := 'TIMESTAMP';
    tt(9).old_data.timestamp_value := sysdate;

    FND_AUDIT_UTIL.CREATE_AUDIT_ROW(
        p_base_table_name,
        'DELETE',
        tt);
END;
```
12.2.2 How to Set Up Auditing

As with most Oracle Fusion applications, Audit setup is done from Functional Setup Manager. When you start the setup, search in Functional Setup Manager for "Audit." When it is located, select Audit Setup.

A list of Oracle Fusion applications is displayed, as shown in Figure 12-2.

**Figure 12-2  Initial Audit Setup Display**

You will notice that some have only an Audit Level drop-down list that lets you pick Low, Medium or High levels. These are Oracle Fusion Middleware products that generate event-based entries in the table that is read by the Audit system, and the user just sets the granularity that is desired. (Refer to the product documentation and to the online help for a description of how the levels work in each particular product.)

In the example figure, click the **Configure Business Object Attributes** button to display the Configure Business Objects Attributes dialog. When it first displays, the fields will be empty.

To populate the Objects list, open the Application drop-down list and select the name of the application you want to audit. The example shown in Figure 12-3 uses the Applications Core Setup application.
There are three buttons at the top of the Configure Business Object Attributes dialog:

- Click **Save** to save your work and remain in the Audit Setup dialog.
- Click **Save and Close** to save your work and exit the Audit Setup dialog.
- Click **Cancel** to cancel any changes you have made since the last Save action and exit the Audit Setup dialog.

**Objects List**

The Objects list has three columns:

- **Audit**

  There is no limit to the number of levels that can be included in an audit.

  You will notice that items with the same name are displayed and can be selected. The item at the top of the tree is the root item; the other listed items of the same name are reflections of the root item and are not separate. That is, if a view object appears multiple times in the Setup list, there really is only one view object. Selecting or deselecting any instance of that view object will select or deselect all instances.

  **Example:**

  You pick a view object and select five of its attributes to audit and save. If you then choose the same view object, but somewhere else in the setup UI, it will have those five attributes already selected. Now select two more, so that there are seven attributes selected. When you return to the first instance of the view object, it also will show seven attributes selected.

  Similarly, if you delete one of the five selected attributes, all instances of the affected view object will show only four selected attributes.

  Another way of saying this is "last edit wins."

  Any item that is checked in the Audit column will have all its selected attributes audited. Unless the view objects’ Attributes list has been edited, the attributes that will be audited are default attributes.

  If you edit a view object to select specific attributes, the Audit box must still be checked to audit the selected attributes. (You can edit the attributes, but that, by
itself, does not mean they will be included in an audit, unless the Audit box is checked.)

- **Name**
  The names of the application modules and view objects.

- **Description**
  A brief description of the associated application module or view object.

The Objects list has two menus.

- **Actions menu**
  The Actions menu provides the **Synchronize** option.
  Attributes of objects that are being audited are tracked. On a patch or update, or if customized attributes, such as flexfield attributes, have been added, they must be tracked if they are meant to be included in the audit. That is, the attribute was marked as `<fnd:FND_AUDIT_ATTR_ENABLED Value="true"/>`. Synchronize will do this.

  **Note:** Synchronization is carried out by product. That is, it will synchronize all objects in the current product shown in the UI, if those objects have been selected for audit at any time previously.

  Flexfield and custom attributes are always included by default (`<fnd:FND_AUDIT_ATTR_ENABLED Value="true"/>`), so with these you want to be sure to do a synchronization.

- **View menu**
  Use the View menu to select the columns you want to display, and to expand and collapse entries in various combinations.

**Audited Attributes List**

When you click a view object entry in the Objects list, its attributes that will be included in an audit are displayed in the Audited Attributes fields. Note that the name of the selected object is added before the Audited Attributes heading; for example Document Entities: Audited Attributes.

**Note:**

The permitted limit on selected attributes is 20,000 bytes (num_attributes x attribute_size) for a given view object in the Audit Setup UI. This limit is checked during setup. Note that custom text attributes are pre-allocated with 1,500 chars per field. Therefore, it would only take 13 Text fields to consume the available character width.

These are not necessarily all the attributes of the selected view object; they either are the default attributes or the attributes selected during a previous edit. To see a list of all a view object’s attributes, select **Actions > Create**, or click the **Create** icon. A dialog, similar to that shown in Figure 12-4, lists all the attributes and lets you shuttle them between the Available Attributes and the Selected Attributes.
Click **Save and Close** to save your selections. Remember that your selections will not be included in an audit unless the related Audit checkbox also is selected.

### 12.3 Using Audit Reports

Open Audit Reports from the Navigator menu.

The Audit Reports Search page, shown in **Figure 12-5**, is displayed.

**Figure 12-5  Default Audit Reports Display**

To perform a search, a Date value and *either* a User or Product value are required. Use the Date picker to select the date, and the drop-down lists to select a User or a Product or both. The search results can be further fine-tuned by using the Event Type, Business Object and Description fields, and the Include child objects checkbox.

**Note:**

These parameters can be saved and recalled by selecting the user-supplied name in the Saved Search drop-down list. See also "If the search parameter set you are using is one that you expect to reuse, click Save to display the Create Saved Search dialog that has these options:’’
12.3.1 How to Search in Audit Reports

To search for Audit Reports for an Oracle Fusion application, you must supply this information:

- **Date.** Select an operator, such as Equals, Before, After or Between, and click the picker to display a calendar from which to choose a date.

- **User** or **Product** or both.

When you use the drop-down to select a User, you will notice a **Search** link at the bottom of the list. Click it to access all the available Users. The dialog, shown in Figure 12-6, is displayed.

**Figure 12-6  Searching for a User**

You can enter a name or part of a name in the User field and click **Search.** You also can click **Advanced** to add a search operators drop-down list, as shown in Figure 12-7.

**Figure 12-7  User Name Operators**

To select a user, highlight the name in the search results, shown in Figure 12-8, and click **OK.**
**Event Type.** Note that the first drop-down list always is set to Equals. Use the second drop-down list to select any or a combination of the available types. You also can select All.

For Oracle Fusion applications, the Types are Object Data Insert, Object Data Update, and Object Data Delete.

For Oracle Fusion Middleware, the Type selection is dynamic and depends on the selected Product.

**Business Object Type.** Note that this field applies only to Oracle Fusion applications and not to Oracle Fusion Middleware.

**Description.** You can further limit the search results display by entering a string in this field that matches a string in the Description column of the search results.

**Include child objects.** If there is a hierarchy of view objects, such as Opportunity > Revenue Line > Revenue Line Split, and the search is done on Opportunity, it only checks the Opportunity view object for changes. But if this option is checked, it will search all children. So if an Opportunity has five Revenue Lines and each has some Revenue Line Splits, then if anything in any of them changed, they also would be reported.

When the necessary fields are filled-in, click **Search** to display the results in the Search Results table.

---

**Note:**

When a search is performed for broad criteria, such as “Specific Product Before Today” or “All Products Before Today,” Audit Report may take a long time to query Audit History.

To avoid intermittent connection reset errors, *the search time is limited to 5 minutes.* If the History search time exceeds 5 minutes, this message is displayed: “Query run time exceeded the permissible time limit and failed to display results. Refine the search criteria and try again.”

---

**Deleting an Object Referenced by a Foreign Key**

In some instances, resolving a foreign key may fail when an audit row display name is trying to do a foreign key lookup of an object that has been deleted. It then will display the raw value or just leave it blank.
One example of this behavior involves trying to get a foreign key resolution from the same base object. If rows were deleted from an object, there will not be a row in the base table and foreign key resolution may fail.

Another example involves foreign key resolution with a parent table. For instance, given a person object, a person email object may use foreign key resolution to show a person’s name instead of a person ID. If the person’s name has been deleted in the base table, the foreign key resolution for the person email object may fail because there is no row in the corresponding base table.

Click **Reset** to clear all the fields so you can enter new search parameters.

If the search parameter set you are using is one that you expect to reuse, click **Save** to display the Create Saved Search dialog that has these options:

- **Name**
  This option is mandatory.
  This field defaults to showing the name that is displayed in the Saved Search field. However, if the Saved Search displayed name is “My Recent Changes,” the Name field here will show “My Recent Changes copy.”

- **Set as Default**
  Select this option to designate this named set of search parameters as the default instead of My Recent Changes.
  This option can be set and cleared by opening the Saved Search drop-down list and selecting Personalize.

- **Run Automatically**
  Select this option to run this named set of search parameters automatically.
  This option can be set and cleared by opening the Saved Search drop-down list and selecting Personalize.

- **Show in Search List**
  This option is available only from the Saved Search Personalize option, and is active only for the My Recent Changes named search.

### 12.3.1.1 Using the Search Results Table

The Search Results table has these components:

- **Actions menu**
- **Export to Excel icon** that duplicates the function of the Actions menu option of the same name
- **Detach icon**
- **Show Attribute Details checkbox.** This option becomes active when the Business Object Type field is populated and a search has been performed.
  
  When this option is selected, a dropdown list lets you select either All Attributes or Select Attribute.
When this option is selected, three columns are added to the table: Attribute, Old Value and New Value. Attribute contains the attribute name. An Old Value will be shown if there was an old value. New Value shows the current value. A scroll bar will become available at the bottom of the display so you can view all the columns.

Select this option when you want the information for only one specific attribute. When selected, a popup similar to this example is displayed.

You must click the Business Object to populate the Select Attribute list. Click OK to apply the change to the table.

The search results table now shows only results with the selected attribute, plus the Old Value and New Value columns that are shown when the All Attributes option is selected.

- Show Extended Object Identifier Columns checkbox.
When this option is selected, three new pairs of columns are added to the Search Results table: Context Name1 with Context Value1 through Context Name3 with Context Value3. These are additional information to help identify the object. For instance, if you need a 4-part key to uniquely identify an object, the Description could be 1 and these 3 context values could be the remaining.

Note that when a search is conducted on a view object, the search result also will include rows from the child view objects.

**Actions Menu**

The Actions menu has the Export to Excel option that is duplicated with the Export to Excel icon. Select the menu option or click the icon to export all the entries in the Search Results list to an Excel XLS file. When this option is selected, the standard Save prompts will guide you through the process.
Get Started with Your Web Interface

This chapter provides information that you may need before you begin developing your web pages. It introduces the UI Shell page template and UI patterns and features that are available in JDeveloper.

This chapter includes the following sections:

• Introduction to Developing a Web Application
• Oracle Fusion Guidelines, Patterns, and Standards
• Basic Building Blocks
• Introduction to the UI Shell
• Applications UI Patterns and Features

13.1 Introduction to Developing a Web Application

To help you get started with your web interface, this chapter discusses information about how to create a page, what the wizard settings should be, as well as information about patterns, such as UI Shell.

For more information about how to get started with your web interface, see the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADFFaces guide.

13.2 Oracle Fusion Guidelines, Patterns, and Standards

There are some basic guidelines for defining how an Oracle Fusion application’s web interface is constructed. These guidelines are universally shared by all pages built for Oracle Fusion Applications. There are two types of pages - Dashboards and Work Areas. A dashboard is a collection of information summaries (high-level data views) that enable users to monitor different objects and data within a subdomain or functional area of interest. A Work Area is the complete set of tasks, reports, business intelligence, searches and other content that a user needs to accomplish the tasks associated with a business goal. Depending on the type of page you have, the construction can differ.

For more information about Standards and Guidelines, see Chapter 1, "Getting Started with Oracle Fusion Applications."

13.3 Basic Building Blocks

Dashboards and Work Areas define the basic structure of a page. Oracle Fusion Guidelines, Patterns and Standards (GPS) defines a set of design patterns. Design patterns are common flow or page designs that are used across all product families. By using design patterns in all phases of product development, valuable development time may be spent innovating other areas in the product, consistency is ensured across
the entire enterprise, and users only have to learn the interaction once with the expectation that their experience will be the same in any product they encounter.

Dashboard

There are two types of dashboards: Home Based Dashboards and Transaction Dashboards. A Home Based Dashboard consists of one or more tabs. Each tab is a container for a set of configurable regions displaying content that a user may want to monitor. Transaction Dashboards are built with a specific role in mind. The basic building blocks are the individual regions. Every dashboard can choose which regions it wants to include. In Figure 13-1, these are the Watchlist, Reports and Analytics, Worklist, and Gallery. Each of these is built as Oracle Application Development Framework (Oracle ADF) Bounded Task Flows.

Figure 13-1  Home Based Dashboard Example

Work Area

A Work Area, as shown in Figure 13-2, consists of a Regional Area, a Local Area and a Contextual Area. Each area is intended to have content for a specific purpose.

Figure 13-2  Work Area example

The Regional Area is the collapsible region on the left of the page that contains a column of panels that provides information and actions that drive the business process that a work area supports. The Local Area is the focus of the users work. The contents of it should contain all of the information and actions required to accomplish the task.

The Contextual Area is the collapsible region on the right-hand side of the page that is filled with a column of panels. It provides additional space above the fold of the page to present actions and information, based on the information and state of the local area, that can assist the user in the task.
Designing Your UI

Your web user interface will be designed using the Oracle Fusion GPS concepts and design patterns. Many of these designs are delivered through the Oracle Fusion Middleware Extensions for Applications (Applications Core). Dashboards and Work Areas are built using the UI Shell. A set of design-time wizards and components that help support many of the Oracle Fusion GPS design patterns is also provided. These components, with those provided by Oracle ADF and WebCenter, provide the basis for all web interfaces.

13.4 Introduction to the UI Shell

The UI Shell is a page template containing default information, such as a logo, menus and facets. To supplement the UIShell template, there also is a UIShellMainArea template. Because you can load information into dynamic tabs, the Main area cannot be a part of the page itself since it is loaded dynamically. The UIShellMainArea template helps you create the flows that run within the tabs.

The UI Shell design supports task-based and user-based navigation and way-finding, and organizes screen real estate more effectively by collating tasks, providing dedicated spaces for primary-task supporting information, and maintains general order and appropriate hierarchy between various elements on the screen.

The UI Shell for Applications User Experience (Applications UX) patterns provides a system of containers that fulfill common layout and navigational requirements in a structured, consistent manner. The UI Shell focuses on providing detailed design for defining and organizing various types of navigation and other functionality such as search and auxiliary information for Oracle Fusion alone.

In particular, the UI Shell template supports:

- Global Search
- Navigation menus
- Cross-application navigation

For more information, see Implementing the UI Shell.

13.5 Applications UI Patterns and Features

Applications UI Patterns are high-level UI composite components that encapsulate standards and guidelines for common layouts, behaviors and flows across Oracle Fusion Applications, as set forth by the Applications User Experience group. The objective is to provide applications development teams with a higher level starting point and reduce duplication of effort in building the UI for their applications, while adhering to Oracle Fusion standards. The standards and guidelines are tightly integrated with JDeveloper.

Patterns can be implemented as custom components, declarative components or task flows. Patterns that are implemented as declarative components wrap the mandatory and pattern-specific UI components within the declarative component.

The UI patterns components provide several key benefits for developers when they are building pages and fragments:

- Enforcement of patterns.
- Faster development.
• Changes can be made to one component definition rather than to each instance in every application.

Supported patterns are:

• Applications Tables
• Applications Panels
• Applications Master-Detail
• Applications Detail On Demand
• Applications Tree
• Applications Tree Tables
• Applications Dialog Details
• Using the Custom Wizard with Applications Popups

**Applications Tables**

Applications tables are UI components that already contain an ADF table, a menu bar, a toolbar, and related popups. Developers do not need to create and assemble all these components separately.

**Applications Panels**

Applications Panels help you create the following UI components as part of the UI applications patterns:

• Page title
• Form title
• Page button bar (including navigation bar)
• Facets for page-specific UI components

You must use Applications Panels to standardize layout and appearance for all your page forms and buttons, including read-only pages.

**Applications Master-Detail**

Master-Detail refers to the interaction of selecting an object from a master list, and refreshing the details in an adjacent area. It is not the relationship of the data.

The Master-Detail composite is used in situations where the information is too large, dynamic, or complex to show in a flat table. The user can see the Master, or summary, information in one area, and the corresponding details in a separate area. This can be achieved using different master and detail components, such as table, tree table, and tree.

For instance, when the user selects an employee from the master table, the corresponding employee details are displayed in the region below in a label/data format.

**Applications Detail On Demand**

Dialog details are appropriate for use when information must be accessed quickly and then dismissed. The details are shown in a modeless dialog window.

Dialog details are accessed by clicking a details icon in a row in a table.
Applications Tree
The Applications Tree component provides these basic capabilities:

- Tree toolbar with default buttons
- Facets for adding ADF tree, custom toolbar buttons, and so on
- Default implementations for tree actions

Applications Dialog Details
The Applications Dialog Details component provides a user interface for launching a popup that contains detail information. Popups are an option when editing rows. The UI can be a detail icon, a link, or a button.

Using the Custom Wizard with Applications Popups
af:popup is a generic function documented in the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide.

While the standard af:popup component does not provide buttons or data binding, the Applications Popup wizard provides the base af:popup with:

- a title
- standard buttons
- customized button capability
- data binding
- code that developers can use to invoke the popup
- design-time support
- popup facets and properties that can be customized

Popups can be used as standalone components or with certain patterns.

Applications Tree Tables
The Application Tree Table component provides these basic capabilities:

- Tree Table toolbar with default buttons
- Facets for adding items such as ADF tree table and custom toolbar buttons
- Default implementations for tree actions

For more information, see:

- Implementing UIs in JDeveloper with Application Tables_ Trees and Tree Tables
- Implementing Applications Panels_ Master-Detail_ Hover_ and Dialog Details
This chapter discusses the UI Shell page template used to build web pages, and the components used to implement user interface features in Oracle JDeveloper (JDeveloper), such as menus and task flows.

This chapter includes the following sections:

- Introduction to Implementing the UI Shell
- Populating a UI Shell
- Implementing Application Menu Security
- Controlling the State of Main and Regional Area Task Flows
- Working with the Global Menu Model
- Using the Settings and Actions Menu
  - How to Implement End User Preferences
  - How to Use the Administration Options
  - How to Use the Troubleshooting Options

For more information about the features, see:

- Getting Started with Your Web Interface
- Implementing Search Functions in the UI Shell
- Implementing Additional Functions in the UI Shell
- Implementing UIs in JDeveloper with Application Tables, Trees and Tree Tables
- Implementing Applications Panels, Master-Detail, Hover, and Dialog Details

### 14.1 Introduction to Implementing the UI Shell

The UI Shell is a page template containing default information, such as a logo, menus, and facets. To supplement the UI Shell template, there is a UIShellMainArea template. Because you can load information into dynamic tabs, the main area (the center and the right as shown in Figure 14-1) cannot be a part of the page itself because it is loaded dynamically.

The UI Shell design supports task-based and user-based navigation, and organizes screen real estate more effectively by collating tasks, providing dedicated spaces for primary-task supporting information, and maintains general order and appropriate hierarchy among various elements on the screen.
The UI Shell for Applications User Experience (Applications UX) patterns provides a system of containers that fulfill common layout and navigational requirements in a structured, consistent manner. The UI Shell focuses on providing detailed design for defining and organizing various types of navigation and other functionality such as search and auxiliary information for Oracle Fusion Middleware alone.

**Note:**

Two UI Shell templates are implemented: the classic shell and the Simplified Experience UI (usually called FUSE+). Items can be shown or hidden based on the template. The API `getShellType()` will return "simple" or "classic" depending on the page template used in the current page. Developers can determine the active template by using the Expression Language expression `#{applcoreShellBean.shellType}` to identify the shell type.

---

**Before You Begin:**

You should be familiar with JDeveloper, be able to create and run JavaServer Faces (JSF) pages, and be able to create an Oracle Application Development Framework (Oracle ADF) task flow.

### 14.1.1 Standard Related to the UI Shell

Almost all shipped Oracle Fusion Applications pages are built using the UIShell page template. Exceptions include the login page, and the password preferences page.

### 14.1.2 UI Shell Description

The UI Shell is composed of four default areas: global, regional, local, and contextual, as shown in Figure 14-1.
The basic information about the UI Shell includes:

- The shell is optimized for a screen resolution of 1280x1024 pixels.
- The four areas (refer to the circled numbers on the image) are:

  1. **Global Area**: The global area, across the full width at the top of the UI Shell, is static, consistent, and persistent for an individual user. It contains controls that generally affect the contents of the other three areas. See Global Area Standard Icons.

  2. **Regional Area**: The regional area is in the left-hand pane of the UI Shell. It has controls and content that generally affect the contents of the local and contextual areas. Tasks lists in the regional area automatically are bulleted to make it clear when a line item wraps to the next line.

  3. **Local Area**: The local area is in the center of the UI Shell where users do their work. It is the main work area and typically contains the transaction form with the menus and controls that enable users to be productive. Controls in, and the content or state of, the local area generally affect the contents of the contextual area.

     - **Main Area**: This term designates the combination of the local area and the contextual area.

  4. **Contextual Area**: The contextual area is in the right-hand pane of the UI Shell, with controls and contents that generally are affected by controls in, or the content or state of, the local area; although in specific cases the contextual area can also affect the contents of the local area (causing a local-area reload).
• Application designers, customers, and administrators can set the regional and contextual areas as collapsed for specific applications. End users can expand those areas at runtime.

• If there is no content in the regional or contextual area, the area is collapsed and the ability to expand it is disabled.

• The contextual area is directly bound to the local area. The application developer can bind the contextual area content to the local area such that each invocation of a local area automatically causes a relevant contextual area in the correct state to appear alongside the local area.

14.1.2.1 Global Area Standard Icons

The global area incorporates several built-in icons, as shown here:

Figure 14-2  Global Area Standard Icons

From 1 (Home) to 10 (User Name), the numbered icons are:

• (1) Home

  Click this icon to return to the defined Home page. See Implementing the Oracle Fusion Home Page UI.

• (2) Navigator

  The Navigator, shown in Figure 14-23, is rendered when the Navigator icon is clicked on the UI Shell. See Displaying the Navigator.

• (3) Favorites, Recent Items and Tags

  This icon combines the Favorites, Recent Items and Tags functions. When you click this icon, the dialog shown in Figure 14-3 is displayed.

  Figure 14-3  Favorites, Recent Items and Tags

  – Favorites adds the currently-focused task flow to the Favorites list.
  – Recent Items tracks a list of the last 20 task flows visited by a user. See Implementing Recent Items.
  – Tags is a service that allows users to add tags to selected resources in Oracle Fusion Applications to contribute to resources other users have visited. See Implementing Tagging Integration.

• (4) Watchlist
Click the Watchlist icon to display a user-accessible UI that provides a summary of items the user can track using shortcuts. See Implementing the Watchlist.

- (5) **Notification**
  Click the icon to display the Notification dialog shown in Figure 14-4.

  **Figure 14-4  Recent Notifications Dialog**

<table>
<thead>
<tr>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recent Notifications</td>
</tr>
<tr>
<td>🌐 Action Required: Saved Transaction</td>
</tr>
<tr>
<td>1/29/13 05:27</td>
</tr>
<tr>
<td>More... (0 unread)</td>
</tr>
</tbody>
</table>

- (6) **Social**
  Click the Social icon to display Oracle Social Network conversations. See Implementing Oracle Social Network Integration.

  **Note:**
  - The link displays only if Oracle Social Network is provisioned on the system and registered in the application topology.
  - The link is supplied automatically by the UI Shell; it requires no developer work.

- (7) **Accessibility**
  The Accessibility icon appears on all pages. It will allow users to set their accessibility preferences because the Personalization menu, which includes preferences, is hidden for anonymous users.

- (8) **Search**
  Click the icon to display the Global Search dialog shown in Figure 14-5.

  **Figure 14-5  Global Search Dialog**

<table>
<thead>
<tr>
<th>Close</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search</td>
</tr>
</tbody>
</table>

  See How to Use Basic Search.

- (9) **Help**
  When you click the Help icon, it turns orange. Then, if there is contextual help on the page, smaller orange icons will display, as shown in this figure.
14.2 Populating a UI Shell

The UI Shell is a page template with some facets for content that may be placed directly on the page, but it usually has its content inserted dynamically. The dynamic insertion happens by reading metadata in the form of menu metadata. This informs the UI Shell about which task flows to load and where. The UI Shell also can create a list of tasks, from the same metadata, that, when clicked, can load into the main area. All task flows and the page built by the UI Shell template follow the standard ADF Security framework.

When you create an application using the Oracle Fusion Web Application (ADF) template, two projects automatically are created for you: the model and the user interface projects. The default names for these projects that JDeveloper provides are Model and ViewController. You then add the Applications Core (ViewController) tag library to the user interface project. See Adding the Applications Core Tag Library to Your User Interface Project.

Related Links
The following document provides additional information related to subjects discussed in this section:
• For more security framework information, see the Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework guide.

14.2.1 How to Create a JSF Page

Creating an Oracle Fusion application also creates your application’s workspace, where you will later place your page fragments and task flows. For more information about task flows, see the “Getting Started with ADF Task Flows” section of the Developing Fusion Web Applications with Oracle Application Development Framework.

For more information about starting JDeveloper, see Chapter 2, “Setting Up Your Development Environment.”

To create a JSF page:

1. Select the user interface project in the Application Navigator.

2. Choose File > New > Web Tier > JSF > JSF Page.

The Create JSF Page dialog is displayed, as shown in Figure 14-8.

3. In the dialog:

   • Enter a file name and directory path. The file name should follow the naming patterns required by your group.

   • From the Use Page Template list, select UIShell.

   • Select Create as XML Document (*.jspx).

   • Click OK.

4. The new JSF page is displayed in the editor. Note that the page headers in the Design view do not display exactly as they will at runtime.
**Note:**

This JSPX page is just the container for the UI Shell template. All other page content, such as the regional, local, and contextual area flows, and the dynamic task flows, are defined independently. At runtime, the menu definition assembles the various parts. All task flows are loaded into a page created with the UI Shell template by configuring the Menu file. This is done to control the behavior and the dynamic loading of task flows at runtime. It also creates the Navigator and Task List menu. See *Working with the Global Menu Model* and *Working with the Applications Menu Model*.

Now you can add components to the page. Table 14-1 lists the `itemNode` properties that can be used for a JSF page. See *Working with the Applications Menu Model* for how to add a menu to the page.

**Table 14-1  itemNode Properties of a JSF Page**

<table>
<thead>
<tr>
<th>ItemNode Property</th>
<th>Property Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>Name that has been assigned to the action.</td>
<td>Go to the page defined by the action.</td>
</tr>
<tr>
<td>dataControlScope</td>
<td>String</td>
<td>The values are shared (the default) or isolated. This is set at the page level <code>itemNode</code>. When <code>dataControlScope</code> is set to <code>isolated</code>, the UI Shell loads the main area and regional area task flows with <code>dataControlScope</code> set to <code>isolated</code>. When <code>dataControlScope</code> is set to <code>shared</code>, the UI Shell loads the main area and regional area task flows with <code>dataControlScope</code> set to <code>shared</code>. For example: &lt;itemNode id=&quot;itemNode_AppsPanelTests_TabsWA&quot; label=&quot;label_AppsPanelTests_TabsWA&quot; action=&quot;AppsPanelTests_TabsWA&quot; focusViewId=&quot;/AppsPanelTests_TabsWA&quot; dataControlScope=&quot;isolated&quot;&gt;</td>
</tr>
<tr>
<td>ItemNode Property</td>
<td>Property Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>isDynamicTabNavigation</td>
<td>True or False</td>
<td>This property provides an option to suppress dynamic tab navigation and just display one main area at a time. To do this, add the following property and value to the itemNode that represents your JSPX: isDynamicTabNavigation=&quot;false&quot; Other menu metadata stays the same. The Task List menu will continue to render. Clicking a Task link will replace the current main area task flow with the new one. Multiple defaultMain definitions are allowed and will open multiple tabs on page load. The first one with disclosed=&quot;true&quot; will be the tab in focus. If the property value is not defined, it defaults to true.</td>
</tr>
</tbody>
</table>
| id                     | Unique identifier | This is what appears in the work area title.  
Note: For all UI Shell work area pages with Data Visualization Tool (DVT) components in the default main area task flow, and for Home pages with DVT components, you must create the af:document title as an Expression Language expression that sets the title with the default main area task flow label, as shown in this example: <af:document id="d1" title="#{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.DefaultMain']} - #{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.WorkAreaLabel']} - #{adfBundle['oracle.apps.common.acr.resource.ResourcesGenBundle']['Header.OracleApplications']}" > For UI Shell pages with DVT components in their dynamic main area task flows, the title is set on the AdfRichDocument by UI Shell code for the openMainTask, closeMainTask and tab switch. |
| label                  | String          | This is what appears in the work area title.  
Note: For all UI Shell work area pages with Data Visualization Tool (DVT) components in the default main area task flow, and for Home pages with DVT components, you must create the af:document title as an Expression Language expression that sets the title with the default main area task flow label, as shown in this example: <af:document id="d1" title="#{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.DefaultMain']} - #{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.WorkAreaLabel']} - #{adfBundle['oracle.apps.common.acr.resource.ResourcesGenBundle']['Header.OracleApplications']}" > For UI Shell pages with DVT components in their dynamic main area task flows, the title is set on the AdfRichDocument by UI Shell code for the openMainTask, closeMainTask and tab switch. |
| focusId                | Name of the view activity | This is what appears in the work area title.  
Note: For all UI Shell work area pages with Data Visualization Tool (DVT) components in the default main area task flow, and for Home pages with DVT components, you must create the af:document title as an Expression Language expression that sets the title with the default main area task flow label, as shown in this example: <af:document id="d1" title="#{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.DefaultMain']} - #{adfBundle['oracle.apps...resource.xyzGenBundle']['Header.WorkAreaLabel']} - #{adfBundle['oracle.apps.common.acr.resource.ResourcesGenBundle']['Header.OracleApplications']}" > For UI Shell pages with DVT components in their dynamic main area task flows, the title is set on the AdfRichDocument by UI Shell code for the openMainTask, closeMainTask and tab switch. |
Table 14-1  (Cont.) ItemNode Properties of a JSF Page

<table>

<td>True or False</td>
<td>See How to Control Regional Area Task Flows.</td>
</tr>
</tbody>
</table>

14.2.1.1 Working with the Applications Menu Model

Page and task flow information are local to a particular Oracle Fusion application and are exposed using the Applications menu model.

An Applications menu is related to a local JSPX file and includes the task lists, defaultMain, and defaultRegional. A menu is created for each Java EE application.

14.2.1.1.1 How to Create an Applications Menu

The following information describes how to create an ADF menu to access page elements through the Navigator on JSF pages or task flows that are based on the UI Shell template.

Select the JSPX page in the Application Navigator, then right-click and select the Create Applications Menu option.

This step creates the menu file with one itemNode. The menu file will be named `<view id>_taskmenu.xml`. For example, if there is a PageA.jspx, its view ID in the adfc-config.xml file is PageA, and the menu file name is PageA_taskmenu.xml. This step also should add the ApplicationsMenuModel managed bean entry into the adfc-config.xml file. The managed bean entry should not have the topRootModel managed bean property set. Example 14-1 shows a sample of the generated content in the PageA_taskmenu.xml file.

Creating ADF Menus for Multiple JSF Pages

Use this alternate method to create menus for multiple pages at once. This will create an empty menu on each page.

1. Right-click the adfc-config.xml file and choose Open to display the file in the JDeveloper editor.

   The adfc-config.xml file is located in the following location: `<project_name> > WEB INF`.

2. Drag pages from the Application Navigator to the adfc-config.xml file in the editor.

   View nodes that represent the pages or task flows are displayed in the editor.
When you drag the pages or task flows, they automatically are grouped into the same menu.

3. Right-click the adfc-config.xml file and choose Create Applications Menus. An empty panel, as shown in Figure 14-9, is displayed.

![Figure 14-9 Initial Create Applications Menus Display](image)

4. Click Find Pages to populate the display with all the JSPX pages that have been added to the adfc_config.xml file. As shown in Figure 14-10, pages that do not yet have a menu associated with them will have a checkbox that defaults to being selected, and pages that already have an associated menu are shown with a checkmark to the right.

![Figure 14-10 Populated Create Applications Menus Display](image)

5. Click OK to automatically create a menu file for each selected page and to update the task flow with a managed bean.

**Note:**

Menu files will follow the `<focusViewId>_taskmenu.xml` naming standard. For example, the menu file for the Example.jspx file will be `/WEB-INF/menus/Example_taskmenu.xml`.

When you create this menu file, the following occurs:

- The menu file is generated and placed into the following directory: `ViewController/public_html/WEB-INF/menus`
- The following are generated and appear in the adfc-config.xml file:
  - A new control-flow rule
  - A managed bean entry

The new menu that contains your pages is now accessible from the Navigator panel.
Example 14-1   Example of Generated Content in a taskmenu.xml

<?xml version="1.0" encoding="UTF-8" ?>
<menu xmlns="http://myfaces.apache.org/trinidad/menu">
<!-- This is the page level node -->
<itemNode id="itemNode_PageA" label="label_PageA" action="adfMenu_PageA"
focusViewId="/PageA"/>
<!-- Optional itemNode for Regional Task List task flow. Your task menu
definition may omit this if your page does not display a Regional Task List. -->
<itemNode id="__myProduct_RegionalTaskList"
focusViewId="/PageA"
label="#{applcoreBundle.TASKS}" taskType="defaultRegional"
taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/patterns/uishell/ui/publicFlow/TaskList.xml#TasksList"
disclosed="true"
parametersList="fndPageParams=#{pageFlowScope.fndPageParams}"/>
<!-- Typical itemNode entry for a task flow -->
<itemNode id="__myProductTFId"
focusViewId="/PageA"
label="#{myBundle.myProductTFxyz}" taskType="defaultMain"
taskFlowId="<fully qualified-TFid>"
disclosed="true"/>
<!-- .. Additional itemNodes for other task flows on PageA -->
</itemNode>
</menu>

14.2.2 How to Add Default Main Area Task Flows to a Page

When a user opens an application, he or she expects something to be displayed automatically. A task flow in the main area accomplishes this.

To add a task flow to the default Main Area:

   The Create JSF Page Fragment dialog shown here is displayed.

   Figure 14-11   Create New JSF Page Fragment Dialog

   ![Create New JSF Page Fragment Dialog]

   2. In the Create New JSF Page Fragment dialog:
      a. Enter a page fragment name, for example:
The file name should follow these patterns:

- `<Object><Function>.jsff`, such as PoSearch.jsff.
- `<Object>.jsff`, such as PurchaseOrder.jsff.

The page name should convey the object it presents (an employee, a supplier, an item, a purchase order, an applicant, and so on), and the function being performed (search, promote, hire, approve, view). For some pages, the object is sufficient.

For update or create pages, just the object is necessary (unless the create and update pages are different as shown in the examples).

Never give pages step number names, such as PoCreateStep1.jsff or PoCreateStep2.jsff. Always describe the page function, such as PoDesc.jsff or PoLines.jsff.

b. From the Use Page Template list, select UIShellMainArea.

---

**Note:**

The UIShellMainArea template is only for main area task flows, not regional area task flows.

---

3. Click OK.

The Local and Contextual area facets of the page fragment appear in the editor.

4. Choose File > New > JSF > ADF Task Flow to create a default task flow.

---

**Note:**

Most applications will have multiple task flows for the Regional, Local and Contextual areas. For instance, Figure 14-1 shows 12 task flows.

---

The Create Task Flow dialog shown here is displayed.
In the Create Task Flow dialog:

a. The file name defaults to task-flow-definition.xml. Enter a descriptive file name.

The file name should follow these patterns:

- `<Object><Function>.xml`, such as PoSearch.xml.
- `<Object>.xml`, such as PurchaseOrder.xml.

The page name should convey the object it presents (an employee, a supplier, an item, a purchase order, an applicant, and so on), and the function being performed (search, promote, hire, approve, view). For some pages, the object is sufficient.

For update or create pages, just the object is necessary (unless the create and update pages are different as shown in the examples).

Never give pages step number names, such as PoCreateStep1.jsff or PoCreateStep2.jsff. Always describe the page function, such as PoDesc.jsff or PoLines.jsff.

b. From the Use Page Template list, select UIShellMainArea.
5. Ensure that the JSF page fragment file is selected in the Application Navigator and is displayed in the Edit view.

   a. In the Edit view, click the Source tab.

   b. Locate the line `<f:facet name="localArea"/>`.

   c. In the Application Navigator, select an applicable task flow, such as the one you created in Step 4, to add to the `localArea`. This should be an XML file located under `ViewController > Web Content > WEB-INF > oracle > apps > application_name > ui > flow`.

   d. Drag and drop the appropriate flow from the Navigator pane to immediately following `<f:facet name="localArea"/>`.

   e. From the Create menu that is displayed, select Region.

      The `af:region` tag is nested within the `localArea` facet and code resembling that shown in Example 14-2 will be inserted after it.

      In the Structure window, an `af:region` entry is added following the `f:facet - localArea` entry.

   f. Note: The instructions for the remainder of step 5 are optional. If you do not need a `contextualArea`, go to Step 6.

      In the Structure window, select `f:facet - contextualArea`.

   g. In the Component Palette, select ADF Faces > Layout.

   h. Click Panel Accordion. An `af:showDetailItem` entry is created automatically under `af:panelAccordion`.

   i. In the Source view, find and highlight the new `af:showDetailItem ...>` entry.

   j. In the Application Navigator, select an applicable task flow, such as the one you created in Step 4, and drag and drop it onto the highlighted entry in the Source view.

   k. From the Create menu that is displayed, select Region.

   l. Click OK on the Edit Task Flow Binding dialog that is displayed.

      Code resembling that shown in Example 14-3 will be inserted after `af:showDetailItem ...>`.

6. Now that you have created the main area page fragment, you must wrap it in an ADF task flow.

   Again, select File > New > Web Tier > JSF > ADF Task Flow and in the Create ADF Task Flow dialog:

   a. Enter a descriptive name for the task flow.

      For example, enter `def_main_task-flow-definition.xml`. 

---

Note:

The `UIShellMainArea` template is only for main area task flows, not regional area task flows.
b. Ensure that the **Create as Bounded Task Flow** and the **Create With Page Fragments** boxes are selected.

Do not change the other default settings.

7. Click **OK**.

The new task flow is displayed as a blank visual editor in the JDeveloper middle section.

8. In the Application Navigator, select your recently created page fragment (.jsff file), and drag and drop it onto the editor.

The page fragment **itemNode** appears in the editor, as shown in **Figure 14-13**.

![Figure 14-13 Page Fragment itemNode](image)

9. To load the menu metadata:

---

**Note:**

The menu data accomplishes several important jobs for you:

- It defines properties of the page for you. For instance, it will be displayed in no-tab mode or with dynamic tabs, and define the width of the regional area.
- It can create a task list menu for each page.
- It can create labels for groups of tasks.

---

a. In the Application Navigator, select the **test_menu_taskmenu.xml** file that you created using the ADF Menu Model dialog. For details about creating the menu, see **How to Create an Applications Menu**.

b. In the **test_menu_taskmenu.xml** structure view menu tree, shown in **Figure 14-14**, right-click the **itemNode** item and choose **Insert inside itemNode <task_flow_name> > itemNode**.
The Insert itemNode - Common Properties dialog, shown in Figure 14-15, is displayed.

Figure 14-15  Insert itemNode - Common Properties Dialog

10. In the id field, enter a unique ID using this standard format:
    
    <pageID>_<taskFlowName>
    
    This ID example consists of the concatenated page ID (or page name), an underscore, and the task flow name, for example, ExpenseWorkArea_CreateExpense.

11. In the focusViewId field, enter the ADFc View Activity ID of the page under which you are registering the task flow.

12. Click Finish.
    
The new item node is displayed in the structure view, under the menu tree.

13. With the item node selected in the structure view, click the Property Inspector tab, as shown in Figure 14-16.
14. In the **label** field, enter a label for the task flow, such as **CreateExpense**.
   This label will be the title of the tab that is opened by the Task Type defaultMain.

   **Note:**
   Do not leave this field null. This is the label that will appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites, or when the system tracks the Recent Items.

15. Select **test_menu_taskmenu.xml** in the Project Navigator tree, and your task flow in the structure view to display its Property Inspector, or select the Property Inspector tab.

   In the Advanced section of the Property Inspector, enter the following values:

   - **Task Type**: defaultMain (the task flow is displayed by default whenever the page is rendered).
     The Data Control Scope should have been set to **isolated**, inside the task flow definition for any task flow in the menu (defaultMain or dynamicMain) or any call from openMainTask. See **dataControlScope** in Table 14-1.

   - **Task Flow Id**: ID of the task flow to be loaded.
     To enter the ID, click the ellipsis to display the Select Task Flow Id dialog, shown in **Figure 14-17**, and browse to the task-flow definition location. By default, following the standard naming structure, the location will be in...
Click Open to automatically enter the location in the Task Flow field. The task flow ID is a concatenation of the file location for the task-flow definition and the task-flow name. It typically resembles /WEB-INF/MyTaskFlow.xml#MyTaskFlow. The Property Inspector for the itemNode should resemble the example shown in Figure 14-16.

16. To run the JSPX page, select the page in the Application Navigator, right-click the page file, and choose Run.

The new page, similar to that shown in Figure 14-18, is displayed in a web browser.

17. Check that the newly rendered page contains one tab whose content is the task flow that you defined in this procedure.
The available `itemNode` properties for main area and regional area task flows for application menus are shown in Table 14-2.

<table>
<thead>
<tr>
<th>ItemNode Property</th>
<th>Property Value</th>
<th>What Happens on the Rendered Page</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>taskType</code></td>
<td>Note: <code>taskType</code> can have four values:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• dynamicMain</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• defaultMain</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• defaultRegional</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• taskCategory</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the value is <code>dynamicMain</code>, the page contains a new link in the regional area. When you click the link, a new tab with the loaded task opens. If the no-tabs model is used, no new tab is opened. Rather, the current main area contents are replaced. (See Supporting No-Tab Work Areas.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the value is <code>defaultMain</code>, the page contains a tab already running this task in the main area. If the no-tabs model is used, only one <code>itemNode</code> should be defined as a <code>defaultMain</code>. (See Supporting No-Tab Work Areas.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If the value is <code>defaultRegional</code>, the task is loaded into the regional area.</td>
<td></td>
</tr>
<tr>
<td><code>label</code></td>
<td>String</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Note: When passing parameters, do not leave the label field null. This is the label that would appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites, or when the system tracks the Recent Items.</td>
<td></td>
</tr>
<tr>
<td><code>taskFlowId</code></td>
<td>ID of the task flow to be loaded. The task flow ID is a concatenation of the file location for the task flow definition, and the task flow name. For example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>/WEB-INF/MyTaskFlow.xml#MyTaskFlow</td>
<td></td>
</tr>
<tr>
<td><code>reuseInstance</code></td>
<td>True or False</td>
<td></td>
</tr>
</tbody>
</table>
| (optional)        | If `True`, when the link is clicked a second time, the tab is brought to the top. A `False` value means that clicking the corresponding task link opens new tabs. However, if the no-tabs model is used, no new tab is opened. Rather, the current main area contents are replaced. (See Supporting No-Tab Work Areas.)
Table 14-2  (Cont.) itemNode Properties for Main and Regional Task Flows for Application Menus

<table>
<thead>
<tr>
<th>itemNode Property</th>
<th>Property Value</th>
<th>What Happens on the Rendered Page</th>
</tr>
</thead>
</table>
| keyList           | String         | Important: keyList is used with the task flow ID to identify the target tab in the main area. As such, keyList is only applicable in dynamic tabs mode, and is ignored in no-tabs mode. keyList provides a way to identify a task flow instance. When reuseInstance is true, use the specified keyList in addition to the task flow ID to identify the target tab. The keyList parameter has been implemented for the following FndUIShellController data control methods:  
  • openMainTask  
  • discloseRegionalTask  
  • collapseRegionalTask  
  • navigate  
  • openSubTask  

In dynamic tabs mode, when looking for a match of an existing tab, these APIs will first look for any instances of the task flow that is already open, which has the same task flow ID as the one passed into them as the parameter. In addition, it will compare the keyList values, such that the existing task flow will be picked only if its keyList values match the ones specified in the keyList parameter. It does not matter if the task flow parameters are the same or different. If the keyList is not set in the menu metadata, you can reuse a tab only if you pass in a null keyList. |
<p>| loadPopup         | True or False  | See Implementing the Task Popup. This provides a way to load the task flow into a Popup when the user clicks one of the Task List links. |</p>
<table>
<thead>
<tr>
<th>itemNode Property</th>

</tr>
</thead>
<tbody>
<tr>
<td>loadDependentFlow</td>
<td>True or False</td>
<td>The no-tab navigation mode can load a main area task flow and a dependent task flow simultaneously, while displaying only one flow at a time. (See Supporting No-Tab Work Areas.) The UI Shell is limited to 12 task flows: 10 tabs in tab mode; 1 tab in no-tab mode and 1 dependent in no-tab mode. Dependent Flow is applicable only to the no-tab navigation model. Instead of having only one region for the no-tab navigation model, there are two regions: one for the main task flow and another for the dependent flow. These regions are in a switcher, so that only one is visible at a time. If a dependent task flow is loaded, only the dependent task flow region is shown, and the main task flow region is hidden. When the dependent task flow is closed, the main task flow region is redisplayed, with its state preserved. When loadDependentFlow is true, the openMainTask API will load the target task flow in the dependent region. Loading a new task flow in the main task flow will close both the existing main task flow and, if any, the existing dependent task flow. Loading a new task flow in the dependent task flow will replace only the existing dependent task flow, if any, and leave the main task flow intact.</td>
</tr>
<tr>
<td>forceRefresh</td>
<td>True or False</td>
<td>If forceRefresh = true, the contents are refreshed. If forceRefresh is set to false, if the task flow parameters are identical, no refresh will occur, but if they are different, the task flow is refreshed using the new parameters.</td>
</tr>
<tr>
<td>stretch</td>
<td>True (default) or False</td>
<td>When the UIShellMainArea stretch attribute is set to true, contents under localArea will be stretched when rendered in the local area. When set to false, contents under localAreaScroll will not be stretched, but will be rendered with a scroll bar, if necessary, in the local area. (This facet is contained within an af:panelGroupLayout with layout=scroll.)</td>
</tr>
<tr>
<td>disclosed</td>
<td>True or False</td>
<td>All the task flows will be rendered in the main area. The task flow that has disclosed set to true will be in focus. More than one defaultRegional task can have a true disclosed value, because more than one detail item may be disclosed at a time under a panelAccordion component. If the disclosed value is true, the regional area is expanded. If the disclosed value is false, the regional area is collapsed.</td>
</tr>
</tbody>
</table>
### Table 14-2  (Cont.) itemNode Properties for Main and Regional Task Flows for Application Menus

<table>
<thead>
<tr>
<th>itemNode Property</th>
<th>Property Value</th>
<th>What Happens on the Rendered Page</th>
</tr>
</thead>
</table>
| active            | True or False (default) | Task flow definitions use conditional activation. There are several cases in which Oracle Fusion Applications run with the regional area collapsed by default. Unless the user expands it, there is no need to activate the task flows for the regional area. However, some use cases depend on the task flow that is under the regional area being active even when collapsed. In this case, the active attribute can be set in the property inspector for the item node. active has three possible values:  
  - default <False>  
  - False  
  - True  
  If you require that your task flows be activated or run even though they are not displayed, you must change the active property on the itemNode to True. |
| taskFlow          | String         | The Task List is exposed as a task flow. See *How to Pass Parameters into Task Flows from Tasks List*. |
| destination       | String         | The destination attribute is supported on the item nodes for Task List; that is, for item nodes that have the task type set to dynamicMain. The destination attribute is intended only for navigating to an external web site. When it is defined, it takes precedence over all other attributes. Example of the menu data:  
  <itemNode id="__ServiceRequest_itemNode_externalUrl" destination="http://www.yahoo.com"/> |
| parametersList    | String         | Use to specify which parameters to pass into a task flow. The value of this property is a delimited list of parameter name-value pairs. See *How to Pass Parameters into Task Flows from Tasks List*. |
| contextCode       | Domain name in which the J2EE application belongs. Valid values are: CommonDomain, BI, FIN, SCM, CRM, PRJ, HCM, PRC, or IC. | This value would be used for the Auto-suggest feature in Global Search. See *Implementing Auto-suggest*. |
| objectType        | String         | Classification for the Recent Item object (for example: opportunity, contact, lead, quote). This value would be used for the Auto-suggest feature in Global Search. |
Table 14-2  (Cont.) itemNode Properties for Main and Regional Task Flows for Application Menus

<table>
<thead>
<tr>

<th>Property Value</th>
<th>What Happens on the Rendered Page</th>
</tr>
</thead>
<tbody>
<tr>
<td>objectName</td>
<td>String</td>
<td>User recognizable string for a given Recent Item instance. This value is used as a string to match keystrokes entered in the auto-suggest field of Global Search. This value will be in the language of the user at the point of navigation (that is, when the record is saved). It will not change if the user changes language.</td>
</tr>
</tbody>
</table>

Example 14-2  Creating Region localArea Facet Added Code

```xml
<af:region value="#{bindings.EmpCreateUpdateFlow1.regionModel}"
    id="EmpCreateUpdateFlow1"/>
</f:facet>
```

Example 14-3  Example Edit Task Flow Binding Code

```xml
<af:region value="#{bindings.EmpSummaryTF2.regionModel}"
    id="EmpSummaryTF2"/>
```

14.2.3 How to Add Dynamic Main Area and Regional Area Task Flows to a Page

Unless otherwise noted, follow the procedure outlined in How to Add Default Main Area Task Flows to a Page, to insert the appropriate itemNode properties listed in Table 14-2.

- To add a dynamic main area task flow, set `taskType="dynamicMain"`.
- To add a default regional area task flow, set `taskType="defaultRegional"`.

14.2.3.1 Adding the Tasks List Menu to the Page

A tasks list is not a default widget as part of the UI Shell regional area. A tasks list is packaged as an ADF Controller task flow. You must manually add this task flow as you would any other defaultRegional task.

Specify the tasks list task flow as a defaultRegional task explicitly. If you do not do this, the tasks list does not render.

Add the following entry to your `menu.xml` file before the item node of tree structure and tree versions:

```xml
<itemNode id="__YourPage_itemNode__FndTasksList"  
    focusViewId="/YourPage" label="#{applcoreBundle.TASKS}" 
    taskType="defaultRegional"
    taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/patterns/ 
    uishell/ui/publicFlow/TasksList.xml#TasksList"
    disclosed="true" 
    parametersList="fndPageParams=" 
        #{pageFlowScope.fndPageParams}"/>
```

**Note:** The `taskFlowId` value path must appear in a single line to avoid an exception during runtime.

- `Id` must be unique within the menu metadata.
- focusViewId is the focusViewId of your page.
- Set label to the default label provided by the Oracle Fusion Middleware Extensions for Applications (Applications Core).
- taskType should be defaultRegional.
- taskFlowId should point to the tasks list task flow provided by Applications Core.
- The disclosed attribute is usually set to true. Although, it can be set to false if you do not want to disclose tasks list by default.
- parametersList should set fndPageParams as previously shown so that this object is available in the pageFlowScope of the tasks list task flow. This context is necessary for Single Object WorkArea. For more information, see Using the Single Object Context Workarea.

14.2.3.2 Group Tasks in the Tasks Pane into a Category

The Task Category is a label that is used to group tasks in a task list.

1. In the Structure window for the menu, right-click the page itemNode whose taskType value is dynamicMain and choose Surround with...

   The Surround dialog is displayed.

2. Select itemNode and click OK.

   The Insert Item Node dialog page opens to the Common properties tab.

3. In the Common properties tab, enter these values:
   - id field: Concatenation of the page ID and a short category name, using the following format, is suggested:
     pageId_categoryName
     For example, you might enter: ExpenseWorkArea_NewExpense.
   - focusViewId: Click the ellipsis to open the Advanced Editor.
     Select the focusViewId of the page.

4. Click Finish.

5. In the Property Inspector for itemNode - ExpenseWorkArea_NewExpense, enter these values:
   - label: Name of the label, such as NewExpense.
     Do not leave this field blank. This is the label that would appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites or when the system tracks the Recent Items.
Note:
The label should be defined in a resource bundle so it can be translated more readily.

- **Task Type:** taskCategory

6. Run the page by right-clicking the JSPX page file in the Projects tree view and choosing Run

   Confirm that the page contains task links arranged by category. The Task List is in the left regional area of the page. Items in the Task List are bulleted to make it clear when a line wraps.

### 14.2.3.3 Linking to a Task Flow in a Different Page

The Tasks Pane can link to a task flow in a different JSPX and pass page-level and task-level parameters.

The `navigateViewId` attribute supports this feature.

**Example 14-4** shows a sample of the metadata for a link in a Task List that links to another page.

**Example 14-4  Example Metadata for a Link in a Task List that Links to Another Page**

```xml
<ItemNode id="__ServiceRequest_itemNode__toTestPage1" focusViewId="/ServiceRequest" label="Go to different page" navigateViewId="/TestPage1" taskType="dynamicMain" taskFlowId="/oracle/apps/fnd/appcore/patterns/demo/SRTree.xml#SRTree"/>
```

### 14.2.3.4 Support No-Tab Work Areas

You can suppress dynamic tab navigation and just display one main area at a time. To do this, add `isDynamicTabNavigation="false"` to the `itemNode` that represents your JSPX page, as shown in **Example 14-5**.

Note that the default value of `isDynamicTabNavigation` is `true`.

You also can set the no-tab mode declaratively in the Property Inspector:

1. Select the `itemNode` from the Structure window.
2. Go to Property Inspector.
4. Set the Dynamic Tab Navigation property to `false`.

**Example 14-5  Implementing a No-Tab Work Area**

```xml
<ItemNode focusViewId="/SelTestWorkarea" id="stp1" taskType="dynamicMain" taskFlowId="/WEBINF/oracle/.../ProductMainFlow.xml#ProductMainFlow" label="#{adfBundle['oracle.apps....SelTestWorkarea_taskmenuBundle'].DEFINE_PRODUCT}" isDynamicTabNavigation="false"/>
```

Other menu metadata stay the same. Tasks List will continue to render. Clicking a Tasks Link will replace the current main area task flow with the new one.
14.2.3.5 Implementing the Task Popup

The Task Popup provides a way for you to:

- Load a task flow into a popup when the user clicks one of the Tasks List links.
- Cancel from the popup or open a new main area task flow, passing in parameter values from the popup.

Implementation Notes

The UI Shell provides an af:popup component with a modal af:panelWindow as its immediate child, which would contain a dynamic region defined in it. When selected by the user, the UI Shell will load the task flow into the dynamic region, and show the modal af:popup panelWindow without any buttons. Therefore, the task flow must include the OK and Cancel buttons that are used to open a dynamic tab and dismiss the popup, respectively. The dialog title will be set according to the label mentioned in the menu metadata of the dynamic task link. There is a refresh condition set on the dynamic region that refreshes the task flow and reloads it each time the popup is opened.

Remember the following when you implement the Task Popup feature:

- For a dynamicMain task that you would like to load into the popup, specify the loadPopup property as true. For example, as shown in Example 14-6, the ChooseSR task flow would be loaded in a popup when the user clicks its link in the Tasks List. The label that is mentioned will be displayed as the dialog title of the popup that starts the task flow.

- You can define any components within this task flow, except the af:popup and its child components, such as af:dialog, af:panelWindow, and af:menu.

- You cannot have a UIShellMainArea page template or any other templates inside the popup task flow.

- You must add the necessary buttons as part of the task flow. For example, if the task flow has a simple .jsff file, it should contain OK and Cancel buttons, along with other components.

- Create a managed bean to set the action listener for the Cancel button. See Implementing OK and Cancel Buttons in a Popup.

- Create another method for the OK button that calls the method in Example 18-5, and any additional processing logic. The common use case would be opening a new task in the main area by using the openMainTask API. For example, you can bind the OK button to a managed bean and add your own action listeners. See Implementing OK and Cancel Buttons in a Popup.

- You then can pass the parameters directly from the managed bean to the openMainTask API bindings for the popup task flow page to open a new dynamic tab. The menu data entries for parameters will not have any bearing on the dynamic taskFlow tab that they are loading in the main area. The details of that task flow should come from the openMainTask API that is bound to the OK button.

Example 14-6   Example Use of loadPopup Property

14.2.4 How to Pass Parameters into Task Flows from Tasks List

Item nodes with a `taskType` of `dynamicMain`, `defaultMain`, and `defaultRegional` have parameter support. In addition to specifying the `taskFlowId` to load when the user clicks a task flow link, you can specify which parameters to pass into that task flow. This is accomplished with the `parametersList` and `methodParameters` properties on the `itemNode`.

For the `itemNode` where you would like to specify parameter passing, add the `parametersList` property. The value of this property is a delimited list of parameter name-value pairs that will resemble Example 14-7.

Code in the managed bean for passing a hashmap to the task flow would resemble Example 14-8. A hashmap is a data structure that uses a hash function to map identifying values, known as keys (such as a person’s name), to their associated values (such as their telephone number).

Then, in the managed bean of the task flow, the Java object can be read, as shown in Example 14-9.

The `testValue` parameter is bound to an `af:outputText` value attribute, such as `<af:outputText value="#{TestPanelSplitter1MBean.testValue}"/>`, in the page fragment of the task flow.

**Example 14-7 Using the parametersList Property**

```xml
<itemNode id="__ServiceRequest_itemNode__SRDefault" focusViewId="/ServiceRequest"
  label="Pending Service Requests"
  taskType="dynamicMain"
  taskFlowId="/oracle/apps/fnd/appcore/patterns/demo/SRTable.xml#SRTable"
  parametersList="param1=value1;param2=value2;param3=#{ELForValue3}"/>
```

**Example 14-8 Example Code for Passing a Hashmap**

```java
private FndMethodParameters fndMethodParams;
...
public void setRichCommandLink1(RichCommandLink richCommandLink1)
{
    this.richCommandLink1 = richCommandLink1;
    FndMethodParameters methodParams = new FndMethodParameters();
    HashMap testHashMap = new HashMap();
    testHashMap.put("param1", "12345");
    testHashMap.put("param2", "67890");
    methodParams.setCustomObject(testHashMap);
    fndMethodParams = methodParams;
}
```

**Example 14-9 Reading Java Object in Managed Bean**

```java
public String getTestValue()
{
    Map pageFlowScope = 
        AdfFacesContext.getCurrentInstance().getPageFlowScope();
    Object custom = pageFlowScope.get("fndCustomObject");
    String outputTextString = "";
    if (custom != null && custom instanceof HashMap)
    {
        HashMap myHashMap = (HashMap)custom;
```
String temp1 = (String)myHashMap.get("param1");
String temp2 = (String)myHashMap.get("param2");
outputTextString = temp1 + temp2;
}
testValue = outputTextString;
return testValue;
}

### 14.2.5 How to Open Data Files from a Tasks List Link

The UI Shell implements this feature by using the **URLView** activity that is a task flow component of ADF. **URLView** generally is used to redirect the current request state of the application to an external or internal URL. With UI Shell, this **URLView** activity is only being used to open files that are internal to the current web application.

Therefore, the only input that the task list link will need is the internal path (within the webApp) of the file. After the path is provided to UI Shell, it will determine the current contextual root of the application and append it to the internal path of the file. After the Universal Resource Identifier (URI) for the file is generated, this is set on the **URLView** activity and an action expression is set on the task link to open the URL view. UI Shell also must call an **actionEvent** JavaScript method on the client side that will not allow the page to lose its current state upon redirection from the **URLView** activity.

**Note:**
You can only open data files that are part of your webApp, such as `/oracle/apps/fin/acc/file1.xls`. This feature supports only opening data files through the task list. Any other URI paths, such as a JSPX or a JSF page, are not supported.

---

**Implementation Notes**

For a **dynamicMain** task item that you would like to use to open the data file, there is a property called **filePath** in the Menu panel for the UI Shell page XML file. To enable this property in the Menu panel, during design time, the task type of the **itemNode** must be **dynamicMain**. The file URI path then should be specified against the **filePath** attribute in the Menu panel, as shown in Example 14-10.

You can specify any file type, such as xls, doc, pdf, txt, rtf, and ppt, that is within the application.

**Example 14-10  Specifying the File URI Path**

```xml
<itemNode id="__ServiceRequest_itemNode__ChooseSR"
    focusViewId="/ServiceRequest" label="Download File"
    taskType="dynamicMain" filePath="/WEB-INF/oracle/apps/Accounts.xls" />
```

### 14.3 Implementing Application Menu Security

Security of menus has two parts: actual access to the page or task flow, and the rendering of the menu itself. Any page or task flow is protected to run for a user only if that user has access to run the page or task flow. Directions for setting this up are in the Adding Security to an Oracle Fusion Web Application section in the *Developing Fusion Web Applications with Oracle Application Development Framework*.

Application menus and task list menus will automatically have their page security checked by the menu utilities. If the user does not have access, the menu entry will not
be rendered. If the following three conditions are true, security checks if a logged-in user has view privilege for a given task flow:

- The application has enabled authorization.
- The `taskType` is `dynamicMain` for the `itemNode`.
- The `taskFlowId` attribute is defined in the `itemNode`.

If any one of these conditions is not true, security is not checked and the `itemNode` will be protected only by the rendered attribute.

Application menus can have a security Expression Language expression on the rendered attribute that, if it returns false, will not render the menu entry. To do this, set the rendered attribute of the menu entry to an expression that evaluates to `true` or `false`. For instance, if the task list is to edit certain tax forms, this could be a business rule to hide or show links based on whether the customer is a nonprofit company. If it evaluates to false, the menu will not appear. For more information on all the security expressions, see the Adding Security to an Oracle Fusion Web Application section in the *Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework*.

If your UI Shell pages are secured by ADF Security, you must add a policy similar to that in Example 14-11 to the `jazn-data.xml` file.

**Task Flow Example**

Bounded task flows are secure by default, and require the policy shown in Example 14-12.

If the policy is missing, then framework-level checks will prevent access to the task flow (typically by throwing an error).

But how would a menu item or command link disable or hide itself based on a preliminary check of the same permission? Example 14-13 shows the generic Expression Language expression being used to perform a preliminary check of the Task Flow Permission. Note that this is only needed for an `itemNode` with `taskType="defaultMain"` or "defaultRegional". The security check is performed automatically for an `itemNode` with `taskType="dynamicMain"` (that is, what is in the tasks list).

Example 14-14 shows the task flow-specific Expression Language expression.

Note that both of these checks actually go directly against the policy store; that is, they do not query the task flow definition. This avoids the overhead of loading a large number of ADF artifacts to render links and menus.

**Example 14-11 Adding a Security Policy to the jazn-data.xml File**

```xml
<grant>
  <grantee>
    <principals>
      <principal>
        <class>oracle.security.jps.internal.core.principals.JpsAnonymousRoleImpl</class>
        <name>anonymous-role</name>
      </principal>
    </principals>
  </grantee>
  <permissions>
    <permission>
      <class>oracle.adf.share.security.authorization.RegionPermission</class>
    </permission>
  </permissions>
</grant>
```
14.4 Controlling the State of Main and Regional Area Task Flows

As described in How to Control Main Area Task Flows, UI Shell tasks to open or close a main area tab are exposed as data control methods so that you can create such UI artifacts through drag and drop. You do not need to create your own data control methods and manually raise Contextual Events.
Note:

openMainTask and closeMainTask only work when the calling task flow is loaded into the Main Area directly and locally.

For example, assume a UIShell page of Application1 that is running in Server1 is loading Taskflow1 in its Main Area. This Taskflow1 shows another task flow, Taskflow2, from Application2 running on Server2 and using a portlet mechanism or remote task flow mechanism.

If Taskflow2 uses openMainTask to open another task, it will not work. The task flow that invokes openMainTask should be loaded directly in the Main Area, and the task flow that is loaded should be available to the application locally.

14.4.1 How to Control Main Area Task Flows

The methodParameters parameter can be used to pass a Java object into the task flow that is specified in the taskFlowId parameter. Use the setCustomObject() method in FndMethodParameters to set the Java object. Note that passing a Java object is not supported in Navigate API.

Example of Passing a Java Object Using openMainTask

Bind the methodParameters parameter value to a managed bean property. Example 14-15 shows the methodAction binding in the page definition of the page fragment that calls openMainTask. Also see Table 14-2.

Data control APIs are:

- FndUIShellController.openMainTask

Note:

When passing parameters, do not leave the label field null. This is the label that would appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites, or when the system tracks the Recent Items.

- FndUIShellController.closeMainTask. See closeMainTask History for more information.

To open or close a main area tab, drag and drop the appropriate data control method to create the UI functionality. Having specified the parameter values for these methods, user clicks will prompt the UI Shell to react accordingly.

To use the openMainTask data control method:

1. Expand the Data Controls and select the openMainTask item, as shown in Figure 14-19.
2. Drag **openMainTask** and drop it onto the page fragment. When you do, the Applications Context menu shown in Figure 14-20 is displayed so you can choose one of the three options.

![Figure 14-20](image)

To use the **closeMainTask** data control method:

1. Expand the Data Controls and select the **closeMainTask** item, as shown in Figure 14-21.

![Figure 14-21](image)

2. Drag **closeMainTask** and drop it onto the page fragment. When you do, the Applications Context menu shown in Figure 14-22 is displayed so you can choose one of the three options.
Bind the `methodParameters` parameter value to a managed bean property. Example 14-15 shows the `methodAction` binding in the page definition of the page fragment that calls the `openMainTask` method.

Example 14-8 shows code in a managed bean for passing a hashmap to the task flow.

Then, in the managed bean of the task flow, the Java object can be read, as was shown in Example 14-9.

The `testValue` parameter is bound to an `af:outputText` value attribute, such as `<af:outputText value="#{TestPanelSplitter1MBean.testValue}"/>`, in the page fragment of the task flow.

**Example 14-15  methodAction Binding in Page Definition of Page Fragment That Calls openMainTask**

```xml
<methodAction id="openMainTask" RequiresUpdateModel="true"
Action="invokeMethod" MethodName="openMainTask"
IsViewObjectMethod="false" DataControl="FndUIShellController"
InstanceName="FndUIShellController.dataProvider"
ReturnName="FndUIShellController.methodResults.openMainTask_FndUIShellController_dataProvider_openMainTask_result">
    <NamedData NDName="taskFlowId" NDValue="/WEB-INF/TestPanelSplitterTaskFlow#TestPanelSplitterTaskFlow" NDType="java.lang.String"/>
    <NamedData NDName="keyList" NDValue="" NDType="java.lang.String"/>
    <NamedData NDName="parametersList" NDValue="" NDType="java.lang.String"/>
    <NamedData NDName="label" NDValue="Test App Panel" NDType="java.lang.String"/>
    <NamedData NDName="reuseInstance" NDValue="" NDType="java.lang.Boolean"/>
    <NamedData NDName="forceRefresh" NDValue="" NDType="java.lang.Boolean"/>
    <NamedData NDName="loadDependentFlow" NDValue="" NDType="java.lang.Boolean"/>
    <NamedData NDName="methodParameters" NDValue="" NDType="oracle.apps.fnd.applcore.patterns.uishell.ui.bean.FndMethodParameters"/>
</methodAction>
```

14.4.1.1 closeMainTask History

The dynamic tabs mode tracks the last tab that was displayed before the current tab. When the current tab is closed, that last tab is brought back into focus.

In no-tabs mode, a stack of all the task flows that were opened is maintained, along with the parameter values. When the current task is closed, the task flow (with its original parameters) that was open before the current one, is reinitialized.

There are two ways in which the previous tab information is set for a given tab. When a new tab is opened, the tab that was in focus is the new tab's previous tab. When the user clicks a tab UI, the last tab that had the focus becomes the current tab's previous tab.

**Figure 14-22  Selecting a Close Option from the Applications Context Menu**
The `MainAreaHandler.handleOpenMainTaskEvent` method has a mechanism to handle the new tab. The managed bean for the tab adds an additional property for the previous tab. When a new tab is configured to be opened, the current tab is set as the previous tab for the managed bean for the new tab.

A disclosure listener, the `MainAreaBackingBean.setLastDisclosedItem`, handles user clicks in the tab UI. When the user clicks a tab, two events occur: one for the tab that is going out of focus, and one for the tab that is coming into focus. First, during the out-of-focus event, the tab that is going out of focus is captured in the managed bean's instance variable. Then, during the in-focus event, that instance variable's value is set as the previous tab in the managed bean for the newly focused tab.

Through user clicks, it is possible to create a circular dependency in which TabA's previous tab is TabB, whose previous tab is TabA. In this case, when TabA is closed, TabB would come into focus. However, when TabB is consequently closed, TabA would have to be focused, but it has already been closed. This corner case is handled by moving the focus to the first tab in the main area.

**No-Tab Navigation**

To keep track of all task flows that have been opened, a Stack instance variable is introduced in the `MainAreaHandler` method. When a new task flow is opened, the task flow ID and its associated parameter values are added to the stack.

Having this information, the call to `closeMainTask` pops the stack to get the last task flow ID and its parameter values that were displayed, and reinitializes the main area with that task flow and parameter information.

See also Supporting No-Tab Work Areas.

### 14.4.2 How to Control Regional Area Task Flows

The UI Shell exposes the means to control the disclosure state of the regional area as a whole, and the disclosure state of individual panels within the regional area panel accordian.

**Declarative support:** Allows you to specify the initial state of the following on loading a work area JSPX page.

- Within the regional area, whether a regional area task panel is collapsed or disclosed.
- A given regional area panel that is disclosed on initial rendering of the page should reflect its assigned pixel height to determine how much screen real estate it occupies.

**Programmatic support:** Allows you to control the initial or subsequent state of the following within a work area JSPX page.

- By default, the disclosure state is driven by what is specified declaratively. However, after initial page load, you can override the declarative default and, for example, render the work area with the regional area collapsed (overriding the declarative setting of rendering that work area with the regional area disclosed). Disclosing a collapsed regional area splitter programmatically in response to a UI action by the user (such as a button click or menu selection).

Declarative support is provided using attributes exposed on the respective item node in the Menu Model.

For regional panels:
There are separate APIs that expose parameters to refresh the task flow and set the disclosure state for the showDetail items in the panel accordian. The showDetail items are identified by the task flow ID specified.

**Implementation Notes**

- Specify the default values for the regional or main splitter position and collapsed state in the menu for the item node that represents the page, using the `regionalAreaWidth` and `isRegionalAreaCollapsed` properties. A sample entry in the menu file resembles Example 14-16.

- If these properties are not set in the menu for the top-level item node that represents the page, then these default values are used:
  
  ```
  regionalAreaWidth="256"
  isRegionalAreaCollapsed ="false"
  ```

- For programmatic control, drag and drop one of the following corresponding methods from the `FndUIShellController` data control.
  
  - `discloseRegionalArea`
  - `collapseRegionalArea`
  - `setRegionalAreaWidth`

Two APIs shown in Example 14-17 are exposed as data control methods under `FndUIShellController` data control.

---

**Note:**

- Declarative support allows the `inflexibleHeight` property to control the pixel height of the regional area panel. Programmatic support does not have this allowance.

- Programmatic support allows the `forceRefresh` property to make it possible to refresh a task without passing in any parameters. Declarative support does not have this allowance.

- Refreshing a regional area task without disclosing the task is not supported.

- Multiple regional area tasks are allowed to be disclosed at the same time. A switch to force showing only one task at a time is not provided.

- Support for persisting any of these settings explicitly altered by the user during a session, across sessions, is not a part of this feature.

---

**Example 14-16  Sample Menu File Entry**

```
<itemNode id="itemNode_SvcCenter"

label="#{adfBundle['oracle.apps.fnd.appcore.patterns.demo.patterns_demo_menuBundle'].SERVICE_CENTER]"

action="adfMenu_SvcCenter" focusViewId="/SvcCenter"

isDynamicTabNavigation="false" regionalAreaWidth="250"

isRegionalAreaCollapsed="false">
```
**Example 14-17  APIs Exposed as Data Control Methods Under FndUIShellController**

```java
/**
 * Discloses a regional area task.
 * @param taskFlowId Task flow to disclose
 * @param keyList Key list to locate the task flow instance.
 * This is a semicolon-delimited keys or key-value pair.
 * For example, "key1;key2=value2". If only the key is specified,
 * the value is picked up from the parametersList with the same
 * name as the key.
 * @param parametersList Parameters list for the task flow.
 * This is a semicolon-delimited String
 * of name-value pairs. For example,
 * "param1=value1;param2=value2".
 * @param label Label for the task flow
 * @param forceRefresh Default false. If false, task flow reinitialization
 * depends on whether some parameters are passed into parametersList, where
 * the presence of parameter values causes reinitialization and the absence of
 * parameter values does not. forceRefresh true always causes reinitialization
 * of the task flow regardless of the value for parametersList.
 * @return For internal Contextual Event processing
 */
public FndMethodParameters discloseRegionalTask(String taskFlowId,
                                                String keyList,
                                                String parametersList,
                                                String label,
                                                Boolean forceRefresh,
                                                FndMethodParameters methodParameters);
```

```java
/**
 * Collapses a regional area task.
 * @param taskFlowId Task flow to collapse
 * @param keyList Key list to locate the task flow instance.
 * This is a semicolon-delimited list of key-value pairs.
 * For example, "key1=value1;key2=value2".
 * @return For internal Contextual Event processing
 */
public FndMethodParameters collapseRegionalTask(String taskFlowId,
                                                 String keyList,
                                                 FndMethodParameters methodParameters);
```

### 14.4.3 How to Control the State of the Contextual Area Splitter

The UI Shell provides the means to control the disclosure state of the contextual area through either declarative or programmatic support.

**Declarative support** lets you specify the initial state when loading a work area JSPX page. It determines whether the contextual area (as a whole) is collapsed or disclosed.

**Programmatic support** lets you control the initial or subsequent state of the contextual area within a work area JSPX page.

- By default, the disclosure state is driven by what is specified declaratively. However, after the initial page load, you can override the declarative default and, for example, render the work area with the contextual area collapsed (overriding
the declarative setting of rendering that work area with the contextual area disclosed).

- Disclosing the collapsed contextual area splitter programmatically in response to a UI action by the user, such as a button click or menu selection.

**Samples of Expected Behavior**

- A work area JSPX page loads with the contextual area collapsed or disclosed when the page renders, based on the declarative setting. If the work area is loaded because of a Main Menu invocation, then declarative options always are used for the disclosure state.

- If a work area loads because of a page navigation from another work area, programmatically set options may override declarative settings.

### 14.4.3.1 Implement the Contextual Area Splitter

Follow these steps to implement the contextual area splitter:

1. Extend the `contextual-area-task-flow-template` task flow template into the page task flow, as shown in Example 14-18.

2. Specify values for the contextual area splitter position and the collapsed state in the menu for the item node that represents the page using the `contextualAreaWidth` and `contextualAreaCollapsed` properties. A sample entry in the menu file will resemble Example 14-19.

3. If these properties are not set in the menu for the top-level item node that represents the page, then these default values are used:

   ```
   contextualAreaWidth="256"
   contextualAreaCollapsed ="false"
   ```

4. For programmatic control, drag and drop one of the corresponding methods from the `FndUIShellController` data control:

   - `collapseContextualArea`
   - `contextualAreaWidthSelection`

5. To set these values when opening a new task, drag and drop the `openMainTask` method from `FndUIShellController` data control and pass in the `contextualAreaWidth` and `contextualAreaCollapsed` parameters through "methodsParameters > NamedData" as shown in Example 14-20.

   Set the method in the page managed bean to set the `contextualAreaWidth` and `contextualAreaCollapsed` values, as shown in Example 14-20.

6. To set these values using the Navigate API to navigate to a task flow, drag and drop the `navigate` method from `FndUIShellController` and pass in the `contextualAreaWidth` and `contextualAreaCollapsed` parameters through "methodsParameters > NamedData" as shown in Example 14-21.

   First you need to set the `FndMethodParameters`; this should be done by adding code similar to this to a managed bean that we will call `myBean` for this example.

   ```java
   private methodParameters fndMethodParams;
   ...
   public void myNavParameters()
   ```
FndMethodParameters methodParams = new FndMethodParameters();
HashMap testHashMap = new HashMap();
testHashMap.put("contextualAreaWidth", "200");
testHashMap.put("contextualAreaCollapsed", "true");
methodParams.setCustomObject(testHashMap);
fnMethodParams = methodParams;

Properties

Example 14-20    Setting the contextualAreaWidth and contextualAreaCollapsed
Values for openMainTask

Example 14-21    Setting the contextualAreaWidth and contextualAreaCollapsed
Values for navigate
14.4.4 Sizing Regional Area Panels

Multiple regional area panels can be open at the same time, instead of showing only one panel at a time.

Because the desired size of each panel will be different, you can set the pixel height for each of the panels by specifying the `inflexibleHeight` property in the item node that represents a regional area panel, as shown in Example 14-22.

**Example 14-22 Using `inflexibleHeight` to Set Panel Height**

```xml
<itemNode id="__ServiceRequest__itemNode__SRSearch" focusViewId="/ServiceRequest" label="SR Search" taskType="defaultRegional" taskFlowId="/oracle/apps/fnd/applcore/patterns/demo/SRSearch.xml#SRSearch" inflexibleHeight="200"/>
```

14.5 Working with the Global Menu Model

Menu metadata used in Oracle Fusion Applications is divided into global menu data, consisting of the Home page tabs, the Navigator (also known as the Main menu), and the Preferences menu.

The Navigator and Home page tabs contain information from different applications, yet each application must be able to be developed independently. To bring this information together, a Global Menu Model is provided.

Navigation to a page is accomplished by constructing and executing a URL. Matching the application name from the distributed menu metadata to its deployment information will dynamically create the host/port portion of the URL. Other page parameters are held in the existing page-level menu metadata.

The Task Menu, create URL, and navigation API allow other declarative and programmatic access to page navigation. The UI Shell global area also will support a Home page link for page navigations.

**Global Menu Model Service**

This model:

- Contains at least the label, the application name, and the `viewID`
- Calls the Policy Store (optimized bulk authorization) to get the subset of these menu items to be rendered for that user
- [Restore post V1] Combines the results from all pillars and renders them
- Is distributed for multiple pillars
Example of Global Menus
The Global Menu Model presents a cascading appearance, shown in Example 14-27.

Global Menu Behavior

- Items to which the user does not have access will not be displayed.
- A category is hidden if there is no child to display.
- If a menu entry length is greater than 27 characters, ellipses (…) are displayed. The entire entry will be displayed in a tool tip when the pointer hovers over the entry.
- Parent and children categories will not be split into different columns.

14.5.1 How to Implement a Global Menu

Note:
Before you create menus, you first must create JSF pages using the UI Shell template.

These global menus span JavaEE applications.

- **Navigator**: This is the global menu that is displayed in the UI Shell global area.
- **Home Page Menu**: The Home page tabs are actually each a JSPX page assembled using menu metadata.
- **Preferences Menu**: The User Preferences page has a task list link to all other preferences pages within Oracle Fusion Middleware. This is assembled using menu metadata.

14.5.1.1 Menu Attributes Added by Oracle Fusion Middleware Extensions for Applications (Applications Core)

Table 14-3 and Table 14-4 list the menu attributes added by Applications Core to the menu XML in addition to what is provided by Oracle ADF.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>labelKey</td>
<td>xsd:string</td>
<td>N</td>
<td>Bundle key used for label; the key will be looked up in the resource bundle specified by the resourceBundle attribute of &lt;menu&gt;.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>webApp</td>
<td>xsd:string</td>
<td>Y</td>
<td>The webApp attribute is used to look up the host and port of the associated work area or Dashboard from the Oracle Fusion Applications Functional Core (ASK) deployment tables. These tables are populated at deployment time through Oracle Fusion Functional Setup Manager tasks.</td>
</tr>
</tbody>
</table>
Table 14-4  (Cont.) <itemNode> Attributes for Global Menus

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Data Type</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>focusViewId</td>
<td>xsd:string</td>
<td>N</td>
<td>This is the page ID. This can be found by looking in the adfc-config.xml file. The name under each page in the diagram view is the page ID.</td>
</tr>
<tr>
<td>securedResourceName</td>
<td>xsd:string</td>
<td>N</td>
<td>The resource name that is used for securing the item node.</td>
</tr>
<tr>
<td>applicationStripe</td>
<td>String</td>
<td>N/A</td>
<td>This attribute is used for pages. Check the security of the page against the policies that are located in LDAP. The applicationStripe name must be the same as the stripe name of the LDAP policy store, which is the same as the web.xml application.name attribute.</td>
</tr>
<tr>
<td>parametersList</td>
<td>String</td>
<td>N/A</td>
<td>This is a task-level itemNode attribute that is a parameters list to pass in to the task flow to open in the target workspace. This is a semicolon-delimited string of name-value pairs. For example, &quot;param1=value1;param2=value2&quot;</td>
</tr>
<tr>
<td>pageParametersList</td>
<td>String</td>
<td>N/A</td>
<td>This is a page-level itemNode attribute that is the parameters list for the page. This is a semicolon-delimited string of name-value pairs. For example, &quot;param1=value1;param2=value2&quot;. If the Expression Language expression evaluates to an object, the toString value of that object will be passed as the value of the parameter.</td>
</tr>
</tbody>
</table>
| destination        | String    | N/A      | The destination attribute is supported on the item nodes for the Navigator. The destination is necessary only for navigating to an external web site. When it is defined, it takes precedence over all attributes. Example of the menu data: <itemNode id="itemNode_otn" destination="http://www.oracle.com/technology/index.html"/>

14.5.1.2 Displaying the Navigator

The Navigator, shown in Figure 14-23, is rendered when the Navigator icon is clicked on the UI Shell.

Figure 14-23  Navigator Example

<table>
<thead>
<tr>
<th>Accounts Receivable</th>
<th>Expenses</th>
</tr>
</thead>
<tbody>
<tr>
<td>Revenue</td>
<td>Auditing</td>
</tr>
<tr>
<td>Billing</td>
<td>Corporate Cards</td>
</tr>
<tr>
<td>Receivables Balances</td>
<td>Fixed Assets</td>
</tr>
<tr>
<td>Budgets</td>
<td>Additions</td>
</tr>
<tr>
<td>Budgets</td>
<td>Financial Transactions</td>
</tr>
<tr>
<td>Career</td>
<td>Retirements</td>
</tr>
<tr>
<td>Profile Content</td>
<td>Tracking</td>
</tr>
<tr>
<td>Cash Management</td>
<td>Analysis and Reporting</td>
</tr>
<tr>
<td>Bank Statements and</td>
<td>General Accounting</td>
</tr>
<tr>
<td>Reconciliation</td>
<td>Inquiry and Reporting</td>
</tr>
</tbody>
</table>

Items in bold are groups, and items in blue are links. So some groups also are links.
14.5.1.3 Implement a Global Menu

**Note:**
The Navigator is used as the example for how a developer implements a Global Menu, but the steps will be similar for the Preferences and Home menus.

The Navigator metadata may be pointing to target work area pages in various applications. To simplify the runtime behavior, one XML file contains all the menu entries. An Applications Core application will deploy these menus to Oracle Metadata Services (MDS). Each application will read these directly from MDS.

Each application must be configured so that the shared library can read the menus from MDS.

**To implement a Global Menu:**

1. Verify that the `web.xml` file of the application has the correct Java Authentication and Authorization Service (JAAS) filter to enable checking menu security against Oracle Platform Security Services (OPSS), as shown in Example 14-23.

   The `application.name` parameter, as shown in the example, in the `web.xml` file is the application family value. The choices are crm, fscm, and hcm. This value is used to create the stripe in LDAP.

2. Update the `weblogic-application.xml` file. As shown in Example 14-24, set the `application-param` that has the `param-name` `jps.policystore.migration` to `OFF`.

3. In the `weblogic-application.xml` file, ensure that the `application-param` that has the `param-name` `jps.policystore.applicationid` is set to the correct stripe, as shown in Example 14-25. This is the same as the `application.name` property of the `web.xml` file.

4. Add the following entry in the `web.xml` file:

   ```xml
   <listener>
   <listener-class>oracle.apps.fnd.applcore.menu.service.MenuFragmentServiceContextListener</listener-class>
   </listener>
   
   Example 14-23   Sample JAAS Filter
   
   ```xml
   <filter>   
   <filter-name>JpsFilter</filter-name>   
   <init-param>   
   <param-name>enable.anonymous</param-name>   
   <param-value>true</param-value>   
   </init-param>   
   <init-param>   
   <param-name>remove.anonymous.role</param-name>   
   <param-value>false</param-value>   
   </init-param>   
   <init-param>   
   <param-name>application.name</param-name>   
   ```
Example 14-24 Setting jps.policystore.migration to OFF

Example 14-25 Setting jps.policystore.applicationid to the Correct Stripe

14.5.2 How to Set Up Global Menu Security

Global menu security depends on applications using a standalone LDAP server.

Note:

Global security only works with standalone WebLogic Server.

ADF Menu Security is enabled by default. If you need to disable menu security, such as for testing, start WebLogic Server after setting the JAVA_OPTIONS environment variable in the setDomainEnv.sh file:

JAVA_OPTIONS = -DAPPLCORE_TEST_SECURED_MENU=N

14.5.2.1 Enforcing User Privileges and Restrictions

Before you enforce user actions, define roles, principals, and actions in the database. Functional security will always prevent a user from accessing a page or task flow for which the user does not have privilege. To improve the user experience, global menus can be hidden if the user does not have access to that page. There are two different security features for this:

- The global menus have a securedResourceName attribute, which should be the value of the page resource against which security can be checked. For pages, this is the page definition file.

- The menus also have a rendered attribute. This can be used to evaluate an Expression Language security expression. If rendered="false" (false being the outcome of the expression), the menu item will be hidden even if the user has access to the page. There are certain times you would want to do this. For instance, consider a person working in HR as a consultant, not an employee. You might want a menu entry for editing employee data under an HR category, without showing an entry under the Employee Self-Service category that also leads to the same page. See Example 14-26.
The Expression Language expression should never check the page definition. However, you can use the Expression Language expression to check security of a person’s role because that is in LDAP.

- The applicationStripe attribute determines which LDAP stripe is checked for the securedResourceName attribute.

Example 14-26  Expression Language Expression to Evaluate a User’s Access Rights

rendered="#{securityContext.userInRole['EMPLOYEE_ROLE']}"

14.5.3 How to Create the Navigator

Menu files will be referenced through MDS. This means they can be located in a table or in a file system directory. Determine where you want this directory to be located. This is where your root_menu.xml file and other menu files will be located. For Global menu attributes, see Menu Attributes Added by ()

1. Create the Navigator.

   Example 14-27 shows a sample Navigator.

2. Create the application's Navigator files.

   The next files in the menu hierarchy can contain groupNodes that appear as non-clickable categories, itemNodes that are clickable to start a page, or references to more menu files. If itemNodes were included that were not deployed, they will not appear because what was deployed is checked against the deployment tables. Applications Core requires that if a groupNode has no child nodes, which could happen through security enforcement, the groupNode itself will not be rendered.

Example 14-27  Example of a Navigator

<menu xmlns="http://myfaces.apache.org/trinidad/menu">
  <groupNode id="groupNode_my_information"
    idref="_groupNode_my_information_
    label="#{menuBundle['oracle.apps.menu/ResourcesAttrBundle'].MY_INFORMATION}"
    securedResourceName="oracle.apps.hcm.people.portrait.ui.page.MyPortraitPageDef"
    applicationStripe="hcm"
  
    <itemNode id="itemNode_my_information_my_portrait"
      label="#{bundleVar.MY_PORTRAIT}" focusViewId="/MyPortrait" webApp="HcmCore"
      securedResourceName="oracle.apps.hcm.people.portrait.ui.page.MyPortraitPageDef"
      applicationStripe="hcm"
    
    <groupNode id="groupNode_my_information_compensation"
      idref="_groupNode_my_information_compensation_
      label="#{menuBundle['oracle.apps.menu/ResourcesAttrBundle'].COMPENSATION}"
      securedResourceName="oracle.apps.hcm.goals.core.publicUi.page.ManageGoalsWorkAreaPageDef"
      applicationStripe="hcm"
    
    <itemNode id="itemNode_my_information_goals"
      label="#{menuBundle['oracle.apps.menu/ResourcesAttrBundle'].GOALS}"
      focusViewId="/ManageGoalsWorkArea" webApp="HcmTalent"
      securedResourceName="oracle.apps.hcm.goals.core.publicUi.page.ManageGoalsWorkAreaPageDef"
      applicationStripe="hcm"
    
    <groupNode id="groupNode_my_information_career"
      idref="_groupNode_my_information_career_
      label="#{menuBundle['oracle.apps.menu/ResourcesAttrBundle'].CAREER}"
      securedResourceName="oracle.apps.hcm.goals.core.publicUi.page.ManageGoalsWorkAreaPageDef"
      applicationStripe="hcm"
    
    <itemNode id="itemNode_my_information_performance_management"
      label="#{menuBundle['oracle.apps.menu/ResourcesAttrBundle'].PERFORMANCE}"
      applicationStripe="hcm"
      focusViewId="/PerformanceWorkArea" webApp="HcmTalent"
    
</menu>
14.5.3.1 Render the Navigator as Dropdown Buttons

There are situations, particularly with simpler applications, when the default enterprise-level menu structure is not suitable. In these cases, you may want to display the Navigator as a series of dropdown buttons.

To switch the UI Shell rendering so the Navigator renders as dropdown buttons in a horizontal row, set the `isSelfService` attribute to "true" on the `.jspx` page that extends the UI Shell template. That is, inside the `<af:pageTemplate>` tag, add the following:

```html
<f:attribute name="isSelfService" value="true"/>
```

14.6 Using the Settings and Actions Menu

The Settings and Actions menu, shown in Figure 14-24, is accessed by clicking the name of the logged-in user on the right edge of the global area. It consolidates several menus that previously were stand-alone.
• **Sign In / Sign Out**

**Note:** When signing in, users *always* are directed to the application's home page.

This list provides two possible scenarios during runtime:

1. The application is not secured. In this case, there is no concept of the user being logged in (authenticated) or logged out (not authenticated).
   - The commandLink displays the text Sign In and is disabled.

2. The application is secured with ADF Security.
   - If the user is logged in:
     - The commandLink displays the text Sign Out and is enabled.
     - If Oracle WebLogic Server is configured to authenticate with Oracle Internet Directory LDAP, the user name is the display name of the authenticated user principal. The display name is indexed by a general end user preference. See [How to Implement End User Preferences](#).

If the user is logged out, the only way for an unauthenticated user to view a page is if a page either has no databinding (no pagedef) or has databinding but is granted to the anonymous role:

   - The commandLink displays the text Sign In and is enabled.

When the **Sign Out** link is clicked, the page is redirected to the application’s default home page if it is accessible. There are cases in which a default home page is not available to the current user. In such cases, the user application should implement the `setLogoutUrl()` API that is included in the `oracle.apps.fnd.appcore.common.ApplSession` class of the Oracle.
Fusion Middleware extensions for Applications Core API. This API is implemented as:

```java
public void setLogoutURL(String pLogoutURL);
```

The UI Shell’s Sign Out logic will get the logout URL from ApplSession using the `getLogoutURL()` API and redirect to it. This API is implemented as:

```java
public String getLogoutURL();
```

If the logout URL was not set in ApplSession, the application will be redirected to the default home page.

On clicking the Sign Out link, the user session is cleared from the cookie and terminated. If the home page is secured, the login prompt will first appear. If the home page is not secured, the page will appear and the Sign In link will be enabled.

- **Switch To / Impersonation**

  The Switch To menu is available only if the user has the security privilege to impersonate others and has been given access to impersonate at least one other user. When clicked, the menu displays the name of the logged-in user and any user names he or she can impersonate.

  ![Figure 14-25 Switch To Menu](image)

  See How to Set Up a Proxy User (Session Impersonation).

**14.6.1 How to Use the Personalization Options**

The options in the Personalization section of the Settings and Actions menu let you set your preferences, edit the current page, and reset the content and layout.

The Set Preferences option only appears if you have the ApplSession filter and mapping set up. See Configuring Your Project to Use Application User Sessions.

**Set Preferences**

You create the actual Preferences dialog, such as shown in Figure 14-28. See How to Implement End User Preferences for the details of how to implement the Preferences menu.

**Edit Current Page**

This option is displayed only if the displayed page has been marked as able to be user-edited (if the isPersonalizableInComposer attribute in af:pageTemplate is set to true). Selecting this option will start the editing feature and the page will resemble Figure 14-26. Click Close to return to the page. Click Customization Manager to change the displayed page in Oracle Composer. For more information about the Customization Manager, see the Oracle Fusion Middleware Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper guide. Note that changes are for just this user and therefore are called personalization. See Creating Customizable Applications.
Reset to Default Content and Layout
Select this option to discard any personalization changes and return to the default settings. Note that resetting layout and content is for that page. In particular, if any task flows are personalized on that page using Oracle Composer, they are not reset by this menu item.

When you select this option, this confirmation dialog is displayed:

**Figure 14-27  Confirm Reset Content and Layout**

---

### 14.6.2 How to Implement End User Preferences

The Set Preferences option provides easy access to setting preferences for the current application, general user preferences, or for any other application preference in Oracle Fusion Middleware. For more information about this Global menu, see *Working with the Global Menu Model*.

Preferences are pages that can set system wide settings that applications can access. There are general preferences that affect all applications, and there can be applicationspecific preferences. General preferences include language, date format, and currency. General preferences are stored in LDAP so they can be accessed from any application. Application preferences are usually stored in the applications on database tables, but they can be stored in LDAP also.

#### 14.6.2.1 Using the Set Preferences Option

Click **Set Preferences** to open a work area that shows the preferences related to the currently displayed page.

Links in the left hand side will allow navigation to any Preferences work area page within the entire Oracle Fusion product. This page will be rendered using Applications Core menu federation abilities. As the developer, you will own the menu files.
If an application is not installed, or the user does not have access, the entry in the task list menu should not appear. If a user does not have access to a particular setting within a page, you must use the rendered property with a security expression behind it.

For each application, there should be a preferences page. The preferences page uses the same path of the current application, but it uses a page name of preferences.jspx.

If no associated preferences page exists, a default General Preferences page will be shown. This page shows global Applications Core most-used preferences.

If there are several preference pages associated with an application, such as a Common Setting page and more specific pages, only one preferences page as a target from the global preferences link can be defined per application. (There will be a default name for the target focusViewID of the preferences page for an application.) In the preferences work area, other links are available from the task list to more specific pages or task flows. (Links in the task list can contain other focusViewIDs that belong to the same application as the default preference page.)

When the first application is deployed, it will become the location of the General Preferences page.

Several pages of an application can all point to the same preferences page.

More than one application cannot point to the same preferences page. This implies that each application can have its own preferences page, and if two applications want to share a common preferences page, they can, but it can be navigated to only from the task list. Therefore, from the Preferences link, the user always sees the more specific preferences page of that application.

**14.6.2.2 Using the Preferences Work Area Page**

A preferences page will be like any other work area page. Preference values are not supported in integrated Oracle Weblogic Server LDAP, only an external LDAP is supported. The task list will be loaded as a defaultRegional task flow and the main area will be a defaultMain task flow.

**Work Area Title**

Each preferences page should display a title similar to {Category_name:Page_name}. This can be done through an Expression Language expression and will not be created automatically from the framework.

The name that appears in the task list can be different from the page title. This is allowed because the task list name is generated from the task list preference distributed menu metadata, while the page title will be from the local page-level menu metadata.

**Tasklist and Navigation Pane**

Each page needs its Application Menu metadata to specify that it wants the Preferences task list menu in the defaultRegional area as well as in the defaultMain task flow.

This menu can be a two-level menu having categories with links under each category.

**Task List Federation**

The task list will be a task flow that will contain links to all preference pages throughout Oracle Fusion Middleware.
Each application will provide the preferences menu files that contain task list links to preferences pages delivered by that application. The preferences task list should follow the Navigator architecture recommendations where it uses sharedNode references to bring in menus from each application so they can be patched independently. Applications Core will automatically federate the menu metadata so the task list that is rendered will contain all the entries from all applications (filtered by security).

Individual menu files will have versions like other distributed menu files, so any application can apply a patch and the new menu will take precedence over an older version when federated.

**Task List Can Link Only to Full Pages (Not to Specific Task Flows)**

The task list will not start task flows dynamically, but will load a Preferences workarea page. This is because the task list menu must be federated and only page-level entries are allowed in a federated menu.

**No-Tabs Mode**

The Preferences page should use a no-tabs mode. This is a standard, not controlled through any code. You can use tabs if all task flows are defaultMain. See Supporting No-Tab Work Areas for more information.

**Task List Security**

The task list will be filtered by functional page-level security for that user. If all entries in a category are restricted, then the category should not appear either.

**Preferences Settings**

Settings will be a view activity in a task flow. It will follow other user experience standards so it should be built using an Applications Panel. This means the action buttons will appear at the top.

Different preferences pages can change the same backend setting, depending upon applications design. If this is needed, it should be stored in a common area, such as LDAP, or be in the General Preferences page.

**14.6.2.3 Deploying Preferences Pages and Designing General Preferences Content**

Application preferences pages are deployed with the corresponding product pages. The design should be similar to that shown in Figure 14-28.

**Figure 14-28  General Preferences Example**

![General Preferences Example](image)

**14.6.2.4 Configure and Implement End-User Preferences**

After the WebLogic Server console is configured, follow these steps to create an Oracle Fusion web application that uses UI Shell pages:
1. Create a UI Shell page that is used solely for the user preferences, such as PreferencesUI.jspx.

2. Set the isDynamicTabNavigation property to false for the PreferencesUI page entry in the menu.

3. Add the following task flow as a default regional area under the preferences page entry: 
   "WEB-INF/oracle/apps/fnd/applcore/pref/ui/mainflow/GeneralPreferencesFlow.xml#GeneralPreferencesFlow"

   The final menu entries for the page will appear similar to those shown in Example 14-28.

   The results of this example should display the basic Preferences menu entries in the default regional area that can be opened to display subflows for each preferences subtask (for instance, Accessibility and Appearance).

Example 14-28 Sample General Preferences Menu Entries

```xml
<itemNode id="itemNode_untitled2" label="Preferences"
    action="adfMenu_PreferencesUI" focusViewId="/PreferencesUI"
    isDynamicTabNavigation="false" webApp="Demo">
    <itemNode id="def1" focusViewId="/PreferencesUI" label="General Preferences"
        taskType="defaultRegional"
        taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/pref/ui/mainflow/GeneralPreferencesFlow.xml#GeneralPreferencesFlow"/>
</itemNode>
```

14.6.2.4.1 How to Use the Preferences Menu Model

The General Preferences task flow that is exposed also renders the Preferences Menu Model links by using a call to the Menu Service API.

The Preferences menu will be part of a central Utility application (menu web service) that will be deployed in the server. As a developer, you maintain the Preferences menu.

On any UI Shell page, the global area contains a Personalization menu that contains a Set Preferences link. This link will redirect the user to an application-specific Preferences page, depending upon the entry in the menu data.

Example 14-29 shows sample Preferences menu data.

In the example menu XML file, each parent item node represents a Preferences UIShell page. Its child nodes refer to the application-specific task flow in which the Preferences page exists.

For example, the first itemNode entry refers to the preferencesA page that is part of the FND webApp. The Service Flow child node is a task flow that belongs to the FND webApp.

For each parent itemNode, there is an attribute called prefForApps that contains a list of webApp names. This means that the itemNode is a common preferences page for those listed webApps.

For example, the Preferences page is common for two webApps -- gl and hr. This essentially means that all the Dashboards and work area UI Shell pages in the gl and hr webApps will be redirected to this preferencesA page, which is in webApp FND, when the Set Preferences link is clicked.
All the task flows under each preferences page `itemNode` will be displayed in the General Preferences task flow as navigation links. Therefore, all preferences pages will have access to these task flows.

**Example 14-29  Example Preferences Menu Data**

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<menu xmlns="http://myfaces.apache.org/trinidad/menu" version="1">
  <itemNode id="preferences_node_a" label="Preferences Page A" action="preferences_node_a" focusViewId="/preferencesA" webApp="fnd" prefForApps="gl, hr">
    <itemNode id="Flow 1" label="Service Flow" focusViewId="/preferencesA" taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/finance/ServiceFlow.xml#ServiceFlow" parametersList="id=userName" />
  </itemNode>
  <itemNode id="preferences_node_b" label="Preferences Page B" action="preferences_node_b" focusViewId="/preferencesB" webApp="fnd" prefForApps="fn">
    <itemNode id="Flow 2" label="Request Flow" focusViewId="/preferencesB" taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/finance/RequestFlow.xml#RequestFlow" parametersList="id=userName" />
  </itemNode>
  <itemNode id="preferences_node_d" label="Preferences Page D" action="preferences_node_d" focusViewId="/PreferencesUI" webApp="Demo" prefForApps="Demo">
    <itemNode id="Flow 2" label="Request Flow" focusViewId="/preferencesB" taskFlowId="/WEB-INF/oracle/apps/fnd/applcore/finance/AcceptanceFlow.xml#AcceptanceFlow" />
  </itemNode>
</menu>
```

14.6.2.4.2 How to Configure User Session and ADF Security

To test the general preferences task flows, configure user session and ADF Security for the test application. See Implementing Application User Sessions.

When configuring ADF Security, there is no need to define users, because you already are using an Oracle Internet Directory store that will authenticate the users existing in the policy store.

14.6.2.4.3 How to Retrieve Preference Values and Check Accessibility Mode by Using an Expression Language Expression

See Working with Localization Formatting.

A use case exists where the UI must use an Expression Language expression to check whether the accessibility mode is set to `screenReader` to render screen reader-friendly components in screenReader mode. The recommended method to do this uses `#{requestContext.accessibilityMode}` and is documented in the How to Configure Accessibility Support in trinidad-config.xml section of the Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide.

14.6.2.4.4 How to Implement the Password Management Page

The Password link on the General Preferences page will point to the Password Management page from the Oracle Identity Management administration application, as shown here:
For the Password link to redirect to the pwdmgmt.jspx page, the deployment information of the current application and the Oracle Identity Management administration application must be populated correctly in the Oracle Fusion Applications Functional Core (ASK) tables. You may need to talk to the person or team responsible for maintaining this information.

### 14.6.2.5 Using the Most Common Preferences

The Preferences most end users want to set are Language, Accessibility, and Regional. This section discusses how to configure these Preferences and what the default rules are, such as what happens if you do not set the Language Preference.

See [Working with Localization Formatting](#) for more information about localization of Preferences.

#### 14.6.2.5.1 How to Configure the Language Preference

When a session is created, it will use the language provided in the ORA_COMMON_PREFS cookie if it is set to a valid language. Inside the cookie, the fusionapps_language attribute is used to determine the language. There also is a local attribute that is for non-Oracle Fusion applications so that Oracle Fusion applications have their own attribute in the cookie and allowing other applications to keep their own language preference. Oracle Identity Management knows which to use based on a system value oracle.fusion.appsmode that is set at provisioning time.

If it is not a valid language or if the cookie does not exist, the browser language is used.

If for some reason the browser language is not valid, the seeded FND_LANGUAGE profile option is checked to determine the default language, which defaults to American English. If accessing a protected page, the login screen appears. This login screen may allow the user to select a language for the session. If selected, this will override the language. If the user does not select anything on login and if the user has a language preference previously saved, this will override the language if it is an installed language. If saved, it would be held in the LDAP settings for the Oracle Fusion applications Language setting in the orclFALanguage attribute of the orclIDXPerson object. This is controlled by Oracle Identity Management.
Users can set the Language preference by selecting the **Set Preferences** link from the Personalization menu in the global area. The Language option will look similar to Figure 14-30.

**Figure 14-30  Setting the User Preference Language Option**

14.6.2.5.2 How to Configure the Accessibility Preference

Oracle Fusion applications follow the Apache Trinidad standards for Accessibility.

Users can set the Accessibility preference by selecting the **Set Preferences** link from the Personalization menu in the global area. The Accessibility option will look similar to Figure 14-31.

**Figure 14-31  Setting the Accessibility User Preference Options**

14.6.2.5.3 How to Configure the Regional Preferences

The default Regional settings are based on the selected Language setting unless the Regional setting is saved explicitly. That is, no matter how the current language is derived, whether it is from login, the browser or LDAP, if the Regional settings are not yet set, they will default from the language. But if the user sets the Regional settings and then sets the Language setting, the Regional settings will not be changed.

Users can set the Regional preferences by selecting the **Set Preferences** link from the Personalization menu in the global area. The Regional options will look similar to Figure 14-32.

**Figure 14-32  Setting the Regional User Preferences Options**
14.6.3 How to Use the Administration Options

The Administration options in the Settings and Actions menu are displayed only if the logged-in user has the appropriate privileges. See Securing the Administration Menu.

Customize [name_of_page] Pages...
Select this option to customize the current page for multiple users using the customization layer picker dialog.

For information about customization, see Creating Customizable Applications.

Customize Global Page Template
Select this option to open the page in composer mode. All the global items can be selected so you can customize them. Customization is done at the site layer so it will apply to all pages, not just the one you are on. (When you use Customize [name of page] Pages, all the content except the global content is available for customization.)

Manage Customizations...
Select this option to start the Customization Manager.

For information about customization, see Creating Customizable Applications. For more information about the Customization Manager, see the Extending Runtime Editing Capabilities Using Composer section and the "Introduction to Composer" section of Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper.

For information about defining and configuring namespaces when promoting a page fragment to a label, see "Updating Your Application’s adf-config.xml File" in the "Performing Composer-Specific MDS Configurations" section of Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper.

Manage Sandboxes...
Select this option to manage sandboxes on your system.

The Sandbox is built on top of the standard Sandbox feature from Oracle Metadata Service.

Setup and Maintenance...
Select this option to start the Oracle Fusion Functional Setup Manager application. See the Oracle Fusion Functional Setup Manager User’s Guide.

Highlight Flexfields
No separate implementation is required. This option is available to any user who has the permission to view the Administration menu.

Select this option to highlight the Descriptive Flexfields (DFF), Key Flexfields (KFF) and Extensible Flexfields (EFF) on the runtime page.

When this mode is on, the page displays an information icon by each DFF, KFF and EFF. This will be displayed whether any Flexfield segments have been configured.

Hovering over the icon shows the Flexfield details. Administrators can note the DFF, KFF or EFF code so they can search for it in the Manage Descriptive Flexfields, Manage Key Flexfields, and Manage Extensible Flexfields setup tasks in Oracle Fusion Functional Setup Manager.

The option changes to Unhighlight Flexfields so that administrators can return to the normal view of the page.
For more information about Flexfields, see Getting Started with Flexfields.

14.6.3.1 Securing the Administration Menu

If you need the Administration link, include the privilege and the permission in the JAZN file as defined in Example 14-30. All administrator roles must inherit the Applications Core "Administration Link View Duty" duty role. This duty role gives access to the "View Administration Link" privilege.

Example 14-30  Required Privilege and Permission in JAZN File

```xml
<app-role>
  <name>FND_ADMINISTRATION_LINK_VIEW_DUTY</name>
  <display-name>Administration Link View Duty</display-name>
  <description>Provides access to the Administration Link on the UI Shell</description>
  <guid>EA1D0BF0BC096F11B18BDEB05F4BD0B48</guid>
  <class>oracle.security.jps.service.policystore.ApplicationRole</class>
  <members>
    <member>
      <class>oracle.security.jps.internal.core.principals.JpsXmlEnterpriseRoleImpl</class>
      <name>FND_APPLICATION_DEVELOPER_JOB</name>
    </member>
    <member>
      <class>oracle.security.jps.internal.core.principals.JpsXmlEnterpriseRoleImpl</class>
      <name>FND_APPLICATION_ADMINISTRATOR_JOB</name>
    </member>
  </members>
</app-role>

Privilege

```xml
<app-role>
  <name>FND_VIEW_ADMIN_LINK_PRIV</name>
  <display-name>View Administration Link</display-name>
  <description>Privilege to view administration link in UI shell. This privilege is available from Roles(s): Supply Chain Application Administrator,Cost Accountant,Application Implementation Consultant,Application Developer,Application Administrator</description>
  <guid>B14A4E74ECC63A3C6E4AF95816474D</guid>
  <class>oracle.security.jps.service.policystore.ApplicationRole</class>
  <members>
    <member>
      <class>oracle.security.jps.service.policystore.ApplicationRole</class>
      <name>FND_ADMINISTRATION_LINK_VIEW_DUTY</name>
      <guid>EA1D0BF0BC096F11B18BDEB05F4BD0B48</guid>
    </member>
  </members>
</app-role>

Permission and Grant to be included in JAZN file

```xml
<grant>
  <grantee>
    <principal>
      <class>oracle.security.jps.service.policystore.ApplicationRole</class>
      <name>FND_VIEW_ADMIN_LINK_PRIV</name>
      <guid>B14A4E74ECC63A3C6E4AF95816474D</guid>
    </principal>
  </grantee>
</grant>
```
14.6.4 How to Use the Troubleshooting Options

The Troubleshooting options provide user access to the standard help system and to troubleshooting and diagnostic tools.

Run Diagnostics Tests

Selecting this Settings and Actions menu Troubleshooting option opens the Diagnostics Dashboard user interface in a new window. For more information, see "Understanding Oracle Fusion Applications Incidents and Log Files" in the Administrator’s Guide.

Troubleshooting Options

Select this option to display the Options dialog, as shown in Figure 14-33.

**Figure 14-33  Troubleshooting Options Dialog**

- **Enable all**: Select this option to enable all other options on the dialog. When Enable all is selected, removing the selection from any of the other check boxes will deselect Enable all.

Applications logging, severity level and modules are stored as user-level profile options in profile tables. The corresponding profile option names are AFLOG_ENABLED, AFLOG_LEVEL, and AFLOG_MODULE. See “Configuring Settings for Log Files and Incidents” in Administrator’s Guide for information.

Because applications logging, severity level, and modules are profiles, when users click Save and Close, user-specific profile values will be inserted into the profiles. If users decide to revert the setting to the default site profile, they must use the Functional Setup Manager to remove their own profile.

After making changes to any one of the options for applications logging, severity level, or modules, the user must log out of the Oracle Fusion application, close the browser session, and log back in for the new options to take effect. These logging profiles are cached in the user session and initialized when a user logs into an Oracle Fusion application.
• **Database trace:** This option enables the SQL trace feature for all database connections used by the current user session.

For SQL trace, the trace file will have the FND session ID appended to the end. For example, `mysid_ora_4473_881497BF7770BE6604E040A0D807881.trc`.

The trace file can be found on the database host in the directory specified by the `user_dump_dest` init.ora parameter.

  – **Capture bind variables:**
    
    Select this option to enable the SQL trace option to also capture bind variables.

  – **Capture wait events:**
    
    Select this option to enable the SQL trace option to also capture wait events.

• **PL/SQL profiler:** This option enables the PL/SQL hierarchical profiler for all the connections used by the current user session.

For the PL/SQL profiler, the output will be in the directory defined by `APPLLOG_DIR`. The exact path for `APPLLOG_DIR` can be found on the database host by using the SQL statement:

```
select directory_name, directory_path from dba_directories
where directory_name like 'APPLLOG%'
```

The file names would be `PLS_<some number>_<FND session id>_<timestamp>.txt`, such as `PLS_49774696_88740EC94E3A0D2CE040A0D8036D8_100607104716.txt`.

To process the collected PL/SQL profiles and view results, run the `plshprof` command under the `$ORACLE_HOME/bin` directory.

• **Applications logging:** Applications logging is selected by default. Disabling logging will warn users that no logging will take place.

  – **Severity Level:**
    
    Use this option to set what types of information to log, and how much of it to log.

    For more information, see "Understanding Oracle Fusion Applications Incidents and Log Files" in the *Administrator’s Guide*.

  – **Modules:**
    
    This is the module filter for logging. This is a comma-separated list of modules to be logged. The percent sign (%) is used as a wildcard. For example, `% or %financial%`. The percent sign (%) is the default value and if no other value is specified, then it means everything will be logged.

    When a customer logs a service request with Oracle, the support person will help the customer enter the values necessary to filter the diagnostic logs for the needed information.

**Tracing Options**

This feature is designed for customers to collect diagnostic data to send back to Oracle for analysis.
When there is a performance issue that is reproducible, the tracing feature streamlines
the data collection process by allowing the end user who is experiencing the problem
to record a trace that will contain the necessary diagnostic information.

Before the user can access this function, the security administrator needs to assign the
Business Flow Troubleshooting role to the user. On each managed server, a maximum
of three users can be tracing at a time. By requiring the troubleshooting role to be
granted, an administrator can grant access to users who actually need to trace, and
revoke access when the issue is resolved.

To grant the role, the administrator will follow these basic steps:

- Log in to Oracle Identity Management.
- Click Administration on top right.
- Search for and select the target user.
- Click the Roles tab.
- Click Assign.
- Search for the display name Business Flow Troubleshooting.
- Select the role in the search results and click Add.

To run the trace, the user will follow these steps:

- Start the trace.

  The trace should be started only after navigating to the target managed server
  where the issue is happening. Note that the tracing feature only works within a
  single managed server; it will not span a flow involving more than one
  application (unless both applications happen to be on the same managed server).

  - Navigate to the target application.
  - Right before starting the problematic flow, select Troubleshooting > Tracing
    Options. The dialog shown in Figure 14-34 is displayed.

    Figure 14-34 Initial Tracing Options Dialog

    - Depending on the type of issue, select Performance or Functional trace type.
      The selection affects what diagnostic information is captured.

      In general, the user would select Performance when the problem is an
      application running too slowly, and Functional when the application does not
      behave as expected or when the information displayed is incorrect.
Trace Options defaults are based on the Trace type selection. Click Advanced Options to see what trace settings are enabled. For fine-grained control, select different trace options, as shown in Figure 14-35.

**Note:**
The user should accept the default settings or contact Oracle support for additional instructions.

---

**Figure 14-35  Advanced Tracing Options Dialog**

- Click **Start Trace**. A confirmation dialog, similar to Figure 14-36, with the trace ID will be displayed. Make a note of the trace ID.

---

**Figure 14-36  Trace Start Confirmation**

Subsequent clicks will be traced. The trace will run for a maximum of 30 minutes. If there are more than three simultaneous tracing sessions, an error message will be displayed.

If the Applications Trace option is selected (enabled by default for the Performance trace type), the server also needs to have at least 200MB of free memory in the JVM heap.

- Run the flow to reproduce the issue.
- Stop the trace.
– After executing the steps that have issues, select **Troubleshooting > Tracing Options** again. When tracing is active, only **Stop Trace** and **Cancel** will be active, as shown in Figure 14-37.

*Figure 14-37  Stop Trace*

![Stop Trace](image)

– Click **Stop Trace**. Figure 14-38 shows the two options to control whether to create an incident.

*Figure 14-38  Select Stop Trace Option*

![Select Stop Trace Option](image)

If the issue is reproduced, select **Stop trace and create incident**.

Click **OK**. A confirmation will be displayed with the incident number. Note the incident number in addition to the trace ID captured earlier.

The collected diagnostic information will be captured in an incident with the given incident number. See the “Troubleshooting Oracle Fusion Applications Using Incidents, Logs, QuickTrace, and Diagnostic Tests” chapter in the *Administrator’s Guide*.

If **Stop trace and do not create incident** is selected, then the confirmation will not have an incident number.

**User Productivity Kit**

The User Productivity Kit (UPK) is an optional, separately-purchased application that provides a content development, deployment, and maintenance platform for increasing project, program, and user productivity. The menu option will be available if Oracle UPK has been purchased, installed and configured.

This context-param entry must be added to the `web.xml` file:

```xml
<context-param>
    <description>This parameter notifies ADF Faces that the ExecutionContextProvider service provider is enabled. When enabled, this will start monitoring and aggregating user activity information for the client initiated requests. By default this param is not set or is false.</description>
    <param-name>oracle.adf.view.faces.context.ENABLE_ADF_EXECUTION_CONTEXT_PROVIDER</param-name>
    <param-value>true</param-value>
</context-param>
```

For recording, it may be necessary to turn on automation if all client components need to be sent down. The following parameter should be present in the application
web.xml:

<context-param>
<description>
This parameter notifies ADF Faces that test automation is being used. When enabled, this will cause the ids of components with testId attributes to be set to the value of the testId and the client component attribute of the component to be forced to true.

TestId attribute is now deprecated; use the 'id' attribute instead.
</description>
<param-name>oracle.adf.view.rich.automation.ENABLED</param-name>
<param-value>true</param-value>
</context-param>

Also, "upk" must be provisioned by the System Administrator. That is, an entry with DEPLOYED_MODULE_NAME = "upk" must be added in the ASK deployment tables. These tables are populated at deployment time through Oracle Fusion Functional Setup Manager tasks. Without the entry, the menu item "User Productivity Kit ..." will not be shown in the Help menu.

**Applications Help**
Select this option to open the help system in a separate window.

**Privacy Statement**
Select this option to display the privacy statement, which will appear in a new browser window. This option is always inactive until it is implemented. To set up the privacy statement, enter a fully-qualified URL in the PRIVACY_PAGE profile option.

Open the Setup and Maintenance work area, and use the Manage Applications Core Administrator Profile Values task to find the Privacy Statement URL profile option. In the Profile Value column, enter the full URL of the web page that contains the privacy content you want the menu item to link to.

Also see About Setting and Accessing Profile Values.

**About Applications**
Select this option to display the Oracle copyright statement and information about the application.

**About This Page**
Select this option to display version information for Oracle Fusion Applications, including details of the Oracle Application Development Framework, Oracle Metadata Services, the database, and the Applications Core. This makes it easier to know to which product the current page belongs and makes it easy to log a Service Request or find a patch for the correct product.

**Note:** This information is visible only to users with specific privileges. The privileges are controlled by the profile option FND_VIEW_VERSION_INFORMATION_PRIV, which an Administrator can enable or disable.

**14.6.5 How to Set Up a Proxy User (Session Impersonation)**

Session impersonation is a feature that enables a user (the impersonatee) to allow other users (impersonators) to log in and act as himself without sharing his password to the other user. The impersonator can login as himself and switch to the impersonatee. Once switched, he can access all the roles of the impersonatee. This
switch will be valid only for the current session; it must be done again in the next login. The impersonator can switch back to himself at any time.

**Note:**

Only users who have the `FND_IMPERSONATE_USER_PRIV` privilege will be available for the impersonatee to grant impersonation. The administrator must associate this privilege to the users who can serve as proxy users and can revoke it at any time. The grant is stored in LDAP as part of the impersonatee user attribute, `orclImpersonationGrantee`.

To set up the impersonation, follow these steps.

1. Log in as user Impersonatee (the user who will be impersonated by an authorized user).
2. Click your user name to open the Settings and Actions menu.
3. Click Set Preferences…
4. In the Tasks list, select Proxies.

*Figure 14-39  Selecting the Proxies Task*

The Proxies pane is displayed.

*Figure 14-40  Proxies Pane*

5. In the Proxies pane, click the Create icon to open the Select and Add: People dialog.

*Figure 14-41  Initial Select and Add: People Dialog*
6. Enter known data in any of the fields and click **Search**. This example uses the User Name field and the APPLICATION_DEVELOPER name.

*Figure 14-42  Completing the Select and Add Dialog*

![Select and Add: People](image)

7. Highlight the name you want to use.

8. Click **OK**. The information is entered on the Proxies pane, as shown here.

*Figure 14-43  Proxy Name Entered In Proxies Pane*

![Proxies](image)

9. Enter the necessary dates in the Start Date and End Date fields and click **Save**.

Now Impersonatee has granted proxy access to APPLICATION_DEVELOPER. APPLICATION_DEVELOPER can impersonate Impersonatee and perform transactions on his or her behalf.

10. Open the Settings and Actions menu and click **Sign Out**.

11. Sign back in as APPLICATION_DEVELOPER using the password for that user ID.

12. Click **Switch To**. The menu shows the names of the logged-in user and the users he or she can impersonate.

*Figure 14-44  Switch To Menu*

![Settings and Actions](image)

13. Select the name of the Impersonatee. You will be asked to confirm the switch.
The name of the impersonatee now is displayed with an icon indicating that the user is being impersonated.
This chapter discusses how to implement search functions in the UI Shell page template that is used to build web pages.

This chapter includes the following sections:

- Adding Attachments Support to Global Search
- Implementing Recent Items
- Implementing the Watchlist
- Implementing Group Spaces
- Implementing Activity Streams and Business Events
- Implementing the Search Results UI
- Implementing Auto-suggest
- Attachments in Global Search
- Supporting Global Search Alternate Words in the Cloud
- Implementing List Search

For more information about the features, see:

- Getting Started with Your Web Interface
- Implementing the UI Shell
- Implementing Additional Functions in the UI Shell
- Implementing UIs in JDeveloper with Application Tables, Trees and Tree Tables
- Implementing Applications Panels, Master-Detail, Hover, and Dialog Details

15.1 Adding Attachments Support to Global Search

This section assumes that you already have performed the basic attachments setup tasks on your searchable view object, just like you would any other view object.

Oracle Fusion applications has support for attachments using functionality delivered by Oracle Enterprise Crawl and Search Framework (ECSF). This functionality is integrated at crawl time of the Search view object, whereby ECSF will look at the crawled Search view object for attachment child view objects. If there are attachments defined this way, it will use Oracle Fusion Middleware Extensions for Applications Attachments APIs to retrieve the contents of the attachment, and they are added to the crawled document. All attachments found this way are added, and become a blob of
data in the indexed document. All references to the file name, file type, and so on, are lost. Refer to the ECSF class oracle.ecsf.fusion.FusionAttachmentImpl for details.

Note that existing ECSF implementation will only crawl attachments attached to the Search view object, not the attachments of child objects. For example, a Purchase Order with attachments will have the attachments crawled, but if the Purchase Order has Purchase Order lines, which also have attachments, these will not be crawled.

Searching attachments includes these features:

- **Keyword Search**: Users can perform a keyword search through several different entities within Oracle Fusion applications.
- **Search results drilldown**: Users can drill down on a specific record or documents included in the search results UI.
- **Entity keyword search**: Users can perform keyword search on a specific entity.
- **Keyword search configuration**: Administrators can configure the behavior of the keyword search by specifying what entities and fields will be used during the search process.
- **Attachments Search Security**: Attachments inherit security from the parent object to which the attachment is attached. This parent object security should be taken in consideration when defining attachments on searchable view objects and exposing them to the ECSF crawl.

**Overview of Attached Documents Search**

In a similar way to the existing ECSF crawl functionality, the Applications Core PreIndexProcessor can detect Attached documents at crawl time. It then stores in the indexed document this additional metadata about those attached documents to use when rendering the search result:

- Document Id
- Document Name
- Document Type

At search time, this data is used to show secured links in the existing search result so the user can click them and open the attachment.

Advantages of the Applications Core Attachments search functionality include:

- Minimal increase in data volumes or crawl time.
- Attachments are immediately available from the search results screen and can be opened in the same way as they can on the attachments UI.
- Attachments can be searched by file name and type.

**15.1.1 How ECSF Crawl Operates**

The ECSF Crawl of attachments does not handle categories or data security. In fact, due to the way it breaks the view links, it breaks the data security built into the view link and attachment code that uses it. No data security clause is added to the attachment query.
Background on how ECSF crawls master/detail relations

When ECSF crawls a Search view object that has detail relations, it does not use the default BC4J view links to generate the object tree of view objects. It breaks the view links and runs the master and detail queries separately, then joins the data using knowledge of the foreign keys in the view link. (This applies also to grandchildren and has nothing to do with attachments specifically; however, because an attachment is implemented as a child object, it is handled this way.)

For example, in crawling a simple Search view object with attachments, the basic algorithm is:

For each batch of Search view object row keys (typically 100)
  Query the Search view object for batch (1),
  Obtain key values of parent end of view link,
  Query child (attachment view object) with IN clause with parent PK values (2),
  For each record, match the parent (1) record with the child (2) based on the
key values defined for view link.
End For;

This shows an example of the attachment query for (2). PK1_VALUE and ENTITY_NAME are the attributes used in the view link in this example, and the values 1, 2, 3 and 'GS_PRODUCTS' come from the master Search view object.

```
SELECT * FROM (SELECT FndAttachedDocumentsEO.ATTACHED_DOCUMENT_ID,
    FndAttachedDocumentsEO.DOCUMENT_ID,
    FndAttachedDocumentsEO.LAST_UPDATE_DATE,
    FndAttachedDocumentsEO.LAST_UPDATED_BY,
    FndAttachedDocumentsEO.ENTITY_NAME,
    FndAttachedDocumentsEO.PK1_VALUE,
    FndAttachedDocumentsEO.PK2_VALUE,
    FndAttachedDocumentsEO.PK3_VALUE,
    FndAttachedDocumentsEO.PK4_VALUE,
    FndAttachedDocumentsEO.PK5_VALUE,
    FndAttachedDocumentsEO.DOCUMENT_ID AS DOCUMENT_ID1,
    FndDocumentsEO.DATATYPE_CODE,
    FndDocumentsEO.DESCRIPTION,
    FndDocumentsEO.FILE_NAME,
    FndDocumentsEO.USAGE_TYPE,
    FndDocumentsEO.DM_NODE,
    FndDocumentsEO.DM_FOLDER_PATH,
    FndDocumentsEO.DM_TYPE,
    FndDocumentsEO.DM_DOCUMENT_ID,
    FndDocumentsEO.DM_VERSION_NUMBER,
    FndDocumentsEO.URL,
    FndDocumentsEO.TITLE,
    decode(datatype_code, 'SHORT_TEXT', nvl(FndDocumentsEO.title, 'Undefined'),
    'FILE', nvl(FndDocumentsEO.title, FndDocumentsEO.file_name), 'WEB_PAGE',
    nvl(FndDocumentsEO.title, FndDocumentsEO.url)) attachment,
    FndAttachedDocumentsEO.ENTITY_ATTRIBUTES,
    FndDocumentsEO.DM_REPOSITORY,
    FndDocumentEntitiesEO.DOCUMENT_ENTITY_ID,
    FndAttachedDocumentsEO.CATEGORY_NAME,
    FndDocumentsEO.STATUS,
    FndDocumentsEO.DOWNLOAD_STATUS,
    FndDocumentCategoriesEO.CATEGORY_ID,
    FndDocumentCategoriesEO.USER_NAME,
    FndDocumentCategoriesEO.MODULE_ID,
    FndDocumentsEO.URI,
    FndDocumentsEO.ENT_APP_SHORT_NAME,
```

Implement Search Functions in the UI Shell
What this means is that all attachments directly attached to the Search view object are crawled, regardless of their category or the existence of security.

As the attachment is effectively inlined in the searchable document (this is how any attachment in SES currently works), a user with access to the Search view object can search on content from a secured attachment, even if the user has no data security rights on the attachment.

There is a fundamental mismatch in the security of the Search view object and secured attachments due to the “public user” nature of the crawl. The security of the attachment is effectively promoted to the functional security of the Search view object.

These secure attachments should not be crawled if they cannot be independently secured.

Due to this breaking of the View Link, if more than one child attachment is present, the attachments will be doubled up. This is because the View Link does not capture the attachment category (it is a custom attribute on the View Link).
15.1.2 How the Global Search Results UI Shows Existing Attachments

This section explains the design and behavior of how the results UI shows attachments.

The design:

• Shows attachments in the results UI using the same descriptions, tooltips, and so on, that the attachments component does.

• Allows the user to click an attachment in the results UI and have the attachment open.

• Shows keyword bolding in the attachment name (if any).

• Allows developers to promote grandchildren attachments if they want. So, for example, Purchase Order line attachments are shown with the Purchase Order result.

• Works across attachment categories.

• Suppresses secured attachments.

• Picks up Search view objects with changes attachments and flag for recrawling (but not grandchildren attachments).

• Works with the existing tag crawl functionality.

15.1.3 How Crawling Is Done

Crawling is done using the FndSearchPlugin that can be referenced by developers, either directly or as a base class to existing plugins.

The TagSearchPlugin is deprecated and stubbed with the removal of Webcenter tags. Developers should switch to FndSearchPlugin.
There are two arguments to determine how attachments are crawled:

- **ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS** - A comma-separated list of accessor paths to Attachment view objects.

- **ATTACHMENT_INCREMENTAL_CRAWL_ENTITY_NAME** - The name of the attachment entity used in incremental crawls to reverse lookup changed attachments.

**Attribute ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS**

This *required* attribute defines the attachments that will be considered as part of the crawl. Without it, the default attachment behavior of ECSF will be unchanged. That is, all direct attachments of the Search view object will be crawled, but nothing will be shown in the Search UI.

It is possible to have multiple attachment view links from a master view object, as well as attachments stored against detail view objects in a master-detail relation.

An accessor path is a dot-separated set of accessors to an Attachment view object. For example, `GsProductAttachmentsAccessor` is the view link accessor to the AttachmentVO directly under the Search view object.

`GsProductDetails.GsProductDetailsAttachmentsAccessor` is for an attachment under a detail-level view object.

Any number of these paths can be specified, although it is expected to be small (likely only 1).

As an example, accessors in the Master view object for this would be:
Accessors in the Detail view object for this would be:

When creating master-detail relations like this, do not include the accessor in the detail view object. If you do, ECSF will try to follow the links from Master to Detail to Master to Detail until it reaches the maximum depth of 7 levels.

In this case, you will see a crawl error similar to:

**Attribute ATTACHMENT_INCREMENTAL_CRAWL_ENTITY_NAME**

This attribute defines the attachment entity name that will be used when determining which Search view object records need to be flagged for re-crawl because they have had changes to their attachments. Because adding an attachment does not change the Last_update_date of the parent view object row, there needs to be a reverse lookup mechanism to force these additional rows onto the incremental crawl queue.

Note that only newly-added attachments and updated attachments (including the title) will be found for recrawl. There is no mechanism to detect deleted attachments.

This attribute is not required. If it is not supplied, attachment additions to a view object row that is otherwise unchanged (and hence on last_update_date change) will go un-noticed.

**Internal Stored Attribute FND_ATTACHMENT_METADATA**

Attachments found during the crawl will be recorded in the Search view object in the predefined stored string attribute FND_ATTACHMENT_METADATA. This attribute needs to be defined by the developer in the Search view object definition and flagged as a stored attribute. It should have no data in it; it will be over-written by the Applications Core preIndexProcessor at crawl time. An example of defining an attribute is shown here using a transient attribute.
What is stored in this attribute is an XML structure for all the attachments stored against a searchable object. As an example, here are four attachments stored against a row:

```xml
<Attachments>
  <Attachment documentId="300100024947778" datatypeCode="FILE" title="Latte.doc" fileName="Latte.doc" />
  <Attachment documentId="300100024947776" datatypeCode="FILE" title="UIShell_dtpreview.png" fileName="UIShell_dtpreview.png" />
  <Attachment documentId="300100024881786" datatypeCode="WEB_PAGE" title="oracle" description="Oracle homepage" fileName="http://oracle.com" />
  <Attachment documentId="300100024881784" datatypeCode="TEXT" title="a quick note" description="a quick note" fileName="a quick note" />
</Attachments>
```

Having these attributes, which are defined in this table, stored in the Search view object means they are searchable by default, and the UI can use the values to quickly decode the values without costly database look-ups when rendering the result.
Table 15-1 Attributes Definitions

<table>
<thead>
<tr>
<th>datatype Code</th>
<th>documentId</th>
<th>Title</th>
<th>Description</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>documentId</td>
<td>nvl(title, fileName)</td>
<td>description</td>
<td>fileName</td>
</tr>
<tr>
<td>WEB_PAGE</td>
<td>documentId</td>
<td>nvl(title, URL)</td>
<td>description</td>
<td>URL</td>
</tr>
<tr>
<td>TEXT</td>
<td>documentId</td>
<td>nvl(title, fileName)</td>
<td>description</td>
<td>fileName</td>
</tr>
<tr>
<td>TMURL</td>
<td>Not supported and there will be no attributes stored for it in SES.</td>
<td>nvl(title, URI)</td>
<td>description</td>
<td>URI (not URL)</td>
</tr>
<tr>
<td>FOLDER</td>
<td>Not supported and there will be no attributes stored for it in SES.</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

15.1.3.1 Mapping AttachmentVO Attributes into Search Metadata

Note that the XML is supplied without a schema; it is an internal part of applcore search and may change at any time without notice.

Attachments found at detail levels are pulled up to the parent level. If this is not required, do not include an accessor path to this level so these attachments will not be crawled.

Attachments in all categories are included. However, if that document entity has security enabled (no matter what the data security rules are), the attachments assigned to that document entity are removed from the indexed document and therefore not crawled. Their details will not be in the example XML.

The following types of attachments will be available as links:

- **FILE**
  An attached file. This is the primary use case.

- **WEB_PAGE**
  A URL, such as http://www.companyname.com. The link will be placed verbatim in the results UI as an af:goLink. Note that ECSF does not crawl Web page attachments.

- **TEXT**
  Text typed by the user. This is implemented by attachments internally as a hidden file, so is practically the same as FILE.

The following types of attachments will not be available as links:

- **FOLDER**
  A reference to a folder in Oracle WebCenter Content. Requires use of a WebCenter Content folder taskflow.

- **TMURI**
Topology Manager URI. This is a URI offset to a web application defined in topology. This is a minor use case used in migration and is not supported by search.

15.1.4 How Attachments Are Shown

Attachments will be shown on a line below the Other Actions in the Search Results. That is the lowest part of a result item.

The text of the link will be the Attachment title, which generally defaults to the file name in the Attachments UI, but may be over-ridden by the user when the attachment is uploaded.

The tool tip of the attachment will be the attachment description entered by the user. If this is not present, the title value will be used.

Attachments will be sorted and displayed in the results alphabetically.

All information is available in the stored attribute of the Search view object to render attachment links in the UI with no additional lookup work, and therefore no significant performance overhead.

Figure 15-3 Attachments Displayed in the Search Results

15.1.5 How Attachments Are Opened

Clicking an attachment will open the content for the user. The browser settings will determine how this is done and should be in line with what the Attachment component does.
For example, clicking a JPG attachment normally will open it directly in a browser tab, while clicking a .doc file will likely open it in Microsoft Word; this depends on the individual web browser configuration.

The different attachment types have different requirements to be able to download the attachment; some can be directly clicked; others need intermediate lookups done in the middle tier.

In addition, there is a security implication for attachments stored in WebCenter Content. The "real" url to the WebCenter Content attachment is long and needs to be determined within a few minutes of being used, because it has an implicit timeout in it. This means it cannot be pre-determined and stored in the Oracle Secure Enterprise Search Indexed Document. Similarly, on rendering of the results, it is not possible to look up the link in an efficient manner and show the user an af:goLink to the Attachment for all attachments in the search result. (The user may walk away from the screen and come back and click the link.)

The link that the user clicks needs to do the work of determining the "real link" at the point of click.

15.1.6 How to Implement Attachments Search

There are two cases to consider:

- If the Search view object has no plugin currently configured, simply use the Applications Core plugin.
- If the Search view object has a plugin already, set up the existing plugin to inherit the Applications Core plugin.

15.1.6.1 Using the Applications Core Plugin

In the ECSF Search view object design time, add a Search Plugin to the Applications Core class oracle.apps.fnd.applcore.search.plugin.FndSearchPlugin.
Configure attachments that will be crawled

Add a parameter with a comma-separated list of accessor paths with the key
ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS.

Configure Search view object incremental crawl detection of Search view objects with new attachments

Optionally, add an attribute with the key
INCREMENTAL_CRAWL_ATTACHMENT_ENTITY_NAME and a value of the Attachment Entity Name (the value you enter in the Attachment View Link wizard, such as GS_PRODUCTS).

This will add Search view objects to the crawl list when new attachments are added. This is useful because the Search view object last_update_date value is not updated when an attachment is added, and the document will not be detected as needing a re-crawl. This process will flag the individual Search view object row to be recrawled. Note that it is not possible to detect changed attachments this way at the detail level (for example a purchase order line's attachments), because the reverse lookup would obtain the primary key of the line item and not the Search view object.

15.1.6.2 Enhancing an Existing Plugin

Developers that have an existing plugin should extend the Applications Core plugin and call super() on the methods that implement attachment functionality. Use the same parameters to the plugin as already described.

```java
public class AppsSearchPlugin
extends FndSearchPlugin
implements PreIndexProcessor,
ChangeListener
{
/**
 * Hook into the pre index process of the crawl so we can annotate the Search view object
 * with apps specific information such as tags and attachment metadata.
 * @param ctx Search Context.
 * @param docs Documents to iterate and find tag children for.
 */
public void preIndexProcess(SearchContext ctx,
List<IndexableDocument> docs)
{
  super.preIndexProcess(ctx, docs);
  // custom apps functionality ...
}
/**
 * Get the change list for crawling.
 * @param ctx Search Context.
 * @param changeType the type of the change requested. Must be one of following
 * <ul>
 * <li>ChangeListener.UPDATE</li>
 * <li>ChangeListener.INSERT</li>
 * <li>ChangeListener.DELETE</li>
 * </ul>
 * @return an iterator of a list of primaryKeys. Returns an empty iterator if nothing changed.
 */
public Iterator getChangeList(SearchContext ctx, String changeType)
{
  Iterator ret = super.getChangeList(ctx, changeType);
  // custom apps functionality ...
}
```

Adding Attachments Support to Global Search
15.1.6.3 Adding the Transient Stored Attribute FND_ATTACHMENT_METADATA

Add a transient string attribute to the Search view object named FND_ATTACHMENT_METADATA to store Applications Core attribute metadata. Flag this attribute as stored in the Search view object definition.

15.2 Implementing Recent Items

Recent Items tracks a list of the last 20 task flows visited by a user. The Recent Items list is persistent across user sessions and a task can be restarted from the Recent Items list. The feature is automatically turned on and will be available automatically in pages using the UI Shell template. Security must be disabled to turn Recent items off.

Before You Begin

For the Recent Items feature to work, you must configure the user session and ADF Security. See Implementing Application User Sessions. Without security enabled, recent items will not be captured because the data is recorded for each authenticated user.

15.2.1 How to Choose Labels for Task Flows

Recent Items records the task flow labels for a task flow that has started. Therefore, you must carefully choose the labels for task flows, and must provide task flow labels for all task flows, even if they are meant to be used in no-tab mode (see Supporting No-Tab Work Areas).

15.2.2 How to Call Sub Flows

The openMainTask method is used to open a new task in the main area of Oracle Fusion web applications that use UI Shell templates. Besides opening a new tab, openMainTask also pushes a new task flow history object onto a stack, which is used to keep track of all task flows that have been opened. The task flow ID and its associated parameter values are encapsulated in the task flow history object.

Having this information, the call to closeMainTask pops the stack to get the last task flow ID and its parameter values that were displayed, and reinitializes the main area with that task flow and parameter information.

When a task flow is called from the local area task flow using task flow call activity, it is called a sub flow. By default, sub flows will not be recorded on the stack as described. Two new APIs are exposed in FndUIShellController data control for registering sub flows: openSubTask and closeSubTask.

15.2.2.1 Sub Flow Registration APIs

Use the openSubFlow and closeSubFlow APIs to record sub flows to Recent Items. Whenever an ADF Controller task flow call takes place, no notification is raised to Applications Core or UI Shell. So, unlike starting a task from a tasks list, you need to explicitly notify the UI Shell for sub flow calls.

When the openSubTask API is called before a subflow is started, the sub flow ID and its parameter values are pushed onto the stack. Applications Core also notifies the Recent Items implementation with recorded task flow information. This essentially
makes a sub flow able to be bookmarked by Recent Items, and can be started directly from the selection of menu items on Recent Items.

Note that registering sub flows to Recent Items is optional.

**Implementation**

This API is exposed as the data control methods
FndUIShellController.openSubTask and
FndUIShellController.closeSubTask that can be dragged and dropped to page fragments to create links to notify the UI Shell. The FndUIShellController data control is automatically available to all Oracle Fusion applications that reference Applications Core libraries.

Example 15-1 shows the signature and Javadoc of the method.

All the parameters required to be passed in openSubTask are exactly same as used by the Navigate API. For more information, see Introducing the Navigate API.

**Example 15-1  Recent Items API**

```java
/**
 * Notify UIS hell to record a given sub flow on the stack and
 * also notify Recent Items to include it on the list.
 *
 * @param taskFlowId Task flow to open
 * @param parametersList Parameters list for the task flow.
 *                    This is a semicolon delimited String
 *                    of name-value pairs. For example,
 *                    "param1=value1;param2=value2".
 *
 * @param label Label for the task flow.
 * @param keyList Key list to locate the task flow instance.
 *                This is a semicolon delimited keys or key-value pairs.
 *                For example, "key1;key2=value2". If only the key is specified,
 *                the value is picked up from parametersList with the same
 *                name as the key.
 *
 * @param taskParametersList Parameters list to pass in to the task flow to open
 *                            in the target workspace. This is a semicolon delimited String
 *                            of name value pairs. For example,
 *                            "param1=value1;param2=value2".
 *
 * @param methodParameters This can be used for passing
 *                            Java object into the task flow that is specified
 *                            in taskFlowId parameter. Use <code>setCustomObject() API</code>
 *                            in FndMethodParameters for setting the java object.
 *
 * @return For internal Contextual Event processing
 */

public FndMethodParameters openSubTask(String taskFlowId,
String parametersList,
String label,
String keyList,
String taskParametersList,
String viewId,
String webApp,
FndMethodParameters methodParameters)

/**
 * Closes the currently-focused sub-task and the focus moves to the
 * task from which this sub-task was started.
 */
```
public FndMethodParameters closeSubTask(FndMethodParameters methodParameters)

### 15.2.2.2 openSubTask API Labels

The openSubTask API accepts the same set of parameters as used by the Navigate API. If no label is specified in the openSubTask API, Recent Items will register it with the name of the parent task flow’s label. You should set a different label based on the business use case in the openSubTask API. Failing to do so will register this flow with the same label as the parent task flow’s label and, therefore, will make it impossible to distinguish between the parent flow and the sub flow entry in the Recent Items list.

### 15.2.2.3 Starting from Recent Items

Whatever task flow details are registered while invoking the openSubTask API will be used by Recent Items to start it. Recent Items takes care of starting the task flow in the right work area and web application. You do not need to do anything for that. Because the openSubTask API supports parameters, you can pass some requirement-specific values to it while registering the task flow to Recent Items. On starting, those passed values are available in the pageFlowScope. You can analyze these values and make decisions, such as if you need to first initialize the parent flow, or if you need to set Visible to False on some of the actions on the page.

### 15.2.3 How to Enable a Sub Flow to Be Bookmarked in Recent Items

To record sub flows into the Recent Items list, applications need to call the openSubTask API right before sub flows are started. openSubTask takes parameters similar to the Navigate API. One of these is task flow ID. For this, you need to specify the parent flow’s ID (or main task’s ID). In other words, sub flows need to be executed by using the parent flow, even though they are started from the Recent Items menu.

If your sub flow does not need to be bookmarked by Recent Items, you do not need to change anything. Otherwise, you need to modify your parent flow and sub flow as described in this section. After the changes, sub flows can be started in two ways:

- From original flows
- From Recent Items menu items using recorded information

Both will start the execution in the parent flow. Because the sub flow must be piggybacked on the parent flow when it is started from the Recent Items menu, you need to change the parent flow following these directions:

- Add a new router activity at the beginning of the parent flow. Based on a test condition, it will route the control to either the original parent flow or the task flow call activity (that is, the sub flow).
- Add an optional method call activity to initialize the sub flow before it is started from the Recent Items menu. Product teams can code the method in such a way that it can navigate to the sub flow after initializing the parent state. This allows product teams to render the contextual area, navigating back to the parent flow from the sub flow, and any other customizations.
• Bind `openSubTask` to the command component (such as a link or button) which causes the flow to navigate to the task flow call activity in the original parent flow. The `openSubTask` API registers the parent flow details and input parameters to the sub flow (to be started as a sub flow later) to the Applications Core task flow history stack.

Usually, you do not need to modify your sub flow for this task. However, you can consolidate the initialization steps from two execution paths in this way:

• Remove initialization parts from both paths in the parent flow. Instead, set input parameters in both paths only.
• Modify the sub flow to take input parameters.
• Add a new method call (such as `initsubflow`) at the beginning of the sub flow to initialize states in the parent flow (for example, parent table) so that the sub flow can be started in the appropriate context.

Note that the design pattern also requires the application to be able to navigate back to the parent flow from the sub flow. The initialization code should take this into consideration, such as by setting up states to allow the sub flow to navigate back.

In this example, you will use an Employee sample implementation to demonstrate the details of this design pattern.

**Sub Flow Sample Application**

As shown in Figure 15-5, users select *Subflow Design Pattern* from the task list. They then specify some criteria to search for a specific employee or employees. From the list, they can choose the employee for whom they want to show the details.

*Figure 15-5  Example List of Employees*

The Ename column in the search result table is a link that can be used to navigate to the employee detail page of a specific employee. When this link is clicked, a sub flow (or nested bounded task flow) is called to display the Employee Complete Detail page, as shown in Figure 15-6.
15.2.3.1 Implementing the Sub Flow Design Pattern

The parent task flow named `ToParentSFFlow` is shown in Figure 15-7.

The router activity `decideFlow` decides whether the control task flow should go to the original parent task flow path (`initParent`) or to the sub task flow path (`toChild`). The condition is defined as:

```xml
<router id="decideFlow">
  <case>
    <expression>#{pageFlowScope.Empno == null}</expression>
    <outcome id="__9">initParent</outcome>
  </case>

  <case>
    <expression>#{pageFlowScope.Empno != null}</expression>
    <outcome id="__10">toChild</outcome>
  </case>

  <default-outcome>initParent</default-outcome>
</router>
```
The test checks whether the Empno variable in the parent task flow's pageFlowScope is null. #{pageFlowScope.Empno} is set using its input parameter Empno when the parent task flow is called. The input parameters on the parent task flow (that is, ToParentSFFlow) are defined as:

```
<input-parameter-definition>
  <name>Empno</name>
  <value>#{pageFlowScope.Empno}</value>
  <class>java.lang.String</class>
</input-parameter-definition>
```

When the parent task flow is started from the task list, the Empno parameter is not set (that is, it is not defined in the application menu's itemNode). Therefore, the parameter is null and the router will route it to the initParent path.

When the sub task flow is recorded through the openSubTask API, the Empno parameter is set on parametersList as:

```
<methodAction id="openSubTask" RequiresUpdateModel="true"
  Action="invokeMethod" MethodName="openSubTask"
  IsViewObjectMethod="false" DataControl="FndUIShellController"
  InstanceName="FndUIShellController.dataProvider"
  ReturnName="FndUIShellController.methodResults.openSubTask_FndUIShellController_dataProvider.openSubTask_result">
  <NamedData NDName="taskFlowId" NDType="java.lang.String"
    NDValue="/WEB-INF/oracle/apps/xteam/demo/ui/flow/ToParentSFContainerFlow.xml#ToParentSFContainerFlow"/>
  <NamedData NDName="parametersList" NDType="java.lang.String"
    NDValue="Empno=#{row.Empno}"/>
</methodAction>
```

You also set up:

- `taskFlowId` to be the parent task flow's, not the sub task flow's
- `label` to be the sub task flow's

When users click the link (the Ename) to which the openSubTask method is bound, openSubTask will be called. This link component is defined as:

```
<af:column sortProperty="Ename" sortable="false"
  headerText="#{bindings.ComplexSFEmpVO.hints.Ename.label}"
  id="resId1c2">
  <af:commandLink id="ot3" text="#{row.Ename}"
    actionListener="#{bindings.openSubTask.execute}"
    disabled="#{bindings.openSubTask.enabled}"
    action="toChild">
  </af:commandLink>
</af:column>
```
Note that when the link is clicked:

- **actionListener** and the **action** specified on the link are executed, in that order.

- **openSubTask** is called only from the original parent task flow path (that is, **initParent**), not from the sub task flow path (that is, **toChild**).

The **EmployeeDetails** activity in Figure 15-7 is a Task Flow Call activity that invokes the **ToChildSFFlow** sub task flow. Before the sub task flow is executed, add initialization steps. These initialization steps could include, but are not limited to:

- Set up parent states. For this example, set the selected employee's row to be the current row.

- Set up the Contextual Area state.

- Set up states to allow the sub task flow to navigate back to the parent task flow.

There are two approaches to setting up the initialization steps:

- In the parent task flow

- In the sub task flow

For the first approach, you can add logic to initialize both paths before the task flow call activity in the parent task flow. For the second approach, you initialize states in the sub task flow by using input parameters of the sub task flow. For example, the sub task flow will take an input parameter named **Empno**. In effect, the second approach just postpones the initialization to the sub task flow.

The definition of input parameters in the task flow call activity is:

```xml
<task-flow-call id="EmployeeDetails">
  <task-flow-reference>
    <document>/WEB-INF/oracle/apps/xteam/demo/ui/flow/ToChildSFFlow.xml</document>
    <id>ToChildSFFlow</id>
  </task-flow-reference>
  <input-parameter>
    <name>Empno</name>
    <value>#{pageFlowScope.Empno}</value>
  </input-parameter>
</task-flow-call>
```

Note that this means that the calling task flow needs to store the value of **Empno** in \#{pageFlowScope.Empno}. For example, from the original parent task flow path, it is set to be \#{row.Empno} using the **setActionListener** tag. For the sub task flow path, it is set using the parent task flow's input parameter **Empno**. On the sub task flow, you need to specify its input parameters as:

```xml
<task-flow-definition id="ToChildSFFlow">
  <default-activity>TochildSFPF</default-activity>
  <input-parameter-definition>
    <name>Empno</name>
    <value>#{pageFlowScope.Empno}</value>
    <class>java.lang.String</class>
  </input-parameter-definition>
  ...
</task-flow-definition>
```
Note that the name of the input parameter (Empno) must be the same as the parameter name defined on the task flow call activity. When the parameter is available, Oracle ADF will place it in #{pageFlowScope.Empno} to be used within the sub task flow. However, this pageFlowScope is different from the one defined in the task flow call activity because they have a different owning task flow (that is, parent task flow versus sub task flow).

The definition of the sub task flow is shown in Figure 15-8:

**Figure 15-8   Example Sub Task Flow Definition**

In the sample implementation, you implemented the initialization step in the sub task flow. The Empno variable is passed as a parameter to the sub task flow and used to initialize the parent state. When the sub task flow is started, the default view activity (TochildSFPF) is displayed. Before it renders, the initPage method on the ChildSFBean will be executed. The page definition of the default page is defined as:

```xml
<pageDefinition xmlns="http://xmlns.oracle.com/adfm/uimodel">
  <parameters/>
  <executables>
    ...
    <invokeAction id="initPageId" Binds="initPage" Refresh="always"/>
  </executables>
  <bindings>
    ...
    <methodAction id="initPage" InstanceName="ChildSFBean.dataProvider"
                  DataControl="ChildSFBean" RequiresUpdateModel="true"
                  Action="invokeMethod" MethodName="initPage"
                  IsViewObjectMethod="false"
                  ReturnName="ChildSFBean.methodResults.initPage_ChildSFBean_dataProvider_initPage_result"/>
    ...
  </bindings>
</pageDefinition>
```

The initPage method is specified in the executables tag and will be invoked when the page is refreshed. The initPage method itself is defined as:

```java
public void initPage() {
    FacesContext facesContext = FacesContext.getCurrentInstance();
    ExpressionFactory exp = facesContext.getApplication().getExpressionFactory();
    DCBindingContainer bindingContainer =
        (DCBindingContainer)exp.createValueExpression(
```
facesContext.getELContext(),"#{bindings}",DCBindingContainer.class).getValue(facesContext.getELContext());
ApplicationModule am = bindingContainer.getDataControl().getApplicationModule();

ViewObject vo = am.findViewObject("ComplexSFEmpVO");
vo.executeQuery();

Map map = AdfFacesContext.getCurrentInstance().getPageFlowScope();
if(map !=null){
    Object empObj = map.get("Empno");
    if(empObj instanceof Integer){
        Integer empno = (Integer)map.get("Empno"); // new Integer(empnoStr);
        Object[] obj = {empno};
        Key key = new Key(obj);
        Row row = vo.getRow(key);
        vo.setCurrentRow(row);
    } else {
        String empnoStr = (String)map.get("Empno");
        Integer empno = new Integer(empnoStr);
        Object[] obj = {empno};
        Key key = new Key(obj);
        Row row = vo.getRow(key);
        vo.setCurrentRow(row);
    }
}

The initPage method takes the input parameter Empno from
#{pageFlowScope.Empno} as a key to select a row and set it to be the current row
in the master Employee table.

15.2.4 How to Use Additional Capabilities of the Recent Items openSubTask API

The openSubTask API has additional capabilities. For example, consider an
employee search page in which you enter parameters such as department number and
manager ID, and search for the matching employee records. You can use the
openSubTask API to register a search page with search parameters. The next time the
user can see the search results by just starting it from the Recent Items menu. This is
similar to using parametersList to specify search parameters while registering the
search task flow. While starting, additional programming can be done to retrieve the
search parameters and execute the query with the parameter values.

Favorites

As soon as tasks are recorded on the Recent Items list, they are eligible for Favorites.
The Favorites menu is implemented on top of Recent Items. Any current task on the
Recent Items list can be bookmarked and placed in the Favorites folders. Currently,
only a one-level folder is supported. Similar to Recent Items, tasks on the Favorites list
can be started directly from the list. So, the description in this section for Recent Items
applies also to the Favorites implementation. For example, sub flows based on the
design pattern described in this section can be registered on the Favorites list as well
as the Recent Items list.
15.2.5 How to Implement Data Security for Recent Items and Favorites

Data security controls access to the data displayed on the target. When data security is enforced on the target page, any changes to the access that the user has is properly reflected on the data.

However, there are use cases in Oracle Fusion Applications where the Recent Items and Favorites features may cause security issues. In some cases there is a master/detail relationship between objects in which only the parent object has data security implemented. The child object has no data security enforced and is expected to inherit security from the parent. In such cases, the user can only navigate to the child task flow through the parent task flow. But because the child task flow can be added as a Recent Item or Favorite, users can navigate directly to the child through Recent Items, whether they still have access to the parent.

Data security ensures that user access is properly enforced on all flows that can be accessed from Recent Items or Favorites.

Implementation

Implementation consists of ensuring that security is enforced consistently in all scenarios and that authorization exceptions are handled by the standard central method.

Security Enforcement

For function security, no additional implementation is required. The recommendations for data security are:

- Data security should be applied on an appropriate level. For example, in a master/detail relationship, security definitions should be created on both parent and child objects and applied on a proper level.

- If the child record inherits the security from its parent, then the parent’s security must be programmatically enforced on a sub flow. This should be done by adding a default method activity on the task flow and calling the data security API to check that the user has access to the parent. If the user does not have proper access, an authorization exception is generated.

  In addition, you should programmatically enforce the parent data security where applicable. For instance, if a view object takes the parent primary key as a parameter, before executing the query the code should check that the user has access to the parent.

15.2.6 Known Issues

- Recent Items are persistent across user sessions.

- You may see a null pointer exception when all the task flow parameters are not supplied values.

15.3 Implementing the Watchlist

The Watchlist is a portlet or menu, accessible to Oracle Fusion Applications users, that provides a summary of items that a user wants to track. The Watchlist includes seeded items (items that are provided out of the box) categorized by functional areas, and items created by the user. Technically, the Watchlist presents a list of pre-queried searches (saved searches or standard queries) of things the user wants to track. Each
item is composed of descriptive text followed by a count. Each item also is linked to a page in a work area where the individual items of interest are listed.

The Watchlist is available both as a dashboard region in the Welcome tab of the Home dashboard, and as a global menu. These are two views of the same content. The dashboard region is available to users as soon as they log in, while the global menu is accessible as they navigate through the suite.

The Watchlist will be refreshed to fetch new counts and items whenever the user navigates to the Home page. The Watchlist can refresh the entire list or individual categories as needed. Users can personalize the Watchlist to hide or show items.

Figure 15-9 shows an example of the Watchlist portlet and menu.

Figure 15-9   Example Watchlist Portlet and Menu

You have these high-level tasks:

- Code view objects with bind variables and default values for bind variables as needed for calculating the Watchlist count. These view objects will be executed at runtime by the Watchlist API to get the Watchlist count for the user.

- Code task flows to enable drill-down from the Watchlist UI.

- Seed FND deployments to specify host, port, and context root information for UI drilldown and service invocation.

- Seed FND standard lookups for each Watchlist category and item meaning.

- Seed information to tell the Watchlist what counts to track, how to display them to the user, which view objects to execute, and how to drill down to the work area and tasks.

- Import Watchlist JAR files as ADF libraries in service and UI projects.

- Set up a service interface method so that product code and Watchlist code can interact.
15.3.1 Watchlist Data Model Effects

Product teams will seed data into the ATK_WATCHLIST_CATEGORIES and ATK_WATCHLIST_SETUP tables. Rows in the ATK_WATCHLIST_ITEMS will be managed by Watchlist code, but you will query it for testing verification.

The only other data model effect will be in the creation of summary tables. These summary tables help with retrieving the count of Watchlist items with data security. See Summary Tables.

15.3.2 Watchlist Physical Data Model Entities

The Watchlist data model is supported by ATK. The tables are:

- **ATK_WATCHLIST_CATEGORIES**: Represents the functional categories in which each Watchlist item will fit. See Table 15-2.
- **ATK_WATCHLIST_SETUP**: Represents a type of count that a Watchlist item can track. The primary key is a Watchlist item code. See Table 15-3.

### Table 15-2  ATK_WATCHLIST_CATEGORIES

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Datatype</th>
<th>Required</th>
<th>Comments</th>

15.3.3 Supported Watchlist Items

Supported Watchlist items are all *asynchronous* (that is, queries are executed on demand when the user requests a refresh or just before the Watchlist UI is shown). There are four types of asynchronous Watchlist items (watchlist_item_type):

- Seeded queries (SEEDED_QUERY)
- Seeded saved searches (SEEDED_SAVED_SEARCH)
- User-created saved searches (USER_SAVED_SEARCH)
- Human task-flow items (HUMAN_TASK)

15.3.3.1 Asynchronous Items Overview: Expense Reports Saved Search

For asynchronous Watchlist items, the count is updated only upon request. For example, in Expenses, there is an expense reports search panel from which users can make searches and save them in MDS for future use. Users should be able to promote their saved searches to the Watchlist for tracking. This Watchlist item (of type USER_SAVED_SEARCH) is asynchronous in that the Watchlist count will be updated only upon request, and events that change the count will not be updating the Watchlist simultaneously. In this case, Watchlist code is responsible for querying the count of an asynchronous Watchlist item on demand.

For the Expense report saved search panel example:

- Because this item is of type USER_SAVED_SEARCH, Watchlist items are created when the user promotes a saved search on the search panel in Expenses. This invokes a Watchlist service on the Watchlist that does the Watchlist item creation. This is not needed for Watchlist items of type SEEDED_QUERY or SEEDED_SAVED_SEARCH.

- A request to refresh the Watchlist item count comes from the Watchlist portlet. This will invoke an exposed service, which delegates the call to a method on a provided Watchlist JAR file.
• The method on the Watchlist JAR file will take care of rerunning the query (on the expenses database) and taking the results to update the Watchlist item count (on the Watchlist database).

15.3.3.2 Summary of Implementation Tasks

At a high level, for asynchronous Watchlist items, your development tasks are:

• Determine or set up view objects to execute the query for Watchlist count. You may want to include view criteria with bind variables and specify default values for bind variables. (Not needed for Human Task)

For example, most view objects seeded for the Watchlist would filter by user to show counts specific to the logged-in user. You could create a view criteria with a bind variable called `userId` and specify the default value as a groovy expression to determine the current user ID from the security context. You then would seed this view criteria ID in the setup table along with the view object. The Watchlist API would execute the view object by applying this view criteria to get the row count. Example 15-2 shows code from the view object xml for a bind variable with a default value.

• (Optional) Set up a summary view object to facilitate a refresh count and specify the `summary` attribute in the Watchlist setup table. Watchlist code would use this information to query the count instead of doing a rowcount on the executed view object results.

• Include Watchlist model JAR files in your service project and set up a `refreshWatchlistCategory` service method. This method only will contain code to delegate the call to the nested Watchlist application module method that actually executes the view object queries by reading your Watchlist setup data. This requires that all the corresponding model projects are included as JAR files in this service project so view objects are available in the class path. This service should be exposed so that the Watchlist UI can use it to start the refresh process.

• Determine and code task flows for drilldown from the Watchlist UI. There is no special coding required for these task flows; the key-value parameter string that you specify in the setup table will be used as the input parameter list when invoking the specified task flow for the UI drilldown on Watchlist items.

• (Optional) Enable saved search promotion to the Watchlist. Include Watchlist model JAR files in the corresponding project for the query panel and work with the Watchlist API. For promotion and demotion of user-saved searches, code must invoke a method in the provided Watchlist JAR, which then will handle interaction back to the Watchlist. Add promotion and demotion components on the search panel so that saved searches can be used as Watchlist items.

• Include Watchlist UI and Protected model JAR files in your UI SuperWeb project, to enable Watchlist menu drilldown in the UI Shell Global Area, as shown in Figure 15-10.
Create FND_LOOKUPS for the displayed Watchlist category and item meaning (FND_STANDARD_LOOKUP_TYPES.LOOKUP_TYPE). Product teams must seed the lookup type with the meaning for the category (VIEW_APPLICATION_ID = 0 and SET_ID = 0). The translated lookup type meaning is shown in the Watchlist UI for the category, while the corresponding lookup value meanings are shown in the Watchlist UI for items (user saved search item meanings come from the saved search directly). Product teams must create seed data for this lookup.

Example 15-3 presents sample code to create or update the lookup.

Seed Watchlist categories and setup information. Create your category in ATK_WATCHLIST_CATEGORIES and then seed your items in the reference data table (ATK_WATCHLIST_SETUP). The watchlist_item_type determines how the Watchlist code will handle the item.

Note:

HUMAN_TASK items only require seeding in the tables to work; there are no view objects to create.

Example 15-2  Example Code from the View Object XML for Bind Variable with Default Value

```xml
<Variable
   Name="userId"
   Kind="where"
   Type="java.lang.String">
   <TransientExpression><![CDATA[return adf.context.securityContext.userName;]]></TransientExpression>
</Variable>
```

Example 15-3  Sample Code to Create or Update Watchlist Lookup

```java
declare
begin
   FND_LOOKUP_TYPES_PKG.CREATE_OR_UPDATE_ROW {
      X_VIEW_APPSNAME => 'FND',
      X_LOOKUP_TYPE => 'FIN_EXM_WATCHLIST_CATEGORY',
      X_APPLICATION_SHORT_NAME => 'EXM',
   }
```
15.3.4 How to Use the Watchlist

Follow the procedures described in this section to use the Watchlist.

15.3.4.1 Make the Watchlist Link in the UI Shell Global Area Work

To ensure the Watchlist link works in your pages, complete these steps.

1. Add this ADF Library JAR file to the SuperWeb user interface project for your application (the JAR file must be part of your Web Archive (WAR) in the WEB-INF/lib directory):

   fusionapps/jlib/AdfAtkWatchListPublicUi.jar

2. Add this dependent model ADF Library JAR file in your application (the JAR file must be part of your Enterprise Archive (EAR) in the APP-INF/lib directory):

   fusionapps/jlib/AdfAtkWatchListProtectedModel.jar

3. Add this dependent resource bundle ADF Library JAR file in your application (the JAR file must be part of your EAR in the APP-INF/lib directory):

   fusionapps/jlib/AdfAtkWatchListPublicResource.jar

4. Add these resource-ref entries to the web.xml file in your SuperWeb user interface project:

   ```xml
   <resource-ref>
     <res-ref-name>wm/WorkManager</res-ref-name>
     <res-type>commonj.work.WorkManager</res-type>
     <res-auth>Container</res-auth>
   </resource-ref>
   <resource-ref>
     <res-ref-name>jdbc/ApplicationDBDS</res-ref-name>
     <res-type>javax.sql.DataSource</res-type>
     <res-auth>Container</res-auth>
   </resource-ref>
   ```
15.3.4.2 Seed Reference Data (All items)

See Watchlist Physical Data Model Entities for details of the entire Watchlist data model. Seed only ATK_WATCHLIST_CATEGORIES and ATK_WATCHLIST_SETUP.

15.3.4.3 Create a Summary View Object (SEEDED_QUERY)

- By default, Watchlist code will access the application module or view object that is specified in the setup table, and rerun the query to refresh the Watchlist count. The summary view object is one way to get the count. Usually this will be for efficiency reasons.

- The product team can signal that it wants the Watchlist code to use its summary view object by seeding something in SUMMARY_VIEW_ATTRIBUTE of ATK_WATCHLIST_SETUP. If this is not null, the Watchlist code will get the view object, but instead of running the query, it will take only the first row and get the specified attribute.

- Your task is to create a view object with the correct count in the attribute specified in the setup table.

15.3.4.3.1 Summary Tables

One common reason to use a summary view object is if the seeded query is based on Multiple-Organization Access Control (MOAC) data security. This is because you can calculate the count of this query for each Business Unit ID (BUID). The count of a user is just the sum of the counts of the BUIDs that the user can access.

For example, say you have a table (or query) that has three rows of BUID #1, three rows of BUID #2, and three rows of BUID #3. The current user has access to BUIDs #1 and #2.

If you wanted to get the count, MOAC would filter the rows by BUID and return six rows.

However, because you are interested only in the count, a more efficient way would be to create a summary table for this table. The summary table keeps track of the count for each BUID. For the example table, the summary table would resemble Table 15-4.

<table>
<thead>
<tr>
<th>BUID</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
</tr>
</tbody>
</table>

Now, instead of using MOAC to find a count for a particular user, you use MOAC to find the sum of counts for the user. The example user would get the first two rows returned, and you can calculate the total count by summing the count column.

You can use summary tables to populate the summary view object attribute.

15.3.4.4 Create Seeded Saved Searches in MDS (SEEDED_SAVED_SEARCH)

In addition to seeding seeded saved searches in the reference tables, the saved searches need to be seeded in MDS so that when the user visits the saved search panel,
the saved search will show as one of the choices in the drop-down box. Saved searches in MDS are stored in the file system as an XML file for each view object. The steps to create this file are:

1. Ensure you have enabled MDS for your application.
2. Run the application and visit the desired search page.
3. Use the UI to create saved searches and name them. For each saved search, select **Run Automatically**.
4. Examine the `adf-config.xml` file to determine where your file-based MDS repository is located.
5. In a terminal, change to the directory:
   ```
   <MDS repository>/persdef/oracle/apps/.../mdssys/cust/user/
   <user>/
   ```
   The `<user>` directory would be the user you used to save the search with, or anonymous by default.
6. Inside that directory, there should be an `xxxVO.xml.xml` file that contains the created saved searches. Keep that file.
7. In that XML file, note the saved search ID, which should match the View Criteria ID in the reference data.

   **Note:**
   This ID can be different than the display name that you entered in the saved search UI.

15.3.4.5 Creating Application Module and View Objects (All except HUMAN_TASK)
Refer to [Implementing the Watchlist](#).

15.3.4.6 Setting Up Service (All except HUMAN_TASK)
For the same Watchlist items, the Watchlist portlet must be able to invoke a refresh. You will set up and expose a service that includes local JAR files for this purpose. The nested Watchlist JAR file can use those local JAR files in its refresh code.

The service will expose the `refreshCategory` method that will delegate the call to the same method in the nested Watchlist application module. This method will be provided in the Watchlist JAR file and will contain code to perform the category-wide refresh.

15.3.4.7 Importing All Watchlist-Related Application Modules
Your Service project must import the other JAR files from your product that must be used by the Watchlist code.

15.3.4.8 Nesting Watchlist Application Modules
Include `AdfAtkWatchListProtectedModel.jar` and `AdfAtkWatchListPublicModel.jar` in your service project, and nest `AdfAtkWatchListPublicUi.jar` in your service application module.
Set up the AppMasterDB connection that comes with it. Point it to the database where you have seeded your data in the Watchlist tables. This usually is your development database that is used for the ApplicationDB connection.

15.3.4.9 Using the refreshWatchlistCategory Method

This method, shown in Example 15-4, refreshes all Watchlist items in the corresponding category.

**Example 15-4  Refreshing Watchlist Items**

```java
public void refreshWatchlistCategory(String categoryCode) {
    AtkWatchlistPublicAMImpl wlAM = this.getAtkWatchlistPublicAMImpl();
    wlAM.refreshWatchlistCategory(categoryCode);
}
```

15.3.4.10 Importing Watchlist JAR Files into the Saved Search Project (USER_SAVED_SEARCH)

For subsequent steps that require running Watchlist APIs from your code, you must import the Watchlist JAR files. These also contain an AppMasterDB connection that must point to the Watchlist database.

- Add AdfAtkWatchlistProtectedModel.jar and AdfAtkWatchlistPublicService.jar (fusionapps > jlib) as ADF libraries in the appropriate data model projects, preferably in a model project that is visible to both service and user interface model project application modules.
- Add AdfAtkWatchlistPublicUi.jar as an ADF library to your user interface project.
- Configure the AppMasterDB connection.

15.3.4.11 Promote Saved Search to the ATK Watchlist (USER_SAVED_SEARCH)

Every Watchlist-enabled saved search panel must include a component to let the user control which of the saved searches to promote. The pre-seeded saved searches will be shown as static, while the user can use checkboxes to determine which saved searches should be promoted. There will be listeners to this component that will publish business events to make the appropriate worklist changes.

Before You Begin

Ensure that the following steps have been performed.

- Populate ATK tables with SEED watchlist category information. Product teams need to provide information about the service that refreshes the watchlist item count.
- Populate ATK tables with appropriate watchlist setup information. There must be a watchlist setup item of type USER_SAVED_SEARCH.
- Ensure the application is MDS enabled so users can save their searches and that the saved searches exist across sessions.
- From the watchlist UI, users can drill down to the transactional UI flows. Ensure that the transactional UI flow is properly set up so that it can show the search page when the user clicks the Watchlist item in the Watchlist UI.
• In the application project, create a backing bean and register it as a backingBeanScope bean. In the backing bean, create the Java method shown in Example 15-5:

**Example 15-5   Creating the Backing Bean**

```java
import oracle.adf.view.rich.model.QueryDescriptor;
import oracle.adf.view.rich.model.QueryModel;

public List<String> getWatchListUserSavedSearchList() {
    if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
        AppsLogger.write(this, "Watchlist saved search promotion: Entering method getWatchListUserSavedSearchList", AppsLogger.FINEST);
    }
    List<String> WatchListUserSavedSearchList = new ArrayList<String>();
    QueryModel queryModel = (QueryModel) evaluateEL("#{bindings.ImplicitViewCriteriaQuery.queryModel}"); // See next code sample for evaluateEL()
    if (queryModel != null) {
        if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
            AppsLogger.write(this, "Watchlist saved search promotion: queryModel is not null", AppsLogger.FINEST);
        }
        List userQueries = queryModel.getUserQueries();
        if (userQueries != null & userQueries.size() > 0) {
            if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
                AppsLogger.write(this, "Watchlist saved search promotion: User Saved Searches exist", AppsLogger.FINEST);
            }
            for (int i = 0; i < userQueries.size(); i++) {
                QueryDescriptor qd = (QueryDescriptor) userQueries.get(i);
                if (qd != null) {
                    if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
                        AppsLogger.write(this, "Watchlist saved search promotion: Adding user saved search name to the watchListUserSavedSearchList using QueryDescriptor getName: " + qd.getName(), AppsLogger.FINEST);
                    }
                    WatchListUserSavedSearchList.add(qd.getName());
                }
            }
        }
    }
    if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
        AppsLogger.write(this, "Watchlist saved search promotion: Exiting method getWatchListUserSavedSearchList: returning watchListUserSavedSearchList: " + WatchListUserSavedSearchList, AppsLogger.FINEST);
    }
    return WatchListUserSavedSearchList;
}
```

**15.3.4.11.1 How to Promote a User-Saved Search to the Watchlist**

Follow these steps to integrate the ATK task flow to promote saved searches to the Watchlist.
1. Ensure the AdfAtkWatchListPublicUi.jar file is available (usually in the fusionapps/jlib directory).

2. Start JDeveloper and open the .jspx or .jsff page containing the query region whose saved searches have to be promoted.

3. In the query region, add a toolbar facet.
   a. Right-click the component.
   b. In the menu that opens, select Facets-Query.
   c. From the submenu, select Toolbar, as shown in Figure 15-11.

![Figure 15-11    Adding Toolbar Facet to Query Region](image)

3. In the toolbar facet of the query region, drag and drop an ADF Toolbar component, such as Toolbar (ADF Faces.Common Components) shown in Figure 15-12, onto the page.

![Figure 15-12    Adding an ADF Toolbar Component](image)

The toolbar facet in the Source view will look similar to:

```xml
<f:facet name="toolbar">
  <af:group id="g1">
    <af:toolbox id="t1">
      <af:region value="#{bindings.AtkWatchlistUserSavedSearchPromotionTF1.regionModel}" id="r7"/>
    </af:toolbox>
  </af:group>
</f:facet>
```

4. Open the Resource Palette and create a File System connection to the directory containing the AdfAtkWatchListPublicUI.jar file, as shown in Figure 15-13.
6. Expand the connection node and the ADF library node in the Resource Palette as shown in Figure 15-14.

Figure 15-14  Expanding the Connection Node

When the ADF Task Flows node is expanded, you should see two task flows. The task flow AtkWatchlistUserSavedSearchPromotionTF is the one to be used.

7. Drag and drop the AtkWatchlistUserSavedSearchPromotionTF task flow as a region into the toolbar component (present in the query region toolbar facet), created in the previous steps. As soon as the task flow is dropped onto the page, the Edit Task Flow Binding dialog is displayed. Enter the following values for the mandatory parameters.

- **categoryCode**: Provide the WATCHLISTCATEGORY_CODE that has been seeded in the ATK tables.
- **watchlistItemCode**: Provide the WATCHLISTITEM_CODE provided while creating the Watchlist setup data.
- **userSavedSearchList**: This represents the model object of the query region. To populate this field:
  a. Select the userSavedSearchList input field, click the small “v” icon present at the end of the field and select the Expression Builder option.
b. Select the value from the Java method shown in Example 15-5. In this case, the value is `watchListUserSavedSearchList`, found in `ADF Managed Beans > backingBeanScope > searchOrderScheduleBackingBean > watchListUserSavedSearchList`.

The Expression will be:

```java
#{backingBeanScope.searchOrderScheduleBackingBean.watchListUserSavedSearchList}
```

c. Click OK to insert the value in the `userSavedSearchList` field.

- **internalCriteriaName**: This represents the ViewCriteria Name of the search binding executable of the query region present in the UI page. To populate this field, follow the same steps as you did to populate the `userSavedSearchList` field, but select `internalCriteriaName`. Also see Additional Steps for Existing Consumers.

When you are finished, the Edit Task Flow Binding dialog will resemble Figure 15-15.

**Figure 15-15 Completed Edit Task Flow Binding Dialog**

![Edit Task Flow Binding dialog](image)

8. Click OK. This creates a region component in the UI page, as shown in Figure 15-16.

**Figure 15-16 Created Region Component**

![Created Region Component](image)

9. Open the page definition file and select the executable associated with the Watchlist-related task flow.

10. Open the Property Inspector and set the Refresh field to `ifNeeded`, as shown in Figure 15-17. The ATK saved search promotion task flow has to be refreshed each time the query model changes. This step ensures that the task flow is refreshed whenever the query model changes.
11. Add a task flow security permission to the AtkWatchlistUserSavedSearchPromotionTF task flow in the jazn-data.xml file.

   a. Open the jazn-data.xml file and select the ADF Policies tab.

   b. From the Task Flow list, select AtkWatchlistUserSavedSearchPromotionTF, grant it to an appropriate role, and select appropriate actions as shown in Figure 15-18.

12. Run the UI page. In the toolbar facet of the query region, there will be a Watchlist Options button, as shown in Figure 15-19.

   When you click the button, a popup with the list of all saved searches is displayed, as shown in Figure 15-20.
Additional Steps for Existing Consumers

If you already have implemented promoting Saved Search to the ATK Watchlist, there are four additional steps.

1. In your pageDef, change the WatchList task flow parameter called queryModel from:
   
   `<parameter id="queryModel" value="#{bindings.ExistingCriteria.queryModel}"/>
   
   to:
   
   `<parameter id="userSavedSearchList" value="#{backingBeanScope.YourBean.watchListUserSavedSearchList}"/>

2. Use the public List<String> getWatchListUserSavedSearchList() Java method by passing the QueryModel binding of your af:query.

3. Change the old queryBinding parameter to the new internalCriteriaName parameter. For example, change:
   
   `<parameter id="queryBinding" value="#{bindings.SearchPageVOCriteriaQuery}"/>
   
   to:
   
   `<parameter id="internalCriteriaName" value="#{backingBeanScope.searchRelatedBean.internalCriteriaName}"/>

4. In someBackingBeanScopeBean.java, such as the one you created in Example 15-5, add the two methods shown in Example 15-6.

   Note: In someBackingBeanScopeBean.getInternalCriteriaName(), the queryBinding variable in the first line is the one you see in af:query. For example, af:query
   
   queryListener="#{bindings.SearchPageVOCriteriaQuery.processQuery}"
   
   Just take the QueryBinding,
   
   #{bindings.SearchPageVOCriteriaQuery}.

**Example 15-6  Additions to the backingBeanScopeBean**

```java
import javax.el.ExpressionFactory;
import javax.el.MethodExpression;
import javax.el.ValueExpression;
import javax.faces.context.FacesContext;
import oracle.adf.model.binding.DCBindingContainer;
import oracle.jbo.uicli.binding.JUSearchBindingCustomizer;

public Object evaluateEL(String expr)
{
    FacesContext facesContext=FacesContext.getCurrentInstance();
    ExpressionFactory exprFactory=facesContext.getApplication().getExpressionFactory();
    ValueExpression valueExpr=exprFactory.createValueExpression(facesContext.getELContext(), expr, Object.class);
    return valueExpr.getValue(facesContext.getELContext());
}

public String getInternalCriteriaName() {
    if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
        AppsLogger.write(this, "Watchlist saved search promotion: Entering method getInternalCriteriaName", AppsLogger.FINEST);
    }
    return 
```
String queryBinding = "#{bindings.SearchPageVOCriteriaQuery}"
DCBindingContainer searchBinding = (DCBindingContainer)evaluateEL(queryBinding);
internalCriteriaName = JUSearchBindingCustomizer.getCriteriaName(searchBinding);
if (AppsLogger.isEnabled(AppsLogger.FINEST)) {
    AppsLogger.write(this, "Watchlist saved search promotion: Exiting method
getInternalCriteriaName with return value for internalCriteriaName: " +
    internalCriteriaName, AppsLogger.FINEST);
}
return internalCriteriaName;
}

15.3.4.12 Code Task Flows to Accept Parameters (All except HUMAN_TASK)

If you have seeded the information properly, your normal task flows should work
when expanded into from the Watchlist portlet.

15.3.4.12.1 Saved Search

For saved search Watchlist items, you will want the drilldown to load a specific saved
search by default.

One function of the Watchlist portlet will be to take a user to the corresponding action
area when the user clicks a Watchlist item. For saved searches, the desired
functionality is to open the task flow containing the saved search panel and by default,
show the clicked saved search.

On the portlet, upon clicking the link, code will put the proper ViewCriteria name
into the PageFlowScope with the parameter name vcName.

When loaded, the destination task flow will have two tasks:

- Look into the PageFlowScope to retrieve the ViewCriteriaName.
- Obtain the RichQuery object, and apply the ViewCriteriaName to it, if one is
given.

You will be concerned with implementing the two steps for the destination task flow.
First, you can retrieve the ViewCriteriaName from the PageFlowScope with the
code shown in Example 15-7.

Second, you can use the code shown in Example 15-8 to apply the ViewCriteria to
the search panel. If no ViewCriteria was passed, the code loads the default
ViewCriteria.

This code should be run once upon loading the destination task flow. One solution is
to connect it to the rendered property of the search panel, and use a static variable to
ensure that it only runs once.

Example 15-7 Retrieving the ViewCriteriaName from the PageFlowScope

Map pfs = RequestContext.getCurrentInstance().getPageFlowScope(); String vcName =
(String) pfs.get("vcName");

Example 15-8 Applying ViewCriteria to the Search Panel

if (vcName == null || vcName.equals("")) {
    // If no ViewCriteria is given, load default VC
    DCBindingContainer dcbbc = (DCBindingContainer)BindingContext.getCurrent()
        .getCurrentBindingsEntry();
    FacesCtrlSearchBinding fcsb =
        (FacesCtrlSearchBinding)dcbbc
Implement Search Functions in the UI Shell 15-41
.findExecutableBinding("ImplicitViewCriteriaQuery");
FacesCtrlSearchDef def = (FacesCtrlSearchDef)fcsb.getDef();
DCParameterDef paramDef =
(DCParameterDef)def.getParameterDef(
JUSearchBindingCustomizer.PARAMCRITERIA);
fcsb.evaluateParameter(paramDef.getExpression(),false));
} else {
    QueryModel model = search_query.getModel();
    QueryDescriptor selDescriptor = model.create(vcName, null);
    if (selDescriptor != null) {
        model.setCurrentDescriptor(selDescriptor);
    }
    BindingContext.bindings =
    BindingContext.getCurrent().getCurrentBindingsEntry();
    OperationBinding method = (OperationBinding)
    bindings.getControlBinding("applyViewCriteriaByName");
    method.getParamsMap().put("name", vcName);
    method.execute();
}

15.3.4.13 Import Watchlist UI JAR File in User Interface Project

There is a link in the UI Shell for Watchlist in the global area. To make it work, the
user interface project must include these Watchlist UI JAR files:
AdfAtkWatchListPublicUI and its dependent model JAR file
AdfAtkWatchListProtectedModel.

15.3.4.14 Additional Entries for Standalone Deployment

These entries are required for the Watchlist service and UI to be able to work in a
standalone deployment.

- Add this entry in the ejb-jar.xml file in your service project that contains the
  watchlist service next to the similar entry for ApplicationDB. You need
  resource-ref entries for both ApplicationDB and AppMasterDB:

```xml
<resource-ref>
    <res-ref-name>jdbc/AppMasterDBDS</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
</resource-ref>
```

- Add this entry in the web.xml file in your SuperWeb project next to the similar
  entry for ApplicationDB. You need resource-ref entries for both
  ApplicationDB and AppMasterDB:

```xml
<resource-ref>
    <res-ref-name>jdbc/AppMasterDBDS</res-ref-name>
    <res-type>javax.sql.DataSource</res-type>
    <res-auth>Container</res-auth>
</resource-ref>
```

- The connections.xml file should have a valid database entry for
  AppMasterDB.

15.4 Implementing Group Spaces

Group Spaces bundle all the collaboration tools and provide an easy way for users to
create their own ad hoc collaborative groups around a project or business artifact.
This section describes how to implement the Group Spaces functionality that is available in UI Shell.

Assumptions
These assumptions are made:

- The implementation is occurring in a label that is either dependent on ATGPF_MAIN or uptakes ATGPF_MAIN on a regular basis.
- The spaces application and the JDeveloper Standalone WebLogic Server that would run the application have the requisite setup done.
- The consuming applications are secure. Group Spaces functionality attempts to retrieve the group spaces for the logged-on user. Without a secure application, this functionality would fail.

15.4.1 How to Implement Group Spaces

Follow these steps to implement Group Spaces.

1. Ensure the Oracle WebCenter Portal Spaces Client library, spaces-webservice-client.jar, has been added to the Project.

2. Define an application connection to point to the URL of the WebCenter Portal Spaces WebService. To do this:
   a. Right-click Connections in the Application Resource palette.
   b. Select New Connection > URL.
   c. Enter the value $HOST:$PORT/webcenter/SpacesWebService, where $HOST and $PORT are the hostname and the port on which the spaces application is running.
   d. Save this connection with the name SpacesWebServiceEndpoint.

3. To make a homepage tab appear within UI Shell, deploy the Functional Setup Manager application.

15.4.2 Overview of Group Spaces Functionality

The Group Spaces functionality implements these features:

- When the Group Spaces link is clicked, a popup displays the logged-in user's Group Spaces.
- When the user clicks a Group Space from the list, the Group Space's home page is opened in an iFrame. This iFrame is rendered within a Home Page tab called WebCenter. The Group Space is opened suppressing the WebCenter Portal chrome but will still render all the tabs within that Group Space. (Note: Chrome is a term for the visible graphical interface features of an application.) This chrome level suppresses the WebCenter Portal chrome but will still render all the tabs within that Group Space.
- When the user clicks View All Group Spaces, the same UI as the My Group Spaces in the spaces application is rendered. This is also rendered as an iFrame within the WebCenter Portal HomePage tab where it suppresses the chrome as well as the top level WebCenter Portal tabs.
15.4.3 How to Pass a Chromeless Template

When navigating to the WebCenter Portal home page, a WebCenter Portal template that does not contain the header chrome is desired. This can be done by appending &wc.pageTemplate=oracle.webcenter.spaces.siteTemplate.gsContent.

Pass this parameter when navigating to a Group Space from the Group Spaces global dialog, Tag Center, Global Search, or an Activity Stream link.

Use a question mark (?) instead of an ampersand (&) if this is the only request parameter for that URL.

15.5 Implementing Activity Streams and Business Events

Activity Streams is a feature provided by the WebCenter Portal. Use Activity Streams to capture changes and publish Activity messages. Customer Relations Management (CRM), in particular, makes heavy use of this feature to keep abreast of service requests and opportunities. Users subscribe to Activity Streams by using the Activity Streams user interface.

For business events, Activities are shown only to users who subscribe to the stream and who have the necessary security access.

Activity Streams can be connected to:

- **Business Objects.** At a high level, business objects correspond to a workarea, such as Sales or Contacts.

- **Group Spaces.** For example, a team lead can set up a Group Space that team members can use to share information about a project.

- **People Connection.** This is similar to the various social networking sites on the Internet that let people interact with friends and business associates.

This section is concerned only with business objects.

15.5.1 Introduction to WebCenter Portal Activities

A WebCenter Portal Activity is comprised of the following:

- **Actor** - The user who performed the action that triggered the business event. For Oracle Fusion Applications, this will be the userid fetched from the user session.

- **ActivityType** - The type of Activity to be published. This defines the format of the Activity message.

- **Objects** - The objects associated with the Activity. There could be multiple objects associated with an Activity, but for business events, only the event source is used as an object.

WebCenter Portal Activities are defined in the service-definition.xml file. The scope of service_definition.xml is per business object. The service ID attribute should match the name of the entity object. The service-definition.xml file contains ActivityTypes, ObjectTypes and resource-view definitions. An ActivityType must be defined for every business event on the entity object. The type name should match the business event's name. The messageFormatKey attribute in the ActivityType element points to a message key in a Resource Bundle.
It defines the format of the message displayed in the Activity Stream UI. These tokens are supported in a message.

- `{actor[0]}`: Replaced by the display name of the user who triggered the event.
- `{object[0]}`: Replaced by the value of the attribute in the event payload whose attribute name matches the object type name.
- `{custom[attr1].value}`: Replaced by the value of the `attr1` attribute in the event's payload.

The message format would look similar to:

```
{actor[0]} updated Opportunity {object[0]} status to {custom[status].value}
```

### 15.5.2 How to Publish Business Events to Activities

ADF Business Components business events are, by default, published to SOA Event Delivery Network (EDN). Applications Core implements a `BusinessEventAdapter` to listen to these events, transition them to Activities, and asynchronously publish them to the ActivityStream Service. This adapter is a singleton per application and publishes the business events raised to the `ActivityService` in the order they are produced. A business event is published as an Activity only when an `ActivityType` matching the name of the event is found in the service definition for the business object.

While mapping a business event to an Activity, keep these notes in mind:

- There is one-to-one mapping between an Activity Service definition and a business object. The service ID attribute in the `service-definition.xml` file should match the Entity name.
- The `ActivityType` name should match the name of the business event.
- Define an `ObjectType` with the name attribute matching an attribute name in the payload. This attribute value will replace the `{object[0]}` token in the message format. WebCenter Portal supports multiple object types for an Activity, but for business events-related Activities, only one Object that corresponds to the event source is supported. The Object type name should match the name of the attribute whose value should be displayed in the hyperlink for the object.
- Define a message format using tokens for `Actor`, `Object` and `customAttributes`. The custom attribute names used in the token should match the attribute names in the payload.
- In the Activity message displayed in the UI, only `Actor` and `Object` display values will be rendered as hyper links. If an Activity involves multiple objects, hyper links will be supported only for the event source object. Multiple attributes from the event payload can be referenced in the message.
- The hyperlink for the object allows users to navigate to the business object’s work area. The target page for navigation can be configured through the `resource-view` element in the `service-definition.xml` file.

### 15.5.3 How to Publish Activities Using a Programmatic API

For certain scenarios, Oracle Fusion Applications are required to publish Activities for model changes that are not based on entity objects. Since Oracle ADF Business Components business events are based on entity objects, it is not possible to use these
events for publishing Activities for non entity object-based model changes. For such scenarios, product teams could use the Applications Core API shown in Example 15-9 to programmatically publish Activities to the ActivityStream service.

**BusinessActivityPublisher**

This class provides the publishActivity API that can be used to publish Activities asynchronously. This is a singleton per Java EE application. An instance of this class can be obtained using the getInstance API. This lets product teams define such things as ActivityTypes, ObjectTypes, and resource-view definitions, declaratively in the service-definition.xml file, similar to business event-related activities. This would allow product teams to follow the same mechanism to define and publish Activities for both entity object and non-entity object-based model changes with very little code changes.

**BusinessActivity Class**

This is an abstract class that is used to represent an Activity corresponding to a business event. BusinessActivityPublisher:publishActivity() takes an instance of this class as a parameter. You would implement an instance of this class to encapsulate the details of the Activity corresponding to the non entity object-based model changes and invoke the publishActivity API with this as a parameter. BusinessActivityPublisher will find the matching ActivityType and ObjectType defined for this Activity in service-definition.xml and publish the Activity to the ActivityStreaming Service asynchronously. Details of the API on this class are shown in Example 15-10.

**BusinessActivity**

This is an abstract class that is used to represent an Activity corresponding to a business event. BusinessActivityPublisher:publishActivity() takes an instance of this class as a parameter. You would implement an instance of this class to encapsulate the details of the Activity corresponding to the non entity object-based model changes and invoke the publishActivity API with this as a parameter. BusinessActivityPublisher will find the matching ActivityType and ObjectType defined for this Activity in the service-definition.xml file and publish the Activity to the ActivityStreaming Service asynchronously. Details of the API on this class are shown in Example 15-11.

**Example 15-9  BusinessActivityPublisher.java**

```java
/**
 * This class is responsible for publishing business events as WebCenter Portal
 * Activities to the ActivityStreaming service. This is a singleton per Java EE
 * application. An instance of this object is obtained using the getInstance() 
 * method. This class transforms business events into Activities and publishes them
 * to Activity Service asynchronously. Resources held by the class are released by
 * using release() method. In Java EE container, release is done by
 * Applications Core when the application is undeployed or stopped.
 */

public class BusinessActivityPublisher
{
  /**
   * Returns and instance of BusinessActivityPublisher if one exists or
   * creates a new one.
   *
   */

  public synchronized static BusinessActivityPublisher getInstance()

  /**
   * Queues the Activity for publishing. The queued activities are published
   */
```
* to the Activity Streaming service asynchronously if there is a matching
* ActivityType defined for the source business event. If no matching
* ActivityType is found in the service-definition.xml corresponding to the
* source entity object, the activity is ignored.
* @param activity
 */
public void publishActivity(BusinessActivity activity)

/**
 * Should be called during App undeploy to stop the publisher thread.
 * In a Java EE container, this method is called by Applications Core
 * ServletContextListener.
 */
public void release()

Example 15-10  BusinessActivity.java

/**
 * Name of the ActivityType defined in service-definition that
 * corresponds to serviceId returned by getServiceId().
 * @return Name of the ActivityType
 */
public String getName()

/**
 * ID of the service-definition containing the metadata for this
 * Activity.
 * @return serviceId
 */
public abstract String getServiceId();

/**
 * Array of GUIDs for Actors of the Activity.
 * @return array of guids for the Actors.
 */
public abstract String[] getActors();

/**
 * This api will return additional service ids
 * @return Array of ServiceIds
 */
public String[] getAdditionalServiceIds(){ return null;}

/**
 * This attr provides a "," separated list of object type
 * names associated with a particular Activity.
 * @return
 */
protected String getActivityObjectTypeNames(){
    return null;
}

/**
 * Payload for the Activity. Every attribute that is part of this payload is
 * persisted in WC as custom attribute of the Activity Object so only
 * attributes needed for the Activity Message should be added to the payload
 * to avoid performance overhead.
 * The payload typically contains:
 * 1. Attribute(s) whose name matches the object-type name attribute in
 *    service-definition. This value is used in generating the object-id
 *    of the object referenced in the Activity Stream message.
2. All the attributes referenced in the Message format using {custom} token.
   @return a map containing the attribute names and their values needed to
display the Activity Message for this Activity.
*/
public abstract Map getPayload();

Example 15-11 BusinessActivity.java

/**
 * Name of the ActivityType defined in service-definition that
 * corresponds to serviceId returned by getServiceId().
 * @return Name of the ActivityType
 */
public String getName()

/**
 * ID of the service-definition containing the metadata for this
 * Activity.
 * @return serviceId
 */
public abstract String getServiceId();

/**
 * Array of GUIDs for Actors of the Activity.
 * @return array of guids for the Actors.
 */
public abstract String[] getActors();

/**
 * This api will return additional service ids
 * @return Array of ServiceIds
 */
public String[] getAdditionalServiceIds(){ return null;}

/**
 * This attr provides a "," separated list of object type
 * names associated with a particular Activity.
 * @return
 */
protected String getActivityObjectTypeNames(){
  return null;
}

/**
 * Payload for the Activity. Every attribute that is part of this payload is
 * persisted in WC as custom attribute of the Activity Object so only
 * attributes needed for the Activity Message should be added to the payload
 * to avoid performance overhead.
 * The payload typically contains:
 * 1. Attribute(s) whose name matches the object-type name attribute in
   service-definition. This value is used in generating the object-id
   of the object referenced in the Activity Stream message.
 * 2. All the attributes referenced in the Message format using {custom}
   token.
 * @return a map containing the attribute names and their values needed to
display the Activity Message for this Activity.
 */
public abstract Map getPayload();
15.5.4 How to Implement Activity Streams

This section provides details about the steps involved in integrating this feature with Oracle Fusion Applications.

15.5.4.1 Defining and Publishing Business Events in JDeveloper

To define a business event, follow these steps:

1. In the Application Navigator, double-click an entity object.
2. In the overview editor, click the business events navigation tab.
3. On the business events page, expand the Event Publication section and click the Edit event publications icon.
4. In the Edit Event Publications dialog, click New to create a new event.
5. Double-click the new cell in the Event column, and select the appropriate event.
6. Double-click the corresponding cell in the Event Point column, and select the appropriate event point action.
7. You optionally can define conditions for raising the event using the Raise Conditions table.
8. Click OK.

An event definition in the Entity XML file would look similar to:

```
<EventDef Name="OpportunityStatusUpdate">
  <Payload>
    <PayloadItem AttrName="OpptyId"/>
    <PayloadItem AttrName="Status"/>
    <PayloadItem AttrName="Customer.CustomerId"/>
  </Payload>
</EventDef>
```

15.5.4.2 Overriding isActivityPublishingEnabled() to Enable Activity Publishing

By default, business events are not published as Activities. You should override the isActivityPublishingEnabled() method to enable Activity publishing for an entity object. Table 15-5 shows the details about the APIs exposed in OAEntityImpl that you can override.

Note that, except for the isActivityPublishingEnabled() method, other methods mentioned in Table 15-5 should be avoided in favor of transient attributes specified in Defining Activity Attributes Declaratively.
<table>
<thead>
<tr>
<th>Method</th>
<th>Return Type</th>
<th>Description</th>
<th>Optional/ Required</th>
<th>Corresponding Declarative Transient Attribute (See Defining Activity Attributes Declaratively)</th>
</tr>
</thead>
<tbody>
<tr>
<td>isActivityPublishingEnabled()</td>
<td>boolean</td>
<td>By default the base class implementation returns false. This will enable activity publishing for this entity object.</td>
<td>Required</td>
<td>None</td>
</tr>
<tr>
<td>getActivityActorsGUIDs()</td>
<td>String []</td>
<td>This can be overridden to provide an array of GUIDs for the Actors involved with the activity. By default, the framework will use the GUID of the user currently logged in when the business event is raised.</td>
<td>Optional</td>
<td>WCActivityActorGuid1, WCActivityActorGuid2</td>
</tr>
<tr>
<td>getActivityStreamServiceId()</td>
<td>String</td>
<td>This returns the service ID to be used to publish the activities for the business events raised for this entity. By default this returns null. When null is returned, the service ID defaults to the full name of the entity object.</td>
<td>Optional</td>
<td>WCActivityStreamServiceId</td>
</tr>
<tr>
<td>getAdditionalServiceIds()</td>
<td>String []</td>
<td>Override this API to support publishing multiple Activities in response to a single event. So additional service IDs can be passed for a single activity.</td>
<td>Optional</td>
<td>WCAdditionalActivityServiceId1, WCAdditionalActivityServiceId2</td>
</tr>
<tr>
<td>getActivityObjectTypeNames()</td>
<td>String</td>
<td>This API can be overridden to return multiple object type names. Values provided should be a comma-separated list of object type names associated with a particular Activity. The first object-type in this string will be used to create the custom attributes needed for the primary object. When creating the primary object for an Activity, the object-type of the first object listed in the service-definition.xml file is necessary even though the custom attributes used to construct this object are fetched from a different object-type based on get(ActivityObjectTypeNames) or WCActivityObjectTypeNames(). This is necessary for the follow model to work. The order of the objects in this array can be used to reference the objects in an Activity message format string.</td>
<td>Optional</td>
<td>WCActivityObjectTypeNames</td>
</tr>
</tbody>
</table>
15.5.4.3 Defining Activity Attributes Declaratively

Some of the attributes, such as Actor, Service Ids and Additional Service Ids, can be passed as a part of the payload. The basic process steps are:

- Define a transient attribute in the entity object.
- Give a default value to the transient attribute.
- Include the transient attribute as a part of the payload.

The different transient attributes that can be passed with the payload are shown in Table 15-6.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>WCActivityServiceId</td>
<td>String</td>
<td>This attribute’s value is used to identify the business object service to be associated with the Activity.</td>
<td>oracle.apps.crmdeemo.model.OpportunityEO</td>
</tr>
<tr>
<td>WCAdditionalActivityServiceId1</td>
<td>String</td>
<td>This attribute’s value is used to identify any additional service that must be associated with the Activity.</td>
<td>Values are similar to those of WCActivityServiceId</td>
</tr>
<tr>
<td>WCAdditionalActivityServiceId2</td>
<td>String</td>
<td>This attribute’s value is used to identify any additional service that must be associated with the Activity.</td>
<td>Values are similar to those of WCActivityServiceId</td>
</tr>
<tr>
<td>WCActivityActorGuid1</td>
<td>String</td>
<td>This attribute’s value is used to identify any actor that must be associated with the Activity if the default actor value must be overridden. For instance, in the message it can be accessed as actor[0]</td>
<td>&lt;User_GUID&gt;</td>
</tr>
<tr>
<td>WCActivityActorGuid2</td>
<td>String</td>
<td>This attribute’s value is used to identify any actor that must be associated with the Activity if the default actor value must be overridden. For instance, in the message it can be accessed as actor[1]</td>
<td>&lt;User_GUID&gt;</td>
</tr>
</tbody>
</table>
Table 15-6  (Cont.) Transient Attributes that Can Be Passed with the Payload

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Description</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>WCActivityObjectTypeNames</td>
<td>String</td>
<td>This attribute should provide a comma-separated list of object-type names associated with a particular Activity. Programmatically getActivityObjectTypeNames() API in the entity object’s EntityImpl. The first object-type in this string will be used to create the custom attributes needed for the primary object. When creating the primary object for an Activity, the object type of the first object listed in the service-definition.xml file is necessary even though the custom attributes used to construct this object are fetched from a different object type based on getActivityObjectTypeNames() or WCActivityObjectTypeNames. This is necessary for the follow model to work. The order of the objects in this array can be used to reference the objects in the Activity message format string.</td>
<td>Emp, Dept</td>
</tr>
</tbody>
</table>

15.5.5 How to Define Activities

Defining Activities requires:

- Adding the ActivityStream UI task flow
- Defining Activities in the service-definition.xml file

15.5.5.1 Add the ActivityStream UI Task Flow

To add the ActivityStream task flow:

1. Ensure your user interface project includes the Oracle WebCenter Portal Activity Streaming Service library in the Libraries and Classpath section in the project properties dialog.

2. From Resource Catalog > TaskFlows, drag and drop either an "Activity Stream" or "Activity Stream Summary - View" task flow onto the page where you want to display the Activity Stream UI.

3. Set the taskFlow resourceId parameter to #{securityContext.userName}. This will tie the task flow to the current user at runtime.
4. For additional details about the Activity Stream task flow, see the chapters in the Working with the People Connections Service partition in the Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper.

15.5.5.2 Define Activities in the service-definition.xml File

The default location of the service-definition.xml file is under META-INF in the project. For Oracle Fusion Applications, this file will be stored in MDS so you need to put it into a directory that can be added to your Metadata Archive (MAR) file.

The standardized location that all applications should use is:

```xml
<app>/<lba>/<product>/*project*//*meta/oracle/apps/meta*/<lba>/<product>/service-definition.xml
```

The name must be unique, such as:

```xml
```

To define Activities in the service-definition.xml file, follow these steps.

1. If necessary, add the directory to the application’s MAR profile. To add a MAR, select Application > Application Properties > Deployment. In the dialog that is displayed, select the MAR file and click Edit.

2. In the Edit dialog, select User Metadata and click Add. Browse to the metadata directory that was just added and click OK.

3. Set the id attribute on the service-definition element to the entity object name for which you want to define the Activities.

```xml
<service-definition xmlns="http://xmlns.oracle.com/webcenter/framework/service" id="oracle.apps.crmdemo.model.OpportunityEO" version="11.1.1.0.0">
```

4. Define an activity type for every business event in the entity object for which you want to display the Activities in the Activity Stream UI. Ensure the event name of the entity object matches the activity-type name attribute value.

```xml
<activity-types>
  <generic-activity-category name="UPDATE">
    <activity-type name="OpportunityStatusUpdate" displayName="Opportunity Status Update" description="Opportunity Status Update" messageFormatKey="OPPTY_STATUS_UPDATED" iconURL="" defaultPermissionLevel="SHARED"/>
  </generic-activity-category>
</activity-types>
```

5. Set message format strings.

Each activity-type should have a message format defined. The message format string can be translated and is stored in a Resource Bundle or an XLIFF bundle. Oracle Fusion Applications uses XLIFF bundles to store the Activity message format strings. The activity-type element in the service-definition.xml file has messageFormatKey attributes that are used to refer to the format strings in the XLIFF bundle.

Activity Stream supports only Java Resource Bundles. The Common String Repository is used for the message format strings.
These attributes are supported on the activity-type element:

- `messageFormatKey` - Used on the Activity Stream full view task flow.
- `summaryByListMessageFormatKey` - Used in the summary view Activity Stream task flow.
- `summaryByCountMessageFormatKey` - Used in the summary view task flow.

**messageFormatKey**

The value of this attribute points to the key defined in the Resource Bundle. These tokens are supported in the message format string.

- `{actor[0]}`: Replaced by the display name of the user who triggered the event.
- `{object[0]}`: Replaced by the value of the attribute in the event payload whose attribute name matches the object type name.
- `{custom[attr1].value}`: Replaced by the value of the `attr1` attribute in the event's payload.

The following sample uses the Java Resource Bundle class:

```
<activity-types>
  <generic-activity-category name="OPPTYUPDATE">
    <activity-type name="OpptyStatusUpdate"
      displayName="OPPTY_UPDATE"
      description="OPPTY_UPDATE_DESCRIPTION"
      messageFormatKey="OPPTY_STATUS_UPDATED"
      defaultPermissionLevel="SHARED"/>
  </generic-activity-category>
</activity-types>
```

In OpportunityResourceBundle, the `OPPTY_STATUS_UPDATED` key is defined as:

```
{"OPPTY_STATUS_UPDATED", "{actor\[0\]} updated {object\[0\]} status to {custom\['status'\].value}"}
```

**summaryByListMessageFormatKey** and **summaryByCountMessageFormatKey**

These attributes are used only when the Activity Stream summarized view task flow is used. The summarized view task flow is used on the portrait page in My Activities and Network Activities mini cards. In summarized view, the Activity messages are summarized or grouped based on an Activity Type. For instance, if multiple Activities of the same type are published, they are combined and displayed as a single Activity message. Within the group of Activities of the same type, the following algorithm is used to generate summarized messages:

a. Summarize activities by finding a common object referenced in the Activity.

b. Summarize or aggregate the Actors either by listing them if there are three or fewer, or by counting them if there more than three.
c. For remaining activities, summarize by finding a common Actor. Summarize or aggregate the objects either by listing them if there are three or fewer, or by counting them if there are more than three.

For example, note the following activities:

b. Viju updated Project Alpha tasks.
c. Ling updated Project Alpha tasks.
d. Monty updated Oppty 200 laptops status
e. Monty updated Oppty Solaris workstations status
f. Monty updated Oppty 2 DB machines status.

In the summarized view, the Activities are summarized as follows:

• Activities a-c: James, Viju, Ling updated Project Alpha tasks.
• Activities d-f: Monty updated 200 laptops, Solaris workstations, 2 DB machines opportunities status.

Example 15-12 shows sample format strings for the preceding scenario.

In the OpportunityResourceBundle, the keys are defined as:

"OPPTY_STATUS_UPDATED_SUMMARY_LIST", "{actor\[0\]} updated status for opportunity {object\[0\]}"
"OPPTY_STATUS_UPDATED_SUMMARY_CNT", "{actor\[0\]} updated {object\[0\].count} opportunities status"

6. Define an object type for the entity object that is the source of the events. Even though Oracle WebCenter Portal supports multiple object types, for Oracle Fusion Applications, only one object type that corresponds to the source of the events is supported. The value of the name attribute should match the name of the attribute in the business event’s payload. This attribute’s value will be used as the display name of the object when displayed in the Activity message. The primary key of the event source will be used as the object ID.

7. The ObjectType custom attributes can be used to provide additional metadata for handling business object references in Activity Stream messages. The custom attributes shown in Table 15-7 will be used.
### Table 15-7  ObjectType Custom Attributes

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service-ref-id</td>
<td>ID of the service-definition of a business object referenced in the Activity message of the current business object. This is used when an Activity message contains multiple object references and is used to reference the serviceId of some other business object.</td>
</tr>
<tr>
<td>object-id-attr</td>
<td>The name of the attribute in the business event payload that is necessary as the object-id for an Activity object. Typically this corresponds to the primary key attribute of a business object. If this attribute is not specified, the object-type element's name attribute is used as the default.</td>
</tr>
<tr>
<td>display-name-attr</td>
<td>The name of the attribute in the business event payload that is necessary as the display name of the Activity object. This attribute's value will be used to replace the {object} token in the Activity's message format.</td>
</tr>
</tbody>
</table>

```xml
<object-type>
  <custom-attributes>
    <custom-attribute name="service-ref-id" defaultValue="oracle.apps.crm.model.OpptyEO"/>
    <custom-attribute name="object-id-attr" defaultValue="opptyId"/>
    <custom-attribute name="display-name-attr" defaultValue="opptyName"/>
  </custom-attributes>
</object-type>
```

8. Define resource view handler parameters to allow custom navigation for links rendered in the Activity message. Navigation from the Actor link in the Activity message navigates to the user's portrait page. Custom navigation to the business object workarea is supported. Important fields include:

- `taskFlowId`: The task flow where you want to go.
- `resourceParamList`: The list of parameters that you want to pass to the task flow. For example, if a business object task flow takes the `opptyId` parameter, in `resourceParamList` you should specify "opptyId". If multiple parameters are required, the parameters should be separated by a semi-colon (;), for example "opptyId;opptyType". When the hyper link is clicked, parameters `opptyId="oppty id value"` and `opptyType="type value"` will be passed as input parameters to the task flow.

```xml
<resource-view taskFlowId="/WEB-INF/OpportunityTF.xml#OpportunityTF">
  <parameters>
    <parameter name="viewId" value="Opportunity"/>
    <parameter name="webApp" value="CRMApp"/>
    <parameter name="pageParametersList" value=""/>
    <parameter name="taskParametersList" value=""/>
    <parameter name="resourceParamList" value="opptyId"/>
  </parameters>
</resource-view>
```

Custom navigation is handled by the Applications Core ResourceViewHandler registered in the `adf-config.xml` file. You must add this entry to all `adf-config.xml` files:

```xml
<wpsC:adf-service-config xmlns:wpsC="http://xmlns.oracle.com/webcenter/framework/service">
  <resource-handler
```

---

Implementing Activity Streams and Business Events  
Oracle Fusion Applications Developer's Guide
15.5.6 How to Implement Comments and Likes

Commenting allows users to comment on objects that are created or published by various users on the site, and engage in discussions revolving around those objects using replies to comments and comments upon comments. This feature in Activity Stream allows users to comment on a specific Activity related to a object.

The Likes feature allows users to express their liking for any object in the system to which they have access. This feature is exposed in message boards, Activity Streams, doclib and replies on topics in discussion forums. In Activity Stream, this feature allows users to indicate if they like a particular Activity.

To enable Comments and Likes for a service, add these Activity Types to the service-definitio.xml file:

```xml
<activity-type name="postComment"
    messageFormatKey="ACTIVITY_COMMENT_STATUS"/>
<activity-type name="expressLike"
    messageFormatKey="ACTIVITY_LIKE_STATUS"/>
```

Ensure the `activity-type` names are as shown. The `messageFormatKey` values refer to the `ResourceBundle` keys that provide strings displayed for "comments" and "likes" links displayed in the Activity message.

15.5.7 How to Implement Follow for an Object

Users will be able to see Activity messages belonging to the business objects they are following. Users should either explicitly follow a business object, or you should provide a way for users to follow certain business objects implicitly. A business object can be followed for a user by using the Oracle WebCenter Portal Follow API. A sample implementation of the Follow model is shown in Example 15-13.

Example 15-13  Sample Implementation of the Follow Model

```java
public void follow() {
    System.out.println("Follow method invoked!!");
    try {
        OAViewObjectImpl vo = getCaseList1();
        Row row = vo.getCurrentRow();
        Object id = row.getAttribute("Id");
        System.out.println("Case Id in follow : " + id);
    }
    catch (Exception e) {
        System.out.println(e.getMessage());
    }
}
```
ActivityStreamingService asService = ActivityStreamingServiceFactory.getInstance().getActivityStreamingService();
FollowManager followManager = asService.getFollowManager();
String serviceID = "oracle.apps.fnd.applcore.crdemo.model.business.CasesEO";
String userGUID = ApplSessionUtil.getSession().getUserGuid();
ActivityActor actor = asService.createActor(userGUID);
String objectType = "Id";
ServiceObjectType objectType = asService.findObjectType(serviceID, objectType);
ActivityObject followedObject = asService.createObject(id.toString(), objectType, "");
System.out.println("Calling Follow for Case : " + id);
followedObject.setServiceID(serviceID);
followManager.followObject(actor, followedObject);
}
catch(ActivityException ae) {
    ae.printStackTrace();
    System.out.println("Case follow failed");
}

15.5.7.1 Defining the Service Category

The Follow model is enforced for Activity messages when the category-id of a service contains "business" in its name. A sample service-category-definition and its reference in service-definition are provided in Example 15-14 and Example 15-15.

Note that the ID in the service-category-definition file matches the category-id in the service-definition.xml file and it contains "business".

Example 15-14    Sample service-category-definition.xml File

<service-category-definition xmlns="http://xmlns.oracle.com/webcenter">
    <category id="oracle.apps.fnd.applcore.crdemo.model.business.CasesEO" resourceBundle="oracle.apps.fnd.applcore.crdemo.BusinessActivityServiceResourceBundle" titleKey="CASE_SERVICE_CATEGORY" icon="/a/s/g.gif"/>
</service-category-definition>

Example 15-15    Sample service-category-definition Reference

<category-id>oracle.apps.fnd.applcore.crdemo.model.business.CasesEO</category-id>

15.5.7.2 Adding ActivityTypes for Follow and Unfollow

The Activity types shown in Example 15-16 should be added to the service-definities of all services that use the Follow model. These Activity types are used to construct the message published when an object belonging to the service is Followed or Unfollowed.

Example 15-16    Adding ActivityTypes for Follow and Unfollow

<activity-type name="followObject" display="Follow Object" messageFormatKey="ACTIVITY_FOLLOW_OBJECT_MSG" description="Follow Object"/>
15.5.8 How to Render Contextual Actions in Activity Streams

Contextual Actions are rendered for business objects or other resources referenced in Activity Stream messages when `contextInfoPopupId` is configured in the `service-definition.xml` file of the business object or resource. The Activity Stream starts an Oracle ADF popup using the popup ID from the `service-definition.xml` file. The `contextInfoPopupId` should provide the absolute ID of the popup used for the Contextual Action. A popup with the specified ID should exist in the pages where the Activity Stream is used. This is a requirement for all pages where Contextual Actions-enabled objects are rendered. The Activity Stream will make the `serviceId`, `resourceId`, and `resourceType` properties available to the started popup. The popup should process these parameters and convert them to Contextual Actions-specific parameters and make them available to the Contextual Actions task flow or another component.

This element, which is the direct child of the `service-definition` element, is used to configure the Contextual Actions popup ID in the `service-definition.xml` file.

```xml
<contextInfoPopupId>:pt1:r1:casePopup</contextInfoPopupId>
```

The popup sample shown in Example 15-17 uses the `serviceId`, `resourceId`, and `resourceType` properties from the Activity Stream that are made available through the `launch` variable, and makes them available to the popup.

**Example 15-17 Sample Popup for ActivityStream**

```xml
<af:popup id="casePopup" contentDelivery="lazyUncached" eventContext="launcher" launcherVar="source" clientComponent="true">
    <af:noteWindow id="nw">
        <af:panelFormLayout id="pflTst">
            <af:inputText id="itSID" label="Service ID" value="#{pageFlowScope.serviceId}" readOnly="true"/>
            <af:inputText id="itRID" label="Resource ID" value="#{pageFlowScope.resourceId}" readOnly="true"/>
            <af:inputText id="itRType" label="Resource Type" value="#{pageFlowScope.resourceType}" readOnly="true"/>
        </af:panelFormLayout>
    </af:noteWindow>
    <af:setPropertyListener from="#{source.attributes.serviceId}" to="#{pageFlowScope.serviceId}" type="popupFetch"/>
    <af:setPropertyListener from="#{source.attributes.resourceId}" to="#{pageFlowScope.resourceId}" type="popupFetch"/>
    <af:setPropertyListener from="#{source.attributes.resourceType}" to="#{pageFlowScope.resourceType}"/>
</af:popup>
```
15.6 Implementing the Oracle Fusion Applications Search Results UI

The Oracle Fusion Applications Search Results UI is an implementation of the Oracle Enterprise Crawl and Search Framework (ECSF) within the Applications Core UIShell and SimpleUIShell (FUSE+) page templates. It allows all users on any page to perform searches in a consistent manner.

The minimum requirement is to implement and run a UI Shell template page. A page using the UI Shell template automatically will contain the search components in the Global Area and can be activated when running the page.

Where you have implemented ECSF for your product, you must ensure that you have followed all of the instructions in Set Up Your Development Environment, Getting Started with Oracle Enterprise Crawl and Search Framework, and Creating Searchable Objects and in particular:

- "How to Create a Database Connection" in Set Up Your Development Environment. The database connection must be defined inside the project using the UI Shell template. The Oracle Fusion Applications Search Results UI functionality uses the database connection SearchDB defined in this section to connect to the Oracle database to query the results.

- Creating Searchable Objects to make your view objects searchable. ECSF uses these search-enabled objects in the construction of the result set.

If you have implemented ECSF and defined the SearchDB connection, the saved and recent searches are saved to the Oracle database and are persisted across sessions.

Security on search is implemented by a combination of Functional Security over search categories at the ECSF layer, and Data Security (limiting search results to only those items to which the user has authorized access) using Applications Core data security rules on the searchable view objects.

15.6.1 How to Disable Oracle Fusion Applications Search

There are occasions when you will want to disable Oracle Fusion Applications Search for an application, such as for public (unauthenticated) pages. There are four ways to disable the function:

- The preferred method is to set the profile option Fusion Apps Search Enabled to 'N', either at site level or user level.

- Setup switch using a JVM system property.
  -DFUSION_APPS_SEARCH_ENGINE_AVAILABLE=N

- Use Customization by setting rendered to false on the panelGroupLayout with id "_UISGlobalSearch" (the panel containing the Oracle Fusion Applications Search fields) in the UI Shell main area. Note that by customizing the fields from the current page, you are not disabling search; the Expression Language bindings on the fields are still evaluated and if the user opens a non-customized page, Oracle Fusion Applications Search will be available.

- Remove the ECSF libraries (oracle.ecsf shared lib). Oracle Fusion Applications Search will detect the missing dependency and disable itself for all
pages in the current user session, even if the user opens a web application that does have the ECSF libraries available.

15.6.2 How to Use Basic Search

From the main page of the project in the Global Area, click the Search icon to display the Search dialog:

**Figure 15-21  Initial Search Dialog**

When you click the search icon, a popup will show suggestions. By default, these will contain any Recent Searches, Saved Searches and Recent Items the user has performed. As the user types, these suggestions will narrow down, and other suggestions, such as previous search terms, will be shown.

The Groups of suggestions shown to the user are determined by the search configuration in effect (see Using Setup Task Flows in), and personalizations made by the user.

By clicking the gear icon, the user can access these personalizations and can select/deselect suggestion groups, reorder them, and so on.

When you click **OK**, the selections are saved as MDS personalizations that will be stored across login sessions for the user.

**Hint:** To reset the personalizations, hold down the **Ctrl** key and click the gear icon. Your previous selections will be deleted and you will see the default configuration the next time you log in.
When you click a Recent Searches link or a Saved Searches link, the search will be run. When you click a Recent Items link, the task flow will be re-opened. As you type in the search field, the characters typed will narrow down the suggestions shown for the Recent Items, Recent Searches and Saved Searches. In addition, suggestions for previous searches will be shown.

**Recent Searches**

When you start to type in the search field, the Recent Searches list will refresh and narrow down based on the substring you type.

Keywords entered by the user serve as the name of the recent search.

Recent searches are implemented using the ECSF recent searches feature. See [About Managing Recent Searches](#).

A recent search is uniquely identified by its filters, such as search term, categories, and facet selections.

A search will be added to the front of the recent search list when performed. If it already exists in the list, it will be moved from its current place in the list to the front.

**Search Term**

This is a text field for the values on which to search. The field can hold a maximum of 2048 characters.

The term is searched for in any of the crawled data, which includes the title, fixed and variable content, attached documents, and tags. So if the search term is foo, the search returns any data containing the word foo.

Click the **Play** button or press **Enter** to initiate the search.

Click the **Show Filters** link to view and change the filters that will be used for the search.
Once a search has been performed, the Search terms field and the search results are displayed, as shown in Figure 15-24.

Sort

If multiple results are displayed, the Sort icon to the right of the More than X Results heading becomes active. Click the icon to display the Sort By dialog.

This function requires no developer implementation; it is built in.

Users can sort results in the results table. The sort may be done in ascending or descending order, and may be switched using a toggle button.

The sort will be available in two forms, depending on the search parameters:

- Multiple categories or a single category
The sort can be based only on Relevance (an implicit universal attribute) and LastModifiedDate (a universal attribute).

- A Single Searchable Object in a category
  The sort also can be based on Relevance and LastModifiedDate, and any stored attributes defined on the searchable object.

The Search result will be expanded in the background from the initial 10 results returned with the query, to 100 results returned by a background search started in a separate thread as soon as the 10 results are successfully returned. This is to give a reasonable result to sort. The sort UI will show a spinner and will be disabled until this is finished, and the UI will poll for completion every two seconds and enable those fields. This polling will stop when the background search is complete, or after a fixed number of polls (to stop infinite polling in case of error).

The default Sort is Relevance descending, which is the way that records are returned by SES.

The sort is done in memory using a standard Java Collections.sort function, and a comparator that takes into account the date type of the attribute (Date/Number/String) and direction.

15.6.2.1 Using the Search Filters

Click **Show Filters** to display them on the left side of the display. They are sized to make them easy to use on touch-screen appliances.

Last Updated Date and Categories are default filters.

*Figure 15-26  Search Filters Buttons*

**Last Updated Date**

Click **Last Updated Date** to display the selections panel, similar to *Figure 15-27*. 
The valid values are:

- **All**
  
  Clears the current filter and displays results for all available dates.

- **Today**
  
  LastModifiedDate equals "todays date."

- **This Week**
  
  LastModifiedDate >= "last Sunday" AND LastModifiedDate <= "this Saturday"

- **This Month**
  
  LastModifiedDate >= "first day of month" AND LastModifiedDate <= "last day of month"

- **This Year**
  
  LastModifiedDate >= "first day of year" AND LastModifiedDate <= "last day of year"

- **Custom Date Range**
  
  As appropriate for the range. A date picker will be displayed. The dates in the custom date range default to the last year (last 365 days).

### Categories

**Note:**

Categories are not set up at design time by developers. They should be set up either by customers or seeded by teams. Categories are created and stored in ECSF schema, and ECSF provides an API to get a list of categories to the UI for a given user. See How to Control the Look and Feel of Search.

When you click **Categories**, a list, similar to that shown in Figure 15-28, is displayed:
The user can select from the list of Categories. Unchecking the All category unchecks all of the categories. The subset of selected categories will be displayed in the entry area of the dropdown list as a concatenated list separated by commas.

Alternate Word List

Oracle Secure Enterprise Search (SES) will show alternate words to the user when they do a search as suggestions to frequent typos, or better used terms. This list is based on statically defined lists stored in SES.

Oracle Fusion Applications Search uses the ECSF APIs to show the alternate words to the user. Clicking the alternate word does a new search using the selected alternate word as the new keyword.

Saved Searches

Click Save to open a list of saved searches.

To create a new saved search that uses the last search string seen in the Search window as the search criteria, enter a name in the Name field and click OK. Make sure you have not selected an existing search.

To rename a saved search, select it, enter a new name in the Name field, and click OK.

To delete a saved search, select it and click Delete.

15.6.2.2 Search Results

After clicking Search, a modal dialog will display the results of the search. Hovering over the main link will show the last crawled date. Figure 15-31 shows typical results.
Note:

If a search application, such as Finance or HCM, does not respond to the search request within a predetermined period, the search results will be displayed but there will be a notice that one or more applications did not respond.

Figure 15-31  Search Results Example

The Search Results display consists of:

- A repetition of the fields displayed in the Global Area.
- A set of filter tiles: Selected filter values will be applied to the search results.

A category is a group of related objects. Examples include any Oracle Fusion business object, and Oracle WebCenter Portal objects such as wikis and blogs.

A Searchable Object is the second level. A searchable object is the view object.

If a category has only one Searchable Object, it is not shown as a filter because there is no action a user can take on it; it is automatically selected. Figure 15-31 shows an "Emp Cat" that has one searchable Object (not shown) that has three facet filters.

Facets are formed by the Lists of Values defined on an attribute in the Searchable Object. There may be many facets for a Searchable Object, and the facets may be hierarchical, such as is the case in Figure 15-31, where a State facet contains a County facet, which contains a City facet. Only the name of the highest level facet in the hierarchy is shown.

- A Results section. The search results use the keywords in the search field with the filters applied.

Each result found under a category provides a navigation link back to the record.

The format of a search result is:
- A line containing the default or primary action for the result. This may include an icon if it is defined on the search action. This line will be seen for all search results. Clicking the link navigates the user to the primary destination for the result.

- A line containing the fixed content of the result. If any search terms match in this text, they are shown in bold. The Fixed Content is derived from the Search Properties Title field as defined in ECSF.

- A line containing the variable content of the result. If any search terms match in this text, they are shown in bold. This text will wrap if it overflows the width of the line. The Fixed Content is derived from the Search Properties Body field as defined in ECSF.

- A line of tags attached to this result of the form "Tags: tag1 tag2 ...". If there are no tags, this line is not shown.

- A line of other actions in alphabetic order. Other actions are similar to the default action in that they may consist of an icon followed by a link. Clicking the link navigates the user to subsidiary destinations for the result. For example, the primary action for a result on a purchase order search may be to open the found purchase order. Other actions may include approval or rejection of the purchase order.

- A line of attachments for this result of the form "Attachments: attach1 attach2 ...". Each attachment may consist of an icon followed by the attachment name. A search may match the search term within the attachment. Clicking an attachment will download and open the attachment. If there are no attachments, this line is not shown.

**Result Counts Do Not Add Up**

It is possible when viewing the search results, and narrowing your selections using the facet tree, to see counts against the nodes that do not add up. For example, a search on Glasses might return 16. Then if you filter the result by color, you may find Blue (5) and Red (10), which do not add up to 16. This count is the Oracle Secure Enterprise Search (SES) Approximate count based on heuristics, and not an exact count. To make the count exact, start SES and select Global Settings > Query Configuration, and click the Exact count radio button, as shown in Figure 15-32. Note that SES warns against this for performance reasons. See the Oracle Secure Enterprise Search Administration Online Help.
15.6.3 How to Control the Look and Feel of Search

15.6.3.1 Using the Setup Task Flows

Two setup task flows are available for developers and customers to use in extending the Global Search metadata.

They will be available in the following Applications Core Libraries.

Table 15-8  Exported JAR Files

<table>
<thead>
<tr>
<th>JAR</th>
<th>Level</th>
<th>Library</th>
</tr>
</thead>
<tbody>
<tr>
<td>GlobalSearch-Model.jar</td>
<td>Model</td>
<td>Applications Core (oracle.applcore.model.ea)</td>
</tr>
<tr>
<td>GlobalSearch-View.jar</td>
<td>ViewController</td>
<td>Applications Core (Setup UI) (oracle.applcore.setupui.war)</td>
</tr>
</tbody>
</table>

The created task flows are:

Table 15-9  Created Task Flows

<table>
<thead>
<tr>
<th>Task Flow Name</th>
<th>Task Flow Id</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Global Search Configurations</td>
<td>/WEB-INF/oracle/apps/fnd/applcore/globalSearch/uiPublic/GlobalSearchManageConfigurationsTF.xml#GlobalSearchManageConfigurations</td>
<td>Set up and manage the options passed to Global Search on a per View basis.</td>
</tr>
</tbody>
</table>
### Table 15-9  (Cont.) Created Task Flows

<table>
<thead>
<tr>
<th>Task Flow Name</th>
<th>Task Flow Id</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Global Search Suggestion</td>
<td>/WEB-INF/oracle/apps/fnd/applcore/globalSearch/uiPublic/GlobalSearchManageGroupsTF.xml#GlobalSearchManageGroups</td>
<td>Set up and manage Search Suggest Groups.</td>
</tr>
</tbody>
</table>

#### 15.6.3.2 Using Setup Task Flows in Fusion Applications

To access the setup flows in Fusion Applications:

1. Select **Setup and Maintenance** from the Settings and Actions dropdown on the top of the page. See [Using the Settings and Actions Menu](#).

2. On the **Overview** page, select the **All Tasks** tab.

3. Set the **Search** dropdown to "Task Lists and Tasks."

4. Enter "global search" in the **Name** field and click **Search**.

The Application Global Search Configuration and Manage Suggestion Groups task flows are available under Define Global Search:

![Figure 15-33 Searching for Define Global Search in Settings and Actions](image)

Select the task flow you want to manage and click the Go to Task icon. The details are described in [Setting Up a Global Search Configuration](#).

#### 15.6.3.3 How a Configuration Lookup Is Processed

The configuration is loaded for the page each time it is loaded.

The algorithm is as follows:

- Determine the `viewId` and `application` for the loading page.
- Search for a configuration of type `Page` that matches the current `viewId` (unSEEDED, then SEEDED). If found, use it.
• Search for a configuration of type Application that matches the current application (unSEEDED, then SEEDED). If found, use it.

• Load the default.

In all cases, "like" searches are done, so SQL wildcards can be used and are recommended. For Application, these are required at the end because the application name often comes back with a version number, such as "HomePageApp(2.0)", so use an expression such as "HomePageApp%".

In all cases, if there is a customer (non SEEDED) configuration, it will be loaded before the SEEDED version.

15.6.3.4 Set Up a Global Search Configuration

As a developer there is no need to set up and ship a configuration to control the look and feel of Global Search. There is a default configuration that ships and Global Search will behave exactly how it always has. However, if you wish to change how Global Search appears to your customers, you can make and ship your own configuration. How this affects the search UI is described in this section.

Once you have clicked the Go to Task icon, described above, this dialog is opened:

Figure 15-34    Manage Global Search Configurations

From 1 (Short Name) to 11 (Last Updated Date), the fields are:

• (1) **Short Name**: The short name of the configuration. This is not shown in the Global Search UI.

• (2) **Display Name**: The display name of the Configuration. This is not shown in the Global Search UI. This value is translated.

• (3) **Description**: The Description of the Configuration. This is not shown in the Global Search UI. This value is translated.

• (4) **Default**: Is this the default configuration. There can be two Default configurations - a SEEDED configuration supplied by applcore that is the default configuration of Global Search. It cannot be changed or edited (the UI will prevent this), and a single default designated by the customer. A customer default will be loaded before the SEEDED default.

No Oracle group should create a default group and ship it as SEED data. This is not shown in the Global Search UI.

• (5) **Enabled**: Is the group enabled. Only enabled groups can be used. This is not shown in the Global Search UI.

• (6) **Product Family**: The product family of the configuration. A configuration can only configure search groups in the Common product family (shipped by applcore and available on every pillar) and the same Product Family. This ensures that the Suggestion Group class can be loaded at runtime.
This is not shown in the Global Search UI.

- **Module**: The module of the Configuration. This is used by the SEED data extraction process to distinguish between different groups’ SEED data. This is not shown in the Global Search UI.

- **Created By**: Row Who. This is not shown in the Global Search UI. A row that has Created By = SEED_DATA_FROM_APPLICATION is considered SEED data.

- **Creation Date**: Row Who. This is not shown in the Global Search UI.

- **Last Updated By**: Row Who. This is not shown in the Global Search UI.

- **Last Updated Date**: Row Who. This is not shown in the Global Search UI.

### 15.6.3.5 Edit Global Search Configuration

To edit a global search configuration, follow these steps:

1. Select the configuration, as shown in Figure 15-34, and click the Edit icon.

   **Note**: SEEDED configurations cannot be edited. In particular, the SEEDED DEFAULT configuration can never be edited by developers or end users.

   This dialog, with the Autosuggest tab selected, is shown:
The fields in the top portion are described with Figure 15-34.

From 12 (Enable personalization ...) to 19 (Maximum Number ...), the fields are:

- **(12) Enable personalization of search groups**: Is the tab of Suggest groups seen in the search field popup behind the gear icon?  
  If this and "Enable personalization of search categories" are no set, the gear icon is not shown.

- **(13) Suggestion Groups**: The set of Suggestion groups to show. This is an initial developer design decision and determines the groups the user sees in the search popup. The user then can select a subset of these and this selection
will be remembered in MDS. Shuttle the groups across that you want to show and override the default enabled state using the picker.

- (14) **Show Suggestion Group Headings**: Whether to show the suggestion group header. The header includes an icon (if available) and the heading text. Be aware that turning headings off may run suggestions from different groups together making it hard to distinguish them.

- (15) **Show Icons**: Should the suggestions show icons? If there is no icon available, or this is set to no, a bullet is shown.

- (16) **No Suggestions Message**: Message to show if there are no matching suggestions. If there are no matching suggestions, the suggestion popup will not be shown.

- (17) **Show Top Suggestions**: Whether to show top suggestions. Top suggestions are those shown in the suggestion list before the user has entered the “Minimum Characters for Autosuggest” and typically contains a static list of highly used suggestions as desired by the suggestion group author.

- (18) **Minimum Characters for Autosuggest**: The minimum number of characters in the search field before search suggest switches from showing top suggestions to suggestions specific to the typed values.

- (19) **Maximum Number of Suggestions**: The total maximum number of suggestions shown in the suggest list, spread evenly across all groups.

2. When finished editing the Autosuggest features, click the Search Field tab to display these settings:

![Figure 15-36 Edit Global Search Search Field Configuration](image)

From 20 (Minimum Number ...) to 24 (Placeholder), the fields are:

- (20) **Minimum Number of Characters**: The Minimum number of characters required for searching. By default this is 1. This will affect the error message “You must enter keywords to search”, “You must enter x character(s) to search.”

- (21) **Maximum Number of Characters**: The maximum number of characters the search field will allow. This sets the underlying af:inputText columns attribute.

- (22) **Automatically Clear Field Value after Search**: Is the search field cleared after the search. This is a convenience allowing the user to enter new text without having to clear or edit the previous search terms.
• **Label**: The Label of the Search field. To have no label, leave this value blank. For accessibility purposes, the hidden label value will be "Search."

• **Placeholder**: The placeholder or shadow text of the Search field. To have no placeholder, leave this value blank.

3. When finished editing the Search Field features, click the Search Results tab to display these settings:

**Figure 15-37  Edit Search Results Configuration**

![Image of Edit Search Results Configuration](image)

From 25 (Enable saved searches) to 36 (Show Icons), the fields are:

• **Enable saved searches**: Whether the user can save a search. The **Save** button will be hidden.

• **Enable recent searches**: Whether recent searches are saved automatically as the user runs and filters searches.

• **Filter Display Style**: Whether the filters (Category filters only) are shown inline or using a popup.
(28) **Enable personalization of search categories**: Is the tab of Search Categories seen in the search field popup behind the gear icon? If this and "Enable personalization of suggest groups" are not set, the gear icon is not shown.

(29) **Show subcategories in the search results**: Should Searchable Objects, also called subcategories, be shown? If they are not shown, "Show Facets" is also false.

(30) **Show Facets**: Should facets for the selected subcategory be shown?

(31) **Show hit counts**: Should hit counts in the facets be shown?

(32) **Enable clear all filters**: Should the *Clear Filters* button be shown?

(33) **Application**: The application to which to restrict the search categories. This is optional and will restrict the categories shuttle to only the categories from that application. This drop box is populated with the unique applications with which all categories are registered in the ECSF database.

(34) **Categories**: The set of categories to show. This is an initial developer design decision and determines the categories the user sees in the search popup. The user then can select a subset of these and this selection will be remembered in MDS. To pick all categories (including those added in the future), leave the categories unshuttled.

(35) **Last Updated Date Filters**: The set of Last Updated Date to show. To pick all filters (including those added in the future), leave the filters unshuttled.

(36) **Show Icons**: Whether icons are shown in the results.

4. When finished editing the Search Results features, click the Pages tab to display these settings:

*Figure 15-38  Edit Global Search Pages Configuration*

The two fields are:

(37) **View Type**: The View Type to which to map this configuration. There are two types of view type: Application and Page. You may enter as many rows as needed here.

(38) **View ID**: This value depends on the View Type:

- **Application**: Enter the application short name with a wildcard at the end, for example HomePageApp%.

  To find the application name:
  1. Open the Setup and Maintenance work area and go to the Manage Taxonomy Hierarchy task.
2. Expand the Oracle Fusion node, select a row with the Application module type, and click **Edit Module**.

3. In the Application Details section, see the Application Short Name column for the value to use. 

   **Page**: Enter the last part of the URL you get when you open that page. For example, enter ExamplePage from the URL.

   ```
   http://exampleServer/homePage/faces/ExamplePage
   ```

   Note that you cannot enter blind expressions, such as "%" because this effectively short cuts the configuration lookup algorithm. You **must** enter at least 5 characters that are **not** wildcard characters.

5. Click **Save and Close** or click the Manage Suggest Groups Configuration tab if it is available at the top of the page.

### 15.6.3.6 Manage Suggestion Groups Configuration

If Suggestion Groups have been implemented (see Create Suggestion Groups, the Manage Suggest Groups Configuration tab will be made available next to the Search Configurations tab, as shown here:

![Manage Suggestion Groups Configuration](image)

To manage a Suggestion Group, follow these steps:

1. Select a group and click the Edit icon. This configuration dialog is displayed:

   ![Edit Suggestion Group](image)
From 1 (Short Name) to 16 (Icon), the fields are:

- **(1) Short Name**: The Short name of the Suggestion Group. This is not shown in the Global Search UI.
- **(2) Display Name**: The Display name of the Suggestion Group. This is not shown in the Global Search UI. This value is translated.
- **(3) Description**: The Description of the Suggestion Group. This is not shown in the Global Search UI. This value is translated.
- **(4) Displayed by default**: Is this group displayed by default? This determines whether the suggestion group (see item 13 for Figure 15-35) is enabled by default. If it is not, the developer or customer can override the setting to enable the group. This allows a group to be registered and shipped in different configurations with different enabled items.
- **(5) Product Family**: The product family of the suggestion group. A Global Search Configuration can only configure search groups in the Common product family (shipped by applcore and available on every pillar) and the same Product Family as the group is declared in. This ensures that the Suggestion Group class can be loaded at runtime by configurations in effect. This is not shown in the Global Search UI.
- **(6) Module**: The Module of the Configuration. This is used by the SEED data extraction process to distinguish between different groups' SEED data. This is not shown in the Global Search UI.
- **(7) Created By**: Row Who - this is not shown in the Global Search UI. A row that has "Created By" = SEED_DATA_FROM_APPLICATION is considered SEED data.
- **(8) Creation Date**: Row Who. This is not shown in the Global Search UI.
- **(9) Last Updated By**: Row Who. This is not shown in the Global Search UI.
- **(10) Last Updated Date**: Row Who. This is not shown in the Global Search UI.
- **(11) Data Source**: The suggestion group. This can be:
  - One of the predefined suggestion groups. These are supplied in an autosuggest list on the field.
- **(12) Context Code**: The Context Code for the suggest group, if it is known at registration time and is to be used in Global Search. Different group use contextCode as an initialization value in different ways. For example the Recent Items group will strip items by the contextCode and objectType. By default, Global Search sets no contextCode and objectType.
- **(13) Object Type**: The Object Type for the suggest group; a sub-classification of Context Code, if it is known at registration time and is to be used in Global
Search. Different groups use `objectType` as an initialization value in different ways. For example, the Recent Items group will strip items by the `contextCode` and `objectType`. By default, Global Search sets no `contextCode` and `objectType`.

- **(14) Heading Visible:** Should the heading be shown for this group? Note that heading can be turned off for all groups at the "Global Search Configuration" level (see call out 14 in that section) overriding this value, though if the heading is off here it cannot be turned on at all.

  Be aware that turning headings off may run suggestions from different groups together and make it hard to distinguish them.

- **(15) Text:** The Heading Text for the group. If set will override the heading text set in the java code of the Suggestion Group.

- **(16) Icon:** The Heading Icon for the group. If set will override the icon set in the java code of the Suggestion Group.

2. Click **Save and Close**.

### 15.6.3.7 Create Suggestion Groups

Developers can create a suggestion group by extending the `oracle.apps.fnd.applicore.patterns.ui.behaviors.searchSuggest.AbstractSearchSuggestGroup` class.

The simplest way to test at this stage in development is to attach it to an `af:inputText` field in a simple UI:

```xml
<af:inputText label="My Test Suggest Group: " id="simple">
  <fnd:searchSuggestBehavior suggestGroup1="oracle.apps.tla...MySuggestGroup" contextCode1="ifNeeded" objectType1="ifNeeded"/>
</af:inputText>
```

To create, register and ship the suggestion group, follow these steps:

1. Use this boilerplate example to create a suggestion group. You will need to fill in the TODO items.

```java
import oracle.apps.fnd.applicore.patterns.ui.behaviors.searchSuggest.AbstractSearchSuggestGroup;
import oracle.apps.fnd.applicore.patterns.ui.behaviors.searchSuggest.SearchSuggestItem;

public class RequiresSubmitSearchSuggestGroup extends AbstractSearchSuggestGroup {
  /**
   * Unique name of this group. Must be unique across all groups.
   */
  public static final String NAME = "uniquegroupname";
  // TODO add NAME.
  @Override
  public String getName() {
    return NAME;
  }
}
```
@Override
public String getDisplayName()
{
    // Allow override of Heading in Manage Suggest Groups UI.
    String overRiddenDisplayName = super.getDisplayName();
    if (overRiddenDisplayName != null)
    {
        return overRiddenDisplayName;
    }
    return "Translated Heading";
    // TODO add translated heading.
}

@Override
public String getIconURL()
{
    // Allow override of Icon in Manage Suggest Groups UI.
    String overRiddenIconURL = super.getIconURL();
    if (overRiddenIconURL != null)
    {
        return overRiddenIconURL;
    }
    return "some/path/to/image.png";
    // TODO add icon.
}

@Override
public List<SearchSuggestItem> getItems(String searchText,
    int maxSuggestedItems)
{
    List<SearchSuggestItem> ret = new ArrayList<SearchSuggestItem>();
    // TODO add suggestion items based on searchText.
    // This call MUST return as fast as possible.
    ret.add(...);
    return ret;
}

@Override
public List<SearchSuggestItem> getTopSuggestions(String searchText,
    int maxSuggestedItems)
{
    List<SearchSuggestItem> ret = new ArrayList<SearchSuggestItem>();
    // TODO add top items.
    // This call MUST return as fast as possible.
    ret.add(...);
    return ret;
}

@Override
public void init(Map<String, Object> attributes)
{
    // TODO: Look-up suggestions to use in getItems / getTopSuggestions if needed
to allow fast calls of getItems / getTopSuggestions.
    // If they need to be looked up during those calls, you MUST ensure the
lookup is fast as it will block the suggest field.
}
```java
@Override
public boolean requiresSubmit()
{
    // TODO: true if the group value selection needs processSubmit(..) to process
    // the selection, false if the suggestions are keywords
    return true;
}

@Override
public boolean placeSelectedItemInField()
{
    // TODO: true to place the selected item in the search field, false
    // otherwise.
    return true;
}

@Override
public void processSubmit(String item, Map<String, Object> attributes)
{
    // TODO: Write code to look-up item and process it according to business
    // rules.
}
}
```

2. Register the group in the setup UI.

If your suggestion group is to be used in your own UI, just add it to your code.

If the group is to be used in Global Search, register it in the "Manage Suggestion Group" UI. Use the fully qualified class name as the "Data Source". Use your "Product Family" and "Module".

Set a "Context Code" and "Object Type" if necessary.

3. Register a configuration and include your group in it.

Create a new configuration, or re-use an existing one that you control. The "Product Family" and "Module" should be the same as for the group you have registered.

Set options as appropriate for your use case. Include the new group and any Common (Applications Core defined) groups you need. Override the display status using the "Enabled" drop box if you wish to change it.

Map the configuration to your UI pages and applications.

Do not set the configuration as a default configuration. There should be only one default configuration and that is developed and shipped by applcore. A customer can set a configuration of their own as a default to override the Applications Core default, but it should not be Seeded.

4. Extract and ship the setup.

Development teams will:

- Use the setup UI to define their metadata.
- Ensure their module is set correctly for their LBA.
- Use standard Seed data extraction utilities to extract that metadata and ship in their patches.

Seed data will be extracted separately for:
Teams will only extract and ship Seed data for the modules they own.

Use commands similar to these:

```
-AM oracle.apps.fnd.applicore.search.model.applicationModule.FusionSearchAM \
-VO FndFusionSuggestGroups \
-ExtractRootPath $ADE_VIEW_ROOT/atgpf/applcore/db/data
```

Use the

```
[-PartitionKeyIds <Taxonomy ModuleId values> | -PartitionKeyNames <Taxonomy short name values>]
```

parameter to get the Seed data for your product. See Initializing Oracle Fusion Application Data Using the Seed Data Loader for a full description of Seed Data.

### 15.6.4 Introduction to the Crawled Objects Project

The Crawled Objects Project lets you crawl your Search view objects in Oracle WebLogic Server, and set up Oracle Fusion Applications Search to use those crawled view objects.

The business component objects you will create (specifically the Searchable view object) will contain references to the Oracle Fusion Middleware Extensions for Applications base classes.

Update the ECSF command-line script (`runCmdLinScript.sh`) to reference the JAR files containing the base classes. Example 15-18 shows the UNIX version; the DOS version is similar.

#### Example 15-18 Updating ECSF Command-Line Script to Reference Applications Core JAR Files

Run these commands if you are using a Linux operating system:

```
export APPLCORE_CP=${ORACLE_HOME}/jdeveloper/jdev/oaext/adflib/Common-Model.jar:$ORACLE_HOME/jdeveloper/jdev/oaext/adflib/Tags-Model.jar
export ADMIN_CLASS=oracle.ecsf.cmdlineadmin.CmdLineAdmin

${JAVA_HOME}/java -cp ${ADMIN_CP}:${APPLCORE_CP} ${ADMIN_CLASS} ${CONNECT_INFO}
```

Run these commands if you are using a Windows operating system:
set APPLCORE_CP=%ORACLE_HOME%\jdeveloper\jdev\oaext\adflib\Common-Model.jar;
%ORACLE_HOME%\jdeveloper\jdev\oaext\adflib\Tags-Model.jar
set ADMIN_CLASS=oracle.ecsf.cmdlineadmin.CmdLineAdmin

%JAVA_HOME%\java -cp %ADMIN_CP%;%APPLCORE_CP% %ADMIN_CLASS% %CONNECT_INFO%

15.6.5 How to Implement Tags in Oracle Fusion Applications Search

A view object is available to reference Oracle WebCenter Portal Tags. This view object is available in the ORACLE_HOME/jdeveloper/jdev/oaext/adflib/Tags-Model.jar library JAR file.

You may use this view object using a view link and a predefined Search extension to enable the crawling of Oracle WebCenter Portal Tags, both in initial and incremental (someone has updated the tags) crawls.

Follow these steps:

1. Create your Searchable view object as usual. Example 15-19 uses a Searchable view object over FND_LOOKUPS_VL in the query.

   The SERVICE_ID specifically identifies your Searchable view object.

   The RESOURCE_ID identifies the specific row for the SERVICE_ID. It is a dot-separated primary key of the entity.

   These two values will be used when setting up tags in your regular UI and must match. For example, if you have a page with a form and a tag button, the Oracle WebCenter Portal tag would be set up as shown in Example 15-20.

   **Note:**

   Do not forget to mark your key columns and ensure the order is consistent between the view object and the tag:taggingButton.resourceId attribute.

---

**Figure 15-41  Tags - Searchable View Object Lookup Types**

Figure 15-42 shows the attributes for Searchable view object lookup types.
2. Add a view link to the TagSVO (service view object) linking the Search view object and the Applications Core Tag view object. The view link should look similar to Figure 15-43.

3. Update the Body field to include the tags of the child view object in the relevant position in the string as defined by your management.
This will be an expression of the form `<accessor Name>.Tag`, such as `tagSVO.Tag`.

**How to Do an Incremental Crawl**

To do an incremental crawl:

1. Update the Searchable View Object Search Plugin field (see Figure 15-43) to "oracle.apps.fnd.applcore.search.TagSearchPlugin", or as shown in Example 15-21, create a subclass so that you can incorporate your security rules.

Ensure you add a parameter passing the service ID of the Search view object. This may be done by clicking the LOV symbol next to the Search Plugin field, shown in Figure 15-42. See Figure 15-44.

**Figure 15-44  Search Plugin**

![Search Plugin](image)

Note that the Plugin Class Name is the same as that described in Adding Attachments Support to Global Search.

There are two parameters, shown in Table 15-10, that may be passed to the extension.

**Table 15-10  Parameters that can be passed to the plug-in**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TAG_SERVICE_ID</td>
<td>Yes</td>
<td>Service ID of the Searchable view object. This value must match the value in the tag:taggingButton component and the service_id of the Searchable view object.</td>
</tr>
</tbody>
</table>
Table 15-10  (Cont.) Parameters that can be passed to the plug-in

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>KEY_SPLITTER_CLASS</td>
<td>No</td>
<td>An optional class that extends oracle.apps.fnd.applcore.search.BaseKeySplitter. This is a strategy class for splitting the resourceId value into individual primary key attribute values. By default, oracle.apps.fnd.applcore.search.DefaultKeySplitter is used, which will split values based on a period separator (the applications standard). The separated PS attribute values are matched to the primary key columns in the order the primary key columns are defined in the view object flat table editor. For more flexible arrangements, teams can implement any scheme they want (such as name-value pairs) by creating their own key splitter class and setting this parameter.</td>
</tr>
</tbody>
</table>

2. Start the SearchFeedServlet in the user interface project.

Example 15-19  Creating a Searchable View Object

```
SELECT LOOKUP_TYPE,
    VIEW_APPLICATION_ID,
    LANGUAGE,
    SOURCE_LANG,
    MEANING,
    DESCRIPTION,
    CREATED_BY,
    CREATION_DATE,
    LAST_UPDATED_BY,
    LAST_UPDATE_DATE,
    LAST_UPDATE_LOGIN,
    'oracle.apps.fnd.applcore.lookuptype' AS SERVICE_ID,
    lookup_type||'.'||to_char(view_application_id)||'.'||language||'.'||meaning
as RESOURCE_ID
FROM FND_LOOKUP_TYPES_TL
```

Example 15-20  Setting up the Oracle WebCenter Portal Tag

```
<af:panelFormLayout id="pf11">
    <tag:taggingButton serviceId="oracle.apps.fnd.applcore.lookuptype" resourceName="#{bindings.Description.inputValue}" resourceID="#{(bindings.LookUpType.inputValue).#(bindings.ViewApplicationId.inputValue).#(bindings.Language.inputValue).#(bindings.Meaning.inputValue)}/">
        <af:region value="#{bindings.tagginglaunchdialog1.regionModel}" id="r1"/>
        <af:panelLabelAndMessage label="#{bindings.LookUpType.hints.label}" id="plam4">
            <af:outputText value="#{bindings.LookUpType.inputValue}" id="ot9"/>
        </af:panelLabelAndMessage>
    </tag:taggingButton>
</af:panelFormLayout>
```
**Example 15-21  Creating a Subclass**

```java
package oracle.apps.fnd;
import oracle.apps.fnd.applcore.search.TagSearchPlugin;
public class WlsTestTagSearchPlugin
extends TagSearchPlugin
{
    // All implementation through super class, or override methods important to you.
    // Be careful if implementing
    //  public Iterator getChangeList(SearchContext ctx, String changeType)
    // to call super(ctx, changeType) to get the applcore functionality.
}
```

You now can crawl using the command-line script. A full crawl will be done first, then on subsequent crawls the incremental functionality will call the `getChangeList()` method.

**15.6.6 How to Use the Actionable Results API with Oracle Fusion Applications Search**

This section details how to set up ECSF searchable objects to use with Oracle Fusion Applications Search. For information about setting up your global search infrastructure, see *Getting Started with Oracle Enterprise Crawl and Search Framework.*

*Figure 15-45* shows the result that will be produced (a single row in the search results table).

*Figure 15-45  Search Results Example*

<table>
<thead>
<tr>
<th>Flat Table URL Action</th>
<th>Title for Flat Table 1:Col1619:Col2619</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Include for Flat Table 1 with extra information to form a description: Col1619: Information for Col4: Col144: Any other required information would be added later</td>
</tr>
</tbody>
</table>

The terminology referred to in this result is:

- **Flat Table URL Action** is the Action Link.
- **Title for Flat Table 1:Col1619:Col2619** is the Fixed Content.
- **Any other required information would be added later** is the Variable Content.
- **Task Action 1** is Other Actions.

As shown in *Figure 15-46*, ECSF searchable objects support two distinct Action Types: URL and Task. See also *Figure 15-47* and *Figure 15-48*.

Most Oracle Fusion Applications will use the Task type with specific named parameters to integrate with the UI Shell; however both types will work.
Fixed Content
The Fixed Content is derived from the Search Properties Title field.

Variable Content
The Variable Content is derived from the Search Properties Body field.

15.6.6.1 Implementing the URL Action Type
Figure 15-47 shows a URL Action.
For URL Action Types, the Oracle Fusion Applications Search will open a new browser tab or window containing the URL. To configure this type, add a URL Search Result Action with these parameters.

- A unique name
- Action Type of URL
- An Action Target to the required destination, including groovy substitution parameters
- A Title

No Parameters are required; however a single iconURL parameter may be defined if an icon is required for the URL action. See Table 15-11.

### Table 15-11  iconURL Parameter

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iconURL</td>
<td>No</td>
<td>URL of icon to show next to the Action. Can be a relative reference such as /media/search/mime_doc.gif or a full URL such as <a href="http://host:port/path/to/icon.gif">http://host:port/path/to/icon.gif</a>.</td>
</tr>
</tbody>
</table>

The icon will be shown in the search results with the title given in the Title field. When clicked, a new browser tab or window will open with this URL.

### 15.6.6.2 Implementing the Task Action Type

**Figure 15-48** shows a Task Action.
For Action Types of Task, the Oracle Fusion Applications Search will open a UI Shell tab in the current page, or a new page containing the task flow. To configure this type, add a Task Search Result Action with these parameters:

- A unique name
- Action Type of Task
- A Title

Parameters are shown in Table 15-12. Note that, although this table resembles Table 15-13, it presents the use case that the majority of users will use. The information in Table 15-13 is for a very small use case.

The action will be shown in the search results with the title given in the Title field. When clicked, a new UI Shell tab window will open with this task flow. If the viewId parameter is for the current page, the UI Shell tab will be in the current page; otherwise the current page will be replaced with a new UI Shell page with the search result.

---

**Note:**

Do not enter double quotation marks around the groovy expressions; use single quotation marks instead.

---

**Table 15-12  Task Action Type Parameters**

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>viewId</td>
<td>Y</td>
<td>Name of the page. This is shown in the browser URL bar. For example, in <code>http://127.0.0.1:8989/context-root/faces/TestUIShellPage</code>, it would be <code>/TestUIShellPage</code> (Note the leading slash).</td>
</tr>
</tbody>
</table>
Table 15-12  (Cont.) Task Action Type Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageParametersList</td>
<td>N</td>
<td>Parameters list for the page. This is a semicolon delimited String of name-value pairs. For example, &quot;param1=value1;param2=value2&quot;</td>
</tr>
<tr>
<td>taskFile</td>
<td>Y</td>
<td>Name of the task definition file. For example, /WEB-INF/task-flow-definition.xml. See Passing Parameters in Search.</td>
</tr>
<tr>
<td>taskName</td>
<td>Y</td>
<td>The task flow definition ID. Available from the task definition file &lt;task-flow-definition&gt; ID attribute. For example, &lt;task-flow-definition id='task-flow-definition'&gt; would be &quot;task-flow-definition&quot;. See Passing Parameters in Search.</td>
</tr>
<tr>
<td>navTaskKeyList</td>
<td>N</td>
<td>Key list to pass into the task flow to open in the target workspace. This is a semicolon delimited string of keys or key-value pairs. For example &quot;key1;key2=value2&quot;</td>
</tr>
<tr>
<td>navTaskParametersList</td>
<td>N</td>
<td>Parameters list to pass in to the task flow to open in the target workspace. This is a semicolon delimited string of name-value pairs. For example &quot;param1=value1;param2=value2&quot;</td>
</tr>
<tr>
<td>iconURL</td>
<td>N</td>
<td>URL of an icon to show next to the Action. Can be a relative reference such as /media/search/mime_doc.gif or a full URL such as <a href="http://host:port/path/to/icon.gif">http://host:port/path/to/icon.gif</a>.</td>
</tr>
<tr>
<td>toolTip</td>
<td>N</td>
<td>Tooltip of the action. This also is available for URL actions.</td>
</tr>
<tr>
<td>navTaskLabel</td>
<td>N</td>
<td>Label to show on the results tab. Set the tab title of the tab that is opened after clicking a search result action. If not set, it will use the Action Name (the value shown in the results).</td>
</tr>
<tr>
<td>webApp</td>
<td>Y</td>
<td>Attribute used to look up the host and port of the associated WorkArea or Dashboard from the Oracle Fusion Applications Functional Core (ASK) deployment tables. These tables are populated at deployment time through Oracle Fusion Functional Setup Manager tasks.</td>
</tr>
<tr>
<td>contextCode</td>
<td>N</td>
<td>Used for Recent Items striping of data by business line. This attribute will divide recent items into groups. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CommonDomain</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• BI</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• FIN</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• SCM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• CRM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PRJ</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• HCM</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• PRC</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• IC</td>
</tr>
<tr>
<td>objectType</td>
<td>N</td>
<td>Used for Recent Items striping of data by business line. This is a further subdivision within the contextCode classification for the recent item object (such as opportunity, contact, lead, quote). If objectType is supplied, contextCode should be set.</td>
</tr>
<tr>
<td>Name</td>
<td>Required</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>objectName</strong></td>
<td>N</td>
<td>User recognizable String for a given recent item instance. Used as string to match keystrokes entered in auto suggest field. This value will be in the language of the user at the point of navigation (that is, when the record is saved). It will not change if the user changes language. If <code>objectName</code> is supplied, <code>contextCode</code> and <code>objectType</code> also should be set.</td>
</tr>
</tbody>
</table>
| **FUSECardCode**  | N        | When navigating to FUSE, this is the `globalItemNodeId` of the global menu entry that describes the page to which to navigate. If this parameter is specified, `FUSEObjectCode` and `FUSETaskflowParamsList` also should be specified; these three parameters are passed to the `FndUIShellController.globalMenuNavigate()` API:  
    ```java
    public void globalMenuNavigate(String globalItemNodeId,  
                                   String taskItemNodeId,  
                                   String taskParametersList,  
                                   FndMethodParameters methodParameters)
    ```  
    This can be added as a parameter-value pair using the Figure 15-48 dialog. |
| **FUSEObjectCode**| N        | When navigating to FUSE, this is the `taskItemNodeId` of the global menu entry that describes the page to which to navigate. If this parameter is specified, `FUSECardCode` and `FUSETaskflowParamsList` also should be specified; these three parameters are passed to the `FndUIShellController.globalMenuNavigate()` method:  
    ```java
    public void globalMenuNavigate(String globalItemNodeId,  
                                   String taskItemNodeId,  
                                   String taskParametersList,  
                                   FndMethodParameters methodParameters)
    ```  
    This can be added as a parameter-value pair using the Figure 15-48 dialog. |
<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FUSETaskflowParamsList</td>
<td>N</td>
<td>When navigating to FUSE, this is the FUSETaskflowParamsList of the global menu entry that describes the page to which to navigate. This parameter likely will contain a groovy expression that embeds the primary keys of the search result to allow navigation to the exact search result. If this parameter is specified, FUSECardCode and FUSEObjectCode also should be specified; these three parameters are passed to the FndUIShellController.globalMenuNavigate() API: public void globalMenuNavigate(String globalItemNodeId, String taskItemNodeId, String taskParametersList FndMethodParameters) This can be added as a parameter-value pair using the Figure 15-48 dialog.</td>
</tr>
<tr>
<td>FUSETaskFlowId</td>
<td>N (conditionally)</td>
<td>The taskId of the required dynamic navigation results flow in the form: /WEB-INF/oracle/apps/fnd/appcore/patterns/uishell/GlobalSearchDummyResultsTaskFlow.xml#GlobalSearchDummyResultsTaskFlow</td>
</tr>
<tr>
<td>FUSENavTaskKeyList</td>
<td>N</td>
<td>The task keylist used to identify dynamic tabs.</td>
</tr>
<tr>
<td>FUSENavTaskLabel</td>
<td>N</td>
<td>The label to show on dynamic tabs.</td>
</tr>
</tbody>
</table>

This information applies to the next three parameters: FUSETaskFlowId, FUSENavTaskKeyList and FUSENavTaskLabel.

Starting with Release 11, Applications Core ships a single FuseOverview page used by all Oracle Fusion applications. All content is supplied by the menus.

The pre-Release 11 navigation will continue to work, however there is a limitation on the taskflows that can be opened. That is addressed by these new parameters.

The navigation made by this call will only navigate to a defaultMain taskflow: FndUIShellController.globalMenuNavigate(FUSECardCode, FUSEObjectCode, FUSETaskflowParamsList, null)

This is okay for some teams because they open the results in a popup using adfc navigation flow cases built into their flows.

For teams coming new to FUSE search in Release 11, the requirement is to open a dynamicMain taskflow, much the same as in classic UIShell.

With the addition of these parameters a user can be sent to a dynamicMain taskflow.

There are now two use-cases for configuring FUSE Task Action parameters:

- The original defaultMain navigation:
Enter FUSECardCode, FUSEObjectCode, FUSETaskflowParamsList parameters only.

- New dynamicMain navigation:
  Enter FUSECardCode, FUSETaskflowParamsList, FUSETaskFlowId and, optionally, FUSENavTaskKeyList and FUSENavTaskLabel.
  Do not enter FUSEObjectCode.

The Classic UIShell and FUSE parameters can continue to co-exist in the same action.

---

**Caution:**
If you have a searchable view object with a task search action, the parameters passed to the task flow from FndUIShellController.navigate(...) will be Strings, not the native type of the view object attributes. You must ensure that these values are converted from their native type to a String (in the navTaskParametersList) and back correctly (in your task flow).

For Integer types, this is largely automatic (if you reference the parameter as a String in the task flow), but use caution for dates and decimals.

---

### 15.6.6.2.1 How to Determine the Navigation Target

Navigation depends on the defined parameters. You may have classic UIShell parameters, FUSE parameters (those starting with FUSE%) or both defined. The algorithm used to determine the navigation is:

```java
TaskSearchAction tsa = ...get the clicked action ...
boolean isClassicNav = get value of profile FND_CLASSIC_INTERFACE.
if isClassicNav
    // try to navigate to UIShell.
    if tsa has UIShellParameters
        UIShellNavigate(tsa);
    else if tsa hasFUSEParameters
        FUSEPlusNavigate(tsa);
else
    // log error, no nav can be done.
else
    // try to navigate to FUSE.
    if tsa has FUSEParameters
        FUSEPlusNavigate(tsa);
    else if tsa has UIShellParameters
        UIShellNavigate(tsa);
else
    // log error, no nav can be done.
```

### 15.6.6.2.2 How to Implement Preferred Navigation

Global Search will read the standard profile option FND_CLASSIC_INTERFACE that is used to determine where the user wants to be, and use the appropriate parameters to navigate. If there no parameters for that style of page, then it tries to use the other style, as shown in this example:

```java
TaskSearchAction tsa = ...get the clicked action ...
boolean isClassicNav = get value of profile FND_CLASSIC_INTERFACE.
if isClassicNav
    // try to navigate to UIShell.
    if tsa has UIShellParameters
        UIShellNavigate(tsa);
```
Global Search supports two parameters, `applicationStripe` and `pageDefinitionName`, in task search actions that, if they are present, change the definition of the other task action parameters used for navigation. These parameters all become “caret delimited.” That is, instead of having one value per parameter, they have multiple values, and they are delimited by the caret “^” character. In this case, all parameters must have the same number of delimited parts.

This additional configuration allows you as the developer to set up different navigation targets for the same action. The actual target followed will be determined when the user clicks the result and will be based on a permissions check based on the `applicationStripe` and `pageDefinitionName` parameters. If these two parameters are not supplied, the other parameters will be used “as is,” and navigation will be performed based on their values.

If the `applicationStripe` and `pageDefinitionName` parameter values are supplied, the algorithm used is the same as for tagging:

- Divide all delimited parameters based at the caret, and produce an ordered list of targets that can be opened.
- If there is only one target defined, use it with no permission check.
- For each target, determine if the user can open the page and task flow.
- If a target that can be opened is in the current view, use it.
- Take the first target that can be opened.

Whatever the outcome of the permissions check, you must ensure that at least one target can be opened, otherwise users will be presented with a blank page when they click the search result.

The parameters and descriptions for Preferred Navigation are shown in Table 15-13. Note that, although this table resembles Table 15-12, it presents a more complicated use case in which developers want to do a security check and direct the user to the most secure end point (the first allowed one in the list). The meaning of these columns changes with the caret delimitation; that is, a caret-delimited list of the old values, as well as two new parameters. Most users need to use only the information in Table 15-12.
### Table 15-13  Parameters for Preferred Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Delimited by caret</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>applicationStripe</td>
<td>Y</td>
<td>N</td>
<td>(This attribute is used for pages.) Check security of the page against the policies that are located in LDAP. The applicationStripe name must be the same as the stripe name of the LDAP policy store, which is the same as the web.xml application.name attribute. If this parameter is supplied, the pageDefinitionName parameter must be supplied also. Example: crm^hcm</td>
</tr>
<tr>
<td>pageDefinitionName</td>
<td>N</td>
<td>Y</td>
<td>A delimited string of page definition names. If this parameter is supplied, the applicationStripe parameter also must be supplied. Example: oracle.apps.view.pageDefs.Test1PageDef^oracle.apps.view.pageDefs.AnotherPageDef</td>
</tr>
<tr>
<td>viewId</td>
<td>Y</td>
<td>Y</td>
<td>Name of the page for the pillar. This is shown in the browser URL bar. For example, in <a href="http://127.0.0.1:8989/context-root/faces/TestUIShellPage">http://127.0.0.1:8989/context-root/faces/TestUIShellPage</a>, it would be &quot;TestUIShellPage&amp;AnotherUIShellPage&quot;.</td>
</tr>
<tr>
<td>webApp</td>
<td>Y</td>
<td>Y</td>
<td>Attribute used to look up the host and port of the associated Work Area or Dashboard from the ASK deployment tables. These tables are populated at deployment time through Functional Setup Manager tasks.</td>
</tr>
<tr>
<td>pageParametersList</td>
<td>Y</td>
<td>N</td>
<td>Parameters list for the page. This is a semicolon delimited string of name-value pairs. For example, &quot;param1=value1;param2=value2^anotherParam1=value1;anotherParam2=value2&quot;</td>
</tr>
<tr>
<td>taskFile</td>
<td>Y</td>
<td>Y</td>
<td>Name of the task definition file. For example, &quot;/WEB-INF/task-flow-definition.xml^/WEB-INF/anotherTask-flow-definition.xml&quot;. See Passing Parameters in Search.</td>
</tr>
<tr>
<td>taskName</td>
<td>Y</td>
<td>Y</td>
<td>The task flow definition ID that is available from the task definition file &lt;task-flow-definition&gt; id attribute. For example, &lt;task-flow-definition id='task-flow-definition'&gt; would be &quot;task-flow-definition^another-task-flow-definition&quot;. See Passing Parameters in Search.</td>
</tr>
<tr>
<td>navTaskKeyList</td>
<td>N</td>
<td>Y</td>
<td>Key list to pass into the task flow to open in the target workspace. This is a semicolon delimited string of keys or key-value pairs. For example &quot;key1;key2=value2^anotherKey1;anotherKey2=value2&quot;</td>
</tr>
<tr>
<td>navTaskParametersList</td>
<td>N</td>
<td>Y</td>
<td>Parameters list to pass in to the task flow to open in the target workspace. This is a semicolon delimited string of name-value pairs. For example &quot;param1=value1;param2=value2^anotherParam1=value1;anotherParam2=value2&quot;</td>
</tr>
</tbody>
</table>
Table 15-13 (Cont.) Parameters for Preferred Navigation

<table>
<thead>
<tr>
<th>Name</th>
<th>Required</th>
<th>Delimited by caret &quot;^&quot;</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>navTaskLabel</td>
<td>N</td>
<td>Y</td>
<td>The label to show on the results tab. (Set the tab title of the tab that is opened after clicking a search result action.) If not set, it will use the Action Name (the value shown in the results). For example: &quot;Manage user ^ View User&quot; (Note: This will be shown on the UI, so use resource bundles.)</td>
</tr>
<tr>
<td>iconURL</td>
<td>N</td>
<td>N</td>
<td>The URL of the icon to show next to the Action. It can be a relative reference, such as /media/search/mime_doc.gif or a full URL, such as <a href="http://host:port/path/to/icon.gif">http://host:port/path/to/icon.gif</a>.</td>
</tr>
<tr>
<td>Tooltip</td>
<td>N</td>
<td>N</td>
<td>A tooltip of action. This also is available for URL actions.</td>
</tr>
</tbody>
</table>

15.6.6.3 Passing Parameters in Oracle Fusion Applications Search

Ordinarily, taskFlowID uses the format <path><name>.xml#<name>; for instance taskFlowID="/WEB-INF/CaseDetails.xml#CaseDetails". However, Oracle Fusion Applications Search has taskFile and taskName attributes as shown in Figure 15-48. The code will merge them, adding the "," so they become <taskFile>#<taskName>.

Parameters always are passed as parameter name=value. Often, it is either a literal value or an expression to an attribute such as col1. Example 15-22 shows how to pass four parameters.

**Example 15-22 Parameter Passing in Oracle Fusion Applications Search**

```xml
<SearchResultActions>
  <Action
    Name="View Lookup Type"
    ActionType="Task"
    DefaultAction="true">
    <Title>
      <![CDATA["Lookup: " + Meaning]]>
    </Title>
    <ActionTarget>
      <![CDATA[null]]>
    </ActionTarget>
    <Parameters>
      <Parameter Name="navTaskParametersList">
        <Value>
          <![CDATA["lookupType=" + LookupType + ";viewApplicationId=" + ViewApplicationId + ";language=US;meaning=" + Meaning]]>
        </Value>
      </Parameter>
      <Parameter Name="webApp">
        <Value>
          <![CDATA["GlobalSearch"]]
        </Value>
      </Parameter>
      <Parameter Name="TaskFile">
        <Value>
          <![CDATA["/WEB-INF/LookupTypeSearchResultsTaskFlow.xml"]]
        </Value>
      </Parameter>
    </Parameters>
  </Action>
</SearchResultActions>
```
15.6.6.4 Ordering the Other Actions

In the ECSF search UI in JDeveloper, it is possible to define no action, or a single default action.

If a default action is defined, it will be used. The other actions will be shown in sorted order based on task title. If no default action is defined, the first sorted action will be used as the default action.

This sorting mechanism is used because there is no way, using the current ECSF APIs, to provide a stable order of actions.

Due to this sorting mechanism, it is strongly recommended to have stable, sortable task titles (they may be groovy bound and therefore mutate based on an individual search result) to prevent confusing the end user.

15.6.6.5 Using Click Path and the Saved Search

When the user is using Oracle Fusion Applications Search before saving a search, he or she may perform several interactions with the UI including:

- Expanding the attribute filters by selection (performs searches)
- Narrowing the search terms
- Opening unsearched groups (which performs searches in those groups)
- Scrolling through results in a group

This is called the click path of the user.

When a search is saved, some of this information (the structural part at the tip of the click path) is saved, but prior actions and exact scroll positions are not. This means that when running a saved search, the following items are not restored to the user:

- Exact expanded groups in the result at the time of save
- Scroll positions within a group
- Full LOV expansion state of attribute filters
When ECSF returns facet information, it returns facet entries only for the level below that which is selected. For example, if there are no filters, the facets will be shown correctly with one level of detail. If a first-level facet is selected, that selection will be shown, but not its siblings. If there are facets below that level, this next level will be shown as these are returned. As the user starts to refine or expand the attribute filters, the search filters will be filled in based on this new click path.

15.6.7 How to Integrate Non-Applications Data into Oracle Fusion Applications Search

Oracle Fusion Applications Search can also be used with non-standard ECSF searchable view objects.

15.6.7.1 Oracle Business Intelligence Integration

Oracle Business Intelligence results will be shown in a results area separate from Oracle Fusion Applications Search view object results. To implement this separation, Oracle Fusion Applications Search shows results in a multiple-tab format. The tabs are named Applications, where all Search view objects and WebCenter Portal results will reside, as well as Business Intelligence. The split is performed at a category (or searchable groups) level, so you will see a consolidated list of categories in the multi-select category dropdown. These categories are split at search time.

The business rule that splits categories into the Oracle Business Intelligence table is a lowercase category_name, such as `bi_%`.

Although the formatting of Oracle Business Intelligence results will be slightly different, no developer action is required.

**Oracle Secure Enterprise Search (SES) Setup**

To set up SES, you need to set up these parameters:

- **Source**
  
  See the Oracle Fusion Middleware Developer’s Guide for Oracle Business Intelligence Enterprise Edition guide for how to create your Oracle Business Intelligence source. Define a source based on the Oracle EBusiness Suite R12, and give the following parameters:

  SES Source Configuration:
  
  Configuration URL: `http://10.156.30.40:9704/bisearch/crawler/oracle.biee.search.BISearchableTreeObject/ConfigFeed?forceInitialCrawl=true`
  
  User ID: Administrator
  
  Password: password

  Authorization Tab:
  
  
  User ID: Administrator
  
  Password: password
  
  Business Component: `oracle.biee.search.BISearchableTreeObject`
  

  where the IP address is your Oracle Business Intelligence server installation, and the user name/password are for a sufficiently authorized Oracle Business Intelligence user.

  Leave all other values at default.

- **Source Group**
Create a source group (SES Searchtab then Source groups) and name it <some code name>.

You may go into Global Settings and translate the group name so the users see a more recognizable name.

Import the group as an external category into ECSF.

- **Searching**

  When you click a link, you will be redirected to Oracle Business Intelligence. If you do not have a consolidated Oracle Internet Directory (OID) setup, you will be asked to log in again.

**15.6.7.2 Ensuring Parity of Users**

Users must be defined in multiple applications if you do not have a single authentication store.

Ensure that you have a user defined that is common across both Fusion Applications and any external applications such as Oracle WebCenter Portal or Oracle Business Intelligence.

For instance, you can create an fmwadmin user on the Oracle Fusion Applications side by adding to the jazn-data.xml file.

With Oracle Secure Enterprise Search (Oracle SES) Authentication pointing to the ECSF SearchFeedServlet, which is using the WebLogic Server container security, this user will be verified by the Oracle SES authentication callbacks.

In a true enterprise environment, both the Oracle Fusion Applications web container and WebCenter Portal would be set up with the same OID.

Using two different authentication stores will mean you get multiple logins when clicking results.

**15.7 Implementing Auto-suggest**

The fnd:searchSuggestBehavior tag implements suggestion functionality, often known as typeahead. It is added to an af:inputText field, and will display as a popup menu below the field as a user types into the field. Its primary use is in Global Search to show groupings of suggestions from various sources, and for CRM to show suggestions in its search fields. The search suggest configuration for Global Search is done using the setup task flows described in How to Control the Look and Feel of Search. The tag is available in JDeveloper under the Applications Components in the Component Palette, as shown in Figure 15-49.
The suggestions in the group fall into two types of values:

- **Search suggestions.** These are keywords on which the user wants to search, and when selected, these words will be placed in the search field.

  **Note:** Keywords can be deleted using the Oracle Enterprise Scheduler Service submission UI. No additional coding is required.

- **Shortcuts to other functionality.** Selecting these entries will perform a specific function for that entry; the text will not be placed in the search field because it is not a keyword. For example, if the user types part of a Navigator entry, the Navigator link will be suggested to them; clicking it will navigate to that menu entry, just the same as if the user had selected the entry from the Navigator.

The `fnd:SearchSuggestBehavior` is developed as an Oracle ADF Behavior that closely follows the Oracle ADF version `af: autoSuggestBehavior`.

`fnd:searchSuggestBehavior` is similar in functionality to `af: autoSuggestBehavior` but adds:

- the rendering of group headings and items
- the expanded scrolling behavior to skip heading selection
- selection into the field only of keyword entries (not menu items)
- rendering of icons for each group and suggestion

It also adds to the communication to the server with new initialization, top suggestion and selection messages.

The user interacts with the suggestion list as follows:

- Auto-suggest starts with the third typed character. This can be configured.
- The user starts to type into the field against which the search suggest is defined.
- If there are no matching suggestions in a section, the section is not shown.
• As soon as the user selects the search field, a message is sent to the server to start to pre-load the lists of suggest items, so that by the time the user has typed the second character (expect a second or so), any delay on startup is done. As many groups as possible are loaded in a background thread to speed up the load of data.

• A user can navigate in the popup by using arrow keys, **Home** and **End** to circle among entries. As they do this, the currently-selected entry will be highlighted, and if it is a keyword, it will be entered in the search field. If it is a Recent Item or a Favorite, it will not be placed in the search field because it is not a search term.

• Pressing **Enter** will perform the search if the highlighted item is a search term. Otherwise, if it represents a navigation, the relevant task flow with parameters will be called. This can be configured.

• The match done is a *case insensitive* in string. The matched substring is highlighted in bold.

• A maximum of 25 items will be spread over the groups as evenly as possible. This can be configured.

• Any item that is to open a URL in a new window will show as a URL in the popup. This is required to set target="_blank" so the URL opens in a new browser window or tab, and not by overwriting the current Fusion Applications window.

• Groups are shown in the order defined in the JSPX tag.

Skinning keys are used for the items in the popup:

• .FndSearchSuggestItem

• .FndSearchSuggestItem:selected

• .FndSearchSuggestGroup

• .FndSearchSuggestGroup:first-child

• .FndSearchSuggestItemNormal

• .FndSearchSuggestItemCount

• .FndSearchSuggestItemCount:rtl

• .FndSearchSuggestItemHilight

The attributes of the `fnd:searchSuggestBehavior` tag are shown in Table 15-14.

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>EL capable?</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Yes</td>
<td>No</td>
<td>Popup</td>
<td>The type of search suggest behavior. Valid values are inline and popup. Inline is where the suggestions will be placed in the content of an existing panel. This panel is identified by <code>inlineSuggestionComponentId</code>. The popup is the normal popup UI that will show below the search field. Popup is the default and the majority use case.</td>
</tr>

</tr>
<tr>
<td>topSuggestions</td>
<td>Yes, resolves to a string</td>
<td>No</td>
<td>On</td>
<td>Determines whether to show top suggestions when the field is first clicked. These suggestions are provided without filters and provide a starting point for the user. Once the user starts to type, regular filtered selections are shown. This is only processed if type=popup, as inline suggestions handle this using a dedicated panel identified by inlineSuggestionComponentId. Valid values are on and off. Off is the default.</td>
</tr>
<tr>
<td>postSelectionFocusComponentId</td>
<td>Yes, resolves to a string</td>
<td>No</td>
<td>null</td>
<td>A relative Component ID representing a component to give focus after a selection is made. This is primarily of use so that focus is no longer in the search field, and topSelections will be shown immediately when the user re-enters the field. By default, focus will remain in the search field.</td>
</tr>
<tr>
<td>adfPopupId</td>
<td>No</td>
<td></td>
<td></td>
<td>The relative component Id of an Oracle ADF popup in which inline suggestions are to be shown. This popup must have contentDelivery=&quot;immediate&quot; and childCreation=&quot;immediate&quot; so that it is immediately available on the client. The Oracle ADF popup should have a panel with Id corresponding to inlineSuggestionComponentId and may have inlineReplaceComponentId and adfMessageComponentId components. This attribute is only relevant when type=&quot;inline&quot;.</td>
</tr>
<tr>
<td>adfMessageComponentId</td>
<td>No</td>
<td></td>
<td></td>
<td>A relative Component Id of a component on which to set a &quot;search for 'linda'&quot; message. This attribute is only relevant when type=&quot;inline&quot;.</td>
</tr>
<tr>
<td>adfShowComponentIds</td>
<td>No</td>
<td></td>
<td></td>
<td>A space-separated list of relative Component Ids representing components to make visible once the loading suggestions message is finished. This attribute is only relevant when type=&quot;inline&quot; and adfPopupId is set, and is a way of not allowing the user to select options on the inline popup that are not yet ready to be selected because their data is not initialized (for example clicking a button).</td>
</tr>
<tr>
<td>noMatchMessage</td>
<td>No</td>
<td></td>
<td></td>
<td>The message shown to the user when there are no matches. If this attribute is not set, no message will be shown, and any existing suggestions will be hidden.</td>
</tr>
</tbody>
</table>
### Table 15-14 (Cont.) find:searchSuggestBehavior Attributes

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>EL capable?</th>
<th>Required?</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>groupIcons</td>
<td>No</td>
<td></td>
<td></td>
<td>Do you want to show the icons in group headings for all defined groups? This is an override for the group-specific generation of icons in group headings. groupHeadings must be 'on' (the default) for this attribute to have any effect, because the icons are shown in the heading. If a group does not have a heading icon, this setting will have no effect because there is nothing to show or hide. However if the group does have a heading icon, this setting will show or hide it. Valid values are 'on' and 'off'.</td>
</tr>
<tr>
<td>adfPopupId</td>
<td>No</td>
<td></td>
<td></td>
<td>This attribute is only relevant when type=&quot;inline&quot;. The relative component Id of an ADF popup in which inline suggestions are to be shown. This popup must have contentDelivery=&quot;immediate&quot; and childCreation=&quot;immediate&quot; so that it is immediately available on the client. The ADF popup should have a panel with Id corresponding to inlineSuggestionComponentId and may have inlineReplaceComponentId and adfMessageComponentId components.</td>
</tr>
<tr>
<td>adfMessageComponentId</td>
<td>No</td>
<td></td>
<td></td>
<td>This attribute is only relevant when type=&quot;inline&quot;. A relative component Id of a component on which to set a &quot;search for search_term&quot; message.</td>
</tr>
<tr>
<td>adfShowComponentIds</td>
<td>No</td>
<td></td>
<td></td>
<td>A space-separated list of relative component Ids representing components to make visible once the loading suggestions message is finished. This attribute is only relevant when type=&quot;inline&quot; and adfPopupId is set, and is a way of not allowing the user to select options on the inline popup that are not yet ready to be selected because their data is not initialized (for example clicking a button).</td>
</tr>
<tr>
<td>noMatchMessage</td>
<td>No</td>
<td></td>
<td></td>
<td>The message shown to the user when there are no matches. If it is not set, no message will be shown and any existing suggestions will be hidden.</td>
</tr>
</tbody>
</table>

These will be used by Global Search in the 'Global Search Field with Results Popup' taskflow to show suggestions and to provide personalization UI (by clicking the gear icon).

Additional behaviors are:

- Top Suggestions Loading. If topSuggestions='on' and this is the first time the search field has been clicked, then static loading UI will be shown.

- Show More. If there is more than one group of suggestions and if any of those groups have been truncated to fit within the maximum number of suggestions, a Show More link will be shown on each group. Once clicked, only this group's selections will be shown with a Show Less link.
• If no suggestions are found, the noMatchMessage is shown. If this is empty or
null, the suggest popup will not be shown. If it is already open, it will be closed. If
type='inline', the suggest content will be hidden; if
inlineReplaceComponentId is specified, this content will be re-showed.

• If adfMessageComponentId is specified, a message "Search for 'contents of
search field'" will be set as the text of that component (on the client).

• If adfShowComponentIds are specified, these will be made visible after the top
suggestions loading banner has been shown.

• If in screen reader mode, fnd:searchSuggestBehavior will no longer be
disabled if type='inline' (it is still disabled if type = 'popup').

• Top suggestions will be shown all the time using the defined suggest groups. This
means the suggest content is completely consistent and symmetrical for top and
autosuggest content in both types of popup and inline.

15.7.1 How to Implement fnd:searchSuggestBehavior

To implement fnd:searchSuggestBehavior, the basic developer steps are:

• Drag-and-drop the component onto an af:inputText field.

• Set the appropriate attributes. suggestGroups is required.

• If creating a custom group, extend AbstractSearchSuggestGroup, and
reference it using Expression Language.

These examples show how you can implement fnd:searchSuggestBehavior.

Using suggestGroups containing a predefined and custom group

```xml
<af:inputText id="SearchField"
value="#{pageFlowScope.searchString}"
maximumLength="2048"
required="false" simple="true" autoComplete="off"
clientComponent="true" usage="search">
    <fnd:searchSuggestBehavior suggestGroups="#{SomeBean.searchSuggestBehaviorGroups}"/>
</af:inputText>

/**
 * Get the Search Behavior groups.
 * This is based on the GlobalSearchOptions set for the current page. If no
 * options are set it defaults based on the method
 * GlobalSearchOptions.getDefaultGlobalSearchOptions().
 * @return List of behavior groups.
 */
public List<SearchSuggestGroupOption> getSearchSuggestBehaviorGroups()
{
    List<SearchSuggestGroupOption> ret = new ArrayList<SearchSuggestGroupOption>();
    ret.add(new SearchSuggestGroupOption(KeywordSearchSuggestGroup.NAME));
    ret.add(new SearchSuggestGroupOption("#{SomeBean.customGroup}",
            GroupHeading.ON,
            "/path/to/icon.png",
            "Group Heading",
            null,
            null));

    return ret;
}
```
Implementing Auto-suggest

public AbstractSearchSuggestGroup getCustomGroup()
{
    // This group will have any heading name, icon,
    // context code and object code set on it by the framework
    // to override code (developer set) values.
    return new MyCustomSearchSuggestGroup();
}

Simple popup with all predefined groups

Simple Default: 

Popup with 3-second delay

Popup with maximum of 10 suggestions

Popup with submit on Enter

Oracle Fusion Applications Developer's Guide
Implementing Auto-suggest

Common data for two suggestion popups

```xml
<af:inputText id="it6" label="common behavior 1">
    <fnd:searchSuggestBehavior suggestionSourceId="common1"
        suggestGroup1="searchterms"
        suggestGroup2="navigator"/>
</af:inputText>

<af:inputText id="it7" label="common behavior 2">
    <fnd:searchSuggestBehavior suggestionSourceId="common1"
        suggestGroup1="searchterms"
        suggestGroup2="navigator"/>
</af:inputText>
```

Custom group with topSuggestions

```xml
<af:inputText id="topSuggestions" label="Top Suggestions: " value="seahawk">
    <fnd:searchSuggestBehavior
        suggestGroup1="#{SuggestGroupFactory.bookSearchSuggestGroup}"
        topSuggestions="on"/>
</af:inputText>
```

Where SuggestGroupFactory is some Expression Language-reachable managed bean:

```java
public class SuggestGroupFactory
    implements Serializable
{
    public SearchSuggestGroup getBookSearchSuggestGroup()
    {
        return new BookSearchSuggestGroup();
    }
}
```

Group that uses object striping

```xml
<af:inputText id="crmRIMenu1" label="CRM RI Menu" value="Lin">
    <fnd:searchSuggestBehavior
        suggestGroup1="recentitems"
        contextCode1="CRM"
        objectType1="Search"/>
</af:inputText>
```

Group that hides and shows content in the base page

The following suggestion will be shown in the "suggestions" panelgrouplayout. The content in "swapout" will be hidden when suggestions are shown.

```xml
<af:inputText id="suggestinline" label="Suggest inline:">
    <fnd:searchSuggestBehavior
        inlineSuggestionComponentId="suggestions"
        type="inline"
        inlineReplaceComponentId="swapout"
        suggestGroup1="#{SuggestGroupFactory.bookSearchSuggestGroup}"
        contextCode1="Book"
        objectType1="theseahawk.txt"
        noMatchMessage="No suggestions found."
        minCharCount="3"/>
</af:inputText>
```

```xml
<af:panelGroupLayout layout="vertical" id="suggestions" rendered="true"
    styleClass="fndGlobalSearchSuggestPanel"
    clientComponent="true" visible="false">
<!-- Autosuggest content will be added here. -->
</af:panelGroupLayout>
```
15.7.2 How to Implement a Custom Suggestion Group

If you wish to create your own list of suggestions to show the user, you need to create a SearchSuggestGroup and register it with the af:searchSuggestBehavior tag for the af:inputText field that will show the suggestions.

Before you begin, you must implement the oracle.apps.fnd.applcore.patterns.ui.behaviors.searchSuggest.SearchSuggestGroup interface by extending the AbstractSearchSuggestGroup interface directly; this is not supported.

This interface is available in the UICOMPONENTS-View.jar, which is available by including the Applications Core (ViewController) library in your project. This dependency should be met already.

The developed class, and all resources it needs, should be available to all applications that consume the functionality. For example, for CRM implementation, it should be available in common CRM libraries. URL references used for icons in the group headings, or for suggestion items, should not be local to the web application unless the icon comes from a common icon repository that is available across web applications.

BookSearchSuggestGroup

This is an example implementation that loads a book from a text file, word counts it and provides the words as suggestions.

```java
public class BookSearchSuggestGroup extends AbstractSearchSuggestGroup {
    /**
     * Unique name of this group. Must be unique across all groups.
     */
    public static final String NAME = "booksearchterms";
    private List<SearchSuggestItem> _keywords = new ArrayList<SearchSuggestItem>();

    public BookSearchSuggestGroup() {
        super();
    }

    @Override
    public String getDisplayName() {
        return "My Book Terms";
    }

    @Override
    public String getIconURL() {
        return "images/applcore/uishell/globalSearch/search_ena.png";
    }

    @Override
    public List<SearchSuggestItem> getItems(String searchText,
```
int maxSuggestedItems)
{
    long now = System.currentTimeMillis();
    List<SearchSuggestItem> ret = new ArrayList<SearchSuggestItem>();

    String upperFilter = searchText.toUpperCase();
    int size = _keywords == null ? 0 : _keywords.size();
    for (int i = 0; i < size; i++)
    {
        SearchSuggestItem kw = _keywords.get(i);
        String keyword = kw.getText();
        String upperKw = keyword.toUpperCase();
        int index = upperKw.indexOf(upperFilter);
        if (index >= 0)
        {
            ret.add(new SearchSuggestItem(keyword, kw.getCount()));
            if (ret.size() >= maxSuggestedItems)
                break;
        }
    }

    if (AppsLogger.isEnabled(AppsLogger.FINEST))
    {
        long later = System.currentTimeMillis();
        long duration = later - now;
        AppsLogger.write(this,
            "Global Search: BookSearchSuggestGroup, getItems: Found: " +
            ret.size() + " items for: " + searchText + " in " + duration +
            " mSecs.",
            AppsLogger.FINEST);
    }
    return ret;
}

@Override
public List<SearchSuggestItem> getTopSuggestions(String searchText,
    int maxSuggestedItems)
{
    long now = System.currentTimeMillis();
    List<SearchSuggestItem> ret = new ArrayList<SearchSuggestItem>();

    ret.add(new SearchSuggestItem("sea"));
    ret.add(new SearchSuggestItem("seahawk"));
    ret.add(new SearchSuggestItem("Rafael"));
    ret.add(new SearchSuggestItem("Sabatini"));
    ret.add(new SearchSuggestItem("pirate"));
    ret.add(new SearchSuggestItem("English"));
    ret.add(new SearchSuggestItem("Spanish"));
    ret.add(new SearchSuggestItem("privateer"));
    ret.add(new SearchSuggestItem("Armada"));

    Collections.sort(ret);

    if (AppsLogger.isEnabled(AppsLogger.FINEST))
    {
        long later = System.currentTimeMillis();
        long duration = later - now;
        AppsLogger.write(this,
            "Global Search: BookSearchSuggestGroup, getTopSuggestions:

            Implement Search Functions in the UI Shell
            15-111"};
Implementing Auto-suggest

15.7.3 How to Implement fnd:searchSuggestBehavior in Global Search

The Search Suggest functionality has been implemented in Applications Core Global Search; there is nothing the developer needs to do to get this feature.

By default, the user will see predefined sources of suggestions as described in each suggestion group described in Table 15-15.
Table 15-15  Search Suggestions Sections

<table>
<thead>
<tr>
<th>Section</th>
<th>Live data</th>
<th>Supports Striping using contextCode, objectType</th>
</tr>
</thead>
<tbody>
<tr>
<td>Search Terms</td>
<td>Essentially Yes. Data is loaded at start but updated in memory. Data is saved to table on each Search.</td>
<td>No</td>
</tr>
<tr>
<td>Recent Items</td>
<td>Yes. Data is the same as that in the Recent Items list. Data is updated live in the list and saved on logout.</td>
<td>Yes</td>
</tr>
<tr>
<td>Favorite Items</td>
<td>No, loaded up front.</td>
<td>No</td>
</tr>
<tr>
<td>Navigator</td>
<td>No, loaded up front.</td>
<td>Yes</td>
</tr>
<tr>
<td>Watchlist</td>
<td>No, loaded up front.</td>
<td>No</td>
</tr>
<tr>
<td>Saved Global Searches</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Recent Global Searches</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

My Search Terms

Alternate search words that will be placed in the search field if the user clicks them.

The user then can perform a search by pressing Enter or clicking the Search icon.

The keywords are those from previous unfiltered searches by the user, using the result count of that search. These values are stores in a new table:

CREATE TABLE FND_FUSION_SEARCH_KEYWORDS
(
    FUSION_SEARCH_KEYWORDS_ID NUMBER(18,0) NOT NULL,
    USER_ID VARCHAR2(64 CHAR) NOT NULL,
    KEYWORDS VARCHAR2(260 CHAR) NOT NULL,
    SEARCH_COUNT NUMBER(18,0) NOT NULL,
    RESULT_COUNT NUMBER(18,0),
    ENTERPRISE_ID NUMBER(18,0) DEFAULT NVL(SYS_CONTEXT('FND_VPD_CTX', 'ENTERPRISE_ID'), 1) NOT NULL,
    CREATION_DATE TIMESTAMP (6) NOT NULL,
    CREATED_BY VARCHAR2(64 CHAR) NOT NULL,
    LAST_UPDATE_DATE TIMESTAMP (6) NOT NULL,
    LAST_UPDATED_BY VARCHAR2(64 CHAR) NOT NULL,
    LAST_UPDATE_LOGIN VARCHAR2(32 CHAR),
    CONSTRAINT FND_FUSION_SEARCH_KEYWORDS_PK PRIMARY KEY (FUSION_SEARCH_KEYWORDS_ID, ENTERPRISE_ID)
) DISABLE

My Recent Items

Recent Items from the recent items menu that match the search String.

When the user clicks a recent item, the task flow opens up directly.

The value shown to the user is the objectName, if present, otherwise it is the taskflow label (what is shown in the Recent Items UI). Striping is possible using contextCode and objectType if present. Note that Global Search does not use the striping values.
My Favorite Items
This is similar to recent items, however the favorite items need to be loaded from tables when first used and are thereafter cached in memory.

My Navigator
The Navigator items are loaded by using the same APIs the navigator menu uses, and will reuse any loaded or cached menu structure.

The value shown is the itemNode label. Striping is possible using contextCode and objectType if present. Note that Global Search does not use the striping values.

Support entries that are navigation targets (the FunUIShellController.navigate(...)), as well as pure URLs (<a href=...>) that open in a new frame. URLs will be shown in the popup as URLs; that is, with the underline.

My Watchlist
Watchlist items are loaded when first referenced.

Clicking an item expands into the watchlist item.

Saved Searches
Saved searches are referenced directly from Global Search.

Clicking an item runs the search.

Recent Searches
Recent searches are referenced directly from Global Search.

Clicking an item runs the search.

15.7.4 How to Implement Dynamic UI Support for searchSuggestBehavior

Dynamic UI support for searchSuggestBehavior satisfies these three requirements:

1. Dynamic configuration adds Java level configuration for fnd:searchSuggestBehavior. This allows developers to add input text fields dynamically through code using metadata available in MDS.

2. Enables table support for fnd:searchSuggestBehavior so, for example, developers can add flexfields to tables. fnd:searchSuggestBehavior works in repeating and stamped structures, and with various combinations of rowSelection.

3. Can show one set of suggestions but return a different value to the field. To provide alias lookup support, suggestions will be shown only when a prefix character (# by default) is typed. The suggestions shown are aliases and may show different values; they will not show the prefix character. When a suggestion is picked, the prefixed value is returned to the field.

User Interaction
User interaction for requirements 1 and 2 are the same as the existing fnd:searchSuggestBehavior solution. That is, the user clicks in an af:inputText field, the popup shows, and the user selects from it.

For requirement 3, the interaction is:
• User selects the field and types the prefix character ('#', though it could be anything). If the user does not type the prefix character, no suggestions are shown.

• User types another character and autosuggest shows suggestions based on the second character. The '#' is not part of the suggestions, which may not even contain the characters typed.

• As the user continues to type, the suggestions narrow.

• User selects a value and an alias value for the selection is returned to the field. This value will contain the prefix character and may not look like the suggestion selected.

Requirement 1 - Dynamic Configuration Design
Provides a factory and a bean for setting all suggest attributes, and the ability to apply to an af:inputText field.

class: SearchSuggestBehaviorFactory
method: createSearchSuggestBehaviorBean()

Class SearchSuggestBehaviorBean is obtained from SearchSuggestBehaviorFactory.

methods:
• applyTo(RichInputText it)
• setXXXX(ValueExpression ve) (1 method per attribute you can see in the property inspector for fnd:searchSuggestBehavior).

Use as shown in this example.

RichInputText it = .. somehow get an input text field.
SearchSuggestBehaviorBean ssb = SearchSuggestBehaviorFactory.createSearchSuggestBehaviorBean();
ssb.setSuggestGroup1(ssb.createValueExpression("oracle.apps.fnd.searchSuggest.ReflectiveSearchSuggestGroup"));
ssb.setContextCode1(ssb.createValueExpression("ContextCode" + numChildren));
ssb.setObjectTyep1(ssb.createValueExpression("ObjectCode" + numChildren));
ssb.setTopSuggestions(ssb.createValueExpression("on"));
... set other attributes as appropriate ...
ssb.applyTo(it);

Requirement 2 - Enable Table Support
The developer can get the clientId of the input text field on which the search suggest field is configured.

For tables and other repeating structures, the af:inputText field and fnd:searchSuggestBehavior are defined once in a column (for an af:table) and only exist once in the server-side JSF component tree. When the markup is rendered, it is stamped out repeatedly for the number of rows in question. Numeric Ids are added into the client ID of the component (:0 for row 0, :1 for row 1, and so on).

The following APIs are added to AbstractSearchSuggestGroup (the class all suggestion group writers must extend):

/**
 * Set the suggestFieldClientId. This is called by the search suggest framework
* when suggestions are requested for a field, and before the groups are polled for * those suggestions. This value can be used to distinguish between multiple fields * sharing the same suggestion data, and perhaps different columns in a table. * @param suggestFieldClientId client id, for example pt1:USma:0:MAt2:1:pt1:t1:1:it1 */

public void setSuggestFieldClientId(String suggestFieldClientId)
{
    _suggestFieldClientId = suggestFieldClientId;
}

/**
 * Get the suggestFieldClientId. This will be set by the default init() method,
 * and updated on every click in the suggest field.
 * @return suggest field client id of the form a:b:c.
 */
public String getSuggestFieldClientId()
{
    return _suggestFieldClientId;
}

The suggestion group developer then can use logic similar to that below to determine the row. If the developer is using a table with rowSelection="single", then common rowSelection APIs can be used (id1 below). However if any other rowSelection method is used, this will be unreliable. A variant of Method 2, below, can be used.

/**
 * Use the clientId to find the InputText component, the enclosing table and
 * thereby the selected row.
 * @return selected row, -1 if cannot find for any reason.
 */
private int getSelectedRow()
{
    // There are 2 ways to find the cell: one is to know which column we are
    // in by being told (I use contextCode here) and determining the row using
    // the table's selected row. However this requires the table to have
    // rowSelection="single" which is likely but not always the case.
    // The second is to use the clientId of the component and a bit of internal
    // knowledge of the encoding of the ids.

    int id1 = getSelectedRowUsingTable();
    int id2 = getSelectedRowUsingClientId();
    System.out.println("TableCellSuggestGroup: getSelectedRow: found row using table
    selected row: " + id1 + 
        ", by clientId: " + id2);
    if (id1 != id2)
    {
        if (AppsLogger.isEnabled(AppsLogger.WARNING))
        {
            AppsLogger.write(this,
                "TableCellSuggestGroup: getSelectedRow: found differing rows,
            row using table selected row: " + id1 + 
                ", by clientId: " + id2,
                AppsLogger.FINEST);
        }
        // client id is more accurate across different rowSelection attribute settings.
        return id2;
    }

    // client id is more accurate across different rowSelection attribute settings.
    return id2;
}

private int getSelectedRowUsingTable()
{ // Method 1:
UIComponent field = SearchUtils.findComponentByClientId(_searchFieldClientId);

if (field != null)
{
RichTable table =
(RichTable)PatternsUtil.getParentByType(field, RichTable.class);

if (table != null)
{
    // find the selected row.
    RowKeySet selectedRowKeys = table.getSelectedRowKeys();
    if (selectedRowKeys != null && selectedRowKeys.size() > 0)
    {
        // This works for Java ArrayLists, but will not work for BC collections.
        Integer row = (Integer)selectedRowKeys.iterator().next();
        return row;
    }
}
return -1;
}

private int getSelectedRowUsingClientId()
{
    // Method 2:
    String clientId = getSuggestFieldClientId();
    String[] clientIds = clientId.split("::");
    if (clientIds.length > 2)
    {
        return Integer.valueOf(clientIds[clientIds.length - 2]);
    }
    return -1;
}

Requirement 3 - Alias Lookup Design
This requirement is met by the suggestion group developer, with one enhancement to allow the transposition of the display and Id values.

find:searchSuggestBehavior supports the ability to have a displayed value with a different id behind the scenes. It is achieved by the suggestion group developer adding suggestions using one of the more detailed constructors of SearchSuggestItem, using a different Id and text:

/**
 * Create an Item.
 * @param text translatable text shown to user.
 * @param id unique identifier.
 * @param count Optional count.
 * @param url fully qualified url the user can click. Must be of the form http://
 * it will result in a html href.
 */

public SearchSuggestItem(String text, String id, Number count, String url)

Until this point, the Id could be used only when the AbstractSuggestGroup suggestions were submitted to the server as a shortcut, such as selecting a navigator menu item.
In this case the selected suggestion was not placed in the search field (this is achieved by over-riding `requiresSubmit()` and returning true).

If different Ids and text were returned as suggestions and `requiresSubmit()` returned false, the text would be shown and placed into the search field when selected. This is the typical search terms use case commonly seen with auto suggest.

A new method added to the `AbstractSuggestGroup` indicates that the value to be returned to the field is the Id and not the text. This can be used only when `requiresSubmit()` is false:

```java
/**
 * Given `placeSelectedItemIdInField()` returns true, do we place the SearchSuggestItem Id in the search field, or in the display value.
 * It is almost always the case that the display value will be used. However it is possible to perform a transposition where the user sees one thing in the list of the suggestions, but another is returned to the field.
 * An example of this is for typing aliases. The user may type a prefix character into the field to trigger suggest, such as '#'. The suggest group responds only when # is entered and it will then suggest a list of descriptive values without the '#' (they may be completely different to what is typed).
 * When the value is selected by the user, the #value is placed in the field, not the value seen in the suggest popup.
 * If this is set to true and no Id is set, then the display value is used as normal.
 * This does not apply if `requiresSubmit()` is true. In this case, if it is available, the Id is always sent.
 * @return true if to place the id and not the display value in the field when selected.
 * @see #placeSelectedItemIdInField
 * @see #requiresSubmit
 * @see SearchSuggestItem
 */
public boolean placeSelectedItemIdInField()
{
    return false;
}
```

The suggestion group developer has complete control of the rest of the requirements for this use case:

- In the `getItems(String searchText, int maxSuggestedItems)` method, only return suggestions when the `searchText` starts with the prefix character.
- Configure the `fnd:SearchSuggestBehavior` to start the suggestion at character 2 (the `minCharCount` attribute).
- Return `SearchSuggestItems` with a different Id and text. The text will be shown in the suggestion list.
- Override `placeSelectedItemIdInField` and return true to put the Id, not the text, into the field when selected.

**Example Dynamic Suggestion Group in a Form Field**

```java
public void addTextField(ActionEvent actionEvent)
{
    FacesContext context = FacesContext.getCurrentInstance();
    Application application = context.getApplication();
```
UIComponent btn = actionEvent.getComponent();
UITComponent pfl = PatternsUtil.getParentByTypeAndId(btn, RichPanelFormLayout.class, "suggestPanel");

int numChildren = pfl.getChildren().size();
RichInputText it = (RichInputText)
application.createComponent(RichInputText.COMPONENT_TYPE);
it.setId("it" + numChildren);
ValueExpression value = createValueExpression("#{pageFlowScope.DynamicSuggestInFormBean.it" + numChildren + "}");
it.setValueExpression("value", value);
it.setLabel("Input Text " + numChildren + ":");
it.setImmediate(true);
MethodBinding vcl = createMethodBinding("#{pageFlowScope.DynamicSuggestInFormBean.valueChanged}");
it.setValueChangeListener(vcl);

SearchSuggestBehaviorBean ssb = SearchSuggestBehaviorFactory.createSearchSuggestBehaviorBean();
ssb.setSuggestGroup1(ssb.createValueExpression("oracle.apps.fnd.searchSuggest.Prefixe
dSearchSuggestGroup");
ssb.setContextCode1(ssb.createValueExpression("ContextCode" + numChildren));
ssb.setObjectType1(ssb.createValueExpression("ObjectType" + numChildren));
ssb.setTopSuggestions(ssb.createValueExpression("on"));
ssb.setMinCharCount(new ConstantExpression(2));
ssb.applyTo(it);
pfl.getChildren().add(it);

Example Dynamic Suggestion Group in a Table Field

public void generateContent(ActionEvent e)
{
    _contentGenerated = true;
    for (int i = 0; i < _numTextFields; i++)
    {
        FacesContext context = FacesContext.getCurrentInstance();
        Application application = context.getApplication();
        UIViewRoot uiRoot = context.getViewRoot();

        RichColumn col = (RichColumn)PatternsUtil.findComponentByTypeAndId(uiRoot, RichColumn.class, "c" + i);
        RichInputText it = (RichInputText)
        application.createComponent(RichInputText.COMPONENT_TYPE);
        it.setId("it" + i);
        ValueExpression value = createValueExpression("#{row.it" + i + "}");
        it.setValueExpression("value", value);

        SearchSuggestBehaviorBean ssb = SearchSuggestBehaviorFactory.createSearchSuggestBehaviorBean();
        ssb.setSuggestGroup1(ssb.createValueExpression("oracle.apps.fnd.searchSuggest.TableCe
llSuggestGroup");
        ssb.setContextCode1(ssb.createValueExpression("" + i));
        ssb.setObjectType1(ssb.createValueExpression("ObjectCode" + i));
        ssb.setTopSuggestions(ssb.createValueExpression("on"));
        ssb.applyTo(it);
Implementing Auto-suggest

col.getChildren().add(it);
}
}

15.8 Attachments in Global Search

This section details the design and behavior of the implementation of Attachments in Global Search.

The implementation:

- Shows attachments in the results UI using the same descriptions and tooltips that the attachments component does.
- Allows the user to click an attachment in the results UI and have the attachment open.
- Shows keyword bolding in the attachment name (if any).
- Allows the developer to promote grandchildren attachments if desired. For instance, PO Line attachments are shown with the PO result.
- Works across attachment categories.
- Suppresses secured attachments.
- Picks up searchable view objects with changed attachments and flags for recrawling (but not grandchildren attachments).
- Works with the existing tag crawl functionality.
- Does not allow uploading or deleting of attachments directly from the search UI. This must be done from the user UI that the attachments component is on. This is because attachment requires view links to the Business view objects to which they are attached. This is not available in a search result that may be displayed anywhere in Fusion Applications. However, it is probable that clicking the search result will take the user directly to this UI, so this functionality is only a click away.

15.8.1 Crawl Functionality

Crawl is done using the FndSearchPlugin that can be used either directly, or as a base class to existing plugins.

The plugin replicates the features of the TagSearchPlugin and adds Attachment functionality, as shown in the next image. Developers still can use TagSearchPlugin, but it will not do attachments. Use the FndSearchPlugin to get
both sets of functionality (tags and attachments). The tag setup in the FndSearchPlugin is the same as it is in the TagSearchPlugin.

**Figure 15-50  Search Plugin for Attachments**

There are two arguments to determine how attachments are crawled:

- **ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS**: A comma-separated list of accessor paths to Attachment view objects.

- **ATTACHMENT_INCREMENTAL_CRAWL_ENTITY_NAME**: The name of the attachment entity used in incremental crawls to reverse lookup changed attachments.

**Attribute ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS**

[Optional] This attribute defines the attachments that will be considered as part of the crawl. Without this attribute, the default attachment behavior of ECSF will be unchanged; that is, all direct attachments of the searchable view object will be crawled, but nothing will be shown in the Search UI.

It is possible to have multiple attachment view links from a master view object, and attachments stored against detail view objects in a master-detail relation.

An accessor path is a dot-separated set of accessors to an Attachment view object. The attribute **ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS** is a comma-separated value (CSV) list of these accessor paths. For example, if GsProductAttachmentsAccessor is the view link accessor to the AttachmentVO directly under the Search view object, then this would be the accessor path to these attachments.

Similarly, if GsProductDetails is the accessor to a detail level view object that has an accessor GsProductDetailsAttachmentsAccessor to the attachments, then GsProductDetails.GsProductDetailsAttachmentsAccessor is the accessor path to these attachments.
Any number of these paths can be specified, though it is expected to be small (usually only 1).

As an example, accessors in the Master view object for this would be:

```xml
<ViewLinkAccessor
    Name="GsProductAttachmentsAccessor"
    ViewLink="oracle.apps.model.GsProductAVL"
    Type="oracle.jbo.RowIterator"
    IsUpdateable="false"/>
<ViewLinkAccessor
    Name="GsProductDetails"
    ViewLink="oracle.apps.model.GsProductToDetailsVL"
    Type="oracle.jbo.RowIterator"
    IsUpdateable="false"/>
```

and in the detail view object:

```xml
<ViewLinkAccessor
    Name="GsProductDetailsAttachmentsAccessor"
    ViewLink="oracle.apps.model.GsProductDetailsAVL"
    Type="oracle.jbo.RowIterator"
    IsUpdateable="false"/>
```

When creating master detail relations like this, do not include the accessor in the detail view object. If you do include the accessor in the detail view object, ECSF will try to follow the links from Master > Detail > Master > Detail in a recursive manner until it hits the maximum depth of 7 levels.

In such a case, you will see a crawl error similar to:

```xml
<VODocumentImpl> <assign> Deep-level view objects not supported. VO is: oracle.apps.model.GsProductDetailsVO Level: 7
```

**Attribute ATTACHMENT_INCREMENTAL_CRAWL_ENTITY_NAME**

Because adding an attachment does not change the Last_update_date of the parent view object row, there needs to be a reverse lookup mechanism used to force these additional rows onto the incremental crawl queue.

This attribute is not required. If it is not supplied, attachment additions to a view object row that is otherwise unchanged (and therefore on last_update_date change) will go un-noticed.

This attribute defines the attachment entity name that will be used when determining which searchable view object records need to be flagged for re-crawl because they have had changes to their attachments.

Note that only newly-added attachments and updated attachments (including the title) will be found for re-crawl. There is no mechanism to detect deleted attachments.

**Internal Stored Attribute FND_ATTACHMENT_METADATA**

Attachments found during the crawl will be recorded in the searchable view object in the predefined stored String attribute FND_ATTACHMENT_METADATA. This attribute needs to be defined in the searchable view object definition and flagged as a stored attribute. It should have no data in it because it will be over-written by the Applications Core preIndexProcessor at crawl time. An example of defining an attribute is shown below using a transient attribute.
What is stored in this attribute is an XML structure for all the attachments stored against a searchable object. It does not store the attachment data itself here. The attachment data is stored in the Oracle SES indexed document in an inline for making it available for text search. This example shows four attachments stored against a row:

```xml
<Attachments>
  <Attachment documentId="300100024947778" datatypeCode="FILE" title="Latte.doc" fileName="Latte.doc" />
  <Attachment documentId="300100024947776" datatypeCode="FILE" title="UIShell_dtpreview.png" fileName="UIShell_dtpreview.png" />
  <Attachment documentId="300100024881786" datatypeCode="WEB_PAGE" title="oracle" description="Oracle homepage" fileName="http://oracle.com" />
  <Attachment documentId="300100024881784" datatypeCode="TEXT" title="a quick note" description="a quick note" fileName="a quick note" />
</Attachments>
```

The meaning of the attributes is defined in the below table.

Having these attributes stored in the searchable view object means they are searchable by default, and the UI can use the values to quickly decode the values without costly database look-ups during the rendering of the result.
Table 15-16  Attachment Attributes

<table>
<thead>
<tr>
<th>datatype</th>
<th>Code</th>
<th>Document ID</th>
<th>Title</th>
<th>Description</th>
<th>File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE</td>
<td>Content server documentId</td>
<td>nvl(title if available, otherwise fileName)</td>
<td>description</td>
<td>fileName</td>
<td></td>
</tr>
<tr>
<td>WEB_PAGE</td>
<td>documentId</td>
<td>nvl(title if available, otherwise URL)</td>
<td>description</td>
<td>URL</td>
<td></td>
</tr>
<tr>
<td>TEXT</td>
<td>documentId</td>
<td>nvl(title if available, otherwise fileName)</td>
<td>description</td>
<td>fileName</td>
<td></td>
</tr>
<tr>
<td>TMURL</td>
<td>Not supported and there will be no attributes stored for it in SES.</td>
<td>nvl(title if available, otherwise URI)</td>
<td>description</td>
<td>URI (not URL)</td>
<td></td>
</tr>
<tr>
<td>FOLDER</td>
<td>Not supported and there will be no attributes stored for it in SES.</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

### Mapping of AttachmentVO attributes into search metadata

**Important:** The XML is supplied without a schema. It is an internal part of Applications Core search and may change at any time without notice.

Attachments found at detail levels are pulled up to the parent level. If this is not required, do not include an accessor path to this level and these attachments will not be crawled.

Attachments in all categories are included. However, if that document entity has security enabled (no matter what the data security rules are), the attachments assigned to that document entity are removed from the indexed document and therefore are not crawled. Their details will not be in the XML.

The following types of attachments are available as links:

- **FILE**
  An attached file is the primary use case.

- **WEB_PAGE**
  A URL, such as http:www.oracle.com. The link will be placed verbatim in the results UI as an af:goLink. Note that ECSF does not crawl Web page attachments.

- **TEXT**
  Text typed in by the user. This is implemented by attachments internally as a hidden file, so is practically the same as FILE.

The following types of attachments are *not* available as links:

- **FOLDER**
  A reference to a folder in UCM. It requires use of UCM folder taskflow.

- **TMURL**
  Topology Manager URI. This is a URI offset to a web application defined in topology. This is a minor use case used in migration and is not supported by search.
Attachment documentId compared to Attached Document Id

documentId is a globally-unique number identifying an attachment. It will return the latest version of the attachment.

Attached DocumentId is a globally-unique number identifying a specific version of an attachment. It will return a specific version of the attachment.

As an example, documentId 100000000001 is for file BRD.doc. It has Attached DocumentId 100000000002 for the initial version of the file, and 100000000003 for the next version of the document.

Global Search will use the documentId and always download the latest version of the file.

15.8.2 Show Attachments

Attachments will be shown on a line below the "Other Actions" in the Search Result. That is the lowest part of a result item.

The text of the link will be the Attachment title, which generally defaults to the filename in the Attachments UI, but may be overridden by the user when the attachment is uploaded.

The tool tip of the attachment will be the attachment description entered by the user. If this is not present, the title value will be used.

Attachments will be sorted alphabetically.

All information is available in the stored attribute of the Search view object to render attachment links in the UI with no additional lookup work, and therefore there is no significant performance overhead.

This image shows documents attached to a search result and the tooltip.

Figure 15-52 Documents Attached to a Search Result

15.8.3 Open Attachments

Clicking an attachment link, shown in this figure, will open the content for the user. The browser settings should determine how this is done and should be in line with what the Attachment component does.
For example, clicking a JPG file attachment link usually will open it directly in a browser tab, while clicking a .doc file link usually will open it in Microsoft Word.

15.8.4 Implement the Attachment Plugin

There are two cases to consider:

- The searchable view object has no plugin currently configured: Simply use the Applications Core plugin.
- The searchable view object has a plugin already: Set up the existing plugin to inherit the Applications Core plugin.

15.8.4.1 Use the Applications Core Plugin

To use the existing Applications Core plugin, follow these steps:

1. In the ECSF Search view object design time, add a Search Plugin to the Applications Core class `oracle.apps.fnd.applcore.search.plugin.FndSearchPlugin`.

2. Configure attachments that will be crawled.

   Add a parameter with a comma-separated list of accessor paths with key `ATTACHMENT_VIEW_LINK_ACCESSOR_PATHS`.

3. Configure searchable view object incremental crawl detection of searchable view objects with new attachments.

   Optionally, add an attribute with key `INCREMENTAL_CRAWL_ATTACHMENT_ENTITY_NAME` and value of the Attachment Entity Name (the value you enter in the Attachment View Link wizard, such as `GS_PRODUCTS`).

   This will add searchable view objects to the crawl list when new attachments are added. This is useful as the searchable view object last_update_date value is not updated when an attachment is added, and the document will not be detected as needing a re-crawl. This will flag the individual searchable view object row to be recrawled. Note that it is not possible to detect changed attachments this way at the detail level (for example a purchase order line's attachments), because the reverse
lookup would obtain the primary key of the line item and not the searchable view object.

**15.8.4.2 Enhance Existing Plugin**

If you have your own plugin, extend your plugin using the following steps:

1. Extend the Applications Core plugin and call super() on the methods that implement attachment functionality. Use the same parameters to the plugin as described above.

   ```java
   public class AppsSearchPlugin
       extends FndSearchPlugin
       implements PreIndexProcessor,
                   ChangeListener
   {
       /**
        * Hook into the pre index process of the crawl so we can annotate the SVO
        * with apps specific information such as tags and attachment metadata.
        * @param ctx Search Context.
        * @param docs Documents to iterate and find tag children for.
        */
       public void preIndexProcess(SearchContext ctx,
                                   List<IndexableDocument> docs)
       {
           super.preIndexProcess(ctx, docs);
           // custom apps functionality ...
       }

       /**
        * Get the change list for crawling.
        * @param ctx Search Context.
        * @param changeType the type of the change requested. Must be one of following
        * <ul>
        * <li>ChangeListener.UPDATE<li>
        * <li>ChangeListener.INSERT<li>
        * <li>ChangeListener.DELETE<li>
        * </ul>
        * @return an iterator of a list of primaryKeys. Returns an empty iterator if
        * nothing changed.
        */
       public Iterator getChangeList(SearchContext ctx, String changeType)
       {
           Iterator ret = super.getChangeList(ctx, changeType);
           // custom apps functionality ...
           return ret;
       }
   }
   ```

2. Add the transient stored attribute FND_ATTACHMENT_METADATA.

   Add a transient String attribute to the searchable view object named FND_ATTACHMENT_METADATA to store Applications Core attribute metadata. Flag this attribute as stored in the searchable view object definition.

**15.9 Support Global Search Alternate Words for the Cloud**

To support Cloud customers, a Fusion Applications user interface allows upload and download of alternate search words to Oracle Secure Enterprise Search.
Oracle SES is the standalone database and Oracle WebLogic Server applications server used for search. It provides a store of alternate words and web service endpoints for searching and administration.

**Overview**

A new taskflow provides maintenance of Oracle SES alternate words.

It uses APIs to determine the Oracle SES Administration service endpoint, username and password, and uses the Oracle SES web service stubs available in the Oracle Enterprise Crawl and Search Framework shared library.

The setup taskflow is available in the `GlobalSearch.jws` application.

FndSetup will host the taskflow, as it does for all setup flows. It already has the "ECSF Runtime Server" library in the `weblogic-application.xml` file:

```xml
<library-ref>
  <library-name>oracle.ecsf</library-name>
</library-ref>
```

The taskflow will talk to Oracle SES directly, instead of to ECSF search that federates through search servers that talk to Oracle SES. There is no need for federation because there is only one Oracle SES for Fusion Applications.

The setup flow dialog appears similar to this example:

**Figure 15-54   Example of the Alternate Words Maintenance Taskflow Dialog**

<table>
<thead>
<tr>
<th>Welcome</th>
<th>Maintain SES Alternate Words x</th>
</tr>
</thead>
</table>

**Manage Alternate Words**

| Filter: | | |
|---------| | |

| Actions | View | | | |
|---------|------| | | |

<table>
<thead>
<tr>
<th>User Input Keyword</th>
<th>Alternate Keyword</th>
<th>Automatically Search Both</th>
</tr>
</thead>
<tbody>
<tr>
<td>bea</td>
<td>oracle</td>
<td>✓</td>
</tr>
<tr>
<td>cloud</td>
<td>oracle</td>
<td>✓</td>
</tr>
<tr>
<td>database</td>
<td>oracle</td>
<td>✓</td>
</tr>
<tr>
<td>oracle</td>
<td>oracle</td>
<td>✓</td>
</tr>
</tbody>
</table>

The taskflow has one parameter:

<table>
<thead>
<tr>
<th>Name</th>
<th>Optional</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pageTitle</td>
<td>Yes</td>
<td>Title to be shown at the top of the page. The default is &quot;Manage Alternate Words&quot;</td>
</tr>
</tbody>
</table>
The dialog uses these buttons:

- **Add** - Add a new row above the selected one (or row 0 if none are selected).
- **Duplicate** - Duplicate the existing row.
- **Edit** - Edit the current row (all fields).
- **Delete** - Delete the current row.

Note that a row is identified by the "User Input Keyword" and "Alternate Keyword."
A user can edit any field on the row, including the two key fields. This will delete the old record and add the new one.

### 15.9.1 Look Up the SES Endpoint (ECSF APIs)

ECSF/SES does not use the connections architecture (connections.xml) to determine SES endpoints, which are saved in ECSF tables.

This code, which mimics ECSF directly, is used to look up the endpoint. Because there is only one SES per Fusion Applications instance, the first configured endpoint will be used.

```java
private MetaEngineInstance getActiveLocalInstance()
{
    MetaEngineInstance ret = null;
    List<MetaEngineInstance> allECSFComponents = MetaDataManager.getEngineInstances(3);
    for (MetaEngineInstance localInstance : allECSFComponents)
    {
        Map params = localInstance.getParameters();
        String sesAdminUsername = (String)params.get("SES_ADMIN_USERNAME");
        String sesAdminService = (String)params.get("SES_ADMIN_SERVICE");
        String isActive = (String)params.get("IS_ACTIVE");
        if (sesAdminUsername != null && sesAdminUsername.indexOf("[CHANGE_ME]") == -1
            && sesAdminService != null && sesAdminService.startsWith("http"))
        {
            ret = localInstance;
            break;
        }
    }
    return ret;
}
```

The endpoint, username and password will be used to create the Administration port connection (see below).

If no endpoint can be found, an error will be shown - see the error messages section below for details on the error messages that may be shown.
15.9.2 SES Web Service Calls

There are four web service calls used by Global Search Alternate Words for the Cloud.

Administration Port Connection

```java
private AdminPortType getStatefulWebServiceClient(
    String webServiceURL,
    String userName,
    String password) throws Exception
{
    AdminService adminService = new AdminService(
        new URL( webServiceURL ),
        new QName(
            "http://search.oracle.com/Admin",
            "AdminService"
        )
    )
    
    AdminPortType adminPort = adminService.getAdmin();

    // Tell client proxy to maintain HTTP session for stateful behavior
    ((BindingProvider)adminPort).getRequestContext().put(
        BindingProvider.SESSION_MAINTAIN_PROPERTY, true
    )

    // Create credentials argument
    Credentials credentials = new Credentials();
    credentials.setUserName( userName );
    credentials.setPassword( password );

    adminPort.login( credentials, getLanguage() );

    return adminPort;
}
```

Alternate Word Retrieval

This example shows how to retrieve an alternate word.

```java
private List<AlternateWord> getAltWords(AdminPortType adminPort) throws Exception
{
    ObjectOutput oo = adminPort.exportAll(
        "altWord",
        null,
        null, // "password",
        null, // credentials,
        null,
```

Figure 15-55  Endpoint Not Found Message
Alternate Word Deletion

This example shows how to delete an alternate word.

```java
private void removeAltWords(AdminPortType adminPort,
                            List<AlternateWord> altWords)
    throws Exception {
    List<ObjectKey> objectKeys = new ArrayList<ObjectKey>();
    for (AlternateWord word : altWords) {
        // Need to use the original key values in case the user has updated, then
        // deleted the row. Note that do not need to worry about new rows as these
        // will never be in the deleted list.
        objectKeys.add(createKeyPairs(word.getOrigKeyword(), word.getOrigAltWord()));
    }

    List<OperationControl> ops = toOperationControlList("IGNORE_NOT_FOUND", "true");
    adminPort.deleteList("altWord", objectKeys, null, // credentials,
                        ops, getLanguage());
}
```

Alternate Word Insertion

This example shows how to insert an alternate word.

```java
private void createAltWords(AdminPortType adminPort,
                            List<AlternateWord> altWords)
    throws Exception {
    StringBuilder sb = new StringBuilder(
    "<?xml version="1.0" encoding="UTF-8"?>
    <!DOCTYPE search:config PUBLIC "http://xmlns.oracle.com/search/search.dtd">
    " +
    "<search:altWords>");
    for (AlternateWord word : altWords) {
        sb.append(toAltWordXML(word.getKeyword(), word.getAltWord(),
                                word.isAutoExpand()));
    }
    sb.append("</search:altWords>" +
              "</search:config>");

    List<OperationControl> ops = toOperationControlList("DUPE_METHOD", "overwrite");
    adminPort.createAll("altWord", sb.toString(), null, //"password",
                        null, // credentials,
                        ops, getLanguage());
}
```
null, // credentials,
null,
ops,
getLanguage()
);}

15.9.3 Alternate Words Error Messages

This table shows error messages that may be shown to the user for setup or web service communications issues.

<table>
<thead>
<tr>
<th>Message</th>
<th>Where Shown</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>Secure Enterprise Search is not configured in this environment.</td>
<td>When retrieving the list of alternate words when the taskflow starts.</td>
<td>The ECSF metadata that configures SES is not available or is not complete. The SES web service endpoint cannot be determined. It is likely Global Search is also not available.</td>
</tr>
<tr>
<td>Secure Enterprise Search is not responding.</td>
<td>When retrieving the list of alternate words when the taskflow starts, or saving after the &quot;Save and Close&quot; button is pressed.</td>
<td>The SES endpoint cannot be contacted.</td>
</tr>
<tr>
<td>Cannot retrieve the list of Alternate Words from Secure Enterprise Search.</td>
<td>When retrieving the list of alternate words when the taskflow starts</td>
<td>The SES endpoint cannot be contacted, but the list of alternate words cannot be retrieved from it.</td>
</tr>
<tr>
<td>The following Alternate Words already exist for the User Keyword. Delete the duplicates:</td>
<td>When saving alternate words.</td>
<td>Within the list of alternate words there are duplicate keyword/altword pairs.</td>
</tr>
</tbody>
</table>

15.10 Implement List Search

List Search, sometimes known as "local search," is for implementing search functions on a single data source (also known as a View Object).

It comprises a keyword search box, autosuggest recent items and saved searches, and a collapsible Filters panel that uses ADF Query. Use the full List Search component when users need keyword search augmented by fielded search and saved searches. This image shows an overview of List Search.
A new declarative component supports List Search. It is available from the Applications Core component gallery and from the Data Control palette for drag-and-drop of View Criteria to the page.

A running List Search would resemble this image.
Figure 15-57  List Search Declarative Component with Suggestions

This image shows:

- The omnibox is labelled "Search" with shadow text.
- A set of suggestions (note the UI is pre-Rel 10 so has changed a bit),
- Recent items from the existing recentitems suggest group,
- Three saved searches - "All People", "Analyst" and "ElizabethDirects."

15.10.1 How to Implement List Search at Design Time

The developer develops View Criteria using normal BC DT. The default BC View Object View Criteria UI in JDeveloper can be used, although many options need to be disabled or simplified.

View Criteria

There should be one View Criteria that will be later designated the "Default Saved Search." This saved search is run when the `fnd:listSearch` component is first run. It is important that this criteria is well tuned and runs quickly because it directly affects the initial rendering of the `fnd:listSearch` component.

There should be another saved search that later will be designated the "Keyword Saved Search." This saved search is used whenever the user enters keywords and clicks Search. It must have a Text field of at least 30 characters in width that is tuned to provide fast query responses (30 characters is the width of the search field). If the field is shorter than this, the keywords will be truncated.

Developers should not use only one View Criteria to perform as both the default and keyword saved searches.

Once generated, these saved searches will display in the JDeveloper Data Controls Palette as "Named Criteria," also known to `af:query` as system saved searches.

The development of these two View Criteria is mandatory before the `fnd:listSearch` component can be configured.

An example Keyword Saved Search View Criteria is shown below using the BC View Object UI in JDeveloper.
Click the Criteria Definition tab.
The **Criteria Name** (not the Display Name) is used as the `keywordSavedSearch` attribute later in the `fnd:listSearch` component.

Click the Criteria UI Hints tab, then the Custom Operators tab.
Figure 15-60  Custom Operators Tab

**Component**

Developers will drag and drop the VO View Criteria they wish to be the Design Time default saved search (Data First DT). The developer will drag and drop the listview component from the Component Palette (Component First DT).

The user will be able to change the default saved search later by personalizing the saved searches and selecting another default, but this will be the initial default for all users.

The Create List Search wizard starts and displays the Specify data source and criteria dialog.

Turn off Custom Operators.
When dragged-and-dropped from the Data Controls Palette, this is the View Criteria that is dropped.

The user must select a default saved search to continue. The "All Queriable Attributes" saved search produced by ADF cannot be selected.

Click Next to specify the Keyword Saved Search.
Figure 15-62  Keyword Saved Search

Select the keyword saved search from the list of all View Criteria, and the keyword field from this View Criteria.

The developer designated saved search is the view criteria previously selected. It can be changed by the user at runtime.

Default Saved Search:  DefaultCriteria

Select the criteria to be used as the keyword saved search from the list of named view criteria, and the field that will be used to query against.

Keyword Saved Search:  DefaultCriteria
Keyword Field:  Ename

Select the keyword saved search from the list of all View Criteria, and the keyword field from this View Criteria.

The "All Queriable Attributes" criteria produced by ADF will not be available for selection.

Click Next to specify the Search Field Properties.
Set the Search Field Label and Search Field Placeholder.

Select Suggestion Groups and their contextCode and objectTypes. Three suggestion groups will be available:

- **Search Terms** - A new suggest group for keywords, and a contextCode/objectType to save these under.

- The contextCode and objectType will allow the keywords to be specific to the list search view object.

- **Recent items** - The existing recent items suggest group with a contextCode/objectType.

- **List Saved Searches** - The list search names, this will be the same values seen in the af:query saved search drop down.
Click **Next** to specify the type of results.

**Figure 15-64  Select Results Type**

The developer can select from a number of result types:

- **Card and List View** - This will invoke the Card and List Layout wizard.
- **Applications Table** - This will invoke the Applications Table wizard.
- **ADF List View - panelFormLayout** - This will allow results in a `listView` using a `panelFormLayout` to format the results in the List View row.
- **ADF List View - Grid Templates** - Allow the use of the Quick Grid wizard to configure data in a `listView`.
- **ADF List View - Detailed Grid** - Allow the use of the Detail Grid wizard to configure data in a `listView`.
- **ADF Table** - Use an `af:table` as the results.

This selection determines the rest of the steps except for the final (summary) step.

**Results Card and Listview**

This image shows the first of the four wizard dialogs used when the Card and Listview option was selected in the previous dialog.

**Applications Table**

If Applications Table was selected, another three wizard dialogs are displayed. See [Adding Applications Table Components Using the Applications Table Wizard](#) for
descriptions of the Set Row Selection and Layout Columns, the Select the table CRUD patterns, and the Set Table Features dialogs.

After these dialogs, click Next to display the Summary. This example shows the Summary information for the Card and Listview selection. The information for the Application Table selection is almost identical.

Click Finish to create the code, or Back to make changes.

These images show examples of the code that is created.
Implement List Search

This chapter discusses additional functions, such as the Navigate API and how to implement the Home Page UI, that are included in the UI Shell page template used to build web pages.

This chapter includes the following sections:

- Introducing the Navigate API
- Warning of Pending Changes in the UI Shell
- Implementing the Oracle Fusion Home Page UI
- Using the Single Object Context Workarea
- Implementing the Third-Party Component Area
- Developing an Activity Guide Client Application with the UI Shell
- Implementing Touch Device Support in the UI Shell
- Implementing the Translation Editor
- About the Create Page Wizard
- Troubleshooting UI Shell Issues

For more information about the features, see:

- Getting Started with Your Web Interface
- Implementing the UI Shell
- Implementing Search Functions in the UI Shell
- Implementing UIs in JDeveloper with Application Tables_Trees and Tree Tables
- Implementing Applications Panels_Master-Detail_Hover_ and Dialog Details

16.1 Introducing the Navigate API

You can create a link in the task flow to open a different UI Shell page. Because navigation can occur across different web applications, a single consistent API performs browser redirect. See Table 16-1. This API is exposed as the FndUIShellController.navigate Data Control method.
Note:
When opening a new window, whenever possible, you should use the Navigate API instead of using the ADF Controller sub-flow calls. This is because the UI Shell has no information about sub flows. For instance, if you perform a search that returns clickable results and use sub flows to display the results, and if you then choose to save the page to your Favorites, the search page is saved; not the results page you want. If you use the Navigate API, however, the UI Shell knows about the opened results page and saving the page to your Favorites works as you expect.

16.1.1 How to Use the Navigate API Data Control Method

Drag and drop the Data Control method on page fragments to create links to start navigation.

1. Expand the Data Controls and select the navigate item, as shown in Figure 16-1.

![Figure 16-1 Selecting navigate from Data Controls](image)

2. Drag navigate and drop it onto the page fragment. When you do, the Applications Context menu shown in Figure 16-2 is displayed so you can choose one of the options.

![Figure 16-2 Selecting a Navigate Option from the Applications Context Menu](image)

Example 16-1 Navigating from One Work Space to Another

```java
/**
 * Navigate from one work space to another. If the current view id is the
 * same as the viewId parameter, and if navTaskFlow is null, the current page
 * will be refreshed. If the current view id is the same as the viewId
 * parameter and if navTaskFlowId is not null, the current page will not
 * be refreshed. The Navigate API will delegate to openMainTask API to open the
 */
```
* task flow in the main area. This can be overridden by passing in *
* forcePageRefresh=true in pageParametersList to force the page refresh so *
* that openMainTask would not be used.
*
* @param viewId viewId of the target workspace
* @param webApp Deployed Module Name of the target workspace.
*   It only must be set when the target workspace is in a different *
*   deployed module than the origin workspace. When this is null, it means *
*   the target workspace is in the same deployed module of the origin *
*   workspace. The webApp attribute is used to look up the host and port of *
*   the associated Workarea or Dashboard from the ASK deployment *
*   tables. These tables are populated at deployment time through *
*   Oracle Fusion Functional Setup Manager tasks.
* @param pageParametersList Parameters list for the page. This is a semicolon *
*   delimited String of name value pairs. For example, *
*   "param1=value1;param2=value2"
*   If the Expression Language expression evaluates to an Object, *
*   toString value of that Object will be passed as the value of *
*   the parameter.
*   When forcePageRefresh=true is added to the pageParametersList, *
*   the current page will be refreshed even if navTaskFlowId *
*   is not null and current view id is the same as viewId *
*   parameter value.
* @param navTaskFlowId Id of the taskFlow to open in the target workspace
* @param navTaskKeyList Key list to pass in to the task flow to open in the *
*   target workspace. This is a semicolon delimited *
*   keys or key-value pairs. For example, *
*   "key1;key2=value2"
* @param navTaskParametersList Parameters list to pass in to the task flow to open *
*   in the target workspace. This is a semicolon delimited String *
*   of name value pairs. For example, *
*   "param1=value1;param2=value2."
*   When loadDependentFlow=true is added to the *
*   navTaskParametersList, the task flow specified in *
*   navTaskFlowId will be loaded as dependent flow.
* @param navTaskLabel Label for the task flow to open in the target workspace.
* @param methodParameters Construct FndMethodParameters object for setting the *
*   width of the contextual area, and/or setting the disclosed *
*   state of the contextual area.
* @throws IOException
*/

public FndMethodParameters navigate(java.lang.String viewId,
        java.lang.String webApp,
        java.lang.String pageParametersList,
        java.lang.String navTaskFlowId,
        java.lang.String navTaskKeyList,
        java.lang.String navTaskParametersList,
        java.lang.String navTaskLabel,
        FndMethodParameters methodParameters)
        throws java.io.IOException

Example 16-2 Setting contextualAreaWidth and contextualAreaCollapsed Parameters

FndMethodParameters methodParameters = new FndMethodParameters();
methodParameters.setContextualAreaCollapsed(Boolean.FALSE);
methodParameters.setContextualAreaWidth(200);

You can specify a task flow to load on the target page. Page level parameters also can be specified.
### Navigate API Parameters

<table>
<thead>
<tr>
<th>Navigate API Parameter</th>
<th>Attribute Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>viewId</td>
<td>navigateViewId</td>
</tr>
<tr>
<td>webApp</td>
<td>Attribute used to look up the host and port of the associated Workarea or Dashboard from the Oracle Fusion Applications Functional Core (ASK) deployment tables. These tables are populated at deployment time through Oracle Fusion Functional Setup Manager tasks. You need to pass the deployed module name to the webApp parameter.</td>
</tr>
<tr>
<td>pageParametersList</td>
<td>navigateParamsList</td>
</tr>
<tr>
<td>navTaskFlowId</td>
<td>Equates to the openMainTask taskFlowId parameter. This is the Id of the task flow to be loaded. The task flow Id is a concatenation of the file location for the task flow definition, and the task flow name. For example: /WEB-INF/MyTaskFlow.xml#MyTaskFlow</td>
</tr>
<tr>
<td>navTaskKeyList</td>
<td>Equates to the openMainTask keyList parameter. Important: navTaskKeyList is used with the task flow Id to identify the target tab in the main area. As such, navTaskKeyList is applicable only in dynamic tabs mode, and is ignored in no-tabs mode. navTaskKeyList provides a way to identify a task flow instance. When reuseInstance is true, use the specified navTaskKeyList in addition to the task flow Id to identify the target tab. The navTaskKeyList parameter has been implemented for the following FndUIShellController data control methods: openMainTask discloseRegionalTask collapseRegionalTask navigate openSubTask In dynamic tabs mode, when looking for a match of an existing tab, these APIs will first look for any instances of the task flow that is already open, which has the same task flow Id as the one passed into them as the parameter. In addition, it will compare the navTaskKeyList values, such that the existing task flow will be picked only if its navTaskKeyList values match the ones specified in the navTaskKeyList parameter. It does not matter if the task flow parameters are the same or different. If the keyList is not set in the menu metadata, you can reuse a tab only if you pass in a null keyList.</td>
</tr>
</tbody>
</table>
Table 16-1  (Cont.) Navigate API Parameters

<table>
<thead>
<tr>
<th>Navigate API Parameter</th>
<th>Attribute Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>navTaskParametersList</td>
<td>You can load the task flow specified in the navTaskFlowId parameter of the Navigate API as a dependent flow if the destination page is in no-tab mode by adding a name-value pair of &quot;loadDependentFlow=true&quot; to navTaskParametersList. For example: &quot;customerId=123;loadDependentFlow=true&quot;</td>
</tr>
<tr>
<td>navTaskLabel</td>
<td>Equates to the openMainTask label parameter. Note: When passing parameters, do not leave the navTaskLabel field null. This is the label that would appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites, or when the system tracks the Recent Items.</td>
</tr>
</tbody>
</table>

Certain parameters, summarized in Table 16-2, can be passed using the Navigate API's argument list.

Table 16-2  Parameters Passed Using Navigate API Arguments

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Passed Using</th>
<th>Description</th>
</tr>
</thead>
</table>
| forcePageRefresh     | pageParametersList   | Default: false
The Navigate API is used to navigate from one work space to another. If the current view Id is the same as the viewId parameter, and if navTaskFlow is null, the current page will be refreshed. If the current view Id is the same as the viewId parameter, and if navTaskFlowId is not null, the current page will not be refreshed, and the Navigate API will delegate to the openMainTask API to open the task flow in the main area. This can be overridden by passing in forcePageRefresh=true in pageParametersList to force the page refresh so that openMainTask would not be used.
Example:
pageParametersList = "forcePageRefresh=true;param2=value2"
Details:
pageParametersList is a semicolon delimited string of name-value pairs. |

<td></td>
<td></td>
<td>FndMethodParameters methodParameters = new</td>
</tr>
<tr>
<td></td>
<td></td>
<td>FndMethodParameters();</td>
</tr>
<tr>
<td></td>
<td></td>
<td>methodParameters.setContextCode(&quot;CRM&quot;);</td>
</tr>
</tbody>
</table>
Table 16-2  (Cont.) Parameters Passed Using Navigate API Arguments

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Passed Using</th>
<th>Description</th>
</tr>
</thead>
</table>
| objectType     | methodParameters | This value should be passed only when the navTaskFlowId input parameter has a value.  
Example: 
FndMethodParameters methodParameters = new FndMethodParameters();
methodParameters.setContextCode("CRM");
methodParameters.setObjectType("Opportunity"); |
| objectName     | methodParameters | This value should be passed only when the navTaskFlowId input parameter has a value.  
Example: 
FndMethodParameters methodParameters = new FndMethodParameters();
methodParameters.setContextCode("CRM");
methodParameters.setObjectType("Opportunity");
methodParameters.setObjectName("Opportunity 123"); |

Note:
When passing parameters, do not leave the label field null. This is the label that would appear in the tab header when in a tabs page. Even if you are in a no-tabs page (see Supporting No-Tab Work Areas), do not leave it blank because this label will be used in other ways, such as Add to Favorites, or when the system tracks the Recent Items.

The signature and Javadoc of the method are shown in Example 16-1.
The main navigation is driven by two attributes: viewId and webApp.

• webApp determines which web application to open.
• viewId determines the view activity within the target web application.

pageParametersList defines custom URL parameters that you can define.
The three parameters navTaskFlowId, navTaskParametersList, and navTaskLabel, provide support for loading a task flow on the target page, in addition to the default Main Tasks of the target page.

FndMethodParameters are placed as a future extension mechanism. The parameters that can be set through FndMethodParameters are: contextualAreaWidth and contextualAreaCollapsed. Example 16-2 shows how to set up these two parameters.
Note:

- The task flow to be opened in the target Work Area does not need to be pre-registered as a `defaultMain` or `dynamicMain` task for that page. The TaskFlow Id, parameters for it, and the label are all explicitly passed to the target page, and the target page does not perform any validation.

- The `webApp` value that is passed into the Navigate API is used to look up the host and port of the associated WorkArea or Dashboard from the Oracle Fusion Applications Functional Core (ASK) deployment tables. These tables are populated at deployment time through Functional Setup Manager tasks.

- Because the Navigate API is based on URL redirect, only string representations of the parameter values can be passed to the target page. It is not possible to pass an object as a parameter value. For example, a Java map that is set as a `customObject` on `FndMethodParameters` cannot be passed as a parameter (this is only supported in `openMainTask` API).

- When navigating to the current page with the `forcePageRefresh=true` option using this API, the ADF Controller state of the source page is not cleaned up.

16.1.2 How to Implement Navigation Across Web Applications

Navigating across web applications requires the `webApp` parameter in the menu meta data. For this parameter to work properly, the ApplicationDB and the AppMasterDB connections must be set. The `webApp` parameter must be specified for each parent node in the menu meta data. Child nodes inherit the value of this parameter from the parent node if not specified. The Navigate API is also modified to add the `webApp` parameter. Similarly, when using the `openSubTask` API, you must specify the `webApp` parameter correctly. There are no design or compile time checks that can catch an invalid value for the `webApp` parameter. It will throw null pointer exceptions at runtime only.

Note that you need to pass the `DEPLOYED_MODULE_NAME` in the ASK_DEPLOYED_MODULES table as the `webApp` parameter. The `DEPLOYED_MODULE_NAME`, by standard, should be the same as the context root of the application you are trying to open.

16.2 Warning of Pending Changes in the UI Shell

When there are pending changes in the UI Shell main area, and the user is leaving the page, or is refreshing the tab or task flow, or is closing the tab, the UI Shell will provide a modal confirmation dialog to the user. If confirmed, the operation will be allowed to proceed. Otherwise, the user will remain on the original page or tab.

Cases where pending changes are checked in the UI Shell main area include:

- TaskList links in regional area relaunch a task flow in the main area (with `reuseInstance=true` and either `forceRefresh=true` or with different parameters).

- Closing a tab by clicking the Close icon on the tab.
• Closing the currently focused tab by using closeMainTask.
• Relaunching a task flow by using openMainTask (with reuseInstance=true and either forceRefresh=true or with different parameters).
• Relaunching a task flow using navigate (navigating within the same web application and viewId).
• Opening a different work area or web application using navigate.

Search Panel and Warning of Pending Changes

Search is treated as a special case and no warning for pending changes is shown when a user enters some data in a query panel provided by the Oracle Application Development Framework. But, from the search results page, drilling down to a sub flow and making the flow dirty marks the sub flow as a candidate for warn about changes.

16.2.1 How to Implement Warning of Pending Changes

To implement warning of pending changes, developers need to follow these steps.

• All the main taskflows that render in MainArea should have the data-control-scope set to isolated.

```xml
<data-control-scope id="dc">
  <isolated/>
</data-control-scope>
```

• Make changes to the main area.

Note that inner taskflows and regions inside the main flow can have the data-control-scope set to shared.

Other than tasklist, if developers are using Data Control APIs, such as openMainTask, closeMainTask or navigate, to relaunch or close a flow in the MainArea, they should add the clientListener to post the changes. Adding the clientListener on a commandButton that is bound to closeMainTask to post pending changes before the currently focused tab/flow is closed is shown in Example 16-3.

When a command link/button invokes Data Control APIs programmatically, developers should add a client listener on the command link/button, as shown in Example 16-4.

In addition to adding the clientListener, when Data Control APIs are executed from within the MainArea, developers must add the methodAction shown in Example 16-5 to their main page fragment's pageDef whose taskflow is attached to the tab in MainArea.

The Data Control API shown in Example 16-5 lets you check for data dirty from within the child region and identify any pending changes in the child region.

After adding above API to the main page fragment's pageDef, developers should let the UI Shell know about that by sending the parameter "fndCheckDataDirty=true" in the parametersList or navTaskParametersList.

Example 16-3 Adding the clientListener on a commandButton

```af:commandButton actionListener="#{bindings.closeMainTask.execute}"
text="closeMainTask- with - CL"
```
Example 16-4   Adding a client listener when a command link/button invokes Data Control APIs programmatically

<af:commandButton text="Calling datacontrol api programmatically"
    binding="#{backingBeanScope.backing_Navigateviaprogrammatically.cb1}"
    id="cb1" action="go">
    <af:clientListener method="queueActionEventOnMainArea" type="action"/>
</af:commandButton>

Example 16-5   Adding the checkDataDirty methodAction

<methodAction id="checkDataDirty"
    InstanceName="FndUIShellController.dataProvider"
    DataControl="FndUIShellController" RequiresUpdateModel="true"
    Action="invokeMethod" MethodName="checkDataDirty"
    IsViewObjectMethod="false"
    ReturnName="FndUIShellController.methodResults.checkDataDirty_FndUIShellController_dataProvider_checkDataDirty_result"/>

16.2.2 How to Suppress Warning of Pending Changes

Developers can suppress warning of pending changes for a particular flow by sending the parameter "fndWarnChanges=false" to the parametersList or navTaskParametersList, as shown in Example 16-6.

Example 16-6   Suppressing warning of pending changes for a flow

<methodAction id="openMainTask" RequiresUpdateModel="true"
    Action="invokeMethod" MethodName="openMainTask"
    IsViewObjectMethod="false" DataControl="FndUIShellController"
    InstanceName="FndUIShellController.dataProvider"
    ReturnName="FndUIShellController.methodResults.openMainTask_FndUIShellController_dataProvider_openMainTask_result">
    <NamedData NDName="taskFlowId" NDValue="/WEB-INF/task-flow-definition.xml#task-flow-definition" NDType="java.lang.String"/>
    <NamedData NDName="keyList" NDType="java.lang.String"/>
    <NamedData NDName="parametersList" NDValue="fndWarnChanges=false" NDType="java.lang.String"/>
    <NamedData NDName="label" NDValue="Suppress Warn About Msg" NDType="java.lang.String"/>
    <NamedData NDName="reuseInstance" NDValue="true" NDType="java.lang.Boolean"/>
    <NamedData NDName="forceRefresh" NDValue="true" NDType="java.lang.Boolean"/>
    <NamedData NDName="loadDependentFlow" NDType="java.lang.Boolean"/>
    <NamedData NDName="methodParameters" NDType="oracle.apps.fnd.applicore.patterns.uishell.ui.bean.FndMethodParameters"/>
</methodAction>

16.3 Implementing the Oracle Fusion Home Page UI

The Oracle Fusion Home Page UI consists of a series of JSPX pages, each of which provides product- or role-specific content, that are visually tied together using a tabbed navigation interface.
16.3.1 Supported Behavior

The following key requirements are supported by the Oracle Fusion UI Shell:

- To conform to Oracle Fusion Applications modularity requirements, the Oracle Fusion Home provides a common entry point across multiple Java EE web applications. A given home page can be hosted on any one of these distinct Java EE web applications. A tab click on a given home page therefore must issue a request for another home page that may be hosted on a different web application. When the new page is displayed, its tab must be visually selected.

- Each home page should display content that includes navigation means to resources that may be hosted on a different web application. For example, a command navigation link on a home page may target a bounded task flow located on a different web application and designed to run on a Workarea or Dashboard page located on that web application.

- A given home page may include content from a bounded task flow (presumably displayed within an ADF region or portlet) that has command navigation links within its view activities. These links or other navigation means must work correctly on the home page. For example, on click, navigate to the correct Workarea page and launch the intended task flow.

- The Home icon in the Global Area will be disabled on all home pages.

- By default, clicking the Home icon will open the Welcome tab and, if a different tab is selected, clicking the Home icon will go back to the last tab that was selected for that session. If, however, the user navigates to any Oracle Fusion page through a direct URL navigation, such as an email that contains a link to a Workarea, the Home icon will again return to the Welcome tab. By default, the Welcome tab will be the first itemNode defined.

- A home page will display the same layout and content in the Global Area and for the page footer as other pages that extend the UI Shell page template. Unlike a Workarea page, however, the intervening content and its layout between the Global (top) and footer (bottom) sections of the page will be determined and provided by product teams.

16.3.2 How to Create a Home Page

To create a home page, follow these basic steps.

1. Create a JSPX page that extends UIShell.jspx.

2. From the JSPX page, select the <af:pageTemplate> tag. On the property inspector, set the isHomePage attribute to true. Note that when isHomePage is set to true, the Regional, Local and Contextual Areas of the UI Shell will not be rendered.

3. Add content to the HomePageContent facet, following the ADF Layout Basics guideline for laying out the components.
4. Drop the JSPX to adfc-config.xml.

5. Repeat Steps 1 through 4 for all home page JSPX pages.

6. Create the Home Page menu. See Working with the Global Menu Model.

7. When running a home page JSPX, the page should look similar to Figure 16-3.

**Figure 16-3  Home Page Example**

See Global Area Standard Icons for a description of the icons.

### 16.3.3 Getting the URL

There are two APIs located in the UIShellContext class that you can use to return a URL without actually performing the navigation to the URL:

- **getURL**: getURL is the same as a navigate call, but it returns the URL as a string instead of doing the navigation. See Example 16-7.

- **getURLForCurrentTask**: getURLForCurrentTask, shown in Example 16-8, is good for getting the URL of the main area flow in focus so you could send it in an email to someone else. When clicked, it would open the correct workarea (.jspx page) and the correct flow with the correct parameters. If you did have other dynamic tabs open when you called getURLForCurrentTask, it would not open those when clicked.

**Example 16-7  Example Use of getURL**

```java
public java.lang.String getURL(     java.lang.String    viewId,
    java.lang.String    webApp,
    java.lang.String    pageParametersList,
    java.lang.String    navTaskFlowId,
    java.lang.String    navTaskKeyList,
    java.lang.String    navTaskParametersList,
    java.lang.String    navTaskLabel,
    FndMethodParameters methodParameters)
    throws java.io.IOException
```

**Example 16-8  Example Use of getURLForCurrentTask**

```java
public java.lang.String getURLForCurrentTask( )
    throws java.io.IOException
```

### 16.4 Using the Single Object Context Workarea

The Single Object Context Workarea is a facet that defines an area between the Global Area and the Main and Regional areas into which developers can add what they want. If the facet is empty, the area does not appear. You also can create a view scope parameter so other flows on the page can get the context. See Figure 16-4.
This area is useful for creating Single Object Workareas, which are particularly useful in tabbed page mode. A Single Object Workarea is a page that is devoted to one object so the information of that one object can be put above the Workarea.

Single Object Workareas provide a context for addressing the tasks and processes for the business process of a single complex object instance at a time. Usually, single object workareas will use multiple defaultMain flows. Each flow can be about a different aspect of the same object. For instance, you could have one tab showing recent activity, and another tab showing payments.

### 16.4.1 Implementation Notes

The SingleObjectContextArea facet has been added to the UI Shell template for Context Area task flow.

A managed bean entry, shown in Example 16-9, has been added to adfc-config.xml for viewScope Hashmap.

Support for URL parameters defined in the view activity for the page (JSPX) in adfc-\config is to be set in the fndPageParams Hashmap defined in viewScope. This Hashmap is also passed onto the pageFlowScope of the task flows in the context area, regional area and main area.

This is accomplished by enabling the Bookmarkable property on the view activity for the page and specifying the URL parameter names with the value set to be added to the fndPageParams Hashmap defined in viewScope. See the “How to Create a Bookmarkable View Activity” section in the Developing Fusion Web Applications with Oracle Application Development Framework.

Product team task flows running in the Single Object Context Workarea must be designed to take in the appropriate context values as input parameters. The pageFlowScope values must be passed to the appropriate input parameters through the parametersList for the item node in the menu or the openMainTask API.

Product teams can cause URL navigation (using the navigate data control method provided by UI Shell by passing required parameters in the pageParametersList) for changing context or updating context information. This will cause the entire page to be refreshed based on new context parameter values.

Product teams can also check for the input parameter values (the context) within the context area task flow. If invalid, a modal dialog can be launched for the end user to
choose a context (rendered as links based on the navigate data control method provided by UI Shell) before proceeding.

**Example 16-9   Managed Bean viewScope Hashmap Entry in adfc-config.xml**

```xml
<managed-bean>
    <managed-bean-name>fndPageParams</managed-bean-name>
    <managed-bean-class>java.util.HashMap</managed-bean-class>
    <managed-bean-scope>view</managed-bean-scope>
</managed-bean>
```

16.4.1.1 Developer Implementation

Enable the Bookmarkable property on the view activity for the single object context page and specify the URL parameter names with the corresponding fndPageParams viewScope Hashmap key where the value should be stored. See the "How to Create a Bookmarkable View Activity" section in the Developing Fusion Web Applications with Oracle Application Development Framework.

**Example 16-10** shows a sample entry in adfc-config.xml for such a view activity.

Product teams must create a bounded task flow for the Context Area that appears at the top of the page. This task flow must accept the context values as input parameters. This task flow is dropped as a static region onto the Context Area facet in the JSPX page based on the UI Shell template. In the task flow binding, set the input parameter values to the corresponding key in fndPageParms viewScope Hashmap.

**Example 16-11** shows a sample entry in the page definition for the JSPX file for passing the viewScope values into the Context Area task flow as input parameter.

The UI Shell code passes this viewScope hashmap onto the pageFlowScope of the main area and regional area task flows. Product team task flows, which are initialized in the regional area and main area, can access this in pageFlowScope (of a main area or regional area container task flow owned by Applications Core) for the appropriate input parameters through the menu model and openMainTask API.

**Example 16-12** shows a sample entry for a child item node for defaultMain task in the menu.xml file to pass the appropriate deptno in the single object context to a task flow that is initialized based on this input value.

Product teams can cause URL navigation (through the navigate data control method provided by UI Shell) for changing context or after updating context information. This will cause the entire page to be refreshed based on new context parameter values.

Product teams can also check for the input parameter values within the pageFlowScope of the context area task flow. If invalid, a modal dialog can be launched for the end user to choose a context (by providing links based on the navigate data control method provided by the UI Shell by passing required parameters in the pageParametersList) before proceeding. This can be achieved by defining an invoke action executable in the page def for the context area page fragment which checks for existence of the pageFlowScope value and programmatically shows a modal dialog for the user to choose the context. The other alternative is to use this approach to cause navigation to a completely different page where the user can select the context.

Also, it is important to note that all the bounded task flows that will be initialized in the Single Object Context Workarea need to check for input parameter values and show/query data only if the input parameter values are passed. Basically, if the input parameter values are empty, the task flows handle that, such as in a router activity, and avoid showing any transaction data to the end user.
16.5 Implementing the Third-Party Component Area

The Third-Party Component Area, shown in Figure 16-5, is a facet in the UI Shell template for showing content just above the Single Context Workarea in the global area. Although originally designed to contain a Call Telephony Interface (CTI) showing incoming calls in a call center operation, the facet can contain anything.

**Figure 16-5  Third Party Component Area Facet Containing A CTI**

16.5.1 How to Implement the ThirdPartyComponentArea Facet Developer

The ThirdPartyComponentArea facet should be added within a flexible layout component that will allow you to control the amount of screen real estate that the content added to the facet can consume.

- A facet reference is under the global area content with its width set to 100 percent.
- Add content to this facet.
• You should create a bounded task flow with page fragment for the content and drop it into this facet as a static region. This supports personalization through web composer since the content is within a page template.

• The height property of the panelStretchLayout in the UI Shell template defaults to 33 px. To view or enable the third party component area (see the dark blue area at the top of Figure 14-1), specify the globalAreaHeight property as auto in the pageTemplate property Inspector.

When the height of the top facet is specified as a CSS length or as auto, this facet will no longer be stretched and instead will consume the initial offsetHeight given to its children by the browser. It is important to note that in an average page, a switch to a layout using automatic heights exhibited a 5- to 10-percent degradation in initial layout speed. Also, an automatic height will cause the facet child to not be stretched both vertically and horizontally.

• You can set the height of the root layout component within the facet to auto to ensure auto-resizing of contents within the facet. Consider a showDetailHeader that is the root element within the facet (in the default view activity for the bounded task flow dropped in as a region). If the height property for this showDetailHeader component is set to auto, collapsing the header would resize the contents and open more real estate in the screen for showing other components in the page.

16.6 Developing an Activity Guide Client Application with the UI Shell

The Oracle UI Shell can be used to develop an Activity Guide client application.

Before you begin:

Copy the file oracle.bpm.activityguide-ui_11.1.1.jar to a local directory from the following location in the bpm-jdev-extension.zip file:

jdev_install/jdeveloper/soa/modules/oracle.bpm.activityguide-ui_11.1.1.jar

16.6.1 How to Develop an Activity Guide Client Application Using Oracle UI Shell

To develop an activity guide client application using Oracle UI Shell, follow these steps:

1. Create a new application. In the Application Package Prefix field, enter oracle.ag.
When prompted to create a new project, click **Cancel**.

2. In the new application, create a new project using the Web Project template by right-clicking the application and selecting **New Project > Project > Web Project**. Select **Servlet 2.5/JSP 2.1 (Java EE 1.5)**. Click through the wizard, accepting all default values.

3. Add the **ADF Faces** and **ADF Page Flow** technologies to the client application project. Right-click the project and select **Project Properties > Technology Scope**. Shuttle **ADF Faces** and **ADF Page Flow** from the Available Technologies list to the Selected Technologies list.

Make sure the following technologies are also selected: HTML, Java, JSP and JSF and Servlets.
Figure 16-7 Adding the ADF Faces and ADF Page Flow Technologies to the Client Application

4. Right-click the client application and select Project Properties > JSP Tag Libraries. Select the Distributed Libraries folder and click Add. In the Choose Tag Libraries window, select the tag library Applications Core (ViewController) 11.1.1.0.0 and click OK.

Figure 16-8 Select the Tag Library Applications Core (ViewController) 11.1.1.00

5. In the Project Properties window, select Libraries and Classpath and click the Add Library button. From the window that is displayed, select the Applications Core library and click OK.
6. In the Project Properties window, click the **Add JAR/Directory** button and browse for the file `oracle.bpm.activityguide-ui_11.1.1.jar`. The file is located under `jdev_install/jdeveloper/soa/modules/oracle.bpm.activityguide-ui_11.1.1.jar`. Click **Select** to add the JAR to the project classpath.

7. Add Activity Guide runtime libraries or JAR files to the classpath. Use either shared libraries or JAR files; do not use both.

   a. Using shared libraries for Activity Guide runtime JAR files

      Add the shared library references `oracle.soa.bpmel` and `oracle.soa.workflow.wc` to the `weblogic-application.xml` file.

      ```xml
      <library-ref>
        <library-name>oracle.soa.bpmel</library-name>
      </library-ref>
      <library-ref>
        <library-name>oracle.soa.workflow.wc</library-name>
      </library-ref>
      
   b. Using JAR files for Activity Guide runtime

      Add the following JAR files to the classpath:

      ```
      FMW_home/AS11gR1SOA/soa/modules/oracle.soa.workflow_11.1.1/bpm-services.jar
      FMW_home/AS11gR1SOA/soa/modules/oracle.soa.bpmel_11.1.1/orabpel-common.jar
      FMW_home/AS11gR1SOA/soa/modules/oracle.soa.bpmel_11.1.1/orabpel.jar
      FMW_home/AS11gR1SOA/soa/modules/oracle.soa.fabric_11.1.1/bpm-infra.jar
      FMW_home/AS11gR1SOA/soa/modules/oracle.soa.fabric_11.1.1/fabric-runtime.jar
      FMW_home/oracle_common/modules/oracle.webservices_11.1.1/wsclient.jar
      FMW_home/oracle_common/modules/oracle.xdk_11.1.1/xml.jar
      ```

8. Create a file called `Config.jar` using the `wf_client_config.xml` file and add it to the application classpath. The `wf_client_config.xml` file should include the host name and port of the WLS instance running the Activity Guide instances.
9. Create a JSF page. Right-click the application name and click **New**. In the New Gallery, select **JSF > JSF Page** and click **OK**. Use **UIShell** as a page template and select the checkbox **Create as XML Document (*.jspx)**.

If a dialog box displays the message "Confirm Add Form Element," click **No**.

10. Create Application menu metadata. See **Implementing Application Menu Security**.

### 16.6.2 How to add a task flow to the Oracle UI Shell client application

Follow these steps to add a task flow to the Oracle UI Shell client application:

1. Open the menu metadata menu XML file created in "How to Develop an Activity Guide Client Application Using Oracle UI Shell".

2. Right-click itemNode_<JSF page name> and select **Insert inside itemNode_<JSF page name> > itemNode**.

3. In the Common Properties window, browse for the name of the JSF page and enter a unique Id for the itemNode property using the standard format <pageID>_<taskFlowName>. For example: ItemNode_MainArea_TaskFlow.

4. Click the **Browse** button to the right of the focusViewId field. In the Edit Property window that is displayed, select the focusViewId of the page under which you are registering the task flow. Click **OK**.

5. In the Property Inspector, select the Applications tab and enter a label for the itemNode such as **Main Taskflow**.

6. From the Project Navigator, select the menu metadata XML file. In the Structure view, select the task flow itemNode - Main Taskflow. In the Property Inspector, enter the following values under the Advanced section:

   - **Task Type**: defaultMain
   - **Task Flow ID**: Click the **Browse** button to display the Select Task Flow ID window and select the location of the task flow definition: `/WEB-INF/oracle/bpel/activityguide/ui/taskflows/ag-humantask-task-flow.xml#ag-humantask-task-flow`. This is the Id of the main area task flow.
   - **Disclosed**: Optionally, set this value to **false**. This property enables opening a new tab when clicking the relevant task link at run time. For tabs, the first defaultMain with disclosed=true is the one that will be in focus.

7. Repeat Steps 1 through 6 for the regional task flow, naming the label and Id accordingly. Provide the following values for the regional task flow in step 6:

   - **Task Type**: defaultRegional
   - **Task Flow ID**: Click the **Browse** button to display the Select Task Flow ID window and select the location of the task flow definition: '/WEB-INF/oracle/bpel/activityguide/ui/taskflows/ag-tasktree-task-flow.xml#ag-tasktree-task-flow'. This is the Id of the regional area task flow.
   - **Disclosed**: Set this value to **true** for the regional task flow. This property enables opening a new tab when clicking the relevant task link at run time.
8. Create a file called `activityguide.properties`. If you choose another name then you must provide its value to the ag-tasktree-task-flow using the parameter `AGPropsBeanName`.

If using identity propagation to secure the Activity Guide, the properties `WorkflowAdminUser` and `WorkflowAdminPassword` are not required.

You can customize Activity Guides behavior by configuring their properties. To configure these properties you must edit the Activity Guide properties file.

Table 16-3 shows the properties you can specify in this file.

Example 16-13 shows a typical Activity Guide properties file:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
</table>
| ServerConnectionMode    | Specifies the mode for the transmission of data.                           | • SOAP  
                          |                                                              | • REMOTE |
| WorklistHttpURL         | Only required when using digital signatures. Specifies the URL to access the  | http://host:port/integration/                        |
                          | Oracle BPM Worklist application.                                            | worklistapp                                          |
| SelectionFilter         | Specifies the filter used to filter the processes in an activity guide.      | • MY  
                          |                                                              | • PREVIOUS  
                          |                                                              | • REPORTEES  
                          |                                                              | • ADMIN |
| AGDefinitionFilter      | Specifies the definition ID used to filter the process in an activity guide. | `activity guide definition ID`                      |
| AGInstanceOrdering      | Specifies the order used to display the processes in the activity guide.     | • `column_name`:ASC  
                          | For example: CREATION_DATE:ASC                                              | • `column_name`:DESC  
                          |                                                              | Default value: ASC |
| AGInstanceID            | Specifies the instance ID used to display the activity guide tree.           | `activity guide instance ID`                        |
|                         | For example: 10001                                                          |                                                      |
| CustomPredicate1        | Specifies an additional predicate to filter the list of processes in an activity guide. For example: CREATOR, EQ, jstein | `column name, operator, value`   |
| CustomPredicate2        | Specifies a different additional predicate to filter the list of processes in an activity guide. This predicate is used with CustomPredicate1 | `column name, operator, value`   |
| ShowAllAGTreeNodesProperties | Specifies if the activity guide shows a section at the top that describes the properties of activity guides, milestones and tasks. | • true  
                          |                                                              | • false  
                          |                                                              | Default value: true |
| ShowRefreshButton       | Specifies if the regional area displays a refresh button.                    | • true  
                          |                                                              | • false  
                          |                                                              | Default value: false |
### Table 16-3 (Cont.) Activity Guide Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Possible Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGTasksPopupTaskFlowID</td>
<td>Specifies the content to display in the task pop-up.</td>
<td>fully qualified TaskFlow ID</td>
</tr>
<tr>
<td>HideAGTreeRootNode</td>
<td>Hides the Guided Business Process title on the Activity Guide Tree root node.</td>
<td>true, false</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
<td></td>
</tr>
<tr>
<td>ShowCustomBlockedIcon</td>
<td>Specifies if the Guided Business Process shows the custom task blocked icon.</td>
<td>true, false</td>
</tr>
<tr>
<td></td>
<td>Default value: false</td>
<td></td>
</tr>
</tbody>
</table>

9. In the page definition of Oracle UI Shell JSF fragment page, navigate to `pageTemplateBinding` and set the Refresh property to `ifNeeded`.

10. Open the file `adfc-config.xml`.

11. Edit the file `adfc-config.xml` to include the location of the `activity.properties` file. This should be the absolute path to the `activityguide.properties` file.

   An example `adfc-config.xml` is shown in **Example 16-14**.

12. To enable a task flow popup with summary information, add the property `AGTasksPopupTaskFlowID` to the `activityguide.properties` file.

   Use this parameter to display a task flow summary in dynamic regions. Enter the relevant task flow Id. If this parameter is not set, the value of `OutputText` is shown as the default task summary.

13. Create a Workflow Service client configuration file. An example is shown in **Example 16-15**.

14. Deploy the Activity Guide client application with Oracle UI Shell as described in Deploying an Activity Guide Client Application with Oracle UI Shell to Integrated or in Deploying an Activity Guide Client Application with Oracle UI Shell to Standalone.

**Example 16-13 An Activity Guide Properties File**

```xml
#ActivityGuide Properties
ServerConnectionMode=SOAP
SelectionFilter=MY
ShowRefreshButton=true
#ShowAllAGTreeNodesProperties=true
## Sample value for AGDefinitionFilter: default/BPMAGPrj2!2.0*31fcd931-6263-4b58-97cf-6fb084addabc
#AGDefinitionFilter=
#AGDefinitionFilter=
#AGInstanceID=110003
#AGInstanceOrdering=CIKEY:DESC
#CustomPredicate1=STATE,EQ,OPEN
#CustomPredicate2=STATUS,EQ,In Progress
## Example Value for AGTasksPopupTaskflowID is /WEB-INF/ag-popup-task-flow.xml#ag-p
#AGTasksPopupTaskflowID=
#ShowCustomBlockedIcon=true
#HideAGTreeRootNode=false
```
## WorklistHttpURL is required only for digital signatures

```
#WorklistHttpURL=http://host:port/integration/worklistapp
```

### Example 16-14  `adfc-config.xml` File with Reference to `activityguide.properties` File

```xml
<managed-bean>
  <managed-bean-name>agProps</managed-bean-name>
  <managed-bean-class>
    oracle.bpel.activityguide.ui.beans.model.AGProperties
  </managed-bean-class>
  <managed-bean-scope>request</managed-bean-scope>
  <managed-property>
    <property-name>absAgPropsFileName</property-name>
    <property-class>java.lang.String</property-class>
    <value> <!---absolute path on your machine should be given here-->/activityguide.properties
      <!-- For example:
        Windows: C:\AG\activityguide.properties
        Linux: /scratch/<user>/AG/activityguide.properties
      -->
    </value>
  </managed-property>
</managed-bean>
```

### Example 16-15  Workflow Services Client Configuration File

```xml
<workflowServicesClientConfiguration xmlns="http://xmlns.oracle.com/bpel/services/client">
  <server default="true" name="default">
    <localClient>
      <participateInClientTransaction>false</participateInClientTransaction>
    </localClient>
    <remoteClient>
      t3://host:port
      <initialContextFactory>weblogic.jndi.WLInitialContextFactory</initialContextFactory>
      <participateInClientTransaction>false</participateInClientTransaction>
    </remoteClient>
    <soapClient>
      http://host:port
      <identityPropagation mode="dynamic" type="saml">
        <policy-references>

        </policy-references>
      </identityPropagation>
    </soapClient>
  </server>
</workflowServicesClientConfiguration>
```

### 16.6.3 How to Secure the Activity Guide Oracle UI Shell Client Application

Securing the Activity Guide client application ensures that only users with proper credentials can complete the tasks outlined in the Activity Guide. Security features include authentication, authorization, realm verification and policy enforcement.

Follow the instructions for securing a Web application as described in the Enabling ADF Security in an Oracle Fusion Web Application section of the *Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework*.
You can deploy an Activity Guide client application with Oracle UI Shell directly from JDeveloper or to the standalone Oracle WebLogic Server.

### 16.6.3.1 Deploy an Activity Guide Client Application with Oracle UI Shell to Integrated Oracle WebLogic Server

From the Application Navigator, right-click the JSF page created in How to Develop an Activity Guide Client Application Using Oracle UI Shell and select Run.

### 16.6.3.2 Deploy an Activity Guide Client Application with Oracle UI Shell to Standalone Oracle WebLogic Server

Follow these steps to deploy an Activity Guide client application with Oracle UI Shell to a standalone Oracle WebLogic Server:

1. Create a connection to the standalone Oracle WebLogic Server.
2. From the Application Navigator, right-click the project created in step 2 of How to Develop an Activity Guide Client Application Using Oracle UI Shell.
3. Select Project Properties.
   - From the Project Properties dialog, select Deployment.
4. Create a new WAR deployment profile.
5. Right-click the project and select Deploy. Deploy the project to the standalone Oracle WebLogic Server connection created in step 1.
6. Launch the client page from a browser.

### 16.7 Implementing Touch Device Support in the UI Shell

The Global Area display on a tablet device is the same as the standard Global Area design except these menu options and display area are not available:

- **Administration** menu options
- **Personalization > Customize** this page menu option

The items that are not available on a tablet device take up too much space to be used comfortably on a small screen.

The page template will also collapse the left-side Regional area by default to save space.

Also see the Creating Web Applications for Touch Devices Using ADF Faces section in the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Face guide.

**How to use flow mode on a touch screen device**

Implementing flow mode follows the Best Practices When Using ADF Faces Components in a Mobile Browser section in the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Face guide.

To use flow mode on a touch screen device, but making sure that nothing is changed when displaying pages on a desktop system, add this `context-param` to the `web.xml` file of the J2EE application:

```xml
<context-param>
  <description>
    This parameter controls the default value for component geometry on the page.
  </description>
</context-param>
```
Supported values are:
  legacy - component attributes use the default values as specified for
  the attributes
  auto - component attributes use the correct default value given the
  value of their parent component. For example, with this setting, the
  panelStretchLayout will use "auto" as the default value for its
  "dimensionsFrom" attribute instead of "parent".
</description>
<param-name>oracle.adf.view.rich.geometry.DEFAULT_DIMENSIONS</param-name>
<param-value>#{requestContext.agent.capabilities['touchScreen'] eq 'none' ? 'legacy' : 'auto'}</param-value>
</context-param>

In this case, the dimensionsFrom attribute is set to auto only when running on a
touch screen device. But when running on a desktop system, the context-value is
set to legacy and the dimensionsFrom attribute will use the old default value,
which is parent.

The UI Shell sets the dimensionsFrom attribute to children on the root panel
component on a page when running on a tablet device. Setting the dimensionsFrom
attribute to auto, and placing the context-param in the web.xml file, will allow all
other components to use the dimensionsFrom attribute.

16.8 Implementing the Translation Editor

The Translation Editor is a standard UI component that allows translated data to be
edited in all languages, regardless of the session language. It is accessible in Table
layout. It also:

- Allows all translated data stored in multi-lingual (TL) tables to be edited on the
  same setup UI as untranslated data for the same object.
- Automatically synchronizes any updates required by source_lang defaulting.
- Does not require the user to change session language, even temporarily.

The Translation Editor is implemented as a popup window, launched at the row level.
The Edit Translations popup has a row for each language that is installed and
implemented by the Translation Editor. When the user highlights an editable row and
clicks the Translations Editor button and the popup displays, the user can enter, for
instance, a description in German in the row marked German. This then places the
German text in the correct field in a database.

This example shows that the ABSENCE_STATUS row is selected:
Click the Translation Editor button to display the Edit Translations dialog:

A user can enter other language descriptions in any other available language row without having to close the Edit Translations dialog and restarting it.

Assume the user’s job is to enter data in multiple languages: Korean, German and English. When the Edit Translations dialog opens, the user would see Korean, German, and English rows.

When the system first starts, there may be no data. When data is added, it would be in a single language. That is the source language. So if a Korean user first adds the data, when any user views the data, it would be in Korean, even if the user were an English or German user. Then when the translation editor opens, it would have Korean data in all rows, and the Source Language in the right-hand column for each row would say Korean in all rows. If a German user then opens the translation editor and changes the German row, the Source Language for that row will change to German.

Note: If the source language value is updated, all values that show the same source language also will update.

Note: A user can enter a translation in the wrong field; such as entering a German translation in the French field.

Limiting languages shown: This is to help someone that is translating many UIs for a certain language to limit the popup to only show the language on which he or she is currently working. This control is accomplished by setting the profile option FND_TRANS_EDITOR_LANGS to the languages that you want to see. This profile can be set at Site or User level.

To access the profile option, click Setup and Maintenance > Manage Administrator Profile Option Values > then search for FND_TRANS_EDITOR_LANGS.
16.8.1 How to Implement the Translation Editor

**Important:** This section assumes that developers will have completed all coding necessary to support the OA Base Class Translation Model. See OADEE58122 “Using Oracle Fusion Middleware Extensions for Oracle Applications Base Classes.”

To implement the Translation Editor, follow these steps:

1. Define a view object for the translatable table (TL). For more information, see the Defining SQL Queries Using View Objects section in the *Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework.*

   If the Multi-language support (MLS) coding standard has been followed (see Understanding Multi-Language Support Features), every TL should have an entity object that is linked to an entity object based on the view link (VL) view, but only the VL-based entity object has a view object. To support the Translation Editor, a view object also must be added for the TL entity object. Define a new view object based on the TL entity object. The view object should be the default and should include all attributes in the TL entity object. No other changes are needed. This view object must be added to the Application Module as a child of the VL view object. The translated attributes in this new view object will inherit custom properties fnd:OA_TRANSLATABLE from the TL entity object that should have been set previously.

2. On the new TL view object, define the custom property at the view object level to `fnd:OA_TRANSLATION_TABLE = true`, as shown here.
The translated attributes in this new view object will inherit custom properties fnd:OA_TRANSLATABLE from the TL entity object that should have been set previously.

3. Add a view link for the view object. This new TL view object must be a child of the base VL view object. A view link must be defined between the VL view object and the new TL view object.

4. Copy validators from VL entity object to TL entity object. Using the MLS coding standard, only the VL entity object will have any validation; the TL entity object has no validation, it relies on validation in the VL entity object before values are copied to the TL entity object by the OA base classes. This will not be sufficient though if translated values can be updated directly. Any validators on the VL entity object that reference translated attributes must be copied to the TL entity object.

5. Copy control hints from VL entity object to TL entity object. If you did not set the control hints to your TL entity object, add control hints to the TL entity object, for prompt, display length, widget, and so on. These control hints will be used when rendering the Translation Editor. Generally these will be the same control hints as the attributes on the VL entity object, but under some circumstances might be different (for example, display length may be shorter.)

6. Set the display name for the Language and SourceLang attributes. Note that the TL view object needs to join to LanguagePEO so that you get the correct display name for the Language and SourceLang attributes.

- To do that, you will need to create two entity object associations. One is from your Language attribute to the LanguagePEO.LanguageCode. The other one is from your SourceLang attribute to the LanguagePEO.LanguageCode. For example, the two entity object associations created for this test case are LookupTypeTranslationVOLanguageToLanguagePEO and lookupTypeTranslationVOSourceLangToLanguagePEO.

Look for LanguagePEO as shown here and add it to the TL view object as an entity object.
You will need to add it twice. Once for the Language attribute that would use the association `LookupTypeTranslationVOLanguageToLanguagePEO` and once for the SourceLang attribute that would use `LookupTypeTranslationVOSourceLangToLanguagePEO`. The two `LanguagePEO` instances should be named `LanguagePEOForLanguage` and `LanguagePEOForSourceLang`.

Add the `LanguageDisplayName` and `SourceDisplayName` attributes into your translation view object.
Figure 16-16 Adding Attributes to Translation View Object

In the translation popup window, you should show the language description instead of the language code, such as American instead of US.

Note:
When adding these attributes to the entity object, you must give them the Aliases LanguageDisplayName and SourceLangDisplayName.

Figure 16-17 Required Aliases for Attributes Added to Entity Object

The LanguageDisplayName and SourceLangDisplayName attributes now should be included in the TL view object.
Figure 16-18  Required Attributes Added to TL View Object

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Alias Name</th>
<th>Entity Usage</th>
<th>Info</th>
</tr>
</thead>
<tbody>
<tr>
<td>LookupType</td>
<td>String</td>
<td>LookupType</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Language</td>
<td>String</td>
<td>LANGUAGE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SourceLang</td>
<td>String</td>
<td>SOURCE_LANG</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Meaning</td>
<td>String</td>
<td>MEANING</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Description</td>
<td>String</td>
<td>DESCRIPTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LanguageDisplayName</td>
<td>String</td>
<td>DESCRIPTION2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LanguageCode</td>
<td>String</td>
<td>LANGUAGE_CODE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>SourceLangDisplayName</td>
<td>String</td>
<td>DESCRIPTION2</td>
<td></td>
<td></td>
</tr>
<tr>
<td>LanguageCode</td>
<td>String</td>
<td>LANGUAGE_CODE</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note:

Set the Query Column Alias of the LanguageDisplayName attribute to LANGUAGE_DISPLAY_NAME. The Translation Editor uses the Language Display Name to set the order when displaying the translation data in the popup. You do not need to set the Query Column Alias for SourceLangDisplayName.

Figure 16-19  Setting the Query Column Alias of the LanguageDisplayName Attribute

The TL model should now be complete. The next step is to add the Translation Editor to the UI.

16.8.2 How to Add the Translation Editor to Existing Application Tables During Design Time

This section describes how to add the Translation Editor to an Application Table on an existing JSF page. If you are creating a new Application Table, skip to How to Add the Translation Editor to New Application Tables During Design Time.
You will use a design time wizard to add the Translation Editor to a UI.

For example, if you drag a translatable table (TL) view object instance from the dataControl to an existing ApplicationTable > additionalToolbarButton > af:toolbar or ApplicationTable > f:facet-popup > panelGroupLayout, you can pick the Translation Editor under applications. You can drop the Translation Editor on either facet; the result will be the same.

Note that you cannot drag and drop directly onto an ApplicationTable.

This shows an example drag-and-drop of a TL view object onto an ApplicationTable > additionToolbarButton-> af:toolbar.

**Figure 16-20 Example Drag-and-Drop of A TL View Object**

You also can drag and drop your TL view object onto ApplicationTable > f:facet-popup > panelGroupLayout.

After the drag-and-drop, the Create Translation Popup wizard will open. The wizard will include input for a list of all the columns in the TL view object and you can remove the ones you do not want. The list will show all the attributes in the TL view object, except for Who columns, LANGUAGE, SOURCE_LANG and the Primary Key.

You can remove the translation attributes you do not want to display. You also can pick input text field or text region as the type. All other display properties (such as prompts) will be defaulted from control hints on the TL view object.

**Figure 16-21 Create Translation Popup Wizard**

When you click **Continue**, designer will add the popup code into your JSFF file. You should not edit anything in the code that is added to your page.
16.8.3 How to Add the Translation Editor to New Application Tables During Design Time

The Application Table Configure Table Patterns wizard has an option for users to choose whether to have the translation editor ability. The View Instances that will be available to enable for the Translation Editor will be those view objects marked with the fnd:OA_TRANSLATION_TABLE custom property (see Model layer changes below). If there are no such view objects, the Translation Editor option will be disabled.

16.8.4 Handle Multi-Language Data Entry

The Translation Editor allows translated data to be edited in all languages, regardless of session language.

- Allow all translated data stored in multi-lingual (TL) tables to be edited on the same setup UI as untranslated data for the same object
- Automatically synchronizes any updates required by source_lang defaulting
- Does not require the user to change session language, even temporarily
- Accessible in either Form or Table layout
- Is a standard component that require minimal hand-coding by consuming developers
- Properly handles validation of translated values

Runtime Design

The Translation Editor is implemented as a popup window, launched at the row level by a button. The button and popup window will appear as shown in these two images:

Figure 16-22 Example of the Translation Editor in a Table
Implementing the Translation Editor

The translation button will be in the primary button region of Application Table. If there is only 1 language active, the icon will not be visible.

The popup window will show a table of translated data for a single data row, with 1 row per active language (translated data for disabled languages will not be displayed, even if present). The columns of the table will include language and source language (both read-only), and 1 column for each translated attribute. Translated attributes may be editable or read-only. Column prompts and display properties (such as display size) should match the prompt and display properties of the base attribute. (NOTE: TBD how to do this.)

When a value is updated:

- The row will be marked at "translated," meaning the language and source language will be set to the same value.
- Any other languages with the same source language as the updated row will be re-defaulted.

If the window is closed:

- If closed with OK, values will be written back to be committed (or not) with the main transaction. If any translated values for the session language have been updated, they will be updated in the main UI.
- If closed with Cancel, all changes in the popup are discarded without affecting anything in the main transaction.

When the entire transaction is committed, any updates performed in the Translation Editor will be validated and committed at the same time. If any validation errors occur in translated data, they will be reported along with all other validation errors. The user will need to re-open the popup window to correct the error. If the error is associated with an attribute, that attribute will have a "red box" indicator in the popup, only on the language row in error.

**Ability to limit languages shown:** The languages that are shown can be limited. This is to help someone that is translating many UIs for a certain language to limit the
popup to only show the language on which he or she is currently working. This control is accomplished by setting the profile option FND_TRANS_EDITOR_LANGS to the languages that will be shown. This profile can be set at SITE or USER level. If null, all active languages are shown. The values (US, KO, F) can be found in the Manage Languages setup UI.

*Figure 16-24 Setting the FND_TRANS_EDITOR_LANGS Profile*

Launching the Translation Editor from a form is shown in this example.

*Figure 16-25 Launching the Translation Editor from a Form*

When you click the Translation Editor button, the same popup described for the Application Table case will show.

*Figure 16-26 Edit Translations Popup*
If your form has multiple regions that involve more than one TL ViewObject, then we recommended that you drag-and-drop the TL ViewObject onto the desired location in your form. For example, in the below case, the Translation Editor button is placed at the end of the form.

**Figure 16-27 Edit Profile Category**

</table>

### 16.8.4.1 Implement Multi-Language Data Entry

**Prerequisite**

Before starting this, developers will have completed all coding necessary to support the OA Base Class Translation Model. See Understanding Multi-Language Support Features for setting up translation tables.

**Prepare the TL EO and Entity Associations**

1. Copy validators from VL EO to TL EO. In accordance with the MLS coding standard, only the VL EO will have any validation; the TL EO has no validation, it relies on validation in the VL EO before values are copied to the TL EO by the OA base classes. This will not be sufficient if translated values can be updated directly. Any validators on the VL EO that reference translated attributes must be copied to the TL EO.

2. Copy control hints from VL EO to TL EO. If you did not set the control hints to your TL EO, add control hints to the TL EO for prompt, display length, widget, and so on. These control hints will be used when rendering the Translation Editor. Generally, these will be the same control hints as the attributes on the VL EO, but under some circumstances might be different (for example display length may be shorter.)

3. Create Entity Associations for Language attributes. Create two EO associations from the TL EO to LanguagePEO: one from your Language attribute to the LanguagePEO.LanguageCode, and one from the SourceLang attribute to the LanguagePEO.LanguageCode. Both associations are 0,1 .. *, everything else can be left as default. For example, the two EO associations created for this test case are LookupTypeTranslationVOLanguageToLanguagePEO and LookupTypeTranslationVOSourceLangToLanguagePEO.
Create the TL VO and View Link

1. Define a VO for the TL table. If the MLS coding standard has been followed, every TL table should have an EO, linked to an EO based on the VL view, but only the VL-based EO has a VO. To support the Translation Editor, a VO must be added for the TL EO as well. Define a new VO based on the TL EO. The VO should be the default, and include all attributes in the TL EO. No other changes are needed. The translated attributes in this new VO will inherit custom properties \texttt{fnd:OA_TRANSLATABLE} from the TL EO that should have been set previously.

2. On the new TL VO, define the custom property at the VO level to \texttt{fnd:OA_TRANSLATION_TABLE = true}. The translated attributes in this new VO will inherit custom properties \texttt{fnd:OA_TRANSLATABLE} from the TL EO that should have been set previously.

3. Add \texttt{LanguagePEO} to the VO for Language and \texttt{SourceLang}. The \texttt{LanguagePEO} must be added to the model for the new TL VO for Language and \texttt{SourceLang}, using the 2 entity associations created above.

   a. Add \texttt{LanguagePEO} to the TL VO as an Entity Object, using the Entity Association created for the Language attribute.
b. Add LanguagePEO to the TL VO as an Entity Object again, using the Entity Association created for the SourceLang attribute.

4. Add Language and SourceLang display name attributes. Create 2 attributes in your VO for the Language and SourceLang display name, using the Description attribute from the LanguagePEO entity objects just added.

In the translation popup window, show the language description instead of the language code. For example, American instead of US.
Important:
When adding these attributes to the EO you must give them the alias `LanguageDisplayName` and `SourceLangDisplayName`, as shown below.

**Figure 16-32  Creating LanguageDisplayName Alias for Description Attribute**
The `LanguageDisplayName` and `SourceLangDisplayName` attributes should now be included in the TL VO.

Figure 16-34  Example Showing LanguageDisplayName and SourceLangDisplayName Included in TL VO
Important:

Set the Query Column Alias of the `LanguageDisplayName` attribute to "LANGUAGE_DISPLAY_NAME". The Translation Editor uses the Language Display Name to do the "order by" when displaying the translation data in the popup. You do not need to set the Query Column alias for `SourceLangDisplayName`, only `LanguageDisplayName`, as shown here.

**Figure 16-35  LanguageDisplayName Alias**

---

Important:

Set the Control hint label text of your `LanguageDisplayName` to "Language".
Set the Control hint label text of your `SourceLangDisplayName` to "Source Language."

---

5. Add a View Link for the VO. This new TL VO must be a child of the base VL VO. A View Link must be defined between the VL VO and the new TL VO.

### Add Translation VL to AM

1. Add Translation VO to the AM. Use this View Link to add the Translation VO to the AM, as a child of the VL VO.

2. Exclude this TLVO from loader VO list. If you are using the same model for both your UI and loader purpose, you will need to exclude this TLVO so that loader will skip this TLVO. For example, assume `StandardLookupTypeUIVO` is the loader VO and it now has a TLVO child. If you don’t exclude this child, the TLVO will appear in the loader file. What you do is to add `SD_EXCLUSION_LINKLIST` into your AM.xml file as shown here:

```xml
<CustomProperties>
  <Property
    Name= "SD_EXCLUSION_LINKLIST_StandardLookupTypeUI1"
    Value = "StandardLookupTypeUIVOToLookupTypeTL1"/>
</CustomProperties>
```
Important:

Note that in the above example, `StandardLookupTypeUI1` is the View Instance Name. And in the Value portion of `StandardLookupTypeUIVOToLookupTypeTL` is the View Link Instance Name. You can get the exact name in your AM > DataModel, as shown here.

Figure 16-36   StandardLookupType UI1 in Data Model

Figure 16-37   LookupTypeTL1 in Data Model

Your TL model should now be complete. Continue to the Design Time section to add the Translation Editor to your UI.

16.8.4.1.1 Design Time for Existing Application Tables

This section describes how to add a Translation Editor to an Application Table on an existing JSFF page. If you are creating a new Application Table, skip to the “Design Time for New Application Tables” section.

A design time wizard is used to add the Translation Editor to a setup UI.

For example, if you drag a TLVO Instance from the dataControl to your existing ApplicationTable > additionalToolbarButton > af:toolbar or ApplicationTable > f:facet-popup > panelGroupLayout then under Applications you can pick Translation Editor. You can drop the Translation Editor on either facet; the result will be exactly the same.

Note that you can not drag and drop directly onto ApplicationTable because it is not an ADF component that can be dropped.

This is an example drag and drop of your TLVO onto ApplicationTable > additionToolbarButton > af:toolbar.
You also can drag and drop your TLVO onto ApplicationTable > f:facet-popup > panelGroupLayout.

After the drag and drop, the wizard will show. The wizard will include input for a list of all the columns in the TL VO and you can remove the ones you do not want. The list will show all the attributes in the TL VO, except for WHO columns, LANGUAGE, SOURCE_LANG and the Primary Key. You can remove the translation attributes you do not want to display. You also can pick input text field or text region as the type. All other display properties (such as prompt) will be defaulted from control hints on the TL VO.
Figure 16-40  Create Translation Popup

When you click Continue, designer will add the popup code into your JSFF file. You should not edit anything in the code added to your page.

Turn On Auto Submit

Turn on the autoSubmit property for all your translation attributes so that any changes you make in your base table are immediately seen inside your Translation Editor popup table.

All updates you make inside the Translation Editor popup table will automatically be brought back to your base table.

Adjust your code accordingly if it is sensitive with autoSubmit turned on.

16.8.4.1.2 Design Time for Creating a New Application Table

The Application Table wizard lets the user choose whether or not to have the Translation Editor ability. The View Instances that will be available to enable for the Translation Editor will be those VOs marked with the fnd:OA_TRANSLATION_TABLE custom property. If there are no such VOs, the Translation Editor option will be disabled.
LookupTypeTL1 is shown automatically because it has defined the custom property \texttt{OA\_TRANSLATION\_TABLE = yes.}

Further steps are identical to the procedures in Design Time for Existing Application Tables.

**Information Written to the JSFF File**

Whether you add the Translation Editor feature for an existing application table or enable it when creating a new application table, Translation Editor writes two pieces of information into the JSFF page whether you create it within the Application Table wizard or you create it by dragging and dropping the TLVO into an existing application table.

This example shows information that will be written inside the JSFF file.

```xml
<fnd:applicationsTable tableId="ATt1" id="AT1"
..................................>
<af:table ............
<!-- Design time add the TL dialog id into your af:table partialTriggers !-->
  partialTriggers="............:::TlAfd1"

  <!-- TL button is placed inside ApplicationTable additionToolbarButtons -->
  <f:facet name="additionalToolbarButtons">
    <af:toolbar id="t1">
      <af:commandToolbarButton shortDesc="#{applcoreBundle.TRANSLATION_EDITOR}"
        icon="/images/applcore/patterns/language_qualifier_ena.png"
        hoverIcon="/images/applcore/patterns/language_qualifier_ovr.png"
        depressedIcon="/images/applcore/patterns/language_qualifier_dwn.png"
        disabledIcon="/images/applcore/patterns/language_qualifier_dis.png"
        disabled="#{backingBeanScope.TranslationEditorBean.checkNewRow.tlt2}"
        id="ctb1">
        <af:showPopupBehavior popupId="::TlAfp1"  <<---- Translation Editor popup id
          triggerType="action"/>
    </af:toolbar>
  </f:facet>
</fnd:applicationsTable>
```
Implementing the Translation Editor

</af:commandToolBarButton>
</af:toolbar>
</f:facet>

........................................
</f:facet>
</f:facet>
</af:table>

<!-- Design Time place the the TL popup dialog code at the end of your table -->
<f:facet name="popup">
<af:panelGroupLayout id="pgl2">
<af:popup contentDelivery="lazyUncached"
popupFetchListener="#{backingBeanScope.TranslationEditorBean.handlePopupFetch}"
popupCanceledListener="#{backingBeanScope.TranslationEditorBean.handlePopupCanceled}"
id="TlAfp1">
<af:dialog title="#{applcoreBundle.EDIT_TRANSLATIONS}"
cancelTextAndAccessKey="#{applcoreBundle.CANCEL}"
type="okCancel"
affirmativeTextAndAccessKey="#{applcoreBundle.OK}"
imodal="true"
dialogListener="#{backingBeanScope.TranslationEditorBean.updateBaseParent}"
id="TlAfd1">
<af:panelStretchLayout id="psl1" dimensionsFrom="children">
<f:facet name="center">
<af:table value="#{bindings.LookupTypeTL1.collectionModel}" var="row"
rows="#{bindings.LookupTypeTL1.rangeSize}"
emptyText="#{bindings.LookupTypeTL1.viewable ? applcoreBundle.TABLE_EMPTY_TEXT_NO_ROWS_YET : applcoreBundle.TABLE_EMPTY_TEXT_ACCESS_DENIED}" fetchSize="#{bindings.LookupTypeTL1.rangeSize}" rowBandingInterval="0" inlineStyle="width:840px; height:200px;"
selectedRowKeys="#{bindings.LookupTypeTL1.collectionModel.selectedRow}"
selectionListener="#{bindings.LookupTypeTL1.collectionModel.makeCurrent}" sortProperty="#{bindings.LookupTypeTL1.hints.LanguageDisplayName.name}" headerText="#{bindings.LookupTypeTL1.hints.LanguageDisplayName.label}" sortable="false" id="c19">
<af:column sortProperty="#{bindings.LookupTypeTL1.hints.Meaning.name}" sortable="false" headerText="#{bindings.LookupTypeTL1.hints.Meaning.label}" id="c21">
</af:column>
</af:table>
</f:facet>
</af:dialog>
</af:panelStretchLayout>
</af:popup>
</af:panelGroupLayout>
</af:dialog>
<af:column> and <af:inputText> Properties Copied from Base Attribute

If you have any properties set on the translatable attribute in the base table, design time will copy the same properties into the attribute inside the translation popup table.

These are the properties Designer will copy:

- `align`, `headerNoWrap`, `headerText`, `helpTopicId`, `minimumWidth`, `noWrap`, `rendered`, `shortDesc`, `showRequired`, `sortProperty`, `sortTable`, `visible`,...
16.8.4.1.3 Design Time for Adding Translation Editor into ADF Form

This is the start of your topic.

The Translation Editor feature is designed outside of the native ADF. Therefore, you must create your ADF form first and then drag and drop the Translation Editor view object onto the desire location in the ADF form.

If you have a simple form, you should drag and drop onto the applicationsPanel > actionButtonBar facet.

• Locate the Data Control created for the new Translation VO.
• Open the JSFF page. Drag-drop this data control onto the fnd:applicationsPanel > f:facet - actionButtonBar in the Structure window.
• In the Create menu, choose Applications > Translation Editor.

After the drag and drop, the Translation Editor wizard already described for the application table will open.

You also can choose to drag and drop the Translation Editor button inside your ADF form. For example:

Figure 16-43 Drag and Drop into ADF Form
**Note:**

Turn On Auto Submit.

Turn on the `autoSubmit` property for all of your translation attributes so that any changes you make in your base form will be seen immediately inside your Translation Editor popup table.

All updates you make inside the Translation Editor popup table will automatically be brought back to your base form.

Adjust your code accordingly if it is sensitive to having `autoSubmit` turned on.

This is the code written into your JSFF file:

```xml

</f:facet>
</f:facet>
</f:facet>
</f:facet>
</f:facet>
</af:message id="msg1"
If you have a more complicated form that involves multiple regions (multiple TL ViewObject), you should drag and drop to the location that makes the most sense to you.

For example, if you have five fields on your form, A, B, C, D, E and if you drag and drop the TL ViewObject onto attribute C, the Translation Editor button will appear after attribute C.

16.8.4.1.4 Removing the Translation Editor

The two pieces of information written to your page file are the Translation Editor button and the dialog. You can search for “TlAfp” to find the button and dialog locations in your page so that you can remove them manually.

If you add a new translation attribute into your TLVO and you would like to include this new attribute, you can remove them. Then you can drag and drop the TLVO again so that the new attribute will be included.

16.9 About the Create Page Wizard

If the implementing code is in place, Create Page lets a user create, text, and export a new application page without having to use JDeveloper. This is useful, for instance, in creating a new homepage, testing it, and finally moving it from one system to another, such as from a test environment to a production environment.

The basic steps to create a page are:

1. Create and then enter a sandbox. Using a sandbox is described in the Oracle Sales Cloud Customizing Sales guide.
2. In the Navigator menu, select New Page.
3. Complete the Create Page wizard.
4. Edit and test the page.
5. Publish the page.

16.9.1 How to Complete the Create Page Wizard

When you click New Page on the Navigator menu, the Create Page wizard displays.
Name: Enter a name for the page.

Menu Category Title: Enter a menu category title. The page name will be displayed under this title.

Icon: Click the Search icon to select an icon to represent this page. This step is mandatory and the icon must be selected from the choices presented; a user-supplied icon cannot be used.

Web Page: [Optional] Enter the URL of the application that you wish to host in this page in an iFrame. For example, if you want to run a calculator in your page, you can enter this URL:

http://www.embedcalculator.com/flash/StandardCalculator.swf

This usually is used to create a page where content is coming from another application. This can be a link to a related application, or to a public web site, as shown in the calculator example.

Secure Token: If you need to add a secure token to the URL, click the key icon.

This option is used when you link a menu item to a secure token URL of an application outside Fusion Applications.

An HTTPS protocol is required to access the application.

The secure token expires if the user session is inactive. Refresh the page to regenerate the tokens.

This additional dialog displays:

Web Application: This is a dropdown menu that shows third-party applications that have been registered in the topology tables. To register an application, use the Register Enterprise Applications task in Setup and Maintenance. Registered content usually includes the protocol (such as http or https), the host, port and context root. This means that the beginning section of the URL can be built from this information.

Destination for Web Application: The destination is anything else to be appended on the URL.

Secure Token Name: [Optional] This can be any name you choose.
For example:

Web Application = "BlueApp"
Destination for Web Application = "/faces/showItem.asp" - The beginning "/" is optional, the design time will insert it if it is not included.
Secure Token Name = "userToken"

When saved, the design time will create a menu node with just a destination field with the following:

destination="#{EndPointProvider.externalEndpointByModuleShortName['BlueApp']}/faces/showItem.asp?userToken=#{applCoreSecuredToken.trustToken}"

At runtime, this could evaluate to:

https://BlueAppsHost:9001/BlueApp/faces/showItem.asp?
userToken=9439439432JHU8I53KL88E3

Click Save and Close.

Click Save and Continue.

16.10 Troubleshooting UI Shell Issues

This section presents the more-common problems, with their solutions, that may be experienced by Oracle Fusion applications developers. Also see "Troubleshooting Customizations" in the Extensibility Guide for Developers.

16.10.1 ApplSession Is Not Created

Problem

When ApplSession is not created, these problems occur:

• User Language settings are not set.
• Data security policies are not applied.
• Webservice requests are run as anonymous users instead of named users.

Solution

To resolve this problem:

• Check that the JpsFilter section is correct in web.xml: Applcore Session code depends on the JPS subject. The entry must appear exactly as shown in Example 16-16.

• Check that the ApplSessionFilter section is correct in web.xml: ApplSession must be configured immediately after JpsFilter. The entry must appear exactly as shown in Example 16-16.

• If the issue is with the ApplSession not being created over a web service request using SOA, check how the ApplSession context interceptor is configured.

ApplSession information is preserved over SOA/Web Service requests with context interceptors that fire when requests are sent and received. The ApplSessionContext interceptor, in particular, will handle propagating all session attributes from the caller to the web service, and will even attempt to reuse the same session Id if running against the same database. To enable the context
interceptor, the `weblogic-application.xml` on both the caller and the called should include the `oracle.applcore.config` shared library:

```xml
<library-ref>
    <library-name>
        oracle.applcore.config
    </library-name>
</library-ref>
```

If the context interceptor has not been enabled, the `prepareSession()` of the root application module call should still be able to create the session as the right user, so long as the Subject has been established correctly in the Oracle Web Services Manager layer. But in that case, no other session attributes will be propagated, and the session cannot be reused.

- Obtain the session Id from the cookie. The cookie is located in the browser's cookies folder.
  
  The session cookie is obtained so that subsequent queries can be run to verify the session's existence and obtain additional info about the session. Note that it is the session cookie that is stored in the browser cookie location, not the session Id. They represent the same session, but the actual session Id is internal.
  
  Cookie name: `ORA_FND_SESSION_<db_instance_name>`

  The session cookie value will appear similar to: `DEFAULT_PILLAR:wvlul8CU14FJyjySCPQtwaePhBOyiUT2wexYdIYXh5VwV9i9koUL8L3Qhm0bNrZ8:1282160020177`

  To retrieve the actual session id, run this SQL statement: `select session_id from fnd_sessions where session_cookie=value_obtained_from_cookie_value`.

  **Note:** The `value_obtained_from_cookie_value` is the alpha-numeric string between the two colons. In the example, it is `wvlul8CU14FJyjySCPQtwaePhBOyiUT2wexYdIYXh5VwV9i9koUL8L3Qhm0bNrZ8`. This value will always be different.

**Example 16-16  ApplSessionFilter and JpsFilter Configuration in web.xml**

```xml
<filter-mapping>
    <filter-name>JpsFilter</filter-name>
    <url-pattern>/*</url-pattern>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
    <dispatcher>INCLUDE</dispatcher>
</filter-mapping>
<filter-mapping>
    <filter-name>ApplSessionFilter</filter-name>
    <servlet-name>Faces Servlet</servlet-name>
    <dispatcher>FORWARD</dispatcher>
    <dispatcher>REQUEST</dispatcher>
</filter-mapping>
```

### 16.10.2 Navigator Shows a Little White Box

**Problem**

Clicking the Navigator in the global area shows a little white box.

This is an issue that developers would see.
Solution when in a production environment

- Make sure that you are signed in as a user that has access to some pages in the Navigator menu. You can type the full URL of the page directly into the browser and see if the user can access it.

- Make sure there is a valid connection to the LDAP server. This is needed to check the policies of each entry in the Navigator menu.

- Use Enterprise Manager to make sure the Applications are registered in the topology tables.

- Make sure the Applications Core Setup application is deployed. (From JDeveloper, run .../atgpf/applcore/applications/FndSetup/FndSetup.jws.) This contains the Navigator menu file and usually is deployed to the Oracle Fusion Applications Global domain.

- Check that the menus are in MDS. Check for entries with the path oracle/apps/menu.

Solution when in a development environment

- You usually should run without menu security. The first thing to check is if you have started your web server with this parameter to turn off security checking:
  
  -DAPPLCORE_TEST_SECURED_MENU=N

- Then check steps 3 through 5 in the solution for a production environment.

16.10.3 Navigator Shows Unfiltered Entries

Problem
The Navigator menu is showing all entries, rather than being filtered by what the user has access to, and the Welcome page has all tabs exposed.

Solution
This is caused by menu security being turned off. This should happen only in development environments.

Because menu security is on by default, check that the web server was not started with -DAPPLCORE_TEST_SECURED_MENU=N.
This chapter discusses the Applications Tables, Trees and Tree Tables components used to implement user interface features in JDeveloper.

This chapter includes the following sections:

- Implementing Applications Tables
- Implementing the Applications Tree
- Implementing Applications Tree Tables
- Using the Custom Wizard with Applications Popups

For basic information, see:

- Getting Started with Your Web Interface
- Implementing the UI Shell
- Implementing Applications Panels_Master-Detail_Hover_and Dialog Details

17.1 Implementing Applications Tables

Applications tables are UI components that already contain an Oracle ADF table, a menu bar, a toolbar, and related popups. Developers do not need to create and assemble all these components separately.

Tables include the following:

- Table toolbars with default buttons
- Elements, such as an ADF table and custom toolbar buttons
- Default table actions
- Create actions, such as Create Inline and Create a Duplicate.
- Edit actions, such as Table Row Edit (Dialog Window) and Table Row Edit (Page)

You must use Applications tables to standardize layout and appearance consistency for all your page tables, including read-only pages. When you create an Applications table, you can add table components that allow users to select the table’s contents.

When you add an Applications Table to your JSF page, components of the Applications Table, such as the ADF table, are bound to the model.
Before you begin:
Before you can use Applications tables, you must be familiar with JDeveloper and be able to create JSF pages.

17.1.1 Understanding Applications Tables Facets and Properties

Each table has properties and facets. Properties include table qualities, such as the unique identification number and the type of pattern exposed in the table. Facets are locations for table data, such as locations where you can add toolbars or menu bars. This section describes Applications table properties and facets.

Note:
Any buttons or menu items added in a facet render with a separator because adding more than one component to a facet requires having `<af:group>` around the element. By default, having a group component introduces a separator as an ADF rule.

Table 17-1 describes Applications table facets and facet contents.

<table>
<thead>
<tr>
<th>Facet Name</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>table</td>
<td>Holds ADF table.</td>
<td>ADF Table</td>
</tr>
<tr>
<td>additionalToolbarButtons</td>
<td>Holds toolbar buttons.</td>
<td>ADF command toolbar buttons under an ADF toolbar</td>
</tr>
<tr>
<td>additionalActionItems</td>
<td>Holds menu items to be added to default Action pulldown menu items.</td>
<td>ADF menu item component</td>
</tr>
<tr>
<td>appsTableSecondaryToolbar</td>
<td>Facet for adding more commandToolbar button components to secondary toolbar.</td>
<td>ADF Command Toolbar Buttons</td>
</tr>
<tr>
<td></td>
<td>(Adds more icons.)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Icons usually perform the same actions as menus, but you put the most common as icons so you do not need to pull down the menu.</td>
<td></td>
</tr>
<tr>
<td>appsTableStatusBar</td>
<td>Holds components that contain status bar items. These status bar items are merged with standard items provided by the panelCollection property.</td>
<td>ADF menu item component</td>
</tr>
<tr>
<td>appsTableViewMenu</td>
<td>Holds menu items to be added to default View pulldown menu items of the panelCollection. To add multiple menu items to the view menu, add <code>af:group</code> components containing <code>af:menuItems</code>.</td>
<td>ADF menu item component</td>
</tr>
</tbody>
</table>
Table 17-1  (Cont.) Applications Table Facets

<table>
<thead>
<tr>
<th>Facet Name</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>appsTableAfter</td>
<td>Facet for adding more commandToolbar button components after toolbar. In this facet, any toolbar buttons added appear in a separate row below the normal group of toolbars.</td>
<td>af:toolbar or af:groups of af:toolbars</td>
</tr>
<tr>
<td>Toolbar</td>
<td></td>
<td></td>
</tr>
<tr>
<td>popup</td>
<td>Holds popups. See Using the Custom Wizard with Applications Popups.</td>
<td>Popups under a layout component.</td>
</tr>
<tr>
<td></td>
<td>Important: When a popup is used to create or duplicate a row in an Applications Table, you need to write your own logic behind the popup's Cancel button (Action/ ActionListener) to remove the newly-created row. This can be done by either:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A managed bean method that removes the newly-created row.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Setting the Cancel button's Action property to the rollback method defined in the pageDef file. This method would be defined in the pageDef file if the &quot;rollback&quot; from the operations of the dataControl is dragged and dropped onto the page.</td>
<td></td>
</tr>
</tbody>
</table>

Table 17-2 describes Applications table properties (including properties that are part of the default managed bean), their allowable values, and default actions.

Table 17-2  Applications Table Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Unique identification number for this applications table.</td>
<td>string</td>
</tr>
<tr>
<td>rendered</td>
<td>Whether the applications table is rendered (that is, converted from an object-based description into a graphical image for display).</td>
<td>boolean expression</td>
</tr>
<tr>
<td>tableId</td>
<td>Unique identification number of the underlying ADF table corresponding to this applications table.</td>
<td>string</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------------</td>
<td>------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------</td>
</tr>
<tr>
<td>createPatternType</td>
<td>Whether a Create pattern is enabled and, if so, which pattern. User action: Click Create.</td>
<td><code>&lt;default&gt;</code>, <code>inline</code>, <code>secondaryWindow</code>, <code>page</code>&lt;br&gt;<strong>&lt;default&gt;:</strong> No rows are created. You might choose this value if your table is read-only.&lt;br&gt;<code>inline</code>: New row is created at the top of the current table. If you choose this value, the createpartialTriggers property on the ADF table is set automatically.&lt;br&gt;<code>secondaryWindow</code>: Popup is displayed, allowing users to enter values into a new table row. The new row is added to the top of the table. If you choose this value, you must also set the corresponding Create Popup Id. In addition, you must create the popup UI that shows input fields.&lt;br&gt;<code>page</code>: An ADFc Controller outcome is returned such that navigation to the next view activity occurs.</td>
</tr>
<tr>
<td>editPatternType</td>
<td>Whether an Edit pattern is enabled and, if so, which pattern. User action: Click Edit.</td>
<td><code>&lt;default&gt;</code>, <code>secondaryWindow</code>, <code>page</code>&lt;br&gt;<strong>&lt;default&gt;:</strong> No rows become editable. You might choose this value if your table is read-only.&lt;br&gt;<code>secondaryWindow</code>: Popup is displayed, allowing users to edit values in the currently selected table row. If you choose this value, you must also set the corresponding Edit Popup Id.&lt;br&gt;<code>page</code>: A standard outcome is returned. In this case, users can edit the values in the currently selected table row.</td>
</tr>
<tr>
<td>duplicatePatternType</td>
<td>Whether a Duplicate pattern is enabled and, if so, which pattern. This pattern lets you create an object by duplicating an existing object. The duplication helps you by pre-filling some values. You have full control and can change any of the values during the creation process. User action: Click Duplicate.</td>
<td><code>&lt;default&gt;</code>, <code>inline</code>, <code>secondaryWindow</code>, <code>page</code>&lt;br&gt;<strong>&lt;default&gt;:</strong> No rows are duplicated.&lt;br&gt;<code>inline</code>: Selected row is duplicated. If you choose this value, you must also set the partialTriggers property on the ADF table to:&lt;br&gt;<code>&lt;Applications_Table_Id&gt;:duplicate</code>&lt;br&gt;<code>secondaryWindow</code>: Popup is displayed, allowing users to duplicate the currently selected table row but not its contents. If you choose this value, you must also set the Duplicate Popup Id.&lt;br&gt;<code>page</code>: Currently selected row is duplicated, but not the values it contains. If the applications table is part of an applications panel, set the partialTriggers property on the ADF table to:&lt;br&gt;<code>&lt;Applications_Panel_Id&gt;:&lt;Applications_Table_Id&gt;:duplicate</code></td>
</tr>
<tr>
<td>deleteEnabled</td>
<td>Whether a Delete pattern is enabled. User action: Click Delete.</td>
<td><code>boolean</code>&lt;br&gt;Selected row is deleted.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------</td>
<td>-----------------</td>
</tr>
<tr>
<td>createActionListener</td>
<td>Action binding for the Create button.</td>
<td>method expression</td>
</tr>
<tr>
<td>editActionListener</td>
<td>Action binding for the Edit button.</td>
<td>method expression</td>
</tr>
<tr>
<td>duplicateActionListener</td>
<td>Action binding for the Duplicate button.</td>
<td>method expression</td>
</tr>
<tr>
<td>deleteActionListener</td>
<td>Action binding for the Delete button.</td>
<td>method expression</td>
</tr>
<tr>
<td>createPopupId</td>
<td>Id assigned to the popup to be invoked when users click the Create button.</td>
<td>string</td>
</tr>
<tr>
<td>editPopupId</td>
<td>Id assigned to the popup to be invoked when users click the Edit button.</td>
<td>string</td>
</tr>
<tr>
<td>duplicatePopupId</td>
<td>Id assigned to the popup to be invoked when users click the Duplicate button.</td>
<td>string</td>
</tr>
<tr>
<td>createText</td>
<td>Value that overrides the default label for Create menu item. It also will be shown as the short description for the Create button.</td>
<td>expression</td>
</tr>
<tr>
<td>editText</td>
<td>Value that overrides the default label for Edit menu item. It also will be shown as the short description for the Edit button.</td>
<td>expression</td>
</tr>
<tr>
<td>duplicateText</td>
<td>Value that overrides the default label for Duplicate menu item. It also will be shown as the short description for the Duplicate button.</td>
<td>expression</td>

<tr>
<td>deleteText</td>
<td>Value that overrides the default label for Delete menu item. It also will be shown as the short description for the Delete button.</td>
<td>expression</td>
</tr>
<tr>
<td>attachText</td>
<td>Value that overrides the default label for Attach menu item. This attribute is deprecated.</td>
<td>expression</td>
</tr>
</tbody>
</table>
### Table 17-2 (Cont.) Applications Table Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>featuresOff</td>
<td>List of default features to turn off for the panelCollection</td>
<td>string</td>
</tr>
<tr>
<td>inlineStyle</td>
<td>The CSS styles to use for the panelCollection component inside Applications Table component. This is intended for basic style changes. *Note: Do not set the width using the inlineStyle attribute on either Applications Table or panelStretchLayout. Applications Table can be stretched by placing it in the center facet of an ADF panelStretchLayout component.</td>
<td>string</td>
</tr>
<tr>
<td>styleClass</td>
<td>styleClass to use for the panelCollection component inside Applications Table component.</td>
<td>string</td>
</tr>
<tr>
<td>exportEnabled</td>
<td>Rendered attribute for Export button and menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>createImmediate</td>
<td>Sets immediate attribute value of &quot;Create&quot; toolbar button and &quot;Create&quot; menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>deleteImmediate</td>
<td>Sets immediate attribute value of &quot;Delete&quot; toolbar button and &quot;Delete&quot; menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>duplicateImmediate</td>
<td>Sets immediate attribute value of &quot;Duplicate&quot; toolbar button and &quot;Duplicate&quot; menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>editImmediate</td>
<td>Sets immediate attribute value of &quot;Delete&quot; toolbar button and &quot;Delete&quot; menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>attachImmediate</td>
<td>Sets immediate attribute value of &quot;Attach&quot; toolbar button and &quot;Attach&quot; menu item.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>primaryToolbarRendered</td>
<td>Sets the rendered attribute value of the primary toolbar. When Create, Duplicate, Update, Delete actions, attach, export are not turned on, the primaryToolbarRendered should be set to false so that an empty toolbar will not be displayed.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
<td>Values</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>secondaryToolBarRendered</td>
<td>Sets rendered attribute value of the secondary toolbar. When no af:commandToolbarButton is added to appsTableSecondaryToolbar facet, secondaryToolBarRendered should be set to false so that an empty toolbar will not be displayed.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>&lt;button_name&gt;PartialTriggers</td>
<td>Partial triggers attribute for the &lt;button_name&gt; toolbar button. For example: deletePartialTriggers</td>
<td>String of IDs. Important: The PartialTriggers attribute must be entered manually by the developer. This is because, at design time, the JDeveloper Property Inspector can: • Select the incorrect ID. • Append square brackets around the selected id, such as [id1 id2]. Example 1: To disable the Edit, Delete and Duplicate buttons when the table is empty, set this property on the editDisabled, deleteDisabled or duplicateDisabled property of the Applications Table. #{bindings.VOiterator.estimatedRowCount == 0 ? true: false} where VOiterator is your iterator name Example 2: Disable any of the buttons in the Applications Table according to the functional rules or by setting disable=false when create is selected on an empty table (considering these buttons were disabled following Example 1). To do this, create an attribute binding on the view object attribute that will decide whether the row can be deleted/edited/duplicated. For example, you can use a binding similar to this example on the disable property of a button: #{bindings.MyAtttrBinding.inputValue == 'compare value' ? true : false} Add Partial Page Refresh (PPR) on the button to the table ID of the af:table. This does not require any change in the selectionListener of the table. Keep the default one.</td>
</tr>
<tr>

</tr>
</tbody>
</table>

**Note:**
If you choose secondaryWindow as the pattern type for any property, and you have set the popup Id for that button, selecting the button invokes the popup.

**Model**
The Applications Table does not expose any bindings to the model. However, components within the Applications Table, like the ADF table, will be bound to the model.

**Controller**
The Applications Table component ships a default managed bean that performs the following functions that only work with rowSelection="single" on the ADF table:

- Default event handlers for all toolbar button action events. Event handler delegates to custom action method if set on the button action property.
  - A new row is added into the table when the Create icon is clicked, and the Create Pattern Type is inline.
  - A new row is added into the table and a popup is invoked with the newly-created row available for inserting values (the UI for the popup to show input fields for the new row has to be created separately by the developer), when the Create Pattern Type is secondaryWindow.
  - A new row is not added when the Create Pattern Type is Page. The developer is responsible for wiring the navigation to the page when the icon or menu item is clicked. Only a standard outcome is returned from the default handler. The developer could use this default outcome to define a navigation rule.
  - The selected row is made available for editing in a popup when the Edit icon is clicked, and Edit Pattern Type is secondaryWindow.
– When the Edit icon is clicked, and Edit Pattern Type is Page, only a standard outcome is returned.

– The Duplicate icon is handled the same way as Create. All attribute values except the primary key values are duplicated.

– Clicking the Delete icon deletes the selected row.

• If the secondaryWindow option is chosen for any pattern type, and the corresponding popup Id is set for that button (mandatory), selecting the button invokes the popup.

• If Page is chosen for any pattern type, a standard outcome is returned on clicking the button. Standard outcomes are create, edit, duplicate and delete for the four respective toolbar buttons.

To allow Applications developers access to some of the implementation, the Applications Table exposes a public class oracle.apps.fnd.appcorepatterns.ApplicationsTableEventHandler that contains default event handlers for all the buttons. The button methods are named as process<buttonName>, such as processCreate and processEdit. Application developers writing custom action handlers can also use the default implementation by calling these methods.

Use

For example, to attach a custom button handler to the Create button, follow these steps:

1. Define a managed bean class, as shown in Example 17-1.

2. Register the managed bean in the faces-config of the project.

3. Bring up the Property Inspector for the Applications Table, and choose the Create Action property. Set #{CustomEventHandler.processCreate} as the expression for the property.

Example 17-1  Defining a Managed Bean Class to Attach a Custom Handler to a Button

```java
import oracle.apps.fnd.appcorepatterns.ui.ApplicationsTableEventHandler;
import oracle.apps.fnd.appcorepatterns.ui.util.PatternUtils;

public class CustomEventHandler
{
    public String processCreate()
    {
        // Custom code
        ...

        // Call default event handler if required. It will return a standard outcome for this button click.
        ApplicationsTableEventHandler appTableHandler = ApplicationsTableEventHandler.getInstance();
        String outcome = appTableHandler.processCreate();

        // If popup is required to be invoked after event handling
        PatternUtils.invokePopup(popupId);

        return outcome;
    }
}
```
17.1.2 How to Create an Applications Table

You can create and add Applications tables to pages or page fragments. Using the wizard will create a working table without you having to hand-code every step. When the table is created, you can change any parameters from the Property Inspector.

17.1.2.1 Add Applications Tables to JSF Pages or Page Fragments

You create Applications tables in the Applications Tables wizard, which is displayed when you add the tables to your JSF pages (or page fragments) from the Component Palette or the Data Controls panel.

To start the Applications Table wizard from the Component Palette:

1. Open the Component Palette.
2. In the list, choose Applications.
3. In the list, click Table. JDeveloper will attempt to place the table at the current cursor location. If the current location is not appropriate, an error message displays. You also can drag the Table icon to the page in either the Design or the Source view. A plus + sign will be added to the arrow when it is over a location in which a table can be inserted.

The Applications Table wizard is displayed.

To start the Applications Table wizard using the Data First method:

1. In the Application Navigator, open the Data Control panel.
2. Navigate to the data source that you want to bind to the Applications table. The data source must represent a rowset; that is, it must be a view object.
3. Drag and drop the data control to the JSF page.
4. In the Create context menu that is displayed, choose Applications > Table.

The Applications Table wizard is displayed.

17.1.2.2 Add Applications Table Components Using the Applications Table Wizard

This section explains how to use the Applications Table wizard to add components to your table.

In the Applications Table wizard you can:

- Bind your table to a data source
- Create placeholder columns and define their attributes
- Enable table ADF behaviors
- Select table default actions

The Applications Table wizard has five main dialogs. Click Cancel in any dialog to cancel your actions and exit the wizard. Click Next to accept your settings and continue.
To add an Applications Table using the Applications Table wizard:
When the Applications Table wizard is launched, the Specify the data source ... dialog is displayed.

Figure 17-1  Create Applications Table Dialog (Step 1 of 5)

In this dialog:

- Bind data to the table (optional):
  - Select the Bind Data Now box to bind a data control to the table.
  - In the Data Source field, click Browse to choose from a list of data sources available for binding.
    This step might take a few minutes.
    The Select Table Data Collection dialog is displayed.
Select the data source to bind to your table and click **OK**.

If you do not bind the data, the table creates placeholder columns that can be used for layout purposes.

Click **Next** to display the Set Row Selection and Layout Columns dialog.
Select Read-only Table to prevent users from modifying the data. If you select Read Only, the options in the Component To Use column will change from Input to Output components.

When you choose a data source to bind to your table, these options become available.

**Row Selection**

Select None to disable row selection by users.

Select Single to allow users to be able to select individual rows in the table. This will set the rowSelection attribute to single. Selecting this option means that instead of the UI component determining the selected row, the iterator binding will access the iterator to determine the selected row. This is recommended when using ADF Model data binding.
Select **Multiple** to allow users to be able to select multiple table rows.

**Sorting**

Select to allow users to be able to sort columns. Selecting this option means that the iterator binding will access the iterator which will perform an order-by query to determine the order. This is recommended when using ADF Model data binding. Only keep this checkbox unselected if you do not want to allow column sorting.

**Filtering**

Select to allow users to be able to filter the table based on given criteria. Selecting this option allows the user to enter criteria in text fields above each column. That criteria is then used to build a query-by-example search on the collection, so that the table will display only the results returned by the query.

- The **Columns** section is used to set the behavior of the table's columns.

  **Group**

  Select two or more columns then click this link to group the columns together in the table. The selected columns will be grouped together under a parent column.

  **Ungroup**

  Select columns that are grouped then click this link to ungroup the columns.

**Display Label**

By default, the label is bound to the labels property for the attribute on the table binding. You can instead enter text or an Expression Language expression to bind the label value to something else, for example, a key in a resource file.

**Value Binding**

Shows the attribute to which the value is bound. Use the drop-down list to choose a different attribute. If you simply want to rearrange the columns, you should use the order buttons. If you do change the attribute binding for a column, the label for the column also changes.

**Component to Use**

Shows the component used to display the value. Use the drop-down list to choose a different component. By default, output text components are selected for read only tables. Input text components are selected for all other tables. Input date components are used for attributes that are dates. If you want to use a different component, such as a command link or button, you need to use this dialog to select the outputText component, and then in the Structure window, replace the component with the desired UI component (such as a command link). By default, only ADF Faces components are shown in the menu. You can allow JSF Implementation components to also be chosen.

**Add Column**

Select a column name from the attributes list and click + to add the column name to your table. Repeat this step for all your table column names.

**Delete Column**

Click X to delete a column name.

**Sort Column Order**

Click the up or down arrows to sort the order of the columns.
Click **Next** to display the Select Table CRUD Patterns (Create, Read, Update and Delete) dialog.

**Figure 17-4   Select table CRUD Patterns Dialog (Step 3 of 5)**

Select default actions for your Applications table (optional):

- **Create / Pattern**: Creates a table row.
  
  When you have chosen to enable row creation, choose a pattern from the list to invoke an action.
  
  - **Inline**: Perform the action on the current table row (only available for the Duplicate action)
  
  - **Popup**: Bring up a div modal window on top of the current page for the requested action
If you choose the Popup pattern, click **Configure Popup** to display the Applications Popup wizard (see Using the Custom Wizard with Applications Popups) and follow the instructions to configure the popup associated with this pattern. See Understanding Applications Tables Facets and Properties for important information about the popup’s **Cancel** button.

- **Page** - Replace the current page or page fragment with a completely separate page or page fragment to perform the action. Page fragments are used when using bounded task flows.

- **Duplicate / Pattern**: Duplicates the row.
  
  When you have chosen to enable row duplication, choose a pattern from the list to invoke an action.

- **Edit / Pattern**: Enables row modification.
  
  When you have chosen to enable row editing, choose a pattern from the list to invoke an action.

- **Delete**: Allows users to delete the row.
  
  **Confirm Delete**: Select this option so that the default **The selected record(s) will be deleted. Do you want to continue?** prompt displays in a popup when the delete row function is used.
  
  When you set the `confirmDelete` attribute to true, the confirmation popup displays and the row is deleted when you click **Yes**. For this to work correctly, the `partialTriggers` on the `af:table` inside the `fnd:applicationsTable` should include `::confirm`, and the `::delete` and `::deleteConfirm` ids must be removed so the `partialRefresh` happens only when you click **Yes** in the popup. Developers can choose to set the immediate property on the **Yes** button by using the `deleteImmediate` attribute. The **No** button has immediate set to true by default. See Manually Enabling Delete Confirmation.

  **Confirmation Message**: If you want to replace the default confirmation message with a custom one, enter the string here. The string will be converted to a text resource and added to the default resource bundle.
  
  If you already have a confirmation message defined in a resource bundle, click the ellipsis and choose from the list.
  
  If you need to manually create or edit the Delete Confirmation parameter, see "Manually Enabling Delete Confirmation."

- **Export**: Export the data to a Microsoft Excel-compatible file.

For more information on pattern types, see Table 19-2, "Applications Table Properties".

Click **Next** to display the Set Table Features dialog.
This dialog allows selection of options to simplify the output.

**Table Summary:** Enter a summary description of the table. The attribute is written to the `af:table` as:

```javascript
summary='#{viewControllerBundle.SUMMARY_TEXT_RESOURCE}'
```

The default selection, **Use Default Configuration**, selects the most simplified UI output.

The business rules on what each of these options render to the page are explained below. Refer to the callout numbers (1–9) in the image above.

1. **Show Actions Menu:** Sets `fnd:applicationsTable actionsMenuRendered = "false"` when it is not selected. Nothing is written when it is selected.

2. **Show View Menu:** Adds `fnd:applicationsTable featuresOff= "viewMenu"` when it is not selected. Nothing is written when it is selected.

3. **Show Format Menu:** Adds `fnd:applicationsTable featuresOff= "formatMenu"` when it is not selected. Nothing is written when it is selected.

4. **Icons and Text:** Set `fnd:applicationsTable defaultToolbarItemDisplay= "icon" or "iconAndText"`.

5. **Show Detach:** Adds `fnd:applicationsTable featuresOff= "detach"` when it is not selected. Nothing is written when it is selected.

6. **Show Wrap:** Adds `fnd:applicationsTable featuresOff= "wrap"` when it is not selected. Nothing is written when it is selected.

7. **Show Freeze:** Adds `fnd:applicationsTable featuresOff= "freeze"` when it is not selected. Nothing is written when it is selected.

8. **Show Status Bar:** Adds `fnd:applicationsTable featuresOff= "statusBar"` when it is not selected. Nothing is written when it is selected.

9. **Row Headers:**
   - If "False" does nothing.
   - If "True" sets `af:column rowHeader="true"` for every column defined by the view object as a key.
   - If "Unstyled (default)" sets `af:column rowHeader="unstyled"` for every column defined by the view object as a key.
Other actions:

- If nothing is selected in the CRUD patterns page, that is, nothing to go into the toolbars: set `fnd:applicationsTable primaryToolbarRendered = "false"` and `fnd:applicationsTable secondaryToolbarRendered = "false"

- Set `af:table styleClass = "verticalGridVisible"` if there are nested columns.

- If no CRUD patterns are set, leave `rowSelection=single` and remove the `selectedRowKeys` and `selectionListener` attributes. This prevents client server communications to synchronize the selected row.

Click Next to review the table structure.

**Figure 17-6  Review the Table Structure (Step 5 or 5)**
Click **Finish** to save your choices and create the Applications table, or click **Cancel** to delete your choices.

If you click **OK**, the table and its components appear in the editor.

**Figure 17-7  Applications Table and Its Components in the Editor**

<table>
<thead>
<tr>
<th>Code</th>
<th>Name</th>
<th>Enabled (Yes/No)</th>
<th>Zulu Offset</th>
<th>DST (Yes/No)</th>
</tr>
</thead>
<tbody>
<tr>

<td>GMTSettled</td>
<td>DaylightSavingsFlag</td>
</tr>
</tbody>
</table>

17.1.2.2.1 Manually Enabling Delete Confirmation

This section describes how to enable Delete Confirmation, or add or edit the custom confirmation message, if you have an existing table.

When you set the `confirmDelete` attribute to `true`, the confirmation popup displays and the row is deleted when you click **Ok**. For this to work correctly, the `partialTriggers` on the `af:table` inside the `fnd:applicationsTable` should include `::confirm`, and the `::delete` and `::deleteConfirm` ids must be removed so the partialRefresh happens only when you click **Ok** in the popup. Setting `deleteImmediate="true"` when enabling delete confirmation sets the immediate attribute of the **Ok** button in the confirmation popup to true. The **Cancel** button of the delete confirmation popup has immediate set to true by default.

See **Example 17-2** for sample code that shows both the delete confirmation enabled and the custom message.

With `af:table` selected in the Structure view, **Figure 17-8** shows the PartialTriggers entries in the Property Inspector view.

**Figure 17-8  Delete Confirmation PartialTriggers in Property Inspector**

With `fnd:applicationsTable` selected in the Structure view in JDeveloper, the Property Inspector showing the custom message settings will appear similar to **Figure 17-9**.
**Figure 17-9  Message Settings in Property Inspector**

![Message Settings in Property Inspector](image)

**Example 17-2  Sample Code Showing Delete Confirmation and Custom Message**

```xml
<fnd:applicationsTable tableId="ATt2" id="AT2" confirmDelete="true"
    deleteMsg="#{viewcontrollerBundle.ARE_YOU_SURE_YOU_WANT_TO_DELETE}"
    deleteEnabled="true" createPatternType="inline"
    duplicatePatternType="inline" editPatternType="inline"
    exportEnabled="true"
    createText="#{viewcontrollerBundle.NEW}">
   <f:facet name="additionalToolbarButtons"/>
   <f:facet name="additionalActionItems"/>
   <f:facet name="appsTableSecondaryToolbar"/>
   <f:facet name="appsTableStatusbar"/>
   <f:facet name="appsTableViewMenu"/>
   <f:facet name="table">
      <af:table var="row" rowBandingInterval="0" id="ATt2"
        partialTriggers="::confirm ::create ::createMenuItem ::duplicate ::duplicateMenuItem">
   </f:facet>
</fnd:applicationsTable>
```

### 17.1.2.2.2 Multiple Row Selection on Table

If multiple row selection is enabled, editing functions will behave as shown in Table 17-3.

**Table 17-3  Function Behavior with Multiple Row Selection Enabled**

<table>
<thead>
<tr>
<th>Function</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete</td>
<td>Selecting more than one row and selecting Delete deletes all the selected rows.</td>
</tr>
<tr>
<td>Create</td>
<td>Selecting more than one row and selecting Create will create a new row as the first row.</td>
</tr>
<tr>
<td>Edit</td>
<td>Selecting more than one row and selecting Edit will show an alert window asking you to select a single row to edit.</td>
</tr>
<tr>
<td>Duplicate</td>
<td>Selecting more than one row and selecting Duplicate will show an alert window asking you to select a single row to duplicate.</td>
</tr>
</tbody>
</table>
Enabling Multiple Row Selection Manually

If multiple row selection is selected in the Create Applications Table wizard (see Figure 17-1), this step is not required.

You can not change pages created with single row selection to multiple row selection by just changing the `rowselection` attribute on the ADF table inside the Applications Table. This is because multiple row selection does not work with the `selectedrowkeys` attribute. To enable multiple row selection on existing tables, set `rowselection="multiple"` and remove the `selectedrowkeys` attribute, as shown in Example 17-3.

**Example 17-3   Example of Enabling Multiple Row Selection**

```xml
<fnd:applicationstable tableid="att3" id="at3" deleteenabled="true"
    createpattern="inline"
    dupplicatepattern="inline"
    editpattern="inline"
    createtext="#{viewcontrollerbundle.new}"
    <f:facet name="additionaltoolbarbuttons"/>
    <f:facet name="additionalactionitems"/>
    <f:facet name="table">
        <af:table value="#{bindings.gsflattable1.collectionModel}" selectionListener="#{bindings.gsflattable1.collectionModel.makeCurrent}" var="row" rows="#{bindings.gsflattable1.rangesize}"
            emptytext="#{bindings.gsflattable1.viewable ? applcorebundle.table_empty_text_no_rows_yet : applcorebundle.table_empty_text_access_denied}"
            fetchsize="#{bindings.gsflattable1.rangesize}"
            rowbandinginterval="0" id="att3"
            partialtriggers="::delete ::deletemenuitem ::create ::createmenuitem ::duplicate ::duplicatemenuitem ::selectionlistener ::selectedrowkeys"
            rowselection="multiple">
```

17.1.2.2.3 Toggle Click to Edit / Edit All in Applications Table

The Applications Table toolbar has an icon that can be clicked to toggle the Click to Edit and Edit All functions, and the View Menu on the toolbar includes the same toggle feature. Figure 17-10 shows the Edit All menu option and icon when the table is in the Click to Edit mode.

**Figure 17-10   Table Edit All Menu Option and Icon**

![Table Edit All Menu Option and Icon](image)

Figure 17-11 shows the Click to Edit menu option and icon when the table is in the Edit All mode.
The toggle mode should only display if the table is editable. If it contains only output components, there should be no toggle button. This is a true/false property (see toggleEditRendered in Table 17-2) on the Applications Table and does not happen automatically.

17.1.3 Introduction to Selected Elements in the Table Property Inspector

When a table is added to a page, code similar to that shown in Example 17-4 is inserted and displayed in the Source view.

Many of these settings are easily changed using the Table Property Inspector, which contains these sub-sections: Common, Patterns, Style, Customization, and Other. This section discusses certain selected settings.

Example 17-4  Sample Code Added When a Table Is Added

```
<fnd:applicationsTable tableId="AT1" id="AT1" confirmDelete="true"
    deleteMsg="#{viewcontrollerBundle.DO_YOU_WANT_TO_DELETE_THIS_ROW}"
    deleteEnabled="true" createPatternType="inline"
    duplicatePatternType="secondaryWindow"
    editPatternType="inline" exportEnabled="true"
    createText="#{viewcontrollerBundle.NEW}"
    duplicatePopUpId="Afp2">
    <f:facet name="additionalToolbarButtons"/>
    <f:facet name="additionalActionItems"/>
    <f:facet name="table">
        <af:table value="#{bindings.ServiceRequests1.collectionModel}"
                var="row" rows="#{bindings.ServiceRequests1.rangeSize}"
                emptyText="#{bindings.ServiceRequests1.viewable ?
                    applcoreBundle.TABLE_EMPTY_TEXT_NO_ROWS_YET :
                applcoreBundle.TABLE_EMPTY_TEXT_ACCESS_DENIED}"
                fetchSize="#{bindings.ServiceRequests1.rangeSize}"
                rowBandInt="0"
                selectedRowKeys="#{bindings.ServiceRequests1.collectionModel.selectedRow}"
                selectionListener="#{bindings.ServiceRequests1.collectionModel.makeCurrent}"
                rowSelection="single" id="AT1"
                partialTriggers="::confirm ::create ::createMenuItem">
```

17.1.3.1 Common Properties Section

The Common properties section of the Table Property Inspector resembles Figure 17-12.
The selected Common settings are:

- **Primary Toolbar Rendered**: Set this to False if no default actions or buttons will be used. If this is set to True and there will be no actions or buttons, the separators around buttons will display even if no button displays.

- **Secondary Toolbar Rendered**: Set this to False if no default actions or buttons will be used. If this is set to True and there will be no actions or buttons, the separators around buttons will display even if no button displays.

- **Actions Menu Rendered**: If no default actions were selected in the wizard, set this to False to avoid doubled separator lines.

- **ActionsContentDelivery**: Sets the Content Delivery attribute on the actions menu of the table. The options are Immediate (the default) and Lazy. Immediate populates the action menus as soon as the page is displayed. Lazy only populates an action menu when it is selected. There will be a slight delay the first time the menu is selected; there will be no delay the next time the menu is selected because the menu items are cached. You should set the ActionsContentDelivery to Lazy when you do not have any partialTriggers set on the items in the Actions menu because setting the value to Immediate affects the performance.

### 17.1.3.2 Patterns Properties

The Patterns properties section of the Table Property Inspector resembles Figure 17-13. The properties for Create, Duplicate, Edit, and Delete are the same.
The selected Patterns settings are:

- **Disabled**: Sets whether the button is disabled (shown as grayed). This does not determine if the button is displayed; it only sets its appearance and functionality.

- **Enabled**: Sets the rendered attribute on the Create/Duplicate/Edit/Delete button icon and menu item. If you are using the default action, a string called `create` (or `duplicate/edit/delete`) is returned.

- **Immediate**: Sets whether data validation - client-side or server-side - should take place when events are generated by the button. When immediate is set to `true`, the default ActionListener provided by the JavaServer Faces implementation should be executed during the Apply Request Values phase of the request processing lifecycle, rather than waiting until the Invoke Application phase.

- **Partial Triggers**: A partial trigger affects only the selected item, rather than the entire page. For instance, Example 17-5 sets the partialTrigger attribute value on the Create button icon and Create menu item.

**Example 17-5  Example of a Partial Trigger**

```xml
<af:inputComboboxListOfValues id="ledgerIdId" popupTitle="Search and Select: #{bindings.LedgerId.hints.label}" value="#{bindings.LedgerId.inputValue}" label="#{bindings.LedgerId.hints.label}" model="#{bindings.LedgerId.listOfValuesModel}" required="#{bindings.LedgerId.hints.mandatory}" columns="#{bindings.LedgerId.hints.displayWidth}" shortDesc="#{bindings.LedgerId.hints.tooltip}"
    <f:validator binding="#{bindings.LedgerId.validator}"/>
    <af:convertNumber groupingUsed="false" pattern="#{bindings.LedgerId.format}"/>
</af:inputComboboxListOfValues>

<fnd:applicationsTable tableId="AT1" id="AT1" deleteEnabled="true" createPatternType="inline"
    duplicatePatternType="inline" editPatternType="inline"
    createText="#{viewcontrollerBundle.NEW}"/>```
17.1.3.3 Other Properties

The Patterns properties section of the Table Property Inspector resembles Figure 17-14.

Figure 17-14 Other Properties Section

- AttachImmediate and AttachText: Do not use. These have been deprecated.

17.1.4 How to Modify Applications Table Components and Properties

When you create an Applications table in the Applications Table wizard, you can add data controls to the table and icons and menu actions to the table menu bar.

17.1.4.1 Add Data Controls to Tables

To add Data Controls to tables:

1. Find the data source in the Data Controls panel.

2. Drag and drop either the entire data source or individual fields:

   - To the table in the page Design view.

     Use the context menu that is displayed when you drag to the Design view to choose which component to use for this attribute.

     For example, you might drag and drop the data control component TimezoneServiceAMDataControl > Timezone > Name, then choose Create > Texts > ADF Input Text w/ Label from the context menu, as shown in Figure 17-15.

     Figure 17-15 Example of Context Menu Choices in Design View

   - To the page Structure view.
For example, to add a field from a data source to a table, drag the field from the data source to this path: \texttt{fnd:applicationsTable > f:facet – table > af:table <tableId>}. When you drop the field on the component, you are prompted to choose which component to use for this attribute. Using the example in Figure 17-16, you would choose either the ADF Read-only Column, or the ADF Column, depending on whether the fields need to be read-only or not.

\textbf{Figure 17-16} \hspace{1em} \textit{Example of Context Menu Choices in Structure View}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{image168x420.png}
\caption{Example of Context Menu Choices in Structure View}
\end{figure}

\subsection{17.1.4.2 Working with Table Menus and Icons}

To add buttons, icons and menu items to the table menu bar, in the Component Palette, drag and drop any component (such as an icon component) to the menuBar facet to add the component.

If you have multiple buttons added to the additionalToolbarButton facet, they may display vertically, instead of horizontally, at runtime. To correct this display, surround the toolbar buttons with an af:toolbar, as shown in Example 17-6:

\begin{example}
\textbf{Example 17-6 \hspace{1em} Surrounding the Toolbar Buttons with af:toolbar}

\begin{verbatim}
<af:facet name="additionalToolbarButtons">
  <af:toolbar>
    <af:commandToolbarButton text="Button1"/>
    <af:commandToolbarButton text="Button2"/>
  </af:toolbar>
</af:facet>
\end{verbatim}
\end{example}

\begin{note}
The Format menu is part of Applications Table. It provides several functions, including move rows and sort selection. Rows have to be selectable to enable this.

For tables and treeTables with selectable columns, the default top level menu items are View and Format. To turn off the Format menu, the af:table should not have selectable columns.
\end{note}
17.1.4.3 Increasing Table Width to Fill 100% of Its Container

Applications Table can be stretched by placing it in the center facet of an ADF panelStretchLayout component. Do not set the width using the inlineStyle attribute on either Applications Table or panelStretchLayout. For more information about basic page layout and the inlineStyle attribute, see the "Organizing Content on Web Pages" and the "Customizing the Appearance Using Styles and Skins" chapters in the Developing Web User Interfaces with Oracle ADF Faces.

17.1.4.4 Using an Applications Table with a Query Component

Note:

If you use just the ApplicationTable ID in the resultComponentId of the ADF Query component, the underlying table is not refreshed with the results of the search.

When using an Applications Table as a resultant table that shows the results from a search on a query component, follow these steps to set the resultComponentId attribute on af:query:

1. In the JSF page that contains the query component and the Applications Table, select the query component.

2. In the Property Inspector, select the resultComponentId property and then Edit.

3. From the edit panel, select the af:table (the ADF table that is present in the "table" facet of the Applications Table).

The resultComponentId would follow this format:

::<applicationsTableId>:_ATp:<tableId>

and would appear similar to:

resultComponentId="::AT1:_ATp:ATt7"

17.2 Implementing the Applications Tree

The Applications Tree component provides the following basic capabilities that satisfy the requirements specified in the user experience designs:

- Tree toolbar with default buttons
- Facets for adding ADF tree, custom toolbar buttons, and so on
- Default implementations for tree actions

17.2.1 How to Add an Applications Tree to Your Page

You can add an Applications Tree to your page in two ways.

- You can select the Applications Tree from the Applications component palette and drag and drop it on your page.
- You can drag and drop a data collection from the data control palette to your page and select the Applications Tree from the list of available UI components.
The facets shown in Table 17-4 are exposed on the Applications Tree.

### Table 17-4  Applications Tree Facets

<table>
<thead>
<tr>
<th>Facet</th>
<th>Description</th>
<th>Allowed Children</th>
</tr>
</thead>
<tbody>
<tr>
<td>tree</td>
<td>Facet for holding the ADF tree</td>
<td>ADF Tree</td>
</tr>
<tr>
<td>additionalToolbarButtons</td>
<td>Facet for adding toolbar button icons by the developer.</td>
<td>ADF Command Toolbar Buttons</td>
</tr>
<tr>
<td>additionalActionItems</td>
<td>Facet for adding more menu items to default menu items.</td>
<td>ADF menu item component</td>
</tr>
<tr>
<td>appsTreeSecondaryToolbar</td>
<td>Facet for adding more commandToolbar components to secondary toolbar.</td>
<td>ADF Command Toolbar Button component</td>
</tr>
<tr>
<td>appsTreeStatusBar</td>
<td>Facet for adding component containing statusbar item(s). These statusbar items are merged with standard items provided by the panelCollection.</td>
<td>ADF component</td>
</tr>
<tr>
<td>appsTreeViewMenu</td>
<td>Facet for adding Menu Item(s) to added to the default view menu of the panelCollection. To add multiple menuItems into the view menu please add af:group component containing af:menuItems.</td>
<td>ADF menu item component</td>
</tr>
<tr>
<td>appsTreeAfterToolBar</td>
<td>Facet for adding more commandToolbar button components to after toolbar. In this facet any toolbar buttons added appear in a separate row below the normal group of toolbars.</td>
<td>&quot;af:toolbar&quot; or &quot;af:groups&quot; of &quot;af:toolbars&quot;</td>
</tr>
<tr>
<td>popup</td>
<td>Facet for adding popups. See Using the Custom Wizard with Applications Popups.</td>
<td>Any number of popups under a layout component</td>
</tr>
</tbody>
</table>

**Important:** When a popup is used to create or duplicate a row in an Applications Tree, you need to write your own logic behind the popup’s Cancel button (Action/ActionListener) to remove the newly-created row.

This can be done by either:

- A managed bean method that removes the newly-created row.
- Setting the Cancel button’s Action property to the rollback method defined in the pageDef file. This method would be defined in the pageDef file if the “rollback” from the operations of the dataControl is dragged and dropped onto the page.

The properties shown in Table 17-5 are exposed on the Applications Tree.
### Table 17-5 Exposed Applications Tree Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>The unique ID for this Applications Tree</td>
<td>string</td>
</tr>
<tr>
<td>rendered</td>
<td>Whether the Applications Tree is rendered or not</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>treeId</td>
<td>The unique ID of the ADF tree underneath this Applications Tree</td>
<td>string</td>
</tr>
<tr>
<td>createPatternType</td>
<td>Whether any Create pattern is enabled, and if yes, which pattern</td>
<td>none, secondaryWindow (then Create Popup Id must also be set), page</td>
</tr>
<tr>
<td>editPatternType</td>
<td>Whether any Edit pattern is enabled, and if yes, which pattern</td>
<td>none, secondaryWindow (then Edit Popup Id must also be set), page</td>
</tr>
<tr>
<td>duplicatePatternType</td>
<td>Whether any Duplicate pattern is enabled, and if yes, which pattern</td>
<td>none, inline (see &quot;Inline Duplicate Pattern Type&quot;), secondaryWindow (then Duplicate Popup Id must also be set), page</td>
</tr>
<tr>
<td>createEnabled</td>
<td>Rendered attribute for create</td>
<td>string</td>
</tr>
<tr>
<td>editEnabled</td>
<td>Rendered attribute for edit</td>
<td>boolean value or Expression Language expression</td>
</tr>
<tr>
<td>duplicateEnabled</td>
<td>Rendered attribute for duplicate</td>
<td>boolean value or Expression Language expression</td>
</tr>
<tr>

<tbody>
<tr>
<td>exportRowLimit</td>
<td>This property sets the row limit for exported rows when &quot;Export to Excel&quot; is used to export records to Excel. If this is not set, then the row limit is picked from the value that is set for the profile option FND_EXPORT_ROWLIMIT.</td>
<td>Positive integer.</td>
</tr>
</tbody>
</table>

### Inline Duplicate Pattern Type

For inline patterns, the ADF tree underneath the Applications Tree should get refreshed when the icon or the menu item is clicked. For this to happen, the ADF tree needs to know that it should partially refresh itself. For this, set the partialTriggers attribute on the ADF tree to the ids of the menu item and the icon. For example, to refresh the tree when the **Delete** menu item or icon is clicked, set partialTriggers="delete deleteMenuItem" on the ADF tree. The partialTriggers attribute is set by the Applications Tree Creation wizard automatically; Applications developers should not need to set it explicitly. **Example 17-7** shows a sample markup that is generated by the Applications Tree Creation wizard.

### Model

The Applications Tree does not expose any bindings to the model. However, components within the Applications Tree, like the ADF tree, will be bound to the model.

### Controller

The Applications Tree component ships a default managed bean that performs the following functions:

- Default event handlers for all toolbar button/menu item action events. Event handler delegates to custom action method if set on the button/menu item action property.
  - A new row is created in the data collection, a popup invoked with the newly created row available for inserting values (the UI for the popup to show input fields for the new row has to be created separately by the developer), when Create Pattern Type is secondaryWindow. After the popup is dismissed, the tree is refreshed to display the newly-created node:
    - If **No Node** is selected when the **Create** button or menu item is clicked: The new node is created in the first-level of the Tree.
    - If **Leaf Node** or **Expanded Parent Node** is selected when the **Create** button or menu item is clicked: The new node is created as a child of the selected node, and placed directly below it.
    - If **Collapsed Parent Node** is selected: The parent is expanded to show the newly created child node placed directly below it.
  - A new row is *not* added when the Create Pattern Type is **page**, and the developer is responsible for wiring the navigation to the page when the icon or menu item is clicked. Only a standard outcome is returned from the default handler. The developer could use this default outcome to define a navigation rule.
− The selected row is made available for editing in a popup when the Edit icon is clicked, and Edit Pattern Type is secondaryWindow.

− When the Edit icon is clicked, and Edit Pattern Type is page, only a standard outcome is returned.

− When the Duplicate icon or menu item is clicked: A new node is added into the tree when the Create icon is clicked, and Create Pattern Type is inline. All non-primary key values of the selected node are copied to the new node.

− If Duplicate Pattern Type is inline, the newly created node is placed next to the selected node.

− If Duplicate Pattern Type is popup, a popup invoked with the newly created row is available for modifying the duplicated values (the UI for the popup to show input fields for the new row has to be created separately by the developer).

− Clicking the Delete icon deletes the selected node. It currently does not perform a cascade delete when a parent node is selected for delete. Applications developers need to handle deleting the child nodes if it is necessary.

• If the secondaryWindow option is chosen for any pattern type, and the corresponding popup id is set for that button (mandatory), then selecting the button invokes the popup.

• If page is chosen for any pattern type, then a standard outcome is returned on clicking the button. Standard outcomes are: create, edit, duplicate and delete for the four respective toolbar buttons.

• A default selection listener for the ADF tree is provided (the markup shows selectionListener="#{ApplicationsTreeBean.treeSelectionHandler}"). If you need to add custom logic to the selection listener, you should call this default selection listener from the custom logic. The treeSelectionHandler method of the ApplicationsTreeBean provides the following behavior:

  − When xxxxPatternType="secondaryWindow" and when there is no popup configured for the level where the node must be created, the icon and the menu item are disabled by default. But this behavior can be overridden by the xxxxDisabled attribute, where “xxxx” could be create, edit or duplicate.

  − Calls the ADF default tree listener:
    #{bindings.xxxx.treeModel.makeCurrent}

Example 17-8 shows sample code for calling the default selection listener from the custom selection listener.

To allow developers access to some of the implementation, the Applications Tree exposes a public class, oracle.apps.fnd.appcore.patterns.ApplicationsTreeEventHandler, that contains default event handlers for all the buttons. The button methods are named as process<buttonName>, such as processCreate and processEdit. Applications developers writing custom action handlers can also use the default implementation by calling these methods.
Use

For example, to attach a custom button handler to the Create button, follow these steps.

1. Define a managed bean class, as shown in Example 17-9:

2. Register the managed bean in the faces-config of the project.

3. Select the Property Inspector for the Applications Tree, and choose the Create Action property. Set #{CustomEventHandler.processCreate} as the expression for the property.

Example 17-7  Sample Markup Generated by the Applications Tree Creation Wizard

```xml
<fnd:applicationsTree treeId="tree1" id="appsTree1"
  createPatternType="secondaryWindow"
  createPopupId="create1,create2"
  duplicatePatternType="inline"
  deleteEnabled="true">
  <af:tree value="#{bindings.ServiceRequestsView1.treeModel}"
    var="node" rowSelection="single"
    selectionListener="#{ApplicationsTreeBean.treeSelectionHandler}"
    id="tree1"
    partialTriggers="::duplicate ::duplicateMenuItem ::delete ::deleteMenuItem">
    ...
  </af:tree>
</fnd:applicationsTree>
```

Example 17-8  Calling the Default Selection Listener from the Custom Selection Listener

```java
String defaultListener = "#{ApplicationsTreeBean.treeSelectionHandler}";
FacesContext fc = FacesContext.getCurrentInstance();
ExpressionFactory ef = fc.getApplication().getExpressionFactory();
MethodExpression me = ef.createMethodExpression(fc.getELContext(), defaultListener,
  String.class, new Class[] {SelectionEvent.class});
me.invoke(fc.getELContext(), new Object[] {selectionEvent});
```

Example 17-9  Defining Managed Bean Class to Attach Custom Handler to a Button

```java
import oracle.apps.fnd.applcore.patterns.ui.ApplicationsTreeEventHandler;
import oracle.apps.fnd.applcore.patterns.ui.util.PatternUtils;

public class CustomEventHandler
{
  public String processCreate()
  {
    // Custom code
    ...

    // Call default event handler if required. It will return a standard outcome for
    // this button click.
    ApplicationsTreeEventHandler appTreeHandler =
    ApplicationsTreeEventHandler.getInstance();
    String outcome = appTreeHandler.processCreate();

    // If popup is required to be invoked after event handling
    PatternUtils.invokePopup(popupId);

    return outcome;
  }
}
```
17.2.1.1 Adding the Applications Tree

The Applications Tree can be added to a page or page fragment using either the Component First or the Data First approach. Valid drop locations in the page or page fragment include ADF Form, and ADF Layout components and the Applications Panel (jsp:root, af:form, af:root, fnd:applicationsPanel, af:group, af:panelBorderLayout, af:panelBox, af:panelCollection, af:panelFormLayout, af:panelGroupLayout, af:panelHeader, af:panelStretchLayout, af:showDetailItem, af:panelWindow, af:popup, af:showDetail, af:subform, f:facet, f:panelGrid, f:panelGroup, af:pageTemplateDef, af:pageTemplate#$<localArea_Facet>).

The Applications Tree can be added to a page or page fragment using either the Component First or the Data First approach. Both approaches launch a wizard that helps you quickly define the appropriate tree layout which adhere to the user experience standards. When you complete this wizard, you can further refine the tree definition by editing the resulting tree component as needed.

Component First

Navigate to the Component Palette. Click the list of libraries and select Applications. Drag the Applications Tree from the list of components and drop it onto the page. The wizard will launch after dropping the Applications Tree on the page.

Data First

Navigate to the Data Controls panel of the Application Navigator. Open the panel by clicking its bar, then navigate through the hierarchy to locate the data source that you would like to include in the Applications Tree. Select that data source and drag it onto the page. A context menu will appear with a list of components. Move the mouse over the Applications category list. Select Tree under the Applications menu to launch the Applications Tree wizard, as shown in Figure 17-17.

Figure 17-17  Data First Method

17.2.1.2 Applications Tree Create Wizard

The Applications Tree Create wizard consists of two panels: Create Applications Tree and Configure Tree Patterns.
Create Applications Tree Panel

The Create Applications Tree panel will vary depending on the approach used to launch the Applications Tree creation process.

Using the Data First approach the Bind Data Now properties are hidden. The selected data source is automatically bound to the tree.

With the Component First approach, it is up to the developer to decide whether to bind a Data Collection to the tree component. You can skip the data control binding step when creating the Applications Tree. In this case, the Applications Tree will create an ADF tree without data binding.

If you wish to bind a data control to the tree component using the Component First approach, check the Bind Data Now checkbox. This will enable the Browse button for the Data Source property. Click Browse to display a list of data sources available for binding. Navigate through the list, select the desired data source, and click OK, as shown in Figure 17-18.

Figure 17-18 Create Applications Tree Data Source

When the Data Source is selected, you can configure the ADF tree. Use the Add icon to add one of the children of the selected Data Source to be the next level of the tree, as shown in Figure 17-19.
Tree Level Rules: This pane displays rules that control the display order of the hierarchical tree or tree table UI components. The tree binding populates the tree UI component starting from the top of the Tree Level Rules list and continues until it reaches the last rule or until it encounters a rule whose accessor cannot find a target attribute. The more rules you choose, the more nodes you can display in the tree or tree table UI component.

Folder Label: Specify an Expression Language expression that selects labels to display in the tree, such as #{label.countryLabel}.
You also can use the Expression Language expression #{node.accessorLabel} to obtain information that allows you to traverse up and down a tree of data, not necessarily starting at the logical root node of the tree. This is useful if you want to access a parent node rather than the root node of the tree.

Enable Filtering: Select to filter the data that displays in the tree or tree table. After you select this checkbox, you can select an attribute on the data collection that will be used to filter the table data that display in the tree or tree table.

Available Attributes and Selected Attributes: The shuttle at the bottom of the Create Applications Tree panel allows you to control the attributes at each tree level you wish to display as a tree node in the tree. When finished, click Continue to proceed to the Configure Tree Patterns Dialog. Select Cancel to abort the creation of the Applications Tree.
Configure Tree Patterns Panel

Use the Configure Tree Patterns panel to select the default actions offered by your Applications Tree. See Figure 17-20.

**Figure 17-20  Configure Tree Patterns**

You may select any or all of the following five actions for your Applications Tree: Create, Duplicate, Edit, Delete and Export. If you enable Create, Duplicate, or Edit, you must choose the appropriate pattern that will be used to invoke that action (Inline, Popup, or Page).

- **Inline** - Perform the action on the current table row (only available for the Duplicate action)
- **Popup** - Bring up a div modal window on top of the current page for the requested action
- **Page** - Replace the current page or page fragment with a completely separate page or page fragment to perform the action. Page fragments are used when using bounded task flows.

The **Add** button for configuring the **Popup** button is enabled when the Popup pattern is selected. When you click **Add**, a dropdown of the data collection name of each tree level is displayed. You need to choose the tree level that needs the popup to be configured. When a data collection name is selected, the Applications Popup wizard is displayed. (See Using the Custom Wizard with Applications Popups.) This same data collection will automatically be bound to the Applications Popup. The Popup will also be defaulted as having Editable Content on the Window Buttons page in the wizard.

**Export**: Export the data to a Microsoft Excel-compatible file.

**Delete**: Allows users to delete the row.
• **Confirm Delete**: Select this option so that the default *The selected record(s) will be deleted. Do you want to continue?* prompt displays in a popup when the delete row function is used.

When you set the `confirmDelete` attribute to **true**, the confirmation popup displays and the row is deleted when you click **Ok**. For this to work correctly, the `partialTriggers` on the `af:tree` inside the `fnd:applicationsTree` should include `::confirm`, and the `::delete` and `::deleteConfirm` ids must be removed so the `partialRefresh` happens only when you click **Ok** in the popup. See [Manually Enabling Delete Confirmation](#).

• **Confirmation Message**: If you want to replace the default confirmation message with a custom one, enter the string here. The string will be converted to a text resource and added to the default resource bundle.

If you already have a confirmation message defined in a resource bundle, click the ellipsis and choose from the list.

When finished, click **OK** to complete creation of the Applications Tree. Selecting **Cancel** will abort the creation of the Applications Tree.

### 17.2.1.3 Working with the Applications Tree

This section discusses modifying settings in the JDeveloper Property Inspector. For more information, see [Introduction to Selected Elements in the Table Property Inspector](#).

**Editing - Properties**

When you have created the Applications Tree, you can modify the property values by using the Property Inspector. You can select the Applications Tree in one of three ways:

- Select the component in the Design view of the page.
- Select the `<fnd:applicationsTree ...>` line in the Source view of the page.
- Select `fnd:applicationTree` from the hierarchy in the Structure View.

All the components created as part of the Applications Tree are editable using this same approach, as shown in [Figure 17-21](#).

**Figure 17-21 Tree Property Inspector**

![Tree Property Inspector](image_url)

**Adding a Data Source**

When you have created the Applications Tree, you can add data controls to the facets / content containers within that tree using the following steps:
1. Navigate to the Data Controls panel of the Application Navigator.

2. Open the hierarchy to find the data source.

3. Drag and drop either the entire data source or individual fields into the correct location on the page. The correct location is dependent on the component.

**Adding UI Content**

To achieve the final goals for a page design, you will likely need to add other components to the Applications Tree. Common facets are provided to help you achieve these goals. The facet names and use are documented in the Facet tree of the Component Structure and Functions. For example, your tree may require an additional action beyond the standard actions that are provided by the Applications Tree. You can navigate to the Component Palette and drag and drop a commandToolbarButton component on to the additionalToolbarButtons facet to add a new icon to the Tree toolbar.

**Increasing Tree Width to Fill 100% of Its Container**

An Applications Tree can be stretched by placing it in the center facet of an ADF panelStretchLayout component. Do not set the inlineStylewidth on panelStretchLayout. For more information about basic page layout and the inlineStyle attribute, see the "Organizing Content on Web Pages" and the "Customizing the Appearance Using Styles and Skins" chapters in the Developing Web User Interfaces with Oracle ADF Faces.

### 17.3 Implementing Applications Tree Tables

The Application Tree Table component implements the tree table portion of the user experience pattern.

The Application Tree Table component provides these basic capabilities to satisfy the requirements specified in the user experience designs:

- Tree Table toolbar with default buttons.
- Facets for adding items such as ADF tree table and custom toolbar buttons.
- Default implementations for tree actions.

**Adding an Application Tree Table to Your Page**

You can add the Application Tree Table to your page in two ways.

- Select the Application Tree Table from the Applications component palette and drag and drop it on your page.
- Drag and drop a data collection from the data control palette to your page and select the Applications Tree Table from the list of available UI components.

The properties shown in Table 17-6 are exposed on the Applications Tree Table:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Unique ID for this Applications Tree Table.</td>
<td>string</td>
</tr>
</tbody>
</table>
### Table 17-6  (Cont.) Applications Tree Table Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

Table 17-6 (Cont.) Applications Tree Table Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>PartialTriggers</td>
<td>Partial triggers attribute for the toolbar button.</td>
<td>String of IDs.</td>
</tr>
<tr>
<td></td>
<td>For example: deletePartialTriggers</td>
<td></td>
</tr>
<tr>
<td></td>
<td>The partial triggers property of the Create, Edit, Duplicate and Delete buttons, and menu items are exposed. Users can enable and disable buttons according to rows selected or other actions carried out on the page. The same partialTrigger attribute for each one is used both for the command toolbar button and the menu item. For example, when the createPartialTriggers is set in the Applications Tree Table, the value for this attribute is set on the partialTrigger property of both the create command toolbar button and create menu item.</td>
<td></td>
</tr>
</tbody>
</table>

**Important:** The PartialTriggers attribute must be entered manually by the developer. This is because, at design time, the JDeveloper Property Inspector can:
- Select the incorrect ID.
- Append square brackets around the selected id, such as [id1 id2].

**Example 1:**
To disable the Edit, Delete and Duplicate buttons when the table is empty, set this property on the editDisabled, deleteDisabled or duplicateDisabled property of the Applications Tree Table.

\[#{bindings.VOiterator.estimatedRowCount == 0 ? true : false}\]
where VOiterator is your iterator name

**Example 2:**
Disable any of the buttons in the Applications Tree Table according to the functional rules or by setting disable=false when create is selected on an empty table (considering these buttons were disabled following Example 1).

To do this, create an attribute binding on the view object attribute that will decide whether the row can be deleted/edited/duplicated. For example, you can use a binding similar to this example on the disable property of a button:

\[#{bindings.MyAttrBinding.inputValue == 'compare value' ? true : false}\]

Add Partial Page Refresh (PPR) on the button to the table ID of the af:table. This does not require any change in the selectionListener of the table. Keep the default one.
Table 17-6  (Cont.) Applications Tree Table Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>exportRowLimit</td>
<td>This property sets the row limit for exported rows when &quot;Export to Excel&quot; is used to export records to Excel. If this is not set, then the row limit is picked from the value that is set for the profile option FND_EXPORT_ROWLIMIT.</td>
<td>Positive integer.</td>
</tr>
<tr>
<td>defaultToolbarItemDisplay</td>
<td>Use to hide the DETACH/FREEZE/WRAP labels and just display the related icons in the toolbar to reclaim space used by the display of the labels on the table’s panel collection.</td>
<td>iconAndText will display the labels.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>icon will hide the labels.</td>
</tr>
</tbody>
</table>

Note:

For inline patterns, the ADF tree table beneath the Applications Tree Table should be refreshed when the icon or the menu item is clicked. For this to happen, the ADF tree table needs to know that it should partially refresh itself. To do this, set the partialTriggers attribute on the ADF tree table to the Ids of the menu item and icon. For example, to refresh the tree table when the Delete menu item is selected or the icon is clicked, set partialTriggers="delete deleteMenuItem" on the ADF tree table. The partialTriggers attribute is set by the Applications Tree Table Creation wizard automatically. Applications developers should not need to set it explicitly. Example 17-10 shows a sample markup that is generated by the Applications Tree Table Creation wizard.

Table 17-7 shows the facets that are exposed on the Applications Tree Table.

Table 17-7  Applications Tree Table Facets

<table>
<thead>
<tr>
<th>Facet</th>
<th>Description</th>
<th>Allowed Children</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeTable</td>

<tr>
<td>appsTreeTable Statusbar</td>
<td>Facet for adding component containing statusbar items. These statusbar items are merged with standard items provided by the panelCollection.</td>
<td>ADF component</td>
</tr>
<tr>
<td>appsTreeTable ViewMenu</td>
<td>Facet for adding Menu Items to the default view menu of the panelCollection. To add multiple menuItems to the view menu, add an af:group component containing af:menuItems.</td>
<td>ADF menu item component</td>
</tr>
<tr>
<td>popup</td>
<td>Facet for adding popups. See Using the Custom Wizard with Applications Popups.</td>
<td>Any number of popups under a layout component.</td>
</tr>
</tbody>
</table>

**Important:** When a popup is used to create or duplicate a row in an Applications Tree Table, you need to write your own logic behind the popup’s Cancel button (Action/ActionListener) to remove the newly-created row.

This can be done by either:

- A managed bean method that removes the newly-created row.
- Setting the Cancel button’s Action property to the rollback method defined in the pageDef file. This method would be defined in the pageDef file if the "rollback" from the operations of the dataControl is dragged and dropped onto the page.

## Model

The Applications Tree Table does not expose any bindings to the model. However, components within the Applications Tree Table, such as the ADF tree table, will be bound to the model.

## Controller

The Applications Tree Table component ships a default managed bean (internal to the Oracle Fusion Middleware Extensions for Applications team) that performs the following functions that will only work with rowSelection="single" on the ADF tree table:

- Default event handlers for all toolbar button/menu item action events. Event handler delegates to custom action method if set on the button/menu item action property.

  - When Create Pattern Type is secondaryWindow, a new row is created in the data collection and a popup is invoked with the newly-created row available for inserting values. (The UI for the popup to show input fields for the new row has to be created separately by the developer.) After the popup is dismissed, the tree table is refreshed to display the newly-created row:

    * If no row is selected when the Create button or menu item is clicked, the new row is created in the first-level of the Tree.
* If Leaf Node or Expanded Parent Node is selected when the Create button/menu item is clicked, the new row is created as a child of the selected node and placed directly below it.

* If the Collapsed Parent Node is selected, the parent is expanded to show the newly-created child node that placed directly below it.

* A new row is not added when the Create Pattern Type is page. Only a standard outcome is returned

* A new row is added into the tree table when the Create icon is clicked, and Create Pattern Type is inline.

* The selected row is made available for editing in a popup when the Edit icon is clicked, and Edit Pattern Type is secondaryWindow.

* When the Edit icon is clicked and Edit Pattern Type is page, only a standard outcome is returned.

* When the Duplicate icon or menu item is clicked, a new node is added into the tree when the Create icon is clicked, and Create Pattern Type is inline. All non-primary key values of the selected node are copied to the new node.

* If Duplicate Pattern Type is inline, the newly-created row is placed above the selected row.

* If Duplicate Pattern Type is popup, a popup invoked with the newly-created row is available for modifying the duplicated values (the UI for the popup to show input fields for the new row has to be created separately by the developer).

* Clicking the Delete icon deletes the selected row. It currently does not perform cascade delete when a parent node is selected for delete. The Applications developer needs to handle deleting the child nodes if it is necessary.

• If the secondaryWindow option is chosen for any pattern type, and the corresponding popup id is set for that button (mandatory), selecting the button invokes the popup.

• If page is chosen for any pattern type, a standard outcome is returned on clicking the button. Standard outcomes are Create, Edit, Duplicate and Delete for the four respective toolbar buttons.

• The Oracle Fusion Middleware Extensions for Applications (Applications Core) provides a default selection listener for the ADF tree (the markup shows: selectionListener="#{ApplicationsTreeBean.treeSelectionHandler}"). If a developer needs to add custom logic to selection listener, the developer should call this default selection listener from the custom logic. The treeSelectionHandler method of ApplicationsTreeBean provides the following behavior:

  – When xxxxPatternType="secondaryWindow" and when there is no popup configured for the level where the node must be created, the icon and the menu item are disabled by default. But this behavior can be overridden by xxxxDisabled attribute ("xxxx" could be "create", "edit" or "duplicate").
- Calls the ADF default tree listener:
  #{bindings.xxxx.treeModel.makeCurrent} See Example 17-11.

To allow Applications developers access to some of the implementation, the
Applications Tree Table exposes a public class
oracle.apps.fnd.appcore.patterns.ApplicationsTreeEventHandler
that contains default event handlers for all the buttons. The button methods are named
as process<buttonName>, such as processCreate and processEdit. Developers writing
custom action handlers can also use the default implementation by calling these
methods.

Example
To attach a custom button handler to the Create button:

1. Define a managed bean class, as shown in Example 17-12.
2. Register the managed bean in the faces-config of the project.
3. Open the Property Inspector for the Applications Tree Table and choose the
Create Action property. Set #{CustomEventHandler.processCreate} as the
expression for the property.

Example 17-10  Sample Markup Generated by the Applications Tree Table Creation
Wizard

```
<fnd:applicationsTreeTable treeTableId="treeTable1" id="appsTree1"
createPatternType="secondaryWindow"
createPopupId="create1,create2"
duplicatePatternType="inline"
deleteEnabled="true">
  <f:facet name="treeTable">
    <af:treeTable value="#{bindings.ServiceRequestsView1.treeModel}"
var="node" rowSelection="single"
selectionListener="#{ApplicationsTreeBean.treeSelectionHandler}"
id="treeTable1"
partialTriggers="::duplicate ::duplicateMenuItem ::delete ::deleteMenuItem">
```

Example 17-11  Sample Code for Calling the Default Selection Listener from a
Custom Selection Listener

```
String defaultListener = "#{ApplicationsTreeBean.treeSelectionHandler}";
FacesContext fc = FacesContext.getCurrentInstance();
ExpressionFactory ef = fc.getApplication().getExpressionFactory();
MethodExpression me =
  ef.createMethodExpression(fc.getELContext(), defaultListener,
String.class, new Class[]{SelectionEvent.class});
me.invoke(fc.getELContext(), new Object[] {selectionEvent});
```

Example 17-12  Define a Managed Bean Class to Attach Custom Handler to a Button

```
import oracle.apps.fnd.appcore.patterns.ui.ApplicationsTreeEventHandler;
import oracle.apps.fnd.appcore.patterns.ui.util.PatternUtils;

public class CustomEventHandler
{
  public String processCreate()
  {
    // Custom code
    ...
```
// Call default event handler if required. It will return a standard outcome for this button click.
ApplicationsTreeEventHandler appTreeHandler = ApplicationsTreeEventHandler.getInstance();
String outcome = appTreeHandler.processCreate();

// If popup is required to be invoked after event handling
PatternUtils.invokePopup(popupId);

return outcome;
}

17.3.1 How to Add an Applications Tree Table

The Applications Tree Table can be added to a page or page fragment using either the Component First or the Data First approach. Both approaches launch a wizard that is intended to help you quickly define the appropriate tree layout that adheres to the user experience standards. When you complete this wizard, you can further refine the tree definition by editing the resulting tree component as needed.

Component First

Navigate to the Component Palette. Click the list of libraries and select Applications. Drag the Applications Tree Table from the list of components and drop it onto the page to launch the wizard.

Data First

Navigate to the Data Controls panel of the Application Navigator. Open the panel and navigate through the hierarchy to locate the data source that you would like to include in the Applications Tree Table. Select that data source and drag it to the page. A context menu will display a list of components. Select Tree under the Applications menu to launch the Applications Tree Table wizard, as shown in Figure 17-22.

Figure 17-22 Data First Method to Add a Tree Table
17.3.1.1 Applications Tree Table Create Wizard

The Applications Tree Table Create wizard consists of four panels: Create Applications Tree Table, Select Tree Table Columns, Configure Tree Table Patterns, and Summary.

Create Applications Tree Table Panel

This step creates a tree binding and node definitions of the tree. The Create Applications Tree Table Panel will vary depending on the approach used to launch the Applications Tree Table creation process.

Using the Data First approach, the Bind Data Now properties are hidden. The selected data source is automatically bound to the tree.

With the Component First approach, the developer must decide whether to bind a Data Collection to the tree table component. You can skip the data control binding step when creating the Applications Tree Table. In this case the Applications Tree Table will create an adf tree table without data binding.

If you wish to bind a data control to the tree component using the Component First approach, select the Bind Data Now checkbox. This will enable the Browse button for the Data Source property. Click Browse to display a list of data sources available for binding. Navigate through the list and select the desired data source. Click OK, as shown in Figure 17-23.

![Create Applications Tree Table Panel](image)

When the Data Source is selected, you can configure the ADF tree. Click the Add icon to add one of the children of the selected Data Source to be the next level of the tree, as shown in Figure 17-24.
The shuttle at the bottom of the Create Applications Tree Table panel allows you to select the attributes at each tree level you wish to display as a tree node or columns in the tree table, as shown in Figure 17-25.

When finished, click **Next** to proceed to the Select Tree Table Columns panel. Select **Cancel** to abort the creation of the Applications Tree Table.

**Select Tree Table Columns Panel**

The Select Tree Table Columns panel shown in Figure 17-26 allows you to select an attribute for displaying as node stamp and select an attribute for displaying as path stamp. You can also configure the columns to be displayed inside the tree table here. When finished, click **Next** to proceed to the Configure Tree Table Patterns Dialog. Selecting **Cancel** will abort the creation of the Applications Tree Table.
The Configure Tree Table Patterns panel allows you to select the default actions offered by your Applications Tree Table, shown in Figure 17-27.

Figure 17-27 Configure Tree Table Patterns
You may select any or all of the following five actions for your Applications Tree Table: Create, Duplicate, Edit, Delete and Export. If you enable Create, Duplicate, or Edit, you must choose the appropriate pattern that will be used to invoke that action (Inline, Popup, Page).

- **Inline** - Perform the action on the current table row.
- **Popup** - Bring up a div modal window on top of the current page for the requested action.
- **Page** - Replace the current page or page fragment with a completely separate page or page fragment to perform the action. (Page fragments are used when using bounded task flows.)

The **Add** button for configuring the Popup button is enabled when the Popup pattern is selected. When you click **Add**, a dropdown of the data collection name of each tree level is displayed. You need to choose the tree level that needs the popup to be configured. When a data collection name is selected, the Applications Popup Wizard is displayed. (See **Using the Custom Wizard with Applications Popups**.) This same data collection will automatically be bound to the Applications Popup. The Popup will also be defaulted as having Editable Content on the Window Buttons page in the wizard. Refer to **Using the Custom Wizard with Applications Popups**.

**Export**: Export the data to a Microsoft Excel-compatible file.

**Delete**: Allows users to delete the row.

- **Confirm Delete**: Select this option so that the default **The selected record(s) will be deleted. Do you want to continue?** prompt displays in a popup when the delete row function is used.

  When you set the **confirmDelete** attribute to true, the confirmation popup displays and the row is deleted when you click **Ok**. For this to work correctly, the **partialTriggers** on the **af:treetable** inside the **fnd:applicationsTreeTable** should include **::confirm**, and the **::delete** and **::deleteConfirm** ids must be removed so the **partialRefresh** happens only when you click **Ok** in the popup. See **Manually Enabling Delete Confirmation**.

- **Confirmation Message**: If you want to replace the default confirmation message with a custom one, enter the string here. The string will be converted to a text resource and added to the default resource bundle.

  If you already have a confirmation message defined in a resource bundle, click the ellipsis and choose from the list.

Click **Finish** to complete creation of the Applications Tree Table. Select **Cancel** to abort the creation of the Applications Tree Table.

**17.3.1.2 Working with the Applications Tree Table**

When you have created the Applications Tree Table, you can modify the property values by using the Property Inspector editor. The Property Inspector for the Applications Tree Table component can be viewed by selecting the component in the page. You can select the Applications Tree Table in one of three ways:

- Select the component in the Design view of the page.
- Select the `<fnd:applicationsTreeTable...>` line in the Source view of the page.
- Select `fnd:applicationTreeTable` from the hierarchy in the Structure View. All of the components created as part of the Applications Tree Table are editable using this same approach, as shown in Figure 17-28.

**Figure 17-28  Tree Table Property Inspector**

17.3.1.2.1 Add a Data Source

When you have created the Applications Tree Table, you can add data controls to the facets and content containers within that tree table using the following steps:

1. Navigate to the Data Controls panel of the Applications Navigator.
2. Expand the hierarchy to find the data source.
3. Drag and drop either the entire data source or individual fields into the correct location on the page. The correct location depends on the component.

17.3.1.2.2 Adding UI Content

To achieve the final goals for a page design, you probably will need to add other components to the Applications Tree Table. Common facets are provided to help you achieve these goals. The facet names and use are documented in the Facet table of the Component Structure and Functions. For example, the tree table may require additional actions beyond the standard actions that are provided by the Applications Tree Table. You can open the Component Palette and drag and drop a `commandToolbarButton` component onto the `additionalToolbarButtons` facet to add a new icon to the Tree Table toolbar.

17.3.1.2.3 Increasing Tree Table Width to Fill 100% of Its Container

An Applications Tree Table can be stretched by placing it in the center facet of an ADF `panelStretchLayout` component. Do not set the `inlineStylewidth` on `panelStretchLayout`. For more information about basic page layout and the `inlineStyle` attribute, see the "Organizing Content on Web Pages" and the

---

Implement UIs in JDeveloper with Application Tables, Trees and Tree Tables 17-55
"Customizing the Appearance Using Styles and Skins” chapters in the *Developing Web User Interfaces with Oracle ADF Faces*.

17.3.1.2.4 Toggle Click to Edit / Edit All in Applications Tree Table

The Applications Tree Table toolbar has an icon that can be clicked to toggle the Click to Edit and Edit All functions, and the View Menu on the toolbar includes the same toggle feature. This functions the same as described for the Applications Table in *Toggle Click to Edit / Edit All in Applications Table*.

17.4 Using the Custom Wizard with Applications Popups

**Note:**

`af:popup` is a generic function documented in the *Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces* guide. This section discusses using the Popup wizard in JDeveloper Oracle Fusion design time.

---

Popups are an option when editing rows. While the standard `af:popup` component does not provide buttons or data binding, the Applications Popup wizard provides the base `af:popup` with:

- a title
- standard buttons
- customized button capability
- data binding
- code that developers can use to invoke the popup
- design-time support
- popup facets and properties that can be customized

Popups can be used as standalone components or with the patterns shown in Table 17-8.

**Table 17-8 Patterns That Require Popups**

<table>
<thead>
<tr>
<th>Pattern Set</th>

</tbody>
</table>

17.4.1 Creating a Popup

You create Applications Popups in the wizard that is displayed when you add the popups to your previously-created JavaServer Faces (JSF) pages (or page fragments) from the Data Controls panel. You also can create popups from within other applications component wizards, such as Applications Table.

17.4.1.1 How to Add Applications Popups to JSF Pages or Page Fragments

Before you can add popup components, you must add the Applications Popup to your pages from the Data Controls panel.

To add a Popup using a data control:

1. In the Application Navigator, open the Data Controls panel.
2. Navigate to the data source that you want to bind to the popup.
3. Drag and drop the data control to the JSF page, as shown in Figure 17-29.
4. In the Create context menu that is displayed, choose Applications > Popup.

The Popup wizard is displayed.

To add an applications popup from a table:

1. Launch the Applications Table wizard, such as by selecting the Applications option from the Component Palette and then clicking the Table option.

2. In the Configure Table Patterns dialog, set the Create, Duplicate or Edit Pattern to Popup.

3. Click Configure Popup to display the Popup wizard.

4. Follow the steps in How to Add Applications Popup Components Using the Wizard.

---

**Note:**

The data source for the table becomes the default data source for the popup.

---

**17.4.1.2 How to Add Applications Popup Components Using the Wizard**

This section explains how to use the Popup wizard to add components to your popups.

In the Popup wizard you can:

- Create titles and related layout.
- Add, move, or delete components.
- Define buttons.
- Create a preview.

All mandatory fields in the wizard contain default values, allowing you to accept the defaults and work through the steps quickly. Clicking Cancel on any of the dialogs cancels the popup creation and discards any values you entered.

Clicking Finish on any of the dialogs has the following effects:

- Displays a preview of the popup.
- Creates the popup with the values you provided on that screen and any previous screens, and default values for the remaining screens.
Caution:
Each wizard dialog contains a Messages field that displays errors for that step. Do not proceed to the next wizard step without correcting the errors in the present step.

Using the Applications Popup Wizard:
When the Popup wizard launches, the Set Title and Panel Layout dialog is displayed, as shown in Figure 17-30.

**Figure 17-30  Set Title and Panel Layout Dialog**

1. Choose title and panel properties:
   - Enter a popup Id. The Id is a string that must be unique to the page fragment. It is used when other components want to be related to this component. For example, if you have a table with Create in Popup, the Create button needs to include this popup Id so it can call it.
   - Enter a title for the popup window.
     The title is prepopulated with the Oracle Fusion Applications Standard for the title, which is a combination of the action of the task, the type of object, and the specific object name:

     \[
     \text{[Action] [Object Type]: [Object Name]}
     \]

     The title should be a reference to a single message with appropriate tokens, because, according to Oracle internationalization standards, you should not concatenate translatable messages in the code. See the "Internationalizing and Localizing Pages" chapter in the *Developing Web User Interfaces with Oracle ADF Faces*, and the expanded information in "To add an Applications Table using the Applications Table wizard:"

     So, in this example, the title reference in the JSF page fragment source would resemble:
but in the resource bundle, it would be defined as:

```xml
<trans-unit id="EDIT_INVOICE"> <source>Edit Invoice: {INVOICE_NUMBER}</source> <target/></trans-unit>
```

- [Optional] Enter a title icon location or click Browse to navigate to the icon's location.

- Select the number of layout columns -- 2 or 3 -- for the popup. This affects the data you bind to. For instance, if you are showing an address with name, street, and town, you could put this information in two or three columns.

2. Click Next to display the Select Components to Display dialog, as shown in Figure 17-31.

![Select Components to Display Dialog](image)

- The Components table is automatically populated with the data source fields.

- In the Fields section:
  - Click X to delete the selected component.
  - Click + to add a component.
  - Click the Reorder icons to change the position of the selected component in the list.
  - Click an entry in the Display Label column to enter a new label, such as Dept. Number instead of DeptNo.
  - Click an entry in the Component to Use column to choose a component from the list, as shown in Figure 17-32.
Figure 17-32  Components to Use List

See the description of "Components to Use" in the "Using Attributes to Create Text Fields" section in the Developing Fusion Web Applications with Oracle Application Development Framework.

- Click **Next** to display the Enable Window Buttons dialog, as shown in Figure 17-33.

**Figure 17-33  Enable Window Buttons Dialog**

3. In the Enable Window Buttons dialog, you can perform the following actions:

- If the popup requires navigation workflow, such as when choices within the popup lead users to another window:
  - Check the **Enable Record Navigation** box.
  - Choose **linear** or **non-linear** navigation from the **Navigation Type** menu.

- Choose **View Only Content** to create a read-only popup, or choose **Editable Content** to allow users to edit the popup.

When you choose View Only Content, you automatically enable Slots 1 and 2. When you choose Editable Content, you automatically enable Slots 1, 2, and 3, as shown in **Figure 17-34**.
Click **Next** to display the Review Panel Configuration dialog, as shown in Figure 17-35.

4. The dialog displays a list of your choices.

   In the dialog:
   - Click **Back** to revise your choices.
   - Click **Finish** to save your choices and create the popup.
   - Click **Cancel** to delete the popup information and exit the wizard.

5. When you click **Finish**, the `af:popup` component is displayed in the page, as shown in Figure 17-36.
17.4.2 How to Modify Popup Components and Properties

This section describes how to bind data sources to the popup, and edit popup components and properties after you create the popup in the Popup wizard.

17.4.2.1 Access the Popup on a JSF Page

Before you can edit the popup components and properties or bind the popup to a data source, you must access the popup in the Property Inspector section of your JSF page.

To Access the Popup on a JSF Page

1. Make the JSF page the active file.

2. Access the popup by double-clicking one of the following on the JSF page:
   - `af:popup` component in the Design view.
   - `<af:popup...>` line in the Source view.
   - `af:popup` entry in the Structure view hierarchy.

   When you select the popup, the Popup - Property Inspector is displayed below the page.

17.4.2.2 Add a Data Source to an Existing Popup

This section describes how to add a data source after you have created a popup in the Popup wizard.

To add a data source to an existing popup:

1. In the Application Navigator, expand the Data Control panel.

2. Navigate to the data source you want to bind to the `af:popup`.

3. Drag and drop the entire data source, or individual fields, to the JSF page in Design mode.

   Data-source fields are bound to popup components. Components are stored in the contents facet under the `af:panelFormLayout` hierarchy.

17.4.2.3 Add User-Interface Content to an Existing Popup

To add components to an existing popup, drop the new components into facets.
To add UI content to existing popups:

1. Open the Component Palette.
2. In the list, choose the ADF Faces library.
3. Drag and drop the component to the appropriate popup facet.
   For example, to add a new button, drag and drop the icon to the buttonBar facet.

17.4.2.4 Adding action and actionListener Methods to the Popup Buttons

Either method bindings or managed bean methods can be assigned to the action and actionListener attributes to provide functionality for the buttons that were selected for the popup at design time.
This chapter discusses the Applications Panels, Master-Detail, Hover and Dialog Details components used to implement user interface features in JDeveloper. This chapter includes the following sections:

- Implementing Applications Panels
- Implementing the Simple Panel
- Implementing Applications Master-Detail
- Implementing Hover
- Implementing Applications Dialog Details

For basic information, see:

- Getting Started with Your Web Interface
- Implementing the UI Shell
- Implementing UIs in JDeveloper with Application Tables, Trees and Tree Tables

### 18.1 Implementing Applications Panels

Applications panels help you create the following user interface (UI) components as part of the UI Applications patterns:

- Page title
- Form title
- Page button bar (including navigation bar)
- Facets for page-specific UI components

You must use Applications panels to standardize layout and appearance for all your page forms and buttons, including read-only pages.

**Before you begin:**

Before you can use Applications panels, you must be familiar with JDeveloper and be able to create JavaServer Faces (JSF) pages.

### 18.1.1 Overview of Applications Panel Components

Applications panels provide a button bar containing these buttons:
• **Canceling processes**: Cancel, Revert

• **Data-saving processes**: Save, Submit, Save and Continue, Save and Next, Save and Create Another, Continue, Create Another, Save and Close

• **Navigational processes**: Next, Previous, Back

The buttons are organized into four *slots*, as shown in Figure 18-7.

All panel buttons have attributes, and some buttons have facets. Button attributes include button qualities, such as the title string and the button name. Button facets are locations that contain panel data, such as content locations and button information locations.

Table 18-1 contains attributes that are exposed for the buttons.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Unique identification number for the panel.</td>
<td>string</td>
</tr>
<tr>
<td>rendered</td>
<td>Whether the panel is rendered (that is, converted from an object-based description into a graphical image for display).</td>
<td>boolean or expression</td>
</tr>
<tr>
<td>title</td>
<td>Panel title.</td>
<td>string or expression</td>
</tr>
<tr>
<td>navigationType</td>
<td>Type of navigation for that panel.</td>
<td>Navigation types:</td>
</tr>
<tr>
<td></td>
<td>• linear - sends users to an adjacent or contiguous window. This commonly is used when a series of actions or steps need to be followed in a sequential order.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• nonlinear - sends users to a non-adjacent or non-contiguous window. This is used when an action does not need to take place in a specific sequence.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• none - navigation is disabled.</td>
<td></td>
</tr>
<tr>
<td>&lt;button_name&gt;Visible</td>
<td>Whether the button is visible in the UI.</td>
<td>boolean or expression</td>
</tr>
<tr>
<td>For example:</td>
<td>submitVisible</td>
<td></td>
</tr>
<tr>
<td>&lt;button_name&gt;Rendered</td>
<td>Whether the button is rendered in the UI (that is, converted from an object-based description into a graphical image for display).</td>
<td>boolean or expression</td>
</tr>
<tr>
<td>For example:</td>
<td>submitRendered</td>
<td></td>
</tr>
<tr>
<td>&lt;button_name&gt;Action</td>
<td>Type of action that the button performs.</td>
<td>EL expression</td>
</tr>
<tr>
<td>&lt;button_name&gt;PopupId</td>
<td>ID of the popup that appears when users press the button.</td>
<td>string</td>
</tr>
<tr>
<td>For example:</td>
<td>submitPopupId</td>
<td></td>
</tr>
</tbody>
</table>
### Table 18-1 (Cont.) Attributes of Standard Panel Buttons

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;button_name&gt;ShortDesc</code></td>
<td>Tooltip text for the button.</td>
<td>string</td>
</tr>
<tr>
<td>For example: previousShortDesc</td>
<td></td>
<td></td>
</tr>
<tr>
<td><code>&lt;button_name&gt;Disabled</code></td>
<td>Next and Previous buttons only: Whether the button should be disabled in the UI.</td>
<td>boolean or expression</td>
</tr>
<tr>
<td>For example: submitDisabled</td>
<td></td>
<td></td>
</tr>
<tr>
<td>submitText</td>
<td>Submit button text: Text associated with the OK button.</td>
<td>string or expression</td>
</tr>
<tr>
<td>scrollable</td>
<td>Sets to true when scroll bar must be enabled. When scrollable is set to true, it sets <code>layout=&quot;scroll&quot;</code> on the af:panelGroupLayout component inside Applications Panel. Thus, the developer does not need to place af:panelGroupLayout with layout=&quot;scroll&quot; directly under the Applications panel.</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>saveOptionsStyle</td>
<td>Sets the appearance of the Save button. The Save button can be rendered as a normal button, or as a drop button, depending on the value of this attribute. When it is set to dropButton, the developer is expected to have other save options turned on (such as saveAndContinue or saveAndClose), or add af:commandMenuItem to the saveButtonMenu facet.</td>
<td>button or dropButton</td>
</tr>
<tr>
<td>savePartialSubmit</td>
<td>Sets the partialSubmit attribute on the Save button. For instance, you can set partialSubmit=true on the Save button to prevent a popup from being dismissed when the Save button is clicked.</td>
<td>True or false (default)</td>
</tr>
<tr>
<td>instructionText</td>
<td>The instructionText attribute places instruction text for the Applications Panel title. This instruction text appears right below the title if the collaborationToolbar facet and scalingInfo facet are empty. If they are not empty, the instructionText is placed under the scalingInfo that appears after the collaboration toolbar.</td>
<td>The instructionText attribute can take a String value or an EExpression. A helpTopicId can be passed to this attribute as an EExpression. For example: instructionText=&quot;#{adfFacesContext.helpProvider['helpTopicId'].instructions}&quot; or instructionText=&quot;#{adfFacesContext.helpProvider['helpTopicId'].definition}&quot; or instructionText=&quot;#{adfFacesContext.helpProvider['helpTopicId'].externalUrl}&quot;</td>
</tr>
</tbody>
</table>
### Table 18-1 (Cont.) Attributes of Standard Panel Buttons

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>panelToolbarRendered</td>
<td>If no default buttons that are provided by the Applications Panel are used, set this value to false to avoid displaying unnecessary separators.</td>
<td>Boolean</td>
</tr>
<tr>
<td>revertImmediate</td>
<td>Sets the <code>immediate</code> attribute on the Revert button. Sets whether data validation - client-side or server-side - should take place when events are generated by this component. When immediate is true, the default ActionListener provided by the JavaServer Faces implementation should be executed during the Apply Request Values phase of the request processing lifecycle, rather than waiting until the Invoke Application phase.</td>
<td>Boolean. Default is <code>false</code>.</td>
</tr>
<tr>
<td>submitStyle</td>
<td>Sets the appearance of the <strong>Submit</strong> button. The <strong>Submit</strong> button can be rendered as a normal button, or as a drop button, depending on the value of this attribute. When it is set to <code>dropButton</code>, the developer is expected to have other submit options turned on, or add <code>af:commandMenuitem</code> to the <code>submitButtonMenu</code> facet.</td>
<td>String. The two values are <code>button</code> (the default) and <code>dropButton</code>.</td>
</tr>
<tr>
<td>previousPartialSubmit</td>
<td>Sets the <code>partialSubmit</code> attribute on the <strong>Previous</strong> button.</td>
<td>True or false (default)</td>
</tr>
<tr>
<td>nextPartialSubmit</td>
<td>Sets the <code>partialSubmit</code> attribute on the <strong>Next</strong> button.</td>
<td>True or false (default)</td>
</tr>
<tr>
<td>saveAndCreateAnotherText</td>
<td>Sets the text that is displayed on the <strong>saveAndCreateAnother</strong> button.</td>
<td>String</td>
</tr>
<tr>
<td>createAnotherText</td>
<td>Sets the text that displays on the <strong>createAnother</strong> button.</td>
<td>String</td>
</tr>
<tr>
<td><code>&lt;button_name&gt;</code>Action</td>
<td>Sets the action attribute on the button with <code>&lt;button_name&gt;</code>. Users must provide their own action; there is no default action.</td>
<td>String or EL Expression.</td>
</tr>
<tr>
<td><code>&lt;button_name&gt;</code>ActionListener</td>
<td>Sets the actionListener attribute on the button with <code>&lt;button_name&gt;</code>. Users must provide their own actionListener; there is no default actionListener.</td>
<td>EL Expression.</td>
</tr>
<tr>
<td><code>&lt;button_name&gt;</code>PartialTriggers</td>
<td>partialTriggers attribute for <code>&lt;button_name&gt;</code> button.</td>
<td>String or EL Expression.</td>
</tr>
</tbody>
</table>

**Important:** The `PartialTriggers` attribute must be entered manually by the developer. This is because, at design time, the JDeveloper Property Inspector can:

- Select the incorrect ID.
- Append square brackets around the selected id, such as `[id1 id2]`. 

Implementing Applications Panels
Table 18-1  (Cont.) Attributes of Standard Panel Buttons

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Data Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>submitAccessKey</td>
<td>submitAccessKey property for the Submit toolbar button. submitAccessKey maps to submitText and accepts one character given to the submitText property as the access key. submitAccessKey sets the accessKey HTML property internally.</td>
<td>Character</td>
</tr>
<tr>
<td></td>
<td>The value to this must be one of the characters given for the submitText property to get an access key. The character will be displayed as underlined on the component name.</td>
<td></td>
</tr>
<tr>
<td>createAnotherAccessKey</td>
<td>createAnotherAccessKey property for the createAnother button. createAnotherAccessKey maps to createAnotherText and accepts one character given to the createAnotherText property as the access key. createAnotherAccessKey sets the accessKey HTML property internally.</td>
<td>Character</td>
</tr>
<tr>
<td></td>
<td>The value to this must be one of the characters given for the createAnotherText property to get an access key. The character will be displayed as underlined on the component name.</td>
<td></td>
</tr>
<tr>
<td>saveAndCreateAnotherAccessKey</td>
<td>saveAndCreateAnotherAccessKey property for the saveAndCreateAnother commandMenuItem. saveAndCreateAnotherAccessKey maps to saveAndCreateAnotherText and accepts one character given to the saveAndCreateAnotherText property as the access key. saveAndCreateAnotherAccessKey sets the accessKey HTML property internally.</td>
<td>Character</td>
</tr>
<tr>
<td></td>
<td>The value to this must be one of the characters given for the saveAndCreateAnotherText property to get an access key. The character will be displayed as underlined on the component name.</td>
<td></td>
</tr>
</tbody>
</table>

By default, a managed bean that ships with the Applications Panel enables certain actions when certain conditions exist. For example, default actions occur when users click buttons, and when developers set certain Applications Property values. These default actions are overridden if you change the value of the default button action property.

Table 18-2 contains facets that are exposed for each panel button.

Table 18-2  Facets of Standard Panel Buttons

<table>
<thead>
<tr>
<th>Facet</th>
<th>Description</th>
<th>Allowed Children</th>
</tr>
</thead>
<tbody>
<tr>
<td>contents</td>
<td>Facet for holding developer-defined content or content generated at design time.</td>
<td>Any ADF component.</td>
</tr>
<tr>
<td>navigationBar</td>
<td>Facet for holding the navigation choice list if the chosen Record Navigation Type is non-linear.</td>
<td>ADF selectOneChoice</td>
</tr>
<tr>
<td>actionButtonBar</td>
<td>Facet for holding custom action buttons.</td>
<td>ADF commandButtons and commandToolbarButtons under some ADF layout components.</td>
</tr>
<tr>
<td>saveButtonMenu</td>
<td>Facet for holding the custom menu and menu items for the Save button.</td>
<td>af:commandMenuItem or af:group</td>
</tr>
</tbody>
</table>

<td>--------------------------------</td>
<td></td>
</tr>
</tbody>
</table>
| contentsStretch     | The contents facet is a child of the panelGroupLayout so that scrolling can be enabled around the contents. But the panelGroupLayout does not allow its children to be stretched. The contentsStretch facet is not a child of the panelGroupLayout. Components placed inside this do not need to use an inlineStyle to set width and with declarative components placing them inside a panelStretchLayout will stretch the components. **Note:** The Applications Panel can be stretched by placing it in the center facet of an ADF panelStretchLayout component. Do not set the width using the inlineStyle attribute on either Applications Panel or panelStretchLayout. To use this facet, place your components inside the contentsStretch facet and set the attribute contentsFacet="stretch" on the Applications Panel. The user needs to trade between using scrollable or stretchable contents. A switcher reads the contentsFacet attribute from the ApplicationsPanel component to decide which facet to use. The default facet is scroll; to use the contentsStretch facet, set contentsFacet="Stretch" on the Applications Panel. Example:  
```xml
<fnd:applicationsPanel id="AP1" title="#{viewControllerBundle.APPLICATIONS_PANEL__STRETCH_FA}"
  scrollable="true"
  navigationType="none"
  cancelVisible="true"
  cancelRendered="true"
  submitVisible="true"
  submitRendered="true"
  contentsFacet="stretch">
  <f:facet name="contentsStretch">
    <af:panelStretchLayout id="psl1">
      <f:facet name="bottom"/>
      <f:facet name="center">
        <fnd:applicationsTable tableId="ATt2" id="AT2"
          deleteEnabled="true"
          createPatternType="inline"
          duplicatePatternType="inline"
          editPatternType="inline"
``` | Scroll (the default) or Stretch. |

<td></td>
</tr>
<tr>
<td>contentsFacet</td>
<td>This can be either scroll (the default) or stretch. Set to stretch when using the contentsStretch facet.</td>
<td></td>
</tr>
</tbody>
</table>

Model

The Applications panel does not expose any bindings to the model. However, components within the panel can be bound to the model.

Controller

The Applications Panel component ships with a default managed bean (internal to the Oracle Fusion Middleware Extensions for Applications team) that performs the following functions:

- Default event handlers for all button action events. Event handler delegates to custom action method if set on the button action property. Each button event handler simply returns a standard outcome which is the name of the button clicked. For example, clicking the Cancel button will return an outcome “cancel”.

- If popup ID is set for any button, selecting the button invokes the popup.

To allow developers access to some of the implementation, the Applications Panel exposes a public class `oracle.apps.fnd.appcore.patterns.ApplicationsPanelEventHandler` that contains default event handlers for all the buttons. The button methods are named as `process<buttonName>` such as `processSave` and `processCancel`. Application developers writing custom action handlers can also use the default implementation by calling these methods.

18.1.1.1 Implement a Custom Button Handler

Follow these steps to attach a custom button handler to the Cancel button.

1. Define the managed bean class, as shown in Example 18-1.

2. Register the managed bean in your project’s `faces-config` file.

3. Open the Property Inspector for the Applications panel and choose the Cancel Action property. As shown in the example in Figure 18-1, set `#{CustomeEventHandler.processCancel}` as the expression for the property.
4. Click the **Create** tab.

5. In the **Create Action** expression field, enter the following expression:

   `#{CustomEventHandler.processCreate}`

6. Click **Set**.

**Example 18-1    Example of Attaching a Custom Handler to a Button**

```java
import oracle.apps.fnd.applcore.patterns.ui.ApplicationsPanelEventHandler;
import oracle.apps.fnd.applcore.patterns.ui.util.PatternUtils;

public class CustomEventHandler {
    public String processCancel() {
        // Custom code
        ...
        // Call default event handler if required. It will return a standard outcome
        // for this button click.
        ApplicationsPanelEventHandler appPanelEventHandler = ApplicationsPanelEventHandler.getInstance();
        String outcome = appPanelEventHandler.processCancel();

        // If popup is required to be invoked after event handling
        PatternUtils.invokePopup(popupId);

        return outcome;
    }
}
```

### 18.1.2 How to Create an Applications Panel

You create Applications panels in the Applications Panel wizard, which is displayed when you add panels to your JSF pages (or page fragments) from the Component Palette or the Data Controls panel.

To Add an Applications Panel Using the Component Palette:

1. Open the **Component Palette**.

2. In the list, choose **Applications**.

3. In the list, click **Panel**. JDeveloper will attempt to place the panel at the current cursor location. If the current location is not appropriate, an error message
displays. You also can drag the Panel icon to the page in either the Design or the Source view. A plus (+) sign will be added to the arrow when it is over a location in which a panel can be inserted.

The Applications Panel wizard is displayed.

To Add an Applications Panel Using the Data Control Dialog:

1. In the Application Navigator, open the **Data Control** panel.
2. Navigate to the data source that you want to bind to the Applications panel.
3. Drag and drop the data control to the JSF page.
4. In the Create context menu that is displayed, choose **Applications > Panel**.

The Applications Panel wizard is displayed.

### 18.1.2.1 Add Applications Panels Using the Applications Panel Wizard

This section explains how to use the Applications Panel wizard to add panels to your page.

In the Applications Panel wizard you can:

- Specify panel titles and subsections
- Select panel components
- Bind a data source to the panel
- Arrange panel components
- Select panel buttons

In any Applications Panel wizard dialog, click **Cancel** to cancel your actions and exit the wizard. Click **Finish** on any dialog to accept the defaults and exit the wizard.

**To Add an Applications Table Using the Applications Panel Wizard:**

When the Applications Panel wizard is launched, the Title and Subsections dialog is displayed, as shown in Figure 18-2.
1. In the dialog:

- Enter the panel title. In the example, LABEL should be predefined in a bundle as "Edit Journal: ID {OBJ_ID}".

The title is prepopulated with the Oracle Fusion Applications Standard for the title, which is a combination of the action of the task, the type of object, and the specific object name:

[Action] [Object Type]: [Object Name]

The Object Name usually is something specific so you can identify a specific object. For instance, if you were dealing with part numbers, the Object Name could be a specific part number; if you were dealing with customer information, it could be the customer's name.

The title should be a reference to a single message with appropriate tokens, because, according to Oracle internationalization standards, you should not concatenate translatable messages in the code. See the Internationalizing and Localizing Pages section in the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces. You should use the following message formatters: af:formatNamed/af:formatFor example:

- Click the Add icon (+) to add Panel Subsections, or click the Delete icon (X) to delete the highlighted subsection.

Each subsection has editable title fields, panel type fields (Panel Header for a basic view or Show Detail Header for a more detailed view), and number of columns (1-3) fields.

The Panel Subsections is used to divide the Applications Panel facet (contents) with other layout components, such as panelHeader, show detail header, and panelGroupLayout. This lets the developer decide the layout during Design Time without needing to add each of these layouts manually after the panel creation. Of course, the user can add more or new layouts as needed after the panel is created.
Use the up or down arrows to change row order.

2. **Click Next.**

The Select an initial set of panel components dialog is displayed, as shown in Figure 18-3.

![Figure 18-3  Selecting an Initial Set of Panel Components](image)

3. In the Panel Components dialog:

   a. **Click Read-only Form** to create a read-only form. (optional) If you select Read-only, the choices in the Component to Use column will change from Input Text to Output Text types.

   b. **If** you have added the panel from the Component Palette, the Bind Data Now field displays. To bind a data source to the panel component:

      • **Select Bind Data Now.**
      
      • **Click Browse** to display the Data Source dialog, shown in Figure 18-4.
Figure 18-4    Data Source Dialog

Select the data source, then click **OK** to add it to the component. Optionally, you can bind the component to a data source at a later time.

When you choose a data source, the component fields in the dialog are automatically populated with the data source fields, which contain panel-component information.

c. To reorder component fields, click the up and down arrows. To delete component fields, click the Delete icon (X). You will be able to add more component fields later. See Adding a Data Source to an Existing Panel.

d. **Display Label:** In general, the labels defined in the selected Data Control will be what you want and you can leave this value at the default <Default> setting. Otherwise, enter a new label name.

e. **Value Binding:** In general, the label and the Value Binding will match and you can accept the displayed value. Otherwise, you can click in the field to display a drop-down list of the values available in the selected Data Control.

f. **Component To Use:** Data in Dialog Details can be read-only or updatable. Component to Use is similar to what Component does while creating a table. Clicking it reveals a choice list of values, and the dialog details popup would then at runtime show that particular column from the datacontrol as the selected component to use. The choice list is changed according to whether you choose read-only. If you selected Read-only, the choices will change from Input Text to Output Text types.

4. Click **Next.** The Components Layout dialog is displayed, as shown in Figure 18-5.
5. Drag components from their default locations to your previously defined subsections. The result will appear similar to Figure 18-6.

Figure 18-6 Example of Component Layout

6. Click Next. The Page Buttons dialog is displayed, as shown in Figure 18-7.
7. In the Page Level Buttons dialog:

- To enable panel navigation (optional):
  - Select **Enable Navigation**.
  - Choose a navigation type (Linear or Non-Linear).
    - Linear sends users to an adjacent or contiguous window. This commonly is used when a series of actions or steps need to be followed in a sequential order.
    - Non-Linear sends users to a non-adjacent or non-contiguous window. This is used when an action does not need to take place in a specific sequence.

- To disable editing of panel contents, select **View Only Content**.

- To enable editing of panel contents:
  - Select **Editable Content**.
  - Choose the transactional buttons to display in each panel slot from the respective slot dropdown menus.

  Note that Slot 3 defaults to Continue. However, as shown in Figure 18-7, if you select Submit, a text input field displays to the right. You can enter alternate text that makes more sense in your application for the submit action, such as OK or Purchase.

  You can create a Save or Submit pull down menu. When you choose Save in Slot 2, or Save and Close in Slot 3, an Add Menu option will appear. Click it to display a list similar to Figure 18-8.
These are options that can appear in a pull down menu at runtime under Save. To select, click the option you want. To add more than one, select Add Menu again and choose a second option. As they are chosen, check marks will appear next to each selected item, shown in Figure 18-9.

When an item is selected from the Add Menu of Slot 3, the selection of the drop-down in Slot 3 will become the label of af:commandToolbarButton and the selections in the Add Menu will become the af:commandMenuItem under af:menu in the popup facet of the af:commandToolbarButton. The af:commandToolbarButton will be added to the customSaveDropButton facet (see Table 18-2).

If an option is chosen in the Add Menu of Slot 2, it will be grayed-out as an option for Slot 3 to prevent you from making the same choice multiple times, as shown in Figure 18-10.

• **Enable Social Network**

The Enable Social Network and Social Row fields become available if the view object that was selected as the Data Source (in step 2 of 5) is Oracle Social Network enabled. You can deselect the option and edit the Social Row value if necessary. See Implementing Oracle Social Network Integration.  

8. Click Next. The Summary dialog is displayed, as shown in Figure 18-11.
9. Check to make sure your panel choices are correct.

10. Click Finish to create the panel. When you run this page, it will appear similar to Figure 18-12.

---

18.1.3 How to Modify Applications Panels Components and Properties

This section describes how to edit Applications Panel properties and components, how to add a data source to the panel, and how to add more UI content.

18.1.3.1 Stretching the Applications Panel

The Applications Panel can be stretched by placing it in the center facet of an ADF panelStretchLayout component. Do not set the width using the inlineStyle attribute on either Applications Panel or panelStretchLayout. For more
information about basic page layout and the inlineStyle attribute, see the Organizing Content on Web Pages and Customizing the Appearance Using Styles and Skins sections in the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide.

18.1.3.2 Access the Applications Panel on a JSF Page

Before you can edit the panel properties and components or bind the panel to a data source, you must access the panel in the Property Inspector section of your JSF page.

To access the panel on a JSF page:

1. Make the JSF page the active file.
2. Access the panel by double-clicking one of the following on the JSF page:
   - Applications Panel component in the Design view.
   - Applications Panel line in the Source view:
     `fnd:applicationsPanel...
   - Applications Panel entry in the Structure view hierarchy:
     `fnd:applicationsPanel`

When you select the panel as described in this section, the Applications Panel - Property Inspector is displayed.

18.1.3.3 Edit Applications Panel Properties and Components

This section describes how to edit Applications Panel properties and components.

To edit an application panel property:

1. Access the panel as described in Accessing the Applications Panel on a JSF Page.
2. Select the Applications Panel to display the Property Inspector.
3. Follow the instructions in the Property Inspector to modify the panel property.

To edit an application panel component:

1. Access the panel as described in Accessing the Applications Panel on a JSF Page.
2. Select, then double-click the component or subsection. For example, to select a panel header, select `af:panelHeader` in the Source view.
3. When you double-click the component, the Property Inspector for the component is displayed. Edit the component in the Inspector.

   For example, to edit a subsection display name, select the subsection and edit the Text property in the Property Inspector for that subsection.

18.1.3.4 Add a Data Source to an Existing Panel

This section describes how to add a data source after you create a panel in the Application Panel wizard.
To add a data source to an existing panel:

1. In the Application Navigator, open the Data Control panel.

2. Navigate to the data source to bind to the Applications panel.

3. Drag and drop the data source itself (or its individual fields) to the JSF page in Design mode.

Data-source fields are bound to panel components. Components are stored in the contents facet as *af:panelFormLayout* components, and in the various subsections.

For example, Figure 18-13 shows a panel’s Structure view, which contains added components.

![Figure 18-13 Panel Structure View](image)

To create an additional field in a subsection, drag an attribute from the data source to the corresponding container. For example, drag the attribute to *fnd:applicationsPanel > f:facet - contents > af:panelGroupLayout > af:panelFormLayout*. When prompted for the component to associate with the attribute, choose *ADF Input Text w/Label*.

### 18.1.3.5 Add User-Interface Content to Applications Panels

Although Applications panels already provide common layout components, your JSF page might require additional UI elements, such as additional action buttons. When you add new components to a panel, you drop the new components into facets.

To add UI content to existing panels:

1. Open the Components Palette.

2. Drag and drop the button component on to the appropriate popup facet.

   For example, to add a new button, drag and drop the button to the *actionButtonBar* facet.

For more information on facets, see Table 18-2.

### 18.2 Implementing the Simple Panel

The Simple Panel Applications Core declarative component for FUSE Plus is a lighter version of the Applications Panel component. It supports these facets:
• Header Title
• Header Context
• Header Toolbar (Page Actions)
• Horizontal Train
• Content

Built-in buttons for the Simple Panel include:
• Actions (menu button)
• Save and Continue/Save and Close
• Save and Close/Save (Save and Close is the default action while Save is in the dropdown menu)
• Save and Close
• Cancel
• Submit
• Done

This image shows the basic content and appearance of a Simple Panel.

**Figure 18-14  Example Simple Panel**

This table shows the facets supported by the Simple Panel.

18.2.1 How to Implement the Simple Panel

Use this sample code as the basis to use the fnd:simplePanel component.

```xml
<?xml version='1.0' encoding='UTF-8'?>
<jsp:root xmlns:jsp="http://java.sun.com/JSP/Page" version="2.1"
    xmlns:af="http://xmlns.oracle.com/adf/faces/rich"
    xmlns:fnd="http://xmlns.oracle.com/apps/fnd/applcore"
    xmlns:h="http://java.sun.com/jsf/html"
    xmlns:f="http://java.sun.com/jsf/core">
    <fnd:simplePanel id="sp1" title="Simple Panel: Title"
        cancelRendered="true" cancelShortDesc="cancel"
        doneRendered="true" doneVisible="true" doneShortDesc="done"
        saveAndContinueRendered="true"
        submitRendered="true" submitText="Submit"
        submitStyle="dropButton">
        <f:facet name="contents">
            <af:panelBorderLayout id="pbl1"
                inlineStyle="border-style:groove; outline-color:Black; height:300.0px;">
                <f:facet name="start"/>
                <f:facet name="bottom"/>
                <f:facet name="end"/>
                <f:facet name="top">
                    <af:outputText value="contents facet here" id="op1" inlineStyle="font-size:large;"/>
                </f:facet>
            </af:panelBorderLayout>
        </f:facet>
        <f:facet name="ActionButtonBar">
            <h:panelGroup id="pg1">
                <af:commandButton text="CustomButton1" id="cb1"/>
                <af:commandButton text="CustomButton2" id="cb2"/>
            </h:panelGroup>
        </f:facet>
        <f:facet name="saveButtonMenu">
            <af:commandMenu id="cm1" text="CustomSaveButtonMenu"/>
        </f:facet>
        <f:facet name="submitButtonMenu">
            <af:commandMenu id="cm2" text="CustomSubmitButtonMenu"/>
        </f:facet>
        <f:facet name="popup"/>
        <f:facet name="panelContext">
            <af:outputText value="(panelContext facet here)" id="ot1"/>
        </f:facet>
        <f:facet name="customSaveDropButton">
            <af:commandToolBarButton text="CustomSaveDropButton" id="cb3"/>
        </f:facet>
        <f:facet name="panelTrain">
            <af:outputText value="panelTrain facet here" id="ot2"/>
        </f:facet>
    </fnd:simplePanel>
</jsp:root>
```

Implement Applications Panels, Master-Detail, Hover, and Dialog Details
18-29
18.2.2 How to Add Simple Panel at Design Time

**Note:**

- As is done with the Applications Panel, the visible attribute and the rendered attribute are set to `true` for each button that is selected at design time.
- For the `submitStyle` attribute, the `dropButton` and `sideBySide` options let the user pick something to indicate the "any other string" that hides the dropdown. `sideBySide` is set as the attribute value to be consistent with the `saveOptionsStyle`.

To add a Simple Panel to your page, follow these steps:

1. As shown here, you can click-and-drag the Simple Panel from the Data Control palette or from the Component palette.

![Figure 18-15 Dragging and Dropping Simple Panel onto Page](image)

When you drop the Simple Panel component, the Simple Panel wizard is started.

2. If you dragged from the Component Panel, you can specify the data source for the component or just click Next to create prototype data.

![Figure 18-16 Select a Data Source](image)
To bind a data source to the panel component:

- Select Bind Data Now.
- Click **Browse** to display the Data Source dialog.

![Data Source Dialog](image)

- Select the data source, then click **OK** to add it to the component. Optionally, you can bind the component to a data source at a later time.

Click **Next** to configure the panel Title.

3. Configure the panel title.

![Configure the Panel Title](image)

**Note:** See Using Simple Panel Title Templates.

There are four title templates from which to choose:

- **Single Title Template**

  A single string can be selected as the Simple Panel title.

  Example Title Format: `<single string>`

  Example: John Jones

  Using the picker drop box, shown here, to the right of the text field, three options are available:
Figure 18-19  Single Title Template Pick Options

- **Select Text Resource.** This will open the same Text panel commonly available in the property inspector. The developer can select an existing translation value, or create a new one. See the Select Text Resource image and description.

- **Text Expression Builder.** This will open a dialog in which the developer can type a value to be translated and allows the insertion of any attribute in the current Collection as bind variables.

- **Clear.** Clear the current field value.

In addition, the user can just type a string into the field. If it exists as an existing Text resource it will be used, otherwise a new resource will be created.

• **Tabbed Page Template**

When Tabbed Page is selected, the options appear similar to this example:

**Figure 18-20  Tabbed Page Title Options**

Three fields can be selected as the Simple Panel title.

Example Title Format: `<tab name>: <object type> <object value>`

**Example:** Suppliers: Negotiation 123456

The options available to the two String fields Tab Name and Object Type are the same as for the Single option, while for Object Value a list of attributes in the current collection is shown. If desired, a text expression can be selected from the pickers.

• **Train Page Template**

When Train Page is selected, the options appear similar to this example:

**Figure 18-21  Train Page Title Options**

Three fields can be selected as the Simple Panel title.

Example Title Format: `<object type> <object value>: <train stop name>`

**Example:** Negotiation 123456: Select Suppliers

The options available to the two String fields Object Type and Train Stop Name are the same as for the Single option, while for Object Value a list of attributes in the current collection is shown. If desired, a text expression can be selected from the pickers. For the Maximum length in train attribute which is
supposed to resolve to an integer number, either enter the number or select from the EL picker which is available. No Text resource picker is provided.

- **Title Object and Value Template**
  When Title Object and Value is selected, the options appear similar to this example:

  **Figure 18-22  Title Object and Value Title Options**

  ![](image)

  Two fields can be selected as the Simple Panel title.

  **Example Title Format:** `<object type> <object value>`

  **Example:** Expense Report: 123456

  The String field Object Type option is the same as for the Single option, while for "Object Value" a list of attributes in the current collection is shown. If desired, a text expression can be selected from the pickers.

  An example of the markup produced is:

  ```xml
  <fnd:simplePanel id="SP1" titleTemplate="objectTypeAndValue"
                   titleObjType="#{viewcontrollerBundle.EMPLOYEE}" titleObjValue="#{bindings.Ename.inputValue}"
                   doneVisible="true" doneRendered="true"
                   panelPartialTriggers="ASPRNnext1 ASPRNprev1 ASPSelId1">
  Click Next.

  4. Select the initial set of panel components.

  **Figure 18-23  Select Panel Components**

  ![](image)

  In the Panel Components dialog:

  Click Read-only Form to create a read-only form. (optional) If you select Read-only, the choices in the Component to Use column will change from Input Text to Output Text types.

  To reorder component fields, click the up and down arrows. To delete component fields, click the Delete icon (X). You will be able to add more component fields later.
• **Display Label:** In general, the labels defined in the selected Data Control will be what you want and you can leave this value at the default <Default> setting. Otherwise, enter a new label name.

• **Value Binding:** In general, the label and the Value Binding will match and you can accept the displayed value. Otherwise, you can click in the field to display a drop-down list of the values available in the selected Data Control.

• **Component To Use:** Data in Dialog Details can be read-only or can be updated. Component to Use is similar to what Component does while creating a table. Clicking it reveals a choice list of values, and the dialog details popup would then at runtime show that particular column from the datacontrol as the selected component to use. The choice list is changed according to whether you choose Read-only. If you selected Read-only, the choices will change from Input Text to Output Text types.

Click Next.

5. Select a navigation button template.

The Navigation Buttons page is designed to allow the selection of different template types.

Each selection allows the specification of different attributes. See the Simple Panel Title templates, above, for definitions.

**Figure 18-24 Select Navigation Button Template**

Four navigation button templates are available:

• **None**
  
  No navigation buttons will be generated. This is the default option unless the title on the title step of the wizard was selected as Train Page. In this case, Train is selected here.

• **Train**
  
  Select this option to provide navigation between page fragments in a bound taskflow using a train.

  If Train is selected, the options resemble this example:
Select Train Navigation Template

To just create the buttons, make sure the Generate train checkbox is not selected.

To bind to a train, check the Generate train checkbox. It is assumed that the page is in a bound taskflow that has train selected and that a train stop display-name has been added for each view activity.

Example markup generated:

```xml
<fnd:simplePanel id="SP1" titleTemplate="trainPage"
   titleObjType="#{viewControllerBundle.EMPLOYEE}"
   titleObjValue="#{bindings.Ename.inputValue}"
   titleObjValueMaxLengthInTrain="40"
   titleName="#{viewControllerBundle.FIRST}"
   saveAndCloseVisible="true" saveAndCloseRendered="true"
   cancelVisible="true" cancelRendered="true"
   panelTrainRendered="true">
   <f:facet name="contents">
     <af:panelGroupLayout id="pgl2">
       <af:panelFormLayout rows="1" id="pfl1">
         ...
       </af:panelFormLayout>
     </af:panelGroupLayout>
   </f:facet>
   <f:facet name="actionButtonBar">
     <af:panelGroupLayout layout="horizontal" id="pgl3">
       <af:commandImageLink id="ASPprev1" icon="/images/applcore/fuseplus/patterns/
          func_arrowheadleft_16_ena.png"
          hoverIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadleft_16_hov.png"
          depressedIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadleft_16_onb.png"
          disabledIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadleft_16_dis.png"
          partialSubmit="true"
          action="#{controllerContext.currentViewPort.taskFlowContext.trainModel.previous == null}"
         />
       <af:spacer width="10" id="s1"/>
       <af:commandImageLink id="ASPnext1" icon="/images/applcore/fuseplus/patterns/
          func_arrowheadright_16_ena.png"
          hoverIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadright_16_hov.png"
          depressedIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadright_16_onb.png"
          disabledIcon="/images/applcore/fuseplus/patterns/
          func_arrowheadright_16_dis.png"
          partialSubmit="true"
         />
     </af:panelGroupLayout>
   </f:facet>
</fnd:simplePanel>
```
• **Linear Record**

Select this option for navigation between data records on the same page.

If Linear Record is selected, the options resemble this example:

**Figure 18-26  Select Linear Record Navigation Template**

A text resource in the style of "1 of 5" is created binding to the current record number and total number of records. This can be changed with the pickers.

Example markup generated:

```xml
<fnd:simplePanel id="SP1" titleTemplate="objectTypeAndValue" titleObjType="#{viewcontrollerBundle.EMPLOYEE}" titleObjValue="#{bindings.Ename.inputValue}" doneVisible="true" doneRendered="true" panelPartialTriggers="ASPRNnext1 ASPRNprev1 ASPSelId1">
  <f:facet name="contents">
    <af:panelGroupLayout id="pgl1">
      <af:panelFormLayout rows="1" id="pfl1">
        ...
      </af:panelFormLayout>
    </af:panelGroupLayout>
  </f:facet>
  <f:facet name="actionButtonBar">
    <af:panelGroupLayout layout="horizontal" id="pgl2">
      <af:commandImageLink id="ASPRNprev1" icon="/images/applcore/fuseplus/patterns/func_arrowheadleft_16_ena.png" hoverIcon="/images/applcore/fuseplus/patterns/func_arrowheadleft_16_hov.png" depressedIcon="/images/applcore/fuseplus/patterns/func_arrowheadleft_16_onb.png" disabledIcon="/images/applcore/fuseplus/patterns/func_arrowheadleft_16_dis.png" partialSubmit="true" actionListener="#{bindings.Previous.execute}" disabled="#{!bindings.Previous.enabled}"/>
    </af:panelGroupLayout>
  </f:facet>
</fnd:simplePanel>
```
• Non-Linear Record
Select this template for data navigation between data records on the same page with the ability to skip across records.

• When this template is selected, the options appear similar to this example:

**Figure 18-27  Select Non-Linear Record navigation Template**

![Non-Linear Record template]

Pick an attribute, either in the current Collection or in a parent Collection (master-detail style) to act as the non-linear record identifier. Click the pick icon by the List Attribute field to display the List Attribute picker:

**Figure 18-28  Selecting the List Attribute**

![List Attribute picker]

Select a collection, such as CreatedBy in the example and click **OK** to place the attribute in the List Attribute field, shown here:

**Figure 18-29  Populated List Attribute**

![Populated List Attribute]

Example markup generated:
Implementing the Simple Panel

Binding generated for a combo box:

6. Select which of the available buttons to display.
Figure 18-30  Select Buttons to Display

- **Editable**
  Select this option if the user needs to be able to edit the content of the panel.

- **Read-only**
  Select this option to prevent changes to the content of the panel. Only a default **Done** button will be made available to the user.

- **No buttons**
  Select this option to display no buttons in the panel.
  
  One use for this option is on work area landing pages. These would have a panel without buttons because they are read-only and not directly transactional. Users can navigate to a new task from the landing page or initiate lightweight transactions that can be performed in a dialog box. Consequently, no final page-level actions appear on the page.

- **Button options**
  The available buttons are grouped into selections. Select the group that contains the buttons and options you want.

  **Submit Button Name**
  
  You can change the name of this button from the default Submit to another name that is more descriptive of the operation.
  
  To change the **Submit** button name, enter the string here. The string will be converted to a text resource and added to the default resource bundle.
  
  If you already have a name defined in a resource bundle, click the edit icon and choose from the list, as shown here.
Figure 18-31  Select Text Resource for Submit Button

- **Resource Bundle**: Select the bundle containing the string you want to use. You can select a single bundle or all available bundles. The strings will display in the Matching Text Resources field.

- **Display Value**: You can enter a new string for a name here.

- **Key**: Each resource must have a unique Key. This generally is, in all upper-case characters, the words of the Display Value separated by an underscore character.

- **Description**: This is an optional entry.

- **Matching Text Resources**: This field displays the entries of the selected resource bundle. Select an existing title from the list.

**Drop down menu**

When this option is selected, the buttons will display in a drop-down menu, instead of side-by-side.

- **Cancel**
  
  This is a default button and cannot be removed.

  Click Next.

7. Select whether or not to enable the side panel.
The side panel is a slide in/out panel on the right in which Oracle Social Network can be located, so you can slide it out and see an Oracle Social Network conversation.

Enable **Generate Additional Draw item** to create another place in the side panel in which to put things. It would get the label provided in the Label field and would be populated in a later design time step.

8. Review the panel structure. When it is correct, click **Finish** to add the Simple Panel to your page.

**Using Simple Panel Title Templates**

The Simple Panel component is enhanced to let developers configure the Page Title so it is appropriate to the product line, page template type, or page context. This section covers the Title templates that are supported, their respective format, and their runtime behavior.

**Supplied Templates**

The supplied templates are:

- **Single string**
  
  A single string has:

  1 field
  
  Title format = <single string>
  
  Example: John Jones
• **Object Type and Value**
   An Object type and Value string has:
   - 2 fields
   - Title format = <object type>:<object value>
   - Example: Expense Report: 123456

• **Tabbed page**
   A Tabbed page string has:
   - 3 fields
   - Title format = <tab name>:<object type> <object value>
   - Example: Suppliers: Negotiation 123456

• **Train page**
   A Train page string has:
   - 3 fields
   - Title format = <object type> <object value>:<train stop name>
   - Example: Negotiation 123456: Select Suppliers

**Note:** The separator character is coded inside the component and cannot be changed.

### Runtime Behavior
For the attributes that support the Title based on a template, see “Title template related attributes” in Attributes Supported by the Simple Panel.

These attributes will be used to support Title based on template:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Default Value</th>
<th>Mandatory?</th>
<th>Valid Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>title</td>
<td>java.lang.String</td>
<td>NA</td>
<td>No</td>
<td>NA</td>
</tr>
<tr>
<td>titleTemplate</td>
<td>java.lang.String</td>
<td>single</td>
<td>No</td>
<td>single, objectTypeAndValue, tabbedPage, trainPage</td>
</tr>
<tr>
<td>titleObjType</td>
<td>java.lang.String</td>
<td>NA</td>
<td>No</td>
<td>String value representing Object Type</td>
</tr>
<tr>
<td>titleObjValue</td>
<td>java.lang.String</td>
<td>NA</td>
<td>No</td>
<td>String value representing Object Value</td>
</tr>
<tr>
<td>titleName</td>
<td>java.lang.String</td>
<td>NA</td>
<td>No</td>
<td>String value representing Tab name or Train Stop name</td>
</tr>
</tbody>
</table>
Based on the Title template chosen, the title is shown using these formats at runtime:

### Table 18-8 Title Template Formats

<table>
<thead>
<tr>
<th>titleTemplate Value</th>
<th>Attributes Forming the Title</th>
</tr>
</thead>
<tbody>
<tr>
<td>single</td>
<td>title</td>
</tr>
<tr>
<td>objectTypeAndValue</td>
<td>titleObjType: titleObjValue</td>
</tr>
<tr>
<td>tabbedPage</td>
<td>titleName: titleObjType titleObjValue</td>
</tr>
<tr>
<td>trainPage</td>
<td>titleObjType titleObjValue: titleName</td>
</tr>
<tr>
<td></td>
<td>(For this template, as Object Value comes in the middle and can hold values of bigger length, titleObjValueMaxLengthInTrain can be used by developers to specify the maximum length Object Value can be shown in the UI. If it is specified, Object Value is truncated to the maximum length and shown by appending &quot;...&quot;.)</td>
</tr>
</tbody>
</table>

This table shows examples of attributes and the text that is displayed:

### Table 18-9 Examples of Attributes and Displayed Text

<table>
<thead>
<tr>
<th>Simple Panel Attributes</th>
<th>Title Shown at Runtime</th>
</tr>
</thead>
<tbody>
<tr>
<td>titleTemplate='single' title='John Jones'</td>
<td>John Jones</td>
</tr>
<tr>
<td>title='John Jones'</td>
<td>John Jones</td>
</tr>
<tr>
<td><em>(titleTemplate not specified)</em></td>
<td></td>
</tr>
<tr>
<td>titleTemplate='objectTypeAndValue' titleObjType='Expense Report' titleObjValue='123456'</td>
<td>Expense Report: 123456</td>
</tr>
<tr>
<td>titleTemplate='tabbedPage' titleName='Suppliers' titleObjType='Negotiation' titleObjValue='123456'</td>
<td>Suppliers: Negotiation 123456</td>
</tr>
<tr>
<td>titleTemplate='trainPage' titleName='Select Suppliers' titleObjType='Negotiation' titleObjValue='123456'</td>
<td>Negotiation 123456: Select Suppliers</td>
</tr>
<tr>
<td>titleTemplate='trainPage' titleName='Select Suppliers' titleObjType='Negotiation' titleObjValue='123456' titleObjValueMaxLengthInTrain=&quot;4&quot;</td>
<td>Negotiation 1234...: Select Suppliers</td>
</tr>
</tbody>
</table>
18.3 Implementing Applications Master-Detail

Note:
Master-Detail refers to the interaction of selecting an object from a master list, and refreshing the details in an adjacent area. It is not the relationship of the data.

The Master-Detail composite is used in situations where the information is too large, dynamic or complex to show in a flat table. The user can see the Master, or summary, information in one area, and the corresponding details in a separate area. This can be achieved using different master and detail components, such as table, tree table, and tree.

For instance, when the user selects an Employee from the master table, the corresponding employee details are displayed in the region below in a label/data format.

For more information, see the Displaying Master-Detail Data section in the Oracle Fusion Middleware Developing Fusion Web Applications with Oracle Application Development Framework guide.

18.3.1 Component Structure and Functions

You should review and understand the Applications Table before proceeding to implement the Applications Master-Detail in your development pages.

Facets

Table 18-10 shows the facets that are exposed on the Applications Master-Detail.

<table>
<thead>
<tr>
<th>Facet</th>
<th>Description</th>
<th>Allowed Children</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master</td>
<td>facet for holding the Applications table</td>
<td>formLayout and Applications Table</td>
</tr>
<tr>
<td>Detail</td>
<td>facet for holding the Applications Table</td>
<td>Applications Table</td>
</tr>
</tbody>
</table>

View Properties

See Table 18-2 in Implementing Applications Tables for a list of properties exposed on the Applications Table. These properties can be used to configure the Applications Table under either the Master or Detail section of the Applications Master-Detail component.

Model

The Applications Master-Detail does not expose any bindings to the model on its own, but the ADF tables or formLayout components that are encapsulated within the Applications Table under the master or detail section will be bound to the model.
Controller
The Applications Master-Detail ships a default managed-bean (internal to the Oracle Fusion Middleware Extensions for Applications (Applications Core) team) that currently supports translation functions. You can access the implementation of the Applications Table managed bean which will be exposed as either the Master or the Detail section of the component. For use and implementation information, see Controller in Implementing Applications Tables.

18.3.2 Introduction to Master-Detail Components

The Master-Detail can exist at the page level, or at the subheader level in a page. The Master-Detail component will support these layouts:

- Panel over FormLayout
- Panel over TreeTable
- Panel over Heterogeneous
- Panel over Subtabs
- Panel over Table
- Tree over LevelSpecific
- Table over Table
- Table over Form Layout
- Table over sub tabs
- Table over Heterogeneous (every row can have a different detail section)
- Table over Tree (available via Table over Heterogeneous)
- Form Layout over Table
- Form Layout over Form Layout
- Form Layout over sub tabs
- Form Layout over Heterogeneous
- Form Layout over Tree (available via Form Layout over Heterogeneous)
- Table over Tree Table
- Tree Table over Table
- Tree Table over Sub tabs
- Tree Table over Form Layout

Tables are the most common master component. When a table row is selected, the details appear in the area below the table. A table is also a very common detail component.

A Tree Table is a layout option in a Master-Detail composite for either a Master or a Detail (not both). When a Tree Table row is selected, the details appear in the area below the Tree Table.
Sub tabs are a detail layout option in a Master-Detail composite.
Form Layout is a detail layout option in a Master-Detail composite.

18.3.3 How to Create a Master-Detail

The Applications Master-Detail can be added to a page or page fragment using the Data First approach. Valid drop locations in the page or page fragment include ADF Form, and ADF Layout components and the Applications Panel (jsp:root, af:form, af:root, fnd:applicationsPanel, af:group, af:panelBorderLayout, af:panelBox, af:panelCollection, af:panelFormLayout, af:panelGroupLayout, af:panelHeader, af:showDetailItem, af:panelWindow, af:popup, af:showDetail, af:subform, f:facet, f:panelGrid, f:panelGroup, af:pageTemplateDef, af:pageTemplate#<localArea_Facet>.

For more information on creating a JSF page, see the Oracle Fusion Middleware Developing Web User Interfaces with Oracle ADF Faces guide.

Be sure to save your work after you create each component.

18.3.3.1 Add a Master-Detail to JSF Pages or Page Fragments

You create a Master-Detail in the Applications Master-Detail wizard, which is displayed when you add the details to your JSF pages (or page fragments) from the Data Controls panel.

To add a Master-Detail from the Data Control panel:
For Master-Detail to work, you need to define the model-layer such that the Master and Detail are linked by a ViewLink that establishes a relationship from the Master to the Detail.

1. In the Application Navigator, open the Data Control panel.
2. Navigate to the data source that you want to bind to the Master-Detail.
3. Drag the detail data-source onto the page.
4. In the Create context menu that is displayed, choose Applications > Master-Detail. Figure 18-34 shows the parent-child relationship of the selected Data Control, how the child is dragged to the page, and the Master-Detail option on the Create menu.

Figure 18-34    Example of Master-Detail Relationships
The Applications Master-Detail wizard is displayed.

18.3.3.2 Adding Master-Details Components Using the Applications Master-Details Wizard

This section explains how to use the Applications Master-Detail wizard to add Master-Details to your pages.

All mandatory fields in the wizard contain default values, allowing you to accept the defaults and work through the steps quickly. Clicking Cancel on any of the dialogs cancels the creation of the Master-Detail and does not save the values you entered.

When you click Finish on any of the dialogs, the software:

- Displays a preview of the Master-Detail.
- Creates the Master-Detail with the values you provided on that screen and any previous screens, and default values for the remaining screens. However, not all wizards have a Finish button, or they only appear in a wizard when you have enough information to default the rest of the steps. For example, in almost all wizards, the last step is the Summary. This step often is omitted, so there is almost always a Finish button on the step before the Summary step.

Caution:
Each wizard dialog contains a Messages field that displays errors for that step. Do not proceed to the next wizard step without correcting any errors in the present step.

Creating a Master-Detail Using Tables

When the Create Applications Master-Detail wizard launches, the Select Pattern Type dialog displays, shown in Figure 18-35.

Figure 18-35 Select Pattern Type Dialog
Enclose Master Detail in

If the Pattern Type supports either the Panel Splitter or the Master Header Label, this option becomes active and a list, shown in Figure 18-36, offers these choices.

**Figure 18-36  Enclose Master Detail Choices**

- **<none>**: This is the default selection. No special action will be performed.
- **Panel Splitter**: Select this option to activate the **Splitter Position** field and set the position, in pixels, of the horizontal position of the split. Figure 18-37 shows an example of a Splitter in use at the default position.

**Figure 18-37  Example of Panel Splitter**

- **Panel Header / Show Detail Header**: Select one of these options to activate the **Master Header Label** field to enclose the Master-Detail with a header. There are basically two types of headers:
  - with a hide/show icon
  - without the hide/show icon

In the example in Figure 18-38, the Edit Element Entries text is the Panel Header and the Basic Information text with the expand/collapse icon is the Show Detail Header. The picture, Name and Social Security Number are the content, which is enclosed by the Show Detail Header. Then everything is enclosed by the Panel Header, shown in Figure 18-38.
• **Master Header Label**: Enter the label to be used by either the Panel Header or the Show Detail Header.

Select the Pattern Type (the example uses Table/Table) and any options and click **Next**.

The Configure Master dialog displays, shown in **Figure 18-39**.

**Figure 18-39 Table/Table Configure Master Dialog**

To create your Master-Detail for your Master table columns:

1. **Click Read-only Table** to create a read-only Master table. (optional) If you select Read-only, the choices in the Component to Use column will change from Input Text to Output Text types.

2. In the **Enable ADF Behavior** section, choose whether to allow users to Select, Sort, and Filter rows.
3. In the **Columns** field:
   - Click the **Display Label** field to enter a column label.
   - Click the menu arrow to select value bindings for each value.
   - Choose what component to associate with the column.
   - After selecting a component, click the Delete icon (X) to delete it, the Add icon (+) to edit it, and the Reorder icons to change its position in the field.

Click **Next** to display the Configure Master Table Patterns dialog, shown in Figure 18-40.

**Figure 18-40 Configuring Master Table Patterns**

4. Choose the patterns to be enabled in your table.

5. Click **Next** to display the Configure Detail Header dialog, shown in Figure 18-41.
6. Enter a Detail header name and choose a corresponding attribute.

7. Click Next to display the Configure Details dialog:
   Configuring the Details table is the same as configuring the Master table; see Figure 18-39 and steps 1 through 4.

8. Click Next to display the Configure Detail Table Patterns dialog.
   Configuring the Details Table Patterns is the same as configuring the Master Table Patterns; see Figure 18-40 and step 5.

9. Click Next to display the Review panel configuration dialog, shown in Figure 18-42.

When you click Finish, the Table/Table Master-Detail is added to the editor, and appears similar to Figure 18-43 in Design mode.
Creating a Master-Detail Using Forms

When the Create Applications Master-Detail wizard launches, the Select Pattern Type dialog displays, shown in Figure 18-35.

To create your Master-Detail for your Master form fields or Detail table columns:

1. To create a Master-Detail consisting of two forms, select FormLayout/FormLayout and click Next to display the Configure Master dialog, shown in Figure 18-44.
This configure dialog is the same as the one for creating a Table, except that it does not have the Enable ADF Behavior settings, as shown in Figure 18-39.

2. Click Next to display the Configure Navigation Buttons dialog, shown in Figure 18-45.

![Figure 18-45  Form/Form Configure Navigation Buttons Dialog](image)

Select the navigation buttons you want to appear on the Main form.

3. Click Next to display the Detail Header dialog, shown in Figure 18-41 for details.

4. Click Next to display the Configure Details dialog, shown in Figure 18-46.
Use this dialog to create as many tabs on the Details form as you need. To create a new tab, enter a name in the Name field and click the Add icon. The tab is added in the area beneath the Name field.

Each tab is the same as the dialog for creating a Table, except that it does not have the Enable ADF Behavior settings, shown in Figure 18-39.

5. Click Next to display the Configure Navigation Buttons for the Detail section dialog, shown in Figure 18-45.

6. Click Next to display the Summary dialog.

7. Click Finish to save your changes.

Your new Master-Detail displays in the JSF Page editor, shown in Figure 18-47.
18.3.4 Master-Detail Guidelines for Creating New Records

Developers should follow these guidelines to use the updatable Master-Detail task flow and to investigate some solutions for creating a detail record for a newly-created master record. Several cases have been identified for using Master-Detail. The master and the detail can be a form, table, tree, or tree table.

18.3.4.1 Master-Detail without a Default Primary Key Generator

If you have a Master-Detail in your page and the primary key for the master is not generated using a sequence, the best way to create a detail row for a freshly-created master row is to have a page-level Submit or Save button that must be clicked to save the master data before creating detail data.

18.3.4.2 Master-Detail with a Default Primary Key Generator

In this case there are two solutions:

1. Have a page-level Submit or Save button that would save the newly-created master record before creating a detail record.

2. Set the autoSubmit property on all the elements (components) of the master to true. For example, if the master is a table, set autoSubmit="true" on all the components inside the af:column.

18.3.4.3 Master-Detail with a Composite Primary Key

In this case, you need to provide a page-level Submit or Save button and click it to commit the master record before creating a detail record.

18.3.4.4 Any Other Case

The preferred solution is to have a page-level Submit or Save button that can commit the master record before creating a detail record.
18.3.5 How to Modify Master-Detail Components and Properties

To modify Master-Detail components and properties, double-click a Master-Detail component in the page editor.

18.4 Implementing Hover

Hover is a subset of Detail On Demand that presents the same information when the user hovers over a link.

This is a Design Time (DT) only pattern, no component has been created. For this reason there is no UI First creation option.

The Design Time works when dragging a collection from the Component palette onto an allowed drop component, shown in Figure 18-48.

**Figure 18-48 Dragging from the Component Palette onto a Drop Component**

The allowed drop components are:

- af:commandLink
- af:commandImageLink
- af:commandToolbarButton

The DT will verify whether the component is in a table already bound, and if that binding is for the collection being dropped.

- If so, it will create additional table bindings for the attributes selected.
- If not, it will create form bindings for the collection.

If it is not dragged into an allowed table component, it will create additional bindings for that collection.

If the allowed component already has a showPopupBehavior component child, the menu option will not show. This behavior helps prevent double adding of hovers.

A dialog displays so you can select the attributes to see in the hover popup, and the alignment of the popup over the "hovered" component, shown in Figure 18-49.
The valid values for alignment are:

- afterEnd
- afterStart (default value)
- beforeEnd
- beforeStart
- endAfter
- endBefore
- startAfter
- startBefore

All JSF components created in the popup will be read-only.

When the OK button is clicked:

- The drop component will be given an Id if it does not have one already, and have the clientComponent attribute set to true.
- The drop component will have a `<af:showPopupBehavior>` component added as a child.
- A popup `<af:popup>` will be added as the previous sibling of the drop component, shown in Example 18-2 for the sample markup, and Figure 18-50 for a sample of the result.
Example 18-3 shows the sample markup for a table-based layout and Figure 18-51 shows an example of how the result appears.

**Figure 18-51  Example of a Table-based Layout**

<table>
<thead>
<tr>
<th>MasterId</th>
<th>Col1</th>
<th>Col2</th>
</tr>
</thead>
<tbody>
<tr>
<td>row1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>MasterId</td>
<td></td>
<td></td>
</tr>
<tr>
<td>row2</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Links in the Popup**

It is possible to add command links / buttons into the popup so the user can navigate to a separate page/page flow. Adding these links is up to the developer, because it is not a valid option in the Design Time, as command links are not an available component in any binder GUI. The developer must ensure the popup is closed after navigation in this case, although the default behavior may do this.

**Example 18-2  Example Markup for a Form-based Layout**

```xml
<af:popup id="popup1">
    <af:panelFormLayout labelAlignment="start">
        <af:panelLabelAndMessage label="# {bindings.MasterId.hints.label}"
            value="# {bindings.MasterId.inputValue}"
            pattern="# {applCorePrefs.numberFormatPattern}"/>
        <af:outputText/>
    </af:panelLabelAndMessage>
    <af:commandLink actionListener="# {bindings.Last.execute}" text="# {applcoreBundle.LAST}" id="rolloverComponent2" clientComponent="true">
        <af:showPopupBehavior triggerType="mouseOver" popupId="popup1" alignId="rolloverComponent2" align="afterStart"/>
    </af:commandLink>
</af:panelFormLayout>
```

**Example 18-3  Example Markup for a Table-based Layout**

```xml
```
18.5 Implementing Applications Dialog Details

The Applications Dialog Details component provides a user interface for launching a popup that contains detail information. The UI can be a detail icon, a link, or a button.

18.5.1 How to Add Applications Dialog Details to Your Page

You can add the Applications Dialog Details to your page in two ways:

- Select the Applications Dialog Details from the Applications component palette and drag and drop it on your page.
- Drag and drop a data control to your page and select the Applications Dialog Details from the list of available UI components.

View

Table 18-11 shows the properties that are exposed on the Applications Dialog Details.
### Table 18-11  Applications Dialog Details Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>Allowed Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>Id (id)</td>
<td>The unique ID for this Applications Table</td>
<td>string</td>
</tr>
<tr>
<td>Rendered (rendered)</td>
<td>Whether the Applications Table is rendered or not</td>
<td>boolean / expression</td>
</tr>
<tr>
<td>Detail Pattern Type</td>
<td>Detail pattern type</td>
<td>image, link or button</td>
</tr>
<tr>
<td>(detailPatternType)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Popup Id (popupId)</td>
<td>ID of the popup to be invoked when Detail image/link/button is clicked</td>
<td>string</td>
</tr>
<tr>
<td>Text (text)</td>
<td>Overrides default label for Detail button, or defines link text for Detail link</td>
<td>expression</td>
</tr>
<tr>
<td>Short Description</td>
<td>Overrides default roll-over text for detail image/button</td>
<td>expression</td>
</tr>
<tr>
<td>(shortDesc)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Disabled (disabled)</td>
<td>Sets whether the component needs to be disabled</td>
<td>boolean / expression</td>
</tr>
</tbody>
</table>

### Model

The Applications Dialog Details does not expose any bindings to the model. However, components within the Applications Dialog Details, like the layout inside ADF popup, will be bound to the model.

### Controller

The Applications Dialog Details component does not ship a default managed bean.

#### 18.5.1.1 Adding Applications Dialog Details

The Applications Dialog Details can be added to a page or page fragment using either the Component First or the Data First approach. Valid drop locations in the page or page fragment include ADF Form, and ADF Layout components and the Applications Panel (jsp:root, af:form, af:root, fnd:applicationsPanel, af:column, af:form, af:group, af:panelBox, af:panelFormLayout, af:panelGroupLayout, af:panelHeader, af:showDetailItem, af:panelWindow, af:showDetail, f:facet, f:panelGrid, f:panelGroup, af:pageTemplateDef, af:pageTemplate#<localArea_Facet>).

The Applications Dialog Details can be added to a page or page fragment using either the Component First or the Data First approach. Both approaches launch a wizard which helps you to quickly define the appropriate attribute values. When you complete this wizard, you can further refine the dialog details definition by editing the resulting component as needed.

#### Component First

Navigate to the Component Palette. Click the list of libraries and select Applications. Drag the Applications Dialog Details from the list of components and drop it onto the
page. The wizard will launch after dropping the Applications Dialog Details on the page.

**Data First**

Navigate to the Data Controls panel of the Application Navigator. Open the panel by clicking its bar, then navigate through the hierarchy to locate the data source that you would like to include in the Applications Dialog Details. Select that data source and drag it on to the page. A context menu will appear with a list of components. Move the mouse over the Applications category list. Select **Applications > Dialog Details** to launch the Applications Dialog Details wizard, shown in Figure 18-52.

*Figure 18-52  Launch the Applications Dialog Detail Wizard*

The Applications Dialog Details Create wizard consists of only one panel.

**Create Applications Dialog Details Panel**

The Create Applications Dialog Details Panel will vary depending on the approach used to launch the Applications Dialog Details creation process.

Using the Data First approach, the Bind Data Now and Data Source properties are hidden. The selected data source is automatically bound to the components in the formLayout of the popup.

Using the Component First approach, it is up to the developer to decide whether to bind a Data Source to the dialog details component, shown in Figure 18-53.
You can skip the data control binding step when creating the Applications Dialog Details. In this case, the Applications Dialog Details will create several default placeholder `outputText` fields that you can use for layout purposes in the popup. You can decide how many placeholder columns you wish to display. When you have selected the appropriate number of fields, click **OK** to finish the creation process.

If you wish to bind a data control to the table component using the Component First approach, check the **Bind Data Now** checkbox. This will enable the **Browse** button for the Data Source property. Click the **Browse** button to display a list of data sources available for binding. Navigate through the list, select the desired data source, and click **OK**.

When the Data Source is selected, the developer can enter the title for the popup and choose the Detail Pattern Type.

When **link** is selected for the Detail Pattern Type, you will need to select an attribute of the data source that binds to the Text attribute. This is the displayed text of the link. When **image** or **button** is selected for Detail Pattern Type, choosing an attribute is not needed, as shown in Figure 18-54.

**Figure 18-54 Select a Data Source Attribute**

<table>
<thead>
<tr>
<th>Title</th>
<th>Example Dialog Details</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detail Pattern Type</td>
<td>link</td>
</tr>
<tr>
<td>Text Attribute</td>
<td>LastName</td>
</tr>
</tbody>
</table>

When the dialog will be read-only:

- If the dialog will be read-only:
The format should be `<Object Type> <Object Name>` (such as Expense Report WBJ3008D)

- If the dialog contains editable fields:
  The format should be `<Action> <Object Type>: <Object Name>` (such as Approve Expense Report: WBJ3008D)

If you want a new Title, enter the string here. The string will be converted to a text resource and added to the default resource bundle.

If you already have a Title defined in a resource bundle, click the ellipsis and choose from the list, as shown in Figure 18-55.

**Figure 18-55 Select Text Resource for Dialog Details Title**

- **Resource Bundle**: Select the bundle containing the string you want to use. You can select a single bundle or all available bundles. The strings will display in the Matching Text Resources field.
- **Display Value**: You can enter a new string for a title here.
- **Key**: Each resource must have a unique Key. This generally is, in all upper-case characters, the words of the Display Value separated by an underscore character.
- **Description**: This is an optional entry.
Matching Text Resources: This field displays the entries of the selected resource bundle. Select an existing title from the list.

When a title is selected from the list, the Title field will appear similar to Figure 18-56.

**Figure 18-56  Dialog Details Title Field Using Resource Bundle**

![Create Dialog Details](image)

<table>
<thead>
<tr>
<th>Title</th>
<th>#{viewcontrollerBundle.WATCHLIST}</th>
</tr>
</thead>
</table>

**Detail Pattern Type**

The Detail Pattern Type is how the data control is shown; it can be an image, a link or a button.

- **Image**: Shows the Dialog Details component as an image. The image is the same as in the component palette. Clicking the image will open the Dialog Details popup.

- **Button**: Shows the Dialog Details component as a button that opens the Dialog Details popup when clicked.

- **Link**: In this case, you will need to select the Text Attribute, which is a list of columns in the Data Control you have selected (or dragged). This column data is used as the link text.

Use of a specific pattern type is your choice and does not affect the way Dialog Details behaves.

- To display what the popup would show, you can choose a link that shows data from the selected data control, such as a column in a table. For instance, in the Employee table, to show more employee data, you can use the employee name as the text attribute. Clicking an employee name then would open more data about that employee.

- A button can be used if there is only one Dialog Details popup for the page. Clicking it gives more information about the data on the page.

- Image could be used the same way as button, or on pages with form data.

**Text Attribute**

This setting is available only if the Detail Pattern Type is link. The text entered here is shown as the Dialog Details link. This helps give the user an idea about the data contained in the popup.

**Read-only Form**

- If content in the dialog is read-only, the window should be non-modal.

- If content in the dialog contains editable fields, the window should be modal.

- If you select Read-only, the choices in the Component to Use column will change from Input Text to Output Text types.

If this option is not selected; that is, the form can be edited by the user, two buttons automatically are added to the form: **Save and Close**, and **Cancel**. Figure 18-57 shows the default buttons in the form in the JDeveloper Design view.
If this option is selected; that is, the form cannot be edited by the user, only an OK button automatically is added to the form, as shown in Figure 18-58.

**Figure 18-58  Default Button Added to Read-only Form**

### Fields

- **Display Label:** This value will be displayed for the column heading. The default value is the text that is displayed in the Value Binding field.

- **Value Binding:** This field lists the names of the columns from the selected data control. Clicking an entry opens a list of the columns so you change the order in which they appear.

- **Component To Use:** Data in Dialog Details can be read-only or updatable. Component to Use is similar to what Component does while creating a table. Clicking it reveals a choice list of values, and the dialog details popup would then at runtime show that particular column from the datacontrol as the selected component to use. The choice list is changed according to whether you choose read-only. If you selected Read-only, the choices will change from Input Text to Output Text types.
18.5.1.2 Working with the Applications Dialog Details

This section discusses how to edit Dialog Details properties.

Editing - Properties

When you have created the Applications Dialog Details, you can modify the property values by using the Property Inspector. There are three ways to select the Applications Dialog Details:

- Select the component in the Design view of the page.
- Select the `<fnd:applicationsDialogDetails ... >` line in the Source view of the page.
- Select `fnd:applicationDialogDetails` from the hierarchy in the Structure View.

All components created as part of the Applications Dialog Details are editable using this same approach, shown in Figure 18-59.

Figure 18-59  Dialog Details Property Inspector

Adding a Data Source

When you have created the Applications Dialog Details, you can see that an `af:popup` has also been created above `fnd:applicationsDialogDetails`. You can add data controls to the facets / content containers within that popup using the following steps:

1. Navigate to the Data Controls panel of the Application Navigator.
2. Open the hierarchy to find the data source.
3. Drag and drop either the entire data source or individual fields into the correct location on the page. The correct location is dependent on the component.

For example, inside the popup that the Applications Dialog Details wizard generates, the fields of the data source are bound to components. Figure 18-60 shows the Structure view of a page with components already added.
To add a field from a data source to the `af:panelFormLayout` inside the popup, drag the field from the data source to the following path: `up > af:dialog > af:panelFormLayout`. As is the case with the data first approach, you will be prompted to choose which ADF component to use for this attribute.

**Note:**
This example uses the Structure view because it provides an efficient overview of the page. The field could also be dropped onto the page in Design or Source view to achieve the same result.

**Adding UI Content**
To achieve the final goals for a page design, you will likely need to add other components to the `af:dialog` inside `af:popup`.

**18.5.1.3 Implementing OK and Cancel Buttons in a Popup**
A product team’s task flow must include the **OK** and **Cancel** buttons that are used to launch a dynamic tab and dismiss the popup, respectively. When the buttons have been added, create a managed bean to set each button’s action listener. Use the method in Example 18-4 as the **Cancel** button’s action listener.
Note:

Although the closePopup() implementation shown in Example 18-4 closes the popup properly, if you reopen the popup by clicking the tasklist link, it shows the previously-entered values. If you do not want to show previously-entered values, you need to add a taskflow return activity, navigate to it, and then close the popup. However, after adding this taskflow return activity to the example closePopup() implementation, the popup is closed only partially. This is a side effect of the Javascript hide that is used. A solution is to use this closePopup() method, which works whether you have the taskflow return activity.

```java
public void closePopup()
{
    FacesContext facesCtx = FacesContext.getCurrentInstance();
    String taskPopupId =
        PatternsUtil.findComponentById(facesCtx.getViewRoot(),
        "TaskPopup").getClientId(facesCtx);
    PatternsPublicUtil.hidePopup(taskPopupId);
}
```

Create another method for the OK button that calls the method in Example 18-4, and any additional processing logic. The common use case would be opening a new task in the Main Area by using the openMainTask API. For example, you can bind the OK button to a managed bean and add your own action listeners, as shown in Example 18-5.

**Example 18-4  Example Method to Create a Managed Bean to Be the Cancel Button’s Action Listener**

```java
import org.apache.myfaces.trinidad.render.ExtendedRenderKitService;
import org.apache.myfaces.trinidad.util.Service;
import javax.faces.component.UIComponent;

public void closePopup(ActionEvent actionEvent)
{
    UIComponent source = (UIComponent) actionEvent.getSource();
    String sourceId =
        source.getClientId(FacesContext.getCurrentInstance());
    ExtendedRenderKitService service =
        Service.getRenderKitService(FacesContext.getCurrentInstance(),
        ExtendedRenderKitService.class);
    String popup =
        "AdfPage.PAGE.findComponent('" + sourceId + 
        ")\'\'.findComponent('::TaskPopup').hide();";
    service.addScript(FacesContext.getCurrentInstance(), popup);
}
```

**Example 18-5  Example Method to Create a Managed Bean to Be the OK Button’s Action Listener**

```java
import javax.el.ExpressionFactory;
import javax.el.MethodExpression;
import javax.faces.event.MethodExpressionActionListener;

public void setOkButton(RichCommandButton okButton)
{
    this.okButton = okButton;
    if(okButton.getActionListeners().length==0)
    {
        FacesContext context = FacesContext.getCurrentInstance();
```
ExpressionFactory ef = context.getApplication().getExpressionFactory();

String methodLink = "#{bindings.openMainTask.execute}";
MethodExpression me =
    ef.createMethodExpression(context.getELContext(), methodLink,
        null, new Class[]{
            ActionEvent.class });
MethodExpressionActionListener methodActionListener =
    new MethodExpressionActionListener(me);
okButton.addActionListener(methodActionListener);

methodLink = "#{pageFlowScope.PopupBean.closePopup}";
me =
    ef.createMethodExpression(context.getELContext(), methodLink,
        null, new Class[]{
            ActionEvent.class });
methodActionListener =
    new MethodExpressionActionListener(me);
okButton.addActionListener(methodActionListener);
This chapter provides guidelines for implementing attachments at design time in a quick and simple manner using Oracle Fusion Middleware components. This chapter includes the following sections:

- Introduction to Attachment Components
- About Creating Attachments
- About Displaying Attachments for Multiple Entities in the Same Table
- About Configuring Attachments Component Properties
- About Working with Attachments Programmatically
- About Setting Up Miscellaneous Attachments Features
- About Integrating Attachments Task Flows into
- About Securing Attachments
- Understanding How to Use Attachments (Runtime)

For general information about Oracle Fusion Middleware user interface (UI) components, see:

- Working with Page Definition Files for an Integrated Excel Workbook Oracle ADF chapter in the Developing Fusion Web Applications with Oracle Application Development Framework
- Introduction to ADF Faces Rich Client chapter in the Developing Web User Interfaces with Oracle ADF Faces

19.1 Introduction to Attachment Components

Attachment components provide a declarative programming mechanism for you to add attachments to the user interface (UI) pages that you create for Fusion web applications. After it is added to a UI page, the component gives users the ability to associate a URL, desktop file, repository file or folder, or text with a business object, such as an expense report, contract, or purchase order.

There are four Attachment components available for use in your page. Attachment Views, Attachment Link, Attachment, and Attachments Carousel. The Attachment Views and Attachment Link components incorporate the latest design concepts. The Attachment component was the original component available.
**Note:**

The Attachment and Attachments Carousel components are still supported. Any UI enhancements being delivered will not be applied to these components.

**Note:**

All Attachments of type File, Folder or Text are stored on a WebCenter Content Server. You will be asked to establish a connection to that server in the pre-requisite configuration steps.

### 19.1.1 About the Attachment Views Component

The attachment views component is a declarative component designed specifically for use with Fuse+. It can be shown in a page or page segment.

The following figure shows what the component looks like, before the advanced features are enabled.

**Note:**

When first accessed, the component displays in table format. Clicking the icons in the top right-hand corner toggles among the table, list and card views.

#### Figure 19-1 Attachment Views Component

![Attachment Views Component](image)

The following element is rendered:

- **Toolbar**
  - Add button - opens the Add Attachments pane
  - Delete button - deletes the selected rows

**Note:**

There is no concept of a selected card in the Cards view. Therefore, Delete Attachment will not appear in the Actions menu for that view.

- **Views**

  There are three views available:
– Table view - shows the Attachments in a table format. Currently showing columns for Type (icon), Title, and Description. Title will be shown as a link when there is a preview version of the Attachment to view. shows the table view.

– List view - shows the Attachments in a list format. Currently showing Attachment values of Thumbnail, Type (icon), Title, Description, Actions. You can click Type to download the Attachment. Title will be shown as a link when there is a preview version of the Attachment to view.

* Cards View — Shows the Attachments in a card format. Currently showing Attachment values of Thumbnail, Title, and Actions. Title will be shown as a link when there is a preview version of the Attachment to view.

• Add Attachments pane - allows the user to provide the minimum details required to create an Attachment (Attachment Type, Category and File, Text or URL)
The Add Attachments pane stays open to allow the user to continue to add attachments. When finished, the user can hide the pane by clicking the close icon (X), located in the top right-hand corner of the pane.

Valid Attachment Types are File (default), Text, URL, and Repository File/Folder.

- File: The user can select multiple files can be selected either through file browser, or by dragging and dropping onto the drop area. The selected files will automatically be uploaded and added. The contents of a compressed file can now also be added automatically by checking the Unzip all compressed files after upload checkbox. By default the checkbox is unchecked allowing the compressed files to be uploaded, but not extracted.

- Text or URL: The user enters the text or URL and then clicks **Add** to create the Attachment.

- Repository File/Folder: The same document picker used with the Attachments component is shown in the Add Attachments pane. The user navigates through the virtual folder structure to find files or folders. When a file is found the user selects it and then clicks **Select** at the bottom of the table to add it as an Attachment. There is also the option to search for files using a query. It is initiated by clicking on the Advanced link at the top of the table. This opens the Advanced Search dialog, as shown in the following figure.
Use the keywords field to perform a search on the contents of the files in Oracle WebCenter Content. In order for this search to be successful, the Content Server must be configured for a full content search. See "Managing Search Tools" in the Oracle WebCenter Content System Administrator’s Guide for Content Server for options.

Additional query filters are enabled when a content type other than "All Content Types" is selected. The other options in the list are all Oracle WebCenter Content profiles. These profiles allow an administrator to control the fields that appear, and the order in which they appear. Selecting this option determines the fields that you can add as additional query filters. A targeted profile limits the number of fields from which to choose to only those that are relevant. A global profile showing all fields is also available.

- Details pane - provides additional details about the current Attachment. You can edit any updateable value of the Attachment in this pane.
Open the pane by clicking the right-arrow button associated with the Attachment. Close the pane by clicking the right-arrow button again, or by clicking the "X" in the top-right corner.

The user controls the changes made. Clicking **Update** saves the edits. Changes are discarded when the pane is closed (by clicking **X**), or when the current Attachment is changed.

File Attachment types are updateable. If a file is already checked out, it will be checked out again after it has been updated. To ensure against file loss in the event of a high-availability failover, a file updates immediately. Discarding changes does not apply to file updates.

The "More Information" section displays extra attributes from the Content Server that are not already in use by Attachments.

When files are stored on the Content Server, it may be necessary to include different formats of the original document for distribution purposes. For example, an Adobe PDF version of a Word file or images that are uploaded in various sizes. Content Server supports this through renditions. The "Rendition" section displays all of the different renditions that have been added to the original file on the Content Server.

Edit text button (text Attachments only) - downloads and displays the text for the Attachment. The text is editable for the remainder of the session. A warning displays when text files are larger than 1 MB.

Editable text displays when you click **Edit**, as shown in the following figure.
19.1.2 About the Attachment Link Component

The Attachment Link component renders these elements on the page or page segment:
The Attachment Link component provides a link to the most recently attached document or URL. Where there is a preview version of the attachment, this will show when clicking this link. Hovering your mouse on the link supplies a detail window with attachment information. The detail window contains the following information about the most recent attachment:

- Type – represented by an icon for File/URL/Text/Folder
- link to the most recently attached document or URL
- Preview, where a preview view is available.
- Last Updated By
- Last Updated Date

If there are no attachments, the value of this field will be None.

The Add Attachment icon. When clicked, the Attachments window is launched showing any existing attachments. The Add pane will be displayed allowing the user to start adding attachments.
When there are one or more attachments, a folder icon will be displayed. Clicking this link opens the Attachments window, which displays the attachments.

Hovering over the folder icon will display a small dialog with a list of up to the next three most recent attachments. When clicked, the link (by default) will prompt the user to download the file. If there is only one attachment, there will be an entry indicating No More. If there are more than four attachments, the last bullet is a link with the format "<# of remaining attachments> more...". The number of attachments shown in the small dialog list is be configured. Clicking this link opens the Attachments window, which displays the full list of attachments in a table.

The Delete Attachments icon. This is shown only when there is an attachment. It allows the most recent attachment to be deleted without having to launch the Attachment window.

**Note:** The Attachment label originates from outside the Attachment component to allow the Attachment component to correctly align with the other components in the page layout.

The Attachment Window displays the Attachments Views component. The popup includes an **OK** button, which closes the popup, and a **Cancel** button. On opening the popup, a savepoint in the transaction will be created. Clicking **Cancel** will initiate a rollback to that point and revert any changes made to Attachments on the database.

**Abridged Mode**

The Attachment Link component also can display with a smaller footprint on the page. In Abridged mode, the component will show a single icon dependent on the number of attachments.

- No attachments: The Add Attachment icon will display. Clicking the icon will open the Attachment window with the Add panel displayed.
- One attachment: A document icon will display.
- More than one attachment: A folder icon will display. Clicking the file or folder icon will display the Attachment window.

**19.1.3 About the Attachment Component**

The component can be displayed in a UI page in any of the following ways:

- **Attachment field in a page or page segment:**
  
  The following elements are rendered on the page or page segment:

  - A link to the most recently attached document or URL. Hovering your mouse on a link supplies a detail window with attachment information. The detail window contains the following information about the most recent attachment:

    * Type - File/URL/Text
    * Attached By
    * Attached Date

    When clicked, the link (by default) will prompt the user to download the file.

    If there are no attachments the value of this field will be **None**.
– When there are more attachments, a link will be displayed in the format "<# of additional attachments> more...". Clicking this link opens the Attachments window, which displays the full list of attachments in a table. Hovering over this link will display a small dialog with a list of up to the next three most recent attachments. When clicked, the link (by default) will prompt the user to download the file. If there are more than four attachments the last bullet is a link with the format "<# of remaining attachments> more...". The number of attachments shown in the small dialog list is configurable. Clicking this link opens the Attachments window, which displays the full list of attachments in a table.

– The **Manage Attachments** icon. When clicked, the Attachments window is launched showing any existing attachments as well as a new empty row at the top of the list to allow the user to add new attachments.

– The **Delete Attachments** icon. Only shown when there is only one attachment added. Allows the one attachment to be deleted without having to launch the Attachment window.

*Figure 19-9* shows an example of an attachment field in a page or page segment with attachments.

*Figure 19-9  Attachment Field in a Page or Page Segment*

Note:
The Attachment label originates from outside the Attachment component to allow the Attachment component to correctly align with the other components in the page layout.

• **Attachment column in a table:**
The following elements are rendered in the table:

– A column header titled Attachments

– A link to the most recently attached document or URL. Hovering your mouse on a link supplies a detail window with attachment information. The detail window contains the following information about the most recent attachment:

  * Type - File/URL/Text
* Attached By
* Attached Date

When clicked, the link (by default) will prompt the user to download the file. If there are no attachments the value of this field will be None.

- When there are more attachments, a link will be displayed in the format "<# of additional attachments> more...". Clicking this link opens the Attachments window, which displays the full list of attachments in a table.

Hovering over this link will display a small dialog with a list of up to the next three most recent attachments. When clicked, the link (by default) will prompt the user to download the file. If there are more than four attachments the last bullet is a link with the format "<# of remaining attachments> more...". The number of attachments shown in the small dialog list is configurable. Clicking this link opens the Attachments window, which displays the full list of attachments in a table.

- The Manage Attachments icon. When clicked, the Attachments window is launched showing any existing attachments as well as a new empty row at the top of the list to allow the user to add new attachments.

- The Delete Attachments icon. Only shown when there is only one attachment added. Allows the one attachment to be deleted without having to launch the Attachment window.

Figure 19-10 shows an example of an attachment column in a table.

Figure 19-10  Attachment Column in a Table

<table>
<thead>
<tr>
<th>Invoice Header 12345</th>
<th>Save and Close</th>
<th>Cancel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Purchase Order: 12345</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Operating Unit: John</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Terms Date: 21-Sep-2006</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Invoice Amount: 1,656.00</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Invoice Number: 123</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Invoice Date: 04-Apr-2006</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

- Attachment table:

The Attachment table can be shown in:

- A page or page segment

This occurs when you choose to display all attachments for the current record in a table.

- A dialog

Occurs when:
* The user clicks the **Manage Attachments** icon associated with an attachment field either on a page or page segment, or an attachment column in a table

* The user clicks **Add** or **Edit** in the toolbar of the Attachments Carousel component

The following elements are rendered in the Attachment table:

- **Table Toolbar**
  - **Add** button, which adds a new row at the top of the table
  - **Delete** button, which deletes the selected rows from the table
  - **Set Primary** button, which sets the selected row to be the primary attachment for its category. Displays when the setting the `enablePrimaryCategory` property attribute for the Attachment component to `true` (this button is optional)

- **Reorder Attachments** (**Actions** Menu)
  Launches a window that allows you to modify the order of the Attachments. It displays when the `enableOrdering` attribute has been set to `true`. The objects being ordered are defaulted from the label attribute.

  **Figure 19-11** shows an example of the window.

  **Figure 19-11  Reorder Attachments**

- **Set Primary** (**Actions** Menu)
  Sets the selected row to be the primary attachment for its category. It displays when you set the `enablePrimaryCategory` property attribute for the Attachment component to `true`.

- **Type** (required field that determines the type of Attachment)
  - **File** (default)
Category values are defined at implementation time. Make sure to use functionally relevant category names. If two or more categories are defined, the category column is displayed. If only one category is defined, the column is not displayed.

One attachment out of all the attachments that have the same category value can be designated as the primary. This is option can be enabled by setting the `enablePrimaryCategory` property to true. By default it is off. When enabled a new column title Primary will appear before the Category column. The primary attachment will be indicated by a tick mark.

File Name or URL (required field)

If the value is an existing attachment, a link is shown. When clicked, the link (by default) will prompt the user to download the file. For new rows:

* If Type is File, will show a file upload field
* If Type is Text, will show a text field
* If Type is URL, will show a text field
* If Type is Repository File/Folder, will show a text field and browse button. Clicking on Browse will launch a document picker for finding files in the repository.

Title

The user name for the attachment, as the file name or URL may not adequately convey the contents of the attachment. If users do not enter a title, it defaults to the value in the File Name or URL field.

Description

The field to include additional information on the attachment.

Attached By

Shows the name of the user that last updated the attachment relationship.

Attached Date

Shows the date on which the attachment relationship was updated.

Figure 19-12 is an example of an Attachments table with the `repositoryMode` attribute set to `false`. 
19.1.4 About the Attachments Carousel

The attachments carousel is a popular component for browsing through images. It integrates the attachments and carousel components, simplifying the uptake work for pages that have a heavy image usage with attachments. It can be shown in a page or page segment.

The following elements are rendered in the Attachment table:

- **Toolbar**
  - Add button - opens the Attachment Table in a dialog with a new row.
  - Edit button - opens the Attachment Table in a dialog
  - Delete button - deletes the current attachment item shown in the carousel

The toolbar can be hidden by setting the carouselToolbarRendered property to false.

- **Carousel and CarouselItem**

The carousel controls the display of the attachments. The CarouselItem stamps out the same display settings for each attachment item. All of the properties for the standard Carousel and CarouselItem components are available for you to control the display and behavior of the Carousel.
Any attachment that cannot be displayed as an image will show as its title. The current item in the carousel is also linked. When clicked, the link (by default) will prompt the user to download the file.

**Note:**

The current implementation is showing the actual file and not a thumbnail or preview version. Until thumbnail support can be introduced, it is recommended that users consider the size of the files that are adding for display inside the carousel.

- **Detail**
  The detail section contains the following information about the most current attachment:
  - Type - File/URL/Text
  - Attached By
  - Attached Date

The detail section is hidden by default. However, it can be displayed by setting the attachmentsDetailsRendered property to `true`.

### 19.2 About Creating Attachments

This section provides information about creating attachments and describes how to set up your model project for attachments, how to create an attachment field or an attachments table, and an attachments column in an Applications table. Also included is how to set up required properties, as well as information about what happens when you implement attachments and what happens at runtime.

#### 19.2.1 Performing Prerequisite Tasks

Before you start creating attachments, do the following:

1. Add the *Applications Core (Attachments Model)* library to your Model project:

2. After adding the library to your model, navigate to Application Navigator > Application Resources > Descriptors > META-INF and add the following XML snippet to your `jazn-data.xml` file:

   ```xml
   
   Note:
   Be aware that the URLs and `<class>` entries cannot contain any spaces or line breaks.
   
3. Create the view object representation of the business object that requires attachments in your model project.

4. Create a Content Repository connection in JDeveloper.
Note:

• Attachments stores the name of the Content Repository connection used when creating a new attachment. This value is then used when retrieving the attachments. It is important to co-ordinate the naming and registration of Content Repository connections. So that the Attachments code can connect to the correct server to retrieve the requested file.

• Developers need to create a Content Repository connection with the name "FusionAppsContentRepository". This connection should used jaxws as the socket type and Identity Propagation for Authentication.

For information about how to create a Content Repository connection in JDeveloper, see Creating a Content Repository Connection.

For additional information see the Oracle Fusion Middleware Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper guide.

5. Do the following to add libraries and configurations that are required to support working with the Content Repository connection:

a. Select a JSF page in the View Controller project that is being enabled for Attachments. Changes made to this page must be manually removed at the completion of this pre-installation step.

b. Navigate to Application Navigator > Application Resources > Content Repository and select the Content Repository connection defined in Step 4. Then, drag it onto the page you selected in Step a.

c. On the context menu that is displayed, choose Document Library and remove the changes made to the page.

Note:

• An alternative to modify an existing page is to create a new JSF page in the project, and then delete the page when you get to Step 5.

• At the time this process was documented, these steps changed the following files in a typical Application. If these files were not been changed, it might have to check them out manually and repeat Steps a through c.
  - Application Resources/Descriptors/ADF META-INF/adf-config.xml
  - Application Resources/Descriptors/META-INF/orion-application.xml
  - Projects/View Controller (that is, the name of your ViewController.jpr file)
  - Projects/View Controller/Web Content/WEB-INF/orion-web.xml
  - Projects/View Controller/Web Content/WEB-INF/web.xml
6. Log onto the Content Repository and confirm that the following has been created:

- *Attachments* folder under the *Contribution Folders* folder
- *Attachments* security group used for unshared attachments
- *SharedAttachments* security group used for shared attachments
- *AttachmentsUser* role with no permissions set
- *AttachmentsRead* user role with read (R) permission to the Attachments security group for unshared attachments
- *AttachmentsWrite* user role with write (W) permission to the Attachments security group for unshared attachments
- *AttachmentsDelete* user role with delete (D) permission to the Attachments security group for unshared attachments
- *AttachmentsAdmin* user role with read, write, delete, and admin (RWDA) permissions to the Attachments security group for unshared attachments
- *SharedAttachmentsWrite* user role with write (W) permission to the SharedAttachments security group - for shared attachments
- *SharedAttachmentsDelete* user role with delete (D) permission to the SharedAttachments security group - for shared attachments
- *SharedAttachmentsAdmin* user role with read, write, delete, and admin (RWDA) permissions to the SharedAttachments security group - for shared attachments.

**Note:**
This setup is required for Attachments to function correctly. You must log in to the Content Server as a user with System Administrator privileges to see the above information. If you cannot see these details in your Content Server, please contact your system administrator to ensure that they have enabled the FusionAppsAttachments component in the Content Server.

7. Set the maximum size for files that can be uploaded. This setting is made to your Application and will apply to any page that uses a multi-part form to upload from the desktop to the Oracle WebLogic Server, not just Attachments.

This step does not need to be completed before continuing with the rest of the implementation. By default the maximum size is defaulted to 2MB, which allow an end-to-end implementation to be completed. However, it is important to modify this setting before deployment. When deciding on the maximum size, considering the type of files that your typical customer will be uploading with your Application will help you determine a value.

For information about how to apply the settings, see "Setting Parameters to Upload Files to Content Repositories" in *Developing WebCenter Portal Assets and Custom Components with Oracle JDeveloper*.

```

19.2.2 Understanding Content Repository Prerequisites

The attachment views component can display more detail from the Oracle WebCenter Content repository. Enabling this functionality, however, requires additional
configuration of the repository. Since the attachment views component is not dependent on this configuration, you can do it when required.

**Thumbnails**

Thumbnails are small preview images. The attachment views component shows thumbnails in the list view, and for any renditions generated in the Details pane. For information about generating thumbnails, see setup steps for "Setting Up Thumbnails" in *Managing Oracle WebCenter Content*.

By default, thumbnails are displayed as 100 x 100 pixels. For information about how to change the default size, see "Changing the Size of Thumbnails" in *Managing Oracle WebCenter Content*.

**Digital Asset Management**

Digital asset management defines and provides specified formats and sizes from the original file for images, video and audio. A defined *rendition set* determines all of the conversions that must be performed. When an Attachment is added, or updated, the default rendition set is applied.

Rendition sets can be defined to create a thumbnail rendition. Consider this before enabling thumbnails and renditions for file formats that will also be processed by rendition sets.

For more information about digital asset management, see "Working With Image and Video Conversions" in *Managing Oracle WebCenter Content*.

For information about how to change the default image rendition set (DefaultPackedConversionSet) see "Modifying the Content Repository Configuration File" in *Managing Oracle WebCenter Content*.

### 19.2.3 About Setting Up Your Model Project for Attachments

The Model project must be set up correctly before you can add attachments to your page.

Part of the Model setup involves creating an attachment view link between the business object view object and the attachments view object. When defining this attachment view link, you must select *Primary Key* values and enter an *Attachment Entity Name*. This unique name is used to identify all attachments for your business object.

The first time you create an attachment view link for your business object, the unique attachment entity name is stored in the database. If you need to link the same set of attachments to another view object on a different page, reselect the existing attachment entity name when creating the attachment view link.

After creating the attachment view link, you will need to assign a set of categories to your attachment entity. When creating the attachment view link, you can choose to show all of the categories assigned to your entity in your UI, or a subset of these categories. If you do not need to reduce the list of categories that will be displayed in your UI, you can select to "Show All Categories" on the Categories step in the Attachment View Link Wizard. This will make all categories that are assigned to your attachment entity available in your UI. For more information, see *How to Create Attachment View Links*.

After you have finished setting up your Model project, you must decide how you would like to display the attachments in your page: As an attachment field, as a table of attachments, an attachment column in an applications table, or as an attachment carousel. This design-time setup is performed in your ViewController project. For
more information about setting up your ViewController project for attachments, see How to Create an Attachments Field_ Attachments Table_ Attachments Carousel_ or Attachment Views, How to Create an Attachments Column in an Applications Table, and About Displaying Attachments for Multiple Entities in the Same Table.

After adding attachments to your UI page, you must complete the required steps to ensure that the attachments functionality works correctly at runtime. For more information about these setup steps, see What Happens When You Implement Attachments and What Happens at Runtime.

19.2.4 How to Create Attachment View Links

Attachment view links are used to establish master-detail relationships between your view objects and the attachments view object. Attachment view links are created using the Attachment View Link wizard.

To create an attachment view link, do the following

1. In JDeveloper, choose Application Navigator > Model Project. Right-click and choose New from the menu to open the New Gallery.

2. Choose the Business Tier > ADF Business Components category. Select the Attachment View Link item, as shown in Figure 19-14.

   Figure 19-14    New Gallery Dialog

3. Click OK to access Step 1 of the Create Attachment View Link wizard, as shown here.
4. Select the New View Link option to Create a New View Link. Click Next. The Name dialog appears as shown here.
5. Complete the following information:

a. Select the name of the module that your view object belongs to.

   Seed data can be created as part of the Wizard flow. Any seed data created will be striped by the provided module so that it can be extracted and shipped as part of deploying your Application. Any existing seed data belonging to your module will also be displayed in the wizard steps.

b. Select the package where the attachment view link will reside.

   The new View Link will be created in this package.

c. Enter a unique name for the attachment view link.

6. Click **Next** to access Step 3. The View Object dialog appears, as shown here.
7. Enter the name for the view link accessor that will be added to the data control of selected view object. Then, from the **Available** column, select the view object that you want to create attachments for.

**Tip:**

There is no need for you to select a destination view object because the Attachment view link always uses the Attachments view object as the destination view object.

8. Click **Next** to access Step 4. The Attachment Entity dialog appears, as shown here. The Attachment Entity is used to uniquely identify your business object.
9. Select an existing Entity Name or create a new Entity Name.

**Note:** The Entity Name is used to map an entity object to its attachments. An entity object can be used across many business objects. In the figures the business object is for a Department. If there were a Department to Employee business object. A View Link could also be created for that business object as well. As the Department Number is also in that table as a foreign key. That View Link would also use the same Entity Name.

**Note:** Historically the name of the primary database table the business object is based on is used.
Where the Entity Name has already been created, click **Browse...** to open the List of Values to search and select. The Selected column will be automatically updated with the stored primary key values from the selection.

For a new Entity Name, click **New...**. You will be prompted to supply an Entity Name, User Entity Name and Data Object Code. The Data Object Code ideally should be the database table. Use the data object code, primary keys and the data collected to create an Attachment. A SQL query could be generated to return the row. Click **OK** to close the window.

**Available / Selected:** Select only those columns that make up the primary key of the entity object by shuttling them from the Available column to the Selected column. Making changes to the Selected columns for an existing Entity Name will update the stored entries.

10. Click **Next** to access Step 5. The Categories Mapping dialog appears, as shown in here. An Entity Name must have at least one Category assigned. This dialog will facilitate mapping Categories to the Entity Name from Step 4.
Click **New**... to create a new Category. A popup will appear to provide the Category Name and Category User Name. This new Category will be stored in the database and stripped by the Module provided in Step 2.

Click **Add**... to choose from other Category values that have already been created for your Module. This list will also include a Miscellaneous category that is centrally-seeded by Attachments. If you cannot anticipate the Category values a customer may want to use with Attachments, choose the Miscellaneous category.

Click **Edit**... to modify the Category User Name for a Category.

Click **Remove**... to remove a Category from being mapped to the Entity Name.
Note: It is not necessary to re-enter the wizard to make changes to the categories or mapping. Management pages are available for administering this information during development and production. For more information, see About Assigning Categories to the Attachment Entity.

11. Click Next to access Step 6. The Categories dialog appears, as shown here. (The Display All Available Categories checkbox is not selected when you first enter this page.) The View Link created can be restricted to a subset of the categories mapped to the entity name in Step 5. This is useful where your functionality needs to ensure that only Attachments of a specific category will be shown and managed using this View Link.

Figure 19-20  Create Attachment View Link Wizard — Categories (Step 6)

Select the Display All Available Categories checkbox to place no restrictions on the categories the View Link can use.
To control which categories are available to the View Link, deselect the Display All Available Categories checkbox. Then move the mapped categories required in the Available column to the Selected column.

The selected list of categories will be stored as a custom property on the newly created attachment view link. The value will consist of a concatenated string of values. All the selected categories are concatenated in a comma-separated list.

**Note:** The custom property on the view link cannot be customized. A customer can map custom categories to your entity name in production. But the new category won’t be seen in any UI that uses a view link with the custom property set.

**Note:** If the all of the categories in the custom property are removed from the mapping, the view link will no longer return any results.

You should choose the Display All Available Categories option to allow for customization of the Category list without code changes. Additionally, be aware that the list of available categories, and the list of Attachments displayed, can be further controlled using Category data security. For more information, see About Attachment Category Data Security

12. Click Next to open the Application Module dialog, as shown here. For the attachments view object to be available to include in your pages, it needs to be registered in the Application Module Data Model. Select Add or Modify an Application Module to create a new instance of the view object that you selected on the View Object page, and create an instance of the attachments view object as a child of the new instance.
Click **Browse**… to open a popup to help select the Application Module to update.

Click **New**… to create a new entry in the table. The attachments view object also includes its own child collections for Extra Attributes and Renditions. These collections are required for showing additional information in the Attachment Views and Attachment Link components. Select Enable Extra Attributes or Enable Renditions based on whether it is required to show this information. If additional custom metadata is to be stored with the attachment then select the Enable Flexfields option.

Click **Remove** to remove the selected View Link Usage from the Application Module.

13. Click **Next** to access the Summary page, shown here. Review your selections and click **Finish** to create your attachment view link.
14. If you chose to keep the Application Module option unselected in Step 10, you need to add your newly-created attachments view link to your application module data model as follows:

a. Choose **Application Navigator > AM name**. Right-click and choose to open the application module in the editor.

b. Choose Data Model from the list of categories to open the Data Model Components dialog.

c. Select the newly created Attachment View Link located in the left column and select the view object that you created the view link for in the right column. Shuttle the Attachment View Link over to the right column.

d. To enable Extra Attributes, select the Attachments Extra Attribute view object located in the Available View Objects (left column). Select
AttachmentsExtraAttributeVO, by opening oracle.apps.model.Model > oracle.apps.fnd.appcore.attachments.Model > oracle.apps.fnd.appcore.attachments.uiModel.view > AttachmentsVO. In the Data Model (right column), select the Attachments View. Shuttle the AttachmentsExtraAttribute View Link over to the right column.

e. To enable Renditions, select the Attachments Attachments Rendition view object located in the Available View Objects (left column). Select AttachmentsRenditionVO, by opening oracle.apps.model.Model > oracle.apps.fnd.appcore.attachments.Model > oracle.apps.fnd.appcore.attachments.uiModel.view > AttachmentsVO. In the Data Model (right column), select the Attachments View. Shuttle the AttachmentsRenditionVO View Link over to the right column.

f. Save your changes.

---

**Note:** To enable the Flexfield at a later point in time it is recommended that the Attachments View Link be edited and selected during that wizard flow.

---

### What Happens When You Create an Attachment View Link

After you have completed all the steps in the wizard by clicking Finish to create your Attachment view link:

- The Attachment view link is created, using the Name and Package provided in Step 2.

- If the view link was selected to display only a subset of the categories in Step 6. A custom property (OAF_ATTACHMENT_CATEGORY) is created on the Attachments view link, with a comma separated list of the categories that you selected in Step 6 of the wizard. If the decision was to show all categories. The custom property will still be created, but with an empty list.

- The AttachmentEntityName transient attribute is created on the Entity view object. Its value is the entity name that you entered in Step 4 of the wizard.

---

**Note:** This transient attribute should not be included in your UI.

- An Accessor is created on the Entity view object, using the View Link Accesor Name supplied in Step 3.

- New Attachment Entity information (Step 4) is stored to the FND_DOCUMENT_ENTITIES and FND_DOCUMENT_ENTITIES_TL tables.

- All new or changed category information (Step 5) is stored to the FND_DOCUMENT_CATEGORIES and FND_DOCUMENT_CATEGORIES_TL tables.

- All new or changed mapping information (Step 5) between the Entity Name and the Categories is stored in the FND_DOC_CATEGORIES_TO_ENTITIES table.

- New Entries defined will be added to the Data Model of the Application Module selected in Step 7.

The WHERE clause that links the Entity view object to the Attachments view object is derived based on the selected entity primary key columns. For example, if the entity
primary key for the FND_DEMO_DEPT entity is made up of the column DEPT_NUM then the view link query would be as follows:

Example Source WHERE Clause

{(:Bind_DeptNum = PK1_VALUE) AND
 (:Bind_AttachmentEntityName = ENTITY_NAME)}

Example Destination WHERE Clause

{(:Bind_Pk1Value = FndDemoDeptEO.DEPT_NUM) AND
 (:Bind_EntityName = 'FND_DEMO_DEPT')

where FND_DEMO_DEPT is the value that you entered in the Entity Name field in Step 4 of the wizard.

To Edit an attachment view link:

1. In JDeveloper, choose Application Navigator > Model Project. Right-click and choose New from the menu to open the New Gallery.

2. Choose the Business Tier > ADF Business Components category. Select the Attachment View Link item, as shown in Figure 3.

3. Click OK to access Step 1 of the Attachment View Link wizard, as shown here.
4. Select **Edit View Link**, click **Next** to move to Step 2 View Link, as shown here. Select the attachment view link to edit from the available list.
5. Click Next to access Step 3. The Name dialog will appear.

**Note:** The steps from this point mirror their similarly named counterparts in the Edit flow. The rest of this section will focus on what modifications are allowed.

**Note:** The edits to each step are currently independent. For example, changing the Entity Name will not move the categories mapped to the old Entity Name to the new Entity Name. This will still need to be performed on subsequent steps.
6. Step 3 – Name. The Module can be changed at this step. The new module will be used in any queries against stored data. Any changes to Entity Name or Categories will be stored using the module.

**Note:** Changing the View Link Accessor Name currently has no effect.

8. Step 5 – Attachment Entity. Create a New Entity, or select a different existing Entity.

9. Step 6 – Category Mappings. Create Categories, Add existing Categories, Modify mapped Categories, Remove Categories from being mapped to the Entity Name.

10. Step 7 – Categories. Switch whether the View Link is to Display All Categories, manage which Categories to show if the View Link isn’t displaying all.

11. Step 8 – Application Module. After selecting the Application Module, the table will show the existing usages for the View Link in the Application Module Data Model. Use **Add** to create additional View Link Usages, or **Remove** to delete any existing View Link Usages.

**Selecting from the Content Server Configuration Step**

Setting the RefreshCondition property is only required when the repositoryMode property is set to true on the Attachment component. Setting this property for the taskflow allows the Document Picker to be used more than once within the Attachments table or popup in the same session.

1. Go to the Bindings tab for that page.
2. Click the link to the Page Definition File, which is located at the top of the page.
3. Select the attachmentRepositoryBrowseTaskFlow1 task flow from the list of Executables.
4. Go to the Property Inspector and set the RefreshCondition property based on the component in use. For the Attachments and Attachments Carousel components, use #{AttachmentsTaskflowListener.refreshTaskflow}. For Attachment Views and Attachment Link components, use #{AttachmentsV2TaskflowListener.refreshTaskflow}.
5. Save your changes.

**Update Page Bindings (recommended)**

Page Bindings need to be manually created to include AttachmentsExtraAttributes, AttachmentsRendition and Attachments DFF. They are not essential to the operation of any of the Attachment components. They are required for the Details Pane of the Attachments View component to show More Information or Renditions sections.

**Note:** Ensure that the Update Application Module steps have already been completed first. Otherwise, there will be no child entries available in Step 3. This step can be completed by using the Edit View Link option in the Attachments View Link Wizard in Step 8 – Application Module. Manual instructions are included in step 14 of To Create an Attachment View Link.
Reviewing the Bindings tab of a page will indicate whether the following steps are necessary. Check for entries in the Executables list starting with AttachmentsExtraAttributes and AttachmentsRenditions.

1. Open the page that contains the Attachment Views component.
2. In the Data Controls section of JDeveloper find the Attachments Data Control entry which was used to create the Attachment Views component. (Step 2 of To create an Attachment Views).
3. Expand the Attachments entry, drag the AttachmentsExtraAttribute child onto the page and choose a Read-Only table with all columns.
4. Remove the af:table just created from the page.
5. Back in the Data Controls drag the AttachmentsRendition child onto the page and choose a Read-Only table with all columns.
6. Remove the af:table just created from the page.
7. Back in the Data Controls, drag the AttachedDocumentsDFF child onto the page and choose Applications > Oracle Descriptive Flexfield.
8. Remove the fnd:descriptiveFlexfield just created from the page.
9. Open the page definition of the Page and go to the Source.
   Add the following source inside the <tree> node for the Attachments definition:
   ```xml
   <Properties>
   <CustomProperties>
   <Property Name="ExtraAttributes" Value="<ExtraAttributesId>" />
   <Property Name="Renditions" Value="<RenditionTreeId>" />
   <Property Name="DFF" Value="<DffIteratorId>" />
   </CustomProperties>
   </Properties>
   ```
10. Replace <ExtraAttributesId> with the Id of the tree node for the Attachments Extra Attribute that was created in step 3.
11. Replace <RenditionTreeId> with the Id of the tree node for the Attachments Rendition that was created in step 5.
12. Replace <DffIteratorId> with the Id of the iterator node for the Attachments DFF that was created in step 7.
13. Save the page definition.

   The Attachments View component will detect these exist properties have been configured and will start to use them.

**About Attachments Descriptive Flexfield**

The Attachment Views component has the ability to display additional custom metadata in the details pane using a descriptive flexfield. There is a new flexfield definition, FND_ATTACHED/Documents_DFF, which can be customized to allow additional custom metadata values to be entered and stored with each individual attachment. The structure of the descriptive flexfield can be configured using instructions from the Descriptive Flexfields chapter. The Attachments descriptive flexfield is context sensitive to the Attachments Category. Any change to the category in the details panel triggers the panel to refresh with the updated flexfield segments.
displayed. By default, the Attachment Views component does not show the descriptive flexfield, unless the page bindings have been updated. The flexfield is shown in the More Information section of the Attachment Views detail panel, if the correct view links and bindings have been created.

**Note:** There is a limitation to the use of the attachments descriptive flexfield. Only one instance of an attachment descriptive flexfield can be within an application module. This instance must be a child of a single attachments view object instance, and the descriptive flexfield instance must be named AttachedDocumentsDFF1.

**Note:** Most environments will have the Attachment DFF automatically patched. Some standalone environments may require the DFF to be manually deployed. A manual deployment is required where the following message is displayed:

```
Definition
oracle.apps.flex.fnd.applcore.attachments.model.view.AttachedDocumentsDFFVO
of type View Definition is not found.
```

Sign on to Fusion Applications and perform the following:

1. Navigate to Setup And Maintenance
2. Search for task Manage Applications Core Descriptive Flexfields
3. Perform a Blind Search
4. Click Attached Documents DFF
5. Click the Deploy Flexfield button

See Deploying Flexfields in a Standalone WebLogic Server Environment for more details.

**Custom Actions**

Attachment Views provides the capability of overriding the default items rendered in the List, Card and Carousel views with your own. A facet is provided for each View for product teams to develop their own item. The actions and any custom actions for the item will still be included in the same spot. To activate, set the value of the Rendering Property to “custom”.

<table>
<thead>
<tr>
<th>View</th>
<th>Facet</th>
<th>Rendering Property</th>
</tr>
</thead>
<tbody>
<tr>
<td>List</td>
<td>customListItem</td>
<td>listItemViewer</td>
</tr>
<tr>
<td>Card</td>
<td>customCardItem</td>
<td>cardItemViewer</td>
</tr>
<tr>
<td>Carousel</td>
<td>customCarouselItem</td>
<td>carouselItemViewer</td>
</tr>
</tbody>
</table>
19.2.4.1 How to Create an Attachment View Link Without Selecting an Application Module

If you chose to keep the Application Module option unselected in Step 10, you need to add your newly created attachments view link to your application module data model as follows:

1. Choose Application Navigator > AM name. Right-click and choose to open the Application Module in the editor.

2. Choose Data Model from the list of categories to open the Data Model Components dialog.

3. Select the newly created Attachment View Link located in the left column and select the view object that you created the view link for in the right column. Shuttle the Attachment View Link over to the right column.

4. Save your changes.

19.2.4.2 How to Update the Application Module

Dragging and dropping the Attachments collection automatically adds the Attachments collection as a page binding. These page bindings are required to make Attachment views function. There are additional child collections that also must be added to the page binding to provide support for renditions in the "More Information" and "Renditions" sections of the Details pane. To make the child collections available, you must add them to the Application Module's data model.

To add the child collections to the Application Module, do the following:

1. In the Application Navigator, find the Application Module in the Model project in which the Attachment View Link for the attachment views component is found. Right-click and choose to open the Application Module in the editor.

2. Select Data Model from the list of categories to open the Data Model Components dialog.

3. From the Available View Objects list, go to oracle.apps.model.Model > oracle.apps.fnd.applcore.attachments.Model > oracle.apps.fnd.applcore.attachments.uiModel.view > AttachmentsVO and select AttachmentsExtraAttributeVO.

4. In the Data Model list, select the attachments view. Then, shuttle the AttachmentsExtraAttribute view link over to the right column.

5. Repeat this process for any other attachment views in the data model that must be included the extra attributes.

6. Repeat Steps 4 and 5 for the AttachmentsRenditionVO, which is located in the same package as AttachmentsExtraAttributeVO.

7. Save your changes.

19.2.5 What Happens When You Create an Attachment View Link

After you have completed all the steps in the wizard by clicking Finish to create your Attachment view link:
• The Attachment view link is created, including generating the Accessor in the source view object.

• All new or changed category information is stored to the FND_DOCUMENT_CATEGORIES and FND_DOCUMENT_CATEGORIES_TL tables.

• A custom property (OAF_ATTACHMENT_CATEGORY) is created on the Attachments view link, which is a list of all the categories that you select in Step 4 of the wizard.

  The custom property stores an empty list when you select the Display All Available Categories checkbox. When this checkbox is not selected, the custom property stores a comma-separated list of categories (using the CATEGORY_NAME from the FND_DOCUMENT_CATEGORIES table) that you manually selected from the list of available categories.

• The AttachmentEntityName transient attribute is created on the Entity view object. Its value is the entity name that you entered in Step 3 of the wizard.

  Note:
  This transient attribute should not be included in your UI.

• New Attachment Entity information is stored to the FND_DOCUMENT_ENTITIES and FND_DOCUMENT_ENTITIES_TL tables.

  The WHERE clause that links the Entity view object to the Attachments view object is derived based on the selected entity primary key columns. For example, if the entity primary key for the PO_INVOICES entity is made up of the columns INVOICE_HEADER_ID and INVOICE_LINE_ID then the view link query would be as follows:

  where PO_INVOICES is the value that you entered in the Entity Name field in Step 3 of the wizard.

  Example 19-2  Source WHERE Clause

  (:Bind_InvoiceHeaderId = PK1_VALUE) AND
  (:Bind_InvoiceLineId = PK2_VALUE) AND
  (:Bind_AttachmentEntityName = ENTITY_NAME)

  Example 19-3  Destination WHERE Clause

  (:Bind_Pk1Value = PoInvoiceLines.INVOICE_HEADER_ID) AND
  (:Bind_Pk2Value = PoInvoiceLines.INVOICE_LINE_ID) AND
  (:Bind_EntityName = PO_INVOICES)

19.2.6 About Deleting the Business Object

Deleting the business object from the database does not automatically apply to any of its Attachments. Subsequently, if your business functionality calls for the deletion of the business object (as opposed to a programmatic deletion, where the record is flagged as deleted but is kept around for auditing purposes), you also must delete all of its Attachments. Otherwise, these records will continue to persist in the Attachments tables. If another business object for your entity is created with the same primary key values, these Attachments will immediately be attached to the new record.
What you do depends on the method or methods you used to delete the business object in your own functionality. The programmatic method to delete the attachments will be the same. Typically, overriding the `remove()` method of the business object view object will allow you to programmatically access the Attachments detail collection via the View Link Accessor. When you have access to this collection, you can loop through calling the `remove()` method of the collection, shown in Example 19-4.

**Example 19-4 remove() Method**

```java
public void remove() {
    Row currRow = this.getCurrentRow();
    RowSet attachedItems = (RowSet) currRow.getAttribute("Attachments1");
    while (attachedItems.hasNext()) {
        Row currAttachment = attachedItems.next();
        currAttachment.remove();
    }
    super.remove();
}
```

### 19.2.7 About Assigning Categories to the Attachment Entity

It is necessary to assign one or more attachment categories to your attachment entity. The "Manage Attachment Categories" setup UI can be used to create and update the relationships between your categories and entities. You can search for a particular attachment category, then search and select the attachment entities to assign to the category. For more information, see About Integrating Attachments Task Flows into .

Relationships between categories and entities can also be maintained using the Manage Attachment Entities setup UI.

The Entity-Category relationships are stored in the `FND_DOC_CATEGORIES_TO_ENTITIES` table. There is a many-to-many relationship between Entities and Categories, allowing one category to be assigned to multiple Entities.

The relationships stored in this table are striped by `MODULE_ID` for seeding purposes, and the seed data loader can be used to seed this data for your product.

---

**Note:**

It is important to ensure that you seed your attachment entities and attachment categories before you seed the data in the `FND_DOC_CATEGORIES_TO_ENTITIES` table when extracting and uploading the data.

---

See the "Available Seed Data Loaders" table in Chapter 65 for information about Attachments Seed Data Loaders.

### 19.2.8 How to Create an Attachments Field, Attachments Table, Attachments Carousel, or Attachment Views

This section describes how to create an Attachments field, table, carousel, or views.

1. Create a page, page segment, or an applications panel that is bound to the attachments-enabled Master Data Collection (your business object data collection).
2. Drag the Detail Data Collection (the Attachments data collection) onto a databound drop target. The Create context menu appears.

3. Select Applications > Attachments to display the Create Attachments dialog, as shown in Figure 19-25.

![Create Attachments](image)

Choose Attachments Field, Attachments Table, Attachments Carousel, or Attachment Views. Click OK to display the Edit Taskflow Binding dialog.

The ConnectionName parameter is automatically set to 
#(AttachmentsTaskflowListener.connectionName) on the attachmentRepositoryBrowseTaskFow1 taskflow in the page bindings for your page. This parameter is used to derive the connection name of the content server connection to be used when the Document Picker taskflow is used in the Attachments UI at runtime.

4. Click OK. Do not make any changes on the Edit Taskflow Binding dialog.

Selecting Attachments Field or Attachments Table will add the Attachments component to the page. The mode will be set automatically to link or table. Selecting Attachments Carousel will add the Attachments Carousel component to the page. Selecting Attachment Views will add the Attachment Views component to the page. The selected component will be bound to the Detail Data Collection.

**Example 19-5 Adding Event IDs to the PartialTriggers**

```af
c<af:panelLabelAndMessage label="Attachment" partialTriggers="btnNext btnPrevious">
  c<fnd:attachment mode="link" repositoryMode="true" attachmentModel="#{bindings.Attachments1}"/>
</af:panelLabelAndMessage>
```

When using attachments in link mode, the Attachment component must be displayed inside a panelLabelAndMessage component and a partialTrigger must be added as an attribute. You must then add the IDs for the appropriate events on the page to the partialTriggers that cause the underlying business object record to change, which in turn requires the Attachments data to change. For example, the navigation buttons Next and Previous as shown here:

**19.2.9 What Happens When You Implement Attachments**

The following are examples of the generated source code:

**Example 19-6 Source Code for an Attachment Field**

```fnd
c<fnd:attachment mode="link" id="a1" attachmentModel="#{bindings.AttachmentsIterator}"/>
```
Example 19-7  Source Code for an Attachment Table

```xml
<fnd:attachment mode="table" id="a1"
    attachmentModel="#{bindings.AttachmentsIterator}"/>
```

Example 19-8  Source Code for an Attachments Carousel

```xml
<fnd:AttachmentsCarousel id="acl"
    attachmentModel="#{bindings.AttachmentsIterator}"/>
```

Example 19-9  Source Code for an Attachment View

```xml
<fnd:attachmentView id="aView"
    attachmentModel="#{bindings.AttachmentsIterator}"/>
```

19.2.10 How to Create an Attachments Column in an Applications Table

You can create an attachments column in an applications table by dragging a Master Data Collection (your business object data collection) onto your drop target.

---

**Note:**

- The `mode` attribute is automatically set to `columnLink` on the Attachment component when creating an attachment column.
- The bindings, shown in Example 19-10, only show when the Attachments are bound to a data control.
- In `columnLink` mode, the `columnModel` attribute also must be set with the value of the Attachments Accessor.

---

To create an attachments column when creating your applications table, do the following:

1. Drag your Master Data Collection (your business object data collection) onto your drop target (Page, Page Segment, or Applications Panel). The Create Context Menu is displayed.
2. Select Create, Applications Table to open the Applications Table wizard, Configure Table Patterns dialog.
3. Select the Attachments option.
4. Click OK. Do not make any changes on the Edit Taskflow Binding dialog.
   
   An Applications Table is created with an Attachments column located in the rightmost position.
5. Manually add the `columnLinkTableModel` attribute to the attachments component. This attribute must be set to the value that identifies the Master Data Collection Model and must match the value set for the value property of the `af:table` component that contains the Attachment column. For example:

   ```xml
columnLinkTableModel="#{bindings.AuEmployee1.collectionModel}"
```
19.2.11 How to Create an Attachments Column in an Existing Applications Table

You can create an attachments column in an existing applications table by dragging a Detail Master Collection (the Attachments data collection) onto your drop target.

1. Drag your Detail Data Collection (the Attachments data collection) onto your drop target (af:table within the table facet of the Applications table). The Create Context Menu is displayed.

2. Select Create, Applications, Attachments Column. The Edit Taskflow Binding dialog is displayed.

3. Click OK. Do not make any changes on the Edit Taskflow Binding dialog.

4. Manually add the columnLinkTableModel attribute to the attachments component. This attribute must be set to the value that identifies the Master Data Collection Model and must match the value set for the value property of the af:table component that contains the Attachment column. For example:

   ```
columnLinkTableModel="#{bindings.AuEmployee1.collectionModel}"
```

Example 19-10  Source Code for an Attachment Column

```
<af:column sortable="false"
   headerText="#{applcoreBundle.ATTACHMENTS_COLUMN_HEADER}"
   width="200">
  <fnd:attachment mode="columnLink"
     attachmentModel="#{bindings['Attachments1']}"
     columnModel="#{row.attachments}"/>
  columnLinkTableModel="#{bindings.AuEmployee1.collectionModel}"
</af:column>
```

19.2.12 About Setting Up Required Properties

To implement your attachments successfully you must set the following required properties:

- usesUpload for a standard JSPX page
- usesUpload on the UI Shell

Note:

usesUpload must be set using either of the above methods when uptaking either a taskflow or component that contains the attachments component.
Ensure that your uptake document includes this instruction.

This property serves as a reminder for anyone including Attachments as part of an "object" being provided that the destination JSPX page or UIShell must have the same settings so that the users can upload.

- RefreshCondition for the task flow

19.2.12.1 About Setting the usesUpload Property for a Standard JSPX Page

To be able to upload files from the desktop to the Content Server, you must set the usesUpload property to true.
For a standard JSPX page, you must set the `usesUpload` property on the `af:form` that contains your attachment component. For example:

```<af:form usesUpload="true">```

**19.2.12.2 Set the `usesUpload` Property on the UI Shell**

To set the `usesUpload` property value on the UI Shell's `af:form`, you need to set the Form Uses Upload property on the `itemNode` that represents the JSPX in the appropriate menu XML file.

1. Go to the Application Navigator and select the menu XML file.
2. Go to the Structure pane and select the item node representing the JSPX page.
3. Go to the Property Inspector > Advanced Properties > Page tab and set the Form Uses Upload property to `true`.
4. Save your changes.

**19.2.12.3 Set the `RefreshCondition` Property for the Taskflow**

Setting the `RefreshCondition` property is only required when the `repositoryMode` property is set to `true` on the Attachment component. Setting this property for the taskflow allows the Document Picker to be used more than once within the Attachments table or popup in the same session.

1. Go to the Bindings tab for that page.
2. Click on the link to the Page Definition File, which is located at the top of the page.
3. Select the `attachmentRepositoryBrowseTaskFlow1` task flow from the list of Executables.
4. Go to the Property Inspector and set the `RefreshCondition` property to `#(AttachmentsTaskflowListener.refreshTaskflow)`.
5. Save your changes.

**19.2.13 What Happens at Runtime**

Users have the ability to associate a URL, desktop file, repository file or folder, or text with a business object, such as an expense report, contract, or purchase order.

---

**Note:**

The ability to associate repository files or folders is available when the `repositoryMode` property is set to `true`.

---

When a user chooses to attach a repository file or folder, they are presented with the Document Picker dialog from which they can select one or more repository files or folders. After a repository file or folder has been attached, the type is displayed as either File or Folder.

The ability for a user to add, update, view, or delete an attachment is programmatically controlled using the `addAllowed`, `updateAllowed`, `deleteAllowed`,...
viewAllowed, deleteAllowed, and ReadOnly attributes on the Attachment component.

The ability to control what type of attachments can be added in the Attachments UI is controlled by the following attributes on the Attachment component: fileTypeEnabled, textTypeEnabled, urlTypeEnabled, and attachFolderAllowed.

The type of attachment that is used determines how the attachment is displayed when the user clicks the attachment link. The browser and client configuration determines what desktop application is used to display the attachment. When clicking on the link to access the content of a File or Text type Attachment, the user will be prompted to save the file. For their protection, users should be encouraged not to open files inside the browser.

Repository files are viewed in the same way as desktop files. However, if you click the link in the File Name/URL column in the Attachments table for an attached folder, a browser window/tab opens and displays the list of files and folders within the attached folder.

19.2.14 How to Update Page Bindings for the Attachment Views Component

Page bindings must be manually created to include AttachmentsExtraAttributes and AttachmentsRendition. They are not required for the operation of any of the Attachment components. However, in order to display the "More Information" and "Renditions" sections in the Details pane of the Attachments View component, page bindings are required.

**Note:**

- Review the **Bindings** tab of a page to determine if the following procedure is necessary. Check for entries in the list of executables, starting with AttachmentsExtraAttributes and AttachmentsRenditions.

- Before you update page bindings, ensure that you have updated the Application Module so that child entries will be available when you perform Step 3 in the procedure that follows. For more information, see How to Update the Application Module.

To update page bindings, do the following:

1. Open up the page that contains the Attachment Views component.

2. In the Data Controls section of Oracle JDeveloper, find the Attachments Data Control entry that was used to create the Attachment Views component.

3. Expand the Attachments entry, drag the AttachmentsExtraAttribute child onto the page, and select a read-only table with all columns.

4. Remove the **af:table** just created from the page.

5. In the Data Controls section, drag the AttachmentsRendition child onto the page and choose a Read-Only table with all columns.

6. Remove the **af:table** just created from the page.
7. In the Data Controls, drag the AttachedDocumentsDFF child onto the page and choose **Applications > Oracle Descriptive Flexfield**.

8. Remove the `fnd:descriptiveFlexfield` just created from the page.

9. Open the page definition of the page and go to the source. Add the following source inside the tree node for the Attachments definition:

   ```xml
   <Properties>
   <CustomProperties>
     <Property Name="ExtraAttributes" Value="<ExtraAttributesId>" />
     <Property Name="Renditions" Value="RenditionTreeId" />
     <Property Name="DFF" Value="<DffIteratorId>" />
   </CustomProperties>
   </Properties>
   ```

10. Replace `ExtraAttributesId` with the Id of the tree node for the Attachments extra attribute that was created in Step 3.

11. Replace `RenditionTreeId` with the Id of the tree node for the Attachments Rendition that was created in Step 5.

12. Replace `<DffIteratorId>` with the Id of the iterator node for the Attachments DFF that was created in step 7.

13. Save the page definition.

   The Attachments View component will detect that these properties have been configured and will start using them.

### 19.3 About Displaying Attachments for Multiple Entities in the Same Table

For a user interface that shows information for more than one business object, the Attachments component can be configured to display the attachments for two or more of these business objects.

For example, when opening up the Attachments from the Department section of your UI page, you might want to display attachments for all Employees that exist in that Department. This example will be used throughout this section to help clarify the instructions.

This configuration is only possible when the underlying view object for your page contains the primary keys for each of the business objects whose attachments you want to show in your page. For example, the `DeptEmpVO` would need to include attributes for both the Department primary key and the Employee foreign key. In this example, the Department is considered to be the primary business object and the Employee is the secondary business object. The example uses only two business objects, but it is possible to display the attachments for more than two business objects using this feature.

Your primary business object is the one that you linked to the AttachmentsVO at design time, when you created your Attachment view link. Attachments can only be added to the primary business object when using this feature.

The `actionEntity` property can be used to set the primary business object and controls which attachments can be updated and deleted. When set, any document attached to a different entity is displayed for reference purposes only. It cannot be updated or deleted.
19.3.1 About Configuring the Attachments Component to Display Attachments for Multiple Entities

This section provides details on how to configure your data model to display attachments for two or more business objects. These instructions assume that you have already created the Attachments view link between one business object view object and the Attachments view object, as described in How to Create Attachment View Links.

19.3.1.1 How to Configure the Attachments Component to Display Attachments for Two or More Business Objects

Do the following:

1. Open the page that contains the Attachment component that is bound to the ViewLink modified above.
2. Select the Attachment component.
3. Set the `actionEntity` property to the `ENTITY_NAME` of the primary business object. By setting this property, you are allowing users to update and delete attachments belonging to the primary business object whilst disabling the ability for users to update and delete attachments for the secondary and all subsequent business objects.

19.3.1.2 How to Configure the Data Model to Display Attachments for Two or More Business Objects

Do the following:

1. Open the view object for your business object.
2. Navigate to the Attributes tab. Add a new transient attribute for the secondary business object for which you want to display attachments. Use the existing `AttachmentEntityName` attribute as an example, naming the new attribute `AttachmentEntityName1`.
3. Change the Expression value in the View Attribute screen to be the Attachment `ENTITY_NAME` as defined for your business object in the `FND_DOCUMENT_ENTITIES` and `FND_DOCUMENT_ENTITIES_TL` tables.
4. Repeat Steps 2 and 3 for any subsequent business objects for which you want to show attachments. Make sure that you modify the attribute name and expression value for each.
5. Close the view object.
6. Open the attachment view link.
7. Link your secondary business object to the Attachments view object.
   a. Navigate to the Relationship tab and click the Attributes Edit icon.
   b. Select the foreign key reference column in your view object from the Source Attribute list and then select the corresponding `PknValue` column in the Attachments view object (starting with `PknValue`) from the Destination Attribute list. Click Add to add this pair.
Repeat this for each column that makes up the foreign key, which identifies your secondary business object.

c. Select the `EntityName` attribute (created in Step 2) in the Attachments view object from the Destination Attribute list. Click Add to add this pair.
Repeat this for each of the AttachmentEntityName transient attributes.

d. Navigate to the Query tab, and click the Source Edit icon.

e. Modify the auto-generated Source and Destination queries to match the appropriate Entity Names and Primary Key values. Put parentheses around the criteria that pertain to one business object and change the AND to an OR in between each business object. Make sure your parentheses are matched correctly, as shown in examples Example 19-11 and Example 19-12.

7. Navigate to the Source view for the view link and edit the source XML to include the extra attributes in the Destination array. Make sure you include attributes for each additional business object for which you want to display attachments.

The AttrArray for the destEnd ViewLinkDefEnd must map to the AttrArray for the sourceEnd ViewLinkDefEnd.

The design time code inserts an array of unique items where the runtime code needs a matching item list, as shown in Example 19-13. (The added items are in bold).

8. Navigate back to the General tab and expand the Custom Properties section. Modify the value of the OAF_ATTACHMENT_CATEGORY custom property to control the attachments that are displayed in your page, based on category and to control the Category droplist values.

Note:
This can be further controlled using data security.

9. Save all your changes.

Example 19-11 Source Query

```
((:Bind_EmployeeId = PK1_VALUE) AND (:Bind_AttachmentEntityName = ENTITY_NAME))
```

```
OR
```

```
((:Bind_DeptNum = PK1_VALUE) AND (:Bind_AttachmentEntityName1 = ENTITY_NAME))
```

Example 19-12 Destination Query

```
((:Bind_Pk1Value = FndDemoDeptEmpEO.EMPLOYEE_ID) AND (:Bind_EntityName = 'FND_DEMO_EMP'))
```

```
OR
```

```
((:Bind_Pk1Value = FndDemoDeptEmpEO.DEPT_NUM) AND (:Bind_EntityName = 'FND_DEMO_DEPT'))
```

Example 19-13 Source and Destination Attribute Arrays

```
<AttrArray Name="Attributes">
```

```
<AttrArray Name="Attributes">
```
19.4 About Configuring Attachments Component Properties

You can use properties to change the default behavior of the Attachments, Attachments Carousel, and Attachment Views components user interfaces.

For a complete list of these properties, see Configuring Attachments Component Properties.

19.4.1 About Using FUSE

Support has been included for using Attachments in pages built for Oracle Fusion Applications User Simplified Experience (FUSE). When using Attachments in a FUSE page, you will need to adhere to the following rules in order to implement a FUSE compliant design:

<table>
<thead>
<tr>
<th>Table 19-1</th>
<th>FUSE Implementation Rules</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rule</td>
<td>Description</td>
</tr>
<tr>
<td>fuse</td>
<td>Boolean: true / false. True renders the attachment component for a FUSE UI page. Only link mode is supported for FUSE.</td>
</tr>
<tr>
<td>mode=&quot;link&quot;</td>
<td>Link mode is the only supported mode of operation.</td>
</tr>
<tr>
<td>repositoryMode=&quot;false&quot;</td>
<td>Only Attachments of type File or URL are allowed. The Repository File/Folder and Text attachment types need to be disabled.</td>
</tr>
<tr>
<td>textTypeEnabled=&quot;false&quot;</td>
<td>You will not be prompted for confirmation before an Attachment is deleted.</td>
</tr>
<tr>
<td>confirmDelete=&quot;false&quot;</td>
<td>String. Value selected as the default in the Category poplist when adding new attachments.</td>
</tr>
</tbody>
</table>

The following properties are not used when in FUSE mode:

- ApprovalEnabled
About Working with Attachments Programmatically

19.5 About Working with Attachments Programmatically

To support headless or automated processing of Attachments, methods have been provided in the
oracle.apps.fnd.appcore.attachments.attachmentService.applicationModule.AttachmentServiceAM class.

Before you begin:

- If the Application or Project has not already been configured to use Attachments, follow the instructions in Performing Prerequisite Tasks.
- Find or create an instance of the AttachmentServiceAM.

Working with streams:

The Attachment APIs use the stream type for receiving and sending the actual files. When implementing your designs, keep the following rules in mind to avoid common issues that can occur.

- Ensure that Response Streams are always closed (is.close()) in a finally block.
- Ensure responses are processed immediately in full, and in order, prior to beginning the next request in the context of a thread. A delay in processing might result in a time out.
An example of this would be when downloading a stream that contains a set of instructions that are processed from the stream one line at time with each requiring several seconds before the next line is processed. With enough instructions lines, this might cause the stream to time out. The better approach would be to process the stream and store the instructions in another memory structure.

- Do not attempt to work with the Attachment API with two steams open in the context of a thread.

**Example 19-15  AttachmentServiceAM**

```java
// Enable the Attachments Service AM
AttachmentServiceAMImpl attachmentServiceAMImpl =
    (AttachmentServiceAMImpl) am.findApplicationModule("attachmentsServiceAM");
if (attachmentServiceAMImpl == null)
{
    attachmentServiceAMImpl =
    (AttachmentServiceAMImpl)am.createApplicationModule("attachmentsServiceAM",
        "oracle.apps.fnd.applcore.attachments.attachmentService.applicationModule.
            AttachmentServiceAM");
}
```

### 19.5.1 About Creating New Attachment Types

Methods have been provided for programmatically creating the File, Text and URL types. There is also an additional type, ManagedURL.

A managed URL attachment is intended for use with pages that are hosted on internal servers that are administered by Topology Manager. Since changes made by the Topology Manager might invalidate the scheme://domain:port portion of a URL resulting in a dead link, support for this variation of the URL type was created. To the end-user, this link will still appear as a URL. Internally, however, this Attachment will be created with a different Attachment type, TMURI.

Methods for attaching files that have been uploaded from a third-party application are also available. In this case, the developer has gotten the required information returned from uploading the file to complete the attachment. Where the file is already attached to another record, using the `copyAttachments` method to attach the file to the require record is recommended.

Table 19-2 summarizes the available methods for Attachments APIs.

**Table 19-2  Method Summary for Attachment APIs**

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
</table>
| void                | `attachFile(AttachmentsVORowImpl row, java.lang.String fileName,
               java.lang.String contentType, java.io.InputStream fileStream)` |
|                     | Updates the supplied attachments row with the information to attach a file. A new version is checked in if the file has already been uploaded. |
| AttachmentsVORowImpl | `attachFile(java.lang.String fileName, java.lang.String contentType,
               java.io.InputStream fileStream)` |
<p>|                     | Creates a new row from the internal attachments view object and populates the attributes to attach a file. |</p>

</tr>
<tr>
<td></td>
<td>Upload a rendition to the Content Server.</td>
</tr>
</tbody>
</table>

When end-user ordering has been enabled in the view for the attachment component, any programmatically created rows for the entity must have their sequence value set as well. Calling the method `setAttachmentSequence`, passing in the newly created row, will set the correct sequence value.

All methods are overloaded, providing two options for creating a new Attachment. The first option creates the new Attachment row from the Attachment collection linked to the parent view object. This is illustrated in Example 19-16.

The second option is to allow the method to create the Attachment row at the same time, as shown in Example 19-17.

If you use the second option, it is essential for the Entity and Primary Key values to be set programmatically as well. Getting any of these values wrong may result in the Attachment being lost or assigned to the wrong record. While the second type looks like less work it would be a better practice to use the first approach for creating new Attachments.

**Note:**

Assigning an Attachment to the wrong record could allow an end-user to view a document they would not normally be able to view.

It will also be necessary to set the Category value for the new row before committing the transaction as shown in both examples. The value expected is the CATEGORY_NAME from the FND_DOCUMENT_CATEGORIES table. Since the value is not validated, use the following method to ensure that you are providing a category value that is mapped to your Document Entity Name:

```java
newAttachment.setCategoryName("MISC");
```

**Example 19-16  Code for Creating a New Attachment Row: Option 1**

```java
// Retrieve the department for adding the new Attachment row to
ViewObject vo = am.findViewObject("FndDemoDepl1");
vo.setWhereClause("DEPT_NUM = :deptNum");
vo.defineNamedWhereClauseParam("deptNum", null, null);
vo.setNamedWhereClauseParam("deptNum", departmentNumber);
vo.executeQuery();
Row currDepartment = vo.next();
```
// Retrieve the Attachments Collection
RowSet attachments = (RowSet) currDepartment.getAttribute("Attachments");
// Create new Attachment Row
AttachmentsVORowImpl newAttachment = (AttachmentsVORowImpl) attachments.createRow();
// Add Managed Link
attachmentServiceAMImpl.attachManagedUrl(newAttachment, textEntAppShortName, textURI);
// Set the Category Value
newAttachment.setCategoryName("MISC");

Example 19-17  Code for Creating a New Attachment Row: Option 2

// Add Managed Link
newAttachment =
attachmentServiceAMImpl.attachTopologyManagedUrl(textEntAppShortName, textURI);
newAttachment.setEntityName("FND_DEMO_DEPT");
newAttachment.setPk1Value(departmentNumber);
// Set the Category Value
newAttachment.setCategoryName("MISC");

19.5.2 About Retrieving Attachments

The InputStream and OutputStream methods have been supplied for retrieving Attachment types of FILE or TEXT. The URL or TMURI types are not stored on the content server. Their URL values can be retrieved with the getAttachmentUrl() method, which is described in Table 19-3.

Table 19-3  Methods for Retrieving Attachments

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.io.InputStream</td>
<td>getAttachmentInputStream(AttachmentsVORowImpl row)</td>
</tr>
<tr>
<td></td>
<td>This method is deprecated. Use</td>
</tr>
<tr>
<td></td>
<td>getInputStream(AttachmentsVORowImpl row) instead.</td>
</tr>
<tr>
<td>java.io.InputStream</td>
<td>getInputStream(AttachmentsVORowImpl row)</td>
</tr>
<tr>
<td>Retrieve the attachment content for the supplied attachment row as a stream.</td>
<td></td>
</tr>
<tr>
<td>Unlike</td>
<td>getAttachmentInputStream(AttachmentsVORowImpl row), which embedded an error message in InputStream, this method throws an exception if there is an error downloading the data from the content server.</td>
</tr>
<tr>
<td>java.io.OutputStream</td>
<td>getAttachmentStream(AttachmentsVORowImpl row)</td>
</tr>
<tr>
<td>Retrieve the attachment content for the supplied attachment row as a stream.</td>
<td></td>
</tr>
<tr>
<td>java.lang.String</td>
<td>getAttachmentUrl(AttachmentsVORowImpl row)</td>
</tr>
<tr>
<td>Retrieve URL for the attachment content for the supplied attachment.</td>
<td></td>
</tr>
</tbody>
</table>
Table 19-3 (Cont.) Methods for Retrieving Attachments

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.io.InputStream</td>
<td>getInputStream(AttachmentsVORo java.lang.String rendition, java.lang.Boolean requireRendition) pl1 row, throws java.io.IOException, RenditionNotFoundException</td>
<td>Retrieve the named rendition for the attachment content for the supplied attachment row as a stream. Rendition name is case sensitive. Setting requireRendition to true validates the availability of the rendition against the local rendition collection. If the rendition is not available, a RenditionNotFoundException is thrown.</td>
</tr>
</tbody>
</table>

**Note:**

InputStream and OutputStream provide a handle to a file on the Content Server. The connection to the Content Server can only support one Stream at a time. Ensure that you have finished all processing on the current Stream before starting the next. Otherwise you may experience a loss of data in the first Stream. If it is important to have two open Streams, create a second thread and open the second Stream there.

19.5.3 About Using Attachment Utilities

Two utility methods are provided enable a list of Attachments to be copied to another record as identified by the unique combination of the Document Entity Name and Primary Key values. The list is constructed of the Attachment rows from one or more other records.

The copyAttachments utility does not duplicate the files on the content server. When the method is complete, the destination record will point to the same files in the content server as the source record.

The duplicateAttachments utility does duplicate the files on the content server. When the method is complete, the destination record will point to the new content on the content server.

When constructing the list of Attachments, consider whether Category Data Security has been implemented (see About Attachment Category Data Security). If implemented, the list of Attachments available may not be the full list depending on the permissions granted to the current user. If the full list is required it will be necessary to bypass Category Data Security by setting the dataSecurityDisabled flag on AttachmentsVOImpl to true, as shown in Example 19-18.

**Note:**

If order is important, the list is processed in the order it is received. Based on the default ordering the UI, this would place the first attachment in the list last when viewed.
### Table 19-4  AttachmentsVORowImpl

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Creates copies of the supplied attachment rows assigning them to the entity values as provided.</td>
</tr>
<tr>
<td></td>
<td>Creates copies of the supplied attachment rows assigning them to the entity values as provided. Content on the content server is also copied.</td>
</tr>
</tbody>
</table>

### Example 19-18  AttachmentsVOImpl

AttachmentsVOImpl attachmentVO = attachmentServiceAMImpl.getAttachments1();
attachmentVO.setDataSecurityDisabled(true);
// assign where clause conditions
attachmentVO.executeQuery;

### 19.5.4 About Managing Attachments HTTP Sessions

Generally, the Attachments component handles resources effectively; there is normally no need to manage resources programatically. However, if the Attachments component is holding a large number of HTTP sessions open for a long time, you might need to dispose of the unnecessary sessions. You can do this by calling the `dispose` method, which is described in Table 19-5.

### Table 19-5  Method Summary for Handling a Large Number of Sessions

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>public static void dispose()</td>
</tr>
<tr>
<td></td>
<td>Cleans up resources held by the Oracle WebCenter Content connection.</td>
</tr>
</tbody>
</table>

### 19.5.5 About Creating Third-Party Attachments

By default, the Attachment files on the Content Server are locked down. When a request is made using the Attachments functionality, it includes additional parameters that are processed on the Content Server. The user’s privileges are temporarily elevated so that the request can be performed.
Note:
These requests are always made in the security context of the application that owns the Attachment. Access to Attachments is through the View Link defined in the model. A user that is unable to access your business record cannot access that record’s Attachments. In using the Attachments programmatically it is important that the implementation does not circumvent this design.

Methods that support attaching files to business-object records using third-party applications are described in the table that follows.

### Table 19-6 Methods Supporting Third-Party Attachments

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>java.util.Map</td>
<td>signUpload(java.lang.String title)</td>
<td>Creates a digital signature to allow documents to be checked into the Attachments security group on the Content Server.</td>
</tr>
</tbody>
</table>

The process to create an Attachment using a third-party application is the following:

1. The third-party application makes a request to the business object to retrieve a signature for uploading a file with a provided title to a record in the business object.

2. The business object evaluates whether the requesting user is allowed to attach a file to the record.

3. The business object makes a call to the `signUpload` method, which returns an array of name value pairs that make up the signature.

4. The business object returns the array to the third-party application.

5. The third-party application creates the request to create the new file. The request includes the array of name value pairs returned from the business object.

6. The third-party application sends the request to the Content Server.

7. The response from the Content Server includes the document ID and version number of the new document.

8. The third-party application makes a request to the business object to create a new Attachment for the record using the new document ID and version number.
9. The business object calls the attachRepositoryFile method for its record to create the new Attachment record.

Since the attachRepositoryFile method validates that the user making the request to create the attachment is the same user that created the file on the Content Server, all of the steps in this process must be performed by the same user.

The service call made to create the file on the Content Server (Step 5) is the CHECKIN_UNIVERSAL service. For more information, see the Services Reference for Oracle WebCenter Content.

When setting parameters, you must use the guidelines described in the table that follows.

<table>
<thead>
<tr>
<th>Table 19-7 Service-Call Parameter Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>dDocAuthor</td>

<tr>
<td>dDocAccount</td>
</tr>
<tr>
<td>primaryFile</td>
</tr>
<tr>
<td>alternateFile</td>
</tr>
<tr>
<td>dDocName</td>
</tr>
</tbody>
</table>

19.5.6 About Implementing Attachments with PL/SQL

PL/SQL equivalents exist for some of the Java methods described in About Creating New Attachment Types and About Using Attachment Utilities. These PL/SQL operations appear in the following table.

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>There can be no PL/SQL equivalents of the Java APIs that interact with the Content Server. PL/SQL is limited to working with the information stored in the Application Database only. There are no options available to access or create files stored on the Content Server.</td>
</tr>
</tbody>
</table>
About Working with Attachments Programmatically

Table 19-8  PL/SQL Attachments Implementation

</tr>
<tr>
<td></td>
<td>X_DST_CATEGORY_NAME in VARCHAR2 DEFAULT NULL );</td>
</tr>
</tbody>
</table>

Updates the supplied attachments row with the information to attach a static URL.

Creates copies of the supplied attachment rows assigning them to the entity values as provided. This utility does not copy the content on the server; it creates a copy of the reference to the content.
Table 19-8  (Cont.) PL/SQL Attachments Implementation

<table>
<thead>
<tr>
<th>Method</th>
<th>PL/SQL Implementation</th>
</tr>
</thead>
</table>
| copyAttachment | PROCEDURE COPY_ATTACHMENT (  
|              | X_ATTACHED_DOCUMENT_ID in VARCHAR2,  
|              | X_ENTITY_NAME in VARCHAR2,  
|              | X_PK1_VALUE in VARCHAR2,  
|              | X_PK2_VALUE in VARCHAR2 DEFAULT NULL,  
|              | X_PK3_VALUE in VARCHAR2 DEFAULT NULL,  
|              | X_PK4_VALUE in VARCHAR2 DEFAULT NULL,  
|              | X_PK5_VALUE in VARCHAR2 DEFAULT NULL,  
|              | X_CATEGORY_NAME in VARCHAR2 DEFAULT NULL );  
|             | Creates a copy of the supplied attachment row. This utility does not copy the content on the server; it creates a copy of the reference to the content. |
| deleteAttachment | PROCEDURE DELETE_ATTACHMENT (  
|               | X_ATTACHED_DOCUMENT_ID in FND_ATTACHED_DOCUMENTS.ATTACHED_DOCUMENT_ID%TYPE );  
|               | Deletes an attachment from the database for the X_ATTACHMENT_DOCUMENT_ID. This does not delete the file in the content repository. |
| deleteAttachments | PROCEDURE DELETE_ATTACHMENTS (  
|               | X_ENTITY_NAME in FND_ATTACHED_DOCUMENTS.ENTITY_NAME%TYPE,  
|               | X_PK1_VALUE in FND_ATTACHED_DOCUMENTS.PK1_VALUE%TYPE,  
|               | X_PK2_VALUE in FND_ATTACHED_DOCUMENTS.PK2_VALUE%TYPE DEFAULT NULL,  
|               | X_PK3_VALUE in FND_ATTACHED_DOCUMENTS.PK3_VALUE%TYPE DEFAULT NULL,  
|               | X_PK4_VALUE in FND_ATTACHED_DOCUMENTS.PK4_VALUE%TYPE DEFAULT NULL,  
|               | X_PK5_VALUE in FND_ATTACHED_DOCUMENTS.PK5_VALUE%TYPE DEFAULT NULL );  
|               | Deletes all the attachments from the database for the specified parent record. This does not delete any files in the content repository. |

Note:

The Attachments procedures listed in About Creating New Attachment Types and About Using Attachment Utilities, but not listed in Table 19-8, cannot be implemented in PL/SQL.

A debugging utility is also included. When enabled, messages are written to the console. This feature is not enabled by default. At runtime the same messages will be written as log messages if logging is set to FINEST for the applcore.db.plsql.attachments.FND_ATTACHMENTS module.

To begin writing log messages to the console, use the `PROCEDURE START_DEBUG` command.

To stop writing log messages to the console, use the `PROCEDURE STOP_DEBUG` command.

Example 19-19 displays sample code for implementing Attachments with PL/SQL with debugging enabled.
Example 19-19 Implementing Attachments with PL/SQL

```
SET SERVEROUTPUT ON;
DECLARE
    BAD_ENTITY_NAME_EXCEPTION EXCEPTION;
    PRAGMA EXCEPTION_INIT(BAD_ENTITY_NAME_EXCEPTION, -20001);
    P_ENTITY_NAME VARCHAR2(40)  := 'FND_DEMO_DEPT1';
    P_PK1_VALUE   VARCHAR2(150) := '10';
BEGIN
    BEGIN
        FND_ATTACHMENTS.START_DEBUG;
        FND_ATTACHMENTS.ATTACH_URL (P_ENTITY_NAME,
                                      P_PK1_VALUE, NULL, NULL, NULL,
                                      'MISC',
                                      'http://www.oracle.com', 'Oracle Coorporation',
                                      NULL);
        FND_ATTACHMENTS.END_DEBUG;
    EXCEPTION
        WHEN BAD_ENTITY_NAME_EXCEPTION THEN
            DBMS_OUTPUT.PUT_LINE ('The entity name supplied, ' || P_ENTITY_NAME || ', is not a registered document entity.');
    END;
END;
```

19.6 About Setting Up Miscellaneous Attachments Features

Custom actions include the following:

- Custom actions for the attachments component
- Custom actions for the attachment views components
- Approvals
- Redlining

19.6.1 About Custom Actions for the Attachments Component

Four facets (placeholders) are provided on the attachments component for product teams to add toolbar buttons to the toolbar and actions to the Action menu of the attachments table.

The facet `tableAppsTableSecondaryToolbar` is provided to add toolbar buttons to the Attachments Table toolbar.

The facet `linkAppsTableSecondaryToolbar` is provided for Link mode.

**Note:**

When using the `tableAppsTableSecondaryToolbar` or `linkAppsTableSecondaryToolbar` facets, you must also set the `SecondaryToolbarRendered` property on the attachments component to true to expose this facet in the Attachments table.

The facet `tableAdditionalActionItems` is provided to add action items to the Action menu in the attachments table menus.

The facet `linkAdditionalActionItems` is provided for Link mode.
19.6.2 About Custom Actions for the Attachment Views and Attachment Link Component

Facets are provided on the Attachment Views component to add custom actions. The following facets are provided:

- **appsTableSecondaryToolbar**: adds toolbar buttons to the Attachment Views toolbar. Three buttons, Sel, All, and One, are shown in the following figure.

- **additionalActionItems**: adds action items to the Action menu in the Attachment Views menu. Five menu options, Show Selected Items, Show All Items, Show One Item, Selected Row Count, and All Row Count, are shown in the following figure.

![Custom Actions and Facets](image)

You can also use facets inline for adding icons or action items. These facets are incorporated into the actions section of the attachment, as shown in the previous figure. There is no central facet for the inline facets. As Oracle Application Development Framework rules do not allow this type of sharing, you must add each icon and item that must be identical for each view. This provides the flexibility for icons or actions to change from view to view for any implementation.

The rendering of the facets are controlled with properties. By default, the facets are not rendered.

<table>
<thead>
<tr>
<th>View</th>

<td>additionalGridInlineIconItemsRendered</td>
</tr>
</tbody>
</table>

19.6.2.1 About Working with Custom Actions Programmatically

In support of developing the custom action functionality, utility methods are provided in the
oracle.apps.fnd.applcore.attachments.v2.uiPublic.utils.AttachmentPublicUtils class.

Two methods return an array of Attachment rows. One method returns all of the rows; the other returns only the selected rows. The rows contain all of the information that the Attachments component uses to display itself. The data is for reference purposes only, and the row returned by the method cannot be modified.

Two methods return either the total number of attachments, or the number of attachments that are currently selected.

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.apps.fnd.applcore.attachments.publicModel.AttachmentsReadOnlyRow ()</td>
<td>findSelectedAttachmentsForEvent(javax.faces.event.FacesEvent event)</td>
</tr>
<tr>
<td></td>
<td>Finds the list of rows selected in the attachment component from which the event originated. If the event is null or its source is not from a sub-component of an attachments component, or if an exception occurs during processing, an empty list is returned.</td>
</tr>
<tr>
<td>oracle.apps.fnd.applcore.attachments.publicModel.AttachmentsReadOnlyRow()</td>
<td>findAllAttachmentsForEvent(javax.faces.event.FacesEvent event)</td>
</tr>
<tr>
<td></td>
<td>Finds the list of rows selected in the attachment component from which the event originated. If the event is null or its source is not from a sub-component of an attachments component, or if an exception occurs during processing, an empty list is returned.</td>
</tr>
<tr>
<td>long</td>
<td>findAttachmentCountForEvent(javax.faces.event.FacesEvent event)</td>
</tr>
<tr>
<td></td>
<td>Finds the list of rows selected in the attachment component from which the event originated. If the event is null or its source is not from a sub-component of an attachments component, or if an exception occurs during processing, -1 is returned.</td>
</tr>
<tr>
<td>long</td>
<td>findSelectedAttachmentCountForEvent(javax.faces.event.FacesEvent event)</td>
</tr>
<tr>
<td></td>
<td>Finds the list of rows selected in the attachment component from which the event originated. If the event is null or its source is not from a sub-component of an attachments component, or if an exception occurs during processing, -1 is returned.</td>
</tr>
</tbody>
</table>

19.6.3 About Approvals

Approval functions are added to the Attachments component using the Custom Actions feature, which is documented in the previous section of this chapter.

The approvalEnabled property on the Attachments component can be used to control whether the Status column (from the FND_DOCUMENTS_TL table) is displayed in the Attachments Table. This column indicates the status of the attachment relationship between the business object and the file, not the status of the file in the content repository.
Product teams are responsible for programmatically setting the status as necessary, but are required to set this value using a lookup code provided in the `FND_ATTACHMENT_STATUSES` lookup. The following table has the full list of valid values found in this lookup table. (*Null* is also a valid value):

<table>
<thead>
<tr>
<th>Lookup Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPROVED</td>
<td>Approved</td>
</tr>
<tr>
<td>REJECTED</td>
<td>Rejected</td>
</tr>
<tr>
<td>REVIEWED</td>
<td>Reviewed</td>
</tr>
<tr>
<td>SUBMITTED_FOR_APPROVAL</td>
<td>Submitted for Approval</td>
</tr>
<tr>
<td>SUBMITTED_FOR_REVIEW</td>
<td>Submitted for Review</td>
</tr>
<tr>
<td>UNAPPROVED</td>
<td>Unapproved</td>
</tr>
</tbody>
</table>

**Note:**

The *Status* column is a read-only column when displayed in the Attachments Table.

19.6.4 About Redlining

*Redlining* is a function that shows the changes to an attachment from one version of the parent record to another. It gets its name from the format applied to the attachments that were deleted between the versions.

Redlining requires the following:

- Your business object must be tracking different versions of the same record
- There can be only one current record. All previous versions of the record are no longer editable.

At runtime, attachment views compare the attachments of the current record with that of its nominated predecessor.

- New attachments have their line prefixed with the word "Added". The *Title*, *Description*, and *Category* fields are formatted in green.
- Modified attachments have their line prefixed with the word "Edited". The *Title*, *Description*, and *Category* fields are formatted in blue. Previous values are formatted in red with a strikethrough.
- Deleted attachments have their line prefixed with the word "Removed". The *Title*, *Description*, and *Category* fields are formatted in red with a strikethrough. Deleted Attachments cannot be modified.
- Attachments that are unchanged have no prefix. The *Title* field displays in blue text.

The following figure shows an example of redlining.
19.6.4.1 How to Enable the Redlining Function

To enable redlining, do the following:

1. Fix the attachment versions for the retiring current record.

   Perform this task during the time between when the new record is created and when the current record is retired. When creating a new record, all of the attachments for the current record must be duplicated in the new record. (For information about the `duplicateAttachments` method, see About Using Attachment Utilities.) The duplication links the current and new records to the same files on the Content Server server. Once the new record becomes the current record, the attachments on the now retired record must be fixed. Use the `version` method to fix each attachment's version.

**WARNING:**

By setting the versions and then copying the attachments to the new parent record, you are copying fixed attachments and not attachments that point to the latest attachment.
Table 19-11  version Method

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>static void</td>
<td>To version the attachments row:</td>
</tr>
<tr>
<td></td>
<td>version(java.util.List&lt;AttachmentsVORowImpl&gt; attachments)</td>
</tr>
</tbody>
</table>

2. Configure the attachment views component to display the redlining formatting.

Set the redlineKey attribute on the attachment views component to the key of the retired record with which to compare the current record. EL Expressions are supported for retrieving the key.

As shown in the following example, the previous key is generated as a transient attribute of the parent view object. The value of the previous item key is then included as a page binding.

```xml
<fnd:attachmentView attachmentModel="#{bindings.Attachments1}" id="aview"
  redlineKey="#{bindings.PreviousItemKey.inputValue}"
  attributeCategoryVisible="true"/>
```

The supplied key must be a comma-separated concatenation of the attachment entity name and the attributes that were selected when the attachment entity was created (see Step 8 in How to Create Attachment View Links). The key can support up to five attributes. The trailing attributes do not need to be supplied if they are empty.

19.7 About Integrating Attachments Task Flows into Oracle Fusion Functional Setup Manager

Every application registers task flows with a product called Oracle Fusion Functional Setup Manager. The Functional Setup Manager provides a single, unified user interface that allows customers and implementers to configure all Oracle Fusion applications by defining custom configuration templates or tasks based on their business needs.

The Functional Setup Manager UI enables customers and implementers to select the business processes or products that they want to implement.

Function Security controls your privileges to a specific task flow, and users who do not have the required privilege cannot view the task flow. For more information about how to implement function security privileges and roles, see Implementing Function Security.

Table 19-12 lists the task flows and their parameters.

<table>
<thead>
<tr>
<th>Task Flow Name</th>
<th>Task Flow XML</th>
<th>Parameters Passed</th>
<th>Behavior</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>Manage Attachment Entities</td>
<td>/WEB-INF/oracle/apps/fnd/applcore/attachments/publicUi/flow/ManageAttachmentEntities.xml#ManageAttachmentEntities</td>
<td>[moduleType] [moduleKey] [pageTitle]</td>
<td>Search and edit Attachment entities.</td>
<td>NA</td>
</tr>
</tbody>
</table>
Table 19-12  (Cont.) Attachments Task Flows and Parameters

<td>None</td>
<td>Search and edit Attachment file formats</td>
<td>NA</td>
</tr>
</tbody>
</table>

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.

2. See the Implementing Common Features guides for your product family.

19.8 About Securing Attachments

All attachments users must be assigned the "AttachmentsUser" role to use attachments. This role gives users read access to all shared file attachments. Depending on the security defined for attachments, further access privileges will be assigned to users on a per-file basis at the time of accessing the attachments.

Attachments can be secured using the Attachment Category data-security method.

A user can choose whether to Share a file when creating a file attachment. File sharing impacts the way in which files are secured. For more information, see About File Sharing.

19.8.1 About Entity Instance-Level Security

Many product teams define data security on their business objects. This data security controls which instances of that business object each user can access. Oracle Fusion attachments reuses this data security when users try to access documents directly, either via a URL or via the Content Server user interface, to ensure that users can only access files that are attached to the business object instances that they have permission to access. This security is important for controlling access to attached files when accessed directly.

19.8.1.1 About Setting Up Attachments to Uphold Entity Instance-Level Security

To enable attachments to reuse the data-security setup for your business object, you need to seed data in the DATA_OBJECT_CODE column in the FND_DOCUMENT_ENTITIES table. The value in the DATA_OBJECT_CODE column must match the value stored in the OBJ_NAME column in the FND_OBJECTS table for database resource for your business object.
Note:
Oracle Fusion attachments require product teams to have used and seeded the standard read, update, and delete functions when setting up the data security on their business objects.

For more information about Oracle Fusion Data Security, see Implementing Oracle Fusion Data Security.

19.8.2 About Attachment Category Data Security

Attachments can be secured using attachments categories. This security determines which attachments a user has access to, and what actions they can perform on that attachment, based on the Category that is assigned to it. Uptaking this security is not a mandatory requirement for product teams.

Before uptaking category data security, ensure you have assigned one or more categories to the attachment entity defined for your business object. For more information, see About Assigning Categories to the Attachment Entity.

To incorporate category data security, you need to seed data security for your attachment categories to control which roles have access to each of the categories.

The following seed data has been provided and must be used when you set up category data security:

- "FND_DOCUMENT_CATEGORIES": The seeded database resource for attachment categories data security
- Three actions (form functions) seeded for attachments. These are listed in Table 19-13.

<table>
<thead>
<tr>
<th>Action</th>
<th>FUNCTION_NAME</th>
<th>USER_FUNCTION_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>Seeded Read Action</td>
<td>FND_READ_APPLICATION_ATTACHMENT_DATA</td>
<td>Read Application Attachment</td>
</tr>
<tr>
<td>Seeded Update Action</td>
<td>FND_UPDATE_APPLICATION_ATTACHMENT_DATA</td>
<td>Update Application Attachment</td>
</tr>
<tr>
<td>Seeded Delete Action</td>
<td>FND_DELETE_APPLICATION_ATTACHMENT_DATA</td>
<td>Delete Application Attachment</td>
</tr>
</tbody>
</table>

19.8.2.1 How to Set Up Category Data Security

Do the following to set up category data security:

1. Define the conditions (object instance sets) that identify the category or set of categories you are securing. The CATEGORY_ID, CATEGORY_NAME, or USER_NAME condition items can be used in your condition definitions.

2. Ensure the Roles to which you want to assign data security have been created in Oracle Platform Security Services (OPSS).

3. Grant the actions that you will allow a user to perform on the set of Categories identified by your condition in Step 2. You can grant one or more of the seeded...
actions: read, update, and delete (see Table 19-13) to a role, but a role must be assigned the read action to view attachments from the Attachments UI.

The "Manage Database Resources and Policies" setup UI in the FndSetup application can be used to create these grants after you have defined your conditions in the database.

4. (Optional) The "Applications Common Reference Data Review Duty” role (GUID: 7BC1484030A9EE43499AB0EBBE17B104) provides users with read, update, and delete actions for all attachments that are assigned the "Miscellaneous" category.

To setup your own category data security for the "Miscellaneous" category, you will need to follow Steps 1 to 4.

The following condition (object instance set) is seeded with Oracle Fusion attachments and can be reused by using the "Miscellaneous” category for your product:

- **INSTANCE_SET_NAME**: FNDDOCUMENTCATEGORIESFND214
- **PREDICATE**: category_name = 'MISC'

5. Using the Manage Attachment Entities Setup UI, "switch on" category data security for your attachment entity.

For more information, see Implementing Oracle Fusion Data Security.

19.8.3 About File Sharing

File sharing impacts the way in which your files are secured. Files are stored on the Content Server as either Shared or Not Shared. Users can choose which option to use when they attach files to their business objects. For more, see About Using Attachments File-Level Security.

Shared files are files that are stored in virtual folders within the Content Server and are available to all attachments users. An attachments user is any user who has been assigned the “AttachmentsUser” role. Shared files are exempt from data security.

Unshared files are only available to those users who have access to the file via data security. Therefore, if an Oracle Fusion Applications user has privileges to access to an attachment through a business object instance and they have privileges to access attachments with a particular category, then they have access to the file in the Content Server.

Users are defined on a single Lightweight Directory Access Protocol (LDAP) server. Each of these users can log in to both Oracle Fusion Applications and Oracle Content Server using the same username and password. Users will be given appropriate privileges to each system based on their assigned roles.

19.8.4 About File Format Filtering

Most complex file formats include scripting support to assist users with automating common tasks. This has led to the rise of Cross Site Scripting (XSS attacks, where attackers gain access by including scripts in a file that an unsuspecting user then opens. The challenge, then, is how to recognize and balance the need for users to be able to include automation within their files with the need to prevent malicious scripts inflicting damage to the site.
When opening a file, the default Attachments behavior is to prompt the user to download. This removes native-browser file types from being opened in the session context. It also gives the user more control over when to open the file and, in the case of where the file is suspect, which viewer to use.

The new "Manage Attachment File Formats" page provides a site with additional options for managing the behavior of Attachments based on the file format. Since all file formats are downloaded by default, no file formats are shipped. Sites can use the management page to add file formats, identified by their mime type, either by entering their mime-type directly or by using the option to supply a sample file to source the mime-type. See About Integrating Attachments Task Flows into for more information about task flows.

File formats are set to have a state of either Deny, Download, or Open. If you do not want a file format in use on your site, you would add and set a file format to the Deny state using the management page. Subsequently, any attempt to upload a file of that type will be rejected. Any existing files of that file type will still appear in the Attachments UI, but they cannot be downloaded. Instead, an explanatory message will appear when clicking on the file link.

Setting the state to Open will open any file of a specific format when a link is clicked. Clicking on the link for these files will open based on the browser's settings.

If a file format is in a state of flux, setting the state of that file format to Download will revert it to its default behavior. This eliminates the need of having to delete the file format and re-add at a later time.

Files whose file types are not on the Open state list can still be treated individually as Open when uploaded by users who have been granted the FND_Attachment_File_Trusted_Status (ADFMethodResourceType) permission with the Invoke action. A user with this permission is able to verify that the contents of the file can be opened safely.

19.8.5 About Attachments SaaS

Software as a Service (SaaS) support has been added for Oracle Fusion attachments to ensure that the attachments belonging to organizations using the same environment are all kept completely separate to each other.

19.9 Understanding How to Use Attachments (Runtime)

This section discusses how to use Attachments file-level security, update attachments, use the Attachments update functions, and how to check file attachments out and in.

19.9.1 About Using Attachments File-Level Security

With Oracle Fusion Applications attachments, users have the ability to set attachments to be either Shared or Not Shared using the Shared option, as shown in Figure 19-28.
The Shared column is only shown in the Attachments table when the repositoryMode property is set to true. The default state for this option is Not Shared for both Text and File type attachments.

**Note:**

The option is not available for all URL and Folder type attachments, as shown in Figure 19-28. By default, all Folder type attachments are shared, and all URL type attachments are not shared. Therefore, the check box is hidden because these default values cannot be changed by the user.

All repository File or Folder attachments are shared by default. This is because only shared files are visible in the Document Picker, which is used to select the Repository Files or Folders.

If the user hovers the mouse pointer over the Shared check box, the following hint displays: Checking this box will make this file available to other users.

If the user attempts to change a File type attachment from Shared to Not Shared, the system checks to see if the file is attached to any other business object instances. If the file is attached to other business object instances, the following message is displayed and the file attachment remains shared: This change cannot be made as this file is attached to other business objects.

### 19.9.2 About Updating Attachments

Users have the ability to update attachments within the Attachments table or popup. As well as being able to update the category, title, and description of an attachment, users can update existing URL and Text attachments and replace the file of existing File attachments with a new version of the file.

**Note:**

Only one attachment can be updated at any one time.
The updateAllowed and repositoryMode properties on the Attachments component, and the Checked Out status of the Content Repository files, control how the update functionality works for a particular user.

19.9.2.1 About Attachments Update Functions

The Attachments update functions are available in the Attachments table toolbar and Actions menu.

The rendering of the update buttons in the Attachments table toolbar and the corresponding actions in the Actions menu are controlled in the following way using the updateAllowed property on the Attachments component:

updateAllowed = true:

- The Category, Title, and Description columns in the Attachments table are updateable.

  The title and description values are kept in sync with the corresponding values stored in the Content Server. When a user updates the title or description, the values are updated in the Content server when the changes are saved.

- If repositoryMode = true:
  - The Check In, Check Out, and Cancel Check Out buttons are rendered in the Attachments table toolbar, as shown in Figure 19-29.

These buttons are enabled or disabled based on the type of attachment and the checked out status of File and Text type attachments.

Figure 19-29 Attachment Table with Update Functions set to True

<table>
<thead>
<tr>
<th>Icon</th>
<th>Function</th>
<th>File</th>
<th>Property</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="versioncheckout_ena.png" alt="Check Out" /></td>
<td>Check Out</td>
<td>versioncheckout_ena.png</td>
<td>repositoryMode = true</td>
</tr>
<tr>
<td><img src="versioncheckin_ena.png" alt="Check In" /></td>
<td>Check In</td>
<td>versioncheckin_ena.png</td>
<td>repositoryMode = true</td>
</tr>
<tr>
<td><img src="versionrollback_ena.png" alt="Cancel Check Out" /></td>
<td>Cancel Check Out</td>
<td>versionrollback_ena.png</td>
<td>repositoryMode = true</td>
</tr>
</tbody>
</table>
• If repositoryMode = false:
  – The Check In, Check Out, and Cancel Check Out buttons are not rendered in the Attachments table toolbar.

  **Figure 19-30  Attachment Table with Update Functions set to False**

![Attachment Table](image)

updateAllowed = false:

• None of the fields in the table are updateable when this property is set to false.

• If repositoryMode = true:
  – The Check In, Check Out, and Cancel Check Out buttons are rendered and disabled in the Attachments Table toolbar.

• If repositoryMode = false:
  – The Check In, Check Out, and Cancel Check Out buttons are not rendered in the Attachments table toolbar.

19.9.2.2 Understanding How to Determine the Checked Out Status of File and Text-Type Attachments

The Checked Out By column indicates the checked-out status in the Attachments table. This column is only rendered when the repositoryMode is set to true.

This column is always empty for URL and Folder type attachments. For File and Text attachments, this column is either:

• Empty, indicating that the file is not checked out.

• Displays the Oracle Fusion Applications username of the user who currently has the file checked out.

The user name is derived from the Checked Out By value that is stored against the file in the Content server. The stored Content Server username is mapped to the appropriate Oracle Fusion Applications username. If the value cannot be mapped, the Content server username is displayed in the column. This value is never stored in the Attachments Table.
19.9.2.3 About Enabling or Disabling Attachments Update Functions

The update functions apply to a single selected row in the Attachments table. If no rows are selected or more than one row is selected in the Attachments table, all of the update buttons and the corresponding actions in the Actions menu are disabled.

When a single row is selected in the Attachments table, the enabling or disabling of the update buttons in the Attachments table toolbar and the corresponding actions in the Actions menu are controlled using the following rules when the `updateAllowed` property is set to true:

**URL attachments**

The following rules apply regardless of the `repositoryMode` value:

- The Category, Title, and Description fields are updateable.
- The Check Out, Check In, and Cancel Check Out functions are always disabled.

**Folder attachments**

If `repositoryMode = true`:

- The Category, Title, and Description fields are updateable.
- All of the update functions are disabled.

**Text and File attachments**

If `repositoryMode = true`:

- The Category, Title, and Description fields are updateable.
- All of the update functions are disabled when the file is checked out by a user other than the current user.
- The Check Out function is disabled, and the Check In, and Cancel Check Out functions are enabled when the file is checked out by the current user.
- The Check Out function is enabled, and the Check In and Cancel Check Out functions are disabled when the file is not checked out.

19.9.3 How to Check Out and Check In File Attachments

This section describes how to check out and check in file attachments.

To check out and check in file attachments, do the following:

1. Highlight the File attachment in the Attachments table. Click the Check Out button located on the toolbar.

   The file is immediately checked out in the Content Repository. The Checked Out By column is updated to show your user name.

   **Tip:**
   
   Clicking the Cancel Check Out button cancels the check out without making any updates to the file. The check out is cancelled immediately in the Content Repository.

2. Go to your local file system and make the necessary updates to this file.
3. Return to the Attachments table and highlight the checked out file. Click the **Check In** button located on the toolbar to open the Check In File dialog, as shown in Figure 19-31.

![Figure 19-31 Check In File Dialog](image)

4. Click **Browse** to browse your local file system. Select the updated file that you want to upload.

5. Click **OK** to save your changes and close the dialog.

   The selected file is uploaded to the content server. The **Checked Out By** column is cleared.

6. Click **Save** on the Attachments Table page to commit your transaction.

   **Tip:**

   If you cancel the entire transaction, the checked out status returns to the state that it was in before the transaction took place.
This chapter describes how to create, edit, and delete tree structures, trees, and tree versions, and how to develop applications using trees.

The chapter includes the following sections:

- Introduction to Trees
- About Configuring the Trees Application Launch Page
- Working with Tree Structures
- Working with Trees
- Working with Tree Versions
- Managing Labels in the Generic Label Data Source
- About Using the Applications Hierarchy Component to Develop Applications
- About Integrating Custom Task Flows into the Applications Hierarchy Component
- About Using the fnd:hierarchy Property Inspector to Specify Tree Versions
- About Using the Expression Builder to Bind TreeCode, TreeStructureCode, and TreeVersionId Properties
- Embedding the Tree Picker Component in a User Interface
- About Setting Bind Variables and View Criteria
- About Using Service APIs to Manage Trees
- Advanced Topics

20.1 Introduction to Trees

Oracle Fusion tree management allows data in applications to be organized into a hierarchical fashion, and allows you to create tree hierarchies based on specific data.

Here are some of the advantages of how using tree hierarchies to develop applications can help you:

- *Reusable code* that results in a one-time-only implementation of many tree-management features, and can be used immediately by every type of application hierarchy.
• Open metadata that can be read by any application that needs to use tree-management hierarchies. This does the following:
  – Minimizes the number of application programming interfaces (APIs) that need to be written for accessing hierarchies
  – Allows the sharing and understanding of hierarchies across multiple applications
  – Allows the sharing of hierarchies with Oracle Business Intelligence reporting and analytics systems

• Tree structures that capture the business rules the data must adhere to.

• ADF Business Components view objects that are used as data sources, eliminating the need to build new types of data sources.

• Hierarchical relationships between entities that are external to the entity itself, allowing multiple hierarchical views to be implemented for the same set of entities. Each of these hierarchies can be used to implement a different business function.

• Data flattening that improves query performance against the hierarchical data, especially for hierarchical queries such as roll-up queries.

• Business events that can be consumed by any application requiring additional processing on specific tree operations.

• Tree and node-level access control that eliminates the need for product teams to write their own access-control code.

• Well-defined APIs available for metadata and data that make it easy for the Oracle Fusion Upgrade Office to write migration tools for existing hierarchies in E-Business Suite, PeopleSoft, and Siebel.

As a developer, you will work mostly with tree structures. The task of working with trees and tree versions normally will fall to customers. However, since you probably also will be required to work with trees and tree versions, both types of tasks are described in this chapter.

20.1.1 Understanding Tree Structures, Trees, and Tree Versions

A tree structure is a way of describing a hierarchy. A tree is an instance of this hierarchy. Every tree structure contains a tree. Trees may have one or more versions. Each tree version contains at least one root node; that is, a member that has no superior. (Occasionally, a tree version may have more than one root node.) The lines connecting elements in a tree structure are branches; the elements themselves are nodes.

The names of relationships are modeled after family relations:

• A node is a parent of another node if it is one step higher in the hierarchy and closer to the root node.

• Sibling nodes share the same parent node.

For example, in the following picture, XYZ Corp. is the parent of Marketing and Finance, which are its children. Accounts Receivable and Accounts Payable are siblings, and are the children of Finance.
In Oracle Fusion tree management, a tree structure defines a group of common business rules for a family of trees, for example, Department, Account, or Project, and allows an application to select and enable a subset of trees to fulfill a specific purpose in that application.

A tree contains data that is organized in a hierarchy, allowing the creation of groupings and rollups of information that already exist within an organization. A tree can have one or more tree versions. Typically, when changes are made to an existing tree, a new version is created and published.

A tree structure data source supplies the data for a tree through its nodes. Multiple data sources can be associated with a tree structure and can have well-defined relationships among them. Using the example in the previous picture, the Accounts Receivable data source is a child of the Finance data source. Data sources also support business rules that define how the data from a data source participates in a tree.

The following table lists other commonly used tree terms and their descriptions.

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Depth</td>
<td>The depth of a node is the length of the path from the root to the node. The root node is at depth zero.</td>
</tr>
</tbody>
</table>
| Label          | Allows for a storage of "tags" that can be used on each tree node in a tree. There are three labeling schemes:  
                 | • Level - Labels that are automatically assigned based on the data source that the tree node belongs to. A level label points to a specific data source.  
                 | • Group - Labels that a user can assign to tree nodes arbitrarily.  
                 | • Depth - Labels that are automatically assigned based on the depth of the tree node within the tree. No manual assignment is performed. Note that in an unbalanced hierarchy, a level may not be equal to depth.  
                 | Labels can be stored in any table and the label data source is registered with the tree structure. |
| Tree label     | When a labeling scheme is used for trees, the selected labels are stored in the tree label entity and each tree node references a tree label. See "Label." |
| Node           | A logical term that refers to the actual data, whatever that may be. Technically, the node may be stored either in a product-specific table or in an entity that has been established by the Tree Management solution as the default storage mechanism. However, since all data in Oracle Applications usually already has a storage home, only customers should store the node in an entity. |
| Tree node      | A node that is included in a tree. |

Figure 20-1 Example of a Tree

XYZ Corp.

</tr>
<tr>
<td></td>
<td>future effective dates when reporting on current or historic data.</td>
</tr>
<tr>
<td>Reference data set</td>
<td>A value that determines which reference data set will be used for each reference data object.</td>
</tr>
<tr>
<td>determinant (external)</td>
<td>Business units, regulatory regions, and reference data sets all can determine which reference data sets</td>
</tr>
<tr>
<td></td>
<td>are valid for the creation of a transaction or reference data object.</td>
</tr>
<tr>
<td>Audit</td>
<td>A process that runs a series of tests against tree metadata and tree data to validate its integrity.</td>
</tr>
</tbody>
</table>

20.2 About Configuring the Trees Application Launch Page

Before you can manage tree structures, trees, and tree versions using the web-browser-based trees application, you must create the application launch page in Oracle JDeveloper. The launch page contains links to the Tree Structures, Trees and Tree Versions, and Manage Labels applications, which contain the management task flows you will use.
You also will need to perform additional steps that are required to schedule the concurrent processes that the trees application uses for audit and flattening.

**Before you begin:**
Create an application initialized for use with Oracle Middleware Extensions for Applications. For more information, see Chapter 2, "Setting Up Your Development Environment."

### 20.2.1 How to Create the Launch Page

To create the launch page, do the following:

1. Configure a UIShell launcher page for your ViewController project using the procedure described in Populating a UI Shell.

2. Add a taskflow entry in the ADF menu as a node with the following properties:
   - **focusViewId** - /jspx file
   - **id** - tree_<jspx file>
   - **Label** - Trees and Tree Versions
   - **Task Type** - dynamicMain
   - **taskFlowId** - /WEB-INF/oracle/apps/fnd/applcore/trees/ui/taskflow/TreeStructureSummary.xml#TreeStructureSummary

3. Repeat Steps 1 and 2 to create a second itemNode with the following properties:
   - **focusViewId** - /jspx file
   - **id** - tree_<jspx file>
   - **label** - Trees and Tree Versions
   - **Task Type** - dynamicMain
   - **taskFlowId** - /WEB-INF/oracle/apps/fnd/applcore/trees/ui/taskflow/TreeSummary.xml#TreeSummary

4. Repeat Steps 1 and 2 to create a third itemNode with the following properties:
   - **focusViewId** - /jspx file
   - **id** - tree_<jspx file>
   - **label** - Manage Labels
   - **Task Type** - dynamicMain
   - **taskFlowId** - /WEB-INF/oracle/apps/fnd/applcore/trees/ui/taskflow/FndLabelSummary.xml#FndLabelSummary

5. Ensure you have an itemNode for defaultRegional. If you do not, define one with the following properties:
   - **focusViewId** - /jspx file
   - **id** - __<jspx file>_itemNode__FndTasksList
Note:
Use double underscores where indicated.

- **label** - #{applcoreBundle.TASKS}
- **Task Type** - defaultRegional
- **taskFlowId** - /WEB-INF/oracle/apps/fnd/applcore/patterns/uishell/ui/publicFlow/TasksList.xml#TasksList
- **Disclosed** - true

6. Click **OK** in the Set Run Configuration window.

The trees application launch page opens in a browser window, as shown in the following picture.

**Figure 20-2   Trees Application Launch Page**

7. Do one of the following:

   - Click the **Tree Structures** link to open the Tree Structure summary page.
   - Click the **Trees and Tree Versions** link to open the Trees summary page.
   - Click the **Central Labels** link to open the Central Labels summary page.
   - Click the **Trees Picker** link to open the Trees Picker application.

The following picture shows the launch page with all applications open, and the Tree Structure application's summary page displayed.
20.3 Working with Tree Structures

Tree Structures define hierarchical relationships between information stored in one or more data sources. Working with tree structures includes the following tasks:

- Managing tree structure data sources
- Specifying data source parameters
- Searching for, creating, duplicating, editing, or deleting tree structures
- Setting tree structure status
- Auditing tree structures.

A flag named \texttt{PROTECTED\_FLAG} is available for the tree structures. By default, this flag is set to \texttt{N}. If you set this flag to \texttt{Y}, you cannot modify the tree structure. When you want to protect a tree structure from being updated, you can set this flag to Yes. A protected tree structure can be modified or deleted only by the \texttt{SEED\_DATA\_FROM\_APPLICATION} user.

You can create an exclusion list and tree structures to that list. Any tree structure that is a part of the exclusion list will not be considered for export. The tree structures which have been excluded can be populated by writing an SQL statement.

20.3.1 About Managing Tree Structure Data Sources

Tree structure data sources provide the data items for a hierarchy. In the tree-management infrastructure, these are ADF Business Components view objects. You should define view objects for all the intended data sources before setting up a tree structure. For each view object attribute that is to be displayed in the hierarchy column
of an ADF Faces Tree or ADF Faces TreeTable, the Application property 
HierarchyDisplay is set to true.

Figure 20-4 View Object Attributes: HierarchyDisplay Property

Tree management provides a generic data source for holding nodes: 
oracle.apps.fnd.applcore.trees.model.view.FndNodeVO. This data source 
may be used for tree-only nodes, that is, nodes that do not exist in any other entity in 
the system. Likewise, a generic label data source has also been provided: 
oracle.apps.fnd.applcore.trees.model.view.FndLabelVO.

20.3.2 About Specifying Data Source Parameters

Tree data sources have optional data source parameters with defined view criteria and 
associated bind variables. You can specify view criteria as a data source parameter 
when creating a tree structure, and edit the parameters when creating a tree.

Note:

Parameter values customized at the tree level will override the default values 
specified at the tree-structure level.

The parameters will be applied when performing node operations, and the display of 
the nodes in the hierarchy, for any tree version under that data source. Data source 
parameters also provide an additional level of filtering for different tree structures.

Tree management supports three data source parameter types:

- VIEW_CRITERIA - Used to capture the view criteria name, which will be applied 
to the data source view object
- BOUND_VALUE - Used to capture any bound value, which will be used as part 
of the view criteria condition
- VARIABLE - Used to capture and bind variable that is being used by the data 
source view object, particularly for WHERE clause support

In addition to parameter values provided by the customer, tree management provides 
support for those special parameters whose values for any bind variable are seeded at 
runtime by tree management.

For example, to use the effectiveStartDate attribute of a tree version that a data source 
uses as one of the bind variables from which the value for the effectiveStartDate bind
variable will be retrieved from the trees effective start date, you can specify a data source parameter `effectiveStartDate` with the value 
`#{treeVersion.effectiveStartDate}`. You would then need to expose an `effectiveStartDate` bind variable for the data source view object either in view criteria or a WHERE clause.

You can specify parameters using the syntax for value and name shown in the following table.

**Table 20-2 Parameter Syntax**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tree Structure</td>
<td><code>#{treeStructure.ATTR_NAME_WITH_FIRSTCHAR_IN_LOWER_CASE}</code> For example, <code>#{treeStructure.treeStructureCode}</code>.</td>
</tr>
<tr>
<td>Tree</td>
<td><code>#{tree.ATTR_NAME_WITH_FIRSTCHAR_IN_LOWER_CASE}</code> For example, <code>#{tree.treeCode}</code>.</td>
</tr>
<tr>
<td>Tree Version</td>
<td><code>#{treeVersion.ATTR_NAME_WITH_FIRSTCHAR_IN_LOWER_CASE}</code> For example, <code>#{treeVersion.treeVersionId}</code>.</td>
</tr>
</tbody>
</table>

**Note:**

Binding parameters are supported for String, Number, and Date data types only.

In 11gR1, tree management does not support View Criteria and Variable when used in combination, or multiple View Criteria as data source parameters.

### 20.3.2.1 About Implementing Use Cases

This section includes an example use case and discusses basic use cases and their settings.

**20.3.2.1.1 Example Use Case**

The data source DemoEmpVO has the view criteria DemoEmpVC1, which is based on the bound values DemoEmpBV1 and DemoEmpBV2. These are to be applied to the data source view object for tree versions under the DEMO_EMP_TS tree structure, with varying bound values DemoEmpBV1 and DemoEmpBV2 for trees under this tree structure.

When creating the tree structure FND_DEMO_EMP_TS, the following parameters must be added to the tree structure data source that corresponds to DemoEmpVO:

- Parameter name: `VIEW_CRITERIA_NAME`
- Parameter type: View Criteria
- Parameter value: `<name of the view criteria to be applied>`, in this case DemoEmpVC1

The following two bindings also must be added:

- Parameter names: DemoEmpBV1 and DemoEmpBV2
- Parameter type: Bound Value
Parameter value: `<actual value, which can be overridden at tree level>`

Note:
Binding parameters are supported for String and Number data types only.

20.3.2.1.2 Basic Use Cases and Their Settings
The following are examples of use cases and settings that you can implement using the parameter infrastructure for tree structure data sources.

Data source having a view criteria defined with a bind variable:

*Figure 20-5  View Object Setup Wizard*
Data source has a WHERE clause using a bind variable:

![Figure 20-6  Parameters in Data Source Parameter UI](image1)

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Parameter Type</th>
<th>Parameter Value</th>
<th>Mandatory</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeptNoBV</td>
<td>Bind Variable</td>
<td>10</td>
<td></td>
</tr>
<tr>
<td>VIEW_Criteria_NAME</td>
<td>View Criteria</td>
<td>ParamVOEmpWO</td>
<td></td>
</tr>
</tbody>
</table>

![Figure 20-7  View Object Setup Wizard](image2)
Figure 20-8 Parameters in Data Source Parameter UI

Data source has a view criteria defined with a bind variable for special parameters:

Figure 20-9 View Object Setup Wizard (View Criteria)
Data source has a WHERE clause using a bind variable for special parameters:

**Figure 20-11  View Object Setup Wizard (WHERE Clause)**
20.3.3 How to Search for a Tree Structure

If you wish to duplicate, edit, or delete an existing tree structure and it is not currently visible in the results list, you can search for it using the following procedure. The procedure assumes that the Tree Structure summary page is open in your web browser.

To search for an existing tree structure, do the following:

1. In the Search area of the page, construct a search using any or all of the following search criteria:
   - Code
   - Name
   - Status

2. Click **Search**.

   All tree structures matching your search criteria appear in the Results area of the page.

   Click **Advanced** to perform an advanced search by specifying additional options for search. You also can save your search criteria for future use.

20.3.4 About Using the Search Field

Throughout the trees application you will see a search field located to the right of many field names, as shown in the following picture.

![Search Field](Image)

Click the down arrow to display a dropdown list that contains the available values for that field. You can select from the list, or search for other values. For example, the following picture shows the dropdown list that displays when you click the down arrow associated with the **Application** search field found on the Create Tree Structure: Specify Definition page.
From each search field dropdown list, you can do one of the following:

- Select a value from the list that displays.
- Click the **Search** link to search for a value that does not exist in the list.

If you select a value from the list, the dropdown list closes and that value appears in the search field.

If you click the **Search** link, a search-and-select window similar to the one shown in the following picture opens:
You now can search for a value and then click OK to select it.

20.3.5 How to Create a Tree Structure

The following procedure explains how to create a new tree structure. The procedure assumes that the Tree Structure summary page is open in your web browser.

To create a tree structure, do the following:

1. Click the Create icon, or choose Create from the Actions dropdown menu.

   The Create Tree Structure: Specify Definition page, shown in the following picture, opens.

   ![Create Tree Structure: Specify Definition Page (1)]

2. Enter a code for the tree structure.

   The code can be any combination of alphanumeric characters, but cannot contain more than 30 characters. Codes are used in APIs to work with trees, and uniquely identify the tree structure metadata. You cannot create a tree structure with ORA_ as prefix in code. ORA_ is a reserved word.

3. Enter a name for the tree structure.

   The name is a user-friendly name for a tree structure. It appears only in graphical user interfaces (GUIs), and cannot contain more than 80 characters.

4. Enter the name of an appropriate application, or click the down arrow to select or search for one.

5. Enter a description.

6. Enter the name of an appropriate tree node table, or click the down arrow to select or search for one.
If you enter the name of a custom tree node table or select a tree node table other than the FND_TREE_NODE default, the page re-displays with a new (optional) field asking you to enter a view object definition name for that custom tree node table. This field is shown in the following picture.

**Figure 20-17  Create Tree Structure: Specify Definition Page (2)**

7. Select a tree-sharing method.
   - **Open** - indicates that the tree will be associated with all Set IDs
   - **Set ID** - indicates that the tree will be associated with a specific Set ID.

8. Select a creation mode:
   - **Customer** - indicates that the customer is creating the tree structure
   - **Oracle** - indicates that an Oracle developer is creating the tree structure.

9. Select **Customizable** if the tree structure can be customized by the customer.

10. Select **Allow Multiple Active Tree Versions** to allow two or more tree versions to be in an ACTIVE state for the same date range.

11. Select a versioning type for editing tree versions to specify whether the user is allowed to edit an active tree version or must create a new one.

12. Click **Next**.

   The Create Tree Structure: Data Sources page, shown in the following picture, opens.
13. Select a labeling scheme:

- **None** - Specifies that no labeling scheme will be used.
- **Level based** - Specifies a label that points to a specific data source.
- **Group based** - Specifies a label that the user can assign arbitrarily.
- **Depth based** - Specifies a label that the depth-from-top parent decides to display. No manual assignment is performed.

If you choose a level-based, depth-based, or group-based labeling scheme, the Labeling Scheme area of the page changes, displaying additional options, as shown in the following picture.

**Figure 20-19  Additional Labeling Scheme Options**

14. Select any or all of the following:

- **Date Range** - Specifies whether a selection of nodes should be restricted to the same date range as the tree version.
- **Allow Multiple Root Nodes** - Allows you to add multiple root nodes when creating a tree version.
- **Set ID** - Specifies whether a selection of nodes should be restricted to the same set as the tree. (All versions belong to the same set.)
- **Allow Ragged Nodes** (for Labeling Schemes Level based, Depth based, or Group based only) - Specifies whether a hierarchy can be unbalanced; that is, if
it can contain nodes that are not leaf nodes and contain no children. In the
following picture, "ICs" does not have any children, making its rooted path
shorter than all the others in the hierarchy.

**Figure 20-20  Example of a Ragged Hierarchy**

- **Allow Skip-Level Nodes** (for Labeling Schemes Level based, Depth based, or
  Group based only) - Specifies whether a hierarchy can have two nodes at the
  same level with parent nodes at different levels. In Figure 20-21, Washington,
  DC, does not have a node at the State level.

**Figure 20-21  Example of a Skip-Level Hierarchy**

- **Optional Label Enforcement** - Specifies whether label is enforced in the audit
  of the tree structure. By default, this option is not selected and specifying a
  label data source is enforced while adding a data source for the tree structure.
  Alternatively, if this option is selected, **Label Data Source** in the Add Data
  Source page is not an optional field.

15. Click the **Add** icon.

The Add Data Source window, shown in the following picture opens.

**Figure 20-22  Add Data Source Window**
If you chose a level-based, depth-based, or group-based labeling scheme, the top portion of the page changes, displaying an additional Label Data Source field, as shown in the following picture. The Label Data Source will be optional if Optional Label Enforcement option is selected, else this is a mandatory field.

Figure 20-23 Additional Add Data Source Field

16. Enter the name of the view object.

17. Optionally, enter a name.

18. If you do not enter a name, the same name as that of the view object is copied to this field and is used.

19. Select a maximum depth value from the dropdown list.

   Maximum depth specifies how many levels are allowed. For example, in Project[max depth=2] > Task[max depth=infinite], one project, one sub-project, and an infinite number of tasks are allowed.

20. Enter the name of the label data source (for Level based, Depth based, or Group based labeling schemes only).

   The view object oracle.apps.fnd.applcore.trees.model.view.FndLabelVO can be used as an ad-hoc label data source. For more information about label data sources, see Managing Labels in the Generic Label Data Source.

21. Select any or all of the following:

   - Use non defined primary key columns - indicates that you can specify other attributes as primary key columns. If not selected, existing primary keys defined as primary key columns for a data source view object will be used.

     If selected, the additional fields shown in the following picture display.

     Figure 20-24 Primary Key Columns

     - Allow use as leaves - indicates that data from the data source can form a leaf

     - Allow duplicates - indicates that a data item can exist multiple times in the same hierarchy. For example, in an "Item" hierarchy for an automobile, a particular bolt may appear multiple times in the hierarchy.

     - Use as free node - indicates that this node can be used as a free node.
• Select a Usage Limit:

  – **None** - Specifies that there are no restrictions.
  
  – **Use all values** - Specifies that all available nodes must be included in the tree version.
  
  – Select a Child Definition:

• **Allow range children** - indicates that the hierarchy supports nodes that are a range of values.

• **Allow linked foreign key children** - indicates that the relationship is external to Tree Management.

If you select this option, you also can select a **View Link Accessor** value from the dropdown list that displays, as shown in the following picture.

*Figure 20-25  View Link Accessor Dropdown List*

22. Click **Add** under **Data Source Parameters**.

The window now displays data source parameters text-entry fields, as shown in the following picture.

*Figure 20-26  Data Source Parameters Text-Entry Fields*

23. Enter a parameter, select a parameter type, and enter a value.
When specified, a parameter applies to every version under that tree. Parameter values also can be overridden at the tree level. For more information, see About Specifying Data Source Parameters.

24. Select Mandatory if the parameter is to be required.

25. Click OK.

The Create Tree Structure: Specify Data Sources page refreshes, displaying the view object, as shown in the following picture.

*Figure 20-27  Create Tree Structure: Specify Data Sources Page with View Object*

26. Click Next.

The Create Tree Structure: Specify Performance Options page opens, as shown in the following picture.
27. Enter the name of an appropriate row-flattened table or click the down arrow to select or search for one.

28. Enter the name of an appropriate column-flattened table or click the down arrow to select or search for one.

29. Enter the name of an appropriate column-flattened entity object if the field does not already contain one.

30. Enter the name of an appropriate BI View Object.

31. Click Next.

   The Create Tree Structure: Specify Access Rules page opens.

   **Note:**

   The Create Tree Structure: Specify Access Rules page is not yet implemented.

32. Click Submit.

33. Click OK to close the Confirmation window.

   The Create Tree Structure Confirmation Window opens, as shown in the following picture.

   **Figure 20-29  Create Tree Structure Confirmation Window**

20.3.6 How to Duplicate a Tree Structure

Duplicating a tree structure simply copies the metadata definition from an existing tree structure to the duplicate. This operation does not copy the underlying tree and tree versions defined for the source tree structure.
To duplicate a tree structure, do the following:

1. Select the tree structure you want to duplicate.

   See How to Search for a Tree Structure, if the tree structure you want to duplicate is not in the current Results list.

2. Click the Duplicate icon, or choose Duplicate from the Actions dropdown menu.

   The Create Tree Structure window opens, as shown in the following picture:

   ![Create Tree Structure Window](image)

3. Enter a new name for the duplicate tree structure if you want to replace the name that already displays in the field.

4. Enter a duplicate tree structure code if you want to replace the code that already displays in the field.

5. Click Save and Close to create the duplicate.

### 20.3.7 How to Edit a Tree Structure

When you edit an existing tree structure, you simply step through many of the same pages you used to create a tree structure.

To edit an existing tree structure, do the following:

1. Select the tree structure you want to edit.

   See How to Search for a Tree Structure, if the tree structure you want to duplicate is not in the current Results list.

2. Do one of the following:

   - Click the Edit icon.
   - Choose Edit from the Actions dropdown menu.
   - Click the tree-structure name.

3. Edit the appropriate data on the Edit Tree Structure: Specify Definition page.

4. Click Next.

5. Do any of the following:

   - Edit the data on the Edit Tree Structure: Specify Data Sources page.
   - Click Add to add another view object.
• Select an existing view object and click **Edit** to edit it.
• Select an existing view object and click the Delete icon to delete it.

6. Click **Next**.

7. Edit the appropriate data on the Edit Tree Structure: Specify Performance Options page.

8. Click **Next**.

   The Edit Tree Structure: Specify Access Rules page opens.

   **Note:**
   The Edit Tree Structure: Specify Access Rules page is not yet implemented.

9. Click **Submit**.

10. Click **OK** to close the Confirmation window.

**20.3.8 How to Delete a Tree Structure**

Deleting a tree structure also deletes all associated tree and tree versions defined under that specific tree structure.

To delete a tree structure, do the following:

1. Select the tree structure you want to delete.

   See **How to Search for a Tree Structure**, if the tree structure you want to delete is not in the current Results list.

2. Click **Delete**, or choose **Delete** from the **Actions** dropdown menu.

   The Delete Tree Structure warning window opens, as shown in the following picture:

   **Figure 20-31  Delete Tree Structure Warning Window**

3. Do one of the following:

   • Click **No** to cancel the operation.
   • Click **Yes** to delete the tree structure.

**20.3.9 How to Set Tree Structure Status**

Changing the status of a tree structure also changes the status of the trees and tree versions contained in that tree structure. You can set the status of a tree structure to any one of the following:
• Draft
• Active
• Inactive

Setting a tree structure's status to Active automatically triggers an audit of that tree structure. See the following section for more information about auditing.

To set the status of a tree structure, do the following:

1. Select a tree structure.
   See How to Search for a Tree Structure, if the tree structure is not in the current Results list.

2. Choose the appropriate status option from the Actions > Set Status dropdown menu.

3. Click OK to close the Warning window. The Warning window appears only when you want to set the status as Draft or Inactive.

4. Click OK to close the Confirmation window.

20.3.10 About Auditing a Tree Structure

Auditing tree-structure metadata verifies that it conforms to all rules and ensures data integrity. Running an audit allows you to view audit details and messages, and to correct any validation errors that the audit detects.

Setting a tree structure's status to Active automatically triggers an audit of that tree structure. You also can audit a tree structure manually.

The following table describes what each validator checks for, as well as possible reasons why each validator might fail.

<table>
<thead>
<tr>
<th>Table 20-3 Validator Descriptions</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Validator</th>
<th>Checks for...</th>
<th>Validation may have failed because...</th>
<th>To correct...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Restrict by SetID Validator</td>
<td>If the tree structure has Restrict Tree Node List of Values Based on SetID flag set to Yes, each of its data source view objects must have a SetID attribute. This restriction does not apply when the flag is set to No.</td>
<td>The tree structure has Restrict Tree Node List of Values Based on SetID flag = Y, but one or more of its data source view objects do not contain a SetID attribute.</td>
<td>Consult the owning developer. If SetID restriction is desired for this tree structure, ensure your developer has included a SetID attribute on all data sources. If SetID restriction is not desired, ensure your developer sets the flag to No.</td>
</tr>
<tr>
<td>Validator</td>
<td>Checks for...</td>
<td>Validation may have failed because...</td>
<td>To correct...</td>
</tr>
<tr>
<td>-----------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Row Flattened Table Name Validator | A valid "Row Flattened Table" should be specified for the tree structure on the "Specify Performance Options" page. It can be the standard row flattened table FND_TREE_NODE_RF, or a custom table can be specified.                                                                 | • No table is specified in "Row Flattened Table" on the "Specify Performance Options" page of the Manage Tree Structures UI.  
• The specified table does not exist in the database.  
• The specified table does not contain the same columns that FND_TREE_NODE_RF table contains.                                                                                             | Consult the owning developer to correct the row flattened table definition.                                                                                                                                                                                      |
| Available Label Data Sources Validator | If the tree structure has a Labeling Scheme specified, the label data source view object specified for each data source must be accessible and the primary keys must be valid.  
This restriction does not apply when the Labeling Scheme has been set to None.                                                                                                               | • Any of the specified label data source view objects do not exist.  
• Any of the specified label data source view objects do not have primary keys.  
• At the time a label data source view object is initially defined, the backend registers the primary keys for the view object at that time. If the view object is later modified such that its primary keys no longer match the primary keys that were registered earlier, this validator will fail.  
• Consult the owning developer to correct the label data source view object specified.  
• Consult the owning developer to correct the primary keys of the label data source view object specified.  
• Consult the owning developer to either correct the primary keys in the label data source view object to match the primary keys that were earlier registered in FND_TS_DATA_SOURCE, or correct the primary keys registered in that table to match the new view object definition. |
### Table 20-3 (Cont.) Validator Descriptions

<table>
<thead>
<tr>
<th>Validator</th>
<th>Checks for...</th>
<th>Validation may have failed because...</th>
<th>To correct...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Available Data Sources Validator</td>
<td>Each data source view object specified for the tree structure must be accessible and all its primary key attributes should be valid.</td>
<td>• Any of the specified data source view objects do not exist.</td>
<td>• Consult the owning developer to correct the data source view object specified.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• At the time a data source view object is initially defined, the backend registers the primary keys for the view object at that time automatically if “Use non-defined primary key columns” is not selected. If it is selected, the backend registers the primary keys specified explicitly by the user on the Add Data Source page. The validator will fail if the registered primary keys contain any duplicates.</td>
<td>• Consult the owning developer to correct the duplicate column in the registered primary keys.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• “Use non defined primary key columns” is checked in a data source, but the list of specified primary key columns does not match the primary keys defined in the corresponding data source view object.</td>

<tr>
<td><strong>Tree Node Table Name Validator</strong></td>
<td>A valid &quot;Tree Node Table&quot; should be specified for the tree structure on the 'Specify Performance Options' page. It can be the standard row flattened table FND_TREE_NODE, or a custom table can be specified.</td>
<td>No table is specified in &quot;Tree Node Table&quot; field when editing a Tree Structure. The specified table does not exist in the database. The specified table does not contain the same columns that the standard FND_TREE_NODE table contains.</td>
<td>Consult the owning developer to correct the tree node table definition.</td>
</tr>
<tr>
<td><strong>Allow Node Level Security Validator</strong></td>
<td>If &quot;Allow Node Level Security&quot; flag is set to N for the tree structure, the same flag cannot be set to Y on any of its data sources. This is a backend setting that is not viewable through the Manage Tree Structures page.</td>
<td>&quot;Allow Node Level Security&quot; flag is set as No for the tree structure, but one or more associated data sources have that flag set to Yes.</td>
<td>Consult the owning developer to correct the &quot;Allow Node Level Security&quot; flags in the tree structure and/or its data sources.</td>
</tr>
</tbody>
</table>

20.3.10.1 How to Audit a Tree Structure Manually

To edit a tree structure manually, do the following:

1. Select a tree structure.

   See How to Search for a Tree Structure, if the tree structure is not in the current Results list.

2. Choose Audit from the Actions dropdown menu.

   The Tree Structure Audit Result page opens, as shown in the following picture. The table displays a list of validations run against the selected tree structure.
The audit table contains the following columns:

- **Validator Name** - Displays the name of the validator
- **Validation Result** - Displays either a green check mark (success) or a red "X" (failure)
- **Validation Message** - When clicked, displays a validation message and a description
- **Execute Validator** - When clicked, reruns the selected validator.
- **Corrective Action** - When clicked, opens the Edit Tree Structure: Specify Definition page, allowing you to fix a validation error

3. Click **Done** to return to the Tree Structure summary page.

### 20.4 Working with Trees

When you work with trees, you can do any of the following:

- Search
- Create
- Duplicate
- Edit
- Delete

You also can audit trees. For more information, see About Auditing Trees and Tree Versions.

### 20.4.1 How to Search for a Tree

If you wish to duplicate, edit, or delete an existing tree and it is not currently visible in the results list, you can search for it using the following procedure. The procedure assumes that the Tree summary page is open in your web browser.

To search for an existing tree, do the following:

1. In the Search area of the page, construct a search using any or all of the following search criteria:
   - Tree Structure Code
   - Tree Code
• Tree Name

2. Click Search.

All trees matching your search criteria appear in the Results area of the page.

Click Advanced to perform an advanced search by specifying additional options for search. You also can save your search criteria for future use.

20.4.2 How to Create a Tree

The following procedure explains how to create a tree. You will also need to create a tree version with a root node. For more information, see How to Create a Tree Version.

To create a tree, do the following:

1. Click Create, or choose Create Tree from the Actions dropdown menu.

The Create Tree: Specify Definition page opens.

**Figure 20-33  Create Tree: Specify Definition Page**

2. Enter a name for the tree.

3. Enter a code for the tree.

4. Enter a tree-structure name or click the down arrow to select or search for one.

If the tree structure has data sources and parameters defined for it, the Data Source Parameters area also displays, allowing you to edit the parameter values at the tree level.
Note:
Parameter values customized at the tree level will override the default values specified at the tree-structure level.

5. Enter a description of the tree.

6. Enter an image name or click the down arrow to select or search for one.

The image appears in the Preview area.

7. Click Next.

The Create Tree: Specify Labels page displays. The information that appears on the page depends on whether or not a labeling scheme has been selected previously.

*Figure 20-34  Create Tree: Specify Labels - No Labeling Scheme*

If the page shown in Figure 20-34 opens, click Next and skip to Step 11.
If the page shown in Figure 20-35 opens, click Add in the Specify Labels area. The Select and Add: Labels window opens.

**Figure 20-36  Select and Add: Labels Window**

8. Choose a data source from the dropdown list.

9. Select the appropriate available labels and use the arrows to move them back and forth between the Available Labels and Selected Labels areas.

10. Click OK to accept your selections and close the window.

11. Do one of the following:
   - Click Cancel to abort the operation and return to the top-level Manage Trees and Tree Versions page.
   - Click Back to return to the previous page.
   - Click Next to continue to the Create Tree: Specify Access Rules page.

   **Note:**
   The Create Tree: Specify Access Rules page is not yet implemented.

12. Do one of the following:
   - Click Cancel to abort the operation and return to the Manage Trees and Tree Versions page.
   - Click Back to return to the previous page.
   - Click Submit to save the tree without creating a tree version and return to the top-level Manage Trees and Tree Versions page.
   - Click the down arrow next to Submit and select Submit and Add Version to save the tree and begin creating a tree version. For more information, see How to Create a Tree Version.
20.4.3 How to Duplicate a Tree

Duplicating a tree copies only the selected tree. The operation does not copy any of the underlying tree versions.

To duplicate a tree, do the following:

1. Select the tree you wish to duplicate.

   See How to Search for a Tree, if the tree you want to duplicate is not in the current Results list.

2. Click Duplicate, or choose Duplicate from the Actions dropdown menu.

   The Duplicate Tree window opens.

   Figure 20-37  Duplicate Tree Window

3. Enter a duplicate tree code.

4. Do one of the following:

   • Click Cancel to cancel the operation.
   • Click Save and Close to create the duplicate.

5. Click OK to close the Confirmation window.

20.4.4 How to Edit a Tree

When you edit an existing tree, you step through many of the same pages you used to create a tree.

To edit a tree, do the following:

1. Select the tree you wish to edit.

   See How to Search for a Tree, if the tree you want to edit is not in the current Results list.

2. Click Edit, or choose Edit from the Actions dropdown menu.

   The Edit Tree: Specify Definition page opens.

3. Do any of the following:

   • Edit the name of the tree.
   • Edit the description
   • Choose another icon image
   • Edit data-source-parameter values, if this option is available
4. Click **Next**.

The Edit Tree: Specify Labels page opens. The page that displays depends on whether or not the tree structure used while creating the tree has a labeling scheme associated with it.

**Note:**
This procedure assumes that a labeling scheme is present. Skip to Step 6 if the tree you are editing has no labeling scheme associated with it.

5. Do either of the following:
   - Click **Add** to open the Select and Add: Labels window and add a new label. For more information, see *How to Create a Tree*.
   - Select a label and click **Delete** to delete it.

6. Click **Next**.

The Edit Tree: Specify Access Rules page opens.

**Note:**
The Edit Tree: Access Rules page is not yet implemented.

7. Review the data and then do one of the following:
   - Click **Submit** and then click **OK** to close the Confirmation window.
   - Click the arrow to the right of **Submit** and select **Submit and Add Version** from the dropdown list to display the Create Tree Version: Specify Definition page.
     Follow the steps in *How to Create a Tree Version*, to create a new tree version.

### 20.4.5 How to Delete a Tree

When you delete a tree, you also delete the tree versions the tree contains.

To delete a tree, do the following:

1. Select the tree you wish to delete.
   - See *How to Search for a Tree*, if the tree you want to delete is not in the current Results list.

2. Click **Delete**, or choose **Delete** from the **Actions** dropdown menu.

3. Click **Yes** to confirm the deletion.
20.5 Working with Tree Versions

When you work with tree versions, you can do any of the following:

- Search
- Create
- Add nodes to a tree version
- Edit existing nodes
- Drag and drop nodes to move them
- Perform CRUD Operations on Tree Nodes using APIs
- Perform Sub-tree Node Operations using PL/SQL APIs
- Create a new record for a data source
- Duplicate
- Edit
- Delete
- Set tree version status
- Audit tree versions

20.5.1 How to Create a Tree Version

Trees require tree versions. You can create a tree with no tree version, but you must add at least one tree version to the tree after it has been created. You either can create the tree version during the tree-creation process, or by editing an existing tree.

To create a tree version, do the following:

---

**Note:**

This procedure assumes you are editing an existing tree.

---

1. Select the tree to which you want to add a tree version from the list of trees that appears in the Results list.

   See How to Search for a Tree if the tree is not in the current Results list.

2. Do one of the following:

   - Select **Actions > Create Tree Version**.
   - Choose **Create Tree Version** from the **Create** dropdown list

     The Create Tree Version: Specify Definition page opens.
3. Enter a name for the tree version.

4. Enter a description of the tree version.

5. Enter a note, if you have one.

6. Enter an effective start date or click on the calendar icon to select one.

7. Enter an effective end date or click on the calendar icon to select one.

---

**Note:**

Since tree versions are time based, you must select a start date. Selecting an end date is optional.

---

8. Click **Next**.

A tree version with no nodes is created automatically at this point. Procedures for adding nodes to the tree version are described in the following section.

9. Click **OK** to close the Confirmation window.

The Create Tree Version: Specify Nodes page displays.
10. Do one of the following:

- Click **Add** to add a tree node.
- Click **Create** to create a new node in the data source and add it to the hierarchy.

The Add Tree Node window opens.
11. Select a node type:

- **Specific Value** - Indicates that a data source and label will be specified for the node. A data source is required for all labeling schemes. A label is required only if the labeling scheme is set to something other than **None**. If the labeling scheme is **None**, a label is not required. To configure this page's options, see *How to Configure the Add Tree Node: Specific Values*.

- **Values within a range** - Indicates that the node represents a range of values.

**Note:**

This option appears only if **Children Definition: Allow range children** has been selected on the Choose Data Source and Parameters window. If you are adding a root node that you want to specify as range-based node, make sure you have selected **Allow Multiple Root Nodes** for the underlying tree structure on the Create Tree Structure: Data Sources page.
If you select this option, the following window replaces the default Add Tree Node window.

**Figure 20-41  Add Tree Node: Values Within a Range**

![Add Tree Node: Values Within a Range](image)

To configure this page's options, see How to Configure the Add Tree Node: Values Within a Range.

- **Values from referenced hierarchy** - Indicates that the node is a referenced tree node. This option creates a pointer to a tree and node that already exist. Referenced tree nodes do not require a data source and do not allow labeling. If you select this option, the following window replaces the default Add Tree Node window.

**Figure 20-42  Add Tree Node: Referenced Hierarchy**

![Add Tree Node: Referenced Hierarchy](image)

To configure referenced-tree options, see How to Configure the Add Tree Node: Referenced Hierarchy.

12. Click **Save and Close** to add the node(s).

13. Click **Submit** to add the new tree version.

### 20.5.2 About Adding Tree Nodes to a Tree Version

Tree nodes are elements in a tree structure. A tree version must contain at least one root node. If specified, a tree version also can contain multiple root nodes. A node can be the parent of another node if it is one step higher in the hierarchy and closer to the root node.

There are three types of tree nodes:

- Those with specific values
• Those that have a range of values
• Those that have values from a referenced tree

Each type of node has its own configuration options. In addition, you can add tree nodes using a custom Search UI, use drag-and-drop to move nodes once they have been added, and edit existing nodes.

The procedures used to perform these tasks are described in the sections that follow.

### 20.5.2.1 How to Configure the Add Tree Node: Specific Values

The following procedure explains how to configure the Add Tree Node options when the **Specific Value** node type has been selected.

To configure specific values, do the following:

---

**Note:**
This procedure assumes that the Add Tree Node window is open.

---

1. Select a data source.
2. If applicable, select a label.
3. Select an option from the Node Navigator. The navigator enables you to access other available nodes.
4. Select a root node from the Available Nodes list.
5. Click the single Move arrow to move the node to the Selected Nodes area.

---

**Note:**
If the tree structure allows multiple root nodes to be selected, use the single or double Move arrows to move additional nodes.

---

6. Click **Save and Close**.

The Add Tree Node window closes.

The following window shows the root node that has been created. The node name, its description (if any), its label, and the data source details are displayed.
7. Optionally, do one of the following:
   - Highlight the root node and click Add to add a child node, using the same steps listed in this section.
   - Click Create to create a new node in the data source. For more information, see How to Create a Record for a Data Source.

8. Review the data and click Submit.

9. Click OK to close the Confirmation window.

20.5.2.2 How to Configure the Add Tree Node: Values Within a Range

The following procedure explains how to configure the Add Tree Node options when the Values within a range node type has been selected.

To configure values within a range, do the following:

**Note:**

This procedure assumes that the Add Tree Node window is open.

1. Select a data source.

2. Enter a range of values.

3. Click Save and Close.

   The Add Tree Node window closes.
4. Review the data and click Submit.

5. Click OK to close the Confirmation window.

20.5.2.3 How to Configure the Add Tree Node: Referenced Hierarchy

The following procedure explains how to configure the Add Tree Node options when the Values from a referenced hierarchy node type has been selected.

To configure values from a referenced hierarchy, do the following:

**Note:**

This procedure assumes that the Add Tree Node window is open.

This procedure assumes that the Add Tree Node window shown is open.

1. Select a referenced tree.

2. Select a referenced tree version.

**Note:**

The referenced tree and tree version must belong to the same tree structure.

3. Optionally, click the Preview link to ensure you have specified the correct referenced tree version for the selected referenced tree. Confirm the data and click OK to close the window.
4. Click **Save and Close**.

The Add Tree Node window closes and the Create Tree Version: Specify Nodes page refreshes with the referenced-node data.

5. Review the data and click **Submit**.

6. Click **OK** to close the Confirmation window.

**20.5.2.4 About Using Drag-and-Drop to Move Nodes**

Once you have added value-based nodes to a tree version, you can move these nodes around simply by dragging and dropping them.

You can move individual nodes, an entire range of nodes, or an entire referenced node. You cannot, however, move a single node in a range of nodes or a single node in a referenced node.

**20.5.2.5 How to Add a Node Using a Custom Search UI**

If the Search UI is not registered for a data source, the default behavior for all nodes displayed in the Add Tree Node window will be used. However, if you register your own Search UI, it will be used to add and select value nodes instead of the default Search UI.

To add a node using a custom Search UI, do the following:

The procedures for adding a node using a custom Search UI are the same as those found in **About Adding Tree Nodes to a Tree Version**. However, the Add Tree Node window that displays will be the registered custom Search UI rather than the default...
UI. Note that Select Value Nodes has replaced the default Node Navigator, Available Nodes, and Selected Nodes options.

**Figure 20-47  Custom Search UI: Specific Values**

20.5.2.6 How to Edit a Tree Node

You can edit any existing tree node’s details.

To edit a tree node, do the following:

---

**Note:**

This procedure assumes that the Manage Trees and Tree Versions page is open.

---

1. Select a tree version and do one of the following:
   - Click **Edit**.
   - Choose **Edit** from the **Actions** dropdown list.

2. Click **Next** on the Edit Tree Version: Specify Definition page to skip to the Edit Tree Version: Specify Nodes page.

3. Highlight the node you wish to edit and click **Edit**. The Edit Tree Node window.

---

**Note:**

The window opens with the default **Specific value** tree node type selected. You also can edit the node using the other tree node types. For more information, see About Adding Tree Nodes to a Tree Version.
4. Select a data source and click **Edit Node**. The Edit Node window opens.

5. Edit the appropriate details and click **Submit**.

### 20.5.2.7 About Exporting Tree Nodes

You can export all the nodes or selected nodes of a tree version to a CSV file. This export feature helps you in reviewing the tree versions easily, especially when you have a large number of tree nodes.

#### 20.5.2.7.1 How to Export All Nodes in a Tree Version

To export all nodes in a tree version, do the following:

- **Note:**
  
  This procedure assumes that the View Tree Version page is open.

1. Select **Export Nodes** in the **Actions** menu. You can also use the Export Nodes button.
2. All the nodes in a tree version are exported to a CSV file as shown below:

![CSV File for Exporting All Nodes](image)

### 20.5.2.7.2 How to Export the Selected Nodes in a Tree Version

**Note:**

This procedure assumes that the View Tree Version page is open.

1. Select **Export Selected Nodes** in the **Actions** menu.

Select **Export Nodes** in the **Actions** menu. You can also use the Export nodes button.

![Export Selected Nodes in a Tree Version](image)
2. The selected nodes of the selected Tree Version are exported to a CSV file as shown below:

**Figure 20-53 CSV File for Exporting Selected Nodes**

<table>
<thead>
<tr>

</tbody>
</table>

20.5.3 How to Create a Record for a Data Source

You can create a record for a data source "on the fly" and add it to the hierarchy. Doing so calls the custom UI you registered with the data source.

You can create a record either when creating a tree version or when editing an existing one.

To create a new data-source record, do the following:

**Note:**

This procedure assumes the following:

- You are editing an existing tree version
- The tree version does not allow multiple root nodes

1. Select the tree version for which you want to create the record and click **Edit**.
2. Click **Next** to access the Edit Tree Version: Specify Nodes window.
3. Highlight an existing node and click **Create**. The Create Tree Node window displays.

**Figure 20-54 Create Tree Node Window**

4. Select a data source and click **Continue**. The Create New Record window opens.

**Note:**

The actual name of the window depends on the node being created.
5. Enter the appropriate information and click **Submit**.
   The Create Tree Node confirmation window displays.

6. Click **OK** to close the window.

### 20.5.4 How to Duplicate a Tree Version

The following procedure explains how to duplicate a tree version.

To duplicate a tree version, do the following:

1. Select a tree version.
2. Click **Duplicate**, or choose **Duplicate** from the **Actions** dropdown menu.
   The Duplicate Tree Version window opens.

3. Enter a duplicate tree version name.
4. Do one of the following:
• Click **Cancel** to cancel the operation.
• Click **Save and Close** to duplicate the tree version.

5. Click **OK** to close the Confirmation window.

### 20.5.5 How to Edit a Tree Version

The following procedure explains how to edit a tree version.

To edit a tree version, do the following:

1. Select a tree version.

2. Click **Edit**, or choose **Edit** from the **Actions** dropdown menu.

   The Edit Tree Version: Specify Definition page opens.

   ![Edit Tree Version: Specify Definition Page](figure20-58)

3. Use the steps in **How to Create a Tree Version** as a guide to editing the tree version.

### 20.5.6 About Performing CRUD Operations on Tree Nodes Using APIs

This section describes the APIs that allow you to perform *Create, Read, Update, and Delete* (CRUD) operations on the Tree Nodes. These APIs do not commit for each CRUD operation, but give you the control to decide whether to commit or not.

The APIs are listed below:

- **add_value_tree_node**

  This API allows you to add a primary key value based tree node.

**Table 20-4 add_value_tree_node API Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Datatype</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tree_structure_code</td>
<td>Code of the tree structure</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_tree_code</td>
<td>Code of the tree</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>
Table 20-4 (Cont.) *add_value_tree_node* API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>

<td>ID of the tree node</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_commit_flag</td>
<td>Commit flag</td>
<td>VARCHAR2</td>
<td>Optional</td>
</tr>
</tbody>
</table>

Default value is Yes.
If commit flag is passed as "N", the control to commit is handed over to the API call.

*update_tree_node*

This API allows you to update a tree node.

Table 20-8  *update_tree_node* API Parameters

20.5.7 About Performing Sub-tree Node Operations Using PL/SQL APIs

PL/SQL APIs allow you to move, copy, and remove sub-tree nodes. The following are the PL/SQL APIs that allow you to perform the operations:

- **move_sub_tree_node**

  This API allows you to move a given node along with its descendants from one hierarchy version to another hierarchy or within the same hierarchy tree version. The destination hierarchy can belong to same tree code or a different tree code belonging to same tree structure. When move_sub_tree_node operation happens across the hierarchy or within the same hierarchy, flattening logs will be reset to ensure that next run of flattening generates accurate flattening data. A tree node id pointing to details of new subtree in destination hierarchy will be returned.

Table 20-10  move_sub_tree_node API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Datatype</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tree_structure_code</td>
<td>Code of the tree structure</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_tree_code</td>
<td>Code of the tree</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_tree_version_id</td>
<td>ID of the tree version</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_tree_node_id</td>
<td>ID of the tree node</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_dest_parent_tree_node_id</td>
<td>ID of the destination parent tree node</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_dest_tree_version_id</td>
<td>ID of the destination parent tree version</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_dest_tree_code</td>
<td>Destination tree code</td>
<td>VARCHAR2</td>
<td>Mandatory</td>
</tr>
<tr>
<td>p_commit_flag</td>
<td>Commit flag</td>
<td>VARCHAR2</td>
<td>Optional</td>
</tr>
<tr>
<td>x_tree_node_id</td>
<td>ID of the tree node</td>
<td>VARCHAR2</td>
<td>Optional</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Default value is Yes. If commit flag is passed as &quot;N&quot;, the control to commit is handed over to the API call.</td>
</tr>
</tbody>
</table>

- **copy_sub_tree_node**
This API allows you to copy a given node along with its descendants within the same hierarchy tree version. The tree version must allow duplicates for the copy operation to be successful. The destination hierarchy can belong to same tree code or a different tree code belonging to same tree structure. When copy_sub_tree_node operation happens, flattening logs will be reset to ensure that next run of flattening generates accurate flattening data. A tree node id pointing to details of new subtree in destination hierarchy will be returned.

**Table 20-11  copy_sub_tree_node API Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Datatype</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_tree_structure_code</td>
<td>Code of the tree structure</td>

<td>API call.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>x_tree_node_id</td>
<td>ID of the tree node</td>
<td>VARCHAR2</td>
<td>Optional</td>
</tr>
</tbody>
</table>

- **remove_sub_tree_node**

This API allows you to remove a given node along with its descendants from any hierarchy. When remove_sub_tree_node operation happens, all the descendants will be deleted.

**Table 20-12  remove_sub_tree_node API Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Datatype</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>

<tbody>
<tr>
<td>p_commit_flag</td>
<td>Commit flag</td>
<td>VARCHAR2</td>
<td>Optional</td>
</tr>
</tbody>
</table>

Default value is Yes.
If commit flag is passed as "N", the control to commit is handed over to the API call.

20.5.8 How to Set Tree Version Status

Although trees do not have status, tree versions do. You can set tree version status to any one of the following:

- Draft
- Active
- Inactive

To activate a tree version, the tree version’s tree structure must already be in Active status.

Setting a tree version’s status to Active automatically triggers an audit of that tree structure.

To set the status of a tree version, do the following:

1. Select a tree version.
2. Choose the appropriate status option from the Actions > Set Status dropdown menu.
3. Click OK to close the Confirmation window.

20.5.9 About Auditing Trees and Tree Versions

Auditing tree and tree version data verifies that it conforms to all rules and ensures data integrity. Running audits allow you to view audit details and messages, and to correct any validation errors that the audit detects. There are three ways to run an audit:

- Run an immediate audit
- Schedule an audit
- Trigger an audit through a service API

The following table describes what each validator checks for, as well as possible reasons why each validator might fail.
## Table 20-13  Validator Descriptions

<table>
<thead>
<tr>
<th>Validator</th>
<th>Checks for...</th>
<th>Validation may have failed because...</th>
<th>To correct...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Effective Date Validator</td>
<td>The effective start and end dates of the tree version should be valid.</td>
<td>Effective end date is set to a value that is not greater than effective start date.</td>
<td>Modify the effective start and/or end dates so that effective start date falls before effective end date.</td>
</tr>
<tr>
<td>Root Node Validator</td>
<td>If Allow Multiple Root Nodes flag on the tree structure has been set to No, the tree version must contain exactly one root node if it is not empty. If the flag has been set to Yes, this restriction does not apply.</td>
<td>Allow Multiple Root Nodes flag has been set to No at the tree structure, but the tree version has multiple root nodes.</td>
<td>Modify the tree version so that there is exactly one root node.</td>
</tr>
<tr>
<td>Data Source Max Depth Validator</td>
<td>For each data source in the tree structure, if the data source is depth-limited, the data in the tree version must adhere to the specified depth limit. This restriction does not apply to data sources that have no depth restriction (depth = -1 means unlimited depth).</td>
<td>Tree version has data at a depth greater than the specified depth limit on one or more data sources.</td>
<td>Modify the tree version so that all nodes are at a depth that complies with the data source depth limit.</td>
</tr>
<tr>
<td>Duplicate Node Validator</td>
<td>If Allow Duplicate Nodes flag on the data source has been set to No, the tree version should not contain more than one node with the same primary key from the data source. If the flag has been set to Yes, duplicate nodes are permitted.</td>
<td>Your tree version contains duplicate nodes with the same primary key.</td>
<td>Remove any duplicate nodes from the tree version.</td>
</tr>
<tr>
<td>Validator</td>
<td>Checks for...</td>
<td>Validation may have failed because...</td>
<td>To correct...</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-------------------------------------------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Available Node Validator</td>
<td>All the nodes in the tree version should be valid and available in the underlying data source.</td>
<td>• A node in the tree version does not exist in the data source. Deletion of data items from the data source without removing the corresponding nodes from the tree version can result in orphaned nodes in the tree version. For example, if you have added node A into your tree version, but node A was subsequently deleted from your data source but not from the tree version, it will fail this validation. • Your tree version contains a tree reference node, which references another tree version that does not exist.</td>
<td>• Remove any orphaned nodes from the tree version. • Correct any tree reference nodes so they reference existing tree versions.</td>
</tr>
<tr>
<td>Node Relationship Validator</td>
<td>All nodes should adhere to the relationships mandated by the data sources registered in the tree structure.</td>
<td>The tree structure has data sources arranged in a parent-child relationship, but the nodes in the tree do not adhere to the same parent-child relationship. For example, if the tree structure has a Project data source with a Task data source as its child, Task nodes should always be under Project nodes in the tree version. This validator will fail if there are instances where a Project node has been added as a child of a Task node.</td>
<td>Modify the tree version so that the nodes adhere to the same parent-child relationships as the data sources.</td>
</tr>
<tr>
<td>SetID Restricted Node Validator</td>
<td>For each data source that has Restrict Tree Node List of Values Based on SetID flag set to Yes, for each tree node, the underlying node in the data source must belong to the same set as the tree itself. This restriction does not apply when the flag is set to No.</td>
<td>The data source has Restrict Tree Node List of Values Based on SetID flag set to Yes, but the tree version has nodes whose data source values belong to a different set than the tree.</td>
<td>Modify the tree version so that all nodes in the tree have data sources with SetID matching that of the tree.</td>
</tr>
</tbody>
</table>
## Table 20-13  (Cont.) Validator Descriptions

<table>
<thead>
<tr>
<th>Validator</th>
<th>Checks for...</th>
<th>Validation may have failed because...</th>
<th>To correct...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Label Enabled Node Validator</td>
<td>If the tree structure has a Labeling Scheme specified, all nodes should have labels. This restriction does not apply when the Labeling Scheme is set to None.</td>
<td>The tree structure has a labeling scheme but the tree version has nodes without labels.</td>
<td>Assign labels to any nodes that do not have labels.</td>
</tr>
<tr>
<td>Date Restricted Node Validator</td>
<td>If Restrict Tree Node List of Values Based on Date Range flag on the tree structure has been set to Yes, each node in the underlying data source must have date effectivity during the date effectivity range of the tree version. If the flag is set to No, this restriction does not apply.</td>
<td>Restrict Tree Node List of Values Based on Date Range flag has been set to Y, but there are data source nodes that are not have effective during the tree version's effective date range. For example, if the tree version is effective from Jan-01-2012 to Dec-31-2012, all nodes in the tree version must be effective from Jan-01-2012 to Dec-31-2012 at a minimum. It is acceptable for the nodes to be effective for a date range that exceeds the tree version's effective date range (for example, the node data source value is effective from Dec-01-2011 to Mar-31-2012). It is not acceptable if the nodes are effective for none or only part of the tree version's effective date range (for example, the node data source value are only effective from Jan-01-2012 to June-30-2012).</td>
<td>Ensure that for all nodes in the tree version, they have date effectiveness at least for the effective date range for the tree version.</td>
</tr>
<tr>
<td>Multiple Active Tree Version Validator</td>
<td>If Allow Multiple Active Tree Flags on the tree structure has been set to No, there should not be more than one active tree version under a tree at any time. If Allow Multiple Active Tree Versions is set to No, this restriction does not apply.</td>
<td>Allow Multiple Active Tree Versions has been set to N but there is more than one active tree version in the tree for the same date range.</td>
<td>Make no more than one tree version Active within the same date range and set the others to Inactive or Draft.</td>
</tr>
</tbody>
</table>
Table 20-13  (Cont.) Validator Descriptions

<table>
<thead>
<tr>
<th>Validator</th>
<th>Checks for...</th>
<th>Validation may have failed because...</th>
<th>To correct...</th>
</tr>
</thead>
<tbody>
<tr>
<td>Range Based Node</td>
<td>If Allow Range Children on the data source has been set to No, range-based nodes are not permitted from that data source. If the flag is set to Yes, this restriction does not apply.</td>
<td>There are range-based nodes from a data source that has Allow Range Children set to N.</td>
<td>Ensure that any range nodes in your tree version are from a data source that has Allow Range Children set to Y.</td>
</tr>
<tr>
<td>Terminal Node Validator</td>
<td>If Allow Usage as Leaves flag is set to N at the data source level, values from that data source cannot be added as leaves (terminal nodes) to the tree version. If Allow Usage as Leaves flag is set to Y, this restriction does not apply.</td>
<td>There are leaf nodes (terminal nodes) whose values come from a data source marked with Allow Usage as Leaves flag set to N. Only data sources with Allow Usage as Leaves set to Y can have their values used as leaves.</td>
<td>Modify the tree version so that all terminal nodes come from data sources with Allow Usage as Leaves set to Y.</td>
</tr>
<tr>
<td>Usage Limit Validator</td>
<td>If Usage Limit is set to Use All Values at the data source level, every value in the data source must appear as a node in the tree. If Usage Limit is set to None, this restriction does not apply.</td>
<td>The data source has Usage Limit set to Use All Values, but there are values in the data source that are not in the tree version.</td>
<td>Add nodes to the tree version for each data source value that is not yet present.</td>
</tr>
</tbody>
</table>

20.5.9.1 How to Run an Immediate Audit

To run an immediate audit, do the following:

Note:

The following procedure assumes the Manage Trees and Tree Versions page is open.

1. Select the tree or tree version you wish to audit.

   Selecting a tree runs an audit on all tree versions in that tree. Selecting a specific tree version runs an audit only on that tree version.

2. Choose Audit from the Actions dropdown menu.

   The audit runs and the Trees Audit Result page opens.
Figure 20-59  Trees Audit Result Page

The page contains two sections:

- **Audit Results** - displays a list of all previously run audits
- **Validation Details** - displays validation results and messages and allows you correct validation errors

The Audit Results section contains the following columns:

- **Audit Request** - displays the audit request ID number
- **Tree Version Name** - displays the name of the tree version
- **Audit Result** - displays either a green check mark (success) or a red "X" (failure)
- **Tree Structure Code** - displays the tree structure code
- **Tree Code** - displays the tree code
- **Start Time** - displays the date and time the audit began
- **End Time** - displays the date and time the audit was completed

The Validation Details section contains the following columns:

- **Name** - displays the names of the tree or tree version and the audit validators
- **Validation Result** - displays either a green check mark (success) or a red "X" (failure)
- **Validation Message** - when clicked, displays a validation message and a description
- **Corrective Action** - when clicked, opens the appropriate trees application task flow page, allowing you to fix a validation error

### 20.5.9.2 How to Schedule an Audit

To schedule an audit, do the following:

1. Click **Schedule Audit**.
   
   The Schedule Audit window opens.
2. Do any of the following:

- Configure the basic options.
- Click **Process Options** to configure language, territory, timezone, and other options.
- Click **Advanced** to configure detailed schedule, output, and notification options.

3. Click **Submit** and then click **OK** to close the confirmation dialog.

### 20.5.9.3 How to Trigger an Audit Through a Service API

To trigger an audit, through a service API, use the service API shown in the example that follows.

**Example 20-1 Audit Service API**

```java
/**
 * Processes the audit scheduled for any tree or tree version.
 * @param requestId Request ID for scheduled audit (for online can be defaulted as -1)
 * @param auditType Auditing mode where audit invoked for tree/tree version (pass as TREE_AUDIT for tree and TREE_VERSION_AUDIT for tree version).
 * @param tsCode Tree Structure Code
 * @param treeCode Tree Code
 * @param treeVersionId Tree Version Id
 */
public void processAudit(Long requestId, String auditType, String tsCode, String treeCode, String treeVersionId)
```

### 20.5.10 About Flattening Rows and Columns

The tree-flattening process filters an implicit tree structure into a simple sequence of leaves. It coalesces nodes so that each sub-tree has a single cache list representing all of its children at one transformed level.
Tables that store flattened data are either row or column flattened. By eliminating recursive queries, row flattening is particularly useful for efficiently performing operations across an entire sub-tree.

**Understanding Row Flattening**

Row flattening is a technique where parent-child information is optimized for runtime performance by storing additional rows in a table (as compared to just normalized parent-child rows) to instantly find all descendants to a parent value, without initiating a Connect By SQL statement.

Normalized data, for example, might be the following:

**Corporation - Sales Division**

**Sales Division - Region**

In a row flattened table, the above rows are still stored but one additional row is added:

**Corporation - Region**

In addition, additional columns are added to store the “depth” from top parent.

**Understanding Column Flattening**

Column flattening is a technique where parent-child information is optimized for runtime performance by storing additional column in a table for all parents of a child.

Normalized data, for example, might be the following:

**Corporation - Sales Division**

**Sales Division - Region**

**Sales Division**

In a column-flattened table, the above data is converted to rows and columns.

<table>
<thead>
<tr>
<th>Table 20-14</th>
<th>Rows and Columns in a Column-Flattened Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>Column 1</td>
<td>Column 2</td>
</tr>
<tr>
<td>Region</td>
<td>Sales Division</td>
</tr>
</tbody>
</table>

Usually, the number of levels (possible parents) are pre-defined to a maximum number and may also have additional "dummy" values on levels where real values are missing.

**20.5.10.1 How to Flatten a Row or Column**

The following procedure assumes the Manage Trees and Tree Versions page is open.

1. Select the tree version you want to flatten.
2. Choose **Column Flattening** or **Row Flattening** from the **Actions** dropdown menu.

The Flattening page opens.

*Figure 20-62  Schedule Flattening Page*

3. Click **Schedule Flattening**.

4. The **Schedule Flattening** page opens. Configure the options and click **Submit**.

5. Click **Online Flattening** or **Force Flattening**. Either of these actions will flatten the row.

6. Click **OK** to close the confirmation window.

*Figure 20-63  Flattening Confirmation*

7. Click **Done** to return to the Manage Trees and Tree Versions page.

### 20.6 Manage Labels in the Generic Label Data Source

When a label is chosen for a tree structure, the label data source can be either of the following:

- A custom, product-team-owned label data source
- The generic data label source.

This section describes how to use the **Central Labels** tab of the trees application launch page to create, edit, and delete values in the generic label data source.

All procedures assume that the Manage Labels summary page is open in your web browser.

#### 20.6.1 How to Search for a Label

If you wish to edit or delete an existing label and it is not currently visible in the results list, you can search for it using the following procedure.

**To search for a label:**

1. In the Search area of the page, construct a search using any or all of the following search criteria:
   - Tree Structure Code
   - Name
2. Click **Search**.

   All labels matching your search criteria appear in the Results area of the page. Click **Advanced** to perform an advanced search by specifying additional options. You also can save your search criteria for future use.

### 20.6.2 How to Create a Label

The following procedure explains how to create a new label.

**To create a label:**

1. From the Manage Labels summary page, click **Create**, or choose **Create Label** from the **Actions** dropdown menu.

   The Create Label page displays An additional field Set Name will appear if it is used by the selected tree structure.

   ![Create Label Page](image)

2. Enter a tree structure code or click the down arrow to select or search for one.

   The page refreshes and the **Data Source** field populates with an appropriate value.

3. Enter a short name for the label.

4. Enter a name for the label.

5. If you wish, enter a description.

6. If you wish, enter an icon name.

7. Enter an effective start date, or click the calendar icon to select one.

8. Enter an effective end date, or click the calendar icon to select one.

9. Enter a Set Name or click the down arrow to select or search one.
10. Click **Save and Close** to create the label.

11. Click **OK** to close the Confirmation window.

The Manage Labels summary page displays showing the new label in the Results list.

### 20.6.3 How to Edit a Label

The following procedure explains how to edit an existing label.

**To edit a label:**

1. Select the label you want to edit.

   See **How to Search for a Label**, if the label is not in the current Results list.

2. From the Manage Labels summary page, click **Edit**, or choose **Edit** from the **Actions** dropdown menu.

   The Edit Label page displays.

![Figure 20-65   Edit Label Page](image)

3. Edit the appropriate data.

4. Do one of the following:
   - Click **Save and Close** to save your changes and exit the editing session.
   - Click **Cancel** to cancel the operation.

### 20.6.4 How to Delete a Label

The following procedure explains how to delete an existing label.

**To delete a label:**

1. Select the label you want to delete.

   See **How to Search for a Label**, if the label is not in the current Results list.
2. From the Manage Labels summary page, click **Delete**, or choose **Delete** from the **Actions** dropdown menu.

The warning page displays.

*Figure 20-66  Delete Label Warning Page*

![Delete Label Warning Page](image)

3. Do one of the following:
   
   - Click **No** to cancel the operation.
   
   - Click **Yes** to delete the label.

20.7 About Using the Applications Hierarchy Component to Develop Applications

Now that you have worked with tree structures, trees, and tree versions, you can start developing applications in JDeveloper using the Applications Hierarchy component.

The Applications Hierarchy component is denoted by the **fnd:hierarchy** tag and contains two facets: **hierarchy** and **toolbar**. The **hierarchy** facet holds the **af:tree** or **af:treeTable**; the **toolbar** facet can hold action buttons used with items within the **tree** or **treeTable**.

The following picture shows an example of the Applications Hierarchy component in JDeveloper.

*Figure 20-67  Applications Hierarchy Component*

![Applications Hierarchy Component](image)

You can add any JSF or ADF Faces component to these facets, even with the generated **af:tree** or **af:treeTable**. The **fnd:hierarchy** tag supports the TreeCode and TreeVersionId properties to display specific trees or tree versions.

You can create two types of Hierarchy applications: Tree and Tree Table.

20.7.1 How to Create a Tree Application

The following section explains how to create a tree application using the Applications Hierarchy component.
Before you begin:
Create an application initialized for use with Oracle Middleware Extensions for Applications. For more information, see Set Up Your Development Environment.

To create a Tree application, do the following:

1. Create a new JSF/JSPX page.
2. From the ADF Faces page in the Component Palette, select Applications.
3. From the Applications page in the Component Palette, select Hierarchy and drag it to your .jspx file's visual editor.

The Initialize Applications Connection window opens:

4. Choose a connection from the dropdown menu and click OK.
If there is no existing connection, click Add to create a new one.
A second Initialize Applications Connection window opens.

5. Choose a tree structure from the dropdown list.
6. Select Tree.
7. Select Read-only if you want the application to be read only.
8. Click OK.

The tree appears in the visual editor.
9. Do one of the following:
   • Run the .jspx file from the Application Navigator.
   • Run the .jspx file from the visual editor.
   A browser window opens and the application runs.

20.7.2 How to Create a Tree Table Application

   The following section explains how to create a tree table application using the applications Hierarchy component.

   **Before you begin:**

   Create an application initialized for use with Oracle Middleware Extensions for Applications. For more information, see Set Up Your Development Environment.

   To create a Tree Table application, do the following:

   1. Follow Steps 1 through 5 in How to Create a Tree Application.

   2. Select Tree Table.

      The Initialize Applications Connection window redisplayes with additional fields.
3. Select Read-only if you want the application to be read only.
4. Select the available attributes to display at each tree level.
5. Click OK.

The tree table appears in the visual editor.

6. Run the .jspx from either the Application Navigator or the visual editor.

A browser window opens and the application runs.
20.7.3 How to Sort Hierarchies

The Sort option allows you to sort tree-node hierarchies in ascending or descending order, and is enabled by default.

1. Select a column.
2. Navigate to View > Sort.
3. Select Ascending or Descending.

20.8 About Integrating Custom Task Flows into the Applications Hierarchy Component

The Applications Hierarchy component supports six node operations – Add, Create, Duplicate, Edit, Remove, and Delete – which are performed in a standard popup window in the user interface. Since all nodes in a tree come from their data sources, you must create a custom task flow for each operation that requires one, and register it in your data source before you can use it.

Node operations that only manage data in the tree table do not require custom task flows. For example, adding a node affects only the data in the tree table. However, searching for a node requires access to the data source. Subsequently, you must create and register a custom task flow that will enable node searches.

In addition, since removing a node affects only the data in the tree table, you do not need to create and register a custom task flow for this operation.
Related Links
The following document provides more information about the topic discussed in this section:

- For more information about task flows, see Getting Started with ADF Task Flows in the Developing Fusion Web Applications with Oracle Application Development Framework.

20.8.1 About Registering Custom Task Flows
You use the Property Inspector in Oracle JDeveloper to register custom task flows.

Figure 20-76  Data Source Properties

The full code used to register each custom task flow in the data-source view object is shown in the examples that follow.

Example 20-2  Search Task Flow for the Add Node Operation

```xml
<Properties>
  <SchemaBasedProperties>
    <fnd:SEARCH_PAGE Value="/WEB-INF/EmpSearch.xml#EmpSearchTF"/>
    ...
    ...
  </SchemaBasedProperties>
</Properties>
```

Example 20-3  Create Task Flow

```xml
<Properties>
  <SchemaBasedProperties>
    <fnd:CREATE_PAGE Value="/WEB-INF/CreateEmpNode.xml#CreateEmpNode"/>
    ...
    ...
  </SchemaBasedProperties>
</Properties>
```

Example 20-4  Duplicate Task Flow

```xml
<Properties>
  <SchemaBasedProperties>
    <fnd:DUPLICATE_PAGE Value="/WEB-INF/DupEmpNode.xml#DupEmpNode"/>
    ...
  </SchemaBasedProperties>
</Properties>
```
20.8.2 About Creating Custom Task Flows

This section discusses how to create custom task flows for the Search, Create, Duplicate, Edit, and Delete node operations.

20.8.2.1 How to Create a Search Task Flow for the Add Node Operation

The Search task flow provides a shortcut to select nodes. In the task flow, you specify the Search page fragment, task-flow parameters, back-end Java bean, and task-flow activities.

To create the Search task flow, do the following:

1. Define a task-flow parameter, searchHierParamBean, to pass values between the Hierarchy component and the registered Search task flow in pageFlowScope.

   ```xml
   <input-parameter-definition>
   <name>searchHierParam</name>
   <value>${pageFlowScope.searchHierParam}</value>
   <class>oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean</class>
   </input-parameter-definition>
   ```

2. Define Search task-flow return activities and use them as the ends of the task flow. For example, to define the Submit and Cancel task-flow return activities:

   ```xml
   <task-flow-return id="Submit">
   <outcome>
   <name>Submit</name>
   </outcome>
   </task-flow-return/>

   <task-flow-return id="Cancel">
   <outcome>
   <name>Cancel</name>
   </outcome>
   </task-flow-return/>
   ```

   Normally, Cancel is a free event. However, you must pass values back when Submit is triggered. Therefore, you can have a submit() ActionListener mapping to it.

3. In your back-end bean, use the following code to get the task-flow parameter:
import oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean;
...

HierParamBean searchParam = (HierParamBean) AdfFacesContext.getCurrentInstance().getPageFlowScope().get("searchHierParam");
...

For the Search task flow, you do not need any input parameters from the Hierarchy component. The only thing this task flow does is to return the search results. Therefore, after looking up tree nodes in Search task flow, you must pass back the primary keys of the selected nodes by calling the HierParamBean method setSelectedNodes(List) when the Submit return activity is invoked:

public void submit(ActionEvent event) {
    // The inner list is the list of primary keys for each node. Trees supports up to five primary keys.
    // The outer list is the list of selected nodes
    List<List<String>> nodes = ...
    ...
    searchParam.setSelectedNodes(nodes);
}

4. In the page definition file of the page using the Hierarchy component, add the following task-flow entry in the "executables" section:

    <taskflow id="searchTaskflow"
        taskFlowId="#{backingBeanScope.AddNodeBean.searchTaskflow}"
        activation="deferred"
        Refresh="ifNeeded"
        xmlns="http://xmlns.oracle.com/adf/controller/binding">
        <parameters>
            <parameter id="searchHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel"
                value="#{pageFlowScope.searchHierParam}"/>
        </parameters>
    </taskflow>

5. A page definition file is created at design time for each JSF/jspx file created, with the following taskflows created in it under the "executables" section:

    </taskFlow>
    </taskFlow>
    <taskFlow id="searchTaskflow"
        taskFlowId="#{backingBeanScope.AddNodeBean.searchTaskflow}"
        activation="deferred"
        Refresh="ifNeeded"
        xmlns="http://xmlns.oracle.com/adf/controller/binding">
        <parameters>
            <parameter id="searchHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel"
                value="#{pageFlowScope.searchHierParam}"/>
        </parameters>
    </taskFlow>
20.8.2.2 How to Create a Create Task Flow

The Create task flow is used to create a new node in the data-source table. In the task flow, you specify the Create page fragment, task-flow parameters, back-end Java bean, and task-flow activities.

To create the Create task flow, do the following:

1. Define a task-flow parameter, createHierParamBean, to pass values between the Hierarchy component and the registered Create task flow in pageFlowScope.

   ```xml
   <input-parameter-definition>
   <name>createHierParam</name>
   <value>${pageFlowScope.createHierParam}</value>
   <class>oracle.apps.fnd.appcore.trees.ui.managed.HierParamBean</class>
   </input-parameter-definition>
   ```

2. To capture the event of dismissing the Create popup window, define Create task-flow return activities and use them as the ends of the task flow. For example, to define the Submit and Cancel task-flow return activities:

   ```xml
   <task-flow-return id="Submit" />
   <outcome>
   <name>Submit</name>
   </outcome>
   </task-flow-return>

   <task-flow-return id="Cancel" />
   <outcome>
   <name>Cancel</name>
   ```
Normally, Cancel is a free event. However, you must pass values back when Submit is triggered. Therefore, you can have a submit() actionListener mapping to it.

3. In your back-end bean, use the following code to get the task-flow parameter:

```java
import oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean;
...
HierParamBean createParam =
(HierParamBean)AdfFacesContext.getCurrentInstance().getPageFlowScope().get
("createHierParam");
...
```

For the Create task flow, you do not need any input parameters from the Hierarchy component. The only thing this task flow does is to return the new node. Therefore, you must pass back its primary keys by calling the HierParamBean method setNewPkValue() after creating the node. The Hierarchy component will get the new node's primary keys after the Create task-flow is dismissed. For example, in the submit() actionListener that maps to the Submit return activity, you pass new primary keys back:

```java
public void submit(ActionEvent event) {
    List<String> newPk = ...
    ...
    createParam.setNewPkValue(newPk);
}
```

4. In the page definition file of the page using the Hierarchy component, add the following task-flow entry in the "executables" section:

```xml
<taskFlow id="createTaskflow"
    taskFlowId="#{backingBeanScope.CreateNodeBean.createTaskflow}"
    activation="deferred"
    Refresh="ifNeeded"
    xmlns="http://xmlns.oracle.com/adf/controller/binding">
    <parameters>
        <parameter id="createHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel"
            value="#{pageFlowScope.createHierParam}"/>
    </parameters>
</taskFlow>
```

20.8.2.3 How to Create a Duplicate Task Flow

The Duplicate task flow is used to duplicate a node in the data-source table. In the task flow, you specify the Duplicate page fragment, task-flow parameters, back-end Java bean, and task-flow activities.

To create a Duplicate task flow, do the following:

1. Define a task-flow parameter, dupHierParamBean, to pass values between the Hierarchy component and the registered Duplicate task flow in pageFlowScope.

```xml
<input-parameter-definition>
    <name>dupHierParam</name>
    <value>#{pageFlowScope.dupHierParam}</value>
    <class>oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean</class>
</input-parameter-definition>
```
2. To capture the event of dismissing the Duplicate popup window, define Duplicate task-flow return activities and use them as the ends of the task flow. For example, to define the Submit and Cancel task-flow return activities:

```xml
<task-flow-return id="Submit">
  <outcome>
    <name>Submit</name>
  </outcome>
</task-flow-return/>

<task-flow-return id="Cancel">
  <outcome>
    <name>Cancel</name>
  </outcome>
</task-flow-return/>
```

Normally, Cancel is a free event. However, you must pass values back when Submit is triggered. Therefore, you can have a submit() actionListener mapping to it.

3. In your back-end bean, using the following code to get the task-flow parameter:

```java
import oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean;
...

HierParamBean dupParam =
(HierParamBean)AdfFacesContext.getCurrentInstance().getPageFlowScope().get("dupHierParam");
...
```

For the Duplicate task flow, you need to know the selected node from the Hierarchy component. In the Duplicate popup window, the selected node’s attributes are shown by default so that users can create another tree node. After creating a new node, you pass back its primary key. You can perform all of these tasks by calling HierParamBean methods.

For example, in the task-flow initializer, you can use the following code to get the primary keys of the selected node:

```java
List<String> pkValue = dupParam.getPkValue();
```

In the submit() actionListener that maps to the Submit return activity, you pass the new primary keys back:

```java
public void submit(ActionEvent event) {
  List<String> newPk = ...
  ...
  dupParam.setNewPkValue(newPk);
}
```

4. In the page definition file of the page using the Hierarchy component, add the following task-flow entry in the "executables" section:

```xml
<taskflow id="dupTaskflow" 
  taskFlowId="#{backingBeanScope.DupNodeBean.dupTaskflow}" 
  activation="deferred" 
  Refresh="ifNeeded" 
  xmlns="http://xmlns.oracle.com/adf/controller/binding">
  <parameters>
    <parameter id="dupHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel" 
      value="#{pageFlowScope.dupHierParam}"/>
```
20.8.2.4 How to Create an Edit Task Flow

The Edit task flow is used to edit an existing node in the data-source table. In the task flow, you specify the Edit page fragment, task-flow parameters, back-end Java bean, and task-flow activities.

To create the Edit task flow, do the following:

1. Define a task-flow parameter, editHierParamBean, to pass values between the Hierarchy component and the registered Edit task flow in pageFlowScope.

   ```xml
   <input-parameter-definition>
   <name>editHierParam</name>
   <value>${pageFlowScope.editHierParam}</value>
   <class>oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean</class>
   </input-parameter-definition>
   ```

2. To capture the event of dismissing the Edit popup window, define Edit task-flow return activities and use them as the ends of the task flow. For example, to define the Submit and Cancel task-flow return activities:

   ```xml
   <task-flow-return id="Submit">
   <outcome>
   <name>Submit</name>
   </outcome>
   </task-flow-return/>
   
   <task-flow-return id="Cancel">
   <outcome>
   <name>Cancel</name>
   </outcome>
   </task-flow-return/>
   ```

   Normally, Cancel is a free event. However, you must pass values back when Submit is triggered. Therefore, you can have a submit() actionListener mapping to it.

3. In your back-end bean, using the following code to get the task-flow parameter:

   ```java
   import oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean;
   ...
   
   HierParamBean editParam = (HierParamBean)AdfFacesContext.getCurrentInstance().getPageFlowScope().get("editHierParam");
   ...
   ```

   For the Edit task flow, you need to know the current node from the Hierarchy component. In the Edit popup window, the current node's attributes are shown by default so that users can update the tree node. After updating the node, you must indicate whether or not the update was successful. You can perform all of these tasks by calling HierParamBean methods.

   For example, in the task-flow initializer, you can use the following code to get the primary keys of the selected node:

   ```java
   List<String> pkValue = editParam.getPkValue();
   ```

   In the submit() actionListener that maps to the Submit return activity, you specify the result:
public void submit(ActionEvent event) {
    ...
    editParam.setUpdated(true);
}

4. In the page definition file of the page using the Hierarchy component, add the following task-flow entry in the "executables" section:

```
<taskflow id="editTaskflow"
    taskFlowId="#{backingBeanScope.EditNodeBean.editTaskflow}"
    activation="deferred"
    Refresh="ifNeeded"
    xmlns="http://xmlns.oracle.com/adf/controller/binding">
    <parameters>
        <parameter id="dupHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel"
            value="#{pageFlowScope.editHierParam}"/>
    </parameters>
</taskflow>
```

20.8.2.5 How to Create a Delete Task Flow

The Delete task flow is used to delete an existing node in the data-source table. In the task flow, you specify the Delete page fragment, task-flow parameters, back-end Java bean, and task-flow activities.

To create the Delete task flow, do the following:

1. Define a task-flow parameter, delHierParamBean, to pass values between the Hierarchy component and the registered Delete task flow in pageFlowScope.

```
<input-parameter-definition>
    <name>delHierParam</name>
    <value>#{pageFlowScope.delHierParam}</value>
    <class>oracle.apps.fnd.applcore.trees.ui.managed.HierParamBean</class>
</input-parameter-definition>
```

2. To capture the event of dismissing the Delete popup window, define Edit task-flow return activities and use them as the ends of the task flow. For example, to define the Submit and Cancel task-flow return activities:

```
<task-flow-return id="Submit">
    <outcome>
        <name>Submit</name>
    </outcome>
</task-flow-return/>

<task-flow-return id="Cancel">
    <outcome>
        <name>Cancel</name>
    </outcome>
</task-flow-return/>
```

Normally, Cancel is a free event. However, you must pass values back when Submit is triggered. Therefore, you can have a submit() actionListener mapping to it.

3. In your back-end bean, using the following code to get the task-flow parameter:

```
import oracle.apps.fnd.appcore.trees.ui.managed.HierParamBean;
...
HierParamBean delParam =
```
For the Delete task flow, you need to know the selected node from the Hierarchy component. In the Delete popup window, delete the node and confirm the deletion. After deleting the node, you must indicate whether or not the deletion was successful. You can perform all of these tasks by calling **HierParamBean** methods.

For example, in the task-flow initializer, you can use the following code to get the primary keys of the selected node:

```java
List<String> pkValue = delParam.getPkValue();
```

In the `submit()` actionListener that maps to the Submit return activity, you specify the result:

```java
public void submit(ActionEvent event)
{
    ...
    delParam.setDeleted(true);
}
```

4. In the page definition file of the page using the Hierarchy component, add the following task-flow entry in the "executables" section:

```xml
<taskFlow id="delTaskflow"
    taskFlowId="#{backingBeanScope.DelNodeBean.delTaskflow}"
    activation="deferred"
    Refresh="ifNeeded"
    xmlns="http://xmlns.oracle.com/adf/controller/binding">
    <parameters>
        <parameter id="delHierParam" xmlns="http://xmlns.oracle.com/adfm/uimodel"
            value="#{pageFlowScope.delHierParam}"/>
    </parameters>
</taskFlow>
```

### 20.9 About Using the fnd:hierarchy Property Inspector to Specify Tree Versions

Using the Hierarchy component to develop applications in JDeveloper requires you to specify a tree structure in the Property Inspector.

To access the Hierarchy-Property Inspector, highlight **fnd:hierarchy** in the Structure window and select the **Hierarchy-Property Inspector** tab.
The Hierarchy component has facets and properties listed in the next tables.

### Table 20-15  Hierarchy Facets

<table>
<thead>
<tr>
<th>Facet</th>
<th>Description</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>hierarchy</td>
<td>Holds ADF Tree or TreeTable</td>
<td>af:tree or af:treeTable</td>
</tr>
<tr>
<td>toolbar</td>
<td>Additional toolbar buttons to be added for custom use</td>
<td>ADF command toolbar buttons under an ADF toolbar</td>
</tr>
</tbody>
</table>

### Table 20-16  Hierarchy Properties

<table>
<thead>
<tr>
<th>Property</th>

<td>boolean</td>
</tr>
</tbody>
</table>

```xml
<dnd:hierarchy registerTaskflow="true">
...  
</dnd:hierarchy>
```

**Note:**

Since only customers create tree versions, you must use service APIs to generate lists of tree versions or active tree versions.
The data that displays in your application depends on the tree structure you specify in the Property Inspector. The tree structure automatically determines the following at run time:

- The tree available under this particular tree structure. If there are multiple trees, the first one is chosen.
- The active tree version (for the current date) available under the tree. If there are multiple tree versions, the first one is chosen.

20.10 About Using the Expression Builder to Bind TreeCode, TreeStructureCode, and TreeVersionId Properties

You also can use the Expression Builder to bind some of the properties mentioned in the previous section. They are the following:

- TreeCode
- TreeStructureCode
- TreeVersionId

Use the following expressions:

**TreeCode expression:**

${HierarchyHandler.treeModelsList[hierarchyId].treeCode}$

**TreeStructureCode expression:**

${HierarchyHandler.treeModelsList[hierarchyId].treeStructureCode}$

**TreeVersionId expression:**

${HierarchyHandler.treeModelsList[hierarchyId].treeVersionId}$

---

**Note:**

The hierarchyId variable is the ID of the Hierarchy component.

---

20.11 Embed the Tree Picker Component in a User Interface

Tree Picker is a reusable Oracle ADF task flow, similar to a date picker, that enables you to select tree data from a list of values. It is found in the Trees-View.jar section of the Component Palette.

To add a Tree Picker component to your user interface, do the following:

1. On the page from which the Tree Picker will be launched, create an icon or button with Action set to launch.
2. Drag and drop the Tree Picker from Component Palette > Trees-View.jar onto your task flow.
3. Connect the launch page to the Tree Picker using an appropriate Control Flow Case with from-outcome set to launch and run-as-dialog set to true.
4. In the **Property Inspector > Parameters** section for the task flow, enter the appropriate parameters for the following:

- **treeStructureCode** (required) - The code assigned to the tree structure. For example, FND_DEMO_EMP_TS.
- **treeCode** (optional) - The code assigned to the tree. For example, FND_DEMO_EMP_T.
- **treeVersionId** (optional) - String representation of an automatically generated binary value (Raw) identifier. You cannot hard code a TreeVersionId.
- **selectMode** (optional) - A parameter to control the row selection behavior of tree table on a user interface page. Acceptable values are single and multiple. The default is single.

The Tree Picker returns a list of TreeNodes:

- If the Tree Picker is launched as a popup window, the return value can be obtained in the returnListener of the icon or button using:
  
  ```java
  List<TreeNode> selectedTreeNodes = List<TreeNode>()event.getReturnValue();
  ```

- If the Tree Picker is launched in place, the return value can be obtained from the pageFlowScope using:
  
  ```java
  Map pageFlow = AdfFacesContext.getCurrentInstance().getPageFlowScope();List <TreeNode> selectedNodes = (List<TreeNode>()) pageFlow.get("return TreeNodes");
  ```

The following picture shows an example of a Tree Picker user interface.

**Figure 20-78  Example Tree Picker**

The following picture shows the results window that displays when you enter a tree-structure-code value and click **Select Tree Node**.
20.12 About Setting Bind Variables and View Criteria

Every data source requires a view object. If the data source view object has bind variables and view criteria that tree management needs to apply, you must set them manually in JDeveloper.

20.12.1 How to Set Bind Variables and View Criteria

Use the following procedure to set bind variables and view criteria.

1. In JDeveloper, click on the appropriate data source view object. (Ensure that it is highlighted in the Structure window.)

2. Select the Query option from the Overview tab. The following picture shows the Bind Variables and View Criteria sections after the Query option is selected.
3. Do any of the following:
   - Click the **Bind Variables Add** icon to add any necessary bind variables.
   - Click the **View Criteria Add** icon to add any necessary view criteria.

### 20.13 About Using Service APIs to Manage Trees

An application programming interface, or **API**, is a source code interface that a library provides to support requests for services to be made of it by computer programs. In other words, APIs provide the building blocks that make it easier to develop these programs. Although an API specifies an interface and the behavior of the identifiers specified in that interface, it does not specify how the behavior might be implemented.

There are three service application modules that you can use to interact with the tree management infrastructure:

- **TreeStructureService**
- **TreeService**
- **TreeNodeService**

**Note:**

No Service Data Objects (SDOs) are provided and these application modules must be instantiated and invoked in a co-located mode.
20.13.1 How to Use TreeStructureService

The TreeStructureService application module is defined in oracle.apps.fnd.applicore.trees.service.applicationModule.TreeStructureService and allows access to tree structure metadata. This application module exposes the TreeStructureVO under the name “TreeStructure” as well as the hierarchy of ADF Business Components objects accessible through the TreeStructureVO. This application module does not include any of the tree or tree version entities. The Javadoc for the available APIs is included with JDeveloper. To access the Javadoc in JDeveloper, do the following:

1. Choose the Go to Java Class... option from the Navigate dropdown menu.
   
The Go to Java Class window opens.

2. Enter TreeStructureService in the Name: field.

3. Choose Go to: > Javadoc and click OK.

This application module is considered a public API to work with tree structure metadata and exposes the APIs shown in the following table.

</tr>
</tbody>
</table>

#### 20.13.2 How to Use TreeService

The TreeService application module is defined in `oracle.apps.fnd.applcore.trees.service.applicationModule.TreeService` and provides access to trees and tree versions. TreeService also provides flattening APIs. The Javadoc for the available APIs is included with JDeveloper.

To access the Javadoc, do the following:

1. Choose the Go to Java Class... option from the Navigate dropdown menu.
   
The Go to Java Class window opens.

2. Enter TreeService in the Name: field.

3. Choose Go to: > Javadoc and click OK.

This application module is considered a public API to work with trees and tree versions and exposes the APIs shown in the following table.

### Table 20-18 TreeService APIs

</tbody>
</table>

Organize Hierarchical Data with Tree Structures 20-91
20.13.3 How to Use TreeNodeService

The TreeNodeService application module is defined in oracle.apps.fnd.applcore.trees.service.applicationModule.TreeNodeService and provides the core node operations such as adding and deleting nodes. The APIs support three types of nodes:

- value nodes
- range nodes
- tree-in-tree nodes.

The Java APIs are covers to the PL/SQL APIs that are provided in the FND_TREE_UTILS PL/SQL package.

To access the Javadoc, do the following:

1. Choose the Go to Java Class... option from the Navigate dropdown menu.
   
   The Go to Java Class window opens.

2. Enter TreeNodeService in the Name: field.

3. Choose Go to: > Javadoc and click OK.

This application module is considered a public API to work with tree nodes and exposes the APIs shown in the next table.

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addValueTreeNode</td>
<td>String addValueTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String dataSourceId, String pk1Value, String pk2Value, String pk3Value, String pk4Value, String pk5Value);</td>
</tr>
<tr>
<td></td>
<td>String addValueTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String dataSourceId, String pk1Value, String pk2Value, String pk3Value, String pk4Value, String pk5Value, String treeLabelId);</td>
</tr>
<tr>
<td></td>
<td>This API adds a value-based tree node to a specific tree version. It is a front end to the PL/SQL API FND_TREE_UTILS.add_value_tree_node. It returns the tree node ID of the newly added node. The API has two signatures - one that takes in a tree label to be associated with the tree node and one that does not.</td>
</tr>
</tbody>
</table>
### Table 20-19 (Cont.) TreeNodeService APIs

<table>
<thead>
<tr>
<th>API</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>addRangeTreeNode</td>
<td>String addRangeTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue); String addRangeTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue, String treeLabelId); This API adds a range-based tree node to a specific tree version. It is a front end to the PL/SQL API FND_TREE_UTILS.add_range_tree_node. It returns the tree node ID of the newly added node. The API has two signatures - one that takes in a tree label to be associated with the tree node and one that does not.</td>
</tr>
<tr>
<td>addTreeTreeNode</td>
<td>String addTreeTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String referenceTreeCode, String referenceTreeVersionId); String addTreeTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String referenceTreeCode, String referenceTreeVersionId, String treeLabelId); This API adds a tree node that references another tree version. It is a front end to the PL/SQL API FND_TREE_UTILS.add_tree_tree_node. It returns the tree node ID of the newly added node. The API has two signatures - one that takes in a tree label to be associated with the tree node and one that does not.</td>
</tr>
<tr>
<td>deleteTreeNode</td>
<td>void deleteTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String treeNodeId); This API is a front end to the PL/SQL API FND_TREE_UTILS.delete_tree_node and deletes a specific tree node. Any children of that node are automatically promoted up the hierarchy.</td>
</tr>
<tr>
<td>updateTreeNode</td>
<td>void updateTreeNode(String treeStructureCode, String treeCode, String treeVersionId, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue, String referenceTreeCode, String referenceTreeVersionId, String treeLabelId); This API is a front end to the PL/SQL API FND_TREE_UTILS.update_tree_node and is used to update the data associated with a specific tree node. It cannot be used to move the tree node.</td>
</tr>
</tbody>
</table>

20.14 Advanced Topics

This section includes information about the following advanced topics:

- Tree data model
- PL/SQL APIs
- Web services APIs
- Incremental flattening
• Oracle Enterprise Scheduler Service for auditing and flattening trees
• Trees business events
• WebLogic Scripting Tool (WLST) commands for flattening
• XML report formats for WLST commands
• Purging unused tree logs

20.14.1 About Using the Tree Data Model

The following are new or modified tables and views that are used by and relevant to the Tree Management infrastructure. They are set up in the FUSION schema.

Tables:

• FND_TREE_STRUCTURE
• FND_TREE_STRUCTURE_TL
• FND_TS_DATA_SOURCE
• FND_TS_DATA_SOURCE_REL
• FND_TS_DATA_SOURCE_PARAMS
• FND_LABEL
• FND_LABEL_TL
• FND_TREE
• FND_TREE_TL
• FND_TREE_DATA_SOURCE_PARAMS
• FND_TREE_VERSION
• FND_TREE_VERSION_TL
• FND_NODE
• FND_NODE_TL
• FND_TREE_LABEL
• FND_TREE_NODE
• FND_TREE_NODE_RF
• FND_TREE_NODE_CF
• FND_TREE_AUDIT_JOB
• FND_TREE_VERSION_AUDIT_RES
• FND_TREE_VERSION_AUDIT_RES_TL
• FND_TREE_LOG
• FND_TREE_LOG_PARAMS
20.14.2 About Using PL/SQL APIs

Tree Management provides public PL/SQL APIs to work with trees. You can find these APIs in the PL/SQL package FND_TREE_UTILS in the FUSION schema.

**Note:**
The PL/SQL package FND_TREE_UTILS_PVT contains private APIs for internal use with Oracle Fusion tree management. No other use of these APIs is supported.

20.14.3 About Using Web Services APIs

Oracle Fusion Applications uses the trees framework for modeling several hierarchies, and for managing tree structures, trees, and tree versions. In addition to APIs, hierarchical components, and task flows, the framework exposes web services to accomplish integration.

The following tables include web services APIs for TreeService and TreeNodeService.

### Table 20-20  Web Services APIs for TreeService

<table>
<thead>
<tr>
<th>Operation</th>
<th>API</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create tree</td>
<td>public void createTree(String treeStructureCode, String treeCode, String treeName);</td>
</tr>
<tr>
<td></td>
<td>Creates a tree.</td>
</tr>
<tr>
<td>Update tree</td>
<td>public void updateTree(String treeStructureCode, String treeCode, String updatedTreeName, String updatedTreeDescription);</td>
</tr>
<tr>
<td></td>
<td>Updates a tree.</td>
</tr>
<tr>
<td>Update tree data source parameter values</td>
<td>public void updateTreeDataSourceParamValues(String treeStructureCode, String treeCode, String dataSourceId, String paramId, String paramValue);</td>
</tr>
<tr>
<td></td>
<td>Updates the value of the data source parameter for a given tree. Parameter values customized at the tree level will override the default values specified at the tree-structure level.</td>
</tr>
</tbody>
</table>
### Table 20-20  *(Cont.)* Web Services APIs for TreeService

<table>
<thead>
<tr>
<th>Operation</th>
<th>API</th>
</tr>
</thead>
<tbody>
<tr>
<td>Duplicate tree</td>
<td>public void duplicateTree(String treeStructureCode, String treeCode, String duplicateTreeCode); Duplicates a tree without duplicating the underlying tree versions.</td>
</tr>
<tr>
<td>Delete tree</td>
<td>public void deleteTree(String treeStructureCode, String treeCode); Deletes a tree.</td>
</tr>
<tr>
<td>Create tree version</td>
<td>public String createTreeVersion(String treeStructureCode, String treeCode, String treeVersionName, String treeVersionDescription, String effectiveStartDate, String effectiveEndDate, String treeVersionNote); Creates a tree version and returns a string with the ID of the tree version that has been created.</td>
</tr>
<tr>
<td>Update tree version</td>
<td>public String updateTreeVersion(String treeStructureCode, String treeCode, String treeVersionName, String updatedTreeVersionName, String updatedTreeVersionDescription, String updatedEffectiveStartDate, String updatedEffectiveEndDate, String updatedTreeVersionNote); Updates a tree version.</td>
</tr>
<tr>
<td>Duplicate tree version</td>
<td>public String duplicateTreeVersion(String treeStructureCode, String treeCode, String treeVersionName, String duplicateTreeVersionName); Duplicates a tree version.</td>
</tr>
<tr>
<td>Delete tree version</td>
<td>public void deleteTreeVersion(String treeStructureCode, String treeCode, String treeVersionName); Deletes the specified tree version.</td>
</tr>
<tr>
<td>Row flatten tree version</td>
<td>public void rowFlatten(String treeStructureCode, String treeCode, String treeVersionName); Row flattens a tree version.</td>
</tr>
<tr>
<td>Column flatten tree version</td>
<td>public void columnFlatten(String treeStructureCode, String treeCode, String treeVersionName); Column flattens a tree version.</td>
</tr>
</tbody>
</table>

### Table 20-21  Web Services APIs for TreeNodeService

<table>
<thead>
<tr>
<th>Operation</th>
<th>API</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add tree value node</td>
<td>public String addRangeTreeNode(String treeStructureCode, String treeVersionName, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue, String treeLabelId); Adds a value-based tree node and returns the ID of the tree node that was added.</td>
</tr>
</tbody>
</table>
### Table 20-21 (Cont.) Web Services APIs for TreeNodeService

<table>
<thead>
<tr>
<th>Operation</th>
<th>API</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add tree range node</td>
<td>public void updateTree(String treeStructureCode, String treeCode, String updatedTreeNodeName, String updatedTreeDescription);</td>
</tr>
<tr>
<td></td>
<td>Adds a range-based tree node and returns the ID of the tree node that was added.</td>
</tr>
<tr>
<td>Add reference tree node</td>
<td>public String addRangeTreeNode(String treeStructureCode, String treeCode, String treeVersionName, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue, String treeLabelId);</td>
</tr>
<tr>
<td></td>
<td>Adds a reference tree node and returns the ID of the tree node that was added.</td>
</tr>
<tr>
<td>Delete tree node</td>
<td>public void deleteTreeNode(String treeStructureCode, String treeCode, String treeVersionName, String treeNodeId);</td>
</tr>
<tr>
<td></td>
<td>Deletes a tree node.</td>
</tr>
<tr>
<td>Move tree node</td>
<td>public void moveTreeNode(String treeStructureCode, String treeCode, String treeVersionName, String treeNodeId, String destParentTreeNodeId);</td>
</tr>
<tr>
<td></td>
<td>Moves a tree node under specified parent tree node.</td>
</tr>
<tr>
<td>Update tree node</td>
<td>public void updateTreeNode(String treeStructureCode, String treeCode, String treeVersionName, String treeNodeId, String parentTreeNodeId, String dataSourceId, String pk1StartValue, String pk2StartValue, String pk3StartValue, String pk4StartValue, String pk5StartValue, String pk1EndValue, String pk2EndValue, String pk3EndValue, String pk4EndValue, String pk5EndValue, String treeLabelId);</td>
</tr>
<tr>
<td></td>
<td>Updates an existing tree node.</td>
</tr>

</tr>
<tr>
<td></td>
<td>Moves a sub-tree under specified parent tree node within the same tree or across trees.</td>
</tr>
<tr>
<td>Copy sub-tree</td>
<td>public String copySubTree(String treeStructureCode, String treeCode, String treeVersionName, String treeNodeId, String destParentTreeNodeId, String destParentTreeVersionName, String destParentTreeCode, String newTreeNodeId);</td>
</tr>
<tr>
<td></td>
<td>Copies a sub-tree under specified parent tree node within the same tree or across trees.</td>
</tr>
<tr>
<td>Remove sub-tree</td>
<td>public void removeSubTree(String treeStructureCode, String treeCode, String treeVersionName, String treeNodeId);</td>
</tr>
<tr>
<td></td>
<td>Removes the sub-tree under the specified parent tree node.</td>
</tr>
</tbody>
</table>
20.14.4 About Using Incremental Flattening

Incremental flattening optimizes the process by starting with the results of a previous flattening instead of flattening the data from scratch.

Figure 20-81  Flattening Delta

To flatten incrementally, a delta of flattening operations that occurred between these two sets of start and end points is created, and information about what happened during those operations is stored in three tables:

- FND_TREE_FLATTENING_HISTORY
- FND_TREE_LOG
- FND_TREE_LOG_PARAMS

These tables are described in the sections that follow.

20.14.4.1 About Using FND_TREE_FLATTENING_HISTORY

This table records the flattening history for a specific tree version. For optimization, only the last process point is recorded. Process_Point records the time of the last tree-node operation that has been flattened.

The following table shows the contents of the FND_TREE_FLATTENING_HISTORY table.

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tree_Structure_Code (Primary Key)</td>
<td>Varchar2(30)</td>
<td>No</td>
</tr>
<tr>
<td>Tree_Code (Primary Key)</td>
<td>Varchar2(30)</td>
<td>No</td>
</tr>
<tr>
<td>Tree_Version_ID (Primary Key)</td>
<td>Varchar2(32)</td>
<td>No</td>
</tr>
<tr>
<td>Process_Point</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
<tr>
<td>Flattening_Type (Primary Key)</td>
<td>Varchar2(32)</td>
<td>No</td>
</tr>
<tr>

<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Update_Date</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
</tbody>
</table>
Table 20-22  (Cont.) FND_TREE_FLATTENING_HISTORY

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Last_Update_Login</td>
<td>Varchar2(32)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

20.14.4.2 About Using FND_TREE_LOG

FND_TREE_LOG is a log of all flattening operations for one tree version. The log enables database administrators (DBAs) to move data easily and efficiently to external systems such as a data warehouse, or from test to production systems.

FND_TREE_LOG stores tree-node operations. For each specific tree-version operation, a unique Log_Entry_ID is assigned and the operation type is logged.

There are three types of tree nodes:

- value
- range
- tree node

There also are three types of tree-node operations:

- add
- move
- delete

Subsequently, there are nine types of operations:

- add value node
- move value node
- delete value node
- add range node
- move range node
- delete range node
- add tree node
- move tree node
- delete tree node

The following table shows the contents of the FND_TREE_LOG table.

Table 20-23  FND_TREE_LOG

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log_Entry_ID (Primary Key)</td>
<td>Varchar2(32)</td>
<td>No</td>
</tr>
<tr>
<td>Tree_Structure_Code</td>
<td>Varchar2(30)</td>
<td>No</td>
</tr>
</tbody>
</table>
Table 20-23  (Cont.) FND_TREE_LOG

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tree_Code</td>
<td>Varchar2(30)</td>
<td>No</td>
</tr>
<tr>
<td>Tree_Version_ID</td>
<td>Varchar2(32)</td>
<td>No</td>
</tr>
<tr>
<td>Operation_Type</td>
<td>Varchar1(32)</td>
<td>No</td>
</tr>
<tr>
<td>Created_By</td>
<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Creation_Date</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Updated_By</td>
<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Update_Date</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Update_Login</td>
<td>Varchar2(32)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

20.14.4.3 About Using FND_TREE_LOG_PARAMS

Since the FND_TREE_LOG table does not record parameters for each operation, the FND_TREE_LOG_PARAMS table is used to log them. The two tables are referenced by a foreign key, Log_Entry_ID. This design helps save space and clearly organizes the information.

The following table shows the contents of the FND_TREE_LOG_PARAMS table.

Table 20-24  FND_TREE_LOG_PARAMS

<table>
<thead>
<tr>
<th>Column</th>
<th>Data Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Log_Entry_ID (PK)</td>
<td>Varchar2(32)</td>
<td>No</td>
</tr>
<tr>
<td>Param_Name (PK)</td>
<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Param_Value</td>
<td>Varchar2(100)</td>
<td>No</td>
</tr>
<tr>
<td>Created_By</td>
<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Creation_Date</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Updated_By</td>
<td>Varchar2(64)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Update_Date</td>
<td>Timestamp(6)</td>
<td>No</td>
</tr>
<tr>
<td>Last_Update_Login</td>
<td>Varchar2(32)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

20.14.4.4 About Row Flattening

Row-flattening results are stored in the table registered as the row-flattening table for the tree structure. If you register a custom row-flattening table for your tree structure, ensure it has the same schema as FND_TREE_NODE_RF.

IS_LEAF and DISTANCE are two important row-flattening-table columns. For more information, see the following sections.
20.14.4.1 About IS_LEAF

This column provides information about whether or not a tree node is a leaf. In many instances, only a leaf contain meaningful information, while other nodes provide a structural purpose. IS_LEAF makes it easier to differentiate a leaf from other nodes, and makes it simpler to write simple queries and get faster responses. Valid values are Y (yes) and N (no).

20.14.4.2 About DISTANCE

This column indicates the distance between the node and its ancestor, which is specified in the row. For example, the distance between a node and its parent or children is 1, between a node and its grandparent or grandchildren is 2, and so on. DISTANCE, then, helps developers to get the entire path - from the root node to the intermediate leaf/node without having to perform any additional queries.

In the FND_TREE_NODE table, DISTANCE is stored in the form of an adjacency list, as shown in the next table.

![Figure 20-82 Example of DISTANCE](image)

Table 20-25 Adjacency List

<table>
<thead>
<tr>
<th>Node</th>
<th>Parent</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Null</td>
</tr>
<tr>
<td>B</td>
<td>A</td>
</tr>
<tr>
<td>C</td>
<td>A</td>
</tr>
<tr>
<td>D</td>
<td>C</td>
</tr>
</tbody>
</table>

After flattening, DISTANCE is stored in the FND_TREE_NODE table.

---

**Note:**

The node ancestor also includes itself.

---

Table 20-26 Flattened FND_TREE_NODE Table

<table>
<thead>
<tr>
<th>Node</th>
<th>Ancestor</th>
<th>Distance</th>
<th>IS_LEAF?</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>Null</td>
<td>1</td>
<td>N</td>
</tr>
<tr>
<td>A</td>
<td>A</td>
<td>0</td>
<td>N</td>
</tr>
<tr>
<td>B</td>
<td>Null</td>
<td>2</td>
<td>Y</td>
</tr>
</tbody>
</table>
### Table 20-26  (Cont.) Flattened FND_TREE_NODE Table

<table>
<thead>
<tr>
<th>Node</th>
<th>Ancestor</th>
<th>Distance</th>
<th>IS_LEAF?</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>A</td>
<td>1</td>
<td>Y</td>
</tr>
<tr>
<td>B</td>
<td>B</td>
<td>0</td>
<td>Y</td>
</tr>
<tr>
<td>C</td>
<td>Null</td>
<td>2</td>
<td>N</td>
</tr>
<tr>
<td>C</td>
<td>A</td>
<td>1</td>
<td>N</td>
</tr>
<tr>
<td>C</td>
<td>C</td>
<td>0</td>
<td>N</td>
</tr>
<tr>
<td>D</td>
<td>Null</td>
<td>3</td>
<td>Y</td>
</tr>
<tr>
<td>D</td>
<td>A</td>
<td>2</td>
<td>Y</td>
</tr>
<tr>
<td>D</td>
<td>C</td>
<td>1</td>
<td>Y</td>
</tr>
<tr>
<td>D</td>
<td>D</td>
<td>0</td>
<td>Y</td>
</tr>
</tbody>
</table>

To find the path from the root of D, the query would be the following:

```sql
select * 
from fnd_tree_node_rf 
where tree_node_id = D order by distance
```

### 20.14.4.5 About Column Flattening

Column flattening generally applies only to level-based trees. In the case of a view object for Business Intelligence (BICVO), however, value-based trees also can be column-flattened. (For more information, see Designing and Securing View Objects for.)

For level-based trees, the maximum level of a tree version is 32. Subsequently, if a tree version is not level-based or if it has a tree-version level that exceeds 32, only row flattening can be performed.

Column-flattening results are stored in the table specified in the tree structure, which has the same schema as FND_TREE_NODE_CF.

Each row in the FND_TREE_NODE_CF table represents a path in a tree, and can hold a maximum of 32 nodes. The rows are arranged from leaf to root.

### Figure 20-83  Leaf-to-Root Order

- **Continent level**
  - North America
- **Country level**
  - USA
- **State level**
  - CA
- **City level**
  - LA
  - SF
  - D.C.
The following table shows the results after flattening.

<table>
<thead>
<tr>
<th>Dep0</th>
<th>Dep1</th>
<th>Dep2</th>
<th>Dep3</th>
<th>Dep4</th>
<th>...</th>
<th>Dep31</th>
</tr>
</thead>
<tbody>
<tr>
<td>LA</td>
<td>CA</td>
<td>USA</td>
<td>North America</td>
<td>Null</td>
<td>...</td>
<td>Null</td>
</tr>
<tr>
<td>SF</td>
<td>CA</td>
<td>USA</td>
<td>North America</td>
<td>Null</td>
<td>...</td>
<td>Null</td>
</tr>
<tr>
<td>DC</td>
<td>Null</td>
<td>USA</td>
<td>North America</td>
<td>Null</td>
<td>...</td>
<td>Null</td>
</tr>
</tbody>
</table>

Note:
All fields not containing nodes will be filled with Null.

20.14.5 About Trees Auditing and Flattening of Oracle Enterprise Scheduler Service Job Submissions

For trees with thousands of nodes, the auditing and flattening process for tree versions can take a very long time. To shorten the process, you can submit Oracle Enterprise Scheduler Service jobs using the Oracle Fusion Middleware Extensions for Applications (Applications Core) Setup UI.

From the UI, you can select any tree version on the fly and choose to do the auditing and flattening either "Online" or "Offline". The "Online" option triggers the process in synchronous mode. The "Offline" option allows you to audit or flatten without having to write additional code or create a custom job. It submits a PL/SQL API call that invokes the trees Oracle Enterprise Scheduler Service program for performing the flattening or auditing based on selected options.

Online/Offline Options

Online/offline options are available on the Manage Tree and Tree Versions page. The figures that follow show the Online/Offline options and confirmation dialog in the Applications Core Setup UI.

Figure 20-84  Trees Auditing: Online/Offline Options
20.14.6 About Configuring Oracle Enterprise Scheduler Service for Trees Auditing and Flattening

Configuring Oracle Enterprise Scheduler Service to audit and flatten trees involves the following tasks:

- **Verifying Your Application for Configuration**
- **Implementing the Trees Jobs**
- **Understanding How to Flatten Concurrent Programs**
- **Implementing the Concurrent Programs for the Trees Jobs**
- **Configuring Security for the Jobs**
- **Testing and Verifying**

### 20.14.6.1 Verifying Your Application for Oracle Enterprise Scheduler Configuration

Do the following:

- Ensure that you have a hosting Oracle Enterprise Scheduler Service application for carrying the trees jobs. For example, for Oracle Fusion Human Capital Management, it is the HcmESS application; for Oracle Fusion Financials, it is the FinancialESS application, which is being centrally hosted.

- Ensure that the Setup application consuming the trees taskflow has been configured properly for Oracle Enterprise Scheduler Service so that it can refer the Central Oracle Enterprise Scheduler Service application.

- Prior to uptaking any trees jobs, install Oracle Enterprise Scheduler Service and validate that you are able to deploy the two applications referenced in the first bullet item.

### 20.14.6.2 Implement the Trees Jobs

There are two `.xml` files for trees jobs: one for auditing and one for flattening. 

*Example 20-7* and *Example 20-8* show sample jobs.

Do the following to audit and flatten jobs:
1. Extract the jobs from $BUILD_HOME/jdeveloper/oaext/applcore/trees/Trees-SampleJob.xml to some writeable local file.

2. Open AuditJob.xml, found in essmeta/oracle/apps/ess/fnd/applcore/trees/Jobs and set <parameter name="SYS_effectiveApplication" data-type="string">EarFinLedgerEss</parameter> and <parameter name="SYS_product" data-type="string">EarFinLedgerEss</parameter> to reflect the correct application name for your Central Oracle Enterprise Scheduler Service application. For example, for Oracle Human Capital Management it can be set as something like HCMEss, and Oracle Financials can be set to FinancialEss per their Central Oracle Enterprise Scheduler Service hosting application name.

3. Repeat Steps 1 and 2 for FlattenJob.xml, which also can be found in essmeta/oracle/apps/ess/fnd/applcore/trees/Jobs.

4. Copy both jobs from essmeta/oracle/apps/ess/fnd/applcore/trees/Jobs to your hosting Oracle Enterprise Scheduler Service application.

5. Ensure that your hosting Oracle Enterprise Scheduler Service project compiles without errors, and that both your existing MAR profile and generated MAR picks up the jobs.

Example 20-7 Sample Audit Job

```xml
<?xml version = '1.0'?>
<job-definition xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" name="AuditJob" job-type="/oracle/as/ess/ext/JobType/JavaJobType.xml" xmlns="http://xmlns.oracle.com/scheduler">
  <display-name>AuditJob</display-name>
  <description>Audit for Trees and Tree Versions</description>
  <parameter-list>
    <parameter name="SYS_product" data-type="string">EarFinLedgerEss</parameter>
    <parameter name="SYS_className" data-type="string">oracle.apps.fnd.applcore.trees.ess.program.AuditCP</parameter>
    <parameter name="SYS_effectiveApplication" data-type="string">EarFinLedgerEss</parameter>
  </parameter-list></job-definition>
```

Example 20-8 Sample Flatten Job

```xml
<?xml version = '1.0'?>
<job-definition xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" name="FlattenJob" job-type="/oracle/as/ess/ext/JobType/JavaJobType.xml" xmlns="http://xmlns.oracle.com/scheduler">
  <display-name>FlattenJob</display-name>
  <description>Flattening for Trees and Tree Versions</description>
  <parameter-list>
    <parameter name="SYS_product" data-type="string">EarFinLedgerEss</parameter>
    <parameter name="SYS_className" data-type="string">oracle.apps.fnd.applcore.trees.ess.program.Flattening</parameter>
  </parameter-list></job-definition>
```
20.14.6.3 Understand How to Flatten Concurrent Programs

`FlattenCP.java` is the concurrent program provided for flattening Oracle Enterprise Scheduler Service jobs. To support various flattening requirements, the program accepts the parameters in the following table as part of Oracle Enterprise Scheduler Service request.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>TreeStructureCode</td>
<td>Mandatory parameter to pass the tree structure code value of the hierarchy for which flattening needs to be scheduled</td>
</tr>
<tr>
<td>TreeCode</td>
<td>Mandatory parameter to pass the tree code value of the hierarchy for which flattening needs to be scheduled</td>
</tr>
<tr>
<td>TreeVersionId</td>
<td>Mandatory parameter to pass the tree version ID value of the hierarchy for which flattening needs to be scheduled</td>
</tr>
<tr>
<td>FlatteningMode</td>
<td>Mandatory parameter to pass the type of flattening requested. Accepted values are the following:</td>
</tr>
<tr>
<td></td>
<td>• ROW: To request row flattening only</td>
</tr>
<tr>
<td></td>
<td>• COLUMN: To request column flattening only</td>
</tr>
<tr>
<td></td>
<td>• BOTH: To request both row and column flattening simultaneously</td>
</tr>
<tr>
<td>Force</td>
<td>Mandatory parameter to indicate if force flattening is requested. (Values: Y or N)</td>
</tr>
</tbody>
</table>

20.14.6.4 Implement the Concurrent Programs for the Trees Jobs

For your Central hosting Oracle Enterprise Scheduler Service application, open `weblogic-application.xml` and ensure that you have referenced the Oracle Fusion Middleware Extensions for Applications / Oracle Enterprise Scheduler Service library.

```xml
<library-ref>
  <library-name>oracle.applcore.ess</library-name>
</library-ref>
```

**Note:**

It is assumed that all trees being audited through the Central Oracle Enterprise Scheduler Service hosting application have access to the `.jar` files that contain the related view objects for the data source. Otherwise, you will encounter "class not found" exceptions during audit or flattening.

20.14.6.5 Configure Security for the Jobs

It is necessary to add the metadata security permission for the two jobs you packaged in your hosted Oracle Enterprise Scheduler Service application.

Add `jazn-data.xml` entries, like the ones shown below, for these trees jobs.

```xml
<permission>
  <class>oracle.as.scheduler.security.MetadataPermission</class>
  <name>oracle.apps.ess.fnd.applcore.trees.JobDefinition.FlattenJob</name>
</permission>
```
20.14.6.6 Test and Verifying

You now should be able to launch the Trees Summary page and perform the following operations:

- Schedule an audit for a tree or tree version and view the results of the audit.
- Activate a tree version by setting its status to “Active.” (If an audit is needed, the Audit page will open; otherwise, the tree version will be activated.)
- Schedule flattening for rows and columns.

You can schedule flattening for rows and columns in both incremental and force modes, as shown in the following figure.

![Figure 20-87 Schedule Force Flattening Option](image)

20.14.7 About Using Trees Business Events

A business event typically is a one-way, fire-and-forget, asynchronous way to send a notification of a business occurrence. You can raise business events when a situation of interest occurs. The Tree Management infrastructure provides create, update, and delete business events on tree structures, trees and tree versions. The event definitions are available in `$MW_HOME/jdeveloper/jdev/oaext/events/Trees-Model-Events.jar`.

The following table includes details of the create, update, and delete events.

<table>
<thead>
<tr>
<th>Entity</th>
<th>Event Name</th>
<th>Condition</th>
<th>Payload</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tree Structure</td>
<td>TreeStructureCreateEvent</td>
<td>Create</td>
<td>TreeStructureCode</td>
</tr>
</tbody>
</table>
### Table 20-29  (Cont.) Trees Business Events

<table>
<thead>
<tr>
<th>Entity</th>
<th>Event Name</th>
<th>Condition</th>
<th>Payload</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tree Structure</td>
<td>TreeStructureUpdateEvent</td>
<td>Update</td>
<td>TreeStructureCode</td>
</tr>
<tr>
<td>Tree Structure</td>
<td>TreeStructureDeleteEvent</td>
<td>Delete</td>
<td>TreeStructureCode</td>
</tr>
<tr>
<td>Tree</td>
<td>TreeCreateEvent</td>
<td>Create</td>
<td>TreeStructureCode, TreeCode</td>
</tr>
<tr>
<td>Tree</td>
<td>TreeUpdateEvent</td>
<td>Update</td>
<td>TreeStructureCode, TreeCode</td>
</tr>
<tr>
<td>Tree</td>
<td>TreeDeleteEvent</td>
<td>Delete</td>
<td>TreeStructureCode, TreeCode</td>

- For more information, see *Using Business Events and the Event Delivery Network* in *Developing SOA Applications with Oracle SOA Suite*.

### 20.14.8 About Using WLST Commands for Flattening

WebLogic Scripting Tool (WLST) is a command line scripting interface that you can use to create, manage, and monitor WebLogic Server domains.
Tree management provides the data flattening feature that improves query performance against the hierarchical data. It supports two types of flattening: column flattening and row flattening. Column flattening optimizes the parent-child information for run-time performance by storing additional column in a table for all parents of a child. Row flattening optimizes parent-child information for run-time performance by storing additional rows in a table (as compared to just normalized parent-child rows) to instantly find all descendants to a parent value, without initiating a CONNECT BY SQL statement.

WLST commands are to be executed from the `wlst` prompt. Execute the shell script located at `$JDEV_HOME/oracle_common/common/bin` to navigate to the `wlst` prompt.

```
cd $JDEV_HOME/oracle_common/common/bin/
sh wlst.sh
```

The `treeManagement.py` Python Script defines the WLST commands that can be executed at the WLST prompt. Each command corresponds to a method in the python script. The python script is available at `$ADE_VIEW_ROOT/atgpf/applcore/etc/wlst/`.

A package `oracle.apps.fnd.applcore.trees.mbean` is added to the Trees ViewController Layer. This package includes the following files:

<table>
<thead>
<tr>
<th>File</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TreeFlatteningMBeanLifeCycleCallBack.java</td>
<td>Manages registration and de-registration of Trees MBean</td>
</tr>
<tr>
<td>TreeMBeanUtil.java</td>
<td></td>
</tr>
<tr>
<td>TreeFlatteningMBean.java</td>
<td>Defines the signature and implements the java based code logic for all WLST commands</td>
</tr>
<tr>
<td>TreeFlatteningMBeanImpl.java</td>
<td></td>
</tr>
<tr>
<td>FlatteningBean.java</td>
<td>Bean Data Structure for the object that stores flattening results for all individual Tree Versions</td>
</tr>
<tr>
<td>TreeFlatteningXMLReport.java</td>
<td>Outlines the design and generates the output XML Report for the WLST commands</td>
</tr>
<tr>
<td>TreeMBeanUtil.java</td>
<td>Serves as the supporting utility and resource files</td>
</tr>
<tr>
<td>UIModelConstants.java</td>
<td></td>
</tr>
<tr>
<td>UIModelMsgBundle.java</td>
<td></td>
</tr>
</tbody>
</table>

The defined contextual parameter in `TreeDeployMBeanLifeCycleCallBack.java` and the class need to be registered as a listener in the `web.xml` file of the Fnd Setup application.

**Contextual Parameter:**

```
<context-param>
  <param-name>oracle.apps.fnd.internal.trees.mbean.ENABLED</param-name>
  <param-value>true</param-value>
</context-param>
```

**Listener Class:**

```
<listener>
  <listener-class>
```
Ensure the following before you execute the WLST commands for flattening:

- Integrated WebLogic Server is up and running.
- Connection is established to the WebLogic Server.
- Connection is established to the Trees MBean package.
- Each WLST command is defined.

The MBean package exposes the following set of APIs:

- flattenAll
- flattenTreeStructure
- flattenTree
- flattenTreeVersion
- flattenTreeVersionAsync
- flattenTreeVersionId
- forceFlattenTreeVersion
- auditTreeVersion
- auditTreeVersionAsync

### 20.14.8.1 How to Invoke Flattening APIs

The flattening APIs exposed by the MBean package can be invoked in two ways:

1. by passing the required parameters.

   **Note:**
   You can pass the parameters in any order.

2. by passing the parameter name and the corresponding value.

   **Note:**
   The order in which you pass the parameter and its value must match with the signature of the API.

### 20.14.8.2 About Using the `flattenAll` API

This API performs incremental flattening of all active Tree Versions under all the available Tree Structures in the application.
Note:
Only active Tree Versions are flattened.

The following table describes the parameters of this API:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:

**Example 20-9 flattenAll API Example**

```python
flattenAll(type='COLUMN')
```

20.14.8.3 About Using the flattenTreeStructure API

This API performs incremental flattening for all active hierarchies for a given Tree Structure.

Note:
Only active Tree Structures are flattened.

The following table describes the parameters of this API:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:

**Example 20-10 flattenTreeStructure API Example**

```python
flattenTreeStructure(treeStructureCode='FND_DEMO_EMP_TS')
```
20.14.8.4 About Using the flattenTree API

This API performs incremental flattening for all active Tree Versions for the specified Tree Code.

Note:
Only active Tree Versions are flattened.

The following table describes the parameters of this API:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeCode</td>
<td>String</td>
<td>Code of the tree on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:

Example 20-11 flattenTree API Example

flattenTree(treeCode='FND_DEMO_EMP_T',treeStructureCode='FND_DEMO_EMP_TS')

20.14.8.5 About Using the flattenTreeVersion API

This API performs incremental flattening for the specified tree version synchronously.

Note:
Only the tree structures that are in active or draft state are flattened.

The following table describes the parameters of this API:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeCode</td>
<td>String</td>
<td>Code of the tree on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>
### flattenTreeVersion API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeVersionName</td>
<td>String</td>
<td>Name of the tree version that needs to be flattened</td>
<td>Mandatory</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:

**Example 20-12 flattenTreeVersion API Example**

```java
flattenTreeVersion(treeStructureCode='FND_DEMO_EMP_TS',treeCode='FND_DEMO_EMP_T',treeVersionName='FND Demo Employee Tree Version',type='ROW')
```

### flattenTreeVersionAsync API

This API performs incremental flattening for the specified tree version asynchronously.

**Note:**

Only the tree structures that are in active or draft state are flattened.

The following table describes the parameters of this API:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeCode</td>
<td>String</td>
<td>Code of the tree on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeVersionName</td>
<td>String</td>
<td>Name of the tree version that needs to be flattened</td>
<td>Mandatory</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:
Example 20-13 flattenTreeVersionAsync API Example
flattenTreeVersion(treeStructureCode='FND_DEMO_EMP_TS',treeCode='FND_DEMO_EMP_T',treeVersionName='FND Demo Employee Tree Version',type='ROW')

20.14.8.7 About Using the flattenTreeVersionId API
This API performs incremental flattening for the specified tree version with the given ID.

The following table describes the parameters of this API:

Table 20-36 flattenTreeVersionId API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeCode</td>
<td>String</td>
<td>Code of the tree on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeVersionId</td>
<td>String</td>
<td>Id of the tree version that needs to be flattened</td>
<td>Mandatory</td>
</tr>
<tr>
<td>type</td>
<td>String</td>
<td>Type of flattening to be performed. It can be COLUMN or ROW flattening. By default, this API triggers both types of flattening</td>
<td>Optional</td>
</tr>
</tbody>
</table>

The following is an example of this API:

Example 20-14 flattenTreeVersionId API Example
flattenTreeVersion(treeStructureCode='FND_DEMO_EMP_TS',treeCode='FND_DEMO_EMP_T',treeVersionId='FNDDemoEmployeeTreeVersion',type='ROW')

20.14.8.8 About Using the forceFlattenTreeVersion API
This API forces flattening on the specified tree version.

Note:
Only the tree versions that are in active or draft state are flattened.

The following table describes the parameters of this API:

Table 20-37 forceFlattenTreeVersion API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>
Table 20-37  (Cont.) forceFlattenTreeVersion API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeCode</td>
<td>String</td>
<td>Code of the tree on which flattening needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeVersionName</td>
<td>String</td>
<td>Name of the tree version that needs to be flattened</td>
<td>Mandatory</td>
</tr>
</tbody>
</table>

The following is an example of this API:

**Example 20-15  forceFlattenTreeVersion API Example**

forceFlattenTreeVersion(treeStructureCode='FND_DEMO_EMP_TS',treeCode='FND_DEMO_EMP_T',treeVersionName='FND Demo Employee Tree Version')

20.14.8.9 About Using the **auditTreeVersion** API

This API performs an audit of the specified tree version synchronously.

The following table describes the parameters of this API:

Table 20-38  auditTreeVersion API Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Datatype</th>
<th>Description</th>
<th>Mandatory/Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>treeStructureCode</td>
<td>String</td>
<td>Code of the tree structure on which auditing needs to be performed</td>
<td>Mandatory</td>
</tr>
<tr>
<td>treeCode</td>
<td>String</td>

Example 20-17  auditTreeVersionAsync API Example

auditTreeVersionAsync(treeStructureCode='FND_DEMO_EMP_TS', treeCode='FND_DEMO_EMP_T', treeVersionName='FND Demo Employee Tree Version', setActive=true)

20.14.9 Understanding XML Report Formats for WLST Commands

A WLST Command Report is generated and printed on the console when a WLST command is executed. The following details are displayed on the console:

- WLST command that is executed
- registration of the MBean
- flattening call invoked
- XML report

Note:
You can redirect the details printed on the console to a file, if required.

An XML Report is generated every time you execute a WLST command. The XML report contains all the results of the flattening APIs invoked. The following examples illustrate the XML report generated in various scenarios.

Example 20-18  WLST Command Report

wls:/DefaultDomain/serverConfig>
flattenTree(treeStructureCode='TEST_VS_BICVO_TS',treeCode='TEST_VSBICVO_TREE')
<FLATTENING_INFO>Trees Flattening Mbean name:oracle.apps.fnd.applcore.trees.mbean:name=TreeFlatten,*<SUCCESS> Connected to Weblogic Server Location changed to domainRuntime tree. This is a read-only tree with DomainMBean as the root.

</TreeCode>
</TreeStructure>
</TreesFlatteningReport>
XML Report Ends
<FLATTENING_INFO>Completed flattenTree.

Example 20-19  Success Report

</xml version = '1.0' encoding = 'UTF-8'>
<TreesFlatteningReport status="SUCCESS">
<TreeStructure treeStructureCode="TEST_PLSQL_EXTN_TS" treeCodeCount="2" success="2" error="0">
</TreeCode>
</TreeStructure>
</TreesFlatteningReport>

Example 20-20  Error Report with Flattening Errors but no Exception

<xml version = '1.0' encoding = 'UTF-8'>
<TreesFlatteningReport status="ERROR">
    <TreeStructure treeStructureCode="TEST_PLSQL_EXTN_TS" treeCodeCount="1" success="0" error="1">
        <TreeCode treeCode="TEST_PLSQL_EXTN_TR1" treeVersionCount="3" success="2" error="1">
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V1" treeVersionId="B7598796828D8027E040449895F14B45" flatteningType="ROW" time="4.0secs" status="SUCCESS"/>
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V1" treeVersionId="B7598796828D8027E040449895F14B45" flatteningType="COLUMN" time="0.0secs" status="ERROR">
                ERROR:JBO-FTM-S-0045: Flattening cannot proceed due to the failure of auditing tree version TEST_PLSQL_EXTN_TS, TEST_PLSQL_EXTN_TR1, B7598796828D8027E040449895F14B45.
            </TreeVersion>
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V2" treeVersionId="B7598796829A8027E040449895F14B45" flatteningType="ROW" time="0.0secs" status="SUCCESS"/>
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V2" treeVersionId="B7598796829A8027E040449895F14B45" flatteningType="COLUMN" time="1.0secs" status="SUCCESS"/>
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V3" treeVersionId="B7598796829F8027E040449895F14B45" flatteningType="ROW" time="0.0secs" status="SUCCESS"/>
            <TreeVersion treeVersionName="TEST_PLSQL_EXTN_TR1_V3" treeVersionId="B7598796829F8027E040449895F14B45" flatteningType="COLUMN" time="1.0secs" status="SUCCESS"/>
        </TreeCode>
    </TreeStructure>
</TreesFlatteningReport>

Example 20-21  Error Report with Exception but no Flattening Errors

<xml version = '1.0' encoding = 'UTF-8'>
<TreesFlatteningReport status="ERROR">
    <Exception>null releaseTreeService Exception: Cannot release TreeService Handle</Exception>
    <TreeStructure treeStructureCode="FND_DEMO_EMP_TS" treeCodeCount="1" success="1" error="0">
        <TreeCode treeCode="FND_DEMO_EMP_T" treeVersionCount="1" success="1" error="0">
            <TreeVersion treeVersionName="FND Demo Employee Tree Version" treeVersionId="A43EE0B37975BF52E040449833F06958" flatteningType="ROW" time="0.0secs" status="SUCCESS"/>
            <TreeVersion treeVersionName="FND Demo Employee Tree Version" treeVersionId="A43EE0B37975BF52E040449833F06958" flatteningType="COLUMN" time="0.0secs" status="SUCCESS"/>
        </TreeCode>
    </TreeStructure>
</TreesFlatteningReport>
20.14.10 About Purging Unused Tree Logs

Node operations performed for a tree hierarchy also generate logs in trees tables that identify the changes made during the tree-flattening process. Once the flattening is processed for a hierarchy version, the logs that were generated prior to the last flattening run become obsolete. Over time, these obsolete records can accumulate in the log table, slowing the querying process that occurs during tree duplication or flattening.

You can purge all of these unused or archived logs for all underlying tree and tree versions associated with a selected tree structure by going to **Tree Structure Search UI > Actions > Purge Logs** in the Manage Tree Structures task flow.

**Note:**
You can only purge logs that were generated at least one day prior to the last flattening run for any tree version.
This chapter describes the Oracle Fusion Applications standards and guidelines for working with localization formatting.

- Introduction to Localization Formatting
- Formatting Currency
- Formatting Numbers
- Formatting Date and Timestamp Values
- Formatting Time Zones
- Formatting Numbers, Currency and Dates Using Localization Expression Language Functions
- Implementing Bi-directional Support
- Supporting Mnemonic Keys
- Implementing Localization Formatting in ADF Desktop Integration
- Implementing Localization Formatting in Reports
- Implementing Localization Formatting in ADF Data Visualization Components
- Configuring National Language Support Attributes
- Standards and Guidelines for Localization Formatting

### 21.1 Introduction to Localization Formatting

When developing applications for international users, it is often necessary to format the display of certain location-dependent data. In the context of Oracle JDeveloper and Oracle Application Development Framework, localization requires implementing formatting patterns so as to properly display the data according to local standards.

Currency, dates, numbers and time zones are localized using Oracle ADF Faces components that bind to the attribute to be localized. In some cases, Groovy or Expression Language methods are used to localize a particular UI component.

### 21.2 Formatting Currency

Currency values may be formatted differently, depending on the currency code associated with the value. Each currency code is associated with formatting such as precision and currency symbols.
You can format currency using the default formatting behavior, or by overriding the default formatting. Alternatively, you can format currency on the fly using partial page rendering.

Currency fields are represented by `java.lang.BigDecimal` in entity objects and view objects.

A currency field should always be formatted according to the currency code chosen in the context UI of the transaction.

For example, if the user selects JPY as the currency code from the context UI, then the currency value should be formatted according to the Japanese Yen standard.

There are two implementations to format numerical values according to the corresponding currency code.

- One is the Expression Language function `fnd:currencyPattern(currencyCode)` that takes the currency code input in the context user interface as a parameter. If JPY is input to this Expression Language function, then the number would be formatted according to the Japanese Yen pattern: #,##0;-#,##0 without showing any decimal digits, whereas if the same Expression Language function is used for the US dollar input parameter, the number would be formatted according to the USD pattern: #,##0.00;-#,##0.00. For example, the numerical value 135.6789 that is fetched from the database must be shown as 135.68 USD, whereas the same number in JPY would be shown as 136 JPY.

  The syntax is:
  
  ```
  fnd:currencyPattern(bindingToAmountCurrencyCode)
  ```

- The other implementation to format currency values is the `fnd:currencyPatternWithPrecisionAndSymbol` Expression Language function, which is a more flexible function than `fnd:currencyPattern`. The `fnd:currencyPatternWithPrecisionAndSymbol` function takes these input parameters:
  
  - currency code to be used for formatting
  - number of precision digits required in the formatted number
  - whether the currency code or symbol is to be shown in the formatted number

  The syntax is shown in Example 21-1.

  For example, if JPY is entered as the formatting currency code, and `symbol` is used as the currency code/symbol parameter, and the number of precision digits is set to 1, then the number would be formatted as #,##0 @ - #,##0 @. The numerical value 135.6789 retrieved from the database must be shown as 135.68$ in USD, whereas the same number will need to be shown as 136@ in JPY. (This example considers that the `currencySymbol` parameter has been set to `symbol`). The `currencySymbol` parameter can only take the values `symbol`, `code`, or `none`.

Currency codes are stored in the `FND_Currencies` table located in the Oracle Fusion Middleware Extensions for Applications schema. The currency code determines the format mask for the currency field, including:

**Precision**: Determines the use and number of decimal digits, comma placement, and so on.

**Currency symbol**: Displays the standard symbol for the currency.
The Expression Language function `fnd:currencyPattern()` determines formatting for the currency field using the default precision associated with the currency code. No currency symbol or code is displayed in the user interface. The Expression Language function `fnd:currencyPatternWithPrecisionAndSymbol()` determines formatting for the currency field using an extra parameter for precision. It also uses the currency code to show a currency symbol/code in the user interface. User preferences for grouping and decimal separators are used to format the value in both these functions.

**Example 21-1  Syntax of fnd:currencyPatternWithPrecisionAndSymbol**

```java
fnd:currencyPatternWithPrecisionAndSymbol(
    bindingToAmountCurrencyCode, bindingToAttrNamePrecision,
    bindingToAttrNameCurrencySymbol)
```

21.2.1 How to Format Currency

To format currency, you must first set the view object custom attribute to type `currency` and then select the currency code to be used in formatting the currency field. You can specify the currency code by entering its value explicitly, or by writing a Groovy expression in the transient attribute.

**Before you begin:**

Create an entity object and a view object.

**Example 21-2  Expression that Identifies the Currency Code**

```java
object.currencyCode
```

21.2.1.1 Formatting Currency Values

To format currency values, use the `fnd:currencyPattern()` function to obtain the format pattern of different currency codes. Therefore, a currency field, whether it is used in `inputText` or `outputText`, should be formatted with code similar to that shown here.

```xml
<af:convertNumber type="currency" currencyCode="#{bindingToAmountCurrencyCode}" pattern="#{fnd:currencyPattern(bindingToAmountCurrencyCode)}" />
```

Here, `bindingToAmountCurrencyCode` should be replaced with the actual name of the field that allows users to select a currency code.

If `<af:convertNumber type="currency" pattern="#{applCorePrefs.numberFormatPattern}"/>` is found, then the currency field will be formatted as a number. *This is incorrect.*

If the field requires displaying currency numbers combined with a currency code or currency symbol, the Expression Language function `fnd:currencyPatternWithPrecisionAndSymbol()` is necessary to get the format pattern.

In Example 21-3, the Amount field is formatted according to the currency code set in the `af:convertNumber` tag.

In Example 21-4, the grouping separator and decimal separator are taken from the user's number preferences, and the number of precision digits is set to 2. Also, the symbol shown corresponds to the currency code set in the `af:convertNumber` tag.

The fields Ordered, Total Tax, and Total in Figure 21-1 show how currency values are formatted in Oracle Fusion Applications.
21.2.1.2 What Happens When You Format Currency

When dragging and dropping the view object onto a JSF page, Applications Core generates relevant bindings to the Oracle ADF Faces Number Converter attached to the user interface component.

Example 21-5 shows bindings to the Number Converter.

As the developer, you should change the generated code according to either the fnd:currencyPattern() Expression Language function or the fnd:currencyPatternWithPrecisionAndSymbol() Expression Language function as shown in Example 21-6.

The bindings indicate that the Expression Language method fnd:currencyPattern() is to be used to return the currency code for the value of the attribute.

Example 21-5   Bindings to the Number Converter

Example 21-6   Changing the Generated Code
21.2.1.3 What Happens at Runtime: How Currency Is Formatted

At runtime, Applications Core Technology evaluates the bindings generated during design time to generate the correct currency format mask for the value. The `fnd:currencyPattern()` and `fnd:currencyPatternWithPrecisionAndSymbol()` Expression Language methods return the format mask for a given currency code, accounting for currency precision, currency symbol, and so on.

21.2.2 How to Format Currency and Override the Default Formatting Behavior

You can change the default currency formatting behavior by editing the bindings and implementing a different Expression Language method from the one used in How to Format Currency.

To format currency, overriding the default formatting behavior:

1. Follow the procedure described in How to Format Currency up to step 5.
2. To display currency symbols and override the default currency code precision, use the `fnd:currencyPatternWithPrecisionAndSymbol()` Expression Language method as shown in Example 21-7.

   The `currencySymbol` parameter can take the values `symbol`, `code`, or `none`.

   **Note:**
   The type and currency code are not specified as the formatting pattern is generated by the Oracle FND function, and not by Oracle ADF Faces.

   The Expression Language method `fnd:currencyPatternWithPrecisionAndSymbol()` is to be used to return the currency code, currency symbol, and precision values for the value of the attribute.

   For more information on the `currencyPatternWithPrecisionAndSymbol` method, see the Javadoc for the `oracle.apps.fnd.applcore.common.Preferences` class.

3. To display currency values in a user interface, drag and drop the view object including the currency attribute onto the JSF page.

   **Example 21-7  Bindings to the Number Converter with Specified Precision and Symbol Display**

   ```xml
   <af:outputText label="Amount" value="#{bindingToOrderTotal}">
   <af:convertNumber pattern="#{fnd:currencyPatternWithPrecisionAndSymbol(
     bindingToAmountCurrencyCode, bindingToAttrNamePrecision,
     bindingToAttrNameCurrencySymbol)}" />
   <af:outputText>
   ```

21.2.3 How to Immediately Format Currency Using Partial Page Rendering

Partial page rendering (PPR) can be used to immediately format or validate a currency-based UI component on the client.
Bug 7699549: The properties `autoSubmit=true` and `partialTriggers=<source attr>` are used not only for currencies but also for ordinary number values. This workaround is required when the pattern property is specified for Trinidad NumberConverter as Trinidad NumberConverter does not support client-side conversion by Javascript when the pattern property is specified. This workaround is only required for Trinidad NumberConverter, and not for DateTimeConverter. This workaround is not required for trinidad DateTimeConverter as client-side Javascript conversion is supported even when specifying a pattern property.

Once this fix has been implemented, the `autoSubmit` and `partialTriggers` workaround will no longer be necessary and should be removed.

To immediately format currency using partial page rendering:

- For the UI component with a currency type value, do the following:
  1. Set the `autoSubmit` attribute to `true`.
  2. Set the `partialTriggers` attribute to the ID of the current UI component, as shown in Example 21-8.

```
Example 21-8 Formatting Currency Using Partial Page Rendering

<af:inputText label="fld1" id="fld1" value="#{simplebean.fld1}"
  autoSubmit="true" partialTriggers="fld1">
  <af:convertNumber pattern="#,#00.00" />
</af:inputText>
```

### 21.2.4 What Happens When You Format Currency

When formatting currency, Applications Core automatically generates a transient view object attribute with the name `attributeNameCurrencyCode`. This transient attribute identifies the currency code to be used when formatting the currency field.

When dragging and dropping the view object onto a JSF page, Applications Core generates relevant bindings to the Oracle ADF Faces Number Converter attached to the user interface component as shown in Example 21-9.

The bindings indicate that the Expression Language method `fnd:currencyPattern()` is to be used to return the currency code for the value of the attribute.

```
Example 21-9 Bindings to the Number Converter

<af:outputText label="Amount" value="#{bindingToOrderTotal}"
  currencyCode="#{bindingToAmountCurrencyCode}"
  pattern="#{fnd:currencyPattern(bindingToAmountCurrencyCode)}" />
<af:outputText>
```

### 21.2.5 What Happens at Runtime: How Currency Is Formatted

At runtime, Applications Core evaluates the bindings generated during design time to generate the correct currency format mask for the value. The `fnd:currencyPattern()` and `fnd:currencyPatternWithPrecisionAndSymbol()` Expression Language methods return the format mask for a given currency code, accounting for currency precision, currency symbol, and so on.
21.3 Format Numbers

All numerical values need to be formatted correctly when they are presented to a user in Oracle Fusion Applications. Users expect that they can enter numerical values based on their formatting preferences, which include such things as options to change the grouping and the decimal separators. Number formatting preferences also let users choose the number format mask that will be used to display the number. For instance, a user might choose that the grouping separator has to be shown once every three digits with a maximum of three decimal digits (#,##0.###). An example is a value of 1234.5 in the database that might have to be displayed as 1,234,500 or 1,234.500 or 1.234,500.

21.3.1 How to Format Numbers

Before you begin:

Create an entity object and a view object with number fields, including any of these attribute types:

The number one thousand two hundred and thirty four point five six can display in any of the following formats:

- 1,234.56
- 1’234.56
- 1’234,56
- 1.234,56
- 1234.56 (ISO standard)
- 1234,56
- 1 234.56
- 1 234,56

View objects and entity objects can be formatted so as to display date and number data in accordance with local standards. The ISO standard is typically used when it is not desirable to use local standards.

21.3.1.1 Formatting Decimal Numbers

Decimal output fields should be formatted according to the user’s number formatting preferences. Use the <af:convertNumber pattern...> entry to retrieve the number formatting pattern from the applCorePrefs bean, as shown in Example 21-10.

Input decimal fields should be formatted according to the user’s number preferences. In Example 21-11, use the <af:convertNumber pattern...> entry to retrieve the number formatting pattern from the applCorePrefs bean.

The Threshold Start field in Figure 21-2 is an example of a number field that is formatted according to the user’s number formatting preferences.
When a decimal number is to be shown as a part of a larger string object on the user interface, the fn:formatNumber and fn:formatNumber2 Expression Language functions provided in the applCore library is necessary to format such numbers. When either of these functions is used, the user’s number formatting preferences are implemented according to applCorePrefs.numberFormatPattern.

The syntaxes of the two Expression Language functions are:

- fn:formatNumber(java.lang.Number decimalValueToBeFormatted)
- fn:formatNumber2(java.lang.Number decimalValueToBeFormatted, int maximumNumberOfFractionDigits)

Example 21-12 shows how to use these two functions for decimal number formatting.

As shown in Example 21-12, the variable ActiveResponsesChangeAmt will be formatted according to the user’s number preferences according to applCorePrefs.numberFormatPattern. This formatted number is then concatenated to the externalized string FavorablyIncreasedbyVALUE and displayed to the user.

The fn:formatNumber2 function has the advantage of explicitly specifying the maximum number of fraction digits in the formatted number, as shown in Example 21-13.

Here, the text attribute of the af:showDetailItem tag includes a number that must be formatted before being displayed. Therefore, the fn:formatNumber2 Expression Language function has been used to format the number to be added to the SubmittedValues string. Here, the second parameter has been set to 2 and indicates that a maximum of two fractional digits can be shown in the decimal number. So, for example, after formatting, the number 1234.56789 that is retrieved from the database will be displayed as SubmittedValues: 1,234.57.

Example 21-10  Formatting Decimal Output Fields

```html
<af:outputText value="${bindings.FromValue.inputValue}" id="ot19">
<af:convertNumber pattern="${applCorePrefs.numberFormatPattern}"/>
</af:outputText>
```

Example 21-11  Formatting Input Decimal Fields

```html
<af:inputText value="${row.bindings.FromValue.inputValue}"
label="${bindings.PerformanceThreshold21hints.FromValue.label}"
required="${bindings.PerformanceThreshold21hints.FromValue.mandatory}"
columns="${bindings.PerformanceThreshold21hints.FromValue.displayWidth}"
maximumLength="${bindings.PerformanceThreshold21hints.FromValue.precision}"
shortDesc="${bindings.PerformanceThreshold21hints.FromValue.tooltip}"
id="inputText9"
autoSubmit="true">
```
Example 21-12  Decimal Number Formatting

Example 21-13  Using the fnd:formatNumber2 Function

21.3.1.2 Formatting Integer Numbers

In Figure 21-3, Point 1 is an example of an input integer field that is formatted according to the user's number preferences without showing the decimal separator or any precision digits.
When an integer number is to be shown as a part of a larger string object on the user interface, the \texttt{fnd:formatNumber2} function provided in the applCore library is necessary to format such numbers. When this function is used with the maximum number of precision digits set to 0, the user's number formatting preferences are used from \texttt{applCorePrefs.numberFormatPattern} with no precision digits.

The syntax of the \texttt{fnd:formatNumber2} function is as follows:

\begin{verbatim}
\texttt{fnd:formatNumber2(}java.lang.Number integerValueToBeFormatted, int maximumNumberOfFractionDigits\texttt{)}
\end{verbatim}

The \texttt{fnd:formatNumber2} function can be used to format integer numbers by explicitly specifying the maximum number of fraction digits as 0 in the formatted number. \textbf{Example 21-16} shows how to use the \texttt{fnd:formatNumber2} function for integer number formatting.

Here, the text attribute of the \texttt{af:showDetailItem} tag includes a number that must be formatted before being displayed. The \texttt{fnd:formatNumber2} function is used to format the integer to be added to the \texttt{SubmittedInvoices} string. The second parameter has been set to 0 and indicates that no fractional digits can be shown in the formatted number. For example, after formatting, the number 1234 that is retrieved from the database will be displayed as \texttt{SubmittedInvoices: 1,234}.

\textbf{Example 21-14} \quad Formatting Integer Numbers

\begin{verbatim}
<af:outputText value="#{bindings.integerQuantity.inputValue}" id="ot19">
<af:convertNumber pattern="#{applCorePrefs.integerFormatPattern}"/>
</af:outputText>
\end{verbatim}

\textbf{Example 21-15} \quad Formatting Input Integer Fields

\begin{verbatim}
<af:inputText value="#{bindings.Point1.inputValue}"
label="#{bindings.Point1.hints.label}"
required="#{bindings.Point1.hints.mandatory}"
columns="#{bindings.Point1.hints.displayWidth}"
maxLength="#{bindings.Point1.hints.precision}"
shortDesc="#{bindings.Point1.hints.tooltip}"
inlineStyle="width:100%; border-color:InactiveBorder; border-width:thin;"
\end{verbatim}
21.3.1.3 Formatting ID Numbers

An ID field is a number field that uniquely identifies an object. Typical examples of ID fields include TransactionID, Sequence Number, and Item Number. Such ID output fields should be formatted without using the user's number formatting preferences. That is, ID output fields should not display decimal precision digits or grouping separators. For example, a student's admission number should be displayed as 14567 instead of 14,567.00. The `<af:convertNumber pattern...` entry in Example 21-17 retrieves the number formatting pattern from the `applCorePrefs` bean.

Note:

ID fields always should be aligned to the left. As a developer, you must not hardcode the align attribute of the column attribute of an `af:table`, or the `contentStyle` attribute of the `af:outputText` tag displaying an ID field. By default, Oracle ADF supports start alignment that is appropriate for ID fields.

The field Sales Order Line in Figure 21-4 corresponds to the output ID field shown in Example 21-17.

Figure 21-4 Sample Output ID Field

Input integer fields should be formatted according to the user's number preferences without showing any decimal precision digits or grouping separators. The `<af:convertNumber pattern...` entry in Example 21-18 indicates that the number formatting pattern is being retrieved from the `applCorePrefs` bean.
Format Numbers

The Sequence field in Figure 21-5 corresponds to the input ID field shown in
Example 21-6.
Figure 21-5

Example Input ID Field

The fnd:formatNumber() and fnd:formatNumber2() functions must not be used
for ID fields appearing in strings, because they introduce a grouping separator in
number fields, which should not be displayed in ID fields. In such cases, output ID
fields should be treated as normal text fields.
Example 21-17

Formatting ID Numbers

<af:column headerText="#{bindings.Deliveries.hints.SalesOrderLine.label} id="c9" >
<af:outputText value="#{row.bindings.SalesOrderLine.inputValue}"
label="#{bindings.Deliveries.hints.SalesOrderLine.label}" id="outputText3">
<af:convertNumber pattern="#{applCorePrefs.numericCodeFormatPattern}"/>
</af:outputText>
</af:column>

Example 21-18

Formatting Input Integer Fields

<af:inputText value="#{bindings.SequenceNumber.inputValue}"
label="#{bindings.SequenceNumber.hints.label}"
required="#{bindings.SequenceNumber.hints.mandatory}"
columns="#{bindings.SequenceNumber.hints.displayWidth}"
id="inputText1"
partialTriggers="asgStat"
helpTopicId="InvCoreSetup_755E15370133C364E040D30A688161D5V000"
contentStyle="text-align:start"
autoSubmit="true">
<f:validator binding="#{bindings.SequenceNumber.validator}"/>
<af:convertNumber pattern="#{applCorePrefs.numericCodeFormatPattern}"/>
</af:inputText>

21.3.1.4 How to Format Numbers in Hyperlinks
In Oracle Fusion Applications, hyperlinks are represented by af:commandLink and
af:goLink. All numbers found in the labels of hyperlinks in the user interface must
be formatted according to the user's number preferences. The number might either
have to be formatted according to numberFormatPattern if the number value is
decimal in nature, integerFormatPattern if the number value is integer only, and
need not be formatted at all if the value corresponds to an ID value. Code to format
numbers in hyperlinks is shown in Example 21-19.
Because af:convertNumber is not a valid child tag of af:commandLink, the best
way to format a number on a link is by making the text attribute of the
af:commandLink tag empty and then adding an af:outputText tag as a child tag
that displays the formatted numerical value. In this case, the number is an integer
(java.lang.Integer), so the pattern applCorePrefs.integerFormatPattern has
been used. In cases of decimal numbers (java.math.bigDecimal),
applCorePrefs.numberFormatPattern has to be used, while in cases of ID fields
(java.lang.Long), af:convertNumber can be removed and the field can be honored

21-12 Oracle Fusion Applications Developer's Guide


as plain text. The parent hyperlink tag can be either `af:commandLink` or `af:goLink`.

Similarly, numbers that are found on links represented by the `af:goLink` tag in Oracle Application Development Framework (Oracle ADF) should be formatted according to the user's number formatting preferences using the Preferences bean. The procedure to be followed is very similar to that of the `af:commandLink` tag. Sample code for number formatting in `af:goLink` is shown in Example 21-20.

Again, `af:goLink` cannot have an `af:convertNumber` as its child tag, so the text attribute of the `goLink` tag should be made empty and `af:outputText` should be added as a child tag of `af:goLink`. The `af:convertNumber` then can be added as a subtag of the `outputText` tag. The pattern attribute can be changed for this `af:convertNumber` tag, according to whether the number is decimal or an integer. If the number represents an ID field, no number formatting is needed.

Another way of formatting the text in `af:commandLink` and `af:goLink` is by using the Expression Language functions `fnd:formatNumber` and `fnd:formatNumber2` in their text attributes. Sample code to format a number in a `commandLink` using the `fnd:formatNumber2` Expression Language function is shown in Example 21-21.

Here, the second parameter has been set to 0 so that no precision digits are shown. This is the same as using

```
(pattern="#{applCorePrefs.integerFormatPattern}" as used in Example 21-19). The only added feature in this example is that there is no need to add a child `af:outputText` tag for number formatting.
```

Similarly, `af:goLink` can also be formatted using the `fnd:formatNumber` and `fnd:formatNumber2` Expression Language functions. An example of formatting the `af:goLink` shown in Example 21-20 using the `fnd:formatNumber` function is shown in Example 21-22:

```
Here, the `fnd:formatNumber` Expression Language function has been used to format the value in the `af:goLink`. This is the same as using pattern="#{applCorePrefs.numberFormatPattern}" as shown in Example 21-20.
```

Example 21-19  Formatting Numbers in Hyperlinks

```
<af:commandLink id="outputText6" text="" partialSubmit="true" immediate="true" action="#{LocalAreaHandlerBean.showInventory}"
<af:outputText value="#{row.InvPendingCount}" id="ot1">
    <af:convertNumber type="number" pattern="#{applCorePrefs.integerFormatPattern}"/>
</af:outputText>
</af:commandLink>
```

Example 21-20  Formatting a Number in `af:goLink`

```
<af:goLink text="" id="g1l" destination="#{row.children[0].FileUrl}"
<af:outputText id="id1" value="#{bindings.fromValue.inputValue}"
    <af:convertNumber type="number" pattern="#{applCorePrefs.numberFormatPattern}"/>
</af:outputText>
</af:goLink>
```

Example 21-21  Formatting a Number in a `commandLink`

```
<af:commandLink id="outputText6" text="#{fnd:formatNumber2(row.InvPendingCount,0)}"
    partialSubmit="true" immediate="true"
```

Work with Localization Formatting 21-13
Example 21-22  Formatting af:goLink Using fnd:formatNumber

21.3.1.5 How to Format Percentage Values

A percentage value maps to java.math.BigDecimal in entity object and view object files and NUMBER(n, m) (where m! = 0) in underlying database columns.

Such percentage values in output fields must be displayed in a locale-sensitive format. For example, 75.68% in en_US (Language: English Territory: United States) should be displayed as 75,68 % (there is a space between the number and the percentage sign) in the fr_FR (Language: French Territory: France) locale.

The number and percentage sign of a percentage value should always be displayed in a user preferred format in Oracle Fusion Applications. Sample code that can display percentage values is shown in Example 21-23.

Here, maxFractionDigits can be determined by the underlying database column type using this formula:

maxFractionDigits = The scale of database Column Data Type - 2

For example, if the database column data type is NUMBER(8,4), maxFractionDigits can be “2”. If “The scale of database Column Data Type - 2” <= 0, attribute maxFractionDigits should not be added to the convertNumber tag.

This formula arises from the fact that a percentage value like 1% usually is stored in the database column as 0.01. Hence, the maximum number of fraction digits in the percentage value to be displayed on the user interface will always be 2 less than the scale of the database column.

In Oracle Fusion Applications, you must not hardcode the % sign in the value attribute of the outputText tag, because this makes the percentage values locale-insensitive.

The Percent of Project Work Complete field in Figure 21-6 corresponds to the output percentage field shown in Example 21-23.

Figure 21-6    Results of Output Percentage Field

A percentage value in an input field generally is formatted exactly like the output percentage field. Sample code to format input percentage fields is shown in Example 21-24.
Example 21-23  Displaying Percentage Values

```af:outputText value="#{row.PercentComplete != null ? (row.PercentComplete * 0.01): row.PercentComplete}"
   id="outputText5">
   <af:convertNumber minFractionDigits="2" maxFractionDigits="2"
      type="percent"/>
   <af:showPopupBehavior triggerType="click"
      popupId=":::progressTrendPopup"
      alignId="rowHeadCol"/>
</af:outputText>

Example 21-24  Formatting Input Percentage Fields

```af:inputText value="#{bindings.PercentQuantity.inputValue}"
   label="#{bindings.PercentQuantity.hints.label}"
   autoSubmit="true"
   id="inputText10"
   <f:validator binding="#{bindings.PercentQuantity.validator}"/>
   <af:convertNumber type="percent" minFractionDigits="2"
      maxFractionDigits="2"/>
</af:inputText>

21.3.2 How to Format Numeric IDs and Integers

Not all number values should be formatted using the numberFormatPattern property. For example, a numeric identifier should always be a series of numbers with no locale-sensitive punctuation. The applCorePrefs managed bean provides the numericCodeFormatPattern property to format a numeric code in the same way for all users.

Example 21-25 shows the bindings to the property numericCodeFormatPattern.

The integerFormatPattern property enables formatting an integer, as shown in Example 21-26. No fractions are printed.

Example 21-25  Bindings to the numericCodeFormatPattern Property

```af:convertNumber pattern="#{applCorePrefs.numericCodeFormatPattern}"/>

Example 21-26  Bindings to the integerFormatPattern Property

```af:convertNumber pattern="#{applCorePrefs.integerFormatPattern}"/>

21.3.3 What Happens When You Format Numbers

All number formatting patterns default to the formats described in How to Format Numbers.

When dragging and dropping a view object containing an attribute of type java.math.BigDecimal or java.lang.Integer, or java.lang.Long, Applications Core generates code that binds to the numberFormatPattern property in the applCorePrefs managed bean as shown in Example 21-27.

Example 21-27  Bindings to the numberFormatPattern Property

```af:convertNumber pattern="#{applCorePrefs.numberFormatPattern}"/>
21.3.4 What Happens at Runtime: How Numbers Are Formatted

At runtime, the bindings generated at design time are executed. Numbers are displayed according to user preferences for number formatting patterns, such as 1,234.567.

21.3.5 Standards and Guidelines

The following standards and guidelines apply to formatting dates and numbers:

- All date only fields must be represented only by java.sql.Date data types.
- When a value bound to a field is date only, of type java.sql.Date, make sure not to set the time zone to af:convertDateTime.

21.4 Format Date and Timestamp Values

All date values must be formatted correctly when they are presented to a user. Users expect to input values according to their date formatting preferences. For instance, a value of 13 August, 2011 in the database might have to be displayed as 08/13/2011 or 2011.8.13. A similar example of a date-time value is a value of 26 July 2011, 2:00:00 PM might have to be displayed as 14:00 07/26/2011 or 2011.7.26 02:00:00 PM.

21.4.1 How to Format Dates and Timestamp Values

Before you begin:

Create an entity object and a view object with date fields, including either of these attribute types: java.sql.Date or java.sql.Timestamp.

21.4.1.1 Formatting Dates

Dates without time values (called dates) are mapped to java.sql.Date in the entity object/view object layer. These fields should be formatted according to the user's date formatting preferences.

There are two options for formatting dates using the applCorePrefs bean:

- **dateFormatPattern**: This property formats the date according to user preferences, within a two digit range spanning one hundred years (for example, 1950-2049).
- **longDateFormatPattern**: This property formats the date according to user preferences, within a four digit range. For example, the user-specified date format yy/dd/mm is rendered yyyy/dd/mm. This is useful for applications that require a four digit format for rendering years.

Example 21-28 shows the use of the date formatting pattern.

Both the filter for the date and the date field should be formatted according to the user's date formatting preferences.

The values for the Due Date field in Figure 21-7 are examples of how a date value is formatted according to the user's preferences in Oracle Fusion Applications.
You can also use the property `applCorePrefs.longDateFormatPattern` to format a date value. The property `applCorePrefs.longDateFormatPattern` formats a date value using nearly the same pattern as `applCorePrefs.dateFormatPattern`, except the year is always displayed with the format `yyyy`. For example, when the property `applCorePrefs.dateFormatPattern` is formatted `mm/dd/yy`, the property `applCorePrefs.longDateFormatPattern` is formatted `mm/dd/yyyy`. When the property `applCorePrefs.dateFormatPattern` is formatted `mm/dd/yyyy`, the property `applCorePrefs.longDateFormatPattern` is formatted `mm/dd/yyyy`.

Example 21-28 Formatting Dates with `dateFormatPattern`

```java
<af:column sortProperty="OrderDate" filterable="true" sortable="true" headerText="#{bindings.NlsOrders1.hints.OrderDate.label}" id="c1">
    <f:facet name="filter">
        <af:inputDate value="#{vs.filterCriteria.OrderDate}" id="id8" >
            <af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}" />
        </af:inputDate>
    </f:facet>
    <af:inputDate value="#{row.bindings.OrderDate.inputValue}" label="#{bindings.NlsOrders1.hints.OrderDate.label}" required="#{bindings.NlsOrders1.hints.OrderDate.mandatory}" shortDesc="#{bindings.NlsOrders1.hints.OrderDate.tooltip}" id="id1">
        <f:validator binding="#{row.bindings.OrderDate.validator}" />
        <af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}" />
    </af:inputDate>
</af:column>
```

21.4.1.2 Formatting Current Dates

Applications often show the current date on the user interface. They are mapped to the `java.sql.Date` data type in the entity object/view object layer. Correctly identifying the date requires the use of particular APIs.

A server date is calculated by truncating the time portion of the current time from the system clock. However, it may not be appropriate to display the server date to end users if they are not located in the server time zone. For example, when creating an order, the order form may display with the order date filled out for the end user with the current date. In this case, the order date must be the end user's local date rather than the server date. A server in the US may be serving an end user in China, whose local date may be one day ahead due to time zone differences. It is necessary to adjust the server date to the end user's local date.

The following methods return the current date in UPTZ:

- `ApplSessionUtil.getCurrentLocalDate()`: This method returns an instance of `java.util.Date`. 

Format Date and Timestamp Values

•

ApplSessionUtil.getCurrentLocalSqlDate(): This method returns an instance of
java.sql.Date.

These methods can be used in JSF pages, entity object files, and Java bean classes to
retrieve a current date in UPTZ.
Example 21-29 shows how to adjust the server date to the local date in the Java bean
using the getCurrentLocalDate() method.
Example 21-30 shows how to display the current date in the JSF page.
example shows how to set the current date in UPTZ as a value in entity object files.
The Required Date field in Figure 21-8 should default to the user's preferred time zone
rather than the server time zone, which, in this case, shows a date value with the
format yyyy.mm.dd.
Figure 21-8

Example of a Field to Default to User's Time

Example 21-29

Getting the Current Date in UPTZ Using java Bean Classes

import java.sql.Date;
import oracle.apps.fnd.applcore.common.ApplSessionUtil;
...
Date currentDate = ApplSessionUtil.getCurrentLocalSqlDate();
...

Example 21-30

Displaying the Current Date in the JSF Page

<af:outputText value="#{applCorePrefs.currentLocalSqlDate}" id="ot1">
<af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}"/>
</af:outputText>

Example 21-31

Setting the Current Date in UPTZ as a Value in Entity Object Files

<Attribute
Name="CreationDate"
IsNotNull="true"
ColumnName="CREATION_DATE"
SQLType="TIMESTAMP"
Type="java.sql.Date"
ColumnType="DATE"
TableName="FND_TERRITORIES_B"
RetrievedOnInsert="true">
<DesignTime>
<Attr Name="_DisplaySize" Value="11"/>
</DesignTime>

21-18 Oracle Fusion Applications Developer's Guide


21.4.1.3 Formatting Timestamp Values

Dates with time values (called datetimes) are mapped to java.sql.Timestamp in the entity object/view object layer. Format these fields according to the user’s date and time formatting preferences.

All datetime fields must have at least one of these three patterns in the af:convertDateTime tag to be formatted according to the user’s date and time preferences.

**Note:**

There is a single space between the two Expression Language expressions.

- **Pattern 1**
  
  pattern="#{applCorePrefs.UPTZPattern}"

  applCorePrefs.UPTZPattern returns a pattern by combining the selection of the Date Format and the Time Format in User Preferences. For example, if a user selects M.d.yyyy (4.28.2010) from the Date Format list, and HH.mm (00.55) from the Time Format list, applCorePrefs.UPTZPattern returns a pattern M.dd.yyyy HH:mm. Therefore, applCorePrefs.UPTZPattern may return a pattern with or without Seconds, depending on the selection in User Preferences.

- **Pattern 2**
  
  This pattern is applicable if it always needs to display the Seconds part of a datetime value.

  pattern="#{applCorePrefs.DateFormatPattern} #{applCorePrefs.timeFormatPatternWithSeconds}"

- **Pattern 3**
  
  pattern="#{applCorePrefs.DateFormatPattern} #{applCorePrefs.timeFormatPatternWithoutSeconds}"

  This pattern is applicable if it does not need to display the Seconds part of a datetime value.

- **Pattern 4**
  
  pattern="#{applCorePrefs.timeFormatPattern}"

  This pattern returns the value of timeFormatPattern based on user preferences.

- **Pattern 5**
  
  pattern="#{applCorePrefs.timeFormatPatternWithSeconds}"

  This pattern returns the value of getTimeFormatPattern(), appending seconds to the format if the format does not already contain seconds (hh.mm.ss).
The pattern enforces the addition of the seconds attribute, depending on the value of **timeFormatPattern**.

Examples are as follows.

If the value of **timeFormatPattern** is a **hh.mm.ss**, then **timeFormatWithSeconds** produces the format **a hh.mm.ss**.

If the value of **timeFormatPattern** is a **hh.mm**, then **timeFormatWithSeconds** produces the format **a hh.mm.ss**.

- **Pattern 6**

  ```
  pattern="#{applCorePrefs.timeFormatPatternWithoutSeconds}"
  ```

  This pattern returns the value of the method **getTimeFormatPattern()**, and removes the seconds portion from the time format. This pattern enforces the removal of seconds attributes depending on the value of **timeFormatPattern**.

  Examples are as follows.

  If the value of **timeFormatPattern** is a **hh.mm.ss**, then **timeFormatWithoutSeconds** produces the format **a hh.mm**.

  If the value of **timeFormatPattern** is a **hh.mm**, then **timeFormatWithoutSeconds** produces the format **a hh.mm**.

Both the filter for the date-time and the date-time field should be formatted according to the user's date and time formatting preferences, as shown in **Example 21-32**. If this is not done, these fields will not be processed according to the user's preferences.

The Last Saved field at the top right of Figure 21-9 is an example of how a date-time is formatted according to the user's preferences in Oracle Fusion Applications. In this case, the date and time are displayed in the format **mm.dd.yy** and the time **hh:mm AM**.

**Figure 21-9   Example of a Formatted Date and Time**

**Example 21-32   Formatting Timestamp Values**

```
21.4.2 What Happens When You Format Dates and Timestamps

When dragging and dropping a view object containing an attribute of type `java.sql.Date` or `java.sql.Timestamp`, Applications Core generates code that binds to the `dateFormatPattern` (date fields) or `UPTZPattern` (timestamp fields) property in the `applCorePrefs` managed bean.

Example 21-33 shows bindings to the `dateFormatPattern` property. The pattern according to which the date value is formatted is picked up from the Preferences bean in Applications Core, which in turn accesses these values from the LDAP server configured with users' roles and policies.

This type of code is generated for both date and timestamp fields. For date fields, you should add the `type="date"` attribute, whereas for timestamp fields, you should add the `type="both"` attribute, and make the pattern attribute equal to one of the three patterns discussed above.

Example 21-33  Bindings to the dateFormatPattern Property

```xml
<af:panelLabelAndMessage label="#{bindings.OrderDate.hints.label}" id="plam1">
    <af:outputText value="#{bindings.OrderDate.inputValue}" id="ot1">
        <af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}"/>
    </af:outputText>
</af:panelLabelAndMessage>
```

21.4.3 What Happens at Runtime: How Dates and Timestamps Are Formatted

At runtime, the bindings generated at design time are executed. Dates and Timestamps are displayed according to user preferences for date and time formatting patterns (for example, 01/01/10 and 01/01/10 01:05:00).

21.4.4 Standards and Guidelines for Formatting Dates and Timestamps

The following standards and guidelines apply to formatting dates and timestamps.

- All date-only fields must be represented only by `java.sql.Date` data types.
- When a value bound to a field is date-only of type `java.sql.Date`, do not set the time zone to `af:convertDateTime`.

21.5 Formatting Time Zones

Date values with time (called datetime values) are mapped to `java.sql.TimeStamp` in the entity object and view object layer. In Oracle Fusion Applications, datetime values can be calculated according to one of these time zones:

- **Server Reporting Time Zone**
  
  This is the default and simply is the time zone of the server's operating system.

- **User Preferred Time Zone (UPTZ)**
  
  When UPTZ is used, the date-time changes in the UI when a user changes the Time Zone preference in User Preferences. For example, if a user switches the Time Zone preference from UTC-08:00 to UTC-11:00, the date-time 04/27/2010 01:00:00 will change to 04/26/2010 23:00:00. The value in the database is not
changed, and the conversion occurs after the value is retrieved from the database and before it is shown on the user interface.

- **Legal Entity Time Zone (LETZ)**

  LETZ is defined with legal entities. It is an attribute of a legal entity business object. For example, when creating a legal entity ORACLE-CDC, it can have a time zone attribute (LETZ) which value is UTC+08:00. Thus a date-time 04/27/2010 01:00:00 in UTC will change to 04/27/2010 09:00:00 accordingly. The value in the database is not changed, and the conversion occurs after the value is retrieved from the database and before it is shown on the user interface.

The business logic of the application decides which time zone to use to calculate the date-time value.

### 21.5.1 How to Format Time Zones

The different types of tags required to implement either the User Preferred Time Zone or Legal Entity Time Zone are shown in this section.

**Before you begin:**

Create an entity object and a view object with date fields, and include the java.sql.Timestamp attribute type. Note that the middle-tier time zone and the database time zone always must match. If they do not match, the conversions will be invalid.

**Using the Server Reporting Time Zone**

Use Example 21-34 if the date-time value is to be calculated according to the Server Reporting Time Zone.

This is to say that nothing must be explicitly added into the automatically generated af:convertDateTime tag.

**Using the User Preferred Time Zone**

Use this code sample to calculate the date-time value according to the User Preferred Time Zone.

**Converting a Timestamp to the Legal Entity Time Zone**

Follow this method to convert a timestamp value to the Legal Entity Time Zone:

Retrieval of the Legal Entity time zone. Each legal entity has a LETZ. Determining a LETZ starts with a legal entity’s address that is used to look up a specific location and a unique time zone attribute. This time zone is the LETZ for the legal entity.

Related tables in the database are:

- FND_TIMEZONES_B and FND_TIMEZONES_TL, tables to record time zone related information.
- XLE_REGISTRATIONS, a table of Legal Entity data.
- HZ_LOCATIONS, a table to store geographical locations.

Use this PL/SQL API to obtain the Legal Entity Time Zone code. This API is found in the package XLE_LE_TIMEZONE_GRP and is to be called in the following way:

Get_Le_Tz_Code(?,?)

The ? indicates an input parameter.
Example 21-36 shows sample code for using Get_Le_Tz_Code(?,?)

To retrieve the current date and time in the Legal Entity Time Zone, use this PL/SQL API to calculate the current date and time in the Legal Entity Time Zone. This is particularly useful while creating or saving a transaction, when the legal entity date and time is to be displayed. This API is found in the XLE_LE_TIMEZONE_GRP package and is to be called in the following way:

Get_Le_Sysdate_Time(?,?)

The ? indicates an input parameter.

Example 21-37 uses this API to determine the current date and time in the LETZ.

This function will invoke the API (Get_DefaultLegalEntity) when the input parameter passed is the Business Unit or the Inventory Organization.

To retrieve the server date and time into the LETZ, use this PL/SQL API. This is useful while retrieving an already saved transaction and showing the already saved timestamp in the LETZ. This API is found in the XLE_LE_TIMEZONE_GRP package and is to be called in the following way:

Get_Le_Day_Time(?,?,?)

The ? indicates an input parameter.

Example 21-38 uses Get_Le_Day_Time(?,?,?) to convert a given date and time from the server time zone to the LETZ.

Here the p_trxn_date is the transaction date and time value in the server time zone.

To convert the legal entity date and time into the server time zone, use this PL/SQL API. This API is found in the XLE_LE_TIMEZONE_GRP package and is to be called in the following way:

Get_Server_Day_Time(?,?,?)

The ? indicates an input parameter.

This API will be for reverse LETZ conversion. Calling applications can pass in the Legal Entity Date Time and the Business Unit/Inventory Organization/Legal Entity ID to convert the Legal Entity datetime to the server datetime.

Example 21-39 uses Get_Server_Day_Time(?,?,?) to convert the LETZ timestamp value to server time zone.

These PL/SQL APIs must be called in the Java entity object implementation classes for time zone conversion. The JSF code corresponding to the date field need not be changed.

Here is a sample of a JSF date field in the server time zone and its corresponding conversion into the LETZ. The code in the JSF page corresponding to a date field is shown in Example 21-40.

As shown, you do not need to change the date field’s snippet in the JSF page, or add a time zone attribute in the af:convertDateTime tag for this field.

The calculation of LETZ date values should be triggered when changing the value for the Business Unit field in the user interface. The value change should invoke a method that can calculate values according to the LETZ in the EOImpl class. In this case, this method is the setOrgID() method, shown in Example 21-41.
In Figure 21-10, the field Receipt Date is an example of how a date-time or a timestamp field in Oracle Fusion Applications is calculated according to the user’s preferred time zone rather than the server time zone.

**Figure 21-10 Converting to User Preferred Time Zone**

In Figure 21-11, the Business Unit field determines the LETZ according to which the date fields Date and Terms Date on the right of the screenshot are converted in Oracle Fusion Applications. Thus, the fields Date and Terms Date change according to the Business Unit field in the Create Invoice transaction. In this case, the dates display in the format mm/dd/yy.

**Figure 21-11 Converting to Legal Entity Time Zone**

**Example 21-34 Using the Server Reporting Time Zone**

```
<af:outputText value="#{bindings.StartDate.inputValue}" ... />
<af:convertDateTime type="both" pattern="#{applCorePrefs.UPTZPattern}" />
</af:outputText>
```

**Example 21-35 Using the Preferred Time Zone**

```
<af:outputText value="#{bindings.StartDate.inputValue}" ... />
<af:convertDateTime type="both" pattern="#{applCorePrefs.UPTZPattern}"
   timeZone="#{applCorePrefs.UPTZ}" />
</af:outputText>
```

**Example 21-36 Using Get_Le_Tz_Code(?,?)**

```
l_timezone_code = XLE_LE_TIMEZONE_GRP.Get_Le_Tz_Code('BUSINESS_UNIT_ID', p_ou_id);
l_timezone_code = XLE_LE_TIMEZONE_GRP.Get_Le_Tz_Code('INVENTORY_ORG_ID', p_inv_org_id);
l_timezone_code = XLE_LE_TIMEZONE_GRP.Get_Le_Tz_Code('LEGAL_ENTITY_ID', p_le_id);
```

**Example 21-37 Determining the Current Date and Time in the LETZ**

```
l_sysdate = XLE_LE_TIMEZONE_GRP.Get_Le_SysDate_Time('BUSINESS_UNIT_ID', p_ou_id);
l_sysdate = XLE_LE_TIMEZONE_GRP.Get_Le_SysDate_Time('INVENTORY_ORG_ID', p_inv_org_id);
l_sysdate = XLE_LE_TIMEZONE_GRP.Get_Le_SysDate_Time('LEGAL_ENTITY_ID', p_le_id);
```
Example 21-38  Converting a Date and Time to the LETZ Using Get_Le_Day_Time

```java
l_le_day_time = XLE_LE_TIMEZONE_GRP . Get_Le_Day_Time ('BUSINESS_UNIT_ID', p_ou_id, p_trxn_date);
l_le_day_time = XLE_LE_TIMEZONE_GRP . Get_Le_Day_Time ('INVENTORY_ORG_ID', p_inv_org_id, p_trxn_date);
l_le_day_time = XLE_LE_TIMEZONE_GRP . Get_Le_Day_Time ('LEGAL_ENTITY_ID', p_le_id, p_trxn_date);
```

Example 21-39  Converting the LETZ Timestamp to the Server Time Zone with Get_Server_Day_Time(?,?,?)

```java
l_Server_Date := XLE_LE_TIMEZONE_GRP . Get_Server_Day_Time ('INVENTORY_ORG_ID', p_inv_org_id, p_le_Date);
l_Server_Date := XLE_LE_TIMEZONE_GRP . Get_Server_Day_Time ('BUSINESS_UNIT_ID', p_ou_id, p_le_Date);
l_Server_Date := XLE_LE_TIMEZONE_GRP . Get_Server_Day_Time ('LEGAL_ENTITY_ID', p_inv_org_id, p_le_Date);
```

Example 21-40  Converting a Date Field into the LETZ

```java
<af:inputDate value="#{bindings.InvoiceDate.inputValue}" label="#{bindings.InvoiceDate.hints.label}" required="#{bindings.InvoiceDate.hints.mandatory}" shortDesc="#{bindings.InvoiceDate.hints.tooltip}" showRequired="true" autoSubmit="true" valueChangeListener="#{pageFlowScope.invoiceActionsBean.invoiceDateValueChangeListener}" columns="#{bindings.InvoiceDate.hints.displayWidth}" disabled="#{pageFlowScope.matchPopupVisible}" id="id2">
  <f:validator binding="#{bindings.InvoiceDate.validator}"/>
  <af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}"/>
</af:inputDate>
```

Example 21-41  Using the setOrgID() Method

```java
public void setOrgID(Long orgID)
{

  // To convert the current timestamp to the LETZ, call another method
  this.setInvoiceDate(this.getLEDateTime(orgID, this.getDBTransaction()));
}
```

```
//This method calls the PL/SQL API to get the current date and time in the LETZ.
public Date getLEDateTime(Long orgId, DBTransaction dbTransaction)
{

  // 1. Define the PL/SQL block for the statement to invoke
  String stmt = "begin ? := XLE_LE_TIMEZONE_GRP.Get_Le_Sysdate_Time(?,?);  end;";
  // 2. Create the CallableStatement for the PL/SQL block
  st = (OracleCallableStatement)dbTransaction.createCallableStatement(stmt, 0);
  // 3. Register the positions and types of the OUT parameters
  st.registerOutParameter(1, Types.DATE);
  // 4. Set the bind values of the IN parameters
  st.setObject(2,"BUSINESS_UNIT_ID");
  st.setObject(3,orgId);
  // 5. Execute Query
  st.executeUpdate();
  return st.getDate(1);
}
```
21.5.2 How to Format Time with and without Seconds

The user preferred pattern for time formatting might include seconds. In some cases, it may be necessary for an application to display a time value with seconds under one set of circumstances, and without seconds under another.

By default, the display of seconds depends on the user preferred time format. Example 21-42 prints a datetime value in the user preferred format.

Example 21-43 prints a datetime value in the user preferred format with seconds always included.

Example 21-44 prints a datetime value in the user preferred format without seconds.

Example 21-42  Formatting in the User Preferred Datetime Pattern

Example 21-43  Formatting in the User Preferred Datetime Pattern with Seconds

Example 21-44  Formatting a Datetime Value in the User Preferred Datetime Pattern without Seconds

21.5.3 How to Format Invariant Time Zone Values

Some date-time values are not associated with a specific time zone. For example, an application may execute a job at 9 AM local time in every location across different time zones. Such values are called invariant or floating times. To print an invariant time zone value, use the default time zone such that no specific time zone is applied to the value.

When printing a date-time value for a specific time zone derived from an invariant time zone value, you may need to adjust the formatting so as to neutralize the effect of time zone conversion. This is because the server default time zone is applied implicitly.

21.5.4 What Happens When You Format Time Zones

When you drag and drop a timestamp field onto the JSF page, Applications Core generates the tags shown in Example 21-45.

You need to change the tags depending on whether the field is to be calculated according to the UPTZ or the server time zone (invariant timestamp values), for example Default : Server Time Zone.

This is necessary only for invariant timestamp values. Invariant timestamp values are timestamps in which varying time zone will not make a difference to the business logic of the application.

Example 21-47 shows tags with a user preferred time zone.

At design time, Applications Core uses the date-time sensitive custom property to generate bindings to the time zone attribute on the Oracle ADF Faces Date Time Converter. The attribute is bound to the applCorePrefs managed bean.
21.5.5 What Happens at Runtime: How Time Zones Are Formatted

At runtime, the Applications Core managed bean `applCorePrefs`, implemented by `oracle.apps.fnd.applecore.common.PreferencesBean` and registered with the `faces-config.xml` file, retrieves the relevant formatting masks from Applications Session.

By default, date-time data may display as shown in Example 21-48.

**Example 21-48  Date Time Data Format**

1/1/2009 12:34 AM        for the pattern "M/d/yyyy hh:mm a"

21.5.6 Standards and Guidelines

The following standards and guidelines apply to formatting time zones:

- All date time fields must be represented only by `java.sql.Timestamp` data types (used by default in time zone view object attributes).
- The database and middle-tier Timezone must always be the same in Oracle Fusion Applications.

21.6 Formatting Numbers, Currency and Dates Using Localization Expression Language Functions

Expression Language functions provide an alternative to the formatting procedures described in Formatting Currency, Formatting Numbers and Formatting Time Zones.

21.6.1 How to Format Numbers, Currency and Dates Using Expression Language Functions

Oracle ADF Faces Expression Language functions of the type `af:formatNamed` and `af:format` only support `String` objects as parameters. Consequently, other object types such as `Date` and `BigDecimal` must be converted to the `String` object type.

For example, when binding the date object `dateValue` as shown in Example 21-49, the `dateValue` object must be converted to a `String` object by calling the `toString()` method.
However, the `toString()` method does not support Oracle Fusion Applications user preferences. Oracle Fusion Applications thus require the use of Expression Language format functions to convert the following data objects to String objects:

- Number and currency objects:
  - `java.math.BigDecimal`
  - `java.lang.Integer`
  - `java.lang.Long`

- Date and DateTime (Timestamp) objects:
  - `java.sql.Date`
  - `java.sql.Timestamp`

You can format numbers, currency and dates using Expression Language functions.

**Example 21-49  Binding a Date Object**

```af
af:formatNamed(bundle.NOTE_MESSAGE, 'BIRTHDAY', dateValue)
```

### 21.6.1.1 Formatting Numbers Using Expression Language Functions

Use the following Expression Language functions to format numbers.

The number Expression Language formatting function is shown in **Example 21-50**.

Returns the formatted number value using the user preferences for the number format mask, grouping separator and decimal separator.

This function produces the tag shown in **Example 21-51**.

An additional Expression Language formatting function for numbers is shown in **Example 21-52**.

Returns the formatted number value using the user preferences for the number format mask, grouping separator and decimal separator.

Overrides the scale—the number of digits following the decimal point—of the user preferred number format pattern using the value assigned to `maxFractionDigit`.

This function produces the tag shown in **Example 21-53**.

**Example 21-50  formatNumber(java.lang.Number value) Function**

```fnd
fnd:formatNumber(java.lang.Number value)
```

**Example 21-51  Tag Produced by the Function fnd:formatNumber(java.lang.Number value)**

```af
<af:convertNumber pattern="#{applCorePrefs.numberFormatPattern}"/>
```

**Example 21-52  formatNumber2(java.lang.Number value, int maxFractionDigit) Function**

```fnd
fnd:formatNumber2(java.lang.Number value, int maxFractionDigit)
```

**Example 21-53  Tag Produced by the Function fnd:formatNumber2(java.lang.Number value, int maxFractionDigit)**

```af
<af:convertNumber pattern="#{applCorePrefs.numberFormatPattern}" maxFractionDigits="your scale here"/>
```
21.6.1.2 Formatting Currency Using Expression Language Functions

Use the Expression Language function shown in Example 21-54 to format currency.

Returns the formatted currency amount value in numeric form along with the relevant currency code. Applications Core uses the currency code as defined in FND_CURRENCIES to format the currencyAmount value, rather than the number format mask preference. User preferences for grouping and decimal separators are used to format the value.

This function produces the tag shown in Example 21-55.

**Example 21-54**  
`fnd:formatCurrency(java.lang.Number currencyAmount, java.lang.String currencyCode)` Function

```
fnd:formatCurrency(java.lang.Number currencyAmount, java.lang.String currencyCode)
```

**Example 21-55**  
Tag Produced by the Function  
`fnd:formatCurrency(java.lang.Number currencyAmount, java.lang.String currencyCode)`

```
<af:convertNumber type="currency"  
currencyCode="#{bindings.quantityCurrencyCode.inputValue}"  
pattern="#{fnd:currencyPattern(bindings.quantityCurrencyCode.inputValue)}"/>
```

21.6.1.3 Formatting Dates Using Expression Language Functions

Use the Expression Language function shown in Example 21-56 to format dates.

Returns the formatted date value based on the user preferred date format mask.

This function produces the tag shown in Example 21-57.

Use the Expression Language function shown in Example 21-58 to format date time values.

Returns the formatted date time value using the user preferences for the date and time format masks and time zone.

This function produces the following tag as shown in Example 21-59.

Use the Expression Language function shown in Example 21-60 to format date time values with user formatting masks and the user-specified time zone.

Returns the formatted date time value using the user preferences for date and time format masks and the user-specified time zone.

This function produces the tag shown in Example 21-61.

**Example 21-56**  
`fnd:formatDate(java.util.Date dateValue)` Function

```
fnd:formatDate(java.util.Date dateValue)
```

**Example 21-57**  
Tag Produced by the Function `fnd:formatDate(java.util.Date dateValue)`

```
<af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}"/>
```

**Example 21-58**  
`fnd:formatDateTime(java.util.Date dateTimeValue)` Function

```
fnd:formatDateTime(java.util.Date dateTimeValue)
```
Example 21-59  Tag Produced by the Function fnd:formatDateTime(java.util.Date dateTimeValue)

<af:convertDateTime type="both" timeZone="#{applCorePrefs.UPTZ}" pattern="#{applCorePrefs.UPTZPattern}"/>

Example 21-60  fnd:formatDateTimeTZ(java.util.Date dateTimeValue, java.util.TimeZone timeZone) Function

fnd:formatDateTimeTZ(java.util.Date dateTimeValue, java.util.TimeZone timeZone)

Example 21-61  Tag Produced by the Function fnd:formatDate(java.util.Date dateTimeValue, java.util.TimeZone timeZone)

<af:convertDateTime type="both" timeZone="<your timezone>" pattern="#{applCorePrefs.UPTZPattern}"/>

21.6.2 What Happens When You Format Numbers, Currency and Dates Using Expression Language Functions

Applications Core formats the value as defined by the Expression Language function and produces the tags described in this section.

For example, the date formatting Expression Language function produces a tag such as the one shown in Example 21-62.

Example 21-62  Tag Produced by Expression Language Date Formatting Function

<af:convertDateTime pattern="#{applCorePrefs.dateFormatPattern}"/>

21.6.3 What Happens at Runtime: How Currency, Dates and Numbers and Time Zones are Formatted Using Expression Language Functions

For more information about what happens at runtime when you format numbers, currency and dates using Expression Language functions, see Formatting Currency, Formatting Numbers and Formatting Time Zones.

21.7 Implementing Bi-directional Support

Oracle Fusion applications should be enabled to provide bi-directional support. Examples of bi-directional languages are Arabic (Middle East and North Africa) and Hebrew (Israel). These scripts are generally written from right to left. The entire UI must also render from right to left. That is, if you took a standard English UI and placed a mirror next to your computer screen, the image in the mirror is exactly what is expected of speakers of bi-directional languages. Some rules come into play, such as how to correctly render English text or numerals embedded in a bi-directional script, but this generally is handled by underlying technologies (in this case, Oracle ADF). An example of this is that the following text, which translates to United Arab Emirates:

Oracle

for a user with English locale must be displayed as:

الإمارات العربية المتحدة

for a user with Arabic Locale.
21.7.1 How to Implement Bi-directional Support

Before you begin, create an entity and a view object from ADF Business Components. Drag and drop some of the attributes from the view object into a JSF page.

21.7.1.1 Making Panels and Columns Provide Bi-directional Support

UI Components such as af:panelGroupLayout and af:column have an align or an halign attribute that allows developers to align a particular component in one direction. A typical example of this is a number field that is always aligned to the right by Oracle Fusion Applications standards. Now, if a UI component (a non-number field) is hardcode-aligned to the left or right in the JSF page, the implication in the Arabic locale is that the UI component does not switch to its corresponding mirror image position. Consequently, there are discrepancies in the user interface in the Arabic locale.

To correct this situation, you must not hardcode a UI component (non-number field) to the left or right. You should always use the start or end values for the halign and align attributes to make them bi-directional compatible, as shown in Example 21-63.

Here, the halign attribute for the panel group has been set to end, which means that this component will be bi-directional compatible and will switch to its mirror image position in the Arabic locale.

In the English locale shown in Figure 21-12, the panel containing the three buttons Advanced, Search and Reset is aligned to the right.

**Figure 21-12** Showing Right-aligned Buttons for English Locale

![Right-aligned Buttons for English Locale](image)

Therefore, the expected behavior is that, in the Arabic locale shown in Figure 21-13, the panel, with the buttons’ text in Arabic, is aligned to the left.

**Figure 21-13** Showing Left-aligned Buttons for Arabic Locale

![Left-aligned Buttons for Arabic Locale](image)

**Example 21-63** Making align Attributes Bi-directional

```xml
<af:panelGroupLayout id="pg15" layout="horizontal" halign="end">
    <af:commandButton text="#{ResourcesGenBundle['Action.Advanced.AdvancedSearch']}
                      actionListener="#{ItemRelationshipRegionalSearchBean.
                      onAdvancedButtonClick()"
                      id="cb4"/>
    <af:spacer width="8" height="10" id="s7"/>
    <af:image source="/images/seperator_img.png" id="i2" shortDesc=""/>
    <af:spacer width="8" height="10" id="s8"/>
</af:panelGroupLayout>
```
21.7.1.2 Making Images Provide Bi-directional Support

In Oracle Fusion applications, all UI components should provide bi-directional support. This means that, in bi-directional locales such as Arabic and Hebrew, UI components should be shown from right-to-left instead of left-to-right. This also includes images that are shown on the UI to give a pictorial representation of an instruction to the end user. If an image is directional (unsymmetrical), it should be flipped and shown as its corresponding mirror image from right-to-left. However, if an image is non-directional (symmetrical) it need not be flipped since its mirror image is the image itself. To make an image bi-directional, you have to use the function fnd:bidiImage(<Image-Path>), shown in Example 21-64, that is provided as a part of the ApplCore library.

In bi-directional locales, instead of displaying the image search_ena.png directly, the fnd:bidiImage suffixes an _rtl just before the start of the extension to the parameter file-name given to it (in this case, the image icon search_ena.png becomes search_rtl_ena.png), and then displays the image search_rtl_ena.png on the JSF page. Now, if the latter image has been stored as a mirror image of the former, bi-directionality is ensured for the image.

Figure 21-14 shows how the search image next to the Search by Year option appears in an English locale. Specifically, the icon displays an arrow pointing to the right to the right of the Search by Year field.

Figure 21-14    Showing Command Image Link in English Locale

Figure 21-15 shows how the command image link supports bi-directional behavior in an Arabic locale. Specifically, the icon displays an arrow pointing to the left to the left of the Search by Year field.
21.8 Supporting Mnemonic Keys

A mnemonic key, also called a soft key, is a shorthand name for a key, command, or menu option. Mnemonic keys are used in Oracle Fusion applications to activate the buttons in a page. This is made possible by using a $<\text{Modifier}>+<\text{Access Key}>$. Note that modifiers are browser-specific. Internet Explorer, Safari and Google Chrome use the $\text{Alt}$ key; Firefox uses $\text{Alt+Shift}$.

The Access Key is defined in the source code by the developer.

In Oracle Fusion applications, the access key for a particular button must be externalized so that the keys for different locales are different. Do not hardcode the $\text{accessKey}$ or the $\text{textAndAccessKey}$ attribute provided as a child attribute of the $\text{af:commandButton}$ tag. Hard-coding these keys would cause mnemonic key issues. For example, if an English letter is hardcoded as an access key in the JSF layer, an Arabic user may not be able to use this key because there are no English letters on his keyboard. Instead the $\text{accessKey}$ and $\text{textAccessKey}$ attributes should be externalized using either the $\text{applCoreBundle}$ or any resource bundle defined in an Oracle Fusion application's project.

21.8.1 How to Implement Mnemonic Key Support

Before you begin, create an entity object and a view object from ADF Business Components. Drag and drop some of the attributes from the view object into a JSF page. Create a panel group and add a command button to it.

There are two attributes provided by Oracle ADF for mnemonic keys for buttons: $\text{accessKey}$ and $\text{textAndAccessKey}$. The attribute $\text{accessKey}$ takes as a value just the access key to be typed by the user, whereas the attribute $\text{textAndAccessKey}$ takes as a value the text to be displayed on the button and the short-hand key to be typed by the user. You must make sure that the $\text{accessKey}$ and $\text{textAndAccessKey}$ attributes are never hard-coded. Both should be externalized and read from resource bundles. In the case of the $\text{textAndAccessKey}$ attribute, the value of the access key usually is preceded by an ampersand ($\&$) in the resource bundle. In case the ampersand sign is not present in the bundle, the first letter of the text is treated as the access key.
How to use the `textAndAccessKey` attribute using the `applCoreBundle` is shown in Example 21-65.

How to use the `textAndAccessKey` attribute using the resource bundles is shown in Example 21-66.

Here, the resource bundle `TemporaryBundle` must be defined in the JSF page containing the `af:commandButton` tag. Also, the `textAndAccessKey` has been externalized and is read from the `applCore` bundle and the resource bundle, as shown in the examples, which is the correct way to define mnemonic keys. The values for this particular id `SAVE` in the resource bundles are "Save" in the English locale, "\uC800\uC7A5(&S)" in the Korean locale (S is the access key) and "\u062D\u0641\& \u0638" (\u0638 is the access key) in the Arabic locale.

Example 21-67 shows how to externalize the `accessKey` attribute using the `applCoreBundle`.

Example 21-68 shows how to externalize the `accessKey` attribute using a resource bundle.

Here, the `accessKey` attribute has been externalized and is read from the Applications Core bundle and the resource bundle as shown in the examples. Note that the `TemporaryBundle` has to be defined as the `viewControllerBundle` in the JSF page containing the command button. The values for this particular resource ID `ACCESSKEY` are "S" in the English locale, ""\uC800" in the Korean locale and "\u0638" in the Arabic locale, as defined in the resource bundle.

**Note:**

- When a `textAndAccessKey` attribute has a value with more than one "&", the letter following the first "&" is chosen as the access key.
- When an `accessKey` attribute has more than one letter, the first letter is chosen as the access key.

In Figure 21-16, the buttons on the top right (Run Validations, View Exceptions, Open Target Period) are examples of buttons with soft keys that must not be hardcoded, so that they can change for different locales.

**Figure 21-16   Example of Buttons with Soft Keys**

Example 21-65 Using the `textAndAccessKey` Attribute Using the `applCoreBundle`

```xml
<f:facet name="actionButtonBar">
  <af:panelGroupLayout layout="horizontal"
    id="panelGroupLayout11"
    styleClass="AFStretchWidth">
```
Example 21-66  Using the textAndAccessKey Attribute Using Resource Bundles

Example 21-67  Externalizing the accessKey Attribute Using the applCoreBundle

Example 21-68  Externalizing the accessKey Attribute Using a Resource Bundle

21.9 Implementing Localization Formatting in ADF Desktop Integration

With ADF Desktop Integration technology, users can browse, edit and upload data through a Microsoft Excel spreadsheet. Localization formatting differs from ADF Faces pages:

- Number and date/time values are formatted based on the format pattern specified by the styles in the Excel spreadsheets. The format pattern follows Microsoft standard instead of Java standard.
- Number separators are decided by the client operating system locale.

In ADF Faces pages, number and date/time values are formatted based on the format patterns selected in the Oracle Fusion application’s Preference UI. Number separators are extracted from the application’s number format patterns.

21.9.1 How to Format Numbers

Number separators in ADF Desktop Integration spreadsheets vary according to the client OS locale. Number formatting is decided by the style defined in Excel spreadsheet. For example, when opening an ADF Desktop Integration spreadsheet with French Windows XP and Excel, number 1000.5 (One thousand point 5) displays as 1 000,5. It is displayed as 1.000,5 in German Windows XP and Excel. Assuming one fractional digit is specified in the style.

To achieve this, developers need to specify correct styles for numbers at design time.

21.9.1.1 Formatting Numbers

Before you begin, create a workable ADF Desktop Integration spreadsheet and have the attributes in place. Related attributes are of types: java.math.BigDecimal, java.lang.Integer, or java.lang.Long.

Define styles for each type of cells and configure the cell appearance using the Oracle Fusion Applications UI standard.

Decimal Number Formatting
Follow these steps to modify the existing style for formatting decimal numbers and apply the style to the cell containing a decimal number value.

- In Excel, select Home > Cell Styles.
- Right-click the style name and select Modify from the context menu.
- On the Style dialog, click Format.
- Select the Number tab and select the Number category. Specify the number of decimal places and the format of negative numbers according to your business logic. If you want to see a grouping separator in the number values, select Use 1000 Separator.
- Click OK and save the Excel file.

**Integer Formatting**

Integer formatting is the same as decimal formatting except no fractional digit should display. This can be done by specifying 0 for Decimal places when modifying the style.

**ID Formatting**

An ID value is a sequence of digits, such as an Invoice Number, Service Request ID, or Bank Account. Displaying ID values should not vary based on a user’s preference or client OS locale. That is, ID values should be printed as text instead of numbers.

In Oracle Fusion applications, the length of an ID value typically is 13 or 18. By default, Excel formats such long numbers with Scientific Notation format, which is not desired for Oracle Fusion applications. For instance, an Invoice Number 1234567890123 (13 digits) is displayed as 1.23457E+12. It is not a valid Invoice Number when it is printed out.

To avoid the default formatting of Excel in such cases, developers need to customize the styles for ID values.

- In Excel, select Home > Cell Styles
- Right-click the style name and select Modify from the context menu.
- Click Format.
- Select the Number tab and select the Text category.
- Click OK. In the Style dialog, Figure 21-17 shows that @ is defined as the Number style.

![Figure 21-17 Selecting the Number Style](image)

- Click OK and save the file.

*Figure 21-18* shows that an ID value is displayed as text without any number formatting.
21.9.1.2 What Happens When You Format Numbers

When dragging and dropping a binding to generate the components in an ADF Desktop Integration spreadsheet, the framework generates default styles for those values based on the Java type of the values. However, these styles may not be correct for formatting number values. Therefore, you may need to refine the styles according to business logic.

21.9.1.3 What Happens at Runtime: How Numbers Are Formatted

At runtime, ADF Desktop Integration will pass the style specified in the ADF Desktop Integration unpublished spreadsheet (known as the design time file) to the published spreadsheet during the publication process. When a user opens the published spreadsheet, Excel formats the numbers according to the combination of styles and client OS locale.

21.9.2 How to Format Currency Values

Grouping and decimal separators of currency values vary based on the client OS locale, while the number of fraction digits is controlled by the style defined in the Excel spreadsheet.

You should not display currency symbols or currency codes with currency numbers in the same cell. Instead, you need to display currency symbols or currency codes in a separate cell.

21.9.2.1 Formatting Currency Values

Before you begin, create a workable ADF Desktop Integration spreadsheet and have the attributes in place. The related attribute is of type java.math.BigDecimal.

Define styles for each type of cells and configure the cell appearance using the Oracle Fusion Applications UI standard.

Follow these steps to modify an existing style for formatting currency values and apply it to the corresponding cells.

- In Excel, select **Home > Cell Styles**, right-click the style name and select **Modify** from the context menu.
- Click **Format**.
- Select the Number tab and select the Currency category. Specify the number of Decimal places and the format of negative numbers according to your business logic.
- In Oracle Fusion Applications, display the currency symbol in a separate cell. From the Symbol dropdown list, select **None**.
- Click **OK** and save the file.
21.9.2.2 What Happens When You Format Currencies

When dragging and dropping a binding to generate the components in an ADF Desktop Integration spreadsheet, the framework generates default styles for those values based on the Java type of the values. However, these styles may not be correct for formatting number values. Therefore, you may need to refine the styles according to business logic.

21.9.2.3 What Happens at Runtime: How Currency Values Are Formatted

At runtime, ADF Desktop Integration will pass the style specified in the unpublished spreadsheet (the design time file) to the published spreadsheet during the publication process. When a user opens the published spreadsheet, Excel formats the numbers according to the combination of styles and the client OS locale.

The currency code should be displayed in a cell other than the cell containing the Currency Value. The currency code in this cell should be printed as text.

21.9.3 How to Format Dates and Timestamp Values

The format of date and timestamp values in ADF Desktop Integration spreadsheets varies according to the client OS locale.

For example, when opening an ADF Desktop Integration spreadsheet with French Windows XP and Excel, the date May 25th, 2011 is displayed as 25/05/2011. It displays as 2011-05-25 in Korean Windows XP and Excel.

To achieve this, developers need to specify correct styles for date and timestamp values at design time.

21.9.3.1 Formatting Date and Timestamp Values

Before you begin, create a workable ADF Desktop Integration spreadsheet and have the attributes in place. Related attributes are of types: java.sql.Date or java.sql.Timestamp.

Define styles for each type of cell and configure the cell appearance using Oracle Fusion Applications UI standards.

**Formatting the Date**

Follow these steps to modify an existing style for formatting dates and apply it to the correspondent cells.

- In Excel, select Home > Cell Styles
- Right-click the style name and select Modify from the context menu.
- Click Format.
- Select the Number tab and select the Date category. Set the value of Locale (location) to your Windows OS locale. For example, if you are using English Windows XP, this Locale should be set to English (U.S.).
- Select a type beginning with an asterisk (*), as shown in Figure 21-19. There are two such types: one is a short date format, and the other is a long date format. Choose one according to your business requirement.
Figure 21-19  Selecting the Date Type

Note that date formats display date and time serial numbers as date values. Date formats that begin with an asterisk (*) respond to changes in regional date and time settings that are specified for the operating system. Formats without an asterisk are not affected by operating system settings.

- Click OK and save the file.

Formatting the Timestamp

Follow these steps to define a style for formatting the timestamp and apply it to the corresponding cells.

- In Excel, select Home > Cell Styles.
- Right-click the style name and select Modify from the context menu.
- Click Format.
- Select the Number tab and select the Time category. Set the value of Locale (location) to your Windows OS locale. For example, if you are using English Windows XP, this Locale should be set to English (U.S.).
- Select the type beginning with an asterisk (*), as shown in Figure 21-20.
• Click OK and save the file.

Note: With current ADF Desktop Integration support, it is impossible to display both the date and the time part of a timestamp value in a single cell if you want to see its format varying according to client OS locale.

Workaround
To display the date and time, formatted according to the client OS locale, you can use two cells: One for displaying the date part and another for displaying the time part of the timestamp. Then format each of these cells separately as described for date and time format.

21.9.3.2 Honoring Time Zones

There are two time zones involved in time zone conversion for timestamp values in ADF Desktop Integration spreadsheets. One is the time zone of the Oracle Fusion Applications server, called the server time zone. The other is the time zone of the client system on which the ADF Desktop Integration spreadsheet is open, which is called the client time zone.

At runtime, conversion between server time zone and client time zone happens automatically for timestamp values in ADF Desktop Integration spreadsheets.

For example, if the server time zone is (GMT-8:00) Pacific Time (US & Canada) and the client time zone is (GMT+8:00) Beijing, Chongqing, Hong Kong, Urumqi, the timestamp value in the database 2011-05-22 20:00:00 is converted to 2011-05-23 12:00:00 at runtime and displayed as 2011-05-23 or 12:00:00 in the ADF Desktop Integration spreadsheet, depending on the format style defined for the corresponding cells.

21.9.3.3 What Happens When You Format the Date and Timestamp

When dragging and dropping a binding to generate the components in an ADF Desktop Integration spreadsheet, the framework generates default styles for those values based on the Java type of the values. However, these styles may not be correct for formatting number values. Therefore, you may need to refine the styles according to business logic.
21.9.3.4 What Happens at Runtime: How Date and Timestamp Are Formatted

At runtime, ADF Desktop Integration will pass the style specified in the unpublished spreadsheet (the design time file) to the published spreadsheet during the publication process. When a user opens the published spreadsheet, Excel formats the date or timestamp values according to the combination of styles and the client OS locale.

Related Links

The following document provides additional information related to subjects discussed in this section:

- For more details about Excel styles, refer to the Oracle Fusion Middleware Developing Applications with Oracle ADF Desktop Integration.
- For timestamp values, time zone conversion also happens at runtime. See Honoring Time Zones for more details.

21.10 Implement Localization Formatting in Oracle BI Publisher Reports

Oracle BI Publisher can pass Oracle Fusion applications Preferences Number Format, Date Format and Time Format to Oracle BI Publisher reports using function format-date, format-number or format-currency, if Oracle BI Publisher is running in Oracle BI Publisher and Oracle Fusion applications integration mode.

Note:

To modify RTF templates, Oracle BI Publisher Template Builder for Word should be installed on Microsoft Word 2003, 2007 or higher version. After it is installed, there is a Oracle BI Publisher menu in the Word menu bar.

21.10.1 How to Format Numbers in a Oracle BI Publisher Report

To format numbers in an RTF template with an Oracle Fusion application user-preferred number format pattern, Oracle’s format-number function must be used with 'XDODEFNUM' used as a format mask, for example:

<?format-number:fieldName; 'XDODEFNUM'?>

Follow these steps to format numbers with the Oracle Fusion application user-preferred number format pattern:

- Open your RTF template file with Word.
- Select BI Publisher > Sample XML and select a sample XML file that contains sample data for the number fields to be formatted in the RTF template.
- Double-click the number field to be modified (such as ORDER_TOTAL). In the Oracle BI Publisher Properties dialog, select the Properties tab and make sure that Regular Text is selected for Type.
- Select the Advanced tab and enter the format code, as shown in Figure 21-21.
Follow these steps to format a number value in graphs in Oracle BI Publisher reports:

- To set format masks for graphs, an Oracle Fusion application Oracle BI Publisher report designer needs to change the RTF template graph code manually.
- Edit the graph and change the graph definition code in the Advanced tab of the Graph dialog in the template builder.
- Use an XSLT format such as:

```
<xsl:value-of
    select="xdoslt:xdo_format_number($_XDOXSLTCTX, current-group() / SGT_NUMBER,'XDODEFNUM')" />
```

To format a currency value on the graph.

At runtime, XDODEFNUM is replaced with the number format pattern selected in the Oracle Fusion application Preferences UI. Consequently, the number is formatted with the Oracle Fusion application number format pattern. For example, if a user selects -1'234,567 as the Number Format in the Preferences UI, as shown in Figure 21-22, the number 1000.8888 (one thousand point eight eight eight eight) is displayed as 1'000,889 in the Oracle BI Publisher report.
When using XDODEFNUM as the format mask in format-number, the format of the number is fully controlled by the Oracle Fusion application Number Format, including grouping separator, decimal separator, number of fractional digit, and form of negative numbers.

In the Oracle BI Publisher and Oracle Fusion application integration environment, if format-number is used to format a number, whether XDODEFNUM is used as the format mask, the grouping separator and decimal separator are always derived from the Oracle Fusion application Number Format.

Therefore, an integer could be formatted as:

```xml
<?format-number:fieldName; '999G999'?>
```

In this case, if the Number Format is -1'234,567, the integer 10000 is displayed as 10'000 in the Oracle BI Publisher report.

If you do not wish to display a number with fractional digits or grouping separators (such as PO numbers, Bank Accounts, or Invoice Numbers), enter `<?fieldName?>` in step 4 of [To format numbers]. In such cases, the Number Format has no effect on the field; it always is displayed as text.

### 21.10.2 How to Format Currency Values in Oracle BI Publisher

Currency fields in RTF templates can be formatted with the format-currency function:

```xml
<?format-currency:Amount_Field;CurrencyCode;displaySymbolOrNot?>
```

where

- **Amount_Field** takes the tag name of the XML element that holds the amount value in your data.

- **CurrencyCode** can be set to a static value or it can be set dynamically. If the value will be static for the report, enter the ISO three-letter currency code in single-quotes, such as 'USD'.

To set the value dynamically, enter the tag name of the XML element that holds the ISO currency code. An element containing the currency code must be present in the data.

- At runtime, the **Amount_Field** will be formatted according to the format you set up for the currency code in the report properties.
• **displaySymbolOrNot** takes as a value either 'true' or 'false' in single quotes. When set to 'true', the currency symbol will be displayed in the report based on the value for **CurrencyCode**. If you do not wish the currency symbol to be displayed, you can either enter 'false' or simply omit the parameter.

To use the format-currency function, the currency values in your data source must be in a raw format, with no formatting applied (for example: 1000.00). If the value has been formatted for European countries (for example: 1.000,00), the format will not work.

To format your currency values with the currency code passed dynamically from a particular business flow, you must have the currency code defined in your data source.

In the Oracle Fusion application and Oracle BI Publisher integration environment, Currency is passed to Oracle BI Publisher through XDODEFCC. For example, if US Dollar is selected for Currency in Preferences, as shown in Figure 21-23, at runtime, XDODEFCC is replaced with USD.

**Figure 21-23  Selecting a Currency in Oracle Fusion Application Preferences**

![Figure 21-23](image)

Therefore, to format a currency value with the Currency selected in Oracle Fusion application Preferences, you can use:

```xml
<?format-currency:Amount_Field; 'XDODEFCC'?>
```

or

```xml
<?format-currency:Amount_Field; 'XDODEFCC';'true'?>
```

To format currency values with the currency code selected in a particular business flow instead of the Currency code selected in Oracle Fusion application Preferences, you can use:

```xml
<?format-currency:Amount_Field; CurrencyCode_Field?>
```

or

```xml
<?format-currency:Amount_Field; CurrencyCode_Field;'true'?>
```
where **CurrencyCode_Field** is the tag name of the XML element that holds the currency code selected in the business flow. At runtime, **CurrencyCode_Field** is replaced with a currency code, such as USD, JPY, or EUR.

Note: Whether the currency code is set to a static value, such as XDODEFCC, or a dynamic value passed from a particular business flow, the grouping separator and decimal separator in currency values are always derived from the Number Format selected in Oracle Fusion application Preferences. The parameter currency code in the format-currency function controls the number of fraction digits and the placement of the grouping separator in the output.

**Example**

Assume that `<format-currency:Amount_Field; CurrencyCode_Field?>` is applied in the RTF template for a currency field.

In the report properties, if the format mask for USD is 9G999D99, for JPY it is 9G999 and for INR it is 9G99G99G999D99, and if a user has set the Number Format as -1,234.567 in Preferences (uses comma (,) as the grouping separator and dot (.) as decimal separator), the currency value of 1234567.89 will display as shown here, depending on the currency passed to CurrencyCode field at runtime.

- **If 'USD' is passed to CurrencyCode_Field at runtime, the value displayed is 1,234,567.89.**
- **If 'JPY' is passed to CurrencyCode_Field at runtime, the value displayed is 1,234,568.**
- **If 'INR' is passed to CurrencyCode_Field at runtime, the value displayed is 12,34,567.89.**

If a European user changes the Number Format to -1'234,567 in Preferences (uses the apostrophe (') as the grouping separator and comma (,) as the decimal separator), the currency value of 1234567.89 will display as:

- **If 'USD' is passed to CurrencyCode_Field at runtime, the value displayed is 1'234'567,89.**
- **If 'JPY' is passed to CurrencyCode_Field at runtime, the value displayed is 1'234'568.**
- **If 'INR' is passed to CurrencyCode_Field at runtime, the value displayed is 12'34'567,89.**

Follow these steps to format a currency field in the Oracle BI Publisher RTF template.

- Open the RTF template file with Word.
- Expand **BI Publisher > Sample XML** and select a sample XML file that contains sample data for the number fields to be formatted in the RTF template.
- Double-click the currency field to be modified (for instance ORDER_TOTAL). In the Oracle BI Publisher Properties dialog, click the Properties tab and make sure **Type** is set to **Regular Text**.
- Click the Advanced tab and enter the format code, for example `<format-currency:ORDER_TOTAL; 'XDODEFCC'?>`, as shown in Figure 21-24.
Follow these steps to format a currency value in graphs in Oracle BI Publisher reports:

- To set format masks for graphs, an Oracle Fusion application Oracle BI Publisher report designer needs to change the RTF template graph code manually.
- Edit the graph and change the graph definition code in the Advanced tab of the Graph dialog in template builder.
- Use an XSLT format, such as `<xsl:value-of select="xdoxslt:xdo_format_currency($XDOXSLTCTX,current-group()/'SGT_CURRENCY','XDODEFCC')" />` to format a currency value on the graph.

### 21.10.3 How to Format Dates and Timestamps in Oracle BI Publisher

In the Oracle BI Publisher RTF template, a date or timestamp can be formatted as:

```xml
<?format-date:date_string; 'ABSTRACT_FORMAT_MASK';'TIMEZONE'?>
```

where:

- **ABSTRACT_FORMAT_MASK** can be any date format pattern supported by Oracle BI Publisher, such as YYYY-MM-DD or DD/MM/YYYY.
- **TIMEZONE** is optional. It can be any valid time zone ID, such as PST or UTC. If it is not specified, the Oracle BI Publisher report time zone is applied implicitly.

To use the format-date function, the date from the data source must be in canonical format, which is YYYY-MM-DDThh:mm:ss+HH:MM where:

- YYYY is the year
- MM is the month
- DD is the day
- T is the separator between the date and time component
• hh is the hour in 24-hour format
• mm is the minutes
• ss is the seconds
• +HH:MM is the time zone offset from Universal Time (UTC), or Greenwich Mean Time

For example: 2011-05-26T09:30:10-07:00.

The data after the T is optional, therefore 2011-05-26 is a valid date.

Note:
If the time component and time zone offset are not included in the XML source date, Oracle BI Publisher assumes it represents 12:00 AM UTC (that is, YYYY-MM-DDT00:00:00-00:00).

In the Oracle BI Publisher and Oracle Fusion application integration environment, XDODEFDATE is used to pass the Oracle Fusion application date format pattern to Oracle BI Publisher, and XDODEFTIME can pass the Oracle Fusion application time format pattern to Oracle BI Publisher reports.

Consider that "yyyy-MM-dd (2011-05-27)" is selected for the Date Format, and "a hh:mm:ss (AM 12:49:13)" is selected for the Time Format in Oracle Fusion application Preferences, as shown in Figure 21-25.

Figure 21-25    Selecting Date and Time Format in Oracle Fusion Application Preferences

At runtime, XDODEFDATE is replaced with "yyyy-MM-dd" and XDODEFTIME is replaced with "a hh:mm:ss".

Therefore, to format date or timestamp values in Oracle BI Publisher reports with the Date Format or Time Format selected in Oracle Fusion application Preferences, the format-date function can be used:

• To display date only values
  
  ```xml
  <?format-date:Date_Only_Field; 'XDODEFDATE'?>
  ```

  Only the date is displayed, such as 2011-05-27.

• To display time only values
  
  ```xml
  <?format-date:Time_Only_Field; 'XDODEFTIME'?>
  ```

  Only the time is displayed, such as AM 12:49:13.

• To display datetime values
Both date and time are displayed, such as 2011-05-27 AM 12:49:13.

- To display System Date (sysdate)

```xml
<?format-date:xdoxslt:sysdate_as_xsdformat();' XDODEFDATE XDODEFTIME '?>
```

With these codes, the format of date or timestamp values varies according to the Date Format or the Time Format chosen in Oracle Fusion application Preferences.

Follow these steps to format date or timestamp values in the RTF template.

- Open the RTF template file in Microsoft Word.
- Choose **BI Publisher** > **Sample XML**, and choose a sample XML file that contains sample data for the number fields to be formatted in RTF template.
- Double-click the date or timestamp field to be modified, such as `ORDER_DATE`. In the BI Publisher Properties dialog, click the Properties tab and make sure that Type is set to Regular Text.
- Click the Advanced tab and enter format code, such as `<?format-date:ORDER_DATE; 'XDODEFDATE'??>`, as shown in Figure 21-26.

**Figure 21-26  Entering Date Format Code in Oracle BI Publisher Properties**

- Click **OK** and save the file.

Follow these steps to format date or timestamp values in graphs in Oracle BI Publisher reports.

- To set format masks for graphs, an Oracle Fusion application Oracle BI Publisher report designer needs to change the RTF template graph code manually.
- Edit the graph and change the graph definition code in the Advanced tab of the Graph dialog in template builder.
- Use an XSLT format such as `<xsl:value-of select="xdoxslt:xdo_format_date($_XDOXSLTCTX, current-`
group() / SGT_DATE, 'XDODEFDATE_XDODEFTIME')" /> to format a date-time value on the graph.

If you do not wish to format date or timestamps according to the Oracle Fusion application Date or Time format, you can use Oracle abstract format masks, such as:

- <?format-date:ORDER_DATE; 'SHORT'>
- <?format-date:ORDER_DATE; 'LONG'>
- <?format-date:xdoxslt:sysoxdate_as_xsdformat(); 'MEDIUM'>

With using abstract format masks, date and timestamp values are formatted according to the default format of the Oracle Fusion application user's locale.

21.10.4 How to Honor Time Zones in Oracle BI Publisher

In Oracle BI Publisher and Oracle Fusion application integration environment, the Time Zone selected in Oracle Fusion application Preferences is passed to the Oracle BI Publisher server and overrides the Oracle BI Publisher report time zone automatically. Therefore, if the TIMEZONE parameter is not specified in the format-date function, a date/time field in the Oracle BI Publisher report is formatted with the time zone selected in Oracle Fusion application Preferences. That is, time zone conversion happens between the Oracle BI Publisher server time zone and the Oracle Fusion application Preferences time zone.

If you do not wish to format a date-time field with the Oracle Fusion application Preferences Time Zone, you must explicitly specify a time zone ID in the format-date function:

<?format-date:Datetime_Field; 'XDODEFDATE_XDODEFTIME', 'timezone'>

where timezone is a static value, such as PST, UTC, or IST.

**Note:**

There is no parameter that passes the Oracle Fusion application Corporation Time Zone (CRTZ) or Legal Entity Time Zone (LETZ) to the Oracle BI Publisher server. Therefore, you cannot format a date/time value with CRTZ or LETZ dynamically by using a parameter to pass CRTZ or LETZ to Oracle BI Publisher reports. Instead, you have to hard-code the time zone ID within the format-date function.

21.11 Implement Localization Formatting in ADF Data Visualization Components

All numerical-based values need to be formatted correctly when they are presented to a user in Oracle Fusion applications graphs. For instance, a value of 1234.5 in the database might need to be displayed as 1 234,500 or 1,234.500 or 1.234,5. The user can change the number of digits found after the decimal digit, grouping separator, and decimal separator.

21.11.1 How to Format Numbers on a Graph

Before you begin, create an entity object and a view object with number fields, including any of the following attribute types: java.math.BigDecimal,
java.lang.Integer, or java.lang.Long. Drag and drop the entity and create a data visualization component such as a pie graph, bar graph or a line graph.

Numerical values on all parts of the graph need to be formatted according to the user’s number formatting preferences in Oracle Fusion applications. Developers need to add the tag `<af:convertNumber>` to all the tags in the graph where numerical values are displayed.

The ADF Data Visualization area graph supports number formatting on its Y1 and Y2 axis tick labels, and for marker text that appears on the data points. Users can customize the number formatting by adding `<af:convertNumber>` to the `<dvt:y1TickLabel>, <dvt:y2TickLabel>, <dvt:y1Format>, and <dvt:y2Format>` tags. Example 21-69 shows how to configure these tags.

In Figure 21-27, numbers such as 20,000 and 40,000 on the Y axis and numbers such as 12,003.67 on the tooltip are examples of numbers on an area graph that should be formatted according to the user’s number preferences in graphs in Oracle Fusion applications.

![Figure 21-27 Showing Number Formatting on an Area Graph](image)

Note:
For integer fields, use `pattern="#{applCorePrefs.integerFormatPattern}"` just like integer formatting in ADF Faces.

Generally, an attribute on an ordinal axis (O1 axis and X1 axis) of a graph in ADF Data Visualization is considered to be text, irrespective of its data type in the model or view layer. A developer can add `af:convertNumber` to such a view attribute by first adding `dvt:attributeFormat` to it, and only then will the resultant values on the x-axis and o-axis be formatted according to the user's number preferences. The `name="size"` entry refers to the categorical attribute (attribute on the ordinal/x axis). To format the integers, use `pattern="#{applCorePrefs.integerFormatPattern}"`, as shown in Example 21-70.

In Figure 21-28, numbers such as 2234 and 1014 are examples of numbers on the O axis of an area graph that should be formatted according to the user’s number preferences.
Figure 21-28  Numbers to Format Using User’s Preferences

Other Types of Graphs

Example 21-70 just gives an example of number formatting in area graphs. Table 21-1 presents the tags in which af:convertNumber can be added for number formatting in other types of graphs, such as bar graphs and pie charts, and the graphs in which dvt:attributeFormat can be used to format text attributes on the ordinal axis.

<table>
<thead>
<tr>
<th>Graph Type</th>
<th>Parent Tags for af:convertNumber</th>
<th>Is dvt:attributeFormat Needed for Number Formatting?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar Graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Bar Horizontal</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Bubble Graph</td>
<td><a href="">dvt:x1TickLabel</a>, <a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, <a href="">dvt:y2Format</a> and <a href="">dvt:zFormat</a></td>
<td>Yes (but not for O1 axis, for X1 axis)</td>
</tr>
<tr>
<td>Combination graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Funnel Graph</td>
<td><a href="">dvt:sliceLabel</a></td>
<td>Yes (for funnel section values)</td>
</tr>
<tr>
<td>Line Graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Pareto Graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, and <a href="">dvt:y1Format</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Pie Graph</td>
<td><a href="">dvt:sliceLabel</a></td>
<td>Yes (for slice values)</td>
</tr>
<tr>
<td>Pie Bar Charts</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:sliceLabel</a> and <a href="">dvt:y1Format</a></td>
<td>Yes (for slice values)</td>
</tr>
<tr>
<td>Gantt Chart</td>
<td><a href="">af:column</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>Gauge</td>
<td><a href="">dvt:metricLabel</a> and <a href="">dvt:tickLabel</a></td>
<td>Yes (for O1 axis)</td>
</tr>
<tr>
<td>ADF Pivot Table</td>
<td><a href="">af:inputText</a> or <a href="">af:outputText</a> whose parent tag is <a href="">dvt:dataCell</a></td>
<td></td>
</tr>
<tr>
<td></td>
<td><a href="">af:inputText</a> or <a href="">af:outputText</a> whose parent tag is <a href="">dvt:headerCell</a></td>
<td></td>
</tr>
</tbody>
</table>
21.11.2 Standards and Guidelines for Formatting Numbers in Graphs

- `dvt:numberFormat` has been deprecated and all Oracle Fusion applications developers should use only `af:convertNumber` to format numbers on graphs.

- Before adding an `af:convertNumber` tag to a graph, make sure that the `autoPrecision` attribute of the parent tag (for example `dvt:MarkerText`) is set to `off`. If `autoPrecision` is set to `on`, ADF Data Visualization does not follow the converter correctly, and formats numbers automatically, which will be incorrect in Oracle Fusion applications, as the number will not honor user preferences.

- Set `scaling="none"` before adding the `af:convertNumber` tag to a graph. Otherwise ADF Data Visualization will not follow the converter correctly.

21.11.3 How to Format Currency Values in ADF Data Visualization

Currency fields are represented by `java.lang.BigDecimal` in entity objects and view objects.

A currency field should always be formatted according to the currency code chosen in the context UI of the transaction.

For example, if the user selects "JPY" as the currency code from the context UI, the currency value should be formatted according to the Japanese Yen standard, whereas if USD is chosen as the currency code, the currency value should be formatted according to the American Dollar standard.

Oracle Applications Technology (ATG) provides two implementations to format numerical values according to the corresponding currency code:

- `fnd:currencyPattern(bindingToAmountCurrencyCode)`: This function formats the numerical value according to the currency code input as a parameter (for example, if "USD" is the input parameter, the value is formatted as "#,##0.00")

- `fnd:currencyPatternWithPrecisionAndSymbol(bindingToAmountCurrencyCode, bindingToAttrNamePrecision, bindingToAttrNameCurrencySymbol)`: This function formats the numerical value according to the currency code input as the first parameter; the second parameter indicates the number of decimal digits in the formatted value; the third parameter determines whether the formatted string shows the symbol for the currency code, the currency code itself or nothing after the numerical value. (The third parameter can be symbol, code or none.)
21.11.3.1 Formatting Currency Values on a Graph

Before you begin, create an entity object and a view object with number fields, including any of the following attribute types: java.math.BigDecimal, which is a currency value. Drag and drop the entity and create an ADF Data Visualization component, such as a pie graph, bar graph, or a line graph.

Numbers on the Y and O axis can be formatted as currency and can be displayed with the currency symbol, as shown in Example 21-71.

In Figure 21-29, number values such as 40,000.00 and 80,000.00 on the Y axis, and 13,344.22 on the tooltip, are examples of number fields in an area graph that should be formatted according to the currency code for these values. Numbers on the O1 axis should also be formatted according to the currency code. (In this case, for USD, the format is #,##0.00.)

Figure 21-29  Numbers to Format According to Currency Code

Other Types of Graphs

Example 21-71 gives an example of currency formatting in area graphs. Table 21-2 presents the tags in which af:convertNumber can be added for currency formatting in other types of graphs, and the graphs in which dvt:attributeFormat can be used to format text attributes on the ordinal axis.

Table 21-2  Using af:convertNumber for Currency Formatting and dvt:attributeFormat for Text Formatting

<table>
<thead>
<tr>
<th>Graph Type</th>
<th>Tags in which af:convertNumber Can Be Added for Currency Formatting</th>
<th>Can dvt:attributeFormat Be Added for Currency Formatting of Attributes on the Ordinal Axis?</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bar Graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes</td>
</tr>
<tr>
<td>Bar Horizontal</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes</td>
</tr>
<tr>
<td>Bubble Graph</td>
<td><a href="">dvt:x1TickLabel</a>, <a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:x1Format</a>, <a href="">dvt:y1Format</a>, <a href="">dvt:y2Format</a> and <a href="">dvt:zFormat</a></td>
<td>Yes (but not for O1 axis, for X1 axis)</td>
</tr>
<tr>
<td>Combination Graph</td>
<td><a href="">dvt:y1TickLabel</a>, <a href="">dvt:y2TickLabel</a>, <a href="">dvt:y1Format</a>, and <a href="">dvt:y2Format</a></td>
<td>Yes</td>
</tr>

<td></td>
</tr>
</tbody>
</table>

Example 21-71  Area Graph Y1 Axis Currency Value Formatting

```xml
<dvt:y1TickLabel>
  <af:convertNumber pattern="#{ fnd:currencyPattern(YourCurrencyCode)}"/>
</dvt:y1TickLabel>
<dvt:markerText><dvt:y1Format>
  <af:convertNumber pattern="#{ fnd:currencyPattern(YourCurrencyCode)}"/>
</dvt:y1Format></dvt:markerText>
```

21.11.3.2 Standards and Guidelines for Formatting Currency Values in Graphs

- Before adding an af:convertNumber tag to a graph, make sure that the autoPrecision attribute of the parent tag (such as dvt:MarkerText) is set to off. If autoPrecision is set to on, ADF Data Visualization does not follow the converter correctly, and instead formats numbers automatically, which will be incorrect in Oracle Fusion applications, as the number will not honor user preferences.
- Set scaling="none" before adding the af:convertNumber tag to a graph. Otherwise, ADF Data Visualization will not follow the converter correctly.

21.11.4 How to Format Dates and Timestamp Values in ADF Data Visualization

All date values on a graph need to be formatted correctly when they are presented to a user. Users expect that they can input values according to their date formatting preferences. For instance, a value of 13th August, 2011 in the database might have to be displayed as 08/13/2011 for a certain user. A similar example of a date-time value is that a value of 26th July 2011, 2:00:00 PM might have to be displayed as 14:00 07/26/2011.

21.11.4.1 Formatting Dates and Timestamp Values on a Graph

Before you begin, create an entity object and a view object with date or timestamp fields, including any of these attribute types: java.sql.Date or java.sql.Timestamp. Drag
and drop the entity and create an ADF Data Visualization component, such as a pie graph, a bar graph or a line graph.

A graph typically uses categorical attributes, such as product, geography or year, on an ordinal axis (x axis or dvt:o1Axis) and for the marker tooltips. For the dvt:o1 axis, the data is considered as text no matter what its type in the underlying layers. Therefore, any number or date on the dvt:o1 axis does not honor any formatting.

A user can add af:convertNumber/af:convertDateTime by first adding dvt:attributeFormat to it, and the resultant values on the x-axis will be formatted, as shown in Example 21-72. Also, with this code, wherever the ordinal axis values are used in the user interface, they will appear with the proper formatting.

---

**Note:**

- If there is a single categorical Date attribute being displayed on the O1Axis, the graph displays a TimeAxis instead of the typical O1 / Ordinal Axis. The TimeAxis will show dates in a hierarchical format instead of as a single label on an O1 Axis, for example June 27, 2001. To show a single label on the O1 Axis, the TimeAxis should be turned off (timeAxisType="TAT_OFF") and a <dvt:attributeFormat> is necessary to specify the date format.

- The Area graph displays a time axis when dates (object type java.util.Date) are specified for the column labels. Several timeXXX attributes are defined on the graph tag to customize the time axis. The child tag timeAxisDateFormat controls the format in which the time axis labels are displayed.

  <dvt:timeAxisDateFormat dayFormat="DAY_OF_MONTH" monthFormat="MONTH_LONG" quarterFormat="NONE" yearFormat="YEAR_LONG" timeFormat="HOUR_MINUTE_SECOND"/>

---

Example 21-73 shows timestamp formatting on the O1 axis.

This is the same as the case of ADF Faces, in which the UPTZPattern is used to format timestamp values and dateFormatPattern is used to format date values.

In Figure 21-30, dates such as 2/1/2015 on the O1 axis and 8/9/2009 on the tooltip are examples of date fields on an area graph that should be formatted according to the user’s date formatting preferences.

**Figure 21-30   Dates to Format Using User Preferences**

![Image showing area graph with dates formatted as per user preferences.](image)

Other Types of Graphs

Example 21-73 just gives an example of date and date-time formatting in area graphs. **Table 21-3** shows the tags in which af:convertDateTime can be added for date and timestamp formatting in the other types of graphs.
### Table 21-3  Using `af:convertDateTime` for Date and Timestamp Formatting

<table>
<thead>
<tr>
<th>Graph Type</th>
<th>Is <code>dvt:attributeFormat</code> Required?</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Bar Horizontal</td>
<td>Yes</td>
</tr>
<tr>
<td>Bubble Graph</td>
<td>Yes</td>
</tr>
<tr>
<td>Combination Graph</td>
<td>Yes</td>
</tr>
<tr>
<td>Funnel Graph</td>
<td>Yes (for funnel section values)</td>
</tr>
<tr>
<td>Line Graph</td>
<td>Yes</td>
</tr>
<tr>
<td>Pareto Graph</td>
<td>Yes</td>
</tr>
<tr>
<td>Pie Graph</td>
<td>Yes</td>
</tr>
<tr>
<td>Pie Bar Charts</td>
<td>Yes</td>
</tr>
<tr>
<td>Gantt Chart</td>
<td>No (Add <code>af:convertDateTime</code> as a child tag of <code>af:column</code>)</td>
</tr>
<tr>
<td>Gauge</td>
<td>N/A</td>
</tr>
<tr>
<td>ADF Pivot Table</td>
<td><code>&lt;af:inputText&gt;/&lt;af:outputText&gt;</code> whose parent tag is <code>&lt;dvt:dataCell&gt;</code>/<a href="">af:inputText</a>/<a href="">af:outputText</a><code>whose parent tag is</code><a href="">dvt:headerCell</a>`</td>
</tr>
</tbody>
</table>

**Example 21-72  Date Formatting on the O1 Axis**

```xml
<dvt:attributeFormat id="af1" name="OrderDate">
  <af:convertDateTime type="date" pattern="#{applCorePrefs.dateFormatPattern}"/>
</dvt:attributeFormat>
```

**Example 21-73  Timestamp Formatting on the O1 Axis**

```xml
<dvt:attributeFormat id="af1" name="LastUpdateDate">
  <af:convertDateTime type="both" pattern="#{applCorePrefs.UPTZPattern}"/>
</dvt:attributeFormat>
```

## 21.12 Configure National Language Support Attributes

In Oracle Fusion Applications, National Language Support (NLS) refers to the ability to run an application instance in any single supported language, including specific regional or territorial number and date formats. Typically, to support a given language, only the customer-facing components of the software (user interface, lookup tables, online documentation, and so on) are translated. Translations are delivered via NLS patches.

### 21.12.1 Session National Language Support Attributes

Oracle Fusion Applications manage NLS attributes at the session level. At runtime, these attributes are initialized based on the user’s profile, and are applied when needed by Applications Core. For example, the session date format mask is initialized based on the user’s preferred date format mask. The date format mask is automatically applied when date is rendered and parsed. As such, it is unnecessary to manually specify NLS attributes in design time.
In certain situations, however, you may need to access the NLS attributes for the purposes of data formatting or parsing your code. To do so, use the managed bean `ApplCorePrefs`.

Table 21-4 lists the Oracle Fusion Applications session NLS attributes, the profile used to set each attribute and the possible values for session attributes.

<table>
<thead>

#### 21.12.2 Database Session Attributes

Oracle Fusion Applications does not use most of the database session NLS parameters. Instead, these are set to constant values such that typically, the user’s preferred values are not reflected. This is true for most parameters except the following: NLS_LANGUAGE which is set to view link view access, and NLS_SORT, which is set to use the database linguistic sorting functionality.

The parameters TO_NUMBER, TO_DATE, TO_TIMESTAMP and TO_CHAR are used to format and parse SQL or PL/SQL statements. These parameters are based on constant values, the canonical format. The parameter FND_DATE for PL/SQL packages also works with the canonical format. Formatting and parsing should be done at the presentation, rather than the model layer.

Oracle Fusion Applications session management controls database session parameters. As such, the database NLS session parameter values must not be altered.

Table 21-6 lists the following:

- **Database attribute**: The database NLS session parameter name.
- **Associated session attribute**: The Oracle Fusion Applications NLS session attribute name related to the database attribute name, if one exists. If the attributes are indeed related, configuring a value for the Oracle Fusion Applications NLS session attribute results in an ALTER SESSION in the database layer.
- **Default value**: The default value of the attribute. This value is configured both in the database and init.ora as the database default.
- **Alter Session**: Indicates whether an ALTER SESSION is created in the database. When an ALTER SESSION initiates at session creation or attachment, execute NLS_LANGUAGE and NLS_TERRITORY first, as these may affect other attributes.
  - **Create**: An ALTER SESSION is created once, when the connection is first created.
  - **Update**: The ALTER SESSION updates when the session attaches, or whenever an associated attribute value changes mid-session.
  - **Never**: An ALTER SESSION is not created, and the default database value is unchanged.
<table>
<thead>
<tr>
<th>Database Attribute</th>

<td>CLIENT_ENCODING</td>
<td>FND_CLIENT_ENCODING</td>
<td></td>
<td>The preferred encoding for file uploads, downloads and exports in Java encoding name.</td>
</tr>
</tbody>
</table>

21.13 Standards and Guidelines for Localization Formatting

The following standards and guidelines apply to localization formatting:

- After dragging and dropping a view object onto a JSF page, the Oracle ADF tags for that view object are set. If you change the attributes of the view object after you create the JSF page, new Oracle ADF tags are not created. You must make these changes manually by editing the tags.

- You can change tags generated by Applications Core at design time by editing them manually.
This chapter discusses the basics of using flexfields to enable customers to add custom attributes to a business object in an Oracle Fusion application.

This chapter includes the following sections:

- Introduction to Flexfields
- Participant Roles
- The Flexfield Development Lifecycle
- Flexfields in the Application User Interface

22.1 Introduction to Flexfields

In your role as a developer, it is often impossible for you to anticipate all the database columns and UI fields your customers might need, or how each field should look as end user needs change. Flexfields enable customers to configure their applications to meet their business needs without having to perform custom programming.

The basic premise of a flexfield is to encapsulate all of the pieces of information related to a specific purpose, such as the components of a student's contact information, or the features of a product in inventory, or a key identifying a particular purchase by a particular person for a particular company on a particular date. A flexfield is a set of placeholder fields, called segments, that are associated with a business object. A segment captures a single atomic value, which is represented in the application database as a single column. In the application UI, a flexfield's segments can be presented as individual table columns, as separate fields, or as a concatenated string of values.

Those performing in the role of an implementor, either on behalf of the developer organization for a developer flexfield or on behalf of a customer for a customer flexfield, configure a flexfield by specifying the prompt, length, and data type of each flexfield segment. Configuration includes the specification of valid values for each segment, and the meaning of each value. Configuration also involves defining structure and context.

There are three types of flexfields, all of which enable implementors to configure application features without programming. These configurations are fully supported within Oracle Fusion Applications:

- Descriptive: A descriptive flexfield gives customers the ability to extend a data model with additional attributes. A descriptive flexfield provides a fixed number of segments for a business object, which the customer can optionally use to add custom attributes to meet their business needs, define how the attributes are validated, and configure how the attributes are displayed.
• Extensible: An extensible flexfield is similar to a descriptive flexfield, but with the following additional features:
  – The number of configurable segments is not fixed. That is, the number of segments is extensible.
  – Attributes can be grouped into a context so they will always be presented together in the application user interface.
  – Hierarchical categories enable implementors to reuse contexts for similar entities.
  – Extensible flexfields support one-to-many relationships between the entity and the extended attribute rows.

• Key: A key flexfield enables customers to use their own coding scheme or naming scheme to identify their business entities by giving implementors the ability to configure the business entities to be identified using flexible, multipart, intelligent key codes. Each element (segment) of the key may be individually meaningful, as well as the combination as a whole. For example, key flexfields might represent part numbers and account numbers. Key flexfields are never optional; customers must configure them for their Oracle Fusion applications to operate correctly.

To better understand flexfields and the differences among descriptive flexfields, extensible flexfields, and key flexfields, it is important to understand flexfield structures and contexts.

• Structure: A flexfield structure is a specific configuration of segments. If you add or remove segments, or, in the case of key flexfields, you rearrange the order of segments in a flexfield, you produce a different structure. In some applications, different end users need to see individually tailored segment structures for the same flexfield; for example, the correctly formatted local postal address for customer service inquiries, which would change based on the user's locale.

A flexfield can display different segments and prompts for different end users based on a data condition in the application's data, such as the user's role or a value entered by the user. All types of flexfields allow for multiple structures. All the segments that you might need to use to create all the anticipated structures must be defined as part of the flexfield.

• Context: Descriptive and extensible flexfield segments are context-sensitive — they are varied or made available in your application by implementors to reflect the needs of the customer for which the application is being configured. Segments are made available to an application as groups of attributes called contexts. Each context is defined as part of a flexfield, and includes a set of context-sensitive segments that stores a particular type of related information. The database columns on which segments are based can be reused in as many contexts as desired. For example, an implementor can define a Dimensions context, which uses three of the flexfield's database columns of type NUMBER for the height, width, and depth segments. The implementor can also define a Measurements context, which reuses those database columns for weight, volume, and density segments.
Note:
A descriptive flexfield segment that stores data that is applicable to all entities, regardless of context, is referred to as a global segment.

The following links provide more information within this book:

- For more information about the role of implementor, see Participant Roles.
- For more information about developer and customer flexfields, see Descriptive Flexfields and Extensible Flexfields.

Related Links
The following documents provide additional information related to subjects discussed in this section.

For information about flexfield configuration, see the section about defining flexfields in the Implementing Common Features guide for your product family.

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.

22.1.1 Descriptive Flexfields

Descriptive flexfields provide a way for customers to add custom attributes to business objects, to define how the attributes are validated, and to define display properties for the attributes. These attributes can be standalone attributes. That is, they do not necessarily need to have anything to do with each other and do not need to be treated as a combination. The segments of a descriptive flexfield that are made available to end users are exposed in the user interface as individual fields.

Descriptive flexfields are entirely optional; customers can choose to configure and expose them or not, as they wish. For example, one customer could configure the parts flexfield to store depth, height, and width, and another customer could configure the parts flexfield to store size and color. Some customers might not need any additional attributes.

You create a descriptive flexfield for one of two purposes:

- For use by customer implementors — a customer flexfield.

  In this case, you define and register the descriptive flexfield in your application database, but all configuration is accomplished by the implementor, including creating contexts, creating segments, and adding validation. End users see these additional attributes in the UI and can enter values for them. End users cannot modify the configuration; they can only enter values for attributes that are already configured.

- To support functionality that you build into your application — a developer flexfield.

  For this purpose, you define and register the descriptive flexfield, and then preconfigure (seed) the contexts and segments, value sets, and validation to satisfy a specific purpose. The descriptive flexfield becomes part of your application, and you can code references to its seeded configuration. You might
also enable implementors to extend the developer flexfield, allowing them to configure it as they would a customer flexfield.

Even if implementors never change a flexfield after it has been configured, they can take advantage of useful flexfield features such as automatic segment validation, automatic segment cross-validation, multiple segment structures, and more.

### 22.1.2 Extensible Flexfields

An extensible flexfield is similar to a descriptive flexfield, but with the added ability for customers to add as many context-sensitive segments to a flexfield as they need. In addition, customers can associate more than one context with any particular row of data.

Extensible flexfields also enable implementors to configure contexts as either single row or multiple row. That is, either one set of the context’s segments is stored for a business object instance, or multiple sets of the context’s segments are stored for the instance. For example, a job position requires only one set of educational requirements, but can require more than one certificate or license.

Extensible flexfields also enable implementors to combine the contexts into groups known as pages, which serve to connect the contexts so they will always be presented together in the application user interface. Hierarchical categories can be defined for extensible flexfields, and implementors can associate any combination of contexts with a given category. For example, the Electronics and Computers category hierarchy might include a Home Entertainment category, which in turn might include an Audio category and a TV category, and so on. The Home Entertainment category might have contexts that specify voltage, dimensions, inputs and outputs. Contexts are reusable within a given extensible flexfield. For example, the dimensions context could be assigned to any category that needs to include dimensional information.

Just as with descriptive flexfields, you create a flexfield for one of two purposes:

- For use by customer implementors — a customer flexfield.
- To support functionality that you build into your application — a developer flexfield.

For more information about customer and developer flexfields, see Descriptive Flexfields.

### 22.1.3 Key Flexfields

Key flexfields are configurable multipart intelligent keys, where each element (segment) of the key may be individually meaningful, as well as the combination as a whole. For example, key flexfields might represent part numbers and account numbers.

A key flexfield is implemented in the user interface as a collection of fields that can be displayed in various UI formats. Key flexfields are never optional; customers must configure them for their Oracle Fusion applications to operate correctly.

The ability to individually tailor key flexfield structures to the end user can be essential. For example, Oracle General Ledger uses a key flexfield called the Accounting Flexfield to uniquely identify a general ledger account. It maintains the multiple accounting codes used throughout Oracle Fusion Applications, and provides different Accounting Flexfield structures for users of different sets of books. Oracle General Ledger determines which flexfield structure to use based on the value of a Set of Books user profile option.
This flexfield is preconfigured to include six segments: company code, cost center, account, product, product line, and subaccount, and valid values are defined for each segment, as well as cross-validation rules to describe valid segment combinations. However, customers might structure their general ledger account fields differently. By including the Accounting Flexfield, Oracle General Ledger can accommodate the needs of different customers. One customer can configure the Accounting Flexfield structure to include 6 segments, while another customer includes 12 segments, all without programming.

22.1.4 Value Sets

An end user enters a value into a flexfield segment while using an Oracle Fusion application. The flexfield validates each segment value against a set of valid values — a value set — which is usually predefined by the implementor. To validate a segment means that the flexfield compares the value that the end user enters into the segment against the values that comprise the value set that is assigned to that segment.

Flexfield segments are usually validated, and typically each segment in a given flexfield uses a different value set. A value set can be assigned to more than one segment and value sets can be shared among different flexfields. For most value sets, when you enter values into a flexfield segment, you can enter only values that already exist in the value set assigned to that segment.

When a business component is generated for a flexfield, the value set metadata is used in the creation of the view objects. Value sets (and their view objects) are owned by a module, which can be an application, a Logical Business Area (LBA), or a sub-LBA in the application taxonomy hierarchy.

For more information about the taxonomy hierarchy, see Working with the Application Taxonomy.

The following document provides additional information related to subjects discussed in this section:

For information about value set configuration, see the Define Flexfields section in the Implementing Common Features guide.

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.

22.1.5 Flexfield Integration with Oracle Business Intelligence

Oracle Business Intelligence is a comprehensive collection of enterprise business intelligence functionality that provides the full range of business intelligence capabilities including interactive dashboards, proactive intelligence and alerts, enterprise and financial reporting, real-time predictive intelligence, and more.

A flexfield can be included in Oracle Business Intelligence by business-intelligence enabling the flexfield. However, because the polymorphic view objects that are used to model flexfields are not compatible with Oracle Business Intelligence, the flexfield must be flattened into a static form that Oracle Business Intelligence can work with. You accomplish this by slightly modifying the process when you register the flexfield and incorporate it into your application.

For more information, see the following sections in this book:
• Preparing Descriptive Flexfield Business Components for
• Preparing Extensible Flexfield Business Components for
• How to Prepare Key Flexfield Business Components for

22.2 Participant Roles

Responsibility for flexfield development activities is divided between owners and implementors. These are not formal development roles; they are used only in this documentation to clarify and group the flexfield development activities.

Owner
The owner is the developer (or development team) who determines that a particular flexfield is needed or would be useful within a particular Oracle Fusion application, and makes a flexfield of the appropriate design available. The owner then incorporates the flexfield into an application. With key flexfields, the owner can be either a producer or a consumer, or can assume both roles.

• **Producer**: The flexfield producer is the developer who determines that a particular flexfield is needed or would be useful within a particular application, and makes available a flexfield of the appropriate design. With key flexfields, the producer’s product owns the combinations table for that flexfield.

• **Consumer**: A key flexfield consumer incorporates a flexfield into an application. The consumer typically stores a segment value or combination ID (CCID) on a product database table, and works with the structural and seed data and the business components that have been configured by the flexfield producer.

Implementor
An implementor is an individual who sets up all or part of a flexfield-enabled application for deployment. Implementors typically work for or on behalf of customers to install, configure, or administer their applications. In the case of developer flexfields that have been created to support functionality that has been built into the application, the developer also assumes the role of implementor.

For more information about combinations tables for flexfields, see Creating the Combinations Table.

22.3 The Flexfield Development Lifecycle

The process of developing a flexfield and incorporating it into an application differs for each type of flexfield. In general, the process comprises the following activities:

1. Define and register the flexfield metadata.

2. Create business components for the flexfield. For key flexfields, also create business components for the key flexfield combination filters.

3. For descriptive and key flexfields, link the flexfield business components to the application’s business components.

4. Incorporate the flexfield into UI pages.

5. Define sample flexfield data and use it to test the flexfield.
6. Use the Tester role of the Create Flexfield Business Components wizard to create a model that you can use to test the flexfield.

7. Optionally, share the flexfield business components with other developers using an Oracle Application Development Framework (Oracle ADF) library.

After you have completed the flexfield development process and delivered the application, implementors can use the Manage Flexfields task flows to configure each flexfield. These task flows determine how the flexfield’s segments will be populated, organized, and made available to end users within the application.

**Note:**

You must use the specified tools throughout the development lifecycle to create and update the flexfield metadata and product tables. Do not use database tools unless you are instructed to do so. If you use database tools instead of the specified tools, you risk destroying data integrity and you lose the ability to audit changes to the data.

Because Oracle Fusion Applications tables are interrelated, any changes that you make using the specified tools, such as building business components or UI forms, can update many tables at once. If you do not use the specified tools, you might not update all the necessary tables. In addition, most of these tools perform validation and change tracking.

If tables are not properly synchronized, you risk unpredictable results throughout Oracle Fusion Applications products.

For more information about creating business components for key flexfield combination filters, see Working with Code-Combination Filters for Key Flexfields.

The following document provides additional information related to subjects discussed in this section:

For information about planning and implementing flexfield configuration, such as defining structures, contexts, attributes, labels, behavior, and associated value sets, see the Define Flexfields section in the Implementing Common Features guide.

For information about implementing your specific product family, do the following:

1. Access the Oracle Fusion Applications library.
2. See the Implementing Common Features guides for your product family.

### 22.4 Flexfields in the Application User Interface

Flexfield segments can appear in a user interface as either label/widget pairs or as table fields. After an extensible flexfield is configured, it appears in the UI as one or more regions. Configured descriptive and key flexfields may appear in the UI in either a form layout, a tabular layout, or in a form or table layout in a popup component:

- **Form layout**: A typical label/prompt and either view-only data or a widget (text field, choice list, and so on) that allows an end user to enter values.

- **Tabular layout**: A column of information in a table, where the label of the flexfield segment is the column header, and the values are within each cell of the column.
All segments of a single flexfield are grouped together by default. The layout of the form or table and the positions of the flexfield segments depend on where you place the flexfield on the page. Flexfields may also be presented in a separate section of the page, alone in a table, or on their own page.
This chapter discusses how to use descriptive flexfields to enable customers to add additional attributes to business objects in their Oracle Fusion applications.

This chapter includes the following sections:

- Introduction to Descriptive Flexfields
- Developing Descriptive Flexfields
- Creating Descriptive Flexfield Business Components
- Creating Descriptive Flexfield View Links
- Nesting the Descriptive Flexfield Application Module Instance in the Application Module
- Adding a Descriptive Flexfield View Object to the Application Module
- Adding Descriptive Flexfield UI Components to a Page
- Configuring Descriptive Flexfield UI Components
- Testing Flexfields
- Loading Seed Data
- Working with Descriptive Flexfield UI Programmatically
- Incorporating Descriptive Flexfield into a Search Form
- Preparing Descriptive Flexfield Business Components for
- Publishing Descriptive Flexfields as Web Services
- Accessing Descriptive Flexfields from an ADF Desktop Integration Excel Workbook

23.1 Introduction to Descriptive Flexfields

Descriptive flexfields provide a way for implementors at customer sites to add custom attributes to entities, and to define validation and display properties for them. A descriptive flexfield is a logical grouping of segments that is mapped to a set of database columns that serve as placeholders for custom attributes. These placeholder columns are often referred to as extension columns. The attributes in the group are of three types: global segment, context-sensitive segment, and context segment. The global segments are for custom attributes that apply to all entity rows, while the context-sensitive segments are for custom attributes that apply to certain entity rows based on the value of a context segment.
As the developer, you can define multiple usages for a descriptive flexfield. For example, you might have defined an address flexfield that the implementor may use to add attributes related to addresses. The implementor can define context-sensitive segments for the address that are based on a certain attribute, such as country code. You can reuse the address flexfield with any table for which you need address information, and the implementor needs to configure the flexfield only once.

To complete the development tasks for descriptive flexfields:

1. Create the extension columns to store the flexfield data, and then register the flexfield definition, usage, and parameter metadata.
2. Create descriptive flexfield business components.

   Tip:
   After completing this step, you can regenerate the flexfield business components programmatically at runtime to update your descriptive flexfield implementation without manual intervention.

3. Create view links between the descriptive flexfield business components and the application’s business components.
4. Nest the descriptive flexfield application module instance in the application module.
5. Add an instance of the descriptive flexfield view object to the application module.
6. Add the descriptive flexfield usage to the appropriate application pages.
7. Configure the descriptive flexfield UI components.
8. Test the flexfield.
9. Load any necessary application seed data, such as error messages or lookup values.

After implementing a flexfield, you can define seed or test configurations for the flexfield, and then test it.

After you have completed the flexfield development process and delivered your application, implementors can use the Manage Descriptive Flexfields task flows to define context values and to configure the segments for each flexfield. These task flows determine how the flexfield’s segments will be populated, organized, and made available to end users within the application.

To make the Manage Descriptive Flexfields task flows available to implementors, register them with the Oracle Fusion Functional Setup Manager.

For information about implementing your specific product family, do the following:

• Access the Oracle Fusion Applications Technology library.

• See the Implementing Common Features guides for your product family. Search for flexfields.

23.1.1 Benefits of Descriptive Flexfields

Descriptive flexfields let you satisfy different customers without having to reprogram the application, by enabling the customers to add customized fields. Descriptive flexfields also enable context-sensitive fields that appear only when needed. In essence, a descriptive flexfield enables implementors to extend the data model without writing either XML or Java. A descriptive flexfield is presented as a set of fields on a page, much like the fields of the core application.

For example, consider a retail application that keeps track of customers. The customer form would typically include fields such as Name, Address, State, Customer Number, and so on. However, the page might not include fields to keep track of customer clothing size and color preferences, because these are attributes that can differ for each company that uses the application. For example, if the retail application is used for a tool company, a field for clothing size would be undesirable. Even if you initially
provide all the fields that a company needs, the company might later identify even more customer attributes that it wants to track. You can add a descriptive flexfield to the customer form to provide the desired expansion space. Companies also can take advantage of the fact that descriptive flexfields can be context-sensitive, where the information that the application stores depends on other values that the end users enter on other parts of the page. For example, a company could configure the descriptive flexfield for a fixed asset form to store style, size, and wood type if the asset type was "desk", and store CPU chip and memory size if the asset type was "computer."

Another example is the descriptive flexfield in the Oracle General Ledger journal entry form. Implementors can configure the flexfield to add information of a customer's own choosing. For example, a customer might want to capture additional information about each journal entry, such as source document number, or the name of the person who prepared the entry.

To maximize flexibility for customers, consider defining a descriptive flexfield for every entity in your application to which a customer might need to add attributes.

23.1.2 How Descriptive Flexfields Are Modeled in Oracle Application Development Framework

Flexfields are modeled as a collection of Oracle Application Development Framework (Oracle ADF) polymorphic view rows, as described in the Working with Polymorphic View Rows section in the Developing Fusion Web Applications with Oracle Application Development Framework. In a polymorphic collection of rows, each view row can have its own set of attributes, and all rows have at least one common attribute, the discriminator. The discriminator determines which view row type is used. Given a collection of polymorphic view rows, each row can be a different type.

The attribute sets that are associated with the discriminator are predefined. In fact, Oracle ADF enables each view row to have its own view definition. When a polymorphic collection of rows is created, Oracle ADF selects a view definition for the row to be added based on the value of the discriminator attribute.

Descriptive flexfield segments are exposed as view row attributes in the order that they are defined in the flexfield's metadata. Global segments are exposed as attributes in the base view object of the polymorphic collection. Every context is modeled as an extended view object of the base view object. That is, an extended view object is created for every context value. These extended view objects, which are referred to as subtype view objects, expose context-sensitive segments as subtype-specific view attributes. The context segment is exposed as the discriminator attribute of the polymorphic view rows.

You use a wizard to generate a polymorphic base view object that is based on the descriptive flexfield definition, then create a view link to connect the product view object and the base view object. You can then use the base view object to add the flexfield to a UI page. For more information about the generation of base and subtype view objects, see Creating Descriptive Flexfield Business Components.
Note:

One distinction of the flexfield context-switching mechanism is that during context switching, the context-sensitive segments are initialized as follows:

- If a segment is defined to use a constant value from an underlying entity object as its default, it is initialized to that value.
- If a segment is defined to use a descriptive flexfield parameter by default, it is initialized to that value.
- For all other cases, the context-sensitive segment is set to NULL.

For more information about polymorphic view rows, see the Working with Polymorphic View Rows section in the Developing Fusion Web Applications with Oracle Application Development Framework.

Note:

Because flexfield view objects are modeled as polymorphic view objects, you can use descriptive flexfield view objects in the same manner that you use any other polymorphic view objects, and they will behave in the same way. This includes support for flexfields in ADF Desktop Integration. For more information, see Accessing Descriptive Flexfields from an ADF Desktop Integration Excel Workbook and the Oracle Fusion Middleware Developing Applications with Oracle ADF Desktop Integration guide.

23.2 Develop Descriptive Flexfields

Whenever you have a product table that you think implementors might need to extend for their specific circumstances, you can add columns to the table and register those columns as flexfield segments. After you have registered a flexfield, you can reuse the flexfield with other product tables.

To complete the process for developing a descriptive flexfield:

1. Add extension columns to the product table.
2. Register the flexfield and define its metadata and primary usage.
3. Register the entity details and parameters for the primary usage.
4. Optionally reuse the flexfield by adding the same set of extension columns to other product tables.
5. Register the secondary usages and their entity details.

23.2.1 How to Create Descriptive Flexfield Columns

To implement a descriptive flexfield for a product table, you first add extension columns to that table. You need to add a context column, such as ATTRIBUTECATEGORY, and as many generic attribute (segment) columns of each type, such as ATTRIBUTECHAR1 and ATTRIBUTENUMBER12, as will be needed by the implementors. A segment column must be a VARCHAR2, NUMBER, DATE, or
When using a flexfield to add a custom attribute, the implementor maps the custom attribute to an available extension column.

**Tip:**
There are no constraints on how to name the segment columns. However, these columns are typically named using the patterns ATTRIBUTE_CHAR\textsubscript{n}, ATTRIBUTE_NUMBER\textsubscript{n}, ATTRIBUTE_DATE\textsubscript{n}, and ATTRIBUTE_TIMESTAMP\textsubscript{n}. This convention makes it easy to identify the flexfield segments. It also makes it easier to name the columns for other usages of the flexfield.

The context column, which is required, must be of type VARCHAR2. The context column’s length determines the maximum length of the context codes that can be created by implementors when they configure the flexfields.

Each implementor can configure as many of the segment columns as the end user requires and can choose whether to use the context column.

You must use the Database Schema Deployment Framework tools to create the product table and columns. Using these tools ensures that the table and its columns are registered in the Oracle Fusion Middleware Extensions for Applications (Applications Core) data dictionary. For more information, see Using the Database Schema Deployment Framework.

### 23.2.2 How to Register and Define Descriptive Flexfields

Before you can create business components for a descriptive flexfield, you must first define and register the descriptive flexfield.

The basic steps for defining and registering a descriptive flexfield are as follows:

- Name and describe the flexfield.
- Indicate whether the flexfield should be protected from end-user configuration. If a flexfield is protected, it cannot be edited using setup tasks, such as Manage Descriptive Flexfields. Typically, this option is used for developer flexfields. Note that you must use the APIs to do this step. For information, see Using the Setup APIs To Register and Define Descriptive Flexfields.
- Define the primary usage. The primary usage is the first usage that you define for a flexfield.
- Define the context column to be used for the context segment. The product table that is used for the primary usage is called the primary table.
- Define the product table columns to be used for the flexfield segments.

There are two ways in which you can define a descriptive flexfield:

- Using the Flexfield Registration Metadata wizard. If you use the wizard, you also define the entity details for the primary usage and you define the parameters.
- Using the setup APIs in the FND_FLEX_DF_SETUP_APIS PL/SQL package.

#### 23.2.2.1 Using the Flexfield Registration Metadata Wizard To Register and Define Descriptive Flexfields

You can use the Register new flexfield operation from the Flexfield Registration Metadata wizard to register and define a descriptive flexfield.

Develop Descriptive Flexfields
Tip:
To make subsequent flexfield additions and changes, you can use the Edit flexfield operation from the Flexfield Registration Metadata wizard.

Before you begin:

- Create the extension columns as described in How to Create Descriptive Flexfield Columns.
- Ensure that entity objects exist for the primary table.

To register and define a descriptive flexfield using the Flexfield Registration Metadata wizard:

1. From the File menu, choose New.
2. In the New Gallery, expand Business Tier, select ADF Business Components and then Flexfield Registration Metadata, and click OK.
3. On the Choose Operation page of the Flexfield Registration Metadata wizard, select Register new flexfield as shown in Figure 23-1, and then click Next.

   **Figure 23-1  Flexfield Registration Metadata Wizard — Choose Operation Page**

4. On the Basic Information page, select Descriptive Flexfield from the Type dropdown list, as shown in Figure 23-2.
5. Provide the following values:

- **Code**: Type a code that uniquely identifies the flexfield.
- **Name**: Type a descriptive name for the flexfield.
- **Description**: Type a short description of the flexfield.
- **Application**: Select the application name that has been assigned for the product area.
- **Module**: Select the module that owns the flexfield. This is typically the application or logical business area (LBA) with which the flexfield is delivered.
- **Delimiter**: Select the character to be displayed between flexfield segments, when the segments are displayed in a concatenated format.
- **Enable Business Intelligence**: (Optional) Select the checkbox to enable the flexfield for Oracle Business Intelligence. For more information, see Preparing Descriptive Flexfield Business Components for.

6. Click Next.

7. On the Primary Table page, set the following values to define the primary usage for the flexfield, as shown in Figure 23-3.

- **Base Table**: Enter or select the name of the database table that contains the columns to be used as flexfield segments.
- **Table Usage Code**: Type a code that uniquely identifies the flexfield usage. For the primary usage, this is typically the same code as the flexfield code.
- **Table Usage Name**: Type a descriptive name for the flexfield usage.
8. From the **Context Column** dropdown list, select the database column that you want to map to the flexfield’s context segment. The column must be of type VARCHAR2.

**Tip:**

The context segment database column is typically named ATTRIBUTE_CATEGORY.

9. In the **Available** list in the **Segment Columns** region, select the database columns that you want to map to flexfield segments and move them to the **Selected** list.

10. Click **Next**.

11. On the Entities page, select the entity objects for the table upon which the usage is based and move them to the **Selected** list, as shown in **Figure 23-4**.
12. Select each entity object from the **Selected** list and provide the following values:

- **Object Name Prefix**: Enter a short unique name for the flexfield usage. For example, `PartsDF`. This prefix is used to derive the names of objects that are generated for the flexfield usage.

- **Package Name**: Specify the name of the root package to be used for the generated business components that model the flexfield usage.

- **BI Flattened Fact Name**: If the flexfield is enabled for Oracle Business Intelligence and you know the Oracle Business Intelligence object that this flexfield usage should be mapped to when the flexfield is imported into Oracle Business Intelligence, specify the name of the object.

  For more information about Oracle Business Intelligence, see *Preparing Descriptive Flexfield Business Components for*.

13. Click **Next**.

14. On the Parameters Page, optionally define parameters for the entity object attributes that can be used to pass external reference data to flexfield segments, as shown in *Figure 23-5*. 
15. On the Summary page, optionally select Extract seed data for the flexfield to create a seed data file for uploading the registration information into other implementations. For more information, see Loading Seed Data.

16. If you are ready to create business components for the flexfield, select Launch Flexfield Business Components Wizard.

17. Click Finish.

23.2.2.2 Using the Setup APIs To Register and Define Descriptive Flexfields

You can define and register a descriptive flexfield using procedures from the FND_FLEX_DF_SETUP_APIS PL/SQL package. This package also has procedures for updating, deleting, and querying flexfield definitions.

To learn how to access documentation about using the FND_FLEX_DF_SETUP_APIS PL/SQL package, see What You May Need to Know About the Descriptive Flexfield Setup API.

Before you begin:
Create the extension columns as described in How to Create Descriptive Flexfield Columns.

To register and define a descriptive flexfield using the setup APIs:

1. Run the fnd_flex_df_setup_apis.create_flexfield(...) procedure to register the descriptive flexfield, its context segment, and its primary (master) usage. If you do not want end users to configure the flexfield, set the protected flag to N.

2. Run the fnd_flex_df_setup_apis.create_segment_column_usage(...) procedure for each segment column to register the segment columns.
3. (Optionally) Register the entity details as described in How to Register Entity Details. This step must be completed before you can generate the flexfield usage's business components.

23.2.2.2.1 What You May Need to Know About the Descriptive Flexfield Setup API

In the descriptive flexfield development process, use the FND_FLEX_DF_SETUP_APIS PL/SQL package to manage flexfield registration metadata.

You can learn about the FND_FLEX_DF_SETUP_APIS PL/SQL package by running the following command, which stores package documentation and usage examples in the <db_name>_<user_name>_FND_FLEX_DF_SETUP_APIS_<date>.plsqldoc file.

```
sqlplus <fusion_user>/<fusion_pwd>@<fusion_db> @/ORACLE/fusionapps/atgpf/applcore/db/sql/flex/fnd_flex_pkg_doc.sql FND_FLEX_DF_SETUP_APIS
```

23.2.3 How to Reuse a Descriptive Flexfield on Another Table

A descriptive flexfield configuration can be shared with other product tables. To reuse a descriptive flexfield, you add the same set of extension columns to the product table for which you want to reuse the flexfield, and you register the secondary usage as described in How to Register the Reuse of a Descriptive Flexfield.

The product table that was used to register the flexfield is referred to as the primary table, and it is the owner of the flexfield. The usage that you create when you register the flexfield is called the primary usage. A reuse of a flexfield is referred to as a secondary usage.

The secondary table must have the same number of extension columns as the primary table. The secondary extension columns must have the same data type and size as the corresponding primary table extension columns.

The column names must also be the same as in the primary table, except for an optional prefix. For example, if the column names are ATTRIBUTE1 and ATTRIBUTE2 in the primary table, then in the secondary table they could again be ATTRIBUTE1 and ATTRIBUTE2, respectively, or with a prefix, they could be HOME_ATTRIBUTE1 and HOME_ATTRIBUTE2. They cannot be ATTR1, HOME_ATTR2, or any variation that does not end in the names of the primary table columns.

When configuring the flexfield, the implementor can configure as many of the segment columns as the end user requires and can choose whether to use the context column.

You must use the Database Schema Deployment Framework tools to create the product table and columns. Using these tools ensures that the table and its columns are registered in the Oracle Fusion Middleware Extensions for Applications (Applications Core) data dictionary. For more information, see Using the Database Schema Deployment Framework.

23.2.4 How to Register the Reuse of a Descriptive Flexfield

After you add extension columns to a table for a secondary usage of a flexfield, you must register the usage before you can build a descriptive business component for the secondary usage.

There are two ways in which you can register a secondary usage:
23.2.4.1 Using the Flexfield Registration Metadata Wizard To Register a Secondary Usage

You can use the **Register new flexfield usage operation** from the Flexfield Registration Metadata wizard to register the secondary usage of a descriptive flexfield. The registration wizard uses the primary usage column mappings to determine how to map the secondary table’s column names to the flexfield segments. If you specify a prefix, the wizard uses the prefix to determine the column mappings. For example, if the primary table’s ATTRIBUTE1 column is mapped to a segment, and you specify a prefix of HOME for the secondary usage, the wizard automatically maps its HOME_ATTRIBUTE1 column to a flexfield segment.

Before you begin:

1. Register the descriptive flexfield and its primary usage as described in *How to Register and Define Descriptive Flexfields*.
2. Create the extension columns for the secondary usage as described in *How to Reuse a Descriptive Flexfield on Another Table*.
3. Ensure that entity objects exist for the secondary table.

**To register a second usage using the Flexfield Registration Metadata wizard:**

1. From the **File** menu, choose **New**.
2. In the New Gallery, expand **Business Tier**, select **ADF Business Components** and then **Flexfield Business Components**, and click **OK**.
3. On the Choose Operation page of the Flexfield Registration Metadata wizard, select **Register new flexfield usage**, and then click **Next**.
4. On the Select Usage page, select **Descriptive** from the **Type** dropdown list, as shown in Figure 23-6.
5. To display available usages, provide a value for Application, Code, or Table. You can use a wildcard character, such as a percent sign (%), to match on similar values.

6. Select the primary usage of the flexfield for which you want to create the secondary usage, and then click Next.

7. On the Basic Information page, review the information about the primary usage, and then click Next.

8. On the Secondary Table page, set the following values to define the secondary usage for the flexfield, as shown in Figure 23-7.

   - **Base Table**: Enter or select the name of the secondary table.
   - **Table Usage Code**: Type a code that uniquely identifies the secondary usage.
   - **Table Usage Name**: Type a descriptive name for the flexfield usage.
   - **Column Name Prefix**: If you used a prefix for the flexfield column names, enter the prefix.
9. Click Next.

10. On the Entities page, select the entity objects for the secondary table and move them to the **Selected** list.

11. Select each entity object from the **Selected** list and provide the following values:

- **Object Name Prefix**: Enter a short unique name for the secondary usage. For example, `PartsDFFIntf`. This prefix is used to derive the names of objects that are generated for the flexfield usage.

- **Package Name**: Specify the name of the root package to be used for the generated business components that model the secondary usage.

**Note:**

Each usage must have a unique package name. In addition, the package name must uniquely identify a usage. For example, if the root package for a usage is `oracle.apps.flex.hcm.payroll.dff1`, then you cannot define the `oracle.apps.flex.hcm.payroll` package for another usage, because that package would then identify both usages. Instead, you could use `oracle.apps.flex.hcm.payroll.dff2`.

- **BI Flattened Fact Name**: If the flexfield is enabled for Oracle Business Intelligence and you know the Oracle Business Intelligence object that this usage should be mapped to when the flexfield is imported into Oracle Business Intelligence, specify the name of the object.

For more information about Oracle Business Intelligence, see [Preparing Descriptive Flexfield Business Components](#) for...
12. Click Next.

13. On the Summary page, optionally select Extract seed data for the flexfield to create a seed data file for uploading the registration information into other implementations. For more information, see Loading Seed Data.

14. If you are ready to create business components for the flexfield, select Launch Flexfield Business Components Wizard.

15. Click Finish.

23.2.4.2 Using the Setup APIs To Register a Secondary Usage

You can define and register the secondary usage of a descriptive flexfield using procedures from the `FND_FLEX_DF_SETUP_API` PL/SQL package.

To learn how to generate documentation about using the `FND_FLEX_DF_SETUP_API` PL/SQL package, see What You May Need to Know About the Descriptive Flexfield Setup API.

The definition of a descriptive flexfield usage includes the following information:

- The secondary table name
- The code for identifying the secondary usage
- The column name prefix. For example, if the primary table column is `ATTRIBUTE1`, and the secondary table column is `HOME_ATTRIBUTE1`, then the prefix is `HOME_`.

Before you begin:

1. Register the descriptive flexfield and its primary usage as described in How to Register and Define Descriptive Flexfields.

2. Create the extension columns for the secondary usage as described in How to Reuse a Descriptive Flexfield on Another Table.

To register a secondary usage using the setup APIs:

1. To register the secondary usage of a descriptive flexfield, run the `fnd_flex_df_setup_apis.create_flex_table_usage(...)` procedure.

2. (Optionally) Register the entity details as described in How to Register Entity Details. This step must be completed before you can generate the flexfield usage's business components.

23.2.5 How to Register Entity Details

Before you can create a flexfield business component and create flexfield-specific application module instances, you must register the following information:

- The full class name of the entity object for the table upon which the flexfield usage is based.
- A prefix from which to derive the names of generated objects.
- The package in which to place the generated business components. Each usage must have its own package name.
Note:
Each usage must have a unique package name. In addition, the package name must uniquely identify a usage. For example, if the root package for a usage is `oracle.apps.flex.hcm.payroll.dff1`, then you cannot define the `oracle.apps.flex.hcm.payroll` package for another usage, because that package would then identify both usages. Instead, you could use `oracle.apps.flex.hcm.payroll.dff2`.

If you used the Flexfield Registration Metadata wizard to define the flexfield usage, then you have already registered the entity details. Otherwise, you can use the Flexfield Registration Metadata wizard or the `FND_FLEX_DF_SETUP_APIS` PL/SQL package to register this information for a flexfield usage.

23.2.5.1 Using the Flexfield Registration Metadata Wizard to Register Entity Details
You can use the Edit flexfield usage operation from the Flexfield Registration Metadata Wizard to register entity details.

To register a usage using the Flexfield Registration Metadata wizard:

1. From the File menu, choose New.
2. In the New Gallery, expand Business Tier, select ADF Business Components and then Flexfield Business Components, and click OK.
3. On the Choose Operation page of the Flexfield Registration Metadata wizard, select Edit Flexfield Usage, and then click Next.
4. To display available usages, provide a value for Application, Code, or Table. You can use a wildcard character, such as a percent sign (%), to match on similar values.
5. Select the flexfield usage for which you want to add entity details.
6. Click Next until you are on the Entities page.
7. On the Entities page, select the entity objects for the table upon which the usage is based and move them to the Selected list.
8. Select each newly added entity object from the Selected list and provide the following values:
   - **Object Name Prefix**: Enter a short unique name for the flexfield usage. For example PartsDFF. This prefix is used to derive the names of objects that are generated for the flexfield usage.
   - **Package Name**: Specify the name of the root package to be used for the generated business components that model the flexfield usage.
   - **BI Flattened Fact Name**: If the flexfield is enabled for Oracle Business Intelligence and you know the Oracle Business Intelligence object that this flexfield should be mapped to when the flexfield is imported into Oracle Business Intelligence, specify the name of the object.

For more information about Oracle Business Intelligence, see Preparing Descriptive Flexfield Business Components for.
9. Click Next, and click Next again.

10. On the Summary page, optionally select Extract seed data for the flexfield to create a seed data file for uploading the registration information into other implementations. For more information, see Loading Seed Data.

11. If you are ready to create business components for the flexfield, select Launch Flexfield Business Components Wizard.

12. Click Finish.

23.2.5.2 Using the Setup APIs To Register Entity Details

You can register entity details using procedures from the FND_FLEX_DF_SETUP_APIS PL/SQL package.

To learn how to generate documentation about using the FND_FLEX_DF_SETUP_APIS PL/SQL package, see What You May Need to Know About the Descriptive Flexfield Setup API.

Before you begin:

1. Register the usage as described in How to Register and Define Descriptive Flexfields and How to Register the Reuse of a Descriptive Flexfield.

2. Ensure that the entity object for the usage’s table exists.

To register the entity details using the setup APIs:

• Run the fnd_flex_df_setup.Apis.create_adfbc_usage(...) procedure to register the entity object, package name, and object name prefix for the flexfield usage.

23.2.6 How to Register Extensible Flexfield Parameters

A flexfield parameter is a declared public variable, which can be used to designate which attributes of eligible entity objects that are related to the flexfield can be used to pass external reference data to flexfield segments. These entity object attributes could, in turn, take their values from column values, constant values, session attributes, and so forth.

A flexfield may have zero, one, or many flexfield parameters defined, each one representing a specific type of information that is useful to that flexfield. Implementors can use the parameters to define defaults and value set validation for the flexfield segments.

Some or all of these types of data sources can be referenced in the WHERE clauses for table value sets.

in the following ways:

• At row creation time to provide default segment values.

• In derived segments, which are global, context, or context-sensitive segments for which values are derived from an external reference data source, causing its values to automatically change to reflect any new reference data values.

• In the WHERE clauses for table value sets.
Note:
Although a flexfield parameter is associated with a flexfield in metadata, it is not connected with any specific segment in the flexfield. Rather, it serves as a variable through which flexfield segments can access reference data from other sources.

Every flexfield parameter must be mapped to an appropriate entity object attribute at design time. In this way, implementors are guaranteed that the parameters will always be mapped to entity object attributes, and they can use the parameters as needed.

When you create business components for a descriptive flexfield, you will be required to map each parameter associated with that flexfield to an attribute of the entity object that you are creating. The values accessed from reference data sources by these parameters are then available for you to use in your application. Many of the core (nonflexfield) fields on a page can serve as reference fields.

Consider the example of an Expense Lines entity object with the core fields of Expense Line ID, Expense Date, Amount, Description, and Expense Type. If the flexfield has an ExpenseType parameter that is mapped to the Expense Type field, an implementor can configure the context segment to derive its value from the ExpenseType parameter.

To implement descriptive flexfield parameters, you must map them to the appropriate entity object attributes at design time and configure them. For more information, see Creating Descriptive Flexfield Business Components and How to Configure Descriptive Flexfield Parameters.

To provide flexfield parameter values at runtime, the base implementation of the context entity object must override the method `getFlexfieldParameterValue` of `oracle.apps.fnd.appcore.oaext.model.OAEntityImpl`. You must handle every flexfield parameter in the overriding method. This guarantees that the parameters always contain the most up-to-date information.

The overriding method must return an object of appropriate type based on the flexfield parameter data type, as shown in the following table.

<table>
<thead>
<tr>
<th>Flexfield Parameter Type</th>
<th>Return Data Object Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Text</td>
<td>java.lang.String</td>
</tr>
<tr>
<td>Number</td>
<td>java.math.BigDecimal</td>
</tr>
<tr>
<td>Date</td>
<td>java.sql.Date</td>
</tr>
<tr>
<td>Timestamp</td>
<td>java.sql.Timestamp</td>
</tr>
</tbody>
</table>

The following code sample shows how to provide flexfield parameter values at runtime by overriding the `getFlexfieldParameterValue` method of the context entity object.

Example 23-1 Providing flexfield parameter values at runtime

```
public class BaseContextEOImpl extends OAEntityImpl {  
    @Override 
    public Object getFlexfieldParameterValue(final String localFlexID, final String paramCode) { 
        if ("EXPENSE_TYPE".equals(paramCode)) { 
            return 
```
getAttribute("ExpenseType");  }  else if ("EXPENSE_AMOUNT".equals(paramCode))
{    Double amount = (Double) getAttribute("ExpenseAmount");    return (amount
== null ? null : new java.math.BigDecimal(amount));  }  else
{    return super.getFlexfieldParameterValue(localFlexID, paramCode);  }
}

If you used the Flexfield Registration Metadata wizard to define and register the
flexfield, then you might have already defined the parameters. Otherwise, you can
edit the flexfield using the Flexfield Registration Metadata wizard or the setup APIs.

23.2.6.1 Use the Flexfield Registration Metadata Wizard to Register a Flexfield
Parameter

You can use the Edit flexfield usage operation from the Flexfield Registration
Metadata Wizard to register flexfield parameters.

To register a parameter using the Flexfield Registration Metadata wizard:

1. From the File menu, choose New.
2. In the New Gallery, expand Business Tier, select ADF Business Components and
then Flexfield Business Components, and click OK.
3. On the Choose Operation page of the Flexfield Registration Metadata wizard,
select Edit Flexfield Usage, and then click Next.
4. To display available usages, provide a value for Application, Code, or Table. You
can use a wildcard character, such as a percent sign (%), to match on similar
values.
5. Select the primary usage of the flexfield for which you want to add the
parameters.
6. Click Next until you are on the Parameters page.
7. On the Parameters Page, optionally define parameters for the entity object
attributes that can be used to pass external reference data to flexfield segments.
8. Click Next.
9. On the Summary page, optionally select Extract seed data for the flexfield to
create a seed data file for uploading the registration information into other
implementations. For more information, see Loading Seed Data.
10. If you are ready to create business components for the flexfield, select Launch
Flexfield Business Components Wizard.
11. Click Finish.

23.2.6.2 Register a Flexfield Parameter Using the Setup APIs

You can register a flexfield parameter using procedures from the
FND_FLEX_EF_SETUP_APIS PL/SQL package.

To learn how to generate documentation about using the
FND_FLEX_EF_SETUP_APIS PL/SQL package, see What You May Need to Know
About the Descriptive Flexfield Setup API.

Before you begin:
Define and register the flexfield as described in How to Register and Define Descriptive Flexfields.

To create a parameter using the setup APIs:

- Run the `fnd_flex_ef_setup_apis.create_parameter(...)` procedure and provide a parameter code and data type.

### 23.3 Create Descriptive Flexfield Business Components

Before you can use a descriptive flexfield in your application, you must use the Create Flexfield Business Components wizard to generate flexfield business components for the flexfield. The wizard generates a base view object that is based on the information in the flexfield metadata. After the initial flexfield registration, and before any configuration is completed, the base view object has at least two attributes: the primary key attribute, which links the flexfield view object to the product view object, and the context attribute, which serves as the discriminator.

When implementors configure the flexfields by defining global and context-sensitive segments, the base view object is regenerated and additional flexfield view objects are generated. Figure 23-8 shows an example of the configured ADF Business Components. The product view object contains only the nonflexfield attributes. The base view object contains the primary key attribute, the context attribute, and global attributes. The base view object is extended to define view object rows based on the configured context values. Each context value requires a subtype view object definition that represents the structure of the rows with that context value, as described in How Descriptive Flexfields Are Modeled in.

**Figure 23-8  Descriptive Flexfield Modeled as ADF Business Components Component**
Note:
The product view object might contain other attributes. However, the product view object must not include flexfield view object attributes.
None of the flexfield view objects contains the fixed (nonflexfield) columns.

No Java implementation classes are generated for descriptive flexfield view objects. The product view object may or may not have Java implementation classes.

23.3.1 How to Create Descriptive Flexfield Business Components

You use the Create Flexfield Business Components wizard to create the flexfield business components for a flexfield’s usage.
The business components generated will replace any existing ones that are based on the same flexfield usage.

Before you begin:

• Ensure that you have added the Applications Core library to your project as described in Setting Up Your JDeveloper Application Workspace and Projects.

• Ensure that at least one customization class is included in the adf-config.xml file. This inclusion serves to ensure correct application behavior. It does not matter which customization class you include.

For information about customization layers, see the "Understanding Customization Layers" section in the Extensibility Guide for Developers.

• Verify that the entity object that will be used as the data source for the business component meets the following requirements:
  – All flexfield columns are included in the entity object. In general, all columns should be included.
  – A primary key is defined for the entity object. If an entity object is going to be used to create new application transaction rows, a default primary key must be programmed.
  – All VARCHAR2 columns used for descriptive flexfield attributes are mapped to data type java.lang.String.
  – All number columns used for descriptive flexfield attributes are mapped to data type java.math.BigDecimal.
  – All date columns used for descriptive flexfield attributes are mapped to data type java.sql.Date.
  – All timestamp columns used for descriptive flexfield attributes are mapped to data type java.sql.Timestamp.

• Register the flexfield usage’s entity object, package name, and object name prefix. For more information, see How to Register Entity Details.

To create descriptive flexfield business components:

1. Build your project to ensure that the entity objects are available in classes. The modeler relies on what is in your classes.
2. From the File menu, choose New.

3. In the New Gallery, expand Business Tier, select ADF Business Components and then Flexfield Business Components, and click OK.

4. On the Flexfield page of the Create Flexfield Business Components wizard, select Descriptive from the Type dropdown list as shown in Figure 23-9.

Figure 23-9 Create Flexfield Business Components Wizard — Flexfield Page

5. In the Application field, specify the full name of the application to which your descriptive flexfield belongs.

You can browse for the name, and filter by ID, Short Name, or Name.

6. In the Code field, specify the code of the descriptive flexfield you want to use.

You can browse for and filter by Code.

7. In the Usage section, select the table row that contains your desired descriptive flexfield usage. The descriptive flexfield usage can be one of two possible types:

- The primary usage of the descriptive flexfield on the product table where it was originally defined. Every descriptive flexfield has one primary usage.

- A secondary usage of the descriptive flexfield on a product table, including the one on which it was originally defined. Zero or more secondary usage instances can be defined for a given flexfield, each one potentially on a different product table. You can identify secondary usage instances by the presence of the prefix (Reuse) in the Description field.

8. Click Next.

9. On the Path page, select the path of the directory structure in which to create the flexfield business components and click Next.

10. On the Entity Object page, select the entity object to use as the data source for the descriptive flexfield, as shown in Figure 23-10.
The entity object you select must include all of the attributes representing the columns that are reserved for the descriptive flexfield.

**Note:**

If you select a polymorphic entity object, ensure that the `InheritPersonalization` property for every subtype entity is set to `true`.

Descriptive flexfield attributes will be validated by the entity object along with its other attributes.

11. If the entity object for the descriptive flexfield has attributes that are defined as transient (not based on database table columns), then select **The names of the flexfield attributes match the names of registered columns exactly; do not check the underlying columns.**

When an attribute of a descriptive flexfield entity object is transient, there is no matching underlying column name. When you select this option, the system will match the entity object attribute names to the descriptive flexfield column names, and use the matching attributes to access the flexfield data. Ensure that the entity object has a full set of attributes with matching names before you select this option.

This entity object must be registered under the primary usage. There is no need to register another table for this purpose, even if the entity object is based on some other table. For more information, see **How to Register Entity Details.**
Note:
If the entity object with transient descriptive flexfield attributes is not based on
the primary usage, the transient attributes must be named using the same
prefix as the other attributes of that entity object (and the corresponding table
columns). For more information, see How to Reuse a Descriptive Flexfield on
Another Table.

Caution:
The Create Flexfield Business Components wizard is case-sensitive. All
column names — and the names of the flexfield entity object attributes
associated with them — must be uppercase.

12. Click Next.

13. The Naming page displays the entity object’s package name and object name that
you registered for the usage, as described in How to Register Entity Details. Click
Next.

14. On the Parameters page shown in Figure 23-11, map each flexfield parameter to the
entity object attribute that will be the data source for the parameter.

Parameters are not a requirement for descriptive flexfields. If no parameters are
defined for the descriptive flexfield that you are working with, the Parameters page
will display a message to that effect. However, if any parameters are defined and
associated with a descriptive flexfield, you must map each parameter to an entity
object attribute before you can use the flexfield in your application.

Figure 23-11 Create Flexfield Business Components Wizard — Parameters Page

The names in the Parameter Code column represent parameters that have been
defined for the descriptive flexfield. For each parameter listed, select the entity
object attribute from the Entity Attribute Name dropdown list to use as the data
source for that parameter.
The entity attributes in the dropdown list include the following:

- Attributes that are part of the entity object you selected as the flexfield data source.
- Attributes that are part of any entity object that is directly associated with the flexfield entity object through an accessor.
- Attributes that are part of any entity object that is indirectly associated with the flexfield entity object through a chain of accessors and entity objects.

**Note:**

An entity attribute is available on this list only if all the accessors in the chain to the attribute have an underlying association cardinality of 1-to-1 or many-to-1.

The path through the chain of accessors to each available entity attribute is displayed using the following notation:

`[accessorname1.[accessorname2.]...]attributename`

Although it is not visible, the name of the previously selected flexfield entity object is implied as the first element in the chain, followed by zero or more accessor names, then the target entity attribute name. The names of the entity objects in this chain are also implied.

**Caution:**

- Flexfield parameters can be used only with segments of the same Java type. The data type of each entity attribute you select must match the data type shown for the parameter.

- For any flexfield segment value that is derived from a parameter, the derivation happens only when the value of the mapped attribute is updated. Therefore, if you intend for customers to use a parameter for derivation, then the attribute that you map the parameter to must be updatable. If the parameter’s value must come from a reference-only entity, then create an updatable transient entity attribute and assign that entity to the flexfield parameter.

15. When all of the defined parameters are mapped, click **Next**.

16. On the Summary page, click **Finish**.

**Note:**

This wizard might fail with a "ClassNotFound" exception message. This indicates that one or more required libraries have not been automatically included in your project. You can resolve this issue by manually adding any missing libraries; then you can complete this procedure successfully.
17. Refresh the project to see the newly created flexfield business components in the Application Navigator. The components are in the package that you registered for the flexfield usage and are named using the registered prefix.

23.4 Create Descriptive Flexfield View Links

A view link is needed whenever a product view object references your descriptive flexfield. The product view object and the flexfield base view object are linked through their primary keys.

23.4.1 How to Create Descriptive Flexfield View Links

You create a view link to connect your product view object with the flexfield view object. After you have created the view link, you can use the view object to add the flexfield to an application page.

Before you begin:

1. Create the master view object, which contains only nonflexfield attributes.
2. Create the flexfield business components for the descriptive flexfield as described in How to Create Descriptive Flexfield Business Components.

To create a descriptive flexfield view link:

1. From the File menu, choose New.
2. In the New Gallery, go to Business Tier > ADF Business Components and select Flexfield View Link.
3. Click OK to access the Create Flexfield View Link wizard, as shown in Figure 23-12.

Figure 23-12 Create Flexfield View Link Wizard — Name Page

4. On the Name page, from the Package dropdown list, specify a package for the view link.
Caution:
You cannot move the view link to a different package after you create it. Instead, you must delete the view link and re-create it with the new package name.

5. In the Name field, enter a name for the view link.

6. Click Next. The View Objects page appears, as shown in Figure 23-13.

**Figure 23-13   Create Flexfield View Link Wizard — View Objects Page**

7. In the Select Source View Object tree, expand the available objects from your current project and select the master view object.

8. In the Select Destination Flexfield tree, expand the application and select a destination flexfield usage.

9. In the View Link Accessor Name field, enter an appropriate name for the view link accessor.

10. Click Next.

For descriptive flexfields, the Source Attributes page is informational only. The wizard uses the primary key attributes of the source view object to define the view link.

**Note:**
You can skip the Properties page because view link-specific properties are not supported.

23.5 Nest the Descriptive Flexfield Application Module Instance in the Application Module

You must nest the descriptive flexfield application module instance under the product application module before you can incorporate the descriptive flexfield usage into the UI.

You need to nest only one flexfield application module for a flexfield usage, even if two or more view links exist for the same flexfield usage.

23.5.1 How to Nest the Descriptive Flexfield Application Module Instance in the Application Module

You use the overview editor for your application module to nest the descriptive flexfield application module instance. The descriptive flexfield application module instance that you nest in the product application module shares the same transaction and entity object caches as the application module.

Before you begin:

1. You should have already created the product application module. For information about creating application modules, see the Implementing Business Services with Application Modules chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.
2. Create the master view object, which contains only nonflexfield attributes.
3. Create a flexfield business component for the descriptive flexfield usage as described in How to Create Descriptive Flexfield Business Components.

To nest the descriptive flexfield application module instance in the product application module:

1. In the Application Navigator, double-click the product application module.
2. Click the Data Model navigation tab.
3. On the Data Model Components page, expand the Application Module Instances section, as shown in Figure 23-14.

Figure 23-14 Application Module — Application Module Instances Section

4. In the Available tree, find and expand the applicationModule instance under the flexfield usage’s package. This is the package that you specified when you defined the entity details, as described in How to Register Entity Details.
5. Select the application module for the descriptive flexfield and move it to the Selected tree.

This application module was created when you created the flexfield business component and was named using the prefix that you specified when you defined the usage’s entity details, as described in How to Register Entity Details. For example, if you registered the `CasesDFF` prefix, the application module name is `CasesDFFAM`.

The New App Module Instance field under the list shows the name that will be used to identify instance. You can change this name.

### 23.6 Add a Descriptive Flexfield View Object to the Application Module

You must add a flexfield view object instance that reflects the hierarchy of the view link that you created in How to Create Descriptive Flexfield View Links to the application module for your application.

#### 23.6.1 How to Add a Descriptive Flexfield View Object Instance to the Application Module

Edit the product application module to add the flexfield view object.

**Before you begin:**

1. You should have already created the product application module. For information about creating application modules, see the Implementing Business Services with Application Modules chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.

2. Create the master view object, which contains only nonflexfield attributes.

3. Create the flexfield business components for the descriptive flexfield usage as described in How to Create Descriptive Flexfield Business Components.

4. Create the flexfield view link as described in How to Create Descriptive Flexfield View Links.

**To add a descriptive flexfield view object to the product application module:**

1. In the Application Navigator, double-click the product application module.

2. Click the Data Model navigation tab.

3. In the View Object Instances section, select the master view object from the Available View Objects tree and click the right arrow to add it to the Data Model tree. Next, select the child view object for the flexfield view link and click the right arrow to add it to the Data Model tree, as shown in Figure 23-15.
23.7 Add Descriptive Flexfield UI Components to a Page

To include a descriptive flexfield on an application page, add the flexfield UI component to the page, and then configure the properties of the UI component.

**Note:**

You can also use descriptive flexfields in the following ways:

- Incorporate descriptive flexfield view object attributes as search criteria in an advanced query search form.
  
  See Incorporating Descriptive Flexfield into a Search Form.

- Use ADF Desktop Integration to incorporate descriptive flexfields into an Excel workbook.
  
  See Accessing Descriptive Flexfields from an ADF Desktop Integration Excel Workbook.

To add a descriptive flexfield UI component, you add the component to a page in the one of the following configurations:

- As part of a form component.
- As part of a table component, with the context-sensitive segments of the flexfield presented in a detailStamp facet. This is the typical configuration, which allows for the full range of possible values in the context segment.
- As part of a table component, with context-sensitive segments of the flexfield presented as columns. To use this configuration, you must guarantee that the flexfield context segment will have the same value in all rows of the table.

**Note:**

You cannot use a descriptive flexfield in a tree table component.
If your ADF Table is in an Applications Table component, you must add the following functionality to the UI:

- Create Row and Delete Row functionality if you are using your own **CreateInsert** button to create new rows.
- Empty table handling if you are using a custom **createInsert** method.
- Dynamic refresh of the context-sensitive segment columns whenever the Applications Table component is refreshed by another component, such as a button or a search query.

**Note:**
The following procedures assume that you are using the data-first approach of adding flexfields to your application. The UI-first approach is also available, but is not documented here. For more information, see the **Introduction to Placeholder Data Controls** section in the Developing Fusion Web Applications with Oracle Application Development Framework.

### 23.7.1 How to Add a Descriptive Flexfield UI Component to a Form

Use this procedure to incorporate your descriptive flexfield into a basic form.

**Before you begin:**

1. Create the descriptive flexfield view object as described in How to Create Descriptive Flexfield Business Components.
2. Create the view link as described in How to Create Descriptive Flexfield View Links.
3. Nest the descriptive flexfield application module instance in the product application module as described in How to Nest the Descriptive Flexfield Application Module Instance in the Application Module.
4. Add the view object instance to the application module as described in How to Add a Descriptive Flexfield View Object Instance to the Application Module.

**To add a descriptive flexfield UI component to a form:**

1. From the Data Controls panel, select the master view object and drag it onto the page to create the UI for the master view object.
2. When prompted, select **ADF Form** or select **Applications > Panel**.
3. In the Data Controls panel, expand the master view object and find the flexfield view object, as shown in Figure 23-16.

**Caution:**
You must use the flexfield view object that is the child of the master view object. Do not use the flexfield view object from the flexfield’s application module data control.
4. Drag the flexfield view object onto a form, and select the appropriate flexfield UI component.

**Tips:**

- If you place the flexfield in its own tab, header, or subheader, and you cannot provide a specific label for the region, consider using the label "Additional Information," which is the standard generic label in such a case for Oracle Fusion Applications.

- If a descriptive flexfield is in a region, such as a header, subheader, or tab, that does not contain nonflexfield fields, there is a possibility that the implementor will not use the flexfield segments and the region will be empty. To avoid the display of an empty region on the page, add controlling logic to hide the region if the implementor has not defined the segments that appear in the region. For information about how to determine if a segment has been defined, see How to Determine Whether Descriptive Flexfield Segments Have Been Defined. For information about using an EL expression to hide the region, see the Creating EL Expressions section in the Developing Web User Interfaces with Oracle ADF Faces.

- You can place the segments in a multiple-column layout. Use a multiple-column layout when the number of segments that will be added by the implementor is unknown and you anticipate that a large number of segments will be used. Otherwise, a flexfield with several segments will take up a large amount of space and the end user will have to scroll to see any fields that appear below the flexfield.
5. Optionally, to add Create Row and Delete Row functionality to the UI, drag the appropriate operation of the master view object from the Data Controls panel onto the page.

    **Tip:**
    You can configure the descriptive flexfield UI component to present multiple descriptive flexfield rows using the Panel Form Layout component, with each row's content based on a different context value. For more information, see the *Arranging Content in Forms* section of the *Developing Web User Interfaces with Oracle ADF Faces*.

### 23.7.2 How to Add an Unrestricted Descriptive Flexfield UI Component to a Table

Use this procedure to allow for the full range of possible context segment values. End users will be able to expose or hide the context-sensitive segments of the flexfield separately for each row of data.

**Before you begin:**

1. Create the descriptive flexfield view object as described in *How to Create Descriptive Flexfield Business Components*.

2. Create the view link as described in *How to Create Descriptive Flexfield View Links*.

3. Nest the descriptive flexfield application module in the product application module as described in *How to Nest the Descriptive Flexfield Application Module Instance in the Application Module*.

4. Add the view object instance to the application module as described in *How to Add a Descriptive Flexfield View Object Instance to the Application Module*.

**To add an unrestricted descriptive flexfield UI component to a table:**

1. From the Data Controls panel, select the master view object and drag it onto the page to create the UI for the master view object.

2. When prompted, select *ADF Table* or *Applications > Table*. You must select the **Row Selection** option, and set the appropriate width. Follow the wizard to create tree structure, **pathStamp**, and **nodeStamp** components.

3. In the Data Controls panel, expand the master view object and find the flexfield view object.

    **Caution:**
    You must use the flexfield view object that is the child of the master view object. Do not use the flexfield view object from the flexfield's application module data control.

4. Drag the flexfield view object onto the table on the design tab, as shown in *Figure 23-17*, and select *Oracle Descriptive Flexfield Column* as the UI component. This creates the base flexfield column in the table that the global segments will render.
5. Create a detail region (detailStamp facet) if the table does not have one, as shown in Figure 23-18.

6. Add a panel layout control to the detailStamp facet if you do not already have one.

7. Drag and drop the same flexfield view object into the detail region on the Source tab or the structure view as shown in Figure 23-19; this creates fields for the context-sensitive segments.
23.7.3 How to Add Descriptive Flexfield Context-Sensitive Segments to a Table as Columns

Typically, context-sensitive segments in a table are visible only in a detailStamp facet. This is because the flexfield context segment can contain a different value in each table row; therefore the set of associated context-sensitive segments that appears can vary from row to row. There is no way to present all of these varying results in a predefined column format within a single table.

However, if you can guarantee that a given context segment in every row of the table will always contain the same value for a given application page, the resulting combination of corresponding context-sensitive segments in each row will remain constant. In this circumstance the context-sensitive segments can be displayed as table columns.

For example, if the context segment is a country code, and the purpose of this application page is to manage only Italian tax data, then the context value should always be IT. The table columns for the context-sensitive segments will always be displayed in the configuration appropriate to the Italian tax system.

Before you begin:
1. Create the descriptive flexfield view object as described in How to Create Descriptive Flexfield Business Components.

2. Create the view link as described in How to Create Descriptive Flexfield View Links.

3. Nest the descriptive flexfield application module in the product application module as described in How to Nest the Descriptive Flexfield Application Module Instance in the Application Module.

4. Add the view object instance to the application module as described in How to Add a Descriptive Flexfield View Object Instance to the Application Module.

To add a descriptive flexfield UI component to a table as a column:

1. From the Data Controls panel, select the master view object and drag it onto the page to create the UI for the master view object.

2. When prompted, select ADF Table or Applications > Table. You must select the Row Selection option, and set the appropriate width.

3. In the Data Controls panel, expand the master view object and find the flexfield view object.

   Caution:
   You must use the flexfield view object that is the child of the master view object. Do not use the flexfield view object from the flexfield’s application module data control.

4. Drag the flexfield view object onto the table on the design tab as shown in Figure 23-17, and select Oracle Descriptive Flexfield Column as the UI component. This creates the base flexfield column in the table.

   Caution:
   Do not drop the flexfield view object into an existing column. The displaying of descriptive flexfields in the cell of a table column is not supported.

5. Edit the JSP source code for this page, and remove the following attribute from the <fnd:descriptiveFlexfield> tag:

    mode="global"

   See Table 23-2 for information about the mode attribute.

6. Add a WHERE clause or view criteria to the master view object to enforce the same predetermined context value for all rows of the table.

   If the context segment will be visible on the page, you must configure the segment to be read-only so end users cannot modify it. For more information, see How to Configure Segment-Level UI Properties.
23.7.4 How to Add Create Row and Delete Row Functionality to the Page

If your ADF Table is wrapped in an Applications Table component, and if you are using your own Create Insert button to create new rows, you must complete the following steps.

You do not need to complete these steps if new rows are created using the Applications Table’s New button or the New option on the Actions menu.

Caution:
If you enable end users to add new flexfield rows to the UI table, you can permit them to enter their own unique key values for a new row. However, you must provide a programmatically generated primary key value for the new row, otherwise it will generate an error.

To add Create Row and Delete Row functionality to the page:

1. From the Data Controls panel, drag the appropriate operation of the master view object (such as CreateInsert) onto the page.

2. Delete the newly created button, but not its pageDef entry. Example 23-2 shows an example of the pageDef entry.

3. Add a new button to the layout.

4. In the Property Inspector for the button, expand the Common section and set the ActionListener to the EL expression for the method binding. For example, #{myBean.customCreateInsert}.

Example 23-2 shows how the executables element of the page definition might look. Dff1RefInstanceIterator is the iterator of the master view object.

5. To ensure that new descriptive flexfield rows appear in the UI, add code to the application page (in the Invoke Application phase or just before the Render Response phase) to set the state of each newly created row to STATUS_NEW, as demonstrated in Example 23-3.

6. Add code to the custom createInsert method to handle an empty table as described in How to Add a Row to an Empty Table in a Custom createInsert Method

Example 23-2  Executables Element of Page Definition Code

```xml
<executables>
  <iterator Binds="Dff1RefInstance" RangeSize="25" DataControl="Dff1RefAMDataControl" id="Dff1RefInstanceIterator"/>
  <iterator Binds="Dff1Instance" RangeSize="25" DataControl="Dff1RefAMDataControl" id="Dff1InstanceIterator"/>
</executables>
```

Example 23-3  Code to Set New Table Row State to STATUS_NEW

```java
public void invokeMethod(String expr, Class[] paramTypes, Object[] params) {
    FacesContext fc = FacesContext.getCurrentInstance();
```
MethodBinding mb = fc.getApplication().createMethodBinding(expr,paramTypes);
return mb.invoke(fc,params);
}

public void customCreateInsert(ActionEvent actionEvent)
{
    invokeMethod("#{bindings.CreateInsert.execute}",ActionEvent.class,actionEvent);

    FacesContext fCtx = FacesContext.getCurrentInstance();
    javax.faces.application.Application app = fCtx.getApplication();
    ELContext elCtx = fCtx.getELContext();
    int index = 0;
    Row coreVORow =
        ((RowSetIterator)app.evaluateExpressionGet(fCtx,
        "#{bindings.Dff1RefInstanceIterator.rowSetIterator}",
        RowSetIterator.class)).getRowAtRangeIndex(index);
    coreVORow.setNewRowState(Row.STATUS_NEW);
}

Caution:

• If you enable end users to add new flexfield rows to the UI table, you
  must ensure that the default value of the new row's context segment is
  your predetermined value, matching the existing rows.

• You can permit end users to enter their own unique key values for a new
  row. However, you must provide a programmatically generated primary
  key value for the new row, otherwise it will generate an error.

• The context segment value in any existing row must not change at
  runtime. You must enforce this by hiding the context segment or by
  configuring it as read-only. For more information, see How to Configure
  Flexfield-Level UI Properties and How to Configure Segment-Level UI
  Properties.

23.7.5 How to Add a Row to an Empty Table in a Custom createInsert Method

If you are using a custom createInsert method to add rows to an Applications
Table component, you must include code similar to Example 23-4 to handle an empty
Table. Replace FirstRowInTable with logic to determine whether the table is empty and
the new row is the first row in the table.

Example 23-4    Handling Empty Tables in a Custom createInsert Method

if (FirstRowInTable &&
BindingUtil.getCustomProperty(table, "flexenabled") != null)
{
    List<UIComponent> columns = table.getChildren();
    if (columns != null)
    {
        for (UIComponent column: columns)
        {
            if (column.getChildCount() > 0)
            {
                UIComponent c1 = column.getChildren().get(0);
                if (c1 instanceof DescriptiveFlexfield)
23.7.6 How to Dynamically Refresh a Descriptive Flexfield

If your flexfield is in an ADF Table that is wrapped in an Applications Table component that is refreshed by another component, such as a button or a query, then you must add functionality to dynamically refresh the flexfield segments.

To refresh the flexfield segments based on the current iterator rowset data, create a listener method in the flexfield’s backing bean and bind the listener to the component that is initiating the table refresh. The listener must first call the default listener and then call `DescriptiveFlexfield.updateFlexColumns(RichTable)`, where `RichTable` is the binding for the table that contains the flexfield.

Example 23-5 shows an example of a custom flexfield handler for a query event. Example 23-6 shows the binding of the custom flexfield handler to the query component.

**Note:**

You do not need to handle flexfield refresh for standard Applications Table create and delete operations. However, custom create and delete operations must handle the refreshing of flexfields.

---

**Example 23-5  Flexfield Listener**

```java
public void customDffSearchQueryListener(QueryEvent queryEvent)
{
    FacesContext context = FacesContext.getCurrentInstance();
    String queryListener = "#{bindings.Dff3RefVOCriteriaQuery.processQuery}";
    ELContext elctx = context.getELContext();
    ExpressionFactory elFactory = context.getApplication().getExpressionFactory();
    MethodExpression queryMethod =
        elFactory.createMethodExpression(elctx, queryListener, Object.class,
                                         new java.lang.Class[] { QueryEvent.class });
    queryMethod.invoke(elctx, new Object[] { queryEvent });
    // appTable is the handle of the binding for the table
    // that contains the flexfield
    DescriptiveFlexfield.updateFlexColumns(appTable);
}
```

**Example 23-6  Binding the Flexfield Listener to the Search Query**

```xml
<af:query id="qryId1"
    headerText="#{applcoreBundle.QUERY_SEARCH_HEADER_TEXT}"
    disclosed="true"
    value="#{bindings.criteriaQuery.queryDescriptor}"
    model="#{bindings.criteriaQuery.queryModel}"
    queryListener="#{backingBeanScope.dffBean.customDffSearchQueryListener}"
```
23.7.7 What Happens When You Add a Descriptive Flexfield to a Page

Descriptive flexfield segments appear on a form as a widget with a implementor-defined label, just as core fields do. In a table, the label of the flexfield segment is the column header and the values are within each cell of the column.

Figure 23-20 shows an example of a descriptive flexfield used in a form on an application page.

Figure 23-20  Example of a Descriptive Flexfield in a Form

Figure 23-21 shows an example of a descriptive flexfield used in a table on an application page:

Figure 23-21  Example of a Descriptive Flexfield in a Table

Note:

Descriptive flexfield segments always appear as form fields or table columns in the same order that their corresponding attributes appear in the underlying view object.

23.8 Configure Descriptive Flexfield UI Components

You can control your descriptive flexfield’s behavior in the application UI by modifying properties at the flexfield level and the segment level, configuring descriptive flexfield parameters, and configuring the flexfield to handle value change events.
23.8.1 How to Configure Flexfield-Level UI Properties

You configure flexfield-level behavior by configuring the UI component’s properties.

Before you begin:
Add the descriptive flexfield to the page as described in Adding Descriptive Flexfield UI Components to a Page.

To configure flexfield-level properties:

- Select the descriptive flexfield’s UI component on the page and modify its properties in the Property Inspector, as shown in Figure 23-22.

Figure 23-22  Descriptive Flexfield Property Inspector

The significant properties on the Common, Data, Style and Behavior property tabs are listed in Table 23-2.

Table 23-2  Descriptive Flexfield Properties

<table>
<thead>
<tr>
<th>Tab &gt; Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Common &gt; Id</td>
<td>This is the ID of the flexfield.</td>
</tr>
<tr>
<td>Common &gt; Rendered</td>
<td>This indicates whether the flexfield is rendered on the page. Values can be True (default) or False. EL expressions are allowed.</td>
</tr>
<tr>
<td>Common &gt; Value</td>
<td>This is the value of the flexfield. This should be an EL expression pointing to an iterator object. The iterator value must be statically declared in the page definition. This field is also visible on the Data tab.</td>
</tr>
<tr>
<td>Data &gt; Accessor</td>
<td>This property is the name of the accessor between the product view object and the flexfield view object.</td>
</tr>
<tr>
<td>Tab &gt; Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>Data &gt; Category</td>
<td>This defines which category will be rendered on the page. The category can be set on each attribute’s custom property.</td>
</tr>
<tr>
<td>Style &gt; StyleClass</td>
<td>This property is the style class of the flexfield. A style class allows you to group a set of inline styles.</td>
</tr>
<tr>
<td>Style &gt; InlineStyle</td>
<td>This is the inline style of the component. The InlineStyle property is a string of CSS styles that can set individual properties such as background color, font style, or padding.</td>
</tr>
<tr>
<td>Behavior &gt; Read-Only</td>
<td>This indicates whether the flexfield is rendered as read-only. Values can be True or False (default). EL expressions are allowed.</td>
</tr>
<tr>
<td>Behavior &gt; Mode</td>
<td>This defines the UI mode of the descriptive flexfield component, to render all of the segments or just some of them. Values can be:</td>
</tr>
<tr>
<td></td>
<td>• No value (default): render all of the descriptive flexfield segments.</td>
</tr>
<tr>
<td></td>
<td>• global: render only the global segments of the flexfield. This is the default value for a descriptive flexfield inside a table column, to generate subcolumns for the global segments.</td>
</tr>
<tr>
<td></td>
<td>• contextSensitive: render only the context-sensitive segments of the flexfield (including the context segment). This is the default value for a descriptive flexfield inside a table detail region, to render the context values.</td>
</tr>
<tr>
<td>Behavior &gt; partialTriggers</td>
<td>This property is the IDs of the components that should trigger a partial update in the flexfield (String[]). EL expressions are allowed.</td>
</tr>
<tr>
<td>Behavior &gt; valueChangeListener</td>
<td>This property is a method reference to a value change listener (javax.faces.el.MethodBinding). It requires an EL expression.</td>
</tr>
<tr>
<td>Behavior &gt; binding</td>
<td>This is an EL reference that will store the component instance on a bean (oracle.apps.fnd.appcore.flex.ui.DescriptiveFlexfield). This property requires an EL expression.</td>
</tr>
</tbody>
</table>
Table 23-2 (Cont.) Descriptive Flexfield Properties

<table>
<thead>
<tr>
<th>Tab &gt; Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Other &gt; showRequired</td>
<td>This indicates whether to bypass client-side validation of required segments that have null values. Values can be True or False (default). If the value is True, the end user can submit a form with null values in the fields for required segments (the segment fields that have asterisks). EL expressions are allowed. For related information about server-side validation of required segments, see How to Prevent Validation of Required Segments.</td>
</tr>
</tbody>
</table>

1 For a descriptive flexfield that was added as table columns, you cannot control this property on a row-by-row basis. It must be set to apply to the entire column.

23.8.2 How to Configure Segment-Level UI Properties

Descriptive flexfields support finer control of segments in the UI through the following segment-level UI properties:

- **Rendered**: This boolean property indicates whether the segment is visible on the application page. You can set this property with a literal value or an EL expression.

- **Required**: This boolean property indicates whether the segment must have a value. You can set this property with a literal value or an EL expression.

- **ReadOnly**: This boolean property indicates whether end users can modify the segment. You can set this property with a literal value or an EL expression.

- **Visible**: This boolean property specifies whether the segment is displayed in the page or is hidden. You can set this property with a literal value or an EL expression.

- **AutoSubmit**: This boolean property specifies whether a component automatically submits when a segment’s value changes. You can set this property with a literal value or an EL expression.

- **Label**: This string property provides a display label for a segment.

- **ShortDesc**: This string property provides a short description of a segment.

- **Columns**: This integer property specifies the width of the control in terms of the default font size of the browser. You can set this property with a literal value or an EL expression.

The default values of these properties are derived from the flexfield metadata, but you can override them by inserting the following flexfield hint components from the Applications page of the Component Palette:

- **Flexfield Context Segment Hints**: Use this component to configure the context segment.
• **Flexfield Segment Hints**: Use this component to configure all global segments or to configure all context-sensitive segments. Also use this component as a container for **Flexfield Segment Hint**.

• **Flexfield Segment Hint**: Nest this component in a **Flexfield Segment Hints** component to configure an individual global or context-sensitive segment.

---

**Note:**

If you set a segment’s **Required** property to **True**, for validation purposes you cannot override this by resetting it to **False** in the flexfield hint component. You can, however, do the reverse: Change a nonrequired segment to required in the flexfield hint component.

---

For information about using EL expressions, see the Creating ADF Data Binding EL Expressions section in the Developing Fusion Web Applications with Oracle Application Development Framework.

---

**Before you begin:**

Add the descriptive flexfield to the page as described in Adding Descriptive Flexfield UI Components to a Page.

---

**23.8.2.1 Configure a Context Segment**

Use **Flexfield Context Segment Hints** to set the **Visible**, **ReadOnly**, **Rendered**, **Required**, **Label**, **ShortDesc**, **Columns**, and **AutoSubmit** UI properties for a context segment.

**To configure a context segment:**

1. From the Applications page of the Component Palette, drag **Flexfield Context Segment Hints** and drop it as a child of the **Descriptive Flexfield** component.
2. In the Property Inspector, set the context segment’s UI properties.

---

**23.8.2.2 Configure All Global Segments**

Use **Flexfield Context Hints** to set the **Visible**, **ReadOnly**, **Rendered**, and **Required** properties to the same values for all the global segments.

**To configure all global segments:**

1. From the Applications page of the Component Palette, drag **Flexfield Segment Hints** and drop it as a child of the **Descriptive Flexfield** component.
2. In the Property Inspector, set the **Visible**, **ReadOnly**, **Rendered**, and **Required** properties.
3. Ensure that the **ContextCode** property is blank.

---

**Caution:**

For a descriptive flexfield that was added as table columns, you cannot configure the **Rendered** property of global segments on a row-by-row basis. It must be set to apply to the entire column.
23.8.2.3 Configure Individual Global Segments

Use a Flexfield Segment Hint component nested in a Flexfield Segment Hints component to set the Visible, ReadOnly, Rendered, Required, Label, ShortDesc, Columns, and AutoSubmit UI properties for a global segment.

You typically set the ReadOnly property to True if a default value is assigned to that segment, and you do not want end users to choose a value other than the default. Do not set both Required and ReadOnly to True if the segment does not have a default value.

Before you begin:

From the Applications page of the Component Palette, drag Flexfield Segment Hints and drop it as a child of the Descriptive Flexfield component. Do not set any properties.

To configure a global segment:

1. From the Applications page of the Component Palette, drag Flexfield Segment Hint and drop it as a child of Flexfield Segment Hints.
2. In the Property Inspector, set the SegmentCode property.

   Tip:

   To determine the correct value for the SegmentCode property, examine the FND_ACFF_SegmentName attribute of the segment’s viewAttribute element in the descriptive flexfield view object.

3. Set the global segment’s UI properties.

23.8.2.4 Configure All Context-Sensitive Segments

Use Flexfield Context Hints to set the Visible, ReadOnly, Rendered, and Required UI properties to the same values for all the context-sensitive segments.

To configure all global segments:

1. From the Applications page of the Component Palette, drag Flexfield Segment Hints and drop it as a child of the Descriptive Flexfield component.
2. In the Property Inspector, set the ContextCode property.
3. Set the Visible, ReadOnly, Rendered, and Required properties.

23.8.2.5 Configure Individual Context-Sensitive Segments

Use a Flexfield Segment Hint component nested in a Flexfield Segment Hints component to set the Visible, ReadOnly, Rendered, Required, Label, ShortDesc, Columns, and AutoSubmit UI properties for a context-sensitive segment.

You typically set the ReadOnly property to True if a default value is assigned to that segment, and you do not want end users to choose a value other than the default. Do not set both Required and ReadOnly to true if the segment does not have a default value.

Before you begin:
From the Applications page of the Component Palette, drag a **Flexfield Segment Hints** and drop it as a child of the **Descriptive Flexfield** component. Set the **ContextCode** property.

**To configure a context-sensitive segment:**

1. From the Applications page of the Component Palette, drag **Flexfield Segment Hint** and drop it as a child of **Flexfield Segment Hints**.

2. In the Property Inspector, set the **SegmentCode** property.

**Tip:**

To determine the correct value for the **SegmentCode** property, examine the `FND_ACFF_SegmentName` attribute of the segment's `viewAttribute` element in the descriptive flexfield view object.

3. Set the context-sensitive segment's UI properties.

### 23.8.3 How to Configure Descriptive Flexfield Parameters

You must add all the parameters that you have registered for the flexfield to the `partialTriggers` list so that each parameter's associated UI component is refreshed when its attribute is changed.

**Before you begin:**

1. Define and register the necessary parameters, if any.

2. Add the descriptive flexfield to the page as described in Adding Descriptive Flexfield UI Components to a Page.

**To configure descriptive flexfield parameters:**

1. Identify each UI component that corresponds (through the flexfield view object) to an entity object attribute to which a flexfield parameter is mapped, and ensure that the ID attribute of the UI component is set.

   For example, say you mapped the `Customer` parameter to the entity object `Customer_Name` attribute, which in turn has a corresponding view object attribute called `Customer_Name` and is displayed on the page using an inputText field with the prompt "Customer Name". You would ensure that this UI component has an ID, say, `customerInputText`.

2. In the **Behavior** section of the Property Inspector for the descriptive flexfield UI component, add the UI component ID to the list in the **PartialTriggers** field.

   In the previously introduced example, you would add `customerInputText` to the **PartialTriggers** list. **Example 23-7** shows the source view of the **partialTriggers** attribute.

**Example 23-7  Adding the UI Component ID to the PartialTriggers List**

```xml
<fnd:descriptiveFlexfield value="#{bindings.Dff1Iterator}"
    partialTriggers=customerInputText>
```
23.9 Testing Flexfields

You can test specified flexfields from JDeveloper using the Run with Flexfields dialog or the Debug with Flexfields dialog. You can also test the flexfields by running the application from an Integrated WebLogic Server instance. For more information, see Testing Flexfields.

23.10 Loading Seed Data

Any implementation of flexfields in Oracle Fusion Applications typically requires application seed data, which is the essential data to enable flexfields to work properly in applications. Flexfield seed data can be uploaded and extracted using the Seed Data Loader.

After you complete the registration process described in How to Register and Define Descriptive Flexfields, your flexfield seed data consists of the information that you registered for your flexfield, such as the tables and columns reserved for your flexfield. For a customer flexfield, the seed data contains only this registration data.

If your flexfield is a developer flexfield, you also serve the role of the implementor. In addition to the registration data, your flexfield seed data might include contexts, segments, and value sets that you have defined for your flexfield.

Use the Manage Descriptive Flexfields and Manage Value Sets tasks or use the PL/SQL APIs to create contexts, segments, and value sets, and then use the seed data loader to extract your seed data. To protect flexfield seed data from customer edits, use the PL/SQL flexfield registration API to mark a descriptive flexfield as protected, as described in Using the Setup APIs To Register and Define Descriptive Flexfields. Use the Manage Value Sets task to set the flag to protect a value set.

Only the user with the SEED_DATA_FROM_APPLICATION_USER user name can modify protected flexfields and value sets from the setup tasks, such as the Manage Descriptive Flexfields and Manage Value Sets tasks.

For information about extracting and loading seed data, see Initializing Oracle Fusion Application Data Using the Seed Data Loader.

23.11 Work with Descriptive Flexfield UI Programmatically

When working with descriptive flexfields programmatically, you might need to know how to do the following tasks:

- Update a descriptive flexfield
- Determine whether flexfield segments have been defined
- Configure a descriptive flexfield to handle value change events
- Configure a flexfield to prevent the validation of required segments.

23.11.1 How to Update a Descriptive Flexfield Programmatically

When you update a flexfield programmatically, you must obtain the same flexfield view row that is used by the UI. You use the getFlexfieldVORowFromEvent method to get a handle to a flexfield view row from the ValueChangeEvent instance.

```java
public static Row getFlexfieldVORowFromEvent(ValueChangeEvent vce);
```
Update the context value on the flexfield, not the master view row. Otherwise, the structure will not change. Do not update the entity object directly. The flexfield’s structure logic is in the setter of the view row, so do not bypass it.

23.11.2 How to Determine Whether Descriptive Flexfield Segments Have Been Defined

Your application might require information about any global or context-sensitive segments that exist in a descriptive flexfield’s metadata before it invokes a UI that includes the flexfield.

There is a view attribute in the descriptive flexfield view object, _FLEX_NumOfSegments, that contains the combined total number of global segments and context-sensitive segments in the flexfield. Its value is in the java.lang.Integer data format. This value may vary depending on the context.

The value of this view attribute is the number of segments defined in the metadata. For a given descriptive flexfield view row, a value of 0 means that only the context segment is available. Whether a segment is displayed is not taken into consideration.

23.11.3 How to Configure a Descriptive Flexfield to Handle Value Change Events

You can configure your application to recognize and respond to changes in individual descriptive flexfield segment values.

You register a value change listener to capture any ValueChangeEvent that occurs. When an end user changes a segment value, the input components associated with the flexfield segments on the application page deliver a value change event, and the listener is called.

Before you begin:

Add the descriptive flexfield to the page as described in Adding Descriptive Flexfield UI Components to a Page.

To configure a descriptive flexfield to handle value change events

1. Create the listener handler as a Java method (usually on a backing bean). Example 23-8 is an example of a method that handles a ValueChangeEvent.

Example 23-8 Sample Listener Handler Method

```java
public void dffChangeListener(ValueChangeEvent valueChangeEvent) {
    System.out.println("***** In dffChangeListener()");
    System.out.println("getSource() = " + valueChangeEvent.getSource());
    System.out.println("getOldValue() = " + valueChangeEvent.getOldValue());
    System.out.println("getNewValue() = " + valueChangeEvent.getNewValue());
}
```

2. Specify the handler method as UI metadata on the flexfield’s value change listener property (described in Table 23-2). In the Property Inspector, click the Edit button for the value change listener property, and a wizard appears to help you select an existing event listener or create a new listener. Example 23-9 is an example of the metadata as an EL expression that identifies the dffChangeListener listener from the Java method in Example 23-8.

Example 23-9 Sample EL Expression Identifying dffChangeListener

```xml
<fnd:descriptiveFlexfield value="#{bindings.PJCDFF1Iterator}" valueChangeListener="#{bindings.dffChangeListener}">
</fnd:descriptiveFlexfield>
```
For more information about handling value change events, see the Using Input Components and Defining Forms chapter in Developing Web User Interfaces with Oracle ADF Faces.

23.11.4 How to Prevent Validation of Required Segments

Sometimes you might need to bypass server-side validation of a required segment. For example, you might need to enable end users to save a partially filled form for later submission. To bypass server-side validation of a required segment, override the `getFlexfieldViewUsageConfiguration` method in the class for the master view object to disable this type of validation for the flexfield's view usage and view link accessor. In the case where you need to also bypass client-side validation, additionally set the flexfield's `showRequired` property to `true` as described in Table 23-2. When the `showRequired` property is `true`, the page displays asterisks next to the required segments to indicate that values are required, but will not perform client-side validation of segments with null values.

The `getFlexfieldViewUsageConfiguration` method, which is called whenever a flexfield view object is created through either a view link usage or a view link accessor, must accept the name of the view object and must return a Map object. As shown in Example 23-10, the method must verify that the name of the view object matches the name of the flexfield's master view object and that the name of the view link accessor matches the value passed into the method. If the names match, return a Map that contains a mapping for the key `FlexfieldViewObjectImpl.CONF_BYPASS_VALIDATION_REQUIRED`. The mapping's value must be boolean. A value of `Boolean.TRUE` indicates a null value should not cause a validation failure for any of the flexfield's required segments.

Example 23-10  `getFlexfieldViewUsageConfiguration` Method

```java
@Override
protected Map<String, Object> getFlexfieldViewUsageConfiguration(String accessorName) {
    if ("Parts1".equals(getName()) &&
        "FndCrmPartsDFFVL".equals(accessorName)) {
        Map<String, Object> map = new HashMap<String, Object>(1);
        map.put(            FlexfieldViewObjectImpl.CONF_BYPASS_VALIDATION_REQUIRED, Boolean.TRUE);
        return map;
    }
    else
    {
        return super.getFlexfieldViewUsageConfiguration(accessorName);
    }
}
```

23.12 Incorporate Descriptive Flexfield into a Search Form

You can include descriptive flexfield view object attributes as search criteria in an advanced query search form. This form enables end users to define ad hoc criteria to search for data in the application's master view object and its linked descriptive
flexfield view object. End users can select which attributes of the descriptive flexfield view object to use as search criteria.

**Note:**

If the search form displays the results in a table, the table displays the result set only under the following conditions:

- The end user performs a search.
- The **Run Automatically** check box for the search form's default search has been selected.

If a result set has not been displayed in the table, the only flexfield columns that appear in the table are the columns for the global segments.

### 23.12.1 How to Incorporate Descriptive Flexfields Into a Search Form

To incorporate a descriptive flexfield into a search form, use the **Edit Query Criteria** tab to add view criteria to a view object instance and then drop the view criteria onto the page as an ADF Query Panel with Table component.

**To add a descriptive flexfield to a search form:**

1. Add view criteria to the product view object instance that uses attributes from the view-linked descriptive flexfield view object, as shown in Figure 23-23.

**Figure 23-23  Edit Query Criteria Tab of View Object View Criteria Definition**
a. Enter a name for the view criteria definition and select the view accessor attribute from the master view object. The attributes of the view-linked descriptive flexfield view object appear.

b. Select the context segment (the discriminator) and use it as the attribute in the view criteria definition.

c. Select Equals as the **Operator** and select Literal as the **Operand**.

---

**Note:**

To include segments that use ID-based table-validated value sets or translated value sets in a query panel, the query mode must be set to **Both** to allow both database query and in-memory filtering. The search may be slow if the search results in a large number of rows fetched.

---

2. Create a new JSPX page in the user interface project.

   **Tip:**

   Oracle JDeveloper names the user interface project **ViewController** by default.

3. In the Data Control panel, select the named view criteria that you created previously.

4. Drag and drop the view criteria onto the page as an ADF Query Panel with Table component, as shown in **Figure 23-24**.

   **Figure 23-24** Page with Descriptive Flexfield Search Form

5. If the descriptive flexfield appears on the page as a column in a table, perform the following substeps to enable the execution of a saved search when the page is loaded for the first time:

   a. From the Property Inspector for the table in which the flexfield is displayed, obtain the **TableId** value.

   b. In the Property Inspector for the Query component, set the value of the **ResultComponentId** property to the **TableId** value.

6. Run the new search form page and click the **Advanced** button. When you click **Add Fields**, only the attributes associated with the base descriptive flexfield view object (global segments) are available as additional criteria. To include the context-sensitive attributes for a context, select the **equal to** operator for the **Context Value** criteria item and select a context. The **Add Fields** list refreshes to include the context-sensitive attributes from the subtype view object for the selected context, as shown in **Figure 23-25**.
Note:

Figure 23-8 illustrates the attributes associated with the base descriptive flexfield view object (global segments) and the context-sensitive attributes.

Figure 23-25    Descriptive Flexfield Search Form UI

For more information about working with search forms, see the Creating ADF Databound Search Forms chapter of Developing Fusion Web Applications with Oracle Application Development Framework.

23.13 Prepare Descriptive Flexfield Business Components for Oracle Business Intelligence

Oracle Business Intelligence is a comprehensive collection of enterprise business intelligence functionality that provides the full range of business intelligence capabilities including interactive dashboards, full ad hoc, proactive intelligence and alerts, enterprise and financial reporting, real-time predictive intelligence, and more.

Descriptive flexfields are modeled using polymorphic view objects, which are not compatible with Oracle Business Intelligence. To enable a descriptive flexfield to be used by Oracle Business Intelligence, the corresponding polymorphic view object must be flattened into a usable static form. When you create business components for this descriptive flexfield, the business component modeler recognizes the business intelligence-enabled setting, and a view object that is flattened for business intelligence is generated alongside the standard descriptive flexfield polymorphic view object. You must also slightly modify the process of creating descriptive flexfield view links and application modules.

When the business intelligence-enabled and flattened descriptive flexfield is configured as part of an application, the implementor can select which individual flexfield segments to make available for use with Oracle Business Intelligence. Only the segments that are business intelligence-enabled are included in the flattened view object.

23.13.1 How to Enable a Descriptive Flexfield for Oracle Business Intelligence

To enable implementors to perform business intelligence queries on whatever segments they configure for a flexfield, you must business-intelligence enable the
flexfield in one of the following ways. A flattened view object is generated only if the descriptive flexfield is business-intelligence enabled.

- Edit the flexfield from the Flexfield Registration Metadata wizard as described in Using the Flexfield Registration Metadata Wizard To Register and Define Descriptive Flexfields, and select the Enable Business Intelligence checkbox.
- Set the BI_ENABLED flag at registration time using the `fnd_flex_df_setup_apis.create_flexfield(...)` procedure. For information about using this procedure, see What You May Need to Know About the Descriptive Flexfield Setup API.
- Set the BI_ENABLED flag using the `fnd_flex_df_setup_apis.update_flexfield(...)` procedure. For information about using this procedures, see What You May Need to Know About the Descriptive Flexfield Setup API.

You can optionally provide flattened fact names for the flexfield’s entity details, as described in How to Register Entity Details. This helps to automate the process for importing the descriptive flexfield into Oracle Business Intelligence. If you are using `fnd_flex_df_setup_apis`, you provide the flattened fact name by setting the `BI_FLATTENED_FACT_NAME` value.

When a descriptive flexfield is business intelligence-enabled, implementors use the Manage Descriptive Flexfields task to enable the descriptive flexfield’s segments for business intelligence. Only the segments that are business intelligence-enabled are included in the flattened view object. Administrators must then import the changes into the Oracle Business Intelligence repository to make them available for Oracle Business Intelligence.

### 23.13.2 How to Flatten the Descriptive Flexfield Model for a Business Intelligence-Enabled Descriptive Flexfield

When you create business components for a business intelligence-enabled descriptive flexfield, the business component modeler recognizes the business intelligence-enabled setting. A view object that is flattened for Oracle Business Intelligence is generated alongside the standard descriptive flexfield polymorphic view object. You must also slightly modify the process of creating descriptive flexfield view links and application modules.

**Before you begin:**

1. Enable the flexfield and the desired segments for Oracle Business Intelligence as described in How to Enable a Descriptive Flexfield for.

2. If you have defined trees on any of the value sets that are referenced by the flexfield, ensure that the flattened tree view objects are already in your project. Otherwise, the Create Flexfield Business Components wizard that you use to create the flexfield business components will report the missing view objects as errors.

   For more information about flattened tree view objects, see About Designing a Column-Flattened View Object for Oracle Business Intelligence.

**To produce a business intelligence-enabled flattened descriptive flexfield model:**

1. Create descriptive flexfield business components as described in Creating Descriptive Flexfield Business Components.
For a flexfield that is business intelligence-enabled, the Create Flexfield Business Components wizard generates a business intelligence-specific view object and other business components under a directory called `analytics` in the package root directory. These are generated in addition to the standard descriptive flexfield view object.

2. Create a view link using the procedure described in `Creating Descriptive Flexfield View Links`. Keep the following in mind:

   • The master view object that you create with the standard wizard can be the same master view object that you create for the core descriptive flexfield model.

   • Create the view link from the master view object to the business intelligence-enabled flexfield base view object. The business intelligence-enabled flexfield is distinguished from the core flexfield by the prefix "BI:" as shown in Figure 23-26.

![Figure 23-26 Create Flexfield View Link Wizard — View Objects Page](image)

3. Create an application module for use with Oracle Business Intelligence as described in `Adding a Descriptive Flexfield View Object to the Application Module`. Make the following changes:

   a. On the Data Model page of the Create Application Module wizard, when you create an instance of the master view object, there is no need for a child view object.

   b. On the Application Modules page of the wizard, add an instance of the descriptive flexfield Oracle Business Intelligence application module as a nested instance of this application module. You can identify the Oracle Business Intelligence application module by the `analytics` subpackage under the package root.
4. Define the custom properties required to link the master view object instance to the default view instance inside the nested flexfield Oracle Business Intelligence application module instance.

This is done on the **General** tab of the nested business intelligence-enabled flexfield application module instance definition, as shown in Figure 23-27.

**Figure 23-27 Custom Properties for Business Intelligence-Enabled Application Module**

As you define the custom properties, keep the following points in mind:

- The default view instance inside the business intelligence-enabled flexfield application module is typically called **DefaultFlexViewUsage**.
- The custom property names should be formatted as **BI_VIEW_LINK_mypropertyname**
- The custom property values must be formatted as **source_viewobjectinstance_name, viewlink_definition_name, destination_viewobjectinstance_name**.
- Use the fully qualified view object instance names for the source view object and destination view object, and the fully qualified package name for the view link definition.
- Business intelligence joins between the view object instances that you specify in different application modules are created while importing them from Oracle ADF if custom properties are defined on the application module.

### 23.14 Publish Descriptive Flexfields as Web Services

You can make access to a descriptive flexfield available through web services, which will enable you to create, retrieve, update and delete operations on the flexfield data rows. You accomplish this by exposing utility methods in the product application module to access flexfield service data objects.
Utility methods for flexfield service data objects are helpful to the customers because the identifiers that are used in flexfield services are generally not the same as those in the flexfield definition, such as the customer-defined segment codes and context codes. For example, the name of the service data object for the customer-defined context "Product Type" might be called "CasesDFFProduct_Type." These utility methods help customers quickly identify a service data object or a property of the object by the identifiers with which the customers are familiar.

When you generate a flexfield business component, the descriptive flexfield business components and other artifacts are developed based on the information in the flexfield metadata. As illustrated in Figure 23-8, a base view object is created for the context and global segments. If any contexts have been configured, subtype view objects are generated for each configured context.

The example in Figure 23-28 shows a Business Component Browser view of a descriptive flexfield.

Figure 23-28  Business Component Browser View of a Descriptive Flexfield

To complete the development process to publish descriptive flexfields as web services:

1. Expose the descriptive flexfield as a web service.
2. Test the web service.

23.14.1 How to Expose a Descriptive Flexfield as a Web Service

To make available web service access to a descriptive flexfield, you must complete the following steps:

1. Service-enable the master view object.
2. Expose the application module as a web service.
3. Expose the operations on the master view object.
4. Add utility methods for the flexfield to the product application module. These utility methods, which are exposed to client applications, provide access to information from the FlexfieldSdoSupport object, which is not exposed to clients.

You can then deploy the service and run Java client programs to test the service as described in How to Test the Web Service.
For more information about service-enabling an application module, see *Integrating Service-Enabled Application Modules in Developing Fusion Web Applications with Oracle Application Development Framework*.

**Before you begin:**

1. Create a flexfield business component for the flexfield’s usage as described in *How to Create Descriptive Flexfield Business Components*.

   **Note:**
   
   When you generate a flexfield business component, the Create Descriptive Flexfield Business Components wizard automatically service-enables the business component by generating a Service Data Object (SDO) for the base view object and for every subtype view object.

2. Create a flexfield view link between the master view object, which contains only nonflexfield attributes, and the flexfield business component for the flexfield usage as described in *How to Create Descriptive Flexfield View Links*.

3. Nest the descriptive flexfield application module instance in the product application module as described in *How to Nest the Descriptive Flexfield Application Module Instance in the Application Module*.

4. Add the view object instance to the application module as described in *How to Add a Descriptive Flexfield View Object Instance to the Application Module*.

**To expose a descriptive flexfield as a web service:**

1. In the Application Navigator, open the view link between the master view object and the flexfield base view object.

2. In the overview editor, expand the Custom Properties section and add a SERVICE_PROCESS_CHILDREN property set to true, if one does not already exist.

3. Open the master view object, which is the view object that contains only the nonflexfield attributes.

4. In the overview editor click the *Java* navigation tab.

5. In the Java Classes section, click the *Edit* icon to generate and configure Java implementation classes.

6. In the Select Java Options dialog, select *Generate Service Data Object Class*, as shown in *Figure 23-29*.
7. Click OK.

8. From the Application Navigator, open the product application module.

9. In the overview editor, click the Web Service navigation tab.

10. If the Add icon is enabled, complete the following steps to service-enable the application module and expose the master view object operations:
   a. Click the Add icon to enable the application to support the service interface.
   b. In the Create Service Interface wizard, click Next three times to go to the Service View Instances page.
   c. Move the view instance for the master view object to the Selected list.
   d. Select the master view object from the Selected list as shown in Figure 23-30, select all the operations in the Basic Operations list, and click OK.
e. Click Finish.

11. If the Add icon is disabled, the application is already service enabled. Complete the following steps to expose the master view object operations:

a. In the Service Interface View Instances section, click the Edit icon.

b. Move the view instance for the master view object to the Selected list.

c. Select the master view object from the Selected list as shown in Figure 23-30, select all the operations in the Basic Operations list, and click OK.

12. Expand the Generated Files for Service Interface section, and make a note of the name of the remote server class for the product application module. This is the class that has a name ending with ServiceImpl.java.

13. In the overview editor for the product application module, click the Java navigation tab and click the link for the Application Module Class.

14. Add the utility methods for the flexfield service data objects to the product application module. Include methods that return the namespace and name of the service data object for a given context. Optionally, include methods that return the path of an attribute that is associated with a given segment in the service data object. Use self-explanatory names that reflect the name of the flexfield and what is returned. Example 23-11 shows example utility methods for the CasesDFF flexfield. Example 23-12 shows an example of the methods being invoked in a client application. The self-explanatory utility method names make it easy to understand the client code.
15. In the overview editor for the product application module, click the Web Service navigation tab and click the Edit icon in the Service Interface Custom Methods section.

16. In the Service Custom Methods dialog, move the newly added methods to the Selected list to make them available for clients and click OK.

The application module's remote server implementation class will be modified to expose these methods.

**Example 23-11  Utility Methods for Cases DFF Flexfield Service Data Object Support**

```java
// A private method to retrieve a FlexfieldSdoSupport object
// from the flexfield application module.
private FlexfieldSdoSupport getCasesDFFSdoSupport(String contextValue) {
    // Find the nested flexfield application module instance.
    DFFApplicationModuleImpl am = (DFFApplicationModuleImpl)findApplicationModule("CasesDFFAM1");
    // If contextValue is null, the base type is returned.
    return am.getSdoSupport(contextValue);
}

// Gets the namespace and name of the service data object for a
// given context value. Note how the method name and argument
// name are specific to CasesDFF.
public List<String> getCasesServiceNamespaceAndName(String productType) {
    FlexfieldSdoSupport ss = getCasesDFFSdoSupport(productType);
    if (ss == null) {
        throw new JboException("ERROR: Unable to fetch SDO for context " +
                               productType +
                               ".\nACTION NEEDED: Contact your system administrator. " +
                               "Ensure context " + productType +
                               " exists and the CasesDFF descriptive flexfield" +
                               " is deployed using Manage Descriptive Flexfields.");
    }
    return Arrays.asList(ss.getSdoNamespace(), ss.getSdoName());
}

// Gets the property path for "Product Type," which is the context
// segment of CasesDFF.
public String getCasesProductTypeServicePropertyPath() {
    FlexfieldSdoSupport ss = getCasesDFFSdoSupport(null);
    if (ss == null) {
        throw new JboException("ERROR: Unable to fetch SDO for context" +
                               ".\nACTION NEEDED: " +
                               "Contact your system administrator. " +
                               "Ensure that the CasesDFF descriptive " +
                               "flexfield is deployed using Manage Descriptive Flexfields.");
    }
    return ss.getDiscriminatorSdoPath();
}

// Gets the property paths for a list of segments specific to a
// product type.
public List<String> getCasesServicePropertyPaths(String productType,
                                                  List<String> segmentCodes) {
    FlexfieldSdoSupport ss = getCasesDFFSdoSupport(productType);
    return Arrays.asList();
}
```
if (ss == null) {
    throw new JboException("ERROR: Unable to fetch SDO for context " +
        productType +
        ".\nACTION NEEDED: Contact your system administrator. " +
        "Ensure context " + productType +
        " exists and the CasesDFF descriptive flexfield is " +
        "deployed using Manage Descriptive Flexfields.");
}

List<String> r = new ArrayList<String>(segmentCodes.size());
for (String segmentCode : segmentCodes) {
    r.add(ss.getSegmentSdoPath(segmentCode));
}
return r;

Example 23-12  Client Application for Updating CasesDFF in a CaseList Row

// Obtain the service definition for product type "Office Chair."
List<String> chairObjInfo=
    caseListService.getCasesServiceNamespaceAndName("Office Chair");

// Create a service data object for "Office Chair."
DataObject chairObj = dataFactory.create(chairObjInfo.get(0),
    chairObjInfo.get(1));

// Set the product type, so the product type matches the object type
chairObj.set(caseListService.getCasesProductTypeServicePropertyPath(),
    "Office Chair");

// Obtain the element names of the segments and set the values.
List<String> segmentPaths =
    caseListService.getCasesServicePropertyPaths("Office Chair",
    Arrays.asList("Broken Part"));

// Update the segment "Broken Part."
chairObj.set(segmentPaths.get(0), "Chair Back");

23.14.2 How to Test the Web Service

You can test the service by adding StringRefAddr elements to the Reference element for the product application module's service to the connections.xml file, deploying and manually testing the service, and optionally creating and running Java client programs to test the service.

Before you begin:

- Expose the descriptive flexfield as a web service as described in How to Expose a Descriptive Flexfield as a Web Service.
- Ensure that the BC4J Service Client and BC4J Service Runtime libraries are included in your project.

To test the web service:

1. Expand Application Resources, expand Descriptors, expand ADF Meta-INF, and open the connections.xml file.
2. Locate the Reference element for the product application module's service (DFF1MasterApplicationModuleService in this example).
3. Add the `StringRefAddr` elements that are shown in bold in Example 23-13 to the `Reference` element for the product application module's service. Modify the host and port number in the `jndiProviderURL` entry to point to Oracle WebLogic Server. The port number is typically 7101.

4. Run the remote server class for the product application module to deploy the service to Integrated WebLogic Server and to manually test the web service.

   **Note:**

   The remote server class was generated when you exposed the descriptive flexfield as a web service in *How to Expose a Descriptive Flexfield as a Web Service*. This class has a name that ends with `ServiceImpl.java`.

5. Optionally, create and run Java client programs to test invoking the web service:

   The following examples demonstrate how to write programs to test the web service.

   • Example 23-17 shows how to get a data row. The XML payload output of this program is shown in Example 23-18.

   • Example 23-19 shows how to create a new data row.

   • Example 23-20 shows how to update an existing data row.

   **Note:**

   You must provide the flexfield's `xsi:subtype` value in the payloads that are sent to the service. If you do not provide the `xsi:subtype` value, the attributes for that subtype are ignored, and will not be created or updated.

---

**Example 23-13  StringRefAddr Elements to Add to Service Reference in connections.xml**

```xml
<Reference name="{http://xmlns.oracle.com/oracle/apps/fnd/applcore/flex/test/dff1/model/}DFF1MasterApplicationModuleService" className="oracle.jbo.client.svc.Service" xmlns="" xmlns="">
   <Factory className="oracle.jbo.client.svc.ServiceFactory"/>
   <RefAddresses>
      <StringRefAddr addrType="serviceInterfaceName">
         <Contents>oracle.apps.fnd.applcore.flex.test.dff1.model.DFF1MasterApplicationModuleService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceEndpointProvider">
         <Contents>ADFBC</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="jndiName">
         <Contents>DFF1MasterApplicationModuleServiceBean#oracle.apps.fnd.applcore.flex.test.dff1.model.DFF1MasterApplicationModuleService</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaName">
         <Contents>DFF1MasterApplicationModuleService.xsd</Contents>
      </StringRefAddr>
      <StringRefAddr addrType="serviceSchemaLocation">
         <Contents>DFF1MasterApplicationModuleService.xsd</Contents>
      </StringRefAddr>
   </RefAddresses>
</Reference>
```

Example 23-17  Web Service Get Operation

```java
package oracle.apps.fnd.applcore.flex.test.dff1.model.test;

import ...

public class DFFTester {
private static final String PK1 = "MY_PRIMARY_KEY";
public DFFTester() {
    super();
}
public void getFKRowGivenKey() {
    try {
        DFF1MasterApplicationModuleService dff1Service =
            (DFF1MasterApplicationModuleService)
            ServiceFactory.getServiceProxy(DFF1MasterApplicationModuleService.NAME);
        List<String> dff1Info = dff1Service.getMyFlexfieldSdoNamespaceAndName(null);
        System.out.println(dff1Info);

        final String contextValue = "MY_CONTEXT_VALUE";
        List<String> dffInfo2 =
            dff1Service.getMyFlexfieldSdoNamespaceAndName(contextValue);
        System.out.println(dffInfo2);

        MasterDff masterVOSDO = dff1Service.getMasterDff1(PK1);
        DataObject dataObject = (DataObject) masterVOSDO;
        String uri = dataObject.getType().getURI();
        XMLHelper xmlhelper = ServiceFactory.getXMLHelper(dff1Service);
        String xml = xmlhelper.save(dataObject, uri, "MasterDff");
        System.out.println(xml);
    } catch (Exception e) {
        // Handle exception
    }
}
```

public static void main(String args[])
    {
        DFFTester dfftester = new DFFTester();
        dfftester.getFKRowGivenKey();
    }

    } catch (Exception e) {
        e.printStackTrace();
    }
}
23.15 Accessing Descriptive Flexfields from an ADF Desktop Integration Excel Workbook

ADF Desktop Integration makes it possible to combine desktop productivity applications with Oracle Fusion Applications, so you can use a program like Microsoft Excel as an interface to access application data.

Using ADF Desktop Integration, you can incorporate descriptive flexfields into an integrated Excel workbook, so you can work with the flexfield data from within the workbook.

The Oracle Fusion Middleware Developing Applications with Oracle ADF Desktop Integration guide provides most of the information you need to complete the required activities, including the following:

- Preparing your development environment for desktop integration.
- Creating a page definition file that will expose the Oracle ADF bindings for use in Excel.
- Creating an Excel workbook to integrate with the descriptive flexfield.
- Preparing your Excel workbook to access the column containing the flexfield.
- Incorporating a descriptive flexfield as a dynamic component or a single cell on a worksheet in the workbook.

The Oracle Fusion Middleware Developing Applications with Oracle ADF Desktop Integration guide does not make explicit reference to flexfields. In addition to the standard implementation steps covered in that guide, you must modify your implementation to accommodate flexfields.

There are two ways to access a descriptive flexfield in Excel:

- Using a dynamic column in an ADF Desktop Integration Table.
A web page in a popup dialog can be associated with a dynamic column, enabling end users to pick flexfield segment values. Alternatively, users can enter values directly into the segment fields. No custom code is required in either case.

This is the most typical scenario. Each descriptive flexfield segment is displayed as a distinct column in the ADF Desktop Integration Table.

- Using a static column in a popup dialog associated with a single cell. Use this approach for either of the following reasons:
  - The descriptive flexfield is exposed in an ADF Desktop Integration Table, is context sensitive, and the context changes from row to row. A static column is required in this case.
  - You do not want descriptive flexfield segments to occupy too much space in the worksheet.

In addition to using the popup dialog, end users can enter values directly into the segment field, with the values separated by an appropriate delimiter that you specify.

**Note:**

A static column is any column for which the `DynamicColumn` property is set to `False`.

Individual flexfield segments do not appear in the worksheet. Instead, ADF Desktop Integration invokes a separate JSPX page on which the flexfield will be visible. You can use this scenario with an ADF Desktop Integration Form, or either table type.

The descriptive flexfield's segments are part of your database table, so the flexfield is generated against the same entity object on which your worksheet view object is based.

To complete the process for accessing descriptive flexfields from an ADF Desktop Integration Excel workbook:

1. Configure ADF Desktop Integration with either a dynamic or static column descriptive flexfield.
2. If using a dynamic column descriptive flexfield where the end user can control the context value, modify the application to update the descriptive flexfield structure whenever user-initiated context value changes occur in the dynamic column descriptive flexfield.
3. Create a custom method to process updates or inserts for descriptive flexfield data row and add code to invoke the method.

### 23.15.1 How to Configure ADF Desktop Integration with a Dynamic Column Descriptive Flexfield

When you configure the ADF Desktop Integration Table, make the following changes:

- Add the ADF Desktop Integration Model API library to your data model project.
• In your page definition for the worksheet, add the descriptive flexfield that you want to access to the master worksheet view object as a child node. Do not add any display attribute to the child node that expands as a dynamic column in the worksheet.

For more information about how to create a page definition file for an ADF Desktop Integration project, see the Working with Page Definition Files for an Integrated Excel Workbook section of the Developing Applications with Oracle ADF Desktop Integration.

• To make the descriptive flexfield column of the ADF Desktop IntegrationTable dynamic, set the DynamicColumn property in the TableColumn array of the ADF Desktop Integration Table to True. A dynamic column in the TableColumn array is a column that is bound to a tree binding or tree node binding whose attribute names are not known at design time. A dynamic column can expand to more than a single worksheet column at runtime.

For more information about the binding syntax for dynamic columns, see the Adding a Dynamic Column to Your ADF Table Component section of the Developing Applications with Oracle ADF Desktop Integration.

• For the table’s UpdateComponent and InsertComponent properties, specify one of the following as the subcomponent to use:
  - Inputtext
  - OutputText
  - ModelDrivenColumnComponent

• For the subcomponent’s Value property, access the Expression Builder, expand the Bindings node and your tree binding for the table, and select the flexfield node.

• For the subcomponent’s Label property, access the Expression Builder, expand the Bindings node and your tree binding for the table, and select the flexfield node.

23.15.2 How to Handle User-Initiated Context Value Changes in a Dynamic Column Descriptive Flexfield

ADF Desktop Integration requires that to use a dynamic column implementation, the structure of the descriptive flexfield must remain constant for all rows in a given result set. However, each time a new result set is downloaded into the table, the context value (and thus the structure) can be changed.

If the context value is set globally for the end user of the workbook, changes are not an issue. However, if the user can control the context value (for example, using a list of values (LOV) in a header form), your application must be able to respond appropriately to update the descriptive flexfield structure.

After the end user specifies a context value, you must invoke the worksheet UpSync method to get the new value into the model layer. Then you can use the ADF Desktop Integration Table Download method to get fresh data with the new descriptive flexfield structure.
Note:
For an insert-only table, the Download method is undesirable. For these cases, use either the ADF Desktop Integration Table DownloadForInsert method or the Initialize method to enable the ADF Desktop Integration Table to reconfigure to accommodate the new flexfield structure.

23.15.3 How to Configure ADF Desktop Integration with a Static Column Descriptive Flexfield

If the structure of your descriptive flexfield varies from row to row in a given result set, you cannot implement the flexfield as a dynamic column — it will produce errors. You must use a static column with a popup dialog.

Note:
If a specific dialog title cannot be provided because the configuration of the flexfield will not be known until implementation, use "Additional Information" for the title, which is the standard generic label in such a case for Oracle Fusion Applications.

ADF Desktop Integration supports descriptive flexfields by using tree bindings in an ADF Desktop Integration Table. If you desire, the table can be configured to be read-only.

Note:
A descriptive flexfield appears as a node in the tree binding at design time. Because flexfields are built up dynamically at runtime, you will not see any attributes under the flexfield node in the page definition, but the node itself is present.

When you configure the popup dialog, make the following changes:

- You can use the column’s action set properties to make the descriptive flexfield web page available for editing. Include the attributes used in the web page in the table’s cached attributes unless the row will be committed immediately.

- You must choose a fixed attribute (a descriptive flexfield global segment attribute) to represent the flexfield in the worksheet. Add a Dialog action to the DoubleClickActionSet component action of an InputText or OutputText component, then connect the Dialog action to JSPX page that will display the descriptive flexfield.

For more information about how to create a page definition file for an ADF Desktop Integration Table project, see the Working with Page Definition Files for an Integrated Excel Workbook section of the Developing Applications with Oracle ADF Desktop Integration.

For static display of a descriptive flexfield in an ADF Desktop Integration workbook, you must create an updatable transient attribute in the view object on which the ADF Desktop Integration Table is based. This transient attribute will hold the concatenated value of the descriptive flexfield segments, separated by a delimiter. If one purpose of
Accessing Descriptive Flexfields from an ADF Desktop Integration Excel Workbook

the worksheet is to display existing data from the database, the transient attribute
should be populated using custom application module methods upon returning from
a popup dialog or opening the worksheet.

23.15.4 How to Handle Updating or Inserting of a Descriptive Flexfield Data Row
To handle updating or inserting of a data row containing a descriptive flexfield in an
ADF Desktop Integration Table, you call a custom application module method that
contains appropriate code, as follows:
•

To update an existing row, add your code to the UpdateRowActionId property of
the table.

•

To insert a new row, add your code to the InsertAfterRowActionId property of
the table.

The context value should be set before calling the application module method, which
gets called in the doubleclickactionset component action of the table's
UpdateComponent or InsertComponent properties. This is applicable for both
dynamic column and static column display of descriptive flexfields. Setting the context
value appropriately is important because this controls the structure of the flexfield.
The following examples demonstrate the code needed to accomplish these tasks.
Example 23-21 and Example 23-22 apply to an ADF Desktop Integration
implementation with the descriptive flexfield exposed as a static column.
Example 23-23 presents the isSegmentDisplayable() method that is used in the
other two examples.
Example 23-21
Flexfield

Updating or Inserting a Row with a Static Column Descriptive

//Retrieve your worksheet view object
myworksheet_VOImpl srcVO = myVO
//Retrieve the current row from your view object.
//That is the row that is being processed by ADF Desktop Integration.
myworksheet_VO_Row_Impl srcRow = myworksheet_VO_Row_Impl srcVO.getCurrentRow();
//This gives the transient attribute value from your worksheet.
Object dffAttributeValue = srcRow.getAttribute(mytransientattribute);
//Get the descriptive flexfield row based on the descriptive flexfield view
accessor.
DFFViewRowImpl dffRow = (DFFViewRowImpl)srcRow.getAttribute(mydff_viewaccessor);
//Check if the single cell value is null.
if (dffAttributeValue != null && !("").equals(dffAttributeValue)) {
//Getting DFF metadata information
FlexfieldViewDefImpl dffImpl =
(FlexfieldViewDefImpl)dffRow.getFlexfieldViewDef();
String delim = dffImpl.getDelimiter();
//Parse the DFF string into tokens
StringTokenizer token =
new StringTokenizer(dffAttributeValue.toString(), delim);
while (token.hasMoreTokens()) {
prjValues.add(token.nextToken());
}
}

Use Descriptive Flexfields 23-73


//Get the descriptive flexfield segment information.
ListAttributeDef listSeg =
    dffRow.getFlexfieldViewDef().getFlexfieldAttributes();

Iterator listSegIterator = listSeg.iterator();
AttributeDef seg = null;
List<String> segDisplay = new ArrayList<String>();
while (listSegIterator.hasNext()) {
    seg = (AttributeDef)listSegIterator.next();
    if (isSegmentDisplayable(seg, dffRow)) {
        segDisplay.add(seg.getName());
    }
}

//Get the size of the segment.
int segValueSize = 0;
if (dffAttributeValue != null && !("").equals(dffAttributeValue))
    segValueSize = prjValues.size();
else
    segValueSize = segDisplay.size();

//This check is required to handle a context dependent DFF case.
//If the context is changed before uploading, do not proceed.
if (segValueSize < prjValues.size())
    return;
if (segDisplay.size() == 0)
    return;
for (int i = 0; i < segValueSize; i++) {
    if (dffAttributeValue != null && !("").equals(dffAttributeValue)) {
        if (prjValues.get(i) != null && !prjValues.get(i).equals("")) {
            dffRow.setAttribute(segDisplay.get(i), prjValues.get(i));
        } else {
            dffRow.setAttribute(segDisplay.get(i), null);
        }
    } else {
        dffRow.setAttribute(segDisplay.get(i), null);
    }
}

Example 23-22 Applying Modified Segment Values to a Cell in a Static Column
Descriptive Flexfield

Add this code as an application module method that will be invoked by clicking the OK button of a popup dialog. This method can also be used to populate transient attribute values used for single cell display upon opening the worksheet, if the worksheet is intended to display existing records from the database.

//Retrieve the DFF row through the DFF view accessor.
DFFViewRowImpl dffRow =
    (DFFViewRowImpl)row.getAttribute(  
        "DFF_viewaccessorattribute_from_worksheetVO");

//Get the delimiter information for your DFF.
FlexfieldViewDefImpl dffImpl =
    (FlexfieldViewDefImpl)dffRow.getFlexfieldViewDef();
String delim = dffImpl.getDelimiter();

//Get the segment information for your DFF.
ListAttributeDef listSeg =
    dffRow.getFlexfieldViewDef().getFlexfieldAttributes();
// Your DFF will have many segments, but not all of them will be used for display. 
// This code loops through DFF segments and obtains the name and type 
// of each displayable segment.
Iterator listSegIterator = listSeg.iterator();
AttributeDef seg = null;
List<String> segDisplay = new ArrayList<String>();
List<Integer> segDisplayType = new ArrayList<Integer>();

while (listSegIterator.hasNext()) {
    seg = (AttributeDef) listSegIterator.next();
    if (isSegmentDisplayable(seg, dffRow)) {
        segDisplay.add(seg.getName());
        segDisplayType.add(new Integer(seg.getSQLType()));
    }
}

int segDisplaySize = segDisplay.size();
StringBuffer segmentString = new StringBuffer();

// This loop is constructing a string out of displayed segment values
// with a delimiter in between each segment value.
// If the segment type is date, remove the time from the date.
// For the first segment (i=0), you need to handle it differently
// to construct the string correctly.
for (int i = 0; i < segDisplaySize; i++) {
    if (dffRow.getAttribute(segDisplay.get(i)) != null) {
        if (i == 0) {
            if (segDisplayType.get(i) == 91) {
                StringTokenizer stTime =
                        new StringTokenizer(dffRow.getAttribute(segDisplay.get(i)).toString(), " ");
                segmentString.append(stTime.nextToken());
            } else {
                segmentString.append(dffRow.getAttribute(segDisplay.get(i)));
            }
        } else {
            segmentString.append(delim);
            if (segDisplayType.get(i) == 91) {
                StringTokenizer stTime =
                        new StringTokenizer(dffRow.getAttribute(segDisplay.get(i)).toString(), " ");
                segmentString.append(stTime.nextToken());
            } else {
                segmentString.append(dffRow.getAttribute(segDisplay.get(i)));
            }
        }
    } else {
        if (i==0)
            segmentString.append(" ");
        else {
            segmentString.append(delim);
            segmentString.append(" ");
        }
    }
}
Example 23-23 isSegmentDisplayable() Helper Method Used in the Previous Examples

The input parameters for this method are the segment attribute definition and the descriptive flexfield row.

```java
public boolean isSegmentDisplayable(AttributeDef seg,
                                       DFFViewRowImpl dffRow) {
    if (seg.getProperty("FND_ACFF_DisplayAttributeName") == null) {
        if (seg.getProperty(seg.getUIHelper().ATTRIBUTE_DISPLAY_HINT) ==null ||
            !seg.getProperty(seg.getUIHelper().ATTRIBUTE_DISPLAY_HINT).equals("Hide")) {
            return true;
        } else {
            return false;
        }
    } else {
        int attrIndex =
            dffRow.getFlexfieldViewDef().getAttributeIndexOf(
                seg.getProperty("FND_ACFF_DisplayAttributeName").toString());
        AttributeDef displayAttrDef =
            dffRow.getFlexfieldViewDef().getAttributeDef(attrIndex);
        if (displayAttrDef.getProperty(
                seg.getUIHelper().ATTRIBUTE_DISPLAY_HINT) == null ||
            !displayAttrDef.getProperty(
                seg.getUIHelper().ATTRIBUTE_DISPLAY_HINT).equals("Hide")) {
            return true;
        } else {
            return false;
        }
    }
    return false;
}
```
Use Extensible Flexfields

This chapter discusses how to use extensible flexfields to enable customers to add additional attributes to application business objects in Oracle Fusion Applications. This chapter includes the following sections:

- Introduction to Extensible Flexfields
- Overview of Integrating Extensible Flexfields in an Application
- Creating Extensible Flexfield Data Tables
- Registering Extension Tables as Secured Objects
- Creating and Configuring Extensible Flexfield Entity Objects
- Creating and Configuring Extensible Flexfield View Objects
- Defining and Registering Extensible Flexfields
- Creating Extensible Flexfield Business Components
- Employing an Extensible Flexfield on a User Interface Page
- Incorporating Extensible Flexfields into a Search Form
- Preparing Extensible Flexfield Business Components for Oracle Business Intelligence
- Integrating Extensible Flexfields with Business Intelligence Publisher
- Loading Seed Data
- Customizing the Extensible Flexfield Modelers
- Testing Flexfields
- Making Extensible Flexfields Available to Web Services
- Accessing Information About Extensible Flexfield Business Components
- Using the Advanced Features of Extensible Flexfields.

24.1 Introduction to Extensible Flexfields

An extensible flexfield is similar to a descriptive flexfield in that it provides a customizable expansion space that implementors, such as Oracle Fusion Applications customers, can use to configure additional attributes (segments) without additional programming. As with descriptive flexfields, each segment is represented in the
database as a single column. However, with extensible flexfields, the context values and context-sensitive segments are stored in an extension table.

Implementors can combine and arrange the segments into attribute groups that are tailored to a customer's specific needs. For example, they can group related segments so that they appear together on the page. An attribute group is referred to as a context. You can optionally set up an extensible flexfield to enable implementors to group contexts into categories.

For information about implementors use contexts and categories to configure extensible flexfields, do the following:

• Access the Oracle Fusion Applications Technology library.
• See the Implementing Common Features guides for your product family. Search for flexfields.

To learn more about flexfield basics and terms, including developer and implementor roles, segments, and contexts, see Getting Started with Flexfields. For more details about the differences between descriptive flexfields and extensible flexfields, see The Benefits of Extensible Flexfields.

24.1.1 Understanding Extensible Flexfields

Extensible flexfields include the following key artifacts:

• Contexts (attribute groups)
• Context-sensitive segments
• Logical pages
• Categories
• Category hierarchies
• Usages

24.1.1.1 About Contexts (Attribute Groups)

An extensible flexfield context is a data grouping mechanism that implementors can use to arrange segments into meaningful groups. Each context is a group of attributes that is displayed in its own subregion of the user interface (UI) page at runtime. Implementors create and configure the contexts. After creating a context, an implementor must associate the context with the categories for which that group of attributes is relevant. For example, a Parts flexfield might have a Fax category and an All-in-One Printers category. A Fax context would be associated with both categories, while a Copy context would be relevant only to the All-in-One Printers category. You can learn about categories in About Categories.

The following figure shows the UI page for the Positions business object. The Positions flexfield is embedded in the Additional Position Details region on the page. This region contains the Educational Requirements, Certification and License Requirements, and Travel contexts for the Positions flexfield.
Figure 24-1  Position User Interface Page

Figure 24-2 and Figure 24-3 show UI pages for the Parts business object. The developer has enabled multiple categories for the Parts flexfield, so the page displays the category to which the part shown belongs. In Figure 24-2, the part belongs to the All-in-One Printers category, and in Figure 24-2, the part belongs to the Fax category. In these pages, the Parts flexfield is embedded in the Additional Information region. For the All-in-One Printers category in Figure 24-2, the Additional Information region contains the Copy, Fax, and Scan contexts for the Parts flexfield, while on the Parts page for the Fax category in Figure 24-3, the region contains just the Fax context.

Note:
A flexfield region is empty until the implementor configures the extensible flexfield that is embedded in it.

Extensible flexfields allow implementors to configure contexts as either single row or multiple row. That is, either one set of segments is stored for a business object instance, or multiple sets of segments are stored for the instance. For example, a job position requires only one set of educational requirements, but can require more than one certificate or license.

For single-row contexts, the segments appear as fields in a form. With multiple-row contexts, the segments appear as columns in a table, thus allowing end users to capture a list. In Figure 24-1, Educational Requirements and Travel are single-row contexts, so end users can specify only a single value for each context-sensitive segment, such as the percent of travel time required for the position. The Certification and License Requirements context is a multiple-row context, so end users can enter multiple rows, one for each certificate or license required for the position.
24.1.1.2 Context-Sensitive Segments

With extensible flexfields, every segment is a member of a context (attribute group). That is, every segment is a context-sensitive segment. Implementors define the contexts and their context-sensitive segments. Context-sensitive segments are the lowest-level data points that implementors can define for an extensible flexfield, and each segment is mapped to a column in an extension table. Just as with descriptive flexfields, the segments are rendered as ADF Faces rich client components, such as text box, text area, list of values (LOV) choice list, date picker, checkbox, and radio button group.

In Figure 24-1, the Educational Requirements context contains the High School, Bachelor, Master, J.D., M.D., and Ph.D. context-sensitive segments, and the Certification and License Requirements context contains the Type and Certificate/License context-sensitive segments.

24.1.1.3 About Logical Pages

Extensible flexfields enable implementors to define logical pages with which to group contexts for display purposes. Each page can contain one or more contexts along with their respective context-sensitive segments. There is no limit to the number of contexts
on a logical page. The implementors associate the logical pages with categories on a flexfield usage basis. For information about usages, see About Usages (Data Levels).

In the Parts UI page shown in Figure 24-2, an implementor has defined two logical pages for this category — Printers and All-in-One. The implementor defined the Printers logical page to contain all contexts related to the printing capabilities of the printer, and the All-in-One page to contain all contexts related to the other capabilities of the printer, such as the scanning, copying, and faxing capabilities.

The Parts page that is shown in Figure 24-2 displays the list of logical pages for the category in the left-hand pane. End users view a logical page in the right-hand pane by selecting it from the list. In this figure, the end user has chosen to view the All-in-One logical page. The Printers logical page is shown in the following figure.

**Figure 24-4  Printers Logical Page in the Parts User Interface Page**

Logical pages have several layout options. For example, in Figure 24-1, the developers chose to hide the entire left-hand section because their customers will add attributes to a single page that is known at the time of development. However, in Figure 24-4, developers chose to display the list of logical pages in the left-hand pane. For more information about layout options, see Employing an Extensible Flexfield on a User Interface Page.

### 24.1.1.4 About Categories

Categories enable applications to dynamically display different sets of logical pages and contexts at runtime. In the simplest case, you create a single category for a flexfield, and the same extensible flexfield contexts and logical pages appear for every instance of the business object. In some cases, you might need the application to display different sets of logical pages and contexts depending on a runtime discriminator, such as an instance value. In these cases, you can create multiple categories for the flexfield, or you can provide application-specific logic that enables implementors to define their own categories.

The Positions flexfield in Figure 24-1 has a single category. The same flexfield segments appear in the Additional Position Details region regardless of which position is displayed. In this page, the developer has hidden the name of the category, because there is only one category.
In Figure 24-2 and Figure 24-3, the segments that the region displays depend on which category the part belongs to. In Figure 24-2, the part belongs to the All-in-One Printers category and the UI displays fields related to copying, faxing, and scanning. In Figure 24-3, the part belongs to the Fax category and the UI displays fields related to only faxing.

24.1.1.5 About Category Hierarchies

You can choose to support multiple categories for your flexfield. When you do so, the extensible flexfield respects any hierarchical relationship that is defined for the categories, whether created by developers or defined by implementors. The following figure shows an example of categories that are defined in a hierarchical fashion. In this example, the root category (the category that does not have parent categories) is Computers and Office. One of its child categories is Printers and Ink. The Printers and Ink category, in turn, has a Printers child category. The Printers category has two child categories — All-in-One Printers and Single Function Printers.

![Figure 24-5 Example of a Category Hierarchy](image)

Each child category inherits the contexts and pages from its parent categories. For example, the Printers category contains the Print, Printer Functions, and Supported Operating Systems contexts. The All-in-One Printers category inherits these contexts from the Printers category. It also inherits all logical pages that are defined for its parent categories. Additional contexts can be assigned directly to the All-in-One Printers category, such as Copy and Scan, which are relevant only to All-in-One printers.

24.1.1.6 About Usages (Data Levels)

When you create an extensible flexfield, you create one flexfield usage for each set of tables in the application that uses the flexfield. In the simplest case, you will have one flexfield usage. For example, in Figure 24-1, the Positions application requires a single Positions table with its associated extension tables to store the extensible flexfield values. Implementors simply associate their contexts with that one usage to make them available to the Positions application.

When you have several objects in the application that should be extended using the same extensible flexfield, you must create multiple usages for the flexfield. For example, in the case of an Items application, there might be different data levels, such as items and item revisions. In this case, you create one usage per data level. By
defining separate usages for each set of tables, you enable your implementors to reuse the same extensible flexfield configuration for all data levels.

24.1.2 The Benefits of Extensible Flexfields

When deciding whether to use a descriptive flexfield or an extensible flexfield to extend a business object, consider the following features that you make available for implementors by using extensible flexfields:

- **Custom grouping**: Extensible flexfields enable implementors to group segments into contexts (attribute groups), and each context is displayed in its own region on a page.

- **Multiple logical pages**: When an implementor defines a large number of custom attributes, the implementor can choose to create several logical pages with which to display the attribute groupings. For example, Figure 24-2 and Figure 24-4 show different logical pages for the same part. In addition, the implementors can reuse these pages with different categories.

- **Hierarchical categories**: Extensible flexfields can be configured to enable categories, which can be used to dynamically display different sets of logical pages and contexts based upon a runtime discriminator. The categories can be structured in a hierarchical manner and the children categories inherit all the contexts and logical pages that are configured for their parent categories.

- **Reusable attribute groups**: When you enable multiple categories for an extensible flexfield, implementors can associate contexts with more than one category. When business object instances share common attributes, the implementors can put the common attributes in one context and reuse that context in all applicable categories, thus minimizing setup time. For example, in Figure 24-2 and Figure 24-3, the Fax context is associated with both the Fax category and the All-in-One Printers category.

- **Unlimited expansion space**: While the number of segments that an implementor can define for a context is limited to the number of underlying flexfield extension columns, there is no limit to the number of contexts that an implementor can create for an extensible flexfield. Implementors can use the extension columns over and over in newly created contexts resulting in an unlimited number of custom attributes.

- **Custom lists**: When implementors need to add custom lists to their business objects, they can create multiple-row contexts, which display the context’s segments in a table, as shown in the Certification and License Requirements region in Figure 24-1.

- **Locale-specific values**: You can optionally enable implementors to store different attribute values on a locale-by-locale basis. For example, an implementor could store and maintain the description of a part in English, Chinese, and French. The application displays and stores the value for the end user’s locale.

For more information, see the "Translating Flexfield and Value Set Configurations" section in the Extensibility Guide for Developers.

- **Access control**: Implementors can define who can view and edit the attributes in a context.

- **Unit of measure specifications**: Implementors can define the unit of measure for an attribute.
• Interface tables: Extensible flexfields support the use of interface tables for loading extensible flexfield data.

• Parallel Sets: Extensible flexfields can generate parallel sets of extensible flexfield artifacts for different uses, such as public view objects and private view objects.

Another advantage of using extensible flexfields is that you can create your own custom modeler classes for adding application-specific logic for generating ADF Business Components and UI task flows, as described in Customizing the Extensible Flexfield Modelers.

24.1.3 Extensible Flexfield Structure and Content

Unlike descriptive flexfields, which are mapped to extension columns in a product table, extensible flexfields are mapped to extension columns in extension tables that are separate from the product table. You create the extension tables at design time.

How Extensible Flexfields Are Modeled in Oracle Application Development Framework

Extensible flexfields are modeled as a collection of Oracle Application Development Framework (ADF) polymorphic view rows, as described in the Working with Polymorphic View Rows section in the Developing Fusion Web Applications with Oracle Application Development Framework.

The category hierarchy translates into a hierarchy of view objects that are configured to support polymorphic view rows. The view objects have view links to associated context view objects. A CategoryCode attribute acts as the discriminator that determines which category view row type is used. At application runtime, the category in the base category view object row determines what pages and contexts are displayed. Given a collection of polymorphic view rows, each row can be a different type depending upon the category. An application module that holds the category view object is generated for each category.

Note:

Because flexfield view objects are modeled as polymorphic view objects, you can use extensible flexfield view objects in the same manner that you use any other polymorphic view objects, and they will behave in the same way.

24.2 Overview of Integrating Extensible Flexfields in an Application

The process of developing an extensible flexfield and integrating it in an application comprises several different activities, such as creating the extension tables, creating business components, and adding the flexfield to the appropriate application pages. This section identifies the major tasks for incorporating an extensible flexfield and points to the sections that provide the details for completing the tasks.

Before you begin:

Before you begin developing an extensible flexfield, you must first complete the following tasks:

1. Identify the business object and related product table for which you are implementing the extensible flexfield. For example, you might want to enable implementors to create custom attributes for the Parts business object, which corresponds to the FND_CRM_PARTS table.
2. Decide if you want customers to be able to store translated values for one or more
   segments. For example, for a Parts flexfield, customers might want to store
   translations for the attributes in the Catalog Information context so they can print
   the catalog in different languages.

3. Decide if you want to enable customers to store the information for a context at
different levels (also referred to as flexfield usages). For example, implementors
might choose to set up a context for a Parts flexfield that has both a part supplier
level and a part level. The same context segments appear in both the supplier UI
and the part UI, but the end user would enter different values. Take, for example,
a lead-time segment. At the part level, the end user would supply the average
lead time. At the supplier level, the end user would enter the actual lead time
required for that supplier.

4. Decide if you need more than one set of artifacts generated for a flexfield usage.
   For example, you might need both private user interfaces that are based on
   updatable (entity-based) view objects and public user interfaces that are based on
   read-only view objects. When you have more than one set of artifacts, you will
   need to define multiple groups at the entity-usage level for the flexfield usage,
such as a Private group and a Public group, when you register the flexfield’s
   business components.

5. Determine whether you need to customize the generated model to add additional
   product-specific logic or customize the generated user interface, or both.

To complete the development tasks for an extensible flexfield:

1. Create a base extension table for each flexfield usage. If you want to enable
   customers to store translations on a locale-by-locale basis, create a translation
   extension table and a view of the translation extension table for each usage as
   well.

   See Creating Extensible Flexfield Data Tables.

2. Register the extension tables as secured objects to enable implementors to specify
   view and edit privileges for each context’s attributes.

   See Registering Extension Tables as Secured Objects.

3. Create entity objects for the flexfield’s extension tables. In this step, you create an
   entity object and a view object from the base extension table, and, if they exist, the
   translation extension table and view.

   See Creating and Configuring Extensible Flexfield Entity Objects.

4. Create view objects for the extension tables, create a view object to support
categories, and create a view object to support searching.

   See Creating and Configuring Extensible Flexfield View Objects.

5. Create the flexfield metadata.

   See Defining and Registering Extensible Flexfields .

6. Create and configure business components to support the extensible flexfield.

7. Add the extensible flexfield to the appropriate UI pages.

   See Employing an Extensible Flexfield on a User Interface Page.
8. Optionally, prepare the flexfield for business intelligence.
   See Preparing Extensible Flexfield Business Components for.

9. Load any necessary application seed data, such as error messages and lookup values.
   See Loading Seed Data.

10. Optionally, customize the generated model or the generated UI artifacts, or both.
    See Customizing the Extensible Flexfield Modelers and How to Customize the Runtime User Interface Modeler for Extensible Flexfields.

11. Test the flexfield.
    See Testing Flexfields.

After you have completed the extensible flexfield development process and delivered your application, implementors can use the Manage Extensible Flexfields task flow to define contexts, categories, and pages, and to configure the segments for each extensible flexfield. These task flows determine how the flexfield's segments will be populated, organized, and made available to end users within the application.

For information about planning and implementing flexfield configuration, do the following:

- Access the Oracle Fusion Applications Technology library.
- See the Implementing Common Features guides for your product family. Search for flexfields.

Note:
An extensible flexfield is not displayed at runtime unless at least one context and context-sensitive segment has been configured and associated with a category.

To make the Manage Extensible Flexfields task flow available to application implementors, register it with Oracle Fusion Functional Setup Manager. For more information, see Integrating Flexfield Task Flows into.

### 24.3 Create Extensible Flexfield Data Tables

Before you can define an extensible flexfield, you must create one set of dedicated database tables for each of the flexfield's usages. Each set must be composed of at least a base extension table. If you want to enable customers to store translated values for the segments, the set must include a translation extension table and a view of the translation extension table.

At runtime, as end users enter attribute values for each context, the context and its segment (attribute) values are stored as a row in the base extension table if the context is not translatable, or, if the context is translatable, as rows in the translation extension table (one row per installed language). The translation extension view returns the rows in the current user locale. When an implementor creates a translatable context, the implementor can add only VARCHAR2 segments to the context.

An extensible flexfield must have at least one set of tables, which defines the primary usage. The implementors will expose only the extension columns that they require.
You must use the Database Schema Deployment Framework tools to create the tables and columns. Using these tools ensures that the table and its columns are registered in the Oracle Fusion Middleware Extensions for Applications (Applications Core) data dictionary. For more information, see Using the Database Schema Deployment Framework.

Note:
The steps in this section assume that the product table that the flexfield is extending already exists.

24.3.1 How to Create a Base Extension Table

Each flexfield usage requires a base extension table. This table stores nontranslatable contexts and their segment values. The table name should have a suffix of _B to identify it as the base extension table. The name should have the _B suffix regardless of whether the extensible flexfield has a translation table.

Table 24-1 lists the columns that you must include in a base extension table. You can include additional columns, such as columns that are required by product teams or application standards. For space considerations, the table shows only the first and last attribute columns for each type.

Add as many attribute columns as necessary. The attribute columns can be of type VARCHAR2, NUMBER, and TIMESTAMP. Do not set scale or precision for the NUMBER columns. There are no size requirements for the VARCHAR2 columns. To avoid compatibility and interoperability problems, name the columns ATTRIBUTE_type-and-number, such as ATTRIBUTE_CHAR1 for a VARCHAR2 column, ATTRIBUTE_NUMBER1 for a NUMBER column, and ATTRIBUTE_TIMESTAMP1 for a TIMESTAMP column.

For columns of type NUMBER, you can optionally add a column named ATTRIBUTE_NUMBERn_UOM to store the unit of measure.

The primary key of the base extension table must include the EFF_LINE_ID column, the CONTEXT_CODE column, the CATEGORY_CODE column, and the columns that match the primary key columns of the product table.

Table 24-1  Extensible Flexfield Base Extension Table (_B) Specification

<table>

</tbody>
</table>

#### 24.3.2 How to Create a Translation Extension Table

If you plan to allow customers to store translations for some contexts on a locale-by-locale basis, then you must also create a translation extension table and a single table translation view from that table. The translation extension table and the translation extension view are not required. However, if you do not provide these tables, the customers cannot store translations for their extensible flexfields as described in the “Translating Flexfield and Value Set Configurations” section in the *Extensibility Guide for Developers*. For more information about multilanguage tables, see *Understanding Multi-Language Support Features*. For information about creating the view, see *How to Create a Translation Extension View*.

Note that unlike typical translation tables, the base extension table is completely separate from the translation extension table. All the segment values for a context go in either the base extension table or in the translation extension table. If a context is marked as translatable, all segment values are stored in the translation extension table. If a context is not marked as translatable all segment values are stored in the base extension table. This means that a translatable context cannot contain segments of non-translatable data types, such as numbers or dates.

*Table 24-2* lists the required translation extension table columns. The required columns are similar to those in the base extension table, except that the attribute columns must be of type `VARCHAR2` and you must include the `LANGUAGE` and `SOURCE_LANG` columns. For space considerations, the table shows only the first and last attribute columns. You can include additional columns, such as columns that are required by product teams or application standards.
The translation table name should have a suffix of _TL to identify it as a translation table.

The primary key of the translation extension table must include the EFF_LINE_ID column, the CONTEXT_CODE column, the CATEGORY_CODE column, the LANGUAGE column, and the columns that match the primary key columns of the product table.

Developers typically create the same number of VARCHAR2 type attribute columns in the translation extension table as exist in the base extension table, but you are not required to do so. Create as many VARCHAR2 type attribute columns as you think are necessary for a translatable context. To avoid compatibility and interoperability problems, name the columns ATTRIBUTE_CHARnumber, such as ATTRIBUTE_CHAR1, ATTRIBUTE_CHAR2, and so on. When setting the size of the VARCHAR2 columns in an extension translation table, consider that the columns might need to contain multibyte characters.

Table 24-2 Extensible Flexfield Translation Extension Table (_TL) Specification

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Nullable?</th>
</tr>
</thead>
<tbody>
<tr>
<td>EFF_LINE_ID</td>
<td>NUMBER(18)</td>
<td>No</td>
</tr>
<tr>
<td>Primary key columns of the product table for which this extensible flexfield is being defined.</td>
<td>Same as the column in the application.</td>
<td>No</td>
</tr>
<tr>
<td>CONTEXT_CODE</td>
<td>VARCHAR2(80)</td>
<td>No</td>
</tr>
<tr>
<td>CATEGORY_CODE</td>
<td>VARCHAR2(80)</td>
<td>No</td>
</tr>
<tr>
<td>CREATED_BY</td>
<td>VARCHAR2(64)</td>
<td>No</td>
</tr>
<tr>
<td>CREATION_DATE</td>
<td>TIMESTAMP</td>
<td>No</td>
</tr>
<tr>
<td>LAST_UPDATED_BY</td>
<td>VARCHAR2(64)</td>
<td>No</td>
</tr>
<tr>
<td>LAST_UPDATE_DATE</td>
<td>TIMESTAMP</td>
<td>No</td>
</tr>
<tr>
<td>LAST_UPDATE_LOGIN</td>
<td>VARCHAR2(32)</td>
<td>Yes</td>
</tr>
<tr>
<td>SOURCE_LANG</td>
<td>VARCHAR2(4)</td>
<td>No</td>
</tr>
<tr>
<td>LANGUAGE</td>
<td>VARCHAR2(4)</td>
<td>No</td>
</tr>
<tr>
<td>ATTRIBUTE_CHAR1</td>
<td>VARCHAR2(1000)</td>
<td>Yes</td>
</tr>
<tr>
<td>...</td>
<td>VARCHAR2(1000)</td>
<td>Yes</td>
</tr>
<tr>
<td>ATTRIBUTE_CHAR40</td>
<td>VARCHAR2(1000)</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Note:
To avoid compatibility and interoperability problems, format the column names as indicated.
24.3.3 How to Create a Translation Extension View

If you create a translation extension table, you must also create a view from the translation extension table. To create the view, use a view definition statement that follows the format shown in Example 24-1. The name of the translation extension view should have a suffix of _VL.

Example 24-2 shows a sample view definition.

**Example 24-1 Format for Translation Extension View Definition**

```sql
select ROWID ROW_ID, 
column list
from translation extension table
where LANGUAGE = userenv('LANG');
```

**Example 24-2 Sample Translation Extension View Definition**

```sql
select
ROWID ROW_ID,
EFF_LINE_ID,
CONTEXT_CODE,
CATEGORY_CODE,
ATTRIBUTE_CHAR1,
...
ATTRIBUTE_CHAR40
from MYEFF_TL
where LANGUAGE = userenv('LANG');
```

24.4 Register Extension Tables as Secured Objects

You must register an extensible flexfield’s extension tables as database resources to enable implementors to specify and manage access privileges for context attributes.

You can optionally preconfigure database resource actions and conditions (instance sets) that might be useful for the customers.

---

**Note:**

When an implementor uses Oracle Authorization Policy Manager to define security policies for an extensible flexfield, the implementor must manage the privileges for both the base extension table and the view of the translation extension table. If your application has a separate user interface for managing privileges, this user interface must manage the base extension tables and the views of the translation extension tables for all usages as separate secured objects.

---

24.4.1 How to Register a Table as a Secured Object

You must register an extensible flexfield’s base extension table as a secured object by registering a database resource for the table. If you create a translation extension table and view for an extensible flexfield, then you must register the view as a database resource as well. Use the Manage Database Security Policies task, which is accessed from the Setup and Maintenance work area of any Oracle Fusion Setup application, to create the database resources.
You can optionally create actions and conditions for the database resource. The preconfigured actions appear in the View Privileges and Edit Privileges dropdown lists for a context’s usages in the Manage Extensible Flexfields task. Customers use these actions to restrict view and edit privileges.

To create a database resource:

1. In the Setup and Maintenance work area of any Oracle Fusion Setup application, go to the Manage Database Security Policies task.

2. From the Search Results region, select Actions > Create.

3. Register the database resource.

---

WARNING:

When registering a database resource for the base extension table, you must use the name of the table for the name of the database resource, such as ITEM_EFF_B. When registering a database resource for the view of the translation extension table, you must use the name of the view for the name of the database resource, such as ITEM_EFF_VL. Otherwise, if an implementor creates actions for that database resource and sets the privileges for an extensible flexfield’s context to those actions, the end users who have those privileges will get an oracle.jbo.JboException, such as Object is not registered with Data Security, when they access a page that contains the extensible flexfield context.

---

4. Ensure that the EFF_LINE_ID column is included in the primary key.

5. Optionally, create actions and conditions for the database resource.

**24.5 Create and Configuring Extensible Flexfield Entity Objects**

Before you can register an extensible flexfield, you must create entity objects for the flexfield’s extension tables and you must configure the EFF_LINE_ID attribute for each extensible flexfield entity object as a unique ID.

For information about entity objects, see the Creating a Business Domain Layer Using Entity Objects chapter in the Developing Fusion Web Applications with Oracle Application Development Framework. For information about unique IDs see About Using Unique ID.

---

**Note:**

The packages in which these entity objects are created must not fall under the packages allocated for runtime-generated business components (which are specified in the adf-config.xml file and the flexfield usage metadata).

---

**24.5.1 How to Create and Configure Extensible Flexfield Entity Objects**

Use the Create Entity Object wizard to create and configure an entity object from the base extension table. If a translation extension table exists for the flexfield, create and configure extensible flexfield entity objects from the translation extension table and the translation table view.

**Before you begin:**
1. Create one set of dedicated extension tables per usage, as described in How to Create a Base Extension Table.

2. Ensure that the Applications Core library has been added to the data model project, as described in Adding Necessary Libraries to Your Data Model Project.

3. Verify that at least one customization class is included in the adf-config.xml file. This serves to ensure correct application behavior. It does not matter which customization class you include.

   For information about defining the customization layers, see the "Understanding Customization Layers" section in the Extensibility Guide for Developers.

24.5.1.1 Creating and Configuring an Entity Object from the Base Extension Table

Use the Create Entity Object wizard to create an entity object from the base extension table that is described in Table 24-1, but apply the changes described in the following procedure to support the extensible flexfield. For information about the Create Entity Object wizard, see the How to Create Single Entity Objects Using the Create Entity Wizard section in the Developing Fusion Web Applications with Oracle Application Development Framework.

To create and configure an entity object from the base extension table:

1. On the Attributes page of the wizard, include only the following columns as attributes in your new entity object:
   - EFF_LINE_ID
   - OBJECT_VERSION_NUMBER
   - Primary key columns of the product table
   - CONTEXT_CODE
   - CATEGORY_CODE
   - CREATED_BY
   - CREATION_DATE
   - LAST_UPDATED_BY
   - LAST_UPDATE_DATE
   - LAST_UPDATE_LOGIN

2. On the Attribute Settings page, do the following:
   - Set the EFF_LINE_ID attribute to be a primary key.
   - Set the CONTEXT_CODE attribute to be a discriminator, with a default value of 0.

3. On the Java page, confirm that the objectnameBEOImpl entity object class to be generated extends the oracle.apps.fnd.applcore.oaext.model.OAEntityImpl class.

4. After creating the entity object, click the Attributes navigation tab and complete the following steps:
a. Select the EFF_LINE_ID attribute and, on the Applications tab of the Property Inspector, set Application Unique ID to true to generate a globally unique id.

b. On the UI Hints tab of the Property Inspector for each attribute, set the Display Hint property to Hide

5. Create an alternate key for the flexfield.

When business components are generated from this entity object, this alternate key will be extended to include all multiple-row context segments that implementors designate as a unique key when they configure the flexfield.

**Note:**

If this alternate key does not exist for an extensible flexfield, implementors will not be able to mark a segment in a multiple-row context as a unique key.

---

24.5.1.2 Creating and Configuring an Entity Object from the Translation Extension Table

If you created a translation extension table for the flexfield usage, as described in Table 24-2, use the Create Entity Object wizard to create an entity object from the translation extension table, but apply the changes described in the following procedure to support the extensible flexfield.

For more information about creating entity objects, see the Creating a Business Domain Layer Using Entity Objects chapter in the Developing Fusion Web Applications with Oracle Application Development Framework.

To create and configure an entity object from the extensible flexfield translation extension table:

1. On the Attributes page of the wizard, include only the following columns as attributes in your new entity object:
   - EFF_LINE_ID
   - OBJECT_VERSION_NUMBER
   - Primary key columns of the product table
   - CONTEXT_CODE
2. On the Attribute Settings page, do the following:
   - Set the EFF_LINE_ID attribute to be a primary key.
   - Set the CONTEXT_CODE attribute to be a discriminator, with a default value of 0.

3. On the Java page, confirm that the objectnameTlEOImpl entity object class to be generated extends the oracle.apps.fnd.applcore.oaext.model.OAEntityImpl class.

4. After creating the entity object, click the Attributes navigation tab and complete the following steps:
   a. Select the EFF_LINE_ID attribute and, on the Applications tab of the Property Inspector, set Application Unique ID to true to generate a globally unique id.
   b. On the UI Hints tab of the Property Inspector for each attribute, set the Display Hint property to Hide

5. Configure all of the non-key attributes that are of type String to be translatable.
   On the Applications tab of the Property Inspector for each non-key, String type attribute, set the OA Translatable property to True.

6. Create an alternate key for the flexfield.
   When business components are generated from this entity object, this alternate key will be extended to include all multiple-row context segments that implementors designate as a unique key when they configure the flexfield.

Note:
If this alternate key does not exist for an extensible flexfield, implementors will not be able to mark a segment in a multiple-row context as a unique key.

a. In the Application Navigator, double-click the entity object.

b. In the overview editor, click the General tab.

c. In the Alternate Keys section, click the Add icon.
d. In the Define Alternate Key dialog, type EFF_ALT_KEY in the Alternate Key Name field.

e. Select the primary key of the product table that the extensible flexfield extends and move it to the Selected list.

f. Select the contextCode attribute, move it to the Selected list, and click OK.

24.5.1.3 Creating and Configuring an Entity Object from the Translation Extension View

If you created a translation extension table and view for the flexfield usage, use the standard wizard to create an entity object from the translation extension view that is described in How to Create a Translation Extension View, but apply the changes described in the following procedure to support the extensible flexfield.

To create and configure an entity object from the extensible flexfield translation extension view:

1. On the Attributes page of the wizard, include only the following columns as attributes in your new entity object:
   - EFF_LINE_ID
   - Primary key columns of the product table
   - CONTEXT_CODE
   - CATEGORY_CODE

2. On the Attribute Settings page, do the following:
   - Set the EFF_LINE_ID attribute to be a primary key.
   - Set the CONTEXT_CODE attribute to be a discriminator, with a default value of 0.

3. On the Java page, confirm that the objectnameV1EOImpl entity object class to be generated extends the oracle.apps.fnd.applcore.oaext.model.OAEntityImpl class.

4. After creating the entity object, click the Attributes navigation tab and complete the following steps:
   a. Select the EFF_LINE_ID attribute and, on the Applications tab of the Property Inspector, set Application Unique ID to true to generate a globally unique id.
   b. On the UI Hints tab of the Property Inspector for each attribute, set the Display Hint property to Hide

5. On the Applications tab of the Property Inspector for the entity object General tab, set the OA Base Table property to the name of the view underlying this entity object.
24.6 Create and Configuring Extensible Flexfield View Objects

After you create and configure entity objects from the base extension table, create and configure flexfield view objects to support contexts, categories, and, optionally, searching.

24.6.1 How to Create and Configure Extensible Flexfield View Objects

Use the Create View Object wizard (not the Flexfield Business Components wizard) to create the following types of view objects:

- To support contexts for the extensible flexfield, create one view object from the base extension table entity object and, if the flexfield has a translation extension table, one view object from the translation extension view entity object.

  **Note:**
  No view objects are required from the translation table entity object.

- To support categories for the flexfield, create a view object from the product table entity object for which you are developing this extensible flexfield.

- To support searching, create a declarative SQL-based view object.

For more information about creating view objects, see the Defining SQL Queries Using View Objects chapter in the Developing Fusion Web Applications with Oracle Application Development Framework. For more information about declarative SQL-based view objects, see the How to Create Declarative SQL View Objects section in the Developing Fusion Web Applications with Oracle Application Development Framework.

Before you begin:

1. Create and configure entity objects from the base extension table, translation extension table, and view as described in How to Create and Configure Extensible Flexfield Entity Objects.

24.6.1.1 Creating and Configuring Context View Objects

To support contexts for an extensible flexfield usage, the usage must have a view object from its base extension table entity object. If you created a translation extension table for the usage, you must also create a view object from the translation extension view entity object.

To create and configure context view objects:

1. Use the Create View Object wizard to create the view objects from the base extension table entity object and, if you created a translation extension table for the usage, from the translation extension view entity object.

2. On the Java page for each view object, ensure that the view object classes to be generated extend base classes as follows:

   - `vo_nameImpl extends EFFViewObjectImpl`
   - `vo_nameRowImpl extends EFFViewRowImpl`
• `vo_nameDefImpl extends EFFViewDefImpl`

These base classes are in the `oracle.apps.fnd.applcore.oaext.model` package.

### 24.6.1.2 Creating and Configuring the Base Category View Object

To support categories for the flexfield, there must be a view object for the product table entity object for which you are developing the extensible flexfield.

**To create and configure the base category view object:**

Use the Create View Object wizard to create a view object from the product table for which you are implementing the extensible flexfield in the usual manner. For example, in Figure 24-2, the product table is the Parts table that stores the base attributes for the Parts entity, such as Part Number, Description, and Unit Cost.

This view object must include an attribute called `CategoryCode`, which is used to identify the category to which each row of data belongs. This attribute must be an entity-based attribute of type `VARCHAR2` with a maximum of 80 characters.

Set the `CategoryCode` attribute to be a discriminator, with a default value of 0.

You must ensure that the correct category code is returned for this attribute at runtime.

### 24.6.1.3 Create a Declarative SQL-Based View Object to Enable Searching

To enable searching or to enable business intelligence, you must create a declarative SQL-based view object for searching the product table for which you are implementing the extensible flexfield. You must include the same product table entity object that was used for the base category view object. For more information about the base category view object, see [Creating and Configuring the Base Category View Object](#).

For information about declarative SQL-based views objects, see the *How to Create Declarative SQL View Objects* section in the *Developing Fusion Web Applications with Oracle Application Development Framework*.

**To create a declarative SQL-based view object to enable searching:**

1. In the Application Navigator, right-click the project in which you want to create the view object and choose New.

2. In the New Gallery, expand Business Tier, select ADF Business Components and then View Object, and click OK.

3. On the Name page, enter a package name and a view object name. Keep the default setting **Updatable access through entity objects** enabled to indicate that you want this view object to manage data with its base entity object. Click Next.

4. On the Entity Objects page, select the entity object that was used for the base category view object and move it to the Selected tree.

   The view object can contain additional entity objects, but it must include the entity object that was used for the base category view object.

5. Click Next.
6. On the Attributes page, select all the attributes for which you want to enable search and move them to the Selected tree.
   You must include the CategoryCode attribute and the primary key attributes.

7. Select the other attributes to include in the view criteria, move them to the Selected tree, and click Next.

8. Mark the CategoryCode attribute as a discriminator with a default value of −1.
   a. On the Attribute Settings page, select CategoryCode from the Select Attribute dropdown list.
   b. Select Discriminator.
   c. In the Default Value field, type −1.

   Note:
   CategoryCode must be an entity object attribute. It cannot be a transient attribute.

9. Configure the attribute settings for the remaining attributes as required, and click Next.

10. On the Query page, select Declarative in the SQL Mode dropdown list if it is not already displayed. The wizard changes to declarative SQL mode.

11. On the Java page, select Generate View Object Class and select Generate View Object Definition Class.

12. Click Classes Extend.

13. In Object field in the Override Base Classes dialog, type oracle.apps.fnd.applcore.oaext.model.EFFCategoryViewObjectImpl.
    The EFFCategoryViewObjectImpl class adds the additional WHERE clause that provides security.

14. In the Definition field, type oracle.apps.fnd.applcore.oaext.model.FlexfieldBaseViewDefImpl, and click OK.

15. Complete the steps.
