Oracle® Big Data Connectors
User's Guide
Release 4 (4.6)
E77519-02

November 2016
Describes installation and use of Oracle Big Data Connectors: Oracle SQL Connector for Hadoop Distributed File System, Oracle Loader for Hadoop, Oracle Data Integrator, Oracle XQuery for Hadoop, and Oracle R Advanced Analytics for Hadoop.

### Part I  Setup

#### 1 Getting Started with Oracle Big Data Connectors

1.1 About Oracle Big Data Connectors ............................................................................................... 1-1
1.2 Big Data Concepts and Technologies............................................................................................ 1-2
  1.2.1 What is MapReduce? ................................................................................................................. 1-2
  1.2.2 What is Apache Hadoop? ......................................................................................................... 1-3
1.3 Downloading the Oracle Big Data Connectors Software .............................................................. 1-3
1.4 Oracle SQL Connector for Hadoop Distributed File System Setup .............................................. 1-4
  1.4.1 Software Requirements ........................................................................................................... 1-5
  1.4.2 Installing and Configuring a Hadoop Client on the Oracle Database System ................... 1-5
  1.4.3 Installing Oracle SQL Connector for HDFS ......................................................................... 1-7
  1.4.4 Granting User Privileges in Oracle Database ....................................................................... 1-11
  1.4.5 Setting Up User Accounts on the Oracle Database System ................................................ 1-12
  1.4.6 Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster ............................. 1-12
1.5 Oracle Loader for Hadoop Setup .................................................................................................... 1-13
  1.5.1 Software Requirements ........................................................................................................... 1-13
Part II  Oracle Database Connectors

2  Oracle SQL Connector for Hadoop Distributed File System

  2.1 About Oracle SQL Connector for HDFS................................................................. 2-1
  2.2 Getting Started With Oracle SQL Connector for HDFS .................................................. 2-2
  2.3 Configuring Your System for Oracle SQL Connector for HDFS ................................. 2-6
  2.4 Using Oracle SQL Connector for HDFS with Oracle Big Data Appliance and Oracle
     Exadata ..................................................................................................................... 2-7
  2.5 Using the ExternalTable Command-Line Tool............................................................ 2-7
     2.5.1 About ExternalTable .............................................................................................. 2-7
     2.5.2 ExternalTable Command-Line Tool Syntax ......................................................... 2-7
  2.6 Creating External Tables............................................................................................. 2-9
     2.6.1 Creating External Tables with the ExternalTable Tool ........................................ 2-9
     2.6.2 Creating External Tables from Data Pump Format Files ....................................... 2-10
     2.6.3 Creating External Tables from Hive Tables ............................................................ 2-12
     2.6.4 Creating External Tables from Delimited Text Files ............................................ 2-20
     2.6.5 Creating External Tables in SQL .......................................................................... 2-23
  2.7 Publishing the HDFS Data Paths ................................................................................. 2-23
     2.7.1 ExternalTable Syntax for Publish .......................................................................... 2-24
     2.7.2 ExternalTable Example for Publish ....................................................................... 2-24
  2.8 Exploring External Tables and Location Files ............................................................. 2-24
     2.8.1 ExternalTable Syntax for Describe ......................................................................... 2-25
     2.8.2 ExternalTable Example for Describe ..................................................................... 2-25
  2.9 Dropping Database Objects Created by Oracle SQL Connector for HDFS .................... 2-25
     2.9.1 ExternalTable Syntax for Drop .............................................................................. 2-25
     2.9.2 ExternalTable Example for Drop .......................................................................... 2-26
  2.10 More About External Tables Generated by the ExternalTable Tool ............................ 2-26

3 Oracle Loader for Hadoop

3.1 What Is Oracle Loader for Hadoop? | 3-1 |
3.2 About the Modes of Operation | 3-2 |
3.2.1 Online Database Mode | 3-2 |
3.2.2 Offline Database Mode | 3-4 |
3.3 Getting Started With Oracle Loader for Hadoop | 3-6 |
3.4 Creating the Target Table | 3-7 |
3.4.1 Supported Data Types for Target Tables | 3-7 |
3.4.2 SupportedPartitioning Strategies for Target Tables | 3-8 |
3.4.3 Compression | 3-8 |
3.5 Creating a Job Configuration File | 3-9 |
3.6 About the Target Table Metadata | 3-11 |
3.6.1 Providing the Connection Details for Online Database Mode | 3-11 |
3.6.2 Generating the Target Table Metadata for Offline Database Mode | 3-11 |
3.7 About Input Formats | 3-13 |
3.7.1 Delimited Text Input Format | 3-14 |
3.7.2 Complex Text Input Formats | 3-15 |
3.7.3 Hive Table Input Format | 3-15 |
3.7.4 Avro Input Format | 3-16 |
3.7.5 Oracle NoSQL Database Input Format | 3-17 |
3.7.6 Custom Input Formats | 3-17 |
3.8 Mapping Input Fields to Target Table Columns | 3-18 |
3.8.1 Automatic Mapping | 3-18 |
3.8.2 Manual Mapping | 3-19 |
3.8.3 Converting a Loader Map File | 3-19 |
3.9 About Output Formats | 3-21 |
3.9.1 JDBC Output Format | 3-21 |
3.9.2 Oracle OCI Direct Path Output Format | 3-22 |
3.9.3 Delimited Text Output Format | 3-22 |
3.9.4 Oracle Data Pump Output Format | 3-24 |
3.10 Running a Loader Job | 3-25 |
3.10.1 Specifying Hive Input Format JAR Files | 3-26 |
3.10.2 Specifying Oracle NoSQL Database Input Format JAR Files | 3-26 |
6 Oracle XQuery for Hadoop Reference

6.1.1 Avro File Adapter ......................................................... 6-1
  6.1.1.1 Built-in Functions for Reading Avro Files ......................... 6-2
  6.1.1.2 Custom Functions for Reading Avro Container Files .............. 6-3
  6.1.1.3 Custom Functions for Writing Avro Files ............................. 6-5
  6.1.1.4 Examples of Avro File Adapter Functions ............................ 6-6
  6.1.1.5 About Converting Values Between Avro and XML ................. 6-7

6.1.2 JSON File Adapter ......................................................... 6-17
  6.1.2.1 Built-in Functions for Reading JSON .................................... 6-17
  6.1.2.2 Custom Functions for Reading JSON Files ............................ 6-19
  6.1.2.3 Examples of JSON Functions .............................................. 6-19
  6.1.2.4 JSON File Adapter Configuration Properties ......................... 6-21
  6.1.2.5 About Converting JSON Data Formats to XML ...................... 6-22

6.1.3 Oracle Database Adapter ............................................ 6-23
  6.1.3.1 Custom Functions for Writing to Oracle Database .................. 6-23
  6.1.3.2 Examples of Oracle Database Adapter Functions .................... 6-27
  6.1.3.3 Oracle Loader for Hadoop Configuration Properties and Corresponding
          %oracle-property Annotations ..................................................... 6-29

6.1.4 Oracle NoSQL Database Adapter ..................................... 6-32
  6.1.4.1 Prerequisites for Using the Oracle NoSQL Database Adapter .......... 6-33
  6.1.4.2 Built-in Functions for Reading from and Writing to Oracle NoSQL Database
          using Table API ............................................................................. 6-38
  6.1.4.4 Built-in Functions for Reading from and Writing to Oracle NoSQL Database
          using Large Object API ................................................................. 6-40
  6.1.4.5 Custom Functions for Reading Values from Oracle NoSQL Database ........ 6-42
  6.1.4.6 Custom Functions for Retrieving Single Values from Oracle NoSQL Database .. 6-45
  6.1.4.7 Custom Functions for Reading Values from Oracle NoSQL Database using Table
          API ................................................................................................... 6-46
7 Oracle XML Extensions for Hive

7.1 What are the XML Extensions for Hive? ................................................................. 7-1
7.2 Using the Hive Extensions ......................................................................................... 7-2
7.3 About the Hive Functions ......................................................................................... 7-3
7.4 Creating XML Tables................................................................................................. 7-3
   7.4.1 Hive CREATE TABLE Syntax for XML Tables ......................................................... 7-3
   7.4.2 CREATE TABLE Configuration Properties .......................................................... 7-4
   7.4.3 CREATE TABLE Examples ..................................................................................... 7-5
7.5.1 Oracle XML Functions for Hive Reference ............................................................ 7-11
   7.5.1.1 Data Type Conversions ....................................................................................... 7-11
   7.5.1.2 Hive Access to External Files ............................................................................. 7-12
7.5.2 Online Documentation of Functions ......................................................................... 7-13
7.5.3 xml_exists................................................................................................................ 7-13
7.5.4 xml_query ............................................................................................................... 7-15
7.5.5 xml_query_as_primitive ......................................................................................... 7-17
7.5.6 xml_table ................................................................................................................. 7-20

Part IV Oracle R Advanced Analytics for Hadoop

8 Using Oracle R Advanced Analytics for Hadoop

8.1 About Oracle R Advanced Analytics for Hadoop .................................................... 8-1
   8.1.1 Oracle R Advanced Analytics for Hadoop Architecture ...................................... 8-2
   8.1.2 Oracle R Advanced Analytics for Hadoop packages and functions ................. 8-2
   8.1.3 Oracle R Advanced Analytics for Hadoop APIs ................................................. 8-3
   8.1.4 Inputs to Oracle R Advanced Analytics for Hadoop ......................................... 8-4
8.2 Access to HDFS Files................................................................................................. 8-5
8.3 Access to Apache Hive .............................................................................................. 8-5
   8.3.1 ORCH Functions for Hive .................................................................................... 8-5
   8.3.2 ORE Functions for Hive ....................................................................................... 8-5
   8.3.3 Generic R Functions Supported in Hive ............................................................... 8-6
   8.3.4 Support for Hive Data Types ............................................................................... 8-8
   8.3.5 Usage Notes for Hive Access ............................................................................... 8-9
   8.3.6 Example: Loading Hive Tables into Oracle R Advanced Analytics for Hadoop .... 8-10
8.4 Access to Oracle Database........................................................................................ 8-10
   8.4.1 Usage Notes for Oracle Database Access ............................................................. 8-11
   8.4.2 Scenario for Using Oracle R Advanced Analytics for Hadoop with Oracle R
       Enterprise ...................................................................................................................... 8-11
8.5 Oracle R Advanced Analytics for Hadoop Functions ............................................... 8-11
   8.5.1 Native Analytical Functions ............................................................................... 8-12
   8.5.2 Using the Hadoop Distributed File System (HDFS) ........................................... 8-13
   8.5.3 Using Apache Hive .............................................................................................. 8-13
   8.5.4 Using Aggregate Functions in Hive ..................................................................... 8-14
Part V Oracle DataSource for Apache Hadoop

9 Oracle DataSource for Apache Hadoop (OD4H)

A Additional Big Data Connector Resources

Index
Preface

The Oracle Big Data Connectors User’s Guide describes how to install and use Oracle Big Data Connectors:

- Oracle Loader for Hadoop
- Oracle SQL Connector for Hadoop Distributed File System
- Oracle XQuery for Hadoop
- Oracle R Advanced Analytics for Hadoop
- Oracle Datasource for Apache Hadoop
- Oracle Data Integrator\(^1\)

Audience

This document is intended for users of Oracle Big Data Connectors, including the following:

- Application developers
- Java programmers
- XQuery programmers
- System administrators
- Database administrators

Documentation Accessibility

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

Access to Oracle Support

Oracle customers that have purchased support have access to electronic support through My Oracle Support. For information, visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=info or visit http://www.oracle.com/pls/topic/lookup?ctx=acc&id=trs if you are hearing impaired.

\(^1\) Oracle Big Data Connectors includes a restricted use license for the Oracle Data Integrator when licensed on an Oracle Big Data Appliance. However, additional licensing is required for using it on other Hadoop clusters.
Related Documents

For more information, see the following documents:

- Oracle Loader for Hadoop Java API Reference
- Oracle Big Data Appliance Software User’s Guide

Text Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>

Syntax Conventions

The syntax is presented in a simple variation of Backus-Naur Form (BNF) that uses the following symbols and conventions:

<table>
<thead>
<tr>
<th>Symbol or Convention</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ ]</td>
<td>Brackets enclose optional items.</td>
</tr>
<tr>
<td>{ }</td>
<td>Braces enclose a choice of items, only one of which is required.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>...</td>
<td>Ellipses indicate that the preceding syntactic element can be repeated.</td>
</tr>
<tr>
<td>delimiters</td>
<td>Delimiters other than brackets, braces, and vertical bars must be entered as shown.</td>
</tr>
</tbody>
</table>

Changes in Oracle Big Data Connectors Release 4 (4.6)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.6).

The following table lists the software versions installed with Oracle Big Data Connectors 4.6:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.6.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.7.0</td>
</tr>
</tbody>
</table>
New and Enhanced Features

- **Oracle Datasource for Apache Hadoop (formerly Oracle Table Access for Apache Hadoop)**

  Oracle Datasource for Apache Hadoop (OD4H) is now part of the Oracle Big Data Connectors suite and is licensed for use at no additional cost.

  OD4H turns Oracle Database tables into Hadoop data sources (i.e., external tables), enabling direct, and consistent HiveQL/SparkSQL queries, as well as direct Hadoop API access.

  OD4H optimizes queries execution plans using predicate and projection pushdown as well as partition pruning. Oracle Database table access is performed in parallel using smart and secure connections (Kerberos, SSL, Oracle Wallet), regulated by both Hadoop (i.e., maximum concurrent tasks) and Oracle DBAs (i.e., max pool size).

- **Oracle Shell for Hadoop Loaders 1.1**

  Oracle Shell for Hadoop Loaders (OHSH) was introduced recently in Oracle Big Data Connectors 4.5. OHSH is an intuitive command line tool for data migration. You can set up resources to connect to Hive, HDFS or Oracle Database and access each of these data sources through OHSH’s uniform interface. Copy to Hadoop users can download OHSH from OTN.

  Changes in this release:

  - Interactive command history is now persistent across OHSH sessions.

  - Support for spooling of OHSH output to a text file. By default the spool file is `ohshspool.txt` in the directory where OHSH is invoked. Spooling can be turned on, off, or directed to a user-specified file as follows:
    
    ```
    ohsh>% spool on
    ohsh>% spool off
    ohsh>% set spool <filename>
    ```

  - New Hive CLI. Beeline is now the CLI for Hive resources. The syntax to create a Hive resource is now as follows.

    ```
    ohsh>% create hive resource <resource_id> connectionurl=<DQString>
    ```

    In this case, if the user has specified the `HIVE0_URL` variable in `bin/ohsh`, the command creates a `hive0` resource.

Change History for Previous Releases

The following are changes in previous versions of the product.
• Changes in Oracle Big Data Connectors Release 4 (4.5)
• Changes in Oracle Big Data Connectors Release 4 (4.4)
• Changes in Oracle Big Data Connectors Release 4 (4.3)
• Changes in Oracle Big Data Connectors Release 4 (4.2)
• Changes in Oracle Big Data Connectors Release 4 (4.1)
• Changes in Oracle Big Data Connectors Release 4 (4.0)

Changes in Oracle Big Data Connectors Release 4 (4.5)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.5).

The following table lists the software versions installed with Oracle Big Data Connectors 4.5:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.5.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.6.0</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.5.0</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.6.0</td>
</tr>
<tr>
<td>Oracle Data Integrator</td>
<td>12.2.1</td>
</tr>
</tbody>
</table>

New and Enhanced Features

• **Oracle Shell for Hadoop Loaders**

  Oracle Shell for Hadoop Loaders is a new user interface for Big Data Connectors. Is it not itself a Big Data Connector. Oracle Shell for Hadoop Loaders is a shell and command line that provides the user with a single environment for interacting with Big Data Connectors – Oracle Loader for Hadoop, Oracle SQL Connector for HDFS, and Copy to Hadoop. In addition to providing a single point of access, Oracle Shell for Hadoop Loaders can reduce some of the overhead involved in using the Connectors, because otherwise these products must be configured, managed, and run separately.

• **Oracle R Advanced Analytics for Hadoop (ORAAH) 2.6 Improvements**

  ORAAH 2.6 includes expanded support for predictive modeling algorithms, including integration of many Spark MLlib capabilities, as well as enhancements for existing custom Spark algorithms.

• **Oracle XQuery for Hadoop 4.5.0 Improvements**

  Adds support for W3C XQuery 3.0 including the try/catch expression, the switch expression, and standard functions and operators.
Changes in Oracle Big Data Connectors Release 4 (4.4)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.4).

This table shows the software versions installed with Oracle Big Data Connectors 4.4:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.4.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.5.0</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.2.1</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.4.0</td>
</tr>
<tr>
<td>Oracle Data Integrator</td>
<td>12.2.1</td>
</tr>
</tbody>
</table>

1 Oracle Loader for Hadoop 3.5 supports filtering of data loaded from Hive tables at the individual record level. Previously Hive data could only be filtered at the partition level.

New Features

Changes in Oracle Big Data Connectors Release 4 (4.3)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.3).

This table shows the software versions installed with Oracle Big Data Connectors 4.3:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.4.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.5.0</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.2.1</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.4.0</td>
</tr>
<tr>
<td>Oracle Data Integrator</td>
<td>12.1.3.0</td>
</tr>
</tbody>
</table>

1 Oracle Loader for Hadoop 3.5 supports filtering of data loaded from Hive tables at the individual record level. Previously Hive data could only be filtered at the partition level.

2 For information about requirements and instructions to set up and use Oracle Data Integrator, refer to Hadoop chapter of Oracle Fusion Middleware Application Adapters Guide for Oracle Data Integrator.

New Features

Changes in Oracle Big Data Connectors Release 4 (4.2)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.2).

This table shows the software versions installed with Oracle Big Data Connectors 4.2:
<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.3.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.4.0</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.2.0</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.4.0</td>
</tr>
<tr>
<td>Oracle Data Integrator</td>
<td>12.1.3.0</td>
</tr>
</tbody>
</table>

1 Added support for Oracle NoSQL Database Table API and Oracle NoSQL Database Large Object API. For working with Oracle NoSQL Database Table API functions, you must have Oracle NoSQL Database 3.1 or above.

2 For information about requirements and instructions to set up and use Oracle Data Integrator, refer to Hadoop chapter of Oracle Fusion Middleware Application Adapters Guide for Oracle Data Integrator.

### Changes in Oracle Big Data Connectors Release 4 (4.1)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.1).

This table shows the software versions installed with Oracle Big Data Connectors 4.1:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.3.0</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.3.0</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.2.0</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.4.0</td>
</tr>
<tr>
<td>Oracle Data Integrator</td>
<td>12.1.3.0</td>
</tr>
</tbody>
</table>

1 For information about requirements and instructions to set up and use Oracle Data Integrator, refer to Hadoop chapter of Oracle Fusion Middleware Application Adapters Guide for Oracle Data Integrator.

### Changes in Oracle Big Data Connectors Release 4 (4.0)

The following are changes in Oracle Big Data Connectors User’s Guide for Oracle Big Data Connectors Release 4 (4.0).

This table shows the software versions installed with Oracle Big Data Connectors 4.0:

<table>
<thead>
<tr>
<th>Connector</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle SQL Connector for HDFS</td>
<td>3.1</td>
</tr>
<tr>
<td>Oracle Loader for Hadoop</td>
<td>3.2</td>
</tr>
<tr>
<td>Oracle XQuery for Hadoop</td>
<td>4.0.1</td>
</tr>
<tr>
<td>Oracle R Advanced Analytics for Hadoop</td>
<td>2.4</td>
</tr>
<tr>
<td>Oracle Data Integrator Application Adapter for Hadoop</td>
<td>12.1.3.0</td>
</tr>
</tbody>
</table>

1 For information about requirements and instructions to set up and use Oracle Data Integrator, refer to Hadoop chapter of Oracle Fusion Middleware Application Adapters Guide for Oracle Data Integrator.
For information about requirements and instructions to set up and use Oracle Data Integrator Application Adapter for Hadoop, refer to Hadoop chapter of Oracle Fusion Middleware Application Adapters Guide for Oracle Data Integrator.
Part I contains the following chapter:

- Getting Started with Oracle Big Data Connectors
1 Getting Started with Oracle Big Data Connectors

This chapter describes the Oracle Big Data Connectors and provides installation instructions.

This chapter contains the following sections:

- About Oracle Big Data Connectors
- Big Data Concepts and Technologies
- Downloading the Oracle Big Data Connectors Software
- Oracle SQL Connector for Hadoop Distributed File System Setup
- Oracle Loader for Hadoop Setup
- Oracle Shell for Hadoop Loaders Setup
- Oracle XQuery for Hadoop Setup
- Oracle R Advanced Analytics for Hadoop Setup
- Oracle Data Integrator

1.1 About Oracle Big Data Connectors

Oracle Big Data Connectors facilitate access to data stored in an Apache Hadoop cluster. They can be licensed for use on either Oracle Big Data Appliance or a Hadoop cluster running on commodity hardware.

These are the connectors:

- **Oracle SQL Connector for Hadoop Distributed File System (previously Oracle Direct Connector for HDFS)**: Enables an Oracle external table to access data stored in Hadoop Distributed File System (HDFS) files or a table in Apache Hive. The data can remain in HDFS or the Hive table, or it can be loaded into an Oracle database.

- **Oracle Loader for Hadoop**: Provides an efficient and high-performance loader for fast movement of data from a Hadoop cluster into a table in an Oracle database. Oracle Loader for Hadoop prepartitions the data if necessary and transforms it into a database-ready format. It optionally sorts records by primary key or user-defined columns before loading the data or creating output files.

- **Oracle XQuery for Hadoop**: Runs transformations expressed in the XQuery language by translating them into a series of MapReduce jobs, which are executed in parallel on the Hadoop cluster. The input data can be located in a file system accessible through the Hadoop File System API, such as the Hadoop Distributed...
File System (HDFS), or stored in Oracle NoSQL Database. Oracle XQuery for Hadoop can write the transformation results to HDFS, Oracle NoSQL Database, Apache Solr, or Oracle Database. An additional XML processing capability is through XML Extensions for Hive.

- **Oracle R Advanced Analytics for Hadoop**: Provides a general computation framework, in which you can use the R language to write your custom logic as mappers or reducers. A collection of R packages provides predictive analytic techniques that run as MapReduce jobs. The code executes in a distributed, parallel manner using the available compute and storage resources on the Hadoop cluster. Oracle R Advanced Analytics for Hadoop includes interfaces to work with Apache Hive tables, the Apache Hadoop compute infrastructure, the local R environment, and Oracle database tables.

- **Oracle Data Integrator**: Extracts, loads, and transforms data from sources such as files and databases into Hadoop and from Hadoop into Oracle or third-party databases. Oracle Data Integrator provides a graphical user interface to utilize the native Hadoop tools and transformation engines such as Hive, HBase, Sqoop, Oracle Loader for Hadoop, and Oracle SQL Connector for Hadoop Distributed File System.

- **Oracle Datasource for Hadoop**: Provides direct, fast, parallel, secure and consistent access to master data in Oracle Database using Hive SQL, Spark SQL, as well as Hadoop APIs that support SerDes, HCatalog, InputFormat and StorageHandler.

Individual connectors may require that software components be installed in Oracle Database and either the Hadoop cluster or an external system set up as a Hadoop client for the cluster. Users may also need additional access privileges in Oracle Database. For details on integrating Oracle Database and Apache Hadoop visit the Certification Matrix.

### 1.2 Big Data Concepts and Technologies

Enterprises are seeing large amounts of data coming from multiple sources. Clickstream data in web logs, GPS tracking information, data from retail operations, sensor data, and multimedia streams are just a few examples of vast amounts of data that can be of tremendous value to an enterprise if analyzed. The unstructured and semi-structured information provided by raw data feeds is of little value in and of itself. The data must be processed to extract information of real value, which can then be stored and managed in the database. Analytics of this data along with the structured data in the database can provide new insights into the data and lead to substantial business benefits.

#### 1.2.1 What is MapReduce?

MapReduce is a parallel programming model for processing data on a distributed system. It can process vast amounts of data quickly and can scale linearly. It is particularly effective as a mechanism for batch processing of unstructured and semi-structured data. MapReduce abstracts lower level operations into computations over a set of keys and values.
A simplified definition of a MapReduce job is the successive alternation of two phases, the map phase and the reduce phase. Each map phase applies a transform function over each record in the input data to produce a set of records expressed as key-value pairs. The output from the map phase is input to the reduce phase. In the reduce phase, the map output records are sorted into key-value sets so that all records in a set have the same key value. A reducer function is applied to all the records in a set and a set of output records are produced as key-value pairs. The map phase is logically run in parallel over each record while the reduce phase is run in parallel over all key values.

Note:
Oracle Big Data Connectors 3.0 and later supports the Yet Another Resource Negotiator (YARN) implementation of MapReduce.

1.2.2 What is Apache Hadoop?

Apache Hadoop is the software framework for the development and deployment of data processing jobs based on the MapReduce programming model. At the core, Hadoop provides a reliable shared storage and analysis system. Analysis is provided by MapReduce. Storage is provided by the Hadoop Distributed File System (HDFS), a shared storage system designed for MapReduce jobs.

The Hadoop ecosystem includes several other projects including Apache Avro, a data serialization system that is used by Oracle Loader for Hadoop.

Cloudera’s Distribution including Apache Hadoop (CDH) is installed on Oracle Big Data Appliance. You can use Oracle Big Data Connectors on a Hadoop cluster running CDH or the equivalent Apache Hadoop components, as described in the setup instructions in this chapter.

See Also:

- For conceptual information about the Hadoop technologies, the following third-party publication:

- For information about Cloudera’s Distribution including Apache Hadoop (CDH), the Oracle Cloudera website at
  http://oracle.cloudera.com/

- For information about Apache Hadoop, the website at
  http://hadoop.apache.org/

1.3 Downloading the Oracle Big Data Connectors Software

You can download Oracle Big Data Connectors from Oracle Technology Network or Oracle Software Delivery Cloud. Note that the Oracle Software Delivery Cloud provides downloads for only the major releases of the Oracle Big Data Connectors.

---

The Oracle Technology Network provides supported releases. Both sites are cross-browser compatible.

To download from Oracle Technology Network:

2. Click the name of each connector to download a zip file containing the installation files.

To download from Oracle Software Delivery Cloud:

1. Go to https://edelivery.oracle.com/
2. Sign in and accept the Export Restrictions.
3. Type in the product name in the Product field and select the platform:
   - **Product**: Oracle Big Data Connectors
   - **Platform**: Linux x86-64
4. When Oracle Big Data Connectors appears in the Product List, click Continue. The most recent major release of Oracle Big Data Connectors will appear as the selected option.
5. To choose a different release, click Select Alternate Release and choose another package from the list. Click Continue.
6. Read the Terms and Conditions. Click the checkbox if you accept them, then click Continue.
7. On the download site, select the zip files individually or click Download All.

### 1.4 Oracle SQL Connector for Hadoop Distributed File System Setup

You install and configure Oracle SQL Connector for Hadoop Distributed File System (HDFS) on the system where Oracle Database runs. If Hive tables are used as the data source, then you must also install and run Oracle SQL Connector for HDFS on a Hadoop client where users access Hive.

Oracle SQL Connector for HDFS is installed already on Oracle Big Data Appliance if it was configured for Oracle Big Data Connectors. This installation supports users who connect directly to Oracle Big Data Appliance to run their jobs.

This section contains the following topics:

- Software Requirements
- Installing and Configuring a Hadoop Client on the Oracle Database System
- Installing Oracle SQL Connector for HDFS
- Granting User Privileges in Oracle Database
- Setting Up User Accounts on the Oracle Database System
- Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster
1.4.1 Software Requirements

Oracle SQL Connector for HDFS requires the following software:

**On the Hadoop cluster:**

- Cloudera's Distribution including Apache Hadoop version 5 (CDH5), or Apache Hadoop 2.2.0 to 2.6.0.
- Java Development Kit (JDK). Consult the distributor of your Hadoop software (Cloudera or Apache) for the recommended version.
- Hive 0.12.0, 0.13.0, 0.13.1 or 1.1.0 (required for Hive table access, otherwise optional)

This software is already installed on Oracle Big Data Appliance.

**On the Oracle Database system and Hadoop client systems:**

- Oracle Database 12c (12.1.0.2), Oracle Database 11g release 2 (11.2.0.4 or later).
- The same version of Hadoop as your Hadoop cluster: CDH5, or Apache Hadoop 2.2.0 - 2.6.0.
  
  If you have a secure Hadoop cluster configured with Kerberos, then the Hadoop client on the database system must be set up to access a secure cluster. See “Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster.”
- The same version of JDK as your Hadoop cluster.

**Note:** Oracle SQL Connector for HDFS requires a Hadoop client on the OS platform of the database system. This is straightforward for Linux systems. Platforms other than Linux require a tarball installation of the Hadoop client. Refer to this Oracle Blog post Connecting Hadoop with Oracle. See the following documents in My Oracle Support for details:

- Installation Instructions for Oracle SQL Connector for HDFS on Solaris (Doc ID 2101331.1)
- Using Oracle Big Data Connectors with Hadoop clusters on commodity hardware and Oracle Databases on commodity hardware (Doc ID 2101354.1)
- Configuring Oracle SQL Connector for HDFS for Oracle Database systems on IBM AIX (Doc ID 2152000.1)

1.4.2 Installing and Configuring a Hadoop Client on the Oracle Database System

Oracle SQL Connector for HDFS requires a Hadoop client on the Oracle Database System. The Hadoop installation can be minimally configured for Hadoop client use only. A complete installation of Hadoop is not required. The only parts of Hadoop needed for Oracle SQL Connector for HDFS are the Hadoop JAR files and the configuration files from the Hadoop installation.
**Note:** Even if there is a complete Hadoop installation on the Oracle Database system, do not start Hadoop on this system at any time. If Hadoop is running locally, then Oracle SQL Connector for HDFS attempts to connect to it instead of to the Hadoop cluster.

For Oracle RAC systems including Oracle Exadata Database Machine, you must install and configure Oracle SQL Connector for HDFS using identical paths on all systems running Oracle instances.

### Adding a Hadoop Client for use with Oracle Big Data Appliance

Oracle Big Data Appliance requires that you follow its own system-supported procedures for installing a Hadoop client. If your Hadoop system is an Oracle Big Data Appliance, see Providing Remote Access to CDH in the Oracle Big Data Appliance Software User’s Guide. This section describes how to install the CDH client, configure it for use in a Kerberos-secured or non-secured environment, and verify HDFS access.

### Adding a Hadoop Client for use with Other Hadoop Systems

For connections to Hadoop systems other than Oracle Big Data Appliance, download and install the Hadoop client provided by the distributor. For example, if the Oracle Database system requires a Hadoop client that can connect to a CDH system (one that is not an Oracle Big Data Appliance), you can use these steps to install the appropriate CDH client, configure it for use in either a Kerberos-secured or non-secured environment, and verify access to HDFS on the Hadoop cluster.

1. Log in to the database system running Oracle Database.
   - The account must have write privileges to the chosen installation path. Typically, an admin user account is sufficient. The account must also have login access to Cloudera Manager.

2. Install the CDH files and configure the client:

   **Note:** The CDH client version must be compatible with CDH version on the Hadoop system. Check that the version number segment in the filename (as in hadoop-2.6.0-cdh5.8.0.tar.gz) matches the version of the Hadoop cluster. This is the only tarball you will need from download page.

   - Copy the tarball to a permanent path of your choice on the database system and extract the files from the tarball.
     
     ```
     $ tar xzf hadoop-<version>.tar.gz
     ```

   - Set the HADOOP_PREFIX environment variable to this path and add HADOOP_PREFIX/bin to the PATH variable.
     
     ```
     $ export HADOOP_PREFIX=<install location>
     $ export PATH=${HADOOP_PREFIX}/bin:${PATH}
     ```

   - Click on the ‘hdfs’ service in Cloudera Manager, and select the action ‘Download Client Configuration’ to download the configuration files.

   - Extract the client configuration files to HADOOP_PREFIX/conf.
f. You may set the HADOOP_CONF_DIR environment variable to the path where you installed the client configuration files. (This is optional.)

```bash
export HADOOP_CONF_DIR=${HADOOP_PREFIX}/conf
```

3. Ensure that JAVA_HOME points to a JDK installation with the version required by the Hadoop installation.

4. If your cluster is secured with Kerberos, then configure the Oracle system to permit Kerberos authentication. (See Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster.)

5. Test HDFS access from the Oracle Database system:
   a. Use the Oracle Database account to log on to the system where Oracle Database is running.
   b. Open a Bash shell and enter this command:

   ```bash
   hdfs dfs -ls /user
   ```

   You should see the same list of directories that you see when you run the command directly on the Hadoop cluster. If not, then first ensure that the Hadoop cluster is up and running. If the problem persists, then you must correct the Hadoop client configuration so that Oracle Database has access to the Hadoop cluster file system.

6. For an Oracle RAC system, repeat this procedure for every Oracle Database instance.

To configure the Hadoop client to work with a Kerberos-Secured cluster, see olink:BIGUG-GUID-72E0B3C1-4871-44AB-A2BE-A0AC8E25BE72 in the Oracle Big Data Appliance Software User’s Guide.

### 1.4.3 Installing Oracle SQL Connector for HDFS

Follow this procedure to install Oracle SQL Connector for HDFS on the Oracle Database system.

In addition to this required installation on the database system, you can also install Oracle SQL Connector for HDFS on any system configured as a compatible Hadoop client. This will give you the option to create Oracle Database external tables from that node.

To install Oracle SQL Connector for HDFS on the Oracle Database system:

1. Download the zip file to a directory on the system where Oracle Database runs.

2. Unpack the content of `oraosch-<version>.zip`.

   ```bash
   $ unzip oraosch-<version>.zip
   Archive:  oraosch-<version>.zip
   extracting: orahdfs-<version>.zip
   inflating: README.txt
   ```

3. Unpack `orahdfs-<version>.zip` into a permanent directory:

The unzipped files have the structure shown in Example 1-1.

4. Open the `orahdfs-<version>/bin/hdfs_stream` Bash shell script in a text editor, and make the changes indicated by the comments in the script, if necessary. The `hdfs_stream` script does not inherit any environment variable settings, and so they are set in the script if Oracle SQL Connector for HDFS needs them:

   - **PATH**: If the `hadoop` script is not in `/usr/bin/bin` (the path initially set in `hdfs_stream`), then add the Hadoop bin directory, such as `/usr/lib/hadoop/bin`.
   
   - **JAVA_HOME**: If Hadoop does not detect Java, then set this variable to the Java installation directory. For example, `/usr/bin/java`.

   See the comments in the script for more information about these environment variables.

   The `hdfs_stream` script is the preprocessor for the Oracle Database external table created by Oracle SQL Connector for HDFS.

5. If your cluster is secured with Kerberos, then obtain a Kerberos ticket:

   `> kinit`
   `> password`

6. Run `hdfs_stream` from the Oracle SQL Connector for HDFS /bin directory. You should see this usage information:

   `$ ./hdfs_stream`
   Usage: hdfs_stream locationFile

   If you do not see the usage statement, then ensure that the operating system user that Oracle Database is running under (such as `oracle`) has the following permissions:

   - **Read and execute permissions on the hdfs_stream script**:
   
     `$ ls -l OSCH_HOME/bin/hdfs_stream`
     `-rwxr-xr-x 1 oracle oinstall Nov 27 15:51 hdfs_stream`
   
   - **Read permission on orahdfs.jar**.
$ ls -l OSCH_HOME/jlib/orahdfs.jar
-rwxr-xr-x 1 oracle oinstall Nov 27 15:51 orahdfs.jar

If you do not see these permissions, then enter a chmod command to fix them, for example:

$ chmod 755 OSCH_HOME/bin/hdfs_stream

In the previous commands, OSCH_HOME represents the Oracle SQL Connector for HDFS home directory.

7. For an Oracle RAC system, repeat the previous steps for every Oracle instance, using identical path locations.

8. Log in to Oracle Database and create a database directory for the orahdfs-
<version>/bin directory where hdfs_stream resides. For Oracle RAC systems, this directory must be accessible by all Oracle instances through identical paths.

   In this example, Oracle SQL Connector for HDFS is installed in /etc:

   SQL> CREATE OR REPLACE DIRECTORY osch_bin_path AS '/etc/orahdfs-<version>/bin';

9. To support access to Hive tables:

   a. Ensure that the system is configured as a Hive client.

   b. Add the Hive JAR files and the Hive conf directory to the
      HADOOP_CLASSPATH environment variable. To avoid JAR conflicts among
      the various Hadoop products, Oracle recommends that you set
      HADOOP_CLASSPATH in your local shell initialization script instead of making
      a global change to HADOOP_CLASSPATH. If there are multiple JAR file paths
      in HADOOP_CLASSPATH ensure that the JARs for the current product are
      listed first.

The unzipped files have the structure shown in Example 1-1.

Figure 1-1 illustrates shows the flow of data and the components locations.
Figure 1-1 Oracle SQL Connector for HDFS Installation for HDFS and Data Pump Files
Example 1-1 Structure of the orahdfs Directory

ora$hdfs-<version>
  bin/
    hdfs_stream
  doc/
    README.txt
  examples/
    sql/
      mkhive_unionall_view.sql
  jlib/
    ojdbc7.jar
    oraloader.jar
    ora-hadoop-common.jar
    oraclepki.jar
    orahdfs.jar
    osdt_cert.jar
    osdt_core.jar
  log/

1.4.4 Granting User Privileges in Oracle Database

Oracle Database users require these privileges when using Oracle SQL Connector for HDFS to create external tables:

- CREATE SESSION
- CREATE TABLE
- CREATE VIEW
- EXECUTE on the UTL_FILE PL/SQL package
- READ and EXECUTE on the OSCH_BIN_PATH directory created during the installation of Oracle SQL Connector for HDFS. Do not grant write access to anyone. Grant EXECUTE only to those who intend to use Oracle SQL Connector for HDFS.
- READ and WRITE on a database directory for storing external tables, or the CREATE ANY DIRECTORY system privilege. For Oracle RAC systems, this directory must be on a shared disk that all Oracle instances can access.
- A tablespace and quota for copying data into the Oracle database. Optional. Example 1-2 shows the SQL commands granting these privileges to HDFSUSER.

Note:
To query an external table that uses Oracle SQL Connector for HDFS, users only need the SELECT privilege on the table.

Example 1-2 Granting Users Access to Oracle SQL Connector for HDFS

CONNECT / AS sysdba;
CREATE USER hdfsuser IDENTIFIED BY password
    DEFAULT TABLESPACE hdfsdata
    QUOTA UNLIMITED ON hdfsdata;
GRANT CREATE SESSION, CREATE TABLE, CREATE VIEW TO hdfsuser;
GRANT EXECUTE ON sys.utl_file TO hdfsuser;
GRANT READ, EXECUTE ON DIRECTORY osch_bin_path TO hdfsuser;
GRANT READ, WRITE ON DIRECTORY external_table_dir TO hdfsuser;

1.4.5 Setting Up User Accounts on the Oracle Database System

To create external tables for HDFS and Data Pump format files, users can log in to either the Oracle Database system or another system set up as a Hadoop client.

You can set up an account on these systems the same as you would for any other operating system user. HADOOP_CLASSPATH must include path/orahdfs-<version>/jlib/*. You can add this setting to the shell profile as part of this installation procedure, or users can set it themselves. The following example alters HADOOP_CLASSPATH in the Bash shell where Oracle SQL Connector for HDFS is installed in /usr/bin:

```bash
export HADOOP_CLASSPATH="/etc/orahdfs-<version>/jlib/*:$HADOOP_CLASSPATH"
```

1.4.6 Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster

When users access an external table that was created using Oracle SQL Connector for HDFS, the external table acts like a Hadoop client running on the system where the Oracle database is running. It uses the identity of the operating system user where Oracle is installed.

A secure Hadoop cluster has Kerberos installed and configured to authenticate client activity. You must configure Oracle SQL Connector for HDFS for use with a Hadoop cluster secured by Kerberos.

For a user to authenticate using kinit:

- A Hadoop administrator must register the operating system user (such as oracle) and password in the Key Distribution Center (KDC) for the cluster.

- A system administrator for the Oracle Database system must configure /etc/krb5.conf and add a domain definition that refers to the KDC managed by the secure cluster.

These steps enable the operating system user to authenticate with the kinit utility before submitting Oracle SQL Connector for HDFS jobs. The kinit utility typically uses a Kerberos keytab file for authentication without an interactive prompt for a password.

The system should run kinit on a regular basis, before letting the Kerberos ticket expire, to enable Oracle SQL Connector for HDFS to authenticate transparently. Use cron or a similar utility to run kinit. For example, if Kerberos tickets expire every two weeks, then set up a cron job to renew the ticket weekly.

Be sure to schedule the cron job to run when Oracle SQL Connector for HDFS is not actively being used.

Do not call kinit within the Oracle SQL Connector for HDFS preprocessor script (hdfs_stream), because it could trigger a high volume of concurrent calls to kinit and create internal Kerberos caching errors.
1.5 Oracle Loader for Hadoop Setup

Follow the instructions in these sections for setting up Oracle Loader for Hadoop:

- **Software Requirements**
- **Installing Oracle Loader for Hadoop**
- **Providing Support for Offline Database Mode**
- **Using Oracle Loader for Hadoop on a Secure Hadoop Cluster**

1.5.1 Software Requirements

Oracle Loader for Hadoop requires the following software:

- A target database system running one of the following:
  - Oracle Database 12c (12.1.0.2)
  - Oracle Database 11g release 2 (11.2.0.4)
- Cloudera's Distribution including Apache Hadoop version 5 (CDH5), or Apache Hadoop 2.2.0 to 2.6.0.
- Apache Hive 0.12.0, 0.13.0, 0.13.1 or 1.1.0 if you are loading data from Hive tables.

1.5.2 Installing Oracle Loader for Hadoop

Oracle Loader for Hadoop is packaged with the Oracle Database 12c (12.1.0.2) client libraries and Oracle Instant Client libraries for connecting to Oracle Database 11.2.0.4 or 12.1.0.2.

**Note:**

The system where you install Oracle Loader for Hadoop requires the same resources that an Oracle Client requires. For information about Oracle Client requirements included with Oracle Database 12c Release 1 (12.1), refer to Database Client Installation Guide.

To install Oracle Loader for Hadoop:

1. Unpack the content of oraloader-<version>.x86_64.zip into a directory on your Hadoop cluster or on a system configured as a Hadoop client.

2. Unzip oraloader-<version>-h2.x86_64.zip into a directory on your Hadoop cluster.
A directory named `oraloader-<version>-h2` is created with the following subdirectories:

`doc`
`jlib`
`lib`
`examples`

3. Create a variable named `OLH_HOME` and set it to the installation directory.

4. Add the following paths to the `HADOOP_CLASSPATH` variable:

- For all installations:
  
  `$OLH_HOME/jlib/*`

  When using OLH, `$OLH_HOME/jlib/*` should always be listed first in `HADOOP_CLASSPATH`. Alternatively, you can avoid conflict with other scripts by defining `HADOOP_CLASSPATH` within a script that uses it.

- To support data loads from Hive tables:
  
  `/usr/lib/hive/lib/*`
  `/etc/hive/conf`

  See "oracle.hadoop.xquery.lib.share."

- To read data from Oracle NoSQL Database Release 2:
  
  `$KVHOME/lib/kvstore.jar`

### 1.5.3 Providing Support for Offline Database Mode

In a typical installation, Oracle Loader for Hadoop can connect to the Oracle Database system from the Hadoop cluster or a Hadoop client. If this connection is impossible—for example, the systems are located on distinct networks—then you can use Oracle Loader for Hadoop in offline database mode. See “About the Modes of Operation.”

To support offline database mode, you must install Oracle Loader for Hadoop on two systems:

- The Hadoop cluster or a system set up as a Hadoop client, as described in “Installing Oracle Loader for Hadoop.”
- The Oracle Database system or a system with network access to Oracle Database, as described in the following procedure.

To support Oracle Loader for Hadoop in offline database mode:

1. Unpack the content of `oraloader-<version>.zip` into a directory on the Oracle Database system or a system with network access to Oracle Database. You must use the same version of the software as you installed on the Hadoop cluster.

2. Unzip `oraloader-<version>-h2.x86_64.zip`.

3. Create a variable named `OLH_HOME` and set it to the installation directory. This example uses the Bash shell syntax:

   `$ export OLH_HOME="/usr/bin/oraloader-<version>-h2/"`

4. Add the Oracle Loader for Hadoop JAR files to the `HADOOP_CLASSPATH` environment variable. If there are other JAR file paths in `HADOOP_CLASSPATH`,
ensure that the Oracle Loader for Hadoop JAR file path is listed first when using Oracle Loader for Hadoop. This example uses the Bash shell syntax:

```bash
$ export HADOOP_CLASSPATH=$OLH_HOME/jlib/*:$HADOOP_CLASSPATH
```

### 1.5.4 Using Oracle Loader for Hadoop on a Secure Hadoop Cluster

A secure Hadoop cluster has Kerberos installed and configured to authenticate client activity. An operating system user must be authenticated before initiating an Oracle Loader for Hadoop job to run on a secure Hadoop cluster. For authentication, the user must log in to the operating system where the job will be submitted and use the standard Kerberos `kinit` utility.

For a user to authenticate using `kinit`:

- A Hadoop administrator must register the operating system user and password in the Key Distribution Center (KDC) for the cluster.

- A system administrator for the client system, where the operating system user will initiate an Oracle Loader for Hadoop job, must configure `/etc/krb5.conf` and add a domain definition that refers to the KDC managed by the secure cluster.

Typically, the `kinit` utility obtains an authentication ticket that lasts several days. Subsequent Oracle Loader for Hadoop jobs authenticate transparently using the unexpired ticket.

---

**Note:**

Oracle Big Data Appliance configures Kerberos security automatically as a configuration option. For details about setting up client systems for a secure Oracle Big Data Appliance cluster, see *Oracle Big Data Appliance Software User’s Guide*.

---

### 1.6 Oracle Shell for Hadoop Loaders Setup

Oracle Shell for Hadoop Loaders (OHSH) is integrated with Copy To Hadoop. It provides a set of declarative commands you can use to copy contents from an Oracle Database table to a Hive table. It also integrates with Oracle Big Data Connectors to copy contents from Hadoop and Hive to Oracle tables using Oracle Loader for Hadoop (OLH) and Oracle SQL Connector for Hadoop Distributed File System (OSCH).

Oracle Shell for Hadoop Loaders (OHSH) can work with OLH and OSCH on either a Hadoop client or edge node, a Hadoop node, or on the Oracle Database server.

**Prerequisites**

OHSH requires the installation of either Copy To Hadoop or the Oracle Big Data Connectors.

Table 1-1 identifies OHSH dependencies that are not present by default on the different supported platforms. You need to add these if they do not exist.
### Table 1-1 Prerequisites for Running OHSH

<table>
<thead>
<tr>
<th>Environment</th>
<th>Prerequisites for OHSH</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hadoop clients and Hadoop nodes</td>
<td>• SQL*Plus&lt;br&gt;• OLH and OSCH&lt;br&gt;• JDBC access to Oracle Database</td>
</tr>
<tr>
<td>Oracle Database servers</td>
<td>• Hadoop and Hive libraries installed and configured.&lt;br&gt;• OLH and OSCH&lt;br&gt;• JDBC access to Oracle Database</td>
</tr>
</tbody>
</table>

OHSH can be set up in any of the environments above (Hadoop client, Hadoop node, or Oracle Database Server). You need to install the software in only one of these environments.

### Installing Oracle Shell for Hadoop Loaders

Follow these instructions for setting up Oracle Shell for Hadoop Loaders. The instructions are applicable to set up on a Hadoop client, an edge node, a Hadoop node, or, on the Oracle Database server.

1. Extract the contents of ohsh-<version>.zip to a directory on the database server. The extraction creates a directory named ohsh-<version> with a README.txt file and the following subdirectories:
   - README.txt
   - /bin
   - /conf
   - /doc
   - /examples
   - /jlib

2. Follow the instructions contained in README.txt to configure Oracle Shell for Hadoop Loaders.

### 1.7 Oracle XQuery for Hadoop Setup

You install and configure Oracle XQuery for Hadoop on the Hadoop cluster. If you are using Oracle Big Data Appliance, then the software is already installed.

The following topics describe the software installation:

- **Software Requirements**
- **Installing Oracle XQuery for Hadoop**
- **Troubleshooting the File Paths**
- **Configuring Oozie for the Oracle XQuery for Hadoop Action**

#### 1.7.1 Software Requirements

Oracle Big Data Appliance Release 4.3 and later releases meet the requirements below. However, if you are installing Oracle XQuery for Hadoop on a third-party cluster, then you must ensure that these components are installed.
• Java 7.x or 6.x
• Cloudera's Distribution including Apache Hadoop Version 4.1.2 and above (including CDH 5.x)
• Oracle NoSQL Database 3.x or 2.x to support reading and writing to Oracle NoSQL Database
• Oracle Loader for Hadoop 3.5.0 to support writing tables in Oracle databases

1.7.2 Installing Oracle XQuery for Hadoop

Take the following steps to install Oracle XQuery for Hadoop.

To install Oracle XQuery for Hadoop:

1. Unpack the contents of oxh-<version>.zip into the installation directory:

   $ unzip oxh-4.2.0-cdh-5.0.0.zip
   Archive: oxh-4.2.0-cdh-5.0.0.zip
   creating: oxh-4.2.0-cdh5.0.0/
   creating: oxh-4.2.0-cdh5.0.0/lib/
   creating: oxh-4.2.0-cdh5.0.0/oozie/
   creating: oxh-4.2.0-cdh5.0.0/oozie/lib/
   inflating: oxh-4.2.0-cdh5.0.0/lib/ant-launcher.jar
   inflating: oxh-4.2.0-cdh5.0.0/lib/ant.jar
   .
   .
   .

   You can now run Oracle XQuery for Hadoop.

2. For the fastest execution time, copy the libraries into the Hadoop distributed cache:
   a. Copy all Oracle XQuery for Hadoop and third-party libraries into an HDFS directory. To use the -exportliboozie option to copy the files, see “Oracle XQuery for Hadoop Options”. Alternatively, you can copy the libraries manually using the HDFS command line interface.

      If you use Oozie, then use the same folder for all files. See “Configuring Oozie for the Oracle XQuery for Hadoop Action”

   b. Set the oracle.hadoop.xquery.lib.share property or use the -sharelib option on the command line to identify the directory for the Hadoop distributed cache.

3. To support data loads into Oracle Database, install Oracle Loader for Hadoop:
   a. Unpack the content of oraloader-<version>.x86_64.zip into a directory on your Hadoop cluster or on a system configured as a Hadoop client. This archive contains an archive and a README file.

   b. Unzip the archive into a directory on your Hadoop cluster:

      unzip oraloader-<version>-h2.x86_64.zip

      A directory named oraloader-<version>-h2 is created with the following subdirectories:
c. Create an environment variable named OLH_HOME and set it to the installation directory. Do not set HADOOP_CLASSPATH.

4. To support data loads into Oracle NoSQL Database, install it, and then set an environment variable named KVHOME to the Oracle NoSQL Database installation directory.

Note:
Do not add NoSQL Database jar files to a HADOOP_CLASSPATH.

5. To support indexing by Apache Solr:

a. Ensure that Solr is installed and configured in your Hadoop cluster. Solr is included in Cloudera Search, which is installed automatically on Oracle Big Data Appliance.

b. Create a collection in your Solr installation into which you will load documents. To create a collection, use the solrctl utility.

See Also:

c. Configure Oracle XQuery for Hadoop to use your Solr installation by setting the OXH_SOLR_MR_HOME environment variable to the local directory containing search-mr-<version>.jar and search-mr-<version>-job.jar. For example:

   $ export OXH_SOLR_MR_HOME="/usr/lib/solr/contrib/mr"

Note:
Configure Oracle XQuery for Hadoop and set the OXH_SOLR_MR_HOME environment variable to the local directory before using Apache Tika adapter as well.

1.7.3 Troubleshooting the File Paths

If Oracle XQuery for Hadoop fails to find its own or third-party libraries when running queries, then first ensure that the environment variables are set, as described in “Installing Oracle XQuery for Hadoop.”
Note:
The HADOOP_CLASSPATH environment variable or -libjars command line option must not contain either an OXH or third-party library.

If they are set correctly, then you may need to edit lib/oxh-lib.xml. This file identifies the location of Oracle XQuery for Hadoop system JAR files and other libraries, such as Avro, Oracle Loader for Hadoop, and Oracle NoSQL Database.

If necessary, you can reference environment variables in this file as $\{{\text{env.}\text{variable}}\}, such as $\{{\text{env.OLH\_HOME}}\}. You can also reference Hadoop properties as $\{{\text{property}}\}, such as $\{{\text{mapred.output.dir}}\}.

1.7.4 Configuring Oozie for the Oracle XQuery for Hadoop Action

You can use Apache Oozie workflows to run your queries, as described in “Running Queries from Apache Oozie”. The software is already installed and configured on Oracle Big Data Appliance.

For other Hadoop clusters, you must first configure Oozie to use the Oracle XQuery for Hadoop action. These are the general steps to install the Oracle XQuery for Hadoop action:

1. Modify the Oozie configuration. If you run CDH on third-party hardware, then use Cloudera Manager to change the Oozie server configuration. For other Hadoop installations, edit oozie-site.htm.

   • Add oracle.hadoop.xquery.oozie.OXHActionExecutor to the value of the oozie.service.ActionService.executor.ext.classes property.

   • Add oxh-action-v1.xsd to the value of the oozie.service.SchemaService.wf.ext.schemas property.

2. Add oxh-oozie.jar to the Oozie server class path. For example, in a CDH5 installation, copy oxh-oozie.jar to /var/lib/oozie on the server.

3. Add all Oracle XQuery for Hadoop dependencies to the Oozie shared library in a subdirectory named oxh. You can use the CLI -exportliboozie option. See “Oracle XQuery for Hadoop Options”.

4. Restart Oozie for the changes to take effect.

The specific steps depend on your Oozie installation, such as whether Oozie is already installed and which version you are using.

1.8 Oracle R Advanced Analytics for Hadoop Setup

An overview of Oracle R Advanced Analytics for Hadoop (ORAAH) is provided in Part IV of this guide.

Release notes, installation instructions, comprehensive reference material, and a list of changes in the current release are published separately on the Oracle Technology Network:

• Oracle R Installation Guide.

• Oracle R Release Notes
1.8.1 Installing the Software on Hadoop

Oracle Big Data Appliance supports Oracle R Advanced Analytics for Hadoop without any additional software installation or configuration. However, to use Oracle R Advanced Analytics for Hadoop on a third-party Hadoop cluster, you must create the necessary environment.

1.8.1.1 Software Requirements for a Third-Party Hadoop Cluster

You must install several software components on a third-party Hadoop cluster to support Oracle R Advanced Analytics for Hadoop.

Install these components on third-party servers:

- Cloudera’s Distribution including Apache Hadoop version 4 (CDH5) or Apache Hadoop 0.20.2+923.479 or later.
  Complete the instructions provided by the distributor.

- Apache Hive 0.10.0+67 or later
  See “Installing Hive on a Third-Party Hadoop Cluster.”

- Sqoop 1.3.0+5.95 or later for the execution of functions that connect to Oracle Database. Oracle R Advanced Analytics for Hadoop does not require Sqoop to install or load.
  See “Installing Sqoop on a Third-Party Hadoop Cluster.”

- Mahout for the execution of (orch_lmf_mahout_als.R).

  Complete the instructions provided at the download site at http://www.oracle.com/technetwork/java/javase/downloads/index.html

- Oracle R Distribution 3.0.1 with all base libraries on all nodes in the Hadoop cluster.
  See “Installing R on a Third-Party Hadoop Cluster.”

- The ORCH package on each R engine, which must exist on every node of the Hadoop cluster.
  See “Installing the ORCH Package on a Third-Party Hadoop Cluster”.

- Oracle Loader for Hadoop to support the OLH driver (optional).
  See “Oracle Loader for Hadoop Setup.”
Note:
Do not set HADOOP_HOME on the Hadoop cluster. CDH5 does not need it, and it interferes with Oracle R Advanced Analytics for Hadoop. If you must set HADOOP_HOME for another application, then also set HADOOP_LIBEXEC_DIR in the /etc/bashrc file. For example:

export HADOOP_LIBEXEC_DIR=/usr/lib/hadoop/libexec

1.8.1.2 Installing Sqoop on a Third-Party Hadoop Cluster

Sqoop provides a SQL-like interface to Hadoop, which is a Java-based environment. Oracle R Advanced Analytics for Hadoop uses Sqoop for access to Oracle Database.

Note:
Sqoop is required even when using Oracle Loader for Hadoop as a driver for loading data into Oracle Database. Sqoop performs additional functions, such as copying data from a database to HDFS and sending free-form queries to a database. The driver also uses Sqoop to perform operations that Oracle Loader for Hadoop does not support.

To install and configure Sqoop for use with Oracle Database:

1. Install Sqoop if it is not already installed on the server.
   For Cloudera’s Distribution including Apache Hadoop, see the Sqoop installation instructions in the CDH Installation Guide at http://oracle.cloudera.com/

2. Download the appropriate Java Database Connectivity (JDBC) driver for Oracle Database from Oracle Technology Network at http://www.oracle.com/technetwork/database/features/jdbc/index-091264.html

3. Copy the driver JAR file to $SQOOP_HOME/lib, which is a directory such as /usr/lib/sqoop/lib.

4. Provide Sqoop with the connection string to Oracle Database.
   $ sqoop import --connect jdbc_connection_string
   For example, sqoop import --connect jdbc:oracle:thin@myhost:1521/orcl.

1.8.1.3 Installing Hive on a Third-Party Hadoop Cluster

Hive provides an alternative storage and retrieval mechanism to HDFS files through a querying language called HiveQL. Oracle R Advanced Analytics for Hadoop uses the data preparation and analysis features of HiveQL, while enabling you to use R language constructs.

To install Hive:
1. Follow the instructions provided by the distributor (Cloudera or Apache) for installing Hive.

2. Verify that the installation is working correctly:

3. `$ hive -H usage: hive -d,--define <key=value> Variable subsitution to apply to hive commands. e.g. -d A=B or --define A=B . . .`

4. If the command fails or you see warnings in the output, then fix the Hive installation.

**1.8.1.4 Installing R on a Hadoop Client**

You can download R 2.13.2 and get the installation instructions from the Oracle R Distribution website at

http://oss.oracle.com/ORD/

When you are done, ensure that users have the necessary permissions to connect to the Linux server and run R.

You may also want to install RStudio Server to facilitate access by R users. See the RStudio website at

http://rstudio.org/

**1.8.1.5 Installing R on a Third-Party Hadoop Cluster**

You can download Oracle R Distribution 3.0.1 and get the installation instructions from the website at

**1.8.1.6 Installing the ORCH Package on a Third-Party Hadoop Cluster**

ORCH is the name of the Oracle R Advanced Analytics for Hadoop package.

To install the ORCH package:

1. Log in as root to the first node of the cluster.

2. Set the environment variables for the supporting software:

   ```
   $ export JAVA_HOME="/usr/lib/jdk7"
   $ export R_HOME="/usr/lib64/R"
   $ export SQOOP_HOME "/usr/lib/sqoop"
   ```

3. Unzip the downloaded file:

   ```
   $ unzip orch-<version>.zip
   $ unzip orch-linux-x86_64-<version>.zip
   ```

4. Change to the new directory:

   ```
   $ cd ORCH<version>
   ```
5. Install the packages in the exact order shown here:

   R --vanilla CMD INSTALL OREbase_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL OREstats_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL OREmodels_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL OREserver_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL ORCHcore_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL ORCHstats_<version>_R_x86_64-unknown-linux-gnu.tar.gz
   R --vanilla CMD INSTALL ORCH_<version>_R_x86_64-unknown-linux-gnu.tar.gz

6. You must also install these packages on all other nodes of the cluster:
   - OREbase
   - OREmodels
   - OREserver
   - OREstats

   The following examples use the dcli utility, which is available on Oracle Big Data Appliance but not on third-party clusters, to copy and install the OREserver package:

   $ dcli -C -f OREserver_<version>_R_x86_64-unknown-linux-gnu.tar.gz -d /tmp/
   OREserver_<version>_R_x86_64-unknown-linux-gnu.tar.gz

   $ dcli -C " R --vanilla CMD INSTALL /tmp/OREserver_<version>_R_x86_64-unknown-
   linux-gnu.tar.gz"

1.8.2 Installing Additional R Packages

Your Hadoop cluster must have libpng-devel installed on every node. If you are using a cluster running on commodity hardware, then you can follow the same basic procedures. However, you cannot use the dcli utility to replicate the commands across all nodes. See Oracle Big Data Appliance Owner’s Guide for the syntax of the dcli utility.

To install libpng-devel:

1. Log in as root to any node in your Hadoop cluster.
2. Check whether libpng-devel is already installed:

   # dcli rpm -qi libpng-devel
   bdalnode01: package libpng-devel is not installed
   bdalnode02: package libpng-devel is not installed
   .
   .
   .

   If the package is already installed on all servers, then you can skip this procedure.

3. If you need a proxy server to go outside a firewall, then set the HTTP_PROXY environment variable. This example uses dcli, which is available only on Oracle Big Data Appliance:

   # dcli export HTTP_PROXY="http://proxy.example.com"

4. Change to the yum directory:

   # cd /etc/yum.repos.d
5. Download and configure the appropriate configuration file for your version of Linux:

For Enterprise Linux 5 (EL5):

a. Download the yum configuration file:
   
   ```bash
   # wget http://public-yum.oracle.com/public-yum-el5.repo
   ```

b. Open `public-yum-el5.repo` in a text editor and make these changes:
   
   Under `el5_latest`, set `enabled=1`
   Under `el5_addons`, set `enabled=1`

   ```bash
   ```

c. Save your changes and exit.

d. Copy the file to the other Oracle Big Data Appliance servers:
   
   ```bash
   # dcli -d /etc/yum.repos.d -f public-yum-el5.repo
   ```

For Oracle Linux 6 (OL6):

a. Download the yum configuration file:
   
   ```bash
   ```

b. Open `public-yum-ol6.repo` in a text editor and make these changes:
   
   Under `ol6_latest`, set `enabled=1`
   Under `ol6_addons`, set `enabled=1`

   ```bash
   ```

c. Save your changes and exit.

d. Copy the file to the other Oracle Big Data Appliance servers:
   
   ```bash
   # dcli -d /etc/yum.repos.d -f public-yum-ol6.repo
   ```

6. Install the package on all servers:

   ```bash
   # dcli yum -y install libpng-devel
   ```

   bdalnode01: Running Transaction
   bdalnode01: Installing     : libpng-devel                    1/2
   bdalnode01: Installing     : libpng-devel                    2/2

   bdalnode01: Installed:
   bdalnode01: libpng-devel.i386 2:1.2.10-17.el5_8  ibpng-devel.x86_64
   2:1.2.10-17.el5_8

   bdalnode01: Complete!
   bdalnode02: Loaded plugins: rhnplugin, security
   .
   .
   .
7. Verify that the installation was successful on all servers:

```
# dcli rpm -qi libpng-devel
```

```
bdalnode01: Name        : libpng-devel Relocations: (not relocatable)
bdalnode01: Version     : 1.2.10 Vendor: Oracle America
bdalnode01: Release     : 17.el5_8 Build Date: Wed 25 Apr 2012 06:51:15 AM PDT
bdalnode01: Install Date: Tue 05 Feb 2013 11:41:14 AM PST Build Host: ca-build56.abcd.com
bdalnode01: Group       : Development/Libraries Source RPM: libpng-1.2.10-17.el5_8.src.rpm
bdalnode01: Size        : 482483 License: zlib
bdalnode01: Signature   : DSA/SHA1, Wed 25 Apr 2012 06:51:41 AM PDT, Key ID 66ced3de1e5e0159
bdalnode01: URL         : http://www.libpng.org/pub/png/
bdalnode01: Summary     : Development tools for programs to manipulate PNG image format files.
bdalnode01: Description :
bdalnode01: The libpng-devel package contains the header files and static
bdalnode01: libraries necessary for developing programs using the PNG (Portable
bdalnode01: Network Graphics) library.
```

1.8.3 Providing Remote Client Access to R Users

Whereas R users will run their programs as MapReduce jobs on the Hadoop cluster, they do not typically have individual accounts on that platform. Instead, an external Linux server provides remote access.

1.8.3.1 Software Requirements for Remote Client Access

To provide access to a Hadoop cluster to R users, install these components on a Linux server:

- The same version of Hadoop as your Hadoop cluster; otherwise, unexpected issues and failures can occur
- The same version of Sqoop as your Hadoop cluster; required only to support copying data in and out of Oracle databases
- Mahout; required only for the `orch.ls` function with the Mahout ALS-WS algorithm
- The same version of the Java Development Kit (JDK) as your Hadoop cluster
- Oracle R distribution 3.0.1 with all base libraries
- ORCH R package

To provide access to database objects, you must have the Oracle Advanced Analytics option to Oracle Database. Then you can install this additional component on the Hadoop client:

- Oracle R Enterprise Client Packages

1.8.3.2 Configuring the Server as a Hadoop Client

You must install Hadoop on the client and minimally configure it for HDFS client use.
To install and configure Hadoop on the client system:

1. Install and configure CDH5 or Apache Hadoop 0.20.2 on the client system. This system can be the host for Oracle Database. If you are using Oracle Big Data Appliance, then complete the procedures for providing remote client access in the Oracle Big Data Appliance Software User’s Guide. Otherwise, follow the installation instructions provided by the distributor (Cloudera or Apache).

2. Log in to the client system as an R user.

3. Open a Bash shell and enter this Hadoop file system command:

   $HADOOP_HOME/bin/hdfs dfs -ls /user

4. If you see a list of files, then you are done. If not, then ensure that the Hadoop cluster is up and running. If that does not fix the problem, then you must debug your client Hadoop installation.

1.8.3.3 Installing Sqoop on a Hadoop Client

Complete the same procedures on the client system for installing and configuring Sqoop as those provided in “Installing Sqoop on a Third-Party Hadoop Cluster”.

1.8.3.4 Installing R on a Hadoop Client

You can download R 2.13.2 and get the installation instructions from the Oracle R Distribution website at

http://oss.oracle.com/ORD/

When you are done, ensure that users have the necessary permissions to connect to the Linux server and run R.

You may also want to install RStudio Server to facilitate access by R users. See the RStudio website at

http://rstudio.org/

1.8.3.5 Installing the ORCH Package on a Hadoop Client

To install ORCH on your Hadoop client system:

1. Download the ORCH package and unzip it on the client system.

2. Change to the installation directory.

3. Run the client script:

   # ./install-client.sh

1.8.3.6 Installing the Oracle R Enterprise Client Packages (Optional)

To support full access to Oracle Database using R, install the Oracle R Enterprise Release 1.4 client packages. Without them, Oracle R Advanced Analytics for Hadoop does not have access to the advanced statistical algorithms provided by Oracle R Enterprise.

See Also:

Oracle R Enterprise User’s Guide for information about installing R and Oracle R Enterprise
1.9 Oracle Data Integrator

For the instructions to set up and use Oracle Data Integrator refer to Oracle Fusion Middleware Integrating Big Data with Oracle Data Integrator.

1.10 Oracle Datasource for Apache Hadoop Setup

Software Requirements

Oracle Datasource for Apache Hadoop requires the following software:

- A target database system running Oracle Database 12c, 11.2.0.4, or earlier Oracle database releases that can be queried with the Oracle JDBC driver for 12c.
  Note that Oracle Database 11.2.0.4 and potentially earlier Oracle Database release may work. However, some of the SPLIT patterns have dependencies on Oracle Database 12c and might not provide accurate splits for parallel hadoop jobs when used to query earlier releases of Oracle Database.

- Cloudera’s Distribution including Apache Hadoop version 5 (CDH5), Hortonworks Data Platform (HDP) 2.x, or, Apache Hadoop 2.2.0 to 2.6.0.

- Apache Hive 0.13.0, 0.13.1 or 1.1.0 (in order to query data from Oracle Database tables).

Installing Oracle Datasource for Hadoop

1. Unpack the contents of od4h-* .zip into a directory on your Hadoop cluster or on a system configured as a Hadoop client. A directory named od4h will be created with the following subdirectories:
   
   doc
   jlib

2. Create a variable named OD4H_HOME and set it to the installation directory created in Step 1.

3. Add OD4H_HOME/jlib/* to the HADOOP_CLASSPATH variable. When using OD4H, OD4H_HOME/jlib should be listed first in HADOOP_CLASSPATH to avoid conflict with other versions of JARs with the same name in HADOOP_CLASSPATH.
Part II
Oracle Database Connectors

This part contains the following chapters:

- Oracle SQL Connector for Hadoop Distributed File System
- Oracle Loader for Hadoop
Oracle SQL Connector for Hadoop Distributed File System

This chapter describes how to use Oracle SQL Connector for Hadoop Distributed File System (HDFS) to facilitate data access between Hadoop and Oracle Database. This chapter contains the following sections:

- About Oracle SQL Connector for HDFS
- Getting Started With Oracle SQL Connector for HDFS
- Configuring Your System for Oracle SQL Connector for HDFS
- Using the ExternalTable Command-Line Tool
- Creating External Tables
- Publishing the HDFS Data Paths
- Exploring External Tables and Location Files
- Dropping Database Objects Created by Oracle SQL Connector for HDFS
- More About External Tables Generated by the ExternalTable Tool
- Configuring Oracle SQL Connector for HDFS
- Performance Tips for Querying Data in HDFS

2.1 About Oracle SQL Connector for HDFS

Using Oracle SQL Connector for HDFS, you can use Oracle Database to access and analyze data residing in Apache Hadoop in these formats:

- Data Pump files in HDFS
- Delimited text files in HDFS
- Delimited text files in Apache Hive tables

For other file formats, such as JSON files, you can stage the input as delimited text in a new Hive table and then use Oracle SQL Connector for HDFS. Partitioned Hive tables are supported, enabling you to represent a subset of Hive table partitions in Oracle Database, instead of the entire Hive table.

Oracle SQL Connector for HDFS uses external tables and database views to provide Oracle Database with read access to Hive tables, and to delimited text files and Data Pump files in HDFS. An external table is an Oracle Database object that identifies the location of data outside of a database. Oracle Database accesses the data by using the
metadata provided when the external table was created. Oracle SQL Connector for HDFS creates database views over external tables to support access to partitioned Hive tables. By querying the external tables or views, you can access data stored in HDFS and Hive tables as if that data were stored in tables in an Oracle database.

To create these objects in Oracle Database, you use the `ExternalTable` command-line tool provided with Oracle SQL Connector for HDFS. You provide `ExternalTable` with information about the data source in Hadoop and about your schema in an Oracle Database. You provide this information either as options to the `ExternalTable` command or in an XML file.

When the external table is ready, you can query the data the same as any other database table. You can query and join data in HDFS or a Hive table with other database-resident data.

You can also perform bulk loads of data into Oracle database tables using SQL. You may prefer that the data resides in an Oracle database—all of it or just a selection—if it is queried routinely. Oracle SQL Connector for HDFS functions as a Hadoop client running on the Oracle database and uses the external table preprocessor `hdfs_stream` to access data in HDFS.

## 2.2 Getting Started With Oracle SQL Connector for HDFS

The following list identifies the basic steps that you take when using Oracle SQL Connector for HDFS.

1. Log in to a system where Oracle SQL Connector for HDFS is installed, which can be the Oracle Database system, a node in the Hadoop cluster, or a system set up as a remote client for the Hadoop cluster.

   See “Installing and Configuring a Hadoop Client on the Oracle Database System.”

2. The first time you use Oracle SQL Connector for HDFS, ensure that the software is configured.

   See “Configuring Your System for Oracle SQL Connector for HDFS.” You might also need to edit `hdfs_stream` if your environment is unique. See “Installing Oracle SQL Connector for HDFS”.

3. If you are connecting to a secure cluster, then run `kinit` to authenticate yourself.

   See “Using Oracle SQL Connector for HDFS on a Secure Hadoop Cluster.”

4. Create an XML document describing the connections and the data source, unless you are providing these properties in the `ExternalTable` command.

   See “Exploring External Tables and Location Files.”

5. Create a shell script containing an `ExternalTable` command.

   See “Using the ExternalTable Command-Line Tool.”

6. Run the shell script.

7. If the job fails, then use the diagnostic messages in the output to identify and correct the error. Depending on how far the job progressed before failing, you may need to delete the table definition from the Oracle database before rerunning the script.
8. After the job succeeds, connect to Oracle Database as the owner of the external table. Query the table to ensure that the data is accessible.

9. If the data will be queried frequently, then you may want to load it into a database table to improve querying performance. External tables do not have indexes or partitions.

   If you want the data to be compressed as it loads into the table, then create the table with the COMPRESS option.

10. To delete the Oracle Database objects created by Oracle SQL Connector for HDFS, use the -drop command.

   See “Dropping Database Objects Created by Oracle SQL Connector for HDFS”.

**Example 2-1  Accessing HDFS Data Files from Oracle Database**

```bash
$ cat moviefact_hdfs.sh
# Add environment variables
export OSCH_HOME="/u01/connectors/orahdfs-<version>"

hadoop jar $OSCH_HOME/jlib/orahdfs.jar \%
   oracle.hadoop.exttab.ExternalTable \%
   -conf /home/oracle/movies/moviefact_hdfs.xml \%
   -createTable

$ cat moviefact_hdfs.xml
<?xml version="1.0"?>
<configuration>
  <property>
    <name>oracle.hadoop.exttab.tableName</name>
    <value>MOVIE_FACTS_EXT</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.locationFileCount</name>
    <value>4</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.dataPaths</name>
    <value>/user/oracle/moviework/data/part*</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.fieldTerminator</name>
    <value>\u0009</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.defaultDirectory</name>
    <value>MOVIEDEMO_DIR</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.columnNames</name>
    <value>CUST_ID,MOVIE_ID,GENRE_ID,TIME_ID,RECOMMENDED,ACTIVITY_ID,RATING,SALES</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.colMap.TIME_ID.columnType</name>
    <value>TIMESTAMP</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.colMap.timestampMask</name>
    <value>YYYY-MM-DD:HH:MI:SS</value>
  </property>
</configuration>
```
$ sh moviefact_hdfs.sh

<td>4</td>
</tr>
</tbody>
</table>

Example 2-1 illustrates these steps.

### 2.3 Configuring Your System for Oracle SQL Connector for HDFS

You can run the `ExternalTable` command-line tool provided with Oracle SQL Connector for HDFS on either the Oracle Database system or the Hadoop cluster:

- For Hive sources, log in to either a node in the Hadoop cluster or a system set up as a Hadoop client for the cluster.
- For text and Data Pump format files, log in to either the Oracle Database system or a node in the Hadoop cluster.

Oracle SQL Connector for HDFS requires additions to the `HADOOP_CLASSPATH` environment variable on the system where you log in to run the tool. Your system administrator may have set them up for you when creating your account, or may have left that task for you. See “Setting Up User Accounts on the Oracle Database System”.

**Setting up the environment variables:**

- Verify that `HADOOP_CLASSPATH` includes the path to the JAR files for Oracle SQL Connector for HDFS:
  
  ```
p=path/orahdfs-<version>/jlib/*
  ```

- If you are logged in to a Hadoop cluster with Hive data sources, then verify that `HADOOP_CLASSPATH` also includes the Hive JAR files and conf directory. For example:
  
  ```
/usr/lib/hive/lib/*
/etc/hive/conf
  ```

- For your convenience, you can create an `OSCH_HOME` environment variable. The following is the Bash command for setting it on Oracle Big Data Appliance:

  ```
$ export OSCH_HOME="/opt/oracle/orahdfs-<version>"
  ```
2.4 Using Oracle SQL Connector for HDFS with Oracle Big Data Appliance and Oracle Exadata

Oracle SQL Connector for HDFS is a command-line utility that accepts generic command line arguments supported by the org.apache.hadoop.util.Tool interface. It also provides a preprocessor for Oracle external tables. See the Oracle Big Data Appliance Software User’s Guide for instructions on configuring Oracle Exadata Database Machine for Use with Oracle Big Data Appliance.

2.5 Using the ExternalTable Command-Line Tool

Oracle SQL Connector for HDFS provides a command-line tool named ExternalTable. This section describes the basic use of this tool. See “Creating External Tables” for the command syntax that is specific to your data source format.

2.5.1 About ExternalTable

The ExternalTable tool uses the values of several properties to do the following tasks:

- Create an external table
- Populate the location files
- Publish location files to an existing external table
- List the location files
- Describe an external table

You can specify these property values in an XML document or individually on the command line. See “Configuring Oracle SQL Connector for HDFS.”.

2.5.2 ExternalTable Command-Line Tool Syntax

This is the full syntax of the ExternalTable command-line tool, which is run using the hadoop command:

```bash
hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable \
[-conf config_file]... \
[-D property=value]... \
-createTable [--noexecute [--output filename.sql]] \
| -drop [--noexecute] \
| -describe \
| -publish [--noexecute]
```
You can either create the OSCH_HOME environment variable or replace OSCH_HOME in the command syntax with the full path to the installation directory for Oracle SQL Connector for HDFS. On Oracle Big Data Appliance, this directory is:

```
/opt/oracle/orahdfs-<version>
```

For example, you might run the `ExternalTable` command-line tool with a command like this:

```
hadoop jar /opt/oracle/orahdfs-<version>/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable
```

### Generic Options and User Commands

- `-conf config_file`
  Identifies the name of an XML configuration file containing properties needed by the command being executed. See “Configuring Oracle SQL Connector for HDFS.”

- `-D property=value`
  Assigns a value to a specific property.

- `-createTable [--noexecute [--output filename]]`
  Creates an external table definition and publishes the data URIs to the location files of the external table. The output report shows the DDL used to create the external table and lists the contents of the location files. Oracle SQL Connector for HDFS also checks the database to ensure that the required database directories exist and that you have the necessary permissions.

  For partitioned Hive tables, Oracle SQL Connector for HDFS creates external tables, views, and a metadata table. See Table 2-2.

  Specify the metadata table name for partitioned Hive tables, or the external table name for all other data sources.

  Use the `--noexecute` option to see the execution plan of the command. The operation is not executed, but the report includes the details of the execution plan and any errors. The `--output option writes the table DDL from the -createTable command to a file. Oracle recommends that you first execute a -createTable command with `--noexecute`.

- `-drop [--noexecute]`
  Deletes one or more Oracle Database objects created by Oracle SQL Connector for HDFS to support a particular data source. Specify the metadata table name for partitioned Hive tables, or the external table name for all other data sources. An error occurs if you attempt to drop a table or view that Oracle SQL Connector for HDFS did not create.

  Use the `--noexecute` option to list the objects to be deleted.

- `-describe`
  Provides information about the Oracle Database objects created by Oracle SQL Connector for HDFS. Use this command instead of `-getDDL` or `-listLocations`. 

-publish [--noexecute]
Publishes the data URIs to the location files of an existing external table. Use this command after adding new data files, so that the existing external table can access them.

Use the --noexecute option to see the execution plan of the command. The operation is not executed, but the report shows the planned SQL ALTER_TABLE command and location files. The report also shows any errors.

Oracle recommends that you first execute a -publish command with --noexecute.

See “Publishing the HDFS Data Paths.”

-listLocations [--details]
Shows the location file content as text. With the --details option, this command provides a detailed listing. This command is deprecated in release 3.0. Use “-describe” instead.

-getDDL
Prints the table definition of an existing external table. This command is deprecated in release 3.0. Use “-describe” instead.

See Also:
“Syntax Conventions”

2.6 Creating External Tables
You can create external tables automatically using the ExternalTable tool provided in Oracle SQL Connector for HDFS.

2.6.1 Creating External Tables with the ExternalTable Tool
To create an external table using the ExternalTable tool, follow the instructions for your data source:

- Creating External Tables from Data Pump Format Files
- Creating External Tables from Hive Tables
- Creating External Tables from Delimited Text Files

When the ExternalTable -createTable command finishes executing, the external table is ready for use. ExternalTable also manages the location files for the external table. See “Location File Management.”

To create external tables manually, follow the instructions in “Creating External Tables in SQL.”

ExternalTable Syntax for -createTable
Use the following syntax to create an external table and populate its location files:

```
hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable \
[{-conf config_file}]... \
[{-D property=value}]... \
-createTable [--noexecute]
```
2.6.2 Creating External Tables from Data Pump Format Files

Oracle SQL Connector for HDFS supports only Data Pump files produced by Oracle Loader for Hadoop, and does not support generic Data Pump files produced by Oracle Utilities.

Oracle SQL Connector for HDFS creates the external table definition for Data Pump files by using the metadata from the Data Pump file header. It uses the ORACLE_LOADER access driver with the preprocessor access parameter. It also uses a special access parameter named EXTERNAL VARIABLE DATA, which enables ORACLE_LOADER to read the Data Pump format files generated by Oracle Loader for Hadoop.

To delete the external tables and location files created by Oracle SQL Connector for HDFS, use the -drop command. See “Dropping Database Objects Created by Oracle SQL Connector for HDFS”.

Note:
Oracle SQL Connector for HDFS requires a patch to Oracle Database 11.2.0.2 before the connector can access Data Pump files produced by Oracle Loader for Hadoop. To download this patch, go to http://support.oracle.com and search for bug 14557588.

Release 11.2.0.3 and later releases do not require this patch.

2.6.2.1 Required Properties
These properties are required:

- oracle.hadoop.exttab.tableName
- oracle.hadoop.exttab.defaultDirectory
- oracle.hadoop.exttab.dataPaths
- oracle.hadoop.exttab.sourceType=datapump
- oracle.hadoop.connection.url
- oracle.hadoop.connection.user

See “Configuring Oracle SQL Connector for HDFS” for descriptions of the properties used for this data source.

2.6.2.2 Optional Properties
This property is optional:

- oracle.hadoop.exttab.logDirectory
- oracle.hadoop.exttab.createLogFiles
- oracle.hadoop.exttab.createBadFiles
2.6.2.3 Defining Properties in XML Files for Data Pump Format Files

Example 2-2 is an XML template containing the properties that describe a Data Pump file. To use the template, cut and paste it into a text file, enter the appropriate values to describe your Data Pump file, and delete any optional properties that you do not need. For more information about using XML templates, see “Creating a Configuration File.”

Example 2-2 XML Template with Properties for a Data Pump Format File

```xml
<?xml version="1.0"?>
<!-- Required Properties -->
<configuration>
    <property>
        <name>oracle.hadoop.exttab.tableName</name>
        <value>
            value
        </value>
    </property>
    <property>
        <name>oracle.hadoop.exttab.defaultDirectory</name>
        <value>
            value
        </value>
    </property>
    <property>
        <name>oracle.hadoop.exttab.dataPaths</name>
        <value>
            value
        </value>
    </property>
    <property>
        <name>oracle.hadoop.exttab.sourceType</name>
        <value>datapump</value>
    </property>
    <property>
        <name>oracle.hadoop.connection.url</name>
        <value>
            value
        </value>
    </property>
    <property>
        <name>oracle.hadoop.connection.user</name>
        <value>
            value
        </value>
    </property>
    <!-- Optional Properties -->
    <property>
        <name>oracle.hadoop.exttab.logDirectory</name>
        <value>
            value
        </value>
    </property>
</configuration>
```

2.6.2.4 Example

Example 2-3 creates an external table named SALES_DP_XTAB to read Data Pump files.

Example 2-3 Defining an External Table for Data Pump Format Files

Log in as the operating system user that Oracle Database runs under (typically the oracle user), and create a file-system directory. For Oracle RAC, you must create a clusterwide directory on a distributed file system.

```
$ mkdir /data/sales_dp_dir
```

Oracle SQL Connector for Hadoop Distributed File System 2-11
Create a database directory and grant read and write access to it:

$ sqlplus / as sysdba
SQL> CREATE OR REPLACE DIRECTORY sales_dp_dir AS '/data/sales_dp_dir'
SQL> GRANT READ, WRITE ON DIRECTORY sales_dp_dir TO scott;

Create the external table:

$ export OSCH_HOME="/opt/oracle/orahdfs-<version>"
$ export HADOOP_CLASSPATH="$OSCH_HOME/jlib/*:$HADOOP_CLASSPATH"
$ hadoop jar $OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable \
-D oracle.hadoop.exttab.tableName=SALES_DP_XTAB \
-D oracle.hadoop.exttab.sourceType=datapump \
-D oracle.hadoop.exttab.dataPaths=hdfs:///user/scott/olh_sales_dpoutput/ \
-D oracle.hadoop.exttab.defaultDirectory=SALES_DP_DIR \
-D oracle.hadoop.connection.url=jdbc:oracle:thin:@//myhost:1521/myservicename \
-D oracle.hadoop.connection.user=SCOTT \
-createTable

2.6.3 Creating External Tables from Hive Tables

Oracle SQL Connector for HDFS creates the external table definition from a Hive table by contacting the Hive metastore client to retrieve information about the table columns and the location of the table data. In addition, the Hive table data paths are published to the location files of the Oracle external table.

To read Hive table metadata, Oracle SQL Connector for HDFS requires that the Hive JAR files are included in the HADOOP_CLASSPATH variable. Oracle SQL Connector for HDFS must be installed and running on a computer with a working Hive client.

Ensure that you add the Hive configuration directory to the HADOOP_CLASSPATH environment variable. You must have a correctly functioning Hive client.

For Hive managed tables, the data paths come from the warehouse directory.

For Hive external tables, the data paths from an external location in HDFS are published to the location files of the Oracle external table. Hive external tables can have no data, because Hive does not check if the external location is defined when the table is created. If the Hive table is empty, then one location file is published with just a header and no data URIs.

The Oracle external table is not a "live" Hive table. After changes are made to a Hive table, you must use the ExternalTable tool to drop the existing external table and create a new one.

To delete the external tables and location files created by Oracle SQL Connector for HDFS, use the -drop command. See “Dropping Database Objects Created by Oracle SQL Connector for HDFS”.

2.6.3.1 Hive Table Requirements

Oracle SQL Connector for HDFS supports Hive tables that are defined using ROW FORMAT DELIMITED and FILE FORMAT TEXTFILE clauses. Both Hive-managed tables and Hive external tables are supported.

Oracle SQL Connector for HDFS also supports partitioned Hive tables. In this case Oracle SQL Connector for HDFS creates one or more external tables and database views. See “Creating External Tables from Partitioned Hive Tables”.

Hive tables can be either bucketed or not bucketed. All primitive types from Hive 0.10.0 are supported.
2.6.3.2 Data Type Mappings

Table 2-1 shows the default data-type mappings between Hive and Oracle. To change the data type of the target columns created in the Oracle external table, set the oracle.hadoop.exttab.hive.columnType.* properties listed under “Optional Properties.”.

<table>
<thead>
<tr>
<th>Data Type of Source Hive Column</th>
<th>Default Data Type of Target Oracle Column</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT, BIGINT, SMALLINT, TINYINT</td>
<td>INTEGER</td>
</tr>
<tr>
<td>DECIMAL</td>
<td>NUMBER</td>
</tr>
<tr>
<td>DECIMAL (p, s)</td>
<td>NUMBER (p, s)</td>
</tr>
<tr>
<td>DOUBLE, FLOAT</td>
<td>NUMBER</td>
</tr>
<tr>
<td>DATE</td>
<td>DATE with format mask YYYY-MM-DD</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>TIMESTAMP with format mask YYYY-MM-DD HH24:MI:SS.FF</td>
</tr>
<tr>
<td>BOOLEAN</td>
<td>VARCHAR2 (5)</td>
</tr>
<tr>
<td>CHAR (size)</td>
<td>CHAR (size)</td>
</tr>
<tr>
<td>STRING</td>
<td>VARCHAR2 (4000)</td>
</tr>
<tr>
<td>VARCHAR</td>
<td>VARCHAR2 (4000)</td>
</tr>
<tr>
<td>VARCHAR (size)</td>
<td>VARCHAR2 (size)</td>
</tr>
</tbody>
</table>

2.6.3.3 Required Properties

These properties are required for Hive table sources:

- oracle.hadoop.exttab.tableName
- oracle.hadoop.exttab.defaultDirectory
- oracle.hadoop.exttab.sourceType=hive
- oracle.hadoop.exttab.hive.tableName
- oracle.hadoop.exttab.hive.databaseName
- oracle.hadoop.connection.url
- oracle.hadoop.connection.user

See “Configuring Oracle SQL Connector for HDFS” for descriptions of the properties used for this data source.

2.6.3.4 Optional Properties

These properties are optional for Hive table sources:

- oracle.hadoop.exttab.hive.columnType.*
2.6.3.5 Defining Properties in XML Files for Hive Tables

Example 2-4 is an XML template containing the properties that describe a Hive table. To use the template, cut and paste it into a text file, enter the appropriate values to describe your Hive table, and delete any optional properties that you do not need. For more information about using XML templates, see “Creating a Configuration File.”

Example 2-4  XML Template with Properties for a Hive Table

```xml
<?xml version="1.0"?>
<!-- Required Properties -->
<configuration>
<property>
  <name>oracle.hadoop.exttab.tableName</name>
  <value>value</value>
</property>
<property>
  <name>oracle.hadoop.exttab.defaultDirectory</name>
  <value>value</value>
</property>
<property>
  <name>oracle.hadoop.exttab.sourceType</name>
  <value>hive</value>
</property>
```
2.6.3.6 Example

Example 2-5 creates an external table named SALES_HIVE_XTAB to read data from a Hive table. The example defines all the properties on the command line instead of in an XML file.

Example 2-5  Defining an External Table for a nonpartitioned Hive Table

Log in as the operating system user that Oracle Database runs under (typically the oracle user), and create a file-system directory:

```bash
$ mkdir /data/sales_hive_dir
```

Create a database directory and grant read and write access to it:

```sql
$ sqlplus / as sysdba
SQL> CREATE OR REPLACE DIRECTORY sales_hive_dir AS '/data/sales_hive_dir'
SQL> GRANT READ, WRITE ON DIRECTORY sales_hive_dir TO scott;
```

Create the external table:

```bash
$ export OSCH_HOME="/opt/oracle/orahdfs-<version>"
$ export HADOOP_CLASSPATH="$OSCH_HOME/jlib/*:/usr/lib/hive/lib/*:/etc/hive/conf:
$HADOOP_CLASSPATH"

$ hadoop jar OSCH_HOME/jlib/orahdfs.jar 
oracle.hadoop.exttab.ExternalTable \
-D oracle.hadoop.exttab.tableName=SALES_HIVE_XTAB \
-D oracle.hadoop.exttab.sourceType=hive \
-D oracle.hadoop.exttab.locationFileCount=2 \
-D oracle.hadoop.exttab.hive.tableName=sales_country_us \
```

Oracle SQL Connector for Hadoop Distributed File System  2-15
Note:
For nonpartitioned Hive tables and other data sources the value for property oracle.hadoop.exttab.tableName is the name of the external table.

2.6.3.7 Creating External Tables from Partitioned Hive Tables

Oracle SQL Connector for HDFS supports partitioned Hive tables, enabling you to query a single partition, a range of partitions, or all partitions. You can represent all Hive partitions or a subset of them in Oracle Database.

See Also:
“Creating External Tables from Hive Tables” for required properties, data type mappings, and other details applicable to all Hive table access using Oracle SQL Connector for HDFS.

2.6.3.7.1 Database Objects that Support Access to Partitioned Hive Tables

To support a partitioned Hive table, Oracle SQL Connector for HDFS creates the objects described in Table 2-2.

Table 2-2 Oracle Database Objects for Supporting a Partitioned Hive Table

<table>
<thead>
<tr>
<th>Database Object</th>
<th>Description</th>
<th>Naming Convention⁠¹</th>
</tr>
</thead>
</table>
| External Tables | One for each Hive partition | OSCHtable_name_n  
For example, OSCHDAILY_1 and OSCHDAILY_2 |
| Views           | One for each external table. Used for querying the Hive data. | table_name_n  
For example, DAILY_1 and DAILY_2 |
| Metadata Table  | One for the Hive table. Identifies all external tables and views associated with a particular Hive table. Specify this table when creating, describing, or dropping these database objects. | table_name  
For example, DAILY |

¹ The "_n" suffixed with table name indicates a numeric value.

For example, if a Hive table comprises five partitions, then Oracle SQL Connector for HDFS creates five external tables, five views, and one metadata table in Oracle Database.

To drop the objects described in Table 2-2 and the location files, use the -drop command. See “Dropping Database Objects Created by Oracle SQL Connector for HDFS”.
Note:
For partitioned Hive tables and other data sources the value for property oracle.hadoop.exttab.tableName is the name of the metadata table.

2.6.3.7.2 Querying the Metadata Table

The metadata table provides critical information about how to query the Hive table. Table 2-3 describes the columns of a metadata table.

**Table 2-3 Metadata Table Columns**

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VIEW_NAME</td>
<td>The Oracle Database view used to access a single Hive table partition. The view contains both Hive table and partition columns.</td>
</tr>
<tr>
<td>EXT_TABLE_NAME</td>
<td>An Oracle external table that represents a Hive table partition. The external table contains only the Hive table columns and not the Hive partition columns. To access all the data in a Hive partition, use the corresponding Oracle Database view.</td>
</tr>
<tr>
<td>HIVE_TABLE_NAME</td>
<td>The partitioned Hive table being accessed through Oracle Database.</td>
</tr>
<tr>
<td>HIVE_DB_NAME</td>
<td>The Hive database where the table resides.</td>
</tr>
<tr>
<td>HIVE_PART_FILTER</td>
<td>The Hive partition filter used to select a subset of partitions for access by Oracle Database. A NULL value indicates that all partitions are accessed.</td>
</tr>
</tbody>
</table>

**Partition Columns**

Each column used to partition the Hive table has a separate column in the metadata table. For example, the metadata table has columns for COUNTRY, STATE, and CITY for a Hive table partitioned by a combination of COUNTRY, STATE, and CITY values.

The following SELECT statement queries a metadata table named HIVE_SALES_DATA:

```sql
SQL> SELECT view_name, ext_table_name, Hive_table_name, hive_db_name, country, city
     FROM hive_sales_data
     WHERE state = 'TEXAS';
```

<table>
<thead>
<tr>
<th>VIEW_NAME</th>
<th>EXT_TABLE_NAME</th>
<th>HIVE_TABLE_NAME</th>
<th>Hive_DB_NAME</th>
<th>COUNTRY</th>
<th>CITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>HIVE_SALES_DATA_1</td>
<td>OSCHIVE_SALES_DATA_1</td>
<td>hive_sales_data</td>
<td>db_sales</td>
<td>US</td>
<td>AUSTIN</td>
</tr>
<tr>
<td>HIVE_SALES_DATA_2</td>
<td>OSCHIVE_SALES_DATA_2</td>
<td>hive_sales_data</td>
<td>db_sales</td>
<td>US</td>
<td>HOUSTON</td>
</tr>
<tr>
<td>HIVE_SALES_DATA_3</td>
<td>OSCHIVE_SALES_DATA_3</td>
<td>hive_sales_data</td>
<td>db_sales</td>
<td>US</td>
<td>DALLAS</td>
</tr>
</tbody>
</table>

The views include partition column values. Oracle recommends that you use the views while querying a partitioned Hive table, as the external tables do not include the partition column values.
2.6.3.7.3 Creating UNION ALL Views for Querying

To facilitate querying, you can create UNION ALL views over the individual partition views. Use the mkhive_unionall_view.sql script, which is provided in the OSCH_HOME/example/sql directory. To maintain performance, do not create UNION ALL views over more than 50 to 100 views (depending on their size).

To use mkhive_unionall_view.sql, use the following syntax:

```
@mkhive_unionall_view.sql table schema view predicate
```

**MKHIVE_UNIONALL_VIEW Script Parameters**

**table**
The name of the metadata table in Oracle Database that represents a partitioned Hive table. Required.

**schema**
The owner of the metadata table. Optional; defaults to your schema.

**view**
The name of the UNION ALL view created by the script. Optional; defaults to table ua.

**predicate**
A WHERE condition used to select the partitions in the Hive table to include in the UNION ALL view. Optional; defaults to all partitions.

*Example 2-6 Union All Views for Partitioned Hive Tables*

The following example creates a UNION ALL view named HIVE_SALES_DATA_UA, which accesses all partitions listed in the HIVE_SALES_DATA metadata table:

```
SQL> @mkhive_unionall_view.sql HIVE_SALES_DATA null null null
```

This example creates a UNION ALL view named ALL_SALES, which accesses all partitions listed in the HIVE_SALES_DATA metadata table:

```
SQL> @mkhive_unionall_view.sql HIVE_SALES_DATA null ALL_SALES null
```

The next example creates a UNION ALL view named TEXAS_SALES_DATA, which accesses the rows of all partitions where STATE = 'TEXAS'.

```
SQL> @mkhive_unionallview.sql HIVE_SALES_DATA null TEXAS_SALES_DATA '(STATE = 'TEXAS')'
```

2.6.3.7.4 Error Messages

**table name too long, max limit length**

Cause: The names generated for the database objects exceed 30 characters.

Action: Specify a name that does not exceed 24 characters in the oracle.hadoop.exttab.tableName property. Oracle SQL Connector for HDFS generates external table names using the convention OSCHtable_name_n. See Table 2-2.
table/view names containing string table_name found in schema schema_name

Cause: An attempt was made to create external tables for a partitioned Hive table, but the data objects already exist.

Action: Use the hadoop -drop command to drop the existing tables and views, and then retry the -createTable command. If this solution fails, then you might have "dangling" objects. See “Dropping Dangling Objects”.

2.6.3.7.5 Dropping Dangling Objects

Always use Oracle SQL Connector for HDFS commands to manage objects created by the connector to support partitioned Hive tables. Dangling objects are caused when you use the SQL drop table command to drop a metadata table instead of the -drop command. If you are unable to drop the external tables and views for a partitioned Hive table, then they are dangling objects.

Notice the schema and table names in the error message generated when you attempted to drop the objects, and use them in the following procedure.

To drop dangling database objects:

1. Open a SQL session with Oracle Database, and connect as the owner of the dangling objects.

2. Identify the location files of the external table by querying the ALL_EXTERNAL_LOCATIONS and ALL_EXTERNAL_TABLES data dictionary views:

   SELECT a.table_name, a.directory_name, a.location 
   FROM all_external_locations a, all_external_tables b 
   WHERE a.table_name = b.table_name AND a.table_name 
   LIKE 'OSCHtable%' AND a.owner='schema';

   In the LIKE clause of the previous syntax, replace table and schema with the appropriate values.

   In the output, the location file names have an osch- prefix, such as osch-20140408014604-175-1.

3. Identify the external tables by querying the ALL_EXTERNAL_TABLES data dictionary view:

   SELECT table_name FROM all_external_tables 
   WHERE table_name 
   LIKE 'OSCHtable%' AND owner='schema';

4. Identify the database views by querying the ALL_VIEWS data dictionary view:

   SELECT view_name FROM all_views 
   WHERE view_name 
   LIKE 'table%' AND owner='schema';

5. Inspect the tables, views, and location files to verify that they are not needed, using commands like the following:

   DESCRIBE schema.table;
   SELECT * FROM schema.table;
DESCRIBE schema.view;
SELECT * FROM schema.view;

6. Delete the location files, tables, and views that are not needed, using commands like the following:

EXECUTE utl_file.fremove('directory', 'location_file');

DROP TABLE schema.table;
DROP VIEW schema.view;

- Oracle Database Reference
- Oracle Database PL/SQL Packages and Types Reference

### 2.6.4 Creating External Tables from Delimited Text Files

Oracle SQL Connector for HDFS creates the external table definition for delimited text files using configuration properties that specify the number of columns, the text delimiter, and optionally, the external table column names. By default, all text columns in the external table are VARCHAR2. If column names are not provided, they default to C1 to Cn, where n is the number of columns specified by the oracle.hadoop.exttab.columnCount property.

#### 2.6.4.1 Data Type Mappings

All text data sources are automatically mapped to VARCHAR2(4000). To change the data type of the target columns created in the Oracle external table, set the oracle.hadoop.exttab.colMap.* properties listed under “Optional Properties.”

#### 2.6.4.2 Required Properties

These properties are required for delimited text sources:

- `oracle.hadoop.exttab.tableName`
- `oracle.hadoop.exttab.defaultDirectory`
- `oracle.hadoop.exttab.dataPaths`
- `oracle.hadoop.exttab.columnCount` or `oracle.hadoop.exttab.columnNames`
- `oracle.hadoop.connection.url`
- `oracle.hadoop.connection.user`

See “Configuring Oracle SQL Connector for HDFS” for descriptions of the properties used for this data source.

#### 2.6.4.3 Optional Properties

These properties are optional for delimited text sources:

- `oracle.hadoop.exttab.recordDelimiter`
- `oracle.hadoop.exttab.fieldTerminator`
2.6.4.4 Defining Properties in XML Files for Delimited Text Files

Example 2-7 is an XML template containing all the properties that describe a delimited text file. To use the template, cut and paste it into a text file, enter the appropriate values to describe your data files, and delete any optional properties that you do not need. For more information about using XML templates, see “Creating a Configuration File.”

**Example 2-7 XML Template with Properties for a Delimited Text File**

```xml
<?xml version="1.0"?>
<!-- Required Properties -->

<configuration>
  <property>
    <name>oracle.hadoop.exttab.tableName</name>
    <value>value</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.defaultDirectory</name>
    <value>value</value>
  </property>
  <property>
    <name>oracle.hadoop.exttab.dataPaths</name>
    <value>value</value>
  </property>
</configuration>
```
2.6.4.5 Example

Example 2-8 creates an external table named SALES_DT_XTAB from delimited text files.

Example 2-8  Defining an External Table for Delimited Text Files

Log in as the operating system user that Oracle Database runs under (typically the oracle user), and create a file-system directory:

$ mkdir /data/sales_dt_dir
Create a database directory and grant read and write access to it:

```
$ sqlplus / as sysdba
SQL> CREATE OR REPLACE DIRECTORY sales_dt_dir AS '/data/sales_dt_dir'
SQL> GRANT READ, WRITE ON DIRECTORY sales_dt_dir TO scott;
```

Create the external table:

```
$ export OSCH_HOME="/opt/oracle/orahdfs-<version>"
$ export HADOOP_CLASSPATH="$OSCH_HOME/jlib/*:$HADOOP_CLASSPATH"

$ hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable \
-D oracle.hadoop.exttab.tableName=SALES_DT_XTAB  \
-D oracle.hadoop.exttab.locationFileCount=2  \
-D oracle.hadoop.exttab.dataPaths="hdfs:///user/scott/olh_sales/*.dat"  \
-D oracle.hadoop.exttab.columnCount=10  \
-D oracle.hadoop.exttab.defaultDirectory=SALES_DT_DIR  \
-D oracle.hadoop.connection.url=jdbc:oracle:thin:@//myhost:1521/myservicename  \
-D oracle.hadoop.connection.user=SCOTT  \
-createTable
```

### 2.6.5 Creating External Tables in SQL

You can create an external table manually for Oracle SQL Connector for HDFS. For example, the following procedure enables you to use external table syntax that is not exposed by the `ExternalTable -createTable` command.

Additional syntax might not be supported for Data Pump format files.

**To create an external table manually:**

1. Use the `-createTable --noexecute` command to generate the external table DDL.
2. Make whatever changes are needed to the DDL.
3. Run the DDL from Step 2 to create the table definition in the Oracle database.
4. Use the `ExternalTable -publish` command to publish the data URIs to the location files of the external table.

### 2.7 Publishing the HDFS Data Paths

The `-createTable` command creates the metadata in Oracle Database for delimited text and Data Pump sources, and populates the location files with the Universal Resource Identifiers (URIs) of the data files in HDFS. You might publish the URIs as a separate step from creating the external table in cases like these:

- You want to publish new data into an already existing external table.
- You created the external table manually instead of using the `ExternalTable` tool.

In both cases, you can use `ExternalTable` with the `-publish` command to populate the external table location files with the URIs of the data files in HDFS. See “Location File Management”.

*Oracle SQL Connector for Hadoop Distributed File System 2-23*
Note:
The `publish` option is supported for all sources except partitioned Hive tables. Use the `--drop` and `--createTable` commands of the `ExternalTable` tool for partitioned Hive tables.

### 2.7.1 ExternalTable Syntax for Publish

```sh
class HADOOP_CLASSPATH="OSCH_HOME/jlib/*"
hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable
   [-D oracle.hadoop.exttab.tableName=SALES_DP_XTAB]
   [-D oracle.hadoop.exttab.sourceType=datapump]
   [-D oracle.hadoop.exttab.dataPaths=hdfs:/user/scott/data/]
   [-D oracle.hadoop.connection.url=jdbc:oracle:thin:@myhost:1521/myservicename]
   [-D oracle.hadoop.connection.user=scott]
   [-publish]
```

See Also:
“ExternalTable Command-Line Tool Syntax”

### 2.7.2 ExternalTable Example for Publish

Example 2-9 sets `HADOOP_CLASSPATH` and publishes the HDFS data paths to the external table created in Example 2-3. See “Configuring Your System for Oracle SQL Connector for HDFS” for more information about setting this environment variable.

**Example 2-9 Publishing HDFS Data Paths to an External Table for Data Pump Format Files**

This example uses the Bash shell.

```sh
$ export HADOOP_CLASSPATH="OSCH_HOME/jlib/*"
$ hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable
   [-D oracle.hadoop.exttab.tableName=SALES_DP_XTAB]
   [-D oracle.hadoop.exttab.sourceType=datapump]
   [-D oracle.hadoop.exttab.dataPaths=hdfs:/user/scott/data/]
   [-D oracle.hadoop.connection.url=jdbc:oracle:thin:@myhost:1521/myservicename]
   [-D oracle.hadoop.connection.user=scott]
   [-publish]
```

In this example:
- `OSCH_HOME` is the full path to the Oracle SQL Connector for HDFS installation directory.
- `SALES_DP_XTAB` is the external table created in Example 2-3.
- `hdfs:/user/scott/data/` is the location of the HDFS data.
- `@myhost:1521` is the database connection string.

### 2.8 Exploring External Tables and Location Files

The `describe` command is a debugging and diagnostic utility that prints the definition of an existing external table. It also enables you to see the location file metadata and contents. You can use this command to verify the integrity of the location files of an Oracle external table.

These properties are required to use this command:
• oracle.hadoop.exttab.tableName
• The JDBC connection properties; see “Connections using url, user, and password Properties.”

2.8.1 ExternalTable Syntax for Describe

```
hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable 
[<-conf config_file]... 
[<-D property=value]... 
-drop
```

See Also:
“ExternalTable Command-Line Tool Syntax”

2.8.2 ExternalTable Example for Describe

Example 2-10 shows the command syntax to describe the external tables and location files associated with SALES_DP_XTAB.

```
Example 2-10 Exploring External Tables and Location Files

$ export HADOOP_CLASSPATH="OSCH_HOME/jlib/*"
$ hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable 
-D oracle.hadoop.exttab.tableName=SALES_DP_XTAB 
-D oracle.hadoop.connection.url=jdbc:oracle:thin:@//myhost:1521/myservicename 
-D oracle.hadoop.connection.user=scott -describe
```

2.9 Dropping Database Objects Created by Oracle SQL Connector for HDFS

The -drop command deletes the database objects created by Oracle SQL Connector for HDFS. These objects include external tables, location files, and views. If you delete objects manually, problems can arise as described in “Dropping Dangling Objects”.

The -drop command only deletes objects created by Oracle SQL Connector for HDFS. Oracle recommends that you always use the -drop command to drop objects created by Oracle SQL Connector for HDFS.

These properties are required to use this command:

• oracle.hadoop.exttab.tableName. For partitioned Hive tables, this is the name of the metadata table. For other data source types, this is the name of the external table.
• The JDBC connection properties; see “Connections using url, user, and password Properties.”

2.9.1 ExternalTable Syntax for Drop

```
hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable 
[<-conf config_file]... 
[<-D property=value]... 
-drop
```
2.9.2 ExternalTable Example for Drop

Example 2-10 shows the command syntax to drop the database objects associated with SALES_DP_XTAB.

Example 2-11 Dropping Database Objects

```bash
$ export HADOOP_CLASSPATH="OSCH_HOME/jlib/*"
$ hadoop jar OSCH_HOME/jlib/orahdfs.jar oracle.hadoop.exttab.ExternalTable -D oracle.hadoop.exttab.tableName=SALES_DP_XTAB -D oracle.hadoop.connection.url=jdbc:oracle:thin:@//myhost:1521/myservicename -D oracle.hadoop.connection.user=scott -drop
```

2.10 More About External Tables Generated by the ExternalTable Tool

Because external tables are used to access data, all of the features and limitations of external tables apply. Queries are executed in parallel with automatic load balancing. However, update, insert, and delete operations are not allowed and indexes cannot be created on external tables. When an external table is accessed, a full table scan is always performed.

Oracle SQL Connector for HDFS uses the ORACLE_LOADER access driver. The hdfs_stream preprocessor script (provided with Oracle SQL Connector for HDFS) modifies the input data to a format that ORACLE_LOADER can process.

See Also:

- *Oracle Database Administrator’s Guide* for information about external tables
- *Oracle Database Utilities* for more information about external tables, performance hints, and restrictions when you are using the ORACLE_LOADER access driver.

2.10.1 About Configurable Column Mappings

Oracle SQL Connector for HDFS uses default data type mappings to create columns in an Oracle external table with the appropriate data types for the Hive and text sources. You can override these defaults by setting various configuration properties, for either all columns or a specific column.

For example, a field in a text file might contain a timestamp. By default, the field is mapped to a VARCHAR2 column. However, you can specify a TIMESTAMP column and provide a datetime mask to cast the values correctly into the TIMESTAMP data type. The TIMESTAMP data type supports time-based queries and analysis that are unavailable when the data is presented as text.

2.10.1.1 Default Column Mappings

Text sources are mapped to VARCHAR2 columns, and Hive columns are mapped to columns with the closest equivalent Oracle data type. Table 2-1 shows the default mappings.
2.10.1.2 All Column Overrides

The following properties apply to all columns in the external table. For Hive sources, these property settings override the `oracle.hadoop.exttab.hive.*` property settings.

- `oracle.hadoop.exttab.colMap.columnLength`
- `oracle.hadoop.exttab.colMap.columnType`
- `oracle.hadoop.exttab.colMap.dateMask`
- `oracle.hadoop.exttab.colMap.fieldLength`
- `oracle.hadoop.exttab.colMap.timestampMask`
- `oracle.hadoop.exttab.colMap.timestampTZMask`

2.10.1.3 One Column Overrides

The following properties apply to only one column, whose name is the `column_name` part of the property name. These property settings override all other settings.

- `oracle.hadoop.exttab.colMap.column_name.columnLength`
- `oracle.hadoop.exttab.colMap.column_name.columnType`
- `oracle.hadoop.exttab.colMap.column_name.dateMask`
- `oracle.hadoop.exttab.colMap.column_name.fieldLength`
- `oracle.hadoop.exttab.colMap.column_name.timestampMask`
- `oracle.hadoop.exttab.colMap.column_name.timestampTZMask`

2.10.1.4 Mapping Override Examples

The following properties create an external table in which all columns are the default VARCHAR2 data type:

```sql
oracle.hadoop.exttab.tableName=MOVIE_FACT_EXT_TAB_TXT
oracle.hadoop.exttab.columnNames=CUST_ID,MOVIE_ID,GENRE_ID,TIME_ID,RECOMMENDED,ACTIVITY_ID,RATING,SALES
```

In this example, the following properties are set to override the data type of several columns:

```sql
oracle.hadoop.exttab.colMap.TIME_ID.columnType=TIMESTAMP
oracle.hadoop.exttab.colMap.RECOMMENDED.columnType=NUMBER
oracle.hadoop.exttab.colMap.ACTIVITY_ID.columnType=NUMBER
oracle.hadoop.exttab.colMap.RATING.columnType=NUMBER
oracle.hadoop.exttab.colMap.SALES.columnType=NUMBER
```

Oracle SQL Connector for HDFS creates an external table with the specified data types:

```
SQL> DESCRIBE movie_facts_ext
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
CUST_ID                                            VARCHAR2(4000)
MOVIE_ID                                           VARCHAR2(4000)
```

Oracle SQL Connector for Hadoop Distributed File System  2-27
GENRE_ID VARCHAR2(4000)
TIME_ID TIMESTAMP (9)
RECOMMENDED NUMBER
ACTIVITY_ID NUMBER
RATINGS NUMBER
SALES NUMBER

The next example adds the following property settings to change the length of the VARCHAR2 columns:

```
oracle.hadoop.exttab.colMap.CUST_ID.columnLength=12
oracle.hadoop.exttab.colMap.MOVIE_ID.columnLength=12
oracle.hadoop.exttab.colMap.GENRE_ID.columnLength=12
```

All columns now have custom data types:

```
SQL> DESCRIBE movie_facts_ext
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
cust_id                                    VARCHAR2(12)
movie_id                                   VARCHAR2(12)
genre_id                                   VARCHAR2(12)
time_id                                    TIMESTAMP (9)
recommended                               NUMBER
activity_id                                NUMBER
ratings                                    NUMBER
sales                                      NUMBER
```

2.10.2 What Are Location Files?

A location file is a file specified in the location clause of the external table. Oracle SQL Connector for HDFS creates location files that contain only the Universal Resource Identifiers (URIs) of the data files. A data file contains the data stored in HDFS.

2.10.3 Enabling Parallel Processing

To enable parallel processing with external tables, you must specify multiple files in the location clause of the external table. The number of files determines the number of child processes started by the external table during a table read, which is known as the degree of parallelism or DOP.

2.10.3.1 Setting Up the Degree of Parallelism

Ideally, you can decide to run at a particular degree of parallelism and create a number of location files that are a multiple of the degree of parallelism, as described in the following procedure.

To set up parallel processing for maximum performance:

1. Identify the maximum DOP that your Oracle DBA will permit you to use when running Oracle SQL Connector for HDFS.

   When loading a huge amount of data into an Oracle database, you should also work with the DBA to identify a time when the maximum resources are available.

2. Create a number of location files that is a small multiple of the DOP. For example, if the DOP is 8, then you might create 8, 16, 24, or 32 location files.

3. Create a number of HDFS files that are about the same size and a multiple of the number of location files. For example, if you have 32 location files, then you might...
create 128, 1280, or more HDFS files, depending on the amount of data and the minimum HDFS file size.

4. Set the DOP for the data load, using either the ALTER SESSION command or hints in the SQL SELECT statement.

This example sets the DOP to 8 using ALTER SESSION:

```sql
ALTER SESSION FORCE PARALLEL DML PARALLEL 8;
ALTER SESSION FORCE PARALLEL QUERY PARALLEL 8;
```

The next example sets the DOP to 8 using the PARALLEL hint:

```sql
INSERT /*+ parallel(my_db_table,8) */ INTO my_db_table 
  SELECT /*+ parallel(my_hdfs_external_table,8) */ * 
  FROM my_hdfs_external_table;
```

An APPEND hint in the SQL INSERT statement can also help improve performance.

### 2.10.4 Location File Management

The Oracle SQL Connector for HDFS command-line tool, `ExternalTable`, creates an external table and publishes the HDFS URI information to location files. The external table location files are stored in the directory specified by the `oracle.hadoop.exttab.defaultDirectory` property. For an Oracle RAC database, this directory must reside on a distributed file system that is accessible to each database server.

`ExternalTable` manages the location files of the external table, which involves the following operations:

- Generating new location files in the database directory after checking for name conflicts
- Deleting existing location files in the database directory as necessary
- Publishing data URIs to new location files
- Altering the `LOCATION` clause of the external table to match the new location files

Location file management for the supported data sources is described in the following topics.

#### Data Pump File Format

The `ORACLE_LOADER` access driver is required to access Data Pump files. The driver requires that each location file corresponds to a single Data Pump file in HDFS. Empty location files are not allowed, and so the number of location files in the external table must exactly match the number of data files in HDFS.

Oracle SQL Connector for HDFS automatically takes over location file management and ensures that the number of location files in the external table equals the number of Data Pump files in HDFS.

#### Delimited Files in HDFS and Hive Tables

The `ORACLE_LOADER` access driver has no limitation on the number of location files. Each location file can correspond to one or more data files in HDFS. The number of location files for the external table is suggested by the `oracle.hadoop.exttab.locationFileCount` configuration property.
See “Connections using url, user, and password Properties”.

2.10.5 Location File Names

This is the format of a location file name:

\texttt{osch-timestamp-number-n}

In this syntax:

- \textit{timestamp} has the format \texttt{yyyyMMddhhmmss}, for example, \texttt{20121017103941} for October 17, 2012, at 10:39:41.
- \textit{number} is a random number used to prevent location file name conflicts among different tables.
- \textit{n} is an index used to prevent name conflicts between location files for the same table.

For example, osch-20121017103941-6807-1.

2.11 Configuring Oracle SQL Connector for HDFS

You can pass configuration properties to the \texttt{ExternalTable} tool on the command line with the \texttt{-D} option, or you can create a configuration file and pass it on the command line with the \texttt{-conf} option. These options must precede the command to be executed.

For example, this command uses a configuration file named \texttt{example.xml}:

\begin{verbatim}
  hadoop jar OSCH_HOME/jlib/orahdfs.jar \
          oracle.hadoop.exttab.ExternalTable \
          -conf /home/oracle/example.xml \
          -createTable
\end{verbatim}

See “\texttt{ExternalTable} Command-Line Tool Syntax”.

2.11.1 Creating a Configuration File

A configuration file is an XML document with a very simple structure as follows:

```
<configuration>
  <property>
    <name>property</name>
    <value>value</value>
  </property>
  ...
</configuration>
```

Example 2-12 shows a configuration file. See “Oracle SQL Connector for HDFS Configuration Property Reference” for descriptions of these properties.

\textbf{Example 2-12} \hspace{1em} Configuration File for Oracle SQL Connector for HDFS

```
<configuration>
  <property>
    <name>oracle.hadoop.exttab.tableName</name>
    <value>SH.SALES_EXT_DIR</value>
  </property>
</configuration>
```
The following is a complete list of the configuration properties used by the `ExternalTable` command-line tool. The properties are organized into these categories:

- **General Properties**
- **Connections using url, user, and password Properties**

### General Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>oracle.hadoop.exttab.colMap.columnLength</code></td>
<td>Specifies the length of all external table columns of type <code>CHAR</code>, <code>VARCHAR2</code>, <code>NCHAR</code>, <code>NVARCHAR2</code>, and <code>RAW</code>. Optional.</td>
</tr>
<tr>
<td><strong>Default Value</strong>: The maximum length allowed by the column type. For Oracle Database 12c, Oracle SQL Connector for HDFS sets the length of <code>VARCHAR2</code>, <code>NVARCHAR2</code>, and <code>RAW</code> columns depending on whether the database <code>MAX_STRING_SIZE</code> option is set to <code>STANDARD</code> or <code>EXTENDED</code>.</td>
<td><strong>Valid values</strong>: Integer</td>
</tr>
</tbody>
</table>

2.11.2 Oracle SQL Connector for HDFS Configuration Property Reference

The following is a complete list of the configuration properties used by the `ExternalTable` command-line tool. The properties are organized into these categories:

- **General Properties**
- **Connections using url, user, and password Properties**

### General Properties

- `oracle.hadoop.exttab.colMap.columnLength` Specifies the length of all external table columns of type `CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, and `RAW`. Optional.
  - **Default Value**: The maximum length allowed by the column type
  - For Oracle Database 12c, Oracle SQL Connector for HDFS sets the length of `VARCHAR2`, `NVARCHAR2`, and `RAW` columns depending on whether the database `MAX_STRING_SIZE` option is set to `STANDARD` or `EXTENDED`.
  - **Valid values**: Integer
<table>
<thead>
<tr>

<tr>
<td><strong>Valid values:</strong></td>
<td>A datetime format model as described in the <em>Oracle Database SQL Language Reference</em>. However, it cannot contain quotation marks.</td>
</tr>
</tbody>
</table>
Property | Description
--- | ---
oracle.hadoop.exttab.colMap.column_name.fieldLength | Overrides the character buffer length used by the ORACLE_LOADER access driver for column_name. This property is especially useful for CLOB and extended data type columns. Optional. The column_name is case-sensitive. It must exactly match the name of a column in a Hive table or a column listed in oracle.hadoop.exttab.columnNames. Default value: Oracle SQL Connector for HDFS sets the default field lengths as shown in Table 2-4.

Table 2-4 Field Length Calculations

<table>
<thead>
<tr>
<th>Data Type of Target Column</th>
<th>Field Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR2, NVARCHAR2, CHAR, NCHAR</td>
<td>Value of oracle.hadoop.exttab.colMap.column_name.columnLength</td>
</tr>
<tr>
<td>RAW</td>
<td>2 * columnLength property</td>
</tr>
<tr>
<td>CLOB, NCLOB</td>
<td>Value of oracle.hadoop.exttab.colMap.fieldLength</td>
</tr>
<tr>
<td>All other types</td>
<td>255 (default size for external tables)</td>
</tr>
</tbody>
</table>

Valid values: Integer

oracle.hadoop.exttab.colMap.column_name.timestampMask | Overrides the format mask for column_name. Optional. The column_name is case-sensitive. It must exactly match the name of a column in a Hive table or a column listed in oracle.hadoop.exttab.columnNames. Default value: The value of oracle.hadoop.exttab.colMap.timestampMask. Valid values: A datetime format model as described in the Oracle Database SQL Language Reference. However, it cannot contain quotation marks.

oracle.hadoop.exttab.colMap.column_name.timestampTZMask | Overrides the format mask for column_name. Optional. The column_name is case-sensitive. It must exactly match the name of a column in a Hive table or a column listed in oracle.hadoop.exttab.columnNames. Default value: The value of oracle.hadoop.exttab.colMap.timestampTZMask. Valid values: A datetime format model as described in Oracle Database SQL Language Reference. However, it cannot contain quotation marks.

oracle.hadoop.exttab.columnCount | Specifies the number of columns for the external table created from delimited text files. The column names are set to C1, C2, ..., Cn, where n is value of this property. This property is ignored if oracle.hadoop.exttab.columnNames is set. The -createTable command uses this property when oracle.hadoop.exttab.sourceType=text. You must set either this property or oracle.hadoop.exttab.columnNames when creating an external table from delimited text files.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hadoop.exttab.columnNames</td>
<td>Specifies a comma-separated list of column names for an external table created from delimited text files. If this property is not set, then the column names are set to C1, C2,... Cn, where n is the value of the oracle.hadoop.exttab.columnCount property. The column names are read as SQL identifiers: unquoted values are capitalized, and double-quoted values stay exactly as entered. The -createTable command uses this property when oracle.hadoop.exttab.sourceType=text. You must set either this property or oracle.hadoop.exttab.columnCount when creating an external table from delimited text files.</td>
</tr>
</tbody>
</table>
| oracle.hadoop.exttab.dataCompressionCodec | Specifies the name of the compression codec class used to decompress the data files. Specify this property when the data files are compressed. Optional. This property specifies the class name of any compression codec that implements the org.apache.hadoop.io.compress.CompressionCodec interface. This codec applies to all data files. Several standard codecs are available in Hadoop, including the following:  
  - bzip2: org.apache.hadoop.io.compress.BZip2Codec  
  - gzip: org.apache.hadoop.io.compress.GzipCodec  
  To use codecs that may not be available on your Hadoop cluster (such as Snappy), you must first download, install, and configure them individually on your system. Default value: None |
oracle.hadoop.exttab.dataPaths  Specifies a comma-separated list of fully qualified HDFS paths. This property enables you to restrict the input by using special pattern-matching characters in the path specification. See Table 2-5. This property is required for the –createTable and –publish commands using Data Pump or delimited text files. The property is ignored for Hive data sources.

For example, to select all files in /data/s2/, and only the CSV files in /data/s7/, /data/s8/, and /data/s9/, enter this expression:

/data/s2/,/data/s[7-9]/*.csv

The external table accesses the data contained in all listed files and all files in listed directories. These files compose a single data set.

The data set can contain compressed files or uncompressed files, but not both.

Table 2-5  Pattern-Matching Characters

<table>
<thead>
<tr>
<th>Character</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches any single character</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more characters</td>
</tr>
<tr>
<td>[abc]</td>
<td>Matches a single character from the character set [a, b, c]</td>
</tr>
<tr>
<td>[a-b]</td>
<td>Matches a single character from the character range [a...b]. The character a must be less than or equal to b</td>
</tr>
<tr>
<td>[^a]</td>
<td>Matches a single character that is not from character set or range [a]. The carat (^) must immediately follow the left bracket.</td>
</tr>
<tr>
<td>\c</td>
<td>Removes any special meaning of character c. The backslash is the escape character.</td>
</tr>
<tr>
<td>[ab,cd]</td>
<td>Matches a string from the string set [ab, cd]. Precede the comma with an escape character () to remove the meaning of the comma as a path separator.</td>
</tr>
<tr>
<td>[ab,c(de ,fh)]</td>
<td>Matches a string from the string set [ab, cde, cfh]. Precede the comma with an escape character () to remove the meaning of the comma as a path separator.</td>
</tr>
</tbody>
</table>

oracle.hadoop.exttab.dataPathFilter  Specifies the path filter class. This property is ignored for Hive data sources.

Oracle SQL Connector for HDFS uses a default filter to exclude hidden files, which begin with a dot or an underscore. If you specify another path filter class using this property, then your filter acts in addition to the default filter. Thus, only visible files accepted by your filter are considered.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.exttab.defaultDirectory | Specifies the default directory for the Oracle external table. This directory is used for all input and output files that do not explicitly name a directory object. In Oracle RAC, this directory must be on a shared directory accessible by all Oracle instances. 

**Valid value:** The name of an existing database directory

Unquoted names are changed to upper case. Double-quoted names are not changed; use them when case-sensitivity is desired. Single-quoted names are not allowed for default directory names.

The -createTable command requires this property. |
| oracle.hadoop.exttab.fieldTerminator | Specifies the field terminator for an external table when oracle.hadoop.exttab.sourceType=text. Optional. 

**Default value:** , (comma)

**Valid values:** A string in one of the following formats:

- One or more regular printable characters; it cannot start with \u. For example, \t represents a tab.
- One or more encoded characters in the format \uHHHH, where HHHH is a big-endian hexadecimal representation of the character in UTF-16. For example, \u0009 represents a tab. The hexadecimal digits are case insensitive.

Do not mix the two formats. |
**Property** | **Description**
---|---
**oracle.hadoop.exttab.hive.columnType.** | Maps a Hive data type to an Oracle data type. The property name identifies the Hive data type, and its value is an Oracle data type. The target columns in the external table are created with the Oracle data type indicated by this property.

When Hive `TIMESTAMP` column is mapped to an Oracle `TIMESTAMP` column, then the format mask is `YYYY-MM-DD H24:MI:SS.FF`. When a Hive `STRING` column is mapped to an Oracle `TIMESTAMP` column, then the NLS parameter settings for the database are used by default. You can override these defaults by using either the `oracle.hadoop.exttab.colMap.timestampMask` or `oracle.hadoop.exttab.colMap.timestampTZMask` properties.

**Default values:** Table 2-6 lists the Hive column type properties and their default values.

**Valid values:** See the valid values for `oracle.hadoop.exttab.colMap.columnType`.

<table>
<thead>
<tr>
<th><strong>Table 2-6 Hive Column Type Mapping Properties</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.BIGINT</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.BOOLEAN</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.DECIMAL</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.DOUBLE</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.FLOAT</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.INT</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.SMALLINT</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.STRING</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.TIMESTAMP</code></td>
</tr>
<tr>
<td><code>oracle.hadoop.exttab.hive.columnType.TINYINT</code></td>
</tr>
</tbody>
</table>

**oracle.hadoop.exttab.hive.databaseName** | Specifies the name of a Hive database that contains the input data table. The `-createTable` command requires this property when `oracle.hadoop.exttab.sourceType=hive`. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hadoop.exttab.hive.partitionFilter</td>
<td>Specifies a valid HiveQL expression that is used to filter the source Hive table partitions. This property is ignored if the table is not partitioned.</td>
</tr>
</tbody>
</table>

**Type:** String

**Default value:** None. All partitions of the Hive table are mapped to external tables.

**Valid values:** A valid HiveQL expression.

**Description:** Specifies a valid HiveQL expression that is used to filter the source Hive table partitions. This property is ignored if the Hive table is not partitioned. Including other columns does not raise an error, but unintended consequences can result. Oracle recommends that you exclude other columns.

The expression must conform to the following restrictions:

- Selects partitions and not individual records inside the partitions.
- Does not include columns that are not used to partition the table, because they might cause unintended consequences.
- Does not include subqueries.
- Does not include user-defined functions (UDFs). Built-in functions are supported.
- Does not support Hive variable name spaces (such as env:, system:, hiveconf:, and hivevar:) because Hive variable expansion is disabled when OSCH processes this string. Expand all variables in Hive CLI before setting this property. For example:

  ```sql
  CREATE VIEW view_name AS SELECT * from database.table_name WHERE expression;
  DESCRIBE FORMATTED view_name;
  ```

  The View Original Text field contains the query with all variables expanded. Copy the where clause, starting after where.

  Since all variable expansions are resolved at the Hadoop level, define any Hadoop variables used in the expression using generic options (-D and -conf). Use the Hive CLI to test the expression and ensure that it returns the expected results. The following examples assume a source table defined with this command:

  ```sql
  CREATE TABLE t(c string)
  PARTITIONED BY (p1 string, p2 int, p3 boolean, p4 string, p5 timestamp);  
  ```

  **Example 1: Nested Expressions**

  ```sql
  p1 like 'abc%' or (p5 >= '2010-06-20' and p5 <= '2010-07-03')
  ```

  **Example 2: Built-in Functions**

  ```sql
  year(p5) = 2014
  ```

  **Example 3: Bad Usage: Columns That Are Not Used to Partition the Table**

  These examples show that using c, a column that is not used to partition the table, is unnecessary and can cause unexpected results.

  This example is equivalent to `p2 > 35`:

  ```sql
  p2 > 35 and c like 'abc%'
  ```
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>oracle.hadoop.exttab.hive.tablename</td>
<td>Specifies the name of an existing Hive table. The -createTable command requires this property when oracle.hadoop.exttab.sourceType=hive.</td>
</tr>
</tbody>
</table>
| oracle.hadoop.exttab.initial.FieldEncloser | Specifies the initial field encloser for an external table created from delimited text files. Optional. **Default value**: null; no enclosers are specified for the external table definition. The -createTable command uses this property when oracle.hadoop.exttab.sourceType=text. **Valid values**: A string in one of the following formats:  
  - One or more regular printable characters; it cannot start with \u.  
  - One or more encoded characters in the format \uHHHH, where HHHH is a big-endian hexadecimal representation of the character in UTF-16. The hexadecimal digits are case insensitive. Do not mix the two formats. |
| oracle.hadoop.exttab.locationFileCount | Specifies the desired number of location files for the external table. Applicable only to non-Data-Pump files. **Default value**: 4  
This property is ignored if the data files are in Data Pump format. Otherwise, the number of location files is the lesser of:  
  - The number of data files  
  - The value of this property  
At least one location file is created. See “Enabling Parallel Processing” for more information about the number of location files. |
### oracle.hadoop.exttab.logDirectory

Specifies a database directory where log files and bad files are stored. The file names are the default values used by external tables. For example, the name of a log file is the table name followed by \_\%p.log.

This is an optional property for the `createTable` command.

These are the default file name extensions:
- Log files: log
- Bad files: bad

**Valid values:** An existing Oracle directory object name.

Unquoted names are changed to uppercase. Quoted names are not changed. Table 2-7 provides examples of how values are transformed.

<table>
<thead>
<tr>
<th>Specified Value</th>
<th>Interpreted Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>my_log_dir: 'sales_tab_%p.log'</code></td>
<td><code>MY_LOG_DIR/sales_tab_%p.log</code></td>
</tr>
<tr>
<td><code>my_log_dir: 'sales_tab_%p.log'</code></td>
<td><code>my_log_dir/sales_tab_%p.log</code></td>
</tr>
<tr>
<td><code>&quot;my_log_dir&quot;: &quot;sales_tab_%p.log&quot;</code></td>
<td><code>my_log_dir/sales_tab_%p.log</code></td>
</tr>
</tbody>
</table>

### oracle.hadoop.exttab.preprocessorDirectory

Specifies the database directory for the preprocessor. The file-system directory must contain the `hdfs_stream` script.

**Default value:** `OSCH_BIN_PATH`

The preprocessor directory is used in the `PREPROCESSOR` clause of the external table.

### oracle.hadoop.exttab.preprocessorScript

Specifies the name of the preprocessor script for the external table.

**Default value:** `hdfs_stream`

The preprocessor script name is used in the `PREPROCESSOR` clause of the external table. This property is required only for Oracle Database running on Microsoft Windows platforms and is optional for all other Oracle Database platforms. On Microsoft Windows, the value must be set to `hdfs_stream.cmd`.

### oracle.hadoop.exttab.recordDelimiter

Specifies the record delimiter for an external table created from delimited text files. Optional.

**Default value:** `\n`

The `createTable` command uses this property when `sourceType=text`.

**Valid values:** A string in one of the following formats:
- One or more regular printable characters; it cannot start with `\u`.
- One or more encoded characters in the format `\uHHHH`, where `HHHH` is a big-endian hexadecimal representation of the character in UTF-16. The hexadecimal digits are case insensitive.

Do not mix the two formats.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| `oracle.hadoop.exttab.sourcetype` | Specifies the type of source files. The `-createTable` and `-publish` operations require the value of this property.  
**Default value:** text  
**Valid values:** datapump, hive, or text |
| `oracle.hadoop.exttab.string Sizes` | Indicates whether the lengths specified for character strings are bytes or characters. This value is used in the `STRING SIZES ARE IN` clause of the external table. Use characters when loading multibyte character sets. See Oracle Database Utilities.  
**Default value:** BYTES  
**Valid values:** BYTES or CHARACTERS |
| `oracle.hadoop.exttab.create LogFiles` | Specifies whether the log files should be created when the external tables are queried. Oracle recommends enabling log file creation during development and disabling log file creation during production for best performance.  
**Default value:** TRUE  
Log files are created by default. To stop creating log files you must drop the table, set this property to `FALSE`, and then recreate the table. Use the `-drop` and `-createTable` commands to drop and recreate the table. |
| `oracle.hadoop.exttab.create BadFiles` | Specifies whether bad files should be created when the external tables are queried. Bad files contain information on rows with bad data. Bad files are created only when there is bad data. Oracle recommends creating bad files.  
**Default value:** TRUE  
Bad files are created by default. To stop creating bad files you must drop the table, set this property to `FALSE`, and then recreate the table. Use the `-drop` and `-createTable` commands to drop and recreate the table.  
This property applies only to Hive and Delimited Text sources. |
| `oracle.hadoop.exttab.table Name` | Specifies the metadata table for partitioned Hive tables or schema-qualified name of the external table for all other data sources, in this format:  
`schemaName.tableName`  
If you omit `schemaName`, then the schema name defaults to the connection user name.  
**Default value:** none  
Required property for all operations. |
Property | Description
--- | ---
`oracle.hadoop.exttab.trailingFieldEncloser` | Specifies the trailing field encloser for an external table created from delimited text files. Optional.

**Default value:** null; defaults to the value of `oracle.hadoop.exttab.initialFieldEncloser`

The `-createTable` command uses this property when `oracle.hadoop.exttab.sourceType=text`.

**Valid values:** A string in one of the following formats:
- One or more regular printable characters; it cannot start with `\u`.
- One or more encoded characters in the format `\uHHHH`, where `HHHH` is a big-endian hexadecimal representation of the character in UTF-16. The hexadecimal digits are case insensitive.

Do not mix the two formats.

---

Connections using url, user, and password Properties

The url, user, and password properties provide a distinct connection method. Do not mix these properties with those required for a connection using an Oracle Wallet.

| Property | Description |
--- | --- |
`oracle.hadoop.connection.url` | Specifies the database connection string in the thin-style service name format: `jdbc:oracle:thin:@//host_name:port/service_name`

If you are unsure of the service name, then enter this SQL command as a privileged user:

SQL> show parameter service

This property takes precedence over all other connection properties.

**Default value:** Not defined

**Valid values:** A string

`oracle.hadoop.connection.user` | Specifies an Oracle database log-in name. The `externalTable` tool prompts for a password if the `oracle.hadoop.connection.password` is not specified.

**Default value:** Not defined

**Valid values:** A string
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.connection.password | Password for the Oracle Database user. Oracle recommends that you do not use this property to store a clear text password outside of non-sensitive test or demo environments. You can force a password prompt/response by excluding the password property from the connection. In that case, the externalTable tool prompts for the password. If you require a connection with no prompt/response, use the Oracle Wallet connection method described in the next section instead.  
**Default value:** Not defined.  
**Valid values:** A string |

**Connections Using Oracle Wallet**

When using Oracle Wallet as an external password store, set these properties:

- oracle.hadoop.connection.tnsEntryName
- oracle.hadoop.connection.tns_admin
- oracle.hadoop.connection.wallet_location

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.connection.tnsEntryName | Specifies a TNS entry name defined in the tnsnames.ora file.  
This property is used with the oracle.hadoop.connection.tns_admin property.  
**Default value:** Not defined  
**Valid values:** A string |
| oracle.hadoop.connection.tns_admin | Specifies the directory that contains the tnsnames.ora file. Define this property to use transparent network substrate (TNS) entry names in database connection strings. When using TNSNames with the JDBC thin driver, you must set either this property or the Java oracle.net.tns_admin property. When both are set, this property takes precedence over oracle.net.tns_admin.  
This property must be set when using Oracle Wallet as an external password store. See oracle.hadoop.connection.wallet_location.  
**Default value:** The value of the Java oracle.net.tns_admin system property  
**Valid values:** A string |
oracle.hadoop.connection.wallet_location

Specifies a file path to an Oracle Wallet directory where the connection credential is stored.

Default value: Not defined

Valid values: A string

Tip: Connections using Oracle Wallet can accommodate many TNS entries and are therefore recommended over those using the user, password and url properties which are restricted to a single machine/port/servicename combination.

For a simple step-by-step demonstration, see the posting Using Oracle SQL Connector for HDFS with Oracle Wallet in the Connecting Hadoop With Oracle blog.

2.12 Performance Tips for Querying Data in HDFS

Parallel processing is extremely important when you are working with large volumes of data. When you use external tables, always enable parallel query with this SQL command:

```
ALTER SESSION ENABLE PARALLEL QUERY;
```

Before loading the data into an Oracle database from the external files created by Oracle SQL Connector for HDFS, enable parallel DDL:

```
ALTER SESSION ENABLE PARALLEL DDL;
```

Before inserting data into an existing database table, enable parallel DML with this SQL command:

```
ALTER SESSION ENABLE PARALLEL DML;
```

Hints such as APPEND and PQ_DISTRIBUTE also improve performance when you are inserting data.

See My Oracle Support Document 2111850.1 for additional details and examples for improving performance.
This chapter explains how to use Oracle Loader for Hadoop to load data from Apache Hadoop into tables in an Oracle database. It contains the following sections:

- What Is Oracle Loader for Hadoop?
- About the Modes of Operation
- Getting Started With Oracle Loader for Hadoop
- Creating the Target Table
- Creating a Job Configuration File
- About the Target Table Metadata
- About Input Formats
- Mapping Input Fields to Target Table Columns
- About Output Formats
- Running a Loader Job
- Handling Rejected Records
- Balancing Loads When Loading Data into Partitioned Tables
- Optimizing Communications Between Oracle Engineered Systems
- Oracle Loader for Hadoop Configuration Property Reference

3.1 What Is Oracle Loader for Hadoop?

Oracle Loader for Hadoop is an efficient and high-performance loader for fast loading of data from a Hadoop cluster into a table in an Oracle database. It prepartitions the data if necessary and transforms it into a database-ready format. It can also sort records by primary key or user-specified columns before loading the data or creating output files. Oracle Loader for Hadoop uses the parallel processing framework of Hadoop to perform these preprocessing operations, which other loaders typically perform on the database server as part of the load process. Offloading these operations to Hadoop reduces the CPU requirements on the database server, thereby lessening the performance impact on other database tasks.

Oracle Loader for Hadoop is a Java MapReduce application that balances the data across reducers to help maximize performance. It works with a range of input data formats that present the data as records with fields. It can read from sources that have the data already in a record format (such as Avro files or Apache Hive tables), or it can split the lines of a text file into fields.
You run Oracle Loader for Hadoop using the `hadoop` command-line utility. In the command line, you provide configuration settings with the details of the job. You typically provide these settings in a job configuration file.

If you have Java programming skills, you can extend the types of data that the loader can handle by defining custom input formats. Then Oracle Loader for Hadoop uses your code to extract the fields and records.

### 3.2 About the Modes of Operation

Oracle Loader for Hadoop operates in two modes:

- **Online Database Mode**
- **Offline Database Mode**

#### 3.2.1 Online Database Mode

In online database mode, Oracle Loader for Hadoop can connect to the target database using the credentials provided in the job configuration file or in an Oracle wallet. The loader obtains the table metadata from the database. It can insert new records directly into the target table or write them to a file in the Hadoop cluster. You can load records from an output file when the data is needed in the database, or when the database system is less busy.

Figure 3-1 shows the relationships among elements in online database mode.
About the Modes of Operation

**Figure 3-1 Online Database Mode**

- **Hadoop Cluster**
  - Input Data
  - Job Configuration
  - Oracle Loader for Hadoop
  - CVS or Data Pump Output File

- **Database System**
  - Table Metadata
  - Hadoop Data
  - Target Table

Oracle Loader for Hadoop

Oracle Database
3.2.2 Offline Database Mode

Offline database mode enables you to use Oracle Loader for Hadoop when the Oracle Database system is on a separate network from the Hadoop cluster, or is otherwise inaccessible. In this mode, Oracle Loader for Hadoop uses the information supplied in a table metadata file, which you generate using a separate utility. The loader job stores the output data in binary or text format output files on the Hadoop cluster. Loading the data into Oracle Database is a separate procedure using another utility, such as Oracle SQL Connector for Hadoop Distributed File System (HDFS) or SQL*Loader.

Figure 3-2 shows the relationships among elements in offline database mode. The figure does not show the separate procedure of loading the data into the target table.
Figure 3-2  Offline Database Mode

About the Modes of Operation
3.3 Getting Started With Oracle Loader for Hadoop

You take the following basic steps when using Oracle Loader for Hadoop:

1. The first time you use Oracle Loader for Hadoop, ensure that the software is installed and configured.
   See “Oracle Loader for Hadoop Setup.”

2. Connect to Oracle Database and create the target table.
   See “Creating the Target Table.”

3. If you are using offline database mode, then generate the table metadata.
   See “Generating the Target Table Metadata for Offline Database Mode.”

4. Log in to either a node in the Hadoop cluster or a system set up as a Hadoop client for the cluster.

5. If you are using offline database mode, then copy the table metadata to the Hadoop system where you are logged in.

6. Create a configuration file. This file is an XML document that describes configuration information, such as access to the target table metadata, the input format of the data, and the output format.
   See “Creating a Job Configuration File.”

7. Create an XML document that maps input fields to columns in the Oracle database table. Optional.
   See “Mapping Input Fields to Target Table Columns.”

8. Create a shell script to run the Oracle Loader for Hadoop job.
   See “Running a Loader Job.”

9. If you are connecting to a secure cluster, then you run `kinit` to authenticate yourself.

10. Run the shell script.

11. If the job fails, then use the diagnostic messages in the output to identify and correct the error.
    See “Job Reporting.”

12. After the job succeeds, check the command output for the number of rejected records. If too many records were rejected, then you may need to modify the input format properties.

13. If you generated text files or Data Pump-format files, then load the data into Oracle Database using one of these methods:
    - Create an external table using Oracle SQL Connector for HDFS (online database mode only).
      See Oracle SQL Connector for Hadoop Distributed File System.
• Copy the files to the Oracle Database system and use SQL*Loader or external tables to load the data into the target database table. Oracle Loader for Hadoop generates scripts that you can use for these methods.

See “About DelimitedTextOutputFormat” or “About DataPumpOutputFormat.”

14. Connect to Oracle Database as the owner of the target table. Query the table to ensure that the data loaded correctly. If it did not, then modify the input or output format properties as needed to correct the problem.

15. Before running the OraLoader job in a production environment, employ these optimizations:

   • Balancing Loads When Loading Data into Partitioned Tables
   • Optimizing Communications Between Oracle Engineered Systems

### 3.4 Creating the Target Table

Oracle Loader for Hadoop loads data into one target table, which must exist in the Oracle database. The table can be empty or contain data already. Oracle Loader for Hadoop does not overwrite existing data.

Create the table the same way that you would create one for any other purpose. It must comply with the following restrictions:

• Supported Data Types for Target Tables
• Supported Partitioning Strategies for Target Tables

### 3.4.1 Supported Data Types for Target Tables

You can define the target table using any of these data types:

• BINARY_DOUBLE
• BINARY_FLOAT
• CHAR
• DATE
• FLOAT
• INTERVAL DAY TO SECOND
• INTERVAL YEAR TO MONTH
• NCHAR
• NUMBER
• NVARCHAR2
• RAW
• TIMESTAMP
• TIMESTAMP WITH LOCAL TIME ZONE
The target table can contain columns with unsupported data types, but these columns must be nullable, or otherwise set to a value.

### 3.4.2 Supported Partitioning Strategies for Target Tables

Partitioning is a database feature for managing and efficiently querying very large tables. It provides a way to decompose a large table into smaller and more manageable pieces called partitions, in a manner entirely transparent to applications.

You can define the target table using any of the following single-level and composite-level partitioning strategies.

- Hash
- Hash-Hash
- Hash-List
- Hash-Range
- Interval
- Interval-Hash
- Interval-List
- Interval-Range
- List
- List-Hash
- List-List
- List-Range
- Range
- Range-Hash
- Range-List
- Range-Range

Oracle Loader for Hadoop does not support reference partitioning or virtual column-based partitioning.

#### See Also:

*Oracle Database VLDB and Partitioning Guide*

### 3.4.3 Compression

Oracle Loader for Hadoop does not compress data. Compressing data during load is defined by the table and database properties. To load data into a compressed table define the table and database properties accordingly.
Creating a Job Configuration File

A configuration file is an XML document that provides Hadoop with all the information it needs to run a MapReduce job. This file can also provide Oracle Loader for Hadoop with all the information it needs. See “Oracle Loader for Hadoop Configuration Property Reference”.

Configuration properties provide the following information, which is required for all Oracle Loader for Hadoop jobs:

- How to obtain the target table metadata.
  See “About the Target Table Metadata.”

- The format of the input data.
  See “About Input Formats.”

- The format of the output data.
  See “About Output Formats.”

OraLoader implements the org.apache.hadoop.util.Tool interface and follows the standard Hadoop methods for building MapReduce applications. Thus, you can supply the configuration properties in a file (as shown here) or on the hadoop command line. See “Running a Loader Job.”

You can use any text or XML editor to create the file. Example 3-1 provides an example of a job configuration file.

**Example 3-1   Job Configuration File**

```xml
<?xml version="1.0" encoding="UTF-8" ?>
<configuration>

<!--                          Input settings                             -->

<property>
    <name>mapreduce.job.inputformat.class</name>
    <value>oracle.hadoop.loader.lib.input.DelimitedTextInputFormat</value>
</property>

<property>
    <name>mapreduce.input.fileinputformat.inputdir</name>
    <value>/user/oracle/moviedemo/session/*00000</value>
</property>

<property>
    <name>oracle.hadoop.loader.input.fieldTerminator</name>
    <value>	</value>
</property>

3.6 About the Target Table Metadata

You must provide Oracle Loader for Hadoop with information about the target table. The way that you provide this information depends on whether you run Oracle Loader for Hadoop in online or offline database mode. See “About the Modes of Operation.”

3.6.1 Providing the Connection Details for Online Database Mode

Oracle Loader for Hadoop uses table metadata from the Oracle database to identify the column names, data types, partitions, and so forth. The loader automatically fetches the metadata whenever a JDBC connection can be established. Oracle recommends that you use a wallet to provide your credentials. To use an Oracle wallet, enter the following properties in the job configuration file:

- `oracle.hadoop.loader.connection.wallet_location`
- `oracle.hadoop.loader.connection.tns_admin`
- `oracle.hadoop.loader.connection.url` or `oracle.hadoop.loader.connection.tnsEntryName`

Oracle recommends that you do not store passwords in clear text; use an Oracle wallet instead to safeguard your credentials. However, if you are not using an Oracle wallet, then enter these properties:

- `oracle.hadoop.loader.connection.url`
- `oracle.hadoop.loader.connection.user`
- `oracle.hadoop.loader.connection.password`

3.6.2 Generating the Target Table Metadata for Offline Database Mode

Under some circumstances, the loader job cannot access the database, such as when the Hadoop cluster is on a different network than Oracle Database. In such cases, you can use the OraLoaderMetadata utility to extract and store the target table metadata in a file.

To provide target table metadata in offline database mode:

1. Log in to the Oracle Database system.
2. The first time you use offline database mode, ensure that the software is installed and configured on the database system.
   
   See “Providing Support for Offline Database Mode.”
3. Export the table metadata by running the OraLoaderMetadata utility program. See “OraLoaderMetadata Utility.”
4. Copy the generated XML file containing the table metadata to the Hadoop cluster.
5. Use the `oracle.hadoop.loader.tableMetadataFile` property in the job configuration file to specify the location of the XML metadata file on the Hadoop cluster.
When the loader job runs, it accesses this XML document to discover the target table metadata.

### 3.6.2.1 OraLoaderMetadata Utility

Use the following syntax to run the OraLoaderMetadata utility on the Oracle Database system. You must enter the java command on a single line, although it is shown here on multiple lines for clarity:

```java
java oracle.hadoop.loader.metadata.OraLoaderMetadata
    -user userName
    -connection_url connection
    [-schema schemaName]
    -table tableName
    -output fileName.xml
```

To see the OraLoaderMetadata Help file, use the command with no options.

**Options**

- **-user userName**
  The Oracle Database user who owns the target table. The utility prompts you for the password.

- **-connection_url connection**
  The database connection string in the thin-style service name format:

  ```
  jdbc:oracle:thin:@//hostName:port/serviceName
  ```

  If you are unsure of the service name, then enter this SQL command as a privileged user:

  ```
  show parameter service
  ```

<table>
<thead>
<tr>
<th>NAME</th>
<th>TYPE</th>
<th>VALUE</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_names</td>
<td>string</td>
<td>orcl</td>
</tr>
</tbody>
</table>

- **-schema schemaName**
  The name of the schema containing the target table. Unquoted values are capitalized, and unquoted values are used exactly as entered. If you omit this option, then the utility looks for the target table in the schema specified in the -user option.

- **-table tableName**
  The name of the target table. Unquoted values are capitalized, and unquoted values are used exactly as entered.

- **-output fileName.xml**
  The output file name used to store the metadata document.

**Example 3-2** shows how to store the target table metadata in an XML file.

**Example 3-2 Generating Table Metadata**

Run the OraLoaderMetadata utility:

```bash
```
The OraLoaderMetadata utility prompts for the database password.

3.7 About Input Formats

An input format reads a specific type of data stored in Hadoop. Several input formats are available, which can read the data formats most commonly found in Hadoop:

- Delimited Text Input Format
- Complex Text Input Formats
- Hive Table Input Format
- Avro Input Format
- Oracle NoSQL Database Input Format

You can also use your own custom input formats. The descriptions of the built-in formats provide information that may help you develop custom Java InputFormat classes. See “Custom Input Formats.”

You specify a particular input format for the data that you want to load into a database table, by using the mapreduce.job.inputformat.class configuration property in the job configuration file.
3.7.1 Delimited Text Input Format

To load data from a delimited text file, set `mapreduce.job.inputformat.class` to `oracle.hadoop.loader.lib.input.DelimitedTextInputFormat`.

3.7.1.1 About DelimitedTextInputFormat

The input file must comply with these requirements:

- Records must be separated by newline characters.
- Fields must be delimited using single-character markers, such as commas or tabs. A null replaces any empty-string token, whether enclosed or unenclosed.

`DelimitedTextInputFormat` emulates the tokenization method of SQL*Loader: Terminated by `t`, and optionally enclosed by `ie`, or by `ie` and `te`. `DelimitedTextInputFormat` uses the following syntax rules, where `t` is the field terminator, `ie` is the initial field encloser, `te` is the trailing field encloser, and `c` is one character.

- Line = Token t Line | Token
- Token = EnclosedToken | UnenclosedToken
- EnclosedToken = (white-space)* ie [(non-te)* te te] te (white-space)*
- UnenclosedToken = (white-space)* (non-t)*
- white-space = \{c \ Character.isWhitespace(c) and c!=t\}

White space around enclosed tokens (data values) is discarded. For unenclosed tokens, the leading white space is discarded, but not the trailing white space (if any).

This implementation enables you to define custom enclosers and terminator characters, but it hard codes the record terminator as a newline, and white space as `Java Character.isWhitespace(c)`. A white space can be defined as the field terminator, but then that character is removed from the class of white space characters to prevent ambiguity.

Hadoop automatically decompresses compressed text files when they are read.

3.7.1.2 Required Configuration Properties

None. The default format separates fields with commas and has no field enclosures.

3.7.1.3 Optional Configuration Properties

Use one or more of the following properties to define the field delimiters for `DelimitedTextInputFormat`:

- `oracle.hadoop.loader.input.fieldTerminator`
- `oracle.hadoop.loader.input.initialFieldEncloser`
3.7.2 Complex Text Input Formats

To load data from text files that are more complex than DelimitedTextInputFormat can handle, set mapreduce.job.inputformat.class to oracle.hadoop.loader.lib.input.RegexInputFormat. For example, a web log might delimit one field with quotes and another field with square brackets.

3.7.2.1 About RegexInputFormat

RegexInputFormat requires that records be separated by newline characters. It identifies fields in each text line by matching a regular expression:

- The regular expression must match the entire text line.
- The fields are identified using the capturing groups in the regular expression.

RegexInputFormat uses the java.util.regex regular expression-based pattern matching engine. Hadoop automatically decompresses compressed files when they are read.

See Also:

3.7.2.2 Required Configuration Properties

Use the following property to describe the data input file:

- oracle.hadoop.loader.input.regexPattern

3.7.2.3 Optional Configuration Properties

Use the following property to identify the names of all input fields:

- oracle.hadoop.loader.input.fieldNames

Use this property to enable case-insensitive matches:

- oracle.hadoop.loader.input.regexCaseInsensitive

3.7.3 Hive Table Input Format

To load data from a Hive table, set mapreduce.job.inputformat.class to oracle.hadoop.loader.lib.input.HiveToAvroInputFormat.
3.7.3.1 About HiveToAvroInputFormat

For nonpartitioned tables, HiveToAvroInputFormat imports the entire table, which is all files in the Hive table directory.

For partitioned tables, HiveToAvroInputFormat imports one or more of the partitions. You can either load or skip a partition. However, you cannot partially load a partition.

Oracle Loader for Hadoop rejects all rows with complex (non-primitive) column values. UNIONTYPE fields that resolve to primitive values are supported. See “Handling Rejected Records.”

HiveToAvroInputFormat transforms rows in the Hive table into Avro records, and capitalizes the Hive table column names to form the field names. This automatic capitalization improves the likelihood that the field names match the target table column names. See “Mapping Input Fields to Target Table Columns”.

Note:
This input format does not support Hive tables using quoted identifiers for column names. See HIVE-6013

Also note that HiveToAvroInputFormat does not enforce the SQL Standard Based Hive Authorization. For more information, see https://cwiki.apache.org/confluence/display/Hive/SQL+Standard+Based+Hive+Authorization.

3.7.3.2 Required Configuration Properties

You must specify the Hive database and table names using the following configuration properties:

• oracle.hadoop.loader.input.hive.databaseName
• oracle.hadoop.loader.input.hive.tableName

3.7.3.3 Optional Configuration Properties

To specify a subset of rows in the input Hive table to load, use the following property:

• oracle.hadoop.loader.input.hive.rowFilter

3.7.4 Avro Input Format

To load data from binary Avro data files containing standard Avro-format records, set mapreduce.job.inputformat.class to oracle.hadoop.loader.lib.input.AvroInputFormat

To process only files with the .avro extension, append *.avro to directories listed in the mapreduce.input.fileinputformat.inputdir configuration property.

3.7.4.1 Configuration Properties

None
3.7.5 Oracle NoSQL Database Input Format

To load data from Oracle NoSQL Database, set mapreduce.job.inputformat.class to oracle.kv.hadoop.KVAvroInputFormat

This input format is defined in Oracle NoSQL Database 11g, Release 2 and later releases.

3.7.5.1 About KVAvroInputFormat

Oracle Loader for Hadoop uses KVAvroInputFormat to read data directly from Oracle NoSQL Database.

KVAvroInputFormat passes the value but not the key from the key-value pairs in Oracle NoSQL Database. If you must access the Oracle NoSQL Database keys as Avro data values, such as storing them in the target table, then you must create a Java InputFormat class that implements oracle.kv.hadoop.AvroFormatter. Then you can specify the oracle.kv.formatterClass property in the Oracle Loader for Hadoop configuration file.

The KVAvroInputFormat class is a subclass of org.apache.hadoop.mapreduce.InputFormat<oracle.kv.Key, org.apache.avro.generic.IndexedRecord>

See Also:

3.7.5.2 Required Configuration Properties

You must specify the name and location of the key-value store using the following configuration properties:

- oracle.kv.hosts
- oracle.kv.kvstore

See “Oracle NoSQL Database Configuration Properties.”

3.7.6 Custom Input Formats

If the built-in input formats do not meet your needs, then you can write a Java class for a custom input format. The following information describes the framework in which an input format works in Oracle Loader for Hadoop.

3.7.6.1 About Implementing a Custom Input Format

Oracle Loader for Hadoop gets its input from a class extending org.apache.hadoop.mapreduce.InputFormat. You must specify the name of that class in the mapreduce.job.inputformat.class configuration property.

The input format must create RecordReader instances that return an Avro IndexedRecord input object from the getCurrentValue method. Use this method signature:
Oracle Loader for Hadoop uses the schema of the `IndexedRecord` input object to discover the names of the input fields and map them to the columns of the target table.

### 3.7.6.2 About Error Handling

If processing an `IndexedRecord` value results in an error, Oracle Loader for Hadoop uses the object returned by the `getCurrentKey` method of the `RecordReader` to provide feedback. It calls the `toString` method of the key and formats the result in an error message. `InputFormat` developers can assist users in identifying the rejected records by returning one of the following:

- Data file URI
- `InputSplit` information
- Data file name and the record offset in that file

Oracle recommends that you do not return the record in clear text, because it might contain sensitive information; the returned values can appear in Hadoop logs throughout the cluster. See “Logging Rejected Records in Bad Files.”

If a record fails and the key is null, then the loader generates no identifying information.

### 3.7.6.3 Supporting Data Sampling

Oracle Loader for Hadoop uses a sampler to improve performance of its MapReduce job. The sampler is multithreaded, and each sampler thread instantiates its own copy of the supplied `InputFormat` class. When implementing a new `InputFormat`, ensure that it is thread-safe. See “Balancing Loads When Loading Data into Partitioned Tables.”

### 3.7.6.4 InputFormat Source Code Example

Oracle Loader for Hadoop provides the source code for an `InputFormat` example, which is located in the `examples/jsrc/` directory.

The sample format loads data from a simple, comma-separated value (CSV) file. To use this input format, specify `oracle.hadoop.loader.examples.CSVInputFormat` as the value of `mapreduce.job.inputformat.class` in the job configuration file.

This input format automatically assigns field names of F0, F1, F2, and so forth. It does not have configuration properties.

### 3.8 Mapping Input Fields to Target Table Columns

Mapping identifies which input fields are loaded into which columns of the target table. You may be able to use the automatic mapping facilities, or you can always manually map the input fields to the target columns.

#### 3.8.1 Automatic Mapping

Oracle Loader for Hadoop can automatically map the fields to the appropriate columns when the input data complies with these requirements:

- All columns of the target table are loaded.
• The input data field names in the IndexedRecord input object exactly match the column names.

• All input fields that are mapped to DATE columns can be parsed using the same Java date format.

Use these configuration properties for automatic mappings:

• oracle.hadoop.loader.loaderMap.targetTable: Identifies the target table.

• oracle.hadoop.loader.defaultDateFormat: Specifies a default date format that applies to all DATE fields.

3.8.2 Manual Mapping

For loads that do not comply with the requirements for automatic mapping, you must define additional properties. These properties enable you to:

• Load data into a subset of the target table columns.

• Create explicit mappings when the input field names are not identical to the database column names.

• Specify different date formats for different input fields.

Use these properties for manual mappings:

• oracle.hadoop.loader.loaderMap.targetTable configuration property to identify the target table. Required.

• oracle.hadoop.loader.loaderMap.columnNames: Lists the columns to be loaded.

• oracle.hadoop.loader.defaultDateFormat: Specifies a default date format that applies to all DATE fields.

• oracle.hadoop.loader.loaderMap.column_name.format: Specifies the data format for a particular column.

• oracle.hadoop.loader.loaderMap.column_name.field: Identifies the name of an Avro record field mapped to a particular column.

3.8.3 Converting a Loader Map File

The following utility converts a loader map file from earlier releases to a configuration file:

    hadoop oracle.hadoop.loader.metadata.LoaderMap -convert map_file conf_file

Options

map_file
The name of the input loader map file on the local file system (not HDFS).

conf_file
The name of the output configuration file on the local file system (not HDFS).

Example 3-3 shows a sample conversion.
Example 3-3  Converting a Loader File to Configuration Properties

```
$ HADOOP_CLASSPATH="$OLH_HOME/jlib/*:$HADOOP_CLASSPATH"
$ hadoop oracle.hadoop.loader.metadata.LoaderMap -convert loadermap.xml conf.xml
```

Oracle Loader for Hadoop Release 3.5.0 - Production

Input Loader Map File loadermap.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<LOADER_MAP>
  <SCHEMA>HR</SCHEMA>
  <TABLE>EMPLOYEES</TABLE>
  <COLUMN field="F0">EMPLOYEE_ID</COLUMN>
  <COLUMN field="F1">LAST_NAME</COLUMN>
  <COLUMN field="F2">EMAIL</COLUMN>
  <COLUMN field="F3" format="MM-dd-yyyy">HIRE_DATE</COLUMN>
  <COLUMN field="F4">JOB_ID</COLUMN>
</LOADER_MAP>
```

Output Configuration File conf.xml

```
<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<configuration>
  <property>
    <name>oracle.hadoop.loader.loaderMap.targetTable</name>
    <value>HR.EMPLOYEES</value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.columnNames</name>
    <value>EMPLOYEE_ID,LAST_NAME,EMAIL,HIRE_DATE,JOB_ID</value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.EMPLOYEE_ID.field</name>
    <value>F0</value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.EMPLOYEE_ID.format</name>
    <value></value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.LAST_NAME.field</name>
    <value>F1</value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.LAST_NAME.format</name>
    <value></value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.EMAIL.field</name>
    <value>F2</value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.EMAIL.format</name>
    <value></value>
  </property>
  <property>
    <name>oracle.hadoop.loader.loaderMap.HIRE_DATE.field</name>
    <value>F3</value>
  </property>
</configuration>
```
3.9 About Output Formats

In online database mode, you can choose between loading the data directly into an Oracle database table or storing it in a file. In offline database mode, you are restricted to storing the output data in a file, which you can load into the target table as a separate procedure. You specify the output format in the job configuration file using the `mapreduce.job.outputformat.class` property.

Choose from these output formats:

- **JDBC Output Format**: Loads the data directly into the target table.
- **Oracle OCI Direct Path Output Format**: Loads the data directly into the target table.
- **Delimited Text Output Format**: Stores the data in a local file.
- **Oracle Data Pump Output Format**: Stores the data in a local file.

### 3.9.1 JDBC Output Format

You can use a JDBC connection between the Hadoop system and Oracle Database to load the data. The output records of the loader job are loaded directly into the target table by map or reduce tasks as part of the `OraLoader` process, in online database mode. No additional steps are required to load the data.

A JDBC connection must be open between the Hadoop cluster and the Oracle Database system for the duration of the job.

To use this output format, set `mapreduce.job.outputformat.class` to `oracle.hadoop.loader.lib.output.JDBCOutputFormat`.

#### 3.9.1.1 About JDBCOutputFormat

`JDBCOutputFormat` uses standard JDBC batching to optimize performance and efficiency. If an error occurs during batch execution, such as a constraint violation, the JDBC driver stops execution immediately. Thus, if there are 100 rows in a batch and the tenth row causes an error, then nine rows are inserted and 91 rows are not. The JDBC driver does not identify the row that caused the error, and so Oracle Loader for Hadoop does not know the insert status of any of the rows in the batch. It counts all rows in a batch with errors as “in question,” that is, the rows may or may not be inserted in the target table. The loader then continues loading the next batch. It generates a load report at the end of the job that details the number of batch errors and the number of rows in question.
One way that you can handle this problem is by defining a unique key in the target table. For example, the HR.EMPLOYEES table has a primary key named EMPLOYEE_ID. After loading the data into HR.EMPLOYEES, you can query it by EMPLOYEE_ID to discover the missing employee IDs. Then you can locate the missing employee IDs in the input data, determine why they failed to load, and try again to load them.

### 3.9.1.2 Configuration Properties

To control the batch size, set this property:

```properties
oracle.hadoop.loader.connection.defaultExecuteBatch
```

### 3.9.2 Oracle OCI Direct Path Output Format

You can use the direct path interface of Oracle Call Interface (OCI) to load data into the target table. Each reducer loads into a distinct database partition in online database mode, enabling the performance gains of a parallel load. No additional steps are required to load the data.

The OCI connection must be open between the Hadoop cluster and the Oracle Database system for the duration of the job.

To use this output format, set `mapreduce.job.outputformat.class` to

```properties
oracle.hadoop.loader.lib.output.OCIOutputFormat
```

#### 3.9.2.1 About OCIOutputFormat

OCIOutputFormat has the following restrictions:

- It is available only on the Linux x86.64 platform.
- The MapReduce job must create one or more reducers.
- The target table must be partitioned.
- For Oracle Database 11g (11.2.0.3), apply the patch for bug 13498646 if the target table is a composite interval partitioned table in which the subpartition key contains a CHAR, VARCHAR2, NCHAR, or NVARCHAR2 column. Later versions of Oracle Database do not require this patch.

#### 3.9.2.2 Configuration Properties

To control the size of the direct path stream buffer, set this property:

```properties
oracle.hadoop.loader.output.dirpathBufsize
```

### 3.9.3 Delimited Text Output Format

You can create delimited text output files on the Hadoop cluster. The map or reduce tasks generate delimited text files, using the field delimiters and enclosers that you specify in the job configuration properties. Afterward, you can load the data into an Oracle database as a separate procedure. See “About DelimitedTextOutputFormat.”

This output format can use either an open connection to the Oracle Database system to retrieve the table metadata in online database mode, or a table metadata file generated by the OraloaderMetadata utility in offline database mode.

To use this output format, set `mapreduce.job.outputformat.class` to

```properties
oracle.hadoop.loader.lib.output.DelimitedTextOutputFormat
```
3.9.3.1 About DelimitedTextOutputFormat

Output tasks generate delimited text format files, and one or more corresponding SQL*Loader control files, and SQL scripts for loading with external tables.

If the target table is not partitioned or if oracle.hadoop.loader.loadByPartition is false, then DelimitedTextOutputFormat generates the following files:

- A data file named `oraloader-taskId-csv-0.dat`.
- A SQL*Loader control file named `oraloader-csv.ctl` for the entire job.
- A SQL script named `oraloader-csv.sql` to load the delimited text file into the target table.

For partitioned tables, multiple output files are created with the following names:

- Data files: `oraloader-taskId-csv-partitionId.dat`
- SQL*Loader control files: `oraloader-taskId-csv-partitionId.ctl`
- SQL script: `oraloader-csv.sql`

In the generated file names, `taskId` is the mapper or reducer identifier, and `partitionId` is the partition identifier.

If the Hadoop cluster is connected to the Oracle Database system, then you can use Oracle SQL Connector for HDFS to load the delimited text data into an Oracle database. See Oracle SQL Connector for Hadoop Distributed File System.

Alternatively, you can copy the delimited text files to the database system and load the data into the target table in one of the following ways:

- Use the generated control files to run SQL*Loader and load the data from the delimited text files.
- Use the generated SQL scripts to perform external table loads.

The files are located in the `$mapreduce.output.fileoutputformat.outputdir/_olh` directory.

3.9.3.2 Configuration Properties

The following properties control the formatting of records and fields in the output files:

- `oracle.hadoop.loader.output.escapeEnclosers`
- `oracle.hadoop.loader.output.fieldTerminator`
- `oracle.hadoop.loader.output.initialFieldEncloser`
- `oracle.hadoop.loader.output.trailingFieldEncloser`

Example 3-4 shows a sample SQL*Loader control file that might be generated by an output task.

**Example 3-4 Sample SQL*Loader Control File**

```sql
LOAD DATA CHARACTERSET AL32UTF8
INFILE 'oraloader-csv-1-0.dat'
BADFILE 'oraloader-csv-1-0.bad'
DISCARDFILE 'oraloader-csv-1-0.dsc'
```
3.9.4 Oracle Data Pump Output Format

You can create Data Pump format files on the Hadoop cluster. The map or reduce tasks generate Data Pump files. Afterward, you can load the data into an Oracle database as a separate procedure. See “About DataPumpOutputFormat.”

This output format can use either an open connection to the Oracle Database system in online database mode, or a table metadata file generated by the OraloaderMetadata utility in offline database mode.

To use this output format, set `mapreduce.job.outputformat.class` to `oracle.hadoop.loader.lib.output.DataPumpOutputFormat`

3.9.4.1 About DataPumpOutputFormat

DataPumpOutputFormat generates data files with names in this format:

```
oraloader-taskId-dp-partitionId.dat
```

In the generated file names, `taskId` is the mapper or reducer identifier, and `partitionId` is the partition identifier.

If the Hadoop cluster is connected to the Oracle Database system, then you can use Oracle SQL Connector for HDFS to load the Data Pump files into an Oracle database. See Oracle SQL Connector for Hadoop Distributed File System.

Alternatively, you can copy the Data Pump files to the database system and load them using a SQL script generated by Oracle Loader for Hadoop. The script performs the following tasks:

1. Creates an external table definition using the ORACLE_DATAPUMP access driver. The binary format Oracle Data Pump output files are listed in the LOCATION clause of the external table.

2. Creates a directory object that is used by the external table. You must uncomment this command before running the script. To specify the directory name used in the script, set the `oracle.hadoop.loader.extTabDirectoryName` property in the job configuration file.

3. Insert the rows from the external table into the target table. You must uncomment this command before running the script.

The SQL script is located in the `$ {mapreduce.output.fileoutputformat.outputdir}/_olh` directory.
3.10 Running a Loader Job

To run a job using Oracle Loader for Hadoop, you use the OraLoader utility in a hadoop command.

The following is the basic syntax:

```
hadoop jar $OLH_HOME/jlib/oraloader.jar oracle.hadoop.loader.OraLoader \
-conf job_config.xml \
-libjars input_file_format1.jar[,input_file_format2.jar...]```

You can include any generic hadoop command-line option. OraLoader implements the org.apache.hadoop.util.Tool interface and follows the standard Hadoop methods for building MapReduce applications.

**Basic Options**

- **-conf job_config.xml**
  Identifies the job configuration file. See “Creating a Job Configuration File.”

- **-libjars**
  Identifies the JAR files for the input format.

  - When using the example input format, specify $OLH_HOME/jlib/oraloader-examples.jar.
  
  - When using the Hive or Oracle NoSQL Database input formats, you must specify additional JAR files, as described later in this section.
  
  - When using a custom input format, specify its JAR file. (Also remember to add it to HADOOP_CLASSPATH.)

Separate multiple file names with commas, and list each one explicitly. Wildcard characters and spaces are not allowed.

Oracle Loader for Hadoop prepares internal configuration information for the MapReduce tasks. It stores table metadata information and the dependent Java libraries in the distributed cache, so that they are available to the MapReduce tasks throughout the cluster.

**Example of Running OraLoader**

The following example uses a built-in input format and a job configuration file named MyConf.xml:

```
HADOOP_CLASSPATH="$OLH_HOME/jlib/*:$HADOOP_CLASSPATH"
hadoop jar $OLH_HOME/jlib/oraloader.jar oracle.hadoop.loader.OraLoader \
-conf MyConf.xml -libjars $OLH_HOME/jlib/oraloader-examples.jar
```
### 3.10.1 Specifying Hive Input Format JAR Files

When using HiveToAvroInputFormat, you must add the Hive configuration directory to the HADOOP_CLASSPATH environment variable:

```
HADOOP_CLASSPATH="$OLH_HOME/jlib/*:hive_home/lib/*:hive_conf_dir:$HADOOP_CLASSPATH"
```

You must also add the following Hive JAR files, in a comma-separated list, to the `-libjars` option of the `hadoop` command. Replace the stars (*) with the complete file names on your system:

- `hive-exec-*`.jar
- `hive-metastore-*`.jar
- `libfb303*.jar`

This example shows the full file names in Cloudera's Distribution including Apache Hadoop (CDH) 5.8:

```
# hadoop jar $OLH_HOME/jlib/oraloader.jar oracle.hadoop.loader.OraLoader 
  -conf MyConf.xml  
  -libjars hive-exec-1.1.0-cdh5.8.0.jar, hive-metastore-1.1.0-cdh5.8.0.jar,  
    libfb303-0.9.3.jar
```

### 3.10.2 Specifying Oracle NoSQL Database Input Format JAR Files

When using KVAvroInputFormat from Oracle NoSQL Database 11g, Release 2, you must include `$KVHOME/lib/kvstore.jar` in your HADOOP_CLASSPATH and you must include the `-libjars` option in the `hadoop` command:

```
hadoop jar $OLH_HOME/jlib/oraloader.jar oracle.hadoop.loader.OraLoader  
  -conf MyConf.xml  
  -libjars $KVHOME/lib/kvstore.jar
```

### 3.10.3 Job Reporting

Oracle Loader for Hadoop consolidates reporting information from individual tasks into a file named `${mapreduce.output.fileoutputformat.outputdir}/_olh/oraloader-report.txt`. Among other statistics, the report shows the number of errors, broken out by type and task, for each mapper and reducer.

### 3.11 Handling Rejected Records

Oracle Loader for Hadoop may reject input records for a variety of reasons, such as:

- Errors in the mapping properties
- Missing fields in the input data
- Records mapped to invalid table partitions
Badly formed records, such as dates that do not match the date format or records that do not match regular expression patterns

### 3.11.1 Logging Rejected Records in Bad Files

By default, Oracle Loader for Hadoop does not log the rejected records into Hadoop logs; it only logs information on how to identify the rejected records. This practice prevents user-sensitive information from being stored in Hadoop logs across the cluster.

You can direct Oracle Loader for Hadoop to log rejected records by setting the `oracle.hadoop.loader.logBadRecords` configuration property to `true`. Then Oracle Loader for Hadoop logs bad records into one or more "bad" files in the `_olh/` directory under the job output directory.

### 3.11.2 Setting a Job Reject Limit

Some problems can cause Oracle Loader for Hadoop to reject every record in the input. To mitigate the loss of time and resources, Oracle Loader for Hadoop aborts the job after rejecting 1000 records.

You can change the maximum number of rejected records allowed by setting the `oracle.hadoop.loader.rejectLimit` configuration property. A negative value turns off the reject limit and allows the job to run to completion regardless of the number of rejected records.

### 3.12 Balancing Loads When Loading Data into Partitioned Tables

The goal of load balancing is to generate a MapReduce partitioning scheme that assigns approximately the same amount of work to all reducers.

The sampling feature of Oracle Loader for Hadoop balances loads across reducers when data is loaded into a partitioned database table. It generates an efficient MapReduce partitioning scheme that assigns database partitions to the reducers.

The execution time of a reducer is usually proportional to the number of records that it processes—the more records, the longer the execution time. When sampling is disabled, all records from a given database partition are sent to one reducer. This can result in unbalanced reducer loads, because some database partitions may have more records than others. Because the execution time of a Hadoop job is usually dominated by the execution time of its slowest reducer, unbalanced reducer loads slow down the entire job.

### 3.12.1 Using the Sampling Feature

You can turn the sampling feature on or off by setting the `oracle.hadoop.loader.sampler.enableSampling` configuration property. Sampling is turned on by default.

### 3.12.2 Tuning Load Balancing

These job configuration properties control the quality of load balancing:

- `oracle.hadoop.loader.sampler.maxLoadFactor`
- `oracle.hadoop.loader.sampler.loadCI`
The sampler uses the expected reducer load factor to evaluate the quality of its partitioning scheme. The **load factor** is the relative overload for each reducer, calculated as \( \frac{\text{assigned_load} - \text{ideal_load}}{\text{ideal_load}} \). This metric indicates how much a reducer's load deviates from a perfectly balanced reducer load. A load factor of 1.0 indicates a perfectly balanced load (no overload).

Small load factors indicate better load balancing. The **maxLoadFactor** default of 0.05 means that no reducer is ever overloaded by more than 5%. The sampler guarantees this **maxLoadFactor** with a statistical confidence level determined by the value of **loadCI**. The default value of **loadCI** is 0.95, which means that any reducer's load factor exceeds **maxLoadFactor** in only 5% of the cases.

There is a trade-off between the execution time of the sampler and the quality of load balancing. Lower values of **maxLoadFactor** and higher values of **loadCI** achieve more balanced reducer loads at the expense of longer sampling times. The default values of **maxLoadFactor=0.05** and **loadCI=0.95** are a good trade-off between load balancing quality and execution time.

### 3.12.3 Tuning Sampling Behavior

By default, the sampler runs until it collects just enough samples to generate a partitioning scheme that satisfies the **maxLoadFactor** and **loadCI** criteria. However, you can limit the sampler running time by setting the `oracle.hadoop.loader.sampler.maxSamplesPct` property, which specifies the maximum number of sampled records.

### 3.12.4 When Does Oracle Loader for Hadoop Use the Sampler's Partitioning Scheme?

Oracle Loader for Hadoop uses the generated partitioning scheme only if sampling is successful. A sampling is successful if it generates a partitioning scheme with a maximum reducer load factor of \( (1 + \text{maxLoadFactor}) \) guaranteed at a statistical confidence level of **loadCI**.

Partition report identifies the keys that are assigned to the various mappers. This report is saved in XML for the sampler to use; it does not contain information of use to you. The report is named 

\[
\text{mapreduce.output.fileoutputformat.outputdir}/\_balancer/orabalancer
to_report.xml
\]

It is only generated for sampled jobs. This XML file contains the information about how to assign map output to different reducers, as well as the sampling statistics.

The default values of **maxLoadFactor**, **loadCI**, and **maxSamplesPct** allow the sampler to successfully generate high-quality partitioning schemes for a variety of different input data distributions. However, the sampler might be unsuccessful in generating a partitioning scheme using custom property values, such as when the constraints are too rigid or the number of required samples exceeds the user-specified maximum of **maxSamplesPct**. In these cases, Oracle Loader for Hadoop generates a log message identifying the problem, partitions the records using the database partitioning scheme, and does not guarantee load balancing.

Alternatively, you can reset the configuration properties to less rigid values. Either increase **maxSamplesPct**, or decrease **maxLoadFactor** or **loadCI**, or both.
3.12.5 Resolving Memory Issues

A custom input format may return input splits that do not fit in memory. If this happens, the sampler returns an out-of-memory error on the client node where the loader job is submitted.

To resolve this problem:

• Increase the heap size of the JVM where the job is submitted.
• Adjust the following properties:
  – oracle.hadoop.loader.sampler.hintMaxSplitSize
  – oracle.hadoop.loader.sampler.hintNumMapTasks

If you are developing a custom input format, then see “Custom Input Formats.”

3.12.6 What Happens When a Sampling Feature Property Has an Invalid Value?

If any configuration properties of the sampling feature are set to values outside the accepted range, an exception is not returned. Instead, the sampler prints a warning message, resets the property to its default value, and continues executing.

3.13 Optimizing Communications Between Oracle Engineered Systems

If you are using Oracle Loader for Hadoop to load data from Oracle Big Data Appliance to Oracle Exadata Database Machine, then you can increase throughput by configuring the systems to use Sockets Direct Protocol (SDP) over the InfiniBand private network. This setup provides an additional connection attribute whose sole purpose is serving connections to Oracle Database to load data.

To specify SDP protocol:

1. Add JVM options to the HADOOP_OPTS environment variable to enable JDBC SDP export:
   
   HADOOP_OPTS="-Doracle.net.SDP=true -Djava.net.preferIPv4Stack=true"

2. Set this Hadoop configuration property for the child task JVMs:
   
   -D mapred.child.java.opts="-Doracle.net.SDP=true -Djava.net.preferIPv4Stack=true"

   **Note:**

   This Hadoop configuration property can be either added to the OLH command line or set in the configuration file.

3. Configure standard Ethernet communications. In the job configuration file, set oracle.hadoop.loader.connection.url using this syntax:
   
   jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=(ADDRESS=(PROTOCOL=TCP)(HOST=hostName)(PORT=portNumber)))
   (CONNECT_DATA=(SERVICE_NAME=serviceName))

4. Configure the Oracle listener on Exadata to support the SDP protocol and bind it to a specific port address (such as 1522). In the job configuration file, specify the
listener address as the value of oracle.hadoop.loader.connection.oci_url using this syntax:

```
(DESCRIPTION=(ADDRESS=(PROTOCOL=SDP)
  (HOST=hostName) (PORT=portNumber))
 (CONNECT_DATA=(SERVICE_NAME=serviceName)))
```

Replace `hostName`, `portNumber`, and `serviceName` with the appropriate values to identify the SDP listener on your Oracle Exadata Database Machine.

### 3.14 Oracle Loader for Hadoop Configuration Property Reference

OraLoader uses the standard methods of specifying configuration properties in the hadoop command. You can use the `-conf` option to identify configuration files, and the `-D` option to specify individual properties. See “Running a Loader Job.”

This section describes the OraLoader configuration properties, the Oracle NoSQL Database configuration properties, and a few generic Hadoop MapReduce properties that you typically must set for an OraLoader job:

- **MapReduce Configuration Properties**
- **OraLoader Configuration Properties**
- **Oracle NoSQL Database Configuration Properties**

A configuration file showing all OraLoader properties is in `$OLH_HOME/doc/oraloader-conf.xml`.

| mapreduce.job.outputformat.class   | **Type**: String  
|                                    | **Default Value**: Not defined  
|                                    | **Description**: Identifies the output type. The values can be:  
|                                    |   * oracle.hadoop.loader.lib.output.DataDumpOutputFormat*  
|                                    |     Writes data records into binary format files that can be loaded into the target table using an external table.  
|                                    |   * oracle.hadoop.loader.lib.output.DelimitedTextOutputFormat*  
|                                    |     Writes data records to delimited text format files such as comma-separated values (CSV) format files.  
|                                    |   * oracle.hadoop.loader.lib.output.JDBCOutputFormat*  
|                                    |     Inserts rows into the target table using a JDBC connection.  
|                                    |   * oracle.hadoop.loader.lib.output.OCIOutputFormat*  
|                                    |     Inserts rows into the target table using the Oracle OCI Direct Path interface.  
|                                    | See “About Output Formats.”                                                |
| mapreduce.job.reduces             | **Type**: Integer  
|                                    | **Default Value**: 1  
|                                    | **Description**: The number of reduce tasks used by the Oracle Loader for Hadoop job. The default value of 1 does not support parallel processing, therefore performance improves when the value is increased to support multiple parallel data loads. Choose a value that provides an ample, but not excessive, number of reduce tasks for the job. At a point dictated by the available resources, an excessive increase in the number of reduce tasks result in diminishing improvements, while potentially degrading the performance of other jobs. |
## OraLoader Configuration Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.badRecordFlushInterval  | **Type:** Integer  
**Default Value:** 500  
**Description:** Sets the maximum number of records that a task attempt can log before flushing the log file. This setting limits the number of records that can be lost when the record reject limit (oracle.hadoop.loader.rejectLimit) is reached and the job stops running. The oracle.hadoop.loader.logBadRecords property must be set to true for a flush interval to take effect. |
| oracle.hadoop.loader.compressionFactors      | **Type:** Decimal  
**Default Value:** BASIC=5.0,OLTP=5.0,QUERY_LOW=10.0,QUERY_HIGH=10.0,ARCHIVE_LOW=10.0,ARCHIVE_HIGH=10.0  
**Description:** These values are used by Oracle Loader for Hadoop when sampling is enabled and the target table is compressed. They are the compression factors of the target table. For best performance, the values of this property should match the compression factors of the target table. The values are a comma-delimited list of `name=value` pairs. The names must be one of the following keywords: ARCHIVE_HIGH, ARCHIVE_LOW, BASIC, OLTP, QUERY_HIGH, QUERY_LOW |
| oracle.hadoop.loader.connection.defaultExecuteBatch | **Type:** Integer  
**Default Value:** 100  
**Description:** The number of records inserted in one trip to the database. It applies only to JDBCOutputFormat and OCIOutputFormat. Specify a value greater than or equal to 1. Although the maximum value is unlimited, very large batch sizes are not recommended because they result in a large memory footprint without much increase in performance. A value less than 1 sets the property to the default value. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hadoop.loader.connection.oic_url</td>
<td>Type: String</td>
</tr>
<tr>
<td></td>

<td>including the first at-sign (@) are removed.</td>
</tr>
<tr>
<td>oracle.hadoop.loader.connection.password</td>
<td>Type: String</td>
</tr>
<tr>
<td></td>
<td>Default Value: Not defined</td>
</tr>
<tr>
<td></td>
<td>Description: Password for the connecting user. Oracle recommends that you do not store your password</td>
</tr>
<tr>
<td></td>
<td>in clear text. Use an Oracle wallet instead.</td>
</tr>
<tr>
<td>oracle.hadoop.loader.connection.sessionTimeZone</td>
<td>Type: String</td>
</tr>
<tr>
<td></td>
<td>Default Value: LOCAL</td>
</tr>
<tr>
<td></td>
<td>Description: Alters the session time zone for database connections. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>• [+</td>
</tr>
<tr>
<td></td>
<td>for Eastern Standard Time</td>
</tr>
<tr>
<td></td>
<td>• LOCAL: The default time zone of the JVM</td>
</tr>
<tr>
<td></td>
<td>• time_zone_region: A valid JVM time zone region, such as EST (for Eastern Standard Time) or</td>
</tr>
<tr>
<td></td>
<td>America/New_York</td>
</tr>
<tr>
<td></td>
<td>This property also determines the default time zone for input data that is loaded into TIMESTAMP</td>
</tr>
<tr>

<td>WITH TIME ZONE and TIMESTAMP WITH LOCAL TIME ZONE database column types.</td>
</tr>
<tr>
<td>oracle.hadoop.loader.connection.cluster.tns_admin</td>
<td>Type: String</td>
</tr>
<tr>
<td></td>
<td>Default Value: Not defined</td>
</tr>
<tr>
<td></td>
<td>Description: The TNS admin location on the cluster node if it is different from the client side</td>
</tr>
<tr>
<td></td>
<td>location.</td>
</tr>
<tr>
<td></td>
<td>By default, the client-side TNS admin location is the same as the location on cluster nodes and it</td>
</tr>
<tr>
<td></td>
<td>is specified by oracle.hadoop.loader.connection.tns_admin.</td>
</tr>
<tr>
<td></td>
<td>It is invalid to specify this property without specifying</td>
</tr>
<tr>
<td></td>
<td>oracle.hadoop.loader.connection.tns_admin.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
</tbody>
</table>
| `oracle.hadoop.loader.connection.tns_admin` | **Type:** String  
**Default Value:** Not defined  
**Description:** File path to a directory on each node of the Hadoop cluster, which contains SQL*Net configuration files such as `sqlnet.ora` and `tnsnames.ora`. Set this property so that you can use TNS entry names in database connection strings.  
You must set this property when using an Oracle wallet as an external password store (as Oracle recommends). See `oracle.hadoop.loader.connection.wallet_location`. |
| `oracle.hadoop.loader.connection.tnsEntryName` | **Type:** String  
**Default Value:** Not defined  
**Description:** A TNS entry name defined in the `tnsnames.ora` file. Use this property with `oracle.hadoop.loader.connection.tns_admin`. |
| `oracle.hadoop.loader.connection.url` | **Type:** String  
**Default Value:** Not defined  
**Description:** The URL of the database connection. This property overrides all other connection properties.  
If an Oracle wallet is configured as an external password store (as Oracle recommends), then the property value must start with the `jdbc:oracle:thin:@` driver prefix, and the database connection string must exactly match the credential in the wallet. See `oracle.hadoop.loader.connection.wallet_location`.  
The following examples show valid values of connection URLs:  
  - **Oracle Net Format:**  
    ```sql  
    jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS_LIST=  
      (ADDRESS=(PROTOCOL=TCP)(HOST=myhost)(PORT=1521)))  
      (CONNECT_DATA=(SERVICE_NAME=example_service_name)))  
    ```  
  - **TNS Entry Format:**  
    ```sql  
    jdbc:oracle:thin:@myTNSEntryName  
    ```  
  - **Thin Style:**  
    ```sql  
    jdbc:oracle:thin:@//myhost:1521/my_db_service_name  
    ``` |
| `oracle.hadoop.loader.connection.user` | **Type:** String  
**Default Value:** Not defined  
**Description:** A database user name. This property requires that you also set `oracle.hadoop.loader.connection.password`. However, Oracle recommends that you use an Oracle wallet to store your password. Do not store it in clear text.  
When using online database mode, you must set either this property or `oracle.hadoop.loader.connection.wallet_location`. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| `oracle.hadoop.loader.connection.wallet_location` | Type: String  
**Default Value:** Not defined  
**Description:** File path to an Oracle wallet directory on each node of the Hadoop cluster, where the connection credentials are stored.  
When using an Oracle wallet, you must also set the following properties:  
- `oracle.hadoop.loader.connection.tns_admin`  
- `oracle.hadoop.loader.connection.url` or `oracle.hadoop.loader.connection.tnsEntryName` |
| `oracle.hadoop.loader.connection.cluster.wallet_location` | Type: String  
**Default Value:** Not defined.  
**Description:** The wallet location on the cluster node if it is different from the client-side location.  
By default, the client-side wallet location is the same as the location on cluster node and it is specified by `oracle.hadoop.loader.connection.wallet_location`.  
It is invalid to specify this property without specifying `oracle.hadoop.loader.connection.wallet_location`. |
| `oracle.hadoop.loader.defaultDateFormat` | Type: String  
**Default Value:** `yyyy-MM-dd HH:mm:ss`  
**Description:** Parses an input field into a DATE column using a `java.text.SimpleDateFormat` pattern and the default locale. If the input file requires different patterns for different fields, then use the manual mapping properties. See “Manual Mapping.” |
| `oracle.hadoop.loader.enableSorting` | Type: Boolean  
**Default Value:** `true`  
**Description:** Controls whether output records within each reducer group are sorted. Use the `oracle.hadoop.loader.sortKey` property to identify the columns of the target table to sort by. Otherwise, Oracle Loader for Hadoop sorts the records by the primary key. |
| `oracle.hadoop.loader.extTabDirectoryName` | Type: String  
**Default Value:** `OLH_EXTTAB_DIR`  
**Description:** The name of the database directory object for the external table LOCATION data files. Oracle Loader for Hadoop does not copy data files into this directory; the file output formats generate a SQL file containing external table DDL, where the directory name appears.  
This property applies only to DelimitedTextOutputFormat and DataPumpOutputFormat. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.input.fieldNames       | **Type:** String  
**Default Value:** F0,F1,F2,...  
**Description:** A comma-delimited list of names for the input fields.  
For the built-in input formats, specify names for all fields in the data, not just the fields of interest. If an input line has more fields than this property has field names, then the extra fields are discarded. If a line has fewer fields than this property has field names, then the extra fields are set to null. See “Mapping Input Fields to Target Table Columns” for loading only selected fields.  
The names are used to create the Avro schema for the record, so they must be valid JSON name strings.  
This property applies to DelimitedTextInputFormat and RegexInputFormat only. |
| oracle.hadoop.loader.input.fieldTerminator   | **Type:** String  
**Default Value:** , (comma)  
**Description:** A character that indicates the end of an input field for DelimitedTextInputFormat. The value can be either a single character or \uHHHH, where HHHH is the character's UTF-16 encoding.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| oracle.hadoop.loader.input.hive.databaseName | **Type:** String  
**Default Value:** Not defined  
**Description:** The name of the Hive database where the input table is stored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
**Property**

oracle.hadoop.loader.input.hive.partitionFilter

**Description**

Type: String

Default Value: Not defined

Description: A valid HiveQL expression that is used to filter the source Hive table partitions for HiveToAvroInputFormat. The expression must contain only partition columns. Including other columns does not raise an error, but unintended consequences can result. Oracle recommends that you not include other columns. If the value is not set, then Oracle Loader for Hadoop loads the data from all partitions of the source Hive table. This property is ignored if the table is not partitioned. It is also ignored if oracle.hadoop.loader.input.hive.rowFilter is set.

The expression must conform to the following restrictions:

- Selects partitions and not individual records inside the partitions.
- Does not include columns that are not used to partition the table, because they might cause unintended consequences.
- Does not include subqueries.
- Does not include user-defined functions (UDFs), which are not supported; built-in functions are supported.
- Resolves all variable expansions at the Hadoop level. Hive variable name spaces (such as env:, system:, hiveconf:, and hivevar:) have no meaning. Oracle Loader for Hadoop sets hive.variable.substitute to false, which disables Hive variable expansion. You can choose between these expansion methods:
  - **Expand all variables before setting this property:** In the Hive CLI, use the following commands:
    ```
    CREATE VIEW view_name AS SELECT * from database.table_name WHERE expression;
    DESCRIBE FORMATTED view_name;
    ```
    The View Original Text field contains the query with all variables expanded. Copy the where clause, starting after where.
  - **Define all variables in Oracle Loader for Hadoop:** In the hadoop command to run Oracle Loader for Hadoop, use the generic options (-D and -conf).

You can use the Hive CLI to test the expression and ensure that it returns the expected results.

The following examples assume a source table defined with this command:

```sql
CREATE TABLE t(c string)
    PARTITIONED BY (p1 string, p2 int, p3 boolean, p4 string, p5 timestamp);
```
These examples show that using c, a column that is not used to partition the table, is unnecessary and can cause unexpected results.

This example is equivalent to \( p2 > 35 \):

\[ p2 > 35 \text{ and } c \text{ like } 'abc%' \]

This example loads all partitions. All partitions could contain \( c \text{ like } 'abc%' \), so partitions are filtered out:

\[ p2 > 35 \text{ or } c \text{ like } 'abc%' \]
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.input.hive.rowFilter | **Type:** String  
**Default Value:** Not defined  
**Description:** A valid HiveQL expression that is used to filter the rows of the source Hive table for HiveToAvroInputFormat. If this value is not set (default), Oracle Loader for Hadoop attempts to use the value of oracle.hadoop.loader.input.hive.partitionFilter (provided the table is partitioned). Otherwise, Oracle Loader for Hadoop loads the entire source hive table.  
The expression must conform to the following restrictions:  
- Does not include subqueries.  
- Does not include user-defined functions (UDFs), which are not supported; built-in functions are supported.  
- Resolves all variable expansions at the Hadoop level. Hive variable name spaces (such as env:, system:, hiveconf:, and hivevar:) have no meaning. Oracle Loader for Hadoop sets hive.variable.substitute to false, which disables Hive variable expansion. You can choose between these expansion methods:  
  - **Expand all variables before setting this property:** In the Hive CLI, use the following commands:  
    ```sql  
    CREATE VIEW view_name AS SELECT * from database.table_name WHERE expression;  
    DESCRIBE FORMATTED view_name;  
    ```  
The View Original Text field contains the query with all variables expanded. Copy the expression within the WHERE clause. (Do not include the WHERE keyword itself.)  
  - **Define all variables in Oracle Loader for Hadoop.** In the Hadoop command to run Oracle Loader for Hadoop, use the generic options (-D and -conf).  

In both cases you can use the Hive CLI to test the expression and ensure that it returns the expected results. The following examples assume a source table defined with this command:  
```sql  
CREATE TABLE t(c string)  
    PARTITIONED BY (p1 string, p2 int, p3 boolean, p4 string, p5 timestamp);  
```  
**Example #1: nested expressions**  
c like 'abc%' and (p5 <= '2010-06-20' and p5 <= '2010-07-03')  

**Example #2: built-in functions**  
year(p5) = 2013)  

Oracle recommends that you turn on hive.optimize.index.filter when importing a subset of rows from a native Hive table (a table that is not managed by a storage handler). This is known to help input formats such as ORC and PARQUET, however there are several caveats:  
- The property must be set with a -D (using -conf will not work).  
Alternatively, the property can be set in hive-site.xml.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **oracle.hadoop.loader.input.hive.tableName**                          | Type: String  
**Default Value**: Not defined  
**Description**: The name of the Hive table where the input data is stored.  
- This does not work for ORC tables in Hive 0.12.                                                                                                                                                                                                                                                                                                                                                                                       |
| **oracle.hadoop.loader.input.initialFieldEncloser**                     | Type: String  
**Default Value**: Not defined  
**Description**: A character that indicates the beginning of a field. The value can be either a single character or \uHIIII, where HIIII is the character's UTF-16 encoding. To restore the default setting (no encloser), enter a zero-length value. A field encloser cannot equal the terminator or white-space character defined for the input format.  
When this property is set, the parser attempts to read each field as an enclosed token (value) before reading it as an unenclosed token. If the field enclosers are not set, then the parser reads each field as an unenclosed token.  
If you set this property but not oracle.hadoop.loader.input.trailingFieldEncloser, then the same value is used for both properties.                                                                                                                                                                                                                                                                 |
| **oracle.hadoop.loader.input.regexCaseInsensitive**                     | Type: Boolean  
**Default Value**: false  
**Description**: Controls whether pattern matching is case-sensitive. Set to true to ignore case, so that "string" matches "String", "STRING", "string", "StRINg", and so forth. By default, "string" matches only "string".  
This property is the same as the input.regex.case.insensitive property of org.apache.hadoop.hive.contrib.serde2.RegexSerDe.                                                                                                                                                                                                                                                                                               |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.input.regexPattern | **Type:** Text  
**Default Value:** Not defined  
**Description:** The pattern string for a regular expression. The regular expression must match each text line in its entirety. For example, a correct regex pattern for input line "a,b,c," is "(^[^,]*),([^,]*),([^,]*),". However, "([^,]*)," is invalid, because the expression is not applied repeatedly to a line of input text. RegexInputFormat uses the capturing groups of regular expression matching as fields. The special group zero is ignored because it stands for the entire input line. This property is the same as the input.regex property of org.apache.hadoop.hive.contrib.serde2.RegexSerDe. |
| oracle.hadoop.loader.input.trailingFieldEncloser | **Type:** String  
**Default Value:** The value of oracle.hadoop.loader.input.initialFieldEncloser  
**Description:** Identifies a character that marks the end of a field. The value can be either a single character or \uHHHH, where HHHH is the character's UTF-16 encoding. For no trailing encloser, enter a zero-length value. A field encloser cannot be the terminator or a white-space character defined for the input format. If the trailing field encloser character is embedded in an input field, then the character must be doubled up to be parsed as literal text. For example, an input field must have "'" (two single quotes) to load ' (one single quote). If you set this property, then you must also set oracle.hadoop.loader.input.initialFieldEncloser. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **oracle.hadoop.loader.loadByPartition** | Type: Boolean  
   Default Value: true  
   Description: Specifies a partition-aware load. Oracle Loader for Hadoop organizes the output by partition for all output formats on the Hadoop cluster; this task does not impact the resources of the database system. DelimitedTextOutputFormat and DataPumpOutputFormat generate multiple files, and each file contains the records from one partition. For DelimitedTextOutputFormat, this property also controls whether the PARTITION keyword appears in the generated control files for SQL*Loader. OCIOutputFormat requires partitioned tables. If you set this property to false, then OCIOutputFormat turns it back on. For the other output formats, you can set loadByPartition to false, so that Oracle Loader for Hadoop handles a partitioned table as if it were nonpartitioned. |
| **oracle.hadoop.loader.loaderMap.columnNames** | Type: String  
   Default Value: Not defined  
   Description: A comma-separated list of column names in the target table, in any order. The names can be quoted or unquoted. Quoted names begin and end with double quotes (") and are used exactly as entered. Unquoted names are converted to upper case. You must set oracle.hadoop.loader.loaderMap.targetTable, or this property is ignored. You can optionally set oracle.hadoop.loader.loaderMap.column_name.field and oracle.hadoop.loader.loaderMap.column_name.format. |
| **oracle.hadoop.loader.loaderMap.column_name.field** | Type: String  
   Default Value: Normalized column name  
   Description: The name of a field that contains Avro records, which is mapped to the column identified in the property name. The column name can be quoted or unquoted. A quoted name begins and ends with double quotes (") and is used exactly as entered. An unquoted name is converted to upper case. Optional. You must set oracle.hadoop.loader.loaderMap.columnNames, or this property is ignored. |
| **oracle.hadoop.loader.loaderMap.column_name.format** | Type: String  
   Default Value: Not defined  
   Description: Specifies the data format of the data being loaded into the column identified in the property name. Use a java.text.SimpleDateFormat pattern for a date format or regular expression patterns for text. Optional. You must set oracle.hadoop.loader.loaderMap.columnNames, or this property is ignored. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| `oracle.hadoop.loader.loaderMap.targetTable` | Type: String  
Default Value: Not defined  
Description: A schema-qualified name for the table to be loaded. This property takes precedence over `oracle.hadoop.loader.loaderMapFile`.  
To load a subset of columns, set the `oracle.hadoop.loader.loaderMap.columnNames` property. With columnNames, you can optionally set `oracle.hadoop.loader.loaderMap[column_name].field` to specify the names of the fields that are mapped to the columns, and `oracle.hadoop.loader.loaderMap[column_name].format` to specify the format of the data in those fields. If all the columns of a table will be loaded, and the input field names match the database column names, then you do not need to set columnNames. |
| `oracle.hadoop.loader.loaderMapFile` | Loader maps are deprecated starting with Release 2.3. The `oracle.hadoop.loader.loaderMap.*` configuration properties replace loader map files. See “Manual Mapping.” |
| `oracle.hadoop.loader.logBadRecords` | Type: Boolean  
Default Value: false  
Description: Controls whether Oracle Loader for Hadoop logs bad records to a file.  
This property applies only to records rejected by input formats and mappers. It does not apply to errors encountered by the output formats or by the sampling feature. |
| `oracle.hadoop.loader.log4j.propertyPrefix` | Type: String  
Default Value: `log4j.logger.oracle.hadoop.loader`  
Description: Identifies the prefix used in Apache log4j properties loaded from its configuration file.  
Oracle Loader for Hadoop enables you to specify log4j properties in the hadoop command using the `-conf` and `-D` options. For example:  
```bash  
-D log4j.logger.oracle.hadoop.loader.OraLoader=DEBUG  
-D log4j.logger.oracle.hadoop.loader.metadata=INFO  
```
All configuration properties starting with this prefix are loaded into log4j. They override the settings for the same properties that log4j loaded from `${log4j.configuration}`. The overrides apply to the Oracle Loader for Hadoop job driver, and its map and reduce tasks.  
The configuration properties are copied to log4j with RAW values; any variable expansion is done for log4j. Any configuration variables to be used in the expansion must also start with this prefix. |
| `oracle.hadoop.loader.olh_home` | Type: String  
Default Value: Value of the `OLH_HOME` environment variable  
Description: The path of the Oracle Loader for Hadoop home directory on the node where you start the OraLoader job. This path identifies the location of the required libraries. |
<table>

</tr>
</tbody>
</table>
| oracle.hadoop.loader.output.initialFieldEncloser | **Type**: String  
**Default Value**: Not defined  
**Description**: A character generated in the output to identify the beginning of a field. The value must be either a single character or `\uHHHH`, where `HHHH` is the character's UTF-16 encoding. A zero-length value means that no enclosers are generated in the output (default value). Use this property when a field may contain the value of `oracle.hadoop.loader.output.fieldTerminator`. If a field may also contain the value of `oracle.hadoop.loader.output.trailingFieldEncloser`, then set `oracle.hadoop.loader.output.escapeEnclosers` to `true`. If you set this property, then you must also set `oracle.hadoop.loader.output.trailingFieldEncloser`. |
| oracle.hadoop.loader.output.trailingFieldEncloser | **Type**: String  
**Default Value**: Value of `oracle.hadoop.loader.output.initialFieldEncloser`  
**Description**: A character generated in the output to identify the end of a field. The value must be either a single character or `\uHHHH`, where `HHHH` is the character's UTF-16 encoding. A zero-length value means that there are no enclosers (default value). Use this property when a field may contain the value of `oracle.hadoop.loader.output.fieldTerminator`. If a field may also contain the value of `oracle.hadoop.loader.output.trailingFieldEncloser`, then set `oracle.hadoop.loader.output.escapeEnclosers` to `true`. If you set this property, then you must also set `oracle.hadoop.loader.output.initialFieldEncloser`. |
| oracle.hadoop.loader.rejectLimit              | **Type**: Integer  
**Default Value**: 1000  
**Description**: The maximum number of rejected or skipped records allowed before the job stops running. A negative value turns off the reject limit and allows the job to run to completion. If `mapreduce.map.speculative` is `true` (the default), then the number of rejected records may be inflated temporarily, causing the job to stop prematurely. Input format errors do not count toward the reject limit because they are irrecoverable and cause the map task to stop. Errors encountered by the sampling feature or the online output formats do not count toward the reject limit either. |

Oracle Loader for Hadoop Configuration Property Reference  
User®s Guide
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.sampler.enableSampling | Type: Boolean  
Default Value: true  
Description: Controls whether the sampling feature is enabled. Set this property to false to disable sampling.  
Even when enableSampling is set to true, the loader automatically disables sampling if it is unnecessary, or if the loader determines that a good sample cannot be made. For example, the loader disables sampling if the table is not partitioned, the number of reducer tasks is less than two, or there is too little input data to compute a good load balance. In these cases, the loader returns an informational message. |
| oracle.hadoop.loader.sampler.hint MaxSplitSize | Type: Integer  
Default Value: 1048576 (1 MB)  
Description: Sets the Hadoop mapred.max.split.size property for the sampling process; the value of mapred.max.split.size does not change for the job configuration. A value less than 1 is ignored.  
Some input formats (such as FileInputFormat) use this property as a hint to determine the number of splits returned by getSplits. Smaller values imply that more chunks of data are sampled at random, which results in a better sample.  
Increase this value for data sets with tens of terabytes of data, or if the input format getSplits method throws an out-of-memory error.  
Although large splits are better for I/O performance, they are not necessarily better for sampling. Set this value small enough for good sampling performance, but no smaller. Extremely small values can cause inefficient I/O performance, and can cause getSplits to run out of memory by returning too many splits.  
The org.apache.hadoop.mapreduce.lib.input.FileInputFormat method always returns splits at least as large as the minimum split size setting, regardless of the value of this property. |
| oracle.hadoop.loader.sampler.hint NumMapTasks | Type: Integer  
Default Value: 100  
Description: Sets the value of the Hadoop mapred.map.tasks configuration property for the sampling process; the value of mapred.map.tasks does not change for the job configuration. A value less than 1 is ignored.  
Some input formats (such as DBInputFormat) use this property as a hint to determine the number of splits returned by the getSplits method. Higher values imply that more chunks of data are sampled at random, which results in a better sample.  
Increase this value for data sets with more than a million rows, but remember that extremely large values can cause getSplits to run out of memory by returning too many splits. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.sampler.load CI              | **Type:** Decimal  
**Default Value:** 0.95  
**Description:** The statistical confidence indicator for the maximum reducer load factor.  
This property accepts values greater than or equal to 0.5 and less than 1 (0.5 ≤ value < 1). A value less than 0.5 resets the property to the default value. Typical values are 0.90, 0.95, and 0.99.  
See oracle.hadoop.loader.sampler.maxLoadFactor. |
| oracle.hadoop.loader.sampler.maxHeapBytes          | **Type:** Integer  
**Default Value:** -1  
**Description:** Specifies in bytes the maximum amount of memory available to the sampler.  
Sampling stops when one of these conditions is true:  
- The sampler has collected the minimum number of samples required for load balancing.  
- The percent of sampled data exceeds oracle.hadoop.loader.sampler.maxSamplesPct.  
- The number of sampled bytes exceeds oracle.hadoop.loader.sampler.maxHeapBytes. This condition is not imposed when the property is set to a negative value. |
| oracle.hadoop.loader.sampler.maxLoadFactor         | **Type:** Float  
**Default Value:** 0.05 (5%)  
**Description:** The maximum acceptable load factor for a reducer. A value of 0.05 indicates that reducers can be assigned up to 5% more data than their ideal load.  
This property accepts values greater than 0. A value less than or equal to 0 resets the property to the default value. Typical values are 0.05 and 0.1.  
In a perfectly balanced load, every reducer is assigned an equal amount of work (or load). The load factor is the relative overload for each reducer, calculated as (assigned_load - ideal_load)/ideal_load. If load balancing is successful, the job runs within the maximum load factor at the specified confidence.  
See oracle.hadoop.loader.sampler.loadCI. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.loader.sampler.maxSamplesPct | **Type**: Float  
**Default Value**: 0.01 (1%)  
**Description**: Sets the maximum sample size as a fraction of the number of records in the input data. A value of 0.05 indicates that the sampler never samples more than 5% of the total number of records.  
This property accepts a range of 0 to 1 (0% to 100%). A negative value disables it.  
Sampling stops when one of these conditions is true:  
- The sampler has collected the minimum number of samples required for load balancing, which can be fewer than the number set by this property.  
- The percent of sampled data exceeds `oracle.hadoop.loader.sampler.maxSamplesPct`.  
- The number of sampled bytes exceeds `oracle.hadoop.loader.sampler.maxHeapBytes`. This condition is not imposed when the property is set to a negative value. |
| oracle.hadoop.loader.sampler.minSplits | **Type**: Integer  
**Default Value**: 5  
**Description**: The minimum number of input splits that the sampler reads from before it makes any evaluation of the stopping condition. If the total number of input splits is less than `minSplits`, then the sampler reads from all the input splits.  
A number less than or equal to 0 is the same as a value of 1. |
| oracle.hadoop.loader.sampler.numThreads | **Type**: Integer  
**Default Value**: 5  
**Description**: The number of sampler threads. A higher number of threads allows higher concurrency in sampling. A value of 1 disables multithreading for the sampler.  
Set the value based on the processor and memory resources available on the node where you start the Oracle Loader for Hadoop job. |
| oracle.hadoop.loader.sortKey | **Type**: String  
**Default Value**: Not defined  
**Description**: A comma-delimited list of column names that forms a key for sorting output records within a reducer group.  
The column names can be quoted or unquoted identifiers:  
- A quoted identifier begins and ends with double quotation marks (").  
- An unquoted identifier is converted to uppercase before use. |

</tbody>
</table>
| oracle.kv.subRange   | Type: KeyRange  
 Default Value: Not defined  
 Description: Further restricts the returned values to a particular child under the parent key specified by oracle.kv.parentKey. |
| oracle.kv.depth      | Type: Depth  
 Default Value: PARENT_AND_DESCENDENTS  
 Description: Restricts the returned values to a particular hierarchical depth under the value of oracle.kv.parentKey. The following keywords are valid values:  
 • CHILDREN_ONLY: Returns the children, but not the specified parent.  
 • DESCENDANTS_ONLY: Returns all descendants, but not the specified parent.  
 • PARENT_AND_CHILDREN: Returns the children and the parent.  
 • PARENT_AND_DESCENDANTS: Returns all descendants and the parent. |
| oracle.kv.consistency| Type: Consistency  
 Default Value: NONE_REQUIRED  
 Description: The consistency guarantee for reading child key-value pairs. The following keywords are valid values:  
 • ABSOLUTE: Requires the master to service the transaction so that consistency is absolute.  
 • NONE_REQUIRED: Allows replicas to service the transaction, regardless of the state of the replicas relative to the master. |
| oracle.kv.timeout    | Type: Long  
 Default Value:  
 Description: Sets a maximum time interval in milliseconds for retrieving a selection of key-value pairs. A value of zero (0) sets the property to its default value. |
### Property Description

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.kv.formatterClass | Type: String  
Default Value: Not defined  
Description: Specifies the name of a class that implements the AvroFormatter interface to format KeyValueVersion instances into Avro IndexedRecord strings. Because the Avro records from Oracle NoSQL Database pass directly to Oracle Loader for Hadoop, the NoSQL keys are not available for mapping into the target Oracle Database table. However, the formatter class receives both the NoSQL key and value, enabling the class to create and return a new Avro record that contains both the value and key, which can be passed to Oracle Loader for Hadoop. |

### 3.15 Third-Party Licenses for Bundled Software

Oracle Loader for Hadoop installs the following third-party products:

- Apache Avro 1.7.3
- Apache Commons Mathematics Library 2.2
- Jackson JSON 1.8.8

Oracle Loader for Hadoop includes Oracle 12c Release 1(12.1) client libraries. For information about third party products included with Oracle Database 12c Release 1 (12.1), refer to Oracle Database Licensing Information.

Oracle Loader for Hadoop builds and tests with Hadoop 0.20.2.

Unless otherwise specifically noted, or as required under the terms of the third party license (e.g., LGPL), the licenses and statements herein, including all statements regarding Apache-licensed code, are intended as notices only.

### 3.15.1 Apache Licensed Code

The following is included as a notice in compliance with the terms of the Apache 2.0 License, and applies to all programs licensed under the Apache 2.0 license:

You may not use the identified files except in compliance with the Apache License, Version 2.0 (the "License.")

You may obtain a copy of the License at [http://www.apache.org/licenses/LICENSE-2.0](http://www.apache.org/licenses/LICENSE-2.0)

A copy of the license is also reproduced below.

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.

See the License for the specific language governing permissions and limitations under the License.
3.15.2 Apache License

Version 2.0, January 2004
http://www.apache.org/licenses/

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

Third-Party Licenses for Bundled Software
"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. **Grant of Copyright License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. **Grant of Patent License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. **Redistribution.** You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
   a. You must give any other recipients of the Work or Derivative Works a copy of this License; and
   b. You must cause any modified files to carry prominent notices stating that You changed the files; and
   c. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and
   d. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.
5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don’t include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Ease of Use Tools for Oracle Big Data Connectors

Oracle Big Data Connectors are a powerful toolset for data interchange between Hadoop and Oracle Database. Learning how to set up the environment for these tools and use them to full potential is worthwhile, but there are ways to get started and be productive without fully completing that learning curve. Oracle is developing a set of ease-of-use tools for this purpose.

Oracle Shell for Hadoop Loaders is the first ease-of-use tool for Oracle Big Data Connectors.

4.1 Introducing Oracle Shell for Hadoop Loaders

What is Oracle Shell for Hadoop Loaders?

Oracle Shell for Hadoop Loaders (OHSH) is a helper shell that provides a simple to use command line interface to Oracle Loader for Hadoop, Oracle SQL Connector for HDFS, and Copy to Hadoop. It has basic shell features such as command line recall, history, inheriting environment variables from the parent process, setting new or existing environment variables, and performing environmental substitution in the command line.

The core functionality of Oracle Shell for Hadoop Loaders includes the following:

• Defining named external resources with which Oracle Shell for Hadoop Loaders interacts to perform loading tasks.

• Setting default values for load operations.

• Running load commands.

• Delegating simple pre and post load tasks to the Operating System, HDFS, Hive and Oracle. These tasks include viewing the data to be loaded, and viewing the data in the target table after loading.

Getting Started with Oracle Shell for Hadoop Loaders

To set up Oracle Shell for Hadoop Loaders, follow the instructions in the Oracle Big Data SQL Installation Guide.

The examples directory in the OHSH kit contains many examples that define resources and load data using Oracle Shell for Hadoop Loaders. See <OHSH_KIT>/examples/README.txt for a description of the examples and instructions for running them.

Getting Help

The OHSH shell provides online help for all commands.
To get a list of all possible OHSH commands:

```
> help
```

To get help on a specific command, enter `help`, followed by the command:

```
> help show
```

The table below describes the help categories available.

<table>
<thead>
<tr>
<th>Help Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>help load</td>
<td>Describes load commands for Oracle and Hadoop tables.</td>
</tr>
<tr>
<td>help set</td>
<td>Shows help for setting defaults for load operations. It also describes what load methods are impacted by a particular setting.</td>
</tr>
<tr>
<td>help show</td>
<td>Shows help for inspecting default settings.</td>
</tr>
<tr>
<td>help shell</td>
<td>Shows shell-like commands.</td>
</tr>
<tr>
<td>help resource</td>
<td>Show commands for creating and dropping named resources.</td>
</tr>
</tbody>
</table>

### 4.1.1 Third-Party Licenses for Bundled Software

Oracle Shell for Hadoop Loaders installs the following third-party products:

- ANTLR 4.5.2
- JLine 2.13
- Apache Commons Exec 1.3
- Apache Commons CLI 1.3.1

Unless otherwise specifically noted, or as required under the terms of the third party license (e.g., LGPL), the licenses and statements herein, including all statements regarding Apache-licensed code, are intended as notices only.

#### 4.1.1.1 ANTLR 4.5.2

4.1.1.3 Apache Commons Exec 1.3

Include the following License ONLY ONCE in the documentation even if there are multiple products licensed under the license.

The following applies to all products licensed under the Apache 2.0 License:

You may not use the identified files except in compliance with the Apache License, Version 2.0 (the "License.").

You may obtain a copy of the License at http://www.apache.org/licenses/LICENSE-2.0. A copy of the license is also reproduced below.
4.1.4 Apache Commons CLI 1.3.1

Include the following License ONLY ONCE in the documentation even if there are multiple products licensed under the license.

The following applies to all products licensed under the Apache 2.0 License:

You may not use the identified files except in compliance with the Apache License, Version 2.0 (the "License.")

You may obtain a copy of the License at http://www.apache.org/licenses/LICENSE-2.0. A copy of the license is also reproduced below.

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.

See the License for the specific language governing permissions and limitations under the License.

4.1.5 Apache License

Version 2.0, January 2004

http://www.apache.org/licenses/

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original
work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

   a. You must give any other recipients of the Work or Derivative Works a copy of this License; and

   b. You must cause any modified files to carry prominent notices stating that You changed the files; and

   c. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

   d. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those
notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. APPENDIX: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "[]" replaced with your own identifying information. (Don’t include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

Copyright [yyyy] [name of copyright owner]

http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.

This product includes software developed by The Apache Software Foundation (http://www.apache.org/) (listed below):
This part contains the following chapters:

- Using Oracle XQuery for Hadoop
- Oracle XQuery for Hadoop Reference
- Oracle XML Extensions for Hive
This chapter explains how to use Oracle XQuery for Hadoop to extract and transform large volumes of semistructured data. It contains the following sections:

- **What Is Oracle XQuery for Hadoop?**
- **Getting Started With Oracle XQuery for Hadoop**
- **About the Oracle XQuery for Hadoop Functions**
- **Creating an XQuery Transformation**
- **Running Queries**
- **Running Queries from Apache Oozie**
- **Oracle XQuery for Hadoop Configuration Properties**
- **Third-Party Licenses for Bundled Software**

### 5.1 What Is Oracle XQuery for Hadoop?

Oracle XQuery for Hadoop is a transformation engine for semistructured big data. Oracle XQuery for Hadoop runs transformations expressed in the XQuery language by translating them into a series of MapReduce jobs, which are executed in parallel on an Apache Hadoop cluster. You can focus on data movement and transformation logic, instead of the complexities of Java and MapReduce, without sacrificing scalability or performance.

The input data can be located in a file system accessible through the Hadoop File System API, such as the Hadoop Distributed File System (HDFS), or stored in Oracle NoSQL Database. Oracle XQuery for Hadoop can write the transformation results to Hadoop files, Oracle NoSQL Database, or Oracle Database.

Oracle XQuery for Hadoop also provides extensions to Apache Hive to support massive XML files.

Oracle XQuery for Hadoop is based on mature industry standards including XPath, XQuery, and XQuery Update Facility. It is fully integrated with other Oracle products, which enables Oracle XQuery for Hadoop to:

- Load data efficiently into Oracle Database using Oracle Loader for Hadoop.
- Provide read and write support to Oracle NoSQL Database.

**Figure 5-1** provides an overview of the data flow using Oracle XQuery for Hadoop.
**Figure 5-1  Oracle XQuery for Hadoop Data Flow**

* Parallel processing of a single JSON file is not supported. See the JSON File Adapter.
5.2 Getting Started With Oracle XQuery for Hadoop

Oracle XQuery for Hadoop is designed for use by XQuery developers. If you are already familiar with XQuery, then you are ready to begin. However, if you are new to XQuery, then you must first acquire the basics of the language. This guide does not attempt to cover this information.

See Also:

- "XQuery Tutorial" by W3Schools at http://www.w3schools.com/xquery/
- XQuery 3.0: An XML Query Language at http://www.w3.org/TR/xquery-30

5.2.1 Basic Steps

Take the following basic steps when using Oracle XQuery for Hadoop:

1. The first time you use Oracle XQuery for Hadoop, ensure that the software is installed and configured.

   See “Oracle XQuery for Hadoop Setup.”

2. Log in to either a node in the Hadoop cluster or a system set up as a Hadoop client for the cluster.

3. Create an XQuery transformation that uses the Oracle XQuery for Hadoop functions. It can use various adapters for input and output.

   See “About the Oracle XQuery for Hadoop Functions” and “Creating an XQuery Transformation.”

4. Execute the XQuery transformation.

   See “Running Queries.”

5.2.2 Example: Hello World!

Follow these steps to create and run a simple query using Oracle XQuery for Hadoop:

1. Create a text file named `hello.txt` in the current directory that contains the line `Hello`.

   $ echo "Hello" > hello.txt

2. Copy the file to HDFS:

   $ hdfs dfs -copyFromLocal hello.txt

3. Create a query file named `hello.xq` in the current directory with the following content:

   import module "oxh:text";
   for $line in text:collection("hello.txt")
about the oracle xquery for hadoop functions

5.3 About the Oracle XQuery for Hadoop Functions

Oracle XQuery for Hadoop reads from and writes to big data sets using collection and put functions:

- A **collection function** reads data from Hadoop files or Oracle NoSQL Database as a collection of items. A Hadoop file is one that is accessible through the Hadoop File System API. On Oracle Big Data Appliance and most Hadoop clusters, this file system is Hadoop Distributed File System (HDFS).

- A **put function** adds a single item to a data set stored in Oracle Database, Oracle NoSQL Database, or a Hadoop file.

The following is a simple example of an Oracle XQuery for Hadoop query that reads items from one source and writes to another:

```xquery
for $x in collection(...) return put($x)
```

Oracle XQuery for Hadoop comes with a set of adapters that you can use to define put and collection functions for specific formats and sources. Each adapter has two components:

- A set of built-in put and collection functions that are predefined for your convenience.
- A set of XQuery function annotations that you can use to define custom put and collection functions.

Other commonly used functions are also included in Oracle XQuery for Hadoop.

5.3.1 About the Adapters

Following are brief descriptions of the Oracle XQuery for Hadoop adapters.

```xquery
return text:put($line || " World!")
```
Avro File Adapter
The Avro file adapter provides access to Avro container files stored in HDFS. It includes collection and put functions for reading from and writing to Avro container files.

See “Avro File Adapter.”

JSON File Adapter
The JSON file adapter provides access to JSON files stored in HDFS. It contains a collection function for reading JSON files, and a group of helper functions for parsing JSON data directly. You must use another adapter to write the output.

See “JSON File Adapter.”

Oracle Database Adapter
The Oracle Database adapter loads data into Oracle Database. This adapter supports a custom put function for direct output to a table in an Oracle database using JDBC or OCI. If a live connection to the database is not available, the adapter also supports output to Data Pump or delimited text files in HDFS; the files can be loaded into the Oracle database with a different utility, such as SQL*Loader, or using external tables. This adapter does not move data out of the database, and therefore does not have collection or get functions.

See “Software Requirements” for the supported versions of Oracle Database, and “Oracle Database Adapter”.

Oracle NoSQL Database Adapter
The Oracle NoSQL Database adapter provides access to data stored in Oracle NoSQL Database. The data can be read from or written as Table, Avro, XML, binary XML, or text. This adapter includes collection, get, and put functions.

See “Oracle NoSQL Database Adapter.”

Sequence File Adapter
The sequence file adapter provides access to Hadoop sequence files. A sequence file is a Hadoop format composed of key-value pairs.

This adapter includes collection and put functions for reading from and writing to HDFS sequence files that contain text, XML, or binary XML.

See “Sequence File Adapter.”

Solr Adapter
The Solr adapter provides functions to create full-text indexes and load them into Apache Solr servers.

See “Solr Adapter”.

Text File Adapter
The text file adapter provides access to text files, such as CSV files. It contains collection and put functions for reading from and writing to text files.

The JSON file adapter extends the support for JSON objects stored in text files.

See “Text File Adapter” and “JSON File Adapter”.

XML File Adapter
The XML file adapter provides access to XML files stored in HDFS. It contains collection functions for reading large XML files. You must use another adapter to write the output.
5.3.2 About Other Modules for Use With Oracle XQuery for Hadoop

You can use functions from these additional modules in your queries:

**Standard XQuery Functions**
The standard XQuery math functions are available.
See “About XQuery Language Support.”

**Hadoop Functions**
The Hadoop module is a group of functions that are specific to Hadoop.
See “Hadoop Module.”

**Duration, Date, and Time Functions**
This group of functions parse duration, date, and time values.
See “Oracle XQuery Functions for Duration, Date, and Time.”

**String-Processing Functions**
These functions add and remove white space that surrounds data values.
See “Oracle XQuery Functions for Strings.”

5.4 Creating an XQuery Transformation

This chapter describes how to create XQuery transformations using Oracle XQuery for Hadoop. It contains the following topics:

- XQuery Transformation Requirements
- About XQuery Language Support
- Accessing Data in the Hadoop Distributed Cache
- Calling Custom Java Functions from XQuery
- Accessing User-Defined XQuery Library Modules and XML Schemas
- XQuery Transformation Examples

5.4.1 XQuery Transformation Requirements

You create a transformation for Oracle XQuery for Hadoop the same way as any other XQuery transformation, except that you must comply with these additional requirements:

- The main XQuery expression (the query body) must be in one of the following forms:
  FLWOR₁
  or
  (FLWOR₁, FLWOR₂,..., FLWORₙ)
In this syntax FLWOR is a top-level XQuery FLWOR expression "For, Let, Where, Order by, Return" expression.

See Also:
"FLWOR Expressions" in W3C XQuery 3.0: An XML Query Language at
http://www.w3.org/TR/xquery-30/#id-flwor-expressions

- Each top-level FLWOR expression must have a for clause that iterates over an Oracle XQuery for Hadoop collection function. This for clause cannot have a positional variable.
  See Oracle XQuery for Hadoop Reference for the collection functions.

- Each top-level FLWOR expression can have optional let, where, and group by clauses. Other types of clauses are invalid, such as order by, count, and window clauses.

- Each top-level FLWOR expression must return one or more results from calling an Oracle XQuery for Hadoop put function. See Oracle XQuery for Hadoop Reference for the put functions.

- The query body must be an updating expression. Because all put functions are classified as updating functions, all Oracle XQuery for Hadoop queries are updating queries.
  In Oracle XQuery for Hadoop, a %*:put annotation indicates that the function is updating. The %updating annotation or updating keyword is not required with it.

See Also:
For a description of updating expressions, "Extensions to XQuery 1.0" in W3C XQuery Update Facility 1.0 at
http://www.w3.org/TR/xquery-update-10/#dt-updating-expression

5.4.2 About XQuery Language Support
Oracle XQuery for Hadoop supports W3C XQuery 3.0, except for the following:

- FLWOR window clause
- FLWOR count clause
- namespace constructors
- decimal format declarations
- fn:format-number
- fn:path
- higher order XQuery functions
5.4.3 Accessing Data in the Hadoop Distributed Cache

You can use the Hadoop distributed cache facility to access auxiliary job data. This mechanism can be useful in a join query when one side is a relatively small file. The query might execute faster if the smaller file is accessed from the distributed cache.

To place a file into the distributed cache, use the -files Hadoop command line option when calling Oracle XQuery for Hadoop. For a query to read a file from the distributed cache, it must call the fn:doc function for XML, and either fn:unparsed-text or fn:unparsed-text-lines for text files. See Example 5-7.

5.4.4 Calling Custom Java Functions from XQuery

Oracle XQuery for Hadoop is extensible with custom external functions implemented in the Java language. A Java implementation must be a static method with the parameter and return types as defined by the XQuery API for Java (XQJ) specification.

A custom Java function binding is defined in Oracle XQuery for Hadoop by annotating an external function definition with the %ora-java:binding annotation. This annotation has the following syntax:

%ora-java:binding("java.class.name[#method]")

java.class.name
The fully qualified name of a Java class that contains the implementation method.

method
A Java method name. It defaults to the XQuery function name. Optional. See Example 5-8 for an example of %ora-java:binding.

All JAR files that contain custom Java functions must be listed in the -libjars command line option. For example:

hadoop jar $OXH_HOME/lib/oxh.jar -libjars myfunctions.jar query.xq

See Also:
"XQuery API for Java (XQJ)" at
http://www.jcp.org/en/jsr/detail?id=225

5.4.5 Accessing User-Defined XQuery Library Modules and XML Schemas

Oracle XQuery for Hadoop supports user-defined XQuery library modules and XML schemas when you comply with these criteria:

- Locate the library module or XML schema file in the same directory where the main query resides on the client calling Oracle XQuery for Hadoop.
- Import the library module or XML schema from the main query using the location URI parameter of the import module or import schema statement.
• Specify the library module or XML schema file in the -files command line option when calling Oracle XQuery for Hadoop.

For an example of using user-defined XQuery library modules and XML schemas, see Example 5-9.

See Also:
"Location URIs" in XQuery 3.0: An XML Query Language at http://www.w3.org/TR/xquery-30/#id-module-handling-location-uris

5.4.6 XQuery Transformation Examples

For these examples, the following text files are in HDFS. The files contain a log of visits to different web pages. Each line represents a visit to a web page and contains the time, user name, page visited, and the status code.

mydata/visits1.log

2013-10-28T06:00:00, john, index.html, 200
2013-10-28T08:30:02, kelly, index.html, 200
2013-10-28T08:32:50, kelly, about.html, 200
2013-10-30T10:00:10, mike, index.html, 401

mydata/visits2.log

2013-10-30T10:00:01, john, index.html, 200
2013-10-30T10:05:20, john, about.html, 200
2013-11-01T08:00:08, laura, index.html, 200
2013-11-04T06:12:51, kelly, index.html, 200
2013-11-04T06:12:40, kelly, contact.html, 200

Example 5-1 Basic Filtering

This query filters out pages visited by user kelly and writes those files into a text file:

import module "oxh:text";

for $line in text:collection("mydata/visits*.log")
let $split := fn:tokenize($line, "\s*,\s*)
where $split[2] eq "kelly"
return text:put($line)

The query creates text files in the output directory that contain the following lines:

2013-11-04T06:12:51, kelly, index.html, 200
2013-11-04T06:12:40, kelly, contact.html, 200

Example 5-2 Group By and Aggregation

The next query computes the number of page visits per day:

import module "oxh:text";

for $line in text:collection("mydata/visits*.log")
let $split := fn:tokenize($line, "\s*,\s*)"
let $time := xs:dateTime($split[1])
let $day := xs:date($time)
group by $day
return text:put($day || " => " || fn:count($line))

The query creates text files that contain the following lines:

2013-10-28 => 3
2013-10-30 => 3
2013-11-01 => 1
2013-11-04 => 2

**Example 5-3 Inner Joins**

This example queries the following text file in HDFS, in addition to the other files. The file contains user profile information such as user ID, full name, and age, separated by colons (:

```
mydata/users.txt

john:John Doe:45
kelly:Kelly Johnson:32
laura:Laura Smith:
phil:Phil Johnson:27
```

The following query performs a join between `users.txt` and the log files. It computes how many times users older than 30 visited each page.

```
import module "oxh:text";
for $userLine in text:collection("mydata/users.txt")
let $userSplit := fn:tokenize($userLine, ":")
let $userId := $userSplit[1]
let $userAge := xs:integer($userSplit[3][. castable as xs:integer])
for $visitLine in text:collection("mydata/visits*.log")
let $visitSplit := fn:tokenize($visitLine, ",")
let $visitUserId := $visitSplit[2]
where $userId eq $visitUserId and $userAge gt 30
group by $page := $visitSplit[3]
return text:put($page || " " || fn:count($userLine))
```

The query creates text files that contain the following lines:

about.html 2
contact.html 1
index.html 4

The next query computes the number of visits for each user who visited any page; it omits users who never visited any page.

```
import module "oxh:text";
for $userLine in text:collection("mydata/users.txt")
let $userSplit := fn:tokenize($userLine, ":")
let $userId := $userSplit[1]
for $visitLine in text:collection("mydata/visits*.log")
  [{userId eq fn:tokenize(., ":")[2]}]
```
group by $userId
return text:put($userId || " " || fn:count($visitLine))

The query creates text files that contain the following lines:

john 3
kelly 4
laura 1

Note:
When the results of two collection functions are joined, only equijoins are supported. If one or both sources are not from a collection function, then any join condition is allowed.

Example 5-4  Left Outer Joins
This example is similar to the second query in Example 5-3, but also counts users who did not visit any page.

import module "oxh:text";

for $userLine in text:collection("mydata/users.txt")
let $userSplit := fn:tokenize($userLine, "\s*:\s*")
let $userId := $userSplit[1]

for $visitLine allowing empty in text:collection("mydata/visits*.log")
  [$userId eq fn:tokenize(., "\s*,\s*")[2]]

  group by $userId
  return text:put($userId || " " || fn:count($visitLine))

The query creates text files that contain the following lines:

john 3
kelly 4
laura 1
phil 0

Example 5-5  Semijoins
The next query finds users who have ever visited a page:

import module "oxh:text";

for $userLine in text:collection("mydata/users.txt")
let $userId := fn:tokenize($userLine, "\s*:\s*")[1]

where some $visitLine in text:collection("mydata/visits*.log")
  satisfies $userId eq fn:tokenize($visitLine, "\s*,\s*")[2]

  return text:put($userId)

The query creates text files that contain the following lines:

john
kelly
laura
**Example 5-6  Multiple Outputs**

The next query finds web page visits with a 401 code and writes them to trace* files using the XQuery `text:trace()` function. It writes the remaining visit records into the default output files.

```xquery
import module "oxh:text";

for $visitLine in text:collection("mydata/visits*.log")
let $visitCode := xs:integer(fn:tokenize($visitLine, "\s*,\s*\")[4])
return if ($visitCode eq 401) then text:trace($visitLine) else text:put($visitLine)
```

The query generates a trace* text file that contains the following line:

2013-10-30T10:00:10, mike, index.html, 401

The query also generates default output files that contain the following lines:

<table>
<thead>
<tr>
<th>Date</th>
<th>Time</th>
<th>User</th>
<th>Page</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-10-30</td>
<td>10:00:01</td>
<td>john</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-10-30</td>
<td>10:05:20</td>
<td>john</td>
<td>about.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-11-01</td>
<td>08:00:08</td>
<td>laura</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-11-04</td>
<td>12:51:00</td>
<td>kelly</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-11-04</td>
<td>12:40:00</td>
<td>kelly</td>
<td>contact.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-10-28</td>
<td>06:00:00</td>
<td>john</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-10-28</td>
<td>08:30:02</td>
<td>kelly</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>2013-10-28</td>
<td>08:32:50</td>
<td>kelly</td>
<td>about.html</td>
<td>200</td>
</tr>
</tbody>
</table>

**Example 5-7  Accessing Auxiliary Input Data**

The next query is an alternative version of the second query in Example 5-3, but it uses the `fn:unparsed-text-lines` function to access a file in the Hadoop distributed cache:

```xquery
import module "oxh:text";

for $visitLine in text:collection("mydata/visits*.log")
let $visitUserId := fn:tokenize($visitLine, "\s*,\s*\")[2]
for $userLine in fn:unparsed-text-lines("users.txt")
let $userSplit := fn:tokenize($userLine, "\s*:\s*\")
let $userId := $userSplit[1]
where $userId eq $visitUserId
group by $userId
return text:put($userId || " " || fn:count($visitLine))
```

The hadoop command to run the query must use the Hadoop -files option. See “Accessing Data in the Hadoop Distributed Cache.”

```bash
hadoop jar $OXH_HOME/lib/oxh.jar -files users.txt query.xq
```

The query creates text files that contain the following lines:

<table>
<thead>
<tr>
<th>User</th>
<th>Count</th>
</tr>
</thead>
<tbody>
<tr>
<td>john</td>
<td>3</td>
</tr>
<tr>
<td>kelly</td>
<td>4</td>
</tr>
<tr>
<td>laura</td>
<td>1</td>
</tr>
</tbody>
</table>

**Example 5-8  Calling a Custom Java Function from XQuery**

The next query formats input data using the `java.lang.String#format` method.
import module "oxh:text";

declare %ora-java:binding("java.lang.String#format")
    function local:string-format($pattern as xs:string, $data as xs:anyAtomicType*)
    as xs:string external;

for $line in text:collection("mydata/users*.txt")
let $split := fn:tokenize($line, "\s*:\s*")
return text:put(local:string-format("%s,%s,%s", $split))

The query creates text files that contain the following lines:

john,John Doe,45
kelly,Kelly Johnson,32
laura,Laura Smith,
phil,Phil Johnson,27

Example 5-9 Using User-defined XQuery Library Modules and XML Schemas

This example uses a library module named mytools.xq:

module namespace mytools = "urn:mytools";

declare %ora-java:binding("java.lang.String#format")
    function mytools:string-format($pattern as xs:string, $data as xs:anyAtomicType*)
    as xs:string external;

The next query is equivalent to the previous one, but it calls a string-format function from the mytools.xq library module:

import module namespace mytools = "urn:mytools" at "mytools.xq";
import module "oxh:text";

for $line in text:collection("mydata/users*.txt")
let $split := fn:tokenize($line, "\s*:\s*")
return text:put(mytools:string-format("%s,%s,%s", $split))

The query creates text files that contain the following lines:

john,John Doe,45
kelly,Kelly Johnson,32
laura,Laura Smith,
phil,Phil Johnson,27

Example 5-10 Filtering Dirty Data Using a Try/Catch Expression

The XQuery try/catch expression can be used to broadly handle cases where input data is in an unexpected form, corrupted, or missing. The next query finds reads an input file, ages.txt, that contains a username followed by the user’s age.

USER     AGE
---------
john     45
kelly    
laura    36
phil     OLD!
Notice that the first two lines of this file contain header text and that the entries for
Kelly and Phil have missing and dirty age values. For each user in this file, the query
writes out the user name and whether the user is over 40 or not.

```xml
import module "oxh:text";

for $line in text:collection("ages.txt")
let $split := fn:tokenize($line, "\s+")
return
try {
  let $user := $split[1]
  let $age := $split[2] cast as xs:integer
  return
  if ($age gt 40) then
    text:put($user || " is over 40")
  else
    text:put($user || " is not over 40")
} catch * {
  text:trace($err:code || " : " || $line)
}
```

The query generates an output text file that contains the following lines:

john is over 40
laura is not over 40

The query also generates a trace* file that contains the following lines:

err:FORG0001 : USER        AGE
err:XPTY0004 : ------------------
err:XPTY0004 : kelly
err:FORG0001 : phil        OLD!

5.5 Running Queries

To run a query, call the oxh utility using the hadoop jar command. The following is the
basic syntax:

```
```

5.5.1 Oracle XQuery for Hadoop Options

`query.xq`
Identifies the XQuery file. See “Creating an XQuery Transformation.”

`-clean`
Deletes all files from the output directory before running the query. If you use the
default directory, Oracle XQuery for Hadoop always cleans the directory, even when
this option is omitted.

`-exportliboozie directory`
Copies Oracle XQuery for Hadoop dependencies to the specified directory. Use this
option to add Oracle XQuery for Hadoop to the Hadoop distributed cache and the
Oozie shared library. External dependencies are also copied, so ensure that
environment variables such as KVHOME, OLH_HOME, and OXH_SOLR_MR_HOME are set
for use by the related adapters (Oracle NoSQL Database, Oracle Database, and Solr).
-ls
Lists the contents of the output directory after the query executes.

-output directory
Specifies the output directory of the query. The put functions of the file adapters create files in this directory. Written values are spread across one or more files. The number of files created depends on how the query is distributed among tasks. The default output directory is /tmp/oxh-user_name/output.

See “About the Oracle XQuery for Hadoop Functions” for a description of put functions.

-print
Prints the contents of all files in the output directory to the standard output (your screen). When printing Avro files, each record prints as JSON text.

-sharelib hdfs_dir
Specifies the HDFS folder location containing Oracle XQuery for Hadoop and third-party libraries.

-skiperrors
Turns on error recovery, so that an error does not halt processing.
All errors that occur during query processing are counted, and the total is logged at the end of the query. The error messages of the first 20 errors per task are also logged.
See these configuration properties:

oracle.hadoop.xquery.skiperrors.counters
oracle.hadoop.xquery.skiperrors.max
oracle.hadoop.xquery.skiperrors.log.max

-version
Displays the Oracle XQuery for Hadoop version and exits without running a query.

5.5.2 Generic Options
You can include any generic hadoop command-line option. Oracle XQuery for Hadoop implements the org.apache.hadoop.util.Tool interface and follows the standard Hadoop methods for building MapReduce applications.

The following generic options are commonly used with Oracle XQuery for Hadoop:

-conf job_config.xml
Identifies the job configuration file. See “Oracle XQuery for Hadoop Configuration Properties.”

When you work with the Oracle Database or Oracle NoSQL Database adapters, you can set various job properties in this file. See “Oracle Loader for Hadoop Configuration Properties and Corresponding %oracle-property Annotations ” and “Oracle NoSQL Database Adapter Configuration Properties”.

-D property=value
Identifies a configuration property. See “Oracle XQuery for Hadoop Configuration Properties.”
5.5.3 About Running Queries Locally

When developing queries, you can run them locally before submitting them to the cluster. A local run enables you to see how the query behaves on small data sets and diagnose potential problems quickly.

In local mode, relative URIs resolve against the local file system instead of HDFS, and the query runs in a single process.

To run a query in local mode:

1. Set the Hadoop -jt and -fs generic arguments to local. This example runs the query described in “Example: Hello World!” in local mode:

   ```bash
   $ hadoop jar $OXH_HOME/lib/oxh.jar -jt local -fs local ./hello.xq -output ./myoutput -print
   ```

2. Check the result file in the local output directory of the query, as shown in this example:

   ```bash
   $ cat ./myoutput/part-m-00000
   Hello World!
   ```

5.6 Running Queries from Apache Oozie

Apache Oozie is a workflow tool that enables you to run multiple MapReduce jobs in a specified order and, optionally, at a scheduled time. Oracle XQuery for Hadoop provides an Oozie action node that you can use to run Oracle XQuery for Hadoop queries from an Oozie workflow.

5.6.1 Getting Started Using the Oracle XQuery for Hadoop Oozie Action

Follow these steps to execute your queries in an Oozie workflow:

1. The first time you use Oozie with Oracle XQuery for Hadoop, ensure that Oozie is configured correctly. See “Configuring Oozie for the Oracle XQuery for Hadoop Action”.

2. Develop your queries in Oracle XQuery for Hadoop the same as always.

3. Create a workflow XML file like the one shown in Example 5-11. You can use the XML elements listed in “Supported XML Elements”.

4. Set the Oozie job parameters. The following parameter is required:

   `oozie.use.system.libpath=true`
See Example 5-13.

5. Run the job using syntax like the following:

    oozie job -name http://example.com:11000/oozie -config filename -run

See Also:
"Oozie Command Line Usage" in the Apache Oozie Command Line Interface Utilities at
https://oozie.apache.org/docs/4.0.0/DG_CommandLineTool.html#Oozie_Command_Line_Usage

5.6.2 Supported XML Elements

The Oracle XQuery for Hadoop action extends Oozie's Java action. It supports the following optional child XML elements with the same syntax and semantics as the Java action:

- archive
- configuration
- file
- job-tracker
- job-xml
- name-node
- prepare

See Also:
The Java action description in the Oozie Specification at
https://oozie.apache.org/docs/4.0.0/WorkflowFunctionalSpec.html#a3.2.7_Java_Action

In addition, the Oracle XQuery for Hadoop action supports the following elements:

- script: The location of the Oracle XQuery for Hadoop query file. Required.
  The query file must be in the workflow application directory. A relative path is resolved against the application directory.
  Example: <script>myquery.xq</script>

- output: The output directory of the query. Required.
  The output element has an optional clean attribute. Set this attribute to true to delete the output directory before the query is run. If the output directory already exists and the clean attribute is either not set or set to false, an error occurs. The output directory cannot exist when the job runs.
  Example: <output clean="true">/user/jdoe/myoutput</output>
Any error raised while running the query causes Oozie to perform the error transition for the action.

### 5.6.3 Example: Hello World

This example uses the following files:

- **workflow.xml**: Describes an Oozie action that sets two configuration values for the query in `hello.xq`: an HDFS file and the string `World!`
  
  The HDFS input file is `/user/jdoe/data/hello.txt` and contains this string:

  ```
  Hello
  ```

  See Example 5-11.

- **hello.xq**: Runs a query using Oracle XQuery for Hadoop.
  
  See Example 5-12.

- **job.properties**: Lists the job properties for Oozie. See Example 5-13.

To run the example, use this command:

```
oozie job -oozie http://example.com:11000/oozie -config job.properties -run
```

After the job runs, the `/user/jdoe/myoutput` output directory contains a file with the text "Hello World!"

#### Example 5-11   The workflow.xml File for Hello World

This file is named `/user/jdoe/hello-oozie-oxh/workflow.xml`. It uses variables that are defined in the `job.properties` file.

```xml
<workflow-app xmlns="uri:oozie:workflow:0.4" name="oxh-helloworld-wf">
  <start to="hello-node"/>
  <action name="hello-node">
    <oxh xmlns="oxh:oozie-action:v1">
      <job-tracker>${jobTracker}</job-tracker>
      <name-node>${nameNode}</name-node>

      <!--
      The configuration can be used to parameterize the query.
      -->
      <configuration>
        <property>
          <name>myinput</name>
          <value>${nameNode}/user/jdoe/data/src.txt</value>
        </property>
        <property>
          <name>mysuffix</name>
          <value> World!</value>
        </property>
      </configuration>
      <script>hello.xq</script>
      <output clean="true">${nameNode}/user/jdoe/myoutput</output>
    </oxh>
  </action>
  <ok to="end"/>
  <error to="fail"/>
</workflow-app>
```

---

5-18  User's Guide
<kill name="fail">
  <message>OXH failed: [{wf:errorMessage(wf:lastErrorNode())}]</message>
</kill>
</workflow-app>

Example 5-12 The hello.xq File for Hello World

This file is named /user/jdoe/hello-oozie-oxh/hello.xq.

import module "oxh:text";

declare variable $input := oxh:property("myinput");
declare variable $suffix := oxh:property("mysuffix");

for $line in text:collection($input)
  return
text:put($line | | $suffix)

Example 5-13 The job.properties File for Hello World

oozie.wf.application.path=hdfs://example.com:8020/user/jdoe/hello-oozie-oxh
nameNode=hdfs://example.com:8020
jobTracker=hdfs://example.com:8032
oozie.use.system.libpath=true

5.7 Oracle XQuery for Hadoop Configuration Properties

Oracle XQuery for Hadoop uses the generic methods of specifying configuration properties in the hadoop command. You can use the -conf option to identify configuration files, and the -D option to specify individual properties. See “Running Queries.”

See Also:

Hadoop documentation for job configuration files at http://wiki.apache.org/hadoop/JobConfFile
**Property** | **Description**
---|---
oracle.hadoop.xquery.lib.share | **Type:** String  
**Default Value:** Not defined.  
**Description:** Identifies an HDFS directory that contains the libraries for Oracle XQuery for Hadoop and third-party software. For example:  
http://path/to/shared/folder

All HDFS files must be in the same directory.  
Alternatively, use the -sharelib option on the command line.  
**Pattern Matching:** You can use pattern matching characters in a directory name. If multiple directories match the pattern, then the directory with the most recent modification timestamp is used.  
To specify a directory name, use alphanumeric characters and, optionally, any of the following special, pattern matching characters:

<table>
<thead>
<tr>
<th>Pattern</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>?</td>
<td>Matches any one character.</td>
</tr>
<tr>
<td>*</td>
<td>Matches zero or more characters.</td>
</tr>
<tr>
<td>[a-b]</td>
<td>Matches one character from the character set {a,b}.</td>
</tr>
<tr>
<td>[a-b]</td>
<td>Matches one character from the character range from a to b. Character a must be less than or equal to character b.</td>
</tr>
<tr>
<td>[^a]</td>
<td>Matches one character that is not from the a character set or range. The carat (^) must follow the opening bracket immediately (no spaces).</td>
</tr>
<tr>
<td>\c</td>
<td>Removes (escapes) any special meaning of character c.</td>
</tr>
<tr>
<td>{ab,cd}</td>
<td>Matches a string from the string set {ab, cd}.</td>
</tr>
<tr>
<td>{ab,c(de,fh)}</td>
<td>Matches a string from the string set {ab, cde, fhi}.</td>
</tr>
</tbody>
</table>

**Oozie libraries:** The value oxh:oozie expands automatically to /user/{oozie,user}/share/lib/{oxh,*/oxh*}, which is a common search path for supported Oozie versions. The user is the current user name. However, the Oracle XQuery for
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **oracle.hadoop.xquery.output** | Type: String  
Default Value: /tmp/oxh-user_name/output. The user_name is the name of the user running Oracle XQuery for Hadoop.  
Description: Sets the output directory for the query. This property is equivalent to the -output command line option. See “Oracle XQuery for Hadoop Options.” |
| **oracle.hadoop.xquery.scratch** | Type: String  
Default Value: /tmp/oxh-user_name/scratch. The user_name is the name of the user running Oracle XQuery for Hadoop.  
Description: Sets the HDFS temp directory for Oracle XQuery for Hadoop to store temporary files. |
| **oracle.hadoop.xquery.timezone** | Type: String  
Default Value: Client system time zone  
Description: The XQuery implicit time zone, which is used in a comparison or arithmetic operation when a date, time, or datetime value does not have a time zone. The value must be in the format described by the Java TimeZone class. See the TimeZone class description in Java 7 API Specification at http://docs.oracle.com/javase/7/docs/api/java/util/TimeZone.html |
| **oracle.hadoop.xquery.skiperrors** | Type: Boolean  
Default Value: false  
Description: Set to true to turn on error recovery, or set to false to stop processing when an error occurs. This property is equivalent to the -skiperrors command line option. |
| **oracle.hadoop.xquery.skiperrors.counters** | Type: Boolean  
Default Value: true  
Description: Set to true to group errors by error code, or set to false to report all errors in a single counter. |
| **oracle.hadoop.xquery.skiperrors.max** | Type: Integer  
Default Value: Unlimited  
Description: Sets the maximum number of errors that a single MapReduce task can recover from. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.xquery.skiperrors.log.max | Type: Integer  
 Default Value: 20  
 Description: Sets the maximum number of errors that a single MapReduce task logs. |
| log4j.logger.oracle.hadoop.xquery | Type: String  
 Default Value: Not defined  
 Description: Configures the log4j logger for each task with the specified threshold level. Set the property to one of these values: OFF, FATAL, ERROR, WARN, INFO, DEBUG, or ALL. If this property is not set, then Oracle XQuery for Hadoop does not configure log4j. |

### 5.8 Third-Party Licenses for Bundled Software

Oracle XQuery for Hadoop installs the following third-party products:

- ANTLR 3.2
- Apache Ant 1.7.1
- Apache Xerces 2.9.1
- Apache XMLBeans 2.3, 2.5
- Jackson 1.8.8
- Woodstox XML Parser 4.2.0

Unless otherwise specifically noted, or as required under the terms of the third party license (e.g., LGPL), the licenses and statements herein, including all statements regarding Apache-licensed code, are intended as notices only.

#### 5.8.1 Apache Licensed Code

The following is included as a notice in compliance with the terms of the Apache 2.0 License, and applies to all programs licensed under the Apache 2.0 license:

You may not use the identified files except in compliance with the Apache License, Version 2.0 (the "License.")

You may obtain a copy of the License at

[http://www.apache.org/licenses/LICENSE-2.0](http://www.apache.org/licenses/LICENSE-2.0)

A copy of the license is also reproduced below.

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.

See the License for the specific language governing permissions and limitations under the License.
5.8.2 Apache License

Version 2.0, January 2004
http://www.apache.org/licenses/

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."
"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. **Grant of Copyright License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. **Grant of Patent License.** Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. **Redistribution.** You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

   a. You must give any other recipients of the Work or Derivative Works a copy of this License; and

   b. You must cause any modified files to carry prominent notices stating that You changed the files; and

   c. You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

   d. If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.
5. **Submission of Contributions.** Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. **Trademarks.** This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. **Disclaimer of Warranty.** Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. **Limitation of Liability.** In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. **Accepting Warranty or Additional Liability.** While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

APPENDIX: How to apply the Apache License to your work

To apply the Apache License to your work, attach the following boilerplate notice, with the fields enclosed by brackets "["]" replaced with your own identifying information. (Don’t include the brackets!) The text should be enclosed in the appropriate comment syntax for the file format. We also recommend that a file or class name and description of purpose be included on the same "printed page" as the copyright notice for easier identification within third-party archives.

### 5.8.4 Apache Ant 1.7.1

Copyright 1999-2008 The Apache Software Foundation

This product includes software developed by The Apache Software Foundation (http://www.apache.org).

This product includes also software developed by:

- the W3C consortium (http://www.w3c.org)
- the SAX project (http://www.saxproject.org)

The <sync> task is based on code Copyright (c) 2002, Landmark Graphics Corp that has been kindly donated to the Apache Software Foundation.

Portions of this software were originally based on the following:
The full text of this NOTICE in a location viewable to users of the redistributed or derivative work.

2. Any pre-existing intellectual property disclaimers, notices, or terms and conditions. If none exist, the W3C Software Short Notice should be included (hypertext is preferred, text is permitted) within the body of any redistributed or derivative code.

3. Notice of any changes or modifications to the files, including the date changes were made. (We recommend you provide URLs to the location from which the code is derived.)

This software and documentation is provided "as is," and copyright holders make no representations or warranties, express or implied, including but not limited to, warranties of merchantability or fitness for any particular purpose or that the use of the software or documentation will not infringe any third party patents, copyrights, trademarks or other rights. Copyright holders will not be liable for any direct, indirect, special or consequential damages arising out of any use of the software or documentation.

The name and trademarks of copyright holders may NOT be used in advertising or publicity pertaining to the software without specific, written prior permission. Title to copyright in this software and any associated documentation will at all times remain with copyright holders.

This formulation of W3C's notice and license became active on December 31 2002. This version removes the copyright ownership notice such that this license can be used with materials other than those owned by the W3C, reflects that ERCIM is now a host of the W3C, includes references to this specific dated version of the license, and removes the ambiguous grant of "use". Otherwise, this version is the same as the previous version and is written so as to preserve the Free Software Foundation's assessment of GPL compatibility and OSI's certification under the Open Source Definition. Please see our Copyright FAQ for common questions about using materials from our site, including specific terms and conditions for packages like libwww,
Amaya, and Jigsaw. Other questions about this notice can be directed to site-policy@w3.org.

5.8.6 Apache XMLBeans 2.3, 2.5

This product includes software developed by The Apache Software Foundation (http://www.apache.org/).

Portions of this software were originally based on the following:

Aside from contributions to the Apache XMLBeans project, this software also includes:

- one or more source files from the Apache Xerces-J and Apache Axis products, Copyright (c) 1999-2003 Apache Software Foundation

- W3C XML Schema documents Copyright 2001-2003 (c) World Wide Web Consortium (Massachusetts Institute of Technology, European Research Consortium for Informatics and Mathematics, Keio University)

- resolver.jar from Apache Xml Commons project, Copyright (c) 2001-2003 Apache Software Foundation

- Piccolo XML Parser for Java from http://piccolo.sourceforge.net/, Copyright 2002 Yuval Oren under the terms of the Apache Software License 2.0

- JSR-173 Streaming API for XML from http://sourceforge.net/projects/xmlpullparser/, Copyright 2005 BEA under the terms of the Apache Software License 2.0

5.8.7 Jackson 1.8.8

Licensed under the Apache License, Version 2.0 (the "License"); you may not use this file except in compliance with the License. You may obtain a copy of the License at http://www.apache.org/licenses/LICENSE-2.0

Unless required by applicable law or agreed to in writing, software distributed under the License is distributed on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied. See the License for the specific language governing permissions and limitations under the License.
5.8.8 Woodstox XML Parser 4.2.0

This copy of Woodstox XML processor is licensed under the Apache (Software) License, version 2.0 ("the License"). See the License for details about distribution rights, and the specific rights regarding derivate works.

You may obtain a copy of the License at:

http://www.apache.org/licenses/

A copy is also included with both the downloadable source code package and jar that contains class bytecodes, as file "ASL 2.0". In both cases, that file should be located next to this file: in source distribution the location should be "release-notes/asl"; and in jar "META-INF/"

This product currently only contains code developed by authors of specific components, as identified by the source code files.

Since product implements StAX API, it has dependencies to StAX API classes.

For additional credits (generally to people who reported problems) see CREDITS file.
This chapter describes the adapters available in Oracle XQuery for Hadoop:

- Avro File Adapter
- JSON File Adapter
- Oracle Database Adapter
- Oracle NoSQL Database Adapter
- Sequence File Adapter
- Solr Adapter
- Text File Adapter
- Tika File Adapter
- XML File Adapter
- Serialization Annotations

This chapter also describes several other library modules:

- Hadoop Module
- Utility Module

### 6.1.1 Avro File Adapter

The Avro file adapter provides functions to read and write Avro container files in HDFS. It is described in the following topics:

- Built-in Functions for Reading Avro Files
- Custom Functions for Reading Avro Container Files
- Custom Functions for Writing Avro Files
- Examples of Avro File Adapter Functions
- About Converting Values Between Avro and XML
Note:
Additional Configuration Steps for HDP Users
Oracle XQuery for Hadoop has been verified to run on both Cloudera’s CDH5 and Hortonwork’s HDP 2.3.3. However, to run queries that write to Avro container files in HDP 2.3.2, you must change the OXH classpath definition to use avro-mapred-1.7.4-hadoop2.jar.

1. Download the JAR from the Apache archive https://archive.apache.org/dist/avro/avro-1.7.4/java/
2. In $OXH_HOME/lib/oxh-lib.xml locate the following path tag:

   `<path id="oracle.hadoop.xquery.avro.lib">`<fileset dir="${oracle.hadoop.loader.olh_home}/jlib" erroronmissingdir="false">`<include name="avro-mapred*.jar"/>`</fileset>`</path>`

Replace the path tag above with the following revision. [DIRECTORY] in this example is a placeholder. Replace it with the directory path to the JAR.

   `<path id="oracle.hadoop.xquery.avro.lib">`<fileset dir="[DIRECTORY]">`<include name="avro-mapred-1.7.4-hadoop2.jar"/>`</fileset>`</path>`

6.1.1.1 Built-in Functions for Reading Avro Files
To use the built-in functions in your query, you must import the Avro file module as follows:

   `import module "oxh:avro";`

The Avro file module contains the following functions:

- `avro:collection-avroxml`
- `avro:get`

There are no built-in functions for writing Avro container files. To write Avro files, you must use a custom function that specifies the Avro writer schema.

6.1.1.1.1 avro:collection-avroxml
Accesses a collection of Avro files in HDFS. The files might be split up and processed in parallel by multiple tasks. The function returns an XML element for each object. See “About Converting Values Between Avro and XML.”

Signature

   `declare %avro:collection("avroxml") function
avro:collection-avroxml($uris as xs:string*) as element()* external;`
**Parameters**

$uris$: The Avro file URLs

**Returns**

One XML element for each Avro object.

### 6.1.1.1.2 avro:get

Retrieves an entry from an Avro map modeled as XML

If you omit the $map parameter, then the behavior is identical to calling the two-argument function and using the context item for $map.

**Signature**

```xml
avro:get($key as xs:string?, $map as node()?) as element(oxh:entry)?
```

**Returns**

The value of this XPath expression:

```xml
$map/oxh:entry[@key eq $key]
```

**Example**

These function calls are equivalent:

```xml
$var/avro:get("key")
```

```xml
avro:get("key", $var)
```

```xml
$var/oxh:entry[@key eq "key"]
```

In this example, $var is an Avro map modeled as XML. See “Reading Maps.”

### 6.1.1.2 Custom Functions for Reading Avro Container Files

You can use the following annotations to define functions that read collections of Avro container files in HDFS. These annotations provide additional functionality that is not available using the built-in functions.

**Signature**

Custom functions for reading Avro files must have the following signature:

```xml
declare %avro:collection("avroxml") [additional annotations]
    function local:myFunctionName($uris as xs:string*) as element()* external;
```

**Annotations**

- `%avro:collection("avroxml")`
  
  Declares the avroxml collection function. Required.

  A collection function accesses Avro files in HDFS. The files might be split up and processed in parallel by multiple tasks. The function returns an XML element for each object. See “About Converting Values Between Avro and XML.”
%avro:schema("avro-schema")
Provides the Avro reader schema as the value of the annotation. Optional.
The objects in the file are mapped to the reader schema when it is specified. For example:

```json
%avro:schema(
{
  "type": "record",
  "name": "Person",
  "fields": [
    {"name": "full_name", "type": "string"},
    {"name": "age", "type": ["int", "null"] }
  ]
}
)
```

You cannot combine this annotation with %avro:schema-file or %avro:schema-kv.

---

**See Also:**
"Schema Resolution” in the Apache Avro Specification at
http://avro.apache.org/docs/current/spec.html#SchemaResolution

---

%avro:schema-file("avro-schema-uri")
Like %avro:schema, but the annotation value is a file URI that contains the Avro reader schema. Relative URIs are resolved against the current working directory of the client's local file system. Optional.

For example, %avro:schema-file("schemas/person.avsc").

You cannot combine this annotation with %avro:schema or %avro:schema-kv.

%avro:schema-kv("schema-name")
Like %avro:schema, but the annotation value is a fully qualified record name. The record schema is retrieved from the Oracle NoSQL Database catalog. Optional.

For example, %avro:schema-kv("org.example.PersonRecord").

You must specify the connection parameters to Oracle NoSQL Database when you use this annotation. See “Oracle NoSQL Database Adapter Configuration Properties.”

You cannot combine this annotation with %avro:schema or %avro:schema-file.

%avro:split-max("split-size")
Specifies the maximum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as \( \max(\text{split-min}, \min(\text{split-max}, \text{block-size})) \). Optional.

In a string value, you can append \( K, k, M, m, G, \text{ or } g \) to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

```
%avro:split-max(1024)
%avro:split-max("1024")
%avro:split-max("1K")
```
%avro:split-min("split-size")
Specifies the minimum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as max(%split-min, min(%split-max, %block-size)). Optional.

In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

%avro:split-min(1024)
%avro:split-min("1024")
%avro:split-min("1K")

6.1.1.3 Custom Functions for Writing Avro Files
You can use the following annotations to define functions that write Avro files.

Signature
Custom functions for writing Avro files must have the following signature:

```
declare %avro:put("avroxml") [additional annotations]
    local:myFunctionName($value as item()) external;
```

Annotations
%avro:put("avroxml")
Declares the avroxml put function. Required.
An Avro schema must be specified using one of the following annotations:

- %avro:schema
- %avro:schema-file
- %avro:schema-kv

The input XML value is converted to an instance of the schema. See “Writing XML as Avro.”

%avro:schema("avro-schema")
Specifies the schema of the files. For example:

```xml
%avro:schema(''
    {
        "type": "record",
        "name": "Person",
        "fields": [
            {"name": "full_name", "type": "string"},
            {"name": "age", "type": ["int", "null"] }
        ]
    }
')
```

You cannot combine this annotation with %avro:schema-file or %avro:schema-kv.
%avro:schema-file("avro-schema-uri")
Like %avro:schema, but the annotation value is a file URI that contains the Avro reader schema. Relative URIs are resolved against the current working directory of the client's local file system.
For example: %avro:schema-file("schemas/person.avsc")
You cannot combine this annotation with %avro:schema or %avro:schema-kv.

%avro:schema-kv("schema-name")
Like %avro:schema, but the annotation value is a fully qualified record name. The record schema is retrieved from the Oracle NoSQL Database catalog.
For example: %avro:schema-kv("org.example.PersonRecord")
You must specify the connection parameters to Oracle NoSQL Database when you use this annotation. See “Oracle NoSQL Database Adapter Configuration Properties.”
You cannot combine this annotation with %avro:schema or %avro:schema-file.

%avro:compress("method", [level]?)
Specifies the compression format used on the output.
The codec is one of the following string literal values:

- **deflate**: The level controls the trade-off between speed and compression. Valid values are 1 to 9, where 1 is the fastest and 9 is the most compressed.
- **snappy**: This algorithm is designed for high speed and moderate compression.

The default is no compression.
The level is an integer value. It is optional and only supported when codec is deflate.
For example:

```avro
%avro:compress("snappy")
%avro:compress("deflate")
%avro:compress("deflate", 3)
```

%avro:file("name")
Specifies the output file name prefix. The default prefix is part.

### 6.1.1.4 Examples of Avro File Adapter Functions

These examples use the following text file in HDFS:

```
mydata/ages.txt
```

```
john,45
kelly,36
laura,
mike,27
```

**Example 6-1  Converting a Text File to Avro**

The following query converts the file into compressed Avro container files:

```avro
import module "oxh:text";

declare
  %avro:put("avroxml")
  %avro:compress("snappy")
  %avro:schema('```
function local:put($arg as item()) external;

for $line in text:collection("mydata/ages.txt")
let $split := fn:tokenize($line, ",")
return
local:put(
<rec>
  <user>{$split[1]}</user>
  <age>{$split[2]}</age>
</rec>)

The query generates an Avro file with the following records, represented here as JSON:

{"user":"john","age":{"int":45}}
{"user":"kelly","age":{"int":36}}
{"user":"laura","age":null}
{"user":"mike","age":{"int":27}}

**Example 6-2 Querying Records in Avro Container Files**

The next query selects records in which the age is either null or greater than 30, from the myoutput directory. The query in Example 6-1 generated the records.

import module "oxh:text";
import module "oxh:avro";

for $rec in avro:collection-avroxml("myoutput/part*.avro")
  where $rec/age/nilled() or $rec/age gt 30
return
text:put($rec/user)

This query creates files that contain the following lines:

john
kelly
laura

**6.1.1.5 About Converting Values Between Avro and XML**

This section describes how Oracle XQuery for Hadoop converts data between Avro and XML:

- **Reading Avro as XML**
- **Writing XML as Avro**
6.1.1.5.1 Reading Avro as XML

Both the Avro file adapter and the Oracle NoSQL Database adapter have an `avroxml` method, which you can use with the collection functions to read Avro records as XML. After the Avro is converted to XML, you can query and transform the data using XQuery.

The following topics describe how Oracle XQuery for Hadoop reads Avro:

- Reading Records
- Reading Maps
- Reading Arrays
- Reading Unions
- Reading Primitives

6.1.1.5.1.1 Reading Records

An Avro record is converted to an `<oxh:item>` element with one child element for each field in the record.

For example, consider the following Avro schema:

```json
{
   "type": "record",
   "name": "Person",
   "fields": [
      {"name": "full_name", "type": "string"},
      {"name": "age", "type": ["int", "null"] }
   ]
}
```

This is an instance of the record modeled as XML:

```xml
<oxh:item>
   <full_name>John Doe</full_name>
   <age>46</age>
</oxh:item>
```

Converting Avro records to XML enables XQuery to query them. The next example queries an Avro container file named `person.avro`, which contains Person records. The query converts the records to a CSV text file in which each line contains the `full_name` and `age` values:

```xquery
import module "oxh:avro";
import module "oxh:text";

for $x in avro:collection-avroxml("person.avro")
return
   text:put($x/full_name || "," || $x/age)
```

Null values are converted to nilled elements. A nilled element has an `xsi:nil` attribute set to `true`; it is always empty. You can use the XQuery `fn:nilled` function to test if a record field is null. For example, the following query writes the name of Person records that have a null value for age:
import module "oxh:avro";
import module "oxh:text";

for $x in avro:collection-avroxml("person.avro")
where $x/age/nilled()
return
text:put($x/full_name)

For nested records, the fields of the inner schema become child elements of the
element that corresponds to the field in the outer schema. For example, this schema
has a nested record:

```
{
  "type": "record",
  "name": "PersonAddress",
  "fields" : [
    { "name": "full_name", "type": "string"},
    { "name": "address", "type":
      { "type": "record",
        "name": "Address",
        "fields" : [
          { "name": "street", "type": "string" },
          { "name": "city", "type": "string" }
        ]
      }
    }
  ]
}
```

This is an instance of the record as XML:

```
<oxh:item>
  <full_name>John Doe</full_name>
  <address>
    <street>123 First St.</street>
    <city>New York</city>
  </address>
</oxh:item>
```

The following example queries an Avro container file named people-address.avro that
contains PersonAddress records, and writes the names of the people that live in
New York to a text file:

```xquery
import module "oxh:avro";
import module "oxh:text";

for $person in avro:collection-avroxml("examples/person-address.avro")
where $person/address/city eq "New York"
return
text:put($person/full_name)
```

6.1.1.5.1.2 Reading Maps

Avro map values are converted to an element that contains one child <oxh:entry>
element for each entry in the map. For example, consider the following schema:

```
{
  "type": "record",
  "name": "PersonProperties",
  "fields" : [
    { "name": "full_name", "type": "string"},
```

This is an instance of the schema as XML:

```xml
<oxh:item>
  <full_name>John Doe</full_name>
  <properties>
    <oxh:entry key="employer">Example Inc</oxh:entry>
    <oxh:entry key="hair color">brown</oxh:entry>
    <oxh:entry key="favorite author">George RR Martin</oxh:entry>
  </properties>
</oxh:item>
```

The following example queries a file named `person-properties.avro` that contains PersonAddress records, and writes the names of the people that are employed by Example Inc. The query shows how regular XPath expressions can retrieve map entries. Moreover, you can use the `avro:get` function as a shortcut to retrieve map entries.

```xml
import module "oxh:avro";
import module "oxh:text";

for $person in avro:collection-avroxml("person-properties.avro")
  where $person/properties/oxh:entry[@key eq "employer"] eq "Example Inc"
  return text:put($person/full_name)
```

The following query uses the `avro:get` function to retrieve the `employer` entry. It is equivalent to the previous query.

```xml
import module "oxh:avro";
import module "oxh:text";

for $person in avro:collection-avroxml("person-properties.avro")
  where $person/properties/avro:get("employer") eq "Example Inc"
  return text:put($person/full_name)
```

You can use XQuery `fn:nilled` function to test for null values. This example returns true if the map entry is null:

```xml
$var/avro:get("key")/nilled()
```

### 6.1.1.5.1.3 Reading Arrays

Oracle XQuery for Hadoop converts Avro array values to an element that contains a child `<oxh:item>` element for each item in the array. For example, consider the following schema:

```xml
{
  "type": "record",
  "name": "PersonScores",
  "fields": [
    {"name": "full_name", "type": "string"},
    {"name": "scores", "type":
      {"type": "array", "items": "int"}
    }
  ]
}
```
This is an instance of the schema as XML:

```xml
<oxh:item>
  <full_name>John Doe</full_name>
  <scores>
    <oxh:item>128</oxh:item>
    <oxh:item>151</oxh:item>
    <oxh:item>110</oxh:item>
  </scores>
</oxh:item>
```

The following example queries a file named `person-scores.avro` that contains `PersonScores` records, and writes the sum and count of scores for each person:

```xquery
import module "oxh:avro";
import module "oxh:text";

for $person in avro:collection-avroxml("person-scores.avro")
let $scores := $person/scores/*
return
text:put($person/full_name || "," || sum($scores) || "," || count($scores))
```

You can access a specific element of an array by using a numeric XPath predicate. For example, this path expression selects the second score. XPath indexing starts at 1 (not 0).

```xquery
$person/scores/oxh:item[2]
```

### 6.1.5.1.4 Reading Unions

Oracle XQuery for Hadoop converts an instance of an Avro union type based on the actual member type of the value. The name of the member type is added as an XML `avro:type` attribute to the enclosing element, which ensures that queries can distinguish between instances of different member types. However, the attribute is not added for trivial unions where there are only two member types and one of them is null.

For example, consider the following union of two records:

```json
[
  {
    "type": "record",
    "name": "Person1",
    "fields": [
      {"name": "full_name", "type": "string"}
    ]
  },
  {
    "type": "record",
    "name": "Person2",
    "fields": [
      {"name": "fname", "type": "string"}
    ]
  }
]
```

This is an instance of the schema as XML:
The following example queries a file named person-union.avro that contains instances of the previous union schema, and writes the names of the people from both record types to a text file:

```xquery
import module "oxh:avro";
import module "oxh:text";

for $person in avro:collection-avroxml("examples/person-union.avro")
return
  if ($person/@avro:type eq "Person1") then
    text:put($person/full_name)
  else if ($person/@avro:type eq "Person2") then
    text:put($person/fname)
  else
    error(xs:QName("UNEXPECTED"), "Unexpected record type:" || $person/@avro:type)
```

### 6.1.1.5.1.5 Reading Primitives

Table 6-1 shows how Oracle XQuery for Hadoop maps Avro primitive types to XQuery atomic types.

<table>
<thead>
<tr>
<th>Avro</th>
<th>XQuery</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>int</td>
<td>xs:int</td>
</tr>
<tr>
<td>long</td>
<td>xs:long</td>
</tr>
<tr>
<td>float</td>
<td>xs:float</td>
</tr>
<tr>
<td>double</td>
<td>xs:double</td>
</tr>
<tr>
<td>bytes</td>
<td>xs:hexBinary</td>
</tr>
<tr>
<td>string</td>
<td>xs:string</td>
</tr>
</tbody>
</table>

Avro null values are mapped to empty nilled elements. To distinguish between a null string value and an empty string value, use the XQuery `nilled` function. This path expression only returns true if the field value is null:

```xquery
$record/field/fn:nilled()
```

Avro fixed values are mapped to `xs:hexBinary`, and enums are mapped to `xs:string`.

### 6.1.1.5.2 Writing XML as Avro

Both the Avro file adapter and the Oracle NoSQL Database adapter have an `avroxml` method, which you can use with the `put` functions to write XML as Avro. The following topics describe how the XML is converted to an Avro instance:

- Writing Records
- Writing Maps
6.1.1.5.2.1 Writing Records

Oracle XQuery for Hadoop maps the XML to an Avro record schema by matching the child element names to the field names of the record. For example, consider the following Avro schema:

```
{  
  "type": "record",  
  "name": "Person",  
  "fields": [  
    {"name": "full_name", "type": "string"},  
    {"name": "age", "type": ["int", "null"]}  
  ]  
}
```

You can use the following XML element to write an instance of this record in which the `full_name` field is John Doe and the `age` field is 46. The name of the root element (`Person`) is inconsequential. Only the names of the child elements are used to map to the Avro record fields (`full_name` and `age`).

```
<person>
  <full_name>John Doe</full_name>
  <age>46</age>
</person>
```

The next example uses the following CSV file named `people.csv`:

```
John Doe,46
Jane Doe,37
. .
```

This query converts values from the CSV file to Avro `Person` records:

```
import module "oxh:avro";
import module "oxh:text";

declare %avro:put("avroxml")
%avro:schema(
{
  "type": "record",  
  "name": "Person",  
  "fields": [  
    {"name": "full_name", "type": "string"},  
    {"name": "age", "type": ["int", "null"]}  
  ]
}
)

function local:put-person($person as element()) external;

for $line in text:collection("people.csv")
let $split := tokenize($line, ",")
return
```
local:put-person{
  <person>
    <full_name>{$split[1]}</full_name>
    <age>{$split[2]}</age>
  </person>
}

For null values, you can omit the element or set the xsi:nil="true" attribute. For example, this modified query sets age to null when the value is not numeric:

for $line in text:collection("people.csv")
let $split := tokenize($line, ",")
return
local:put-person{
  <person>
    <full_name>{$split[1]}</full_name>
    [if ($split[2] castable as xs:int) then
      <age>{$split[2]}</age>
    else
      ()
    ]
  </person>
}

In the case of nested records, the values are obtained from nested elements. The next example uses the following schema:

{  
  "type": "record",  
  "name": "PersonAddress",  
  "fields": [  
    {"name": "full_name", "type": "string"},  
    {"name": "address", "type": {  
        "type": "record",  
        "name": "Address",  
        "fields": [  
          { "name": "street", "type": "string" },  
          { "name": "city", "type": "string" }  
        ]  
      }  
    ]  
  ]  
}

You can use following XML to write an instance of this record:

<person>
  <full_name>John Doe</full_name>
  <address>
    <street>123 First St.</street>
    <city>New York</city>
  </address>
</person>
6.1.1.5.2.2 Writing Maps

Oracle XQuery for Hadoop converts XML to an Avro map with one map entry for each `<oxh:entry>` child element. For example, consider the following schema:

```json
{
    "type": "record",
    "name": "PersonProperties",
    "fields": [
        {"name": "full_name", "type": "string"},
        {"name": "properties", "type":
            {"type": "map", "values": "string"}
        }
    ]
}
```

You can use the following XML element to write an instance of this schema in which the `full_name` field is John Doe, and the properties field is set to a map with three entries:

```xml
<person>
    <full_name>John Doe</full_name>
    <properties>
        <oxh:entry key="hair color">brown</oxh:entry>
        <oxh:entry key="favorite author">George RR Martin</oxh:entry>
        <oxh:entry key="employer">Example Inc</oxh:entry>
    </properties>
</person>
```

6.1.1.5.2.3 Writing Arrays

Oracle XQuery for Hadoop converts XML to an Avro array with one item for each `<oxh:item>` child element. For example, consider the following schema:

```json
{
    "type": "record",
    "name": "PersonScores",
    "fields": [
        {"name": "full_name", "type": "string"},
        {"name": "scores", "type":
            {"type": "array", "items": "int"}
        }
    ]
}
```

You can use the following XML element to write an instance of this schema in which the `full_name` field is John Doe and the scores field is set to `[128, 151, 110]`:

```xml
<person>
    <full_name>John Doe</full_name>
    <scores>
        <oxh:item>128</oxh:item>
        <oxh:item>151</oxh:item>
        <oxh:item>110</oxh:item>
    </scores>
</person>
```

6.1.1.5.2.4 Writing Unions

When writing an Avro union type, Oracle XQuery for Hadoop bases the selection of a member type on the value of the `avro:type` attribute.
This example uses the following schema:

```
[
  {
    "type": "record",
    "name": "Person1",
    "fields": [
      {"name": "full_name", "type": "string"}
    ]
  },
  {
    "type": "record",
    "name": "Person2",
    "fields": [
      {"name": "fname", "type": "string"}
    ]
  }
]
```

The following XML is mapped to an instance of the Person1 record:

```xml
<person avro:type="Person1">
  <full_name>John Doe</full_name>
</person>
```

This XML is mapped to an instance of the Person2 record:

```xml
<person avro:type="Person2">
  <fname>John Doe</fname>
</person>
```

The `avro:type` attribute selects the member type of the union. For trivial unions that contain a null and one other type, the `avro:type` attribute is unnecessary. If the member type cannot be determined, then an error is raised.

### 6.1.1.5.2.5 Writing Primitives

To map primitive values, Oracle XQuery for Hadoop uses the equivalent data types shown in Table 6-1 to cast an XML value to the corresponding Avro type. If the value cannot be converted to the Avro type, then an error is raised.

This example uses the following schema:

```
{
  "type": "record",
  "name": "Person",
  "fields": [
    {"name": "full_name", "type": "string"},
    {"name": "age", "type": ["int", "null"]}
  ]
}
```

Attempting to map the following XML to an instance of this schema raises an error, because the `string` value `apple` cannot be converted to an `int`:

```xml
<person>
  <full_name>John Doe</full_name>
  <age>apple</age>
</person>
```
6.1.2 JSON File Adapter

The JSON file adapter provides access to JSON files stored in HDFS. It also contains functions for working with JSON data embedded in other file formats. For example, you can query JSON that is stored as lines in a large text file by using `json:parse-as-xml` with the `text:collection` function.

Processing a single JSON file in parallel is not currently supported. A set of JSON files can be processed in parallel, with sequential processing of each file.

The JSON module is described in the following topics:

- Built-in Functions for Reading JSON
- Custom Functions for Reading JSON Files
- Examples of JSON Functions
- JSON File Adapter Configuration Properties
- About Converting JSON Data Formats to XML

6.1.2.1 Built-in Functions for Reading JSON

To use the built-in functions in your query, you must import the JSON file adapter as follows:

```xquery
import module "oxh:json";
```

The JSON module contains the following functions:

- `json:collection-jsonxml`
- `json:parse-as-xml`
- `json:get`

6.1.2.1.1 `json:collection-jsonxml`

Accesses a collection of JSON files in HDFS. Multiple files can be processed concurrently, but each individual file is parsed by a single task.

The JSON file adapter automatically decompresses files compressed with a Hadoop-supported compression codec.

**Signature**

```xquery
json:collection-jsonxml($uris as xs:string*) as element()* external;
```

**Parameters**

- `$uris`: The JSON file URIs

**Returns**

XML elements that model the JSON values. See “About Converting JSON Data Formats to XML.”
### 6.1.2.1.2 json:parse-as-xml

Parses a JSON value as XML.

**Signature**

\[
\text{json:parse-as-xml($arg\ as \ xs:string?) as element(*)?}
\]

**Parameters**

$arg: Can be the empty sequence.

**Returns**

An XML element that models the JSON value. An empty sequence if $arg is an empty sequence. See “About Converting JSON Data Formats to XML.”

### 6.1.2.1.3 json:get

Retrieves an entry from a JSON object modeled as XML. See “About Converting JSON Data Formats to XML.”

**Signature**

\[
\text{json:get($key\ as \ xs:string?, \ obj\ as \ node())? as element(oxh:entry)?}
\]

\[
\text{json:get($key\ as \ xs:string?) as element(oxh:entry)?}
\]

**Parameters**

$key: The JSON data key

$obj: The JSON object value

**Returns**

The value of the following XPath expression:

\[
\text{obj/oxh:entry[@key eq $key]}
\]

If $input not present, then the behavior is identical to calling the two-argument function using the context item for $obj. See the Notes.

**Notes**

These function calls are equivalent:

\[
\text{$var/json:get("key")}
\]

\[
\text{json:get("key", $var)}
\]

\[
\text{$var/oxh:entry[@key eq "key"]}
\]

$var is a JSON object modeled as XML. See “Reading Maps.”
6.1.2.2 Custom Functions for Reading JSON Files

You can use the following annotations to define functions that read collections of JSON files in HDFS. These annotations provide additional functionality that is not available using the built-in functions.

Signature

Custom functions for reading JSON files must have the following signature:

```
declare %json:collection("jsonxml") [additional annotations]
    function local:myFunctionName($uris as xs:string*) as element()* external;
```

Annotations

- `%json:collection("jsonxml")`
  Declares the collection function. The annotation parameter must be `jsonxml`.

- `%output:encoding("charset")`
  Identifies the text encoding of the input files.
  The valid encodings are those supported by the JVM. If this annotation is omitted, then the encoding is automatically detected from the JSON file as UTF-8, UTF-16 big-endian serialization (BE) or little-endian serialization (LE), or UTF-32 (BE or LE).
  For better performance, omit the encoding annotation if the actual file encoding is specified by JSON Request for Comment 4627, Section 3 "Encoding," on the Internet Engineering Task Force (IETF) website at http://www.ietf.org/rfc/rfc4627.txt

Parameters

- `$uris as xs:string*` Lists the JSON file URIs. Required.

Returns

A collection of XML elements. Each element models the corresponding JSON value. See “About Converting JSON Data Formats to XML.”

6.1.2.3 Examples of JSON Functions

Example 6-3 uses the following JSON text files stored in HDFS:

```
mydata/users1.json
[
  { "user" : "john", "full name" : "John Doe", "age" : 45 },
  { "user" : "kelly", "full name" : "Kelly Johnson", "age" : 32 }
]

mydata/users2.json
[
  { "user" : "laura", "full name" : "Laura Smith", "age" : null },
  { "user" : "phil", "full name" : "Phil Johnson", "age" : 27 }
]
```
The remaining examples query the following text file in HDFS:

```
mydata/users-json.txt
```

```json
{ "user" : "john", "full name" : "John Doe", "age" : 45 }
{ "user" : "kelly", "full name" : "Kelly Johnson", "age" : 32 }
{ "user" : "laura", "full name" : "Laura Smith", "age" : null }
{ "user" : "phil", "full name" : "Phil Johnson", "age" : 27 }
```

**Example 6-3**

The following query selects names of users whose last name is Johnson from `users1.json` and `users2.json`:

```xml
import module "oxh:text";
import module "oxh:json";

for $user in json:collection-jsonxml("mydata/users*.json")/oxh:item
let $fullname := $user/json:get("full name")
where tokenize($fullname, \\
\s+)\[2\] eq "Johnson"
return
text:put-text($fullname)
```

This query generates text files that contain the following lines:

```
Phil Johnson
Kelly Johnson
```

**Example 6-4**

The following query selects the names of users that are older than 30 from `users-json.txt`:

```xml
import module "oxh:text";
import module "oxh:json";

for $line in text:collection("mydata/users-json.txt")
let $user := json:parse-as-xml($line)
where $user/json:get("age") gt 30
return
text:put($user/json:get("full name"))
```

This query generates text files that contain the following lines:

```
John Doe
Kelly Johnson
```

**Example 6-5**

The next query selects the names of employees that have a null value for age from `users-json.txt`:

```xml
import module "oxh:text";
import module "oxh:json";

for $line in text:collection("mydata/users-json.txt")
let $user := json:parse-as-xml($line)
where $user/json:get("age")/nilled()
return
text:put($user/json:get("full name"))
```

This query generates a text file that contains the following line:

```
Phil Johnson
```
6.1.2.4 JSON File Adapter Configuration Properties

Oracle XQuery for Hadoop uses the generic options for specifying configuration properties in the `hadoop` command. You can use the `--conf` option to identify configuration files, and the `--D` option to specify individual properties. See “Running Queries.”

The following configuration properties are equivalent to the Jackson parser options with the same names. You can enter the option name in either upper or lower case. For example, `oracle.hadoop.xquery.json.parser.ALLOW_BACKSLASH_ESCAPING_ANY_CHARACTER` and `oracle.hadoop.xquery.json.parser.allow_backslash_escaping_any_character` are equal.

**oracle.hadoop.xquery.json.parser.ALLOW_BACKSLASH_ESCAPING_ANY_CHARACTER**
- **Type:** Boolean
- **Default Value:** false
- **Description:** Enables any character to be escaped with a backslash (\). Otherwise, only the following characters can be escaped: quotation mark ("'), slash (/), backslash (\), backspace, form feed (f), new line (n), carriage return (r), horizontal tab (t), and hexadecimal representations (u\nnnn)

**oracle.hadoop.xquery.json.parser.ALLOW_COMMENTS**
- **Type:** Boolean
- **Default Value:** false
- **Description:** Allows Java and C++ comments (/* and //) within the parsed text.

**oracle.hadoop.xquery.json.parser.ALLOW_NON_NUMERIC_NUMBERS**
- **Type:** Boolean
- **Default Value:** false
- **Description:** Allows Not a Number (NaN) tokens to be parsed as floating number values.

**oracle.hadoop.xquery.json.parser.ALLOW_NUMERIC_LEADING_ZEROS**
- **Type:** Boolean
- **Default Value:** false
- **Description:** Allows integral numbers to start with zeroes, such as 00001. The zeros do not change the value and can be ignored.

**oracle.hadoop.xquery.json.parser.ALLOW_SINGLE_QUOTES**
- **Type:** Boolean
- **Default Value:** false
- **Description:** Allow single quotes ('') to delimit string values.

**oracle.hadoop.xquery.json.parser.ALLOW_UNQUOTED_CONTROL_CHARS**
- **Type:** Boolean
- **Default Value:** false
**Description:** Allows JSON strings to contain unquoted control characters (that is, ASCII characters with a decimal value less than 32, including the tab and line feed).

**oracle.hadoop.xquery.json.parser.ALLOW_UNQUOTED_FIELD_NAMES**
**Type:** Boolean
**Default Value:** false
**Description:** Allows unquoted field names, which are allowed by Javascript but not the JSON specification.

### 6.1.2.5 About Converting JSON Data Formats to XML

This section describes how JSON data formats are converted to XML. It contains the following topics:

- **About Converting JSON Objects to XML**
- **About Converting JSON Arrays to XML**
- **About Converting Other JSON Types**

#### 6.1.2.5.1 About Converting JSON Objects to XML

JSON objects are similar to Avro maps and are converted to the same XML structure. See “Reading Maps.”

For example, the following JSON object is converted to an XML element:

```json
{
    "user" : "john",
    "full_name" : "John Doe",
    "age" : 45
}
```

The object is modeled as the following element:

```xml
<oxh:item>
    <oxh:entry key="user">john</oxh:entry>
    <oxh:entry key="full_name">John Doe</oxh:entry>
    <oxh:entry key="age">45</oxh:entry>
</oxh:item>
```

#### 6.1.2.5.2 About Converting JSON Arrays to XML

JSON arrays are similar to Avro arrays and are converted to the same XML structure. See “Reading Arrays.”

For example, the following JSON array is converted to an XML element:

```json
[ "red", "blue", "green" ]
```

The array is modeled as the following element:

```xml
<oxh:item>
    <oxh:item>red</oxh:item>
    <oxh:item>blue</oxh:item>
    <oxh:item>green</oxh:item>
</oxh:item>
```

#### 6.1.2.5.3 About Converting Other JSON Types

The other JSON values are mapped as shown in Table 6-2.
Table 6-2  JSON Type Conversions

<table>
<thead>
<tr>
<th>JSON</th>
<th>XML</th>
</tr>
</thead>
<tbody>
<tr>
<td>null</td>
<td>An empty (nilled) element</td>
</tr>
<tr>
<td>true/false</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>number</td>
<td>xs:decimal</td>
</tr>
<tr>
<td>string</td>
<td>xs:string</td>
</tr>
</tbody>
</table>

6.1.3 Oracle Database Adapter

The Oracle Database adapter provides custom functions for loading data into tables in Oracle Database.

A custom put function supported by this adapter automatically calls Oracle Loader for Hadoop at run time, either to load the data immediately or to output it to HDFS. You can declare and use multiple custom Oracle Database adapter put functions within a single query. For example, you might load data into different tables or into different Oracle databases with a single query.

Ensure that Oracle Loader for Hadoop is installed on your system, and that the OLH_HOME environment variable is set to the installation directory. See Step 3 of “Installing Oracle XQuery for Hadoop.” Although not required, you might find it helpful to familiarize yourself with Oracle Loader for Hadoop before using this adapter.

The Oracle Database adapter is described in the following topics:

- Custom Functions for Writing to Oracle Database
- Examples of Oracle Database Adapter Functions
- Oracle Loader for Hadoop Configuration Properties and Corresponding %oracle-property Annotations

See Also:

- “Software Requirements” for the versions of Oracle Database that Oracle Loader for Hadoop supports
- Oracle Loader for Hadoop

6.1.3.1 Custom Functions for Writing to Oracle Database

You can use the following annotations to define functions that write to tables in an Oracle database either directly or by generating binary or text files for subsequent loading with another utility, such as SQL*Loader.

Signature

Custom functions for writing to Oracle database tables must have the following signature:
Annotations

%oracle:put("output_mode"?)
Declares the put function and the output mode. Required.
The optional output_mode parameter can be one of the following string literal values:

- **jdbc**: Writes to an Oracle database table using a JDBC connection. Default.
  See “JDBC Output Format.”
- **oci**: Writes to an Oracle database table using an Oracle Call Interface (OCI) connection.
  See “Oracle OCI Direct Path Output Format.”
- **datapump**: Creates Data Pump files and associated scripts in HDFS for subsequent loading by another utility.
  See “Oracle Data Pump Output Format.”
- **text**: Creates delimited text files and associated scripts in HDFS.
  See “Delimited Text Output Format.”

For Oracle XQuery for Hadoop to write directly to an Oracle database table using either JDBC or OCI, all systems involved in processing the query must be able to connect to the Oracle Database system. See “About the Modes of Operation.”

%oracle:columns(col1 [, col2...])
Identifies a selection of one or more column names in the target table. The order of column names corresponds to the order of the function parameters. See “Parameters.” Optional.

This annotation enables loading a subset of the table columns. If omitted, the put function attempts to load all columns of the target table.

%oracle-property:property_name (value)
Controls various aspects of connecting to the database and writing data. You can specify multiple %oracle-property annotations. These annotations correspond to the Oracle Loader for Hadoop configuration properties. Every %oracle-property annotation has an equivalent Oracle Loader for Hadoop configuration property. “Oracle Loader for Hadoop Configuration Properties and Corresponding %oracle-property Annotations” explains this relationship in detail.

The %oracle-property annotations are optional. However, the various loading scenarios require you to specify some of them or their equivalent configuration properties. For example, to load data into an Oracle database using JDBC or OCI, you must specify the target table and the connection information.

The following example specifies a target table named VISITS, a user name of db, a password of password, and the URL connection string:

```xml
%oracle-property:targetTable('visits')
%oracle-property:connection.user('db')
%oracle-property:connection.password('password')
```
Parameters

$column1 [as xs:allowed_type_name[?]], [$column2 [as xs:allowed_type_name[?]],...]

Enter a parameter for each column in the same order as the Oracle table columns to load all columns, or use the %oracle:columns annotation to load selected columns.

Because the correlation between parameters and database columns is positional, the name of the parameter (column1 in the parameter syntax) is not required to match the name of the database column.

You can omit the explicit as xs:allowed_type_name type declaration for any parameter. For example, you can declare the parameter corresponding to a NUMBER column simply as $column1. In this case, the parameter is automatically assigned an XQuery type of item()*. At run time, the input value is cast to the allowed XQuery type for the corresponding table column type, as described in Table 6-3. For example, data values that are mapped to a column with a NUMBER data type are automatically cast as xs:decimal. An error is raised if the cast fails.

Alternatively, you can specify the type or its subtype for any parameter. In this case, compile-time type checking is performed. For example, you can declare a parameter corresponding to a NUMBER column as $column as xs:decimal. You can also declare it as any subtype of xs:decimal, such as xs:integer.

You can include the ? optional occurrence indicator for each specified parameter type. This indicator allows the empty sequence to be passed as a parameter value at run time, so that a null is inserted into the database table. Any occurrence indicator other than ? raises a compile-time error.

Table 6-3 describes the appropriate mappings of XQuery data types with the supported Oracle Database data types. In addition to the listed XQuery data types, you can also use the subtypes, such as xs:integer instead of xs:decimal. Oracle data types are more restrictive than XQuery data types, and these restrictions are identified in the table.

<table>

<tbody>
<tr>
<td>RAW</td>
<td>xs:hexBinary</td>
</tr>
<tr>
<td></td>
<td>Limit by the RAW maximum size of 2000 bytes.</td>
</tr>
</tbody>
</table>

#### About Session Time Zones

If an xs:dateTime value with no time zone is loaded into `TIMESTAMP W TIME ZONE` or `TIMESTAMP W LOCAL TIME ZONE`, then the time zone is set to the value of the `sessionTimeZone` parameter, which defaults to the JVM time zone. Using Oracle XQuery for Hadoop, you can set the `sessionTimeZone` property, as described in “Oracle Loader for Hadoop Configuration Properties and Corresponding %oracle-property Annotations.”

#### Notes

With JDBC or OCI output modes, the Oracle Database Adapter loads data directly into the database table. It also creates a directory with the same name as the custom `put` function name, under the query output directory. For example, if your query output directory is `myoutput`, and your custom function is `myPut`, then the `myoutput/myPut` directory is created.

For every custom Oracle Database Adapter `put` function, a separate directory is created. This directory contains output produced by the Oracle Loader for Hadoop job. When you use `datapump` or `text` output modes, the data files are written to this directory. The control and SQL scripts for loading the files are written to the `_olh` subdirectory, such as `myoutput/myPut/_olh`.

For descriptions of the generated files, see “Delimited Text Output Format” and “Oracle Data Pump Output Format.”

#### 6.1.3.2 Examples of Oracle Database Adapter Functions

These examples use the following text files in HDFS. The files contain a log of visits to different web pages. Each line represents a visit to a web page and contains the time, user name, and page visited:

```plaintext
mydata/visits1.log
2013-10-28T06:00:00, john, index.html, 200
2013-10-28T08:30:02, kelly, index.html, 200
2013-10-28T08:32:50, kelly, about.html, 200
2013-10-30T10:00:10, mike, index.html, 401

mydata/visits2.log
2013-10-30T06:00:01, john, index.html, 200
2013-10-30T08:30:02, kelly, index.html, 200
2013-10-30T08:32:50, kelly, about.html, 200
2013-10-30T10:00:10, mike, index.html, 401
```

The examples also use the following file in HDFS, which contains anonymous page visits:

```plaintext
mydata/anonymous-visits.log
2013-11-01T08:00:08, laura, index.html, 200
2013-11-04T06:12:51, kelly, index.html, 200
2013-11-04T06:12:40, kelly, contact.html, 200
```
This SQL command creates the VISITS table in the Oracle database:

```
CREATE TABLE visits (time TIMESTAMP, name VARCHAR2(15), page VARCHAR2(15), code NUMBER)
```

**Example 6-6  Loading All Columns**

The first query loads all information related to the page visit (time of visit, user name, page visited, and status code) to the VISITS table. For anonymous access, the user name is missing, therefore the query specifies () to insert a null into the table. The target table name, user name, password, and connection URL are specified with %oracle-property annotations.

The example uses a clear-text user name and password, which is insecure but acceptable in a development environment. Oracle recommends that you use a wallet instead for security, especially in a production application. You can configure an Oracle wallet using either Oracle Loader for Hadoop properties or their equivalent %oracle-property annotations. The specific properties that you must set are described in “Providing the Connection Details for Online Database Mode.”

```
import module "oxh:text";

declare

%oracle:put
%oracle-property:targetTable(©visits©)
%oracle-property:connection.user(©db©)
%oracle-property:connection.password(©password©)
%oracle-property:connection.url(©jdbc:oracle:thin:@//localhost:1521/orcl.example.com©)

function local:myPut($c1, $c2, $c3, $c4) external;

for $line in text:collection("mydata/*visits*.log")
let $split := fn:tokenize($line, "\s*,\s*")
return
if (count($split) > 3) then
  local:myPut($split[1], $split[2], $split[3], $split[4])
else
  local:myPut($split[1], (), $split[2], $split[3])
```

The VISITS table contains the following data after the query runs:

<table>
<thead>
<tr>
<th>TIME</th>
<th>NAME</th>
<th>PAGE</th>
<th>CODE</th>
</tr>
</thead>
<tbody>
<tr>
<td>30-OCT-13 10.00.01.000000 AM</td>
<td>john</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>30-OCT-13 10.05.20.000000 AM</td>
<td>john</td>
<td>about.html</td>
<td>200</td>
</tr>
<tr>
<td>01-NOV-13 08.00.08.000000 AM</td>
<td>laura</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>04-NOV-13 06.12.51.000000 AM</td>
<td>kelly</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>04-NOV-13 06.12.40.000000 AM</td>
<td>kelly</td>
<td>contact.html</td>
<td>200</td>
</tr>
<tr>
<td>28-OCT-13 06.00.00.000000 AM</td>
<td>john</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>28-OCT-13 08.30.02.000000 AM</td>
<td>kelly</td>
<td>index.html</td>
<td>200</td>
</tr>
<tr>
<td>28-OCT-13 08.32.50.000000 AM</td>
<td>kelly</td>
<td>about.html</td>
<td>200</td>
</tr>
<tr>
<td>30-OCT-13 10.00.10.000000 AM</td>
<td>mike</td>
<td>index.html</td>
<td>401</td>
</tr>
<tr>
<td>30-OCT-11 10.01.01.000000 AM</td>
<td>index.html</td>
<td>401</td>
<td></td>
</tr>
<tr>
<td>04-NOV-11 06.15.40.000000 AM</td>
<td>contact.html</td>
<td>401</td>
<td></td>
</tr>
</tbody>
</table>
**Example 6-7  Loading Selected Columns**

This example uses the %oracle:columns annotation to load only the time and name columns of the table. It also loads only visits by john.

The column names specified in %oracle:columns are positionally correlated to the put function parameters. Data values provided for the $c1 parameter are loaded into the TIME column, and data values provided for the $c2 parameter are loaded into the NAME column.

```oxh:text
import module "oxh:text";

declare %oracle:put
  %oracle:columns('time', 'name')
  %oracle-property:targetTable('visits')
  %oracle-property:connection.user('db')
  %oracle-property:connection.password('password')
  %oracle-property:connection.url('jdbc:oracle:thin:@//localhost:1521/orcl.example.com')
function local:myPut($c1, $c2) external;

for $line in text:collection("mydata/*visits*.log")
  let $split := fn:tokenize($line, "\s*,\s*")
  where $split[2] eq 'john'
  return
    local:myPut($split[1], $split[2])
```

If the VISITS table is empty before the query runs, then it contains the following data afterward:

<table>
<thead>
<tr>
<th>TIME</th>
<th>NAME</th>
<th>PAGE</th>
<th>CODE</th>
</tr>
</thead>
<tbody>
<tr>

### 6.1.3.3 Oracle Loader for Hadoop Configuration Properties and Corresponding %oracle-property Annotations

When you use the Oracle Database adapter of Oracle XQuery for Hadoop, you indirectly use Oracle Loader for Hadoop. Oracle Loader for Hadoop defines configuration properties that control various aspects of connecting to Oracle Database and writing data. Oracle XQuery for Hadoop supports many of these properties, which are listed in the last column of Table 6-4.

You can specify these properties with the generic `-conf` and `-D hadoop` command-line options in Oracle XQuery for Hadoop. Properties specified using this method apply to all Oracle Database adapter put functions in your query. See “Running Queries” and especially “Generic Options” for more information about the hadoop command-line options.

Alternatively, you can specify these properties as Oracle Database adapter put function annotations with the %oracle-property prefix. These annotations are listed in the second column of Table 6-4. Annotations apply only to the particular Oracle Database adapter put function that contains them in its declaration.

For example, you can set the target table to VISITS by adding the following lines to the configuration file, and identifying the configuration file with the `-conf option:
You can also set the target table to VISITS with the `-D` option, using the same Oracle Loader for Hadoop property:

```
-D oracle.hadoop.loader.targetTable=visits
```

Both methods set the target table to VISITS for all Oracle Database adapter put functions in your query.

Alternatively, this annotation sets the target table to VISITS only for the particular put function that has the annotation in the declaration:

```
%oracle-property:connection.url('visits')
```

This flexibility is provided for convenience. For example, if a query has multiple Oracle Database adapter put functions, each writing to a different table in the same database, then the most convenient way to specify the necessary information is like this:

- Use the `oracle.hadoop.loader.connection.url` property in the configuration file to specify the database connection URL. Then identify the configuration file using the `-conf` option. This option sets the same database connection URL for all Oracle Database adapter put functions in your query.
- Set a different table name using the `%oracle-property:targetTable` annotation in each Oracle Database adapter put function declaration.

Table 6-4 identifies the Oracle Loader for Hadoop properties and their equivalent Oracle XQuery for Hadoop annotations by functional category. Oracle XQuery for Hadoop supports only the Oracle Loader for Hadoop properties listed in this table.

### 6.1.4 Oracle NoSQL Database Adapter

This adapter provides functions to read and write values stored in Oracle NoSQL Database.

This adapter is described in the following topics:

- Prerequisites for Using the Oracle NoSQL Database Adapter
- Built-in Functions for Reading from and Writing to Oracle NoSQL Database
- Built-in Functions for Reading from and Writing to Oracle NoSQL Database using Table API
- Custom Functions for Reading Values from Oracle NoSQL Database
- Custom Functions for Retrieving Single Values from Oracle NoSQL Database
- Custom Functions for Reading Values from Oracle NoSQL Database using Table API
- Custom Functions for Reading Single Row from Oracle NoSQL Database using Table API
- Custom Functions for Retrieving Single Values from Oracle NoSQL Database using Large Object API
- Custom Functions for Writing to Oracle NoSQL Database
- Custom Functions for Writing Values to Oracle NoSQL Database using Table API
- Custom Functions for Writing Values to Oracle NoSQL Database using Large Object API
• Examples of Oracle NoSQL Database Adapter Functions
• Oracle NoSQL Database Adapter Configuration Properties

6.1.4.1 Prerequisites for Using the Oracle NoSQL Database Adapter

Before you write queries that use the Oracle NoSQL Database adapter, you must configure Oracle XQuery for Hadoop to use your Oracle NoSQL Database server. You must set the following:

• The KVHOME environment variable to the local directory containing the Oracle NoSQL database lib directory.

• The oracle.kv.hosts and oracle.kv.kvstore configuration properties.

• The OXH_SOLR_MR_HOME environment variable to the local directory containing search-mr-<version>.jar and search-mr-<version>-job.jar, only when Tika parser is invoked. That is, only when kv:collection-tika() or kv:get-tika() functions are invoked or, %kv:collection('tika') or %kv:get('tika') annotations are used with external functions.

You can set the configuration properties using either the -D or -conf options in the hadoop command when you run the query. See “Running Queries.”

This example sets KVHOME and uses the hadoop -D option in a query to set oracle.kv.kvstore:

$ export KVHOME=/local/path/to/kvstore/
$ hadoop jar $OXH_HOME/lib/oxh.jar -D oracle.kv.hosts=example.com:5000 -D oracle.kv.kvstore=kvstore ./myquery.xq -output ./myoutput

This example sets OXH_SOLR_MR_HOME environment variable when the Tika parser is invoked:

$ export OXH_SOLR_MR_HOME=/usr/lib/solr/contrib/mr

Note:
The HADOOP CLASSPATH environment variable or -libjars command line option must not contain NoSQL DB jars.

See “Oracle NoSQL Database Adapter Configuration Properties.”

6.1.4.2 Built-in Functions for Reading from and Writing to Oracle NoSQL Database

To use the built-in functions in your query, you must import the Oracle NoSQL Database module as follows

import module "oxh:kv";

The Oracle NoSQL Database module contains the following functions:

• kv:collection-text
• kv:collection-avroxml
• kv:collection-xml
• kv:collection-binxml
• kv:collection-tika
• kv:put-text
• kv:put-xml
• kv:put-binxml
• kv:get-text
• kv:get-avroxml
• kv:get-xml
• kv:get-binxml
• kv:get-tika
• kv:key-range

6.1.4.2.1 kv:collection-text

Accesses a collection of values in the database. Each value is decoded as UTF-8 and returned as a string.

Signature

declare %kv:collection("text") function
kv:collection-text($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as xs:string* external;

declare %kv:collection("text") function
kv:collection-text($parent-key as xs:string?, $depth as xs:int?) as xs:string* external;

declare %kv:collection("text") function
kv:collection-text($parent-key as xs:string?) as xs:string* external;

Parameters

See “Parameters.” Omitting $subrange is the same as specifying $subrange(). Likewise, omitting $depth is the same as specifying $depth().

Returns

One string for each value

6.1.4.2.2 kv:collection-avroxml

Accesses a collection of values in the database. Each value is read as an Avro record and returned as an XML element. The records are converted to XML as described in “Reading Records.”

Signature

declare %kv:collection("avroxml") function
kv:collection-avroxml($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as element()* external;
declare %kv:collection("avroxml") function
  kv:collection-avroxml($parent-key as xs:string?, $depth as xs:int?) as element()*
  external;

declare %kv:collection("avroxml") function
  kv:collection-avroxml($parent-key as xs:string?) as element()*
  external;

**Parameters**

See “Parameters.” Omitting $subrange is the same as specifying $subrange(). Likewise, omitting $depth is the same as specifying $depth().

**Returns**

One XML element for each Avro record

6.1.4.2.3 kv:collection-xml

Accesses a collection of values in the database. Each value is read as a sequence of bytes and parsed as XML.

**Signature**

declare %kv:collection("xml") function
  kv:collection-xml($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as document-node()* external;

declare %kv:collection("xml") function
  kv:collection-xml($parent-key as xs:string?, $depth as xs:int?) as document-node()* external;

declare %kv:collection("xml") function
  kv:collection-xml($parent-key as xs:string?) as document-node()* external;

**Parameters**

See “Parameters.” Omitting $subrange is the same as specifying $subrange(). Likewise, omitting $depth is the same as specifying $depth().

**Returns**

One XML document for each value.

6.1.4.2.4 kv:collection-binxml

Accesses a collection of values in the database. Each value is read as XDK binary XML and returned as an XML document.

**Signature**

declare %kv:collection("binxml") function
  kv:collection-binxml($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as document-node()* external;

declare %kv:collection("binxml") function
  kv:collection-binxml($parent-key as xs:string?, $depth as xs:int?) as document-node()* external;

declare %kv:collection("binxml") function
  kv:collection-binxml($parent-key as xs:string?) as document-node()* external;
Parameters
See “Parameters.” Omitting $subrange is the same as specifying $subrange(). Likewise, omitting $depth is the same as specifying $depth().

Returns
One XML document for each value.

See Also
Oracle XML Developer’s Kit Programmer’s Guide

6.1.4.2.5 kv:collection-tika
Uses Tika to parse the specified value when invoked and returns as a document node.

Signature
declare %kv:collection("tika") function
   kv:collection-tika($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) $contentType as xs:string?) as document-node() external;

Parameters
See “Parameters.” Omitting $subrange is the same as specifying $subrange(). Likewise, omitting $depth is the same as specifying $depth().

Returns
One document node for each value.

6.1.4.2.6 kv:put-text
Writes a key-value pair. The $value is encoded as UTF-8.

Signature
declare %kv:put("text") function
   kv:put-text($key as xs:string, $value as xs:string) external;

6.1.4.2.7 kv:put-xml
Writes a key/value pair. The $xml is serialized and encoded as UTF-8.

Signature
declare %kv:put("xml") function
   kv:put-xml($key as xs:string, $xml as node()) external;

6.1.4.2.8 kv:put-binxml
Puts a key/value pair. The $xml is encoded as XDK binary XML. See Oracle XML Developer’s Kit Programmer’s Guide.

Signature
declare %kv:putbinxml("binxml") function
   ( $key as xs:string, $xml as node() ) external;
**6.1.4.2.9 kv:get-text**

Obtains the value associated with the key. The value is decoded as UTF-8 and returned as a string.

**Signature**

```xml
declare %kv:get("text") function
  kv:get-text($key as xs:string) as xs:string? external;
```

**6.1.4.2.10 kv:get-avroxml**

Obtains the value associated with the key. The value is read as an Avro record and returned as an XML element. The records are converted to XML as described in "Reading Records .".

**Signature**

```xml
declare %kv:get("avroxml") function
  kv:get-avroxml($key as xs:string) as element()? external;
```

**6.1.4.2.11 kv:get-xml**

Obtains the value associated with the key. The value is read as a sequence of bytes and parsed as XML.

**Signature**

```xml
declare %kv:get("xml") function
  kv:get-xml($key as xs:string) as document-node()? external;
```

**6.1.4.2.12 kv:get-binxml**

Obtains the value associated with the key. The value is read as XDK binary XML and returned as an XML document.

**Signature**

```xml
declare %kv:get("binxml") function
  kv:get-binxml($key as xs:string) as document-node()? external;
```

**See Also**

*Oracle XML Developer’s Kit Programmer’s Guide*

**6.1.4.2.13 kv:get-tika**

Obtains the value associated with the key. The value is parsed as byte array and returned as a document node.

**Signature**

```xml
declare %kv:get("tika") function
  kv:get-tika($key as xs:string, $contentType as xs:string?) as document-node()? external;
```

**See Also**

*Oracle XML Developer’s Kit Programmer’s Guide*
### 6.1.4.2.14 kv:key-range

Defines a prefix range. The prefix defines both the lower and upper inclusive boundaries.

Use this function as the `subrange` argument of a `kv:collection` function.

**Signature**

```xml
ekv:key-range($prefix as xs:string) as xs:string;
```

### 6.1.4.2.15 kv:key-range

Specifies a key range.

Use this function as the `subrange` argument of a `kv:collection` function.

**Signature**

```xml
ekv:key-range($start as xs:string, $start-inclusive as xs:boolean, $end as xs:string, $end-inclusive as xs:boolean) as xs:string;
```

**Parameters**

- `$start`: Defines the lower boundary of the key range.
- `$start-inclusive`: A value of `true` includes `$start` in the range, or `false` omits it.
- `$end`: Defines the upper boundary of the key range. It must be greater than `$start`.
- `$end-inclusive`: A value of `true` includes `$end` in the range, or `false` omits it.

### 6.1.4.3 Built-in Functions for Reading from and Writing to Oracle NoSQL Database using Table API

To use the built-in functions in your query, you must have declared the name space and imported the module as follows:

```xml
declare namespace kv-table = "oxh:kv-table";
import module "oxh:kv-table";
```

The Oracle NoSQL Database through Table API module contains the following functions:

- `kv-table:collection-jsontext`
- `kv-table:get-jsontext`
- `kv-table:put-jsontext`

#### 6.1.4.3.1 kv-table:collection-jsontext

These functions iterate over all or a subset of rows stored in a single table in the NoSQL Database. Each row is returned in a form of a JSON string.

**Signature**

```xml
declare %kv-table:collection-jsontext("jsontext") function
kv-table:collection-jsontext($tableName as xs:string) as xs:string*
```
declare %kv-table:collection("json:context") function
   kv-table:collection-jsontext($tableName as xs:string, $primaryKeyJsonValue as xs:string?) as xs:string*

declare %kv-table:collection("json:context") function
   kv-table:collection-jsontext($tableName as xs:string, $primaryKeyJsonValue as xs:string?, $fieldRangeJsonValue as xs:string?) as xs:string*

**Parameters**

$tableName as xs:string – name of the table in NoSQL Database

$primaryKeyJsonValue as xs:string? – a partial primary key specified as JSON text

$fieldRangeJsonValue as xs:string? – field range for a remaining field of the given primary key specified as JSON text

\{ 
   "name": "fieldname",
   "start": "startVal",
   "startInclusive": true|false,
   "end": "endVal",
   "endInclusive": true|false
\}

**Returns**

JSON value of each row

Use “json:parse-as-xml” function to parse JSON string into an XML document

**6.1.4.3.2 kv-table:get-jsontext**

This function reads a single row stored in a table in NoSQL Database. The row is returned in a form of a JSON string. If the row is not found, then an empty sequence is returned.

**Signature**

declare %kv-table:get("json:context") function
   kv-table:get-jsontext($tableName as xs:string, $primaryKeyJsonValue as xs:string) as xs:string?

**Parameters**

$tableName as xs:string – name of the table in NoSQL Database

$primaryKeyJsonValue as xs:string? – a full primary key specified as JSON text

See Also:

Oracle NoSQL Database Adapter
Oracle XQuery for Hadoop Reference 6-39
Returns
JSON value of the row or an empty sequence, if the row is not found.
Use “json:parse-as-xml” function to parse JSON string into an XML document

6.1.4.3.3 kv-table:put-jsontext
This function writes a row into NoSQL Database using its Table API

Signature
declare %kv-table:put("jsontext") function
  kv-table:put-jsontext($tableName as xs:string, $jsonValue as xs:string);

Parameters
$tableName as xs:string – name of the table in NoSQL Database
$jsonValue as xs:string – row specified as JSON text

6.1.4.4 Built-in Functions for Reading from and Writing to Oracle NoSQL Database
using Large Object API

To use the built-in functions in your query you must have declared the name space
and imported the module as follows:

declare namespace kv-lob = "oxh:kv-lob";
import module "oxh:kv-lob";

The Oracle NoSQL Database through Large Object API module contains the following
functions:

- kv-lob:get-text
- kv-lob:get-xml
- kv-lob:get-binxml
- kv-lob:get-tika
- kv-lob:put-text
- kv-lob:put-xml
- kv-lob:put-binxml

6.1.4.4.1 kv-lob:get-text
Obtains the value associated with the key. The value is decoded as UTF-8 and
returned as a string.
6.1.4.4.2 kv-lob:get-xml
Obtains the value associated with the key. The value is read as a sequence of bytes and parsed as XML.

Signature
declare %kv-lob:get("xml")
function kv-lob:get-xml($key as xs:string) as document-node()? 

6.1.4.4.3 kv-lob:get-binxml
Obtains the value associated with the key. The value is read as XDK binary XML and returned as an XML document. See Oracle XML Developer’s Kit Programmer’s Guide.

Signature
declare %kv-lob:get("binxml")
function kv-lob:get-binxml($key as xs:string) as document-node()? 

6.1.4.4.4 kv-lob:get-tika
Obtains the value associated with the key. The value is parsed as byte array and returned as a document node.

Signature
declare %kv-lob:get("tika")
function kv-lob:get-tika($key as xs:string) as document-node()? 

6.1.4.4.5 kv-lob:put-text
Writes a key-value pair. The $value is encoded as UTF-8.

Signature
declare %kv-lob:put("text")
function kv-lob:put-text($key as xs:string, $value as xs:string)

6.1.4.4.6 kv-lob:put-xml
Writes a key/value pair. The $xml is serialized and encoded as UTF-8.

Signature
declare %kv-lob:put("xml")
function kv-lob:put-xml($key as xs:string, $document as node())
6.1.4.7 kv-lob:put-binxml

Puts a key/value pair. The $xml is encoded as XDK binary XML. See Oracle XML Developer’s Kit Programmer’s Guide.

**Signature**

declare $kv-lob:put("binxml")
function kv-lob:put-binxml($key as xs:string, $document as node())

6.1.4.5 Custom Functions for Reading Values from Oracle NoSQL Database

You can use the following functions to read values from Oracle NoSQL Database. These annotations provide additional functionality that is not available using the built-in functions.

**Signature**

Custom functions for reading collections of NoSQL values must have one of the following signatures:

- declare %kv:collection("text") [additional annotations]
  - function local:myFunctionName($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as xs:string* external;
- declare %kv:collection(["xml"|"binxml"|"tika"]) [additional annotations]
  - function local:myFunctionName($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?) as document-node()* external;
- declare %kv:collection("tika") [additional annotations]
  - function local:myFunctionName($parent-key as xs:string?, $depth as xs:int?, $subrange as xs:string?, $contentType as xs:string?) as document-node()* external;

**Annotations**

%kv:collection("method")
Declares the NoSQL Database collection function. Required.

The method parameter is one of the following values:

- **avroxml**: Each value is read as an Avro record and returned as an XML element. The records are converted to XML as described in “Reading Records.”
- **binxml**: Each value is read as XDK binary XML and returned as an XML document.
- **text**: Each value is decoded using the character set specified by the %output:encoding annotation.
- **tika**: Each value is parsed by Tika, and returned as a document node.
- **xml**: Each value is parsed as XML, and returned as an XML document.

%kv:key("true" | "false")
Controls whether the key of a key-value pair is set as the document-uri of the returned value. Specify true to return the key.
The default setting is true when method is xml, avroxml, or binxml, and false when it is text. Text functions with this annotation set to true must be declared to return text()? instead of xs:string?: Atomic xs:string values are not associated with a document node, but text nodes are. For example:

```
declare %kv:collection("text") %kv:key("true")
    function local:col($parent-key as xs:string?) as text()* external;
```

When the key is returned, you can obtain its string representation by using the kv:key() function. For example:

```
for $value in local:col(...)
let $key := $value/kv:key()
return ...
```

%avro:schema-kv("schema-name")
Specifies the Avro reader schema. This annotation is valid only when method is avroxml. Optional.
The schema-name is a fully qualified record name. The record schema is retrieved from the Oracle NoSQL Database catalog. The record value is mapped to the reader schema. For example, %avro:schema-kv("org.example.PersonRecord").

---

See Also:
For information about Avro schemas, the Oracle NoSQL Database Getting Started Guide at

---

%output:encoding
Specifies the character encoding of text values. UTF-8 is assumed when this annotation is not used. The valid encodings are those supported by the JVM.
This annotation currently only applies to the text method. For XML files, the document's encoding declaration is used if it is available.

---

See Also:
"Supported Encodings" in the Oracle Java SE documentation at
http://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html

---

Parameters

Parameter 1: $parent-key as xs:string?
Specify the parent key whose child KV pairs are returned by the function. The major key path must be a partial path and the minor key path must be empty. An empty sequence results in fetching all keys in the store.
See Also:
For the format of the key, Oracle NoSQL Database Java Reference at
http://docs.oracle.com/cd/NOSQL/html/javadoc/oracle/kv/
Key.html#toString

Parameter 2: $depth as xs:int?
Specifies whether parents, children, descendants, or a combination are returned. The following values are valid:

- `kv:depth-parent-and-descendants()`: Selects the parents and all descendants.
- `kv:depth-children-only()`: Selects only the immediately children, but not the parent.
- `kv:depth-descendants-only()`: Selects all descendants, but not the parent.

This example selects all the descendants, but not the parent:
```
kv:collection-text("/parent/key", kv:depth-descendants-only(), ...)
```

Parameter 3: $subRange as xs:string?
Specifies a subrange to further restrict the range under parentKey to the major path components. The format of the string is:
```
<startType>/<start>/<end>/<endType>
```
The `startType` and `endType` are either I for inclusive or E for exclusive.
The `start` and `end` are the starting and ending key strings.
If the range does not have a lower boundary, then omit the leading `startType`/start specification from the string representation. Similarly, if the range does not have an upper boundary, then omit the trailing `end/endType` specification. A KeyRange requires at least one boundary, thus at least one specification must appear in the string representation.
The `kv:key-range` function provides a convenient way to create a range string.
The value can also be the empty sequence.
The following examples are valid subrange specifications:

<table>
<thead>
<tr>
<th>Example</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>I/alpha/beta/E</td>
<td>From alpha inclusive to beta exclusive</td>
</tr>
<tr>
<td>E//0123/I</td>

6.1.4.6 Custom Functions for Retrieving Single Values from Oracle NoSQL Database

The Oracle NoSQL Database adapter has get functions, which enable you to retrieve a single value from the database. Unlike collection functions, calls to get functions are not distributed across the cluster. When a get function is called, the value is retrieved by a single task.

**Signature**

Custom get functions must have one of the following signatures:

- `declare %kv:get("text") [additional annotations]`  
  function local:myFunctionName($key as xs:string) as xs:string? external;

- `declare %kv:get("avroxml") [additional annotations]`  
  function local:myFunctionName($key as xs:string) as element()? external;

- `declare %kv:get(["xml"|"binxml"|"tika"])) [additional annotations]`  
  function local:myFunctionName($key as xs:string) as document-node()?

- `declare %kv:get(["tika"]) [additional annotations]`  
  function local:myFunctionName($key as xs:string $contentType as xs:string?) as document-node()?

**Annotations**

- `%kv:get("method")`  
  Declares the NoSQL Database get function. Required.

  The `method` parameter is one of the following values:

  - `avroxml`: The value is read as an Avro record and returned as an XML element. The records are converted to XML as described in "Reading Records ."

  - `binxml`: The value is read as XDK binary XML and returned as an XML document.

  - `text`: The value is decoded using the character set specified by the `%output:encoding` annotation.

  - `tika`: Each value is parsed by Tika, and returned as a document node.

  - `xml`: The value is parsed as XML and returned as an XML document.

- `%kv:key("true" | "false")`  
  Controls whether the key of a key-value pair is set as the `document-uri` of the returned value. Specify `true` to return the key.

  The default setting is `true` when `method` is `xml`, `avroxml`, or `binxml`, and `false` when it is `text`. Text functions with this annotation set to `true` must be declared to return `text()`? instead of `xs:string?`. Atomic `xs:string` values are not associated with a document node, but text nodes are.

  When the key is returned, you can obtain its string representation by using the `kv:key()` function.
%avro:schema-ky("schema-name")
Specifies the Avro reader schema. This annotation is valid only when method is avroxml. Optional.

The schema-name is a fully qualified record name. The record schema is retrieved from the Oracle NoSQL Database catalog. The record value is mapped to the reader schema. For example, %avro:schema-ky("org.example.PersonRecord").

See Also:
For information about Avro schemas, the Oracle NoSQL Database Getting Started Guide at

%output:encoding
Specifies the character encoding of text values. UTF-8 is assumed when this annotation is not used. The valid encodings are those supported by the JVM.

This annotation currently only applies to the text method. For XML files, the document encoding declaration is used, if it is available.

See Also:
"Supported Encodings" in the Oracle Java SE documentation at
http://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html

6.1.4.7 Custom Functions for Reading Values from Oracle NoSQL Database using Table API

You can use the following functions to read values from Oracle NoSQL Database using Table API. These annotations provide additional functionality that is not available using the built-in functions.

Signature
Custom functions for reading collections of NoSQL values using Table API must have one of the following signatures:

declare %kv-table:collection("jsontext")
function local:myFunctionName($tableName as xs:string) as xs:string* external;

declare %kv-table:collection("jsontext")
function local:myFunctionName($tableName as xs:string, $primaryKeyJsonValue as xs:string?) as xs:string* external;

declare %kv-table:collection("jsontext")
function local:myFunctionName($tableName as xs:string, $primaryKeyJsonValue as xs:string?, $fieldRangeJsonValue as xs:string?) as xs:string* external;

Annotations
%kv-table:collection("jsontext")
Declares the collection function that uses Table API.
6.1.4.8 Custom Functions for Reading Single Row from Oracle NoSQL Database using Table API

You can use the following functions to read single row from Oracle NoSQL Database using Table API. These annotations provide additional functionality that is not available using the built-in functions.

**Signature**

Custom functions to read single row from Oracle NoSQL Database using Table API must have one of the following signatures:

```xml
declare %kv-table:get("jsontext")
function local:myFunctionName($tableName as xs:string, $primaryKeyJsonValue as xs:string?) as xs:string? external;
```

**Annotations**

```
%kv-table:get("jsontext")
```

Declares the get function that uses Table API.

---

**Note:**

*jsontext* is the only supported and required annotation value.

---

**Parameters**

Same as “Parameters.”

**Returns**

Same as “Returns.”

---

6.1.4.9 Custom Functions for Retrieving Single Values from Oracle NoSQL Database using Large Object API

You can use the following functions to read values from Oracle NoSQL Database using Large Object API. These annotations provide additional functionality that is not available using the built-in functions.

**Signature**

Custom functions for reading single values using Large Object API must have one of the following signatures:

---

**Note:**

*jsontext* is the only supported and required annotation value.

---

**Parameters**

Same as “Parameters.”

**Returns**

Same as “Returns.”
declare %kv-lob:get("text") [additional annotations]
function local:myFunctionName($key as xs:string) as xs:string? external;

declare %kv-lob:get(["xml"|"binxml"|"tika"]) [additional annotations]
function local:myFunctionName($key as xs:string) as document-node()?

declare %kv-lob:get(["tika"]) [additional annotations]
function local:myFunctionName($key as xs:string $contentType as xs:string?) as document-node()?

**Annotations**

%kv-lob:get("method")
Declares the NoSQL Database get function that uses Large Object API. Required. Supported method parameters are `binxml`, `text`, `tika`, and `xml`—same as in %kv:get("method").

---

**Note:**
avroxml method is not supported with Large Object API.

---

%kv-lob:key("true" | "false")
Controls whether the key of a key-value pair is set as the document-uri of the returned value. Specify true to return the key. Same as %kv:key().

%output:encoding
Specifies the character encoding of text values. UTF-8 is assumed when this annotation is not used. The valid encodings are those supported by the JVM. This annotation currently only applies to the text method. For XML files, the document encoding declaration is used, if it is available.

### 6.1.4.10 Custom Functions for Writing to Oracle NoSQL Database

You can use the following annotations to define functions that write to Oracle NoSQL Database.

**Signature**

Custom functions for writing to Oracle NoSQL Database must have one of the following signatures:

declare %kv:put("text") function
    local:myFunctionName($key as xs:string, $value as xs:string) external;

declare %kv:put(["xml"|"binxml"|"avroxml"] function
    local:myFunctionName($key as xs:string, $xml as node()) external;
## Annotations

<table>
<thead>
<tr>
<th>Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>%kv:put(&quot;method&quot;)</td>
<td>Declares the NoSQL Database module put function. Required. The method determines how the value is stored. It must be one of the following values:</td>
</tr>
<tr>
<td></td>
<td>• text: $value is serialized and encoded using the character set specified by the %output:encoding annotation.</td>
</tr>
<tr>
<td></td>
<td>• avroxml: $xml is mapped to an instance of the Avro record specified by the %avro:schema-kv annotation. See “Writing XML as Avro.”</td>
</tr>
<tr>
<td></td>
<td>• binxml: $xml is encoded as XDK binary XML.</td>
</tr>
<tr>
<td></td>
<td>• xml: $xml is serialized and encoded using the character set specified by the %output:encoding annotation. You can specify other XML serialization parameters using %output:*</td>
</tr>
<tr>
<td>%avro:schema-kv(&quot;schema-name&quot;)</td>
<td>Specifies the record schema of the values to be written. The annotation value is a fully qualified record name. The record schema is retrieved from the Oracle NoSQL Database catalog. For example: %avro:schema-kv(&quot;org.example.PersonRecord&quot;)</td>
</tr>
<tr>
<td>%output:*</td>
<td>A standard XQuery serialization parameter for the output method (text or XML) specified in %kv:put. See “Serialization Annotations.”</td>
</tr>
</tbody>
</table>

See Also:
“The Influence of Serialization Parameters” sections for XML and text output methods in XSLT and XQuery Serialization 3.0 at [http://www.w3.org/TR/xslt-xquery-serialization-30/](http://www.w3.org/TR/xslt-xquery-serialization-30/)
6.1.4.11 Custom Functions for Writing Values to Oracle NoSQL Database using Table API

You can use the following annotations to define functions that write to Oracle NoSQL Database using Table API.

**Signature**

Custom functions for writing rows using Table API must have one of the following signatures:

```
declare %kv-table:put("jsontext")
function local:myFunctionName($tableName as xs:string, $jsonValue as xs:string?)
external;
```

**Annotations**

%kv-table:put("jsontext")
Declares the put function that uses Table API.

**Note:**

*jsontext* is the only supported and required annotation value.

**Parameters**

Same as “Parameters.”

6.1.4.12 Custom Functions for Writing Values to Oracle NoSQL Database using Large Object API

You can use the following annotations to define functions that write to Oracle NoSQL Database using Large Object API.

**Signature**

Custom functions for writing values using Large Object API must have one of the following signatures:

```
declare %kv-lob:put("text")
function  local:myFunctionName($key as xs:string, $value as xs:string) external;
```

```
declare %kv-lob:put(['"xml"'|"binxml"])
function local:myFunctionName($key as xs:string, $xml as node()) external;
```

**Annotations**

%kv-lob:put("method")
Declares the NoSQL Database put function. Required. Supported method parameters are binxml, text, and xml – same as in “%kv:put("method")”
Note:

avroxml method is not supported with Large Object API.

%output:*
A standard XQuery serialization parameter for the output method (text or XML) specified in %kv-lob:put. See “Serialization Annotations.”

6.1.4.13 Examples of Oracle NoSQL Database Adapter Functions

Example 6-8  Writing and Reading Text in Oracle NoSQL Database

This example uses the following text file that is in HDFS. The file contains user profile information such as user ID, full name, and age, separated by colons ():.

mydata/users.txt

john:John Doe:45
kelly:Kelly Johnson:32
laura:Laura Smith:
phil:Phil Johnson:27

The first query stores the lines of this text file in Oracle NoSQL Database as text values.

import module "oxh:text";
import module "oxh:kv";

for $line in text:collection("mydata/users.txt")
let $split := fn:tokenize($line, ":")
let $key := ":users/text/" || $split[1]
return
  kv:put-text($key, $line)

The next query reads the values from the database:

import module "oxh:text";
import module "oxh:kv";

for $value in kv:collection-text("/users/text")
let $split := fn:tokenize($value, ":")
where $split[2] eq "Phil Johnson"
return
  text:put($value)

The query creates a text file that contains the following line:

phil:Phil Johnson:27

Example 6-9  Writing and Reading Avro in Oracle NoSQL Database

In this example, the following Avro schema is registered with Oracle NoSQL Database:

```
{
  "type": "record",
  "name": "User",
  "namespace": "com.example",
  "fields": [
    {"name": "id", "type": "string"},
    {"name": "full_name", "type": "string"},
```

Oracle XQuery for Hadoop Reference 6-51
The next query writes the user names to the database as Avro records.

```xml
import module "oxh:text";

declare $kv:put("avroxml") $avro:schema-kv("com.example.User")
  function local:put-user($key as xs:string, $value as node()) external;

for $line in text:collection("mydata/users.txt")
let $split := fn:tokenize($line, ":")
let $id := $split[1]
let $key := "/users/avro/" || $id
return
  local:put-user($key,
    <user>
      <id>{$id}</id>
      <full_name>{$split[2]}</full_name>
      {if ($split[3] castable as xs:int) then
      <age>{$split[3]}</age>
      else
      ()
    }
  </user>
)

This query reads the values from the database:

```xml
import module "oxh:text";
import module "oxh:kv";

for $user in kv:collection-avroxml("/users/avro")
  where $user/age gt 30
return
text:put($user/full_name)
```

The query creates a text files with the following lines:

John Doe
Kelly Johnson

**Example 6-10    Storing XML in NoSQL Database**

The following query uses the XML files shown in Example 6-24 of “Examples of XML File Adapter Functions” as input. It writes each comment element as an Oracle NoSQL Database value:

```xml
import module "oxh:xmlf";
import module "oxh:kv";

for $comment in xmlf:collection("mydata/comments*.xml")/comments/comment
let $key := "/comments/" || $comment/@id
return
  kv:put-xml($key, $comment)
```

The query writes the five comment elements as XML values in Oracle NoSQL Database.
For very large XML files, modify the query as follows to improve performance and disk space consumption:

- Use the following `for` clause, which causes each XML file to be split and processed in parallel by multiple tasks:

  ```xquery
  for $comment in xmlf:collection("mydata/comments*.xml", "comment")
  ```

- In the return clause, use `kv:put-binxml` instead of `kv:put-xml` to store the values as binary XML instead of plain text.

Use the `kv:collection-xml` function to read the values in the database. For example:

```xquery
import module "oxh:text";
import module "oxh:kv";

for $comment in kv:collection-xml("/comments").comment
return
text:put($comment/@id || " " || $comment/@user)
```

The query creates text files that contain the following lines:

```
12345 john
23456 john
54321 mike
56789 kelly
87654 mike
```

**Example 6-11  Storing XML as Avro in Oracle NoSQL Database**

This example converts the XML values to Avro before they are stored.

Add the following Avro schema to Oracle NoSQL Database:

```json
{
    "type": "record",
    "name": "Comment",
    "namespace": "com.example",
    "fields": [
        {"name": "cid", "type": "string"},
        {"name": "user", "type": "string"},
        {"name": "content", "type": "string"},
        {"name": "likes", "type": ["array", "items": "string"]}
    ]
}
```

The following query writes five `comment` elements as Avro values in Oracle NoSQL Database:

```xquery
import module "oxh:xmlf";
import module "oxh:kv";

declare %kv:put("avroxml") %avro:schema-kv("com.example.Comment")
function local:put-comment($key as xs:string, $value as node()) external;

for $comment in xmlf:collection("mydata/comments*.xml", "comment")
let $key := "/comments/" || $comment/@id
let $value :=
<comment>
  <cid>{$comment/@id/data()}</cid>
  <user>{$comment/@user/data()}</user>
</comment>
local:put-comment($key, $value)
```

Oracle XQuery for Hadoop Reference 6-53
Use the `kv:collection-avroxml` function to read the values in the database. For example:

```oxh
import module "oxh:text";
import module "oxh:kv";

for $comment in kv:collection-avroxml("/comments")
return
text:put($comment/cid || " " || $comment/user || " " || count($comment/likes/*))
```

The query creates text files that contain the following lines:

12345 john 0
23456 john 2
54321 mike 1
56789 kelly 2
87654 mike 0

**Example 6-12  Reading and writing data using Oracle NoSQL Database Table API**

This example uses the following text file is in HDFS. The file contains user profile information such as user ID, full name, and age, separated by colons (:

```
mydata/users.txt
john:John Doe:45
kelly:Kelly Johnson:32
laura:Laura Smith:
phil:Phil Johnson:27
```

Let us create a table called users in NoSQL DB as follows:

```sql
CREATE TABLE users (id STRING, name STRING, age INTEGER, PRIMARY KEY (id));
```

The first query stores users age into this table.

```oxh
import module "oxh:text";
import module "oxh:kv-table";

for $line in text:collection("mydata/users.txt")
let $split := tokenize($line, ":")
let $id := $split[1]
let $name := $split[2]
let $age := $split[3]
where string-length($age) gt 0
let $row :=
'{
"id": "" || $id || ",", ||
"name": "" || $name || ",", ||
"age": "" || $age ||
'}

return
kv-table:put-jsontext("users", $row)
```
After running this query the table contains the following records:

<table>
<thead>
<tr>
<th>Id</th>
<th>name</th>
<th>age</th>
</tr>
</thead>
<tbody>
<tr>
<td>john</td>
<td>John Doe</td>
<td>45</td>
</tr>
<tr>
<td>kelly</td>
<td>Kelly Johnson</td>
<td>32</td>
</tr>
<tr>
<td>phil</td>
<td>Phil Johnson</td>
<td>27</td>
</tr>
</tbody>
</table>

The second query reads row from the table and returns ids of users whose name ends with *Johnson*.

```xquery
import module "oxh:text ";
import module "oxh:json";
import module "oxh:kv-table";

for $row in kv-table:collection("users")
let $user := json:parse-as-xml($row)
let $id := $user/json:get(ªid")
let $name := $user/json:get("name")
where ends-with($name, "Johnson")
return text:put($id)
```

The query creates a text file that contains the following lines:

```
kelly
phil
```

**Example 6-13  Reading data using Oracle NoSQL Database Large Object API**

Assuming Oracle NoSQL Database contains the following information:

1. **Table userImages**
   
   CREATE TABLE userImages (imageFileName STRING, imageVersion STRING, imageDescription INTEGER, PRIMARY KEY (imageFileName))

<table>
<thead>
<tr>
<th>imageFileName</th>
<th>imageVersion</th>
<th>imageDescription</th>
</tr>
</thead>
<tbody>
<tr>
<td>IMG_001.JPG</td>
<td>1</td>
<td>Sunrise</td>
</tr>
<tr>
<td>IMG_002.JPG</td>
<td>1</td>
<td>Sunrise</td>
</tr>
</tbody>
</table>

2. **Key/Value data loaded with Large Object API** where:

   - Key is the lob/imageFileName/image.lob
   - Value is a JPEG image data that contains geolocation metadata in EXIF format

The following query extracts that metadata and converts it to CSV format as imageFileName, latitude, and longitude.

```xquery
import module "oxh:kv-table";
import module "oxh:kv-lob";
import module "oxh:tika";
import module "oxh:json";
import module "oxh:text ";
```
for $row in kv-table:collection("userImages")

let $imageFileName := json:parse-as-xml($row)/json:get("imageFileName")
let $imageKey := "lob/" || $imageFileName || "/image.lob"
let $doc := kv-lob:get-tika($imageKey, "image/jpeg")
let $lat := $doc/tika:metadata/tika:property[@name eq "GPS Latitude"]
let $lon := $doc/tika:metadata/tika:property[@name eq "GPS Longitude"]
where exists($lat) and exists($lon)

return text:put($imageFileName || "," || $lat || "," || $lon)

6.1.4.14 Oracle NoSQL Database Adapter Configuration Properties

Oracle XQuery for Hadoop uses the generic options for specifying configuration properties in the Hadoop command. You can use the -conf option to identify configuration files, and the -D option to specify individual properties. See “Running Queries.”

You can set various configuration properties for the Oracle NoSQL Database adapter that control the durability characteristics and timeout periods. You must set oracle.kv.hosts and oracle.kv.kvstore. The following properties configure the Oracle NoSQL Database adapter.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.xquery.kv.config.durability | **Type:** String<br>**Default Value:** NO_SYNC, NO_SYNC, SIMPLE_MAJORITY<br>**Description:** Defines the durability characteristics associated with %kv:put operations. The value consists of three parts, which you specify in order and separate with commas (,): MasterPolicy, ReplicaPolicy, ReplicaAck<br>• MasterPolicy: The synchronization policy used when committing a transaction to the master database. Set this part to one of the following constants:<br>NO_SYNC: Do not write or synchronously flush the log on a transaction commit.<br>SYNC: Write and synchronously flush the log on a transaction commit.<br>WRITE_NO_SYNC: Write but do not synchronously flush the log on a transaction commit.<br>• ReplicaPolicy: The synchronization policy used when committing a transaction to the replica databases. Set this part to NO_SYNC, SYNC, or WRITE_NO_SYNC, as described under MasterPolicy.<br>• ReplicaAck: The acknowledgment policy used to obtain transaction acknowledgments from the replica databases. Set this part to one of the following constants:<br>ALL: All replicas must acknowledge that they have committed the transaction.<br>NONE: No transaction commit acknowledgments are required, and the master does not wait for them.<br>SIMPLE_MAJORITY: A simple majority of replicas (such as 3 of 5) must acknowledge that they have committed the transaction.<br>**See Also:** "Durability Guarantees" in Getting Started with Oracle NoSQL Database at http://docs.oracle.com/cd/NOSQL/html/GettingStartedGuide/durability.html
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.hadoop.xquery.kv.config.requestLimit | **Type:** Comma-separated list of integers  
**Default Value:** 100, 90, 80  
**Description:** Limits the number of simultaneous requests to prevent nodes with long service times from consuming all threads in the KV store client. The value consists of three integers, which you specify in order and separate with commas: maxActiveRequests, requestThresholdPercent, nodeLimitPercent.  
  - *maxActiveRequests:* The maximum number of active requests permitted by the KV client. This number is typically derived from the maximum number of threads that the client has set aside for processing requests.  
  - *requestThresholdPercent:* The percentage of maxActiveRequests at which requests are limited.  
  - *nodeLimitPercent:* The maximum number of active requests that can be associated with a node when the number of active requests exceeds the threshold specified by requestThresholdPercent. |
| oracle.hadoop.xquery.kv.config.requestTimeout | **Type:** Long  
**Default Value:** 5000 ms  
**Description:** Configures the request timeout period in milliseconds. The value must be greater than zero (0). |
| oracle.hadoop.xquery.kv.config.socketOpenTimeout | **Type:** Long  
**Default Value:** 5000 ms  
**Description:** Configures the open timeout used when establishing sockets for client requests, in milliseconds. Shorter timeouts result in more rapid failure detection and recovery. The default open timeout is adequate for most applications. The value must be greater than zero (0). |
| oracle.hadoop.xquery.kv.config.socketReadTimeout | **Type:** Long  
**Default Value:** 30000 ms  
**Description:** Configures the read timeout period associated with the sockets that make client requests, in milliseconds. Shorter timeouts result in more rapid failure detection and recovery. Nonetheless, the timeout period should be sufficient to allow the longest timeout associated with a request. |
| oracle.kv.batchSize | **Type:** Key  
**Default Value:** Not defined  
**Description:** The desired number of keys for the InputFormat to fetch during each network round trip. A value of zero (0) sets the property to a default value. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| oracle.kv.consistency | **Type**: Consistency  
**Default Value**: NONE_REQUIRED  
**Description**: The consistency guarantee for reading child key-value pairs. The following keywords are valid values:  
- **ABSOLUTE**: Requires the master to service the transaction so that consistency is absolute.  
- **NONE_REQUIRED**: Allows replicas to service the transaction, regardless of the state of the replicas relative to the master. |
| oracle.kv.hosts      | **Type**: String  
**Default Value**: Not defined  
**Description**: An array of one or more hostname:port pairs that identify the hosts in the KV store with the source data. Separate multiple pairs with commas. |
| oracle.kv.kvstore    | **Type**: String  
**Default Value**: Not defined  
**Description**: The name of the KV store with the source data. |
| oracle.kv.timeout    | **Type**: Long  
**Default Value**: Not defined  
**Description**: Sets a maximum time interval in milliseconds for retrieving a selection of key-value pairs. A value of zero (0) sets the property to its default value. |

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
<th>See Also:</th>
</tr>
</thead>
</table>
| `oracle.hadoop.xquery.kv.config.LOBSuffix`   | Type: String  
Default Value: .lob  
Description: Configures the default suffix associated with LOB keys.                                                                                                                                      | Oracle NoSQL Database Java API Reference at  
| `oracle.hadoop.xquery.kv.config.LOBTimeout`  | Type: Long  
Default Value: Not defined  
Description: Configures default timeout value associated with chunk access during operations on LOBs.                                                                                       | Oracle NoSQL Database Java API Reference at  
http://docs.oracle.com/cd/NOSQL/html/javadoc/oracle/kv/KVStoreConfig.html#setLOBTimeout(long, java.util.concurrent.TimeUnit) |
### Property Description

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| `oracle.hadoop.xquery.kv.config.readZones` | Type: Comma separated list of strings  
Default Value: Not defined  
Description: Sets the zones in which nodes must be located to be used for read operations.  
| `oracle.hadoop.xquery.kv.config.security` | Type: String  
Default Value: Not defined  
Description: Configures security properties for the client.  

### 6.1.5 Sequence File Adapter

The sequence file adapter provides functions to read and write Hadoop sequence files. A sequence file is a Hadoop-specific file format composed of key-value pairs.

The functions are described in the following topics:

- Built-in Functions for Reading and Writing Sequence Files
- Custom Functions for Reading Sequence Files
Custom Functions for Writing Sequence Files

Examples of Sequence File Adapter Functions

See Also:
The Hadoop wiki for a description of Hadoop sequence files at http://wiki.apache.org/hadoop/SequenceFile

6.1.5.1 Built-in Functions for Reading and Writing Sequence Files

To use the built-in functions in your query, you must import the sequence file module as follows:

```java
import module "oxh:seq";
```

The sequence file module contains the following functions:

- `seq:collection`
- `seq:collection-xml`
- `seq:collection-binxml`
- `seq:collection-tika`
- `seq:put`
- `seq:put/xml`
- `seq:put-binxml`

For examples, see “Examples of Sequence File Adapter Functions.”

6.1.5.1.1 seq:collection

Accesses a collection of sequence files in HDFS and returns the values as strings. The files may be split up and processed in parallel by multiple tasks.

**Signature**

```java
declare %seq:collection("text") function
   seq:collection($uris as xs:string*) as xs:string* external;
```

**Parameters**

- `$uris`: The sequence file URIs. The values in the sequence files must be either `org.apache.hadoop.io.Text` or `org.apache.hadoop.io.BytesWritable`. For BytesWritable values, the bytes are converted to a string using a UTF-8 decoder.

**Returns**

One string for each value in each file.

6.1.5.1.2 seq:collection-xml

Accesses a collection of sequence files in HDFS, parses each value as XML, and returns it. Each file may be split up and processed in parallel by multiple tasks.
**Signature**

declare %seq:collection("xml") function
    seq:collection-xml($uris as xs:string*) as document-node() external;

**Parameters**

$uris: The sequence file URIs. The values in the sequence files must be either org.apache.hadoop.io.Text or org.apache.hadoop.io.BytesWritable. For BytesWritable values, the XML document encoding declaration is used, if it is available.

**Returns**

One XML document for each value in each file. See “Tika Parser Output Format.”

---

**6.1.5.1.3 seq:collection-binxml**

Accesses a collection of sequence files in the HDFS, reads each value as binary XML, and returns it. Each file may be split up and processed in parallel by multiple tasks.

**Signature**

declare %seq:collection("binxml") function
    seq:collection-binxml($uris as xs:string*) as document-node() external;

**Parameters**

$uris: The sequence file URIs. The values in the sequence files must be org.apache.hadoop.io.BytesWritable. The bytes are decoded as binary XML.

**Returns**

One XML document for each value in each file.

---

**Notes**

You can use this function to read files that were created by seq:put-binxml in a previous query. See “seq:put-binxml.”

**See Also**

Oracle XML Developer’s Kit Programmer’s Guide

---

**6.1.5.1.4 seq:collection-tika**

Uses Tika to parse the sequence files in the HDFS. The values in the sequence files must be either org.apache.hadoop.io.Text or org.apache.hadoop.io.BytesWritable. For each value a document node returned produced by Tika.

**Signature**

declare %seq:collection("tika") function
    seq:collection-tika($uris as xs:string*) as document-node() external;

declare %seq:collection("tika") function
    seq:collection-tika($uris as xs:string*, $contentType as xs:string?) as document-node() external;
Parameters

$uris: The sequence file URIs. The values in the sequence files must be either
org.apache.hadoop.io.Text or org.apache.hadoop.io.BytesWritable. Tika library automatically detects character encoding. Alternatively, the encoding can be passed in $contentType parameter as charset attribute.

$contentType: Specifies the media type of the content to parse, and may have the charset attribute.

Returns

One document node for each value in each file.

6.1.5.1.5 seq:put

 Writes either the string value or both the key and string value of a key-value pair to a sequence file in the output directory of the query.

This function writes the keys and values as org.apache.hadoop.io.Text. When the function is called without the $key parameter, it writes the values as org.apache.hadoop.io.Text and sets the key class to org.apache.hadoop.io.NullWritable, because there are no key values.

Signature

declare %seq:put("text") function
   seq:put($key as xs:string, $value as xs:string) external;

declare %seq:put("text") function
   seq:put($value as xs:string) external;

Parameters

$key: The key of a key-value pair
$value: The value of a key-value pair

Returns

empty-sequence()

Notes

The values are spread across one or more sequence files. The number of files created depends on how the query is distributed among tasks. Each file has a name that starts with part, such as part-m-00000. You specify the output directory when the query executes. See “Running Queries.”

6.1.5.1.6 seq:put-xml

 Writes either an XML value or a key and XML value to a sequence file in the output directory of the query.

This function writes the keys and values as org.apache.hadoop.io.Text. When the function is called without the $key parameter, it writes the values as org.apache.hadoop.io.Text and sets the key class to org.apache.hadoop.io.NullWritable, because there are no key values.
Signature

```
declare %seq:put("xml") function
  seq:put-xml($key as xs:string, $xml as node()) external;
```

```
declare %seq:put("xml") function
  seq:put-xml($xml as node()) external;
```

**Parameters**

$\text{key}$: The key of a key-value pair

$\text{value}$: The value of a key-value pair

**Returns**

`empty-sequence()`

**Notes**

The values are spread across one or more sequence files. The number of files created depends on how the query is distributed among tasks. Each file has a name that starts with "part," such as part-m-00000. You specify the output directory when the query executes. See “Running Queries.”

6.1.5.1.7 seq:put-binxml

Encodes an XML value as binary XML and writes the resulting bytes to a sequence file in the output directory of the query. The values are spread across one or more sequence files.

This function writes the keys as `org.apache.hadoop.io.Text` and the values as `org.apache.hadoop.io.BytesWritable`.

When the function is called without the $\text{key}$ parameter, it writes the values as `org.apache.hadoop.io.BytesWritable` and sets the key class to `org.apache.hadoop.io.NullWritable`, because there are no key values.

**Signature**

```
declare %seq:put("binxml") function
  seq:put-binxml($key as xs:string, $xml as node()) external;
```

```
declare %seq:put("binxml") function
  seq:put-binxml($xml as node()) external;
```

**Parameters**

$\text{key}$: The key of a key-value pair

$\text{value}$: The value of a key-value pair

**Returns**

`empty-sequence()`

**Notes**

The number of files created depends on how the query is distributed among tasks. Each file has a name that starts with `part`, such as `part-m-00000`. You specify the output directory when the query executes. See “Running Queries.”
You can use the `seq:collection-binxml` function to read the files created by this function. See “seq:collection-binxml.”

**See Also**

*Oracle XML Developer’s Kit Programmer’s Guide*

### 6.1.5.2 Custom Functions for Reading Sequence Files

You can use the following annotations to define functions that read collections of sequence files. These annotations provide additional functionality that is not available using the built-in functions.

**Signature**

Custom functions for reading sequence files must have one of the following signatures:

```xml
declare %seq:collection("text") [additional annotations]
  function local:myFunctionName($uris as xs:string*) as xs:string* external;
```

```xml
declare %seq:collection(["xml"|"binxml"|"tika"]) [additional annotations]
  function local:myFunctionName($uris as xs:string*) as document-node()* external;
```

```xml
declare %seq:collection(["tika"]) [additional annotations]
  function local:myFunctionName($uris as xs:string*, $contentType as xs:string?) as
document-node()* external;
```

**Annotations**

`%seq:collection("method")`

 Declares the sequence file collection function, which reads sequence files. Required.

The optional *method* parameter can be one of the following values:

- **text:** The values in the sequence files must be either `org.apache.hadoop.io.Text` or `org.apache.hadoop.io.BytesWritable`. Bytes are decoded using the character set specified by the `%output:encoding` annotation. They are returned as `xs:string`. Default.

- **xml:** The values in the sequence files must be either `org.apache.hadoop.io.Text` or `org.apache.hadoop.io.BytesWritable`. The values are parsed as XML and returned by the function.

- **binxml:** The values in the sequence files must be `org.apache.hadoop.io.BytesWritable`. The values are read as XDK binary XML and returned by the function. See *Oracle XML Developer’s Kit Programmer’s Guide*.

- **tika:** The values in the sequence files must be either `org.apache.hadoop.io.Text` or `org.apache.hadoop.io.BytesWritable`. The values are parsed by Tika and returned by the function.

`%output:encoding("charset")`

 Specifies the character encoding of the input values. The valid encodings are those supported by the JVM. UTF-8 is the default encoding.
%seq:key("true" | "false")
Controls whether the key of a key-value pair is set as the document-uri of the returned value. Specify true to return the keys. The default setting is true when method is binxml or xml, and false when it is text.

Text functions with this annotation set to true must return text()* instead of xs:string* because atomic xs:string is not associated with a document.

When the keys are returned, you can obtain their string representations by using seq:key function.

This example returns text instead of string values because %seq:key is set to true.

```
declare %seq:collection("text") %seq:key("true")
function local:col($uris as xs:string*) as text()* external;
```

The next example uses the seq:key function to obtain the string representations of the keys:

```
for $value in local:col(...)
let $key := $value/seq:key()
return
  .
  .
  .
```

%seq:split-max("split-size")
Specifies the maximum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as max($split-min, min($split-max, $block-size)). Optional.

In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

```
%seq:split-max(1024)
%seq:split-max("1024")
%seq:split-max("1K")
```

%seq:split-min("split-size")
Specifies the minimum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as max($split-min, min($split-max, $block-size)). Optional.

In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

```
%seq:split-min(1024)
%seq:split-min("1024")
%seq:split-min("1K")
```
6.1.5.3 Custom Functions for Writing Sequence Files

You can use the following annotations to define functions that write collections of sequence files in HDFS.

**Signature**

Custom functions for writing sequence files must have one of the following signatures. You can omit the $key argument when you are not writing a key value.

\[
\text{declare } \%\text{seq}:\text{put}(\text{"text"}) \ [\text{[additional annotations]}] \\
\text{function local:myFunctionName($key as } \text{xs:string, $value as } \text{xs:string) external;}
\]

\[
\text{declare } \%\text{seq}:\text{put}([\text{"xml"}|\text{"binxml"}]) \ [\text{[additional annotations]}] \\
\text{function local:myFunctionName($key as } \text{xs:string, $xml as node()) external;}
\]

**Annotations**

\%seq:put("method")

Declares the sequence file put function, which writes key-value pairs to a sequence file. Required.

If you use the $key argument in the signature, then the key is written as org.apache.hadoop.io.Text. If you omit the $key argument, then the key class is set to org.apache.hadoop.io.NullWritable.

Set the method parameter to text, xml, or binxml. The method determines the type used to write the value:

- text: String written as org.apache.hadoop.io.Text
- xml: XML written as org.apache.hadoop.io.Text
- binxml: XML encoded as XDK binary XML and written as org.apache.hadoop.io.BytesWritable

\%seq:compress("codec", "compressionType")

Specifies the compression format used on the output. The default is no compression. Optional.

The codec parameter identifies a compression codec. The first registered compression codec that matches the value is used. The value matches a codec if it equals one of the following:

1. The fully qualified class name of the codec
2. The unqualified class name of the codec
3. The prefix of the unqualified class name before Codec (case insensitive)

Set the compressionType parameter to one of these values:

- block: Keys and values are collected in groups and compressed together. Block compression is generally more compact, because the compression algorithm can take advantage of similarities among different values.
- record: Only the values in the sequence file are compressed.

All of these examples use the default codec and block compression:
Specifies the output file name prefix. The default prefix is `part`.

**%output:** `parameter`

A standard XQuery serialization parameter for the output method (text or XML) specified in `%seq:put`. See “Serialization Annotations.”

---

**6.1.5.4 Examples of Sequence File Adapter Functions**

These examples queries three XML files in HDFS with the following contents. Each XML file contains comments made by users on a specific day. Each comment can have zero or more "likes" from other users.

**Example 6-14**

The following query stores the `comment` elements in sequence files.
import module "oxh:seq";
import module "oxh:xmlf";

for $comment in xmlf:collection("mydata/comments*.xml", "comment")
return
  seq:put-xml($comment)

Example 6-15

The next query reads the sequence files generated by the previous query, which are stored in an output directory named myoutput. The query then writes the names of users who made multiple comments to a text file.

import module "oxh:seq";
import module "oxh:text";

for $comment in seq:collection-xml("myoutput/part*")/comment
let $user := $comment/@user
group by $user
let $count := count($comment)
where $count gt 1
return
text:put($user || " " || $count)

The text file created by the previous query contain the following lines:

john 2
mike 2

See “XML File Adapter.”

Example 6-16

The following query extracts comment elements from XML files and stores them in compressed sequence files. Before storing each comment, it deletes the id attribute and uses the value as the key in the sequence files.

import module "oxh:xmlf";

declare
%seq:put("xml")
%seq:compress("default", "block")
%seq:file("comments")
function local:myPut($key as xs:string, $value as node()) external;

for $comment in xmlf:collection("mydata/comments*.xml", "comment")
let $id := $comment/@id
let $newComment :=
copy $c := $comment
modify delete node $c/@id
return $c
return
local:myPut($id, $newComment)

Example 6-17

The next query reads the sequence files that the previous query created in an output directory named myoutput. The query automatically decompresses the sequence files.

import module "oxh:text";
import module "oxh:seq";
for $comment in seq:collection-xml("myoutput/comments*")/comment
let $id := $comment/seq:key()
where $id eq "12345"
return
text:put-xml($comment)

The query creates a text file that contains the following line:

<comment id="12345" user="john" text="It is raining :( ">

6.1.6 Solr Adapter

This adapter provides functions to create full-text indexes and load them into Apache Solr servers. These functions call the Solr org.apache.solr.hadoop.MapReduceIndexerTool at run time to generate a full-text index on HDFS and optionally merge it into Solr servers. You can declare and use multiple custom put functions supplied by this adapter and the built-in put function within a single query. For example, you can load data into different Solr collections or into different Solr clusters.

This adapter is described in the following topics:

- Prerequisites for Using the Solr Adapter
- Built-in Functions for Loading Data into Solr Servers
- Custom Functions for Loading Data into Solr Servers
- Examples of Solr Adapter Functions
- Solr Adapter Configuration Properties

6.1.6.1 Prerequisites for Using the Solr Adapter

The first time that you use the Solr adapter, ensure that Solr is installed and configured on your Hadoop cluster as described in “Installing Oracle XQuery for Hadoop”.

6.1.6.1.1 Configuration Settings

Your Oracle XQuery for Hadoop query must use the following configuration properties or the equivalent annotation:

- oracle.hadoop.xquery.solr.loader.zk-host
- oracle.hadoop.xquery.solr.loader.collection

If the index is loaded into a live set of Solr servers, then this configuration property or the equivalent annotation is also required:

- oracle.hadoop.xquery.solr.loader.go-live

You can set the configuration properties using either the -D or -conf options in the hadoop command when you run the query. See “Running Queries” and “Solr Adapter Configuration Properties”

6.1.6.1.2 Example Query Using the Solr Adapter

This example sets OXH_SOLR_MR_HOME and uses the hadoop -D option in a query to set the configuration properties:
$ export OXH_SOLR_MR_HOME=/usr/lib/solr/contrib/mr
$ hadoop jar $OXH_HOME/lib/oxh.jar -D oracle.hadoop.xquery.solr.loader.zk-host=/solr
-D oracle.hadoop.xquery.solr.loader.collection=collection1 -D oracle.hadoop.xquery.solr.loader.go-live=true ./myquery.xq -output ./myoutput

6.1.6.2 Built-in Functions for Loading Data into Solr Servers

To use the built-in functions in your query, you must import the Solr module as follows:

import module "oxh:solr";

The Solr module contains the following functions:

- **solr:put**
  The `solr` prefix is bound to the `oxh:solr` namespace by default.

### 6.1.6.2.1 solr:put

Writes a single document to the Solr index.
This document XML format is specified by Solr at
https://wiki.apache.org/solr/UpdateXmlMessages

**Signature**

```xml
declare %solr:put function
  solr:put($value as element(doc)) external;
```

**Parameters**

*$value*: A single XML element named `doc`, which contains one or more `field` elements, as shown here:

```xml
<doc>
  <field name="field_name_1">field_value_1</field>
  ...
  ...
  <field name="field_name_N">field_value_N</field>
</doc>
```

**Returns**

A generated index that is written into the `output_dir/solr-put` directory, where `output_dir` is the query output directory.

### 6.1.6.3 Custom Functions for Loading Data into Solr Servers

You can use the following annotations to define functions that generate full-text indexes and load them into Solr.

**Signature**

Custom functions for generating Solr indexes must have the following signature:

```xml
declare %solr:put [additional annotations]
  function local:myFunctionName($value as node()) external;
```
Annotations

%solr:put
Declares the solr put function. Required.

%solr:file(directory_name)
Name of the subdirectory under the query output directory where the index files will be written. Optional, the default value is the function local name.

%solr-property:property_name(value)
Controls various aspects of index generation. You can specify multiple %solr-property annotations.

These annotations correspond to the command-line options of org.apache.solr.hadoop.MapReduceIndexerTool. Each MapReduceIndexerTool? option has an equivalent Oracle XQuery for Hadoop configuration property and a %solr-property annotation. Annotations take precedence over configuration properties. See “Solr Adapter Configuration Properties” for more information about supported configuration properties and the corresponding annotations.

See Also:

Parameters
$value: An element or a document node conforming to the Solr XML syntax. See “solr:put” for details.

6.1.6.4 Examples of Solr Adapter Functions

Example 6-18 Using the Built-in solr:put Function

This example uses the following HDFS text file. The file contains user profile information such as user ID, full name, and age, separated by colons (:).

mydata/users.txt
john:John Doe:45
kelly:Kelly Johnson:32
laura:Laura Smith:
phil:Phil Johnson:27

The first query creates a full-text index searchable by name.

import module "bxh:text";
import module "bxh:solr";
for $line in text:collection("mydata/users.txt")
let $split := fn:tokenize($line, ":")
let $id := $split[1]
let $name := $split[2]
return solr:put(
  <doc>
    <field name="id">{$id}</field>
  </doc>
)
The second query accomplishes the same result, but uses a custom put function. It also defines all configuration parameters by using function annotations. Thus, setting configuration properties is not required when running this query.

```xquery
import module "oxh:text";
declare %solr:put %solr-property:go-live %solr-property:zk-host("/solr") %solr-property:collection("collection1")
function local:my-solr-put($doc as element(doc)) external;
for $line in text:collection("mydata/users.txt")
let $split := fn:tokenize($line, ":")
let $id := $split[1]
let $name := $split[2]
return local:my-solr-put{
<doc>
  <field name="id">{ $id }</field>
  <field name="name">{ $name }</field>
</doc>
}
```

### 6.1.6.5 Solr Adapter Configuration Properties

The Solr adapter configuration properties correspond to the Solr MapReduceIndexerTool options.

MapReduceIndexerTool is a MapReduce batch job driver that creates Solr index shards from input files, and writes the indexes into HDFS. It also supports merging the output shards into live Solr servers, typically a SolrCloud.

You can specify these properties with the generic `-conf` and `-D hadoop` command-line options in Oracle XQuery for Hadoop. Properties specified using this method apply to all Solr adapter put functions in your query. See "Running Queries" and especially “Generic Options” for more information about the `hadoop` command-line options.

Alternatively, you can specify these properties as Solr adapter put function annotations with the `%solr-property` prefix. These annotations are identified in the property descriptions. Annotations apply only to the particular Solr adapter put function that contains them in its declaration.

---

**See Also:**

For discussions about how Solr uses the MapReduceIndexerTool options, see the Cloudera Search User Guide at

<table>
<thead>
<tr>
<th>Property</th>
<th>Overview</th>
</tr>
</thead>
</table>
| `oracle.hadoop.xquery.solr.loader.collection` | **Type**: String  
**Default Value**: Not defined  
**Equivalent Annotation**: `%solr-property:collection`  
**Description**: The SolrCloud collection for merging the index, such as `mycollection`. Use this property with `oracle.hadoop.xquery.solr.loader.go-live` and `oracle.hadoop.xquery.solr.loader.zk-host`. Required as either a property or an annotation. |
| `oracle.hadoop.xquery.solr.loader.fair-scheduler-pool` | **Type**: String  
**Default Value**: Not defined  
**Equivalent Annotation**: `%solr-property:fair-scheduler-pool`  
**Description**: The name of the fair scheduler pool for submitting jobs. The job runs using fair scheduling instead of the default Hadoop scheduling method. Optional. |
| `oracle.hadoop.xquery.solr.loader.go-live` | **Type**: String values `true` or `false`  
**Default Value**: `false`  
**Equivalent Annotation**: `%solr-property:go-live`  
**Description**: Set to `true` to enable the final index to merge into a live Solr cluster. Use this property with `oracle.hadoop.xquery.solr.loader.collection` and `oracle.hadoop.xquery.solr.loader.zk-host`. Optional. |
| `oracle.hadoop.xquery.solr.loader.go-live-threads` | **Type**: Integer  
**Default Value**: `1000`  
**Equivalent Annotation**: `%solr-property:go-live-threads`  
**Description**: The maximum number of live merges that can run in parallel. Optional. |
| `oracle.hadoop.xquery.solr.loader.log4j` | **Type**: String  
**Default Value**:  
**Equivalent Annotation**: `%solr-property:log4j`  
**Description**: The relative or absolute path to the `log4j.properties` configuration file on the local file system. For example, `/path/to/log4j.properties`. Optional. This file is uploaded for each MapReduce task. |
| `oracle.hadoop.xquery.solr.loader.mappers` | **Type**: String  
**Default Value**: `-1`  
**Equivalent Annotation**: `%solr-property:mappers`  
**Description**: The maximum number of mapper tasks that Solr uses. A value of `-1` enables the use of all map slots available on the cluster. |
### Property Overview

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Default Value</th>
<th>Equivalent Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hadoop.xquery.solr.loader.max-segments</td>
<td>String</td>
<td>1</td>
<td><code>%solr-property:max-segments</code></td>
<td>The maximum number of segments in the index generated by each reducer.</td>
</tr>
</tbody>
</table>
| oracle.hadoop.xquery.solr.loader.reducers | String | -1 | `%solr-property:reducers` | The number of reducers to use:  
  - -1: Uses all reduce slots available on the cluster.  
  - -2: Uses one reducer for each Solr output shard. This setting disables the MapReduce M-tree merge algorithm, which typically improves scalability. |
| oracle.hadoop.xquery.solr.loader.zk-host | String | Not defined | `%solr-property:zk-host` | The address of a ZooKeeper ensemble used by the SolrCloud cluster. Specify the address as a list of comma-separated `host:port` pairs, each corresponding to a ZooKeeper server. For example, 127.0.0.1:2181,127.0.0.1:2182,127.0.0.1:2183/solr. Optional.  
  If the address starts with a slash (/), such as `/solr`, then Oracle XQuery for Hadoop automatically prefixes the address with the ZooKeeper connection string.  
  This property enables Solr to determine the number of output shards to create and the Solr URLs in which to merge them. Use this property with `oracle.hadoop.xquery.solr.loader.collection` and `oracle.hadoop.xquery.solr.loader.golive`. Required as either a property or an annotation. |

---

### 6.1.7 Text File Adapter

The text file adapter provides functions to read and write text files stored in HDFS. It is described in the following topics:

- **Built-in Functions for Reading and Writing Text Files**
- **Custom Functions for Reading Text Files**
- **Custom Functions for Writing Text Files**
- **Examples of Text File Adapter Functions**

#### 6.1.7.1 Built-in Functions for Reading and Writing Text Files

To use the built-in functions in your query, you must import the text file module as follows:
import module "oxh:text";

The text file module contains the following functions:

- `text:collection`
- `text:collection-xml`
- `text:put`
- `text:put-xml`
- `text:trace`

For examples, see “Examples of Text File Adapter Functions .”

### 6.1.7.1.1 text:collection

Accesses a collection of text files in HDFS. The files can be compressed using a Hadoop-supported compression codec. They are automatically decompressed when read.

The files might be split up and processed in parallel by multiple tasks.

**Signature**

```
declare %text:collection("text") function
text:collection($uris as xs:string*) as xs:string* external;
```

```
declare %text:collection("text") function
    function text:collection($uris as xs:string*, $delimiter as xs:string?) as
    xs:string* external;
```

**Parameters**

- `$uris`: The text file URIs.
- `$delimiter`: A custom delimiter on which the file is split. The default is the newline character.

**Returns**

One string value for each file segment identified by the delimiter; for the default delimiter, a string value for each line in each file.

### 6.1.7.1.2 text:collection-xml

Accesses a collection of text files in HDFS. The files can be compressed using a Hadoop-supported compression codec. They are automatically decompressed when read.

The files might be split up and processed in parallel by multiple tasks. Each delimited section of each file is parsed as an XML document and returned by the function. Therefore, each segment must fully contain a single XML document, and any delimit characters in the XML must be escaped with XML character references. By default, the delimiter is a new line.

**Signature**

```
declare %text:collection("xml") function
text:collection-xml($uris as xs:string*) as document-node()* external;
```
declare %text:collection("xml") function
text:collection-xml($uris as xs:string*, $delimiter as xs:string?) as document-
node()* external;

Parameters
$uris: The text file URIs.
$delimiter: A custom delimiter on which the file is split. The default is the newline
character.

Returns
One string value for each file segment identified by the delimiter; for the default
delimiter, a string value for each line in each file

6.1.7.1.3 text:put
Writes a line to a text file in the output directory of the query. The lines are spread
across one or more files.

Signature
declare %text:put("text") function
text:put($value as xs:string) external;

Parameters
$value: The text to write

Returns
empty-sequence()

Notes
The number of files created depends on how the query is distributed among tasks. Each file has a name that starts with part, such as part-m-00000. You specify the
output directory when the query executes. See “Running Queries.”

6.1.7.1.4 text:put-xml
Writes XML to a line in a text file. The lines are spread across one or more files in the
output directory of the query.
Newline characters in the serialized XML are replaced with character references to
ensure that the XML does not span multiple lines. For example, &#xA; replaces the
linefeed character (\n).

Signature
declare %text:put("xml") function
text:put-xml($value as node()) external;

Parameters
$value: The XML to write
Returns
empty-sequence()

Notes
The number of files created depends on how the query is distributed among tasks. Each file has a name that starts with `part`, such as `part-m-00000`. You specify the output directory when the query executes. See “Running Queries.”

6.1.7.1.5 text:trace

Writes a line to a text file named `trace-*` in the output directory of the query. The lines are spread across one or more files.

This function provides you with a quick way to write to an alternate output. For example, you might create a trace file to identify invalid rows within a query, while loading the data into an Oracle database table.

Signature

```xquery
declare %text:put("text") %text:file("trace") function
text:trace($value as xs:string) external;
```

Parameters

$\text{value}$: The text to write

Returns

empty-sequence()

6.1.7.2 Custom Functions for Reading Text Files

You can use the following annotations to define functions that read collections of text files in HDFS. These annotations provide additional functionality that is not available using the built-in functions.

The input files can be compressed with a Hadoop-supported compression codec. They are automatically decompressed when read.

Signature

Custom functions for reading text files must have one of the following signatures:

```xquery
declare %text:collection("text") [additional annotations]
  function local:myFunctionName($uris as xs:string*, $delimiter as xs:string?) as xs:string* external;
```

```xquery
declare %text:collection("text") [additional annotations]
  function local:myFunctionName($uris as xs:string*) as xs:string* external;
```

```xquery
declare %text:collection("xml") [additional annotations]
  function local:myFunctionName($uris as xs:string*, $delimiter as xs:string?) as document-node() as document-node() external;
```

```xquery
declare %text:collection("xml") [additional annotations]
  function local:myFunctionName($uris as xs:string*) as document-node() external;
```

Annotations
%text:collection("method")
Declares the text collection function. Required.
The optional method parameter can be one of the following values:

- **text**: Each line in the text file is returned as `xs:string`. Default.
- **xml**: Each line in the text file is parsed as XML and returned as `document-node`. Each XML document must be fully contained on a single line. Newline characters inside the document must be represented by a numeric character reference.

%text:split("delimiter")
Specifies a custom delimiter for splitting the input files. The default delimiter is the newline character.
Do not combine this annotation with the $delimiter parameter. To specify a custom delimiter, use either this annotation or the $delimiter parameter.

%text:split-max("split-size")
Specifies the maximum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as `max($split-min, min($split-max, $block-size))`. Optional.
In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

%text:split-max(1024)
%text:split-max("1024")
%text:split-max("1K")

%text:split-min("split-size")
Specifies the minimum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as `max($split-min, min($split-max, $block-size))`. Optional.
In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

%text:split-min(1024)
%text:split-min("1024")
%text:split-min("1K")

**Parameters**

$uris as xs:string*
Lists the HDFS file URLs. The files can be uncompressed or compressed with a Hadoop-supported codec. Required.

$delimiter as xs:string?
A custom delimiter on which the input text files are split. The default delimiter is a new line. Do not combine this parameter with the %text:split annotation.

**Returns**

`xs:string*` for the text method

`document-node(*)*` for the xml method
6.1.7.3 Custom Functions for Writing Text Files

You can use the following annotations to define functions that write text files in HDFS.

**Signature**

Custom functions for writing text files must have one of the following signatures:

```
declare %text:put("text") [additional annotations] function
   text:myFunctionName($value as xs:string) external;
```

```
declare %text:put("xml") [additional annotations] function
   text:myFunctionName($value as node()) external;
```

**Annotations**

`%text:put("method")`

Declares the `text:put` function. Required.

The optional `method` parameter can be one of the following values:

- `text`: Writes data to a text file. Default.
- `xml`: Writes data to an XML file. The XML is serialized and newline characters are replaced with character references. This process ensures that the resulting XML document is one text line with no line breaks.

`%text:compress("codec")`

Specifies the compression format used on the output. The default is no compression. Optional.

The `codec` parameter identifies a compression codec. The first registered compression codec that matches the value is used. The value matches a codec if it equals one of the following:

1. The fully qualified class name of the codec
2. The unqualified class name of the codec
3. The prefix of the unqualified class name before "Codec" (case insensitive)

All of these examples use the default codec and block compression:

```
%text:compress("org.apache.hadoop.io.compress.DefaultCodec", "block")
%text:compress("DefaultCodec", "block")
%text:compress("default", "block")
```

`%text:file("name")`

Specifies the output file name prefix. The default prefix is `part`.

`%output:parameter`

A standard XQuery serialization parameter for the output method (text or XML) specified in `%text:put`. See “Serialization Annotations.”

UTF-8 is currently the only supported character encoding.
6.1.7.4 Examples of Text File Adapter Functions

Example 6-19 Using Built-in Functions to Query Text Files

This example uses following text files in HDFS. The files contain a log of visits to different web pages. Each line represents a visit to a web page and contains the time, user name, and page visited.

mydata/visits1.log

2013-10-28T06:00:00, john, index.html, 200
2013-10-28T08:30:02, kelly, index.html, 200
2013-10-28T08:32:50, kelly, about.html, 200
2013-10-30T10:00:10, mike, index.html, 401

mydata/visits2.log

2013-10-30T10:00:01, john, index.html, 200
2013-10-30T10:05:20, john, about.html, 200
2013-11-01T08:00:08, laura, index.html, 200
2013-11-04T06:12:51, kelly, index.html, 200
2013-11-04T06:12:40, kelly, contact.html, 200

The following query filters out the pages visited by john and writes only the date and page visited to a new text file:

import module "oxh:text";

for $line in text:collection("mydata/visits*.log")
  let $split := fn:tokenize($line, ",\s*,\s*"
  where $split[2] eq "john"
  return
    text:put($split[1] || ": " || $split[3])

This query creates a text file that contains the following lines:

2013-10-28T06:00:00 index.html
2013-10-30T10:00:01 index.html
2013-10-30T10:05:20 about.html

The next query computes the number of page visits per day:

import module "oxh:text";

for $line in text:collection("mydata/visits*.log")
  let $split := fn:tokenize($line, ",\s*,\s*"
  let $time := xs:dateTime($split[1])
  let $day := xs:date($time)
  group by $day
  return
    text:put($day || " => " || count($line))

The query creates text files that contain the following lines:

2013-10-28 => 3
2013-10-30 => 3
2013-11-01 => 1
2013-11-04 => 2
Example 6-20  Querying Simple Delimited Formats

This example uses the `fn:tokenize` function to parse the lines of a text file. This technique works well for simple delimited formats.

The following query declares custom put and collection functions. It computes the number of hits and the number of unique users for each page in the logs.

```xquery
import module "oxh:text";

declare
  %text:collection("text")
  %text:split-max("32m")
function local:col($uris as xs:string*) as xs:string* external;

declare
  %text:put("xml")
  %text:compress("gzip")
  %text:file("pages")
function local:out($arg as node()) external;

for $line in local:col("mydata/visits*.log")
let $split := fn:tokenize($line, "\s*,\s*")
let $user := $split[2]
let $page := $split[3]
group by $page
return
  local:out(
    <page>
      <name>{$page}</name>
      <hits>{count($line)}</hits>
      <users>{fn:count(fn:distinct-values($user))}</users>
    </page>
  )
```

The output directory of the previous query is named `myoutput`. The following lines are written to `myoutput/pages-r-*\.gz`.

```xml
<page><name>about.html</name><hits>2</hits><users>2</users></page>
<page><name>contact.html</name><hits>1</hits><users>1</users></page>
<page><name>index.html</name><hits>6</hits><users>4</users></page>
```

The files are compressed with the `gzip` codec. The following query reads the output files, and writes the page name and total hits as plain text. The collection function automatically decodes the compressed files.

```xquery
import module "oxh:text";

for $page in text:collection-xml("myoutput/page*.gz")/page
return
text:put($page/name || "," || $page/hits)
```

This query creates text files that contain the following lines:

```
about.html,2
contact.html,1
index.html,6
```
The fn:tokenize function might not be adequate for complex formats that contain variety of data types and delimiters. This example uses the fn:analyze-string function to process a log file in the Apache Common Log format.

A text file named mydata/access.log in HDFS contains the following lines:

<table>
<thead>
<tr>
<th>Time</th>
<th>IP Address</th>
<th>Request URL</th>
<th>Status</th>
<th>Size</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.0 - - [30/Sep/2013:16:39:38 +0000]</td>
<td>192.0.2.0 - - [30/Sep/2013:16:40:54 +0000]</td>
<td>GET /inddex.html HTTP/1.1</td>
<td>404</td>
<td>284</td>
</tr>
<tr>
<td>192.0.2.4 - - [01/Oct/2013:12:10:54 +0000]</td>
<td>192.0.2.4 - - [01/Oct/2013:12:12:12 +0000]</td>
<td>GET /index.html HTTP/1.1</td>
<td>200</td>
<td>12390</td>
</tr>
<tr>
<td>192.0.2.1 - - [01/Oct/2013:08:39:38 +0000]</td>
<td>192.0.2.1 - - [01/Oct/2013:08:40:54 +0000]</td>
<td>GET /index.html HTTP/1.1</td>
<td>200</td>
<td>12390</td>
</tr>
</tbody>
</table>

The following query computes the requests made after September 2013 when the server returned a status code 404 (Not Found) error. It uses a regular expression and fn:analyze-string to match the components of the log entries. The time format cannot be cast directly to xs:dateTime, as shown in Example 6-20. Instead, the ora-fn:dateTime-from-string-with-format function converts the string to an instance of xs:dateTime.

```xml
import module "oxh:text";

declare variable $REGEX :=
  '\((\S+) (\S+) (\S+) \[(\[^\]\]+)\] "(\[^\"]\)+" (\S+) (\S+)\';

for $line in text:collection("mydata/access.log")
let $match := fn:analyze-string($line, $REGEX)/fn:match
let $time :=
  ora-fn:dateTime-from-string-with-format{
    "dd/MM/yyyy:HH:mm:ss Z",
    $match/fn:group[4]
  };
let $status := $match/fn:group[6]
where
  $status eq "404" and
  $time ge xs:dateTime("2013-10-01T00:00:00")
let $host := $match/fn:group[1]
let $request := $match/fn:group[5]
return
  text:put($host || "," || $request)
```

The query creates text files that contain the following lines:

192.0.2.1,GET /indexx.html HTTP/1.1
192.0.2.1,GET /aobut.html HTTP/1.1
6.1.8 Tika File Adapter

This adapter provides functions to parse files stored in HDFS in various formats using Apache Tika library. It is described in the following topics:

- Built-in Library Functions for Parsing Files with Tika
- Custom Functions for Parsing Files with Tika
- Tika Parser Output Format
- Tika Adapter Configuration Properties
- Examples of Tika File Adapter Functions

6.1.8.1 Built-in Library Functions for Parsing Files with Tika

To use the built-in functions in your query, you must import the Tika file module as follows:

```xml
import module "oxh:tika";
```

The Tika file module contains the following functions:

For examples, see “Examples of Tika File Adapter Functions.”

6.1.8.1.1 tika:collection

Parses files stored in HDFS in various formats and extracts the content or metadata from them.

**Signature**

```xml
declare %tika:collection function
tika:collection($uris as xs:string*) as document-node() external;
```

```xml
declare %tika:collection function
tika:collection($uris as xs:string*, $contentType as xs:string?) as document-node() external;
```

**Parameters**

- `$uris`: The HDFS file URIs.
$contentType: Specifies the media type of the content to parse, and may have the charset attribute. When the parameter is specified, then it defines both type and encoding. When not specified, then Tika will attempt to auto-detect values from the file extension. Oracle recommends you to specify the parameter.

Returns
Returns a document node for each value. See “Tika Parser Output Format”.

6.1.8.1.2 tika:parse
Parses the data given to it as an argument. For example, it can parse an HTML fragment within an XML or JSON document.

Signature
declare function
tika:parse($data as xs:string?, $contentType as xs:string?) as document-node()* external;

Parameters
$data: The value to be parsed.
contentType: Specifies the media type of the content to parse, and may have the charset attribute. When the parameter is specified, then it defines both type and encoding. When not specified, then Tika will attempt to auto-detect values from the file extension. Oracle recommends you to specify the parameter.

Returns
Returns a document node for each value. See “Tika Parser Output Format”.

6.1.8.2 Custom Functions for Parsing Files with Tika
You can use the following annotations to define functions to parse files in HDFS with Tika. These annotations provide additional functionality that is not available using the built-in functions.

Signature
Custom functions for reading HDFS files must have one of the following signatures:
declare %tika:collection [additional annotations]
    function local:myFunctionName($uris as xs:string*, $contentType as xs:string?) as document-node()* external;
declare %tika:collection [additional annotations]
    function local:myFunctionName($uris as xs:string*) as document-node()* external;

Annotations
%tika:collection("method")
Identifies an external function to be implemented by Tika file adapter. Required.
The optional method parameter can be one of the following values:
• tika: Each line in the tika file is returned as document-node(). Default.
%output:media-type
Declares the file content type. It is a MIME type and must not have the \texttt{charset} attribute as per XQuery specifications. Optional.

%output:encoding
Declares the file character set. Optional.

\textbf{Note:}
%output:media-type and %output:encoding annotations specify the content type or encoding when the $contentType parameter is not explicitly provided in the signature.

\textbf{Parameters}

$\texttt{uris}$ as \texttt{xs:string}\textsuperscript{*}
Lists the HDFS file URIs. Required.

$\texttt{contentType}$ as \texttt{xs:string}?
The file content type. It may have the \texttt{charset} attribute.

\textbf{Returns}
document-node() * with two root elements. See “Tika Parser Output Format”.

\textbf{6.1.8.3 Tika Parser Output Format}

The result of Tika parsing is a document node with two root elements:

\begin{itemize}
  \item Root element #1 is an XHTML content produced by Tika.
  \item Root element #2 is the document metadata extracted by Tika.
\end{itemize}

The format of the root elements look like these:

\textbf{Root element #1}

\begin{verbatim}
<html xmlns="http://www.w3.org/1999/xhtml">
  ...textual content of Tika HTML...
</html>
\end{verbatim}

\textbf{Root element #2}

\begin{verbatim}
<tika:metadata xmlns:tika="oxh:tika">
  <tika:property name="Name_1">VALUE_1</tika:property>
  <tika:property name="NAME_2">VALUE_2</tika:property>
</tika:metadata>
\end{verbatim}

\textbf{6.1.8.4 Tika Adapter Configuration Properties}

The following Hadoop properties control the behavior of Tika adapter:

\begin{verbatim}
oracle.hadoop.xquery.tika.html.asis
Type: Boolean
Default Value: false.
\end{verbatim}
**Description:** When this is set to TRUE, then all the HTML elements are omitted during parsing. When this is set to FALSE, then only the safe elements are omitted during parsing.

**oracle.hadoop.xquery.tika.locale**

**Type:** Comma-separated list of strings

**Default Value:** Not Defined.

**Description:** Defines the locale to be used by some Tika parsers such as Microsoft Office document parser. Only three strings are allowed: language, country, and variant. The strings country and variant are optional. When locale is not defined, then the system locale is used. When the strings are defined it must correspond to the java.util.Locale specification format mentioned in [http://docs.oracle.com/javase/7/docs/api/java/util/Locale.html](http://docs.oracle.com/javase/7/docs/api/java/util/Locale.html) and the locale can be constructed as follows:

- If only language is specified, then the locale is constructed from the language.
- If the language and country are specified, then the locale is constructed from both language and country.
- If language, country, and variant are specified, then the locale is constructed from language, country, and variant.

### 6.1.8.5 Examples of Tika File Adapter Functions

#### Example 6-22 Using Built-in Functions to Index PDF documents with Cloudera Search

This example query uses Tika to parse PDF files into HTML form and then add the HTML documents into Solr’s full-text index.

```
*bibadata*.pdf
```

The following query indexes the HDFS files:

```xml
import module "oxh:tika";
import module "oxh:solr";

for $doc in tika:collection("*bigdata*.pdf")
let $docid := data($doc::*:meta[@name eq "resourceName"]/@content)[1]
let $body := $doc::*:body[1]
return
  solr:put(  
    <doc>
      <field name="id">{ $docid }</field>
      <field name="text">{ string($body) }</field>
      <field name="content">{ serialize($doc/*:html) }</field>
    </doc>
  )
```

The HTML representation of the documents is added to Solr index and they become searchable. Each document Id in the index is the file name.
Example 6-23 Using Built-in Functions to Index HTML documents with Cloudera Search

This example query uses sequence files and Tika to parse, where key is an URL and value is a html.

```xml
import module "oxh:tika";
import module "oxh:seq";
import module "oxh:org.apache.solr";
for $doc in seq:collection-tika("/path/to/seq/files/*")
  let $docid := document-uri($doc)
  let $body := $doc/*:body[1]
  return
      solr:put(
          <doc>
            <field name="id">{$docid}</field>
            <field name="text">{string($body)}</field>
            <field name="content">{serialize($doc/*:html)}</field>
          </doc>
      )
```

The HTML representation of the documents is added to Solr index and they become searchable. Each document Id in the index is the file name.

6.1.9 XML File Adapter

The XML file adapter provides access to XML files stored in HDFS. The adapter optionally splits individual XML files so that a single file can be processed in parallel by multiple tasks.

This adapter is described in the following topics:

- Built-in Functions for Reading XML Files
- Custom Functions for Reading XML Files
- Examples of XML File Adapter Functions

6.1.9.1 Built-in Functions for Reading XML Files

To use the built-in functions in your query, you must import the XML file module as follows:

```xml
import module "oxh:xmlf";
```

The XML file module contains the following functions:

- `xmlf:collection` (Single Task)
- `xmlf:collection-multipart` (Single Task)
- `xmlf:collection` (Multiple Tasks)

See “Examples of XML File Adapter Functions.”

6.1.9.1.1 `xmlf:collection` (Single Task)

Accesses a collection of XML documents in HDFS. Multiple files can be processed concurrently, but each individual file is parsed by a single task.
This function automatically decompresses files compressed with a Hadoop-supported codec.

**Note:**

HDFS does not perform well when data is stored in many small files. For large data sets with many small XML documents, use Hadoop sequence files and the **Sequence File Adapter**.

---

**Signature**

```
declare %xmlf:collection function
   xmlf:collection($uris as xs:string*) as document-node()* external;
```

**Parameters**

$uris: The XML file URIs

**Returns**

One XML document for each file

**6.1.9.1.2 xmlf:collection-multipart (Single Task)**

Accesses a collection of XML documents in HDFS. Multiple files can be processed concurrently, but each individual file is parsed by a single task. This function is the same as `xmlf:collection` except that each file may contain multiple well-formed XML documents concatenated together.

This function automatically decompresses files compressed with a Hadoop-supported codec. For example, a file containing multiple XML documents could be compressed using GZIP and then accessed directly by this function.

**Signature**

```
declare %xmlf:collection("multipart")
   function    xmlf:collection($uris as xs:string*) as document-node()* external;
```

**Parameters**

$uris

The XML file URIs.

**Returns**

One or more XML documents for each file.

**6.1.9.1.3 xmlf:collection (Multiple Tasks)**

Accesses a collection of XML documents in HDFS. The files might be split and processed by multiple tasks simultaneously, which enables very large XML files to be processed efficiently. The function returns only elements that match a specified name.

This function does not automatically decompress files. It only supports XML files that meet certain requirements. See “Restrictions on Splitting XML Files.”
Signature

```
declare %xmlf:collection function
    xmlf:collection($uris as xs:string*, $names as xs:anyAtomicType+) as element()*
external;
```

Parameters

$uris
The XML file URIs

$names
The names of the elements to be returned by the function. The names can be either strings or QNames. For QNames, the XML parser uses the namespace binding implied by the QName prefix and namespace.

Returns
Each element that matches one of the names specified by the $names argument

6.1.9.2 Custom Functions for Reading XML Files

You can use the following annotations to define functions that read collections of XML files in HDFS. These annotations provide additional functionality that is not available using the built-in functions.

Signature

Custom functions for reading XML files must have one of the following signatures:

```
declare %xmlf:collection(["xml"|"multipart"] [additional annotations]
    function local:myFunctionName($uris as xs:string*) as node()*
external;
```

```
declare %xmlf:collection("xml") [additional annotations]
    function local:myFunctionName($uris as xs:string*, $names as xs:anyAtomicType+)
    as element()*
external;
```

Annotations

%xmlf:collection
Declares the collection function. Required.
The method parameter is one of the following values:

- xml: Each value is parsed as XML
- multipart: Each value (or, file) may contain a concatenation of multiple well-formed XML documents. This method cannot be used with parallel XML parsing. (See xmlf:split and the two-argument function signature.)

%xmlf:split("element-name1",...,"element-nameN")
Specifies the element names used for parallel XML parsing. You can use this annotation instead of the $names argument.

When this annotation is specified, only the single-argument version of the function is allowed. This restriction enables the element names to be specified statically, so they do not need to be specified when the function is called.
%output:encoding("charset")
Identifies the text encoding of the input documents.

When this encoding is used with the %xmlf:split annotation or the $names argument, only ISO-8859-1, US-ASCII, and UTF-8 are valid encodings. Otherwise, the valid encodings are those supported by the JVM. UTF-8 is assumed when this annotation is omitted.

See Also:
"Supported Encodings" in the Oracle Java SE documentation at
http://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html

%xmlf:split-namespace("prefix", "namespace")
This annotation provides extra namespace declarations to the parser. You can specify it multiple times to declare one or more namespaces.

Use this annotation to declare the namespaces of ancestor elements. When XML is processed in parallel, only elements that match the specified names are processed by an XML parser. If a matching element depends on the namespace declaration of one of its ancestor elements, then the declaration is not visible to the parser and an error may occur.

These namespace declarations can also be used in element names when specifying the split names. For example:

```
declare
  %xmlf:collection
  %xmlf:split("eg:foo")
  %xmlf:split-namespace("eg", "http://example.org")
  function local:myFunction($uris as xs:string*) as document-node() external;
```

%xmlf:split-entity("entity-name", "entity-value")
Provides entity definitions to the XML parser. When XML is processed in parallel, only elements that match the specified split names are processed by an XML parser. The DTD of an input document that is split and processed in parallel is not processed.

In this example, the XML parser expands &foo; entity references as "Hello World":

```
%xmlf:split-entity("foo", "Hello World")
```

%xmlf:split-max("split-size")
Specifies the maximum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as \( \max(\$split-min, \min(\$split-max, \$block-size)) \). Optional.

In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

```
%xmlf:split-max(1024)
%xmlf:split-max("1024")
%xmlf:split-max("1K")
```
%xmlf:split-min("split-size")
Specifies the minimum split size as either an integer or a string value. The split size controls how the input file is divided into tasks. Hadoop calculates the split size as max($split-min, min($split-max, $block-size)). Optional.

In a string value, you can append K, k, M, m, G, or g to the value to indicate kilobytes, megabytes, or gigabytes instead of bytes (the default unit). These qualifiers are not case sensitive. The following examples are equivalent:

%xmlf:split-min(1024)
%xmlf:split-min("1024")
%xmlf:split-min("1K")

Notes
Restrictions on Splitting XML Files

Individual XML documents can be processed in parallel when the element names are specified using either the $names argument or the $xmlf:split annotation.

The input documents must meet the following constraints to be processed in parallel:

- XML cannot contain a comment, CDATA section, or processing instruction that contains text that matches one of the specified element names (that is, a < character followed by a name that expands to a QName). Otherwise, such content might be parsed incorrectly as an element.

- An element in the file that matches a specified element name cannot contain a descendant element that also matches a specified name. Otherwise, multiple processors might pick up the matching descendant and cause the function to produce incorrect results.

- An element that matches one of the specified element names (and all of its descendants) must not depend on the namespace declarations of any of its ancestors. Because the ancestors of a matching element are not parsed, the namespace declarations in these elements are not processed.

You can work around this limitation by manually specifying the namespace declarations with the %xmlf:split-namespace annotation.

Oracle recommends that the specified element names do not match elements in the file that are bigger than the split size. If they do, then the adapter functions correctly but not efficiently.

Processing XML in parallel is difficult, because parsing cannot begin in the middle of an XML file. XML constructs like CDATA sections, comments, and namespace declarations impose this limitation. A parser starting in the middle of an XML document cannot assume that, for example, the string <foo> is a begin element tag, without searching backward to the beginning of the document to ensure that it is not in a CDATA section or a comment. However, large XML documents typically contain sequences of similarly structured elements and thus are amenable to parallel processing. If you specify the element names, then each task works by scanning a portion of the document for elements that match one of the specified names. Only elements that match a specified name are given to a true XML parser. Thus, the parallel processor does not perform a true parse of the entire document.
6.1.9.3 Examples of XML File Adapter Functions

Example 6-24 Using Built-in Functions to Query XML Files

This example queries three XML files in HDFS with the following contents. Each XML file contains comments made by users on a specific day. Each comment can have zero or more "likes" from other users.

mydata/comments1.xml

```xml
<comments date="2013-12-30">
  <comment id="12345" user="john" text="It is raining :( ">
  </comment>
  <comment id="56789" user="kelly" text="I won the lottery!">
    <like user="john"/>
    <like user="mike"/>
  </comment>
</comments>
```

mydata/comments2.xml

```xml
<comments date="2013-12-31">
  <comment id="54321" user="mike" text="Happy New Year!">
    <like user="laura"/>
  </comment>
</comments>
```

mydata/comments3.xml

```xml
<comments date="2014-01-01">
  <comment id="87654" user="mike" text="I don't feel so good."/>
  <comment id="23456" user="john" text="What a beautiful day!">
    <like user="kelly"/>
    <like user="phil"/>
  </comment>
</comments>
```

This query writes the number of comments made each year to a text file. No element names are passed to xmlf:collection, and so it returns three documents, one for each file. Each file is processed serially by a single task.

```xml
import module "oxh:xmlf";
import module "oxh:text";

for $comments in xmlf:collection("mydata/comments*.xml")/comments
let $date := xs:date($comments/@date)
let $year := fn:year-from-date($date)
group by $year := fn:year-from-date($date)
return
text:put($year || ", " || fn:count($comments/comment))
```

The query creates text files that contain the following lines:

```
2013, 3
2014, 2
```

The next query writes the number of comments and the average number of likes for each user. Each input file is split, so that it can be processed in parallel by multiple tasks. The xmlf:collection function returns five elements, one for each comment.

```xml
import module "oxh:xmlf";
import module "oxh:text";
```
This query creates text files that contain the following lines:

john, 2, 1
kelly, 1, 2
mike, 2, 0.5

**Example 6-25 Writing a Custom Function to Query XML Files**

The following example declares a custom function to access XML files:

```xml
import module "oxh:xmlf";

declare %xmlf:collection
%xmlf:split("comment")
%xmlf:split-max("32M")
function local:comments($uris as xs:string*) as element()* external;

for $c in local:comments("mydata/comment*.xml")
where $c/@user eq "mike"
return text:put($c/@id)
```

The query creates a text file that contains the following lines:

54321
87654

**Example 6-26 Accessing Compressed, Multipart XML Files**

Assume that files comments1.xml, comments2.xml, and comments3.xml from example 5-24 are concatenated together and compressed using GZIP to create a single file named comments.xml.gz. For example:

```bash
cat comments1.xml comments2.xml comments3.xml | gzip > comments.xml.gz
```

The following query accesses this multipart, compressed XML file:

```xml
import module "oxh:xmlf";

for $comment in xmlf:collection-multipart("comments.xml.gz")[comments/comment]
return text:put($comment/@id || "," || $comment/@user)
```

The query creates a text file that contains the following lines:

12345, john
56789, kelly
54321, mike
87654, mike
23456, john
6.1.10 Utility Module

The utility module contains ora-fn functions for handling strings and dates. These functions are defined in XDK XQuery, whereas the oxh functions are specific to Oracle XQuery for Hadoop.

The utility functions are described in the following topics:

- Oracle XQuery Functions for Duration, Date, and Time
- Oracle XQuery Functions for Strings

6.1.10.1 Oracle XQuery Functions for Duration, Date, and Time

You can manipulate durations, dates, and times in XQuery using Oracle XQuery functions.

The Oracle XQuery functions are in namespace http://xmlns.oracle.com/xdk/xquery/function. Namespace prefix ora-fn is predeclared, and the module is automatically imported.

- ora-fn:date-from-string-with-format
- ora-fn:date-to-string-with-format
- ora-fn:dateTime-from-string-with-format
- ora-fn:dateTime-to-string-with-format
- ora-fn:time-from-string-with-format
- ora-fn:time-to-string-with-format

6.1.10.1.1 ora-fn:date-from-string-with-format

Returns a new date value from a string according to the specified pattern.

**Signature**

```xml
ora-fn:date-from-string-with-format($format as xs:string?, $dateString as xs:string?, $locale as xs:string*) as xs:date?
```

```xml
ora-fn:date-from-string-with-format($format as xs:string?, $dateString as xs:string?) as xs:date?
```
Parameters

$format: The pattern; see “Format Argument”
$dateString: An input string that represents a date
$locale: A one- to three-field value that represents the locale; see “Locale Argument”

Example

This example returns the specified date in the current time zone:

\texttt{ora-fn:date-from-string-with-format("yyyy-MM-dd G", "2013-06-22 AD")}

6.1.10.1.2 ora-fn:date-to-string-with-format

Returns a date string with the specified pattern.

Signature

\texttt{ora-fn:date-to-string-with-format($format as xs:string?, $date as xs:date?, $locale as xs:string?) as xs:string?}

Parameters

$format: The pattern; see Format Argument
$date: The date
$locale: A one- to three-field value that represents the locale; see Locale Argument

Example

This example returns the string 2013-07-15:

\texttt{ora-fn:date-to-string-with-format("yyyy-mm-dd", xs:date("2013-07-15"))}

6.1.10.1.3 ora-fn:dateTime-from-string-with-format

Returns a new date-time value from an input string according to the specified pattern.

Signature

\texttt{ora-fn:dateTime-from-string-with-format($format as xs:string?, $dateTimeString as xs:string?, $locale as xs:string?) as xs:dateTime?}

Parameters

$format: The pattern; see Format Argument
$dateTimeString: An input string that represents a date-time
$locale: A one- to three-field value that represents the locale; see Locale Argument
$dateTimeString: The date and time
$locale: A one- to three-field value that represents the locale; see “Locale Argument”

Examples
This example returns the specified date and 11:04:00AM in the current time zone:
ora-fn:dateTime-from-string-with-format("yyyy-MM-dd 'at' hh:mm",
"2013-06-22 at 11:04")

The next example returns the specified date and 12:00:00AM in the current time zone:
ora-fn:dateTime-from-string-with-format("yyyy-MM-dd G",
"2013-06-22 AD")

6.1.10.1.4 ora-fn:dateTime-to-string-with-format
Returns a date and time string with the specified pattern.

Signature
ora-fn:dateTime-to-string-with-format($format as xs:string?,
$dateTime as xs:dateTime?,
$locale as xs:string?)
as xs:string?

Parameters
$format: The pattern; see “Format Argument”
$dateTime: The date and time
$locale: A one- to three-field value that represents the locale; see “Locale Argument”

Examples
This example returns the string 07 JAN 2013 10:09 PM AD:
ora-fn:dateTime-to-string-with-format("dd MMM yyyy hh:mm a G",
xs:dateTime("2013-01-07T22:09:44"))

The next example returns the string "01-07-2013":
ora-fn:dateTime-to-string-with-format("MM-dd-yyyy",
xs:dateTime("2013-01-07T22:09:44"))

6.1.10.1.5 ora-fn:time-from-string-with-format
Returns a new time value from an input string according to the specified pattern.

Signature
ora-fn:time-from-string-with-format($format as xs:string?,
$timeString as xs:string?,
$locale as xs:string?)
ora-fn:time-from-string-with-format($format as xs:string?,
   $TimeString as xs:string?)
as xs:time?

Parameters
$format: The pattern; see “Format Argument”
$TimeString: The time
$locale: A one- to three-field value that represents the locale; see Locale Argument

Example
This example returns 9:45:22 PM in the current time zone:
orafn:time-from-string-with-format("HH.mm.ss", "21.45.22")
The next example returns 8:07:22 PM in the current time zone:
fn-bea:time-from-string-with-format("hh:mm:ss a", "8:07:22 PM")

6.1.10.1.6 ora-fn:time-to-string-with-format
Returns a time string with the specified pattern.

Signature
ora-fn:time-to-string-with-format($format as xs:string?,
   $time as xs:time?,
   $locale as xs:string?)
as xs:string?
ora-fn:time-to-string-with-format($format as xs:string?, $time as xs:time?) as
xs:string?

Parameters
$format: The pattern; see “Format Argument”
$time: The time
$locale: A one- to three-field value that represents the locale; see “Locale Argument”

Examples
This example returns the string "10:09 PM":
orafn:time-to-string-with-format("hh:mm a", xs:time("22:09:44"))
The next example returns the string "22:09 PM":
orafn:time-to-string-with-format("HH:mm a", xs:time("22:09:44"))

6.1.10.1.7 Format Argument
The $format argument identifies the various fields that compose a date or time value.
See Also:

The SimpleDateFormat class in the Java Standard Edition 7 Reference at
http://docs.oracle.com/javase/7/docs/api/java/text/
SimpleDateFormat.html

6.1.10.1.8 Locale Argument

The $locale represents a specific geographic, political, or cultural region.

It is defined by up to three fields:

1. **Language code**: The ISO 639 alpha-2 or alpha-3 language code, or the registered language subtags of up to eight letters. For example, en for English and ja for Japanese.

2. **Country code**: The ISO 3166 alpha-2 country code or the UN M.49 numeric-3 area code. For example, US for the United States and 029 for the Caribbean.

3. **Variant**: Indicates a variation of the locale, such as a particular dialect. Order multiple values in order of importance and separate them with an underscore (_). These values are case sensitive.

See Also:

- The locale class in Java Standard Edition 7 Reference at
  http://docs.oracle.com/javase/7/docs/api/java/util/
  Locale.html

- All language, country, and variant codes in the Internet Assigned Numbers Authority (IANA) Language Subtag Registry at
  http://www.iana.org/assignments/language-subtag-registry/language-subtag-registry

6.1.10.2 Oracle XQuery Functions for Strings

You can manipulate strings in XQuery using Oracle XQuery functions.

The Oracle XQuery functions are in namespace http://xmlns.oracle.com/xdk/
xquery/function. Namespace prefix ora-fn is predeclared, and the module is automatically imported.

- ora-fn:pad-left
- ora-fn:pad-right
- ora-fn:trim
- ora-fn:trim-left
- ora-fn:trim-right
6.1.10.2.1 ora-fn:pad-left

Add padding characters to the left of a string to create a fixed-length string. If the input string exceeds the specified size, then it is truncated to return a substring of the specified length. The default padding character is a space (ASCII 32).

Signature

ora-fn:pad-left($str as xs:string?, $size as xs:integer?, $pad as xs:string?) as xs:string?

ora-fn:pad-left($str as xs:string?, $size as xs:integer?) as xs:string?

Parameters

$str: The input string
$size: The desired fixed length, which is obtained by adding padding characters to $str
$pad: The padding character

If either argument is an empty sequence, then the function returns an empty sequence.

Examples

This example prefixes "01" to the input string up to the maximum of six characters. The returned string is "010abc". The function returns one complete and one partial pad character.

ora-fn:pad-left("abc", 6, "01")

The example returns only "ab" because the input string exceeds the specified fixed length:

ora-fn:pad-left("abcd", 2, "01")

This example prefixes spaces to the string up to the specified maximum of six characters. The returned string has a prefix of two spaces: " abcd":

ora-fn:pad-left("abcd", 6)

The next example returns only "ab" because the input string exceeds the specified fixed length:

ora-fn:pad-left("abcd", 2)

6.1.10.2.2 ora-fn:pad-right

Add padding characters to the right of a string to create a fixed-length string. If the input string exceeds the specified size, then it is truncated to return a substring of the specified length. The default padding character is a space (ASCII 32).

Signature

ora-fn:pad-right($str as xs:string?, $size as xs:integer?, $pad as xs:string?) as xs:string?

ora-fn:pad-right($str as xs:string?, $size as xs:integer?) as xs:string?
ora-fn:pad-right($str as xs:string?,
    $size as xs:integer?)
    as xs:string?

Parameters

$str$: The input string

$size$: The desired fixed length, which is obtained by adding padding characters to $str$

$pad$: The padding character

If either argument is an empty sequence, then the function returns an empty sequence.

Examples

This example appends "01" to the input string up to the maximum of six characters. The returned string is "abc010". The function returns one complete and one partial pad character.

ora-fn:pad-right("abc", 6, "01")

This example returns only "ab" because the input string exceeds the specified fixed length:

ora-fn:pad-right("abcd", 2, "01")

This example appends spaces to the string up to the specified maximum of six characters. The returned string has a suffix of two spaces: "abcd ":

ora-fn:pad-right("abcd", 6)

The next example returns only "ab" because the input string exceeds the specified fixed length:

ora-fn:pad-right("abcd", 2)

6.1.10.2.3 ora-fn:trim

Removes any leading or trailing white space from a string.

Signature

ora-fn:trim($input as xs:string?) as xs:string?

Parameters

$input$: The string to trim. If $input$ is an empty sequence, then the function returns an empty sequence. Other data types trigger an error.

Example

This example returns the string "abc":

ora-fn:trim(" abc ")
6.1.10.2.4 ora-fn:trim-left
Removes any leading white space.

**Signature**
ora-fn:trim-left($input as xs:string?) as xs:string?

**Parameters**
$input$: The string to trim. If $input$ is an empty sequence, then the function returns an empty sequence. Other data types trigger an error.

**Example**
This example removes the leading spaces and returns the string "abc   ":
ora-fn:trim-left("   abc   ")

6.1.10.2.5 ora-fn:trim-right
Removes any trailing white space.

**Signature**
ora-fn:trim-right($input as xs:string?) as xs:string?

**Parameters**
$input$: The string to trim. If $input$ is an empty sequence, then the function returns an empty sequence. Other data types trigger an error.

**Example**
This example removes the trailing spaces and returns the string "   abc":
ora-fn:trim-left("   abc   ")

6.1.11 Hadoop Module

These functions are in the http://xmlns.oracle.com/hadoop/xquery namespace. The oxh prefix is predeclared and the module is automatically imported. The Hadoop module is described in the following topic:

- Hadoop Functions

6.1.11.1 Built-in Functions for Using Hadoop

The following functions are built in to Oracle XQuery for Hadoop:

- oxh:find
- oxh:increment-counter
- oxh:println
- oxh:println-xml
- oxh:property
6.11.11.1 oxh:find
Returns a sequence of file paths that match a pattern.

Signature

\[
\text{oxh:find}(\$\text{pattern as xs:string?}) \text{ as xs:string*}
\]

Parameters

$\text{pattern}$: The file pattern to search for

See Also:
For the file pattern, the \texttt{globStatus} method in the Apache Hadoop API at
\url{http://hadoop.apache.org/docs/current/api/org/apache/hadoop/fs/FileSystem.html#globStatus(org.apache.hadoop.fs.Path)}

6.11.11.2 oxh:increment-counter
Increments a user-defined MapReduce job counter. The default increment is one (1).

Signature

\[
\text{oxh:increment-counter}(\$\text{groupName as xs:string, } \$\text{counterName as xs:string, } \$\text{value as xs:integer})
\]

Parameters

$\text{groupName}$: The group of counters that this counter belongs to.
$\text{counterName}$: The name of a user-defined counter
$\text{value}$: The amount to increment the counter

6.11.11.3 oxh:println
Prints a line of text to \texttt{stdout} of the Oracle XQuery for Hadoop client process. Use this function when developing queries.

Signature

\[
\text{declare %updating function oxh:println}(\$\text{arg as xs:anyAtomicType?})
\]

Parameters

$\text{arg}$: A value to add to the output. A \texttt{cast} operation first converts it to \texttt{string}. An empty sequence is handled the same way as an empty string.

Example

This example prints the values of \texttt{data.txt} to \texttt{stdout}:
for $i in text:collection("data.txt")
return oxh:println($i)

6.1.11.1.4 oxh:println-xml
Prints a line of text or XML to stdout of the Oracle XQuery for Hadoop client process. Use this function when developing queries and printing nodes of an XML document.

Signature
declare %updating function oxh:println-xml($arg as item())

Parameters
$arg: A value to add to the output. The input item is converted into a text as defined by XSLT 2.0 and XQuery 1.0 Serialization specifications. An empty sequence is handled the same way as an empty string.

6.1.11.1.5 oxh:property
Returns the value of a Hadoop configuration property.

Signature
oxh:property($name as xs:string?) as xs:string

Parameters
$name: The configuration property

6.1.12 Serialization Annotations
Several adapters have serialization annotations (%output:*). The following lists identify the serialization parameters that Oracle XQuery for Hadoop supports.

Serialization parameters supported for the text output method:

- encoding: Any encoding supported by the JVM
- normalization-form: none, NFC, NFD, NFKC, NFKD

Serialization parameters supported for the xml output method, using any values permitted by the XQuery specification:

- cdata-section-elements
- doctype-public
- doctype-system
- encoding
- indent
- normalization-form
- omit-xml-declaration
- standalone
See Also:

"The Influence of Serialization Parameters" sections for XML and text output methods in XSLT and XQuery Serialization, at locations like the following:

#XML_DOCTYPE

http://www.w3.org/TR/xslt-xquery-serialization/#XMLCDATA-SECTION-ELEMENTS
This chapter explains how to use the XML extensions for Apache Hive provided with Oracle XQuery for Hadoop. The chapter contains the following sections:

- What are the XML Extensions for Hive?
- Using the Hive Extensions
- About the Hive Functions
- Creating XML Tables
- Oracle XML Functions for Hive Reference

7.1 What are the XML Extensions for Hive?

The XML Extensions for Hive provide XML processing support that enables you to do the following:

- Query large XML files in HDFS as Hive tables
- Query XML strings in Hive tables
- Query XML file resources in the Hadoop distributed cache
- Efficiently extract atomic values from XML without using expensive DOM parsing
- Retrieve, generate, and transform complex XML elements
- Generate multiple table rows from a single XML value
- Manage missing and dirty data in XML

The XML extensions also support these W3C modern standards:

- XQuery 3.0
- XQuery Update Facility 1.0 (transform expressions)
- XPath 3.0
- XML Schema 1.0
- XML Namespaces

The XML extensions have two components:

- XML InputFormat and SerDe for creating XML tables

See “Creating XML Tables.”
• XML function library
  
  See “About the Hive Functions.”

### 7.2 Using the Hive Extensions

To enable the Oracle XQuery for Hadoop extensions, use the `--auxpath` and `-i` arguments when starting Hive:

```
$ hive --auxpath 
$OXH_HOME/hive/lib/oxh-hive.jar,\ 
$OXH_HOME/hive/lib/oxh-mapreduce.jar,\ 
$OXH_HOME/hive/lib/oxquery.jar,\ 
$OXH_HOME/hive/lib/xqjapi.jar,\ 
$OXH_HOME/hive/lib/apache-xmlbeans.jar,\ 
$OXH_HOME/hive/lib/woodstox-core-asl-4.2.0.jar,\ 
$OXH_HOME/hive/lib/stax2-api-3.1.1.jar \ 
-i $OXH_HOME/hive/init.sql
```

**Note:**

On the Oracle BigDataLite VM, `HIVE_AUX_JARS_PATH` contains the Hive extensions by default and hence specifying `--auxpath` is unnecessary.

The first time you use the extensions, verify that they are accessible. The following procedure creates a table named `SRC`, loads one row into it, and calls the `xml_query` function.

**To verify that the extensions are accessible:**

1. Log in to a server in the Hadoop cluster where you plan to work.

2. Create a text file named `src.txt` that contains one line:
   
   `$ echo "XXX" > src.txt`

3. Start the Hive command-line interface (CLI):
   
   `$ hive --auxpath 
   $OXH_HOME/hive/lib/oxh-hive.jar,\ 
   $OXH_HOME/hive/lib/oxh-mapreduce.jar,\ 
   $OXH_HOME/hive/lib/oxquery.jar,\ 
   $OXH_HOME/hive/lib/xqjapi.jar,\ 
   $OXH_HOME/hive/lib/apache-xmlbeans.jar,\ 
   $OXH_HOME/hive/lib/woodstox-core-asl-4.2.0.jar,\ 
   $OXH_HOME/hive/lib/stax2-api-3.1.1.jar \ 
   -i $OXH_HOME/hive/init.sql
   `

   The `init.sql` file contains the `CREATE TEMPORARY FUNCTION` statements that declare the XML functions.

4. Create a simple table:
   
   `hive> CREATE TABLE src(dummy STRING);`

   The `SRC` table is needed only to fulfill a `SELECT` syntax requirement. It is like the `DUAL` table in Oracle Database, which is referenced in `SELECT` statements to test SQL functions.
5. Load data from src.txt into the table:

   hive> LOAD DATA LOCAL INPATH 'src.txt' OVERWRITE INTO TABLE src;

6. Query the table using Hive SELECT statements:

   hive> SELECT * FROM src;
   OK
   xxx

7. Call an Oracle XQuery for Hadoop function for Hive. This example calls the xml_query function to parse an XML string:

   hive> SELECT xml_query("x/y", "<x><y>123</y><z>456</z></x>") FROM src;

   [
   ["123"]
   
If the extensions are accessible, then the query returns ["123"], as shown in the example.

7.3 About the Hive Functions

The Oracle XQuery for Hadoop extensions enable you to query XML strings in Hive tables and XML file resources in the Hadoop distributed cache. These are the functions:

- **xml_query**: Returns the result of a query as an array of STRING values.
- **xml_query_as_primitive**: Returns the result of a query as a Hive primitive value. Each Hive primitive data type has a separate function named for it.
- **xml_exists**: Tests if the result of a query is empty
- **xml_table**: Maps an XML value to zero or more table rows, and enables nested repeating elements in XML to be mapped to Hive table rows.

See “Oracle XML Functions for Hive Reference.”

7.4 Creating XML Tables

This section describes how you can use the Hive CREATE TABLE statement to create tables over large XML documents.

Hive queries over XML tables scale well, because Oracle XQuery for Hadoop splits up the XML so that the MapReduce framework can process it in parallel.

To support scalable processing and operate in the MapReduce framework, the table adapter scans for elements to use to create table rows. It parses only the elements that it identifies as being part of the table; the rest of the XML is ignored. Thus, the XML table adapter does not perform a true parse of the entire XML document, which imposes limitations on the input XML. Because of these limitations, you can create tables only over XML documents that meet the constraints listed in “XQuery Transformation Requirements.” Otherwise, you might get errors or incorrect results.

7.4.1 Hive CREATE TABLE Syntax for XML Tables

The following is the basic syntax of the Hive CREATE TABLE statement for creating a Hive table over XML files:
CREATE TABLE table_name (columns)
ROW FORMAT
  _SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS
  INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
  OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(configuration)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>columns</td>
<td>All column types in an XML table must be one of the Hive primitive types given in “Data Type Conversions.”</td>
</tr>
<tr>
<td>configuration</td>
<td>Any of the properties described in “CREATE TABLE Configuration Properties.” Separate multiple properties with commas.</td>
</tr>
</tbody>
</table>

Note:
Inserting data into XML tables is not supported.

7.4.2 CREATE TABLE Configuration Properties

Use these configuration properties in the configuration parameter of the CREATE TABLE command.

oxh-default-namespace
Sets the default namespace for expressions in the table definition and for XML parsing. The value is a URI.
This example defines the default namespace:
"oxh-default-namespace" = "http://example.com/foo"

oxh-charset
Specifies the character encoding of the XML files. The supported encodings are UTF-8 (default), ISO-8859-1, and US-ASCII.
All XML files for the table must share the same character encoding. Any encoding declarations in the XML files are ignored.
This example defines the character set:
"oxh-charset" = "ISO-8859-1"

oxh-column.name
Specifies how an element selected by the oxh-elements property is mapped to columns in a row. In this property name, replace name with the name of a column in the table. The value can be any XQuery expression. The initial context item of the expression (the "." variable) is bound to the selected element.
Check the log files even when a query executes successfully. If a column expression returns no value or raises a dynamic error, the column value is NULL. The first time an
error occurs, it is logged and query processing continues. Subsequent errors raised by the same column expression are not logged.

Any column of the table that does not have a corresponding oxh-column property behaves as if the following property is specified:

"oxh-column.name" = "(./name | ./@name)[1]"

Thus, the default behavior is to select the first child element or attribute that matches the table column name. See “Syntax Example.”

oxh-elements
Identifies the names of elements in the XML that map to rows in the table, in a comma-delimited list. This property must be specified one time. Required.

This example maps each element named foo in the XML to a single row in the Hive table:

"oxh-elements" = "foo"

The next example maps each element named either foo or bar in the XML to a row in the Hive table:

"oxh-elements" = "foo, bar"

oxh-entity.name
Defines a set of entity reference definitions.

In the following example, entity references in the XML are expanded from &foo; to "foo value" and from &bar; to "bar value".

"oxh-entity.foo" = "foo value"
"oxh-entity.bar" = "bar value"

oxh-namespace.prefix
Defines a namespace binding.

This example binds the prefix myns to the namespace http://example.org:

"oxh-namespace.myns" = "http://example.org"

You can use this property multiple times to define additional namespaces. The namespace definitions are used when parsing the XML. The oxh-element and oxh-column property values can also reference them.

In the following example, only foo elements in the http://example.org namespace are mapped to table rows:

"oxh-namespace.myns" = "http://example.org",
"oxh-elements" = "myns:foo",
"oxh-column.bar" = "./myns:bar"

### 7.4.3 CREATE TABLE Examples

This section includes the following examples:

- Syntax Example
- Simple Examples
- OpenStreetMap Examples
7.4.3.1 Syntax Example

This example shows how to map XML elements to column names.

**Example 7-1 Basic Column Mappings**

In the following table definition, the `oxh-elements` property specifies that each element named `foo` in the XML is mapped to a single row in the table. The `oxh-column` properties specify that a Hive table column named `BAR` gets the value of the child element named `bar` converted to STRING, and the column named `ZIP` gets the value of the child element named `zip` converted to INT.

```sql
CREATE TABLE example (bar STRING, zip INT)
ROW FORMAT SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(
    "oxh-elements" = "foo",
    "oxh-column.bar" = "./bar",
    "oxh-column.zip" = "./zip"
)
```

**Example 7-2 Conditional Column Mappings**

In this modified definition of the `ZIP` column, the column receives a value of -1 if the `foo` element does not have a child `zip` element, or if the `zip` element contains a nonnumeric value:

```sql
"oxh-column.zip" = "
    if (.~/zip castable as xs:int) then
        xs:int(.~/zip)
    else
        -1
    "
```

**Example 7-3 Default Column Mappings**

The following two table definitions are equivalent. Table Definition 2 relies on the default mappings for the `BAR` and `ZIP` columns.

**Table Definition 1**

```sql
CREATE TABLE example (bar STRING, zip INT)
ROW FORMAT SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(
    "oxh-elements" = "foo",
    "oxh-column.bar" = "(.bar | .@bar)[1]",
    "oxh-column.zip" = "(.zip | .@zip)[1]"
)
```

**Table Definition 2**

```sql
CREATE TABLE example (bar STRING, zip INT)
ROW FORMAT SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS
```
7.4.3.2 Simple Examples

These examples show how to create Hive tables over a small XML document that contains comments posted by users of a fictitious website. Each comment element in the document has one or more like elements that indicate that the user liked the comment.

```xml
<comments>
  <comment id="12345" user="john" text="It is raining :(">
    <like user="john"/>
  </comment>
  <comment id="56789" user="kelly" text="I won the lottery!">
    <like user="john"/>
    <like user="mike"/>
  </comment>
  <comment id="54321" user="mike" text="Happy New Year!">
    <like user="laura"/>
  </comment>
</comments>
```

In the CREATE TABLE examples, the comments.xml input file is in the current working directory of the local file system.

**Example 7-4 Creating a Table**

The following Hive CREATE TABLE command creates a table named COMMENTS with a row for each comment containing the user names, text, and number of likes:

```
hive>
CREATE TABLE comments (usr STRING, content STRING, likeCt INT)
ROW FORMAT
  SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS
  INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
  OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(
  "oxh-elements" = "comment",
  "oxh-column.usr" = "./@user",
  "oxh-column.content" = "./@text",
  "oxh-column.likeCt" = "fn:count(./like)"
);
```

The Hive LOAD DATA command loads comments.xml into the COMMENTS table. See “Simple Examples” for the contents of the file.

```
hive> LOAD DATA LOCAL INPATH 'comments.xml' OVERWRITE INTO TABLE comments;
```

The following query shows the content of the COMMENTS table.

```
hive> SELECT usr, content, likeCt FROM comments;
```

```
john  It is raining :(     0
kelly I won the lottery!   2
mike  Happy New Year!      1
```
**Example 7-5  Querying an XML Column**

This CREATE TABLE command is like Example 7-4, except that the like elements are produced as XML in a STRING column.

```
hive>
CREATE TABLE comments2 (usr STRING, content STRING, likes STRING)
ROW FORMAT
  SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS
  INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
  OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(
  "oxh-elements" = "comment",
  "oxh-column.usr" = ".//@user",
  "oxh-column.content" = ".//@text",
  "oxh-column.likes" = "fn:serialize(<likes>{./like}</likes>)"
);
```

The Hive LOAD DATA command loads comments.xml into the table. See “Simple Examples” for the contents of the file.

```
hive> LOAD DATA LOCAL INPATH 'comments.xml' OVERWRITE INTO TABLE comments2;
```

The following query shows the content of the COMMENTS2 table.

```
hive> SELECT usr, content, likes FROM comments2;
```

```
john   It is raining :(    <likes/>
kelly  I won the lottery!  <likes><like user="john"/></likes><like user="mike"/></likes>
mike   Happy New Year!     <likes><like user="laura"/></likes>
```

The next query extracts the user names from the like elements:

```
hive> SELECT usr, t.user FROM comments2 LATERAL VIEW
  > xml_table("likes/like", comments2.likes, struct("./@user")) t AS user;
```

```
kelly  john
kelly  mike
mike   laura
```

**Example 7-6  Generating XML in a Single String Column**

This command creates a table named COMMENTS3 with a row for each comment, and produces the XML in a single STRING column.

```
hive>
CREATE TABLE comments3 (xml STRING)
ROW FORMAT
  SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'
STORED AS
  INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'
  OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'
TBLPROPERTIES(
  "oxh-elements" = "comment",
  "oxh-column.xml" = "fn:serialize(.)"
);
```
The Hive LOAD DATA command loads comments.xml into the table. See “Simple Examples” for the contents of the file.

```
hive> LOAD DATA LOCAL INPATH 'comments.xml' OVERWRITE INTO TABLE comments3;
```

The following query shows the contents of the XML column:

```
hive> SELECT xml FROM comments3;
...
<comment id="12345" user="john" text="It is raining :( ">
<like user="john"/>
<like user="mike"/>
</comment>
<comment id="56789" user="kelly" text="I won the lottery!">
<like user="john"/>
<like user="mike"/>
</comment>
<comment id="54321" user="mike" text="Happy New Year!">
<like user="laura"/>
</comment>
```

The next query extracts the IDs and converts them to integers:

```
hive> SELECT xml_query_as_int("comment/@id", xml) FROM comments3;
...
12345
56789
54321
```

### 7.4.3.3 OpenStreetMap Examples

These examples use data from OpenStreetMap, which provides free map data for the entire world. You can export the data as XML for specific geographic regions or the entire planet. An OpenStreetMap XML document mainly contains a sequence of node, way, and relation elements.

In these examples, the OpenStreetMap XML files are stored in the /user/name/osm HDFS directory.

---

**See Also:**

- To download OpenStreetMap data, go to [http://www.openstreetmap.org/export](http://www.openstreetmap.org/export)

---

**Example 7-7  Creating a Table Over OpenStreetMap XML**

This example creates a table over OpenStreetMap XML with one row for each node element as follows:

- The id, lat, lon, and user attributes of the node element are mapped to table columns.
The year is extracted from the `timestamp` attribute and mapped to the `YEAR` column. If a node does not have a `timestamp` attribute, then -1 is used for the year.

If the node element has any child `tag` elements, then they are stored as an XML string in the `TAGS` column. If node has no child `tag` elements, then column value is NULL.

```hive
CREATE EXTERNAL TABLE nodes (  id BIGINT,  latitude DOUBLE,  longitude DOUBLE,  year SMALLINT,  tags STRING )  ROW FORMAT  SERDE 'oracle.hadoop.xquery.hive.OXMLSerDe'  STORED AS  INPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLInputFormat'  OUTPUTFORMAT 'oracle.hadoop.xquery.hive.OXMLOutputFormat'  LOCATION '/user/name/osm'  TBLPROPERTIES (    "oxh-elements" = "node",    "oxh-column.id" = "./@id",    "oxh-column.latitude" = "./@lat",    "oxh-column.longitude" = "./@lon",    "oxh-column.year" = "if (fn:exists(./@timestamp)) then fn:year-from-dateTime(xs:dateTime(./@timestamp)) else -1",    "oxh-column.tags" = "if (fn:exists(./tag)) then fn:serialize(<tags>{./tag}</tags>) else ()"  );
```

The following query returns the number of nodes per year:

```hive
SELECT year, count(*) FROM nodes GROUP BY year;
```

This query returns the total number of tags across nodes:

```hive
SELECT sum(xml_query_as_int("count(tags/tag)", tags)) FROM nodes;
```

**Example 7-8**

In OpenStreetMap XML, the node, way, and relation elements share a set of common attributes, such as the user who contributed the data. The next table produces one row for each node, way, and relation element.

```hive
CREATE EXTERNAL TABLE osm (  id BIGINT,  uid BIGINT,  type STRING )  ROW FORMAT
```
The following query returns the number of node, way, and relation elements. The TYPE column is set to the name of the selected element, which is either node, way, or relation.

```
hive> SELECT type, count(*) FROM osm GROUP BY type;
```

This query returns the number of distinct user IDs:

```
hive> SELECT count(*) FROM (SELECT uid FROM osm GROUP BY uid) t;
```

See Also:

For a description of the OpenStreetMap elements and attributes, go to http://wiki.openstreetmap.org/wiki/Elements

### 7.5.1 Oracle XML Functions for Hive Reference

This section describes the Oracle XML Extensions for Hive. It describes the following commands and functions:

- `xml_exists`
- `xml_query`
- `xml_query_asprimitive`
- `xml_table`

#### 7.5.1.1 Data Type Conversions

Table 7-1 shows the conversions that occur automatically between Hive primitives and XML schema types.

<table>
<thead>
<tr>
<th>Hive</th>
<th>XML schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>TINYINT</td>
<td>xs:byte</td>
</tr>
<tr>
<td>SMALLINT</td>
<td>xs:short</td>
</tr>
<tr>
<td>INT</td>
<td>xs:int</td>
</tr>
<tr>
<td>BIGINT</td>
<td>xs:long</td>
</tr>
</tbody>
</table>
Table 7-1  (Cont.) Data Type Equivalents

<table>
<thead>
<tr>
<th>Hive</th>
<th>XML schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>BOOLEAN</td>
<td>xs:boolean</td>
</tr>
<tr>
<td>FLOAT</td>
<td>xs:float</td>
</tr>
<tr>
<td>DOUBLE</td>
<td>xs:double</td>
</tr>
<tr>
<td>STRING</td>
<td>xs:string</td>
</tr>
</tbody>
</table>

7.5.1.2 Hive Access to External Files

The Hive functions have access to the following external file resources:

- XML schemas
  See [http://www.w3.org/TR/xquery/#id-schema-import](http://www.w3.org/TR/xquery/#id-schema-import)
- XML documents
  See [http://www.w3.org/TR/xpath-functions/#func-doc](http://www.w3.org/TR/xpath-functions/#func-doc)
- XQuery library modules
  See [http://www.w3.org/TR/xquery/#id-module-import](http://www.w3.org/TR/xquery/#id-module-import)

You can address these files by their URI from either HTTP (by using the `http://...` syntax) or the local file system (by using the `file://...` syntax). In this example, relative file locations are resolved against the local working directory of the task, so that URIs such as `bar.xsd` can be used to access files that were added to the distributed cache:

```xml
xml_query(""
    import schema namespace tns='http://example.org' at 'bar.xsd';
    validate { ... }
    ",
    .
    .
    .
"
)
```

To access a local file, first add it to the Hadoop distributed cache using the Hive `ADD FILE` command. For example:

ADD FILE /local/mydir/thisfile.xsd;

Otherwise, you must ensure that the file is available on all nodes of the cluster, such as by mounting the same network drive or simply copying the file to every node. The default base URI is set to the local working directory.
See Also:

- For examples of accessing the distributed cache, see Example 7-15 for xml_query, Example 7-22 for xml_query_as_primitive, and Example 7-31 for xml_table.
- For information about the default base URI, see XQuery 1.0: An XML Query Language at http://www.w3.org/TR/xquery/#dt-base-uri

7.5.2 Online Documentation of Functions

You can get online Help for the Hive extension functions by using this command:

```
DESCRIBE FUNCTION [EXTENDED] function_name;
```

This example provides a brief description of the xml_query function:

```
hive> describe function xml_query;
OK
xml_query(query, bindings) - Returns the result of the query as a STRING array
```

The EXTENDED option provides a detailed description and examples:

```
hive> describe function extended xml_query;
OK
xml_query(query, bindings) - Returns the result of the query as a STRING array
Evaluates an XQuery expression with the specified bindings. The query argument must
be a STRING and the bindings argument must be a STRING or a STRUCT. If the bindings
argument is a STRING, it is parsed as XML and bound to the initial context item of
the query. For example:

> SELECT xml_query("x/y", "<x><y>hello</y><z/><y>world</y></x>") FROM src LIMIT 1;
["hello", "world"]
```

7.5.3 xml_exists

Tests if the result of a query is empty.

**Signature**

```
xml_exists(
    STRING query,
    { STRING | STRUCT } bindings
) as BOOLEAN
```

**Description**

**query**
An XQuery or XPath expression. It must be a constant value, because it is only read
the first time the function is evaluated. The initial query string is compiled and reused
in all subsequent calls.
You can access files that are stored in the Hadoop distributed cache and HTTP resources (http://...). Use the XQuery `fn:doc` function for XML documents, and the `fn:unparsed-text` and `fn:parsed-text-lines` functions to access plain text files.

If an error occurs while compiling the query, the function raises an error. If an error occurs while evaluating the query, the error is logged (not raised), and an empty array is returned.

**bindings**

The input that the query processes. The value can be an XML STRING or a STRUCT of variable values:

- **STRING**: The string is bound to the initial context item of the query as XML.
- **STRUCT**: A STRUCT with an even number of fields. Each pair of fields defines a variable binding (name, value) for the query. The name fields must be type STRING, and the value fields can be any supported primitive. See “Data Type Conversions.”

**Return Value**

`true` if the result of the query is not empty; `false` if the result is empty or the query raises a dynamic error.

**Notes**

The first dynamic error raised by a query is logged, but subsequent errors are suppressed.

**Examples**

**Example 7-9  STRING Binding**

This example parses and binds the input XML string to the initial context item of the query `x/y`:

```approx
Hive> SELECT xml_exists("x/y", "<x><y>123</y></x>") FROM src LIMIT 1;
```

```
true
```

**Example 7-10  STRUCT Binding**

This example defines two query variables, `$data` and `$value`:

```approx
Hive> SELECT xml_exists(
    "parse-xml($data)/x/y[@id = $value]",
    struct(
        "data", "<x><y id='1'/><y id='2'/></x>",
        "value", 2
    )
) FROM src LIMIT 1;
```

```
true
```
Example 7-11  Error Logging

In this example, an error is written to the log, because the input XML is invalid:

```
hive> SELECT xml_exists("x/y", "<x><y>123</Invalid></x>") FROM src LIMIT 1;
false
```

7.5.4 xml_query

Returns the result of a query as an array of STRING values.

Signature

```
xm1_query(
    STRING query,
    { STRING | STRUCT } bindings
) as ARRAY<STRING>
```

Description

**query**

An XQuery or XPath expression. It must be a constant value, because it is only read the first time the function is evaluated. The initial query string is compiled and reused in all subsequent calls.

You can access files that are stored in the Hadoop distributed cache and HTTP resources (http://...). Use the XQuery `fn:doc` function for XML documents, and the `fn:unparsed-text` and `fn:parsed-text-lines` functions to access plain text files. See Example 7-15.

If an error occurs while compiling the query, the function raises an error. If an error occurs while evaluating the query, the error is logged (not raised), and an empty array is returned.

**bindings**

The input that the query processes. The value can be an XML STRING or a STRUCT of variable values:

- **STRING**: The string is bound to the initial context item of the query as XML. See Example 7-12.

- **STRUCT**: A STRUCT with an even number of fields. Each pair of fields defines a variable binding (name, value) for the query. The name fields must be type STRING, and the value fields can be any supported primitive. See “Data Type Conversions” and Example 7-13.

Return Value

A Hive array of STRING values, which are the result of the query converted to a sequence of atomic values. If the result of the query is empty, then the return value is an empty array.
Examples

Example 7-12  Using a STRING Binding

This example parses and binds the input XML string to the initial context item of the query \texttt{x/y}:

```
hive>
SELECT xml_query("x/y", "\textless x\textgreater \textless y\textgreater hello\textless /y\textgreater \textless z\textgreater \textless /y\textgreater world\textless /y\textgreater \textless /x\textgreater")
FROM src LIMIT 1;
```

```
["hello","world"]
```

Example 7-13  Using a STRUCT Binding

In this example, the second argument is a \texttt{STRUCT} that defines two query variables, \texttt{$data$} and \texttt{$value$}. The values of the variables in the \texttt{STRUCT} are converted to XML schema types as described in “Data Type Conversions.”

```
hive>
SELECT xml_query(  
    "fn:parse-xml($data)/x/y[@id = $value]",  
    struct(  
        "data", "\textless x\textgreater \textless y (id='1')\textgreater hello\textless /y\textgreater \textless /x\textgreater\textless /y\textgreater world\textless /y\textgreater\textless /x\textgreater",  
        "value", 1  
    )  
) FROM src LIMIT 1;
```

```
["hello"]
```

Example 7-14  Obtaining Serialized XML

This example uses the \texttt{fn:serialize} function to return serialized XML:

```
hive>
SELECT xml_query(  
    "for $y in x/y  
    return fn:serialize($y)  
) FROM src LIMIT 1;
```

```
["<y>hello</y>","<y>world</y>"]
```

Example 7-15  Accessing the Hadoop Distributed Cache

This example adds a file named test.xml to the distributed cache, and then queries it using the \texttt{fn:doc} function. The file contains this value:

```
<x><y>hello</y><z/><y>world</y></x>
```

```
hive> ADD FILE test.xml;
Added resource: test.xml
hive>
SELECT xml_query("fn:doc('test.xml')/x/y", NULL) FROM src LIMIT 1;
```

```
["<y>hello</y>","<y>world</y>"]
```
Example 7-16 Results of a Failed Query

The next example returns an empty array because the input XML is invalid. The XML parsing error will be written to the log:

```sql
hive> SELECT xml_query("x/y", "<x><y>hello</y></invalid") FROM src LIMIT 1;
```

`[]`

7.5.5 xml_query_as_primitive

Returns the result of a query as a Hive primitive value. Each Hive primitive data type has a separate function named for it:

- `xml_query_as_string`
- `xml_query_as_boolean`
- `xml_query_as_tinyint`
- `xml_query_as_smallint`
- `xml_query_as_int`
- `xml_query_as_bigint`
- `xml_query_as_double`
- `xml_query_as_float`

**Signature**

```java
xml_query_as_primitive {
    STRING query,
    {STRUCT | STRING} bindings,
} as primitive
```

**Description**

**query**

An XQuery or XPath expression. It must be a constant value, because it is only read the first time the function is evaluated. The initial query string is compiled and reused in all subsequent calls.

You can access files that are stored in the Hadoop distributed cache and HTTP resources (`http://...`). Use the XQuery `fn:doc` function for XML documents, and the `fn:unparsed-text` and `fn:parsed-text-lines` functions to access plain text files. See Example 7-15.

If an error occurs while compiling the query, the function raises an error. If an error occurs while evaluating the query, the error is logged (not raised), and an empty array is returned.
bindings
The input that the query processes. The value can be an XML STRING or a STRUCT of
variable values:

- STRING: The string is bound to the initial context item of the query as XML. See
  Example 7-17.

- STRUCT: A STRUCT with an even number of fields. Each pair of fields defines a
  variable binding (name, value) for the query. The name fields must be type STRING,
  and the value fields can be any supported primitive. See “Data Type Conversions”
  and Example 7-18.
  The first item in the result of the query is cast to the XML schema type that maps
to the primitive type of the function. If the query returns multiple items, then all
but the first are ignored.

Return Value
A Hive primitive value, which is the first item returned by the query, converted to an
atomic value. If the result of the query is empty, then the return value is NULL.

Examples
Example 7-17 Using a STRING Binding
This example parses and binds the input XML string to the initial context item of the
query x/y:

```hive
hive> SELECT xml_query_as_string("x/y", "<x><y>hello</y></x>") FROM src LIMIT 1;
  .
  .
  .
"hello"
```

The following are string binding examples that use other primitive functions:

```hive
hive> SELECT xml_query_as_int("x/y", "<x><y>123</y></x>") FROM src LIMIT 1;
  .
  .
123

hive> SELECT xml_query_as_double("x/y", "<x><y>12.3</y></x>") FROM src LIMIT 1;
  .
  .
12.3

hive> SELECT xml_query_as_boolean("x/y", "<x><y>true</y></x>") FROM src LIMIT 1;
  .
  .
ture
```

Example 7-18 Using a STRUCT Binding
In this example, the second argument is a STRUCT that defines two query variables,$data and $value. The values of the variables in the STRUCT are converted to XML
schema types as described in “Data Type Conversions.”
Example 7-19  Returning Multiple Query Results
This example returns only the first item (hello) from the query. The second item (world) is discarded.

Example 7-20  Returning Empty Query Results
This example returns NULL because the result of the query is empty.

Example 7-21  Obtaining Serialized XML
These examples use the fn:serialize function to return complex XML elements as a STRING value:

Example 7-22  Accessing the Hadoop Distributed Cache
This example adds a file named test.xml to the distributed cache, and then queries it using the fn:doc function. The file contains this value:
Example 7-23 Results of a Failed Query

This example returns NULL because </invalid is missing an angle bracket. An XML parsing error is written to the log:

Hive> SELECT xml_query_as_string("x/y", "<x><y>hello</invalid") FROM src LIMIT 1;
.
.
NULL

This example returns NULL because foo cannot be cast as xs:float. A cast error is written to the log:

Hive> SELECT xml_query_as_float("x/y", "<x><y/foo</y></x>") FROM src LIMIT 1;
.
.
NULL

7.5.6 xml_table

A user-defined table-generating function (UDTF) that maps an XML value to zero or more table rows. This function enables nested repeating elements in XML to be mapped to Hive table rows.

Signature

xml_table{
  STRUCT? namespaces,
  STRING query,
  {STRUCT | STRING} bindings,
  STRUCT? columns
}

Description

namespaces
Identifies the namespaces that the query and column expressions can use. Optional.

The value is a STRUCT with an even number of STRING fields. Each pair of fields defines a namespace binding (prefix, URI) that can be used by the query or the column expressions. See Example 7-26.

query
An XQuery or XPath expression that generates a table row for each returned value. It must be a constant value, because it is only read the first time the function is evaluated. The initial query string is compiled and reused in all subsequent calls.
If a dynamic error occurs during query processing, then the function does not raise an error, but logs it the first time. Subsequent dynamic errors are not logged.

**bindings**
The input that the query processes. The value can be an XML STRING or a STRUCT of variable values:

- **STRING**: The string is bound to the initial context item of the query as XML. See Example 7-24.
- **STRUCT**: A STRUCT with an even number of fields. Each pair of fields defines a variable binding (name, value) for the query. The name fields must be type STRING, and the value fields can be any supported primitive. See “Data Type Conversions.”

**columns**
The XQuery or XPath expressions that define the columns of the generated rows. Optional.

The value is a STRUCT that contains the additional XQuery expressions. The XQuery expressions must be constant STRING values, because they are only read the first time the function is evaluated. For each column expression in the STRUCT, there is one column in the table.

For each item returned by the query, the column expressions are evaluated with the current item as the initial context item of the expression. The results of the column expressions are converted to STRING values and become the values of the row.

If the result of a column expression is empty or if a dynamic error occurs while evaluating the column expression, then the corresponding column value is NULL. If a column expression returns more than one item, then all but the first are ignored.

Omitting the columns argument is the same as specifying `struct("")`. See Example 7-25.

**Return Value**
One table row for each item returned by the query argument.

**Notes**
The XML table adapter enables Hive tables to be created over large XML files in HDFS. See “Hive CREATE TABLE Syntax for XML Tables”.

**Examples**

Note:
You could use the `xml_query_as_string` function to achieve the same result in this example. However, `xml_table` is more efficient, because a single function call sets all three column values and parses the input XML only once for each row. The `xml_query_as_string` function requires a separate function call for each of the three columns and reparses the same input XML value each time.
Example 7-24 Using a STRING Binding

The query "x/y" returns two <y> elements, therefore two table rows are generated. Because there are two column expressions ("./z", "./.w"), each row has two columns.

```sql
hive> SELECT xml_table(
    "x/y",
    
    "<x>
    
    <y>
    
    <z>a</z>
    
    <w>b</w>
    
    </y>
    
    <y>
    
    <z>c</z>
    
    </y>
    
    </x>
    
    
    ,
    
    struct("./z", "./.w")
)
AS (z, w)
FROM src;
```

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>b</td>
</tr>
<tr>
<td>c</td>
<td>NULL</td>
</tr>
</tbody>
</table>

Example 7-25 Using the Columns Argument

The following two queries are equivalent. The first query explicitly specifies the value of the columns argument:

```sql
hive> SELECT xml_table(
    "x/y",
    
    "<x><y>hello</y><y>world</y></x>",
    struct("."")
)
AS (y)
FROM src;
```

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>hello</td>
</tr>
<tr>
<td>world</td>
</tr>
</tbody>
</table>

The second query omits the columns argument, which defaults to `struct (".")`:

```sql
hive> SELECT xml_table(
    "x/y",
    
    "<x><y>hello</y><y>world</y></x>"
)
AS (y)
FROM src;
```

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>hello</td>
</tr>
<tr>
<td>world</td>
</tr>
</tbody>
</table>

Example 7-26 Using the Namespaces Argument

This example specifies the optional namespaces argument, which identifies an ns prefix and a URI of `http://example.org`.

```sql
hive> SELECT xml_table(
    struct("ns", "http://example.org"),
   
```
Example 7-27 Querying a Hive Table of XML Documents

This example queries a table named COMMENTS3, which has a single column named XML_STR of type STRING. It contains these three rows:

```
hive> SELECT xml_str FROM comments3;
```

```
<comment id="12345" user="john" text="It is raining:"/>
<comment id="56789" user="kelly" text="I won the lottery!"><like user="john"/><like user="mike"></comment>
<comment id="54321" user="mike" text="Happy New Year!"><like user="laura"></comment>
```

The following query shows how to extract the user, text, and number of likes from the COMMENTS3 table.

```
hive> SELECT t.id, t.usr, t.likes
FROM comments3 LATERAL VIEW xml_table(
"comment",
comments.xml_str,
struct("./@id", "./@user", "fn:count(./like)"
)
) t AS id, usr, likes;
```

```
12345   john    0
56789   kelly   2
54321   mike    1
```

Example 7-28 Mapping Nested XML Elements to Table Rows

This example shows how to use xml_table to flatten nested, repeating XML elements into table rows. See Example 7-27 for the COMMENTS table.

```
> SELECT t.i, t.u, t.l
FROM comments3 LATERAL VIEW xml_table {  
"let $comment := ./comment
for $like in $comment/like
return
<r>
<id>{$comment/@id/data()}</id>
<User>{$comment/@user/data()}</User>
<like>{$like/@user/data()}</like>
</r>
";

, comments.xml_str,
struct("./@id", "./@user", "/like")
) t AS i, u, l;
```

```
56789   kelly   john
56789   kelly   mike
54321   mike    laura
```
Example 7-29   Mapping Optional Nested XML Elements to Table Rows

This example is a slight modification of Example 7-28 that produces a row even when a comment has no likes. See Example 7-27 for the COMMENTS table.

```sql
> SELECT t.i, t.u, t.l
FROM comments3 LATERAL VIEW xml_table (
"let $comment := ./comment
for $like allowing empty in $comment/like
return
  <r>
    <id>{$comment/@id/data()}</id>
    <user>{$comment/@user/data()}</user>
    <like>{$like/@user/data()}</like>
  </r>
")

12345   john
56789   kelly   john
56789   kelly   mike
54321   mike    laura
```

Example 7-30    Creating a New View

You can create views and new tables using xml_table, the same as any table-generating function. This example creates a new view named COMMENTS_LIKES from the COMMENTS table:

```sql
hive> CREATE VIEW comments_likes AS
SELECT xml_table("comment",
  comments.xml_str,
  struct("./@id", "count(./like)")
) AS (id, likeCt)
FROM comments;
```

This example queries the new view:

```sql
> SELECT * FROM comments_likes
WHERE CAST(likeCt AS INT) != 0;
```

Example 7-31    Accessing the Hadoop Distributed Cache

You can access XML documents and text files added to the distributed cache by using the fn:doc and fn:unparsed-text functions.

This example queries a file named test.xml that contains this string:

```xml
<x><y>hello</y><z/><y>world</y></x>
```

```sql
hive> ADD FILE test.xml;
Added resource: test.xml
hive> SELECT xml_table("fn:doc('test.xml')/x/y", NULL) AS y FROM src;
```

7-24   User's Guide
hello
world
This part contains the following chapter:

- Using Oracle R Advanced Analytics for Hadoop
This chapter describes R support for big data. It contains the following sections:

- About Oracle R Advanced Analytics for Hadoop
- Access to HDFS Files
- Access to Apache Hive
- Access to Oracle Database
- Oracle R Advanced Analytics for Hadoop Functions
- Demos of Oracle R Advanced Analytics for Hadoop Functions
- Security Notes for Oracle R Advanced Analytics for Hadoop

Note:
Oracle R Advanced Analytics for Hadoop was previously called Oracle R Connector for Hadoop or ORCH. ORCH is still mentioned in this document and in the product for backward compatibility.

8.1 About Oracle R Advanced Analytics for Hadoop

Oracle R Advanced Analytics for Hadoop provides:

- a general computation framework, in which you can use the R language to write your custom logic as mappers or reducers. The code executes in a distributed, parallel manner using the available compute and storage resources on the Hadoop cluster.

- an R interface to manipulate Hive tables, which is similar to the transparency layer of Oracle R Enterprise but with a restricted set of functionality.

- a set of pre-packaged parallel-distributed algorithms.

- support for Apache Spark, with which you can execute predictive analytics functions on a Hadoop cluster using YARN to dynamically form a Spark cluster or on a dedicated stand-alone Spark cluster. You can switch on or off Spark execution using spark.connect() and spark.disconnect() functions.

- the ability to use Spark to execute neural network analytical function (orch.neural), for significantly improved performance over MapReduce execution.
8.1.1 Oracle R Advanced Analytics for Hadoop Architecture

Oracle R Advanced Analytics for Hadoop:

- is built upon Hadoop streaming, a utility that is a part of Hadoop distribution and allows creation and execution of Map or Reduce jobs with any executable or script as mapper or reducer.
- is designed for R users to work with Hadoop cluster in a client-server configuration. Client configurations must conform to the requirements of the Hadoop distribution that Oracle R Advanced Analytics for Hadoop is deployed in.
- uses command line interfaces to HDFS and HIVE to communicate from client nodes to Hadoop clusters.
- builds the logic required to transform an input stream of data into R data frame object to be readily consumed by user-provided mapper and reducer functions written into R.
- allows R users to move data from an Oracle Database table or view into Hadoop as an HDFS file, using the Sqoop utility. Similarly data can be moved back from an HDFS file into Oracle Database, using the Sqoop utility or Oracle Loader for Hadoop, depending on the size of data being moved and security requirements.
- supports R’s binary RData representation for input and output, for performance sensitive analytic workloads. Conversion utilities from delimiter separated representation to and from RData representation is available as part of Oracle R Advanced Analytics for Hadoop.
- includes a Hadoop Abstraction Layer (HAL) which manages the similarities and differences across various Hadoop distributions. ORCH will auto-detect the Hadoop version at startup.

8.1.2 Oracle R Advanced Analytics for Hadoop packages and functions

Oracle R Advanced Analytics for Hadoop includes a collection of R packages that provides:

- Interfaces to work with the:
  - Apache Hive tables
  - Apache Hadoop compute infrastructure
  - local R environment
  - Oracle Database tables
  - Proprietary binary RData representations
  - Apache Spark RDD objects
- Predictive analytic techniques for:
  - linear regression
  - generalized linear models
- neural networks
- matrix completion using low rank matrix factorization
- nonnegative matrix factorization
- k-means clustering
- principal components analysis
- multivariate analysis

ORAAH 2.6 introduces full stack of predictive modeling algorithms on Spark. This includes integration of many Spark MLlib capabilities, including Linear Model techniques (Linear Regression, LASSO, Ridge Regression), as well as GLM, SVM, k-Means, Gaussian Mixture clustering, Decision Trees, Random Forests and Gradient Boosted Trees, PCA and SVD. Existing ORAAH custom Spark algorithms are enhanced with the addition of Linear Models and Stepwise capability for both LM and GLM.

While these techniques have R interfaces, Oracle R Advanced Analytics for Hadoop implement them in either Java or R as distributed, parallel MapReduce jobs, thereby leveraging all nodes of your Hadoop cluster.

You install and load this package as you would any other R package. Using simple R functions, you can perform tasks like these:

- Access and transform HDFS data using a Hive-enabled transparency layer
- Use the R language for writing mappers and reducers
- Copy data between R memory, the local file system, HDFS, Hive, and Oracle Database instances
- Manipulate Hive data transparently from R
- Execute R programs as Hadoop MapReduce jobs and return the results to any of those locations
  - With Oracle R Advanced Analytics for Hadoop, MapReduce jobs can be submitted from R for both non-cluster (local) execution and Hadoop cluster execution
  - When Oracle R Enterprise and Oracle R Advanced Analytics for Hadoop are used together on a database server, you can schedule database jobs using the DBMS_SCHEDULER to execute scripts containing ORCH functions

To use Oracle R Advanced Analytics for Hadoop, you should be familiar with MapReduce programming, R programming, and statistical methods.

### 8.1.3 Oracle R Advanced Analytics for Hadoop APIs

Oracle R Advanced Analytics for Hadoop provides access from a local R client to Apache Hadoop using functions with these prefixes:

- **hadoop**: Identifies functions that provide an interface to Hadoop MapReduce
- **hdfs**: Identifies functions that provide an interface to HDFS
- **orch**: Identifies a variety of functions; **orch** is a general prefix for **ORCH** functions
• ore: Identifies functions that provide an interface to a Hive data store

Oracle R Advanced Analytics for Hadoop uses data frames as the primary object type, but it can also operate on vectors and matrices to exchange data with HDFS. The APIs support the numeric, integer, and character data types in R.

All of the APIs are included in the ORCH library. The functions are listed in “Oracle R Advanced Analytics for Hadoop Functions”.

See Also:
The R Project website at http://www.r-project.org/

8.1.4 Inputs to Oracle R Advanced Analytics for Hadoop

Oracle R Advanced Analytics for Hadoop can work with delimited text files resident in an HDFS directory, HIVE tables, or binary RData representations of data. If the input data to an Oracle R Advanced Analytics for Hadoop orchestrated map-reduce computation does not reside in HDFS, a copy of the data in HDFS is created automatically prior to launching the computation.

Before Oracle R Advanced Analytics for Hadoop can work with delimited text files it determines metadata associated with the files and captures the same in a file stored alongside of the data files. This file is named __ORCHMETA__. The metadata contains information such as:

• If the file contains key(s), then the delimiter that is the key separator
• The delimiter that is the value separator
• Number and data types of columns in the file
• Optional names of columns
• Dictionary information for categorical columns
• Other Oracle R Advanced Analytics for Hadoop-specific system data

Oracle R Advanced Analytics for Hadoop runs an automatic metadata discovery procedure on HDFS objects as part of hdfs.attach() invocation to create the metadata file. When working with HIVE tables, __ORCHMETA__ file is created automatically from the HIVE table definition2.

Oracle R Advanced Analytics for Hadoop can optionally convert input data into R’s binary RData representation for I/O performance that is on par with a pure Java based map-reduce implementation.

Oracle R Advanced Analytics for Hadoop captures row streams from HDFS files and delivers them formatted as a data frame object (or optionally matrix, vector, or list objects generated from the data frame object or AS IS, if RData representation is used) to the mapped function written in R. To accomplish this, Oracle R Advanced Analytics for Hadoop must recognize the tokens and data types of the tokens that become columns of a data frame. Oracle R Advanced Analytics for Hadoop uses R’s facilities to parse and interpret tokens in input row streams. If missing values are not represented using R’s “NA” token, they can be explicitly identified by the na.strings argument of hdfs.attach().

Delimited text files with the same key and value separator are preferred over files with a different key delimiter and value delimiter. The Read performance of files with the
same key and value delimiter is roughly 2x better than that of files with different key and value delimiter.

The key delimiter and value delimiter can be specified through the key.sep and val.sep arguments of hdfs.attach() or when running a MapReduce job for its output HDFS data.

Binary RData representation is the most performance efficient representation of input data in Oracle R Advanced Analytics for Hadoop. When possible, users are encouraged to use this binary data representation for performance sensitive analytics.

8.2 Access to HDFS Files

For Oracle R Advanced Analytics for Hadoop to access the data stored in HDFS, the input files must comply with the following requirements:

- All input files for a MapReduce job must be stored in one directory as the parts of one logical file. Any valid HDFS directory name and file name extensions are acceptable.

- Any file in that directory with a name beginning with an underscore (_) is ignored.

All delimiters are supported, and key and value delimiters can be different. You can also convert a delimited file into binary format, using the Rdata representation from R, for the best I/O performance.

8.3 Access to Apache Hive

Apache Hive provides an alternative storage and retrieval mechanism to HDFS files through a querying language called HiveQL, which closely resembles SQL. Hive uses MapReduce for distributed processing. However, the data is structured and has additional metadata to support data discovery. Oracle R Advanced Analytics for Hadoop uses the data preparation and analysis features of HiveQL, while enabling you to use R language constructs.

See Also:
The Apache Hive website at http://hive.apache.org

8.3.1 ORCH Functions for Hive

ORCH provides these conversion functions to help you move data between HDFS and Hive:

hdfs.toHive
hdfs.fromHive

8.3.2 ORE Functions for Hive

You can connect to Hive and analyze and transform Hive table objects using R functions that have an ore prefix, such as ore.connect. If you are also using Oracle R Enterprise, then you will recognize these functions. The ore functions in Oracle R Enterprise create and manage objects in an Oracle database, and the ore functions in Oracle R Advanced Analytics for Hadoop create and manage objects in a Hive database. You can connect to one database at a time, either Hive or Oracle Database, but not both simultaneously.
Note:
For information about requirements and instructions to set up and use Oracle R Enterprise, refer to Oracle R Enterprise library at: http://docs.oracle.com/cd/E40980_01/.

For example, the `ore.connect(type="HIVE")` establishes a connection with the default HIVE database `ore.hiveOptions(dbname='dbtmp')` and allows you to change the default database, while `ore.showHiveOptions()` allows you to examine the current default HIVE database.

See Table 8-7 for a list of ORE `as.ore.*` and `is.ore.*` functions.

### 8.3.3 Generic R Functions Supported in Hive

Oracle R Advanced Analytics for Hadoop also overloads the following standard generic R functions with methods to work with Hive objects.

**Character methods**

- `casefold`, `chartr`, `gsub`, `nchar`, `substr`, `substring`, `tolower`, `toupper`

This release does not support `grep` or `sub`.

**Frame methods**

- `attach`, `show`
- `[, $, $<-`, `[]`, `[[<-`
- Subset functions: `head`, `tail`
- Metadata functions: `dim`, `length`, `NROW`, `nrow`, `NCOL`, `ncol`, `names`, `names<-`, `colnames`, `colnames<-`
- Conversion functions: `as.data.frame`, `as.env`, `as.list`
- Arithmetic operators: `+`, `−`, `*`, `^`, `%%`, `%/%`, `/`
- Compare, Logic, `xor`, `!`
- Test functions: `is.finite`, `is.infinite`, `is.na`, `is.nan`
- Mathematical transformations: `abs`, `acos`, `asin`, `atan`, `ceiling`, `cos`, `exp`, `expm1`, `floor`, `log`, `log10`, `log1p`, `log2`, `logb`, `round`, `sign`, `sin`, `sqrt`, `tan`, `trunc`
- Basic statistics: `colMeans`, `colSums`, `rowMeans`, `rowSums`, `Summary`, `summary`, `unique`
- `by`, `merge`
- `unlist`, `rbind`, `cbind`, `data.frame`, `eval`

This release does not support `dimnames`, `interaction`, `max.col`, `row.names`, `row.names<-`, `scale`, `split`, `subset`, `transform`, `with`, `or`, `within`.

**Logical methods**

- `ifelse`, `Logic`, `xor`, `!`
Matrix methods
Not supported

Numeric methods

- Arithmetic operators: +, -, *, ^, %, %/%, /
- Test functions: is.finite, is.infinite, is.nan
- abs, acos, asin, atan, ceiling, cos, exp, expm1, floor, log, log1p, log2, log10, logb, mean, round, sign, sin, sqrt, Summary, summary, tan, trunc, zapsmall

This release does not support atan2, besselI, besselK, besselJ, besselY, diff, factorial, lfactorial, pmax, pmin, or tabulate.

Vector methods

- show, length, c
- Test functions: is.vector, is.na
- Conversion functions: as.vector, as.character, as.numeric, as.integer, as.logical
- [, [,<-, |,
- by, Compare, head, %in%, paste, sort, table, tail, tapply, unique

This release does not support interaction, lengthb, rank, or split.

Example 8-1 shows simple data preparation and processing. For additional details, see “Support for Hive Data Types.”

Example 8-1 Using R to Process Data in Hive Tables

```r
# Connect to Hive
ore.connect(type="HIVE")

# Attach the current envt. into search path of R
ore.attach()

# create a Hive table by pushing the numeric columns of the iris data set
IRIS_TABLE <- ore.push(iris[1:4])

# Create bins based on Petal Length
IRIS_TABLE$PetalBins = ifelse(IRIS_TABLE$Petal.Length < 2.0, "SMALL PETALS",
+    ifelse(IRIS_TABLE$Petal.Length < 4.0, "MEDIUM PETALS",
+        ifelse(IRIS_TABLE$Petal.Length < 6.0,
+            "MEDIUM LARGE PETALS", "LARGE PETALS")))

# PetalBins is now a derived column of the HIVE object
> names(IRIS_TABLE)

# Based on the bins, generate summary statistics for each group
aggregate(IRIS_TABLE$Petal.Length, by = list(PetalBins = IRIS_TABLE$PetalBins),
+    FUN = summary)
   LARGE PETALS  MEDIUM LARGE PETALS  MEDIUM PETALS  SMALL PETALS
1       6 6.025000 4.418750 1.311538
2      6.200000 4.820000 3.550000
3      6.354545 4.888462 3.581818
4      6.612500 5.275000 3.808333
5      6.9 5.9 3.9
6       0 0 0
```

Access to Apache Hive
Using Oracle R Advanced Analytics for Hadoop 8-7
Warning message:
ORE object has no unique key - using random order

8.3.4 Support for Hive Data Types

Oracle R Advanced Analytics for Hadoop can access any Hive table containing columns with string and numeric data types such as \texttt{tinyint, smallint, bigint, int, float, and double}.

There is no support for these complex data types:

\begin{itemize}
  \item array
  \item binary
  \item map
  \item struct
  \item timestamp
  \item union
\end{itemize}

If you attempt to access a Hive table containing an unsupported data type, you will receive an error message. To access the table, you must convert the column to a supported data type.

To convert a column to a supported data type:

1. Open the Hive command interface:
   \begin{verbatim}
   $ hive
   hive>
   \end{verbatim}
2. Identify the column with an unsupported data type:
   \begin{verbatim}
   hive> describe table_name;
   \end{verbatim}
3. View the data in the column:
   \begin{verbatim}
   hive> select column_name from table_name;
   \end{verbatim}
4. Create a table for the converted data, using only supported data types.
5. Copy the data into the new table, using an appropriate conversion tool.

Example 8-2 shows the conversion of an array. Example 8-3 and Example 8-4 show the conversion of timestamp data.

\textbf{Example 8-2 Converting an Array to String Columns}

\begin{verbatim}
R> ore.sync(table="t1")
Warning message:
  table t1 contains unsupported data types
    ...
    ...
hive> describe t1;
OK
  col1   int
  col2   array<string>

hive> select * from t1;
OK
1   ['a','b','c']
2   ['d','e','f']
3   ['g','h','i']
\end{verbatim}
Example 8-3 uses automatic conversion of the timestamp data type into string. The data is stored in a table named t5 with a column named tstmp.

Example 8-3 Converting a Timestamp Column

```
hive> select * from t5;
```

Example 8-4 uses the Hive `get_json_object` function to extract the two columns of interest from the JSON table into a separate table for use by Oracle R Advanced Analytics for Hadoop.

Example 8-4 Converting a Timestamp Column in a JSON File

```
hive> select * from t3;
OK

```

```
hive> create table t4 (custid int, time string);
hive> insert into table t4 SELECT cast(get_json_object(c1,->{$$.custId'}) as int),
cast(get_json_object(c1,->{$$.time'}) as string) from t3;
```

8.3.5 Usage Notes for Hive Access

The Hive command language interface (CLI) is used for executing queries and provides support for Linux clients. There is no JDBC or ODBC support.

The `ore.create` function creates Hive tables only as text files. However, Oracle R Advanced Analytics for Hadoop can access Hive tables stored as either text files or sequence files.

You can use the `ore.exec` function to execute Hive commands from the R console. For a demo, run the `hive_sequencefile` demo.

Oracle R Advanced Analytics for Hadoop can access tables and views in the default Hive database only. To allow read access to objects in other databases, you must expose them in the default database. For example, you can create views.

Oracle R Advanced Analytics for Hadoop does not have a concept of ordering in Hive. An R frame persisted in Hive might not have the same ordering after it is pulled out of Hive and into memory. Oracle R Advanced Analytics for Hadoop is designed primarily to support data cleanup and filtering of huge HDFS data sets, where ordering is not critical. You might see warning messages when working with unordered Hive frames:
Warning messages:
1: ORE object has no unique key - using random order
2: ORE object has no unique key - using random order

To suppress these warnings, set the ore.warn.order option in your R session:

\[
\text{R> options(ore.warn.order = FALSE)}
\]

### 8.3.6 Example: Loading Hive Tables into Oracle R Advanced Analytics for Hadoop

**Example 8-5** provides an example of loading a Hive table into an R data frame for analysis. It uses these Oracle R Advanced Analytics for Hadoop functions:

- `hdfs.attach`
- `ore.attach`
- `ore.connect`
- `ore.create`
- `ore.hiveOptions`
- `ore.sync`

**Example 8-5 Loading a Hive Table**

```r
# Connect to HIVE metastore and sync the HIVE input table into the R session.
ore.connect(type="HIVE")
ore.sync(table="datatab")
ore.attach()

# The "datatab" object is a Hive table with columns named custid, movieid, activity, and rating.
# Perform filtering to remove missing (NA) values from custid and movieid columns
# Project out three columns: custid, movieid and rating
\[
t1 <- datatab[!is.na(datatab$custid) &
  !is.na(datatab$movieid) &
  datatab$activity==1, c("custid","movieid", "rating")]
\]

# Set HIVE field delimiters to ',' . By default, it is Ctrl+a for text files but
# ORCH 2.0 supports only ',' as a file separator.
ore.hiveOptions(delim=',')

# Create another Hive table called "datatab1" after the transformations above.
ore.create (t1, table="datatab1")

# Use the HDFS directory, where the table data for datatab1 is stored, to attach
# it to ORCH framework. By default, this location is "/user/hive/warehouse"
dfs.id <- hdfs.attach("/user/hive/warehouse/datatab1")

# dfs.id can now be used with all hdfs.*, orch.* and hadoop.* APIs of ORCH for further processing and analytics.
```

### 8.4 Access to Oracle Database

Oracle R Advanced Analytics for Hadoop provides a basic level of database access. You can move the contents of a database table to HDFS, and move the results of HDFS analytics back to the database.

You can then perform additional analysis on this smaller set of data using a separate product named Oracle R Enterprise. It enables you to perform statistical analysis on database tables, views, and other data objects using the R language. You have transparent access to database objects, including support for Business Intelligence and in-database analytics.
Access to the data stored in an Oracle database is always restricted to the access rights granted by your DBA.

Oracle R Enterprise is included in the Oracle Advanced Analytics option to Oracle Database Enterprise Edition. It is not included in the Oracle Big Data Connectors.

See Also:
Oracle R Enterprise User’s Guide

8.4.1 Usage Notes for Oracle Database Access

Oracle R Advanced Analytics for Hadoop uses Sqoop to move data between HDFS and Oracle Database. Sqoop imposes several limitations on Oracle R Advanced Analytics for Hadoop:

- You cannot import Oracle tables with BINARY_FLOAT or BINARY_DOUBLE columns. As a work-around, you can create a view that casts these columns to NUMBER data type.

- All column names must be in upper case.

8.4.2 Scenario for Using Oracle R Advanced Analytics for Hadoop with Oracle R Enterprise

The following scenario may help you identify opportunities for using Oracle R Advanced Analytics for Hadoop with Oracle R Enterprise.

Using Oracle R Advanced Analytics for Hadoop, you can look for files that you have access to on HDFS and execute R calculations on data in one such file. You can also upload data stored in text files on your local file system into HDFS for calculations, schedule an R script for execution on the Hadoop cluster using DBMS_SCHEDULER, and download the results into a local file.

Using Oracle R Enterprise, you can open the R interface and connect to Oracle Database to work on the tables and views that are visible based on your database privileges. You can filter out rows, add derived columns, project new columns, and perform visual and statistical analysis.

Again using Oracle R Advanced Analytics for Hadoop, you might deploy a MapReduce job on Hadoop for CPU-intensive calculations written in R. The calculation can use data stored in HDFS or, with Oracle R Enterprise, in an Oracle database. You can return the output of the calculation to an Oracle database and to the R console for visualization or additional processing.

8.5 Oracle R Advanced Analytics for Hadoop Functions

The Oracle R Advanced Analytics for Hadoop functions are described in R Help topics. This section groups them into functional categories and provides brief descriptions.

- Native Analytical Functions
- Using the Hadoop Distributed File System (HDFS)
- Using Apache Hive
8.5.1 Native Analytical Functions

Table 8-1 describes the native analytic functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>orch.cor</code></td>
<td>Generates a correlation matrix with a Pearson's correlation coefficients.</td>
</tr>
<tr>
<td><code>orch.cov</code></td>
<td>Generates a covariance matrix.</td>
</tr>
<tr>
<td><code>orch.getXlevels</code></td>
<td>Creates a list of factor levels that can be used in the <code>xlev</code> argument of a <code>model.matrix</code> call. It is equivalent to the <code>getXlevels</code> function in the stats package.</td>
</tr>
<tr>
<td><code>orch.glm</code></td>
<td>Fits and uses generalized linear models on data stored in HDFS.</td>
</tr>
<tr>
<td><code>orch.kmeans</code></td>
<td>Perform k-means clustering on a data matrix that is stored as a file in HDFS.</td>
</tr>
<tr>
<td><code>orch.lm</code></td>
<td>Fits a linear model using tall-and-skinny QR (TSQR) factorization and parallel distribution. The function computes the same statistical parameters as the Oracle R Enterprise <code>ore.lm</code> function.</td>
</tr>
<tr>
<td><code>orch.lmf</code></td>
<td>Fits a low rank matrix factorization model using either the jellyfish algorithm or the Mahout alternating least squares with weighted regularization (ALS-WR) algorithm.</td>
</tr>
<tr>
<td><code>orch.neural</code></td>
<td>Provides a neural network to model complex, nonlinear relationships between inputs and outputs, or to find patterns in the data.</td>
</tr>
<tr>
<td><code>orch.nmf</code></td>
<td>Provides the main entry point to create a nonnegative matrix factorization model using the jellyfish algorithm. This function can work on much larger data sets than the R NMF package, because the input does not need to fit into memory.</td>
</tr>
<tr>
<td><code>orch.nmf.NMFalgo</code></td>
<td>Plugs in to the R NMF package framework as a custom algorithm. This function is used for benchmark testing.</td>
</tr>
<tr>
<td><code>orch.princomp</code></td>
<td>Analyzes the performance of principal component.</td>
</tr>
<tr>
<td><code>orch.recommend</code></td>
<td>Computes the top n items to be recommended for each user that has predicted ratings based on the input <code>orch.mahout.lmf.asl</code> model.</td>
</tr>
</tbody>
</table>
Table 8-1  (Cont.) Functions for Statistical Analysis

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orch.sample</td>
<td>Provides the reservoir sampling.</td>
</tr>
<tr>
<td>orch.scale</td>
<td>Performs scaling.</td>
</tr>
</tbody>
</table>

8.5.2 Using the Hadoop Distributed File System (HDFS)

Table 8-2 describes the functions that execute HDFS commands from within the R environment.

Table 8-2  Functions for Using HDFS

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hdfs.cd</td>
<td>Sets the default HDFS path.</td>
</tr>
<tr>
<td>hdfs.cp</td>
<td>Copies an HDFS file from one location to another.</td>
</tr>
<tr>
<td>hdfs.describe</td>
<td>Returns the metadata associated with a file in HDFS.</td>
</tr>
<tr>
<td>hdfs.exists</td>
<td>Verifies that a file exists in HDFS.</td>
</tr>
<tr>
<td>hdfs.head</td>
<td>Copies a specified number of lines from the beginning of a file in HDFS.</td>
</tr>
<tr>
<td>hdfs.id</td>
<td>Converts an HDFS path name to an R dfs.id object.</td>
</tr>
<tr>
<td>hdfs.ls</td>
<td>Lists the names of all HDFS directories containing data in the specified path.</td>
</tr>
<tr>
<td>hdfs.mkdir</td>
<td>Creates a subdirectory in HDFS relative to the current working directory.</td>
</tr>
<tr>
<td>hdfs.mv</td>
<td>Moves an HDFS file from one location to another.</td>
</tr>
<tr>
<td>hdfs.parts</td>
<td>Returns the number of parts composing a file in HDFS.</td>
</tr>
<tr>
<td>hdfs.pwd</td>
<td>Identifies the current working directory in HDFS.</td>
</tr>
<tr>
<td>hdfs.rm</td>
<td>Removes a file or directory from HDFS.</td>
</tr>
<tr>
<td>hdfs.rmdir</td>
<td>Deletes a directory in HDFS.</td>
</tr>
<tr>
<td>hdfs.root</td>
<td>Returns the HDFS root directory.</td>
</tr>
<tr>
<td>hdfs.setroot</td>
<td>Sets the HDFS root directory.</td>
</tr>
<tr>
<td>hdfs.size</td>
<td>Returns the size of a file in HDFS.</td>
</tr>
<tr>
<td>hdfs.tail</td>
<td>Copies a specified number of lines from the end of a file in HDFS.</td>
</tr>
</tbody>
</table>

8.5.3 Using Apache Hive

Table 8-3 describes the functions available in Oracle R Advanced Analytics for Hadoop for use with Hive. See “ORE Functions for Hive”.
### Table 8-3  Functions for Using Hive

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hdfs.fromHive</td>
<td>Converts a Hive table to a HDFS identifier in ORCH.</td>
</tr>
<tr>
<td>hdfs.toHive</td>
<td>Converts an HDFS object identifier to a Hive table represented by an ore.frame object.</td>
</tr>
<tr>
<td>ore.create</td>
<td>Creates a database table from a data.frame or ore.frame object.</td>
</tr>
<tr>
<td>ore.drop</td>
<td>Drops a database table or view.</td>
</tr>
<tr>
<td>ore.get</td>
<td>Retrieves the specified ore.frame object.</td>
</tr>
<tr>
<td>ore.pull</td>
<td>Copies data from a Hive table to an R object.</td>
</tr>
<tr>
<td>ore.push</td>
<td>Copies data from an R object to a Hive table.</td>
</tr>
<tr>
<td>ore.recode</td>
<td>Replaces the values in an ore.vector object.</td>
</tr>
</tbody>
</table>

### 8.5.4 Using Aggregate Functions in Hive

Table 8-4 describes the aggregate functions from the OREstats package that Oracle R Advanced Analytics for Hadoop supports for use with Hive data.

### Table 8-4  Oracle R Enterprise Aggregate Functions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td>Splits the data into subsets and computes summary statistics for each subset.</td>
</tr>
<tr>
<td>fivenum</td>
<td>Returns Tukey’s five-number summary (minimum, lower hinge, median, upper hinge, and maximum) for the input data.</td>
</tr>
<tr>
<td>IQR</td>
<td>Calculates an interquartile range.</td>
</tr>
<tr>
<td>median</td>
<td>Calculates a sample median.</td>
</tr>
<tr>
<td>quantile</td>
<td>Generates sample quantiles that correspond to the specified probabilities.</td>
</tr>
<tr>
<td>sd</td>
<td>Calculates the standard deviation.</td>
</tr>
<tr>
<td>var&lt;sup&gt;1&lt;/sup&gt;</td>
<td>Calculates the variance.</td>
</tr>
</tbody>
</table>

<sup>1</sup> For vectors only

### 8.5.5 Making Database Connections

Table 8-5 describes the functions for establishing a connection to Oracle Database.

### Table 8-5  Functions for Using Oracle Database

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orch.connect</td>
<td>Establishes a connection to Oracle Database.</td>
</tr>
</tbody>
</table>
Table 8-5 (Cont.) Functions for Using Oracle Database

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orch.connected</td>
<td>Checks whether Oracle R Advanced Analytics for Hadoop is connected to Oracle Database.</td>
</tr>
<tr>
<td>orch.dbcon</td>
<td>Returns a connection object for the current connection to Oracle Database, excluding the authentication credentials.</td>
</tr>
<tr>
<td>orch.dbinfo</td>
<td>Displays information about the current connection.</td>
</tr>
<tr>
<td>orch.disconnect</td>
<td>Disconnects the local R session from Oracle Database.</td>
</tr>
<tr>
<td>orch.reconnect</td>
<td>Reconnects to Oracle Database with the credentials previously returned by orch.disconnect.</td>
</tr>
</tbody>
</table>

8.5.6 Copying Data and Working with HDFS Files

Table 8-6 describes the functions for copying data between platforms, including R data frames, HDFS files, local files, and tables in an Oracle database.

Table 8-6 Functions for Copying Data

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hdfs.attach</td>
<td>Copies data from an unstructured data file in HDFS into the R framework. By default, data files in HDFS are not visible to the connector. However, if you know the name of the data file, you can use this function to attach it to the Oracle R Advanced Analytics for Hadoop name space.</td>
</tr>
<tr>
<td>hdfs.download</td>
<td>Copies a file from HDFS to the local file system.</td>
</tr>
<tr>
<td>hdfs.get</td>
<td>Copies data from HDFS into a data frame in the local R environment. All metadata is extracted and all attributes, such as column names and data types, are restored if the data originated in an R environment. Otherwise, generic attributes like val1 and val2 are assigned.</td>
</tr>
<tr>
<td>hdfs.pull</td>
<td>Copies data from HDFS into an Oracle database. This operation requires authentication by Oracle Database. See orch.connect.</td>
</tr>
<tr>
<td>hdfs.push</td>
<td>Copies data from an Oracle database to HDFS. This operation requires authentication by Oracle Database. See orch.connect.</td>
</tr>
<tr>
<td>hdfs.put</td>
<td>Copies data from an R in-memory object (data.frame) to HDFS. All data attributes, like column names and data types, are stored as metadata with the data.</td>
</tr>
<tr>
<td>hdfs.sample</td>
<td>Copies a random sample of data from a Hadoop file into an R in-memory object. Use this function to copy a small sample of the original HDFS data for developing the R calculation that you ultimately want to execute on the entire HDFS data set on the Hadoop cluster.</td>
</tr>
<tr>
<td>hdfs.upload</td>
<td>Copies a file from the local file system into HDFS.</td>
</tr>
<tr>
<td>is.hdfs.id</td>
<td>Indicates whether an R object contains a valid HDFS file identifier.</td>
</tr>
</tbody>
</table>
8.5.7 Converting to R Data Types

Table 8-7 describes functions for converting and testing data types. The Oracle R Enterprise OREbase package provides these functions.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>as.ore</td>
<td>Coerces an in-memory R object to an ORE object.</td>
</tr>
<tr>
<td>as.ore.character</td>
<td>Coerces an in-memory R object to an ORE character object.</td>
</tr>
<tr>
<td>as.ore.date</td>
<td>Coerces an in-memory R object to an ORE date object.</td>
</tr>
<tr>
<td>as.ore.datetime</td>
<td>Coerces an in-memory R object to an ORE datetime object.</td>
</tr>
<tr>
<td>as.ore.difftime</td>
<td>Coerces an in-memory R object to an ORE difftime object.</td>
</tr>
<tr>
<td>as.ore.factor</td>
<td>Coerces an in-memory R object to an ORE factor object.</td>
</tr>
<tr>
<td>as.ore.frame</td>
<td>Coerces an in-memory R object to an ORE frame object.</td>
</tr>
<tr>
<td>as.ore.integer</td>
<td>Coerces an in-memory R object to an ORE integer object.</td>
</tr>
<tr>
<td>as.ore.list</td>
<td>Coerces an in-memory R object to an ORE list object.</td>
</tr>
<tr>
<td>as.ore.logical</td>
<td>Coerces an in-memory R object to an ORE logical object.</td>
</tr>
<tr>
<td>as.ore.matrix</td>
<td>Coerces an in-memory R object to an ORE matrix object.</td>
</tr>
<tr>
<td>as.ore.numeric</td>
<td>Coerces an in-memory R object to an ORE numeric object.</td>
</tr>
<tr>
<td>as.ore.object</td>
<td>Coerces an in-memory R object to an ORE object.</td>
</tr>
<tr>
<td>as.ore.vector</td>
<td>Coerces an in-memory R object to an ORE vector object.</td>
</tr>
<tr>
<td>is.ore</td>
<td>Tests whether the specified value is an object of a particular Oracle R Enterprise class.</td>
</tr>
<tr>
<td>is.ore.character</td>
<td>Tests whether the specified value is a character.</td>
</tr>
<tr>
<td>is.ore.date</td>
<td>Tests whether the specified value is a date.</td>
</tr>
<tr>
<td>is.ore.datetime</td>
<td>Tests whether the specified value is a datetime type.</td>
</tr>
<tr>
<td>is.ore.difftime</td>
<td>Tests whether the specified value is a difftime type.</td>
</tr>
<tr>
<td>is.ore.factor</td>
<td>Tests whether the specified value is a factor.</td>
</tr>
<tr>
<td>is.ore.frame</td>
<td>Tests whether the specified value is a frame.</td>
</tr>
<tr>
<td>is.ore.integer</td>
<td>Tests whether the specified value is an integer.</td>
</tr>
<tr>
<td>is.ore.list</td>
<td>Tests whether the specified value is a list.</td>
</tr>
<tr>
<td>is.ore.logical</td>
<td>Tests whether the specified value is a logical type.</td>
</tr>
<tr>
<td>is.ore.matrix</td>
<td>Tests whether the specified value is a matrix.</td>
</tr>
</tbody>
</table>
### Table 8-7 (Cont.) Functions for Converting and Testing Data Types

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>is.ore.numeric</td>
<td>Tests whether the specified value is numeric.</td>
</tr>
<tr>
<td>is.ore.object</td>
<td>Tests whether the specified value is an object.</td>
</tr>
<tr>
<td>is.ore.vector</td>
<td>Tests whether the specified value is a vector.</td>
</tr>
</tbody>
</table>

#### 8.5.8 Using MapReduce

Table 8-8 describes functions that you use when creating and running MapReduce programs.

### Table 8-8 Functions for Using MapReduce

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hadoop.exec</td>
<td>Starts the Hadoop engine and sends the mapper, reducer, and combiner R functions for execution. You must load the data into HDFS first.</td>
</tr>
<tr>
<td>hadoop.jobs</td>
<td>Lists the running jobs, so that you can evaluate the current load on the Hadoop cluster.</td>
</tr>
<tr>
<td>hadoop.run</td>
<td>Starts the Hadoop engine and sends the mapper, reducer, and combiner R functions for execution. If the data is not already stored in HDFS, then hadoop.run first copies the data there.</td>
</tr>
<tr>
<td>orch.dryrun</td>
<td>Switches the execution platform between the local host and the Hadoop cluster. No changes in the R code are required for a dry run.</td>
</tr>
<tr>
<td>orch.export</td>
<td>Makes R objects from a user’s local R session available in the Hadoop execution environment, so that they can be referenced in MapReduce jobs.</td>
</tr>
<tr>
<td>orch.keyval</td>
<td>Outputs key-value pairs in a MapReduce job.</td>
</tr>
<tr>
<td>orch.keyvals</td>
<td>Outputs a set of key-value pairs in a MapReduce job.</td>
</tr>
<tr>
<td>orch.pack</td>
<td>Compresses one or more in-memory R objects that the mappers or reducers must write as the values in key-value pairs.</td>
</tr>
<tr>
<td>orch.tempPath</td>
<td>Sets the path where temporary data is stored.</td>
</tr>
<tr>
<td>orch.unpack</td>
<td>Restores the R objects that were compressed with a previous call to orch.pack.</td>
</tr>
<tr>
<td>orch.create.parttab</td>
<td>Enables partitioned Hive tables to be used with ORCH MapReduce framework.</td>
</tr>
</tbody>
</table>

#### 8.5.9 Debugging Scripts

Table 8-9 lists the functions available to help you debug your R program scripts.
### Table 8-9 Functions for Debugging Scripts

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>orch.dbg.lasterr</td>
<td>Returns the last error message.</td>
</tr>
<tr>
<td>orch.dbg.off</td>
<td>Turns off debugging mode.</td>
</tr>
<tr>
<td>orch.dbg.on</td>
<td>Turns on debugging mode, which prints out the interactions between Hadoop and Oracle R Advanced Analytics for Hadoop including the R commands.</td>
</tr>
<tr>
<td>orch.dbg.output</td>
<td>Directs the output from the debugger.</td>
</tr>
<tr>
<td>orch.version</td>
<td>Identifies the version of the ORCH package.</td>
</tr>
<tr>
<td>orch.debug</td>
<td>Enables R style debugging of MapReduce R scripts.</td>
</tr>
</tbody>
</table>

### 8.6 Demos of Oracle R Advanced Analytics for Hadoop Functions

Oracle R Advanced Analytics for Hadoop provides an extensive set of demos, which you can access in the same way as any other R demos.

The `demo` function lists the functions available in ORCH:

```r
R> demo(package="ORCH")
Demos in package 'ORCH':

hdfs_cpmv               ORCH's copy and move APIs
hdfs_datatrans          ORCH's HDFS data transfer APIs
hdfs_dir                ORCH's HDFS directory manipulation APIs
hdfs_putget             ORCH's get and put API usage
hive_aggregate          Aggregation in HIVE
hive_analysis           Basic analysis & data processing operations
hive_basic              Basic connectivity to HIVE storage
hive_binning            Binning logic
hive_columnfns          Column function
hive_nulls              Handling of NULL in SQL vs. NA in R
.
.
```

To run a demo from this list, use this syntax:

```r
demo("demo_name", package="ORCH")
```

For example, this package runs the Hive binning demo:

```r
R> demo("hive_binning", package = "ORCH")

demo('hive_binning', package = 'ORCH')

demo(hive_binning)
   ---- ~~~~~~~~~~~

> #
> # ORACLE R CONNECTOR FOR HADOOP DEMOS
> #
```
If an error occurs, exit from R without saving the workspace image and start a new session. You should also delete the temporary files created in both the local file system and the HDFS file system:

```bash
# rm -r /tmp/orch*
# hdfs dfs -rm -r /tmp/orch*
```

Upon completion run these:

1. `hadoop.exec` to cleanup or remove all empty `part` files and Hadoop log files.
2. `hadoop.run` to allow overwriting of HDFS objects with the same name.

### 8.7 Security Notes for Oracle R Advanced Analytics for Hadoop

Oracle R Advanced Analytics for Hadoop can invoke the Sqoop utility to connect to Oracle Database either to extract data or to store results.

**Sqoop** is a command-line utility for Hadoop that imports and exports data between HDFS or Hive and structured databases. The name Sqoop comes from “SQL to Hadoop.” The following explains how Oracle R Advanced Analytics for Hadoop stores a database user password and sends it to Sqoop.

Oracle R Advanced Analytics for Hadoop stores a user password only when the user establishes the database connection in a mode that does not require reentering the password each time. The password is stored encrypted in memory. See the Help topic for `orch.connect`.

Oracle R Advanced Analytics for Hadoop generates a configuration file for Sqoop and uses it to invoke Sqoop locally. The file contains the user’s database password obtained by either prompting the user or from the encrypted in-memory representation. The file has local user access permissions only. The file is created, the permissions are set explicitly, and then the file is open for writing and filled with data.

Sqoop uses the configuration file to generate custom JAR files dynamically for the specific database job and passes the JAR files to the Hadoop client software. The password is stored inside the compiled JAR file; it is not stored in plain text.

The JAR file is transferred to the Hadoop cluster over a network connection. The network connection and the transfer protocol are specific to Hadoop, such as port 5900.

The configuration file is deleted after Sqoop finishes compiling its JAR files and starts its own Hadoop jobs.
Part V

Oracle DataSource for Apache Hadoop

This part describes Oracle DataSource for Apache Hadoop (OD4H) storage handler for Oracle Database. It contains the following chapters:

- Oracle DataSource for Apache Hadoop (OD4H)
Oracle DataSource for Apache Hadoop (OD4H)

Oracle DataSource for Apache Hadoop (OD4H) allows direct, fast, parallel, secure and consistent access to master data in Oracle Database using Spark SQL via Hive metastore. This chapter discusses Oracle DataSource for Apache Hadoop (OD4H) in the following sections:

- Operational Data, Big Data and Requirements
- Overview of Oracle DataSource for Apache Hadoop (OD4H)
- How Does OD4H Work?
- Features of OD4H
- Using Hive SQL with OD4H
- Using Spark SQL with OD4H
- Writing Back to Oracle Database

9.1 Operational Data, Big Data and Requirements

The common data architecture in most companies nowadays generally comprises of the following components:

- Oracle Database(s) for operational, transactional, and master data, that is shared business object such as customers, products, employees and so on
- Big Data

Hadoop applications such as Master Data Management (MDM), Events processing, and others, need access to data in both Hadoop storages (such as HDFS and NoSQL Database as a landing point for weblogs, and so on) and Oracle Database (as the reliable and auditable source of truth). There are two approaches to process such data that reside in both Hadoop storage and Oracle Database:

- ETL Copy using tools such as Oracle’s Copy to BDA
- Direct Access using Oracle Big Data SQL and Oracle DataSource for Apache Hadoop (OD4H).

In this chapter, we will discuss Oracle DataSource for Apache Hadoop (OD4H).

9.2 Overview of Oracle DataSource for Apache Hadoop (OD4H)

Oracle DataSource for Apache Hadoop (OD4H) is the storage handler for Oracle Database that uses HCatalog and InputFormat.
This section discusses the following concepts:

- **Opportunity with Hadoop 2.x**
- **Oracle Tables as Hadoop Data Source**
- **External Tables**

### 9.2.1 Opportunity with Hadoop 2.x

Hadoop 2.x architecture decouples compute engines from cluster resources management and storages. It enables:

- A variety of SQL query engines. For instance, Hive SQL, Spark SQL, Big Data SQL, and so on.
- A variety of programmatic compute engines. For instance, MapReduce, Pig, Storm, Solr, Cascading, and so on.
- Elastic allocation of compute resources (CPU, memory) through YARN.
- A variety of data stores such as HDFS, NoSQL, as well as remote storages through HCatalog, InputFormat, OutputFormat and StorageHandler interfaces.

Oracle DataSource for Apache Hadoop (OD4H) is the storage handler for Oracle Database that uses HCatalog and InputFormat.

Following is an illustration of Hadoop 2.0 Architecture:

*Figure 9-1    Hadoop 2.0 Architecture*

### 9.2.2 Oracle Tables as Hadoop Data Source

OD4H enables current and ad-hoc querying. This makes querying data faster and more secure. You can query data directly and retrieve only the data that you need, when you need it.

OD4H also provides Oracle’s end-to-end security. This includes Identity Management, Column Masking, and Label and Row Security.

OD4H also furnishes direct access for Hadoop and Spark APIs such as Pig, MapReduce and others.
9.2.3 External Tables

External Tables turn Oracle tables into Hadoop and/or Spark datasources. The DDL for declaring External Tables is as follows:

```sql
CREATE[TEMPORARY] EXTERNAL TABLE [IF NOT EXISTS] [db_name.]table_name
[(col_name data_type [COMMENT col_comment],...)]
[COMMENT table_comment]
STORED BY 'oracle.hcat.osh.OracleStorageHandler' [WITHSERDEPROPERTIES(...)]
[TBLPROPERTIES (property_name=property_value,...)]
```

data_type

| SMALLINT |
| INT      |
| BIGINT   |
| BOOLEAN  |
| FLOAT    |
| DOUBLE   |
| STRING   |
| BINARY   |
| TIMESTAMP |
| DECIMAL  |
| DECIMAL(precision, scale) |
| VARCHAR  |
| CHAR     |

See Also: Refer the following link for Hive External Table syntax https://cwiki.apache.org/confluence/display/Hive/LanguageManual+DDL#LanguageManualDDL-CreateTable

Note:
Oracle supports only primitive types.

The properties of external tables can be described as follows:

**9.2.3.1 TBLPROPERTIES**

<table>
<thead>
<tr>
<th>Property</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hcat.osh.columns.mapping</td>
<td>Comma separated list to specify mapping between Hive columns and Oracle table columns. All external tables using OracleStorageHandler must define this.</td>
</tr>
<tr>
<td>mapreduce.jdbc.url</td>
<td>Connection URL to connect to the database</td>
</tr>
<tr>
<td>mapreduce.jdbc.username</td>
<td>Connection user name to connect to the database</td>
</tr>
<tr>
<td>mapreduce.jdbc.password</td>
<td>Connection password to connect to the database</td>
</tr>
<tr>
<td>mapreduce.jdbc.input.table.name</td>
<td>Oracle table name</td>
</tr>
<tr>
<td>mapreduce.jdbc.input.conditions</td>
<td>To be used for querying the database. Must be used for query pushdown.</td>
</tr>
<tr>
<td>Property</td>
<td>Use</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>mapreduce.jdbc.input.query</td>
<td>To be used for querying the database. Query should be used only when a subset of the columns is selected.</td>
</tr>
<tr>
<td>mapreduce.jdbc.input.orderby</td>
<td>ORDER BY clause to be specified for pushing ordering to the database.</td>
</tr>
<tr>
<td>oracle.hcat.osh.splitterKind</td>
<td>To be used to specify how OracleStorageHandler must create splits, so that they are a good match for the physical structure of the target table in Oracle Database. The splitter kind applicable could be SINGLE_SPLITTER, PARTITION_SPLITTER, ROW_SPLITTER, BLOCK_SPLITTER.</td>
</tr>
<tr>
<td>oracle.hcat.osh.rowsPerSplit</td>
<td>Used only when ROW_SPLITTER splitterKind is applied on the table. Represents Number of rows per split for LIMIT_RANGE splitter. Default is 1000</td>
</tr>
<tr>
<td>oracle.hcat.osh.authentication</td>
<td>Authentication method used to connect to Oracle Database. Can be SIMPLE (default), ORACLE_WALLET, KERBEROS</td>
</tr>
<tr>
<td>sun.security.krb5.principal</td>
<td>Kerberos principal. Used only when KERBEROS authentication is applied.</td>
</tr>
<tr>
<td>oracle.hcat.osh.kerb.callback</td>
<td>Callback for Kerberos authentication. Used only when Kerberos authentication is applied.</td>
</tr>
<tr>
<td>oracle.hcat.osh.maxSplits</td>
<td>Maximum number of splits for any splitter kind</td>
</tr>
<tr>
<td>oracle.hcat.osh.useChunkSplitter</td>
<td>Use chunk based ROW_SPLITTER and BLOCK_SPLITTER that use DBMS_PARALLEL_EXECUTE package to divide table into chunks that will map to hadoop splits. The default value is set to ‘true’.</td>
</tr>
<tr>
<td>oracle.hcat.osh.chunkSQL</td>
<td>Used by CUSTOM_SPLITTER to create splits. The SQL string should be a SELECT statement that returns range of each chunk must have two columns: start_id and end_id. The columns must be of ROWID type.</td>
</tr>
<tr>
<td>oracle.hcat.osh.useOracleParallelism</td>
<td>When configured, parallel queries will be executed while fetching rows from Oracle. Default value: ‘false’</td>
</tr>
<tr>
<td>oracle.hcat.osh.fetchSize</td>
<td>JDBC fetchsize for generated select queries used to fetch rows. Default value: 10 (set by Oracle JDBC Driver)</td>
</tr>
</tbody>
</table>

**Note:**

In addition to the above, any JDBC connection properties (oracle.jdbc.* and oracle.net.*) can be specified as TBLPROPERTIES. They will be used while establishing connection to Oracle Database using JDBC driver.
Note:
Oracle DataSource for Apache Hadoop (OD4H) works with Oracle View and Oracle Tables.

### 9.2.3.2 SERDE PROPERTIES

<table>
<thead>
<tr>
<th>Property</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>oracle.hcat.osh.columns.mapping</td>
<td>All external tables using OracleStorageHandler must define this. Its a comma separated list to specify mapping between hive columns (specified in create table) and oracle table columns. WITHSERDEPROPERTIES also enables the external table definition to refer only to select columns in the actual Oracle table. In other words, not all columns from the Oracle table need to be part of the Hive external table. The ordering of oracle columns in the mapping is the same as ordering of hive columns specified in create table.</td>
</tr>
</tbody>
</table>

### 9.2.4 List of jars in the OD4H package

Oracle DataSource for Apache Hadoop (OD4H) contains the following list of jars.

OD4H consists of the following list of jars.

#### Table 9-1  List of jars in OD4H

<table>
<thead>
<tr>
<th>Name of JAR</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>osh.jar</td>
<td>Contains OracleStorageHandler Implementation</td>
</tr>
<tr>
<td>ojdbc7.jar</td>
<td>An OD4H specific JDBC driver (which is optimized with internal calls), used by Spark or Hadoop tasks to connect to the database.</td>
</tr>
<tr>
<td>ucp.jar</td>
<td>For creating connection pools in OracleStorageHandler</td>
</tr>
<tr>
<td>oraclepki103.jar, osdt_core.jar, osdt_cert.jar, osdt_jce.jar</td>
<td>For Oracle Wallet authentication</td>
</tr>
<tr>
<td>orai18n.jar</td>
<td>Oracle Globalization Support</td>
</tr>
<tr>
<td>xdb.jar</td>
<td>Oracle XDB jar</td>
</tr>
</tbody>
</table>

### 9.3 How does OD4H work?

Oracle DataSource for Apache Hadoop (OD4H) does not require creating a new table. You can start working with OD4H using the following steps:

1. Create a new Oracle table, or, reuse an existing table.
2. Create the Hive DDL for creating the external table referencing the Oracle Table.

3. Issue HiveSQL, SparkSQL, or other Spark/Hadoop queries and API calls.

The following sections show how to create a new Oracle Database Table, and a Hive DDL:

- Create a New Oracle Database Table
- Hive DDL
- Creating External Table in Hive

### 9.3.1 Create a new Oracle Database Table or Reuse an Existing Table

Here is an illustration of a partitioned Oracle table that we will use to demo how partition pruning works:

```sql
1. CREATE TABLE EmployeeData ( Emp_ID NUMBER,
                         First_Name VARCHAR2(20),
                         Last_Name VARCHAR2(20),
                         Job_Title VARCHAR2(40),
                         Salary NUMBER)
  PARTITION BY RANGE (Salary)
      ( PARTITION salary_1 VALUES LESS THAN (60000) TABLESPACE tsa,
        PARTITION salary_2 VALUES LESS THAN (70000) TABLESPACE tsb,
        PARTITION salary_3 VALUES LESS THAN (80000) TABLESPACE tsc,
        PARTITION salary_4 VALUES LESS THAN (90000) TABLESPACE tsd,
        PARTITION salary_5 VALUES LESS THAN (100000) TABLESPACE tse);
```

**Note:**

You can use this syntax for table creation, in the following examples listed in this Book.

2. Issue queries from Hive, Spark, or any other Hadoop models (including joins with local Hive Tables.)

### 9.3.2 Hive DDL

In this example, we will associate two Hive external tables to the same Oracle table, using two different split patterns:

- SIMPLE_SPLITTER
- PARTITION_SPLITTER
Note: It is possible that the external table has fewer columns than the base Oracle table. Since columns can have different names, use TBLPROPERTY for mapping with the base table.

In the following examples, we are using the following variables:

- connection_string = `jdbc:oracle:thin:@localhost:1521/<servicename>`
- oracle_user=od4h
- oracle_pwd=od4h

The following command creates a Hive external table with the default split pattern, that is SIMPLE_SPLITTER.

```sql
CREATE EXTERNAL TABLE EmployeeDataSimple (Emp_ID int, First_Name string, Last_Name string, Job_Title string, Salary int) STORED BY 'oracle.hcat.osh.OracleStorageHandler' WITH SERDEPROPERTIES (oracle.hcat.osh.columns.mapping = 'Emp_ID,First_Name,Last_Name,Job_Title,Salary') TBLPROPERTIES (mapreduce.jdbc.url = '${hiveconf:jdbc:oracle:thin:@localhost:1521/<servicename>}', mapreduce.jdbc.username = '${hiveconf:od4h}', mapreduce.jdbc.password = '${hiveconf:od4h}', mapreduce.jdbc.input.table.name = 'EmployeeData');
```

The following example creates a Hive external table using PARTITION_SPLITTER.

```sql
DROP TABLE EmployeeDataPartitioned;
CREATE EXTERNAL TABLE EmployeeDataPartitioned (Emp_ID int, First_Name string, Last_Name string, Job_Title string, Salary int) STORED BY 'oracle.hcat.osh.OracleStorageHandler' WITH SERDEPROPERTIES (oracle.hcat.osh.columns.mapping = 'Emp_ID,First_Name,Last_Name,Job_Title,Salary') TBLPROPERTIES (mapreduce.jdbc.url = '${hiveconf:jdbc:oracle:thin:@localhost:1521/<servicename>}', mapreduce.jdbc.username = '${hiveconf:od4h}', mapreduce.jdbc.password = '${hiveconf:od4h}', mapreduce.jdbc.input.table.name = 'EmployeeData', oracle.hcat.osh.splitterKind = 'PARTITIONED_TABLE');
```
9.3.3 Creating External Tables in Hive

You can create an external table in Hive in the following way:

```
DROP TABLE employees;

CREATE EXTERNAL TABLE employees ( 
    EMPLOYEE_ID INT,
    FIRST_NAME  STRING,
    LAST_NAME   STRING,
    SALARY      DOUBLE,
    HIRE_DATE   TIMESTAMP,
    JOB_ID      STRING
) 
STORED BY 'oracle.hcat.osh.OracleStorageHandler'

WITH SERDEPROPERTIES ( 
    'oracle.hcat.osh.columns.mapping' = 
    'employee_id,first_name,last_name,salary,hire_date,job_id')

TBLPROPERTIES ( 
    'mapreduce.jdbc.url' = 'jdbc:oracle:thin:@localhost:1521:orcl',
    'mapreduce.jdbc.username' = 'hr',
    'mapreduce.jdbc.password' = 'hr',
    'mapreduce.jdbc.input.table.name' = 'EMPLOYEES'
);
```

**Note:** Include ucp.jar, ojdbc7.jar and osh.jar in the Hive auxpath controlled by HIVE_AUX_JARS_PATH environment variable that is present in hive-env.sh,hive.aux.jars.path configuration property or --auxpath option when you invoke Hive. On BDA, you can configure these using Cloudera Manager interface. You should also add these jars to classpath of hadoop tasks using add jar on Hive command line.

For various Hive Command Line options and configuration properties, refer the following sources:

https://cwiki.apache.org/confluence/display/Hive/LanguageManual+Cli
https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties

9.4 Features of OD4H

The following topics discuss features of OD4H.

- Performance and Scalability Features
- Security Features
- Using Hive SQL with OD4H
- Using Spark SQL with OD4H
9.4.1 Performance And Scalability Features

Following sections discuss the performance and scalability features of OD4H:

- Splitters
- Predicate Pushdown
- Projection Pushdown
- Partition Pruning
- Smart Connection Management

HCatalog stores table metadata from Hive DDL. HiveSQL, Spark SQL and others, then use this metadata while submitting queries.

The Oracle table is divided into granules determined by the `splitterKind` property. These granules are then read into a split by `OracleStorageHandler`, by submitting generated queries.

`OracleStorageHandler` will not have to test all possible query types if the query plan determines which splits need to be scanned.

Figure 9-2 OD4H in a Nutshell

9.4.1.1 Splitters

While executing a query on a Hive external table through OTD4H, the underlying Oracle table is dynamically divided into granules, which correspond to splits on the Hadoop side. Each split is processed by a single map task. With the help of the `ORACLE_SPLITTER_KIND` property, you can specify how the splits are created. This ensures that the splits are a good match for the physical structure of the target table in Oracle Database.

The different kinds of splitters available are:
SINGLE_SPLITTER

Creates one split for the table. Use SINGLE_SPLITTER where a single task is sufficient to process the query against the entire table.

ROW_SPLITTER

Limits the number of rows per Split. The default number of rows is 1000. You can specify the number of rows by setting the oracle.hcat.osh.rowsPerSplit property. The default value of oracle.hcat.osh.maxSplits is 1 when ROW_SPLITTER is used. You can increase this value to enable parallel reads.

Based on the values provided in the rowsPerSplit property, OD4H will divide tables into splits. If the number of splits obtained is higher than the maxSplits, then maxSplits property will be used. The rows per split will be divided accordingly.

Note: oracle.hcat.osh.rowsPerSplit is used only by ROW_SPLITTER and not any other splitter kind.

BLOCK_SPLITTER

Creates splits based on underlying storage of data blocks. With Block Splitter, you can specify the maximum number of splits to be generated. The default value of oracle.hcat.osh.maxSplits is 1, when BLOCK_SPLITTER is used. You can increase this value to enable parallel reads. BLOCK_SPLITTER requires SELECT privilege on the SYS.DBA.EXTENTS table, granted to the schema containing the Oracle target table. In the event that this permission does not exist, OD4H will use SINGLE_SPLITTER.

Note: The actual number of splits under BLOCK_SPLITTER may be lesser than the value specified in the oracle.hcat.osh.maxSplits property.

Do not use BLOCK_SPLITTER on partitioned tables or Index Organized tables.

Note: For ROW_SPLITTER and BLOCK_SPLITTER types, use oracle.hcat.osh.useChunkSplitter to specify splitting mechanism. The default property value is true. This enables creating chunks corresponding to splits using the DBMS_PARALLEL_EXECUTE package. When the property value is false, custom SQL is generated for splitting.

PARTITION_SPLITTER

Creates one split per partition. PARTITION_SPLITTER is used by default when the table is partitioned. You can override this setting by specifying ROW_SPLITTER in table properties. With PARTITION_SPLITTER, the default value of oracle.hcat.osh.maxSplits table property is 64.

Following is an illustration of ROW_SPLITTER:

```sql
DROP TABLE employees;
CREATE EXTERNAL TABLE employees (  
    EMPLOYEE_ID INT,  
    FIRST_NAME  STRING,
```
LAST_NAME STRING,
SALARY DOUBLE,
HIRE_DATE TIMESTAMP,
JOB_ID STRING
)
STORED BY 'oracle.hcat.osh.OracleStorageHandler'

WITH SERDEPROPERTIES (  
   'oracle.hcat.osh.columns.mapping' = 'employee_id,first_name,last_name,salary,hire_date,job_id')

TBLPROPERTIES (  
   'mapreduce.jdbc.url' = 'jdbc:oracle:thin:@localhost:1521:orcl',  
   'mapreduce.jdbc.username' = 'hr',  
   'mapreduce.jdbc.password' = 'hr',  
   'mapreduce.jdbc.input.table.name' = 'EMPLOYEES',  
   'oracle.hcat.osh.splitterKind' = 'ROW_SPLITTER',  
   'oracle.hcat.osh.rowsPerSplit' = '1500'  
);

CUSTOM_SPLITTER

Use CUSTOM_SPLITTER If you want to provide a custom split generation mechanism. You can do this using CUSTOM_SPLITTER through oracle.hcat.osh.splitterKind property and a SELECT statement that emits ROWIDs corresponding to start and end of each split in oracle.hcat.osh.chunkSQL.

9.4.1.2 Choosing a Splitter

SINGLE_SPLITTER is used by default if no splitter is specified in the table properties for Hive external table, and the target Oracle table is not partitioned. For an unpartitioned table, the default value of oracle.hcat.osh.maxSplits will be 1. For partitioned table, the default value of the same will be 64, and the default splitter will be PARTITION_SPLITTER. The default for maxSplits is set to limit the number of connections to the Oracle server. To increase this limit, you must increase the value of oracle.hcat.osh.maxSplits explicitly in hive table properties.

Use the following guidelines while choosing a splitter kind for a hive external table:

<table>
<thead>
<tr>
<th>Splitter Kind</th>
<th>Use</th>
</tr>
</thead>
<tbody>
<tr>
<td>SINGLE_SPLITTER</td>
<td>When no parallelism is required.</td>
</tr>
<tr>
<td>PARTITION_SPLITTER</td>
<td>Used by default when target table is partitioned</td>
</tr>
<tr>
<td>BLOCK_SPLITTER</td>
<td>When Oracle user has SELECT privilege on SYS.DBA_EXTENTS, and target table is not partitioned.</td>
</tr>
<tr>
<td>ROW_SPLITTER</td>
<td>When Oracle user does not have SELECT privilege on SYS.DBA_EXTENTS.</td>
</tr>
<tr>
<td>CUSTOM_SPLITTER</td>
<td>For fine grain control over generated splits.</td>
</tr>
</tbody>
</table>
Predicate Pushdown

Predicate Pushdown is an optimization technique, in which you push predicates (WHERE condition) down to be evaluated by Oracle Database at the time of querying. This minimizes the amount of data fetched from Oracle Database to Hive, while performing a query.

Set the configuration property `hive.optimize.ppd` to either `true` or `false` for enabling Predicate Pushdown. The default value on hive-1.1.0 is set to `true`. Hence, Predicate Pushdown is always performed, unless you want to disable it.

Note:

OD4H does not push down all possible predicates. It considers only the part of the execution plan pertaining to Oracle table declared as external table. OD4H also rewrites sub-queries for the Oracle SQL engine and each split task. At present conditions involving operators `>`, `=`, `<` in a single condition over a column (e.g. `key > 10`) or a combination of multiple conditions separated by AND (e.g. `key > 10 AND key < 20 AND key !=17`) are pushed down.

Another option to reduce the amount of data fetched from the Oracle Database is to specify a condition at the time of table creation, using `TBLPROPERTY` `mapreduce.jdbc.input.conditions`. For instance:

```
mapreduce.jdbc.input.conditions = 'key > 10 OR key = 0'.
```

This will restrict the rows fetched from Oracle Database whenever any query is performed based on the condition specified. The external table that gets created, is analogous to a view on Oracle Database. This approach is only useful when you want to push down complex predicates that cannot be analyzed and automatically pushed down by OD4H.

Table Level Predicate Pushdown

For Table Level Predicate Pushdown to be enabled, you must specify a condition at the time of table creation, using `TBLPROPERTY` `mapreduce.jdbc.input.conditions`.

Following is an illustration:

```
mapreduce.jdbc.input.conditions = 'key > 10 OR key = 0'.
```

This will restrict the rows fetched from Oracle Database when any query is performed based on the condition specified. The table created will be analogous to a view on Oracle database.

However, Table Level Predicate Pushdown is ignored when a predicate (WHERE clause) is specified in the query.

Projection Pushdown

Projection Pushdown is an optimization technique that fetches only the required columns from Oracle Database when a query is performed. If you want to fetch all columns during a query (not recommended), you can disable it by setting the `hive.io.file.read.all.columns` connection property to `true`. On Hive-1.1.0, this property is `false` by default.
9.4.1.5 Partition Pruning

If you refer to Employee Data Partition table, the partitions irrelevant to the query are removed from the partition list. This is done by executing an explain plan on the query to obtain the list of partitions and sub-partitions that are relevant to the query.

Table level partition pruning uses table level predicate pushdown, on the other hand partition pruning at the query level uses query level predicate pushdown.

Partition pruning is active when a SELECT query is run, in which the WHERE clause uses the partitioning key. Following is an example of partition pruning:

To query the partition, where salary is in the above range and prune other partitions, perform the following:

Hive External Table:

```sql
CREATE EXTERNAL TABLE EmployeeDataPartitioned (
  Emp_ID int,
  First_Name string,
  Last_Name string,
  Job_Title string,
  Salary int
) STORED BY 'oracle.hcat.osh.OracleStorageHandler'
WITH SERDEPROPERTIES (
  'oracle.hcat.osh.columns.mapping' = 'Emp_ID,First_Name,Last_Name,Job_Title,Salary')
TBLPROPERTIES (
  'mapreduce.jdbc.url' = '${hiveconf:connection_string}',
  'mapreduce.jdbc.username' = '${hiveconf:oracle_user}',
  'mapreduce.jdbc.password' = '${hiveconf:oracle_pwd}',
  'mapreduce.jdbc.input.table.name' = 'EmployeeData',
  'oracle.hcat.osh.oosKind' = 'PARTITIONED_TABLE'
);
```

The following SELECT statement shows how to query the partition, where salary is between 72000 to 78000, and prunes other partitions:

```sql
select * from EmployeeDataPartitioned where salary > 72000 and salary < 78000;
```

9.4.2 Smart Connection Management

Connection Caching

Each map task runs in its own JVM. Each JVM in turn caches a single connection to the Oracle database that you can reuse within the same query. The Mapper checks the cache before establishing a new connection and caching is not done once the query has completed executing.

Oracle RAC Awareness

JDBC and UCP are aware of various Oracle RAC instances. This can be used to split queries submitted to JDBC. The StorageHandler will depend on listener for load balancing.
Handling Logon Storms
Hadoop allows you to limit the number of mappers attempting to connect to the Database. Hadoop allows you to limit the number of mappers attempting to connect to the Database using oracle.hcat.osh.maxSplits. This parameter controls the degree of concurrency. However, subsequent tasks of the same query are guaranteed to query their table granule as per the System Commit Number (SCN) of the query. This ensures consistency of the result sets.

Database Resident Connection Pooling (DRCP)
It is recommended to configure DRCP for OD4H, and limit the maximum number of concurrent connections to the Oracle Database from OD4H.

Configuring Database Resident Connection Pooling
To configure DRCP, use the following steps:

1. Login as SYSDBA.
2. Start the default pool, SYS_DEFAULT_CONNECTION_POOL using DBMS_CONNECTION_POOL.START_POOL with the default settings.

You can use DBMS_CONNECTION_POOL.MINSIZE and DBMS_CONNECTION_POOL.MAXSIZE with the default settings.

Note: Oracle Database Administrator’s Guide for more information on Configuring DRCP.

9.4.3 Security Features
Following are the security features of OD4H:

9.4.3.1 Improved Authentication
OD4H uses Oracle JDBC driver for connecting to Oracle Database. It provides all authentication methods supported by Oracle JDBC. OD4H supports authentication through use of basic authentication (username and password), Oracle Wallet, and Kerberos. You can specify the authentication to be used for a table created in Hive, through the oracle.hcat.osh.authentication table property. This is useful only for strong authentication.

• Kerberos
• Oracle Wallet
• Basic Authentication

Note: Oracle recommends using strong authentication such as Kerberos.

The various authentication processes are described with examples as follows:

1. Kerberos
   Uses Kerberos credentials of the Hadoop engine process. This principal should have access to the table.
You can enable Kerberos configuration on Hive, by adding to hive-env.sh the following:

```bash
export HADOOP_OPTS="$HADOOP_OPTS -Djava.security.krb5.conf=<path to kerberos configuration>"
```

To enable child JVMs to use Kerberos configuration, edit the mapred-site.xml to include the following property on all nodes of the cluster:

```xml
<property>
  <name>mapred.child.java.opts</name>
  <value>-Djava.security.krb5.conf=<path to kerberos configuration></value>
</property>
```

Enable these configurations on BDA using Cloudera manager.

Following is an illustration of Kerberos authentication:

```sql
CREATE EXTERNAL TABLE kerb_example (
id DECIMAL,
  name STRING,
salary DECIMAL
)
STORED BY 'oracle.hcat.osh.OracleStorageHandler'
WITH SERDEPROPERTIES (  
  'oracle.hcat.osh.columns.mapping' = 'id,name,salary')
TBLPROPERTIES (  
  'mapreduce.jdbc.url' = 'jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=tcp)(HOST=adc*******.xxxxxx.com)(PORT=5521))(CONNECT_DATA=(SERVICE_NAME=project_name.xxx.rdbms.xxxx.com)))',  
  'mapreduce.jdbc.username' = 'CLIENT@xxxxxx.COM',  
  'oracle.hcat.osh.authentication' = 'KERBEROS',  
  'oracle.net.kerberos5_cc_name' = '/tmp/krb5cc_xxxxx',  
  'java.security.krb5.conf' = '/home/user/kerberos/krb5.conf',  
  'oracle.hcat.osh.kerb.callback' = 'KrbCallbackHandler',  
  'sun.security.krb5.principal' = 'CLIENT@xxxxxx.COM'  
);
```

The path specified in oracle.security.krb5.conf should be accessible to all nodes of the cluster. These paths should also match with the path of the corresponding properties in Oracle Database sqlnet.ora. The keytab path provided in sqlnet.ora should also be accessible from all nodes of the cluster.

If sun.security.krb5.principal is not specified, OD4H will attempt to authenticate using default principal in Credential Cache specified by the oracle.net.kerberos5_cc_name property.

**Note:**

The callback will be called only if the principal cannot be authenticated using a ticket obtained from the credential cache specified in oracle.net.kerberos5_cc_name property.
A simple callback handler class is described as follows (The callback class must be available to the hive classpath):

```java
class KrbCallbackHandler implements CallbackHandler{

@Override
public void handle(Callback[] callbacks) throws IOException,
        UnsupportedCallbackException{
    for (int i = 0; i < callbacks.length; i++){
        if (callbacks[i] instanceof PasswordCallback){
            PasswordCallback pc = (PasswordCallback)callbacks[i];
            System.out.println("set password to ©welcome©");
            pc.setPassword(new String("welcome").toCharArray());
        } else if (callbacks[i] instanceof NameCallback) {
            ((NameCallback)callbacks[i]).setName("client@xxxxx.COM");
        } else{
            throw new UnsupportedCallbackException(callbacks[i],
                    "Unrecognized Callback");
        }
    }
}
```

2. Oracle Wallet

The wallet should be available in the OS environment of each engine process. Following is an illustration of how to add Wallet authentication:

```sql
CREATE EXTERNAL TABLE wallet_example (id DECIMAL,
                                       name STRING,
                                       salary DECIMAL)
STORED BY 'oracle.hcat.osh.OracleStorageHandler'
WITH SERDEPROPERTIES (
    'oracle.hcat.osh.columns.mapping' = 'id,name,salary')
TBLPROPERTIES (
    'mapreduce.jdbc.url' = 'jdbc:oracle:thin:@inst1',
    'mapreduce.jdbc.input.table.name' = 'wallet_example',
    'oracle.hcat.osh.authentication' = 'ORACLE_WALLET',
    'oracle.net.tns_admin' = '/scratch/user/view_storage/user_project6/work',
    'oracle.net.wallet_location' = '/scratch/user/view_storage/user_project6/work'
);
```

**Note:** The paths specified in `oracle.net.tns_admin` and `oracle.net.wallet_location` should be accessible from all nodes of the cluster.

**See Also:**
Managing the Secure External Password Store for Password Credentials section in the *Oracle Database Security Guide*.

3. Basic Authentication (for demo purposes only)

This is stored in HCatalog TBLPROPERTIES or supplied on HiveQL SELECT statement.
Using HiveQL with OD4H

When Basic Authentication is used, the username and password for Oracle
Schema is specified in Hive external Table properties.
Note:

Oracle does not recommend this in the production environment, since the
password is stored in clear in HCatalog.

9.5 Using HiveQL with OD4H
HiveQL is a SQL like language provided by Hive. It can be used to query hive external
tables created using OD4H.
You can run the Resource Manager web interface in your browser (http://
bigdatalite.localdomain:8088/cluster), to track the status of a running
query on BDA.
You can also see the logs of a query in Cloudera Manager, which also indicates the
actual query sent to Oracle Database corresponding to your query on HiveQL. Hive
and OD4H use slf4j framework for logging. You can control logging level for OD4H
related classes using logging configuration techniques of Hive.

9.6 Using Spark SQL with OD4H
Spark SQL enables relational queries expressed in SQL and HiveSQL to be executed
using Spark. Spark SQL allows you to mix SQL queries with programmatic data
manipulations supported by RDDs (Resilient Distributed Datasets) in Java, Python
and Scala, with a single application.
Spark SQL enables you to submit relational queries using SQL or HiveQL. You can
also use it to query external tables created using OD4H.
Perform the following steps to configure Spark-SQL on BigDataLite-4.2 VM, before
running queries:
1.

Add ojdbc7.jar and osh.jar to CLASSPATH in /usr/lib/spark/bin/
compute-classpath.sh
CLASSPATH="$CLASSPATH:/opt/oracle/od4h/lib/osh.jar"
CLASSPATH="$CLASSPATH:/opt/oracle/od4h/lib/ojdbc7.jar"

2.

Edit SPARK_HOME in /usr/lib/spark/conf/spark-env.sh
export SPARK_HOME=/usr/lib/spark:/etc/hive/conf

3.

You will need to specify additional environment variables in /usr/lib/spark/
conf/spark-env.sh.
The Hive related variables that need to be added are marked in bold. The file
already contains Hadoop related environment variables.
export
export
export
export
export
export

mapreduce
export HADOOP_YARN_HOME=${HADOOP_YARN_HOME:-$(HADOOP_HOME)/../hadoop-yarn}
export HADOOP_CONF_DIR=${HADOOP_CONF_DIR:-$DEFAULT_HADOOP_CONF}
export HIVE_CONF_DIR=${HIVE_CONF_DIR:-$DEFAULT_HIVE_CONF}

CLASSPATH="$CLASSPATH:$HIVE_CONF_DIR"
CLASSPATH="$CLASSPATH:$HADOOP_CONF_DIR"

if [ "x" != "x$YARN_CONF_DIR" ]; then
  CLASSPATH="$CLASSPATH:$YARN_CONF_DIR"
fi

# Let's make sure that all needed hadoop libs are added properly
CLASSPATH="$CLASSPATH:$HADOOP_HOME/client/*"
CLASSPATH="$CLASSPATH:$HIVE_HOME/lib/*"
CLASSPATH="$CLASSPATH:$(HADOOP_HOME/bin/hadoop classpath)"

Once configured, you can run some sample queries on spark SQL using scripts included in demo:/shell/*QuerySpark.sh. By default, Spark prints queries on the console. To modify this behavior you can edit the spark logging configuration file /usr/lib/spark/conf/log4j.properties.

The log printed by OracleRecordReader shows the actual query sent to Oracle Database, as follows:

15/03/18 10:36:08 INFO OracleRecordReader: Reading records from Oracle Table using Query: SELECT FIRST_NAME, LAST_NAME, EMP_ID FROM EmployeeData

9.7 Writing Back to Oracle Database

In the typical use case for OD4H, you store the result sets of Hive or Spark SQL queries back to Oracle Database. OD4H implements OutputFormat to enable you to write back to an Oracle Database table from Hadoop.

After the data is inserted into an Oracle Database table, you can then use your favorite business intelligence tools for further data mining.

The following query is from the OD4H demo code samples. It demonstrates writing back to an external table called EmployeeBonusReport.

**Example 9-1  Writing Hive or Spark Result Sets Back to Oracle Database**

```java
INSERT INTO EmployeeBonusReport
SELECT EmployeeDataSimple.First_Name, EmployeeDataSimple.Last_Name,
EmployeeBonus.bonus
FROM EmployeeDataSimple JOIN EmployeeBonus ON
(EmployeeDataSimple.Emp_ID=EmployeeBonus.Emp_ID)
WHERE salary > 70000 and bonus > 7000"
```
The following are useful resources for learning about and using Oracle Big Data Connectors.

**Oracle Big Data Connector Downloads**
The Oracle Technology Network (OTN) provides downloads of the latest versions as well as earlier versions of the Oracle Big Data Connectors.

**Oracle Big Data Connector Blogs and Community Forums**
Oracle Blogs includes a number of postings on Oracle Big Data Connectors under the topic *Connecting Hadoop with Oracle*, including the following.

- **Oracle Shell for Hadoop Loaders (OHSH)**, an introduction to OHSH.
- **Copy to Hadoop with OHSH**, some OHSH examples using the Oracle Big Data Lite VM.
- **Oracle SQL Connector for HDFS and Oracle Database System Platforms**, a post about OSCH support for the various Oracle Database server platforms.

The Oracle Datasource for Apache Hadoop Community Forum provides blog posts on OD4H and a discussion forum for OD4H users.
