Glossary

Index
Preface

This guide describes how to administer Oracle HTTP Server.

Audience

Oracle HTTP Server Administrator’s Guide is intended for application server administrators, security managers, and managers of databases used by application servers.

Documentation Accessibility

Our goal is to make Oracle products, services, and supporting documentation accessible, with good usability, to the disabled community. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at http://www.oracle.com/accessibility/

Accessibility of Code Examples in Documentation

Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

Accessibility of Links to External Web Sites in Documentation

This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

TTY Access to Oracle Support Services

Oracle provides dedicated Text Telephone (TTY) access to Oracle Support Services within the United States of America 24 hours a day, seven days a week. For TTY support, call 800.446.2398.
Related Documents

For more information, see the Oracle Application Server Documentation Library.

Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><code>monospace</code></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
This chapter describes the Oracle HTTP Server, highlighting the differences between the Oracle distribution and the open source Apache product on which it is based. It also explains how to start, stop, and restart the server.

Topics discussed are:

- Oracle HTTP Server Features
- Oracle HTTP Server Components
- Oracle HTTP Server Support
- Oracle HTTP Server Management
- Starting, Stopping, and Restarting Oracle HTTP Server

Documentation from the Apache Software Foundation is referenced when applicable.

---

**Oracle HTTP Server Features**

Oracle HTTP Server is the Web server component of Oracle Application Server. Based on the Apache infrastructure, Oracle HTTP Server allows developers to program their site in a variety of languages and technologies - Perl (through mod_perl and CGI), C (through CGI, and FastCGI), C++ (through FastCGI), PHP, and Oracle’s PL/SQL. It can also be a proxy server, both forward and reverse. In addition, the features of single sign-on, clustered deployment, and high availability, enhance the operations of the Oracle HTTP Server.

**Based on Apache - HTTP v1.1 Support**

Oracle HTTP Server code is based on Apache 1.3 Web Server (http://www.apache.org). With such a proven code base, Oracle HTTP Server provides Oracle Application Server customers with the stability, flexibility, and scalability required of a Web server.

**Security - Encryption with SSL**

Secure Sockets Layer is required to run any Web site securely. Oracle HTTP Server supports SSL encryption based on industry standard, patented, algorithms. The SSL
works seamlessly with both Internet Explorer and Netscape browsers. In addition, the infrastructure has been upgraded to share the same wallet information as the database users. Features include:

- **SSL HW Acceleration Support**: SSL encryption is slower when done in software. Dedicated hardware support for this purpose is now supported, specifically with nCipher.

- **Variable Security per Directory**: This feature allows individual directories to be protected by different strength encryption.

- **Oracle HTTP Server to OC4J SSL Support**: Oracle HTTP Server and OC4J can communicate using AJP protocol over SSL. Previously, Oracle HTTP Server and OC4J used the AJP 1.3 protocol unencrypted, without support for authentication. Now, Oracle HTTP Server has been modified to extend support to the AJP 1.3 protocol over SSL providing both encryption and authentication.

**Security - Single Sign On**

Oracle HTTP Server supports the standard basic authentication features of HTTP servers. The source for the username and password used here is a flat file (with encrypted passwords). In addition, a module, mod_osso, is included to support single sign on across sites and across applications. This provides for a much better end user experience (they have to login only once), and a much easier development cycle (most of the security is declarative).

**See Also:**

- Oracle Application Server Security Guide
- Chapter 10, ‘Managing Security’
- Chapter 11, ‘Enabling SSL for Oracle HTTP Server’

**Virtual Hosts**

The virtual host facility allows an HTTP server to service multiple domain names over one IP address. Thus, virtual hosts www.north.com might have the same IP address as www.south.com. Oracle HTTP Server provides a "container" environment for a virtual host, thus providing a virtual host with its own set of security and other configuration directives, in addition to locations from which the files are served. This allows an ISP to save on hardware and administrative costs by enabling hundreds to thousands of sites to be served from a single runtime instance of Oracle HTTP Server. Only one virtual host on a single IP address can accommodate SSL. Oracle HTTP Server can support multiple IP addresses and each one of them can have one, but only one virtual host.

**Distributed Authoring and Versioning Support**

WebDAV, an IETF standard, is an HTTP based protocol that allows DAV enabled clients, such as MS Office, Windows Explorer, to edit files on a server. The Apache Software Foundation provides a module, mod_oradav, that provides support for file based storage on the server. In addition to providing this functionality, Oracle HTTP Server enables the server side store to be a database or other repository.

**See Also:** Chapter 9, "Configuring and Using mod_oradav"
Proxy Server and URL Rewriting
Any Web site that is ‘alive’ changes often. Along with that, the directory structure and the URLs change. Oracle HTTP Server makes it easy to accommodate these changes by including an engine that support URL rewriting so that the end users do not have to change their bookmarks. It also supports reverse proxy capabilities, thus making it easier to make content served by different servers to appear from one single server.

Oracle Application Server Proxy Plug-in
A separately available component which enables IIS and Sun ONE Web servers to route requests to Oracle Application Server. Users can benefit from all of the Oracle Application Server features even if their corporate standard requires them to use IIS or Sun ONE Web servers. The proxy plug-in provides Oracle Application Server features, such as single sign-on, load balancing, and AJP port tunneling, to be accessed when using IIS or Sun ONE Web servers.

See Also: Chapter A, "Using Oracle Application Server Proxy Plug-in"

Oracle Application Server SSO Plug-in
A separately available component which enables IIS and Sun ONE Web servers to be integrated with Oracle Application Server Single Sign-on. IIS and Sun ONE listener applications can now be protected by using the single sign-on infrastructure. You can now be authenticated to these listeners using only one single sign-on password. This functionality is similar to what mod_osso provides to Oracle HTTP Server.

See Also:
- Appendix B, "Using Oracle Application Server SSO Plug-in"
- "mod_osso" on page 8-19

Oracle Application Server Containers for J2EE Plug-in
A separately available component which enables IIS, Sun ONE and Apache 1.3.x Web servers to route requests directly to OC4J. This functionality is similar to what mod_oc4j provides for Oracle HTTP Server.

See Also:
- Chapter C, "Using Oracle Application Server Containers for J2EE Plug-in"
- "mod_oc4j" on page 8-9

PL/SQL Stored Procedures
This feature allows access to PL/SQL code stored in the Oracle database.

See Also: Oracle Application Server mod_plsql User’s Guide

PL/SQL Server Pages
Similar in concept to the Java Server Pages, this module allows PL/SQL to be used as the scripting language within an HTML page. It gets translated into a stored procedure, which then uses the module described earlier (for PL/SQL stored procedure) to send the output to the browser.

See Also: Oracle Application Server mod_plsql User’s Guide
Server Side Include
Server Side Includes provide an easy way of adding some dynamic, or uniform static content, across all the site’s pages. It is typically used for header/footer information. Oracle HTTP Server supports special directives to enable these only for certain types of files, or for given virtual hosts.

Perl
Perl is a scripting language often used to provide dynamic content. Perl can either be called as a CGI program, or directly through mod_perl. Oracle Application Server uses Perl version 5.6.1.

See Also: "mod_perl" on page 8-19

PHP
PHP is an open source, widely-used, general-purpose, client-side scripting language, that is embedded in standard HTML. It is used to generate dynamic HTML pages.

See Also:
Chapter 12, "Using PHP with Oracle Application Server"
"mod_php" on page 8-22

C/C++ (CGI and FastCGI)
CGI programs have been commonly used to program Web applications. Oracle HTTP Server enhances them by providing a mechanism to keep them alive beyond the request lifecycle, thus improving the performance tremendously.

Dynamic Monitoring Service
Dynamic Monitoring Services (DMS) metrics give runtime performance statistics for both Oracle HTTP Server and OC4J processes. As applications run, DMS collects detailed performance statistics. This data enables you to monitor the duration of important request processing phases and status information. With this information, you can locate performance bottlenecks and tune the application server to maximize throughput and minimize response time. Process metrics as well as event information is available and can be viewed through Oracle Enterprise Manager.

See Also: Oracle Application Server Performance Guide

Oracle Process Manager and Notification Server
Oracle Application Server provides a high availability infrastructure integration with Oracle Process Manager and Notification Server (OPMN), for process management, death detection, and failover for OC4J and Oracle HTTP Server processes.

See Also:
- Oracle Application Server High Availability Guide
- Oracle Process Manager and Notification Server Administrator’s Guide

Distributed Configuration Management
Distributed Configuration Manager (DCM) enables cluster wide deployments in a very simple way. J2EE applications for OC4J can now be deployed to a cluster, or a new node can be added to the cluster with ease.

See Also: Distributed Configuration Management Administrator's Guide
Load Balancing
Oracle HTTP Server includes a module called mod_oc4j that routes requests from the OC4J instances in a cluster. OPMN helps ensure that mod_oc4j instances knows of all the OC4J in the system without requiring a system administrator to do any configuration.

See Also: Appendix D, "Load Balancing Using mod_oc4j"

Oracle HTTP Server Components

Oracle HTTP Server consists of several components that run within the same process. These components provide the extensive list of features that Oracle HTTP Server offers when handling client requests. The following are the major components:

- **HTTP Listener**: Oracle HTTP Server is based on an Apache HTTP listener to serve client requests. An HTTP server listener handles incoming requests and routes them to the appropriate processing utility.

- **Modules (mods)**: Modules both implement and extend the basic functionality of Oracle HTTP Server. Many of the standard Apache modules are included with Oracle HTTP Server. Oracle also includes several internal modules that are specific to Oracle Application Server components.

See Also: “Oracle HTTP Server Modules” on page 1-5

- **Perl Interpreter**: A persistent Perl runtime environment embedded in Oracle HTTP Server through mod_perl.

Figure 1–1 shows the path of various requests through Oracle HTTP Server components, where a client machine connects to Oracle Application Server Web Cache, which in turn connects to Oracle HTTP Server. Oracle HTTP Server, using various modules, connects to the database through OC4J, FastCGI, or the Perl interpreter.

![Figure 1–1 Oracle HTTP Server Request Flow](image)

See Also: Oracle Application Server Concepts

Oracle HTTP Server Modules

Table 1–1 identifies the modules shipped with Oracle HTTP Server. Modules extend the basic functionality of the Web server, and support integration between Oracle HTTP Server and other Oracle Application Server components. Note that the list differs from the Apache open source distribution (given the inclusion of Oracle modules).
Oracle provides technical support for the following Oracle HTTP Server features and conditions:

- Modules included in the Oracle distribution. Oracle does not support modules obtained from any other source, including the Apache Software Foundation. Oracle HTTP Server will still be supported when non-Oracle provided modules are included. If it is suspected that the non-Oracle provided modules are contributing to reported problems, customers may be requested to reproduce the problems without those modules being included.

- Problems that can be reproduced within an Apache configuration consisting only of supported Oracle Apache modules.

**Oracle HTTP Server Management**

Oracle HTTP Server can be managed using the following two methods:

- Application Server Control Console
- Oracle Application Server Command-line Tools

**Application Server Control Console**

You can manage Oracle HTTP Server using Oracle Enterprise Manager 10g. Oracle Enterprise Manager 10g enables you to manage your server from a Web browser using Oracle Enterprise Manager 10g Application Server Control Console (Application Server Control Console).

**Oracle Application Server Command-line Tools**

You can manage Oracle HTTP Server using the following command line tools:

- opmnctl
- dcmctl

**opmnctl**

Provides a command-line utility for Oracle Process Manager and Notification Server (OPMN) for process management. It is located in

- UNIX: `ORACLE_HOME/opmn/bin`
- Windows: `ORACLE_HOME\opmn\bin`

**dcmctl**

Provides a command-line utility for Distributed Configuration Management (DCM) for configuration management and application deployment. It is located in

- UNIX: `ORACLE_HOME/dcm/bin`
- Windows: `ORACLE_HOME\dcm\bin`

**Using dcmctl** You must use the DCM utility `dcmctl` in circumstances such as:

- Managing clusters and farms of Oracle Application Server instances.
- Managing the configuration of individual components, such as OC4J, Oracle HTTP Server instances, and Oracle Process Manager and Notification Server, or Java Authentication and Authorization Service.
- Performing cluster-wide OC4J application deployment.

**See Also:**

- Chapter 7, "Application Server Control Console Management"
- Oracle Enterprise Manager Concepts
- Oracle Process Manager and Notification Server Administrator's Guide
- Distributed Configuration Management Administrator's Guide
Managing versions of configuration with archive, save and restore, and import and export functions.

See Also: Distributed Configuration Management Administrator's Guide

Starting, Stopping, and Restarting Oracle HTTP Server

Oracle HTTP Server is managed by Oracle Process Manager and Notification Server (OPMN). You can use Oracle Enterprise Manager 10g Application Server Control Console to start, stop, and restart the server.

See Also: Chapter 7, 'Application Server Control Console Management'

For command-line management, you can use the opmnctl utility to start, stop, and restart the server.

You must always use OPMN to start, stop and restart Oracle HTTP Server. Otherwise, the configuration management infrastructure cannot detect or communicate with the Oracle HTTP Server processes, and problems may occur.

Note: Do not use the apachectl utility to manage Oracle HTTP Server.

To determine the state of Oracle HTTP Server, use the following command:

```bash
opmnctl status
```

The processes are listed with their current state (Up, Down, and so on.)

Starting Oracle HTTP Server

To start Oracle HTTP Server, use the startproc command:

- UNIX: `ORACLE_HOME/opmn/bin> opmnctl [verbose] startproc ias-component=HTTP_Server`
- Windows: `ORACLE_HOME\opmn\bin> opmnctl [verbose] startproc ias-component=HTTP_Server`

Stopping Oracle HTTP Server

To stop Oracle HTTP Server, use the stopproc command:

- UNIX: `ORACLE_HOME/opmn/bin> opmnctl [verbose] stopproc ias-component=HTTP_Server`
- Windows: `ORACLE_HOME\opmn\bin> opmnctl [verbose] stopproc ias-component=HTTP_Server`

Restarting Oracle HTTP Server

Restarting Oracle HTTP Server performs a graceful restart, which is invisible to clients. In a graceful restart, on UNIX, a USR1 signal is sent. When the process receives this signal, it tells the children to exit after processing the current request. (Children that are not servicing requests exit immediately.)
The parent re-reads the configuration files and re-opens the log files, replacing the children with new children in accordance with the settings it finds when re-reading the configuration files. It always observes the process creation settings (MaxClients, MaxSpareServers, MinSpareServers) specified, and takes the current server load into account.

To restart Oracle HTTP Server, use the restartproc command:

- UNIX: `ORACLE_HOME/opmn/bin> opmnctl [verbose] restartproc ias-component=HTTP_Server`
- Windows: `ORACLE_HOME\opmn\bin> opmnctl [verbose] restartproc ias-component=HTTP_Server`

**See Also:** Oracle Process Manager and Notification Server Administrator’s Guide
This chapter introduces you to the Oracle HTTP Server directory structure, configuration files, configuration file syntax, modules, and directives.

Topics discussed are:

- Understanding Oracle HTTP Server Directory Structure
- Accessing Configuration Files
- Configuration Files Syntax
- Classes of Directives
- Scope of Directives
- Understanding Modules
- About .htaccess Files

**Understanding Oracle HTTP Server Directory Structure**

Oracle HTTP Server is installed in the `ORACLE_HOME/Apache` directory on UNIX or `ORACLE_HOME\Apache` directory on Windows.

*Figure 2-1* illustrates Oracle HTTP Server directory structure.
The Apache directory is located at the top level under the `ORACLE_HOME`. It contains subdirectories for configuring modules such as `mod_plsql` and `mod_oradav`. It also contains another directory called `Apache`, which is the base directory of Oracle HTTP Server. Table 2-1 contains information about the subdirectories within the `ORACLE_HOME/Apache` directory.

**Table 2-1  Apache Subdirectories**

<table>
<thead>
<tr>
<th>Directory Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>bin</td>
<td>Contains Oracle HTTP Server executables.</td>
</tr>
<tr>
<td>cgi-bin</td>
<td>Contains the CGI scripts. These are programs or shell scripts that can be executed by Oracle HTTP Server on the behalf of its clients.</td>
</tr>
<tr>
<td>conf</td>
<td>Contains the configuration files.</td>
</tr>
<tr>
<td>fastcgi</td>
<td>Contains the fastcgi runtime libraries, the necessary bits that you need to build your own fastcgi applications.</td>
</tr>
<tr>
<td>fcgi-bin</td>
<td>Contains Fastcgi scripts.</td>
</tr>
<tr>
<td>htdocs</td>
<td>Contains the HTML scripts. The htdocs directory and its subdirectories are accessible to anyone on the Web, and therefore pose a severe security risk if used for anything other than publicly available data.</td>
</tr>
<tr>
<td>icons</td>
<td>Contains the icons that Oracle HTTP Server uses when displaying information or error messages.</td>
</tr>
<tr>
<td>include</td>
<td>Contains header files for building custom modules.</td>
</tr>
<tr>
<td>libexec</td>
<td>Contains the shared library files for modules.</td>
</tr>
<tr>
<td>log</td>
<td>Contains the log data, for both access and errors.</td>
</tr>
<tr>
<td>man</td>
<td>Contains the man page for Oracle HTTP Server.</td>
</tr>
</tbody>
</table>

The Apache directory is located at the top level under the `ORACLE_HOME`. It contains subdirectories for configuring modules such as `mod_plsql` and `mod_oradav`. It also contains another directory called `Apache`, which is the base directory of Oracle HTTP Server. Table 2-1 contains information about the subdirectories within the `ORACLE_HOME/Apache` directory.
Accessing Configuration Files

The main configuration file for Oracle HTTP Server is `httpd.conf`. This file, along with other configuration files used by the server are located in:
- **UNIX**: `ORACLE_HOME/Apache/Apache/conf`
- **Windows**: `ORACLE_HOME\Apache\Apache\conf`

Some of these files are read only once when the server starts or is reloaded, whereas some files are read every time a related file or directory is requested.

The configuration files which are read only once are called *server-wide* configuration files.

### Configuration Files Syntax

Directives are configuration instructions for Oracle HTTP Server. Directives are placed in `httpd.conf` and other configuration files to determine the behavior of the server.

Oracle HTTP Server configuration files should contain one directive per line. The back-slash `\` can be used as the last character on a line to indicate that the directive continues onto the next line. There must be no other characters or white space between the back-slash and the end of the line.

Directives in the configuration files are case-insensitive, but arguments to directives are often case-sensitive. Lines which begin with the character `#` are considered comments, and are ignored. Comments may not be included on a line after a configuration directive. Blank lines and white space occurring before a directive are ignored, so you may indent directives for clarity.

For example:

```plaintext
# DocumentRoot: The directory out of which you will serve your
# documents. By default, all requests are taken from this directory, but
# symbolic links and aliases may be used to point to other locations.
# DocumentRoot "/private/oracle/Apache/Apache/htdocs"

# Each directory to which Apache has access, can be configured with respect
# to which services and features are allowed and/or disabled in that
# directory (and its subdirectories).

# First, we configure the "default" to be a very restrictive set of
# permissions.
```

### Configuration Files Syntax

<table>
<thead>
<tr>
<th>Directory Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mod_perl</code></td>
<td>Contains sample code for <code>mod_perl</code>. It also contains <code>mod_perl</code> specific libraries, and man pages.</td>
</tr>
<tr>
<td><code>php</code></td>
<td>Contains sample code for <code>mod_php</code>. On UNIX, the <code>php</code> directory also contains the PHP CLI (PHP executables), man pages, and headers. The headers enable you to build your own PHP extensions. On Windows, it contains the PHP CLI and OCI extension to PHP (on UNIX, the OCI extension is compiled into <code>mod_php</code>).</td>
</tr>
</tbody>
</table>

## Table 2-1 (Cont.) Apache Subdirectories

<table>
<thead>
<tr>
<th>Directory Name</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mod_perl</code></td>
<td>Contains sample code for <code>mod_perl</code>. It also contains <code>mod_perl</code> specific libraries, and man pages.</td>
</tr>
<tr>
<td><code>php</code></td>
<td>Contains sample code for <code>mod_php</code>. On UNIX, the <code>php</code> directory also contains the PHP CLI (PHP executables), man pages, and headers. The headers enable you to build your own PHP extensions. On Windows, it contains the PHP CLI and OCI extension to PHP (on UNIX, the OCI extension is compiled into <code>mod_php</code>).</td>
</tr>
</tbody>
</table>
Classes of Directives

Table 2–2 classifies directives according to the context in which they can be used: global, per-server, and per-directory.

<table>
<thead>
<tr>
<th>Class</th>
<th>Context</th>
<th>Where Used</th>
</tr>
</thead>
<tbody>
<tr>
<td>global</td>
<td>server configuration</td>
<td>Inside server configuration files, but only outside of container directives.</td>
</tr>
<tr>
<td>per-server</td>
<td>server configuration, virtual host</td>
<td>Inside server configuration files, both outside (for the main server) and inside VirtualHost directives.</td>
</tr>
<tr>
<td>per-directory</td>
<td>server configuration, virtual host, directory</td>
<td>Everywhere; particularly inside the server configuration files.</td>
</tr>
</tbody>
</table>

Note: In Table 2-2, each class is a subset of the class preceding it. For example, directives from the per-directory class can also be used in the per-server and global contexts, and directives from the per-server class can be used in the global context.

Scope of Directives

Directives placed in the main configuration files apply to the entire server. If you wish to change the configuration for only a part of the server, you can scope your directives by placing them in specific sections.

There are two types of directives:

- Container Directives
- Block Directives

Container Directives

Container directives specify the scope within which directives take effect. The following container directives are discussed in detail in subsequent sections:

- `<Directory>`
- `<DirectoryMatch>`
- `<Files>`
- `<FilesMatch>`
- `<Limit>`
- `<LimitExcept>`
- `<Location>`
**Scope of Directives**

- `<LocationMatch>`
- `<VirtualHost>`

**<Directory>**
Encloses a group of directives that apply only to the named directory and subdirectories of that directory. Any directory that is allowed in a directory context may be used. The directory is either the full path to a directory, or a wildcard string. In a wildcard string, ? matches any single character, and * matches any sequence of characters. It is important to note that `<Directory />` operates on the whole file system, whereas `<Directory dir>` refers to absolute directories. `<Directory>` containers cannot be nested inside each other, but can refer to directories in the document root that are nested.

**<DirectoryMatch>**
Specifies regular expressions, instead of using the tilde form of `<Directory>` with wildcards in the directory specification. The following two examples have the same result; matching directories starting with `web` and ending with a number from 1 to 9:

```
<Directory ~/web[1-9]/>
<DirectoryMatch /web[1-9]/>
```

**<Files>**
The `<Files file>` and `<Files>` directives support access control by filename. It is comparable to the `<Directory>` and `<Location>` directives. The directives given within this section can be applied to any object within a base name (the last component of the filename) matching the specified file name. `<Files>` sections are processed in the order that they appear in the configuration file, after the `<Directory>` sections, and `.htaccess` files are read, but before `<Location>` sections. Note that the `<Files>` directives can be nested inside `<Directory>` sections to restrict the portion of the file system to which they apply.

**<FilesMatch>**
Provides access control by filename, just as the `<Files>` directive does. However, it accepts regular expressions.

**<Limit>**
`<Limit method>` defines a block according to the HTTP method of the incoming request. The following example limits the application of the directives that follow scripts that use the specified method:

```
<Limit POST PUT OPTIONS>
order deny, allow
deny from all
allow from 127.0.0.192
</Limit>
```

Generally, `<Limit>` should not be used unless needed. It is useful only for restricting directives to particular methods. `<Limit>` is frequently used with other containers, and it is contained in any of them.

**<LimitExcept>**
Restricts access controls to all HTTP methods except the named ones.
Understanding Modules

<Location>
Limits the application of the directives within a block to those URLs specified, rather than to the physical file location like the <Directory> directive. <Location> sections are processed in the order that they appear in the configuration file, after the <Directory> sections, and .htaccess files are read, and after the <Files> sections. <Location> accepts wildcard directories and regular expressions with the tilde character.

<LocationMatch>
Functions in an identical manner to <Location>. You should use it for specifying regular expressions instead of the tilde form of <Location> with wildcards in the location specification.
For example:

<LocationMatch '/(extra|special)/data'>
matches the URLs that contained the /extra/data or /special/data sub string.

<VirtualHost>
Oracle HTTP Server has the capabilities to serve many different Web sites simultaneously. Directives can also be scoped by placing them inside <VirtualHost> sections, so that they will only apply to requests for a particular Web site.

Virtual host refers to the practice of maintaining more than one server on one machine, as differentiated by their apparent hostname. For example, it is often desirable for companies sharing a Web server to have their own domain, and Web servers accessible, for example, www.oracle1.com and www.oracle2.com, without requiring you to know any extra path information.

Oracle HTTP Server supports both IP-based virtual hosts and name-based virtual hosts. The latter variant is sometimes also called host-based or non-IP virtual hosts. Each virtual host can have its own name, IP address, and error and access logs. Within a <VirtualHost> container, you can set up a large number of individual servers run by a single invocation of the Oracle HTTP Server. With virtual hosting, you can specify a replacement set of the server-level configuration directives that define the main host, and are not allowed in any other container.

Block Directives
Specify a condition which must be true in order for directives within to take effect.

<IfModule> and <IfDefine> are block directives rather than container directives because they do not limit the scope of the directives they contain. They define whether Oracle HTTP Server parses the directives inside the block into its configuration, and the directives are ignored once the server is running.

Understanding Modules
Oracle HTTP Server is a modular server. Modules extend the basic functionality of the Web server, and support integration between Oracle HTTP Server and other Oracle Application Server components. Oracle HTTP Server includes Apache modules as well as Oracle HTTP Server modules.
You can add modules using the `LoadModule` directive. Here is an example of `LoadModule` usage:

```
LoadModule status_module modules/mod_status.so
```

**See Also:** Chapter 8, "Understanding Modules"

### About .htaccess Files

Oracle HTTP Server allows for decentralized management of configuration through special files places inside the Web tree. The special files are usually called `.htaccess`, but can be specified in the `AccessFileName` directive. Directives placed in `.htaccess` files apply to the directory where you place the file, and all subdirectories. The `.htaccess` files follow the same syntax as the main configuration files. Since `.htaccess` files are read on every request, changes made in these files take immediate effect.

The server administrator further controls what directives may be placed in `.htaccess` files by configuring the `AllowOverride` directive in the main configuration files.
Specifying Server and File Locations

This chapter explains how to set Oracle HTTP Server and server administrator options, and specify file locations.

Topics discussed are:

- Setting Server and Administrator Functions
- Specifying File Locations

Documentation from the Apache Software Foundation is referenced when applicable.

**Note:** Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

---

### Setting Server and Administrator Functions

The following directives set basic Oracle HTTP Server and administrator functions. They are located in the "Main Server Configuration" portion of the `httpd.conf` file.

**See Also:** "[httpd.conf File Structure](#)" on page E-2

- `ServerName`
- `UseCanonicalName`
- `ServerAdmin`
- `ServerSignature`
- `ServerTokens`
- `ServerAlias`

**ServerName**

Enables the server to set a hostname that can be used to create redirection URLs, through which you can access directories without having to use a `/` at the end.

For example, if `ServerName www.company.com` would be used if the main name of the actual machine was `main.company.com`.

**See Also:** "[ServerName directive](#)" in the Apache Server documentation.
UseCanonicalName
Determined which hostname and port to use when redirecting the URL to the same server.
- On: Server uses the hostname and port values set in ServerName and Port. This is the default setting.
- Off: Server uses the hostname and port that you specify in the request.
For example: UseCanonicalName On.
See Also: UseCanonicalName directive in the Apache Server documentation.

ServerAdmin
Creates an email address that is included with every default error message that clients encounter. It is useful to create a separate email address for this.
For example: ServerAdmin you@your.emailaddress.
See Also: ServerAdmin directive in the Apache Server documentation.

ServerSignature
Enables the server to recognize which server, among the various proxies, created the returned response, such as an error message.
- on: Server creates a footer to the returned document that includes information such as ServerName and server version number. This is the default setting.
- email: Server creates an additional "mailto:" reference to the ServerAdmin of the document.
- off: Footer and "mailto:" reference are not created.
For example: ServerSignature On.
See Also: ServerSignature directive in the Apache Server documentation.

ServerTokens
Controls server information which is returned to clients, such as in error messages. This information includes a description of the generic operating system-type of the server, and compiled-in modules.
- min: Provides information such as server name and version.
  For example: Server: Apache/1.3.0
- OS: Provides information such as server name, version, and operating system.
  For example: Server: Apache/1.3.0 (UNIX)
- full: Provides information such as server name, version, operating system, and compiled modules.
  For example: Server: Apache/1.3.0 (UNIX) PHP/3.0 MyMod/1.2
See Also: ServerTokens directive in the Apache Server documentation.
Specifying File Locations

ServerAlias
Sets alternate names for the current virtual host.

For example:

```html
<VirtualHost *>
  ServerName server.domain.com
  ServerAlias server server2.domain.com server2
  ...
</VirtualHost>
```

See Also: “ServerAlias directive” in the Apache Server documentation.

Specifying File Locations

The following directives control the location of various server files. They are located in
the 'Global Environment' of the httpd.conf file.

See Also: "httpd.conf File Structure" on page E-2

- CoreDumpDirectory
- DocumentRoot
- ErrorLog
- LockFile
- PidFile
- ScoreBoardFile
- ServerRoot

CoreDumpDirectory
Specifies the directory in which the server dumps core. The default is the ServerRoot
directory. This directive is applicable to UNIX only.

For example:

```
CoreDumpDirectory /tmp
```

See Also: “CoreDumpDirectory directive” in the Apache Server documentation.

DocumentRoot
Sets the directory from which httpd serves files. Unless matched by a directive like
Alias, the server appends the path from the requested URL to the document root to
make the path to the document for static content.

For example:

```
DocumentRoot "/oracle/Apache/Apache/htdocs"
```

See Also: “DocumentRoot directive” in the Apache Server documentation.

ErrorLog
Sets the name of the file to which the server notes any errors it encounters. If the name
of the file does not begin with a slash (/), then it is assumed to be relative to the
Specifying File Locations

ServerRoot
If the name of the file begins with a pipe (|), then it is assumed to be a command to spawn to handle the error log.

For example: ErrorLog
*'|/privatel/oracle/Apache/Apache/bin/rotatelogs
/private1/oracle/Apache/Apache/logs/error_log 43200"

See Also: "ErrorLog directive" in the Apache Server documentation.

LockFile
Sets the path to the lockfile used when Oracle HTTP Server is compiled with either USE_FCNTL_SERIALIZED_ACCEPT or USE_FLOCK_SERIALIZED_ACCEPT. It is recommended that default value be used. The main reason for changing it is if the logs directory is NFS mounted, since the lockfile must be stored on a local disk.

For example: LockFile /oracle/Apache/Apache/logs/httpd.lock

See Also: "LockFile directive" in the Apache Server documentation.

PidFile
Enables you to set and change the location of the PID file to which the server records the process identification number. If the filename does not begin with a slash (/), then it is assumed to be relative to the ServerRoot.

For example: PidFile /oracle/Apache/Apache/logs/httpd.lock

See Also: "PidFile directive" in the Apache Server documentation.

ScoreBoardFile
Required in some architectures to set a file that the server uses to communicate between the parent and children processes. To verify if your architecture requires a scoreboard file, run Oracle HTTP Server and see if it creates the file named by the directive. If your architecture requires it, then you must ensure that this file is not used at the same time by more than one invocation of the server.

For example: ScoreBoardFile /oracle/Apache/Apache/logs/httpd.scoreboard

See Also: "ScoreBoardFile directive" in the Apache Server documentation.

ServerRoot
Specifies the directory that contains the conf and logs subdirectories. If the server is started with the -f option, then you will have to specify ServerRoot.

For example: "'/oracle/Apache/Apache'"

See Also: "ServerRoot directive" in the Apache Server documentation.
Managing Server Processes

This chapter provides an overview of the Oracle HTTP Server processes, and provides information on how to regulate, and monitor these processes.

Topics discussed are:

- Oracle HTTP Server Processing Model
- Handling Server Processes
- Configuring the Number of Processes and Connections
- Running Oracle HTTP Server as Root
- Security Considerations
- Getting Information about Processes

Documentation from the Apache Software Foundation is referenced when applicable.

---

**Note:** Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

---

**Oracle HTTP Server Processing Model**

Once Oracle HTTP Server is started, the system is ready to listen for and respond to http(s) requests. The request processing model on UNIX differs from that on Windows.

On UNIX, there is a single parent process that manages multiple child processes. The child processes are responsible for handling requests. The parent process brings up additional child processes as necessary, based on configuration. Although the server has the ability to dynamically bring up additional child processes, it is best to configure the server to start enough children initially so that requests can be handled without having to spawn more child processes.

On Windows, there is a single parent process and a single child process. The child process creates threads that are responsible for handling client requests. The number of threads created is static and can be configured.

**Handling Server Processes**

By default, on UNIX, the main httpd parent process and child processes are configured to run as the user who installed Oracle Application Server. The User and Group...
Configuring the Number of Processes and Connections

directives are used to set the privileges for the child processes. These directives are ignored if you are not running as root. The child processes must be able to read all the content that will be served.

Use the following directives to manage the server processes:

- **ServerType**
- **Group**
- **User**

**ServerType**

Provides the following two options, both being applicable to UNIX only:

- **inetd**: Starts up a new child process every time a request comes in. The program exits once the request is dealt with. This setting eliminates the option of having several child processes in waiting, making it slower and expensive, but more secure. This option should be avoided, if possible.
- **standalone**: Enables several waiting child processes, and requires the server to be started only once. It is the default and recommended setting for a busy Web site.

You must specify the **User** and **Group** under which the servers answer requests.

For example:

```
ServerType standalone
```

See Also: "ServerType directive" in the Apache Server documentation.

**Group**

Specifies the group under which the server answers requests. Run the standalone server as root to use this directive. It is recommended that you create a new group for running the server. This is applicable to UNIX only.

For example:

```
Group myorg
```

See Also: "Group directive" in the Apache Server documentation.

**User**

Specifies the user ID to which the server answers requests. Run the standalone server as root to use this directive. You should have privileges to access files that are available for everyone, and should not be able to execute code which is not meant for httpd requests. It is recommended that you set up a new user for running the server. This is applicable to UNIX only.

For example:

```
User jdoe
```

See Also: "User directive" in the Apache Server documentation.

**Configuring the Number of Processes and Connections**

The following directives tune the performance of Oracle HTTP Server by configuring how clients requests are processed. They are located in the "Global Environment" of the `httpd.conf` file.

See Also: "httpd.conf File Structure" on page E-2
Configuring the Number of Processes and Connections

- StartServers
- ThreadsPerChild
- MaxClients
- MaxRequestsPerChild
- MaxSpareServers
- MinSpareServers

StartServers
Sets the number of child server processes created when Oracle HTTP Server is started. The default is 5. This is applicable to UNIX only.
Usage: StartServers 5

See Also: "StartServers directive" in the Apache Server documentation.

ThreadsPerChild
Controls the maximum number of child threads handling requests. The default is 50. This is applicable to Windows only.
Usage: ThreadsPerChild 50

See Also: "ThreadsPerChild directive" in the Apache Server documentation.

MaxClients
Limits the number of requests that can be dealt with at one time. The default and recommended value is 150. This is applicable to UNIX only.
Usage: MaxClients 150

See Also: "MaxClients directive" in the Apache Server documentation.

MaxRequestsPerChild
Controls the number of requests a child process handles before it dies. If you set the value to 0, which is the default, then the process will never die.
On Windows, it is recommended that this be set to 0. If it is set to a non-zero value, when the request count is reached, the child process exits, and is respawned, at which time it re-reads the configuration file. This can lead to unexpected behavior if you have modified a configuration file, but are not expecting the changes to be applied yet.
Usage: MaxRequestsPerChild 0

See Also: "MaxRequestsPerChild directive" in the Apache Server documentation.

MaxSpareServers
Sets the maximum number of idle child server processes. An idle process is one which is running, but not handling a request. The parent process kills off idle child processes...
that exceed the value set for this directive. The default is 20. This is applicable to UNIX only.

Usage: MaxSpareServers 20

See Also: “MaxSpareServers directive” in the Apache Server documentation.

**MinSpareServers**

Sets the minimum number of idle child server processes. An idle process is one which is running but not handling a request. The parent process will create new children at the maximum rate of one process per second if there are fewer processes running. The default is 5. This is applicable to UNIX only.

Usage: MinSpareServers 5

See Also: “MinSpareServers directive” in the Apache Server documentation.

**Running Oracle HTTP Server as Root**

On UNIX, if you want to run on ports less than 1024, then you will have to run as root.

In order to run Oracle HTTP Server as root, perform the following steps:

1. Stop Oracle HTTP Server using Application Server Control Console, or with the following command:

   ORACLE_HOME/opmn/bin> opmnctl [verbose] stopproc ias-component=HTTP_Server

   See Also: “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3

2. Change to root user.

3. Navigate to `ORACLE_HOME/Apache/Apache/bin` and execute the following command:

   chown root .apachectl
   chmod 6750 .apachectl

4. Exit root.

5. Restart Oracle HTTP Server using Application Server Control Console, or with the following command:

   ORACLE_HOME/opmn/bin> opmnctl [verbose] restartproc ias-component=HTTP_Server

   See Also: “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3

**Security Considerations**

For additional security on UNIX, you can change the user to “nobody”. Be sure that the child processes can accomplish their tasks as the user “nobody”. Change all static content, such as the `ORACLE_HOME/Apache/Apache/htdocs` directory, so that all
the files are readable, but ideally not writable by the user "nobody". Also, verify that all the CGI and FastCGI programs can be run by user "nobody".

If your PL/SQL application is using the file-system caching functionality in nod_plsql, then the httpd processes should have read and write privileges to the cache directory through the parameter PlsqlCacheDirectory in ORACLE_HOME/Apache/modplsql/conf/cache.conf on UNIX or ORACLE_HOME\Apache\modplsql\conf\cache.conf on Windows. By default, this parameter points to ORACLE_HOME/Apache/modplsql/cache on UNIX or ORACLE_HOME\Apache\modplsql\cache on Windows.

For Oracle Application Server Portal, the content cached by mod_plsql is used, or updated by the Parallel Page Engine running under OC4J Portal. This means that the cache directory is readable and writable by the OC4J Portal process as well. If Oracle HTTP Server is configured to run as "nobody", then OC4J_Portal should also run as the same user.

Finally, given that the cached content might contain sensitive data, the final contents of the file-system cache should be protected. So, although Oracle HTTP Server might run as "nobody", access to the system as this user should be well-protected.

See Also: "mod_plsql" on page 8-22

---

Getting Information about Processes

There are several ways to monitor Oracle HTTP Server processes.

1. Use Oracle Enterprise Manager 10g Application Server Control Console to monitor Oracle HTTP Server processes.

   **See Also:** Chapter 7, "Application Server Control Console Management"

   If a network error occurs on a device such as a router or firewall between the application server and the database, JDBC connections may stop responding. In this situation, you must stop Oracle HTTP Server manually, and there may be a delay in stopping the processes.

2. Use the performance monitor on Windows, or the ps utility on UNIX.

   **See Also:** Oracle Application Server Performance Guide and your operating system documentation for more information.

3. Use mod_status for server status. By default, it is available from localhost only.
Managing the Network Connections

This chapter provides information about specifying IP addresses and ports, and managing server interaction, and network connection persistence.

Topics discussed are:

- Specifying Listener Ports and Addresses
- Managing Interaction Between Server and Network
- Managing Connection Persistence
- Obtaining Client IP Address
- Configuring Reverse Proxies and Load Balancers

Documentation from the Apache Software Foundation is referenced when applicable.

**Note:** Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

---

### Specifying Listener Ports and Addresses

The port that Oracle HTTP Server listens on when it is started depends on your installation type.

Table 5–1 contains information about Oracle HTTP Server ports.

<table>
<thead>
<tr>
<th>Platform</th>
<th>Middle Tier Installation</th>
<th>Infrastructure Installation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Solaris</td>
<td>Non-SSL: 7777 (7777-7877 range)</td>
<td>Non-SSL: 7777 (7777-7877 range)</td>
</tr>
<tr>
<td></td>
<td>SSL: 4443 (4443-4543 range)</td>
<td>SSL: 4443 (4443-4543 range)</td>
</tr>
<tr>
<td>Windows</td>
<td>Non-SSL: 80 (7777-7877 range)</td>
<td>Non-SSL: 7777 (7777-7877 range)</td>
</tr>
<tr>
<td></td>
<td>SSL: 443 (4443-4543 range)</td>
<td>SSL: 4443 (4443-4543 range)</td>
</tr>
</tbody>
</table>

If ports 7777 or 80, for example, are occupied, Oracle HTTP Server listens on the next available port number between a range of 7777-7877. Accordingly, it would listen on port 7778, and so on.
A file named `setupinfo.txt` is automatically generated in `ORACLE_HOME/install` on UNIX, or `ORACLE_HOME\install` on Windows. It contains port information for Oracle HTTP Server. This file is generated at install time, and is not updated thereafter. If you restart Oracle HTTP Server, the information in this file becomes inaccurate.

You can change the Oracle HTTP Server listener port (SSL and non-SSL) after installation. If you make a port change, then you have to also update other components to use the new port number.

You can specify that the server listens on more than one port, selected addresses, or a combination. The following directives, located in the “Global Environment” of the `httpd.conf` file, specify listener ports and addresses. Note that `BindAddress` and `Port` can be used only once. Apache group recommends the use of `Listen` instead.

- `BindAddress`
- `Port`
- `Listen`

**See Also:** Oracle Application Server Administrator’s Guide

You can specify that the server listens on more than one port, selected addresses, or a combination. The following directives, located in the “Global Environment” of the `httpd.conf` file, specify listener ports and addresses. Note that `BindAddress` and `Port` can be used only once. Apache group recommends the use of `Listen` instead.

- `BindAddress`
- `Port`
- `Listen`

**See Also:** “httpd.conf File Structure” on page E-2

**BindAddress**

Restricts the server to listen to a single IP address. If the argument to this directive is `*`, then it listens to all IP addresses. This directive has been deprecated. `Listen` offers similar functionality.

For example: `BindAddress *`

**See Also:** “`BindAddress` directive” in the Apache Server documentation.

**Port**

Specifies the port of the listener, if no `Listen` or `BindAddress` are present. If `Listen` is present, the `Port` value becomes the default port value that is used when Oracle HTTP Server builds URLs, or other references to itself. Usually, the values of `Port` and `listen` should match, unless Oracle HTTP Server is fronted by a caching, or proxy server. Then, you can set `Port` to be the port that is being used by the front end server, and `listen` to the port that Oracle HTTP Server is actually listening to. By doing this, redirects or other URLs generated by Oracle HTTP Server point to the front-end server rather than directly to Oracle HTTP Server.

For example: `Port 7779`

**See Also:** “Port directive” in the Apache Server documentation.

**Listen**

Specifies an IP port that Oracle HTTP Server listens on. Multiple `Listen` directives can be used to listen on multiple ports. If present, this value will override the value of

**Note:** SSL is disabled by default. For information on enabling SSL, refer to Chapter 11, “Enabling SSL for Oracle HTTP Server.”
Port. Accordingly, if you have a Port value of 7777 and a Listen value of 7778, then Oracle HTTP Server only listens on one port, 7778.

For example:
- Listen 7778
- Listen 12.34.56.78:80

For platforms that support IPv4 and IPv6 (such as UNIX), setting Listen to localhost:<portnumber> and having IPv6 disabled can result in the following error:

```
(126)Cannot assign requested address: make_sock: could not bind to address [::1]:8000
no listening sockets available, shutting down
```

To resolve the error, either enable IPv6 or do not set Listen to localhost.

See Also: "Listen directive" in the Apache Server documentation.

Managing Interaction Between Server and Network

The following directives are used to specify how the server interacts with the network. They are located in the "Global Environment" of the httpd.conf file.

- **ListenBackLog**
- **SendBufferSize**
- **TimeOut**

See Also: "httpd.conf File Structure" on page E-2

**ListenBackLog**

Specifies the maximum length of the queue of pending connections. This is useful if the server is experiencing a TCP SYN overload, which causes numerous new connections that open up, but do not complete the task.

See Also: "ListenBackLog directive" in the Apache Server documentation.

**SendBufferSize**

Increases the TCP buffer size to the number of bytes specified, thereby improving performance.

See Also: "SendBufferSize directive" in the Apache Server documentation.

**TimeOut**

Sets the maximum time, in seconds, that the server waits for the following:
- The total amount of time it takes to receive a GET request.
- The amount of time between receipt of TCP packets on a POST or PUT request.
- The amount of time between ACKs on transmissions of TCP packets in responses.

The default is 300 seconds.
Managing Connection Persistence

The following directives determine how the server handles persistent connections. They are located in the "Global Environment" of the httpd.conf file.

- **KeepAlive**
- **KeepAliveTimeout**
- **MaxKeepAliveRequests**

**See Also:**
- [Oracle Application Server Performance Guide](#)
- "httpd.conf File Structure" on page E-2

**KeepAlive**

Enables HTTP 1.1 keep-alive support, allowing reuse of the same TCP connection for multiple HTTP requests from a single client, when set to 'On'. The default is 'On'.

**See Also:** "KeepAlive directive" in the Apache Server documentation.

**KeepAliveTimeout**

Sets the number of seconds the server waits for a subsequent request before closing a KeepAlive connection. Once a request has been received, the timeout value specified by the TimeOut directive applies. The default is 15 seconds.

**See Also:** "KeepAliveTimeout directive" in the Apache Server documentation.

**MaxKeepAliveRequests**

Limits the number of requests allowed per connection when KeepAlive is on. If it is set to '0', unlimited requests will be allowed. The default is 100.

**See Also:** "MaxKeepAliveRequests directive" in the Apache Server documentation.

**Obtaining Client IP Address**

UseWebCacheIp is a global directive that enables Oracle HTTP Server to obtain IP address of a client. It can be set to 'On' or 'Off', and defaults to 'Off'. It is not set to 'On' by default because it can open a security hole in some circumstances.

When OracleAS Web Cache acts as a reverse proxy in front of Oracle HTTP Server, the TCP connection from the client is terminated at OracleAS Web Cache. The TCP connection that Oracle HTTP Server sees actually originates at OracleAS Web Cache. Oracle HTTP Server gets the IP address of the client and uses it for various purposes, such as:

- Populating the REMOTE_ADDR CGI variable that can be used by applications in and behind Oracle HTTP Server to identify where the client came from.
Evaluating mod_access allow/deny rules that allow the administrator to restrict access based on IP address.

Without the UseWebCacheIp directive, this functionality fails when OracleAS Web Cache is used in front of Oracle HTTP Server. This is because Oracle HTTP Server sees all connections coming from the same place - the IP address where OracleAS Web Cache is running.

With every request that OracleAS Web Cache forwards to Oracle HTTP Server, it sends a header that contains the IP address of the client connection that it received. If UseWebCacheIp is set to ‘On’, then it directs Oracle HTTP Server to use the IP value from this header, instead of the value from the TCP connection as the client’s IP address. This enables REMOTE_ADDR CGI variable to have the correct value, and allows mod_access to function correctly.

You should set this directive only if you are sure that the clients can only connect to Oracle HTTP Server through OracleAS Web Cache. If clients can connect directly to Oracle HTTP Server, then they have to find out the header that is used to transfer the client IP, and set it so that it would seem to have come from any IP address you want.

In a typical set up, with a firewall and OracleAS Web Cache, the only port open through the firewall is the OracleAS Web Cache port. Hence, the only path from the client to Oracle HTTP Server goes through OracleAS Web Cache. In this case, it is safe to turn on UseWebCacheIp.

---

Configuring Reverse Proxies and Load Balancers

By default, Oracle Application Server installs using the local hostname as set up by ServerName directive in Oracle HTTP Server. Most Web sites tend to have a specific hostname or domain name for their Web or application server. However, this is not possible out of the box because with the ServerName directive, Oracle HTTP Server is instantiated with the local host.

Example 5-1 Using Reverse Proxies and Load Balancers with Oracle HTTP Server

Domain Name: www.oracle.com:80 123.456.7.8 (hosted on a reverse proxy, load balancer, or firewall)

Host Name of Oracle Application Server Host: server.oracle.com 123.456.7.9

ServerName and Port of Oracle Application Server Host: server.oracle.com:7777

Make the following changes in the httpd.conf file:

Port 80
Listen 7777
Listen 80

# Virtual Hosts
# This section is mandatory for URLs that are generated by
# the PL/SQL packages of the Oracle Portal and various other components
# These entries dictate that the server should listen on port
# 7777, but will assert that it is using port 80, so that
# self-referential URLs generated specify www.oracle.com:80
# This will create URLs that are valid for the browser since
# the browser does not directly see the host server.oracle.com.
NameVirtualHost 123.456.7.9:7777
<VirtualHost server.oracle.com:7777>
ServerName www.oracle.com
Port 80
</VirtualHost>

Configuring Reverse Proxies and Load Balancers

</VirtualHost>
# Since the previous virtual host entry will cause all links
# generated by the Oracle Portal to use port 80, the server.company.com
# server needs to listen on 80 as well since the Parallel Page
# Engine will make connection requests to Port 80 to request the
# portlets.
NameVirtualHost 123.456.7.8:80
<VirtualHost server.oracle.com:80>
ServerName www.oracle.com
Port 80
</VirtualHost>

See Also:  Oracle Application Server High Availability Guide
This chapter discusses Oracle Diagnostic Logging, log formats, and describes various log files and their locations.

Topics discussed are:

- Using Oracle Diagnostic Logging
- Specifying Log Level
- Specifying Log Files

Documentation from the Apache Software Foundation is referenced when applicable.

Note: Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

Using Oracle Diagnostic Logging

Oracle offers a new method for reporting diagnostic messages. This new method, Oracle Diagnostic Logging (ODL), presents a common format for diagnostic messages and log files, and a mechanism for correlating all diagnostic messages from various components across Oracle Application Server. Using ODL, each component logs messages to its own private local repository. A tool called LogLoader collects messages from each repository and loads them into a common repository where messages can be viewed as a single log stream, or analyzed in different ways.

You can view Oracle Application Server diagnostic log files using either Application Server Control Console, or a text editor.

See Also: Oracle Application Server Administrator's Guide

ODL is further discussed in the following sections:

- Overview
- Configuring Oracle HTTP Server

Overview

Oracle HTTP Server enables you to choose the format in which you want to generate log messages. You can either continue to generate log messages in the legacy Apache
Using Oracle Diagnostic Logging

message format, or generate log messages using ODL, which complies with the new Oracle-wide standards for generating log messages.

Configuring Oracle HTTP Server

To enable Oracle HTTP Server to use ODL, enter the following directives in the httpd.conf file:

- **OraLogMode oracle | odl | apache**
- **OraLogSeverity module_name <msg_type>{:msg_level]**
- **OraLogDir <bus stop dir>**

Oracle recommends that you enter the directives before any modules are loaded (LoadModule directive) in the httpd.conf file so that module-specific logging severities are in effect before modules have the opportunity to perform any logging.

**OraLogMode oracle | odl | apache**

Enables you to switch between the Oracle logging format, the legacy Apache logging format, and the ODL logging format. Logging formats are defined as follows:

- **oracle**: Fully conformant, multi-line log records in XML format. Provides the most information.
- **odl**: Standard Apache log format and ECID information for log records specifically associated with a request. This is the default setting.
- **apache**: Standard Apache log format. Provides the least information.

**OraLogSeverity module_name <msg_type>{:msg_level]**

Enables you to set message severity. The message severity specified with this directives is interpreted as the lowest message severity that is desired, and all messages of that severity level and higher will be logged.

**OraLogSeverity** may be specified multiple times. It can be specified globally (no module_name) and once for each module for which a module-specific logging severity is desired.

This directive is only used when **OraLogMode** is set to “oracle”. This directive can be used in place of the LogLevel directive, but is not required. If **OraLogSeverity** is present and **OraLogMode** is set to “oracle”, then LogLevel will be ignored.

**module_name** This argument is the internal name of a module, as it appears in the module structure. The <IfModule> directive also makes use of this internal name. The module structure derives the module name from the value of the _FILE_ macro, without path prefix, of the file which defines the module structure. If a module name is not supplied, the **OraLogSeverity** directive is applied globally.

If the module name is specified, then the directive overrides the global directive value of all the messages originating from the specified module. Specifying a module name for a module that does not get loaded generates an error.

**msg_type** Message types may be specified in upper or lower case, but will appear in the message output in upper case. This parameter must be one of the following values:

- **INTERNAL_ERROR**
- **ERROR**
WARNING
NOTIFICATION
TRACE

msg_level  This parameter must be an integer in the range of 1-32. 1 is most severe, 32 is least severe. Using level 1 will result in fewer messages than using level 32.

Table 6-1 lists some examples of OraLogSeverity.

<table>
<thead>
<tr>
<th>OraLogSeverity Example</th>
<th>Action Taken</th>
</tr>
</thead>
<tbody>
<tr>
<td>OraLogSeverity INTERNAL_ERROR:10</td>
<td>Logs all messages of type &quot;internal error&quot; of levels 1-10</td>
</tr>
</tbody>
</table>
| OraLogSeverity WARNING:7 | Logs all messages of type "internal error" of all levels
Logs all messages of type "error" of all levels
Logs all messages of type "warning" of levels 1-7 |
| OraLogSeverity WARNING OraLogSeverity mod_oc4j.c NOTIFICATION:4 | If message source is mod_oc4j, then
- Logs all messages of type "internal error" of all levels
- Logs all messages of type "error" of all levels
- Logs all messages of type "warning" of all levels
- Logs all messages of type "notification" of levels 1-4
For messages from all other sources:
- Logs all messages of type "internal error" of all levels
- Logs all messages of type "error" of all levels
- Logs all messages of type "warning" of all levels

Default  If a message level is not specified, then the level defaults to the lowest severity. If the entire directive is omitted, then the value of the global Apache LogLevel directive is used and translated to the corresponding Oracle message type and the lowest level within the corresponding range, as listed in Table 6-2.

<table>
<thead>
<tr>
<th>Apache Log Level</th>
<th>Oracle Message Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>emerg</td>
<td>INTERNAL_ERROR:16</td>
</tr>
<tr>
<td>alert</td>
<td>INTERNAL_ERROR:32</td>
</tr>
<tr>
<td>crit</td>
<td>ERROR:16</td>
</tr>
<tr>
<td>error</td>
<td>ERROR:32</td>
</tr>
<tr>
<td>warn</td>
<td>WARNING:32</td>
</tr>
<tr>
<td>notice</td>
<td>NOTIFICATION:16</td>
</tr>
<tr>
<td>info</td>
<td>NOTIFICATION:32</td>
</tr>
<tr>
<td>debug</td>
<td>TRACE:32</td>
</tr>
</tbody>
</table>

See Also:  “Specifying Log Level” on page 6-4
Specifying Log Level

`OraLogDir <bus stop dir>`
Specifies the path to the directory which contains all log files. This directory must exist.

Default:
- UNIX: `ORACLE_HOME/Apache/Apache/logs/oracle`
- Windows: `ORACLE_HOME\Apache\Apache\logs\oracle`

Specifying Log Level

Table 6–3 lists all the different logging levels, their descriptions, and, example messages for `LogLevel` directive:

<table>
<thead>
<tr>
<th>Logging Level</th>
<th>Description</th>
<th>Example Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>emerg</td>
<td>Emergencies—system is unusable.</td>
<td>&quot;Child cannot open lock file. Exiting.&quot;</td>
</tr>
<tr>
<td>alert</td>
<td>Action must be taken immediately.</td>
<td>&quot;getpwuid: couldn’t determine user name from uid&quot;</td>
</tr>
<tr>
<td>crit</td>
<td>Critical conditions.</td>
<td>&quot;socket: Failed to get a socket, exiting child&quot;</td>
</tr>
<tr>
<td>error</td>
<td>Error conditions.</td>
<td>&quot;Premature end of script headers&quot;</td>
</tr>
<tr>
<td>warn</td>
<td>Warning conditions.</td>
<td>&quot;child process 1234 did not exit, sending another SIGCHLD&quot;</td>
</tr>
<tr>
<td>notice</td>
<td>Normal but significant condition.</td>
<td>&quot;https: caught SIGDSS, attempting to dump core in...&quot;</td>
</tr>
<tr>
<td>info</td>
<td>Informational.</td>
<td>&quot;Server seems busy, (you may need to increase StartServers, or Min/MaxSpareServers)...&quot;</td>
</tr>
<tr>
<td>debug</td>
<td>Debug-level messages.</td>
<td>&quot;Opening config file...&quot;</td>
</tr>
</tbody>
</table>

Note: `LogLevel` directive may be omitted when `OraLogMode` is 'oracle' and `OraLogSeverity` is set.

Specifying Log Files

The following log files are described in subsequent sections:
- Access Log
- CustomLog
- Error Log
- PID File
- Piped Log
- Rewrite Log
- Script Log
- SSL Log
- Transfer Log
It is important to periodically rotate the log files by moving or deleting existing logs on a moderately busy server. For this, the server must be restarted after the log files are moved or deleted so that new log files are opened.

**See Also:** "Log Rotation" in the Apache Server documentation.

**Access Log**
Records all requests processed by the server. The location and content of the access log is controlled by the `CustomLog` directive. The `LogFormat` directive can be used to simplify the selection of the contents of the logs.

**Specifying LogFormat**
`LogFormat` specifies the information included in the log file, and the manner in which it is written. The default format is the Common Log Format (CLF). The CLF format is:

```
host ident authuser date request status bytes
```

- **host**: This is the client domain name or its IP number.
- **ident**: If `IdentityCheck` is enabled and the client machine runs `identd`, then this is the client identity information.
- **authuser**: This is the user ID for authorized user.
- **date**: This is the date and time of the request in the `<day/month/year:hour:minute:second>` format.
- **request**: This is the request line, in double quotes, from the client.
- **status**: This is the three-digit status code returned to the client.
- **bytes**: This is the number of bytes, excluding headers, returned to the client.

**See Also:** “Access Log” in the Apache Server documentation.

**CustomLog**
Log requests to the server. A log format is specified, and the logging can optionally be made conditional on request characteristics using environment variables.

**See Also:** "CustomLog directive" in the Apache Server documentation.

**Error Log**
The server sends diagnostic information and records error messages to a log file located, by default, in:

- UNIX: `ORACLE_HOME/Apache/Apache/logs/error_log`
- Windows: `ORACLE_HOME\Apache\Apache\logs\error_log`

The file name can be set using the `ErrorLog` directive.

**See Also:** “ErrorLog directive” in the Apache Server documentation.

**PID File**
When the server is started, it notes the process ID of the parent `httpd` process to the PID file located, by default, in.
Specifying Log Files

- UNIX: ORACLE_HOME/Apache/Apache/logs/httpd.pid
- Windows: ORACLE_HOME\Apache\Apache\logs\httpd.pid

This filename can be changed with the PidFile directive. The process ID is for use by the administrator for restarting and terminating the daemon. If the process dies (or is killed) abnormally, then it is necessary to kill the children httpd processes.

See Also: “Pid File” in the Apache Server documentation.

Piped Log

Oracle HTTP Server is capable of writing error and access log files through a pipe to another process, rather than directly to file. This increases the flexibility of logging, without adding code to the main server. In order to write logs to a pipe, replace the file name with the pipe character “|”, followed by the name of the executable which should accept log entries on its standard input. Oracle HTTP Server starts the piped-log process when the server starts, and restarts it if it crashes while the server is running.

Piped log processes are spawned by the parent Oracle HTTP Server httpd process, and inherit the user ID of that process. This means that piped log programs usually run as root so it is important to keep the programs simple and secure.

See Also: “Piped Log” in the Apache Server documentation.

Rewrite Log

Necessary for debugging when mod_rewrite is used. This log file produces a detailed analysis of how the rewriting engine transforms requests. The level of detail is controlled by the RewriteLogLevel directive.

See Also: “Rewrite Log” in the Apache Server documentation.

Script Log

Enables you to record the input to and output from the CGI scripts. This should only be used in testing, and not for live servers.

See Also: “Script Log” in the Apache Server documentation.

SSL Log

When Oracle HTTP Server starts in SSL mode, it creates ssl_engine_log and ssl_request_log in

- UNIX: ORACLE_HOME/Apache/Apache/logs
- Windows: ORACLE_HOME\Apache\Apache\logs

ssl_engine_log tracks SSL and protocol issues, where as ssl_request_log records user activity. Use the SSLLogFile directive to control output.

See Also: Chapter 11, "Enabling SSL for Oracle HTTP Server"

Transfer Log

Specifies the file in which to store the log of accesses to the site. If it is not explicitly included in the conf file, then no log is generated. The server typically logs each request to a transfer file located, by default, in

6-6 Oracle HTTP Server Administrator’s Guide
Specifying Log Files

- UNIX: \$ORACLE_HOME/Apache/Apache/logs/access_log
- Windows: \$ORACLE_HOME/Apache\Apache\logs\access_log

The filename can be set using a `CustomLog` directive.
This chapter provides information for managing Oracle HTTP Server using Oracle Enterprise Manager 10g Application Server Control Console (Application Server Control Console).

Topics discussed are:

- **Overview**
- Accessing Application Server Control Console
- Accessing Oracle HTTP Server Home Page
- Managing Oracle HTTP Server

### Overview

You can manage Oracle HTTP Server in two ways: using Oracle Enterprise Manager 10g, or using command-line utilities such as opmnctl and dcmctl. The subsequent sections provide information on managing Oracle HTTP Server using Oracle Enterprise Manager 10g.

Oracle Enterprise Manager 10g enables you to manage Oracle HTTP Server from a Web browser using Application Server Control Console. Application Server Control Console is installed with each instance of Oracle Application Server, enabling you to administer and monitor a single Oracle Application Server instance. You can access and manage the Oracle HTTP Server from the Application Server Control Console, as described in subsequent sections.

**See Also:** Oracle Enterprise Manager Concepts

### Accessing Application Server Control Console

After installation, you can access the Application Server Control Console from the URL specified in setupinfo.txt file. It is located in ORACLE_HOME/install on UNIX or ORACLE_HOME\install on Windows.

setupinfo.txt also contains the URL for Oracle Application Server Welcome page. You can access the Application Server Control Console by clicking on the "Login to Oracle Enterprise Manager 10g" link on the Oracle Application Server Welcome page. Enter the username, which is ias_admin, and the password, which is specified during the installation process, to access the Application Server Control Console.
Accessing Oracle HTTP Server Home Page

Accessing Oracle HTTP Server Home Page

Oracle HTTP Server Home page enables you to perform tasks such as monitor the status and performance of your server, start and stop the server, create virtual hosts, modify configuration files, change log properties, manage client requests, and specify a port for a listener.

You can access the Oracle HTTP Server Home page by clicking on the "HTTP Server" link in the Name column of the "System Components" table on the Application Server Control Console.

Figure 7–1 displays the Oracle HTTP Server Home page.

Managing Oracle HTTP Server

The Oracle HTTP Server Home page is divided into three sections: Home, Virtual Hosts, and Administration, where you can perform tasks such as:

- Performing Basic Administration
- Managing Virtual Hosts
Performing Basic Administration

You can perform the following basic administration tasks under the "Home" tab of the Oracle HTTP Server Home page:

- Starting, Restarting, and Stopping Oracle HTTP Server
- Managing Default Server Configuration
- Monitoring Status
- Monitoring Response and Load
- Monitoring Performance

Starting, Restarting, and Stopping Oracle HTTP Server

You can start, restart, or stop the server under the "Home" tab of Oracle HTTP Server Home page. To do so, click the appropriate button in the "General" section. You can also see the status, and the start time in this section.

Managing Default Server Configuration

You can verify the name of the server, the path of the document root, and the time the server was last modified on the "Default Server Configuration" section under the "Home" tab of the Oracle HTTP Server Home page.

Monitoring Status

You can monitor the heap usage, CPU usage, memory usage, error rate, number of active connections, and the time the connections have been open, on the "Status" section under the "Home" tab of the Oracle HTTP Server Home page.

Monitoring Response and Load

You can monitor the number of active requests, the request throughput time, request processing time, data throughput, and data processed on the "Response and Load" section under the "Home" tab of the Oracle HTTP Server Home page.

Monitoring Performance

You can view the general server status, and the response and load information under the "Home" tab on Oracle HTTP Server Home page.

Status Metrics

The "Status" section provides information such as heap usage, CPU usage, memory usage, error rate, number of active connections, and the time the connections have been open.

Click "Status Metrics" under the "Performance" section to view detailed status details.

Response and Load Metrics

The "Response and Load" section provides information such as number of active requests, how many requests were submitted, and how long it...
Managing Oracle HTTP Server

took for the server to respond to your request. It also provides information about how many bytes of data were processed with the requests.

Click 'Response and Load Metrics' under the ‘Performance’ section to view detailed response and load information.

**Module Metrics** The ‘Module Metrics’ section enables you to view the status of the modules being used by clicking on ‘Module Metrics’ under the ‘Performance’ section. It provides information such as the number of active requests, number of requests processed since startup, number of current requests throughput, and the current request processing time.

**Error Log** You can view the last 2000 lines of the httpds error log by clicking ‘Error Log’ under the ‘Performance’ section.

---

**Managing Virtual Hosts**

Figure 7-2 displays the Virtual Hosts page. You can view the Virtual Hosts page by clicking on the ‘Virtual Hosts’ tab on the Oracle HTTP Server Home page. The following topics are discussed in this section:

- Requirements for Managing Virtual Hosts
- Performing Basic Tasks on Virtual Hosts Page
- Modifying Virtual Hosts
- Administering Virtual Hosts

See Also: “About the Enterprise Manager Application Server Control” in the Enterprise Manager Online Help.

**Requirements for Managing Virtual Hosts**

Virtual hosts that meet the following requirements can be managed by the Application Server Control Console:

- A `ServerName` directive is specified for each virtual host.

See Also: “`ServerName`” on page 3-1
Only a single `<IP listen address>:<port>` pair that meets the following requirements can be specified for the virtual host:

- The IP listen address is either a numeric IP address, `*` for all addresses, or the keyword `_default_`.
- The port is either a port number or `*` for all the ports that Oracle HTTP Server is using. Alternatively, if `<port>` is omitted, the main server's default port will be used.

The virtual host must be specified in a particular section of the configuration file, as follows:

- Non-SSL virtual hosts must be specified at the top nesting level of the configuration file.
- SSL virtual hosts must be specified just inside an `<IfDefine SSL>` directive, and that directive must be at the top nesting level of the configuration file.

See Also: “Block Directives” on page 2-6

Performing Basic Tasks on Virtual Hosts Page

You can do the following on the Virtual Hosts page:

- View settings for a virtual host.
- Create a new virtual host using the Create Virtual Host wizard. To do so, click Create.
- Create a new virtual host by modifying a copy of the settings of an existing virtual host. To do so, click Create Like. The existing virtual host is left unchanged.
- Delete a virtual host.
- Modify the settings for an existing virtual host. To do so, click the link for the host and access modification features.

Modifying Virtual Hosts

The following sections provide information on modifying or monitoring an existing virtual host. You can monitor the following for specific virtual hosts by clicking on their link on the “Virtual Hosts” page:

- Configuration
- Request Throughput
- Load
- Request Process Time

Configuration

You can verify the type, the IP address, port number, protocol, and path of the document root of the virtual host, in the "Configuration" section of the virtual host page of the virtual host you selected.

Request Throughput

You can monitor the number of active requests, the current throughput, the throughput since startup, and the total number of requests processed since startup, in the "Request Throughput" section of the virtual host page of the virtual host you selected.
Load You can monitor the current data throughput, the data throughput since startup, current response size, average response size since startup, and the total data since startup, in the "Load" section of the virtual host page of the virtual host you selected.

Request Process Time You can monitor the current processing time, and the average processing time since startup, in the "Request Processing Time" section of the virtual host page of the virtual host you selected.

Administering Virtual Hosts
This section contains information about administering virtual hosts. You can perform the following administrative tasks for specific virtual hosts by clicking on their link on the "Virtual Hosts" page:

- Virtual Hosts Properties
- Virtual Host MIME Languages
- Virtual Host MIME Encoding
- Virtual Host MIME Types

Virtual Hosts Properties You can view or modify the following settings on General section of the Virtual Hosts Properties page:

- Virtual Host Type: Displays the type of virtual host. The possible types are name-based, IP-based, or default.
- Server Name: Displays the server name for the virtual host.
- Document Root: Displays the path of the directory from which the server serves files. Note that the document root directory is different from the server root directory, which is only used to store the server files. You can specify the directory using the DocumentRoot directive.
- Directory Index: Specifies the resource or resources that Oracle HTTP Server will look for when the client requests the index of a directory by specifying a slash (/) at the end of the directory name.
- Administrator Email: Displays the server's main contact. This address receives notifications if the server experiences error conditions.
- IP Address: Specifies the IP address or addresses on which you want the virtual host to listen. The IP address you specify for the virtual host must already exist for Oracle HTTP Server.
- Listening Ports: Specifies the port or ports on which you want the virtual host to listen. Any ports you specify for the virtual host must already exist for Oracle HTTP Server. Ports for Oracle HTTP Server appear in the Listening Addresses/Ports section of the Server Properties page.

See Also: "Specifying a Port for a Listener" on page 7-11

- Protocol: Displays the protocol settings.

You can also modify the SSL Wallet path if the virtual host is using the HTTPS protocol, which uses SSL for secure connections. Note that SSL is supported for default virtual hosts and IP-based virtual hosts, but not for name-based virtual hosts.
The value of the SSL Wallet field corresponds to the `SSLWallet` entry in `httpd.conf` file. The path to the SSL Wallet must be in the form of a valid Wallet Resource Locator.

See Also: “SSLWallet” on page 11-14

- **Logging**: Provides access to the server’s error log files and access log files.
  The error log file is an important source of information for maintaining a well-performing server. The error log records all of the information about problem situations so that the system administrator can easily diagnose and fix the problems.
  To provide access to the error log file—without providing access to all of the other configuration files—you may need to move the error log file to a shared directory.
  The access log file contains basic information about every HTTP transaction that the server handles. This information can be used to generate statistical reports about the server’s usage patterns.
  In addition to viewing error log files and access log files in the Logging section, you can also perform these tasks for the virtual host:
  Choose a logging level for the error log file.

  See Also: “Specifying Log Level” on page 6-4

  Setting the error logging level to `Notice`, `Informational`, or `Debug` tends to flood the error log with unimportant informational messages.

  - Change the error log file name or location
  - Remove an access log file
  - Change an access log file name or location
  - Change the log format of an access log file

  See Also: “Specifying LogFormat” on page 6-5

  - Add an access log file (click Add Another Row) and specify a log format and location for it

  When you specify a location for an error log file or access log file, you can enter an absolute path and file name or a relative path and file name for the file. A relative path will be relative to the Server Root directory specified during initial configuration. The Server Root directory is displayed in the General section.

**Virtual Host MIME Languages** The Multipurpose Internet Mail Extension (MIME) Language setting maps the given file extensions to a particular language. This directive is used most commonly for content negotiation, where the Oracle HTTP Server returns the document that most closely matched the preferences set by the client.

To add a new MIME Language:

1. Select “Virtual Hosts MIME Languages” under the Administration section. This opens the Virtual Hosts MIME Languages page.
2. Enter the new language code in the Standard Language code field. Examples include `en` for English, `fr` for French, and `es` for Spanish.
3. Enter the types of files that should be opened with the language code in the \File Extension(s) field. The extension argument is case-insensitive, and can be specified with or without a leading period. Examples include .\en, .\fr, and .\es.

4. In the Default Language Code field, enter the default language type that should be used if no language is specified.

5. Click \Apply at the bottom of the page to accept the changes. If you do not click \Apply, you will lose your changes. If you make a mistake or want to undo any changes, click \Revert.

   Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

6. Click \Yes to restart the Oracle HTTP Server so the changes will take effect. Click \No to restart the server later.

To remove a MIME language, select it and click \Remove.

**Virtual Host MIME Encoding**
The Multimedia Internet Mail Extension (MIME) mapping allows the Oracle HTTP Server to determine the type of file from the given extension. As part of its MIME support, Oracle HTTP Server enables you to add or remove MIME encodings. The Encoding directive maps the given filename extensions to the specified encoding type.

To add a new MIME encoding:
1. Select “Virtual Hosts MIME Encoding” under the Administration section. This opens the Virtual Hosts MIME Encoding page.
2. Click \Add Another Row.
3. Enter the new encoding type in the Encoding field. Examples include \x-gzip, and \x-compress.
4. Enter the types of files that should be opened with the encoding type in the File Extension(s) field. The extension argument is case-insensitive, and can be specified with or without a leading period.
5. Click \Apply at the bottom of the page to accept the changes. If you do not click \Apply, you will lose your changes. If you make a mistake or want to undo any changes, click \Revert.

   Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

6. Click \Yes to restart the Oracle HTTP Server so the changes will take effect. Click \No to restart the server later.

To remove a MIME encoding, select it and click \Remove.

**Virtual Host MIME Types**
The Multipurpose Internet Mail Extension (MIME) type maps the given filename extensions onto the specified content type. The MIME type is used for filenames containing an extension. This mapping is added to any extension already in use, overriding any mappings that already exist for the same extension.

To add a new MIME type:
1. Select “Virtual Hosts MIME Types” under the Administration section. This opens the Virtual Hosts MIME Types page.
2. Click \Add Another Row.
3. Enter the new MIME type in the MIME type field. Examples include: text/plain, text/html, and image/gif.

4. Enter the types of files in the File Extension(s) field that should be opened with the MIME type. The extension argument is case-insensitive, and can be specified with or without a leading period. Examples include .txt, .html, and .gif.

5. In the Default MIME Type field, enter the default MIME type that should be used for unknown file types.

6. Click **Apply** at the bottom of the page to accept the changes. If you do not click **Apply**, you will lose your changes. If you make a mistake or want to undo any changes, click **Revert**.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

7. Click **Yes** to restart the Oracle HTTP Server so the changes will take effect. Click **No** to restart the server later.

To remove a MIME type, select it and click **Remove**.

**Administering Oracle HTTP Server**

Figure 7-3 displays the "Administration" page. You can view the "Administration" page by clicking on the "Administration" tab on the Oracle HTTP Server Application Server Control Home page. The following topics are discussed in this section:

- Server Properties
- MIME Languages
- MIME Types
- MIME Encoding
- PL/SQL Properties
- Advanced Server Properties

**See Also:** "About the Enterprise Manager Application Server Control" in the Enterprise Manager Online Help.
Managing Oracle HTTP Server

Figure 7–3  Administration Page

You can view and modify the following basic settings for your Oracle HTTP Server on the "Server Properties" page.

- **Modifying the DocumentRoot, Administrator E-mail, and Group Settings**
- **Specifying a Port for a Listener**
- **Changing the Error Log Properties**
- **Adding an Access Log File**
- **Changing the Access Log Properties**
- **Managing the Client Request and Connection Handling**

### Server Properties

You can view and modify the following basic settings for your Oracle HTTP Server on the "Server Properties" page.

- **Modifying the DocumentRoot, Administrator E-mail, and Group Settings**
- **Specifying a Port for a Listener**
- **Changing the Error Log Properties**
- **Adding an Access Log File**
- **Changing the Access Log Properties**
- **Managing the Client Request and Connection Handling**

#### Modifying the DocumentRoot, Administrator E-mail, and Group Settings

After you start Oracle HTTP Server, the system is ready to listen for and respond to requests. You may need to make modifications to the document root, administrator email, **User**, and **Group** settings in order to process requests efficiently.

- **Document Root**: The directory from which the server serves files. Note that the document root directory is different from the server root directory, which is only used to store the server files. You can specify the directory using the `DocumentRoot` directive.
- **Administrator Email Address**: The server’s main contact. This address receives notifications if the server experiences error conditions.
- **User**: Specifies the user ID to which the server answers requests. This directive is only used on UNIX systems. You should have privileges to access files that are available for everyone, and should be able to execute code which is not meant for HTTP requests. It is recommended that you set up a new user for running the server.
- **Group**: Specifies the group under which the server answers requests. This directive is only used on UNIX systems. It is recommended that you create a new group for running the server.

To modify these settings:
1. Select “Server Properties” under the “Administration” page. This opens the Oracle HTTP Server Properties page.

2. Type a new path in the “Document Root” field to change the document root directory. The path should be relative to the Server Root directory specified during initial configuration.

3. Type the appropriate email address in the “Administrator Email” field. Oracle HTTP Server uses this email address to issue notices and warnings. The administrator should have full privileges.

4. Add or change the User identifier by typing a new user name in the fields provided.

5. Add or change the Group identifier by typing a new group name in the fields provided.

6. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

7. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.

Specifying a Port for a Listener

When you start Oracle HTTP Server, it connects to a port and awaits client requests. Oracle HTTP Server automatically attempts to listen on port 7777.

To specify a listener port:

1. Select “Server Properties” in the “Administration” page. This opens the Server Properties page.

2. Scroll down to the Listening Addresses/Ports table.

   The first row in the Listening Addresses/Ports table identifies the default listener port. To edit the default listener port, edit the number in the Listening Port column.

   To add port settings, click Add Another Row to add a new row to the table. Enter the IP address and/or port number to the new row.

3. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

4. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.

Changing the Error Log Properties

You can change Error Log properties from the Oracle HTTP Server Home page. The Error Log file is an important source of information for...
maintaining a well-performing server. The Error Log records all of the information about problem situations so that you can easily diagnose and fix the problems.

See Also: "Error Log" on page 6-5

To customize the error log properties:

1. Select "Server Properties" in the "Administration" page. This opens the Server Properties page.
2. Scroll to the "Logging" section of the Server Properties page.
3. Type the full path name of the directory where you want to keep the error log file in the Error Log Filename field. You can also type the relative path name. A relative path is assumed to be relative to the Server Root directory.
4. Select the logging level from the Error Logging Level drop-down menu. The logging level indicates the severity of the error being reported.
5. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

6. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.

Adding an Access Log File
You can change Access Log properties from the Oracle HTTP Server Home page. The Access Log contains basic information about every HTTP transaction that the server handles. Specifically, the access log file contains hostname, remote logname, remote user, time, request, response code, and bytes transferred. This information can be used to generate statistical reports about the server’s usage patterns.

See Also: "Access Log" on page 6-5

Note: At installation time, an access log with the common LogFormat is created.

To create an access log file:

1. Select "Server Properties" in the "Administration" page. This opens the Server Properties page.
2. Scroll to the Logging section of the Server Properties page.
3. Click **Add Another Row** in the Select Access Log table to add a new row. When the page reloads, scroll back to the Logging section.

4. Type the full path and filename of the access log file you want to create in the empty field. For example, you can type the following location:
   - **UNIX:** `ORACLE_HOME/Apache/Apache/logs/access_log`
   - **Windows:** `ORACLE_HOME\Apache\Apache\logs\access_log`

   You can enter an absolute path or a relative path. A relative path will be relative to the Server Root directory specified during initial configuration.

5. Set the log format by typing a new format name. The default is `common`. For information on creating custom log formats, go to “Adding an Access Log File” from the online help for the Server Properties page.

6. Click **Apply** at the bottom of the page to accept the changes. If you do not click **Apply**, you will lose your changes. If you make a mistake or want to undo any changes, click **Revert**.

   Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

7. Click **Yes** to restart the Oracle HTTP Server so the changes will take effect. Click **No** to restart the server later.

---

### Managing the Client Request and Connection Handling

You can specify how the child processes on UNIX, child threads on Windows, and connections should initialize resources during the server’s processing phase through the Oracle HTTP Server Home page. The Child Process and Connection settings impact the ability of the server to...
process requests. You may need to modify these settings as the number of requests
increases or decreases to maintain a well-performing server.

See Also: “Oracle HTTP Server Processing Model” on page 4-1

To modify child process and connection settings:
1. Select "Server Properties" in the "Administration" page. This opens the Server
Properties page.
2. Scroll to the Client Request Handling or Client Connection Handling sections of
the Server Properties page.
3. Modify the Client Request Handling and Client Connections Handling directives
by changing the default values in the appropriate fields.
   For help on individual settings, click Help at the top of the Server Properties page.
4. Click Apply at the bottom of the page to accept the changes. If you do not click
   Apply, you will lose your changes. If you make a mistake or want to undo any
   changes, click Revert.
   Oracle Enterprise Manager 10g Application Server Control Console displays a
   confirmation page, which confirms that the appropriate configuration files have
   been updated.
5. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click
   No to restart the server later.

MIME Languages
The Multipurpose Internet Mail Extension (MIME) Language setting maps the given
file extensions to a particular language. This directive is used most commonly for
content negotiation, where the Oracle HTTP Server returns the document that most
closely matched the preferences set by the client.

To add a new MIME Language:
1. Select "MIME Language" in the "Administration" page. This opens the MIME
   Languages page.
2. Enter the new language code in the Standard Language code field. Examples
   include en for English, fr for French, and es for Spanish.
3. Enter the types of files that should be opened with the language code in the File
   Extension(s) field. The extension argument is case-insensitive, and can be specified
   with or without a leading period. Examples include .en, .fr, and .es.
4. In the Default Language Code field, enter the default language type that should be
   used if no language is specified.
5. Click Apply at the bottom of the page to accept the changes. If you do not click
   Apply, you will lose your changes. If you make a mistake or want to undo any
   changes, click Revert.
   Oracle Enterprise Manager 10g Application Server Control Console displays a
   confirmation page, which confirms that the appropriate configuration files have
   been updated.
6. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click
   No to restart the server later.
To remove a MIME language, select it and click Remove.
MIME Types
The Multipurpose Internet Mail Extension (MIME) type maps the given filename extensions onto the specified content type. The MIME type is used for filenames containing an extension. This mapping is added to any extension already in use, overriding any mappings that already exist for the same extension.

To add a new MIME type:
1. Select “MIME Types” in the “Administration” page. This opens the MIME Types page.
2. Click Add Another Row.
3. Enter the new MIME type in the MIME type field. Examples include: text/plain, text/html, and image/gif.
4. Enter the types of files in the File Extension(s) field that should be opened with the MIME type. The extension argument is case-insensitive, and can be specified with or without a leading period. Examples include .txt, .html, and .gif.
5. In the Default MIME Type field, enter the default MIME type that should be used for unknown file types.
6. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

7. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.

To remove a MIME type, select it and click Remove.

MIME Encoding
The Multimedia Internet Mail Extension (MIME) mapping allows the Oracle HTTP Server to determine the type of file from the given extension. As part of its MIME support, Oracle HTTP Server enables you to add or remove MIME encodings. The Encoding directive maps the given filename extensions to the specified encoding type.

To add a new MIME encoding:
1. Select “MIME Encoding” in the “Administration” page. This opens the MIME Encoding page.
2. Click Add Another Row.
3. Enter the new encoding type in the Encoding field. Examples include x-gzip, and x-compress.
4. Enter the types of files that should be opened with the encoding type in the File Extension(s) field. The extension argument is case-insensitive, and can be specified with or without a leading period.
5. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.
6. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.

   To remove a MIME encoding, select it and click Remove.

**PL/SQL Properties**

Oracle HTTP Server contains the `mod_plsql` module, which provides support for building PL/SQL-based applications on the Web. PL/SQL stored procedures retrieve data from a database, and generate HTTP responses containing data and code to display in a Web browser.

In order to use `mod_plsql`, you must install the PL/SQL Web Toolkit into a database, and create a Database Access Descriptor (DAD) which provides `mod_plsql` with connection information for the database.

**Creating a Database Access Descriptor (DAD) for mod_plsql** You can create a DAD using Oracle HTTP Server Home page:

1. Select "PL/SQL Properties" in the "Administration" page. This opens the `mod_plsql` Services page.
2. On the `mod_plsql` Services page, scroll to the DAD Status section. Click Create. This opens the DAD Type page.
3. If you intend to use `mod_plsql` with Oracle Application Server Portal or Oracle Login Server, select the Portal radio button. Otherwise, select the General radio button. The subsequent screens are populated with default values based on your selection. Click Next. This opens the Database Connection page.
4. Type a unique name in the DAD Name field. Enter the database account, password, and connection information in the Database Connectivity Information section. In the Default page field, type the name of the PL/SQL procedure that should be invoked when one is not specified. In the NLS Language field, type the Oracle Language and Character Set for the back-end database. Choose an Authentication Mode in the Authentication Mode section. Click Next. This opens the Document, Alias, and Session page.
5. On the Document, Alias, and Session page, fill in the fields that are required for your DAD configuration. Click Next. This opens the Advanced page.
6. On the Advanced page, fill in the fields that are required for your DAD configuration. These fields are typically not configured. Refer to the online help for more information. Click Finish. This opens the Confirmation page. Click OK.
7. Restart Oracle HTTP Server.

**Deleting a Database Access Descriptor (DAD) for mod_plsql** You can delete a DAD using Oracle HTTP Server Home page:

1. Select "PL/SQL Properties" in the "Administration" page. This opens the `mod_plsql` Services page.
2. On the `mod_plsql` Services page, scroll to the DAD Status section. Select the radio button in the Select column for the DAD you would like to delete. Click Delete.
3. Restart Oracle HTTP Server.
Advanced Server Properties
You can access the Oracle HTTP Server configuration files directly on the Advanced Server Properties page. Use these files to customize the features of your server.

Editing the Server Configuration Files Perform the following steps to modify the Oracle HTTP Server configuration files:

1. Select “Advanced Server Properties” in the “Administration” section. This opens the Advanced Server Properties page.
2. Select the configuration file you want to edit. A text editor appears where you can make the appropriate changes.
3. Click Apply at the bottom of the page to accept the changes. If you do not click Apply, you will lose your changes. If you make a mistake or want to undo any changes, click Revert.

Oracle Enterprise Manager 10g Application Server Control Console displays a confirmation page, which confirms that the appropriate configuration files have been updated.

4. Click Yes to restart the Oracle HTTP Server so the changes will take effect. Click No to restart the server later.
This chapter describes the modules (mods) included in the Oracle HTTP Server. The modules extend the basic functionality of the Web server, and support integration between Oracle HTTP Server and other Oracle Application Server components.

Documentation from the Apache Software Foundation is referenced when applicable.

Note: Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

List of Modules

Table 8-1 lists all the Oracle HTTP Server modules discussed in this chapter.

<table>

Understanding Modules 8-1
mod_access
Controls access to the server based on characteristics of a request, such as hostname or IP address.

See Also: Module mod_access in the Apache Server documentation.

mod_actions
Enables execution of CGI scripts based on file type or request method.

See Also: Module mod_actions in the Apache Server documentation.

mod_alias
Enables manipulation of URLs in processing requests. It provides mapping between URLs and file system paths, and URL redirection capabilities.

See Also: Module mod_alias in the Apache Server documentation.

mod_asis
Enables sending files that contain their own HTTP headers.

See Also: Module mod_asis in the Apache Server documentation.

mod_auth
Enables user authentication with files based user lists.

See Also: Module mod_auth in the Apache Server documentation.

mod_auth_anon
Enables anonymous user access to protected areas (similar to anonymous FTP, where the email addresses can be logged).

See Also: Module mod_auth_anon in the Apache Server documentation.

mod_auth_dbm
Uses DBM files to provide user authentication.

mod_autoindex
Generates directory indexes automatically.

See Also: Module mod_autoindex in the Apache Server documentation.
mod_cern_meta

Emulates CERN (Conseil Europeen pour le Recherche Nucleaire) HTTPD metafile semantics. Metafiles are additional HTTP headers that can be produced for each file the server accesses, in addition to the typical set.

mod_certheaders

Allows reverse proxies that terminate SSL connections in front of Oracle HTTP Server, such as OracleAS Web Cache, to transfer information regarding SSL connection, such as SSL client certificate information, to Oracle HTTP Server, and applications running behind Oracle HTTP Server. This information is transferred from the reverse proxy to Oracle HTTP Server using HTTP headers. The information is transferred from the headers to the standard CGI environment variable, which mod_ossl or mod_ssl populates if the SSL connection is terminated by Oracle HTTP Server. It is an Oracle module.

It also allows certain requests to be treated as HTTPS requests even though they are received through HTTP. This is done using the SimulateHttps and AddCertHeader directives.

SimulateHttps takes the container it is contained within, such as <VirtualHost>, <Location>, and so on, and treats all requests received for this container as if they were received through HTTPS, regardless of the real protocol that the request was received through.

AddCertHeader is specifically for use with OracleAS Web Cache. For OracleAS Web Cache, it adds a special header that indicates to Oracle HTTP Server which requests OracleAS Web Cache received through HTTPS.mod_certheaders triggers Oracle HTTP Server to only treat those cases where OracleAS Web Cache received the request as HTTPS as if Oracle HTTP Server received it through HTTPS.

Perform the following steps to configure mod_certheaders:

1. Configure Oracle HTTP Server to load mod_certheaders. To do this, add a LoadModule directive to httpd.conf file:
   - UNIX: LoadModule certheaders_module libexec/mod_certheaders.so
   - Windows: LoadModule certheaders_module modules/ApacheModuleCertHeaders.dll

2. Specify which headers should be translated to CGI environment variables. This can be achieved by using the AddCertHeader directive. This directive takes a single argument, which is the CGI environment variable that should be populated from a HTTP header on incoming requests. For example, to populate the SSL_CLIENT_CERT CGI environment variable, add the following lines to httpd.conf:
   ```
   AddCertHeader SSL_CLIENT_CERT
   ```

The AddCertHeader directive can be a global setting if it is placed in the base virtual server section of httpd.conf. It can be specific to a single virtual host by placing it within a <VirtualHost> or <Location> container directive within httpd.conf. The combination of these directives are additive, so that for a given URI, all directives that are specific to that URI will be added to any that are specific to that request's virtual host, which will be added to any that is defined for that base virtual host.
Table 8–2 lists all the supported CGI environment variables with their corresponding HTTP header names.

</table>

---

8-4 Oracle HTTP Server Administrator's Guide
3. `mod_certheaders` can be used to instruct Oracle HTTP Server to treat certain requests as if they were received through HTTPS even though they were received through HTTP. This is useful when Oracle HTTP Server is front-ended by a reverse proxy or load balancer, which acts as a termination point for SSL requests, and forwards the requests to Oracle HTTP Server through HTTPS.

If OracleAS Web Cache is being used as the load balancer, it sends an HTTP header that identifies all requests it received through HTTPS. This means that `mod_certheaders` automatically detects which requests should be treated as HTTPS requests by simply looking for this header. To enable this, add the following directive to `httpd.conf`:

```
AddCertHeader HTTPS
```

This affects all URLs processed by Oracle HTTP Server.

For other load balancers, `mod_certheaders` must be explicitly configured to determine which requests should be treated as HTTPS requests. To do this, use the following directive:

```
SimulateHttps on
```

This can be embedded within a virtual host, such as:

```
<VirtualHost localhost:7777>
  SimulateHttps on
</VirtualHost>
```

This tells `mod_certheaders` to treat every request handled by this virtual host as HTTPS, or the directive can be placed within a `<LocationMatch>`, `<Directory>`, or `<DirectoryMatch>` directive container such as:

```
<LocationMatch /foo/>
  SimulateHttps on
</LocationMatch>
```

This limits it to URLs starting with `/foo/`.

4. Edit the `$ORACLE_HOME/sso/conf/sso_apache.conf`, and comment out the following line:

```
SSL_CLIENT_I_DN_I  SSL-Client-I-DN-I  SSL_SERVER_I_DN_I  SSL-Server-I-DN-I
SSL_CLIENT_I_DN_G  SSL-Client-I-DN-G  SSL_SERVER_I_DN_G  SSL-Server-I-DN-G
SSL_CLIENT_I_DN_D  SSL-Client-I-DN-D  SSL_SERVER_I_DN_D  SSL-Server-I-DN-D
SSL_CLIENT_I_DN_UID SSL-Client-I-DN-Uid SSL_SERVER_I_DN_UID SSL-Server-I-DN-Uid
SSL_CLIENT_I_DN_Email SSL-Client-I-DN-Email SSL_SERVER_I_DN_Email SSL-Server-I-DN-Email
SSL_CLIENT_A_SIG   SSL-Client-A-Sig   SSL_SERVER_A_SIG   SSL-Server-A-Sig
SSL_CLIENT_A_KEY   SSL-Client-A-Key   SSL_SERVER_A_KEY   SSL-Server-A-Key
```

Table 8–2 (Cont.) CGI Environment Variables with Corresponding Header Names

<table>
<thead>
<tr>

</tbody>
</table>
5. Run the following command:
   `dcmctl updateconfig -ct ohs`

6. Run the following command:
   `opmnctl restartproc type=ohs`

7. Test that the SSO server can be logged into with client authentication.

**mod_cgi**

Enables the server to run CGI scripts.

See Also: Module `mod_cgi` in the Apache Server documentation.

**mod_define**

Enables the `Define` directive, which defines a variable that can be expanded on any configuration line. The `Define` directive has the status `Extension`, which means that it is not compiled into the server by default.

This module requires the Extended API (EAPI). Oracle HTTP Server always has EAPI-enabled.

This module is available on UNIX systems only.

**mod_digest**

Uses an older version of the MD5 Digest Authentication specification than that used in `mod_auth_digest` to provide user authentication. `mod_digest` probably only works with older browsers.

See Also: Module `mod_digest` in the Apache Server documentation.

**mod_dir**

Enables the server to perform slash (/) redirects. Directories must contain a trailing slash. If a request for a URL without a trailing slash is received, `mod_dir` redirects the request to the same URL followed by a trailing slash. For example:

```
http://myserver/documents/mydirectory
```

is redirected to

```
http://myserver/documents/mydirectory/
```

See Also: Module `mod_dir` in the Apache Server documentation.

**mod_dms**

Enables you to monitor performance of site components with Oracle’s Dynamic Monitoring Service (DMS). It is an Oracle module.
mod_env

Enables you to control the environment for CGI scripts and SSI (Server Side Includes) pages by passing, setting, and unsetting environment variables. 

`ModifyEnv` appends or prepends a value to an existing `ENV` variable’s value, and passes it into the Oracle HTTP Server environment. The following is the usage:

Let $FOO = "foo"$:

- `ModifyEnv FOO "bar"` modifies the value of $FOO from "foo" to "foo:bar"
- `ModifyEnv FOO "+bar"` modifies the value of $FOO from "foo" to "bar:foo"

Let $FOO$ be undefined:

- `Modify Foo "bar"` sets the value of $FOO$ to "bar"

See Also: Module mod_env in the Apache Server documentation.

mod_example

Provides examples and guidance on how to write modules using the Apache API. When implemented, it demonstrates module callbacks triggered by the server.

mod_expires

Enables the server to generate Expires HTTP headers, which provide information to the client about document validity. Documents are served from the source if, based on the expiration criteria, the cached copy has expired.

See Also: Module mod_expires in the Apache Server documentation.

mod_fastcgi

Supports the FastCGI protocol, which enables you to maintain a pool of running servers for CGI applications, thereby eliminating start-up and initialization overhead.

See Also: Module mod_fastcgi in the Apache Server documentation.

mod_headers

Enables you to merge, replace, or remove HTTP response headers.

See Also: Module mod_headers in the Apache Server documentation.

mod_imap

Enables server-side image map processing.
mod_include

Provides a filter that processes documents for SSI (Server Side Includes) directives.

See Also: Module mod_include in the Apache Server documentation.

mod_info

Summarizes the entire server configuration, including all installed modules and directive settings.

See Also: Module mod_info in the Apache Server documentation.

mod_log_agent

Enables logging of client user agents. It is deprecated; you should use mod_log_config instead of mod_log_agent.

See Also: Module mod_log_config in the Apache Server documentation.

mod_log_referer

Enables logging of documents that reference documents on the server. It is deprecated; you should use mod_log_config instead of mod_log_referer.

See Also: Module mod_log_referer in the Apache Server documentation.

mod_mime

Enables the server to determine the type of a file from its filename, and associate files with handlers for processing.

See Also: Module mod_mime in the Apache Server documentation.

mod_mime_magic

Enables the server to determine the MIME type of a file by examining a few bytes of its content. It is used in cases when mod_mime cannot determine a file type. Make sure that mod_mime appears before mod_mime_magic in the configuration file, so that mod_mime processes the files first.

See Also: Module mod_mime_magic in the Apache Server documentation.
mod_mmap_static
Maps a list of files into memory, useful for frequently requested files that are not changed often.

mod_negotiation
Enables the server for content negotiation (selection of documents based on the client's capabilities).

See Also: Module mod_negotiation in the Apache Server documentation.

mod_oc4j
Routes requests from the Oracle HTTP Server to Oracle Application Server Containers for J2EE (OC4J), through the AJP 1.3 protocol. It is an Oracle module.

mod_oc4j is enabled by default. During installation, the oc4j_deploy_tool.jar adds mount points to mod_oc4j.conf for applications deployed into OC4J instances. Requests that come in for specific mount points in mod_oc4j are routed to the OC4J instance for that mount point.

OC4J instances are started and managed by Oracle Process Manager and Notification Server (OPMN).

See Also:
- Oracle Application Server Containers for J2EE User's Guide
- Oracle Process Manager and Notification Server Administrator's Guide
- Appendix C, "Using Oracle Application Server Containers for J2EE Plug-in"

This section discusses the following topics:
- Configuring mod_oc4j
- Load Balancing Using mod_oc4j
- Enabling SSL between mod_oc4j and OC4J
- Integrating Generic Apache with Oracle Application Server

Configuring mod_oc4j
The following sections describe all relevant directives in httpd.conf and mod_oc4j.conf. Sample configurations are also provided.

mod_oc4j Configuration File and Directives
The mod_oc4j directives are maintained in mod_oc4j.conf. The mod_oc4j.conf file is included by default into the httpd.conf file, using the following directive:

```
include "ORACLE_HOME/Apache/Apache/conf/mod_oc4j.conf"
```

The following directives are used to configure mod_oc4j:
- Oc4jCacheSize
- Oc4jConnTimeout
mod_oc4j

- Oc4jCookieExtension
- Oc4jExtractSSLEntity
- Oc4jEnvVar
- Oc4jMount
- Oc4jMountCopy
- Oc4jUseOHSErrors

See Also: “Using SSL Configuration Directives” on page 11-4

LoadModule
Loads the mod_oc4j module.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>LoadModule oc4j_module mod_oc4j shared library file</td>
</tr>
<tr>
<td>Required</td>
<td>Yes</td>
</tr>
<tr>
<td>Default</td>
<td>■ UNIX: None</td>
</tr>
<tr>
<td></td>
<td>■ Windows: LoadModule oc4j_module modules\ApacheModuleOc4j.dll</td>
</tr>
<tr>
<td>Example</td>
<td>■ UNIX: LoadModule oc4j_module mod_oc4j.so</td>
</tr>
<tr>
<td></td>
<td>■ Windows: LoadModule oc4j_module modules\ApacheModuleOc4j.dll</td>
</tr>
</tbody>
</table>

Oc4jCacheSize
Specifies the size of the OC4J connection cache.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jCacheSize &lt;size of connection cache&gt;</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>■ UNIX: 1</td>
</tr>
<tr>
<td></td>
<td>■ Windows: 32</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jCacheSize 64</td>
</tr>
</tbody>
</table>
| Usage      | Specifies the number of concurrent OC4J connections that can be cached by each Oracle HTTP Server process. Setting this directive to “0” will disable persistent connections between mod_oc4j and the OC4J instances.

Oc4jConnTimeout
Defines maximum idle time (in seconds) for unused connections.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jConnTimeout &lt;timeout value for AJP13 connections&gt;</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jConnTimeout 10</td>
</tr>
</tbody>
</table>
### Oc4jCookieExtension

Directs `mod_oc4j` to use `JSESSIONID_<cookie_name_extension>` as OC4J’s session identifier in the cookie.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jCookieExtension &lt;cookie_name_extension&gt;</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jCookieExtension MYEXT</td>
</tr>
</tbody>
</table>

**Usage**: Useful for cases where there is a firewall between `mod_oc4j` and OC4J that times out connections. The value should be set to a value smaller than the timeout value used by the firewall.

### Oc4jExtractSSL

Governs passing SSL environment variables.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jExtractSSL On</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>Off</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jExtractSSL On</td>
</tr>
</tbody>
</table>

**Usage**: Directs `mod_oc4j` to decide whether or not to pass three SSL environment variables, `SSL_CLIENT_CERT`, `SSL_CIPHER`, and `SSL_SESSION_ID` to OC4J. There is a performance cost associated with copying the SSL environment variables to OC4J, so set it to “On” only if the environment variables must be available to OC4J.

**Note**: If configured, `mod_oc4j` passes some security environment parameters to OC4J set by `mod_ossl` and `mod_osso`, at request time.

### Oc4jEnvVar

Directs `mod_oc4j` to pass some environment variables from Oracle HTTP Server to OC4J.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jEnvVar environment variable name [environment variable default value]</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
</tbody>
</table>
**mod_oc4j**

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Example  | Oc4jEnvVar MY_ENV1  
Oc4jEnvVar MY_ENV2 myenv_value |
| Usage    | For each Oc4jEnvVar entry, you must also configure the Oracle HTTP Server directive, PassEnv, with the environment variable. Otherwise, mod_oc4j cannot acquire and pass the value. Multiple entries are allowed. You could specify the default value for the environment variable as the second parameter, or leave it empty. If the environment variable’s value is found in the Oracle HTTP Server environment, its value will be passed to OC4J. Otherwise, if the default value is set, the default value will be passed. If this environment variable’s value is not found in the Oracle HTTP Server environment and the default value is not set, nothing is passed to OC4J. There is a performance degradation associated with mod_oc4j passing some configured environment variables over to OC4J with each request. |

**Note:** If configured, mod_oc4j passes some security environment parameters to OC4J set by mod_ossl and mod_osso, at request time.

**Oc4jMount**

Directs mod_oc4j to route requests containing a particular path to a destination. A destination can be a single OC4J process, or a set of OC4J instances.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Syntax   | Oc4jMount path [destination]  
where path is the context root. The path parameter must be the same as the application context root specified in the OC4J configuration file xxx-web-site.xml. The application context root is shown in bold text in the example <web-site> element.  
<default-web-app application="default" name="defaultWebApp" root="/j2ee"/>  
and where destination is one of these types:  
* ajp13_dest  
* cluster_dest (this is the default destination type)  
* instance_dest  
If destination is not specified, the default OC4J instance name of home will be used. For example,  
Oc4jMount /myApp/*  
provides the same result as:  
Oc4jMount /myApp/* cluster://local_jax_cluster_name:home |
| Required | No |
| Default  | None |
**Oc4jMountCopy**

Copies mount points from the base server.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jMountCopy On</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>On</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jMountCopy Off</td>
</tr>
</tbody>
</table>
### Oc4jUseOHSErrors

Allows users to configure an error range using Oracle HTTP Server's error pages when errors in the range are returned from OC4J.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jUseOHSErrors On/Off/min-max</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>off</td>
</tr>
<tr>
<td>Example</td>
<td>Oc4jUseOHSErrors 400-410</td>
</tr>
</tbody>
</table>

**Usage**
- Oc4jUseOHSErrors Off: This is the default value if Oc4jUseOHSErrors is not specified. OC4J error pages are passed back to the client for all error values.
- Oc4jUseOHSErrors on: This returns the Oracle HTTP Server error pages for HTTP errors 400-500 inclusive.
- Oc4jUseOHSErrors min-max: This specifies the min and max for HTTP errors. For example, if you set Oc4jUseOHSErrors 400-410, then Oracle HTTP Server error pages for HTTP error 400-410 inclusive are returned from OC4J.

---

### mod_oc4j Sample Configurations

This section provides some sample configurations for mod_oc4j.

**Example 8–1 Sample mod_oc4j configuration**

This configuration mounts all requests starting with the URI /servlet/ to the default instance of OC4J processes.

Make this entry in the httpd.conf file:

```
Oc4jMount /servlet/*
```

**Example 8–2 Sample mod_oc4j configuration**

This configuration performs the same work as the configuration in Example 8–1, using a `<Location>` container directive instead of the Oc4jMount directive.

Make this entry in the httpd.conf file:

```
<Location /servlet>
  SetHandler oc4j-handler
</Location>
```

**Note:** This will only route requests to default the OC4J instance
Example 8–3  Sample mod_oc4j configuration

This configuration mounts all requests starting with the URI /servlet/ or /j2ee/ and all JSP pages to the default OC4J instance of OC4J processes.

Make these entries in the mod_oc4j.conf file:

```
Oc4jMount /servlet/*
Oc4jMount /*.jsp
Oc4jMount /j2ee/*
```

Example 8–4  Sample mod_oc4j configuration

This configuration mounts:

- All requests starting with the URI /applicationA/ and all JSP pages to oc4j_instance_A, in which all OC4J processes are managed by OPMN.
- All requests starting with the URI /applicationB/ to oc4j_instance_B, in which all OC4J processes are managed by OPMN.

Make these entries in the mod_oc4j.conf file:

```
Oc4jMount /applicationA/* oc4j_instance_A
Oc4jMount /applicationB/* oc4j_instance_B
Oc4jMount /j2ee/*
Oc4jMount /*.jsp oc4j_instance_A
```

Load Balancing Using mod_oc4j

mod_oc4j load balancing, including metric based load balancing, is discussed in detail in Appendix D, "Load Balancing Using mod_oc4j".

Enabling SSL between mod_oc4j and OC4J

Optionally, you can have direct SSL support for communication between mod_oc4j and OC4J. To do this, you have to enable SSL on the mod_oc4j side as well as the OC4J side.

- Enabling SSL for mod_oc4j
- Enabling SSL for OC4J

Enabling SSL for mod_oc4j

Add the following directives in mod_oc4j.conf to enable SSL for mod_oc4j:

```
Oc4jEnableSSL
```

Indicates whether mod_oc4j needs to use SSL when communicating with OC4J processes. It should not be configured to 'On' if Oc4jASPTActive is configured to 'On'.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>Oc4jEnableSSL</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>On/Off</td>
</tr>
<tr>
<td>Default Value</td>
<td>Off</td>
</tr>
</tbody>
</table>
Oc4jSSLWalletFile
When Oc4jEnableSSL is set to "On", this directive specifies the location of an Oracle Wallet file that contains SSL certificates that are used for SSL communication with OC4J processes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>Oc4jSSLWalletFile</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Path to a wallet directory location that contains the SSL certificate to be used when establishing SSL connections to OC4J processes.</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Oc4jSSLWalletPassword
When Oc4jEnableSSL is set to "On", this value is the obfuscated password used for authentication when opening the wallet file. This value is obtained using the iasobf utility.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>Oc4jSSLWalletPassword</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Obfuscated password used for authentication when opening the wallet file specified by Oc4jSSLWalletFile.</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
</tbody>
</table>

See Also:
- Oracle Application Server Administrator's Guide for information on Oracle Wallet Manager.
- "Using the iasobf Utility" on page 11-15

Note: Wallet passwords have been deprecated. A warning message is generated in the Oracle HTTP Server log if this directive is used. For secure wallets, Oracle recommends that you get a SSO wallet instead.

Enabling SSL for OC4J
To enable SSL communication between mod_oc4j and OC4J, you have to enable SSL on the OC4J side too.

See Also: Oracle Application Server Containers for J2EE Security Guide for enabling SSL on the OC4J side.

Integrating Generic Apache with Oracle Application Server
You can integrate generic Apache with Oracle Application Server, 10g Release 2 (10.1.2). This enables you route requests from generic Apache to OC4J in the same manner as routing requests using Oracle HTTP Server and mod_oc4j. The generic Apache version supported is 1.3.xx, and not 2.0.
mod_onsint

Provides integration support with Oracle Notification Service (ONS) and Oracle Process Manager and Notification Server (OPMN). It is an Oracle module.

Benefits of mod_onsint

mod_onsint provides the following functionality:

- Provides a subscription mechanism for ONS notifications within Oracle HTTP Server. This is particularly important on UNIX where Oracle HTTP Server employs a multi-process architecture. In such an architecture, it is not feasible to have an ONS subscriber in each process since there are up to 8192 processes that comprise a single Oracle HTTP Server instance. Instead, mod_onsint provides a single process that receives notification for all modules within an Oracle HTTP Server instance.

- Publishes PROC_READY ONS notifications so that other components such as OPMN and OC4J are notified that the listener is up and ready. It also provides information such as DMS metrics and information about how the listener can be contacted. These notifications are sent periodically by mod_onsint as long as the Oracle HTTP Server instance is running.

- Provides functionality that allows Oracle HTTP Server to terminate as a single unit if the parent process fails. The parent process is responsible for starting and stopping all of the child processes for an Oracle HTTP Server instance. The failure of the parent process without first shutting down the child processes leaves Oracle HTTP Server in an inconsistent state that can only be fixed by manually killing all of the orphaned child processes. Until this is done, a new Oracle HTTP Server instance cannot be started since the orphaned child processes still occupy the ports Oracle HTTP Server wants to use. mod_onsint provides a monitor of the parent process. If it detects that the parent process has died, it kills all of the remaining child processes. When combined with OPMN, this provides restartability for Oracle HTTP Server in the case of a parent process failure. mod_onsint ensures that all of the Oracle HTTP Server child processes die, leaving the ports open for a new Oracle HTTP Server instance. OPMN ensures that a new instance is started once the failure of the original instance is detected.

Implementation Differences on UNIX and Windows

Due to the difference in architecture of Oracle HTTP Server on UNIX and Windows, the implementation of mod_onsint varies slightly on these platforms.

On UNIX, mod_onsint spawns a process at module initialization time. This process is responsible for watching the parent process as well as sending and receiving ONS messages. Callback functions from other modules interested in ONS notifications are made in this process. For this information to be shared with other Oracle HTTP Server child processes, the use of an interprocess communication method such as a memory mapped file must be used. If a failure of a parent process is detected on UNIX, a signal is sent to all the other child processes, causing them to shut down.

On Windows, Oracle HTTP Server consists of only two processes, the parent and a multi-threaded child that handles all of the HTTP requests. In this model, mod_onsint runs as a thread within the child process. This thread watches the parent process and provides the same functionality as described above for UNIX.
process as well as sending and receiving ONS messages. Callback functions from other modules interested in ONS notifications are made in the child process. If a failure of the parent process is detected, the mod_onsint terminates the child process, effectively shutting down Oracle HTTP Server.

There is an optional directive called OpmnHostPort that can be configured for mod_onsint. This directive enables you to specify a hostname and port that OPMN should use for pinging the Oracle HTTP Server instance that mod_onsint is running in. If OpmnHostPort is not specified, mod_onsint chooses an HTTP port automatically. In certain circumstances, you may want to choose a specific HTTP port and hostname that OPMN should use to ping the listener with.

OpmnHostPort takes a single argument which is a host:port string that specifies the values to pass to OPMN. For example, the following line would specify that OPMN should use the localhost interface and port 7778 to ping this listener:

```
OpmnHostPort localhost:7778
```

This directive must be in the global section of the httpd.conf file. It cannot be embedded into any virtual host of location container. After installation, an OpmnHostPort directive is located in dms.conf. It points OPMN to the Oracle HTTP Server 'diagnostic port', which is a special localhost only virtual host. It does not log internal diagnostic requests such as OPMN pings and DMS metric requests from Application Server Control Console.

**mod_oradav**

This Oracle module (an OCI application written in C) is an extended implementation of mod_dav, and is integrated with the Oracle HTTP Server. mod_oradav can read and write to local files or to an Oracle database. The Oracle database must have an OraDAV driver (a stored procedure package) that mod_oradav calls to map WebDAV activity to database activity. Essentially, mod_oradav enables WebDAV clients to connect to an Oracle database, read and write content, and query and lock documents in various schemas.

You can configure mod_oradav to an Oracle database using standard Oracle HTTP Server directives. mod_oradav can immediately leverage other module code (such as mime_magic) in order to perform content management tasks. Most OraDAV processing activity involves streaming content to and from a content provider; and mod_oradav uses OCI streaming logic directly within the Oracle HTTP Server.

To configure mod_oradav, you enter parameters within a `<Location>` container directive in httpd.conf. The `<Location>` container directive specifies the DAV-enabled URL. The DAV keyword is followed by a single value: `On`, which tells mod_dav to use the local file system for content.

The following example specifies that the directory `myfiles` under the Web server documents directory (`htdocs` by default) is to be DAV-enabled, along with all directories under `myfiles` in the hierarchy. (Note that there must not be any symlinks defined on `myfiles` or any of its subdirectories.)

```
<Location /myfiles>
  DAV On
</Location>
```
For information about using mod_oradav to access database schemas for access by third-party tools (such as Adobe GoLive and Macromedia Dreamweaver) and Oracle interMedia, refer to the OraDAV information available on OTN at http://www.oracle.com/technology/index.html

mod_ossl

Enables strong cryptography for Oracle HTTP Server. This Oracle module is plug-in to Oracle HTTP Server that enables the server to use SSL. It is very similar to the OpenSSL module, mod_ssl. However, in contrast to the OpenSSL module, mod_ossl is based on the Oracle implementation of SSL, which supports SSL, version 3, and is based on Certicom and RSA Security technology.

See Also:
- Oracle Application Server Security Guide
- "Using mod_ossl to Authenticate Users" on page 10-7
- Chapter 11, "Enabling SSL for Oracle HTTP Server"

mod_osso

Enables single sign-on for Oracle HTTP Server. An Oracle module, mod_osso, examines incoming requests and determines whether the resource requested is protected, and if so, retrieves the Oracle HTTP Server cookie for you.

See Also: Oracle Application Server Single Sign-On Administrator's Guide

mod_perl

Embeds the Perl interpreter into the Oracle HTTP Server. This eliminates start-up overhead and enables you to write modules in Perl. Oracle Application Server uses Perl version 5.6.1.

See Also: mod_perl Guide

Database Usage Notes

This section provides information for mod_perl users working with databases. It explains how to test a local database connection and set character forms.

Using Perl to Access the Database

The following section contains information about using Perl to access the database. Perl scripts access databases using the DBI/DBD driver for Oracle. The DBI/DBD driver is part of Oracle Application Server. It calls Oracle Callable Interface (OCI) to access the databases.
DBI must be enabled in `httpd.conf` for DBI to function. To do this, perform the following steps:

1. Edit `httpd.conf` using a text editor.
2. Search for "Per1Module Apache::DBI".
3. Uncomment the line "Per1Module Apache::DBI".
4. Restart Oracle HTTP Server using Application Server Control Console, or with the following command:

   ```bash
   ORACLE_HOME/opmn/bin/opmnctl [verbose] restartproc ias-component=HTTP_Server
   ```

   **See Also:** “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3

Files must be copied to `ORACLE_HOME/Apache/Apache/cgi-bin`.

```perl
#!<ORACLE_HOME>/perl/bin/perl -w
use DBI;
my $dataSource = "host=<hostname.domain>;sid=<orclsid>;port=1521";
my $userName = "scott";
my $password = "tiger";
my $dbh = DBI->connect("dbi:Oracle:$dataSource", $userName, $password)
  or die "Can't connect to the Oracle Database: $DBI::errstr\n";
print "Content-type: text/plain\n\n";
print "Database connection successful.\n";
$dbh->disconnect
  or warn "Database disconnect failed; $DBI::errstr\n";
exit;
```

You can access the DBI scripts from the following locations:

- `http://<hostname.domain>:<port>/cgi-bin/<scriptname>`
- `http://<hostname.domain>:<port>/perl/<scriptname>`

If the script specifies "use Apache::DBI" instead of "use DBI", then it will only be able to run from `http://<hostname.domain>:<port>/perl/<scriptname>`.

### Testing Database Connection

The following is a sample Perl script for testing the database connection of a local seed database. To use the script to test another database connection, you must replace `scott/tiger` with the user name and password for the target database.

```perl
##### Perl script start ######
use DBI;
pod "Content-type: text/plain\n";
$sth = DBI->connect("dbi:Oracle:","scott/tiger","") || die $DBI::errstr;
$sth->prepare("select * from emp order by empno")|| die $DBI::errstr;
$rc =$sth->execute(); $i = $sth->rowcount();
while (($empno, $name) = $sth->fetchrow()) { print "$empno $name\n";
warn $DBI::err if $DBI::err;
die "fetch error: " . $DBI::errstr if $DBI::err;
$sth->finish(); die "can't close cursor";
```

---

Using SQL NCHAR Datatypes

SQL NCHAR datatypes have been refined since Oracle9i, and are now called reliable Unicode datatypes. SQL NCHAR datatypes such as NCHAR, NVARCHAR2 and NCLOB allow you to store any Unicode characters regardless of the database character set. The character set for those datatypes is specified by the national character set, which is either AL16UTF-16 or UTF8.

See Also: Oracle9i documentation for more about SQL NCHAR datatypes.

This release of DBD::Oracle supports SQL NCHAR datatypes and provides driver extension functions to specify the character form for data binding. The following script shows an example to access SQL NCHAR data:

Example 8-7 Sample Script to Access SQLNCHAR Data

```perl
# declare to use the constants for character forms
use DBD::Oracle qw(:ora_forms);
# connect to the database and get the database handle
$dbh = DBI->connect( ... );
# prepare the statement and get the statement handle
$sth = $dbh->prepare( 'SELECT * FROM TABLE_N WHERE NCOL1 = :nchar1' );
# bind the parameter of a NCHAR type
$sth->bind_param( ':nchar1', $param_1 );
# set the character form to NCHAR
$sth->func( { ':nchar1' => ORA_NCHAR } , 'set_form' );
$sth->execute;
```

As shown in Example 8-7, the `set_form` function is provided as a private function that you can invoke with the standard DBI `func()` method. It takes an anonymous hash that specifies which placeholder should be associated with which character form. The valid values of character form are either `ORA_IMPLICIT` or `ORA_NCHAR`. Setting the character form to `ORA_IMPLICIT` causes the application's bound data to be converted to the database character set, and `ORA_NCHAR` to the national character set. The default form is `ORA_IMPLICIT`.

Another function is provided to specify the default character set form as follows:

```perl
# specify the default form to be NCHAR
$dbh->func( ORA_NCHAR, 'set_default_form' );
```

After this call is made, the form of all parameters is `ORA_NCHAR`, unless otherwise specified with `set_form` calls. Note that unlike the `set_form` function, this is a function on the database handle, so every statement from the database handle with its default form specified has the form of your choice by default.

### set_form

This function sets the character form for parameter(s). Valid forms are either `ORA_IMPLICIT` (default) or `ORA_NCHAR`. The constants are available as `ora_forms` in `DBD::Oracle`.

Example 8-8 Sample for `set_form`

```perl
# a declaration example for the constants ORA_IMPLICIT and ORA_NCHAR
use DBD::Oracle qw(:ora_forms);
```
mod_php

# set the character form for the placeholder :nchar1 to NCHAR
$sth->func( { ':nchar1' => ORA_NCHAR } , 'set_form' );

# set the character form using the positional index
$sth->func( { 2 => ORA_NCHAR } , 'set_form' );

# set the character form for multiple placeholders at once
$sth->func( { 1 => ORA_NCHAR, 2 => ORA_NCHAR } , 'set_form' );

**set_default_form** This function sets the default character form for a database handle.

**Example 8-9 Default Character Form for a Database Handle**

$dbh->func( ORA_NCHAR , 'set_default_form' );

mod_php

PHP (recursive acronym for 'PHP: Hypertext Preprocessor') is an open source, widely-used, general-purpose, client-side scripting language, that is embedded in standard HTML. It is used to generate dynamic HTML pages. On Oracle HTTP Server, PHP support is provided through *mod_php* and has Oracle database support enabled. It uses PHP version 4.3.9.

**Note:** `phpinfo()` prints out very sensitive information about the current state of PHP and Oracle HTTP Server intervals. Users new to PHP, or those who are unaware of `phpinfo()` should not inadvertently leave a PHP script called `phpinfo()` publically accessible.

`phpinfo()` is used heavily for debugging. There is a good chance that such a debug script could be left in the open by mistake once debugging is finished.

**See Also:**
- [http://php.net/](http://php.net/)

mod_plsql

Connects Oracle HTTP Server to an Oracle database, enabling you to create Web applications using Oracle stored procedures. It is an Oracle module.

In order to access a Web-enabled PL/SQL application, configure a PL/SQL Database Access Descriptor (DAD) for *mod_plsql*. A DAD is a set of values that specifies how *mod_plsql* connects to a database server to fulfill an HTTP request. Besides the connect details, a DAD contains important configuration parameters for various operations in the database and for *mod_plsql* in general. Any Web-enabled PL/SQL application which makes use of the PL/SQL Web ToolKit needs to create a DAD to invoke the application.

- Any PL/SQL Application written using the PL/SQL Web ToolKit
- Oracle Application Server Portal
Creating a DAD

If mod_plsql is part of Oracle Application Server, it is recommended that you use Application Server Control Console to create a DAD.

See Also: "Creating a Database Access Descriptor (DAD) for mod_plsql" on page 7-16

If not, then perform the following steps to create a DAD:

1. Edit the DAD configuration file ORACLE_HOME/Apache/modplsql/conf/dads.conf.
2. Add a DAD where the DAD has the following format:
   a. The Oracle HTTP Server <Location> directive which defines a virtual path used to access the PL/SQL Web Application. This directive begins enclosing a group of directives that apply to the named Location.
      For example, the directive <Location /myapp> defines a virtual path called "/myapp" that will be used to invoke a PL/SQL Web Application through a URL like http://host:port/myapp/
   b. The Oracle HTTP Server "SetHandler" directive which directs Oracle HTTP Server to enable mod_plsql to handle the request for the virtual path defined by the named Location
      SetHandler pls_handler
   c. Additional Oracle HTTP Server directives that are allowed in the context of a <Location> directive. Typically, the following directives are used:
      Order deny,allow
      Allow from all
      AllowOverride None
   d. One or more mod_plsql specific directives. For example:
      PlsqlDatabaseUsername        scott
      PlsqlDatabasePassword        tiger
      PlsqlDatabaseConnectString   orcl
      PlsqlAuthenticationMode      Basic
   e. An Oracle HTTP Server </Location> directive which closes the group of directives for the named Location, and defines a single DAD.
3. Save the edits.
4. Obfuscate the DAD password by running the "dadTool.pl" script located in ORACLE_HOME/Apache/modplsql/conf.

See Also: "PlsqlDatabasePassword" on page 8-36 for instructions on performing the obfuscation.
If `mod_plsql` is part of Oracle Application Server, then issue the following command:

```
$ORACLE_HOME/dcm/bin/dcmctl updateConfig -ct ohs
```

6. Restart Oracle HTTP Server using Application Server Control Console, or with the following command:

```
ORACLE_HOME/opmn/bin> opmnctl [verbose] restartproc ias-component=HTTP_Server
```

See Also: “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3

You can create additional DADs by defining other uniquely named `Locations` in `dads.conf`.

Configuration Files

`mod_plsql` configuration parameters reside in the following three configuration files:

- `plsql.conf`
- `dads.conf`
- `cache.conf`

### plsql.conf

This file contains the `LoadModule` directive to load `mod_plsql` into Oracle HTTP Server, any global settings for `mod_plsql`, and include directives for `dads.conf` and `cache.conf`. This file is included by the Oracle HTTP Server configuration file `ORACLE_HOME/Apache/Apache/conf/oracle_apache.conf` on UNIX or `ORACLE_HOME\Apache\Apache\conf\oracle_apache.conf` on Windows, which itself gets included in the primary Oracle HTTP Server configuration file `httpd.conf`.

See Also: “oracle_apache.conf” on page E-4

### dads.conf

This file contains the configuration parameters for the PL/SQL database access descriptor (DAD). A DAD is a set of values that specifies how `mod_plsql` connects to a database server to fulfill a HTTP request.

### cache.conf

This file contains the configuration settings for the file system caching functionality implemented in `mod_plsql`. This configuration file is relevant only if PL/SQL applications use the `OWL_CACHE` package to cache dynamically generated content in the file system.

See Also: Oracle Application Server `mod_plsql` User's Guide for details on caching functionality in `mod_plsql`.

Configuration Parameters

Table 8–3 contains a list of `mod_plsql` configuration parameters. They are discussed in detail in later sections.

---

8-24 Oracle HTTP Server Administrator's Guide
While specifying a value for a configuration parameter, follow Oracle HTTP Server conventions for specifying values. For instance, if a value has white spaces in it, enclose the value with double quotes. For example: `PlsqlNLSLanguage "TRADITIONAL CHINESE_TAIWAN.UTF8"`

Multi-line directives enable you to specify same directive multiple times in a DAD.

<table>
<thead>
<tr>
<th>Table 8-3</th>
<th>mod_plsql Configuration Files and Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configuration File</td>
<td>Parameters</td>
</tr>
<tr>
<td>plsql.conf</td>
<td>PlsqlDMSEnable, PlsqlLogEnable, PlsqlLogDirectory, PlsqlIdleSessionCleanupInterval</td>
</tr>
</tbody>
</table>
This file contains the `LoadModule` directive to load `mod_plsql` into the Oracle HTTP Server, global settings for `mod_plsql`, and include directives for `dads.conf` and `cache.conf`.

The following section discusses the parameters that can be specified in `plsql.conf`:

- **PlsqlDMSEnable**
- **PlsqlLogEnable**
- **PlsqlLogDirectory**
- **PlsqlIdleSessionCleanupInterval**

**PlsqlDMSEnable**
Enables Dynamic Monitoring Service (DMS) for `mod_plsql`.

**PlsqlLogEnable**
Enables debug level logging for `mod_plsql`. Debug level logging is meant to be used for debugging purposes only. When logging is enabled, log files are generated at:

- **UNIX**: `ORACLE_HOME/Apache/modplsql/logs`
- **Windows**: `ORACLE_HOME\Apache\modplsql\logs`

as configured by `PlsqlLogDirectory`. This parameter should be set to "Off" unless recommended by Oracle support to debug problems with `mod_plsql`.

To view more details about the internal processing of `mod_plsql`, set this directive to "On". This causes `mod_plsql` to start logging for every request that is processed. The log files are generated as specified by the `PlsqlLogDirectory` directive.

---

### Table 8–3 (Cont.) mod_plsql Configuration Files and Parameters

<table>
<thead>
<tr>
<th>Configuration File</th>
<th>Parameters</th>
</tr>
</thead>
</table>
| `cache.conf`       | `PlsqlCacheCleanupTime`  
|                    | `PlsqlCacheDirectory`  
|                    | `PlsqlCacheEnable`  
|                    | `PlsqlCacheMaxAge`  
|                    | `PlsqlCacheMaxSize`  
|                    | `PlsqlCacheTotalSize`  |

**Note:** Refer to `plsql.README` located in `ORACLE_HOME/Apache/modplsql/conf` for detailed description of `plsql.conf`.

---

**PlsqlDMSEnable**
Enables Dynamic Monitoring Service (DMS) for `mod_plsql`.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlDMSEnable On/Off</code></td>
</tr>
<tr>
<td>Default</td>
<td>On</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlDMSEnable On</code></td>
</tr>
</tbody>
</table>

**PlsqlLogEnable**
Enables debug level logging for `mod_plsql`.

Debug level logging is meant to be used for debugging purposes only. When logging is enabled, log files are generated at:

- **UNIX**: `ORACLE_HOME/Apache/modplsql/logs`
- **Windows**: `ORACLE_HOME\Apache\modplsql\logs`

as configured by `PlsqlLogDirectory`. This parameter should be set to "Off" unless recommended by Oracle support to debug problems with `mod_plsql`.

To view more details about the internal processing of `mod_plsql`, set this directive to "On". This causes `mod_plsql` to start logging for every request that is processed. The log files are generated as specified by the `PlsqlLogDirectory` directive.
PlsqlLogDirectory
Specifies the directory where debug level logs are written out.

Set the directory name of the location where log files should be generated when logging is enabled. To avoid possible confusion about the location of this directory, an absolute path is recommended.

On UNIX, this directory must have write permissions by the owner of the child httpd processes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlLogEnable On/Off</td>
</tr>
<tr>
<td>Default</td>
<td>Off</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlLogEnable Off</td>
</tr>
</tbody>
</table>

PlsqlIdleSessionCleanupInterval
Specifies the time (in minutes) in which the idle database sessions should be closed and cleaned by mod_plsql.

This directive is used in conjunction with connection pooling of database connections and sessions in mod_plsql. When a session is not used for the specified amount of time, it is closed, and freed. This is done so that unused sessions can be cleaned, and the memory is freed on the database side.

Setting this time to a low number helps in faster cleanup of unused database sessions. Be aware that if this number is too low, then this may adversely affect the performance benefits of connection pooling in mod_plsql.

If the number of open database sessions is not a concern, you can increase the value of this parameter for best performance. In such a case, if the site is accessed frequently enough that the idle session cleanup interval is never reached for a session, then the DAD configuration parameter PlsqlMaxRequestsPerSession can be modified so that it is guaranteed that a pooled database session gets recycled on a regular basis.

For most installations, the default parameter value should suffice.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlIdleSessionCleanupInterval number</td>
</tr>
<tr>
<td>Default</td>
<td>15 (minutes)</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlIdleSessionCleanupInterval 15</td>
</tr>
</tbody>
</table>

dads.conf
This file contains the configuration parameters for the PL/SQL Database Access Descriptor (DAD).
DAD Parameters
This section describes all the DAD level parameters that can be specified in the
dads.conf file. Besides these directives, you can also specify additional Oracle HTTP
Server directives that can be specified in the context of a <Location> directive, such as:

Order deny,allow
AllowOverride None

The following parameters are discussed in detail in the subsequent sections:

- PlsqlAfterProcedure
- PlsqlAlwaysDescribeProcedure
- PlsqlAuthenticationMode
- PlsqlBeforeProcedure
- PlsqlBindBucketLengths
- PlsqlBindBucketWidths
- PlsqlCGIEnvironmentList
- PlsqlCompatibilityMode
- PlsqlConnectionTimeout
- PlsqlConnectionValidation
- PlsqlDatabaseConnectString
- PlsqlDatabasePassword
- PlsqlDatabaseUserName
- PlsqlDefaultPage
- PlsqlDocumentPath
- PlsqlDocumentProcedure
- PlsqlDocumentTablename
- PlsqlErrorStyle
- PlsqlExclusionList
- PlsqlFetchBufferSize
- PlsqlInfoLogging
- PlsqlMaxRequestsPerSession
- PlsqlNLSLanguage
- PlsqlPathAlias
- PlsqlPathAliasProcedure
- PlsqlRequestValidationFunction
- PlsqlSessionCookieName
- PlsqlSessionStateManagement
- PlsqlTransferMode
- PlsqlUploadAsLongRaw
PlsqlAfterProcedure
Specifies the procedure to be invoked after calling the requested procedure. This enables you to put a hook point after the requested procedure is called. This is useful in doing SQL*Traces/SQL Profiles while debugging a problem with the requested procedure. This is also useful when you want to ensure that a specific call be made after running every procedure.

- For all purposes, except for debugging, this parameter should be omitted. You could use this parameter to stop SQL Trace/SQL Profiling.
- In older versions of the product, this parameter was called after_proc.

PlsqlAlwaysDescribeProcedure
Specifies whether mod_plsql should describe a procedure before trying to execute it. If this is set to "On", then mod_plsql will always describe a procedure before invoking it. Otherwise, mod_plsql will only describe a procedure when its internal heuristics have interpreted a parameter type incorrectly.

- For all purposes, except for debugging, you should leave this parameter set to "Off".
- In older versions of the product, this parameter was called always_desc.

PlsqlAuthenticationMode
Specifies the authentication mode to use for allow access through this DAD.

- Most customer applications use Basic Authentication. Custom Authentication modes (GlobalOwa, CustomOwa, PerPackageOwa) are used by very few PL/SQL applications. The SingleSignOn mode is supported only for Oracle Application Server releases, and is used by Oracle Application Server Portal and Oracle Application Server Single Sign-On.
- If the DAD is not using the Basic authentication, then you must include a valid username/password in the DAD configuration. For the Basic mode, if you wish
to perform dynamic authentication, the DAD username/password parameters must be omitted.

- In older versions of the product, this configuration parameter was derived from a combination of enabless0 and custom auth.
  - enabless0 = Yes translates to PlsqlAuthenticationMode SingleSignOn
  - custom_auth = Global translates to PlsqlAuthenticationMode GlobalOwa
  - custom_auth = Custom translates to PlsqlAuthenticationMode CustomOwa
  - custom_auth = PerPackage translates to PlsqlAuthenticationMode PerPackageOwa

All other combinations translate to Basic.

See Also: "Securing Application Database Access through mod_plsql" chapter in the Oracle Application Server mod_plsql User’s Guide for more information regarding different authentication modes.

PlsqlBeforeProcedure
Specifies the procedure to be invoked before calling the requested procedure. This enables you to put a hook point before the requested procedure is called. This is useful in doing SQL Traces/SQL Profiling while debugging a problem with the requested procedure. This is also useful when you want to ensure that a specific call be made before running every procedure.

- For all purposes, except for debugging purposes, this parameter should be omitted. You could use this parameter to start SQL Trace/SQL Profiling.
- In older versions of the product, this parameter was called before_proc.

PlsqlBindBucketLengths
Specifies the rounding size to use while binding the number of elements in a collection bind. While executing PL/SQL statements, the Oracle database maintains a cache of PL/SQL statements in the shared SQL area, and attempts to reuse the cached statement if the same statement is executed again. Oracle’s matching criteria requires that the statement texts be identical, and that the bind variable data types match. Unfortunately, the type match for strings is sensitive to the exact byte size specified, and for collection bindings is also sensitive to the number of elements in the collection. Since mod_plsql binds statements dynamically, the odds of hitting the shared cache are low, and it may fill up with near-duplicates and lead to contention for the latch on the shared area. This parameter reduces that effect by bucketing bind lengths to the nearest level.

All numbers specified should be in ascending order. After the last specified size, subsequent bucket sizes will be assumed to be twice the last one.
This parameter is relevant only if you are using procedures with array parameters, and passing varying number of parameters to the procedure.

The default should be sufficient for most PL/SQL applications.

To see if this parameter needs to be changed, check the number of versions of a SQL statement in the SQL area.

Consider using flexible parameter passing to reduce the problem.

In older versions of the product, this parameter was called bind_bucket_lengths.

**PlsqlBindBucketWidths**

Specifies the rounding size to use while binding the number of elements in a collection bind. While executing PL/SQL statements, the Oracle database maintains a cache of PL/SQL statements in the shared SQL area, and attempts to reuse the cached statement if the same statement is executed again. Oracle’s matching criteria requires that the statement texts be identical, and that the bind variable data types match. Unfortunately, the type match for strings is sensitive to the exact byte size specified, and for collection bindings is also sensitive to the number of elements in the collection. Since mod_plsql binds statements dynamically, the odds of hitting the shared cache are low, and it may fill up with near-duplicates and lead to contention for the latch on the shared area. This parameter reduces that effect by bucketing bind widths to the nearest level.

All numbers specified should be in ascending order. After the last specified size, subsequent bucket sizes will be assumed to be twice the last one.

The last bucket width must be equal to or less than 4000. This is due to the restriction imposed by OCI where array bind widths cannot be greater than 4000.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlBindBucketWidths number multiline</td>
</tr>
<tr>
<td>Default</td>
<td>32, 128, 1450, 2048, 4000</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlBindBucketWidths 40</td>
</tr>
<tr>
<td></td>
<td>PlsqlBindBucketWidths 400</td>
</tr>
<tr>
<td></td>
<td>PlsqlBindBucketWidths 2000</td>
</tr>
</tbody>
</table>

This parameter is relevant only if you are using procedures with array parameters, and passing varying number of parameters to the procedure.

The default should be sufficient for most PL/SQL applications.

To see if this parameter needs to be changed, check the number of versions of a SQL statement in the SQL area.
Consider using flexible parameter passing to reduce the problem.

In older versions of the product, this parameter was called bind_bucket_widths.

**PlsqlCGIEnvironmentList**

Specifies overrides and/or additions of CGI environment variables to the default set of environment variables passed down to a PL/SQL procedure. This is a multi-line directive of name-value pairs to be added, overridden or removed. You can only specify one environment variable for each directive.

You can add CGI environment variables from the Oracle HTTP Server environment by specifying the variable name. To remove a CGI environment variable, set it equal to nothing. To add your own name-value pair, use the syntax myname=myvalue.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCGIEnvironmentList string multiline</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td></td>
</tr>
<tr>
<td></td>
<td>To add a new environment variable from the Oracle HTTP Server environment: PlsqlCGIEnvironmentList DOCUMENT_ROOT</td>
</tr>
<tr>
<td></td>
<td>To remove an environment variable: PlsqlCGIEnvironmentList MYENVAR2=</td>
</tr>
<tr>
<td></td>
<td>To override from the Oracle HTTP Server environment: PlsqlCGIEnvironmentList REQUEST_PROTOCOL=HTTPS</td>
</tr>
<tr>
<td></td>
<td>To add your own environment variable: PlsqlCGIEnvironmentList MY_VARNAME=MY_VALUE</td>
</tr>
</tbody>
</table>

- Environment variables added here are available in the PL/SQL application through the function owa_util.get_cgi_env.
- In older versions of the product, this parameter was called cgi_env_list.

**PlsqlCompatibilityMode**

Specifies the compatibility mode for running mod_plsql. This parameter is supported only for Oracle Application Server releases, and is used when you are using mod_plsql with an older version of Oracle Application Server Portal. In such situations, if you are running mod_plsql against a pre-9.0.2 version of Oracle Application Server Portal, this should be set to 1.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCompatibilityMode BitFlag</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
<tr>
<td>Example</td>
<td></td>
</tr>
<tr>
<td></td>
<td>PlsqlCompatibilityMode 1</td>
</tr>
</tbody>
</table>

This parameter enables an old bug in mod_plsql in which mod_plsql incorrectly converted the plus symbol (+) to space characters for document downloads. Enabling the first bit in this flag will make it impossible to download documents that have a plus symbol (+) in the document name.
PlsqlConnectionTimeout
Specifies the timeout in milliseconds for testing a connection pooled in mod_plsql.
When PlsqlConnectionValidation is set to "Automatic" or "AlwaysValidate", mod_plsql will attempt to test pooled database connections. This parameter specifies the maximum time mod_plsql should wait for the test request to complete before it assumes that the connection is not usable.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlConnectionTimeout $0000</td>
</tr>
<tr>
<td>Default</td>
<td>10000</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlConnectionTimeout $0000</td>
</tr>
</tbody>
</table>

PlsqlConnectionValidation
Specifies the mechanism mod_plsql should use to detect terminated connections in its connection pool.

For performance reasons, mod_plsql pools database connections. If a database instance goes down, and mod_plsql was maintaining a pool of connections to the instance, then each pooled database connection results in an error when it is next used to service a request. This can be a concern in high availability configurations like RAC where even if one node goes down, other nodes servicing the database might have been able to service the request successfully. mod_plsql provides for a mechanism whereby it can self-correct after it detects a failure that could be caused by a database node going down. This mechanism to self-correct is controlled by the parameter PlsqlConnectionValidation.

The following are the valid values for PlsqlConnectionValidation:
- **Automatic**: mod_plsql tests all pooled database connections which were created prior to the detection of a failure that could mean an instance failure.
- **ThrowAwayOnFailure**: mod_plsql throws away all pooled database connections which were created prior to the detection of a failure that could mean an instance failure.
- **AlwaysValidate**: mod_plsql always tests all pooled database connections which were created prior to issuing a request. Since this option has an associated performance overhead for each request, this should be used with caution.
- **NeverValidate**: mod_plsql never pings any pooled database connection. This option always for older behavior in mod_plsql.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlConnectionValidation Automatic/ThrowAwayOnFailure/AlwaysValidate/NeverValidate</td>
</tr>
<tr>
<td>Default</td>
<td>Automatic</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlConnectionValidation ThrowAwayOnFailure</td>
</tr>
</tbody>
</table>

When mod_plsql encounters one of the following errors, it assumes that the database might have been down.
- 00443, 00000, “background process did not start”
- 00444, 00000, “background process failed while starting”
00445, 00000, "background process did not start after x seconds"
00447, 00000, "fatal error in background processes"
00448, 00000, "normal completion of background process"
00449, 00000, "background process unexpectedly terminated with error"
00470, 00000, "LGWR process terminated with error"
00471, 00000, "DBWR process terminated with error"
00472, 00000, "PMON process terminated with error"
00473, 00000, "ARCH process terminated with error"
00474, 00000, "SMON process terminated with error"
00475, 00000, "TRVR process terminated with error"
00476, 00000, "RECO process terminated with error"
00480, 00000, "LCK* process terminated with error"
00481, 00000, "LMON process terminated with error"
00482, 00000, "LMD* process terminated with error"
00484, 00000, "LMS* process terminated with error"
00485, 00000, "DIAG process terminated with error"
01014, 00000, "ORACLE shutdown in progress"
01033, 00000, "ORACLE initialization or shutdown in progress"
01034, 00000, "ORACLE not available"
01041, 00000, "internal error. hostdef extension doesn't exist"
01077, 00000, "background process initialization failure"
01089, 00000, "immediate shutdown in progress- no operations permitted"
01090, 00000, "shutdown in progress- connection is not permitted"
01091, 00000, "failure during startup force"
01092, 00000, "ORACLE instance terminated. Disconnection forced"
03106, 00000, "fatal two-task communication protocol error"
03113, 00000, "end-of-file on communication channel"
03114, 00000, "not connected to ORACLE"
12570, 00000, "TNS: packet writer failure"
12571, 00000, "TNS: packet writer failure"

Specifies the connection to an Oracle database.
Understanding Modules

If the database is running in the same Oracle home, or the environment variable "TWO_TASK" is set, this parameter need not be specified.

If the database is running in a separate Oracle home, then this parameter is mandatory.

If you have problems connecting to the database:

- Check the username and password information in the DAD.
- Make sure that you run "tnsping <string>" and execute commands such as:
  ```sql
  sqlplus DADUsername/DADPassword@<string>
  ```
- Ensure that TNS_ADMIN is configured properly.
- Verify that the HOST:PORT:SERVICE_NAME format makes the connection go through.
- Ensure that the TNS listener and database are up and running.

### mod_plsql

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlDatabaseConnectString stringServiceNameFormat/SIDFormat/TNSFormat/NetServiceNameFormat</code>, where string can be one of the following based on the second argument:</td>
</tr>
<tr>
<td></td>
<td>- <code>ServiceNameFormat</code>: HOST:PORT:SERVICE_NAME format where HOST is the hostname running the database, PORT is the port number the TNS listener is listening on, SERVICE_NAME is the database service name.</td>
</tr>
<tr>
<td></td>
<td>- <code>SIDFormat</code>: HOST:PORT:SID format where HOST is the hostname running the database, PORT is the port number the TNS listener is listening on, SID is the database SID.</td>
</tr>
<tr>
<td></td>
<td>- <code>TNSFormat</code>: A valid TNS alias which resolves using Net8 utilities like <code>tnsping</code> and <code>SQL*Plus</code>.</td>
</tr>
<tr>
<td></td>
<td>- <code>NetServiceNameFormat</code>: A valid net service name which resolves to a connect descriptor. A connect descriptor is a specially formatted description of the destination for a network connection. A connect descriptor contains destination service and network route information.</td>
</tr>
<tr>
<td></td>
<td>If the format argument is not specified, then <code>mod_plsql</code> assumes that &quot;string&quot; is either in the HOST:PORT:SID format, or resolvable by Net8. The differentiation between the two is made by the presence of the colon in the specified string. It is recommended that newer DADs do not use the <code>SIDFormat</code> syntax. This exists only for backward compatibility reasons. Use the new two argument format for newly created DADs.</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>- <code>PlsqlDatabaseConnectString myhost.com:1521:myhost.iasdb.inst ServiceNameFormat</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString myhost.com:1521:iasdb SIDFormat</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString myhost.cn TNSFormat</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString cn=oracle.cn=iasdb NetServiceNameFormat</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString (DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(Host=myhost.com)(Port=1521))(CONNECT_DATA=(SID=iasdb))) TNSFormat</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString myhost.cn</code></td>
</tr>
<tr>
<td></td>
<td>- <code>PlsqlDatabaseConnectString myhost.com:1521:iasdb</code></td>
</tr>
</tbody>
</table>
Ensure that you can ping the host from this machine.

From a mod_plsql perspective, TNSFormat and NetServiceNameFormat are synonymous and denote connect descriptors that are resolved by Net. The TNSFormat is provided as a convenience so that end-users use this to signify that the name resolution happens through the local tnsnames.ora. For situations where the resolution is through an LDAP lookup as configured in sqlnet.ora, it is recommended that the format specifier of NetServiceNameFormat be used.

If your database supports high availability, for example, RAC database, it is highly recommended that you use the NetServiceNameFormat such that the resolution for the net service name is through LDAP. This enables you to add or remove RAC nodes accessible through mod_plsql by just changing Oracle Internet Directory with the new/deleted node information. In such situations, hard-coding database listener HOST:PORT information in dads.conf or in the local tnsnames.ora is not recommended.

In older versions of the product, this configuration parameter was called connect_string.

PlsqlDatabasePassword

Specifies the password to use to log in to the database.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlDatabasePassword string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlDatabasePassword tiger</td>
</tr>
</tbody>
</table>

After making manual configuration changes to DAD passwords, it is recommended that the DAD passwords are obfuscated by running the "dadTool.pl" script located in ORACLE_HOME/Apache/modplsql/conf.

The following are the steps to obfuscate DAD passwords:

1. If necessary, switch user to the Oracle software owner user, typically oracle using the following command:

   $su - oracle

2. Set the ORACLE_HOME environment variable to specify the path to the Oracle home directory for the current release and set the PATH environment variable to include the directory containing the Perl executable and the location of the dadTool.pl script.

   On Bourne, Bash, or Korn Shell:

   ORACLE_HOME=new_ORACLE_HOME_path; export ORACLE_HOME
   PATH=ORACLE_HOME/Apache/modplsql/conf:/ORACLE_HOME/perl/bin:/PATH; export PATH

   On C or tsh Shell:

   setenv ORACLE_HOME new_ORACLE_HOME_PATH
   setenv PATH ORACLE_HOME/Apache/modplsql/conf:/ORACLE_HOME/perl/bin:/PATH

   On Windows:

   set PATH=ORACLE_HOME/Apache/modplsql/conf;ORACLE_HOME/perl5.6.1/bin;WIN32-x86;%PATH%
3. Set the appropriate shared library path environment variable for your platform.
   - On UNIX platforms, include the `ORACLE_HOME/lib` directory in your shared library path. Table 8-4 shows the appropriate environment variable for each platform.

   For example, to set the `SHLIB_PATH` environment in the Bourne shell on HP-UX systems, enter the following command:
   ```
   $SHLIB_PATH=$ORACLE_HOME/lib:$SHLIB_PATH;export SHLIB_PATH
   ```

   On Windows, include `$ORACLE_HOME/bin` in your `PATH`, for example:
   ```
   set PATH=%ORACLE_HOME%in;%PATH%
   ```

4. Change directory to the `mod_plsql` configuration directory for the current release of Oracle HTTP Server:
   ```
   cd $ORACLE_HOME/Apache/modplsql/conf
   ```

5. Invoke the following Perl script to obfuscate DAD password:
   ```
   perl dadTool.pl -o
   ```

Notes:
- This is a mandatory parameter, except for a DAD that sets `PlsqlAuthenticationMode` to `Basic` and uses dynamic authentication.
- For DADs using `SingleSignOn` authentication, this parameter is the name of the schema owner.
- In older versions of the product, this configuration parameter was called `password`.

### PlsqlDatabaseUserName

Specifies the username to use to logon to the database.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlDatabaseUsername string</code></td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlDatabaseUsername scott</code></td>
</tr>
</tbody>
</table>

- This is a mandatory parameter, except for a DAD that sets `PlsqlAuthenticationMode` to `Basic` and uses dynamic authentication.
For DADs using SingleSignOn authentication, this parameter is the name of the schema owner.

In older versions of the product, this configuration parameter was called username.

**PlsqlDefaultPage**

Specifies the default procedure to call if none is specified in the URL.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlDefaultPage string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlDefaultPage myschema.mypackage.home</td>
</tr>
</tbody>
</table>

You can also use Oracle HTTP Server Rewrite rules to achieve the same effect as you get by setting this configuration parameter.

In older versions of the product, this parameter was called default_page.

**PlsqlDocumentPath**

Specifies a virtual path in the URL that initiates document download from the document table. For example, if this parameter is set to docs, then the following URLs will start the document downloading process for URLs of the format:

/pls/dad/docs
/pls/plsqlapp/docs

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlDocumentPath string</td>
</tr>
<tr>
<td>Default</td>
<td>docs</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlDocumentPath docs</td>
</tr>
</tbody>
</table>

Omit this parameter for applications that do not perform document uploads or downloads.

See Also: Oracle Application Server mod_plsql User’s Guide

In older versions of the product, this parameter was called document_path.

**PlsqlDocumentProcedure**

Specifies the procedure to call when a document download is initiated. This procedure is called to process the download.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlDocumentProcedure string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlDocumentProcedure portal.wwdoc_process.process_download</td>
</tr>
</tbody>
</table>
■ Omit this parameter for applications that do not perform document uploads or downloads.

**See Also:** Oracle Application Server mod_plsql User’s Guide

■ In older versions of the product, this parameter was called `document_proc`.

**PlsqlDocumentTablename**
Specifies the table in the database to which all documents are uploaded.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlDocumentTablename string</code></td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlDocumentTablename myschema.document_table</code></td>
</tr>
</tbody>
</table>

■ Omit this parameter for applications that do not perform document uploads or downloads.

**See Also:** Oracle Application Server mod_plsql User’s Guide

■ In older versions of the product, this parameter was called `document_table`.

**PlsqlErrorStyle**
Specifies the Error Reporting Mode for mod_plsql errors. This parameter accepts the following values:

■ **ApacheStyle**: This is the default mode. In this mode, mod_plsql indicates to Oracle HTTP Server the HTTP error that was encountered. Oracle HTTP Server then generates the error page. This can be used with the Oracle HTTP Server `ErrorDocument` directive to produce customized error messages.

■ **ModplsqlStyle**: mod_plsql generates the error pages, usually a short message indicating the PL/SQL error that was encountered and PL/SQL exception stack, if any. For example:

```
scott.foo PROCEDURE NOT FOUND
```

■ **DebugStyle**: This mode provides more details than ModplsqlStyle. mod_plsql provides more details about the URL, parameters and also produces server configuration information. This mode is for debugging purposes only. Do not use this in a production system, since displaying internal server variables could be a security risk.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlErrorStyle ApacheStyle/ModplsqlStyle/DebugStyle</code></td>
</tr>
<tr>
<td>Default</td>
<td>ApacheStyle</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlErrorStyle ModplsqlStyle</code></td>
</tr>
</tbody>
</table>

In older versions of the product, this parameter was called `error_style`. 

---

**Understanding Modules** 8-39
PlsqlExclusionList
Specifies a pattern for procedures, packages, or schema names which are forbidden to be directly executed from a browser. This is a multi-line directive in which each pattern is on one line. The pattern is case-insensitive and can accept a wildcard such as "*". The default patterns disallowed from direct URL access are: sys.*, dbms_*, utl_*, owa_*, owa.*, htp.*, htf.*, wpg_docload.*.

Setting this directive to "#NONE#" will disable all protection. This is not recommended for a live site and should not be done (This is sometimes used for debugging purposes).

If this parameter is overridden, the defaults still apply, which means that you do not have to explicitly add the default list to the list of excluded patterns.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlExclusionList [string/&quot;#NONE#&quot; multiline]</td>
</tr>
</tbody>
</table>
| Default  | sys.*
  dbms_*
  utl_*
  owa_*
  owa.*
  htp.*
  htf.*
  wpg_docload.* |
| Example  | PlsqlExclusionList myschema.private1.*
  PlsqlExclusionList myschema.private.*
  will disallow access to URLs which contain one of:
  sys.*, dbms_*, utl_*, owa_*, owa.*, htp.*, htf.*, wpg_docload.*, myschema.private.*, myschema.private1.*
  PlsqlExclusionList "#NONE#" will disable all protection.
  Again, this is not recommended for live sites as this could be a security concern. |

- Besides the patterns specified with this parameter, mod_plsql also disallows any procedure name which contains special characters like tabs, newlines, carriage-returns, single-quotes, the reverse slash, the form feed, the open parenthesis, close parenthesis, and space. This cannot be changed.
- In older versions of the product, this parameter was called exclusion_list.

See Also: Oracle Application Server mod_plsql User’s Guide

PlsqlFetchBufferSize
Specifies the number of rows of content to fetch from the database for each trip, using either owa_util.get_page or owa_util.get_page_raw.

By default, mod_plsql attempts to fetch 200 response lines of output where each line is of 255 bytes. In situations where the response bytes are single-bytes, the response buffer is populated to the maximum and can pack 255*200=51000 bytes for each round trip. However, for responses containing multi-byte data, the byte packing for each row could be less than ideal resulting in lesser bytes getting transferred for each round trip.

If your application generates large pages frequently and the response does not fit in...
one round trip, then consider setting this parameter higher. However, the memory usage for `mod_plsql` will increase.

- This parameter is changed only for performance reasons. The minimum value for this parameter is 28, but it is seldom reduced.
- Change this parameter only under the following circumstances:
  - The average response page is large and you want to reduce the number of round-trips `mod_plsql` makes to the database to fetch the response.
  - The character set in use is multi-byte, and you want to compensate for the problem of `get_page` or `get_page_raw` fetching fewer bytes for each row (calculations in the PL/SQL Web ToolKit are character-based and in the case of multi-byte characters, OWA packages assume a worst-case character byte size and do not attempt to pack each row to its maximum).
- In older versions of the product, this parameter was called `response_array_size`.
- In older versions of the product, the default for this parameter was 128.

### `PlsqlInfoLogging`

Specifies what mode `mod_plsql` should use to do extra performance logging.

The mode is:

- `InfoDebug`: This logs more information to the Apache's `error_log`. This is used in conjunction with Apache’s “info” logging level. If the Apache’s logging level is not at least set to this high, this setting will be ignored.

This logging setting is useful for debugging problems in your PL/SQL application.

### `PlsqlMaxRequestsPerSession`

Specifies the maximum number of requests a pooled database connection should service before it is closed and re-opened.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlMaxRequestsPerSession number</code></td>
</tr>
<tr>
<td>Default</td>
<td>1000</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlMaxRequestsPerSession 1000</code></td>
</tr>
</tbody>
</table>
This parameter helps relieve memory and resource problems that may occur due to prolonged session reuse by a PL/SQL application.

This parameter should not need to be changed; the default is sufficient in most cases.

Setting this parameter to a low number can degrade performance. A case for a lower value might be an infrequently used DAD whose performance is not a concern, and for which limiting the number of requests provides some benefit.

In older versions of the product, the equivalent to this parameter is `reuse`. Instead of taking a value of "Yes" or "No", the new parameter enables you to have finer control over the connection pool reuse in `mod_plsql`.

**PlsqlNLSLanguage**

Specifies the `NLS_LANG` variable for this DAD. This parameter overrides the `NLS_LANG` environment variable. When this parameter is set, the PL/SQL Gateway uses the specified `NLS_LANG` to connect to the database. Once connected, an alter session command is issued to switch to the specified language and territory. If the middle tier character set matches that of the database, then no alter session call is issued by `mod_plsql`.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlNLSLanguage string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlNLSLanguage America_America.UTF8</td>
</tr>
</tbody>
</table>

Most applications have `PlsqlTransferMode` set to `CHAR` which means that the character set in `PlsqlNLSLanguage` needs to match the character set of the database. In one special case, where the database and `mod_plsql` are both using fixed-size character sets, and the character set width matches, the character set can be different. The response character set is always the `mod_plsql` character set.

If `PlsqlTransferMode` is set to `RAW`, then this parameter can be ignored.

In older versions of the product, this parameter was called `nls_lang`.

**PlsqlPathAlias**

Specifies a virtual path alias to map to a procedure call. This is application specific.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlPathAlias string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlPathAlias url</td>
</tr>
</tbody>
</table>

For applications that do not use path aliasing, this parameter may be omitted.

**See Also:** Oracle Application Server mod_plsql User’s Guide

In older versions of the product, this parameter was called `pathalias`. 
**PlsqlPathAliasProcedure**

Specifies the procedure to call when the virtual path in the URL matches the path alias as configured by PlsqlPathAlias.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlPathAliasProcedure string</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlPathAliasProcedure portal.wwpth_api_alias.process_download</td>
</tr>
</tbody>
</table>

- For applications that do not use path aliasing, this parameter may be omitted.

  **See Also:** Oracle Application Server mod_plsql User’s Guide

- In older versions of the product, this parameter was called `pathaliasproc`.

**PlsqlRequestValidationFunction**

Specifies an application-defined PL/SQL function which gives you the opportunity to allow/disallow further processing of the requested procedure. This is useful in implementing tight security for your PL/SQL application by blocking out package/procedure calls which should not be allowed to execute from this DAD.

The function defined by this parameter must have the following prototype:

```plsql
boolean function_name (procedure_name IN varchar 2)
```

Upon invocation, the argument `procedure_name` will contain the name of the procedure that the request is trying to execute.

For example, if all the PL/SQL application procedures callable from a browser are inside the package "mypkg", then a simple implementation of this function can be as follows:

```plsql
boolean my_validation_check (procedure_name varchar 2 is begin if (upper (procedure_name) like upper ('myschema.mypkg%')) then return TRUE else return FALSE end if; end;
```

- By default, `mod_plsql` already disallows direct URL access to certain schemas/packages. For more information, refer to PlsqlExclusionList.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlRequestValidationFunction [string]</td>
</tr>
<tr>
<td>Default</td>
<td>none</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlRequestValidationFunction myschema.mypkg.my_validation_check</td>
</tr>
</tbody>
</table>
It is highly recommended that you provide an implementation for this function such that it only allows requests that belong to your application, and are callable from a browser.

Since this function will be called for every request, be sure to make this function as performant as possible. Suggested recommendations are:

- Name your PL/SQL packages in a fashion such that the implementation of this function can be similar to the example mentioned earlier.
- If your implementation performs a table lookup to determine what packages/procedures should be allowed, performance can be improved if you pin the cursor in the shared pool.

PlsqlSessionCookieName
Specifies the cookie name when PlsqlAuthenticationMode is set to SingleSignOn. This parameter is supported only for Oracle Application Server releases, and is used by the Oracle Application Server Portal and Oracle Application Server Single Sign-On.

For DADs not using SingleSignOn authentication, this parameter can be omitted. In most other cases, the session cookie name should be omitted (and this parameter automatically defaults to the DAD name).

A session cookie name must be specified only for Oracle Application Server Portal instances that need to participate in a distributed Oracle Application Server Portal environment. For those Oracle Application Server Portal nodes you want to seamlessly participate as a federated cluster, ensure that the session cookie name for all of the participating nodes is the same.

Independent Oracle Application Server Portal nodes need to use distinct session cookie names.

In older versions of the product, this configuration parameter was called sncookiename.

PlsqlSessionStateManagement
Specifies how package and session state should be cleaned up at the end of each mod_plsql request.

- Setting this parameter to StatelessWithResetPackageState causes mod_plsql to call dbms_session.reset_package_state at the end of each mod_plsql request.
- Setting this parameter to StatelessWithPreservePackageState causes mod_plsql to call htp.init at the end of each mod_plsql request. This cleans up the state of session variables in the PL/SQL Web Toolkit. The PL/SQL application is responsible for cleaning up its own session state. Failure to do so causes erratic behavior, in which a request starts recognizing or manipulating state modified in previous requests.
- Setting this parameter to StatelessWithFastResetPackageState causes mod_plsql to call dbms_session.modify_package_state(dbms_
mod_plsql

Understanding Modules

8-45

session.reinitialize) at the end of each mod_plsql request. This API is a
lot faster than the mode of StatelessWithResetPackageState, and avoids
some latch contention issues, but exists only in database versions 8.1.7.2 and
higher. This mode uses up slightly more memory than the default mode.

- In older versions of the product, this configuration parameter was called
  stateful.
- An older value of stateful=no or stateful=STATELESS_RESET corresponds
to PlsqlSessionStateManagement StatelessWithResetPackageState
- An older value of stateful=STATELESS_FAST_RESET corresponds to
  PlsqlSessionStateManagement StatelessWithFastResetPackageState
- An older value of stateful=STATELESS_PRESERVE corresponds to
  PlsqlSessionStateManagement StatelessWithPreservePackageState

mod_plsql does not support stateful mode of operation. To equip PL/SQL
applications with stateful behavior, save state in cookies and/or in the database.

PlsqlTransferMode
Specifies the transfer mode for data from the database back to mod_plsql. Most
applications use the default value of CHAR.

- This parameter only needs to be changed to enable sending back responses in
different character sets from the same DAD. In such a case, the CHAR mode is
  useless, since it always converts the response data from the database character set
to the mod_plsql character set.
- In older versions of the product, RAW transfer mode was not supported.

PlsqlUploadAsLongRaw
Specifies the extensions to be uploaded as LONGRAW data type, as opposed to using the
default BLOB data type. The default can be overridden by specifying multi-line
directives of file extensions for field. A value of "*" in this field causes all documents to
be uploaded as LONGRAW.

<table>

<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlTransferMode CHAR/RAW</td>
</tr>
<tr>
<td>Default</td>
<td>CHAR</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlTransferMode CHAR</td>
</tr>
</tbody>
</table>

Understanding Modules 8-45
For applications that do not do document uploads or downloads, this parameter may be omitted.

**See Also:** Oracle Application Server mod_plsql User’s Guide for more information about upload and download processes and the structure of the restrictions on the document table format.

In older versions of the product, this parameter was called upload_as_log_raw.

cache.conf

*cache.conf* file contains the cache settings for *mod_plsql*. This file contains parameters which specify the characteristics of the *mod_plsql* cache system.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>PlsqlUploadAsLogRaw string multiline</code></td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td><code>PlsqlUploadAsLogRaw jpg, PlsqlUploadAsLogRaw gif</code></td>
</tr>
</tbody>
</table>

The following parameters are specified in *cache.conf* file:

- **PlsqlCacheCleanupTime**
- **PlsqlCacheDirectory**
- **PlsqlCacheEnable**
- **PlsqlCacheMaxAge**
- **PlsqlCacheMaxSize**
- **PlsqlCacheTotalSize**

**PlsqlCacheCleanupTime**

Specifies the time to start the cleanup of the cache storage.

This setting defines the exact day and time in which cleanup should occur. The frequency can be set as daily, weekly, and monthly.

- To define daily frequency, the keyword "Everyday" is used. The cleanup starts everyday at the time defined. For example, Everyday 2:00. This causes the cleanup to happen everyday at 2 AM (local time) in the morning.
- To define weekly frequency, the days of the week such as "Sunday", "Monday", "Tuesday", and so on are used. For example, Wednesday 15:30. This causes the cleanup to happen every Wednesday at 3:30 PM (local time) in the afternoon.
- To define monthly frequency, the keyword "Everymonth" is used. The cleanup starts at the Saturday of the month at the time defined. For example, Everymonth 23:00. This causes the cleanup to happen the first Saturday of every month at 11:00 PM (local time) at night.

**Note:** This file is relevant only if the PL/SQL Application uses the *OWA_CACHE* packages to cache content in the file system. Extremely few customer applications make use of the *OWA_CACHE* packages.
Understanding Modules

PlsqlCacheDirectory
Specifies the directory where cache files are written out by mod_plsql. This directory must exist or else Oracle HTTP Server will not start.

On UNIX, this directory must have write permissions by the owner of the child httpd processes.

In older versions, this parameter was called "cache_dir" and resides in the "[PLSQL Cache]" section of ORACLE_HOME/Apache/modplsql/cfg/cache.cfg.

PlsqlCacheEnable
Enables mod_plsql caching.

If you are sure that your application does not make use of the OWA_CACHE packages, in the PL/SQL Web Toolkit, then you can choose to disable caching. In such situations, there will be a very minor performance benefit.

In older versions, this parameter is called "enabled" and resided in the "[PLSQL Cache]" section of ORACLE_HOME/Apache/modplsql/cfg/cache.cfg.

PlsqlCacheMaxAge
Specifies the maximum time, in days, a cache file can be allowed to reside in a file system cache, after which the cached file will be removed for cache maintenance.

This setting is to ensure that the cache system does not contain old content. This setting removes old cache files and makes space for new ones.

### mod_plsql

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheCleanupTime &lt;Sunday-Saturday, Everyday, Everymonth&gt; <a href="">hh:mm</a></td>
</tr>
<tr>
<td>Default</td>
<td>Saturday 23:00</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheCleanupTime Saturday 23:00</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheDirectory &lt;directory&gt;</td>
</tr>
<tr>
<td>Default</td>
<td>none</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheDirectory ORACLE_HOME/Apache/modplsql/cache</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheEnable On/Off</td>
</tr>
<tr>
<td>Default</td>
<td>Off</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheEnable On</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheMaxAge &lt;number&gt;</td>
</tr>
<tr>
<td>Default</td>
<td>30 (30 days)</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheMaxAge 30</td>
</tr>
</tbody>
</table>
**mod_proxy**

**PlsqlCacheMaxSize**
Specifies the maximum possible size of a cache file.
This setting is to prevent the case in which one file can fill up the entire cache. In general, it is recommended that this be set to about 1-3 percent of the total cache size.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheMaxSize &lt;number&gt;</td>
</tr>
<tr>
<td>Default</td>
<td>1048576 (1 MB)</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheMaxSize 1048576</td>
</tr>
</tbody>
</table>

In older versions, this parameter was called "max_size" and resided in the "[PLSQL Cache]" section of ORACLE_HOME/Apache/modplsql/cfg/cache.cfg.

**PlsqlCacheTotalSize**
Specifies the total size of the cache directory.
This setting limits the amount of space the cache is allowed to use. Both PLSQL cache and Session Cookie cache share this cache space. Note that this setting is not a hard limit. It might exceed the limit temporarily during normal processing. This is normal behavior.
The cleanup algorithm uses this setting to determine how much to reduce the cache files. Therefore, the real space limit is the physical storage’s available size.
This parameter takes bytes as values:
- 1 megabytes = 1048576 bytes
- 10 megabytes = 10485760 bytes

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>PlsqlCacheTotalSize &lt;number&gt;</td>
</tr>
<tr>
<td>Default</td>
<td>20971520 (20 MB)</td>
</tr>
<tr>
<td>Example</td>
<td>PlsqlCacheTotalSize 20971520</td>
</tr>
</tbody>
</table>

In older versions, this parameter was called "total_size" and resided in the "[PLSQL Cache]" section of ORACLE_HOME/Apache/modplsql/cfg/cache.cfg.

**mod_proxy**
Provides proxy capability for FTP, CONNECT (for SSL), HTTP/0.9, HTTP/1.0, and HTTP/1.1.

See Also:
- Module mod_proxy in the Apache Server documentation.
- "Using mod_proxy Directives" on page 11-16

**mod_rewrite**
Oracle HTTP Server provides mod_rewrite as a tool for URL manipulation. A rewriting engine based on a regular-expression parser is used by mod_rewrite to
rewrite requested URLs. The granularity of URL manipulations can be affected by the formats of server variables, environment variables, HTTP headers, and time stamps.

This module operates on the full URLs (including the path-info part) both in per-server context (\texttt{httpd.conf}) and per-directory context (\texttt{.htaccess}) and can generate query-string parts on result.

The following topics are discussed in subsequent sections:

\begin{itemize}
  \item \texttt{mod_rewrite} Rules Processing
  \item \texttt{mod_rewrite} Directives
  \item Rewrite Rules Hints
  \item Redirection Examples
\end{itemize}

\textbf{\texttt{mod_rewrite} Rules Processing}

Apache processes HTTP in phases. A hook for each of these phases is provided by the Apache API. \texttt{mod_rewrite} uses two of these hooks - the URL-to-filename translation hook which is used after the HTTP request has been read but before any authorization starts, and the Fixup hook which is triggered after the authorization phases and after the per-directory configuration files (\texttt{.htaccess}) have been read, but before the content handler is activated.

\texttt{mod_rewrite} reads the configured rulesets from its configuration structure. Server level rulesets are best configured at startup, while directory level rulesets are configured during the directory access of the kernel.

\texttt{mod_rewrite} loops through the ruleset rule by rule (\texttt{RewriteRule} directive) and when a particular rule matches, it loops through corresponding conditions (\texttt{RewriteCond} directives). First the URL is matched against the Pattern of each rule. When it fails, \texttt{mod_rewrite} looks for corresponding rule conditions. If none are present, it just substitutes the URL with a new value which is constructed from the string \texttt{Substitution} and goes on with its rule-looping. But if conditions exist, it starts an inner loop for processing them in the order that they are listed.

For conditions, a string \texttt{TestString} is created by expanding variables, back-references map lookups, and then \texttt{CondPattern} is matched against the expanded \texttt{TestString}. If the pattern does not match, the complete set of conditions and the corresponding rule fails. If the pattern matches, then the next condition is processed until no more conditions are available. If all conditions match, processing is continued with substituting the URL using \texttt{Substitution}.

When request seeks a URL with more than one slash (/), for example, \url{http://yourserver/oldpath/files}, the "//oldpath" may bypass \texttt{RewriteCond} and \texttt{RewriteRule} directives if they are not correctly written.

For example, consider the following rule:

\begin{verbatim}
RewriteRule ^/oldpath/.* /newpath$1 [R]
\end{verbatim}

Requesting \url{http://yourserver/oldpath/files} will redirect and return the page \url{http://yourserver/newpath/files} as expected.

However, requesting \url{http://yourserver//oldpath/files} will bypass this particular rule, potentially serving a page that you were not expecting it to. You can work around the problem by making sure that rules will capture more than one slash (/). To fix the example, you should use this replacement:

\begin{verbatim}
RewriteRule ^/+somepath/.* /otherpath$1 [R]
\end{verbatim}

Understanding Modules 8-49
mod_rewrite Directives

This section discusses the following mod_rewrite directives:

- RewriteEngine
- RewriteOptions
- RewriteLog
- RewriteLogLevel
- RewriteBase

RewriteEngine

Enables or disables the runtime rewriting engine. If it is set to 'Off', this module does no runtime processing at all. Use this directive to disable the module instead of commenting out all the RewriteRule directives.

Rewrite configurations are not inherited by default. This means that you need to have RewriteEngine On directive for each virtual host in which you want to use it.

RewriteOptions

By specifying RewriteOptions 'inherit', you can force the configuration of the parent by the children. In virtual-server context this means that the maps, conditions and rules of the main server are inherited. In directory context this means that conditions and rules of the .htaccess configuration of the parent directory are inherited.

RewriteLog

Sets the name of the file to which the server logs any rewriting action that it performs. If the name does not begin with a slash (/), then it is assumed to be relative to the Server Root. To disable logging, either remove or comment out the RewriteLog directive or use RewriteLogLevel 0. Avoid setting the filename to /dev/null to prevent logging. This can slow down the server with no advantage.

RewriteLogLevel

Sets the verbosity level of the rewriting log file. The default level 0 means no logging, while 9 or more means that practically all actions are logged.

RewriteBase

Explicitly sets the base URL for pre-directory rewrites. Rewrite rule can be used in per-directory configuration (.htaccess) files. When a substitution occurs for a new URL, the base URL should be added into the server processing. To be able to do this, the module needs to know what the corresponding URL-prefix or URL-base is. By default, this prefix is the corresponding file path itself. However, at most Web sites, URLs are not directly related to physical filename paths. In such cases, you have to use the RewriteBase directives to specify the correct URL-prefix.

If the URLs of your Web server are not directly related to physical file paths, you have to use RewriteBase in every .htaccess files where you want to use RewriteRule directives.

Example 8–10 RewriteBase Directive

Assume the following per-directory configuration file:

```bash
## /abc/def/.htaccess - - per-dir config file for directory /abc/def
#
# /abc/def is the physical path of /xyz,
```

8-50 Oracle HTTP Server Administrator's Guide
In Example 8–10, a request to /xyz/oldstuff.html gets correctly rewritten to the physical file /abc/def/newstuff.html.

**Rewrite Rules Hints**

Table 8–5 provide hints for using rewrite rules.

<table>
<thead>
<tr>
<th>Value</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>[char]</td>
<td>Any character listed within a square bracket</td>
</tr>
<tr>
<td>*</td>
<td>Any character b any number of times</td>
</tr>
<tr>
<td>^</td>
<td>Any character any number of times</td>
</tr>
</tbody>
</table>

For example, if you want to redirect requests from /demo1, /demo2, and /demo3 to /alldemos, write the rewrite rule as one of the following:

```
RewriteRule /demo.* /alldemos [R]
```

or,

```
RewriteRule /demo [123] /alldemos [R]
```

If you intend that /DemoA, /DemoB, and /DemoC to be redirected to /alldemos, add NC (no case) to the rewrite rules, such as:

```
RewriteRule /demo [123] /alldemos [R, NC]
```

This rewrite rule will not work to redirect from /demonstration1 to /demos, because "." works form one character only. To enable redirection of all URLs beginning with "demo", irrespective of subsequent characters, use the rewrite rule as follows:

```
RewriteRule ^/demo* /alldemos [R, NC]
```

In the preceding example, ^ means the beginning, * means any character after demo.

If there was a request for /demo1/not_just_index.html, all the preceding rewrite rules would have redirected the request the request to /alldemos/index.html, that may not be what you want. It is quite possible that you may want to redirect to the corresponding files in /alldemos, as listed in Table 8–6.

<table>
<thead>
<tr>
<th>Request for</th>
<th>Redirected to</th>
</tr>
</thead>
<tbody>
<tr>
<td>/demo1/happy.html</td>
<td>/alldemos/happy.html</td>
</tr>
<tr>
<td>/demo1/go.jpg</td>
<td>/alldemos/go.jpg</td>
</tr>
<tr>
<td>/demo1/lucky.jpg</td>
<td>/alldemos/lucky.jpg</td>
</tr>
</tbody>
</table>

Then you have to use substitution in your rewrite rule as follows:

```
RewriteRule "/(.*)$" //alldemos/$1 [R NC]
```
The explanation for this rule is:

Take the value of the expression, such as happy.html, go.jpg, and lucky.jpg, that appears after demo1 as variables ($1) and substitute it after /alldemos/.

**Redirection Examples**

For redirecting requests from the DocumentRoot to a directory called newroot, set the following mod_rewrite directives:

```
RewriteEngine On
RewriteRule ^/(.*)$ /newroot/$1 [R]
```

For directing requested for files from one directory (olddir) to another (newdir), set the following directives:

```
RewriteEngine On
RewriteRule ^/olddir(.*)$ /newdir/$1 [R]
```

In each of these cases, you should ensure that the requested resources are indeed available in the redirected location. The mod_rewrite module does not ensure the existence of the requested resource in the new location.

For disabling all requests using the HTTP TRACE method, set the following mod_rewrite directives:

```
RewriteEngine On
RewriteCond %{REQUEST_METHOD} ^TRACE
RewriteRule .* - [F]
```

See Also: Module mod_rewrite in the Apache Server documentation.

**mod_security**

Increases Web application security by protecting Web application from known and unknown attacks.

See Also: [http://modsecurity.org](http://modsecurity.org)

**mod_setenvif**

Enables you to set environment variables based on characteristics of a request.

See Also: Module mod_setenvif in the Apache Server documentation.

**mod_speling**

Attempts to correct misspelled or miscapitalized URLs.

See Also: Module mod_speling in the Apache Server documentation.

**mod_status**

Displays an HTML page of server activity and performance.

8-52 Oracle HTTP Server Administrator's Guide
mod_wchandshake

See Also: Module `mod_status` in the Apache Server documentation.

mod_unique_id

Creates a unique ID for each request. This module is available on UNIX only.

See Also: Module `mod_unique_id` in the Apache Server documentation.

mod_userdir

Maps requests to user-specific directories.

See Also: Module `mod_userdir` in the Apache Server documentation.

mod_usertrack

Tracks user activity by creating a log.

See Also: Module `mod_usertrack` in the Apache Server documentation.

mod_vhost_alias

Enables dynamically configured mass virtual hosting.

See Also: Module `mod_vhost_alias` in the Apache Server documentation.

mod_wchandshake

Provides automatic discovery of Oracle HTTP Server by OracleAS Web Cache. If OracleAS Web Cache is not used, this module can be disabled. It is an Oracle module.
This chapter describes distributed authoring and versioning concepts, and explains how to configure and use the mod_oradav module. The mod_oradav module enables you to use OraDAV to access content in an Oracle database from a Web browser or a WebDAV client.

Topics discussed are:
- OraDAV Concepts
- OraDAV Architecture
- OraDAV Users
- OraDAV Usage Model
- OraDAV Configuration Parameters
- DAV Directives
- WebDAV Security Considerations
- OraDAV Performance Considerations
- mod_oradav Usage Notes

**OraDAV Concepts**

The term OraDAV refers to the capabilities available through the mod_oradav module. The mod_oradav module is an extended implementation of mod_dav, which is an implementation of the WebDAV specification. This section explains the following concepts:
- WebDAV
- mod_dav
- mod_oradav
- OraDAV

**WebDAV**

WebDAV is a protocol extension to HTTP 1.1 that supports distributed authoring and versioning. With WebDAV, the Internet becomes a transparent read and write medium, where content can be checked out, edited, and checked in to a URL address.

WebDAV enables collaboration among authors building Web sites. WebDAV also serves as universal read and write access protocol to arbitrary hierarchies of content (not necessarily Web sites). With WebDAV, you can save content to a URL provided by
an Internet Service Provider (ISP), and then be able to access and optionally change that content from various devices.

WebDAV was initiated as an Internet Engineering Task Force (IETF) standard. The first phase of WebDAV is specified in RFC 2518, which provides the basic primitives for managing hierarchies of information, locking, reading, writing, and querying properties of a WebDAV document. Subsequent work on WebDAV is ongoing and is focusing on completing issues relating to content management over the Web. This includes WebDAV authentication and authorization (access controls), versioning, bindings, ordered collections, and querying (DAV Advanced Searching and Locating).

Microsoft Web folders is a WebDAV client on Windows 2000, and later versions (using Internet Explorer 5.0 and higher). Office 2000 and Office XP applications and the IIS server support WebDAV, meaning that you can start a Microsoft Office application and specify a URL, edit the content, and save it back to the URL from which it was retrieved. WebDAV also has Java clients (such as DAV Explorer), open source tools (such as Cadaver and Sitecopy), and Apple GUI tools (such as Goliath).

**mod_dav**

mod_dav is the Apache Software Foundation native implementation of the WebDAV specification.

**mod_oradav**

mod_oradav is the Oracle module (an OCI application written in C) that is an extended implementation of mod_dav, and is integrated with Oracle HTTP Server. mod_oradav performs read/write activity to local files and to Oracle databases. Oracle databases must have an OraDAV driver (a stored procedure package) that mod_oradav calls to map WebDAV activity to database activity. Essentially, mod_oradav enables WebDAV clients to connect to an Oracle database, read and write content, and query and lock documents in various schemas.

You can configure mod_oradav to use an Oracle database using standard Oracle HTTP Server directives. mod_oradav can immediately leverage other module code (such as mime_magic) in order to perform content management tasks. Most WebDAV processing activity involves streaming content to and from a content provider; and mod_oradav uses OCI streaming logic directly within Oracle HTTP Server.

**OraDAV**

OraDAV refers to the whole set of capabilities that are available through mod_oradav to Oracle Application Server users. Some OraDAV-specific terms include:

**Note:** When a WebDAV client first connects to Oracle HTTP Server, you must use the full ServerName string (as specified in the httpd.conf file) in the URL for the connection. Do not use an abbreviated form of the server name.

For example, if the ServerName value is server1.acme.com, connect to Oracle HTTP Server using the string http://server1.acme.com:7778, not an abbreviated form such as http://server1:7778.

If you use an abbreviated form, the connection might succeed, but COPY and MOVE operations will fail to execute and generate BAD_GATEWAY errors.
- **Apache OraDAV**: Code in the Apache HTTP server that supports file-based DAV access and makes calls to Oracle.
- **OraDAV driver API**: Set of stored procedure calls that are used by the OraDAV driver to manage content in an Oracle database, providing support for the following WebDAV functions over the Internet: reading and writing documents, locking and unlocking documents, managing (creating, populating, deleting) hierarchies of information, retrieving properties associated with documents, and associating properties with specific documents.
- **OraDAV driver**: Stored procedure implementation of the OraDAV driver API that executes in Oracle and manages a repository.

**OraDAV Architecture**

OraDAV fits into an architecture in which `mod_oradav`, within Oracle HTTP Server, provides access to content in one or more schemas in one or more Oracle databases. A simple form of the architecture is illustrated in Figure 9–1.

Figure 9–1 shows a WebDAV client, such as Microsoft Web folders, passing HTTP requests to Oracle HTTP Server. If the request is for content stored in the file system (not in an Oracle database), `mod_oradav` handles the access. If the request is for content stored in an Oracle database, the OraDAV API handles the access.

The OraDAV API provides capabilities that are equivalent to using `mod_oradav` running with a file system. The following HTTP methods are supported by the OraDAV API:

- COPY
- DELETE
- MOVE
- MKCOL
OraDAV API supports shared and exclusive locking, retrieving basic DAV properties, and defining and retrieving server-defined live properties or client-defined dead properties. Set-based operations such as **COPY**, **MOVE**, **DELETE** can be done completely by a single call to an OraDAV driver.

**OraDAV Users**

The primary direct users of OraDAV are Oracle HTTP Server administrators and database administrators (DBAs) of Oracle databases. End users interact only indirectly with OraDAV through Web browsers or WebDAV client tools.

OraDAV administration involves tasks for a Web master and for a DBA:

- The Web master needs to know how to start and stop Oracle HTTP Server, and how to configure Oracle HTTP Server to direct URL traffic to an OraDAV driver.
- The DBA needs to know how to set up client connectivity to an Oracle database from the system running Oracle HTTP Server, to install and administer the OraDAV driver, and perhaps to tune the content managed by the driver based on physical storage characteristics.

**OraDAV Usage Model**

OraDAV usage can involve any combination of the following activities:

- **Browsing**: Read-only activity which uses WebDAV to access content in an Oracle database. Its usage model is that of a typical read-only Web site.
- **Restructuring**: Deleting, moving, and copying content. Restructuring is usually done infrequently by a restricted set of individuals who have write access to the WebDAV content. Restructuring has the same limitations and complications that one encounters when restructuring a file directory. In some cases, this directory hierarchy is owned and managed by one user. If the directory is shared, the client doing restructuring is given sole access to the hierarchy through WebDAV exclusive locks.
- **Editing**: Modifying one or a small subset of resources in a hierarchy. Properly designed WebDAV clients take out shared or exclusive locks on such resources to coordinate these activities.
- **Property Management**: Associating properties and attributes (for example, author) with documents for ease of lookup and for categorization. WebDAV clients assign properties to documents using the **PROPPATCH** directive and retrieve properties using the **PROPFIND** directive.
OraDAV Configuration Parameters

You configure OraDAV mainly through parameters in the `httpd.conf` file, which is used by an Oracle HTTP Server instance when it is initializing. Some configuration parameters are required for all OraDAV drivers, and others are driver-specific.

When Oracle Application Server is installed, all required OraDAV parameters are set with values that are designed to enable Oracle database content to be accessed through a Web browser or WebDAV client. If the default values do not meet your needs, you can later modify the values for required parameters and specify values for optional parameters. The parameters used in `httpd.conf` to support OraDAV configuration start with `DAV` and `DAVParam`. These parameters are specified within a `<Location>` container directive, and they provide:

- A way of configuring how Oracle HTTP Server connects to the database.
- Coarse controls on OraDAV behavior.

The `DAV` parameter indicates that a URL location is DAV-enabled. The `DAV` keyword is followed by one of the following values:

- `On`, which indicates that `mod_oradav` is to use the local file system for content
- `Oracle`, which indicates that `mod_oradav` is to use OraDAV for all content

`DAVParam` parameters are used to specify name-value pairs. The required pairs are those that enable Oracle HTTP Server to connect to an Oracle database. These include the names `OraService`, `OraUser`, and `OraPassword` or `OraAltPassword`.

Example 9–1 shows a configuration for accessing files on the local system. It specifies that the directory `myfiles` under the Web server documents directory (`htdocs` by default) is to be DAV-enabled, along with all directories under `myfiles` in the hierarchy. Note that there must not be any symlinks defined on `myfiles` or any directory under it in the hierarchy.

```
Example 9–1 Configuration Parameters: File System Access
<Location /myfiles>
  DAV On
</Location>
```

Example 9–2 shows a configuration for accessing content through Oracle Application Server Portal. After OracleAS Portal has been installed in Oracle Application Server, the Oracle HTTP Server configuration file should be populated with a `<Location>` container directive which points to the OracleAS Portal schema. In this example, the location `/portal` will be OraDAV-enabled and will (once populated with the correct values) connect to the OracleAS Portal schema so that users can use WebDAV clients to access OracleAS Portal data.

```
Example 9–2 Configuration Parameters: Portal Access
<Location /portal>
  DAV Oracle
  DAVParam ORACONNECT dbhost:dbport:dbsid
  DAVParam ORAUSER portal_schema
  DAVParam ORAPASSWORD portal_schema_password
  DAVParam ORAPACKAGENAME portal_schema.wwdav_api_driver
</Location>
```

Each OraDAV driver can use the `DAVParam` mechanism to create its own driver-specific settings. All `DAVParam` name-value pairs are passed to the OraDAV
driver. In addition to the OraDAV parameters, you should consider whether to specify certain DAV parameters, such as DAVDepthInfinity.

See Also: "DAV Directives" on page 9-15

Table 9–1 lists each OraDAV parameter, whether it is required or optional, and its default value. ORAGetSource applies only to file system access; the other parameters apply only to OracleAS Portal driver and other (non-file system) access.

OraDAV Configuration Parameters

Configuring and Using mod_oradav

<table>
<thead>
<tr>
<th>Name</th>
<th>Required/Optional</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORAUser</td>
<td>Required</td>
<td>(none)</td>
</tr>
</tbody>
</table>

**ORAAllowIndexDetails**

In an Oracle HTTP Server environment that is not OraDAV-enabled, mod_dav itself does not respond to HTTP GET requests. Instead, normal Oracle HTTP Server mechanisms are used to respond to GET requests. However, when all your content is in an Oracle database, normal Oracle HTTP Server mechanisms cannot be used to respond to GET requests, and thus OraDAV must respond to GET requests.

The `ORAAllowIndexDetails` parameter controls how OraDAV responds when a GET request is performed on a DAV collection and no index.html file is found in that collection (directory). In a typical Oracle HTTP Server environment, a separate module takes control, automatically generating and returning to the client HTML that represents an "index" of the resources (files) in that collection.

An OraDAV-enabled Oracle HTTP Server performs similar actions when responding to a GET request on a collection. A Description column (containing links to more detailed information about each resource) is included in the generated index when `ORAAllowIndexDetails` is set to `TRUE`.

The default is `FALSE`, in which case no Description column appears in the generated index, and if `?details` is used in a URL, it is ignored and the URL contents are returned.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td><code>TRUE/FALSE</code></td>
</tr>
<tr>
<td>Default</td>
<td><code>FALSE</code></td>
</tr>
</tbody>
</table>

**ORAAltPassword**

Specifies the password associated with the user specified by the `ORAUser` parameter, but the password is a base-64 encoded character string. The `ORAAltPassword` parameter provides an alternative if you do not want the password to appear in unencoded plain text in that parameter.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Required, unless <code>ORAPassword</code> is specified</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

Table 9–1 (Cont.) OraDAV Parameters

Note: All OraDAV parameters are passed from Oracle HTTP Server to the routines in the ORAPackageName package as part of the context parameter. Keys are uppercase in Oracle HTTP Server, such as `ORAPASSWORD`, but the values, such as `scott`, are not.
If the `ORAPassword` parameter is not specified, the `ORAAltPassword` parameter is used for the password.

**ORACacheDirectory**

Specifies the directory to use for disk caching operations. If you do not use this parameter, disk caching is not performed for OraDAV operations.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

The specified directory must exist and be readable by Oracle HTTP Server, but cannot be visible to normal `GET` requests. (If the directory is visible to normal `GET` requests, security measures could be bypassed by users accessing the cache directory.)

The directory should not be an NFS-mounted directory, because most UNIX locking mechanisms caution against this. The directory should be located on a file system that supports a "last accessed" time. On Windows systems, this means using NTFS (not FAT) formatted partitions.

Do not use the cache directory for anything other than caching. Any files in the cache directory are subject to deletion.

If you use the `ORACacheDirectory` parameter, you must also use the `ORACacheTotalSize` parameter.

See Also: "Using Disk Caching with OraDAV" on page 9-19

**ORACacheMaxResourceSize**

Specifies a maximum cacheable resource size for disk caching operations.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>(integer, with optional unit character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

Example 9-3 shows how to set `ORACacheMaxResourceSize`:

**Example 9-3 ORACacheMaxResourceSize Parameter**

`DAVParam ORACacheMaxResourceSize 1024KB`

The setting in Example 9-3 prevents OraDAV from caching any resource larger than one megabyte. The goal is to give Web masters the ability to prevent large media files from dominating the cache. However, be aware that the performance benefit from caching a large file is greater than from caching a small file.
You can specify KB (for kilobytes) or MB (for megabytes) after an integer. If you do not specify a unit after the integer, the default unit is bytes.

See Also: "Using Disk Caching with OraDAV" on page 9-19

**ORACachePrunePercent**

Specifies the percentage of disk cache usage to be freed up when the cache is full. When the disk cache is full, the oldest files in the cache are deleted (pruned) until the cache disk usage is reduced by the `ORACachePrunePercent` value.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>integer (1 to 100)</td>
</tr>
<tr>
<td>Default</td>
<td>25</td>
</tr>
</tbody>
</table>

See Also: "Using Disk Caching with OraDAV" on page 9-19

**ORACacheTotalSize**

Specifies the size of the cache to use for disk caching operations.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional, unless ORACacheDirectory is specified</td>
</tr>
<tr>
<td>Values</td>
<td>(integer, with optional unit character string, GB or MB) Maximum value is 4GB.</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

You can specify MB (for megabytes) or GB (for gigabytes) after an integer, as shown in Example 9-4. If you do not specify a unit after the integer, the default unit is bytes.

**Example 9-4** **ORACacheTotalSize Parameter**

```
DAVParam ORACacheTotalSize 1GB
```

If you use the `ORACacheDirectory` parameter, you must also use the `ORACacheTotalSize` parameter.

The `ORACacheTotalSize` value should be large enough to hold either a significant fraction of your Web site, or all of your most frequently accessed files plus 25 percent more space. If the value is too small, overall performance degrades because of the extra work of writing BLOB data to the file system and quickly deleting files to make room for newer cache requests.

The actual space utilized by the disk cache might sometimes exceed the `ORACacheTotalSize` value, possibly by as much as the `ORACacheMaxResourceSize` value. You should also be aware of file system block size issues that could cause the cache to use more disk space than the `ORACacheTotalSize` value.

See Also: "Using Disk Caching with OraDAV" on page 9-19
OraDAV Configuration Parameters

**ORACOnnect**

Specifies the Oracle database to which to connect. The value must be in the following format:

```
database-host:database-port:database-sid
```

**Example 9–5** shows how to use the ORACOnnect parameter.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Required, unless ORAService or ORACOnnectSN is specified</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

**Example 9–5  ORACOnnect Parameter**

DAVParam ORACOnnect my-pc.acme.com:1521:mysid

The ORACOnnect parameter lets you connect to a database that is not included in the tnsnames.ora file.

You must specify one, and no more than one, of the following parameters: ORACOnnect, ORAService, or ORACOnnectSN.

**ORACOnnectSN**

Specifies the Oracle database to which to connect. The value must be in the following format:

```
database-host:database-port:database-service-name
```

**Example 9–6 ORACOnnectSN Parameter**

DAVParam ORACOnnectSN my-pc.acme.com:1521:myservice

The ORACOnnectSN parameter lets you connect to a database that is not included in the tnsnames.ora file, as shown in **Example 9–6**.

You must specify one, and no more than one, of the following parameters: ORAService, ORACOnnect, or ORACOnnectSN.

**ORACOnainerName**

Within the schema specified by the ORAUser parameter, there must exist a container. The ORACOnainerName parameter specifies the name of the container to use for the location.

9-10 Oracle HTTP Server Administrator’s Guide
ORAException

Writes PS/SQL stack dumps into the Oracle HTTP Server log file, error_log, in the event of an exception in the PL/SQL package.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Required</td>
</tr>
<tr>
<td>Values</td>
<td>(any valid character string, up to 20 characters)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

Caution: Use this parameter for debugging problems with PL/SQL packages. However, note that it can use a large amount of disk space and can slow the performance of your system.

ORAGetSource

Applies only to file system access. It specifies one or more file extensions to identify types of files that are not to be executed, but rather opened for editing. Include periods (.) with the file extension and use a comma to separate file extensions. For example: ".htm, .html, .jsp, .jsp2"

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>File system access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>(character string in double quotation marks)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

The ORAGetSource parameter lets you open for editing files that are usually executed as a result of a GET operation.

Note: Because .jsp and .sql.jsp files are by default opened for editing, you do not need to specify them with the ORAGetSource parameter.

ORALockExpirationPad

Intended to be used in high-latency network environments, to adjust for the "refresh lock" behavior in Microsoft Office. Microsoft Office attempts to refresh locks on DAV
resources just before the lock is set to expire. However, if there is network congestion between the Microsoft Office client and the DAV server, the refresh request might arrive too late, that is, after the lock has expired.

OraDAV periodically looks for locks on resources that have expired and deletes those locks. The ORALockExpirationPad parameter can be used to provide some additional (‘pad’) time between when a lock expires and when that lock is deleted. For example, if ORALockExpirationPad is set to 120, OraDAV does not actually delete locks until at least two minutes after the expiration time.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>(number of seconds)</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

**ORAPackageName**

Identifies the OraDAV driver implementation that is to be called when issuing OraDAV commands. The default is the OraDAV driver, which is the `ORDSYS.DAV_API_DRIVER` package.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Required</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td><code>ORDSYS.DAV_API_DRIVER</code></td>
</tr>
</tbody>
</table>

**ORAPassword**

Specifies the password associated with the user specified by the ORAUser parameter.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Required</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>

If you do not want to specify the password as an unencoded text string with the ORAPassword parameter, you can specify the password as a base-64 encoded string with the ORAAHPassword parameter.

**ORARootPrefix**

Specifies the directory within the database repository to use as the root. If this parameter is specified, WebDAV clients see this directory as the root and are not be able to see the repository directories that lead up to it.
In Example 9-7, assume that the database repository contains the directory
\texttt{/first/second/third/fourth}, and that \texttt{ORARootPrefix} is defined as follows
(do not include a trailing slash (/) in the value):

\begin{verbatim}
Example 9–7 ORARootPrefix Parameter
DAVParam ORARootPrefix /first/second
\end{verbatim}

In this case, WebDAV clients will see the \texttt{/third} directory and be able to navigate to
the \texttt{/third/fourth} directory, but will not be able to see or navigate to the \texttt{/first} or
\texttt{/first/second} directories.

\textbf{ORAService}

Specifies the Oracle database to which to connect. The specified value must match a
SID value in the \texttt{tnsnames.ora} file as shown in Example 9–8.

\begin{verbatim}
Example 9–8 ORAService Parameter
DAVParam ORAService mydbsid.mydomain.com
\end{verbatim}

To connect to a database that is not included in the \texttt{tnsnames.ora} file, use the
\texttt{ORAConnect} parameter. You must specify one, and no more than one, of the following
parameters: \texttt{ORAService}, \texttt{ORAConnect}, or \texttt{ORAConnectSN}.

\begin{verbatim}
Category Value
Applies to Portal driver and other (non-file system) access
Required/Optional Required, unless \texttt{ORAConnect} or \texttt{ORAConnectSN} is specified
Values (character string matching an entry in the \texttt{tnsnames.ora} file)
Default (none)
\end{verbatim}

\textbf{ORATraceEvents}

Specifies types of events to be recorded in the Apache error log for debugging.

\begin{verbatim}
Category Value
Applies to Portal driver and other (non-file system) access
Required/Optional Optional
\end{verbatim}
ORATraceLevel

Specifies the level of debugging (trace statements) that will be entered in the Apache error log. The lowest level is 0 (the default), which performs no tracing; the highest level is 4, which performs maximum tracing.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
<tr>
<td>Required/Optional</td>
<td>Optional</td>
</tr>
<tr>
<td>Values</td>
<td>integer (0 to 4)</td>
</tr>
<tr>
<td>Default</td>
<td>0</td>
</tr>
</tbody>
</table>

Caution: Although this parameter is useful for debugging purposes, it can use a large amount of disk space and can slow the performance of your system.

ORAUser

Specifies the database user (schema) to use when connecting to the service specified by the ORAService parameter.

This user must have the following privileges:

- CONNECT
- RESOURCE
- CREATE TABLESPACE
- DROP TABLESPACE
- CREATE ANY TRIGGER

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Applies to</td>
<td>Portal driver and other (non-file system) access</td>
</tr>
</tbody>
</table>
This section describes the following DAV directives that you can set in the httpd.conf file:

- `DAVDepthInfinity`
- `DAVLockDB`
- `DAVMinTimeout`
- `DAVoraNLS`
- `DAVoraReadOnly`
- `DAVoraWebCacheReadOnly`
- `Limit`
- `LimitExcept`
- `LimitXMLRequestBody`

Some of the material in this section is taken or adapted from material written by Greg Stein (gstein@lyra.org) and available at the following URL:

http://www.webdav.org/mod_dav/install.html

### DAVDepthInfinity

A `PROPFIND` request with a `Depth: Infinity` header can impose a large burden on the server. These kinds of requests could "walk" the entire repository, returning information about each resource found. `mod_dav` builds the response in memory, so these types of requests can consume a lot of memory. (The memory is released at the end of the request, but the peak memory usage can be high.)

To prevent these types of requests, the `DAVDepthInfinity` directive is provided. It is a simple on/off directive, which can be used on a per-server, per-directory or location basis. If the value is set to `Off`, these types of requests are not allowed. A value of `On` (that is, allowing depth infinity requests) makes it easier for denial of service attacks to occur. However, some clients, such as `sitecopy`, require a `DAVDepthInfinity` value of `On`.

### DAVLockDB

Creates a DAV lock database. To create the DAV lock database, add a `DAVLockDB` directive at the top level of the configuration file (that is, outside a `<Directory>` or `<Location>` container directive). The `DAVLockDB` directive should specify the name

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required/Optional</td>
<td>Required</td>
</tr>
<tr>
<td>Values</td>
<td>(character string)</td>
</tr>
<tr>
<td>Default</td>
<td>(none)</td>
</tr>
</tbody>
</table>
of a file that `mod_dav` creates. The directory in which the file is to be created must exist, and Oracle HTTP Server process must have write permission to it.

---

**Note:** The directory should not be on an NFS-mounted partition. `mod_dav` uses `flock/fcntl` to manage access to the database. Some operating systems cannot use these operations on an NFS-mounted partition.

---

In Example 9-9, the DAV lock database is stored in the `ORACLE_HOME/Apache/var` directory, which must be writable by Oracle HTTP Server process. When `mod_dav` creates the file, it is named `DAVLock`. (Actually, `mod_dav` creates one or more files using this file name plus an extension).

**Example 9-9  DAVLockDB Directive**

```
DAVLockDB ORACLE_HOME/Apache/var/DAVLock
```

The `DAVLockDB` directive can appear outside any container or within a `<VirtualHost>` specification. It only needs to appear once, and a file extension should not be supplied.

---

**DAVMinTimeout**

Specifies the minimum lifetime of a lock, in seconds. If a client requests a lock timeout less than the `DAVMinTimeout` value, then the `DAVMinTimeout` value is used and returned instead. For example, Microsoft’s Web Folders defaults to a lock timeout of 2 minutes (120 seconds); however, you might decide to specify 10 minutes (600 seconds) instead, to reduce network traffic and the chance that the client might lose a lock due to network latency.

The `DAVMinTimeout` directive is optional, and may be used on a per-server or per-directory or location basis. The `DAVMinTimeout` directive takes a single positive integer. Because this value represents a minimum allowed, setting it to zero (0) disables this feature. The default value for `DAVMinTimeout` is zero.

---

**DAVOraNLS**

Provides globalization support for access to the local file systems. This directive specifies whether or not the file names in the file system need to go through conversion using the `NLS_LANG` setting. A value of `Off`, the default, means that no conversion is needed. A value of `On` means that the character set for the file system provides for conversion of all possible characters in client requests.

**See Also:** “Globalization Support Considerations with OraDAV” on page 9-21

---

**DAVOraReadOnly**

Specifies whether or not WebDAV should be used in a read-only mode by WebDAV clients. A value of `Off`, the default, means that WebDAV clients function normally. A value of `On` prevents WebDAV clients from performing write operations while using WebDAV; however, it does allow read-only activity by Web browsers and WebDAV clients.

**See Also:** “DAVOraWebCacheReadOnly” on page 9-17

---
DAV Directives

Configuring and Using mod_oradav

9-17

DAVoraWebCacheReadOnly

Specifies whether or not OracleAS Web Cache should be used in a read-only mode by WebDAV clients. A value of Off, the default, means that OracleAS Web Cache functions normally. A value of On prevents WebDAV clients from performing write operations while using OracleAS Web Cache; however, it does allow read-only activity by Web browsers and WebDAV clients.

See Also:

- "Using Oracle Application Server Web Cache for Browsing Activities" on page 9-20
- "DAVoraReadOnly" directive on page 9-16

Limit

The DAV and DAVlockDB directives are the only two configuration changes necessary to operate a DAV server. However, it is usually best to secure the site to be writable only by specific authorized users. This requires the use of the <Limit> directive.

The configuration in Example 9-10 allows only authorized users to manipulate the site. However, it does allow them a bit more freedom than you may like. In particular, they may be able to place an .htaccess file into the target directory, altering your server configuration. The server may have already been configured to not read .htaccess files, but it is best to make sure. Also, you may want to disallow other options within the DAV-enabled directory, such as CGI, symbolic links or server-side includes.

Example 9–10  Securing a Site by Using the <Limit> Directive

<Location /mypages>
DAV On
<Limit PUT POST DELETE PROPFIND PROPPATCH MKCOL COPY MOVE LOCK UNLOCK>
Require user greg
</Limit>
</Location>

Example 9–11 shows a modified configuration with the additional restrictions placed on it through the addition of AllowOverride None and Options None:

Example 9–11  Securing Site by Using Additional Restrictions

<Location /mypages>
DAV On
AllowOverride None
Options None
<Limit PUT POST DELETE PROPFIND PROPPATCH MKCOL COPY MOVE LOCK UNLOCK>
Require user greg
</Limit>
</Location>

Configuring and Using mod_oradav 9-17
WebDAV Security Considerations

LimitExcept

Rather than using the `<Limit>` directive and specifying an exhaustive list of HTTP methods to secure, it is also possible to use the `<LimitExcept>` directive, as shown in Example 9–12. This directive applies the access restrictions to all methods except for the methods listed.

Example 9–12  Securing a Site Using the `<LimitExcept>` Directive

```
<Limit /mypages>
DAV On
AllowOverride None
Options None
<LimitExcept GET HEAD OPTIONS>
  require user webadmin
</LimitExcept>
</Location>
```

Choosing to use one or the other is a matter of preference. The `<Limit>` directive is precise and explicit, but the `<LimitExcept>` directive automatically restricts methods that are added in the future.

LimitXMLRequestBody

`mod_dav` parses XML request bodies into memory. One technique used in denial of service attacks is to send a large request body to a `mod_dav` server. Oracle HTTP Server defines a directive named `LimitRequestBody`, which limits all methods’ request bodies. Unfortunately, this is not an effective mechanism for a `mod_dav` server because large `PUT` operations should be allowed.

To limit just the methods that have an XML request body, `mod_dav` provides the `LimitXMLRequestBody` directive. The default for this value is a compile-time constant, which is set to one million (1,000,000) bytes in the standard distribution. Setting the value to zero (0) disables the size limit.

`LimitXMLRequestBody` may be set on a per-server or a per-directory or location basis, and takes a single non-negative integer argument.

WebDAV Security Considerations

Because WebDAV enables read-write capabilities, users on the Internet can write to your Web site or to an Oracle database. A major concern is preventing users from placing an inappropriate file (a “Trojan horse”) that can execute on the Web server system. If the WebDAV configuration and authorization is not set up properly, an inappropriate file from the file system can be executed. This problem does not apply to content from an Oracle database, because such content cannot execute in the middle tier.

The HTTP protocol issues `GET` requests both to static and executable files, without differentiation. Oracle HTTP Server executes files based on their location or extension. For example, a shell script (which typically has no file extension) is executed if it is in the `cgi-bin` directory. On the other hand, a JavaServer Pages (JSP) file, which has a `.jsp` extension, will normally be executed regardless of its location. However, by default, `mod_oradav` prevents a WebDAV-enabled directory from executing a `.jsp` or `.sql.jsp` file. For a file with one of these extensions, `mod_oradav` reads the content directly, bypassing any Oracle HTTP Server logic that attempts to execute the file. Files with these extensions are retrieved as having the `text/plain` MIME type and can be
edited. You can add to the list of file types that are never to be executed and always retrieved as text/plain by using the ORAGetSource parameter.

One way to limit execution of files is to use the Apache ForceType directive in a <Location> container directive. This forces all content under a location to be retrieved as text/plain. However, this simple and sweeping approach may not be what you want in many cases, wherein you want the standard behavior associated with the actual MIME type, for example, for GIF files, to be used.

To decide how to handle these security issues with content on file systems, you should determine what kinds of WebDAV users will have access to the content. WebDAV users typically fall into two categories: Web authors who want to collaborate and manage a Web site, and end users who want to use WebDAV as a public storage area. Because end users should never be able to upload and execute a file, you may want to specify many file extensions with the ORAGetSource parameter or to use the ForceType directive for end users.

Be sure to apply the standard Basic or Digest authentication and authorization mechanisms supported by Oracle HTTP Server. Generally, you do this for the default location, such as dav_public, in the supplied moddav.conf file. This restricts who can use your system for remote storage, preventing unauthorized users from filling up your disks. You should always apply Oracle HTTP Server authentication and authorization to authors of the Web site.

You should also provide both an execution context and an editing context, so that Web authors, after being properly authenticated and authorized, can edit a JSP file or other executable file and then see how it executes. To do this, create an alias for the directory associated with the execution context, and then DAV-enable the aliased location. For example, assume that you want to be able to execute a script if the URL specifies the cgi-bin directory (for example, http://www.acme.com/cgi-bin/printenv), but to edit the script if the URL specifies an alias named edit-cgi-bin (for example, http://www.acme.com/edit-cgi-bin/printenv). In Example 9–13, the configuration file entries achieve this goal, setting up edit-cgi-bin as an editing context for content in the cgi-bin directory:

Example 9–13 Editing Context

```
Alias /edit-cgi-bin /usr/local/apache/cgi-bin
<Location /edit-cgi-bin>
  DAV On
  ForceType text/plain
</Location>
```

### OraDAV Performance Considerations

This section provides information that can help you optimize the performance of various kinds of operations. It contains the following topics:

- Using Disk Caching with OraDAV
- Bypassing Oracle Application Server Web Cache for WebDAV Activities
- Using Oracle Application Server Web Cache for Browsing Activities

### Using Disk Caching with OraDAV

Oracle Application Server can use local file system disk caching with data that is retrieved from an Oracle database. Disk caching is designed to improve the performance of HTTP GET operations on frequently accessed database data. When
data is requested from the database, it is retrieved and is stored in a disk cache on the local file system. If a subsequent request is for the same data and if the data is still in the disk cache, Oracle Application Server checks to see if the data has changed in the database (by examining the etag value). If the data has not changed, it is retrieved from the cache, which is more efficient than retrieving a substantial amount of data from the database.

The performance benefit from disk caching is greatest with medium to large-size files (roughly 50 KB and larger). However, with smaller files, the performance benefit is less, and with very small files the performance can be worse with disk caching than without disk caching. For example, if the file myfile.dat is requested and if the file size is only 24 bytes, the time required for copying the file from the database to the local system is very small compared to the time required for accessing the database to check if the file has changed. If disk caching is not used, there is no check of the database to see if the file has changed, and the file is copied from the database in all cases.

You can set the following OraDAV parameters to control disk caching for OraDAV operations:

- ORACacheDirectory
- ORACacheTotalSize
- ORACacheMaxResourceSize
- ORACachePrunePercent

If you specify ORACacheDirectory, disk caching for OraDAV operations is enabled. In this case, you must also specify a value for ORACacheTotalSize, and you can specify values for ORACacheMaxResourceSize and ORACachePrunePercent parameters. If you do not specify ORACacheDirectory, disk caching for OraDAV operations is not enabled, and other disk cache-related parameters are not relevant.

See Also: "OraDAV Configuration Parameters" on page 9-5

Bypassing Oracle Application Server Web Cache for WebDAV Activities
Oracle Application Server Web Cache enhances performance for most Web activity, which involves client read-only operations of data on the Web server system. However, OracleAS Web Cache does not cache OraDAV operations, which are designed for read/write capability. Thus, for better performance, WebDAV clients can connect directly to Oracle HTTP Server.

To bypass OracleAS Web Cache for WebDAV clients, you can use port 7778, which is the standard port for Oracle HTTP Server. If you do this, WebDAV clients connect directly to the Web server, resulting in better performance than if OracleAS Web Cache was used.

Using Oracle Application Server Web Cache for Browsing Activities
If your WebDAV clients always bypass OracleAS Web Cache, you may want to tune OracleAS Web Cache for read-only clients such as Web browsers. To do so, add the DAV:OraWebCacheReadOnlyOn setting for an OraDAV-enabled location in the httpd.conf file, as shown in Example 9-14.

Example 9–14 Using OracleAS Web Cache for Browsing Activities

```
<Location /dav_public>
  DAV On
</Location>
```
This setting prevents WebDAV clients from performing write operations while using OracleAS Web Cache; however, it does allow read-only activity by Web browsers and WebDAV clients.

See Also: “DAVOraWebCacheReadOnly” on page 9-17

Mapping Containers Under the Root Location

Note the following when mapping containers under the root location:

- Do not map the root itself. That is, do not specify <Location />.
- Do not map a container as a subelement in the hierarchy to another container. For example, do not specify the following two containers: <Location /project1> and <Location /project1/project2>. However, it is acceptable to specify <Location /project1> and <Location /project2>.
- Do not create any symbolic links to the container or any location under the container in the hierarchy.

Globalization Support Considerations with OraDAV

For access to database data, the character set used for client requests, such as in URLs and file names, must be compatible with the character set used for the database. Specifically, if the character set for the database is not the same as for the client requests, the character set for the database must provide for conversion of all possible characters in client requests (and thus must be a superset of the character set for client requests). That is, the character set for the database must not cause replacement characters during the conversion.

When you start Oracle HTTP Server, the NLS_LANG environment variable must reflect the character set for client requests. For example, if file names and URLs contain Kanji characters, you can specify NLS_LANG=JAPANESE_JAPAN.JA16SJIS (for ShiftJIS characters). In this case, the database character set must be one that accommodates SJIS characters, for example, UTF8.

For access to the local file system, as opposed to database access, the character set for the file system must be the same as, or compatible with, the character set for URLs embedded in client requests. The character set for the file system must provide for conversion of all possible characters in client requests. The NLS_LANG parameter value must represent the character set of both the client and the OraDAV server. You must also specify a value of On for the parameter DAVOraNLS.

For example, assume that you are using Web folders on a system where the files have ShiftJIS characters and that the file system under dav_public is represented by the operating system in the JAPANESE_JAPAN.JA16SJIS character sets shown in Figure 9-2.
In this case, you must do the following:

1. Set the NLS_LANG value to JAPANESE_JAPAN.JA16SJIS.
2. Include the following in the httpd.conf file:
   ```
   <Location /dav_public>
   DAV On
   DAVOraNLS On
   </Location>
   ```

**Note:** If you use Microsoft Internet Explorer with OraDAV and a multibyte character set, you must disable (uncheck) the Internet option (Internet Options, Advanced tab) Always send URLs as UTF-8. (By default, this option is enabled.) The requirement to disable this option applies to both database access and file system access.

**PROPFIND Security**

In the example configurations in the preceding sections on the `<Limit>` and `<LimitExcept>` directives, the PROPFIND method was limited, even though it is read-only. This is because the PROPFIND method can be used to list all the files in the DAV-enabled directory. For security reasons, it is probably best to protect the list of files from general read access.

An alternative is to limit the PROPFIND to a group of people, a set of domains, or a set of hosts, while the methods that modify content are limited to just a few authors. This scenario allows, for example, your company’s employees to browse the files on the server, yet only a few people can change them. Anonymous (non-authenticated) visitors cannot browse or modify.

Finally, you can simply omit PROPFIND from the limits if your Web server is intended as a general, read-only repository of files. This allows anybody to arbitrarily browse the directories and then to fetch the files.
Managing Security

This chapter contains an overview of Oracle HTTP Server security features, and provides configuration information for setting up a secure Web site.

Topics discussed are:

- About Oracle HTTP Server Security
- Classes of Users and Their Privileges
- Resources Protected
- Authentication and Authorization Enforcement
- Understanding Port Tunneling
- Leveraging Oracle Identity Management Infrastructure

See Also: For additional information about security, refer to the following documents:

About Oracle HTTP Server Security

Security can be organized into the three categories of authentication, authorization, and confidentiality. Oracle HTTP Server provides support for all three of these categories. It is based on the Apache Web server, and its security infrastructure is primarily provided by the Apache modules, mod_auth and mod_access, and the Oracle modules, mod_ossl and mod_osso. mod_auth provides authentication based on user name and password pairs, mod_access controls access to the server based on the characteristics of a request, such as hostname or IP address, mod_ossl provides confidentiality and authentication with X.509 client certificates over SSL, and mod_osso enables single sign-on authentication for Web applications.

Based on the Apache model, Oracle HTTP Server provides access control, authentication, and authorization methods that can be configured with access control directives in the httpd.conf file. When URL requests arrive at Oracle HTTP Server, they are processed in a sequence of steps determined by server defaults and configuration parameters. The steps for handling URL requests are implemented through a module or plug-in architecture that is common to many Web listeners.
Classes of Users and Their Privileges

Oracle HTTP Server authorizes and authenticates users before allowing them to access, or modify resources on the server. The following are three classes of users that access the server using Oracle HTTP Server, and their privileges:

- Users that access the server without providing any authentication. They have access to unprotected resources only.
- Users that have been authenticated and potentially authorized by modules within Oracle HTTP Server. This includes users authenticated by `mod_auth` and `mod_ossl`. Such users have access to URLs defined in `http.conf` file.
- Users that have been authenticated through `mod_osso` and Single Sign-On server. These users have access to resources allowed by Single Sign-On.

See Also: "Authentication and Authorization Enforcement" on page 10-3

See Also: Oracle Application Server Single Sign-On Administrator’s Guide

Resources Protected

Oracle HTTP Server is configured to protect resources such as:

- Static content such as static HTML pages, graphics interchange format (.gif, files, and other static files that Oracle HTTP Server provides directly.
- CGI/FastCGI scripts, simple scripts or programs that Oracle HTTP Server invokes directly.
- Content generated by modules within Oracle HTTP Server. Modules such as `mod_perl`, `mod_dms` generate responses that are returned to the client.
- Oracle Application Server components that exist behind Oracle HTTP Server, including servlets and JSPs running with OC4J that are accessed through `mod_`
oc4j: Oracle HTTP Server forms the first line of authentication and authorization for these components, although further authentication may occur at the component level.

Authentication and Authorization Enforcement

Oracle HTTP Server provides user authentication and authorization at two stages:

- **Host-based Access Control** (stage one): This is based on the details of the incoming HTTP request and its headers, such as IP addresses or host names.
- **User Authentication and Authorization** (stage two): This is based on different criteria depending on the HTTP server configuration. The server can be configured to authenticate users with user name and password pairs that are checked against a list of known users and passwords. You can also configure the server to use single sign-on authentication for Web applications or X.509 client certificates over SSL.

Host-based Access Control

Early in the request processing cycle, access control is applied, which can inhibit further processing based on the host name, IP address, or other characteristics such as browser type. You use the `deny`, `allow`, and `order` directives to set this type of access control. These restrictions are configured with Oracle HTTP Server configuration directives and can be based on particular files, directories, or URL formats using the `<Files>`, `<Directory>`, and `<Location>` container directives as shown in the Example 10-1:

**Example 10–1  Host-based Access Control**

```http
<Directory /internalonly/>
  order deny, allow
  deny from all
  allow from 192.168.1.* us.oracle.com
</Directory>
```

In Example 10-1, the `order` directive determines the order in which Oracle HTTP Server reads the conditions of the `deny` and `allow` directives. The `deny` directive ensures that all requests are denied access. Then, using the `allow` directive, requests originating from any IP address in the 192.168.1.* range, or with the domain name `us.oracle.com` are allowed access to files in the directory `/internalonly/`. It is common practice to specify both `allow` and `deny` in host-based authentication to make the access policy explicit.

If you want to match objects at the file system level, then you must use `<Directory>` or `<Files>`. If you want to match objects at the URL level, then you must use `<Location>`.

**Note:** Allowing or restricting access based on a host name for Internet access is not considered a very good method of providing security, because host names are easy to spoof. While the same is true of IP addresses, sabotage is more difficult. However, setting access control with intranet IP address ranges is reasonable because the same risks do not apply. This assumes that your firewalls have been properly configured.
Access Control for Virtual Hosts
To set up access control for virtual hosts, place the AccessConfig directive inside a virtual host container in the server configuration file, httpd.conf. When used in a virtual host container, the AccessConfig directive specifies an access control policy contained in a file. Example 10–2 shows an excerpt from an httpd.conf file which provides the syntax for using AccessConfig this way:

Example 10–2 Using AccessConfig to Set Up Access Control

```bash
<VirtualHost ip_address_of_host.some_domain.com>
    AccessConfig conf/access.conf
</VirtualHost>
```

Using mod_access and mod_setenvif for Host-based Access Control
Using host-based access control schemes, you can control access to restricted areas based on where HTTP requests originate. Oracle HTTP Server uses mod_access and mod_setenvif to perform host-based access control. mod_access provides access control based on client hostname, IP address, or other characteristics of the client request, and mod_setenvif provides the ability to set environment variables based upon attributes of the request. When you enter configuration directives into the httpd.conf file that use these modules, the server fulfills or denies requests based on the address or name of the host, or based on the HTTP request header contents.

You can use host-based access control to protect static HTML pages, applications, or components.

Oracle HTTP Server supports four host-based access control schemes:

- **Controlling Access by IP Address**
- **Controlling Access by Domain Name**
- **Controlling Access by Network or Netmask**
- **Controlling Access with Environment Variables**

All of these allow you to specify the machines from which access to protected areas is granted or denied. Your decision to choose one or more of the host-based access control schemes is determined by which scheme most efficiently protects your restricted content and applications, or which scheme is easiest to maintain.

**Controlling Access by IP Address** Controlling access with IP addresses is a preferred method of host-based access control. It does not require DNS lookups that consume time, system resources, and make your server vulnerable to DNS spoofing attacks.

Example 10–3 Controlling Access by IP Address

```bash
<Directory /secure_only/>
    order deny,allow
    deny from all
    allow from 207.175.42.*
</Directory>
```

In Example 10–3, requests originating from all IP addresses except 207.175.42.* range are denied access to the /secure_only/ directory.
Controlling Access by Domain Name  Domain name-based access control can be used with IP address-based access control to solve the problem of IP addresses changing without warning. When you combine these methods, if an IP address changes, then the secure areas of your site are still protected because the domain names you want to keep out will still be denied access.

To combine domain name-based with IP address-based access control, use the syntax shown in Example 10–4:

Example 10–4 controlling Access by Domain Name

```html
<Directory /co_backgr/>
order allow,deny
allow from all
# 141.217.24.* is the IP for malicious.cracker.com
deny from malicious.cracker.com 141.217.24.*
</Directory>
```

In Example 10–4, all requests for directory `/co_backgr/` are accepted except those that originate from the domain name malicious.cracker.com or the IP address 141.217.24.* range. Although this is not a fool proof precaution against domain name or IP address spoofing, it protects your site from malicious.cracker.com even if they change their IP address.

Controlling Access by Network or Netmask  You can control access based on subsets of networks, specified by IP address. The syntax is shown in Example 10–5:

Example 10–5 Controlling Access by Network or Netmask

```html
<Directory /payroll/>
order deny,allow
deny from all
allow from 10.1.0.0/255.255.0.0
</Directory>
```

In Example 10–5, access is allowed from a network/netmask pair. A netmask shows how an IP address is to be divided into network, subnet, and host identifiers. Netmasks enable you to refer to only the host ID portion of an IP address.

The netmask in Example 10–5, 255.255.0.0, is the default netmask setting for a Class B address. The binary ones (decimal 255) mask the network ID and the binary zeroes (decimal 0) retain the host ID of a given IP address.

Controlling Access with Environment Variables  You can use arbitrary environment variables for access control, instead of using IP addresses or domain names. Use `BrowserMatch` and `SetEnvIf` directives for this type of access control.

Use `BrowserMatch` when you want to base access on the type of browser used to send a request. For instance, if you want to allow access only to requests that come from a Netscape browser, then use the syntax shown in Example 10–6:

```
Note: Typically, BrowserMatch and SetEnvIf are not used to implement security policies. Instead they are used to provide different handling of requests based on browser types and versions.
```
Authentication and Authorization Enforcement

**Example 10–6  Controlling Access with Environment Variables**

```
BrowserMatch ^Mozilla netscape_browser
<Directory /mozilla-area/>
  order deny,allow
deny from all
  allow from env=netscape_browser
</Directory>
```

Use `SetEnvIf` when you want to base access on header information contained in the HTTP request. For instance, if you want to deny access from any browsers using HTTP version 1.0 or earlier, then use the syntax shown in Example 10–7:

**Example 10–7  Controlling Access with `SetEnvIf`**

```
SetEnvIf Request_Protocol ^HTTP/1.1 http_11_ok
<Directory /http1.1only/>
  order deny,allow
deny from all
  allow from env=http_11_ok
</Directory>
```

See Also:  “Scope of Directives” on page 2-4

**User Authentication and Authorization**

Basic authentication prompts for a user name and password before serving an HTTP request. When a browser requests a page from a protected area, Oracle HTTP Server responds with an unauthorized message (status code 401) containing a `WWW-Authenticate` header and the name of the realm configured by the `AuthName` directive. When the browser receives this response, it prompts for a user name and password. After the user enters a user name and password combination, the browser sends this information back to the server in an Authorization header. In the authorization header message, the user name and password are encoded as a base 64 encoded string.

User authorization involves checking the authenticated user against an access control list that is associated with a specific server resource such as a file or directory. To configure user authorization, place the `require` directive in the `httpd.conf` file, usually within a virtual host container. User authorization is commonly used in combination with user authentication. After the server has authenticated a user’s user name and password, then the server compares the user to an access control list associated with the requested server resource. If Oracle HTTP Server finds the user or the user’s group on the list, then the resource is made available to that user.

**Using `mod_auth` to Authenticate Users**

User authentication is based on user names and passwords that are checked against a list of known users and passwords. These user name and password pairs may be stored in a variety of forms, such as a text file, database, or directory service. Then configuration directives are used in `httpd.conf` to configure this type of user authentication on the server. `mod_auth` uses the `AuthUserFile` directive to set up basic authentication. It supports only files.

Any authentication scheme that you devise requires that you use a combination of the configuration directives listed in Table 10-1.
Using mod_osso to Authenticate Users

`mod_osso` enables single-sign on for Oracle HTTP Server. `mod_osso` examines incoming requests and determines whether the resource requested is protected, and if so, retrieves the Oracle HTTP Server cookie for the user.

Through `mod_osso`, Oracle HTTP Server becomes a single sign-on (SSO) partner application enabled to use SSO to authenticate users and obtain their identity using Oracle Application Server Single Sign-On, and to make user identities available to Web applications as an Apache header variable.

Using `mod_osso`, Web applications can register URLs that require SSO authentication. When Oracle HTTP Server receives URL requests, `mod_osso` detects which requests require SSO authentication and redirects them to the SSO server. Once SSO server authenticates the users, it passes the user’s authenticated identity back to `mod_osso` in a secure token, or cookie. `mod_osso` retrieves the user’s identity from the cookie and propagates the user’s identity information to applications running in Oracle HTTP Server instance. `mod_osso` can propagate the user’s identity information to applications running in CGI, and those running in OC4J, and it can also authenticate users for access to static files.

See Also:
- Oracle Application Server Single Sign-On Administrator’s Guide
- “Leveraging Oracle Identity Management Infrastructure” on page 10-15

Using mod_ossl to Authenticate Users

`mod_ossl` is a plug-in to Oracle HTTP Server that enables the server to use SSL. `mod_ossl` replaces `mod_ssl` in the Oracle HTTP Server distribution. Oracle no longer supports `mod_ssl`.

See Also: “Enabling SSL for Oracle HTTP Server” on page 11-1

Understanding Port Tunneling

Port tunneling allows all communication between Oracle HTTP Server and OC4J to happen on a single, or a small number of ports. Previously, the firewall configuration had to include port information for many ports to handle communication between Oracle HTTP Server and multiple OC4J instances. Using port tunneling, a daemon called `iaspt` routes requests to the appropriate OC4J instances. Only one, or a small number of ports have to be opened through the firewall regardless of the number of OC4J instances involved, thereby offering a higher degree of security for the communication between Oracle HTTP Server and OC4J.
To enable this, a de-militarized zone environment is provided where a firewall exists typically between the client and the Oracle HTTP Server, and another that exists between Oracle HTTP Server and OC4J. In this configuration, Oracle HTTP Server exists in the DMZ bracketed by the two firewalls. OC4J, and other business logic components, exist behind both firewalls in the intranet. To ensure the highest degree of security, all communication transmitted between machines is encrypted using SSL. Port tunneling provides the framework to support this level of security in a flexible, manageable manner, which enhances performance.

The suggested port range is 7501-7599, the default being 7501, but you can select a port of your choice.

Figure 10–2 Port Tunneling

Figure 10–2 shows an Oracle Application Server configuration using port tunneling. The iaspt daemon, a standalone component, acts as a communication concentrator for connections between Oracle HTTP Server and the Java Virtual Machine (JVM), which contains OC4J. Oracle HTTP Server does not connect directly to OC4J. Instead, it connects to the iaspt daemon which then dispatches communication on to OC4J. By doing this concentration of connections, only one port is opened per port tunneling on the internal firewall, instead of one port per OC4J instance.

The communication between Oracle HTTP Server and the iaspt daemon is encrypted using SSL. Authentication is enabled when these connections are established using SSL Client Certificates. These connections are persistent, and are maintained for a reasonable time depending on connection resources. The AJP 1.3 protocol, modified to include routing information that indicates which servlet engine a request is to be routed to, is used.

Port tunneling supports connections between Oracle HTTP Server and OC4J. To support OC4J, Oracle HTTP Server module mod_oc4j is modified to use SSL.
encrypted communication and to route requests through the port tunneling processes. Port tunneling supports static configurations.

There must be at least one iaspt daemon per machine. More than one iaspt daemon can be run for higher availability. Oracle HTTP Server supports round robin partitioning of requests across iaspt daemons, and supports application partitioning. Oracle HTTP Server also supports automatic failover of requests which cannot be sent to a given iaspt daemon.

Configuring Port Tunneling

Perform the following three tasks to configure port tunneling:

- Task 1: Configure opmn.xml
- Task 2: Configure iaspt.conf
- Task 3: Configure mod_oc4j.conf

Task 1: Configure opmn.xml

Perform the following steps to start one or more iaspt daemons:

1. By default, there is an opmn.xml entry for iaspt that is disabled. Enable iaspt by editing opmn.xml and changing status="disable" to status="enable".
2. Optionally, you may also change the TCP/IP ports used by the iaspt daemon by changing the port 'range' and the number of the iaspt daemon processes by changing 'numprocs'.

The following is a complete example configuration for the iaspt daemon. It contains all possible configuration elements/attributes that can be used with this component.

```xml
<module path="/ORACLE_HOME/opmn/lib/libopmniaspt">
  <module-id id="IASPT" />
</module>

<ias-component id="IASPT" status="enabled" id-matching="false">
  <process-type id="IASPT" module-id="IASPT">
    <port id="ajp" range="6701-6703"/>
    <process-set id="IASPT" restart-on-death="true" numprocs="3"/>
  </process-type>
</ias-component>
```

3. Run the following command to direct the opmn daemon to reload its configuration file:

   `opmnctl reload`

Task 2: Configure iaspt.conf

Perform the following steps to configure iaspt.conf to specify an SSL wallet for the iaspt daemon(s) to use:

1. Communication between mod_oc4j and iaspt is always encrypted, therefore an SSL wallet file must be configured for the iaspt daemon(s). By default, this wallet is the same as the Oracle HTTP Server wallet. You may change the default by editing the following values in iaspt.conf:

   ```ini
   wallet-file=path to wallet file
   wallet-password=password
   ```
Understanding Port Tunneling

See Also:
- "wallet-file" on page 10-13
- "wallet-password" on page 10-14

2. Start the iaspt daemon(s) using the following command:
   opmnctl startall

Task 3: Configure mod_oc4j.conf
Perform the following steps to configure mod_oc4j.conf to route requests using iaspt:
1. Enable port tunneling by adding the following line in mod_oc4j.conf:
   Oc4jIASPTActive on

   See Also: "Oc4jIASPTActive" on page 10-12

2. Specify an SSL wallet and wallet password for mod_oc4j.conf by adding the following two lines in mod_oc4j.conf:
   Oc4jIASPTWalletFile <path to wallet file>
   Oc4jIASPTWalletPassword <password of wallet>

   This wallet may be the same as used by Oracle HTTP Server and/or iaspt.

   See Also:
   - "Oc4jIASPTWalletFile" on page 10-12
   - "Oc4jIASPTWalletPassword" on page 10-13
   - Oracle Application Server Administrator's Guide for information on Oracle Wallet Manager.

3. Specify the host and port addresses of the iaspt daemons. For example, add the following line to mod_oc4j.conf:
   Oc4jIASPTProcess myhost.us.oracle.com:6701

   You may add as many Oc4jIASPTProcess lines as you have iaspt daemons. The host and port addresses must match those of your configured iaspt daemons. For example, to route requests to the three iaspt daemons configured in the example in step 2 of "Task 1: Configure opmn.xml" on page 10-9, add the following three lines:
   Oc4jIASPTProcess myhost.us.oracle.com:6701
   Oc4jIASPTProcess myhost.us.oracle.com:6702
   Oc4jIASPTProcess myhost.us.oracle.com:6703

   See Also: "Oc4jIASPTProcess" on page 10-12

4. Restart Oracle HTTP Server for the changes to take effect, using the following command:
   UNIX: ORACLE_HOME/opmn/bin> opmnctl [verbose] restartproc
   ias-component=HTTP_Server
Windows: \ORACLE_HOME\opmn\bin> opmnctl [verbose] restartproc
ias-component=HTTP_Server

Configuring SSL for Port Tunneling

This section contains information about configuring SSL between iaspt and OC4J.

By default, the iaspt daemons and the OC4J processes communicate with unencrypted data. Perform the following steps to configure SSL communication between these processes:

1. In iaspt.conf, change the value "destination-ssl" from "false" to "true".
2. To configure the OC4J process to use SSL, refer to the Oracle Application Server Containers for J2EE Security Guide.

Port Tunneling Configuration Reference

This section contains information about the following configuration files and their parameters:

- opmn.xml
- mod_oc4j.conf
- iaspt.conf

opmn.xml

Describes the process that OPMN manages within an Oracle Application Server installation.

See Also: "opmn.xml" on page E-3

As part of port tunneling, an entry that describes the iaspt daemon process to be started should exist in OPMN. This entry describes the following:

- number of iaspt daemon processes to start.
- ports that these processes can use.

See Also: iaspt.conf on page 10-13

An out of the box Oracle Application Server installation contains an iaspt component in opmn.xml, but it is disabled by default.

mod_oc4j.conf

Configures mod_oc4j with Oracle HTTP Server.

See Also: mod_oc4j.conf on page E-3

For port tunneling, you need to add directives that specify the following:

- whether port tunneling should be used
- static location for an iaspt daemon process
- location of SSL certificates to be used in establishing connections with the iaspt daemon processes.
By default, mod_oc4j communicates directly to OC4J. For port tunneling process, mod_oc4j should communicate to OC4J through the iaspt daemon.

The following directives used to connect mod_oc4j to the iaspt daemon:

- \texttt{Oc4j\_ASPTActive}
- \texttt{Oc4j\_ASPTProcess}

\textbf{Oc4j\_ASPTActive} Indicates whether mod_oc4j needs to consider port tunneling when routing requests. This should not be configured to "On" if \texttt{Oc4j\_EnableSSL} is configured to "On". To enable port tunneling process, set this directive to "On".

\textbf{Oc4j\_ASPTProcess} Describes the listening host and port of a port tunneling process. There can be multiple instances of this directive within a mod_oc4j.conf file for multiple port tunneling processes.

The syntax for this directive is host:port. The host value should be the hostname of a machine where an iaspt daemon is running. The port value should match the port configured in opmn.xml for that iaspt. Both regular hostname and IP address are allowed for host.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Category} & \textbf{Value} \\
\hline
Parameter Name & \texttt{Oc4j\_ASPTActive} \\
Parameter Type & string \\
Valid Values & On/Off \\
Default Value & Off \\
\hline
\end{tabular}
\end{table}

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Category} & \textbf{Value} \\
\hline
Parameter Name & \texttt{Oc4j\_ASPTProcess} \\
Parameter Type & string \\
Valid Values & host:port values of the available iaspt daemons. \\
Default Value & N/A \\
Syntax & host:port \\
\text{For example: myhost.us.oracle.com:6667} \\
\hline
\end{tabular}
\end{table}

mod_oc4j should use SSL when communicating with the iaspt daemon. The following are the directives used to enable SSL:

- \texttt{Oc4j\_ASPTWalletFile}
- \texttt{Oc4j\_ASPTWalletPassword}

\textbf{Oc4j\_ASPTWalletFile} Specifies the location of an Oracle Wallet file that contains SSL certificates that are used for SSL communication with the iaspt daemon.

\begin{table}[h]
\centering
\begin{tabular}{|c|c|}
\hline
\textbf{Category} & \textbf{Value} \\
\hline
Parameter Name & \texttt{Oc4j\_ASPTWalletFile} \\
Parameter Type & string \\
\hline
\end{tabular}
\end{table}
Understanding Port Tunneling

Managing Security

Oc4jiASPTWalletPassword  Specifies the value of the obfuscated password used for authentication when opening the wallet file. This value is obtained using the utility provided with Oracle Wallet Manager.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>Path to a wallet file that contains the SSL certificate to be used when establishing SSL connections to the iaspt daemon.</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
<tr>
<td>Syntax</td>
<td>Oc4jiASPTWalletPassword</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Password used for authentication when opening the wallet file specified by Oc4jiASPTWalletFile.</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
</tbody>
</table>

See Also: Oracle Application Server Administrator's Guide for information on Oracle Wallet Manager.

iaspt.conf

Configures port tunneling.

See Also: "iaspt.conf" on page E-2

It specifies the following information:

- Wallet file and password that should be used
- Log file location and log level
- Port that iaspt daemon should listen on (optionally). This port can either be specified in iaspt.conf, or can be passed in from opmn.xml by specifying a range of ports. By doing so, more than one port tunneling process can use the same iaspt.conf file.

The iaspt.conf file is a set of name value pairs. The following are the names of the parameters accepted:

- wallet-file
- wallet-password
- log-file
- log-level
- iaspt-port

wallet-file  Specifies the location of an Oracle Wallet file that contains SSL certificates that are used for SSL communication with peers.
wallet-password  Specifies the value of the password used for authentication when opening the wallet file. This value is obtained using the utility provided with Oracle Wallet Manager.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>wallet-password</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Password used for authentication when opening the wallet file specified by wallet-file</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
<tr>
<td>Syntax</td>
<td>Valid filename</td>
</tr>
</tbody>
</table>

For example: `/foo/bar/myfilename`

log-file  Specifies the path to a log file where iaspt daemon logging messages are written to.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>log-file</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Path to a log file where iaspt daemon logging messages are written to.</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
<tr>
<td>Syntax</td>
<td>Valid filename</td>
</tr>
</tbody>
</table>

For example: `/foo/bar/myfilename`

log-level  Specifies the logging level where 9 is the highest and 0 implies no logging.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>log-level</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>integer</td>
</tr>
<tr>
<td>Valid Values</td>
<td>Integer from 0 to 9</td>
</tr>
<tr>
<td>Default Value</td>
<td>5</td>
</tr>
</tbody>
</table>
Leveraging Oracle Identity Management Infrastructure

This section discusses how Oracle HTTP Server uses the Oracle Identity Management Infrastructure.

Overview

Oracle Identity Management is an integrated infrastructure that the Oracle Application Server relies on for distributed security. It consists of Oracle Internet Directory, Oracle Directory Integration and Provisioning, Delegated Administrative Service, Oracle Application Server Single Sign-On, and Oracle Certificate Authority.

See Also: Oracle Identity Management Concepts and Deployment Planning Guide

Using Oracle Application Server Single Sign-On and mod_osso

Oracle Application Server supports single sign-on (SSO) to Web-based applications through Oracle Application Server Single Sign-On. Oracle Application Server Single Sign-On enables you to log in to Oracle Application Server and gain access to those applications for which you have authorization, without requiring to re-enter a user name and password for each application. It is fully integrated with Oracle Internet Directory, which stores user information. It supports LDAP-based user and password management through Oracle Internet Directory.

mod_osso, an Oracle HTTP Server module, enables the transparent use of Oracle Application Server Single Sign-On across all of Oracle Application Server. Through mod_osso, Oracle HTTP Server becomes a SSO partner application enabled to use SSO to authenticate users and obtain their identity, and to make user identities available to Web applications as an Apache header variable.

See Also: "Using mod_osso to Authenticate Users" on page 10-7

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Name</td>
<td>iaspt-port</td>
</tr>
<tr>
<td>Parameter Type</td>
<td>integer</td>

<td>Valid TCP/IP port value</td>
</tr>
<tr>
<td>Syntax</td>
<td>Integer For example: 9898</td>
</tr>
<tr>
<td>Default Value</td>
<td>N/A</td>
</tr>
</tbody>
</table>

iaspt-port Specifies the port value that the iaspt daemon should accept connections on. This is optional.
This chapter contains information about enabling and configuring SSL for Oracle HTTP Server.

Topics discussed are:
- Overview
- Configuring SSL
- Additional SSL Features
- Using SSL Configuration Directives

Overview

Secure Sockets Layer (SSL) is an encrypted communication protocol that is designed to securely send messages across the Internet. It resides between Oracle HTTP Server on the application layer and the TCP/IP layer, transparently handling encryption and decryption when a secure connection is made by a client.

One common use of SSL is to secure Web HTTP communication between a browser and a Web server. This case does not preclude the use of non-secured HTTP. The secure version is simply HTTP over SSL (named HTTPS). The differences are that HTTPS uses the URL scheme `https://` rather than `http://`, and its default communication port is 4443 on UNIX or 443 on Windows.

`mod_ossl` is a plug-in to Oracle HTTP Server that enables the server to use SSL.

See Also: Oracle Application Server Administrator’s Guide

Configuring SSL

By default, SSL is disabled when you install Oracle Application Server. Perform the following tasks to enable and configure SSL:
- Task 1: Creating a Real Wallet
- Task 2: Enabling SSL
- Task 3: (Optional) Customizing Your Configuration

Task 1: Creating a Real Wallet

To configure Oracle HTTP Server for SSL, you need a `wallet` that contains the certificate for the server. Wallets store your credentials, such as certificate requests, certificates, and private keys.
The default wallet that is automatically installed with Oracle HTTP Server is for testing purposes only. A real wallet has to be created for your production server. The default wallet is located in ORACLE_HOME/Apache/Apache/conf/ssl.wlt/default. You can either place the new wallet in that location, or change the SSLWallet directive in ORACLE_HOME/Apache/Apache/conf/ssl.conf to point to the location of your real wallet.

See Also: Oracle Application Server Administrator’s Guide for instructions on creating a wallet. It is important that you do the following:

1. Generate a certificate request. For the Common Name, specify the name or alias of the site you are configuring.
2. Set the auto-login feature for your wallet. Make sure that you enable this auto-login feature. The default wallet has this feature disabled.

Task 2: Enabling SSL

Perform the following steps to enable SSL:

1. Open opmn.xml in a text editor.
2. In the <ias-component id="HTTP_Server"> entry, change the start mode from "ssl-disabled" to "ssl-enabled". After modification is made, the entry should look like the following:
   <data id="start-mode" value="ssl-enabled"/>
3. Save and close opmn.xml.
4. Update the distributed cluster management database with the change:
   ORACLE_HOME/dcm/bin/dcmctl updateconfig -ct opmn
5. Reload OPMN using the following command:
   opmnctl reload
6. Stop Oracle HTTP Server using Application Server Control Console, or with the following command:
   ■ UNIX: ORACLE_HOME/opmn/bin> opmnctl [verbose] stopproc ias-component=HTTP_Server
   ■ Windows: ORACLE_HOME\opmn\bin> opmnctl [verbose] stopproc ias-component=HTTP_Server
   See Also: “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3
7. Start Oracle HTTP Server using Application Server Control Console, or with the following command:
   ■ UNIX: ORACLE_HOME/opmn/bin> opmnctl [verbose] startproc ias-component=HTTP_Server
   ■ Windows: ORACLE_HOME\opmn\bin> opmnctl [verbose] startproc ias-component=HTTP_Server
   See Also: “Starting, Restarting, and Stopping Oracle HTTP Server” on page 7-3
You can verify if SSL was enabled successfully by navigating to the SSL port, for example:

HTTPS://hostname:4443

Task 3: (Optional) Customizing Your Configuration

Optionally, you can further customize your configuration using mod_ossl directives.

To enable client authentication, do the following:

1. Specify SSLVerifyClient on the server side.
2. Use proper client certificate on your client side for the HTTPS connection. Refer to your client documentation for information on getting and using a client certificate. Be sure that your client certificate is trusted by the server wallet.

Additional SSL Features

This section contains SSL features that are supported for this release.

- Global Server ID Support
- PKCS #11 Support

Global Server ID Support

This feature adds support SSL protocol features called variously "step-up", "server gated crypto" or "global server ID". "Step-up" is a feature that allows old, weak encryption browsers, to "step-up" so that public keys greater than 512 bits and bulk encryption keys greater than 64 bits can be used in the SSL protocol. This means that server X.509 certificates that contain public keys in excess of 512 bits and which contain "step-up" digital rights can now be used by Oracle Application Server. Such certificates are often called "128 bit" certificates, even though the certificate itself typically contains a 1024 bit certificate. The Verisign Secure Site Pro is an example of such a certificate which can now be used by Oracle Application Server.

Global Server ID functionality is provided by default, there is no configuration necessary.
PKCS #11 Support

Public-Key Cryptography Standards #11, or PKCS #11 for short, is a public key cryptography specification that outlines how systems use hardware security modules, which are basically "boxes" where cryptographic functions (encryption/decryption) are performed and where encryption keys are stored.

Oracle HTTP Server supports the option of having dedicated SSL hardware through nCipher. nCipher is a certified third party accelerator that improves the performance of the PKI cryptography that SSL uses.

See Also:
- Oracle Application Server Administrator’s Guide
- http://www.ncipher.com

Using SSL Configuration Directives

`mod_ossl` provides standard support for HTTPS protocol connections to Oracle Application Server. It enables secure connections between Oracle HTTP Server and a browser client by using an Oracle-provided encryption mechanism over SSL. It may also be used for authentication over the Internet through the use of digital certificate technology. It supports SSL v. 3.0, and provides:

- Encrypted communication between client and server, using RSA or DES encryption standards.
- Integrity checking of client-server communication using MD5 or SHA checksum algorithms.
- Certificate management with Oracle wallets.

The following `mod_ssl` directives are not supported by `mod_ossl`.

- SSLRandomSeed
- SSLCertificateFile
- SSLCertificateKeyFile
- SSLCertificateChainFile
- SSLCACertificateFile
- SSLCACertificatePath
- SSLVerifyDepth

**Note:** The server will not start if these directives are used.

Using `mod_ossl` Directives

To configure SSL for your Oracle HTTP Server, enter the `mod_ossl` directives you want to use in the `httpd.conf` file.

The following directives are described in subsequent sections:

- SSLAccelerator
- SSLCACertocationFile
- SSLCARevocationPath
Using SSL Configuration Directives

- SSLCipherSuite
- SSLEngine
- SSLLog
- SSLLogLevel
- SSLMutex
- SSLOptions
- SSLPassPhraseDialog
- SSLProtocol
- SSLRequire
- SSLRequireSSL
- SSLSessionCache
- SSLSessionCacheTimeout
- SSLVerifyClient
- SSLWallet
- SSLWalletPassword

**SSLAccelerator**

Specifies if SSL accelerator is used. Currently only nFast card is supported.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>yes/no</td>
</tr>
<tr>
<td>Syntax</td>
<td>SSLAccelerator yes</td>
</tr>
<tr>
<td>Default</td>
<td>SSLAccelerator no</td>
</tr>
<tr>
<td>Context</td>
<td>server configuration</td>
</tr>
</tbody>
</table>

**Note:** The SSLAccelerator directive has been deprecated. For information on enabling SSL acceleration support using a wallet, refer to the Oracle Advanced Security Administrator's Guide on [http://www.oracle.com/technology/documentation](http://www.oracle.com/technology/documentation).

**SSLCARevocationFile**

Specifies the file where you can assemble the Certificate Revocation Lists (CRLs) from CAs (Certificate Authorities) that you accept certificates from. These are used for client authentication. Such a file is the concatenation of various PEM-encoded CRL files in order of preference. This directive can be used alternatively or additionally to SSLCARevocationPath.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLCARevocationFile file_name</td>
</tr>
<tr>
<td>Example</td>
<td>SSLCARevocationFile /ORACLE_HOME/Apache/Apache/conf/ssl.crl/ca_bundle.crl</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
</tbody>
</table>

Enabling SSL for Oracle HTTP Server 11-6
Using SSL Configuration Directives

### SSLCARevocationPath

Specifies the directory where PEM-encoded Certificate Revocation Lists (CRLs) are stored. These CRLs come from the CAs (Certificate Authorities) that you accept certificates from. If a client attempts to authenticate itself with a certificate that is on one of these CRLs, then the certificate is revoked and the client cannot authenticate itself with your server.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLCARevocationPath path/to/CRL_directory/</td>
</tr>
<tr>
<td>Example</td>
<td>SSLCARevocationPath /ORACLE_HOME/Apache/Apache/conf/ssl.crl/</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
</tbody>
</table>

### SSLCipherSuite

Specifies the SSL cipher suite that the client can use during the SSL handshake. This directive uses a colon-separated cipher specification string to identify the cipher suite. Table 11-2 shows the tags you can use in the string to describe the cipher suite you want.

Tags are joined together with prefixes to form a cipher specification string.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values | none: Adds the cipher to the list  
+ : Adds the cipher to the list and place them in the correct location in the list  
- : Remove the cipher from the list (can be added later)  
!: Remove the cipher from the list permanently |
| Example | SSLCipherSuite ALL:!LOW:!DH |

In this example, all ciphers are specified except low strength ciphers and those using the Diffie-Hellman key negotiation algorithm.

| Syntax | SSLCipherSuite cipher-spec |
| Default | ALL:!ADH:!EXPORT56:+HIGH:+MEDIUM:+LOW:+SSLv2:+EXP |
| Context | server configuration, virtual host, directory |

</tbody>
</table>

Note: There are restrictions if export versions of browsers are used. Oracle module, mod_ossl, supports RC4-40 encryption only when the server uses 512 bit key size wallets.
Using SSL Configuration Directives

SSLEngine
Toggles the usage of the SSL Protocol Engine. This is usually used inside a `<VirtualHost>` section to enable SSL for a particular virtual host. By default, the SSL Protocol Engine is disabled for both the main server and all configured virtual hosts.

Example 11–1 is an example for using SSLEngine directive. The default SSL is 4443 on UNIX and 443 on Windows.

Example 11–1 Using SSLEngine Directive

```
<VirtualHost default_:4443>
  SSLEngine on
  ...
</VirtualHost>
```

SSLLog
Specifies where the SSL engine log file will be written. (Error messages will also be duplicated to the standard Oracle HTTP Server log file specified by the ErrorLog directive.)

Place this file at a location where only root can write, so that it cannot be used for symlink attacks. If the filename does not begin with a slash (/), it is assumed to be relative to the ServerRoot. If the filename begins with a bar (|), then the string following the bar is expected to be a path to an executable program to which a reliable pipe can be established.

This directive should occur only once per virtual server configuration.

11-8 Oracle HTTP Server Administrator's Guide
Using SSL Configuration Directives

SSLLogLevel
Specifies the verbosity degree of the SSL engine log file.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values | The levels are (in ascending order, where each level is included in the levels preceding it):
- none: No dedicated SSL logging is done. Messages of type 'error' are duplicated to the standard HTTP server log file specified by the ErrorLog directive.
- error: Only messages of the type 'error' (conditions that stop processing) are logged.
- warn: Messages that notify of non-fatal problems (conditions that do not stop processing) are logged.
- info: Messages that summarize major processing actions are logged.
- trace: Messages that summarize minor processing actions are logged.
- debug: Messages that summarize development and low-level I/O operations are logged. |

Syntax
SSLLogLevel level
Default None
Context server configuration, virtual host

SSLMutex
Type of semaphore (lock) for SSL engine’s mutual exclusion of operations that have to be synchronized between Oracle HTTP Server processes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values | Uses no mutex at all. Not recommended, because the mutex synchronizes the write access to the SSL session cache. If you do not configure a mutex, the session cache can become garbled.
- file:path/to/mutex: Uses a file for locking. The process ID (PID) of the Oracle HTTP Server parent process is appended to the filename to ensure uniqueness. If the filename does not begin with a slash (/), it is assumed to be relative to ServerRoot. This setting is not available on Windows.
- sem: Uses an operating system semaphore to synchronize writes. On UNIX, it would be a Sys V IPC semaphore; on Windows, it is a Windows Mutex. This is the best choice, if the operating system supports it. |

Example
SSLMutex file:/usr/local/apache/logs/ssl_mutex
Syntax
SSLMutex type
Default
SSLMutex none
Context server configuration

SSLOptions
Controls various runtime options on a per-directory basis. In general, if multiple options apply to a directory, the most comprehensive option is applied (options are not merged). However, if all of the options in an SSLOptions directive are preceded by a plus (+) or minus (-) symbol, then the options are merged. Options preceded by a plus are added to the options currently in force, and options preceded by a minus are removed from the options currently in force.

Enabling SSL for Oracle HTTP Server 11-9
### Using SSL Configuration Directives

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values           | • StdEnvVars: Creates the standard set of CGI/SSI environment variables that are related to SSL. This is disabled by default because the extraction operation uses a lot of CPU time and usually has no application when serving static content. Typically, you only enable this for CGI/SSI requests.  
  • ExportCertData: Enables the following additional CGI/SSI variables:
    - SSL_SERVER_CERT
    - SSL_CLIENT_CERT
    - SSL_CLIENT_CERT_CHAIN_n (where n = 0, 1, 2, ...)
    These variables contain the Privacy Enhanced Mail (PEM)-encoded X.509 certificates for the server and the client for the current HTTPS connection, and can be used by CGI scripts for deeper certificate checking. All other certificates of the client certificate chain are provided. This option is 'Off' by default because there is a performance cost associated with using it.  
    - SSL_CLIENT_CERT_CHAIN_n variables are in the following order:
      - SSL_CLIENT_CERT_CHAIN_0 is the intermediate CA who signs SSL_CLIENT_CERT.
      - SSL_CLIENT_CERT_CHAIN_1 is the intermediate CA who signs SSL_CLIENT_CERT_CHAIN_0, and so forth, with SSL_CLIENT_ROOT_CERT as the root CA.  
  • FakeBasicAuth: Translates the subject distinguished name of the client X.509 certificate into an HTTP basic authorization user name. This means that the standard HTTP server authentication methods can be used for access control. Note that no password is obtained from the user; the string 'password' is substituted.  |
| Valid Values (for SSLOptions continued) | • StrictRequire: Denies access when, according to SSLRequireSSL or directives, access should be forbidden. Without StrictRequire, it is possible for a 'Satisfy any' directive setting to override the SSLRequireSSL directive, allowing access if the client passes the host restriction or supplies a valid user name and password. Thus, the combination of SSLRequireSSL or SSLRequire with SSLOptions +StrictRequire gives mod_ossl the ability to override a 'Satisfy any' directive in all cases.  
  • CompatEnvVars: Exports obsolete environment variables for backward compatibility to Apache SSL 1.x, mod_ssl 2.0.x, Sioux 1.0, and Stronghold 2.x. Use this to provide compatibility to existing CGI scripts.  
  • OptRenegotiate: This enables optimized SSL connection renegotiation handling when SSL directives are used in a per-directory context.  |

### Syntax

```
SSLOptions [+-]option
```

### Default

None

### Context

server configuration, virtual host, directory

---

**SSLPassPhraseDialog**

Type of pass phrase dialog for wallet access. *mod_ossl* asks the administrator for a pass phrase in order to access the wallet.
### Using SSL Configuration Directives

#### Enabling SSL for Oracle HTTP Server

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SSLProtocol</strong></td>
<td>Specifies SSL protocol(s) for mod_ossl to use when establishing the server environment. Clients can only connect with one of the specified protocols.</td>
</tr>
<tr>
<td><strong>SSLRequire</strong></td>
<td>Denies access unless an arbitrarily complex boolean expression is true.</td>
</tr>
</tbody>
</table>

#### SSLProtocol

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
<th>Valid Values</th>
<th>Syntax</th>
<th>Default</th>
<th>Context</th>
</tr>
</thead>
<tbody>
<tr>
<td>Valid Values</td>
<td>SSLv2, SSLv3, TLSv1, ALL</td>
<td>To specify only SSL version 3.0, set this directive to the following: SSLProtocol +SSLv3</td>
<td>SSLProtocol [+-] protocol</td>
<td>SSLProtocol ALL</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

#### SSLRequire

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLRequire expression</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Context</td>
<td>directory</td>
</tr>
</tbody>
</table>

The expression must match the following syntax (given as a BNF grammar notation):

- `expr ::= "true" | "false" | "!" expr |
- `expr "&&" expr |
- `expr "||" expr |
- `(" expr ")` |
- ` comp ::= word "=" word | word "eq" word |
- `word ">" word | word ">=" word |
- `word ">=" word | word ">" word |
- `word ">=" word | word ">=" word |
- `word "=~" regex`
Using SSL Configuration Directives

word "!~" regex
wordlist ::= word
wordlist ', word
word ::= digit
cstring
variable
function
digit ::= [0-9]+
cstring ::= "...
variable ::= %{varname}

Table 11–3 and Table 11–4 list standard and SSL variables. These are valid values for varname.

function ::= funcname '(' funcargs ')' 

For funcname, the following function is available:

file(filename)

The file function takes one string argument, the filename, and expands to the contents of the file. This is useful for evaluating the file's contents against a regular expression.

Table 11–3 lists the standard variables for SSLRequire varname.

</tr>
</tbody>
</table>

SSLRequireSSL

Denies access to clients not using SSL. This is a useful directive for absolute protection of a SSL-enabled virtual host or directories in which configuration errors could create security vulnerabilities.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLRequireSSL</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Context</td>
<td>directory</td>
</tr>
</tbody>
</table>

SSLSessionCache

 Specifies the global/interprocess session cache storage type. The cache provides an optional way to speed up parallel request processing.
Using SSL Configuration Directives

### SSLSessionCacheTimeout
Specifies the number of seconds before a SSL session in the session cache expires.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values | ● none: disables the global/interprocess session cache. Produces no impact on functionality, but makes a major difference in performance.  
● shmht: /path/to/datafile[bytes]: Uses a high-performance hash table (bytes specifies approximate size) inside a shared memory segment in RAM, which is established by the /path/to/datafile. This hash table synchronizes the local SSL memory caches of the server processes.  
● shmcb: /path/to/datafile[bytes]: Uses a high-performance Shared Memory Cyclic Buffer (SHMCB) session cache to synchronize the local SSL memory caches of the server processes. The performance of shmcb is more uniform in all environments when compared to shmht. |

<table>
<thead>
<tr>
<th>Syntax</th>
<th>SSLSessionCache type</th>
</tr>
</thead>
</table>

| Examples | SSLSessionCache shmht: /ORACLE_HOME/Apache/Apache/logs/ssl_scache(512000)  
SSLSessionCache shmcb: /ORACLE_HOME/Apache/Apache/logs/ssl_scache(512000) |

| Default | SSLSessionCache none |

### SSLVerifyClient
Specifies whether or not a client must present a certificate when connecting.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
</table>
| Valid Values | ● none: No client certificate is required  
● optional: Client may present a valid certificate  
● require: Client must present a valid certificate |

<table>
<thead>
<tr>
<th>Syntax</th>
<th>SSLVerifyClient level</th>
</tr>
</thead>
</table>

| Default | SSLVerifyClient level None |

| Context    | server configuration, virtual host |

**Note:** The level optional_no_ca included with mod_ssl (in which the client can present a valid certificate, but it need not be verifiable) is not supported in mod_ossl.

### SSLWallet
Specifies the location of the wallet with its WRL.
Using SSL Configuration Directives

Enabling SSL for Oracle HTTP Server

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLWallet wrl&lt;br&gt;The format of wrl is file:path to wallet</td>
</tr>
<tr>
<td>Example</td>
<td>SSLWallet files:/etc/ORACLE/WALLETS/server&lt;br&gt;Other values of wrl may be used as permitted by the Oracle SSL product.</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

SSLWalletPassword

Specifies the Wallet password needed to access the wallet specified within the same context. You can choose either a cleartext wallet password or an obfuscated password. The obfuscated password is created with the command line tool iasobf. If you must use a regular wallet, Oracle recommends that you use the obfuscated password instead of a cleartext password.

See Also: “Using the iasobf Utility” on page 11-15

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLWalletPassword password&lt;br&gt;If no password is required do not set this directive. Note: If a wallet created with the Auto Login feature of Oracle Wallet Manager is used, then do not set this directive because these wallets do not require passwords.</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

Note: SSLWalletPassword has been deprecated. A warning message is generated in the Oracle HTTP Server log if this directive is used. For secure wallets, Oracle recommends that you get a SSO wallet, with auto-login enabled, instead. Refer to the “Task 1: Creating a Real Wallet” on page 11-1.

Using the iasobf Utility

The iasobf utility enables you to generate an obfuscated wallet password from a cleartext password.

If you are using an Oracle Wallet that has been created with Auto Login enabled (an SSO wallet), then you do not need to use this utility. However, if you must use a regular wallet with a password, then Oracle recommends that you use the password obfuscation tool iasobf, which is located in ORACLE_HOME/Apache/Apache/bin, to generate an obfuscated wallet password from a cleartext password.

To generate an obfuscated wallet password, the command syntax is:

`iasobf -p password`

The obfuscated password is printed to the terminal. iasobf requires operating system user of httpd process. Accordingly, use the `root` argument for UNIX or `system`
Using SSL Configuration Directives

argument for Windows. For example, on UNIX, the command will be `iasobf-password root`.

Note: The corresponding tool for Windows environments is called `osslpassword`, which can be used in the same way as `iasobf`.

Using mod_proxy Directives

The following directives are for `mod_proxy` support only:

- `SSLProxyCache`
- `SSLProxyCipherSuite`
- `SSLProxyProtocol`
- `SSLProxyWallet`
- `SSLProxyWalletPassword`

**SSLProxyCache**

Specifies whether the proxy cache will be used. The proxy will use the same session as the SSL server uses.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>SSLProxyCache on/off</code></td>
</tr>
<tr>
<td>Default</td>
<td><code>SSLProxyCache off</code></td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

**SSLProxyCipherSuite**

Specifies the proxy server’s cipher suite.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>SSLCipherSuite cipher-spec</code></td>
</tr>
<tr>
<td>Default</td>
<td><code>None</code></td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

**SSLProxyProtocol**

Controls the proxy server’s SSL protocol flavors.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>SSLProxyProtocol [+-] protocol</code></td>
</tr>
<tr>
<td>Default</td>
<td><code>None</code></td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

**SSLProxyWallet**

Specifies the location of the wallet containing the certificates to use when opening proxy connections.
### SSLProxyWalletPassword

Specifies the proxy wallet password.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>SSLProxyWallet wrl</td>
</tr>
<tr>
<td>Default</td>
<td>None</td>
</tr>
<tr>
<td>Context</td>
<td>server configuration, virtual host</td>
</tr>
</tbody>
</table>

**Note:** `SSLProxyWalletPassword` has been deprecated. A warning message is generated in the Oracle HTTP Server log if this directive is used. For secure wallets, Oracle recommends that you get a SSO wallet instead.
Using PHP with Oracle Application Server

The chapter provides information about PHP Hypertext Preprocessor (PHP) for use with Oracle Application Server.

This chapter contains the following sections:

- PHP Overview
- Using the PHP Extension for Oracle JDeveloper
- Connecting to an Oracle Database with PHP
- Oracle Application Server mod_php Extensions

12.1 PHP Overview

PHP is a scripting language capable of being embedded in HTML. This capability makes PHP well-suited for Web development. PHP’s object model facilitates project development using standard object-oriented methodologies.

PHP is part of the Oracle Application Server installation package located in the following directory:

```
\Oh\10.1.2\OracleAS\portal\Apache\Apache\php
```

Oracle provides information about PHP at the Open Source Developer Center:

You also can find information about PHP at:

http://www.php.net/

12.2 Using the PHP Extension for Oracle JDeveloper

The following link provides information on installing and configuring the PHP Extension for Oracle JDeveloper:

For a tutorial on using JDeveloper with PHP, see "Oracle Application Server Standard Edition One Quick Tour".
12.3 Connecting to an Oracle Database with PHP

The following link provides information on connecting to an Oracle Database with PHP:

12.4 Oracle Application Server mod_php Extensions

Oracle Application Server provides a server side module for PHP named mod_php. Configuration options for mod_php include extensions. Oracle Application Server supports the extensions listed in Table 12–1, "Oracle Application Server mod_php Extensions".

<table>
<thead>
<tr>
<th>mod_php Extension</th>
<th>Installation Support</th>
<th>Description</th>
<th>Runtime Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>BC Math</td>
<td>Default enabled on Windows only</td>
<td>For arbitrary precision mathematics, PHP offers the Binary Calculator which supports numbers of any size and precision, represented as strings.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>Calendar</td>
<td>Default enabled on Windows only</td>
<td>The calendar extension presents a series of functions to simplify converting between different calendar formats.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>C Type</td>
<td>Available on Unix and Windows</td>
<td>The functions provided by this extension check whether a character or string falls into a certain character class according to the current locale.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>COM</td>
<td>Available on Windows only</td>
<td>COM is one of the main ways to glue applications and components together on the Windows platform. Using COM you can launch Microsoft Word, fill in a document template, save the result as a Word document, and send it to a visitor of your web site.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>FTP</td>
<td>Default enabled on Windows only</td>
<td>This extension provides access to an FTP server and provides a wide range of control to the executing script.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>OCI8</td>
<td>Enabled on UNIX and Windows</td>
<td>The OCI8 functions allow you to connect to Oracle 9, Oracle 8 and Oracle 7 databases.</td>
<td>Oracle client libraries are required to use this extension. Oracle client libraries are provided with an Oracle Application Server install. On Windows the dependency is on php_oci8.dll which resides in %ORACLE_HOME%/Apache/Apache/php/extensions. This functionality can be enabled or disabled on Windows from the php.ini file.</td>
</tr>
</tbody>
</table>
### Oracle Application Server mod_php Extensions

<table>
<thead>
<tr>
<th>mod_php Extension</th>
<th>Installation Support</th>
<th>Description</th>
<th>Runtime Dependencies</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Overload</td>
<td>Enabled on UNIX and Windows</td>
<td>The purpose of this extension is to allow overloading of object property access and method calls. This extension is experimental.</td>
<td>No external libraries are needed for this extension.</td>
</tr>
<tr>
<td>ODBC</td>
<td>Default enabled on Windows only</td>
<td>This function is enabled by default on Windows. The Unified ODBC functions allows the user to access most databases like Adabas D, IBM DB2 etc.</td>
<td>During install time, the libraries for the database, which requires support, must be provided. This is not possible to provide hence not supported.</td>
</tr>
<tr>
<td>PCRE</td>
<td>Enabled on UNIX and Windows</td>
<td>Perl compatible regular expressions or PCRE functions are enabled with this directive.</td>
<td>This extension uses the default bundled library and does not require any additional libraries.</td>
</tr>
<tr>
<td>POSIX</td>
<td>Default enabled on UNIX only</td>
<td>This module provides access to POSIX functions and is available only for UNIX systems.</td>
<td>No external libraries are needed to build this extension.</td>
</tr>
<tr>
<td>SESSION</td>
<td>Enabled on UNIX and Windows</td>
<td>Session support in PHP consists of a way to preserve certain data across subsequent accesses. The session related information is either stored in a cookie or propagated through a URL.</td>
<td>No external libraries are needed to build this extension.</td>
</tr>
<tr>
<td>MYSQL</td>
<td>Enabled on UNIX and Windows</td>
<td>This extension is enabled by default in PHP and provides access to MySQL databases. On Solaris it uses the bundled client libraries and on Windows it requires the php_mysql.dll along with the libmysql.dll.</td>
<td>No external libraries are needed to build this extension.</td>
</tr>
<tr>
<td>TOKENIZER</td>
<td>Enabled on UNIX and Windows</td>
<td>The tokenizer functions provide an interface to the PHP tokenizer embedded in the Zend Engine. Using these functions you may write your own PHP source analyzing or modification tools without having to deal with the language specification at the lexical level.</td>
<td>No external libraries are needed to build this extension.</td>
</tr>
<tr>
<td>XML</td>
<td>Enabled on UNIX and Windows</td>
<td>This PHP extension implements support for the XML parser Expat. Since PHP is built using Apache, it uses the bundled expat library from Apache.</td>
<td>No external libraries are needed to build this extension.</td>
</tr>
<tr>
<td>ZLib</td>
<td>Default enabled on Windows only</td>
<td>This module enables the customer to transparently read compressed files like gzip.</td>
<td>No additional extensions are required to use this functionality.</td>
</tr>
</tbody>
</table>

Using Oracle Application Server Proxy Plug-in

This appendix explains how the Oracle Application Server Proxy Plug-in (OracleAS Proxy Plug-in) enables you to use components in conjunction with a third-party HTTP listener. OracleAS Proxy Plug-in works with the Sun ONE Web Server Enterprise Edition on UNIX and Windows systems, or the Microsoft Internet Information Server (IIS) on Windows systems, to send requests to Oracle Application Server.

See Also:

Topics discussed are:
- Overview
- Downloading OracleAS Proxy Plug-in
- Installing OracleAS Proxy Plug-in
- Using Application Server Control Console
- Configuring OracleAS Proxy Plug-in
- Configuring Sun ONE Listener to Use OracleAS Proxy Plug-in
- Configuring IIS Listener to Use OracleAS Proxy Plug-in
- OracleAS Proxy Plug-in Usage Notes
- Troubleshooting

Overview

OracleAS Proxy Plug-in is a reverse HTTP proxy. The plug-in forwards incoming HTTP requests to an Oracle Application Server instance as shown in Figure A–1.
This proxy logic is provided as a plug-in, a shared library that is loaded by the third-party HTTP listeners. The plug-in uses APIs provided with the third-party listeners to directly handle HTTP requests, in much the same way that modules are plugged into Oracle HTTP Server.

Oracle HTTP Server can mimic the address and port that the third-party listener is using. That is, when sending a request to Oracle HTTP Server, the proxy can be configured to send a different Host: HTTP header than the actual hostname and port that the request is being sent to, so that downstream applications are shielded from the introduction of the reverse proxy.

**Figure A–1 OracleAS Proxy Plug-in**

OracleAS Proxy Plug-in is available on the Oracle Application Server 10g Companion CD, which is included in your Oracle Application Server CD Pack.

**Installing OracleAS Proxy Plug-in**

After downloading OracleAS Proxy Plug-in, place the appropriate configuration file and shared library in directories that the third-party listener can access.

On the Oracle Application Server 10g Companion CD, the files are located at /plugins/solaris/ for UNIX and /plugins/win32/ for Windows.

Table A–1 contains information about the shared libraries for OracleAS Proxy Plug-in.

<table>
<thead>
<tr>
<th>Platform</th>
<th>File Name</th>
<th>Location and Description</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX</td>
<td>oracle_proxy.so</td>
<td>oracle_proxy.so is the OracleAS Proxy Plug-in file for Sun ONE Web listener. It is located in the /plugins/solaris/sunone directory.</td>
<td>To install the plug-in into the listener, place oracle_proxy.so in a directory to which the listener has read and execute privileges.</td>
</tr>
<tr>
<td>Windows</td>
<td>oracle_proxy.dll</td>
<td>oracle_proxy.dll is the OracleAS Proxy Plug-in file for the IIS Web listener. It is located in the /plugins/win32/iis directory.</td>
<td>To install the plug-in into the listener, copy oracle_proxy.dll to a directory the listener can access.</td>
</tr>
<tr>
<td></td>
<td>oracle_proxy_sunone.dll</td>
<td>oracle_proxy_sunone.dll is the OracleAS Proxy Plug-in file for Sun ONE Web listener. It is located in the /plugins/win32/sunone directory.</td>
<td>To install the plug-in into the listener, copy oracle_proxy_sunone.dll to a directory the listener can access.</td>
</tr>
</tbody>
</table>

**Using Application Server Control Console**

When you install Oracle Application Server, you can administer Oracle HTTP Server using Application Server Control Console. However, if you choose to use Sun ONE or...
IIS instead of Oracle HTTP Server, then it is recommended that you disable Oracle HTTP Server on Application Server Control Console so that it no longer appears there. Oracle does not support monitoring or administering of non-Oracle HTTP Server listener with Application Server Control Console.

See Also:
- Chapter 7, “Application Server Control Console Management”
- Oracle Enterprise Manager Concepts

**Configuring OracleAS Proxy Plug-in**

There is one configuration file for OracleAS Proxy Plug-in. It controls the proxy functionality. The presence of the configuration file in the Web server’s file system makes the functionality active.

You also need to modify configuration files specific to the third-party listener to enable the plug-in on these listeners.

**Proxy Server Definition File**

The proxy server definition file must reside in a directory that is readable by the third-party listener. For simplicity, you could create a directory called proxy in a convenient location on your system, and place the proxy server definition file, the proxy shared library file, and proxy log files in it.

Described in detail in Proxy Configuration File Parameters section, the proxy server definition file contains:
- Name value pairs that describe the servers that will be used to proxy requests to Oracle Application Server.
- Options for communicating with the servers.
- A set of rules that map URLs to the servers.

You can create this file with the text editor of your choice. The oproxy.serverlist parameter must list at least one server name, or the proxy will not function.

Example A–1 provides a sample proxy server definition file.

**Example A–1 Sample Proxy Server Definition File**

```plaintext
# This file defines proxy server behavior.
#
# Server names that the proxy plug-in will recognize.
# oproxy.serverlist=iaas

# Hostname to use when communicating with a specific server.
# oproxy.iaas.hostname=oaasdocs.us.oracle.com

# Port to use when communicating with a specific server.
# oproxy.iaas.port=7777

# Description of URL(s) that will be redirected to this server.
# oproxy.iaas.urirules=/*
```

**See Also:**
- Chapter 7, “Application Server Control Console Management”
- Oracle Enterprise Manager Concepts
Proxy Configuration File Parameters

The following proxy configuration file parameters are described in the subsequent sections:

- `oproxy.serverlist`
- `oproxy.servername.hostname`
- `oproxy.servername.port`
- `oproxy.servername.alias`
- `oproxy.servername.resolveall`
- `oproxy.servername.urirule`

**oproxy.serverlist**

Lists all of the server names that the plug-in recognizes.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Type</td>
<td>string list</td>
</tr>
<tr>
<td>Allowable Values</td>
<td>Comma separated list of server names, one for each Oracle HTTP Server to which requests will be sent. All servers in the serverlist must also be defined in the file.</td>
</tr>
<tr>
<td>Default Value</td>
<td>None. At least one server name must be provided for the proxy to be functional.</td>
</tr>
<tr>
<td>Example</td>
<td><code>oproxy.serverlist=ias1,ias2</code></td>
</tr>
</tbody>
</table>

**oproxy.servername.hostname**

Defines the hostname to use when communicating with a specific server.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter Type</td>
<td>string</td>
</tr>
<tr>
<td>Allowable Values</td>
<td>Valid hostname</td>
</tr>
<tr>
<td>Default Value</td>
<td>None</td>
</tr>
<tr>
<td>Example</td>
<td><code>oproxy.ias1.hostname=www1.us.oracle.com</code></td>
</tr>
</tbody>
</table>

**oproxy.servername.port**

Defines the port to use when communicating with a specific server.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Allowable Values</td>
<td>Valid port value</td>
</tr>
<tr>
<td>Default Value</td>
<td>80</td>
</tr>
<tr>
<td>Example</td>
<td><code>oproxy.ias1.port=7777</code></td>
</tr>
</tbody>
</table>

**oproxy.servername.alias**

Supports the mimicking feature of the proxy by defining the hostname and port that clients use to access the third-party HTTP listener. If defined, this value will be passed as the Host: HTTP header. If not defined, the hostname and port of the machine actually being communicated with will be sent.
Configuring OracleAS Proxy Plug-in

### Configuring OracleAS Proxy Plug-in

**A-5**

**oproxy.servername.resolveall**

Directs the proxy plug-in to resolve the hostname to the backend server on every request. This enables DNS based failover or routing between the proxy plug-in and backend servers. The use of this parameter incurs the cost of going to the DNS server for every incoming request, and hence should only be used if the mapping from hostname to IP address will change dynamically.

**Category** | **Value**
---|---
Parameter Type | string
Allowable Values | host:port
Default Value | oproxy.servername.hostname:oproxy.servername.port
Example | oproxy.ias1.alias=www.oracle.com:80

**oproxy.servername.urlrule**

Describes a URL or set of URLs that are redirected to this server. A given server can have any number of urlrule properties assigned to it.

Three types of rules can be used: exact match, context match, or suffix match.

- **Exact matches**: One URL is mapped to a server.
  
  For example:
  
  oproxy.ias1.urlrule=/foo/bar/foo.html would map only the URL /foo/bar/foo.html to be proxied to the server with the name ias1 (the details for the server ias1 are configured in the server configuration file).

- **Context matches**: A set of URLs with a common prefix or context are all mapped to a server. For example, oproxy.ias1.urlrule=/foo/* would map URLs beginning with /foo to the server with the name ias1.
  
  For context matches, you can use the stripcontext option with the urlrule parameter to send only the portion of the url following the wildcard to the server.

  The default for the stripcontext option is false, so you do not need to include it unless you are setting it to true. It is shown for completeness of the example.

  Example: In following configuration:
  
  oproxy.ias1.urlrule=/ias1/*
  oproxy.ias1.resolveall=true

  and the URL request:
  
  http://hostname/ias1/header1.gif
Configuring OracleAS Proxy Plug-in

retrieves
ORACLE_HOME/Apache/Apache/htdocs/ias1/header1.gif

In the following configuration:
oproxy.ias1.urlrule=/ias1/*
oproxy.ias1.stripcontext=true

and the URL request:
http://hostname/ias1/header1.gif

retrieves
ORACLE_HOME/Apache/Apache/htdocs/header1.gif

■ Suffix matches: All files with a common file extension are mapped to a server.
For example, oproxy.ias1.urlrule=/*.jsp would map all of the URLs that end in .jsp to the server ias1. This can be combined with the context rule to have something like /foo/bar/* .jsp so that only URLs that start with /foo/bar and end in .jsp would be proxied.

Note: For the oproxy.servername.urlrule, when multiple rules apply to the same URL, the following precedence applies:
1. Exact matches
2. Longest context match plus suffix match
3. Longest context match

Some examples of the precedence are:
/foo/bar/index.html would take precedence over /foo/bar/*
/foo/bar/*.jsp would take precedence over /foo/bar/*
/foo/bar/* would take precedence over /foo/*

Defining OracleAS Proxy Plug-in Behavior
In the proxy server definition file, you define which servers and URLs to proxy to the plug-in.

1. In the first line of the file, specify the list of all the servers that can be used by the plug-in. For example:
oproxy.serverlist=ias1,ias2

2. Set the relevant properties (hostname, port, and server alias) for each server. For example:
oproxy.ias1.hostname=myhost.us.oracle.com
oproxy.ias1.port=7777
oproxy.ias1.alias=www.oracle.com

The hostname must be provided. If you do not specify the port, 80 is assigned. If an alias value is not given, the combination of the hostname and port given are used. The alias enables the back end server to receive requests that have an HTTP
Host: header that looks exactly like the one the client delivers to the third-party listener.

3. Set the urlrule parameter to specify redirection between servers. For example, the rule:
   
   oproxy.ias1.urlrule=*  
   
   maps all incoming requests to be proxied to the Web server on the server ias1. These rules can be of three forms, exact URL, context match, or extension-based. An exact match maps exactly one URL to a server, for example:
   
   oproxy.ias1.urlrule=/*my/path/index.html  
   
   maps only accesses to /my/path/index.html for proxying. An example of a context rule is:
   
   oproxy.ias1.urlrule=/*appl/*  
   
   which maps any URL beginning with /appl. An extension-based rule, such as:
   
   oproxy.ias1.urlrule=/*.jsp  
   
   maps any URL ending with .jsp. All requests sent to a mapped URL are proxied through HTTP/1.1 to the specified server.

---

Configuring Sun ONE Listener to Use OracleAS Proxy Plug-in

This section provides proxy plug-in configuration instructions for Sun ONE Enterprise Server listener on UNIX and Windows systems.

1. Open the magnus.conf file in version 6, or obj.conf in version 4 in the Sun ONE listener /config directory.

2. Add the load-modules line:

   On UNIX:

   Init fn="load-modules" shlib="/path/oracle_proxy.so" func=op_init,op_objecttype[op_service

   On Windows:

   Init fn="load-modules" shlib="/path/oracle_proxy_sunone.dll" func=op_init,op_objecttype[op_service

---

Notes: If you are configuring the Sun ONE listener on Windows, use forward slashes (/) in all paths.

The default configuration files for Sun ONE route all incoming requests for the URL /servlet to the Sun ONE servlet handler.

The OracleAS Proxy Plug-in does not override the Sun ONE server’s configuration settings. You must ensure that the URL mappings to the OracleAS Proxy Plug-in are distinct from the URL mappings to the Sun ONE servlet engine.
where /path/ is the path to the shared library for the plug-in. This line tells the listener where the proxy shared library is, and which functions are exposed by this library.

3. Add the configuration parameters line:

```
Init fn="op_init" server_defs="/path/servers"
logfile="/path/oproxy.log" log_level=error
```

where /path/ is the path to the proxy server definition and log files. The proxy server definition file contains all of the configuration information for the servers that the proxy plug-in can communicate with. A log file and log level to log messages from the plug-in can also be specified (optional).

**See Also:** "Proxy Server Definition File" on page A-3 for a complete description and example.

4. Add the following line to the <Object name=default> section of the obj.conf file, before all other lines beginning with the word ObjectType:

```
ObjectType fn=op_objecttype
```

5. Add the following line before all other lines that begin with the word "Service":

```
Service type="oracle/proxy" fn="op_service"
```

6. Start the listener using the GUI or the shell script.

---

**Configuring IIS Listener to Use OracleAS Proxy Plug-in**

This section provides proxy plug-in configuration instructions for the IIS listener on Windows systems. The process involves creating Windows registry entries and using the IIS management console to add directories and filters. You must restart the listener after configuring the plug-in.

To configure the plug-in, perform the following steps:

1. From the Start menu, select **Run**.
2. In the run dialog box, type **regedit** and click **OK**.
   The Registry Editor window opens.
3. In the Registry Editor window, expand the **HKEY_LOCAL_MACHINE** folder (click the + preceding its name).
4. Expand the **SOFTWARE** folder (click the + preceding its name).
5. Click the **ORACLE** folder.
6. From the Edit menu, select **New**, then **Key**.
   A new folder is added under the **ORACLE** folder with the name **New Key #1**.
7. Type **IIS Proxy Adapter** for the key name.
8. From the Edit menu, select **New**, then **String Value**.
   A new value is added in the right window pane with the name **New Value #1**.
9. Type **server_defs** for the value name.
10. From the Edit menu, select **Modify**. The Edit String dialog box appears.
11. In the Value data field, type the full path of your proxy server definition file. Click OK.

12. Specify log_file and log_level using the procedure specified in steps 8-11. This is optional:
   a. Add a string value with the name log_file and the desired location of the log file (for example, d:\proxy\proxy.log)
   b. Add a string value with the name log_level and a value for the desired log level. Valid values are debug, inform, error and emerg.

13. Using the IIS management console, add a new virtual directory to your IIS Web site with the same physical path as that of oracle_proxy.dll. Name the directory oproxy and give it execute access.

14. Using the IIS management console, add oracle_proxy.dll as a filter in your IIS Web site. The name of the filter should be oproxy and its executable must point to the directory containing oracle_proxy.dll (for example, d:\proxy\oracle_proxy.dll).

15. Restart IIS (stop and then start the IIS Server), ensuring that the oproxy filter is marked with a green upward arrow.

**Note:** To restart IIS, you must stop all of the IIS services through the control panel, or restart the computer. This is the only way to ensure that the .dll is reloaded. Restarting IIS through the management console is not sufficient.

---

**OracleAS Proxy Plug-in Usage Notes**

This section highlights development and usage practices to consider when developing an application that runs behind the OracleAS Proxy Plug-in. Some of these also have relevance when enabling an application to run behind Oracle Application Server Web Cache.

- **Check for configurations based on the Oracle HTTP Server being the entry point into the network.**

  This is usually only relevant if an application has a module that plugs directly into the Oracle HTTP Server. Specifically, look for dependencies on obtaining information about the client based on the connection made to the Oracle HTTP Server, such as using the SSL certificate for authentication. Currently, SSL is not supported, so even if the client uses SSL to connect to the third-party listener, an unencrypted HTTP message will be sent from the third-party listener to the Oracle HTTP Server. This means that client certificates will not be available to components that reside behind the plug-in. The environment variable REMOTE_ADDR has been specifically preserved when OracleAS Proxy Plug-in and Oracle Application Server Web Cache are used, but other client information may, in practice, represent the machine on which the proxy resides rather than the actual client host. These behaviors must be discovered and eliminated in cases where the Oracle HTTP Server is not the external listener for Oracle Application Server.

- **Avoid returning non-relative links in HTML, that is, avoid embedding host names into HTML unless the link is external to the Web site.**

  This includes static HTML pages, dynamic pages generated by servlets, JSPs, PL/SQL and so on. Examine all code that obtains the server name of Oracle HTTP Server to ensure that it is not embedding the server name into pages that are sent...
back to the client. To test for this behavior, use a “spider” application that traverses all links in a Web site. Open source tools with this functionality are available.

- Avoid returning host and port information in applications (such as applets or javascript) downloaded to the client.

  If you have an application that uses browser-based code, ensure that the code does not contain the hostname and port of Oracle HTTP Server that actually delivers the content. Instead, it must have the actual client-accessible address used by the third-party listener.

- Ensure that all URLs within an application can be easily mapped to a set of rules that the proxy can use.

  In order to successfully proxy all requests for an application, the OracleAS Proxy Plug-in must have a complete description of the URL space for that application. Each Oracle Application Server application must describe the set of rules necessary to configure the plug-in for that application. This set of rules must include all URLs that the application could generate. If an application generates a URL that is not described by the proxy urerule parameters, the request will be served by the third-party HTTP listener, and a ‘document not found’ error may occur (or, worse, a document other then the intended document may be delivered to the client).

Developers of applications that use common top level directories (such as a reliance on mapping /images) should be prepared to:

- Change these common links to something that will not conflict with applications that might already be deployed on the third-party listener.

- Instruct the user to copy the necessary content to the third-party listener’s directory structure. For performance reasons, it is a good idea to have the third-party listener handle static .gif and .jpg files anyway, but it requires extra effort.

## Troubleshooting

This section describes common problems and possible solutions.

### Listener Fails to Start

- Ensure that you have the newest version of the OracleAS Proxy Plug-in.

- Verify that your listener configuration is set up correctly. (The IIS listener may need to be restarted in order to make the filter work properly.) A proxy server definition file must exist.

  **See Also:** "Proxy Server Definition File" on page A-3 for a description of this file and parameter requirements.

- Check for problems in the proxy server definition file. Each server in the serverlist line must be defined later in the file, and you must have at least one server defined. If a server name is listed but not defined, the listener may not start (although the reverse is not true). Ensure that there are no typographical errors or missing quotes in the proxy server definition file.

- For Sun ONE 6.0 on UNIX and Windows: Ensure that Init lines are added to the magnus.conf file and ObjectType and Service lines are added to the obj.conf file.
Listener Returns Incorrect URLs

- Verify that changes to the proxy server definition file have been saved and the listener has been restarted.
- Ensure that there are no typographical errors in the proxy server definition file.
- Ensure that the `urirule` parameter is set up correctly, and consider whether the `stripcontext` option should be set to true.
- Verify that the `serverlist` line in the proxy server definition file specifies the back-end server you are trying to reach.
- Verify that the back-end server is running, and that the file you are attempting to retrieve exists and is accessible on the back-end server.
- Verify that the host, port and `urirule` parameters in the proxy server definition file target the correct area on the back-end server.
- Ensure that client requests are being sent to the correct port on the third-party listener machine.
- Check the listener log files, the proxy log (may need to be turned on in `debug` mode, and may require restarting the listener), and the back-end server logs to verify that requests are getting through.

Changes Made to Proxy Server Definition File are Not Reflected

- Ensure that you have saved the proxy server definition file and restarted the listener.
- For IIS: To pick up the changes, you must stop and start the WWW Publishing Service from the Control Panel. This takes a few minutes.

IIS Listener Displays Incomplete Pages or Garbled Characters

Do not display an IIS page with a Sun ONE browser.

Parsing Error Occurs with Sun ONE 6.0

If you try to change the ports or turn on security (for SSL), the server may return the error message "Unable to parse magnus.conf".

Remove any comments and added lines preceding and following the `Init` lines in the `magnus.conf` file.

"File Not Found" Error Occurs

If you are using a context-based `urirule` parameter to retrieve a file that is known to exist, and the listener returns "Not Found", you probably need to set "stripcontext=true".

See Also: "oproxy.servername.urirule" on page A-5

Partial URL Requests Return Unexpected Results

The IIS and Sun ONE servers auto-complete URLs differently. Requests of "http://serviceman", "http://serviceman/", and "http://serviceman/index.html" do not necessarily return the same results on different platforms. The `oproxy.servername.urirule` parameter can be used to work around this problem.

See Also: "oproxy.servername.urirule" on page A-5
Troubleshooting

Sun ONE Server Returns “Server Error” with “/servlet” Request
The default Sun ONE configuration maps any URL requests to “/servlet” to its own servlet handler. You must edit the proxy server definition file, or change the Sun ONE configuration to correct this.

Server Returns Page with Broken Image Links
If you use an exact `urlrule` parameter, for example, “urlrule=/*.html”, in the proxy server definition file (or a similar scenario), the server retrieves the specified page, but all other links are forbidden to the user, including inline images in the page. (If you use an exact `urlrule` with `stripcontext=true`, a “Server Error” is returned.)

Unexpected Pages are Displayed
Clear the memory cache in your client browser. Earlier versions of Sun ONE and IE cache pages even when told to retrieve the page every time, when no memory is allocated for caching (you may need to restart the browser to get this behavior to work). If you see a page you’re not expecting, try refreshing or reloading the page.

REMOTE_ADDR Contains Unexpected IP Address
The `REMOTE_ADDR` field usually contains the IP address of the client machine. In some URL request cases, if there is a proxy server in the environment, the field may contain the IP address of the proxy server.

Redirects Go To Network Entry Point
If the back-end server returns a redirect to the entry point of the network, do one of the following, the first option being the preferred one:

- Set the following directives in the `httpd.conf` file:
  ```
  UseCanonicalName On
  ServerName name of listener host
  Port port of listener host
  ```

- Set the following directives in the `httpd.conf` file:
  ```
  UseCanonicalName port
  Port port of listener host
  ```

  Edit the proxy plug-in server configuration file:
  ```
  oproxy.serverName.alias=name of listener host:port of listener host
  ```

SSL Requests Yield Unexpected Results
The proxy plug-in supports SSL connections made between the client and the proxy host, but does not support SSL connections between the proxy and the back-end server. To implement the latter, set up the listener to receive SSL connections and start the back-end server in non-SSL mode. No changes to the proxy configuration are needed.
Using Oracle Application Server SSO Plug-in

This appendix explains how to use Oracle Application Server SSO Plug-in (OracleAS SSO Plug-in) to protect third-party HTTP listener and its applications. The OracleAS SSO Plug-in works with the Sun ONE Web Server Enterprise Edition on UNIX and Windows systems, and the Microsoft Internet Information Server (IIS) on Windows systems.

- Registering with Single Sign-On
- Configuring OracleAS SSO Plug-in
- Resource Protection
- Configuring Sun ONE Listener for Single Sign-on
- Configuring IIS Listener for Single Sign-On
- Troubleshooting

Overview

OracleAS SSO Plug-in is Oracle’s single sign-on (SSO) solution for third-party listeners such as Sun ONE and IIS. The plug-in is designed to protect native third-party listener applications using the SSO infrastructure. With the help of the OracleAS SSO Plug-in, you can be authenticated to different third-party listener applications using only one SSO password. You can integrate these SSO-protected third-party listener applications with SSO enabled Oracle HTTP Server applications or legacy Oracle SSO enabled application together as long as they are all protected on the same SSO server.

OracleAS SSO Plug-in is a simple version of mod_osso, and only implements some of its basic functionality. Features such as dynamic authentication, global logout, idle timeout and global timeout, and basic authentication for legacy application are not implemented in the current OracleAS SSO Plug-in release.

Figure B–1 illustrates the process involved when you request a URL protected by the OracleAS SSO Plug-in.
1. The user requests a URL through a Web browser.
2. The Web server looks for an OracleAS SSO Plug-in cookie for the user. If the cookie exists, the Web server extracts the user's information and uses it to log the user in to the requested application.
3. If the cookie does not exist, then the OracleAS SSO Plug-in redirects the user to the single sign-on server.
4. The single sign-on server looks for its own cookie in the browser. If it finds none, it tries to authenticate the user with a user name and password. If authentication is successful, the single sign-on server creates a cookie in the browser as a reminder that the user has been authenticated. If a cookie exists, the single sign-on server authenticates using the cookie.
5. The single sign-on server returns the user's encrypted information to the OracleAS SSO Plug-in.
6. OracleAS SSO Plug-in creates its own cookie for the user in the browser and redirects the user to the requested URL.

During the same session, if the user again seeks access to the same or to a different application, the user is not prompted for a user name and password; the application uses an HTTP header to obtain this information from the OracleAS SSO Plug-in session cookie.

**Downloading OracleAS SSO Plug-in**

OracleAS SSO Plug-in is available on the Oracle Application Server 10g Companion CD, which is included in your Oracle Application Server CD Pack.

**Installing OracleAS SSO Plug-in**

Install OracleAS SSO Plug-in on a machine that has an Oracle Application Server installation. This installation is required only for the network and security dependent libraries and single sign-on registration tool; it is not required to be running. After the Oracle Application Server installation on UNIX systems, add $ORACLE_HOME/lib to the LD_LIBRARY_PATH in the listener's start script. For example, the "start" script in
Registering with Single Sign-On

Sun ONE. On Windows systems, the installation automatically sets the environment variable \texttt{PATH}. For example, \texttt{ORACLE_HOME/bin}.

Download, or copy, the plug-in, and place the configuration file and shared libraries in directories that the third-party listener can access. For security reasons, ensure that all the configuration files and plug-in modules are given minimum privileges.

On the Oracle Application Server 10g Companion CD, the files are located at \texttt{/plugins/solaris/} for UNIX and \texttt{/plugins/win32/} for Windows.

Table B–1 contains information about the shared libraries for OracleAS SSO Plug-in.

<table>
<thead>
<tr>
<th>Platform</th>
<th>File Name</th>
<th>Location and Description</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX</td>
<td>oracle_proxy.so</td>
<td>oracle_proxy.so is the OracleAS SSO Plug-in file for Sun ONE Web listener. It is located in the /plugins/solaris/sunone directory</td>
<td>To install the plug-in into the listener, place oracle_proxy.so in a directory to which the listener has read and execute privileges.</td>
</tr>
<tr>
<td>Windows</td>
<td>oracle_osso.dll</td>
<td>oracle_osso.dll is the OracleAS SSO Plug-in file for the IIS Web listener. It is located in the /plugins/win32/lls directory.</td>
<td>To install the plug-in into the listener, copy oracle_osso.dll to a directory the listener can access.</td>
</tr>
<tr>
<td></td>
<td>oracle_proxy_sunone.dll</td>
<td>oracle_proxy_sunone.dll is the OracleAS SSO Plug-in file for Sun ONE Web listener. It is located in the /plugins/win32/sunone directory</td>
<td>To install the plug-in into the listener, copy oracle_proxy_sunone.dll to a directory the listener has read and execute privileges.</td>
</tr>
</tbody>
</table>

Note: You can only run this tool on the same machine where your listener resides. Also, the resulting single sign-on configuration file has to be generated directly on the same machine. Do not copy the single sign-on configuration file across different machines.

Using Oracle Application Server SSO Plug-in...
Registering with Single Sign-On

A different version ossoreg.jar could have very different command arguments. If needed, run the command using "-help" first to get the complete usage information.

Common Single Sign-On Registrar Command Arguments

Table B–2 lists some important common arguments for the single sign-on registrar.

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-oracle_home_path</td>
<td>Absolute path to the Oracle home of the Oracle Application Server installation</td>
</tr>
<tr>
<td>-site_name</td>
<td>Name of the site, typically expressed as the configure string host:port.</td>
</tr>
<tr>
<td>-ssoDBConnect</td>
<td>Single sign-on database JDBC connect string.</td>
</tr>
<tr>
<td>-pass</td>
<td>ORASSO_PA password.</td>
</tr>
<tr>
<td>-mod_osso_url</td>
<td>http://&lt;listener_hostname.domain&gt;:port</td>
</tr>
<tr>
<td>-admin_id</td>
<td>User name of the third-party administrator. This argument is optional.</td>
</tr>
<tr>
<td>-admin_info</td>
<td>Information associated with the administrator’s user name, such as e-mail address. This argument is optional.</td>
</tr>
<tr>
<td>-config_mod_osso</td>
<td>Set to TRUE. This parameter indicates that the application being registered is mod_osso. This argument is necessary to generate the sso_conf file.</td>
</tr>
<tr>
<td>-u</td>
<td>Specifies the name of the account used to start the third-party listener. Use the value of User specified in the magnus.conf for Sun ONE and SYSTEM for IIS. The default is the user who runs the single sign-on registrar tool.</td>
</tr>
<tr>
<td>-sso_server_version</td>
<td>Must be set to v1.2.</td>
</tr>
<tr>
<td>-virtualhost</td>
<td>Be sure to include this argument.</td>
</tr>
<tr>
<td>-config_file</td>
<td>Specifies a path of the final obfuscated single sign-on configuration file. It has to be set under ORACLE_HOME. Default is set to:</td>
</tr>
<tr>
<td></td>
<td>- UNIX: ORACLE_HOME/Apache/Apache/conf/osso.conf</td>
</tr>
<tr>
<td></td>
<td>- Windows: ORACLE_HOME/Apache/Apache/conf/osso.conf</td>
</tr>
</tbody>
</table>

Example B–1 Using Common Single Sign-On Registrar Command Arguments

On UNIX:

```
ORACLE_HOME/jdk/bin/java -jar ORACLE_HOME/sso1/lib/ossoreg.jar \
-ssoDBConnect <host.domain>:1521:iasdb -pass your_password \
-oracle_home_path ORACLE_HOME -site_name <host.domain>:7778 \
-config_mod_osso TRUE -mod_osso_url http://<host.domain>:7778 \
-u nobody -admin_id admin_name -admin_info admin@company.com \
-sso_server_version v1.2 \
-virtualhost \ 
-config_file ORACLE_HOME/Apache/Apache/conf/osso/sso_conf
```

On Windows:

```
ORACLE_HOME/jdk/bin/java -jar ORACLE_HOME/sso1/lib/ossoreg.jar \
-ssoDBConnect <host.domain>:1521:iasdb -pass your_password \ 
-oracle_home_path ORACLE_HOME -site_name <host.domain>:8080 \
-config_mod_osso TRUE -mod_osso_url http://<host.domain>:8080 \
-u SYSTEM -admin_id admin_name -admin_info admin@company.com \
-sso_server_version v1.2 \
-virtualhost \ 
-config_file ORACLE_HOME/Apache/Apache/conf/osso/sso_conf
```
Configuring OracleAS SSO Plug-in

Create a plug-in configuration file such as osso_plugin.conf. This is the file where you define all the plug-in functionality. It can also be referred as the osso property file. The syntax is exactly the same for all third-party listeners. This file must reside in a directory that is readable by the third-party listener. This file also contains the following:

- Plug-in directives such as LoginServerFile and IpCheck
- A set of rules that match resources to be protected.

OracleAS SSO Plug-in Configuration Directives

Table B–3 lists the configuration directives for the OracleAS SSO Plug-in.

### Table B–3 SSO Plug-in Configuration Directives

<table>
<thead>
<tr>
<th>Directive Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoginServerFile</td>
<td>Specifies the location of the Single Sign-On Server configuration file such as sso.conf that is attained from the SSO registration process. This directive gets its name from Login Server, which is now called Single Sign-On Server, for historical reasons. This is a global parameter and should not be used on a per-resource basis. That is, you must provide one and only one Single Sign-On Server configuration file.</td>
</tr>
<tr>
<td></td>
<td>- Parameter Type: string</td>
</tr>
<tr>
<td></td>
<td>- Allowable Values: the full path of your Single Sign-On Server configuration file, such as sso_conf.</td>
</tr>
<tr>
<td></td>
<td>- Default Value: None. You must provide the exact location of the Single Sign-On server configuration file to allow SSO plug-in to be functional.</td>
</tr>
<tr>
<td></td>
<td>- Example: LoginServerFile=/path/config/sso_conf</td>
</tr>
<tr>
<td>IpCheck</td>
<td>Specifies whether the SSO plug-in should check the IP address of each request when it examines the cookie. Valid values are true and false. Setting IpCheck to true prevents cookies being stolen.</td>
</tr>
<tr>
<td></td>
<td>- Parameter Type: Boolean</td>
</tr>
<tr>
<td></td>
<td>- Allowable Values: true/false.</td>
</tr>
<tr>
<td></td>
<td>- Default Value: false.</td>
</tr>
<tr>
<td></td>
<td>- Example: IpCheck=true</td>
</tr>
<tr>
<td></td>
<td>Note: Set IpCheck to false if you have a proxy server or firewall between your Sun ONE server and your clients’ browser.</td>
</tr>
<tr>
<td>HardTimeout</td>
<td>Deprecated.</td>
</tr>
</tbody>
</table>

Resource Protection

Use the following format to protect resources:

```
<OSO url-matching-rule>
SSO_configuration_directives
</OSO>
```

Use the following rules to define the url-matching-rule:

<table>
<thead>
<tr>
<th>Rule Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exact Match</td>
<td>This option identifies an exact file as a protected resource, for example: /examples/Hello.html</td>
</tr>
</tbody>
</table>
When multiple rules apply to the same URL, the following precedence applies:

1. Exact matches
2. Longest context match plus suffix match
3. Longest context match

Some examples of the precedence are:

- `/foo/bar/index.html` would take precedence over `/foo/bar/*`
- `/foo/bar/*.jsp` would take precedence over `/foo/bar/*`
- `/foo/bar/*` would take precedence over `/foo/*`

**Example B–2 Simple Single Sign-on Configuration File, osso_plugin.conf**

```plaintext
LoginServerFile=/path/sso_conf
<OSSO /private/hello.html>
IpCheck = false
</OSSO>
<OSSO /private1/>
</OSSO>
<OSSO /private2/*.jsp>
IpCheck = true
</OSSO>
```

### Rule Name

<table>
<thead>
<tr>
<th>Rule Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Context Match</td>
<td>This option identifies a directory as a protected resource, for example: /examples/*</td>
</tr>
<tr>
<td>Extension Match</td>
<td>This option identifies files with a certain extension in a particular directory as a protected resource, for example: /examples/*.jsp</td>
</tr>
</tbody>
</table>

### Configuring Sun ONE Listener for Single Sign-on

This section provides OracleAS SSO Plugin configuration instructions for the Sun ONE listener on UNIX and Windows systems.

#### Note:
If you are configuring the Sun ONE listener on Windows, use forward slashes (/) in all paths.

1. Open the magnus.conf file, version 6, or obj.conf, version 4, in the Sun ONE listener /config directory.
2. Add the load-modules line:

   **On UNIX:**
   ```sh
   Init fn="load-modules" shlib="/path/oracle_proxy.so" funcs="osso_init,oracle_single_sign_on,osso_redirect_service,osso_success_service"
   ```

   **On Windows:**
   ```sh
   Init fn="load-modules" shlib="/path/oracle_proxy_sunone.dll" funcs="osso_init,oracle_single_sign_on,osso_redirect_service,osso_success_service"
   ```
Configuring IIS Listener for Single Sign-On

where /path/ is the path to the shared library for the plug-in. This line tells the listener where the proxy shared library is, and which functions are exposed by this library.

3. Add the configuration parameters line:

   Init fn="osso_init" osso_properties="/path/osso_plugin.conf" log_file="/path/plugin.log" log_level=error

   where /path/osso_plugin.conf is the exact location of the plug-in configuration file you just created. Also this line can specify a log file and log level to log messages from the plug-in (optional).

4. Add the following line to the <Object name=default> section of the obj.conf file, before all other lines:

   AuthTrans fn="oracle_single_sign_on"

5. Add the following line to the <Object name=default> section before all other lines that begin with the word Service:

   Service type="oracle/sso_redirect" fn="osso_redirect_service"

6. Add the following lines where /path/ is the path of your document root. For example: /home/Sun ONE/docs/ or $docroot.

   <Object ppath="/path/osso_login_success">
   Service fn="osso_success_service"
   </Object>

7. Change the LD_LIBRARY_PATH variable in your start script to include the location of ORACLE_HOME/lib32, where ORACLE_HOME is the Oracle Application Server installation home directory.

8. Restart the listener.

Usage Notes for Sun ONE Enterprise Server Version 6.0

For version 6.0, the same shared library can be used as with version 4.1. The configuration is virtually the same, but the configuration files for Sun ONE have changed slightly in version 6.0. In this version, the two lines beginning with Init that need to be added must be added at the end of the magnus.conf file rather than to the obj.conf file. The other two lines that should be added to obj.conf remain the same.

Configuring IIS Listener for Single Sign-On

This section provides instructions on configuring the IIS Listener to use OracleAS SSO Plug-in. The plug-in consists of a single .dll, oracle_osso.dll. To install the plug-in, copy the .dll to the host on which IIS resides and perform the following steps:

1. Edit your registry to create a new registry key named HKEY_LOCAL_MACHINE\SOFTWARE\Oracle\IIS OSSO Adapter.

2. Specify the exact location of your plug-in configuration file you just created. For example: d:\osso\osso_plugin.conf, by adding this string value with the name cfg_file and a value pointing to the location of your configuration file.

3. Specify a log_file and log_level. This is optional.
Troubleshooting

a. Add a string value with the name log_file and the desired location of the log file. For example: d: \ossoplugin.log

b. Add a string value with the name log_level and a value for the desired log level. Valid values are debug, inform, error and emergency.

4. Using the IIS management console, add a new virtual directory to your IIS Web site with the same physical path as that of oracle_osso.dll. Name the directory osso and give it execute access.

5. Using the IIS management console, add oracle_osso.dll as a filter in your IIS Web site. The name of the filter should be osso and its executable must point to the directory containing oracle_osso.dll. For example, d: \osso \oracle_osso.dll

6. Stop and then start the IIS Server, ensuring that the filter is marked with a green up-pointing arrow.

Note:

• To restart IIS, you must stop all of the IIS services through the control panel, or restart the computer. This is the only way to ensure that the .dll is reloaded. Restarting IIS through the management console is not sufficient.

• If you want multiple Oracle installations on the same home, the ORACLE_HOME/bin PATH entry for the installation that you wish to use in conjunction with the OracleAS SSO Plug-in must appear first in your PATH.

Troubleshooting

This section describes common problems and possible reasons.

Oracle Dependency Libraries Not Found
OracleAS SSO Plug-in could not find the libraries it needs. Possible reason would be that you do not have ORACLE_HOME/lib included in your LD_LIBRARY_PATH on UNIX. On Windows, you do not have ORACLE_HOME/bin included in your PATH.

Single Sign-On Server Configuration File De-obfuscation Fails
Single sign-on server configuration file, for example, sso_conf, is obfuscated using a certain account and this account has to be the one being used to start your listener. For example, use the value of User specified in magnus.conf for Sun ONE and usually SYSTEM for IIS.

IIS Oracle Application Server OracleAS SSO Plug-in Does Not Work with HTML Authentication
OracleAS SSO Plug-in is designed to not work with other authentication modules. It is either a native listener authentication module, or third-party module.
Using Oracle Application Server Containers for J2EE Plug-in

This appendix explains how the Oracle Application Server Containers for J2EE Plug-in (OC4J Plug-in) enables you to use third party HTTP listeners to access servlets running in OC4J J2EE within Oracle Application Server. OC4J Plug-in works with Sun ONE Web Server for UNIX, and Microsoft Internet Information Server (IIS) for Windows.

See Also:

It also contains information about using mod_oc4j in a non-Oracle Apache.
Topics discussed are:

- Overview
- Downloading OC4J Plug-in
- Installing OC4J Plug-in
- Configuring OC4J Plug-in on Sun ONE
- Configuring OC4J Plug-in for IIS
- OC4J Plug-in Configuration File
- Integrating Generic Apache with Oracle Application Server

Overview

OC4J Plug-in is a shared library that can be loaded into IIS, or Sun ONE HTTP listener. It provides functionality to route requests directly from a third party listener to OC4J in the same manner mod_oc4j routes requests from Oracle HTTP Server to OC4J. Thus, requests for OC4J can be directly routed from IIS or Sun ONE to one or more OC4J JVMs using the AJP or AJP over SSL protocol.

Note: OracleAS Proxy Plug-in and OracleAS SSO Plug-in are certified to work with the entire Oracle Application Server stack, such as Oracle Application Server Portal and Oracle Application Server Wireless. However, OC4J Plug-in is only certified to run customer applications. For example, you cannot route requests from Sun ONE using OC4J Plug-in to an OC4J container where Oracle Application Server Wireless is running.
Downloading OC4J Plug-in

OC4J Plug-in is available on the Oracle Application Server 10g Companion CD, which is included in your Oracle Application Server CD Pack.

Installing OC4J Plug-in

On the Oracle Application Server 10g Companion CD, the files are located at /plugins/solaris/ for UNIX and /plugins/win32/ for Windows.

Table C–1 contains information about the shared libraries for OC4J Plug-in.

<table>
<thead>
<tr>
<th>Platform</th>
<th>File Name</th>
<th>Location and Description</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNIX</td>
<td>opii.so</td>
<td>opii.so is the OC4J plug-in for Sun ONE Web listener. It is located in the /plugins/solaris/sunone directory.</td>
<td>To install the plug-in into the listener, place opii.so in a directory to which the listener has read and execute privileges.</td>
</tr>
<tr>
<td>Windows</td>
<td>opii.dll</td>
<td>opii.dll is the OC4J plug-in file for the IIS Web listener. It is located in the /plugins/win32/iis directory.</td>
<td>To install the plug-in into the listener, copy opii.dll to a directory the listener can access.</td>
</tr>
<tr>
<td></td>
<td>opii_sunone.dll</td>
<td>opii_sunone.dll is the OC4J plug-in for SUN ONE Web listener. It is located in the /plugins/win32/sunone directory.</td>
<td>To install the plug-in into the listener, copy opii_sunone.dll to a directory the listener can access.</td>
</tr>
</tbody>
</table>
Configuring OC4J Plug-in on Sun ONE

Place the opii.so file in a directory such as /sunone/opii.so, where it is readable by the Sun ONE listener. The following examples assume that Sun ONE is installed in a directory called /sunone, and that the instance being configured exists under /sunone/https-mymachine.

1. Add the following lines at the end of /sunone/https-mymachine/magnus.conf:

   Init fn="load-modules" shlib="/sunone/opii.so" func=opii_init,opii_objecttype,opii_service,opii_child_init
   Init fn="opii_init" log_file="/sunone/https-mymachine/logs/opii.log" log_level=error server_defs="/sunone/https-machine/config/opii.conf"
   Init fn="opii_child_init" LateInit=yes

   where, log_file points to a file where OC4J Plug-in messages will be logged and server_defs points to an OC4J configuration file.

   See Also: "OC4J Plug-in Configuration File" on page C-5

2. Make the following modifications to /sunone/https-mymachine/obj.conf:
   a. Add the following line before any ObjectType line:

      ObjectType fn=opii_objecttype

   b. Add the following line before all other lines that begin with the word "Service":

      Service type="oracle/opii" fn="opii_service" UseOutStreamSize=8192

   Note: Not all versions of Sun ONE support UseOutputStreamSize. Refer to Sun ONE documentation for details.

3. If you want to enable the OC4J status page, which is equivalent to the URL /oc4j-service in mod_oc4j for Oracle HTTP Server, then make the following two changes to obj.conf:
   a. Add the following line above the other NameTrans entries in obj.conf:

      NameTrans fn=assign-name from="/oc4j-service" name="opii-status"

   b. Add the following section at the end of obj.conf:

   Note: In order to use the OracleAS SSO Plug-in or to turn on SSL with the OC4J Plug-in when using the plug-ins within IIS 6.0 on Microsoft Windows 2003, the permissions on the .dll files in the %ORACLE_HOME%\bin location must be changed. The .dll files must have execution permissions for the user NETWORK SERVICE added.

   Do not complete this operation during normal installation.

   Because IIS 6.0 is run as the user NETWORK SYSTEM, the plug-ins will not function correctly unless the necessary permissions are granted.
Configuring OC4J Plug-in for IIS

Perform the following steps to configure OC4J Plug-in for IIS:

1. Edit your registry to create a new registry key named \HKEY_LOCAL_MACHINE\SOFTWARE\Oracle\OPII
2. Specify the exact location of your configuration file with the name server_defs, and a value pointing to the location of your configuration file, for example d:\opii\opii.conf.

   See Also: “OC4J Plug-in Configuration File” on page C-5

3. (Optional) Specify a log_file and log_level:
   a. Add a string value with the name log_file, and the desired location of the log file, for example, d:\opii\plugin.log.
   b. Add a string value with the name log_level, and a value for the desired log level. Valid values are debug, inform, error, and emerg.
   c. If you want to enable the OC4J Plug-in status page, a page equivalent to mod_oc4j/oc4j-service URL, add a string value with the name status_uri and a value like /oc4j-service.

4. Using the IIS management console, add a new virtual directory to your IIS Web site with the same physical path as that of opii.dll. Name the directory opii and give it execute access.
5. Using the IIS management console, configure the plugin as an allowed Web Service Extension.
6. Using the IIS management console, add opii.dll as a filter in your IIS Web site. The name of the filter should be opii and its executable must point to the directory contain opii.dll, for example, d:\opii\opii.dll.
7. If you want to use dynamic routing, ensure that ORACLE_HOME is set in the system environment or plugin config file using the Oc4jOracleHome directive. Using the IIS management console, set the identity of the Application Pool containing the plugin to “Local System” so that the plugin can communicate with OPMN.
8. Restart IIS (stop and then start the IIS server), ensuring that the filter is marked with a green arrow pointing up.

   Note: To restart IIS, you must stop all of the IIS services through the control panel, or restart the computer. This is the only way to ensure that the .dll is reloaded. Restarting IIS through the management console is not sufficient.

Configuring Anonymous Access for IIS

Perform the following steps if you want OC4J to perform the authentication:

1. In the IIS Management GUI, right click the default Web site and select Properties.
2. Select the Directory Security tab and click the Edit button under Anonymous Access and Authentication Control. Be sure that the Anonymous access is checked and that basic authentication and integrated Windows Authentication are both unchecked.

Note: If you want IIS to perform authentication and simply pass the user name to OC4J, then do not disable authentication in IIS.

**OC4J Plug-in Configuration File**

When you set up the OC4J Plug-in in the third party listener, the configuration file points at a server_defs file, or the OC4J Plug-in configuration file. This file defines the OC4J instances that the OC4J Plug-in communicates with. It has the same syntax as the mod_oc4j file for Oracle HTTP Server. For example, a configuration file that contains only the following line:

```
Oc4jMount /j2ee/* ajp13://localhost:3000
```

routes any requests to URLs that begin with /j2ee/ to the OC4J instance that has an AJP listener on the localhost interface on port 3000.

All of the Oc4j* directives defined for mod_oc4j also work for OC4J Plug-in. In addition to these directives, the OC4J Plug-in-specific directives Oc4jOracleHome can be used in place of setting the ORACLE_HOME directive in the environment for the third party listener. An ORACLE_HOME value is required if you want to use the dynamic functionality of the OC4J Plug-in.

See Also: "mod_oc4j Configuration File and Directives" on page 8-9

The dynamic routing functionality of the OC4J Plug-in provides the same Oc4jMount syntax as mod_oc4j for routing to OC4J instances that are managed by OPMN. Accordingly, you can mount OC4J instances or clusters instead of just pointing at the host and port of a single JVM. In order to accomplish this, the OC4J Plug-in must be able to communicate with an ONS daemon on the same machine. If Oracle Application Server is installed on the same machine as the OC4J Plug-in, then this can be accomplished simply by setting either ORACLE_HOME or Oc4jOracleHome directive to point to the location of the ORACLE_HOME, and ensuring that the third party listener is running as the same user as Oracle Application Server, or root on UNIX.

See Also: "Running Oracle HTTP Server as Root" on page 4-4

If Oracle Application Server is not installed on the same machine, then the standalone ONS daemon must be installed. OC4J Plug-in supports all the mod_oc4j functionality, including AJP over SSL and use of port tunneling.

See Also: "Understanding Port Tunneling" on page 10-7

**Integrating Generic Apache with Oracle Application Server**

In Oracle Application Server, v10g Release 2 (10.1.2), you can integrate generic Apache with Oracle Application Server. In doing so, you can route requests from generic Apache to OC4J in the same manner as routing requests using Oracle HTTP Server and mod_oc4j. Generic Apache is Apache version 1.3.xx, and not Apache 2.x.
Using Oracle Notification Service (ONS), the communication method utilized between mod_oc4j and OC4j, you can load mod_oc4j into a generic Apache instance and use it in a static routing configuration without requiring any other Oracle infrastructure. In combination with mod_onsint and ONS, mod_oc4j can utilize the same dynamic configuration and failover options that are available when using Oracle HTTP Server.

This section discusses the following topics:
- Integration Requirements
- Generic Apache Files
- Setting Up a Static Configuration with mod_oc4j
- Setting Up a Dynamic Configuration with mod_oc4j and mod_onsint
- Integrating with Oracle Process Manager and Notification Server

**Integration Requirements**

mod_oc4j and mod_onsint require the following open source software packages to be included in generic Apache builds that will be integrated with Oracle Application Server:

- Enhanced API (EAPI) provided as part of mod_ssl. EAPI provides a context mechanism that is used extensively by mod_onsint and mod_oc4j to share information and function callbacks between modules without introducing link time dependencies. EAPI is provided by configuring Apache with mod_ssl.

**Note:** mod_ssl does not need to be loaded at runtime as it is the integration of EAPI provided by mod_ssl that is important.

- (UNIX only) mm shared memory library. The mm library is used on UNIX platforms to share routing information between all of the child processes that make up an Apache instance on UNIX. This library is not necessary on Windows platforms since the Apache architecture on Windows uses a single multi-threaded process instead of many single-threaded processes.

**See Also:** http://www.modssl.org

**Note:** mod_oc4j is supported in Apache versions 1.3.x only. It is not supported in Apache 2.0.x versions.

**See Also:** http://www.ossp.org/pkg/lib/mm/

---

**See Also:**
- Oracle HTTP Server Standalone Administrator's Guide Based On Apache 2.0
- Oracle HTTP Server Standalone Administrator's Guide Based On Apache 1.3
Generic Apache Files

Four libraries need to be accessible by the generic Apache instance that is going to be integrated with Oracle Application Server. If mod_oc4j is used in a static configuration and mod_onsint is not used, then you need only two libraries.

On UNIX, the four files and their locations within an ORACLE_HOME are:

$ORACLE_HOME/Apache/Apache/libexec/mod_oc4j.so
$ORACLE_HOME/Apache/Apache/libexec/mod_onsint.so
$ORACLE_HOME/opmn/lib/libons.so
$ORACLE_HOME/lib/libdms2.so

On Windows, the four files and their locations within an ORACLE_HOME are:

%ORACLE_HOME%\Apache\Apache\modules\ApacheModuleOc4j.dll
%ORACLE_HOME%\Apache\Apache\modules\ApacheModuleOnsint.dll
%ORACLE_HOME%\opmn\bin\onsclient.dll
%ORACLE_HOME%\bin\yod.dll

It is easiest if the binaries for the two modules are copied into the same location as the other modules in the generic Apache installation (libexec on UNIX, and modules on Windows), although this is not a requirement. Full paths can be used if you want to place the binaries elsewhere. The dms and ons libraries do not need to be in any specific location, but they must be in the your LD_LIBRARY_PATH on UNIX, and the PATH on Windows. On UNIX, this is most easily accomplished by editing the apachectl script used to start the generic Apache instance to set the LD_LIBRARY_PATH appropriately. On Windows, this is most easily accomplished by placing the appropriate directory into the System environment variable PATH. However, if more than one generic Apache instance is running on the same machine, then some other mechanism might be needed.

Setting Up a Static Configuration with mod_oc4j

A simple configuration can be constructed using generic Apache and only mod_oc4j. In this configuration, the host and port of all OC4J instances must be statically configured. There is no automatic registration of new JVMs, nor are failed JVMs ever removed from the routing table used by mod_oc4j. The advantage of this configuration is its simplicity, including the fact that it does not require the availability of other Oracle Application Server infrastructure components, such as ONS. The following is an example of such a configuration. This configuration loads mod_oc4j and provides routing of all requests starting with /j2ee/ to two different JVMs, both located on the same machine, one at port 3001, and the other at port 3002:

LoadModule onsint_module libexec/mod_onsint.so
LoadModule oc4j_module libexec/mod_oc4j.so
Oc4jMount /j2ee/* ajp13://localhost:3001,localhost:3002

On Windows, change the line used to load mod_oc4j to the following:

LoadModule onsint_module modules/ApacheModuleOnsint.dll
LoadModule oc4j_module modules/ApacheModuleOc4j.dll
On UNIX, this assumes that the mod_oc4j.so file will be copied into the libexec directory within the Apache installation. On Windows, it means that the ApacheModuleOc4j.dll file will be copied to the modules directory within the Apache installation.

In order to utilize mod_oc4j, ORACLE_HOME must be set to point to an Oracle Application Server. On UNIX, this can be accomplished by adding the setting of ORACLE_HOME to the apachectl script used to start the generic Apache instance. On Windows, this is most easily accomplished by setting ORACLE_HOME as a System environment variable.

Setting Up a Dynamic Configuration with mod_oc4j and mod_onsint

In order to provide full mod_oc4j functionality including dynamic detection of new JVMs and Oracle Application Server installations, mod_oc4j must be combined with mod_onsint.

In order to utilize mod_onsint and mod_oc4j, ORACLE_HOME must be set to point to an Oracle Application Server instance where OPMN is running. On UNIX, this can be accomplished by adding the setting of ORACLE_HOME to the apachectl script used to start the generic Apache instance. On Windows, this is most easily accomplished by setting ORACLE_HOME as a System environment variable.

The following configuration shows how to load the modules and mount /j2ee to the OC4J instance, myinstance, running within the Oracle Application Server cluster, mycluster.

```
LoadModule onsint_module libexec/mod_onsint.so
LoadModule oc4j_module libexec/mod_oc4j.so
Oc4jMount /j2ee/* cluster://mycluster/myinstance
```

Any allowable Oc4jMount syntax available from within Oracle HTTP Server is available when used with generic Apache. This configuration supports all of the same routing and availability features that mod_oc4j offers when running within Oracle HTTP Server, including dynamic discovery of new OC4J processes and instances as they are added and failover of both stateless and session based requests.

Integrating with Oracle Process Manager and Notification Server

Oracle Process Manager and Notification Server (OPMN) can be configured to provide process management, such as starting, stopping, and restart capability for a generic Apache installation. To do this, the Apache instance must have mod_onsint configured. It should have the standard Apache directory layout, that is, the directory structure created by doing a standard Apache 1.3 installation.

```
Note:  When generic Apache is started using OPMN, you have to set OpmnHostPort directive in httpd.conf or Apache will fail to start. For more information on OpmnHostPort, refer to "mod_onsint" on page 8-17
```

To configure OPMN to manage this Apache instance, the following changes must be made to opmn.xml:

```
In the module section add the GENERIC_APACHE module-id to the configuration for libopmnohs, such as:
<module path="$ORACLE_HOME/opmn/lib/libopmnohs">
```

C-8  Oracle HTTP Server Administrator's Guide
In the HTTP_Server section, you must set the module to GENERIC_APACHE and set an apache-home, such as:

```xml
<module id="OHS"/>
<module id="GENERIC_APACHE"/>
</module>
```

In the HTTP_Server section, you must set the module to GENERIC_APACHE and set an apache-home, such as:

```xml
<ias-component id="HTTP_Server">
  <process-type id="HTTP_Server" module-id="GENERIC_APACHE">
    <module-data>
      <category id="start-parameters">
        <data id="apache-home" value="/private/my/path/to/APACHE"/>
      </category>
    </module-data>
    <process-set id="HTTP_Server" numprocs="1"/>
  </process-type>
</ias-component>
```

You can configure either an Oracle HTTP Server instance or a generic Apache instance into any opmn.xml. Configuring both in the same opmn.xml is currently not supported.

**See Also:** "opmn.xml" on page E-3
This chapter contains information about mod_oc4j load balancing, including metric-based load balancing. Topics include:

- Load Balancing Policies
- Load Balancing Parameters
- Metric-based Load Balancing

**Load Balancing Policies**

This section contains information about load balancing policies that mod_oc4j supports:

- Random
- Round Robin
- Random with Local Affinity
- Round Robin with Local Affinity
- Random using Routing Weight
- Round Robin using Routing Weight
- Metric Based
- Metric Based with Local Affinity

**Random**

mod_oc4j randomly selects an OC4J instance from a list of OC4J instances that are candidates to service a request.

**Round Robin**

mod_oc4j randomly selects an OC4J instance from an ordered list of OC4J instances that are candidates to service a request. Other OC4J instances are selected from the ordered list in turn, until the initially selected server is selected again. This sequence is repeated. If a particular OC4J instance is stopped or is unavailable, then that instance is skipped (no attempt is made to select it) until it can be brought back in service.
**Load Balancing Parameters**

**Random with Local Affinity**

mod_oc4j randomly selects local OC4J processes to service requests. When no local OC4J processes are available, mod_oc4j randomly selects remote OC4J processes and gives them equal opportunity to be selected.

**Round Robin with Local Affinity**

mod_oc4j routes all requests to local OC4J processes in a round robin manner. When no local processes are available, mod_oc4j routes requests equally to each OC4J process on different hosts.

**Random using Routing Weight**

mod_oc4j distributes requests according to the routing weight configured for each host. One OC4J process is selected randomly from the OC4J processes on that host.

**Round Robin using Routing Weight**

mod_oc4j distributes the total request load to OC4J processes on each host based on the routing weight configured to each host. mod_oc4j selects an OC4J process in round robin manner from the OC4J processes on that host.

**Metric Based**

mod_oc4j routes requests based on run time metrics from OC4J processes that indicate how much load can be placed on the OC4J process.

**Metric Based with Local Affinity**

mod_oc4j routes all requests to local OC4J processes based on the run time performance metrics of OC4J processes. When there are no local OC4J processes available, mod_oc4j routes requests to each OC4J process on different hosts as per their performance metrics only.

**Load Balancing Parameters**

This section discusses the following load balancing parameters:

- **Oc4jSelectMethod**
- **Oc4jRoutingWeight**

**Oc4jSelectMethod**

Selects an OC4J instance for load balancing.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td>Oc4jSelectMethod roundrobin</td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>If Oc4jSelectMethod is not specified, it defaults to &quot;Oc4jSelectMethod roundrobin&quot;</td>
</tr>
</tbody>
</table>
Load Balancing Parameters

This directive is only applicable to the base server for Oracle Application Server 10g Release 2 (10.1.2) and an error will be printed at startup if specified within a VirtualHost container.

`Oc4jRoutingWeight`

Associates a request routing weight for each machine during load balancing. Weighted routing is a load balancing strategy that distributes requests according to a predefined value assigned to each machine based on the predicted ability to handle load.

<table>
<thead>
<tr>
<th>Category</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Syntax</td>
<td><code>Oc4jRoutingWeight &lt;node_name&gt; &lt;routing_weight&gt;</code></td>
</tr>
<tr>
<td>Required</td>
<td>No</td>
</tr>
<tr>
<td>Default</td>
<td>It defaults to OC4J processes on all the nodes with routing weight as 1. If <code>Oc4jRoutingWeight</code> is specified, but some hosts are not specified, it defaults to OC4J processes on any non-specified node with routing weight as 1.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>

Metric-based Load Balancing

Metric-based Load Balancing is a way to distribute request load among OC4Js based on a "health" metric that each OC4J reports. The metric range is between 0 and 100, where 0 is very busy, or unhealthy, and 100 is not busy, or healthy. When metric-based load balancing is enabled, requests are distributed among OC4Js based on a ratio of a metric received for an individual OC4J, divided by the total of the metrics received from all the OC4Js.

For example, OC4J process p1 reports a metric of 20, process p2 reports a metric of 40, and process p3 reports a metric of 90. The requests would be distributed as follows:

- p1 is routed 20 out of every 150 requests (13%)
- p2 is routed 40 out of every 150 requests (27%)
- p3 is routed 90 out of every 150 requests (60%)

### Example

- There are two hosts in an Oracle Application Server cluster: Host_A and Host_B. Each has Oracle HTTP Server and OC4J processes running on them.
  - `Oc4jSelectMethod random:local`
  - `Oc4jRoutingWeight Host_A 3`<br>`Oc4jRoutingWeight Host_B 2`
  - `Oc4jRoutingWeight` directives are ignored. mod_oc4j on Host_A randomly routes all requests to OC4J processes on Host_A. mod_oc4j on Host_B randomly routes all requests to OC4J processes on Host_B.

- There are four hosts in an Oracle Application Server cluster: Host_A, Host_B, Host_C, and Host_D. Each has Oracle HTTP Server and OC4J processes running on them.
  - `Oc4jSelectMethod roundrobin:weighted`
  - `Oc4jRoutingWeight Host_A 3`<br>`Oc4jRoutingWeight Host_B 2`
  - mod_oc4j on all the machines route three times the number of requests to OC4J processes running on Host_A, two times the number of requests on Host_B, one time the number of requests on Host_C, and one time the number of requests on Host_D in a round robin manner.

- There are four hosts in an Oracle Application Server cluster: Host_A, Host_B, Host_C, and Host_D. Each has Oracle HTTP Server and OC4J processes running on them.
  - `Oc4jSelectMethod roundrobin:weighted`
  - mod_oc4j on all the machines route requests equally to OC4J processes on Host_A, Host_B, Host_C, and Host_D in a round robin manner.

### Usage

- `Oc4jRoutingWeight <node_name> <routing_weight>` is taken into account only when `Oc4jSelectMethod` specifies weighted.
- `mod_oc4j` associates a request routing weight to each node. `node_name` can be in host name or IP address format. For hosts with multiple interfaces, if different interfaces are specified, it is assumed that they are different hosts.

This directive is only applicable to the base server for Oracle Application Server 10g Release 2 (10.1.2) and an error will be printed at startup if specified within a VirtualHost container.
You must configure Oracle HTTP Server and OC4J to enable metric-based load balancing. The following sections contain the required configuration information:

- Configuring Oracle HTTP Server
- Configuring OC4J

**Configuring Oracle HTTP Server**

On the Oracle HTTP Server side, specify "Oc4jSelectMethod metric" or "Oc4jSelectMethod metric:local" in mod_oc4j.conf.

**See Also:**

- "Oc4jSelectMethod" on page D-2
- "Metric Based" on page D-2
- "Metric Based with Local Affinity" on page D-2

**Configuring OC4J**

On the OC4J side, you must configure the metric collector in `ORACLE_HOME/j2ee/home/config/server.xml` in UNIX or `ORACLE_HOME\j2ee\home\config\server.xml` on Windows. Configuring the `<metric-collector>` element tells OC4J to start sending a metric to mod_oc4j so that mod_oc4j can make routing decisions to load balance incoming requests to a list of available OC4J instances.

The metric sent from OC4J to mod_oc4j is used only when metric-based load balancing is specified for mod_oc4j and when OC4J runs in an Oracle Application Server environment.

If you specify metric-based load balancing in mod_oc4j and do not specify the `<metric-collector>` element in `server.xml`, then mod_oc4j expects OC4J to send metrics, but OC4J does not send metrics. In this case, mod_oc4j reports the following warning message:

```
No run time metrics for oc4j(opmnid=%s) in notification Oc4jSelectMethod is configured to use run time metrics, please make sure OC4J side is configured accordingly. Default to 50.
```

In this case, mod_oc4j uses the value "50" for each of the OC4J processes and continues.

Likewise, if you specify the `<metric-collector>` element in `server.xml`, but do not specify metric-based load balancing in mod_oc4j, then OC4J sends metrics but mod_oc4j is not configured to receive metrics. In this case, mod_oc4j ignores the metrics and uses whatever the configured method is for load balancing. You specify the load balancing method with Oc4jSelectMethod. If no Oc4jSelectMethod is specified, then mod_oc4j uses the default, which is roundrobin.

All OC4Js that are used from this Oracle HTTP Server instance must be configured identically. Otherwise, the number returned from the OC4Js will not be comparable and can produce some very poor load balancing results.

When mod_oc4j receives a notification containing the metrics information from OC4J, it immediately changes the request routing behavior. The default interval between notifications from OC4J is 30 seconds. This value can be configured using the system property `opmnPingInterval`, which is passed on the command line when OC4J is started by OPMN. To change the interval between notifications, specify the following in `opmn.xml` under the OC4J `<process-set>` configuration element:
Specifying Metrics for OC4J
The following two methods can be used to specify metrics for OC4J:

- Configuring Metric-based Load Balancing to Use the DMSMetricCollector
- Building Your Own Metric Collector

Configuring Metric-based Load Balancing to Use the DMSMetricCollector
In this out of the box method, the `<metric-collector>` element takes a single attribute: `classname`. This attribute defines an interface for gathering and calculating a server-wide metric. Use `oracle.oc4j.server.DMSMetricCollector` for the `classname` attribute when using a DMS-based metric collector. A DMSMetricCollector instance takes several parameters.

The DMS metric is specified using the ‘dms-noun’ parameter, which is shown in the configuration example below. This is the metric on which the DMSMetricCollector bases its calculation. The recommended DMS metric for metric-based load balancing is `/oc4j/default/WEBs/processRequest.time`. This metric represents the processing time of the servlets in the default Web application.

The value sent to OC4J is a weighted average of the value computed based on the current DMS metric value, and the last value computed the last time a value was sent. The default weight is 0.7 for the current value, and 0.3 for the previous value. To modify the weights, one may set the "history-proportion" as shown the following example. This results in a weight of 0.8 for the current value and 0.2 for the previous value.

```xml
<metric-collector classname="oracle.oc4j.server.DMSMetricCollector">
    <init-param>
        <param-name>dms-noun</param-name>
        <param-value>/oc4j/default/WEBs/processRequest.time</param-value>
    </init-param>
    <init-param>
        <param-name>history-proportion</param-name>
        <param-value>0.2</param-value>
    </init-param>
    <init-param>
        <param-name>debug</param-name>
        <param-value>debug</param-value>
    </init-param>
</metric-collector>
```
How DMS Metrics are Converted for Metric-based Load Balancing

When `getMetrics()` is called, the value of the DMS metric specified by the `dms-noun` parameter is obtained. The `delta` with the previous measurement is computed.

Since the scale is from 0 to 100, and the measurement is potentially unbounded, the following formula is applied:

\[
\text{metric} = \frac{100}{(1 + \log(1 + \text{delta}))}
\]

As outlined above, this metric should match the current situation, but also reflect on previous metric history. You can assign a weight of 1/3 to the previous history and 2/3 for the average just collected in order to form the new metric.

This new metric becomes the next metric’s history, and factors in less and less as time passes. As shown in the configuration example, you can specify the proportion of the previous metric that enters in new metrics by setting the `history-proportion` parameter to a floating point value between 0.0 and 1.0. Higher values mean that historical values matter more, making the metric less volatile. A lower value makes the metric reflect the most recent metric. The metric returned is as follows:

\[
\text{smoothedmetric} = ((1 - \text{history-proportion}) \times \text{metric}) + (\text{history-proportion} \times \text{previousmetric})
\]

The `smoothedmetric` is what is sent to `mod_oc4j` for load balancing purposes.

Building Your Own Metric Collector

You can implement the interface `oracle.oc4j.api.MetricCollector` to supply your own metric collector to `mod_oc4j`. The metric has to be between 0 and 100.

All metric collectors must implement the interface `oracle.oc4j.api.MetricCollector`. The concrete metric collector must have a constructor with no parameters so it can be instantiated.

The schema elements for the feature are in `server.xml`, and look like:

```xml
<metric-collector classname="my.package.name.MyClassName">
  <init-param>
    <param-name>mysetting</param-name>
    <param-value>12345</param-value>
  </init-param>
</metric-collector>
```

As per the preceding example, 0 or more parameters can be set on the metric collector, and are passed to it when `setParameters()` method is called. `setEnabled(true)` is called once after `setParameters()`. It signals the metric collector that it can begin gathering data as needed.
After oracle.oc4j.api.MetricCollector has been implemented, package your metric in a jar file and add it to your library path, using the following, in server.xml:

```xml
<library path="<path to>/mymetric.jar"/>
```

oracle.oc4j.api.MetricCollector Here is the oracle.oc4j.api.MetricCollector interface:

```java
package oracle.oc4j.api;
import java.util.Map;

/**
 * Defines an interface for gathering and obtaining a server-wide metric.
 * The metric is used in IAS mode, by mod_oc4j, to load balance between
 * virtual oc4j instances.
 * The metric value is relative, and should be between 0 and 100, both
 * inclusive.
 * When configured for metric load balancing,
 * Mod_oc4j will route preferably to an oc4j with the greater value.
 * Concrete instances of this class must have a public empty constructor in
 * order to be loaded and instantiated.
 */
public interface MetricCollector {

    /**
     * Support for debugging: This is a property name to set to true in order
     * to display the metric that is sent from the server
     */
    String OC4J_METRIC_DEBUG_PROPERTY = "oc4j.metric.debug";

    /**
     * Debugging flag that depends on @see {#OC4J_METRIC_DEBUG_PROPERTY}
     */
    boolean DEBUG = Boolean.getBoolean(OC4J_METRIC_DEBUG_PROPERTY);

    /**
     * Initial metric to return when no measurement has been made (property key)
     */
    String OC4J_INITIAL_METRIC_PROPERTY = "oc4j.metric.initial";

    /**
     * Initial metric to return when no measurement has been made.
     * Default is 50
     */
    int INITIAL_METRIC = Integer.getInteger(OC4J_INITIAL_METRIC_PROPERTY, 50).intValue();

    /**
     * Enabled flag for the collector.
     * @return true if the collector is collecting data
     */
    boolean isEnabled();

    /**
     * If the custom metric collector starts threads, the threads need
     * to be daemon threads. Otherwise they may prevent the server from
     * shutting down in an orderly fashion.
     */
```

Note:

If the custom metric collector starts threads, the threads need to be daemon threads. Otherwise they may prevent the server from shutting down in an orderly fashion.
/**
 * void setEnabled( boolean enabled);
 */

/**
 * The parameters the metric collector is configured with.
 * This method will be called even when the set of parameters is null.
 * @param params the key/value pairs the metric collector is configured with,
 * or <code>null</code> if none
 */
void setParameters( Map params );

/**
 * @return a metric between 0 and 100, inclusive. 100 is better, 0 is worse
 */
int getMetric();
This appendix lists commonly used Oracle HTTP Server configuration files. Files discussed are:

- dms.conf
- httpd.conf
- iaspt.conf
- mime.types
- mod_oci4j.conf
- mod_osso.conf
- opmn.xml
- oracle_apache.conf
- php.ini
- ssl.conf

**dms.conf**

Enables you to monitor performance of site components with Oracle's Dynamic Monitoring Service (DMS).

It is located at:

- UNIX: `ORACLE_HOME/Apache/Apache/conf`
- Windows: `ORACLE_HOME\Apache\Apache\conf`

**See Also:** Oracle Application Server Performance Guide

**httpd.conf**

This is a server configuration file which typically contains directives that affect how the server runs, such as user and group IDs it should use, and location of other files. Because the server configuration file is the main file that the server starts with, Oracle HTTP Server does not include any directive that says where to locate it. The location is passed on command line when the server starts.

It is located at:

- UNIX: `ORACLE_HOME/Apache/Apache/conf`
- Windows: `ORACLE_HOME\Apache\Apache\conf`
You should use only this file, and not srm.conf or access.conf because it is much easier to manage a single configuration file.

**Note:** If you have an Oracle Application Server installation in /home/your_directory/orahome and it is linked to /private/your_directory/orahome, the files in the installation are accessible from either /home/your_directory/orahome or /private/your_directory/orahome.

After installation, the httpd.conf file contains an entry for all the files that are included in it that use the original Oracle home path. For example:

```bash
include /home/your_directory/orahome/Apache/Apache/conf/dms.conf
```

Do not replace the original Oracle home path with the linked Oracle home path.

### httpd.conf File Structure

httpd.conf is arranged in the following sections:

- Global Environment
- Main Server Configuration
- Virtual Hosts Parameters

#### Global Environment

This is section one of the httpd.conf file. It contains configuration directives dealing with Oracle HTTP Server.

**See Also:**

- "Specifying File Locations" on page 3-3
- "Configuring the Number of Processes and Connections" on page 4-2
- "Specifying Listener Ports and Addresses" on page 5-1

#### Main Server Configuration

This is section two of the httpd.conf file. It contains the directives of the default server.

**See Also:** "Setting Server and Administrator Functions" on page 3-1.

#### Virtual Hosts Parameters

This is section three of the httpd.conf file. It contains parameters specific to virtual hosts, which override some of the main server configuration defaults.

### iaspt.conf

Configures the port tunneling process. Port tunneling allows all communication between Oracle HTTP Server and OC4J to happen on a single, or a small number of ports.
It is located at:
- UNIX: ORACLE_HOME/iaspt/conf
- Windows: ORACLE_HOME\iaspt\conf

See Also: "Understanding Port Tunneling" on page 10-7

mime.types

Controls the Multi Internet media types that are sent to the client for the given file extensions. Sending the correct media type to the client is important so that the client knows how to handle the content of the file. You can add extra types in the mime type file or add an AddType directive in the configuration file.

It is located at:
- UNIX: ORACLE_HOME/Apache/Apache/conf
- Windows: ORACLE_HOME\Apache\Apache\conf

See Also: "mod_mime" on page 8-8

mod_oc4j.conf

Configures and loads the mod_oc4j module, and is enabled by default. It routes requests from Oracle HTTP Server to OC4J, and therefore contains routing information.

It is located at:
- UNIX: ORACLE_HOME/Apache/Apache/conf
- Windows: ORACLE_HOME\Apache\Apache\conf

See Also: "mod_oc4j" on page 8-9

mod_osso.conf

Configures mod_osso, which enables single sign-on for Oracle HTTP Server.

It is located at:
- UNIX: ORACLE_HOME/Apache/Apache/conf
- Windows: ORACLE_HOME\Apache\Apache\conf

See Also: "mod_osso" on page 8-19

opmn.xml

Describes the processes that Oracle Process Manager and Notification Server (OPMN) manages within an Oracle Application Server installation.

The opmn.xml file is the main configuration file for OPMN. It contains information for the ONS, the PM, and Oracle Application Server component-specific configuration. opmn.xml shows you which Oracle Application Server components OPMN is managing on your system. It contains Oracle Application Server component entries arranged in the following hierarchical structure:

<ias-component>
  <process-type>
<process-set>

  ■ <ias-component>: This entry represents the Oracle Application Server component. It enables management of the component for processes such as starting and stopping.
  ■ <process-type>: This subcomponent of the <ias-component> entry declares the type of process to run by association with a specific PM module.
  ■ <process-set>: This sub-subcomponent of the <ias-component> entry enables you to declare different sets of optional runtime arguments and environments for the Oracle Application Server component.

opmn.xml is located at:
  ■ UNIX: ORACLE_HOME/opmn/conf
  ■ Windows: ORACLE_HOME\opmn\conf

See Also: Oracle Process Manager and Notification Server Administrator's Guide

oracle_apache.conf

Stores configuration files of supported modules. It contains directives to include the following configuration files:
  ■ aqxml.conf
  ■ moddav.conf
  ■ ojsp.conf
  ■ plsql.conf
  ■ uix.conf

Note: For the Oracle Application Server Infrastructure install type, another configuration file is included by oracle_apache.conf called oracle_ocm.conf. It contains configuration for Oracle Application Server Certificate Authority.

aqxml.conf

Enables and configures Advanced Queuing.
It is located at:
  ■ UNIX: ORACLE_HOME/Apache/Apache/conf
  ■ Windows: ORACLE_HOME\Apache\Apache\conf

moddav.conf

Configures and loads the mod_oradav module to enable distributed authoring and versioning of Web documents.
It is located at:
  ■ UNIX: ORACLE_HOME/Apache/oradav/conf
  ■ Windows: ORACLE_HOME\Apache\oradav\conf
ojsp.conf

Configures Java Server Pages.
It is located at:
- UNIX: \$ORACLE_HOME/Apache/jsp/conf
- Windows: \$ORACLE_HOME\Apache\jsp\conf

See Also:  
- Chapter 9, "Configuring and Using mod_oradav"
- "mod_oradav" on page 8-18

plsql.conf

Configures and loads the PL/SQL module.
It is located at:
- UNIX: \$ORACLE_HOME/Apache/modplsql/conf
- Windows: \$ORACLE_HOME\Apache\modplsql\conf

See Also:  "mod_plsql" on page 8-22

uix.conf

Configures Oracle uix.
It is located at:
- UNIX: \$ORACLE_HOME/uix
- Windows: \$ORACLE_HOME\uix

oiddas.conf

Configures the OiD DAS module.
It is located at:
- UNIX: \$ORACLE_HOME/ldap/das
- Windows: \$ORACLE_HOME\ldap\das

See Also:  "mod_php" on page 8-22

php.ini

Configures mod_php. This file should not be renamed as PHP looks for this specific file name.
It is located at:
- UNIX: \$ORACLE_HOME/Apache/Apache/conf
- Windows: \$ORACLE_HOME\Apache\Apache\conf
ssl.conf

ssl.conf includes the SSL definitions and virtual host container. Out of the box, SSL is disabled by default.

It is located at:

- UNIX: `ORACLE_HOME/Apache/Apache/conf`
- Windows: `ORACLE_HOME\Apache\Apache\conf`

See Also: Chapter 11, "Enabling SSL for Oracle HTTP Server"
Frequently Asked Questions

This appendix provides answers to frequently asked questions about Oracle HTTP Server.

See Also: “Frequently Asked Questions” in the Apache Server documentation.

Documentation from the Apache Software Foundation is referenced when applicable.

Note: Readers using this guide in PDF or hard copy formats will be unable to access third-party documentation, which Oracle provides in HTML format only. To access the third-party documentation referenced in this guide, use the HTML version of this guide and click the hyperlinks.

Creating Application-specific Error Pages

Oracle HTTP Server has a default content handler for dealing with errors. You can use the ErrorDocument directive to override the defaults.

See Also: “ErrorDocument directive” in the Apache Server documentation.

Offering HTTPS to ISP (Virtual Host) Customers

For HTTP, Oracle HTTP Server supports two types of virtual hosts: name-based and IP-based. HTTPS supports only IP-based virtual hosts.

If you are using IP-based virtual hosts for HTTP, then the customer has a virtual server listening on port 80 of a per-customer IP address. To provide HTTPS for these customers, simply add an additional virtual host per user listening on port 4443 of that same per-customer IP address and use SSL directives, such as Using mod_omsl Directives to specify the per-customer SSL characteristics. Note that each customer can have their own wallet and server certificate.

If you are using name-based virtual hosts for HTTP, each customer has a virtual server listening on port 80 of a shared IP address. To provide HTTPS for those customers, you can add a single shared IP virtual host listening on port 4443 of the shared IP address. All customers will share the SSL configuration, including the wallet and ISP’s server certificate.

See Also: “Running Oracle HTTP Server as Root” on page 4-4
Using Oracle HTTP Server as Cache

You can use Oracle HTTP Server as a cache by setting the \texttt{ProxyRequests} to "On" and \texttt{CacheRoot} directives.

\textbf{See Also:} "\texttt{ProxyRequests} and \texttt{CacheRoot} directives in the Apache Server documentation."

Using Different Language and Character Set Versions of Document

You can use \textit{multiviews}, a general name given to the Apache server's ability to provide language and character-specific document variants in response to a request.

\textbf{See Also:} "Multiviews" in the Apache Server documentation.

Using OracleAS Web Cache as Front-end

You can use directives such as \texttt{ExpiresActive}, \texttt{ExpiresByType}, \texttt{ExpiresDefault}, to set the length of time that any cache existing between the client and the Web server will cache the returned Web pages.

\textbf{See Also:} "\texttt{ExpiresActive}, \texttt{ExpiresByType}, \texttt{ExpiresDefault} directives" in the Apache Server documentation.

Sending Proxy Sensitive Requests to HTTP Server Behind a Firewall

You should use the Proxy directives, and not the Cache directives, to send proxy sensitive requests across firewalls.

\textbf{mod_oc4j Information}

\texttt{mod_oc4j} is a module that integrates with Web servers, typically Oracle HTTP Server, and routes request to the backend OC4J processes. OPMN module keeps \texttt{mod_oc4j} aware of the status of different OC4J processes, so \texttt{mod_oc4j} routes only to the processes that are up and running. \texttt{mod_oc4j} also understands the concepts of Oracle Application Server Clusters and OC4J islands, and routes accordingly to provide as much transparent failover as possible.

\textbf{See Also:} "\texttt{mod_oc4j}" on page 8-9

\textbf{mod_oc4j Compatibility with Other Web Servers}

\texttt{mod_oc4j} supports other Web servers including IIS, Sun ONE, and non-Oracle HTTP Server Apache Servers.

\textbf{mod_oc4j Communication to OC4J using SSL}

The AJP communication between \texttt{mod_oc4j} and OC4J processes can now be over AJP/SSL. Previously, this was in the clear. Also, the SSL negotiation does not happen each time \texttt{mod_oc4j} and OC4J communicate, resulting in less performance impact.

\textbf{See Also:} "Enabling SSL between \texttt{mod_oc4j} and OC4J" on page 8-15
Oracle HTTP Server Version Number

Oracle HTTP Server is based on Apache version 1.3.31.

Applying Apache Security patches to Oracle HTTP Server

You cannot apply the Apache security patches to Oracle HTTP Server for the following reasons:

- Oracle tests and appropriately modifies security patches before releasing them to Oracle HTTP Server users.
- In many cases those alerts may not be applicable, for example, openSSL alerts, since Oracle has removed those components from the stack in use.
- Oracle releases these patches soon enough that the time-delay impact of getting the patch from Oracle versus open source organization should be minimal and the benefit with respect to supportability, tremendous.

Compressing Output from Oracle HTTP Server

In general, Oracle recommends the use of OracleAS Web Cache for this purpose. There are other freeware modules, such as mod_gzip that may be plugged in for this purpose, but their use is not supported. When using these, there may be an error message with respect to EAPI, but in general that can be ignored.

Supporting PHP

mod_php is fully supported in Release 2 (10.1.2).

See Also: "mod_php" on page 8-22

Creating Namespace that Works Across Firewalls, Clusters, Web Cache

The general idea is that all servers in a distributed Web site should agree on a single URL namespace. Every server serves some part of that namespace, and is able to redirect or proxy requests for URLs that it does not serve to a server that is "closer" to that URL. For example, your namespaces could be the following:

/app1/login.html
/app1/catalog.html
/app1/dologin.jsp
/app2/orderForm.html
/apps/placeOrder.jsp

We could initially map this namespace to two Web servers by putting app1 on server1 and app2 on server2. Server1’s configuration might look like the following:

Redirect permanent /app2 http://server2/app2
Alias /app1 /myApps/application1
<Directory /myApps/application1>
...
</Directory>

Server2’s configuration is complementary. If you decide to partition the namespace by content type (HTML on server1, JSF on server2), change server configuration and move files around, but do not have to make changes to the application itself. The resulting configuration of server1 might look like the following:

Redirect permanent /app2 http://server2/app2
Alias /app1 /myApps/application1
<Directory /myApps/application1>
...
</Directory>
RedirectMatch permanent (.*) \.jsp$ http://server2/$1.jsp
AliasMatch ^/app(.*) \.html$ /myPages/application$1.html

Note that the amount of actual redirection can be minimized by configuring a hardware load balancer like F5 system's BigIP to send requests to server1 or server2 based on the URL.

Protecting Web Site From Hackers

There are many attacks, and new attacks are invented everyday. The following are some general guidelines for securing your site. You can never be completely secure, but you can avoid being an easy target.

- Use a commercial firewall, such as Checkpoint FW-1 or Cisco PIX between your ISP and your Web server. Recognize, however, that not all hackers are outside your organization.
- Use switched ethernet to limit the amount of traffic a compromised server can sniff. Use additional firewalls between Web server machines and highly sensitive internal servers running database and enterprise applications.
- Remove unnecessary network services such as RPC, Finger, telnet from your server machine.
- Carefully validate all input from Web forms. Be especially wary of long input strings and input that contains non-printable characters, HTML tags, or javascript tags.
- Encrypt or randomize the contents of cookies that contain sensitive information. For example, it should be difficult to guess a valid sessionID to prevent a hacker from hijacking a valid session.
- Check often for security patches for all your system and application software, and install them as soon as possible. Be sure these patches come from bona fide sources; download from trusted sites and verify the cryptographic checksum.
- Use an intrusion detection package to monitor for defaced Web pages, viruses, and presence of "rootkits" that indicate hackers have broken in. If possible, mount system executables and Web content on read-only file systems.
- Have a "forensic analysis" package on hand to capture evidence of a break in as soon as detected. This aids in prosecution of the hackers.
Troubleshooting Oracle HTTP Server

This appendix describes common problems that you might encounter when using Oracle HTTP Server, and explains how to solve them.

It contains the following topics:

- Problems and Solutions
- Need More Help?

Problems and Solutions

This section describes common problems and solutions. It contains the following topics:

- Intermittent HTTP-500 errors
- Firewall Between Oracle HTTP Server and OC4J Blocks Connections
- Client IP Address Not Passed Through OracleAS Web Cache
- Certificate Information Lost When Using OracleAS Web Cache
- Oracle HTTP Server Unable to Start Due to Port Conflict
- Machine Overloaded by Number of HTTPD Processes
- Permission Denied When Starting Oracle HTTP Server on Port Below 1024
- Oracle HTTP Server May Fail To Start If PM Files Are Not Located Correctly
- SSO Client Authentication Fails with Webcache Reverse Proxy

Intermittent HTTP-500 errors

Certain Microsoft Internet Explorer security patches have resulted in intermittent HTTP-500 errors, such as MOD_OC4J_0145, MOD_OC4J_0119, MOD_OC4J_0013 errors, when the KeepAlive directive is set on 'On' in Oracle HTTP Server.

Problem

Intermittent HTTP-500 errors caused by bug in Microsoft Internet Explorer.

Solution

There are two possible solutions for this problem:

- Patch all the client Internet Explorer browsers.
- If the preceding option is not practical, set KeepAlive to 'Off' in Oracle HTTP Server.
Consult Metalink Note 269980.1 on http://metalink.oracle.com for details regarding this issue. The easiest way to access the note is to click the Advanced Search button at the top of the OracleMetalink site, and search for Doc ID “269980.1”.

See Also: “KeepAlive” on page 5-4

**Firewall Between Oracle HTTP Server and OC4J Blocks Connections**

Oracle HTTP Server is unable to forward requests to OC4J when certain firewalls are used between them.

**Problem**

Oracle HTTP Server processes maintain persistent connections with OC4J processes. If the firewall times out a connection before Oracle HTTP Server does, then requests to the OC4J processes can result in errors, or can take a very long time, depending on how the firewall and the operating system are configured.

**Solution**

Set the Oracle HTTP Server directive OC4JConnTimeout to a value less than that of the firewall timeout (this is firewall specific).

See Also: “OC4JConnTimeout” on page 8-10

**Client IP Address Not Passed Through OracleAS Web Cache**

When client IP is not passed through OracleAS Web Cache, it can create issues such as:

- Client IP security does not work for allow/deny.
- Access.log has OracleAS Web Cache IP address instead of the client’s IP address.
- OC4J request.getRemoteAddr() returns OracleAS Web Cache IP address.

**Problem**

Normally, when OracleAS Web Cache is used, its IP address is the address seen by Oracle HTTP Server. You can use the UseWebCacheIp configuration option, which is not set by default, to enable Oracle HTTP Server to obtain the IP address of the client.

**Solution**

See Also: “Obtaining Client IP Address” on page 5-4

**Certificate Information Lost When Using OracleAS Web Cache**

Certificate information is not available to OC4J applications when OracleAS Web Cache is used.

**Problem**

When SSL is terminated at OracleAS Web Cache, information is not passed to Oracle HTTP Server and OC4J applications by default.

**Solution**

Use Certheaders feature, which enables the passing of SSL information, such as configuration information, from OracleAS Web Cache to Oracle HTTP Server.
Problems and Solutions

Oracle HTTP Server Unable to Start Due to Port Conflict

You can get the following error if Oracle HTTP Server is unable to start due to port conflict:

```
[crit] (98) Address already in use: make_sock: could not bind to port 7778
```

**Problem**

Oracle HTTP Server is unable to start as its port number is being used by another process.

**Solution**

Determine what process is already using the port by pointing a browser at the address assigned to Oracle HTTP Server and viewing the results. Depending on the results, either change the IP:port address of Oracle HTTP Server, or that of the conflicting process.

Machine Overloaded by Number of HTTPD Processes

When there are too many httpd processes running on a machine, the response time plummets.

**Problem**

When too many httpd processes are started, there are insufficient resources for normal processing.

**Solution**

Lower value of MaxClients to a value the hardware box can accommodate.

See Also:  "MaxClients" on page 4-3

Permission Denied When Starting Oracle HTTP Server on Port Below 1024

You will get the following errors if you try to start Oracle HTTP Server on port below 1024:

```
Bind errors on ports below 1024: PERMISSION DENIED: MAKE_SOCK: COULD NOT BIND TO PORT 443.
```

**Problem**

Oracle HTTP Server will not start on ports below 1024 because root privileges are needed to bind these ports. Also, steps to configure .apachectl have not been followed.

**Solution**

Perform the following steps to enable Oracle HTTP Server to run as root on ports below 1024:

1. Log in as root.
2. Run the following commands in the middle-tier Oracle home:

```
cd ORACLE_HOME/Apache/Apache/bin
```

See Also:  "mod_certheaders" on page 8-3
chown root .apachectl
chmod 6750 .apachectl

Oracle HTTP Server May Fail To Start If PM Files Are Not Located Correctly

Oracle HTTP Server may encounter the following error, and fail to start:
```
[error] Can't locate mod_perl.pm in @INC (@INC contains:$ORACLE_HOME/perl/...)
```
or,
```
[error] Can't locate Apache::Registry.pm in @INC (@INC contains: $ORACLE_HOME/perl/...)
```

**Problem**

mod_perl needs to locate PM files kept under the `ORACLE_HOME/Apache/Apache/mod_perl` directory. Without these PM files, mod_perl will not start.

**Solution**

For UNIX, check that `apachectl` has correctly defined in the variable `PERL5LIB`. It should point to `ORACLE_HOME/Apache/Apache/mod_perl/lib/site_perl/5.6.1/sun4-solaris`

For Windows, check that the environment sub-section in the HTTP Server section in `opmn.xml` has a correct entry for `PERL5LIB`. It should point to `ORACLE_HOME/Apache/Apache/mod_perl/lib/site_perl/5.6.1/lib`

SSO Client Authentication Fails with Webcache Reverse Proxy

SSO client authentication fails with Webcache reverse proxy.

**Problem**

During SSO client login, the client certificate should be authenticated from the browser with the SSO server and connect successfully. However, it fails because the `ssoServer.log` shows it is trying to authenticate the certificate stored in the Webcache wallet and not the one from the browser.

**Solution**

Perform the following steps:

1. Edit `$ORACLE_HOME/Apache/Apache/conf/httpd.conf` and make sure it has the following:
   ```
   LoadModule certheaders_module libexec/mod_certheaders.so
   AddCertHeader HTTPS
   AddCertHeader SSL_CLIENT_CERT
   ```

2. Edit the `$ORACLE_HOME/sso/conf/sso_apache.conf`, and comment out the following line:
   ```
   #SSLOptions +ExportCertData +StdEnvVars
   ```

3. Run `dcmctl updateconfig -ct ohs`

4. Run `opmnctl restartproc type=ohs`

5. Test that the SSO server can be logged into with client authentication.
Need More Help?

You can find more solutions on OracleMetaLink, http://metalink.oracle.com. If you do not find a solution for your problem, log a service request.

See Also: Oracle Application Server Release Notes, available on the Oracle Technology Network:
http://www.oracle.com/technology/documentation/index.html
This appendix includes the Third Party License for all the third party products included with Oracle Application Server.

Topics discussed are:
- Apache HTTP Server
- Apache SOAP
- DBI Module
- Perl
- PHP
- mod_dav
- FastCGI

Apache HTTP Server

Under the terms of the Apache license, Oracle is required to provide the following notices. However, the Oracle program license that accompanied this product determines your right to use the Oracle program, including the Apache software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the Apache software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or Apache.

The Apache Software License

```c
/* ====================================================================
 * The Apache Software License, Version 1.1
 * Copyright (c) 2000-2002 The Apache Software Foundation. All rights reserved.
 * Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met:
 * 1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.
 * 2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.
 * THIS SOFTWARE IS PROVIDED BY THE APACHE SOFTWARE FOUNDATION "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE APACHE SOFTWARE FOUNDATION OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
 *====================================================================*/
```

Third Party Licenses
Apache SOAP

Distribution.

3. The end-user documentation included with the redistribution,
   if any, must include the following acknowledgment:
   "This product includes software developed by the
   Apache Software Foundation (http://www.apache.org/)."
   Alternately, this acknowledgment may appear in the software itself,
   if and wherever such third-party acknowledgments normally appear.

4. The names "Apache" and "Apache Software Foundation" must
   not be used to endorse or promote products derived from this
   software without prior written permission. For written
   permission, please contact apache@apache.org.

5. Products derived from this software may not be called "Apache",
   nor may "Apache" appear in their name, without prior written
   permission of the Apache Software Foundation.

   This software is provided "AS IS" and any expressed or implied
   warranties, including, but not limited to, the implied warranties
   of merchantability and fitness for a particular purpose are
   disclaimed. In no event shall the Apache Software Foundation or
   its contributors be liable for any direct, indirect, incidental,
   special, exemplary, or consequential damages (including, but not
   limited to, procurement of substitute goods or services; loss of
   use, data, or profits; or business interruption) however caused and
   on any theory of liability, whether in contract, strict liability,
   or tort (including negligence or otherwise) arising in any way out
   of the use of this software, even if advised of the possibility of
   such damage.

   This software consists of voluntary contributions made by many
   individuals on behalf of the Apache Software Foundation. For more
   information on the Apache Software Foundation, please see

   Portions of this software are based upon public domain software
   originally written at the National Center for Supercomputing
   Applications, University of Illinois, Urbana-Champaign.

Apache SOAP

Under the terms of the Apache license, Oracle is required to provide the following notices. However, the Oracle program license that accompanied this product determines your right to use the Oracle program, including the Apache software, and the terms contained in the following notices do not change those rights.

Notwithstanding anything to the contrary in the Oracle program license, the Apache software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or Apache.

Apache SOAP License

Apache SOAP license 2.3.1

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION
1. Definitions.
"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual,
worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity alleging that the Work infringes a patent, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

(b) You must cause any modified files to carry prominent notices stating that You changed the files; and

(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with
the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

Oracle is required to provide the text of the third-party license, but the third-party program will be subject to the Oracle license, and Oracle will NOT provide warranties and technical support for the third-party technology.

This program contains third-party code from DBI. Under the terms of the DBI license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the
Oracle program, including the DBI software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the DBI software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or DBI.

The DBI module is Copyright (c) 1994-2002 Tim Bunce. Ireland. All rights reserved.

You may distribute under the terms of either the GNU General Public License or the Artistic License, as specified in the Perl README file.

Perl Artistic License

The "Artistic License"

Preamble

The intent of this document is to state the conditions under which a Package may be copied, such that the Copyright Holder maintains some semblance of artistic control over the development of the package, while giving the users of the package the right to use and distribute the Package in a more-or-less customary fashion, plus the right to make reasonable modifications.

Definitions

"Package" refers to the collection of files distributed by the Copyright Holder, and derivatives of that collection of files created through textual modification.

"Standard Version" refers to such a Package if it has not been modified, or has been modified in accordance with the wishes of the Copyright Holder as specified below.

"Copyright Holder" is whoever is named in the copyright or copyrights for the package.

"You" is you, if you're thinking about copying or distributing this Package.

"Reasonable copying fee" is whatever you can justify on the basis of media cost, duplication charges, time of people involved, and so on. (You will not be required to justify it to the Copyright Holder, but only to the computing community at large as a market that must bear the fee.)

"Freely Available" means that no fee is charged for the item itself, though there may be fees involved in handling the item. It also means that recipients of the item may redistribute it under the same conditions they received it.

1. You may make and give away verbatim copies of the source form of the Standard Version of this Package without restriction, provided that you duplicate all of the original copyright notices and associated disclaimers.

2. You may apply bug fixes, portability fixes and other modifications derived from the Public Domain or from the Copyright Holder. A Package modified in such a way shall still be considered the Standard Version.

3. You may otherwise modify your copy of this Package in any way, provided that you insert a prominent notice in each changed file stating how and when you changed that file, and provided that you do at least ONE of the following:

   a. place your modifications in the Public Domain or otherwise make them Freely Available, such as by posting said modifications to Usenet or an equivalent medium, or placing the modifications on a major archive site such as uunet.uu.net, or by allowing the Copyright Holder to include your modifications in the Standard Version of the Package.
b. use the modified Package only within your corporation or organization.

c. rename any non-standard executables so the names do not conflict with standard executables, which must also be provided, and provide a separate manual page for each non-standard executable that clearly documents how it differs from the Standard Version.

d. make other distribution arrangements with the Copyright Holder.

4. You may distribute the programs of this Package in object code or executable form, provided that you do at least ONE of the following:

a. distribute a Standard Version of the executables and library files, together with instructions (in the manual page or equivalent) on where to get the Standard Version.

b. accompany the distribution with the machine-readable source of the Package with your modifications.

c. give non-standard executables non-standard names, and clearly document the differences in manual pages (or equivalent), together with instructions on where to get the Standard Version.

d. make other distribution arrangements with the Copyright Holder.

5. You may charge a reasonable copying fee for any distribution of this Package. You may not charge a fee for this Package itself. However, you may distribute this Package in aggregate with other (possibly commercial) programs as part of a larger (possibly commercial) software distribution provided that you do not advertise this Package as a product of your own. You may embed this Package's interpreter within an executable of yours (by linking); this shall be construed as a mere form of aggregation, provided that the complete Standard Version of the interpreter is so embedded.

6. The scripts and library files supplied as input to or produced as output from the programs of this Package do not automatically fall under the copyright of this Package, but belong to whoever generated them, and may be sold commercially, and may be aggregated with this Package. If such scripts or library files are aggregated with this Package through the so-called “undump” or “unexec” methods of producing a binary executable image, then distribution of such an image shall neither be construed as a distribution of this Package nor shall it fall under the restrictions of Paragraphs 3 and 4, provided that you do not represent such an executable image as a Standard Version of this Package.

7. C subroutines (or comparably compiled subroutines in other languages) supplied by you and linked into this Package in order to emulate subroutines and variables of the language defined by this Package shall not be considered part of this Package, but are the equivalent of input as in Paragraph 6, provided these subroutines do not change the language in any way that would cause it to fail the regression tests for the language.

8. Aggregation of this Package with a commercial distribution is always permitted provided that the use of this Package is embedded; that is, when no overt attempt is made to make this Package's interfaces visible to the end user of the commercial distribution. Such use shall not be construed as a distribution of this Package.

9. The name of the Copyright Holder may not be used to endorse or promote products derived from this software without specific prior written permission.

10. THIS PACKAGE IS PROVIDED "AS IS" AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED
Perl

Oracle is required to provide the text of the third-party license, but the third-party program will be subject to the Oracle license, and Oracle will NOT provide warranties and technical support for the third-party technology.

This program contains third-party code from Perl. Under the terms of the Perl license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the Oracle program, including the Perl software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the Perl software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or Perl.

Perl Kit Readme

Copyright 1989-2001, Larry Wall
All rights reserved.
This program is free software; you can redistribute it and/or modify it under the terms of either:
1. the GNU General Public License as published by the Free Software Foundation;
a either version 1, or (at your option) any later version, or
2. the "Artistic License" which comes with this Kit.
This program is distributed in the hope that it will be useful, but WITHOUT ANY WARRANTY; without even the implied warranty of MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE. See either the GNU General Public License or the Artistic License for more details.
You should have received a copy of the Artistic License with this Kit, in the file named "Artistic". If not, I'll be glad to provide one.
You should also have received a copy of the GNU General Public License along with this program in the file named "Copying". If not, write to the Free Software Foundation, Inc., 59 Temple Place, Suite 330, Boston, MA 02111-1307, USA or visit their Web page on the internet at http://www.gnu.org/copyleft/gpl.html.
For those of you that choose to use the GNU General Public License, my interpretation of the GNU General Public License is that no Perl script falls under the terms of the GPL unless you explicitly put said script under the terms of the GPL yourself. Furthermore, any object code linked with perl does not automatically fall under the terms of the GPL, provided such object code only adds definitions of subroutines and variables, and does not otherwise impair the resulting interpreter from executing any standard Perl script. I consider linking in C subroutines in this manner to be the moral equivalent of defining subroutines in the Perl language itself. You may sell such an object file as proprietary provided that you provide or offer to provide the Perl source, as specified by the GNU General Public License. (This is merely an alternate way of specifying input to the program.) You may also sell a binary produced by the dumping of a running Perl script that belongs to you, provided that you provide or offer to provide the Perl source as specified by the GPL. (The fact that a Perl interpreter and your code are in the same binary file is, in this case, a form of mere aggregation.)
is my interpretation of the GPL. If you still have concerns or difficulties understanding my intent, feel free to contact me. Of course, the Artistic License spells all this out for your protection, so you may prefer to use that.

Perl Artistic License

The "Artistic License"
Preamble
The intent of this document is to state the conditions under which a Package may be copied, such that the Copyright Holder maintains some semblance of artistic control over the development of the package, while giving the users of the package the right to use and distribute the Package in a more-or-less customary fashion, plus the right to make reasonable modifications.

Definitions
"Package" refers to the collection of files distributed by the Copyright Holder, and derivatives of that collection of files created through textual modification.
"Standard Version" refers to such a Package if it has not been modified, or has been modified in accordance with the wishes of the Copyright Holder as specified below.
"Copyright Holder" is whoever is named in the copyright or copyrights for the package.
"You" is you, if you're thinking about copying or distributing this Package.
"Reasonable copying fee" is whatever you can justify on the basis of media cost, duplication charges, time of people involved, and so on. (You will not be required to justify it to the Copyright Holder, but only to the computing community at large as a market that must bear the fee.)
"Freely Available" means that no fee is charged for the item itself, though there may be fees involved in handling the item. It also means that recipients of the item may redistribute it under the same conditions they received it.

1. You may make and give away verbatim copies of the source form of the Standard Version of this Package without restriction, provided that you duplicate all of the original copyright notices and associated disclaimers.
2. You may apply bug fixes, portability fixes and other modifications derived from the Public Domain or from the Copyright Holder. A Package modified in such a way shall still be considered the Standard Version.
3. You may otherwise modify your copy of this Package in any way, provided that you insert a prominent notice in each changed file stating how and when you changed that file, and provided that you do at least ONE of the following:
   a. place your modifications in the Public Domain or otherwise make them Freely Available, such as by posting said modifications to Usenet or an equivalent medium, or placing the modifications on a major archive site such as uunet.uu.net, or by allowing the Copyright Holder to include your modifications in the Standard Version of the Package.
   b. use the modified Package only within your corporation or organization.
   c. rename any non-standard executables so the names do not conflict with standard executables, which must also be provided, and provide a separate manual page for each non-standard executable that clearly documents how it differs from the Standard Version.
   d. make other distribution arrangements with the Copyright Holder.
4. You may distribute the programs of this Package in object code or executable form, provided that you do at least ONE of the following:
   a. distribute a Standard Version of the executables and library files, together with instructions (in the manual page or equivalent) on where to get the Standard Version.
b. accompany the distribution with the machine-readable source of the Package with your modifications.

c. give non-standard executables non-standard names, and clearly document the differences in manual pages (or equivalent), together with instructions on where to get the Standard Version.

d. make other distribution arrangements with the Copyright Holder.

5. You may charge a reasonable copying fee for any distribution of this Package. You may charge any fee you choose for support of this Package. You may not charge a fee for this Package itself. However, you may distribute this Package in aggregate with other (possibly commercial) programs as part of a larger (possibly commercial) software distribution provided that you do not advertise this Package as a product of your own. You may embed this Package’s interpreter within an executable of yours (by linking); this shall be construed as a mere form of aggregation, provided that the complete Standard Version of the interpreter is so embedded.

6. The scripts and library files supplied as input to or produced as output from the programs of this Package do not automatically fall under the copyright of this Package, but belong to whoever generated them, and may be sold commercially, and may be aggregated with this Package. If such scripts or library files are aggregated with this Package through the so-called “undump” or “unexec” methods of producing a binary executable image, then distribution of such an image shall neither be construed as a distribution of this Package nor shall it fall under the restrictions of Paragraphs 3 and 4, provided that you do not represent such an executable image as a Standard Version of this Package.

7. C subroutines (or comparably compiled subroutines in other languages) supplied by you and linked into this Package in order to emulate subroutines and variables of the language defined by this Package shall not be considered part of this Package, but are the equivalent of input as in Paragraph 6, provided these subroutines do not change the language in any way that would cause it to fail the regression tests for the language.

8. Aggregation of this Package with a commercial distribution is always permitted provided that the use of this Package is embedded; that is, when no overt attempt is made to make this Package’s interfaces visible to the end user of the commercial distribution. Such use shall not be construed as a distribution of this Package.

9. The name of the Copyright Holder may not be used to endorse or promote products derived from this software without specific prior written permission.

10. THIS PACKAGE IS PROVIDED “AS IS” AND WITHOUT ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, WITHOUT LIMITATION, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.

The End

Oracle is required to provide the text of the third-party license, but the third-party program will be subject to the Oracle license, and Oracle will NOT provide warranties and technical support for the third-party technology.

This program contains third-party code from PHP. Under the terms of the PHP license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the
Oracle program, including the PHP software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the PHP software is provided by Oracle “AS IS” and without warranty or support of any kind from Oracle or PHP.

The PHP License

The PHP License, version 3.0

Copyright (c) 1999-2004 The PHP Group. All rights reserved.

Redistribution and use in source and binary forms, with or without modification, is permitted provided that the following conditions are met:

1. Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer.

2. Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution.

3. The name "PHP" must not be used to endorse or promote products derived from this software without prior written permission. For written permission, please contact group@php.net.

4. Products derived from this software may not be called "PHP", nor may "PHP" appear in their name, without prior written permission from group@php.net. You may indicate that your software works in conjunction with PHP by saying "Foo for PHP" instead of calling it "PHP Foo" or "phppo".

5. The PHP Group may publish revised and/or new versions of the license from time to time. Each version will be given a distinguishing version number.

Once covered code has been published under a particular version of the license, you may always continue to use it under the terms of that version. You may also choose to use such covered code under the terms of any subsequent version of the license published by the PHP Group. No one other than the PHP Group has the right to modify the terms applicable to covered code created under this License.

6. Redistributions of any form whatsoever must retain the following acknowledgment:

   "This product includes PHP, freely available from <http://www.php.net/>".

THIS SOFTWARE IS PROVIDED BY THE PHP DEVELOPMENT TEAM “AS IS” AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE PHP DEVELOPMENT TEAM OR ITS CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
mod_dav

mod_dav has been licensed to Oracle free of charge by Greg Stein under a license similar to the Apache Software Foundation license. The following copyright notice applies to mod_dav and Oracle’s use of mod_dav:

Copyright © 1998-2001 Greg Stein. All rights reserved.

FastCGI

Oracle is required to provide the text of the third-party license, but the third-party program will be subject to the Oracle license, and Oracle will NOT provide warranties and technical support for the third-party technology.

This program contains third-party code from FastCGI. Under the terms of the FastCGI license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use
the Oracle program, including the FastCGI software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the FastCGI software is provided by Oracle “AS IS” and without warranty or support of any kind from Oracle or FastCGI.

**FastCGI Developer’s Kit License**

This FastCGI application library source and object code (the “Software”) and its documentation (the “Documentation”) are copyrighted by Open Market, Inc (“Open Market”). The following terms apply to all files associated with the Software and Documentation unless explicitly disclaimed in individual files.

Open Market permits you to use, copy, modify, distribute, and license this Software and the Documentation solely for the purpose of implementing the FastCGI specification defined by Open Market or derivative specifications publicly endorsed by Open Market and promulgated by an open standards organization and for no other purpose, provided that existing copyright notices are retained in all copies and that this notice is included verbatim in any distributions.

No written agreement, license, or royalty fee is required for any of the authorized uses. Modifications to this Software and Documentation may be copyrighted by their authors and need not follow the licensing terms described here, but the modified Software and Documentation must be used for the sole purpose of implementing the FastCGI specification defined by Open Market or derivative specifications publicly endorsed by Open Market and promulgated by an open standards organization and for no other purpose. If modifications to this Software and Documentation have new licensing terms, the new terms must protect Open Market's proprietary rights in the Software and Documentation to the same extent as these licensing terms and must be clearly indicated on the first page of each file where they apply.

Open Market shall retain all right, title and interest in and to the Software and Documentation, including without limitation all patent, copyright, trade secret and other proprietary rights.

OPEN MARKET MAKES NO EXPRESS OR IMPLIED WARRANTY WITH RESPECT TO THE SOFTWARE OR THE DOCUMENTATION, INCLUDING WITHOUT LIMITATION ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL OPEN MARKET BE LIABLE TO YOU OR ANY THIRD PARTY FOR ANY DAMAGES ARISING FROM OR RELATING TO THIS SOFTWARE OR THE DOCUMENTATION, INCLUDING, WITHOUT LIMITATION, ANY INDIRECT, SPECIAL OR CONSEQUENTIAL DAMAGES OR SIMILAR DAMAGES, INCLUDING LOST PROFITS OR LOST DATA, EVEN IF OPEN MARKET HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. THE SOFTWARE AND DOCUMENTATION ARE PROVIDED “AS IS”. OPEN MARKET HAS NO LIABILITY IN CONTRACT, TORT, NEGLIGENCE OR OTHERWISE ARISING OUT OF THIS SOFTWARE OR THE DOCUMENTATION.

**Module mod_fastcgi License**

This FastCGI application library source and object code (the “Software”) and its documentation (the "Documentation") are copyrighted by Open Market, Inc ("Open Market"). The following terms apply to all files associated with the Software and Documentation unless explicitly disclaimed in individual files.

Open Market permits you to use, copy, modify, distribute, and license this Software and the Documentation solely for the purpose of implementing the FastCGI specification defined by Open Market or derivative specifications publicly endorsed by Open Market and promulgated by an open standards organization and for no other
purpose, provided that existing copyright notices are retained in all copies and that this notice is included verbatim in any distributions.

No written agreement, license, or royalty fee is required for any of the authorized uses. Modifications to this Software and Documentation may be copyrighted by their authors and need not follow the licensing terms described here, but the modified Software and Documentation must be used for the sole purpose of implementing the FastCGI specification defined by Open Market or derivative specifications publicly endorsed by Open Market and promulgated by an open standards organization and for no other purpose. If modifications to this Software and Documentation have new licensing terms, the new terms must protect Open Market's proprietary rights in the Software and Documentation to the same extent as these licensing terms and must be clearly indicated on the first page of each file where they apply.

Open Market shall retain all right, title and interest in and to the Software and Documentation, including without limitation all patent, copyright, trade secret and other proprietary rights.

OPEN MARKET MAKES NO EXPRESS OR IMPLIED WARRANTY WITH RESPECT TO THE SOFTWARE OR THE DOCUMENTATION, INCLUDING WITHOUT LIMITATION ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. IN NO EVENT SHALL OPEN MARKET BE LIABLE TO YOU OR ANY THIRD PARTY FOR ANY DAMAGES ARISING FROM OR RELATING TO THIS SOFTWARE OR THE DOCUMENTATION, INCLUDING, WITHOUT LIMITATION, ANY INDIRECT, SPECIAL OR CONSEQUENTIAL DAMAGES OR SIMILAR DAMAGES, INCLUDING LOST PROFITS OR LOST DATA, EVEN IF OPEN MARKET HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES. THE SOFTWARE AND DOCUMENTATION ARE PROVIDED "AS IS". OPEN MARKET HAS NO LIABILITY IN CONTRACT, TORT, NEGLIGENCE OR OTHERWISE ARISING OUT OF THIS SOFTWARE OR THE DOCUMENTATION.
Apache
Apache is a public domain HTTP server derived from the National Center for Supercomputing Applications (NCSA).

Application Server Control Console
See Oracle Enterprise Manager 10g Application Server Control Console.

authentication
The process of verifying the identity of a user, device, or other entity in a host system, often as a prerequisite to granting access to resources in a system. A recipient of an authenticated message can be certain of the message's origin (its sender). Authentication is presumed to preclude the possibility that another party has impersonated the sender.

availability
The percentage or amount of scheduled time that a computing system provides application service.

CA
See certificate authority.

certificate
Also called a digital certificate. An ITU x.509 v3 standard data structure that securely binds an identity to a public key.

A certificate is created when an entity's public key is signed by a trusted identity, a certificate authority. The certificate ensures that the entity's information is correct and that the public key actually belongs to that entity.

A certificate contains the entity's name, identifying information, and public key. It is also likely to contain a serial number, expiration date, and information about the rights, uses, and privileges associated with the certificate. Finally, it contains information about the certificate authority that issued it.

certificate authority
A trusted third party that certifies that other entities—users, databases, administrators, clients, servers—are who they say they are. When it certifies a user, the certificate authority first seeks verification that the user is not on the certificate revocation list (CRL), then verifies the user’s identity and grants a certificate, signing it with the certificate authority’s private key. The certificate authority has its own certificate and public key which it publishes. Servers and clients use these to verify signatures the
A certificate authority might be an external company that offers certificate services, or an internal organization such as a corporate MIS department.

**CGI**
Common Gateway Interface (CGI) is the industry-standard technique for transferring information between a Web server and any program designed to accept and return data that conforms to the CGI specifications.

**ciphertext**
Data that has been encrypted. Cipher text is unreadable until it has been converted to plain text (decrypted) with a key. See decryption.

**cipher suite**
A set of authentication, encryption, and data integrity algorithms used for exchanging messages between network nodes. During an SSL handshake, for example, the two nodes negotiate to see which cipher suite they will use when transmitting messages back and forth.

**cleartext**
See plaintext.

**cryptography**
The art of protecting information by transforming it (encrypting) into an unreadable format. See encryption.

**DAD**
See database access descriptor.

**database access descriptor**
A database access descriptor (DAD) is a set of values that specify how an application connects to an Oracle database to fulfill an HTTP request. The information in the DAD includes the username (which also specifies the schema and the privileges), password, connect-string, error log file, standard error message, and national language support (NLS) parameters such as NLS language, NLS date format, NLS date language, and NLS currency.

**DCM**
See Distributed Configuration Management.

**decryption**
The process of converting the contents of an encrypted message (ciphertext) back into its original readable format (plaintext).

**DES**
Data Encryption Standard. A commonly used symmetric key encryption method that uses a 56-bit key.

**de-militarized zone**
A de-militarized zone (DMZ) is a set of machines that are isolated from the internet by a firewall on one side, and from a company's intranet by a firewall on the other side. This set of machines are viewed as semi-secure. They are protected from the open internet, but are not completely trusted like machines that are inside the second...
firewall and part of the company's intranet. In a typical application server setup with a DMZ, only the Web listener and the static content for the Web site are placed in the DMZ. All business logic, databases, and other critical data and systems in the intranet are protected.

Diffie-Hellman key negotiation algorithm
Diffie-Hellman key negotiation algorithm is a method that lets two parties communicating over an insecure channel to agree upon a random number known only to them. Though the parties exchange information over the insecure channel during execution of the Diffie-Hellman key negotiation algorithm, it is computationally infeasible for an attacker to deduce the random number they agree upon by analyzing their network communications. Oracle Advanced Security uses the Diffie-Hellman key negotiation algorithm to generate session keys.

digital certificate
See certificate.

digital wallet
See wallet.

directory information tree
A hierarchical tree-like structure consisting of the DNs of the directory entries. See distinguished name.

distinguished name
The unique name of a directory entry. It comprises all of the individual names of the parent entries back to the root in the directory information tree.

Distributed Configuration Management
Distributed Configuration Management (DCM) manages configuration by propagating the cluster-wide configuration for the application server instances and its components. When you add application server instances to the cluster, it is the DCM component that automatically replicates the base configuration to all instances in the cluster. When you modify the cluster-wide configuration, DCM propagates the changes to all application server instances in the cluster.

DIT
See directory information tree.

DMZ
See de-militarized zone.

DN
See distinguished name.

encryption
The process of disguising a message thereby rendering it unreadable to any but the intended recipient. Encryption is performed by translating data into secret code. There are two main types of encryption: public-key encryption (or asymmetric-key encryption) and symmetric-key encryption.
entry
In the context of a directory service, entries are the building blocks of a directory. An entry is a collection of information about an object in the directory. Each entry is composed of a set of attributes that describe one particular trait of the object. For example, if a directory entry describes a person, that entry can have attributes such as first name, last name, telephone number, or e-mail address.

failover
The ability to reconfigure a computing system to utilize an alternate active component when a similar component fails.

HTTP
See Hypertext Transfer Protocol.

Hypertext Transfer Protocol
Hypertext Transfer Protocol (HTTP) is the underlying format used by the Web to format and transmit messages and determine what actions Web servers and browsers should take in response to various commands. HTTP is the protocol used between Oracle Application Server and clients.

LDAP

Lightweight Directory Access Protocol
A standard, extensible directory access protocol. It is a common language that LDAP clients and servers use to communicate. The framework of design conventions supporting industry-standard directory products, such as the Oracle Internet Directory.

MD5
A hashing algorithm intended for use on 32-bit machines to create digital signatures. MD5 is a one-way hash function, meaning that it converts a message into a fixed string of digits that form a message digest.

message digest
Representation of text as a string of single digits. It is created using a formula called a one-way hash function.

modules
Modules extend the basic functionality of the Web server and support integration between Oracle HTTP Server and other Oracle Application Server components.

Oracle Enterprise Manager 10g Application Server Control Console
Oracle Enterprise Manager 10g Application Server Control Console (Application Server Control Console) provides Web-based management tools designed specifically for Oracle Application Server. Using the Application Server Control Console, you can monitor and configure the components of your application server. You can deploy applications, manage security, and create and manage Oracle Application Server clusters.

one-way hash function
An algorithm that turns a message into a single string of digits. "One way" means that it is almost impossible to derive the original message from the string of digits. The
calculated message digest can be compared with the message digest that is decrypted with a public key to verify that the message has not been tampered with.

OPMN
See Oracle Process Manager and Notification Server.

Oracle Process Manager and Notification Server
Oracle Process Manager and Notification Server (OPMN) manages Oracle HTTP Server and OC4J processes within an application server instance. It channels all events from different components to all components interested in receiving them.

PEM
Privacy-Enhanced Electronic Mail. An encryption technique that provides encryption, authentication, message integrity, and key management.

PL/SQL
PL/SQL is Oracle's proprietary extension to the SQL language. PL/SQL adds procedural and other constructs to SQL that make it suitable for writing applications.

plaintext
Also called cleartext. Unencrypted data in ASCII format.

plug-in
A module that adds a specific feature or service to a larger system. For example, Oracle Application Server Proxy Plug-in, Oracle Application Server SSO Plug-in, or Oracle Application Server Containers for J2EE Plug-in.

port
A port is a number that TCP uses to route transmitted data to and from a particular program.

private key
In public-key cryptography, this key is the secret key. It is primarily used for decryption but is also used for encryption with digital signatures. See public/private key pair.

proxy server
A proxy server typically sits on a network firewall and allows clients behind the firewall to access Web resources. All requests from clients go to the proxy server rather than directly to the destination server. The proxy server forwards the request to the destination server and passes the received information back to the client. The proxy server channels all Web traffic at a site through a single, secure port; this allows an organization to create a secure firewall by preventing Internet access to internal machines, while allowing Web access.

public key
In public-key cryptography, this key is made public to all. It is primarily used for encryption but can be used for verifying signatures. See public/private key pair.

public-key cryptography
Encryption method that uses two different random numbers (keys). See public key and public-key encryption.
public-key encryption
The process where the sender of a message encrypts the message with the public key of the recipient. Upon delivery, the message is decrypted by the recipient using its private key.

public/private key pair
A set of two numbers used for encryption and decryption, where one is called the private key and the other is called the public key. Public keys are typically made widely available, while private keys are held by their respective owners. Though mathematically related, it is generally viewed as computationally infeasible to derive the private key from the public key. Public and private keys are used only with asymmetric encryption algorithms, also called public-key encryption algorithms, or public-key cryptosystems. Data encrypted with either a public key or a private key from a key pair can be decrypted with its associated key from the key pair. However, data encrypted with a public key cannot be decrypted with the same public key, and data encrypted with a private key cannot be decrypted with the same private key.

RSA
A public-key encryption technology developed by RSA Data Security. The RSA algorithm is based on the fact that it is laborious to factor very large numbers. This makes it mathematically unfeasible, because of the computing power and time required to decode an RSA key.

scalability
A measure of how well the software or hardware product is able to adapt to future business needs.

SHA
See Secure Hash Algorithm.

Secure Hash Algorithm
Secure Hash Algorithm assures data integrity by generating a 160-bit cryptographic message digest value from given data. If as little as a single bit in the data is modified, the Secure Hash Algorithm checksum for the data changes. Forgery of a given data set in a way that will cause the Secure Hash Algorithm to generate the same result as that for the original data is considered computationally infeasible.

An algorithm that takes a message of less than 264 bits in length and produces a 160-bit message digest. The algorithm is slightly slower than MD5, but the larger message digest makes it more secure against brute-force collision and inversion attacks.

Secure Shell
Secure Shell (SSH) is a well known protocol and has widely available implementation that provide a secure connection tunneling solution, very similar to what port tunneling offers. SSH provides a daemon on both the client and server sides of a connection. Clients connect to the local daemon rather than connecting directly to the server. The local SSH daemon then establishes a secure connection to the daemon on the server side. Communication is then routed from the client, through the client side daemon to the server side daemon and then on to the actual server. This allows a client/server program that uses an insecure protocol to be tunneled through a secure channel. For our purposes, the disadvantage of SSH is that it requires two hops to occur and that the implementations available do not perform and scale well enough. More information on SSH can be obtained from
Secure Sockets Layer
Secure Sockets Layer (SSL) is a standard for the secure transmission of documents over the Internet using HTTPS (secure HTTP). SSL uses digital signatures to ensure that transmitted data is not tampered with.

Single sign-on
Single sign-on enables you to authenticate once, combined with strong authentication occurring transparently in subsequent connections to other databases or applications. It lets you access multiple accounts and applications with a single password, entered during a single connection.

SSL
See Secure Sockets Layer.

SSH
See Secure Shell.

wallet
Also called a digital wallet. A wallet is a data structure used to store and manage security credentials for an individual entity. It implements the storage and retrieval of credentials for use with various cryptographic services. A Wallet Resource Locator (WRL) provides all the necessary information to locate the wallet.

Wallet Resource Locator
A wallet resource locator (WRL) provides all necessary information to locate a wallet. It is a path to an operating system directory that contains a wallet.

WRL
See Wallet Resource Locator.

X.509
Public keys can be formed in various data formats. The X.509 v3 format is one such popular format.
