This book explains how to configure Identity System applications to display information about users, groups, and organizations; how to assign permissions to users for viewing and modifying the data that is displayed in the Identity System applications; and how to configure workflows that link together Identity application functions into a chain of automatically performed steps. This book also describes functions that are common to the Identity and Access Systems, for example, directory profile configuration, password policy configuration, logging, and auditing.
## Contents

### Preface

- Audience ......................................................................................................................... xv
- Documentation Accessibility ............................................................................................ xv
- Related Documents ......................................................................................................... xvi
- Conventions ...................................................................................................................... xvii

### What’s New in Oracle Access Manager?

- Product and Component Name Changes ............................................................................ xix
- Globalization ..................................................................................................................... xx
- Password Policies and Lost Password Management .......................................................... xxi
- Configuring Multiple Searchbases .................................................................................. xxi
- Configuring Workflows ..................................................................................................... xxi
- Auditing ............................................................................................................................ xxi
- Logging ............................................................................................................................. xxi
- Configuring the Directory Server ..................................................................................... xxi
- Active Directory .............................................................................................................. xxi
- Troubleshooting ................................................................................................................ xxi

### Part I  Introducing Oracle Access Manager Administration

#### 1  Preparing for Administration

- Prerequisites ...................................................................................................................... 1-1
- About Identity System Configuration and Administration ................................................ 1-1
- Identity System Components ............................................................................................ 1-2
  - Review of Identity System Installation and Setup .......................................................... 1-3
  - About Configuring the Identity System ......................................................................... 1-3
  - About Managing the Identity System ............................................................................. 1-5
- Introduction to Using Oracle Access Manager ................................................................. 1-5
- Login ................................................................................................................................ 1-6
  - Logging In to the Identity System .................................................................................. 1-6
  - Logging into the Access System .................................................................................... 1-7
- Functional Areas on a page ............................................................................................... 1-8
  - Navigation Elements ...................................................................................................... 1-8
  - Search Functionality ....................................................................................................... 1-9
- The Selector ........................................................................................................................ 1-10
2 Specifying Identity System Administrators

About Identity System Administrators ................................................................. 2-1
Specifying Administrators ................................................................................. 2-4
Deleting Administrators .................................................................................... 2-4
Delegating Administration .................................................................................. 2-5
About Delegating Administration ...................................................................... 2-5
Delegated Administration Models ..................................................................... 2-6
Extranet Model .................................................................................................... 2-6
Intranet Model .................................................................................................... 2-7
ASP Model ......................................................................................................... 2-8
Adding Delegated Administrators ..................................................................... 2-8
Adding Substitute Administrators .................................................................... 2-10

Part II Configuring the Identity System

3 Making Schema Data Available to the Identity System

About Object Classes .......................................................................................... 3-1
About Sending Data to External Systems Using Template Objects .................. 3-2
The Process for Configuring Schema Data ....................................................... 3-2
Objects Configured During Installation ............................................................ 3-3
Structural and Auxiliary Object Classes in the Identity System ...................... 3-3
Template Object Classes ................................................................................... 3-4
Object Class Types ............................................................................................ 3-5
Viewing Object Classes ...................................................................................... 3-5
Modifying Object Classes .................................................................................. 3-6
Selecting a Class Attribute ............................................................................... 3-7
Changing the Structural Object Class ............................................................... 3-7
Adding Object Classes ....................................................................................... 3-8
How Auxiliary Classes Are Used ..................................................................... 3-9
Deleting Object Classes ..................................................................................... 3-9
About Object Class Attributes .......................................................................... 3-9
About Configuring Attributes ............................................................................ 3-10
Attribute Data Types ......................................................................................... 3-10
Attribute Semantic Types .................................................................................. 3-11
Semantic Types Defined During Setup .............................................................. 3-11
Semantic Types Used in Profile Pages ............................................................... 3-12
Semantic Types Used in the Group Manager .................................................... 3-13
Location Coordinates Semantic Type ................................................................. 3-13
Semantic Types for Managing Lost Passwords ............................................... 3-13
Other Semantic Types ....................................................................................... 3-14
Attribute Display Types ..................................................................................... 3-14

Index
There are two administration guides for Oracle Access Manager. This book, *Oracle Access Manager Identity and Common Administration Guide*, provides information on configuring Oracle Access Manager to read and make use of data in your directory, configuring Identity applications to display directory data, assigning read and write permissions to users, and defining workflows that link together Identity application functions into a sequence of automatically initiated steps. This guide also describes functionality that is common to both the Access System and Identity System. Common functionality includes configuring directory servers and password policies.

This Preface covers the following topics:

- **Audience**
- **Documentation Accessibility**
- **Related Documents**
- **Conventions**

**Audience**

This guide is intended for the administrators assigned during Oracle Access Manager installation and setup, as well as Master Identity Administrators and Delegated Identity Administrators. Administrators configure the rights and tasks available to other administrators and end users. A Master Administrator, the highest level administrator, is selected during Identity System setup. This administrator delegates responsibilities to other administrators, as described in this book.

This document assumes that you are familiar with your LDAP directory and Web servers.

**Documentation Accessibility**

Our goal is to make Oracle products, services, and supporting documentation accessible, with good usability, to the disabled community. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to
evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at

http://www.oracle.com/accessibility/

**Accessibility of Code Examples in Documentation**
Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

**Accessibility of Links to External Web Sites in Documentation**
This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

**TTY Access to Oracle Support Services**
Oracle provides dedicated Text Telephone (TTY) access to Oracle Support Services within the United States of America 24 hours a day, seven days a week. For TTY support, call 800.446.2398.

**Related Documents**
For more information, see the following documents in the Oracle Access Manager Release 10g (10.1.4.0.1) documentation set:

- **Oracle Access Manager Introduction**—Provides an introduction to Oracle Access Manager, a road map to the manuals, and a glossary of terms.
- **Oracle Application Server Release Notes**—Read these for the latest Oracle Access Manager updates. The release notes are available with the platform-specific documentation. The most current version of the release notes is available on Oracle Technology Network at:
- **Oracle Access Manager Installation Guide**—Describes how to install and set up the Oracle Access Manager components.
- **Oracle Access Manager Upgrade Guide**—Explains how to upgrade earlier versions of Oracle Access Manager to the latest version.
- **Oracle Access Manager Access Administration Guide**—Describes how to protect resources by defining policy domains, authentication schemes, and authorization schemes; how to allow users to access multiple resources with a single login by configuring single- and multi-domain single sign-on; and how to design custom login forms. This book also describes how to set up and administer the Access System.
- **Oracle Access Manager Identity and Common Administration Guide**—Explains how to configure Identity System applications to display information about users, groups, and organizations; how to assign permissions to users to view and modify the data that is displayed in the Identity System applications; and how to configure workflows that link together Identity application functions, for example, adding basic information about a user, providing additional information about the user, and approving the new user entry, into a chain of automatically performed steps.
This book also describes administration functions that are common to the Identity and Access Systems, for example, directory profile configuration, password policy configuration, logging, and auditing.

- **Oracle Access Manager Deployment Guide**—Provides information for people who plan and manage the environment in which Oracle Access Manager runs. This guide covers capacity planning, system tuning, failover, load balancing, caching, and migration planning.

- **Oracle Access Manager Customization Guide**—Explains how to change the appearance of Oracle Access Manager applications and how to control operation by making changes to operating systems, Web servers, directory servers, directory content, or by connecting CGI files or JavaScripts to Oracle Access Manager screens. This guide also describes the Access Manager API and the authorization and authentication plug-in APIs.

- **Oracle Access Manager Developer Guide**—Explains how to access Identity System functionality programmatically using IdentityXML and WSDL, how to create custom WebGates (known as AccessGates), and how to develop plug-ins. This guide also provides information to be aware of when creating CGI files or JavaScripts for Oracle Access Manager.

- **Oracle Access Manager Integration Guide**—Explains how to set up Oracle Access Manager to run with third-party products such as BEA WebLogic, Siebel 7, and IBM Websphere.

- **Oracle Access Manager Schema Description**—Provides details about the schema.

- Also, read the Oracle Application Server Release Notes for the latest updates. The release notes are available with the platform-specific documentation. The most current version of the release notes is available on Oracle Technology Network ([http://www.oracle.com/technology/documentation](http://www.oracle.com/technology/documentation)).

## Conventions

The following text conventions are used in this document:

<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><strong>italic</strong></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
What’s New in Oracle Access Manager?

This section describes new features of Oracle Access Manager 10g (10.1.4.0.1) and provides pointers to additional information within this book. Information from previous releases is also retained to help those users migrating to the current release.

The following sections describe the new features in Oracle Access Manager that are covered in this book:

- Product and Component Name Changes
- Globalization
- Password Policies and Lost Password Management
- Configuring Multiple Searchbases
- Configuring Workflows
- Auditing
- Logging
- Configuring the Directory Server
- Troubleshooting

**Note:** For a comprehensive list of new features and functions in Oracle Access Manager 10g (10.1.4.0.1), and a description of where each is documented, see the chapter on What’s New in Oracle Access Manager in the Oracle Access Manager Introduction.

### Product and Component Name Changes

The original product name, Oblix NetPoint, has changed to Oracle Access Manager. Most component names remain the same. However, there are several important changes that you should know about, as shown in the following table:

<table>
<thead>
<tr>
<th>Item</th>
<th>Was</th>
<th>Is</th>
</tr>
</thead>
<tbody>
<tr>
<td>Product Name</td>
<td>Oblix NetPoint</td>
<td>Oracle Access Manager</td>
</tr>
<tr>
<td></td>
<td>Oracle COREid</td>
<td></td>
</tr>
<tr>
<td>Product Name</td>
<td>Oblix SHAREid</td>
<td>Oracle Identity Federation</td>
</tr>
<tr>
<td></td>
<td>NetPoint SAML Services</td>
<td></td>
</tr>
<tr>
<td>Product Name</td>
<td>OctetString Virtual Directory Engine (VDE)</td>
<td>Oracle Virtual Directory</td>
</tr>
</tbody>
</table>
All legacy references in the product or documentation should be understood to connote the new names.

### Globalization

- As part of the globalization support, some file formats have changed from the proprietary .lst format to .xml
Oracle Access Manager 10g Release 3 (10.1.4) has undergone a globalization process to provide multibyte support that enables processing of internationalized data and messages in the user’s native language.

password.xml; globalparams.xml; obscoreboard; AppDBfailover.xml and AppDB.xml; ConfigDBfailover.xml and ConfigDB.xml; WebResrcDBfailover.xml -- now WebResrcDB.xml; snmp_agent_config_info.xml; obscoreboard_params.xml

See Also: References to these file names in this manual.

- Oracle Access Manager uses a locale-based case insensitive sorting method when you click the column heading (Full Name, for example) in the search results table.

  See Also: "Search Functionality" on page 1-9.

- In the Identity System Console, some display names are displayed incorrectly if the locale of the browser is different from the local of the characters used in the display name.

  See Also: "Attribute Display Types" on page 3-14.

- When generating a report for an Identity application, save the report file as .txt and re-import it for the characters to display correctly.

  See Also: "Viewing, Modifying, Localizing, and Deleting Reports" on page 4-45.

**Password Policies and Lost Password Management**

- Password policies and Lost Password Management have been enhanced.

  You can configure the minimum and maximum number of characters users can specify in a password. For lost password management, you can set multiple challenge-response pairs, create multiple style sheets, and configure other aspects of the user’s lost password management experience. You can also redirect users back to the originally requested page after resetting a password.

  See Also: "Managing Password Policies" on page 7-47 and "Lost Password Management" on page 7-53.

**Configuring Multiple Searchbases**

- This book contains expanded information on configuring Oracle Access Manager for multiple directory searchbases, also called disjoint domains or realms.

  See Also: "Working With Multiple Directory Searchbases" on page 7-33.

**Configuring Workflows**

- This book contains expanded information on configuring workflows for dynamic targets.

  You can dynamically assign a user to a target on a create user workflow. For example, you can define a create user workflow that enables user A to log in under ou=users, invoke the workflow, and create user B whose entry is
automatically determined to be in the same ou as user A. This ability always existed in the Identity System, and is now explicitly documented in the chapter on workflows.

- The section on the QuickStart tool now mentions that only Master Administrators can use the QuickStart tool.

**See Also:** "Starting a New Workflow Definition" on page 5-19, "Defining an LDAP Target for Create Object Workflows" on page 5-21, and "Using the QuickStart Tool" on page 5-15.

**Auditing**

- You can now audit to an Oracle Database as well as to Microsoft SQL Server. Support for MySQL is deprecated in this release.

  The Crystal Reports package is no longer provided with the Oracle Access Manager package. You must obtain this product from the vendor.

  **See Also:** "Auditing" on page 11-1.

**Logging**

- Changes to logging parameters take effect within one minute, rather than requiring you to restart the server where the changes were made.

  **See Also:** "Logging" on page 10-1.

**Configuring the Directory Server**

- When you configure SSL mode for the directory server, only server authentication is supported. Client certificates are not supported.

  **See Also:** "Transport Security Mode Between Components" on page 8-2.

- The default value for the Maximum Session Time of 0 (no maximum) can cause LDAP caches to become too large. The recommended value is 600 (10 hours).

  **See Also:** "Creating an LDAP Directory Server Profile" on page 7-21.

**Active Directory**

- The samAccountNameLength parameter enables you to increase the number of characters permitted as a SamAccountName attribute value. For Active Directory environments that are running in native mode, you may want to increase the default value for this parameter.

  **See Also:** "About the Length of the SAMAccountName" on page A-9.

**Troubleshooting**

- Information on troubleshooting that was dispersed throughout this manual has been consolidated in a separate appendix.
See Also:  "Troubleshooting Oracle Access Manager" on page F-1.

- New troubleshooting topics have been added.

See Also:  "Unable to Save a Directory Server Profile" on page F-4,
"Active Directory: Adding Members Causes the Group Size to Shrink" on page F-2, "ADSI Cannot Be Enabled for a Directory Profile" on page F-3, "Style Sheet Validation Fails" on page F-4,
"Simple Transport Security Mode Expires After One Year" on page F-3, "JPEG Photo Images Are Not Updated" on page F-6,
""Enable Failed" Error Is Issued When Using a Workflow" on page F-5, ""Cannot Find xenroll.cab" Error Is Issued When Using a Workflow" on page F-5.
Before you begin working with Oracle Access Manager, it is important to understand basic Oracle Access Manager administration concepts.

Part I provides an introduction to Oracle Access Manager administration and contains the following chapters:

- Chapter 1, "Preparing for Administration"
- Chapter 2, "Specifying Identity System Administrators"
Preparing for Administration

Before configuring and administering Oracle Access Manager, you may find it useful to preview the tasks that you perform as an administrator. It may also be useful to log in and view the user interface for the Identity System and Access System.

This chapter contains information you need before starting to configure and administer Oracle Access Manager, including these topics:

- Prerequisites
- About Identity System Configuration and Administration
- Introduction to Using Oracle Access Manager

Note: Although the product name has changed to Oracle Access Manager, in manuals and the product you may see the name NetPoint or Oblix. This is particularly true in file and path names.

Prerequisites

Oracle Access Manager should be installed and set up as described in the Oracle Access Manager Installation Guide. Read the Oracle Access Manager Introduction which provides an overview of Oracle Access Manager not found in other manuals.

This document focuses on Identity System administration as well as common configuration and administration tasks.

About Identity System Configuration and Administration

You use the Identity System and objects in the directory service to manage identity information about individuals, groups, organizations, and other objects. The Master Administrator can delegate authority to other administrators, allowing the Identity System to scale millions of users.

In addition to managing identity information, the Identity System enables you to manage read, write, and modify privileges for a user based on a specific user attribute, membership in a group, or association with an organization. You can link privileges together into a workflow.

For example, you can set up a self-registration workflow so that when a user self-registers, the registration request is forwarded to appropriate people for approval, and upon approval, the user is immediately and automatically granted access to all resources appropriate for his or her identity attributes.
Finally, the Identity System enables you to accurately manage user identities, group memberships, and organizational objects. This information can then be leveraged by the Access System to manage access privileges for users based on user attributes, group membership, or association with an organizational entity.

Identity System Components

The Identity System consists of these components:

- The Identity Server
- WebPass

Identity Server—A standalone server or several instances that manage identity information about users, groups, organizations, and other objects. The Identity Server provides the following applications:

  - User Manager—If you are an administrator or a user, the User Manager enables you to add, modify, and delete user identities provided that you are a participant in a workflow that performs this function. User Manager data can be leveraged by the Access System to provide users with access privileges based on their directory profiles. The User Manager also has reporting capability.

  The User Manager typically enables end users to view other users and to modify their own identity information. The users that a person can view and the identity information that someone can modify depends on the privileges granted by a Master Administrator.

  - Group Manager—Enables administrators and users to create or delete groups, and enables users to subscribe or unsubscribe from groups. You must be a participant in a workflow that performs the desired function. The Group Manager also has reporting capability.

  The Group Manager typically enables end users to view groups and to subscribe to membership in a group. The groups that a person can view and subscription rights are granted by a Master Administrator.

  - Organization Manager—If you are an administrator or a user, the Organization Manager enables you to create and delete organizations and other objects (such as floor plans and assets) that do not belong in the User Manager or Group Manager. You must be a participant in a workflow that performs the desired function. The Organization Manager also has reporting capability.

  The Organization Manager enables end users to view organizational entities such as floor plans. The organizational entities that a person can view depend upon the rights granted by a Master Administrator.

  - Identity System Console—Enables administration and configuration of the Identity System. Using the System Console, you also create Administrators and assign the right to delegate administrative tasks.

  The Identity Server stores user information on a directory server. The Identity Server keeps the directory current so that the Access Server gets the right information.

Details here include:

- Review of Identity System Installation and Setup
- About Configuring the Identity System
About Managing the Identity System

Review of Identity System Installation and Setup
Installation and setup includes the following events:

- At least one Identity Server and one WebPass were installed and the resulting Identity System was set up.
- A transport security mode was chosen to protect communication between the Identity Server and WebPass.
- The Identity Server was configured to communicate with an LDAP directory server or virtual directory.

You are prompted regarding automatic setup of your directory server schema. If you chose not to automatically update your schema, you are prompted to do so manually during configuration. Instructions on manual updates of your directory server schema are provided in this manual.

- Each expected application was installed with the Identity Server.

When you log in to the Identity System, you see a series of tabs on the top navigation bar that match your applications. From these tabs you can configure the look and functionality of the User Manager, Group Manager, and Organization Manager applications.

- Required attributes for the User and Group object classes were set up.

- Other attributes may also have been configured.

- At least one Master Administrator was selected.

This is the highest-level administrator. You must have at least one administrator defined to begin working with Oracle Access Manager. These are the people who configure the System. The Master administrator creates lower-level administrators called Master Identity Administrators.

Table 1–1 provides a review of Identity System installation and setup.

For more information, see the Oracle Access Manager Installation Guide.

About Configuring the Identity System
The Identity System consists of an administrative console and three end-user applications discussed earlier:

- Identity System Console (includes User Manager Configuration, Group Manager Configuration, Org. Manager Configuration, Common Configuration, and System Configuration)
- The User Manager application
- The Group Manager application
- The Organization Manager application

People use the Identity System end-user applications for tasks such as changing personal information, resetting passwords, adding other users, and looking up organizational information. This identity data originates in your LDAP directory. To configure the Identity System applications, you need to know what attributes in the directory you want to display, and what attributes you want to be able to modify.

After configuring the Identity System to work with data in your directory, you configure the Identity System application profile pages. These profile pages display
the directory data. For example, you can display a user’s name, title, address, and phone number on a profile page in the User Manager application. You can also improve the efficiency of your organization by using Identity workflows. Identity workflows enable you to automate Identity System application-related activities, for example, creating a user and assigning email and other accounts to that user.

Finally, you use the Identity System to create Identity workflows. Identity workflows are definitions for a set of actions and the steps you perform to complete the actions. For instance, you can create workflow definitions for the way new employees are added to your various corporate information systems.

Table 1–1 provides an overview of configuring the Identity System:

**Table 1–1 Overview of Identity System Configuration**

<table>
<thead>
<tr>
<th>To perform this task</th>
<th>Description</th>
<th>Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify additional structural object classes for the Organization Manager and auxiliary object classes for all applications</td>
<td>During setup, you configure one structural object class each for the User Manager, Group Manager, and Organization Manager. You can define additional structural object classes for the Organization Manager. For instance, you may want the Organization Manager to display assets. You can also add auxiliary object classes to provide the Identity System applications with data.</td>
<td>“About Object Classes” on page 3-1</td>
</tr>
<tr>
<td>Configure attributes</td>
<td>You can determine what attributes are available to the User, Group, and Organization Manager applications. You also can configure rules for how to display attribute values on an Identity System application profile page. For example, you may want employees to be able to select their department name from a list.</td>
<td>“About Object Class Attributes” on page 3-9</td>
</tr>
<tr>
<td>Configure User, Group, and Organization application tabs</td>
<td>In the User Manager, you configure what the user sees on the My Identity tab. In the Group Manager, you configure what the user sees on the My Groups tab. In the Organization Manager, you configure what the user sees on the Location tab and, optionally, additional tabs.</td>
<td>“Viewing and Modifying Tab Configuration Information” on page 4-3.</td>
</tr>
<tr>
<td>Configure User, Group, and Organization profile pages</td>
<td>Tabs contain one or more profile pages. A profile page contains a set of panels. A panel is a collection of attributes. For example, on a profile page for a user, you can define an Identity panel to display values for attributes such as Name, Photo, Title, and so on.</td>
<td>“Configuring Tab Profile Pages and Panels” on page 4-11.</td>
</tr>
<tr>
<td>Set the searchbase</td>
<td>The searchbase determines the entry point in the directory tree for a search.</td>
<td>“About the Searchbase” on page 4-21.</td>
</tr>
</tbody>
</table>
### Table 1–2 Overview of Identity System Configuration

<table>
<thead>
<tr>
<th>To perform this task</th>
<th>Description</th>
<th>Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure view and modify permissions for attributes</td>
<td>You need to determine who can find what, at what point in the searchbase, and with what filter. These decisions affect who can read or write to data and who receives email notification when an attribute has been modified.</td>
<td>&quot;Allowing Users to View and Change LDAP Data&quot; on page 4-21.</td>
</tr>
<tr>
<td>Define workflows</td>
<td>A workflow is a series of steps for creating, deleting, and modifying attributes in the Identity System. For example, in the User Manager, you may want to define a workflow for creating a user that includes collecting information about the new user from several people in your organization.</td>
<td>&quot;Chaining Identity Functions Into Workflows&quot; on page 5-1.</td>
</tr>
<tr>
<td>Configure password policies</td>
<td>You can determine the length of passwords, frequency of password change, and so on.</td>
<td>&quot;Configuring Password Policies&quot; on page 7-46.</td>
</tr>
<tr>
<td>Delegate administration</td>
<td>To scale your installation, you need multiple administrators, each overseeing a subset of users.</td>
<td>&quot;Specifying Identity System Administrators&quot; on page 2-1.</td>
</tr>
</tbody>
</table>

### About Managing the Identity System

You can extend your Identity System by adding servers, and expanding your network of Identity System administrators. You can configure audits and logs and perform other administrative functions. Table 1–2 provides an overview of managing the Identity System:

**Table 1–2 What to Read for More Information on the Identity System**

<table>
<thead>
<tr>
<th>To perform this task</th>
<th>Read</th>
</tr>
</thead>
<tbody>
<tr>
<td>Add more Identity Servers</td>

</table>

### Introduction to Using Oracle Access Manager

Commonly used functions in the Oracle Access Manager user interface the following:

- Login
- Functional Areas on a Page
Oracle Access Manager **logs** people in based on the roles they have been assigned. As described in "Specifying Identity System Administrators" on page 2-1, you can specify the following roles for users:

**End User:** An end user can perform searches, view profile data, and modify profile data, depending on access permissions set for individual attributes.

**Delegated Access Administrator:** A Delegated Administrator is a user who can perform all of the same tasks as an end user and can create user, group and organization objects, depending on the level of permissions he or she has been granted. A Delegated Administrator can also view requests.

**Delegated Identity Administrator:** A Delegated Identity Administrator is a user who has been delegated the right to view configuration tabs for the User Manager, Group Manager, and Organization Manager applications. This person can set attribute access controls, define workflows, and so on.

**Identity Administrator:** An Identity Administrator can view the User Manager, Group Manager, and Organization Manager applications, and use Identity System configuration functions in the Identity System Console.

For example, if you log in as an Identity Administrator, you can view every screen in every application. But if you log in as an end user, you may only see a subset of the User, Group, and Organization Manager applications, and you cannot access Identity System administrative functions.

By default, single sign-on is configured between the Identity and Access Systems. If you log in to one system, you should not be prompted to log in to the other system.

If you use the Access System to protect the Identity System applications, you can bypass the default login form and implement your own custom form. For details about protecting resources with policy domains, see the *Oracle Access Manager Access System Administration Guide*.

### Logging In to the Identity System

The procedure for logging in to the Identity System depends on whether you customized the login screen, made it available as a portal insert, or protected it with the Access System.

This section covers the default login screen that ships with the Identity System, as well as the impact of the default user type on login. See the *Oracle Access Manager Customization Guide* and the *Oracle Access Manager Developer Guide* for more information on customization.

You must configure an attribute with a semantic type of Login before users can log in to the Identity System. You can either automatically configure this attribute during installation, or manually configure it from the Identity System Console. See "Making Schema Data Available to the Identity System" on page 3-1 for more information.

---

**Note:** Only Master Identity Administrators and Delegated Identity Administrators have access to the Identity System Console. See "Specifying Identity System Administrators" on page 2-1 for more information about configuring these administrators.
**To log in to the Identity System**

1. In your browser, type the path to the Identity System and press Return.
   
   For example:
   
   `https://hostname:port/identity/oblix`
   
   where `hostname` is the name of the computer on which the WebPass is installed and `port` is the Web server port for the WebPass. You can log in using the HTTP or HTTPS protocol.

   The main product page appears. This page will have links to one or more applications, including the User Manager, Group Manager, and Org Manager.

   See the *Oracle Access Manager Customization Guide* for more information about changing this default.

2. Select the desired application.
   
   A login page appears.

3. Enter your user name and password.
   
   For Active Directory users, if the Domain field is present, select the domain in which this installation of the Identity System operates.

   By default, when you log in to the Identity System, you see all of the functions available to an Identity System Administrator. For example, in the User Manager, you will see functions such as "My Identity," "Reports," and the search function.

**Logging into the Access System**

By default, a user is not required to log in to the Access System if he or she is already logged in to the Identity System, and vice versa. Session information is stored in a cookie called the ObTEMC cookie. You may choose to protect the Identity System applications in a policy domain, in which case a different authentication can be used. For details about protecting resources with policy domains, see the *Oracle Access Manager Access System Administration Guide*.

You must configure an attribute with a semantic type of Login before users can log in to the Access System. You can either automatically configure this attribute during installation, or manually configure it from the Identity System Console. See "Making Schema Data Available to the Identity System" on page 3-1 for more information.

This section covers the default login screen that ships with the *Access System*.

---

**Note**: Only Master Administrators and Master Access Administrators have access to the Access System Console. For details about configuring Master Access Administrators, see *Oracle Access Manager Access System Administration Guide*.

---

**To log in to the Access System**

1. In your browser, type the path to Access System and press Return.

   **Example**: `https://hostname:port/access/oblix`

   where `hostname` is the name of the computer on which the Policy Manager is installed and `port` is the Web server port for the Policy Manager. You can log in with the HTTP or HTTPs protocol.
Introduction to Using Oracle Access Manager

The main product page appears. This page will have links to one or more applications, including the Identity System, the Policy Manager, and the Access System Console.

2. Select the application you want.

**Policy Manager**—Only Delegated Access Administrators will see any policy domains. For details about delegating administration in the Policy Manager, see the *Oracle Access Manager Access System Administration Guide*.

**Access System Console**—Only Master Administrators and Master Access Administrators can access its functions. For more information about configuring Master Access Administrators, see the *Oracle Access Manager Access System Administration Guide*.

3. A login page appears.

**Functional Areas on a page**

The following identifies the main components of an Identity System page.

**Navigation Elements**

The following is a portion of an Identity System Console page. This page appears when you access the Identity System landing page, click the Identity System Console link on that page, then click the User Manager Configuration sub-tab.

All pages have the following functional areas:

- **Application Tabs**: A set of tabs that show the Identity System applications: the User Manager, Group Manager, Organization Manager (abbreviated to Org. in the user interface), and the Identity System Console.

- **Application Sub-Tabs**: A set of tabs that show the main functions for the Identity System applications. For example, the Identity System Console contains modules for System Configuration, User Manager Configuration, Group Manager Configuration, and Common Configuration.

- **Help, About, and Logout links**: These links appear at the top of the page.

- **Left Navigation Pane**: The Identity System Console uses a left navigation pane. This pane contains a list of links to functions that are applicable to the tab or sub-tab that has been selected. The user applications use sub-tabs and panels instead of a left navigation pane.
Main Body: The main body displays a description of the currently selected function or the fields to be completed.

Search Functionality
The user interface contains search fields to search for users or groups. These search fields appear on most Identity application pages. The number of fields available to you and the items that you can search on depend on how an administrator has configured the search function.

You query for users or groups by filling in the search criteria and clicking Go. Optionally, you can store the results of a query by clicking the Reports tab and selecting Generate Report. Oracle Access Manager uses a locale-based case insensitive sorting method when you click the column heading (Full Name, for example) in the search results table.

To use the search function
1. Enter your search criteria.
   For the simplest kind of search, type a text string in the Search entry field.
   By default, you need not enter a minimum number of characters. However, to help users narrow their search criteria you can control the minimum number of characters that users must enter in the search field by setting the searchStringMinimumLength parameter in oblixadminparams.xml. See the Oracle Access Manager Customization Guide for details.
2. Click Go.
   Users or groups matching your search criteria appear on the screen.
   By default, 8 results are displayed on a page. This applies to both Selector and Query Builder. If you perform a search or query that results in more than 20 hits, you receive truncated results. For instructions on changing this search cap, refer to the cookieBustLimit parameter documentation in the Oracle Access Manager Customization Guide.
3. In the search results, click the links for the users or groups to select them.
Note: If you receive a "Bad request" message when you click Done, your search string is too long for your browser. Browsers handle the search parameters as URLs, and they generate an error if the search exceeds their maximum URL length.

4. In the search results, click the column heading to sort the list.

Note: Oracle Access Manager uses a locale-based case insensitive sorting method.

The Selector

The selector provides search functionality and the ability to aggregate the results of a search. For example, if you want to create a group, after clicking the Group Manager tab and the Create Group sub-tab, a page appears with selection buttons.

If you click a selection button (Select Member in this example), the Selector appears.

The Selector landing page is a blank search page with Done and Cancel buttons and an empty list of selected items. If you use the search functionality on this page, the Selector enables you to move retrieved items to the Selected list.
Online Help

A Help link is located at the top right of Identity System screens, and in the side navigation bar of Access System screens. To access online Help, click this link.

You can perform the following tasks in an online Help window:

- Scroll to view the entire Help topic.
- Click Contents to display a list of topics.
- Click Back or Forward to see other Help topics.
- Click Exit to close the window.

The About Page Link

A link to the About page is located at the top right of Identity and Access System pages. Click the About link to display the Oracle address, telephone numbers, and other contact information, and copyright information.

The View System Info button displays the server platform and version, and contact information for Oracle.

Logging Out

A Logout link is located at the top of the Identity and Access System pages. By default, if you log out of the Identity System, you are automatically logged out of the Access System and vice versa.

When you finish using Oracle Access Manager, to prevent unauthorized people from accessing your information you should log out and close your browser.

By default, sessions expire after three hours. To change the timeout, see "Configuring Session Timeout" on page 7-10 for details.

Note: On Firefox, users are prompted to manually close their browser window after logging out.

To log out

1. Click Logout in the upper right-hand corner of the page.
2. Click OK when prompted to close your browser.
This chapter explains how to specify Identity System administrators.

This chapter contains the following topics:

- About Identity System Administrators
- Specifying Administrators
- Delegating Administration

### About Identity System Administrators

The Identity System manages user, group, and organization identity information, as described in the *Oracle Access Manager Introduction*.

Administering the Identity System involves a broad range of tasks that are designed to help you manage your data, enhance performance, and control the appearance and functionality of Identity System applications. For details about these tasks, see "Configuring Global Settings" on page 7-1.

The responsibility of administering the Identity System is shared between Master Administrators and Master Identity Administrators:

**Master Administrators**: At least one Master Administrator is specified when the product is set up. This is the highest level administrator. This administrator can specify other Master Administrators and Master Identity Administrators.

**Master Identity Administrators**: Master Identity Administrators can delegate specific responsibilities to administrators called Delegated Identity Administrators.

**Delegated Identity Administrators**: Delegated Identity Administrators are assigned by Master Identity Administrators and created in User Manager.

See Table 2–1 for a description of the types of Identity System administrators and their privileges.
### Table 2–1  Types of Identity System Administrators

Specifying Identity System Administrators 2-3
Specifying Administrators

You use the Identity System Console to assign Delegated Identity Administrators and Master Identity Administrators. As mentioned earlier, you must be a Master Administrator to complete this task.

To specify Master Administrators and Master Identity Administrators
1. Log in to the Identity System as a Master administrator, and from the landing page for the Identity System, click the Identity System Console link.
   If you are already logged in, click the Identity System Console tab.
2. Click the System Configuration sub-tab.
   The System Configuration page appears.
3. Click Administrators in the left navigation pane.
   The Configure Administrators page appears, displaying two options: Master Identity Administrators and Master Administrators.
   See Table 2–1 for a list of the tasks performed by each type of administrator.
4. Click the category of administrator you want to add.
   A Modify type_of_administrator page appears.
   where, type_of_administrator is either a Master Administrator or a Master Identity Administrator.
5. Click Select User to add an administrator.
   See “The Selector” on page 1-10 for information about using this feature.
6. Select a user and click Add.
   The name you select in the Selector page appears in the Modify type_of_administrator page, where type_of_administrator is a Master Administrator or a Master Identity Administrator. You can specify multiple administrators.
7. Click Done to leave the Selector page.
8. Click Save to add the administrator.

Deleting Administrators

When you delete an administrator, you remove administration rights from the user, but you do not remove or deactivate the user from the LDAP directory.

To delete an administrator
1. From the Identity System Console, click the System Configuration sub-tab.
2. Click Administrators.
3. In the Configure Administrators page, click the link for the type of administrator that you want to delete.
   The Modify type_of_administrator page appears, where type_of_administrator is a Master Administrator or a Master Identity Administrator.
   Click Select User.
4. Clear the DEL button next to the administrator who you want to delete.
5. Click Done to confirm the deletion.
Delegating Administration

You can delegate your rights and responsibilities to other administrators. The tasks delegated are specific to the delegated right, the target, and the tree path.

This section covers:

- About Delegating Administration
- Delegated Administration Models
- Adding Delegated Administrators

About Delegating Administration

Delegating administration allows the Master Administrator and Master Identity Administrator to delegate their responsibilities to other, more local administrators. This is particularly useful in large organizations, where it may be necessary to administer thousands or millions of users.

When you delegate administration, you determine what rights you want to grant to another user. Rights include the ability to configure the following:

- Read access for attributes
- Write access for attributes
- Notification by email of attribute modifications
- Setting the searchbase
- Monitoring requests
- Defining workflows
- Containment limits

In addition, you can designate people to act as your substitute. People who are granted substitution rights can temporarily perform any of the functions that you are permitted to perform.

After you have delegated a right to another user, that user becomes a Delegated Identity Administrator. By delegating administration, you determine who can configure or access which feature, at what level, and with which filters. Configuration or access authority may be for a specific user or group of users, a role, or a rule. The resource that can be configured or accessed may include a searchbase, an attribute access control, a workflow definition and so forth. The level is the starting DN.

Task overview: Delegating administrators

1. Start the delegation procedure for the desired application.

   Note: All activities here are described in "Adding Delegated Administrators" on page 2-8.

2. Select the right that you want to grant (for Read, Write, and Notify permissions only).

3. Identify the attribute associated with the right.

4. Specify the level of access control for that attribute, thus setting the scope of the directory tree to which the rights apply.
5. Select the person to whom you are delegating the rights.

For example, as the Master Identity Administrator, you can grant one or more users the ability to set Read access control for the Title attribute. You can specify whether you want the Delegated Identity Administrator to be able to delegate access control to others.

For more information, see "Adding Delegated Administrators" on page 2-8.

Delegated Administration Models

The Identity System enables you to set access controls and delegate administration for directory tree structures that represent different business models. These models include an extranet model, an intranet model, and an ASP model. These models are described in the following sections:

- Extranet Model
- Intranet Model
- ASP Model

Extranet Model

A typical business-to-business extranet might have 500 or more extranet organizations using a site. These organizations represent customers, partners, and suppliers, each having between 1 and 100 users.

The goal in the extranet model is to have the Master Identity Administrators push out administrative responsibilities to each of the partners. But because there are so many partners, it would be a burden to define new roles and responsibilities each time a partner joined. Therefore, the Directory Administrator must define a fixed set of roles and responsibilities that are leveraged across all customers, existing and new. The Master Identity Administrator can then define access controls and create delegated administrator policies that are symmetric across all organizations.

The Delegated Identity Administrator at each partner site is typically a line-of-business person who has a fixed, well-defined set of tasks and rights, such as creating users and changing attribute access permissions. Delegated Identity Administrators can only give others in their organization administrative privileges by adding and deleting people from a set of pre-defined roles.

For example, the Delegated Identity Administrator creates a new user with an attribute of admin=yes. This new user then inherits the ability to change attribute access control permissions, create new users, and other well-defined tasks, as illustrated in Figure 2–1.
Intranet Model

In a typical intranet model, the directory tree is generally organized according to a logical separation of users, such as by geography (North America and Europe) or function (Marketing and Engineering).

The directory might be characterized by only a few branches at each OU, but may be several layers deep in branching. The branches may be very different from each other and may have several thousand users in each branch. At a given node, a European branch might have 500 users under Sales and Marketing, while a North American branch might have 10,000 users under East, Central, and West.

The Master Identity Administrator may choose to delegate administration centrally or at the OU level, depending on where the technical and business process knowledge resides. Or additionally, the Master Identity Administrator may choose to delegate administration across specific tasks; for example, you might delegate the task of provisioning phone numbers—but not managing access permissions or creating new users.

Figure 2–2 illustrates the intranet model:

**Figure 2–2 Intranet Delegated Administration Mode**
**ASP Model**

Some business-to-business extranet sites may follow the application service provider (ASP) model more closely than the extranet model described earlier.

In an ASP model, there are fewer extranet partners but significantly more users at each partner site. For example, there may be only approximately 50 partners but each partner may have 1000 users.

ASPs provide hosted services. Different customers may need different sets of services. This means the scope of data that needs to be managed, such as access rights, may differ for each OU. Further, the directory structure of each OU may be substantially different. Under each OU may be all the complexity of an intranet directory tree as in the intranet model, yet the structure of the tree could be completely different between the OU for Customer 1 and the OU for Customer 2.

The ASP model needs a flexible delegation model similar to the intranet model. The Master Identity Administrators at the ASP site performs some top-level configuration, such as setting the searchbase, and configures an initial delegation model similar to the extranet model. However, each customer site requires the flexibility to create a customized delegated administration model, either by a technical Delegated Identity Administrator at the customer site or by the Master Identity Administrators at the ASP site.

**Figure 2–3  ASP Delegated Administration Model**

![Delegated Administration Model Diagram]

**Adding Delegated Administrators**

Delegating administration allows the Master Identity Administrator or a Delegated Identity Administrator to further delegate responsibility to other local administrators.

**To delegate administration**

1. Log in to the Identity System, and from the landing page select the link for the User Manager, Group Manager, or Organization Manager.
   If you are already logged in, select the tab for the application.

2. Click the Configuration sub-tab.
The Configuration page appears.

3. Click the Delegated Administration link.
   
   On some browsers you may receive a prompt asking if you trust the certificate of the application. If you receive this prompt, select the Trust Always option.
   
   The Delegate Administration page appears.

4. In the Management Domain box, specify the scope of the DIT that this right applies to.
   
   Initially this field displays the searchbase defined during setup. The searchbase is usually defined at the highest (company-wide) level. Depending on the level of your delegated rights, you can specify access control at any level, from the lowest level (an individual user), through intermediate levels (departments, divisions, partners), and then to the highest level (company-wide). For example, if you select the Full Name attribute and select a department such as Sales, you are setting an access control that applies to all full names belonging to the Sales department.
   
   The selection appears in the field beneath the Management Domain box.

5. Optionally, use the Filters field to specify either a variable substitution or LDAP rule to filter the DIT level you selected.
   
   For more information, see "Usage of Rules and Filters" on page 3-23.

6. Optionally, in the Add Filter field, enter another filter, then click Save.
   
   The new filter appears in a field beneath the previous filter.

7. In the Grant Right list, select the right that you want to grant to the delegated administrator:
   
   - **Read**: Allowed to set read (view) permission for the selected attribute
   - **Modify**: Allowed to set modify permission for this attribute
   - **Notify**: Allowed to set notify permission when user requests attribute value change
   - **Set Searchbase**: Allowed to specify the searchbase
   - **Monitor Requests**: Allowed to monitor requests and manage deactivated users
   - **Define Workflow**: Allowed to define workflows
   - **Substitute Rights**: Allowed to designate other people as your substitute

8. Give the new administrator the authority to further delegate this right to other administrators by selecting the Delegate Right check box.

   **Note:** Selecting Delegate does not automatically assign Grant rights. You must define Delegate and Grant rights separately.

9. In the Attribute box, select an attribute to associate with the right.

10. Select a trustee to whom you want to assign one or more rights with one or more of the following methods:

    - **Rule**: Click Build Filter and use the Query Builder to create a rule. See "Writing LDAP Filters Using Query Builder" on page 4-27 for details.
    - **Person(s)**: Click Select User and use the Selector to specify one or more users.
Delegating Administration

- **Group(s):** Click Select Group and use the Selector to specify one or more groups.

  The Rule, Person(s), and Group(s) fields have an or relationship. A user specified in any of these fields is assigned the right.

11. Use the Copy and Paste buttons to copy users and groups from one attribute to another.

  Click Copy, click Reset, select another attribute, and click Paste. The users and groups appear in their respective boxes.

12. Click one of these buttons:

- **Save:** Saves and implements your changes
- **Reset:** Clears all selections
- **Delete:** Clears all rule, group, and user specifications
- **Report:** Generates a report of all attributes and their access permissions across the domain

---

Adding Substitute Administrators

As an Identity System Administrator, if you have been granted substitute rights, you can designate other people to temporarily assume your rights. After your substitute logs into the Identity System, they can assume your identity. When your substitute views the My Identity page, your information is shown rather than the other person's information.

By assigning substitute rights, you allow someone else temporarily to assume your identity. For example, suppose you are a Delegated Identity Administrator. Before leaving for vacation you assign substitute rights to J. Smith. When J. Smith logs in, he assumes your identity. Later, when J. Smith wants to perform his own duties, he reverts the delegated rights. Although the substitute appears to be you while assuming your identity, the Identity System logs all activities with both the substitute's and your identities. All logs and alarms show duplicate entries using both identities.

To assign or remove a substitute

1. From the Identity System landing page, log in and select the link for the User Manager.
   
   If you are already logged in, click the User Manager tab.

2. Click the Substitute Rights link.

   The Substitution Rights page appears.
   
   If you have been granted substitute rights, this page contains a Select User button. If you have designated people to be your substitute, these people are listed in the Substitute(s) field. This page also contains a Substitute for field with a list of people who have designated you as their substitute. If no people are listed, no one has designated you as their substitute.

3. Assuming that you have been granted substitute rights, click Select User.

   The Selector page appears. See “The Selector” on page 1-10 for details.

4. Select the user and click Add.

   The user is added to the Selected list.

5. Select a user and click Delete to remove the user.
The user is removed from the Selected list.

6. Click Done to leave the Selector page.
7. Click Save to save your changes.

To assume an identity
1. From the Identity System landing page, log in and select the link for the User Manager.
   If you are already logged in, click the User Manager tab.
2. Click Substitute Rights.
3. In the Substitute for User section of this page, select the user whose rights you wish to assume.
   This user must already have assigned you to be a substitute.
4. Select Assume Right and click Save.

To revert to your own identity
1. From the User Manager, select Substitute Rights.
2. Select Revert

See "Configuring Global Settings" on page 7-1 for details about configuring styles for Identity System applications, configuring multiple languages for the Identity System, configuring and managing Identity Servers and WebPass, and configuring password policies and the Access Manager SDK for the Identity System.
You use the Oracle Access Manager Identity System to manage user data, configure Identity applications (User Manager, Group Manager, and Organization Manager), define workflows, and send non-LDAP data to external applications.

Part II explains how to configure the Identity System and contains the following chapters:

- Chapter 3, "Making Schema Data Available to the Identity System"
- Chapter 4, "Configuring User, Group, and Organization Manager"
- Chapter 5, "Chaining Identity Functions Into Workflows"
- Chapter 6, "Sending Non-LDAP Data to External Applications"
- Chapter 7, "Configuring Global Settings"
Making Schema Data Available to the Identity System

The Identity System applications (the User, Group, and Organization Manager) enable users to view and modify data about themselves, other users, groups, and other objects. The items that users see on the Identity System applications consist of LDAP directory attributes that you have configured in the Identity System Console. In order for the Identity System applications to display data, you use the Identity System Console to configure objects and attributes from a directory schema that the application is to work with.

The Identity System applications also enable users to send data to back-end applications. For example, users can enter data in a workflow, and that data can be sent to an application that creates new user email accounts. To prepare the Identity System applications to be used in this manner, you use the Identity System Console and configure objects and attributes from a template schema. A generic schema file is supplied with the Identity System.

This chapter discusses the following topics:

- About Object Classes
- Viewing Object Classes
- Modifying Object Classes
- Adding Object Classes
- Deleting Object Classes
- About Object Class Attributes
- Viewing Attributes
- Configuring Attributes
- Configuring Derived Attributes: Matching Values from Different Attributes
- Attributes Configured for an Individual Application

About Object Classes

As an Identity System administrator, you configure three applications for your users (and other administrators). These applications are the User Manager, Group Manager, and Organization Manager.

Figure 3–1 shows a portion of a User Manager Profile page.
The Identity System applications obtain most of the data that they display from entries in an LDAP directory. For instance, the User Manager may show a person’s name, email, and so on. This data is taken from attribute values stored on a person object in the directory. These attributes and their values are displayed on profile pages in the User Manager. In Figure 3–1, the name displayed in the user profile is based on the name attribute for the person object in the directory. The actual name being displayed is a value stored with the attribute. The title is based on the title attribute for the person object.

All of the Identity System applications—the User Manager, Group Manager, and Organization Manager—display attribute values for specific objects on profile pages.

### About Sending Data to External Systems Using Template Objects

In addition to configuring objects and attributes from an LDAP directory, the Identity System enables you to define template schemas. Using the Identity System Console, you configure the objects and attributes from a template schema in the same way that you configure LDAP data. However, LDAP data and template data are used in different ways. You configure LDAP data to populate Identity System applications. Users enter values for LDAP data from either an Identity System application profile page or from a workflow. The LDAP data is displayed on the profile page. In contrast, you can only enter template data during a workflow step. The data is not displayed on the profile page. Instead, it is sent to a back-end application that needs the data.

Unlike LDAP data, you can use only template object data for sending data to back-end systems. For example, you can create an object template schema with attributes that an email system can understand. You would then configure the attributes from this schema in the Identity System, define a workflow that uses these attributes, and use the Identity Event API to send this data to the back-end system.

**Note:** For instructions on how to configure the template object file, see “Sending Non-LDAP Data to External Applications” on page 6-1. The template object file must be finalized before you can configure the template objects in the Identity System Console, as described in “Sending Non-LDAP Data to External Applications” on page 6-1.

### The Process for Configuring Schema Data

When you first install and set up Oracle Access Manager, the User Manager, Group Manager, and Organization Manager applications are empty. You need to configure these applications with information. For example, you may want the User Manager to...
display information about a user such as their name, title, phone number, email, and so on. Before configuring the appearance of these applications, you must first use the Identity System Console to configure the LDAP objects and attributes that you want to display on the application profile page. You must also define how each attribute is to be displayed, for example, if it is a string value, a selection list, or a radio button. You primarily use LDAP directory data to identify in the Identity System Console which objects and attributes you want to display to users on application profile pages.

Once you have configured objects and attributes in the Identity System Console, you can configure Identity System applications to display these attributes and their values. Configuring the Identity System applications is discussed in "Configuring User, Group, and Organization Manager" on page 4-1. Finally, you assign View and Modify rights to determine who can view and modify these attributes.

If you are using the Identity System as the entry mechanism for an external application, you use the Identity System Console to configure template objects and attributes. As with LDAP data, you define how each attribute is to be displayed on a profile page. The primary difference between LDAP and template data is that users may only enter values for template attributes during a workflow step, and you must use the Identity Event API to pass this data to a back-end application.

**Objects Configured During Installation**

During installation and setup of the Identity System, you configured the following object classes:

- **User Manager**: A required person object class
- **Group Manager**: A required group object class
- **Organization Manager**: A predefined location object class

These object classes are taken from the LDAP directory that the Identity System communicates with.

In addition to the object classes that are configured during the installation process, you may want to configure additional LDAP and template-based objects and attributes. The following sections discuss how you configure objects and attributes to provide the Identity System applications with data.

**Note**: Configuring an attribute does not ensure that the attribute is displayed on an Identity System application page. You must associate specific attributes with an Identity System application page, and assign View and Modify rights to these attributes. See "Configuring User, Group, and Organization Manager" on page 4-1 for details.

**Structural and Auxiliary Object Classes in the Identity System**

The Identity System works with structural and auxiliary LDAP object classes. When you install the Identity System, the User, Group, and Organization Manager applications are associated with one structural object class each. A structural object class describes the basic aspects of an object. Examples of structural object classes include person and groupOfNames. The person object class may contain attributes such as name, department, employee ID, and email address.

The User Manager and Group Manager are always associated with only one structural object class.
The Organization Manager can be associated with any number of structural object classes of a generic or location object class type (see "Object Class Types" on page 3-5 for details). During installation and setup, a location structural object class is associated with the Organization Manager. In the Organization Manager, each structural object class is represented as an option in the menu in the top right corner of the page. The work area for a particular object class in the Organization Manager is referred to as a tab.

**Figure 3–2 Organization Manager Tabs**

You use an auxiliary object class to add a set of related attributes to an entry that already belongs to a structural class. Auxiliary object classes are mix-in LDAP object classes that can be added to any structural class. Items such as a billing address, a challenge phrase, a response to a challenge phrase, and so on may be useful for definition in an auxiliary object class.

You must configure attributes for each object class that you want to manage through the Identity System Console. See "About Object Class Attributes" on page 3-9 for more details.

---

**Note:** Before users can see values for attributes that you configure, you must set up the User Manager, Group Manager, and Organization Manager tabs and provide view and modify permissions, as appropriate, to the users. See "Configuring User, Group, and Organization Manager" on page 4-1 for details.

---

The inheritance of all objects is based on the premise of a common super class for both the structural object class and the auxiliary class. Otherwise, object class extension is not feasible. For example, if you don’t choose Top as the inherited Object Class in eDirectory, NDS sets the inherited object class to None. When you configure the object class as an auxiliary class in the Identity System, no problems are evident initially. However, if you execute a Create User Workflow that contains attributes of this auxiliary class, the Enable step fails when trying to commit because the schema is incompatible and the auxiliary class cannot be added to the entry’s object class attribute due to a schema violation.

**Template Object Classes**

In addition to structural and auxiliary object classes, the Identity System recognizes template object classes. Template object classes function in part like auxiliary object classes, in that they are used to augment the functionality in an Identity System application tab, and they cannot be used as the foundation for a tab. However, template objects are not defined in an LDAP directory, and you do not use template objects for configuring the profile pages shown on a tab.

You define template objects in a schema file. The template objects are only used in Identity System workflows, for sending data to back-end applications. Template object classes differ from the other kinds of object class in several respects:
Users interact with the template object class attributes to send data to back-end applications.

Users interact with template object class data attributes only in the context of an Identity System workflow.

Template attribute values are only visible when a user invokes a workflow instance and enters the data. Once the data is submitted, it cannot be displayed again in the Identity System. See “Chaining Identity Functions Into Workflows” on page 5-1 for details. This is different from LDAP data, which you use to configure the fields, labels, and other items displayed on the Identity System application pages.

Note: Template attribute values cannot currently be displayed because the flow of data from the Identity System to the back-end system is one-way. This limitation will be removed in a future release.

Template object data resides a template object file, not an LDAP directory.

For information on defining template objects and the complete process for using them with back-end applications, see “Sending Non-LDAP Data to External Applications” on page 6-1.

Object Class Types

When configuring your object classes, you are asked to specify an object class type. The term object class type refers to how an object class is used within the Identity System. Table 3–1 lists the object class types supported in the Identity System.

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Person</td>
<td>This type contains information about a person. Examples of this type include companyOrgPerson and customerOrgPerson. When you install the Identity System, the oblixOrgPerson type is created. This is an important auxiliary object class. It provides the obUserAccountControl attribute, which you should never modify. This attribute is written to the profile of any user you deactivate.</td>
</tr>
<tr>
<td>Group</td>
<td>This type contains information about a group. Examples include groupOfUniqueNames and mailGroups. When you install the Identity System, the oblixGroup and the oblixadvancedgroup type auxiliary classes are created to help you configure useful information on the Group manager.</td>
</tr>
<tr>
<td>Location</td>
<td>This type contains information about locations. The Organization Manager uses this object class to store and display location information.</td>
</tr>
<tr>
<td>Generic</td>
<td>Any object class that does not fit in the other categories. An example includes the organizationalUnit object class that is managed by the Organization Manager.</td>
</tr>
</tbody>
</table>

Viewing Object Classes

When you install and set up the Identity System, several object classes are already configured. You can view and modify these object classes, and you can create additional object classes.

To view configured object classes

1. From the Identity System Console, click Common Configuration.
The Common Configuration page appears.

2. Click the Object Classes link in the left navigation pane.

The Configure Object Classes page displays object classes that are configured in your LDAP directory and object templates, along with the following information:

<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object Class</td>
<td>Name of the object class.</td>
</tr>
<tr>
<td>Object Class Type</td>
<td>How the object class is used by the Identity System. See “Object Class Types” on page 3-5 for details.</td>
</tr>
<tr>
<td>Object Class Kind</td>
<td>If you have configured an LDAP object, the kind can be Structural, Auxiliary, or other object.</td>
</tr>
<tr>
<td></td>
<td>See “Structural and Auxiliary Object Classes in the Identity System” on page 3-3 for details.</td>
</tr>
<tr>
<td></td>
<td>An object class kind of Other indicates that the object class kind is undefined. Text can be</td>
</tr>
<tr>
<td></td>
<td>Don't care or Unknown.</td>
</tr>
<tr>
<td></td>
<td>If you have configured a template object, the kind can only be Template. See “Template Object Classes” on page 3-4 for details.</td>
</tr>
<tr>
<td>Object Class Attribute</td>
<td>This is used by the Identity System for attribute access and it is also the attribute that the Identity System uses to link search results to a profile page. See “Selecting a Class Attribute” on page 3-7 for a description.</td>
</tr>
</tbody>
</table>

Modifying Object Classes

From the Identity System Console, you can change the class attribute and the type for an object class. It is important to specify a class attribute for your structural object classes.

You can change the structural object class. However, it is best if you plan your configuration so that this task is not necessary.

**Note:** Using the application-specific Tabs function, you can provide a different display name or display type for an attribute on that application-specific Configuration tab only (different than what is configured at the object class level). This will override the information configured for the attribute at the object class level. For details, see “Modifying and Localizing Attributes Displayed on a Panel” on page 4-19.

To modify an object class type

1. From the Identity System Console, click Common Configuration.
   
The Common Configuration page appears.

2. Click the Object Classes link in the left navigation pane.

3. Click the link for the object class you want to modify.
   
The View Object Class page appears.

4. Click Modify.
   
The Modify Object Class page appears.

5. Select a new class type.
   
See “Object Class Types” on page 3-5 for more information on object class types.

6. Save your change.
Selecting a Class Attribute

In the User Manager, Group Manager, and Organization Manager, each tab is associated with a structural object class. Within the structural object class, you select an attribute to be the class attribute. The class attribute is used for attribute access. Users who do not have read access to a class attribute do not have access to the entire entry.

Note: It is not required to set a class attribute for a template object class. You determine user access to template objects and attributes when you configure a workflow, as described in "Chaining Identity Functions Into Workflows" on page 5-1.

The Identity System also uses the class attribute when displaying search results on a profile page. When a user conducts a search, the Identity System returns a list of results. Each returned item has one value that is displayed as a link. The linked value is taken from the class attribute of the returned object. When the user clicks the link, the Identity System displays the profile associated with that link.

For example, if you specify User Name as the class attribute for the orgPerson object class, when someone searches in the User Manager, the list of search results displays user names as links. Clicking a link displays the profile for that user.

Class attributes are usually selected as follows:

- User Manager uses a class attribute for a person’s name.
- Group Manager uses a class attribute for a group’s name.
- Organization Manager uses one class attribute for each tab. For the location structural object class, the attribute would typically be a location name.

To select the class attribute

1. From the Identity System Console, click Common Configuration.
   The Common Configuration page appears.
2. Click the Object Classes link in the left navigation pane.
3. Click the link for the object class you want to modify.
   The View Object Class page appears.
4. Click Modify.
   The Modify Object Class page appears.
5. Select the class attribute from the list of attributes.
   Note that you can only select a class attribute for a structural object class.
6. Click Save.

Changing the Structural Object Class

Changing the user or group structural object class requires you to rerun Identity System setup.

To change user or group structural object classes

1. Shut down all but one Identity Server.
2. Locate IdentityServer_install_dir/identity/oblix/config/setup.xml, and change the status parameter value from "done" to "incomplete," as described in "Rerunning Setup Manually" on page 7-28.

3. Depending on which application you are modifying, delete the top node for the structural object class, as follows:
   
   User Manager node: obapp=userservcenter,o=Oblix,o=company,c=us
   
   Group Manager node: obapp=groupservcenter,o=Oblix,o=company,c=us

4. Restart the Identity Server and navigate to the Identity System Administration Console to initiate and complete the setup process as you reconfigure the structural object classes.

When you restart the Identity Server, the other Identity Servers should pick up the new structural user or group object class from the updated directory tree.

Adding Object Classes

There are two basic methods for adding an object class in the Identity System Console:

- Configure each attribute manually.
- Select the autoconfigure object class option

This method configures the object class using settings from the Identity System. This option is faster than manual configuration. You cannot view or modify the Identity System-provided attributes before importing them.

With either option, you can later modify the attributes from the System Console. See "About Object Class Attributes" on page 3-9.

To add an object class

1. From Identity System Console, click Common Configuration, Object Classes.

2. Click Add.

   The Add Object Class page appears.

   The default schema domain is LDAP. If you have not defined any template object classes, LDAP is the only choice. If you have configured additional template object classes and want to configure objects from the additional class, select the class from the Schema Domain list.

3. In the Schema Domain list, select the type of schema that you want to work with, if applicable.

4. From the Object Class list, select the object class to add.

   This allows the Identity System to manage the object class. The list contains object classes that were defined in your LDAP directory prior to installing the Identity System.

5. In the Class Type field, select what type of Identity System application can manage this object class.

   See "Object Class Types" on page 3-5 for details.

6. In the Class Kind field, select Structural, Auxiliary, Template, or Other.

   If the Identity System can determine the Class Kind from the LDAP directory, these radio buttons are hidden.
7. Select Auto Configure object class to populate this object class with attributes from an Identity System-provided file.

8. Click Save.

When a template object class is saved, it is saved in fully qualified form. For example:

```
obclass=person,o=oblix,o=company,c=us
```

This format is taken from the .tpl file that contains the template object class definition. See "Sending Non-LDAP Data to External Applications" on page 6-1 for details.

**How Auxiliary Classes Are Used**

You can use auxiliary object classes as mix-ins with structural object classes. This can be helpful when you configure the User Manager, Group Manager, and Organization Manager applications. The more object classes you have at your disposal, the more items you can display on the tabs for these applications, and the more information you can configure for users of those applications.

An object assigned to an auxiliary object class must be associated with a structural class. For example, you can add inetOrgPerson as your structural object class and associate it with the tab in the User Manager application. You can then add auxiliary object classes with attributes for particular kinds of people, such as customers, partners, and so on.

To associate one or more auxiliary object classes with the structural object classes chosen for the Identity System applications, see "Adding Auxiliary and Template Object Classes to a User or Org. Manager Tab" on page 4-7.

**Deleting Object Classes**

You can delete auxiliary object classes. You also can delete template object classes that have not yet been added to a tab for a user or group. You cannot delete a structural object class. You can only substitute a new structural object class for an existing one. See "Changing the Structural Object Class" on page 3-7 for details. When you delete an object class, you should also remove any searchbases that you have configured for that object class. See "Setting the Searchbase" on page 4-23 for details.

1. From the Identity System Console, select Common Configuration, Object Classes.

2. Click a link for the object class.

   The object class Kind must be Auxiliary.

3. From the View Object Class page, click Delete.

**About Object Class Attributes**

When installing the Identity System, you configure required structural object classes and their attributes. After completing Identity System setup, you may want to add object classes, configure additional attributes, and modify existing attributes. When adding an object class, you can have the Identity System automatically configure attributes in that object class, as described in "Adding Object Classes" on page 3-8. Use the Modify Attributes feature to change attributes and to configure additional attributes.
The following sections describe attribute configuration:

- **About Configuring Attributes**
- **Attribute Data Types**

---

**Note:** For Active Directory installations, there is a subset of attributes that are unavailable to schema definition by default. To make these attributes visible to the Identity System for configuration, you must remove their entries from the following three files in the `IdentityServer_install_dir/identity/oblix/data/common` directory: `exclude_attrs_config.xml`, `exclude_attrs-ad.xml`, and `ad_exclude_attrs.xml`. Restart the Identity Server for your changes to take effect.

---

### About Configuring Attributes

When configuring an object in the Identity System, you select a class attribute, as described in "Selecting a Class Attribute" on page 3-7. In addition, you need to decide how the Identity System will display and work with other object attributes. For instance, you need to decide what facts about a person you want the User Manager to display. You also need to decide how you want to display data. For instance, you may want to display lists of printers on the Organization Manager. Or you may want to display a list of preferred travel agents based on a user’s geographical location.

You can configure the Identity System to use any attributes stored in your LDAP directory. Having a well-structured set of attributes to work with allows the Identity System to display the data you want to display and to provide fine-grained access controls for your users.

After configuring an attribute, you must perform additional steps to display the attribute on a profile page in the User, Group, or Organization Manager. For more information, see "Configuring Tab Profile Pages and Panels" on page 4-11.

After configuring an attribute you must set view and modify privileges to allow users to see the attributes you are displaying. For information about providing users with read and modify privileges, see "Allowing Users to View and Change LDAP Data" on page 4-21.

Before you configure attributes, you need to understand the relationships between an attribute’s data type, semantic type, and the ability to perform searches. These topics are discussed in the following sections.

### Attribute Data Types

When you modify an attribute as described in "About Object Class Attributes" on page 3-9, a data type for that attribute is displayed. A data type is the format of the attribute’s value. For instance, a name attribute may have a data type of a single text line. Every LDAP attribute has an associated data type. In the Identity System, six data types are supported. Data types have corresponding display types, described in "Attribute Display Types" on page 3-14. You cannot configure the data type for a template or LDAP attribute in the System Console. You configure the data type in the `.tpl` file or the LDAP schema. Supported data types are shown in Table 3-2:
Table 3–2 Supported Data Types

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>A case-insensitive or case-sensitive string.</td>
<td>Boolean, check box, date, email address, filter builder, GIF image URL, multi-line text, numeric string, postal address, radio button, selection menu, single line text</td>
</tr>
<tr>
<td>Distinguished Name</td>
<td>Distinguished names are how you refer to entries. A distinguished name (DN) is like the path name for a file, except that the DN is read in the opposite order of a path, from the bottom of the directory.</td>
<td>Object Selector, Location (LDAP data only)</td>
</tr>
<tr>
<td>Integer</td>
<td>An integer</td>
<td>None, Boolean, check box, date, email address, filter builder, GIF image URL, multi-line text, numeric string, password, postal address, radio button, selection menu, single line text</td>
</tr>
<tr>
<td>Telephone</td>
<td>Telephone number</td>
<td>Any display type</td>
</tr>
<tr>
<td>Binary</td>
<td>A binary file, such as a GIF file</td>
<td>GIF image, media, password, S/MIME certificate</td>
</tr>
<tr>
<td>Postal Address</td>
<td>This is a compound string consisting of one to six sub-strings concatenated with the dollar sign ($) as the delimiter. Each sub-string can have a maximum of 30 characters.</td>
<td>Postal address</td>
</tr>
</tbody>
</table>

Attribute Semantic Types

A semantic type is an optional characteristic that governs the behavior of the attribute within an Identity System application. For example, the value of an attribute assigned to the semantic type Photo appears in the header area of a profile page in an Identity System application. You can only assign a semantic type to one attribute. However, an attribute can have more than one semantic type assigned to it. For example, you can assign the Login and DNPrefix semantic types to the cn attribute.

Once a semantic type is assigned, it cannot be assigned to another attribute within a domain unless you disassociate it from the first attribute. For example, only one LDAP attribute can be assigned the semantic type of Password. If you have configured any other schema domain, you could assign the semantic type of Password to only one attribute in that domain. See "Sending Non-LDAP Data to External Applications" on page 6-1 for details.

To disassociate a semantic type from an attribute, you must first specify a semantic type of None for the attribute, and then assign a new semantic type to it.

Each semantic type is associated with one or more display types, as described in "Attribute Display Types" on page 3-14.

Semantic Types Defined During Setup

Table 3–3 describes semantic types that are required during Identity System setup:
Table 3–3  Semantic Types

<table>
<thead>
<tr>
<th>Semantic Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Full Name</td>
<td>Required for the person and group structural object classes and for all structural object classes in Organization Manager. Typically assigned to the cn attribute. The cn attribute is required for most schemas.</td>
<td>Check box, Date, Email address, Multi-line text, Numeric string, Radio button, Selection menu, Single line text</td>
</tr>
<tr>
<td>Login</td>
<td>Required for the person object class. Specifies the user credentials during login.</td>
<td>Single line text, Email address</td>
</tr>
<tr>
<td>Password</td>
<td>Required for password management for the person object class. It is also required for Active Directory. Specifies the user password for password management. Note: If you are using Sun’s iPlanet directory, passwords cannot use UTF-8 characters. If the user supplies UTF-8 characters, the iPlanet directory default 7-bit plug-in fails the operation. By default the 7-bit plug-in requires the uid, mail, and user password attribute values to be 7-bit. To resolve this problem, turn off the plug-in or remove the user password attribute from the configuration.</td>
<td>Password</td>
</tr>
<tr>
<td>DN prefix</td>
<td>Required for the person and group structural object classes and for all structural object classes in Organization Manager. Specifies the relative distinguished name (RDN) of an object. The RDN is the leftmost part of the distinguished name (DN). The DN prefix is used when creating an object through a workflow. The attribute with this semantic type must be in the initiating step of a workflow.</td>
<td>Check box, date, email address, multi-line text, numeric string, radio button, selection menu, single line text</td>
</tr>
</tbody>
</table>

Semantic Types Used in Profile Pages

Table 3–4 shows semantic types used in profile header panels. For more information about profile panels, see “Configuring User, Group, and Organization Manager” on page 4-1:

Table 3–4  Semantic Types in a Profile Header Panel

<table>
<thead>
<tr>
<th>Semantic Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Photo</td>
<td>Specifies a GIF or JPEG image. The Photo semantic type displays the image in the header of the profile page.</td>
<td>GIF image, GIF image URL</td>
</tr>
</tbody>
</table>
Semantic Types Used in the Group Manager

Table 3–5 shows semantic types used in the Group Manager:

<table>
<thead>
<tr>
<th>Semantic Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group Owner</td>
<td>Specifies the attribute where a group owner is stored. The Identity System uses this information primarily as a role in attribute access and delegated administration. Also, group owners can be notified when a user subscribes or unsubscribes from their groups.</td>
<td>Object Selector</td>
</tr>
<tr>
<td>Group Dynamic Member</td>
<td>Specifies the attribute storing the dynamic filter that defines the dynamic membership of a group. If you are configuring the Group Manager, you must assign this semantic type to an attribute. The attribute must also belong to the group object class.</td>
<td>Object Selector</td>
</tr>
<tr>
<td>Group Static Member</td>
<td>Specifies the attribute where static members of a group are stored. If you are using the Group Manager, you must assign this semantic type to an attribute. The attribute must also belong to the group object class. For NetScape installations, this attribute is uniqueMember. For Active Directory, it is Member.</td>
<td>Object Selector</td>
</tr>
</tbody>
</table>

Location Coordinates Semantic Type

The Location Coordinates semantic type is used to track location. It specifies the position of the location GIF image and is used with the obRectangle attribute. It has no allowable display type because it is used internally by the Identity System.

Semantic Types for Managing Lost Passwords

Two semantic types are used for lost password management. The Identity System provides lost password functionality for both the Identity System and the Access System. Once you configure attributes with these semantic types, end users can enter a challenge-and-response phrase that can later be used to recover their lost passwords:
About Object Class Attributes

Table 3–6  Semantic Types Used for Lost Password Management

<table>
<thead>
<tr>
<th>Semantic Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Challenge</td>
<td>Displays a challenge phrase when an end user initiates lost password management. The end user must type the correct response phrase.</td>
<td>Single line text</td>
</tr>
<tr>
<td>Response</td>
<td>The end user must type the correct response to a challenge phrase when implementing the lost password management feature.</td>
<td>Password</td>
</tr>
</tbody>
</table>

Other Semantic Types

Table 3–7 describes other semantic types:

Table 3–7  Other Semantic Types

<table>
<thead>
<tr>
<th>Semantic Type</th>
<th>Description</th>
<th>Allowed Display Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preferred Email address</td>
<td>Used to send email notifications</td>
<td>Email address</td>
</tr>
<tr>
<td>Map</td>
<td>This semantic type is used with the location feature in the Organization Manager. When an object is configured to be a location, you should configure a binary attribute to be a map semantic type. The binary attribute stores a GIF or JPEG of a map for the location feature.</td>
<td>GIF image</td>
</tr>
<tr>
<td>None</td>
<td>This is a place holder and is not a true semantic type. Select None when you do not want to associate an Identity System business rule with an attribute.</td>
<td>N.A.</td>
</tr>
</tbody>
</table>

Attribute Display Types

The display type specifies the appearance of an attribute value, for instance, whether the possible values are True or False or an email address. The display type determines whether the attribute can be used when users conduct a search. Only certain display types such as Date and Multi-Line Text are searchable, as indicated in the following table.

Once you have assigned an attribute to an Identity System application panel as described in "Configuring Tab Profile Pages and Panels" on page 4-11, if you want to change the attribute display type or semantic type you must delete the panel, change the attribute display type, and re-create the panel.

Table 3–8 describes the attribute display types:

Table 3–8  Object display types

<table>
<thead>
<tr>
<th>Display Type</th>
<th>Description</th>
<th>Configurable Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>A place holder.</td>
<td>N.A.</td>
</tr>
<tr>
<td>Boolean</td>
<td>Displays a True or False choice that the user must make. This display type is not searchable.</td>
<td>N.A.</td>
</tr>
</tbody>
</table>
### Table 3–8 (Cont.) Object display types

<table>
<thead>
<tr>
<th>Display Type</th>
<th>Description</th>
<th>Configurable Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Check Box</td>
<td>Provides a check box. This display type only supports multiple values, and it requires you to specify a rule or a list. See &quot;Using Rules and Lists&quot; on page 3-19 for details. This display type is not searchable.</td>
<td>Rule (LDAP filter and attribute), List (display name and other features)</td>
</tr>
<tr>
<td>Date</td>
<td>Allows users to enter month, day, and year. This display type supports single or multiple values. This display type is searchable.</td>
<td>Data type, data separator</td>
</tr>
<tr>
<td>Email</td>
<td>Displays a link to an end user’s email address. This display type is searchable.</td>
<td>N.A.</td>
</tr>
<tr>
<td>Filter Builder</td>
<td>Creates a button that launches the Filter Builder. The Filter Builder allows users to design custom LDAP queries. This display type is not searchable.</td>
<td>Target object class list</td>
</tr>
<tr>
<td>GIF Image</td>
<td>Allows users to find an image. Some Identity System applications also support JPEGs. This display type is not searchable.</td>
<td>Photo style, height, width</td>
</tr>
<tr>
<td>GIF Image URL</td>
<td>Allows you to specify an external location for the GIF image. This enables you to display the image on a profile page. This display type is searchable.</td>
<td>Photo style, height, width</td>
</tr>
<tr>
<td>Location</td>
<td>Creates a link in the associated profile page to the Locations page. This display type is used internally in the Identity System.</td>
<td>Target object class list</td>
</tr>
<tr>
<td>Media</td>
<td>Used for binary media files. This attribute must have the binary data type. This display type is not searchable.</td>
<td>Description, MIME type</td>
</tr>
<tr>
<td>Multi-Line Text</td>
<td>Two or more lines of text, such as an address. This display type supports single or multiple values. This display type is searchable.</td>
<td>N.A.</td>
</tr>
<tr>
<td>Numeric String</td>
<td>Provides a field for specifying a number. This field does not accept non-numeric characters. This display type is searchable.</td>
<td>N.A.</td>
</tr>
<tr>
<td>Object Selector</td>
<td>Use the Object Selector display type when you want users to modify an attribute using the Selector. This display type is only valid for attributes of type DN. This display type supports single and multiple values and is not searchable. For more information on the Object Selector display type, see “Search Filters for the Object Selector Display Type” on page 3-22.</td>
<td>List of object classes, LDAP filter</td>
</tr>
<tr>
<td>Password</td>
<td>Lets users type a password. The password characters appear as asterisks, and the user is prompted to enter the password twice. This display type is not searchable.</td>
<td>Text size and length</td>
</tr>
<tr>
<td>Postal Address</td>
<td>Six data entry fields in which a user can specify a postal address. Each field can contain a maximum of 30 characters. This display type supports single and multiple values.</td>
<td>N.A.</td>
</tr>
</tbody>
</table>
### Viewing Attributes

You view attributes on the Modify Attribute page.

**To view the Modify Attribute page from the System Console**

1. From the Identity System landing page, click the link for the Identity System Console.
   
   If you have already logged in, click the Identity System Console tab.

2. Click the Common Configuration sub-tab, then click Object Classes in the left navigation pane.

3. Click the link for an object class.
   
   The View Object Class page for the selected class appears.

4. Click Modify Attributes.
   
   The Modify Attributes page appears.

---

### Table 3–8  (Cont.) Object display types

<table>
<thead>
<tr>
<th>Display Type</th>
<th>Description</th>
<th>Configurable Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radio Buttons</td>
<td>Provides a set of radio buttons that allows the user to select one value from the list of radio buttons. This display type requires you to specify a rule or a list. See &quot;Using Rules and Lists&quot; on page 3-19 for details. This display type is not searchable.</td>
<td>Rule (LDAP filter, attribute), list (display name, storage name)</td>
</tr>
<tr>
<td>Selection Menu</td>
<td>Provides a list. This display type supports single or multiple selectable values. This display type requires you to specify a rule or a list. See &quot;Using Rules and Lists&quot; on page 3-19 for details. This display type is not searchable. Do not configure DN attributes using the Selection Menu display type. This display type does not support order, which can be important in a DN. For example, if there are two ou's in a DN, the order is important.</td>
<td>Rule (LDAP filter, attribute), list (display name, storage name)</td>
</tr>
<tr>
<td>Single Line Text</td>
<td>Displays information in a single line of text. There is no maximum number of characters for this field. This display type supports either single or multiple values. This display type is searchable.</td>
<td>N.A.</td>
</tr>
<tr>
<td>S/MIME Certificate</td>
<td>Stores certificate data in the configured attribute rather than on disk. This display type is not searchable.</td>
<td>N.A.</td>
</tr>
</tbody>
</table>

**Note:** In the Identity System Console, the display names that appear as values for items in the list of display types (radio button, checkbox, and so on) may be corrupt due to a known limitation with Java Applets and internationalized characters. The browser's JVM displays only those characters that are in the current locale. Internationalized characters are displayed correctly in applets only if you have set the browser to the same locale.
To view an application-specific Modify Attribute page

1. From the Identity System landing page, click the link for the Identity System Console.
   If you are already logged in, click the Identity System Console tab.

2. In the System Console, click the User Manager Configuration sub-tab.
   You can also click the sub-tab for Group Manager Configuration or Organization Manager Configuration.

3. In the left navigation pane, click Tabs.
   The Configure Tab page appears. The structural object class for that tab is displayed as a link under the heading "Existing Tabs."

4. Click the link under the Existing Tabs label.
   The View Tab page appears.

5. Click the Modify Attributes button.
   The Modify Attributes page appears.

Configuring Attributes

When installing the Identity System, you configure all required attributes for your structural object classes. After installation, you can modify attributes to resolve conflicts among configured attributes and to configure additional attributes.

For Active Directory installations, some attributes are unavailable by default. To make these attributes available for configuration in the Identity System, remove their entries from the following three files in the $IdentityServer_install_dir/identity/oblix/data/common directory: exclude_attrs_config.xml, exclude_attrs-ad.xml, and ad_exclude_attrs.xml and restart the Identity Server.

---

**Note:** In the object class oblixadvancedgroup, the attribute obgroupsubscription has a display type of Check Box and a List sub-type. The list contains two values:

- One value for subscribing (NotifyUponSubscription)
- A second value for unsubscribing (NotifyUponUnsubscription)

If you want to modify the values for this attribute, note that you can change only the values in the Display Name field. Do not change the value in the Storage field.

---

To configure an attribute

1. Open the Modify Attributes page as described in "Viewing Attributes" on page 3-16.
2. In the Attribute list, select an attribute you want to modify. 
   The attribute's data type appears after the list. This is a read-only field.

   **Note:** Novell Directory Server (NDS) maps the attribute and object class names from the native directory server to the LDAP layer of NDS. Some of these attributes or object classes will have multiple mappings (aliases) in the LDAP layer. For example, the native NDS object class is group, while the LDAP layer of NDS maps two aliases called GroupOfNames and GroupOfUniqueNames. For the Identity System to work correctly, make sure the object class or attribute name that you provide during configuration is the one that occurs ahead of the other mappings for the same object class or attribute. You can check the mapping order through consoleOne.

3. In the Display Name field, enter a user-friendly display name for this attribute. 
   The display name appears on an Identity System application page, for instance, the User Manager. For example, for the departmentNumber attribute, you might enter Department Number as the display name.
   
   For template object attributes, the Display Name should indicate the template being used. As noted earlier, users will not be able to see the data values for these attributes. As a result, you should identify these “special case” fields so that users can be advised that it is normal for data not to be shown. For example, in an object template for application ABC, you might want all ABC-related attributes to be identifiable by their display names, such as assistant.person.abc.

   The Data Type field displays the attribute's data type, as described in "Attribute Data Types" on page 3-10. This is a read-only field.
   
   You cannot use attributes with binary, distinguished name, or postal address data types as report criteria or in search attributes.

4. In the Semantic Type list, you can optionally select one or more semantic types. 
   See "Attribute Semantic Types" on page 3-11 for details on semantic types.

5. In the Attribute Values field, specify whether the attribute can have single or multiple values.
   Depending on the attribute, data type, and display type, this option may not be available.

6. In the Display Type list, select the attribute's display type.
   
   If you select a date attribute for the display type, you must select a date type to indicate how you want the date to appear on the Identity System application.
profile page. Do not change the date type after you select it because this may display existing data incorrectly.

Several display types allow you to specify a rule or list. See "Using Rules and Lists" on page 3-19 for details.

Other display types allow you to specify a photo or text. For more information on these fields, see "Configuring Other Display Types" on page 3-26.

Using Rules and Lists

The display types of Selection Menu, Radio Buttons, and Check Box require that you specify a rule or a list. For instance, you may assign a data type of string and a display type of radio button to a Title attribute. To display a list of titles on a User Manager profile page, you need to build a list.

A list is a static set of values. A rule is an LDAP filter that queries the directory before building a list. For example, if you create a filter to find every instance of objectClass=dialUpConnection with an attribute of TelephoneNumber, a list of phone numbers is shown in the selection menu.

For more information about LDAP filters, refer to "Search Filters for the Object Selector Display Type" on page 3-22 for information. Also, the Internet Engineering Task Force's RFC 2254 defines a string representation of LDAP search filters.

Defining a Rule

You can define a static list to display on an Identity System application page, or you can define a rule. For instance, you can provide a static list of available printers, or you can construct this list from entries for printers in your directory. When you configure a rule, you create a dynamic list based on entries in your directory. A rule is a directory query based on an attribute that you specify in the rule. The query returns a set of records from the directory. Using the rule, you cause the Identity System to build the list to be displayed on the application page by doing the following:

- Querying the directory for a specific object or attribute
- Building a list of hits
- Selecting one attribute from each directory hit
- Building a list showing the values for each attribute

The advantage of a rule over a list is that what is displayed as a result of the rule filter is updated whenever the directory is updated.

To define a rule

1. Open the Modify Attributes page as described in "Viewing Attributes" on page 3-16.
2. Select an Attribute from the list.
3. From the Display Type list, select the attribute's display type.  
   To configure a rule for the attribute, the display type must be Selection Menu, Checkbox, or Radio Buttons.
   A Rule button, Add Filter text box, and Attribute field appear.
4. Select the Rule button.  
   A rule must be a valid LDAP filter.
5. In the Add Filter box, type an LDAP filter.
   For example:
   
   (objectclass=printer)

   Suppose you invoked the Modify Attribute page for an attribute called Printer, with a display name of Printers. The rule shown in this step would be appropriate for displaying a list of printers.

   For examples of filters, see "Search Filters for the Object Selector Display Type" on page 3-22.

6. In the Attribute field, type the LDAP name of the attribute that you want to associate with the filter.
   
   In the printer example, you might type PrinterName. This rule causes an LDAP query on the printer object class and builds a list of values taken from the PrinterName attribute of each returned entry.

**Defining a List**

A list is a static set of values presented to a user.

**To define a list**

1. On the Modify attributes page, click the List button.
   
   List-related Display and Storage fields become active.

2. In the Display field, type the list item’s Display Name.
   
   This is a name that the user sees when this attribute is displayed on an application page, for instance, the User Manager.

3. In the Storage field, type a storage name for the attribute.
   
   This value is saved in the database. It can be the same as the display name, or it can follow your own database-naming conventions.
   
   When you click Add, if you omit a storage name, the display name is used as the storage name.
   
   If you want to change a storage name, delete the entry in the Storage field, and retype the Display and Storage names.

4. Click Add.
   
   The information is added to the List field.

   Items in the list appear on the Identity System application page in the order they appear on this page. To rearrange items in the list, or to remove an item, use the Move Up, Move Down, and Delete buttons.

**Localizing Attribute Display Names**

You can localize attribute display names to present to Identity System applications to end-users in their native language. See "Configuring Multiple Languages for Oracle Access Manager" on page 7-7 for information on managing multiple languages.

In order to localize object class attributes, you must manually enter the attribute display names in the Identity System Console for each language that you installed.
After you have localized object class attributes, you can view and modify them in the Identity System Console.

The process for localization is the same for LDAP and template objects. Table 3–9 lists the attributes that can be localized for each object class.

**Table 3–9  Items You Can Localize**

<table>
<thead>
<tr>
<th>Items</th>
<th>What You Can Translate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Object classes configured for tabs</td>
<td>Name</td>
</tr>

<tr>
<td>Attributes</td>
<td>Display name</td>
</tr>
<tr>
<td>Attributes with a media display type</td>
<td>Display name</td>
</tr>
<tr>
<td>Attributes with a choice display type</td>
<td>Display name</td>
</tr>
<tr>
<td>Workflow definitions</td>
<td>Workflow name</td>
</tr>
</tbody>
</table>
|                                            | **Note:** You specify a translation for your workflow name when you create or modify a workflow definition, as described in “Chaining Identity Functions Into Workflows” on page 5-1.

To create, view, or modify localized attribute display names

1. From the Identity System Console, click Common Configuration.

   The Common Configuration page appears.

2. Click the Object Classes link in the left navigation pane.

3. Click the link for the object class you want to modify.

   The View Object Class page appears.

4. Click Translate.

   **Note:** The Translate button appears only if more than one language has been installed.

   The Summary of Attribute Display Names page appears. All language-specific attribute display names appear on this page. Display names that have not been configured are marked as Not Configured and appear in blue text.

5. Click Modify to enter or modify a display name.

   The Configure Attribute Display Names page appears. This page lists links for installed languages and the localized display names for attributes. Display names that have not been configured appear in blue text and are not flush left.

6. Click the language for which you want to modify attribute display names.

7. Enter display names in the Display Name fields.

8. Click Save to save your changes (or Cancel to exit the page without saving your changes).
Search Filters for the Object Selector Display Type

The object selector display type associates a Selector with the LDAP attribute assigned to this display type. (This does not apply to template attributes.) Users invoke the Selector to search for users or groups. The Selector is available when you view, create, or modify a profile or a workflow.

Use the object selector display type to create a search filter for the Selector. See "The Selector" on page 1-10 for details. You can write search filters to help people conduct a Selector search during the following operations:

- Create profile
- Modify profile
- Modify workflow
- Delete workflow

These filters do not apply to the Query Builder.

When a user invokes the Selector, they perform a directory search. When you create a filter for the Selector, the filter is used in an "and" relationship with the search criteria that the user provides.

A filter can be static. For example, you can restrict Selector searches so that the search results only contain people with an organizational unit of Corporate in their directory profile.

A filter can also be dynamic. For example, you can restrict a Selector search to return only people whose organizational unit matches that of the person being displayed on the Modify Profile page where the search was invoked. When using a dynamic filter for a Modify Profile page, the Selector search is based on the directory profile of the person being displayed. In the case of creating profiles, a dynamic filter produces Selector search results based on the login profile of the person performing the task.

Creating a Search Filter for the Object Selector Display Type

A filter helps the user narrow down a search. A filter narrows down the place in the directory tree where a search may be conducted.

To create a filter

1. From the Identity System Console, click Common Configuration, then click Object Classes.
2. Click the link for the object class for which you want to create a filter.
   For example, to develop a search filter for a sales person, you might navigate to the Modify Attribute page for the Person object class.
3. Click Modify Attributes.
4. On the Modify Attribute page, in the Attribute list, choose the attribute for which you want to define a Selector search.
   You must choose a DN attribute. For instance, if you want Selector searches for sales people, you might select a DN attribute called salesPersonDN.
5. On the Display Type list, select Object Selector.
   If the attribute you chose in the previous step is a DN attribute, the Object Selector option appears in the list. The Target Object Class list and the Add Filter input box are also displayed.

6. In the Target Object Class list, select an object class to be used as the primary key in the search filter.
   The target object class determines what is displayed on the Selector search page. For instance, if you want the Selector to help users find sales people, you might use Person as the target object class. If you select more than one Target Object Class on the Modify Attribute page, the Selector application will contain a tab for each object class.

7. Type a valid LDAP filter in the Add Filter input box.
   The filter determines what is displayed on the Selector search results. For examples of the types of LDAP filters you can write, see "Static LDAP Search Filters" on page 3-24 and "Examples of Dynamic LDAP Search Filters" on page 3-25.
   Note that your filter can use only attributes that are contained in the definition of the target object class.

   Note: the Identity System treats white spaces literally. Be aware of extra trailing spaces or carriage returns in your filters.

8. Save your changes.
   This creates a filter that is used in an And relationship with any other criteria the user specifies on the Selector search.

**Search Filters for Multiple Target Object Classes**

If you select more than one target object class on the Modify Attribute page, the Selector application will contain a tab for each object class. Your search filter will need to contain an Or operator ( | ) and separate selection criteria for each object class you selected. An example of this type of search filter is provided in "Static Searches Using Multiple Target Object Classes" on page 3-24.

**Deleting a Search Filter**

Remove a filter by erasing the text in the Filter text box.

**Usage of Rules and Filters**

This section covers important topics related to rules and filters:

- Creating basic static filters
- Creating dynamic filters using substitution syntax
- Use of wild cards in a search
- Proper use of the Not operator when writing a filter
Static LDAP Search Filters
When you implement a static search filter, all search results must match a fixed value. For example, you can restrict a search to return only people whose directory profiles show an organizational unit of Sales.

As an example of a simple static filter, suppose you want to provide Selector searches for the seeAlso attribute. The filter will return search results that show only people whose directory profiles contain a businessCategory value of dealership.

To create a static filter
1. Open the Modify Attributes page as described in "Viewing Attributes" on page 3-16.
   Navigate to the Modify Attribute page for the object type that triggers this search filter (for instance, Person).
2. Select the seeAlso attribute in the Attribute list.
3. From the Display Type list, select Object Selector.
4. In the Target Object Class, select the object class that will be the primary key for the filter (for instance, Person).
5. In the Filter text box, input the following:
   (businessCategory=dealership)

Static Searches Using Wild Cards
As an example of a static filter that uses wild cards, suppose you want only people with the word Manager in their title to be returned on a search using the Selector. You can create a filter that searches for the string Manager.

To create a static search filter using a wild card
1. Navigate to the Modify Attribute page for the object class containing the DN attribute to be associated with the Selector (for instance, the Person object class).
2. In the Attribute list, select the DN attribute (for instance, the Manager attribute).
3. On the Display Type list, select Object Selector.
4. In the Filter text box, input the following:
   (attribute=*value*)
   For example:
   (title=*manager*)

Static Searches Using Multiple Target Object Classes
You can build a static filter that searches for more than one target object class. For example, suppose you want to build a filter for the uniqueMember attribute so that a search using the Selector returns one of two items:

- On a search of people, the search results show only full time employees
- On a search of groups, the search results show only mail groups

In this example, to create an LDAP filter for both characteristics, you need to select people with employee=fulltime in their directory profiles, and you need to select groups with the object class of MailGroup in their directory profile. Each attribute in
the filter must be associated with an appropriate object class. Finally, you need to join
the two searches with an Or operator (\(|\)), as follows:

\(|\&(\text{objectclass=inetOrgPerson})\&(\text{employeetype=FullTime})\)
\&(\text{objectclass=groupOfUniqueNames})\&(\text{objectclass=MailGroup}))

**Substitution Syntax: Returning Targets that Match the DN of the Logged In User**

You can enter substitution syntax using the Advanced button of the Query Builder. See
"Writing LDAP Filters Using Query Builder" on page 4-27 for details.

When using substitution syntax, the variable attribute value for the source DN (the
person logged into the application) is substituted in the rule and evaluated against the
target DN (the entry you are trying to view or modify).

Substitution syntax allows a rule to be evaluated dynamically, according to the person
executing a task. The syntax is as follows:

\(\text{attribute}=$\text{attribute}$\)

For example:

\(\text{ou}=$\text{ou}$\)

This rule filters all those in the same organizational unit as the person logged into the
application.

You can use operators such as And and Or in a filter. For example:

\(|\&(\text{ou}=$\text{ou}$)\&(\text{ou=people})|\)

---

**Note:** For the selected searchbase, users can search only for entries
from the same ou as their own. Additionally, users from ou=people
can search for entries within the selected searchbase.

---

**Examples of Dynamic LDAP Search Filters**

In addition to specifying a conventional LDAP search filter, you can use the Identity
System's filter substitution syntax to create a dynamic filter. A dynamic filter allows a
search to return results that are based on a user profile. For instance, suppose you
create a search filter for the orgPerson attribute that contains the following:

\(\text{ou}=$\text{ou}$\)

Using this search filter, if you conduct a Selector search on a Modify Profile page for a
person, your search results contain only people whose directory profiles match the
organizational unit in the profile of the person you are modifying. For example, if you
invoke the Modify Profile page for John Smith and invoke the Selector to choose John
Smith's manager, the search results show only people in John Smith's organizational
unit.

When you use filter substitution, the profile of the search target is substituted. In the
example (\text{ou}=$\text{ou}$), the value of John Smith's ou is substituted. If a target is not
present, for instance, in the Create Workflow function, the search filter substitutes the
value from the login profile of the person creating the workflow.

For example, suppose you are creating a workflow for a group named Corporate
whose organizational unit is not yet defined in the directory server. In this case, the
Identity System uses the ou value of the logged-in participant who is creating the
group. The logged-in participant's ou value carries over in the workflow until you
commit this group in the directory server. At that point, the ou value in the dynamic filter (ou=$ou$) changes to the group's ou value.

As another example, suppose you want people who have the Secretary attribute in their directory profile to receive search results containing only people who have the same manager that they do. From the Configure Attribute page for the Secretary attribute, you would specify the following:

(manager=$manager$)

**Dynamic Searches Using Wild Cards**

You can use wild cards in a dynamic filter. For example, suppose you want to supply a contactPerson attribute in an organizationalUnit object. The contactPerson attribute should return people in same Zip code as the organizationalUnit object. If the organizationalUnit profile contains an attribute called zipCode, and the Zip code is specified at the end of a postalAddress directory attribute, you would specify the following in the filter:

(postalAddress=*$zipCode$)

**Dynamic Searches Using Multiple Values**

Finally, you can supply multiple values in a dynamic search filter. For example, suppose you want the seeAlso attribute for business objects to select the businessCatagory of dealership, and specifically, dealerships in the same state as the search target. You would specify the following filter for the seeAlso attribute:

(&(businessCategory=dealership)(state=$state$))

**Use of the Not Operator**

You use And (&) and Not (!) operators when constructing a filter. For example:

- **Example of an And Operation** -- ( &(sn=white)(objectclass=personOC) )
- **Example of a Not Operation** -- ( !((sn=white))(objectclass=personOC) )

In the example of the Not filter in the previous example, you might expect the following filter to be valid:

(!((sn=white)))

However, when specifying a Not operation, you need to embed it within an And and specify the person object class. A filter such as (!((sn=white))) is not allowed because a search of this type would be conducted on the entire domain before targeting the reduced domain set specified on the filter. This is costly steps in terms of performance. The optimized algorithm that the Identity System uses causes the search to be conducted on the reduced domain set. The proper use of the Not operation is as follows:

(&(!(sn=white))(objectclass=personOC))

The optimized algorithm causes the filter (!((sn=white))) to not give the expected result.

**Configuring Other Display Types**

There are configuration options for the other display types.

**To configure a GIF image display type**

1. On the Modify Attributes page, select the Attribute Photo.
2. Using the buttons under the Display Type list, select the photo style:

- **True Size**—Select True Size to display the GIF in its actual size.
- **Fixed Size**—Select Fixed Size to specify the height and width for the image.

When you select a text-based display type, you can use XSL style sheets to configure the defaults for the text. This is also true for setting columns and rows. See the *Oracle Access Manager Customization Guide* for details.

When you select an attribute with a display type that uses target object classes, you specify one or more objects for association with this attribute. This display type supports single or multiple values.

- If you want to set a target object class, select one or more required object classes in the Target Object Class list.
- If you want to set the MIME type, select the kind of media file you want to attach from the MIME Type list.

---

**Configuring Derived Attributes: Matching Values from Different Attributes**

Derived attributes are virtual LDAP object class attributes. Derived attributes are generated by comparing the contents of one object class’s attribute with an attribute in the same or a different object class. The main purpose of a derived attribute is reverse lookup.

For example, someone’s profile may contain the name of their administrative assistant, but administrative assistant profiles rarely contain the names of all of the people they administer. A derived attribute allows the administrative assistant’s profile to refer back to all of the people who have the administrative assistant attribute in their profile. In this example, the administrative assistant’s Self attribute value is compared with the AdminAssistant attribute value of the other people in the organization. Similarly, a groupOfUniqueNames object may contain a uniqueMember attribute with links to members of the group. But an object that contains data for a person might not link back to the groupOfUniqueNames object. The derived attribute feature would allow group members to refer back to the group they belong to.

To create derived attributes, you specify two attributes whose values are to be compared. All matches are added to the derived attribute.

Use derived attributes to provide information in profiles that otherwise would require an LDAP filter, search, or report.

Attributes associated with template objects cannot be configured as derived attributes.

---

**Note:** Using derived attributes can result in slower response times, especially if you have multiple attributes or if your attribute references multiple object classes (such as a Group Manager derived attribute performing a lookup on a User Manager attribute). If you experience performance issues with your derived attributes, Oracle recommends you modify your index file to include the corresponding attribute index and reimport it.

---

**Example of a Derived Attribute**

Suppose the administrative assistants of your organization have asked to view all the managers they support in the User Profiles in User Manager. To do this, you can create a derived attribute that takes the attribute of each administrative assistant and
Configuring Derived Attributes: Matching Values from Different Attributes

compares it with the value for Secretary in everyone else's profile. When an administrative assistant views user identities in User Manager, only people who match the derived attribute are displayed.

Here is a summary of the steps required to create a derived attribute.

**Task overview: Configuring a derived attribute**

1. Add a derived attribute in the Identity System Console, giving your new attribute a descriptive display name, such as My Direct Reports.
2. Specify Self as the Match Attribute.
   
   This indicates that the administrative assistants' DNs are the search criteria.
3. Because you are looking for your administrative assistant's direct reports, specify Person object class as the searched object class.
   
   Be sure you are looking for people and not groups or other kinds of objects.
4. Specify secretary as the Lookup Attribute.
   
   You are searching the user identities for users with matching values in the secretary attribute.
5. Save your new attribute and associate it with the Employee tab in User Manager.
   
   Now, whenever an administrative assistant views the User Profile page, the Identity System takes the value of the Self attribute (DN) and compares it against the values of everyone's secretary attribute. Wherever there is a match, the Identity System lists that manager's name in the administrative assistant's My Direct Reports section of the User Profile page.

---

**Note:** The attributes displayed in the profile are determined by the selected object class's Object Class Attribute. To change this value, you must modify the object class.

---

**To configure a derived attribute**

1. From the Identity System Console, click Common Configuration.
   
   The Common Configuration page appears.
2. Click the Object Classes link in the left navigation pane and click the named link of an object class.
   
   The View Object Class page appears.
3. Click the link for the object class whose derived attribute you want to modify.
4. Click Modify Derived Attributes, then click Add.
   
   The Create Derived Attribute page appears.
5. In the Attribute Name field, specify a name for your new derived attribute.

---

**Note:** Since a derived attribute is a virtual attribute, the attribute name must not exist in the schema.

---

6. In the Display Name field, type the name of the derived attribute as it will appear in the Identity System pages.
7. In the Match Attribute field, select the attribute in the current object class whose values you want to match.

8. In the Object Class field, select the object class you want to search.

9. In the Lookup Attribute field, select an attribute in the specified object class whose values you want to compare against.

10. Click Save to save your changes (or Cancel to exit without saving).

Assigning a Derived Attribute to a User Manager Tab

Before you can use your derived attribute, you must assign it to an Identity System application tab.

To add a derived attribute to an application tab
1. From the Identity System Console, click User Manager Configuration (or Group Manager Configuration or Organization Manager Configuration).

2. Click Tabs.

3. Under the Existing Tabs label, click the link for the application tab that you want to modify, then click View Object Profile.

   The page that appears depends on which application you are using. In User Manager, the Configure User Profile page appears. In Group Manager, the Configure Group Profile page appears. In Organization Manager, the Configure Object page appears.

4. If you are working with User Manager Configuration or Organization Manager Configuration, click Configure Panels.

   For the Group Manager, the link name is Configure Group Profiles Panel.

   The Configure Panels (or Configure Group Profile Panels) page displays the panels currently configured to appear in a User Manager profile.

5. Click the name of the panel to which you want to add the derived attribute.

   The View Panel page appears.

6. Click Modify.

   The Modify Panel page appears.

7. In the Attributes menu, select the derived attribute you want to add.

8. In the associated text box, type the name as you want it to appear in the Identity System pages.

9. If you need additional Attribute fields, click Add.

10. Click Save to save your changes (or Cancel to exit without saving).

Permissions for Derived Attributes

You can assign Read permissions to a derived attribute. See “Setting and Modifying LDAP Attribute Permissions” on page 4-30 for information about assigning rights to an attribute.
Attributes Configured for an Individual Application

When you configure attributes as described in this chapter, these attributes are available to any Identity System application. In other words, the attribute can be used within the User Manager, Group Manager, or Organization Manager.

However, you may want to make only certain attributes available to certain applications. For example, you may want an attribute for a person's address to only be available to the User Manager application. If this is the case, you can access the object and attribute configuration functionality described in the preceding sections from the relevant application. In the case of the Organization Manager, you can configure objects and attributes for individual tabs.

For more information on configuring the User, Group, and Organization Managers, see "Configuring User, Group, and Organization Manager" on page 4-1.
The User Manager, Group Manager, and Organization Manager are Identity System applications that enable end users to view and modify information about themselves, other people, groups, inventory, and any other item that you, the administrator, choose to make available.

The chapter on "Making Schema Data Available to the Identity System" on page 3-1 describes how to make the Identity System aware of objects and attributes in your directory and in object template files, and how to configure the way that attributes are displayed on an application page. This chapter explains how to place attributes on specific application pages, and how to enable users to view and modify them. This chapter also touches on end use of these applications.

You must be a Master Identity Administrator or Delegated Identity Administrator to configure the User Manager, Group Manager, and Organization Manager applications. See "Delegating Administration" on page 2-5.

This chapter covers the following topics:

- About User, Group, and Organization Manager
- Configuring Tabs
- Configuring Tab Profile Pages and Panels
- Allowing Users to View and Change LDAP Data
- Examples of Configuring an Application
- End-User Scenarios
- Configuring Auditing Policies
- Generating Reports
- Advanced Configuration

**About User, Group, and Organization Manager**

The User, Group, and Organization Manager are the primary Identity System applications:

- People use the User Manager to view information about their identity, to modify information such as their home phone number, and to find information on other people.
People use the Group Manager to view groups, subscribe to groups, and to manage group subscriptions.

People use the Organization Manager to manage other objects.

Popular uses of the Organization Manager include viewing organization maps and searching for inventory items.

You control who is allowed to see what attributes and values on these applications. You also control what portion of the directory tree is accessed when users conduct searches. You can add filters so that when users search, the results conform to criteria specified on the filters.

When you first install, set up, and configure objects and attributes in the Identity System, the Identity System application pages are empty. You make information available on an Identity System application as follows.

Task overview: Displaying information on an application

1. Configure the objects and attributes to be used by the Identity System applications, as described in "Making Schema Data Available to the Identity System" on page 3-1.

2. Configure the Identity System application pages, or tabs, as described in "Configuring Tabs" on page 4-2.

3. Configure profile pages on each tab by arranging groups of attributes into panels, as described in "Configuring Tab Profile Pages and Panels" on page 4-11.

4. Optionally, set the searchbase to control what portion of the directory tree is included in a search for LDAP attributes only, as described in "About the Searchbase" on page 4-21.

5. Set permissions for users to view and modify the attributes you are displaying on the application tabs, as described in "About View and Modify Permissions" on page 4-30 for details.

Configuring Tabs

The Identity System applications each have one or more tabs, which are configured as follows:

- When you work with the Group Manager Configuration tab in the Identity System Console, you are configuring the My Groups tab in the Group Manager application.

- Similarly, the User Manager Configuration tab in the Identity System Console is used to configure the My Identity tab in the User Manager application.

- Unlike the User Manager and the Group Manager, you can configure multiple tabs in the Organization Manager.

- When you install the Identity System, a default structural object class Location is defined for the Organization Manager. The Organization Manager can manage objects defined in the Identity System as having a Generic or Location data type. See "Object Class Types" on page 3-5 for details.

The tab in the User Manager is associated with the person structural object class. The tab in the Group Manager is associated with the group structural object class. The Organization Manager can have multiple tabs, each associated with a different object class. All tabs may have auxiliary LDAP object classes and template object classes associated with them.
Viewing and Modifying Tab Configuration Information

You can view and modify characteristics of the tabs that are displayed on the User, Group, and Organization Manager pages.

To view or modify tab configuration information

1. Navigate to the Identity System Console and click User, Group, or Org. Manager Configuration.

   The User, Group, or Organization Manager Configuration page appears.

2. Click Tabs.

   The Configure Tab page appears, showing the name of the tab for the application. The Organization Manager may have more than one tab.

3. Click the link for the tab.

   Since there is only one tab for User Manager and Group Manager, there can only be one link. For Organization Manager, there can be more than one tab.

   The View Tab page appears.

Table 4–1 describes the information on this page:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| Tab ID       | Unique identifier for the tab.
4. Click Modify.

5. Make the desired changes and click Save.

If you do not see your changes reflected in the Identity System application, go to Identity System Console, System Configuration, View Server Settings, and click Clear Cache to flush and reload the cache.

**Note:** When you modify a tab image, depressed tab image, and so on, these elements are immediately available for users to view. This is different from adding attributes to a panel, which requires setting permissions before users can view the information.
Localizing Tabs

If you have installed more than one language pack, you can localize tab names to display them in those languages. You create, view, and modify localized tab names in the Administration Console.

See “Configuring Multiple Languages for Oracle Access Manager” on page 7-7 for information on managing multiple languages.

Note: The Translate button appears only if more than one language has been installed.

To create, view, and modify localized tab configuration

1. Log in to the Identity System Console and click User Manager Configuration (or Group Manager Configuration or Org. Manager Configuration).
   The User, Group, or Organization Manager Configuration page appears.

2. Click the Tabs link in the left navigation pane.
   The Tab page appears, showing the name of the tab or tabs for the application.

3. Click the link to an existing tab to view its details.
   The View Tab page appears. Tab details such as the ID, name, class type, and object classes are displayed on this page.

4. Click Translate.
   If this button does not appear on the page, you have only one language installed and you cannot localize the display names. Click Modify to change the display name for the single language that you have installed.

   The Summary of Tab Label Display Names page appears. Display names, if any, that have been configured for the following language-specific fields appear on the page:
   - Tab Name
   - Mouse Over Message

   Display names that have not been configured for a particular language are marked as Not Configured.

5. Click Modify to enter a tab display name or to modify an existing one.
   The Tab Display Names page appears. This page contains fields for the tab display names and links for all the installed languages.

6. Click the language for which you want to localize the tab.

7. Enter the display names in the Tab Name and Mouse Over Message fields.

8. Click Save to save your changes.

Adding a Tab to the Organization Manager

The Organization Manager can contain more than one tab.

To add a tab

1. From the Identity System Console, click Org. Manager Configuration, then click Tabs.
Configuring Tabs

The Configure Tabs page appears.

2. Click Add.

   The Create Tab page appears.

3. Complete the fields in this page, as described in “Viewing and Modifying Tab Configuration Information” on page 4-3.

4. Click Save.

Specifying the Search Attributes on a Tab

At the top of the application page for the User Manager, Group Manager, and Organization Manager there are search fields. See “Adding Auxiliary and Template Object Classes to a Group Tab” on page 4-8 for an example. You specify the attributes that you want to appear in the search function list. Note that search attributes can only be taken from an LDAP directory. Template attributes cannot be used as search attributes.

   Note: You must configure attributes before they can appear on a tab. For more information, see "About Object Class Attributes" on page 3-9.

To specify what attribute can be used in a search

1. From the Identity System Console, click User Manager Configuration (or Group Manager Configuration or Org. Manager Configuration), and click the Tabs link in the left navigation pane.
2. Click the link for the tab.
3. Click View Search Attributes.

   The View Search Attributes page appears.
4. Click the Modify button.
5. Select an attribute check box to make the attribute searchable.
6. Click Save.

Viewing, Modifying, and Localizing Attributes that Appear in Search Results

You choose what attributes are to appear in the results of a search. If you have installed and configured multiple languages, you can localize search result attributes. This enables you to display search results in multiple languages.

To view the search result attributes

1. From the Identity System Console, click User Manager Configuration (or Group Manager Configuration or Org. Manager Configuration).
2. Click the Tabs link in the left navigation pane.
3. Click the link for the tab.
4. Click View Search Result Attributes.

   The View Search Result Attributes page appears.
This page shows the attributes that appear when the results of a user’s search are displayed. If you have configured the Identity System for more than one language, those languages are displayed on the page.

5. Click Modify to change the attributes.

The Modify Search Result Attributes page appears.

The first attribute is always the Class Attribute.

You cannot modify the class attribute Name from this page. It is displayed in bold and is not editable on this page. If you want to modify a class attribute, see “Selecting a Class Attribute” on page 3-7 for details.

6. From the attribute lists, select new attributes for each search field you want to change.

The attribute’s Display Name appears in the editable field to the right of the attribute list. This name appears in the Identity System user application. See “About Object Class Attributes” on page 3-9 for details.

7. Click Add if you need additional attribute fields.

8. Click Save.

To localize search results

1. In the Identity System console, select User Manager Configuration (or Group Manager Configuration or Org. Manager Configuration).

2. In the left navigation pane, click Tabs then click a link.

The View Tab page appears.

3. Click View Search Result Attributes to display the View Search Result Attributes page.

4. Click Translate.

The Summary of Search Results Attribute Display Names page appears. Existing display names in all the locales are listed on this page. Display names that have not been configured for a language are marked as Not Configured.

5. Click Modify to configure a display name for a language.

The Search Results Attribute Display Names page appears.

6. Click the language for which you want to configure a display name.

7. Enter the name in the Display Name field.

8. Click Save to save your changes.

Adding Auxiliary and Template Object Classes to a User or Org. Manager Tab

You can use auxiliary object classes as mix-ins with structural object classes. For instance, if you have an auxiliary class for a person, and the auxiliary contains an attribute for the person’s badge number, you might want to associate this auxiliary class with your structural object class. When you configure the User Manager, Group
Manager, and Organization Manager applications, the more object classes you have at your disposal, the more information you can configure for users of those applications.

If you have created workflows as described in "Chaining Identity Functions Into Workflows" on page 5-1, there are issues when associating an auxiliary object class with a tab:

- If the tab has associated workflows with pending requests, you cannot attach an auxiliary object class.
- If the auxiliary object class you are attempting to attach has any required attributes, you must edit all associated workflows to include those attributes.

You can also associate template objects with a tab. This is required if you plan to configure a workflow that makes use of the template object.

---

**Note:** You cannot remove an auxiliary object class you have added to a User Manager or Organization Manager tab. In Group Manager, under Group Types, you can remove an auxiliary class.

---

**To add an auxiliary or template object class to a User or Org. Manager tab**

1. Ensure that you have configured the object class that you want to add in the Common Configuration tab.
   
   See "Adding Object Classes" on page 3-8 for details.

2. From the Identity System Console, select User Manager Configuration (or Org. Manager Configuration), and click Tabs.

   The Tab page appears.

3. Click the link for the tab.

   The View Tab page appears.

4. Click Modify.

   The Modify Tab page appears.

5. In the menu on the far right of the Object Class(es) label, select an auxiliary or template object class or classes to associate with the tab.

6. Click Save.

   The select object class or classes are added to the list on the left of the selection box when you save your changes.

---

**Adding Auxiliary and Template Object Classes to a Group Tab**

Use Group Types to associate auxiliary object classes with the Group Manager. Oracle Access Manager provides the oblixAdvancedGroup auxiliary object class to enable you to configure attributes for subscribing members to groups, and for creating and expanding dynamic groups.

The following shows page that appears when you click the Group Manager tab and then click the My Group sub-tab. My Groups has been configured with multiple group type panels.
When you create a Group Type panel, the attributes from the associated object class are available in the Group Manager user application.

**To add auxiliary and template object classes to the Group Manager**

1. Ensure that you have configured the object class or classes that you want to add in the Common Configuration tab.
   
   See "Adding Object Classes" on page 3-8 for details.

2. From the Identity System Console, select Group Manager Configuration, then click Configure Group Type.

3. Click Configure Group Type Panels, then click Create.

4. In the topmost menu, select the object class that you want to add.

5. In the Panel Label field, enter the label that you want to display to end users when they view elements from this object class in the Group Manager.

6. Select the Panel Information Is Complete check box.

7. Click Save.

   The object class is added. You can view this new object class by clicking the Tabs link in the left navigation pane for Group Manager Configuration.

**To delete auxiliary and template object classes from the Group Manager**

1. From the Identity System Console, select Group Manager Configuration, then click Configure Group Type.

2. Click Configure Group Type Panels.

3. Click the link for the group type that you want to delete.

4. Click the Delete button.

**Configuring Group Manager Tab Options**

Use the Group Manager Options feature to select what users see in the My Groups and View Members Profile pages of the Group Manager application. This feature enables you to turn off expensive operations. This can be useful if you need to enhance Identity System performance.
To select what users see in My Groups and View Member Profiles

1. From Identity System Console, click Group Manager Configuration, and click Group Manager Options.

   The Group Manager Options page appears.

2. Click Modify to display the Modify Group Manager Options page.

   Table 4–2 describes each option.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Show static group</td>
<td>Displays or hides groups consisting of individual members. Applies to the My Groups page.</td>
</tr>
<tr>
<td>Show nested groups</td>
<td>Displays or hides groups containing individual members and other groups. Applies to the My Groups page.</td>
</tr>
<tr>
<td>Show dynamic groups</td>
<td>Displays or hides groups with members that are determined by a filter. Applies to the My Groups page.</td>
</tr>
<tr>
<td>Show groups you are a member of</td>
<td>Displays the Member of Groups attribute on the My Groups page. You must also enable the Show static group, Show nested group, and Show dynamic group options to enable this function.</td>
</tr>
<tr>
<td>Show groups you are an owner of</td>
<td>Makes the Owner of Group attribute available on the My Groups page. You must also configure an attribute to be a Group Owner semantic type to use this feature.</td>
</tr>
<tr>
<td>Show groups you are an administrator of</td>
<td>Makes the Administrator of Group attribute available on the My Groups page. You must also configure an attribute to be a Group Administrator semantic type to use this feature.</td>
</tr>
<tr>
<td>Show static members of this group</td>
<td>Applies to the View Members page. You must configure an attribute to be a Group Static Member semantic type to use the static membership feature.</td>
</tr>
<tr>
<td>Show nested members of this group</td>
<td>Applies to the View Members page.</td>
</tr>
<tr>
<td>Show dynamic members of this group</td>
<td>Applies to the View Members page. You must configure an attribute to be a Group Dynamic Member semantic type to use the dynamic membership feature.</td>
</tr>
<tr>
<td>Allow users to override the defaults through URL parameters</td>
<td>Specifies whether or not the user can enter URL parameters to customize the Group Manager display options. Applies to the View Members page and My Groups page.</td>
</tr>
</tbody>
</table>

3. Select each option you want to apply to Group Manager.

4. Click Save.

Deleting a Tab in Organization Manager

If you have more than one tab in Organization Manager, you can delete a tab.

To delete a tab

1. From the Identity System Console, click Org. Manager Configuration, the click the Tabs link in the left navigation pane.

2. Click the link for the tab that you want to delete.
The View Tab page appears. If you have more than one tab defined for Organization Manager, a Delete button appears on this page.

3. Click Delete.

You are prompted to confirm your decision.

4. Click OK to delete the tab and all associated information.

Ordering the Tabs in Organization Manager

You can change the order in which tabs appear in the Organization Manager when there is more than one tab listed.

**To order the tabs in the Organization Manager**

1. From the Identity System Console, click Org. Manager Configuration, Tabs.
2. Click the Order Tabs button at the bottom of the list of tabs.
   
The Order Tabs page appears listing Tab 1, Tab2, and so on. Beside each tab number is a list that contains the names of existing tabs.
3. Use the list beside each tab number to specify the order you would like, for example:
   
   Tab 1: Site
   
   Tab 2: Location

4. Click Save.

Configuring Tab Profile Pages and Panels

A *profile page* is a Web page that shows information about an object in an Identity System application. For example, when you search for information about a user in the User Manager, a profile page for that user is displayed. The profile page may contain data such as the user’s:

- Name
- Address
- Department
- Manager
- Phone number
- Email

The information on a profile page is based on objects and attributes in the LDAP directory that the Identity System communicates with, or it can be based on information in an object template file.

You can assemble profile pages from a collection of *panels*. For example, the profile page for a person may contain panels for personal, location, and project information. If you have configured an object template file for provisioning purposes, you may want to place the attributes from the template file on one particular panel.

Users can display profile pages in one of two ways:

- A panel view organizes the data on the profile page into panels.
- A page view organizes the data on the profile page into one long list.
Use of LDAP and Template Objects on a Panel

When you configure LDAP attributes on a panel, the attribute labels and values are shown on the profile pages that use the panel. In contrast, template attributes do not actually appear on the profile page. Template attributes only appear on Modify Profile pages, and then only if you have defined a workflow that uses the attributes.

See “Sending Non-LDAP Data to External Applications” on page 6-1 for details.

Configuring the Header Panel

The header panel appears at the top of a profile in the User Manager or Organization Manager. The header displays attributes with the semantic types of Full Name, Title, and Photo from the structural object class for the tab. You can turn the header off so that it is hidden from a user identity profile page.

Here is a sample header panel for a user:

<table>
<thead>
<tr>
<th>User Profile</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Title</td>
<td>Principal Engineer</td>
</tr>
<tr>
<td>Full Name</td>
<td>Angela Silver</td>
</tr>
<tr>
<td>Photo</td>
<td>![Profile Photo]</td>
</tr>
</tbody>
</table>

---

**Note:** You can configure only LDAP attributes from the structural object class for a tab in header panels.

---

**To configure the header panel**

1. From the Identity System Console, click User or Org. Manager Configuration, Tabs.
   
The Configure Tab page appears. The Organization Manager may have multiple tabs.

2. Click a tab link, then click the View Object Profile button.

3. Click Header, which is listed across the top of the page.
   
The Header Panel page displays the attributes that appear in the Profile header. For example, Map Image, Location Name, Location Title.

4. Click the Modify button, then select each attribute to appear in the header panel.

5. If you want to display the Header Panel in user profiles, click Show Header Panel in User Manager.

6. Click Save.

Viewing Panels That You Have Configured in the End User Application

Panels that you configure in the Identity System Console appear to the user as a collection of attributes on the User Manager, Group Manager, and Organization Manager pages.

The following table shows some examples of panels for a user profile:
Before configuring a panel, be sure the object class for the attribute that you want to place on the panel is configured with the appropriate object class type. See "Object Class Types" on page 3-5.

To view a panel in an end user Identity System application

1. From the User, Group, or Organization Manager, conduct a search for a user, group, or organization object.
2. Click one of the links returned on the search. The profile page for that object appears.
   If the application displays the profile in a page view, click the View Panels button.

Adding, Modifying, Localizing, and Deleting a Panel

You can create panels using the attributes configured during setup and when you performed the tasks described in "Making Schema Data Available to the Identity System" on page 3-1. You can use an attribute once on a panel, and you can usually use the same attribute in more than one panel.

In earlier releases, the challenge phrase and response attributes were allowed on different panels of the User Profile page. In 10g (10.1.4.0.1), however, both the challenge phrase and response attributes must be on the same panel. In 10g (10.1.4.0.1), challenge phrases and responses are displayed one after the other even though these are not configured one after the other in the panel.

If a panel contains only the challenge attribute, it will be displayed in the User Profile page without a response. If the panel contains only the response (without the challenge attribute), the response will not be displayed in User Profile Page.

---

**Table 4–3 User Profile Panel Attributes**

<table>
<thead>
<tr>
<th>Panel</th>
<th>Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Telecommunications</td>
<td>Telephone number</td>
</tr>
<tr>
<td></td>
<td>Fax number</td>
</tr>
<tr>
<td></td>
<td>Cellular phone number</td>
</tr>
<tr>
<td>Location</td>
<td>Room</td>
</tr>
<tr>
<td></td>
<td>Floor number</td>
</tr>
<tr>
<td></td>
<td>Building number</td>
</tr>
<tr>
<td>Personal</td>
<td>Organization name</td>
</tr>
<tr>
<td></td>
<td>Type</td>
</tr>
<tr>
<td></td>
<td>Manager</td>
</tr>
</tbody>
</table>

---

**Note:** You will probably want to configure one or more LDAP attributes or a combination of LDAP and template attributes on a panel. Since template attributes appear only in the context of workflow execution, a panel that consisted only of template attributes would appear to be empty.

If you have configured the Identity System for more than one language, you can view or modify the panel fields for each language. You can localize display names for the following panel fields:
Configuring Tab Profile Pages and Panels

- Panel Label
- Description
- Attributes
- Mouse Over Message

**To create or add a panel**

1. From in the Identity System Console, click User, Group, or Org. Manager Configuration, then click Tabs.
2. Click the link to the tab.
   The View Tab page appears.
3. Click View Object Profile.
4. Click the appropriate button at the top of the page:
   - For the User Manager and Organization Manager, click Configure Panels.
   - For the Group Manager, click Configure Group Profile Panels.
   The Panels page appears. Currently defined panels are displayed.
5. Choose an operation:
   - To add a panel, click Create.
   - To modify a panel, click a panel link and then click Modify.
   - To delete a panel, click a panel link and then click Delete.
   If you selected Create, the Create Panel page appears.
6. Edit the fields.
   The Modify Panel page is similar to the Create Panel page. In both pages, the following fields are available:

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>Panel Label</td>
<td>A name for this panel in the user application. This name can be localized.</td>
<td>Panel Label</td>
</tr>
<tr>
<td>Description</td>
<td>Text displayed in the View Panel page. This text can be localized.</td>
<td>Description</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes selected from the lists. If you need additional attribute fields, click Add at the right side of the page. Note that if you select template attributes, the attribute label will not appear on this panel. Template attributes are only displayed in the context of a workflow. These Attributes can be localized.</td>
<td>Attributes</td>
</tr>
</tbody>
</table>
Configuring Tab Profile Pages and Panels

7. When this panel is ready for use, select Panel information is complete at the bottom of the page.

8. Click Save.

Note: Checking the box beside “Panel information is complete” saves the panel definition. However, a user’s ability to see the contents of a panel is governed by read permissions. The options are described in “Allowing Users to View and Change LDAP Data” on page 4-21.

To view or modify a panel’s configuration

1. From the Identity System Console, click User, Group, or Org. Manager Configuration.

2. Click the Tabs link in the left navigation pane.

3. Click the link for the tab.

   The View Tab page appears.

4. Click the View Object Profile button.

   The Profile page appears.

5. Click Configure Panels at the top of the page.

   The appropriate Panels page appears. Links for each of the configured panels are displayed on the page.

6. Click a panel link to view its details.

### Table: Tab Image and Tab Image (Bottom)

<table>
<thead>
<tr>
<th>Label</th>
<th>Description</th>
<th>Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>Title Image</td>
<td>You can view a user profile as a tab-separated page or as a single page. The Title Image is a GIF image that is used for the panel title when viewing a profile as a single page. The GIF must be stored in WebPass_install_dir/identity/oblix/lang/Tag/style0 where WebPass_install_dir is the directory where you installed WebPass and langTag is the folder that contains the specific language that you are using. Enter the name of the GIF file, not the path. A Title Image can be modified as described in “Configuring Styles for Identity System Applications” on page 7-2.</td>
<td>Title Image</td>
</tr>
<tr>
<td>Tab Image and Tab Image (Bottom)</td>
<td>You can view a user profile as a tab-separated page or as a single page. The Tab Image is a GIF image that is used when viewing a profile as a tab-separated page. The Tab Image usually matches the Panel Label. Until you define a Tab Image, the Panel Label appears as a link on user profile pages. Clicking the link or the Tab Image opens a panel. The (Bottom) version is displayed at the bottom of user profile pages.</td>
<td>Tab Image and Tab Image (Bottom)</td>
</tr>
<tr>
<td>Depressed Tab Image</td>
<td>The image used when a user clicks a panel tab in a user profile.</td>
<td>Depressed Tab Image</td>
</tr>
</tbody>
</table>
7. Click Modify to display the Modify Panel page.
8. Modify the information as needed.
9. Click Save to save your changes.

To localize a panel
1. From the Identity System Console, click User, Group, or Org. Manager Configuration, then click the Tabs link in the left navigation pane.
   The existing tabs appear on the page.
2. Click the link for the tab.
3. Click the View Object Profile button to display the Profile page.
4. Click Configure Panels to display links for each of the configured panels.
5. Click a link to display the View Panel page.
6. Click Translate.
   If the Translate button does not appear, you have only one language installed and you cannot localize the panel. Click Modify to edit display names for panel elements in the one language that you have installed.
   If you click Translate, the Summary of Panel Display Names page appears. This page displays all configured language-specific display names for the following fields:
   - Panel Label
   - Description
   - Attributes
   - Mouse Over Message
   Display names that have not been configured are marked Not Configured.
7. Click Modify to create or modify a display name.
   The Panel Display Names page appears. This page contains fields for the panel display names and links for all the installed languages.
8. Click the language of your choice.
9. Enter the display name in the appropriate field.
10. Click Save to save your changes.

Ordering the Panels
Panels appear in a particular order on a profile page. You can change the order in which they appear in the Group Manager.

To change the order in which panels are displayed
1. From the Identity System Console, click Group Manager Configuration.
2. Click Group Types, then click the Order Group Type Panels at the top of the page.
Configuring Tab Profile Pages and Panels

Configuring User, Group, and Organization Manager

4-17

The Order Panels page appears.

3. Use the lists beside each panel number to identify the name of the panel to display.

4. Click Save.

Viewing Group Type Panels

Group Type panels allow you to organize attributes on the My Groups tab. For example, if you have configured groupOfUniqueNames as a structural object class and oblixAdvancedGroup as an auxiliary class, you can organize attributes from these classes on the My Groups tab by creating Group Type panels.

Note that Group Type panels are reserved for LDAP attributes. You should not configure template attributes on a Group Type panel.

Each object class identified as a Group Type (as described in “Object Class Types” on page 3-5 in the Identity System can be associated with a Group Type panel.

To view Group Type panels

1. In the Identity System Console, click Group Manager Configuration, Group Types, then the Configure Group Type Panels link.

   The Panels page displays a list of configured Group Type panels.

2. Click its link to view a Group Type's settings.

   The View Panel page appears showing the settings for the selected panel.
Adding, Modifying, Localizing, and Deleting a Group Type Panel

You must configure a Group Type panel to organize the attributes for a group object class. At least one panel should be created for the group structural object class. This enables you to view groups that contain only the group structural object class attributes on the My Groups profile page.

If you have installed and configured multiple languages, you can localize display names for the following panel fields:

- Panel Label
- Description
- Mouse Over Message

To add, modify, or delete a Group Type panel

1. From the Identity System Console, click Group Manager Configuration, Group Types.
   
   The Group Types page displays a list of Group Types.

2. Click Configure Group Type Panels to display the Panels page.

3. Choose an operation:
   
   - To add a Group Type panel, click Create.
   - To modify an existing panel, click a panel link and from the View Panel page click Modify.
   - To delete an existing panel, click a panel link and from the View Panel page click Delete.

4. In the field labeled Select the Group Type, select the object class to associate with the Group Type.

Note: Select only auxiliary object classes that extend the group structural object class or are attached to the group structural object class in the schema. Only configured auxiliary classes can be selected from this page. For more information, see "Adding Object Classes" on page 3-8.

5. In the remaining fields, enter values as described in "To create or add a panel" on page 4-14.

6. Select the box beside Panel information is complete.

7. Click Save.

Note: Selecting Tab information is complete saves the panel definition, but a user’s ability to see the contents of a panel is governed by read permissions, as described in "Allowing Users to View and Change LDAP Data" on page 4-21.

To localize panel display names

1. In the Identity System Console, click Group Manager Configuration.

2. Click Configure Group Types in the left navigation pane.
3. Click Configure Group Type Panels.

4. The Panels page displays a list of configured Group Type panels.

5. Click the panel for which you want to configure display names.
   The View Panel page appears.

6. Click Translate.
   This button only appears if you have more than one language installed. If you only have one language installed, click Modify to configure display names for panels elements.
   The Summary of Panel Display Names page appears. This page lists all the configured display names for the following fields:
   - Panel Label
   - Description
   - Mouse Over Message
   Display names that have not been configured for a particular language are marked as Not Configured.

7. Click Modify.
   The Panel Display Names page appears.

8. Click the language for which you want to configure display names.

9. Enter the display names for the panel fields.

10. Click Save to save your changes.

Modifying and Localizing Attributes Displayed on a Panel

The attributes you configure through Common Configuration pages are used in each application using that object class. For instance, through common configuration you can set the display name for the cn attribute to be Full Name. This is what appears on a user Profile page. If you then configure the cn attribute to display as Legal Name from the User Manager configuration screen, it is displayed by default as Legal Name on the user Profile page. See "Making Schema Data Available to the Identity System" on page 3-1 for details.

You can also localize display names of attributes that are displayed on a panel. This enables you to present attributes in the user’s native language. See "Configuring Multiple Languages for Oracle Access Manager" on page 7-7 for information on managing multiple languages.

---

**Note:** The only way to change the display type or semantic type of an attribute once it has been assigned to a panel is to delete and then re-create the panel.

However, as described in the following paragraphs, you can override the information configured for the attribute at the object class level.

Each Identity System application (User, Group, and Org. Manager), provides an application-specific Configuration tab with a Tabs function. Using the application-specific Tabs function, you can provide a different display name or display type for an attribute on that application-specific Configuration tab only (different than
what is configured at the object class level). For example, you may have a different display name for the "description" attribute on the User Manager Configuration tab.

For proper localization when you have more than one language installed, when you reconfigure an attribute at the tab level you must provide display names for that attribute in all installed languages. For example, suppose you have two installed languages. To provide translations for the "description" attribute on the User Manager Configuration tab (for example) in both languages, you must specify the display name for the attribute in the installed languages at the same tab level. The Translate button appears only when more than one language is installed.

The following procedures illustrate how to reconfigure an attribute at the tab level to override the information configured for the attribute at the object class level.

**To modify attributes specific to the User, Group, or Organization Manager**

1. From the Identity System Console, click the User, Group, or Organization Manager Configuration tab.
2. Click the Tabs link in the left navigation pane.
   The Tab page appears. There may be multiple tabs for the Organization Manager.
3. Click the link for the tab.
   The View Tab page appears.
4. Click Modify Attributes.
   The Modify Attributes page appears.
   Details on modifying an attribute are provided in "Configuring Attributes" on page 3-17. You can localize attribute display names as described next.

**To localize attribute display names**

1. From the Identity System Console, click User, Group, or Organization Manager Configuration.
2. Click the Tabs link in the left navigation pane.
   The Configure Tab page appears. There may be multiple tabs for the Organization Manager.
3. Click the link for the tab.
   The View Tab page appears.
4. Click Translate.
   The Summary of Attribute Display Names page appears. This page lists all configured attribute display names for all languages. Display names that have not been configured are marked Not Configured.
5. Click Modify.
   The Attribute Display Names page appears. This page lists display name fields for attributes and links for the installed languages.
6. Click the language for which you want to configure display names.
7. Enter the name in the Display Name field.
8. Click Save to save your changes.

Allowing Users to View and Change LDAP Data

You can think of configuring objects and attributes and assembling attributes into panels on application tabs as being like playing with building blocks. Once you have arranged your building blocks, you can determine who is allowed to play with them.

You must configure the Identity System to allow people to search for and view the LDAP attributes you have configured on the application panels. To do this, you:

- Determine the level of the directory tree that users are permitted to search.
- Set View and Modify permissions for specific attributes in the directory tree.

Note: The following section discusses setting the searchbase as a method of configuring view and modify permissions. The searchbase refers to searching the LDAP directory tree. Template attributes are not relevant to setting a searchbase. To give users the ability to enter values for template attributes, the users must be participants in a workflow where these attributes are used. See "Chaining Identity Functions Into Workflows" on page 5-1 for details.

About the Searchbase

A searchbase is a branch in the directory tree, or it can be the top node of the tree. At installation time, you select the default searchbase. The default searchbase is the node in the directory tree under which all user data is stored and the highest possible base for all user data searches. The searchbase determines the part of the directory tree that is available to a user during a search. You must set a searchbase for each structural object class configured for the Identity System before a user can view its entries. You can set multiple searchbases for each structural object class.

When you set a searchbase, you determine who can search what (an object class, at a particular level of the directory tree), optionally using a search filter.

Before setting a searchbase you need to determine the following:

- What object class (users or groups) do I want to set the searchbase for?
- Where will the search begin?
- Who can search there?

For example, you can configure one searchbase for employees and another for customers to ensure that customers cannot see employee information.

As another example, if two competing suppliers provide you with parts, you can set the searchbase so that users from each supplier can view only their own portion of the DIT.

Note: You set the searchbase from the User Manager application. This is the end user application rather than the User Manager Configuration function. You also need to configure read permissions for your group profile pages for the group class.
Guidelines for Setting the Searchbase

When you set a searchbase, you have the option to define a filter to identify what branch of a searchbase a logged-in user can view. If your directory tree is particularly flat, so that selecting a node does little to filter the searchbase, the filter feature helps narrow searches. The filter is also useful if your directory tree has a large number of branches, for instance, if you have 10,000 dealerships, you probably want to narrow down searches within the dealerships.

However, a filter can affect performance if it yields a large number of entries. Instead of using a searchbase filter, you can set read permissions for the class attribute, as described in "Selecting a Class Attribute" on page 3-7. The class attribute is used for attribute access and to link search results to a Profile page.

For example, suppose you remove the resource filter from the searchbase, allowing the role of Anyone to access the person object class. Instead of setting the searchbase, you define read permissions for the class attribute, using a rule to specify who can access this attribute. This can reduce the number of directory searches that the Identity System conducts. See "Setting and Modifying LDAP Attribute Permissions" on page 4-30 for details.

---

Note: You can set several searchbases for the same user or group if specific users need to access different parts of the directory tree. For example, if employees need to search both the employee and the customer branches of the tree, you can define searchbases for employees and for customers, and give employees permission to view both. However, be sparing when configuring multiple searchbases for a particular object class. Where possible, define read and write permissions for attributes instead. Multiple searchbases for the same object class can degrade performance.

---

If You Need to Modify a Searchbase

If you change the levels being searched in the directory tree or if you change the search attribute, you cannot directly modify a searchbase. If you attempt to do so, the Identity System treats the modified searchbase as a newly defined searchbase. The only way to modify a searchbase is to delete it and create a new one.

---

Note: You can modify a searchbase if the changes are other than those described in this section.

---

Indexing and the Searchbase

Searches of the directory are a significant factor in system performance. See the Oracle Access Manager Deployment Guide for guidelines on indexing.

Indexing Requirements for Oracle Internet Directory

Oracle Internet Directory returns an error when un-indexed attributes are used in a search. For example, suppose that you define a derived attribute using an un-indexed "Match Attribute" and add the attribute to a profile page in Oracle Access Manager. When the page is displayed, Oracle Internet Directory returns an error and no values are displayed for the derived attribute in the profile page. In the Oracle Access Manager log file, an error message "Operation not supported" is logged.
To use additional attributes in search filters, you must add them to the catalog entry. You can index only those attributes that have:

- An equality matching rule
- Matching rules supported by Oracle Internet Directory as listed in "About LDAP Attribute Matching Rules" in Oracle Identity Management User Reference.
- No more than 128 characters in their names.

You can index a new attribute—that is, one for which no data exists in the directory—using the ldapmodify tool. You can index an attribute for which data already exists in the directory by using the Catalog Management tool. You can drop an index from an attribute by using ldapmodify, but Oracle recommends that you use the Catalog Management tool.

Once you have defined a new attribute in the schema, you can add it to the catalog entry by using ldapmodify.

To add an attribute for which no directory data exists, import an LDIF file by using ldapmodify. For example, to add a new attribute foo that has already been defined in the schema, import the following LDIF file to Oracle Internet Directory using ldapmodify:

```
dn: cn=catalogs
changetype: modify
add: orclindexedattribute
orclindexedattribute: foo
```

Do not use this method to index an attribute for which data exists in the directory. To index such an attribute, use the Catalog Management tool.

### Setting the Searchbase

The following procedure describes the steps for setting the searchbase.

**To set the searchbase**

1. In the User Manager application, click the Configuration sub-tab.
   
   The Configuration page appears.

2. Click Set Searchbase.
   
   On some browsers you may receive a prompt asking if you trust the certificate of the application. If this happens, select the Trust Always option.

   The Set Searchbase page appears.
3. In the Object Class list, select an object class.

The object class you select defines what is being searched. For instance, to set a searchbase for widgets, you would select the widget object class.

The Searchbase Domain box indicates the top node for the search. The field beneath the Searchbase Domain box is where you enter or edit information.

4. In the field under the Searchbase Domain box, specify the part of the directory tree where the search for the object may be conducted.

For instance, if you want to define a searchbase for widgets in the Manufacturing Department, you might select the Manufacturing branch of the searchbase.

Selecting the top level of the directory tree indicates that the entire domain is available for searches. You can refine the searchbase by selecting a node further down the tree or by entering a filter. For example, to restrict searches to North America, you could select the top node and enter region=North America as the filter. This example assumes there is a branch called North America in your directory tree. See "Usage of Rules and Filters" on page 3-23 for details on writing a filter.

The Filters box indicates the current filters for the search. You use the Add Filter field, beneath the Filters box, to enter another filter.

5. **Optional:** In the Add Filters field, enter another filter.

6. Click Save.

The new filter appears in a field under the previous filter.
Users and groups permitted to search this portion of the directory tree are defined in the next panel.

7. Specify the user or group that is permitted to search this portion of the directory tree.

For Example:

- **Target Domain**: Any user object in the tree under the node you select.
  
  Do not use full LDAP URL while specifying the filter for target domain (or workflow domain) while creating the workflow. Only the LDAP filter is expected. For example, `cn=Shutterbug Canavan` is expected rather than `ldap://ou=Partners,o=Company,c=US??sub?(cn=Shutterbug Canavan)`.

- **Role**: The role of the users.
  
  If you want to give this right to everyone whether they have logged in or not, select Anonymous.

  If you want to give this right to anyone who has logged in to the User Manager, Group Manager, or Organization Manager, select Anyone.

---

**Note**: Anonymous access is used only in the Self Registration function in User Manager and Organization Manager. Also, anonymous access applies only to display type attributes (a check box, radio button, or list) that are configured as a Rule. For example, suppose you configure the `ou` attribute as a list display type with a rule that uses the LDAP filter `objectclass=organizationalUnit`. To configure this attribute for self registration, you would access the Organization Manager tab for `organizationalUnit`, configure attribute access for the class attribute (as described in “Setting and Modifying LDAP Attribute Permissions” on page 4-30, and grant Anonymous access.

---

- **Rule**: Any person you specify with an LDAP filter. Click Build Filter and use the Query Builder to create a rule. See "Writing LDAP Filters Using Query Builder" on page 4-27 for details.

- **Person(s)**: Any person you select. Click Select User and use the Selector to choose individuals.

- **Group(s)**: Any group you select. Click Select Group and use the Selector to choose one or more groups.

  To copy users and groups from one searchbase to another, click Copy, click Reset, select another Searchbase Domain and Target Domain, and click Paste. The users and groups appear in their respective boxes.

---

**Note**: If you specify users by more than one means (for instance, by a rule and by selecting individual users), both methods apply. The only exception is when Anyone is selected. Anyone supersedes all other methods.

---

8. Click one of these buttons to take the appropriate action:

- **Save**: Save and implement changes.

- **Reset**: Clear all selections.
Allowing Users to View and Change LDAP Data

- **Delete:** Clear all rule, group, and user specifications.
- **Report:** Generate a report summarizing the configured searchbases.

**If You Set a Searchbase for a Group**

You can set the searchbase for the groupOfUniqueNames object class and select the groups for which you are defining the searchbase. Before people in the group can view entries in a searchbase for a group, you need to configure read permissions for your group profile pages for the group class, as described in "Setting and Modifying LDAP Attribute Permissions" on page 4-30.

**Configuring and Deleting Disjoint Searchbases**

A disjoint searchbase is a searchbase that supplements the one you selected when you set up the Identity System. You create a disjoint searchbase to identify an additional LDAP directory tree under which user data can exist.

You can add multiple disjoint searchbases to a domain. The following procedures describe how to add and delete a disjoint searchbase.

For more information on managing disjoint searchbases, see "Working With Multiple Directory Searchbases" on page 7-33.

**To add a disjoint searchbase for a disjoint domain**

1. From the Identity System Console, click System Configuration, Directory Profiles.
2. Click the Directory Server link.
3. Add a disjoint searchbase in the Disjoint Search Base field and click Save.
4. From the Identity System Console, click User Manager Configuration.
5. From the left navigation pane, select Tabs.
   - The Configure Tab page appears.
6. Select the tab link.
7. Click Modify.
8. Make sure there is no value in the Tab Search base field.
9. Save your changes, if necessary.

**To delete a disjoint searchbase**

1. Disable all directory profiles that use this searchbase.
   
   You can view the searchbases that are configured for a directory profile in the Name Space field for the profile. There will be one directory profile for each searchbase in the disjoint domain. See "Creating an LDAP Directory Server Profile" on page 7-33 for details.
2. Remove all access control policies for the disjoint searchbase.
   
   If there are policies defined for the deleted searchbase, a user who has this searchbase on this node will be able to create a filter using Query Builder whose base is this searchbase.
3. From the Identity System Console, select System Configuration, then Directory Profiles.
4. Click the Directory Server link.
5. Remove the information in the Disjoint_domain field, then click Save.

**Writing LDAP Filters Using Query Builder**

The Query Builder enables you to write LDAP filters when you perform activities such as setting the searchbase.

The Identity System enforces a limit of 20 hits for a query. This applies to both Selector and Query Builder. If you perform a search or query that results in more than 20 hits, you receive truncated results. For instructions on changing the search limit, refer to the cookieBustLimit parameter in the *Oracle Access Manager Customization Guide*.

You access the Query Builder function from the Build Filter button. For example, this function is available when setting a searchbase. See "Setting the Searchbase" on page 4-23 for details.

---

**Note:** If you choose the Is Present or Is Not Present operator when building a query, the value specified for the display type is not taken into consideration, since the filter that is used is a presence filter.

---

**To use the Query Builder**

1. Click the User Manager application tab.
   
   These are the Identity System applications.

2. Click the Configuration sub-tab.

3. Click Set Searchbase.

4. From the Set Searchbase page, locate and click the Build Filter button.
   
   The Query Builder page appears. By default, the Basic query page is displayed.

5. In the Attribute list, select an attribute you want to use as search criteria.
   
   For example:
   
   Admin

6. Click Add.
   
   The attribute is added to the filter.

7. From the list beside the new attribute, select a matching method.
   
   For example:
   
   greater than or equals
   
   The available methods depend on the attribute. See "Methods for Retrieving Matches" on page 4-28 for details.

8. In the field beside the method, select or type the query string.
   
   For example:
   
   January 22 2003

9. Click Add to add other attributes.

10. From the list to the left of the attribute, select the relationship between attributes:

    - And: Results must match criteria in all rows.

    - Or: Results can match criteria in one row.
For example, you can search for everyone with the Administrator attribute and a
start date after (greater than) January 22, 2003.

11. Click Test to test your filter.
   If too many or too few results are received, make your criteria more or less
   restrictive.

12. Click Delete next to an attribute to remove it from the filter (or click Delete All to
delete all attributes).

13. Click Save.
   When you Save, the filter appears in the previous page under the Build Filter
   button.

---

**Note:** If you receive a Bad Request message when you save, your
query string is too long for your browser. Browsers handle the filters
as URLs, and they generate an error if the query string exceeds their
maximum URL length.

---

**Methods for Retrieving Matches**

The matching methods that you can select in the Query Builder depend on the display
type of the attribute. For instance, the display type of an attribute may be a list or a set
of radio buttons. See “Attribute Display Types” on page 3-14 for details. When you use
the Query Builder to create a filter for an attribute with a display type that contains
multiple values, for example, a list, the query returns a match even if only one value
satisfies the filter.

When building a filter, you can select multiple values for an attribute in one row only
if the attribute display type is a check box or a radio button.

Table 4–4 lists the matching methods that the Query Builder uses:

### Table 4–4 Matching Methods in the Query Builder

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>equals</td>
<td>Results are an exact match of the value.</td>
</tr>
<tr>
<td>does not equal</td>
<td>Results do not include the specified value.</td>
</tr>
<tr>
<td>less than or equals</td>
<td>Results are less than or equal to the specified value. For example, specifying k for a full name query returns people whose name begins with a letter from A to K.</td>
</tr>
<tr>
<td>greater than or equals</td>
<td>Results are greater than or equal to the specified value. For example, specifying k for a full name query returns people whose name begins with a letter from K to Z.</td>
</tr>
<tr>
<td>less than</td>
<td>Returns any directory entry with a value that is less than the specified value. When filtering a text string, a value of less than returns entries that precede the specified value alphabetically. For example, specifying k for a full name query returns people whose name begins with the letters from A to J.</td>
</tr>
<tr>
<td>greater than</td>
<td>Returns any directory entry with a value that is greater than the specified value. When filtering a text string, a value of less than returns entries that follow the specified value alphabetically. For example, specifying k for a full name query returns people whose name begins with the letters from L to Z.</td>
</tr>
</tbody>
</table>
Building Advanced LDAP Filters Using QueryBuilder

Filters can work on multiple attributes and use logical operators such as And, Or, and Not.

To build a complex filter

1. From the Identity System Console, click the tab for the User Manager application.
2. Click the Configuration sub-tab.
3. Click Set Searchbase.
4. Click the Build Filter button.
5. In the Query Builder page, click the Advanced tab.
6. If you switch from Basic to Advanced, and you choose OK, you lose the current filter (click Cancel to keep the displayed filter).

   The Advanced page appears.

   If the Advanced page does not appear after you click the Advanced tab, the URL could be too long. The length of the URL is determined by the browser.

7. In the Select Attribute list, select the attribute you want to use as the search criteria.
8. In the associated list select a matching method, and in the associated text entry field add a query string.
Allowing Users to View and Change LDAP Data

See "Writing LDAP Filters Using Query Builder" on page 4-27 for details.

9. Click Add.

The attribute is added to the Constructed Visual Filter box.

10. You can perform the following optional steps:

   ■ To add to your LDAP commands, use the And, Or, or ( ) buttons.
   ■ To remove an attribute from the Constructed Visual Filter box, select it, and click Delete (or Delete All to remove all attributes).
   ■ To modify an entry in the Constructed Visual Filter box:
     – Select the entry.
     – Make your changes to the query characteristics at the top of the page.
     – Click Modify.

11. Click Show LDAP Filter to view the filter you are building.

   The LDAP string displays in the LDAP Filter box. You can edit the text in this box and click Update Visual Filter. For examples of LDAP filters, see "Static LDAP Search Filters" on page 3-24 and "Examples of Dynamic LDAP Search Filters" on page 3-25.

   If you manually enter a very complex filter, the Constructed Visual Filter box may not be able to interpret it correctly. However, the filter will work correctly.

12. Click Test to view the results of your query.

   the Identity System displays output that conforms to your filter.

13. Click Save to save and apply your filter.

   If you receive a "Bad request" message when you click Save, your query string is too long for your browser. Browsers handle the filters as URLs, and they generate an error if the query string exceeds their maximum URL length.

About View and Modify Permissions

Until you configure permissions for an attribute, no users can see attributes displayed in the User Manager, Group Manager, and Organization Manager. For example you can allow all users to view employee work phone numbers in the User Manager, but allow only managers to view home phone numbers.

If you are a Master Identity Administrator or a delegated administrator with appropriate permissions, you can configure user permissions. By default, Master Administrators specified during Identity Server installation have full access to all attributes. You can change the default by setting the BypassAccessControlForDirAdmin parameter to false in:

IdentityServer_install_dir/identity/oblix/apps/common/bin

Setting and Modifying LDAP Attribute Permissions

The Attribute Access Control function lets you specify permissions that determine who can read and modify the values for each LDAP attribute. It also lets you create a list of users or groups to be notified when an attribute is changed. As with setting the searchbase, this functionality only applies to LDAP attributes. You configure permissions for template objects when you add participants to workflow steps. See "Chaining Identity Functions Into Workflows" on page 5-1 for details.
Users must have a searchbase defined as well as read permissions to be able to view an attribute. For instance, to be able to view the class attribute on the User Manager, Group Manager, or Organization Manager tab, a user must be a trustee of the appropriate searchbase domain for the class attribute, and they must have read permissions for this attribute.

**To set or modify attribute permissions**

1. In User, Group, or Organization Manager, click Configuration at the top of the page.
   - The Configuration page appears.

2. Click Attribute Access Control.
   - If you receive a prompt asking if you trust the certificate of the application, select the Trust Always option.
   - The Attribute Access Control page appears.

3. In the Management Domain box, specify the scope of the Directory Information Tree (DIT) that this permission applies to.
   - Initially, this field displays the searchbase set during product setup. This searchbase can only be changed by performing setup again. Selecting a lower level in the tree applies access control for that branch. For example, if you select the Full Name attribute, and then select a lower level department such as Sales, you are applying access control to all of the people in Sales with Full Name in their profile.

4. Optional—Use the Filters field to enter an LDAP rule to specify the objects and attributes more precisely.
   - A filter refines the attributes you are allowed to read or modify. If you do not use a filter, the Identity System uses objectclass=*.
   - Add the Filter in the Add Filter field. Once the configuration is saved, the filter is added to the Filters list. If you later want a different filter, you must delete the original searchbase and create a new configuration.

   **Note:** A filter is useful if your database design is particularly flat or has a particularly large number of branches.

5. Specify the Right:
   - Read—Selected users can view the attribute and its value on a profile page.
   - Modify—Selected users can change the attribute value. Note that you must confer read permissions for these users to be able to see the attribute value.
   - Notify—Sends an email to the specified users when an attribute value is changed.

   For example, you can give read and modify permissions to the Title attribute for a manager. Then you can set notification to be sent to the HR department when the value for this attribute is modified in a user profile. For details about email post-notification for a self registration step, see “Descriptions of Step Actions” on page 5-12.

6. In the Attribute box, select the attribute to associate with this right.
If you want to make multiple selections, see "Keys for Selecting Multiple Attributes" on page 4-33.

**Note:** If an attribute in your multi-select range has a different set of trustees, an error appears. This prevents you from inadvertently allowing access to incorrect trustees (participants).

7. Confer this right to one or more of the following:

**Role:** Assigns the right based on the user’s role. Any attribute with a data type of DN and a display type of Object Selector appears in the Role area. Self and Anonymous are shipped with the Identity System. Each application contains different roles, largely dependent on your configured attributes. For example, the User Manager may have the Manager role, but not any role based on the secretary attribute, depending on your configuration. Common roles include the following:

<table>
<thead>
<tr>
<th>Role</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Anyone</td>
<td>All users who log in to the User, Group, or Organization Manager can either view or modify the attribute at the selected level. For example, all logged-in users can view the phone number attribute at the specified level in the directory.</td>
</tr>
<tr>
<td>Anonymous</td>
<td>All users can view entries, whether they are logged in or not. Anonymous access is only used for self-registration.</td>
</tr>
<tr>
<td>Self</td>
<td>The user logged into the User Manager application can view or modify the attribute for his or her own identity, assuming the read and write permissions for attributes is high enough on the directory tree to include the user’s profile. For example, if you select Self to be able to view the Name attribute at the top level, then you, as a person logged into the User, Group, or Organization Manager, are able to view your name. But if you specify ou=Marketing as the level on the directory tree, and the user is not in Marketing, then you cannot view your name.</td>
</tr>
<tr>
<td>Manager</td>
<td>The user logged in to the User Manager application can either view or modify the attribute for their direct reports.</td>
</tr>
<tr>
<td>Secretary</td>
<td>If the user logged in to the User Manager is an administrative assistant, he or she can view or modify the attribute for the people they support.</td>
</tr>
<tr>
<td>Group Owner</td>
<td>The user logged in to the Group Manager can view or modify the attribute for the group that he or she is an owner of.</td>
</tr>
<tr>
<td>Group Administrator</td>
<td>The user logged in to the Group Manager can view or modify the attribute for the group that he or she administers.</td>
</tr>
<tr>
<td>Group Member</td>
<td>The user logged in to the Group Manager can view or modify the attribute for the group that he or she is a member of.</td>
</tr>
</tbody>
</table>

**Rule:** Click Build Filter and use the Query Builder to create a rule. See "Writing LDAP Filters Using Query Builder" on page 4-27 for details.

**Person(s):** Click Select User and use the Selector to specify one or more users.

**Group(s):** Click Select Group and use the Selector to specify one or more groups.

See "Evaluation of LDAP Attribute Permissions" on page 4-33 for information on the order for evaluating permissions.
8. Click Copy, click Reset, select a new attribute, and click Paste to copy users and groups from one attribute to another.

9. Click one of these buttons:
   - **Save**: Save and implement your changes.
   - **Reset**: Clear all selections.
   - **Delete**: Clear all rule, role, group, and user specifications.
   - **Report**: Generate a report of attributes and their access permissions in the domain.

### Keys for Selecting Multiple Attributes

You can configure access control for multiple attributes at one time using the following keyboard combinations:

- **Ctrl + Home**: Selects all attributes above and including the highlighted attribute.
- **Ctrl + End**: Selects all attributes following and including the highlighted attribute.
- **Ctrl + Page Up**: Selects only attributes above the highlighted attribute.
- **Ctrl + Page Down**: Selects only attributes following the highlighted attribute.

**Note:** If an attribute in your multi-select range has a different set of trustees (participants), you receive an error. This prevents you from granting access to incorrect trustees.

<table>
<thead>
<tr>
<th>Browser Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows Browsers</td>
<td>To select multiple attributes, hold down the Ctrl key and select the attributes.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and all attributes before it, hold down the Ctrl+Shift+Home keys and select the attribute.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and all attributes following it, hold down the Ctrl+Shift+End keys and select the attribute.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and an arbitrary number of attributes following it, select it and press Shift+Down Arrow.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and an arbitrary number of attributes before it, select it and press Shift+Up Arrow.</td>
</tr>
<tr>
<td>Unix Browsers</td>
<td>To select multiple attributes, hold down the ESC key and select the attributes.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and all attributes before it, hold down the ESC+Shift+Home keys and select the attribute.</td>
</tr>
<tr>
<td></td>
<td>To select an attribute and all attributes following it, hold down the ESC+Shift+End keys and select the attribute.</td>
</tr>
</tbody>
</table>

### Evaluation of LDAP Attribute Permissions

When you assign multiple methods for view and modify permissions, the Identity System evaluates the methods in this order:

1. Users
2. Roles
3. Groups
4. Rules (LDAP filters)

When the Identity System finds a match, it stops checking. For example, suppose you grant read permission for the Name attribute for User=Lou Reed, but you also have a rule that says (&(!((cn=Lou Reed)) objectclass=person object class)), which allows everyone except Lou Reed. Lou Reed has access because he is a User, which precedes Rule in the evaluation order. As another example, if you specified a rule denying access to the Human Resources department but used the people selector to specify an individual employee in Human Resources, the union of the rule and people categories would allow access to the specified employee.

---

Note: If you select the Anyone role, all users, roles, groups, and filters are superseded.

Examples of Configuring an Application

The following sections describe different scenarios for configuring an application. Separate examples are provided for the User Manager, Group Manager, and Organization Manger.

Displaying Photos in User Profiles

Photos appear in the header panel of a user profile. Users with self-service permissions on relevant attributes can manage their own photos.

There are two ways you can store photos in the Identity System:

- In an LDAP directory
- Referencing photos in a file system.

You cannot use both methods. All of your photos must be stored in either a directory or a file system.

Importing and Storing Photos in a Directory

When you want to store your photos or other images in a directory, place the photos on the Identity Server and use the Identity System to import the photos into the directory and to configure an attribute to be the photo attribute. You can create your own attribute, or you can use an attribute that already exists. This attribute must be defined as a binary type in your directory, and in the Identity System the attribute must be defined as a Photo semantic type with a GIF display type. The GIF display type supports GIF and JPEG formats, and other image file formats that are supported by your Web server.

Before associating a photo with a user's identity, be sure the photo's file name is based on the value of the attribute with the Login semantic type. For example, if your Login semantic type is assigned to the uid attribute, you would use the following file name conventions:

attribute_value_of_uid.gif
or
attribute_value_of_uid.jpg
or
attribute_value_of_uid.jpeg
If your login semantic type is something other than uid, use that instead for your file name. For example, if the Login semantic type is assigned to the email attribute, your photo file names must be the following:

\texttt{attribute\_value\_of\_mail.gif}  
\texttt{attribute\_value\_of\_mail.jpg}  
\texttt{attribute\_value\_of\_mail.jpeg}

The file extension must be compatible with a graphic file format that your Web servers can support.

When the Identity System imports photos and images, it converts the files into Base64 format. This data becomes the value of the Photo attribute. The Identity System uses the Login attribute and the photo or image file name to determine which photo belongs to which user entry.

Steps for configuring the Identity System to use the photos are described in the following discussions.

**To configure photos for importing to a directory**

1. From the Identity System Console, click Common Configuration, then click Object Classes.
2. Select your person object class from the list.
3. Click Modify Attributes.
4. Modify the Photo attribute as follows:
   - **Attribute**: Photo
   - **DisplayName**: Photo
   - **Semantic Type**: Photo
   - **Data Type**: Binary
   - **Attribute Value**: This is always a single value attribute
   - **Display Type**: GIF Image
5. Save your changes.
6. In the User Manager, under Attribute Access Controls, assign Read and Write permissions to this attribute.

**To import photos to the directory**

1. From the Identity System Console, click System Configuration, and click Photos.
2. Specify the path to the photos stored on the Identity Server.
3. Click Save.
   
   This imports all of the GIF and JPEG images into your directory.

**Referencing Photos in a File System**

Another method for storing images and photos for user identities is to store the photos in a location other than the directory. This method is appropriate for GIF and JPEG images, and other image file formats that are supported by your Web server.
The Identity Server’s WebPass must be able to access this location. You can name the photo or image file using any valid file name that the Web server recognizes and supports. Avoid using special characters such as spaces in the file name. The Web server may not recognize file names that use special characters.

**To reference photos that reside in a file system**

1. In the Identity System Console, click Common Configuration, Object Classes.
2. Click the person object class in the Object Class list.
3. Click Modify Attributes.
4. Modify the Photo Path attribute as follows:
   - Attribute: Photo Path
   - DisplayName: Photo
   - Semantic Type: Photo
   - Data Type: String (case-sensitive)
   - Attribute Value(s): Single or multi-valued
   - Display Type: GIF image URL
5. Assign read and write permissions for this attribute.
6. Store the images in GIF or JPEG format in the following directory:
   \`WebPass_install_dir\identity\oblix\lan\langTag\style0\`
   where \`WebPass_install_dir\` is the directory where WebPass is installed and \`langTag\` is the folder that contains the specific language you are using.
7. Enter the photo location URL in the User Profile Page for each user.
   For example, if the image location is:
   \`c:\COREid\WebComponent\identity\oblix\apps\lang\en-us\style0\user1.gif\` 
   you set the photo location to:
   \`user1.gif\`
   More than one GIF image can be displayed by setting the photo URL attribute to be multi-valued.

**The Default Photo Image**

the Identity System supplies a default photo image. This image is presented in case there is no photo image supplied for a user. The image is stored in CIMAGE\defaultphoto.gif in style0 on the Identity Server.

**Enabling the Location Tab in Organization Manager**

the Identity System provides a Location tab by default in the Organization Manager. This tab enables you to create maps and associate users or objects with locations on those maps.

**Task overview: Enabling Location functionality**

1. The Master Identity Administrator modifies the Location tab and adds location attributes to Profile pages for the User and Organization Manager applications.
2. The Master Identity Administrator configures access controls for location attributes.

3. The Master Identity Administrator or Delegated Identity Administrator configures workflows for creating a location. See "Chaining Identity Functions Into Workflows" on page 5-1 for details.

4. The Delegated Identity Administrator creates a new location and establishes the location’s hierarchy in relation to other locations, if applicable.

5. The Delegated Identity Administrator or user assigns a value for the location attribute for a user or object profile.

   Any user with appropriate permissions can now view the user or object location.

The Right to Create Groups in Group Manager

You assign users the right to create a group when you define a Create Group workflow. Only users designated as participants in the workflow can create the group. See "Chaining Identity Functions Into Workflows" on page 5-1 for information about creating workflows.

A user can be assigned the right to modify a group type if the user is a participant in a Create Group workflow for that group type. The user must also have write access for the group type attribute. See "Adding Auxiliary and Template Object Classes to a Group Tab" on page 4-8 for information about group types. Also see "Setting and Modifying LDAP Attribute Permissions" on page 4-30 for information about assigning the modify right to the Group Type attribute.

If you run the Identity System with multiple Active Directory instances and use a dynamic filter to create a group, the filter attribute must be a multi-value attribute.

If you run the Identity System with the NDS directory, the users you select as members of the group are cleared from the page when you click Save. To prevent this from happening, go into the NDS directory and switch the order of the attributes so uniquemember is read first. Also make sure the userCertificate attribute comes before the NDS userCertificate;binary attribute.

End-User Scenarios

The following sections describe how an end user interacts with the Group Manager application once it has been configured:

■ Managing Group Members in Group Manager  
■ Searching for Group Members  
■ Deleting Group Members  
■ Adding Group Members  
■ Managing Group Subscriptions  
■ Subscribing to Groups

Managing Group Members in Group Manager

You can view and manage group members from the Group Profile page if the Master Identity Administrator selected a group-member attribute to display on the group profile page. See "Configuring Tab Profile Pages and Panels" on page 4-11 for more information.
If your group contains a large list of members, this can negatively impact system performance. The Master Identity Administrator can choose not to display group members on the Group Profile page. See "Configuring Group Manager Tab Options" on page 4-9.

---

**Note:** You can also view and manage group members from the Manage Group Members page. When managing large static groups, Oracle recommends using the Manage Group Members page because it is optimized to manage groups with 1000 or more members. This will significantly improve performance when managing large groups (as opposed to defining the member semantic attribute as part of the Group Profile page).

---

### Searching for Group Members

The Manage Group Members page enables you to view the members of a group based on criteria that you provide. This page shows tables for:

- Static members
- Dynamic members
- Nested members

Search results are subject to searchbase and attribute access controls configured for the Group and User Manager applications. See "Setting and Modifying LDAP Attribute Permissions" on page 4-30 for details.

If a user does not have read access to the dynamic member attribute for a group, nothing appears in the dynamic member table and the following error message is shown, "You don't have read access for a dynamic member."

In the nested members table, if the group contains dynamic nested groups and the user does not have read access to the dynamic member attribute for some of the nested groups, the dynamic members are not shown. In this case, no error message is displayed.

### To view a group

1. In the Identity System Console, click the Group Manager tab.
2. In the Search field at the top of the page, enter search criteria.
3. Click Go.
   A list of groups appears.
4. Click the link for the name of the group that you want to view.

### To view group members

1. In the Group Manager, click My Group.
2. Conduct a search on groups and click the desired link.
   The group profile appears.
3. Click Manage Group Members.
4. Select the Member Type you are searching for in this group:
   - Select People to search for users. Search results can include static, nested, and dynamic users.
Select Groups to search for groups. Search results can include static and dynamic nested groups.

5. From the Search Members By list, select an attribute as the basis for the search.

6. Select a search operator.

7. Enter search criteria.

8. Click Go.

The Manage Group Members page displays two levels of nested groups and their members in the search results. This includes a child nested group, its members, and its children.

Deleting Group Members

You can delete group members displayed in the search results from the Manage Group Members page. You can only delete static members. You cannot delete dynamic or nested members.

To delete group members

1. Search for group members from the Manage Group Members page.
   
   See "Searching for Group Members" on page 4-38.

2. From the results that are returned on the search, click the link for the user or group that you want to delete.

3. Click Save on the Manage Group Members page.

Adding Group Members

You can add members to a group.

To add group members

1. Go to the Manage Group Members page, as described in "Searching for Group Members" on page 4-38.

2. From the Manage Group Members page, click the Select Member button beside the Members To Add field.

   The Selector page appears. See "The Selector" on page 1-10 for details.

3. From the Selector page:
   
   ■ If you want to add users to this group, select the person member type.
   
   ■ If you want to add nested groups to this group, select the group member type.

4. Click Add for each member you want to add.

5. Click Done.

6. Click Save on the Manage Group Members page.

Managing Group Subscriptions

The Group Manager provides the ability for users to subscribe and unsubscribe to groups.

Only groups configured as Advanced Groups can include a subscription policy. The oblixAdvancedGroup is provided by the Identity System to give you attributes that
you might need when working with groups. Table 4-5 shows the contents of oblixAdvancedGroup:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Characteristics</th>
</tr>
</thead>
</table>
| obGroupAdministrator       | Display Name: Group Administrator  
|                            | Semantic Type: Group Administrator  
|                            | Display Type: Object Selector                                                                                                                  |
| obGroupDynamicFilter       | Display Name: Dynamic Filter  
|                            | Semantic Type: Group Dynamic Member  
|                            | Display Type: Filter Builder                                                                                                                   |
| obGroupExpandedDynamic     | Display Name: Group Expansion  
|                            | Semantic Type: None  
|                            | Display Type: Radio Buttons  
|                            | Comment: This attribute is used for expanded dynamic groups.                                                                                   |
| obGroupPureDynamic         | Display Name: Dynamic Members Only  
|                            | Semantic Type: None  
|                            | Display Type: Radio Buttons  
|                            | Comment: This attribute indicates whether the group is purely a dynamic group. It affects subscriptions.                                        |
| obGroupSimplifiedAccessControl | Display Name: Group Access  
|                            | Semantic Type: None  
|                            | Display Type: Radio Buttons  
|                            | Comment: This attribute is used for creating a group workflow. It controls the simplified access control feature.                              |
| obGroupSubscribeMessage    | Display Name: Subscription Message  
|                            | Semantic Type: None  
|                            | Display Type: Multi-Line Text  
|                            | Comment: This attribute is used for subscription notification.                                                                                   |
| obGroupSubscribeNotification | Display Name: Notification  
|                            | Semantic Type: None  
|                            | Display Type: Check Box  
|                            | Comment: This attribute is used for subscription notification.                                                                                   |
| obGroupSubscriptionFilter  | Display Name: Subscription Filter  
|                            | Semantic Type: None  
|                            | Display Type: Filter Builder  
|                            | Comment: This attribute is used for group subscriptions using a filter.                                                                          |
| obGroupSubscriptionType    | Display Name: Subscription Policy  
|                            | Semantic Type: None  
|                            | Display Type: Selection Menu  
|                            | Comment: This attribute is used for group subscriptions.                                                                                         |
Subscribing to Groups

There are three ways a user can subscribe to a group, assuming the Master Identity Administrator configured a group subscription policy for that group:

- From the Group Profile page in Group Manager
  This enables users to subscribe to the selected group displayed in the profile.
- As the last step of a Create User workflow
  Users can subscribe to multiple groups during the last step of a create user workflow. See “Chaining Identity Functions Into Workflows” on page 5-1 for more information.
- From the Manage Subscriptions page in Group Manager
  This enables users to subscribe to multiple groups from the Manage Subscriptions page.

To subscribe to a group
1. From the Identity System Console, click the Group Manager tab.
2. Conduct a search for groups using the search bar.
3. Click the link for the group to which you want to subscribe.
4. Click Subscribe.

To subscribe to multiple groups
1. From the Group Manager application, click Manage Subscriptions.
2. Conduct a search for groups using the search bar.
3. In the Groups for Subscription page, check the box next to each group to which you want to subscribe.
4. Click Save Subscriptions at the bottom of the Manage Subscriptions page.

A list of groups to which you are subscribed appears. This includes:
- All groups with an open subscription policy.
- All groups with filter subscription policy, and you satisfy the filter criteria.
- All groups controlled through a workflow subscription policy where you are a participant in the initiating step of the change-attribute workflow that applies to these groups.
Configuring Auditing Policies

You can capture information about user actions performed in each Identity application. Captured information is stored as audits of Identity System events.

You configure auditing policies for each application. These settings determine the data that is captured in an audit file. You configure where audit files are written for each Identity Server. For information about changing the audit file path, see "Managing Identity Servers" on page 7-14.

Viewing Auditing Policies

You can view auditing policies from each Identity System application.

To view auditing policies

1. In the Identity System Console, click User, Group, or Org. Manager Configuration, then click Audit Policies.

   The Application Auditing Policy page appears, displaying the following information:

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile Attributes</td>
<td>Appears only if they have been configured for this application.</td>
</tr>
<tr>
<td>Event Name</td>
<td>the Identity System operation being audited</td>
</tr>
<tr>
<td>Application Auditing Enabled</td>
<td>Indicates whether or not auditing is enabled for this event</td>
</tr>
<tr>
<td>Audit Success</td>
<td>Indicates whether or not event successes are audited</td>
</tr>
<tr>
<td>Audit Failure</td>
<td>Indicates whether or not event failures are audited</td>
</tr>
</tbody>
</table>

Modifying Auditing Policies

If you have appropriate permissions, you can change any auditing policy that you can view. These settings do not overlap with the Global Auditing Policies feature found in the Identity System Console, Common Configuration, Global Auditing Policies.

To set or modify auditing policies

1. In the Identity System Console, click User, Group, or Organization Manager Configuration, Audit Policies.

2. Click Modify.

   The Modify Auditing Policy page appears.

3. In the Profile Attributes lists, select the attributes that can trigger events you want to audit.

4. In the Application Auditing Enabled column, select each event you want to enable for auditing.

5. In the Audit Success and Audit Failure columns, select each event you want to audit.

   For example, you can audit every Modify Location event, but audit only View Profile failures.

6. Click Save.
Generating Reports

Reports enable you to view information about an object class. Reports provide an alternative to searches and enable you to report on attributes that are not available from a search.

Configuring Reports

Master Identity Administrators must define a report from the Identity System Console before users can view the report in the User Manager application.

For example, after configuring an Employees tab for User Manager, as described in "Viewing and Modifying Tab Configuration Information" on page 4-3, you can create reports listing employees in a specific building, employees with specific job titles, or employees in a particular department.

The report functionality uses QueryBuilder to enable you to define complex search criteria that are not possible using a basic search. This provides richer support for searching on various types of attributes that a basic search does not allow. There are two types of reports:

- **Ad-hoc Reports**: Created by end users in the User Manager, Group Manager, and Org. Manager applications. In this case, the Query Builder includes searchable attributes configured in the tab along with other supported display types (see the note).

- **Pre-defined Reports**: Created by an administrator from the System Console. In this case, the Query Builder includes all attributes (whether they are marked as searchable in the tab or not) for all supported display types.

Note: The Query Builder supports building filters on attributes with the following display types: Single line text, Multi-line text, Radio, Select list, Checkbox, Boolean, Date, Mail address, Telephone number, Selector, Postal address and Numeric String.

To configure a report

1. From the Identity System Console, click User Manager Configuration, Reports, then click List Reports.

   The following page appears the first time you create a report.
Generating Reports

2. Click Add to display the Query Builder on the Configure Reports page.
3. Select the first Attribute for the basis of your report criteria, then click Add.
4. In the field beside the attribute, select the appropriate method.
5. Enter the report criteria.
   The format of this criteria depends on the attribute display type.
6. Repeat steps 3-6 for any additional attributes you want added to this report.

   **Note:** When you select more than one attribute for a report, you must select whether this is an And or an Or operation. See the sample page in this procedure.

7. Click Test to verify that the report generates data correctly.
   A verification page appears.
8. Click Save.
   A page like the following one appears. Several buttons become available and are highlighted in the following screen shot. These will be used in the next procedure.
9. Click Next to see additional report results, or click Publish to save the report.

To change the formatting of a report
1. From the Reports page, click Customize to customize the report column headings.
2. Customize the column names in the form that appears, then click Save.
3. Click the Publish button.
4. Enter a Name and an optional description for this report.
5. Click Save to make this report available in the User Manager application, under the Reports tab.

Viewing, Modifying, Localizing, and Deleting Reports

Viewing reports is subject to access control and searchbase settings.

You can display a report's name and description in more than one language if you install the appropriate language packs and configure them for those languages. See "Configuring Multiple Languages for Oracle Access Manager" on page 7-7 for more information.

When you export a generated report in an Identity System application and the values contain non-ASCII characters, you must rename the file with a .txt extension. It will pass through Excel’s Import Wizard and non-ASCII characters will display properly. Note that .csv files opened in OpenOffice will pass through the Import Wizard. In this application, encoding can be chosen without renaming the file to *.txt.

To view or modify reports
1. From the Identity System Console, click User Manager Configuration, then click Reports.
2. Select the type of report you want to view or modify from the list.
3. Click List Reports.
4. Select the link to the report you wish to view.
5. Click the Customize button to change the report criteria.
6. Click Save to save the new report format.

See "Configuring Reports" on page 4-43 for more information on publishing reports for others to view.

To localize reports
1. From Identity System Console, click User Manager Configuration, then click Reports.
2. Click List Reports.
   All existing reports are listed on the page.
3. Click the report that you want to localize.
   The report details appear on the page.
4. Click Publish.
   The Publish Report page appears. This page contains the links for all the installed languages.
5. Click the language in which you want to publish the report.
6. In the Report Name field, enter a display name in the selected language.
7. In the Report Description field, enter a brief description of the report.
   This information is optional.
8. Click Save to save your changes.
   The reports are displayed in the User Manager.

To delete reports
1. From Identity System Console, click User Manager Configuration, then click Reports.
2. Select the tab that contains the report you want to delete.
3. Click List Reports.
4. Select the (-) icon next to the report name to delete it.

Advanced Configuration
The following sections describe expanding dynamic groups, limiting the scope of a directory search, and editing an XML file to configure attribute permissions.

Expanding Dynamic Groups
If a group’s membership is determined by an LDAP filter, you can generate a static membership list by expanding the group. Generating a static list saves the Identity System from having to run the LDAP filter with every group access.

Group expansion updates the static list by running the LDAP rule that specifies dynamic membership, then storing the results in the static member attribute. Many Identity System functions test a group for membership. Since testing static membership is faster than testing dynamic membership, it is preferable to find a member in a static list. Also, third-party applications may only be able to check static
membership. Frequent expansion keeps static membership accurate for third-party applications.

The group expansion operation itself is an expensive process. However, you can expand a group as a background process so the impact is hidden from users.

---

**Note:** If you have static members in a dynamic group and you expand the group, the original list of static members is overwritten with the members who currently satisfy the filter criteria. This is true even if you have set the flag for dynamic members only to false. The filter overrides other group settings.

---

Before a user can expand a group, two conditions must be met:

- The obgroupexpandeddynamic attribute must be set to true.
- The person expanding the group must have Read permission for two attributes, obgroupexpandeddynamic and obgroupdynamicfilter. The user also must have Write permission for the attribute assigned the Group Static Member semantic type.

See the table in "Managing Group Subscriptions" on page 4-39 for a breakdown of the Identity System-supplied group attributes.

**To expand a dynamic group**

1. In Group Manager, click the Configuration option at the top of the page.
   The Configuration page appears.
2. Click Expand Dynamic Groups.
   The Expand Dynamic Group page appears.
3. Select one of these options:
   - Select By Group and click Select Group to choose one or more groups
   - Select All to expand all groups
4. Click Expand.
   The Expanded Groups page displays a list of all groups that have been expanded.
5. Click the group link to display the Group Profile page for that group.
6. Click Done.

**Modifying the Default Searchbase Scope**

Some portions of the Identity System call out to external XML files to get configuration information. The globalparams.xml file is one such file. This file controls search scope among other things.

By default, the search scope is set to subtree for the Identity System, meaning that the search begins at the starting point of the searchbase and includes its children. Depending on the size of your directory, you may want to change the default search scope using the ResourceFilterSearchScope parameter. The possible values for this parameter are:

- 1: Search the top node of the searchbase and the first level under it.
- 2: Start at the top node of the searchbase and proceed to the bottom node.
Figure 4–1 shows that setting ResourceFilterSearchScope to 1 could limit results to just a few returned entries, while setting it to 2 could return thousands of entries.

**Figure 4–1  Search Scope Options**

To set the globalparams.xml file
1. Locate the globalparams.xml file in the following directory:
   
   IdentityServer_install_dir/identity/oblix/apps/common/bin
2. Back up the file.
3. Open the file in an ASCII editor (for instance, Notepad) or an XML editor.
4. Find the ResourceFilterSearchScope parameter and change the value.

**Simplified Attribute Permissions for a Group**

Simplified attribute permissions lets a group creator select Read, Write, and Notify permissions without having to set permissions for each attribute as described under "Setting and Modifying LDAP Attribute Permissions" on page 4-30.

Simplified permissions are applied to newly created groups where the management domain of the policies is the DN of the new group. Later, these policies can be modified through the access control feature.

**Implementing Simplified Permissions**

An administrator can configure as many sets of simplified permissions as needed. The administrator creates permissions in the IdentityServer_install_dir/oblix/apps/gpcenter/bin/gscacparams.xml file.

This file contains embedded compound lists to define the roles, users, and groups the model applies to, the rights assigned, and the attributes to which the rights apply. When this file is applied to a new group, an access control entry is created for each right in the file.

**Sample gscacparams.xml File**

The following is a sample set of permissions within a gscacparams.xml file. The model name is Public:

- In entry 1, the role is ob_any, the right is read, and the attributes are description, uniquemember, and owner.
- In entry 2, the role is owner, the right is write, and the attributes are description, uniquemember, and owner.
**Example 4–1**

```xml
<?xml version="1.0"?>
<ParamsCtlg xmlns="http(s)://www.oblix.com" CtlgName="gscaclparams">
<!--#---------------------------------------------------->
<!-- #Access Control Functions -->
<!--#---------------------------------------------------->
<!--#---------------------------------------------------->
<!-- # Public access -->
<!--#---------------------------------------------------->
<CompoundList ListName="">
<CompoundList ListName="Public">
<CompoundList ListName="entry1">
<ValList ListName="roles">
<ValListMember Value="ob_any"/>
</ValList>
<ValList ListName="rights">
<ValListMember Value="READ" Operation="Add"/>
</ValList>
<ValList ListName="attributes">
<ValListMember Value="description"/>
<ValListMember Value="cn"/>
<ValListMember Value="uniquemember"/>
<ValListMember Value="owner"/>
</ValList>
</CompoundList>
<CompoundList ListName="entry2">
<ValList ListName="roles">
<ValListMember Value="owner" Operation="Add"/>
</ValList>
<ValList ListName="rights">
<ValListMember Value="WRITE" Operation="Add"/>
</ValList>
<ValList ListName="attributes">
<ValListMember Value="description" Operation="Add"/>
<ValListMember Value="cn" Operation="Add"/>
<ValListMember Value="uniquemember" Operation="Add"/>
<ValListMember Value="owner" Operation="Add"/>
</ValList>
</CompoundList>
</CompoundList>
</CompoundList>
</ParamsCtlg>
```

**Simplified Permissions Reserved Words**

The following table summarizes the reserved words for simplified permissions.

<table>
<thead>
<tr>
<th>Reserved Word</th>
<th>When Used</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rights</td>
<td>Once for an entry</td>
<td>Specifies the right: read, modify, or notify.</td>
</tr>
<tr>
<td>attributes</td>
<td>Once for an entry</td>
<td>List that specifies the attributes. Any group object attribute can be added to the list.</td>
</tr>
<tr>
<td>roles</td>
<td>Once for an entry</td>
<td>Roles to which entry applies. Roles can be any pre-defined role, such as uniquemember, owner, ob_anym, or ob_anonymous.</td>
</tr>
<tr>
<td>people</td>
<td>Once for an entry</td>
<td>Specifies the distinguished names to which this entry applies.</td>
</tr>
<tr>
<td>source</td>
<td>Once for a model</td>
<td>Specifies the base uid of the users who will see this model. If a base uid is not specified, everyone can see this entry.</td>
</tr>
</tbody>
</table>
Setting Container Limits in Organization Manager

Use the Container Limits function to control the number of objects and child objects for an organizational unit and its object classes. You can define who receives notifications when the limit is about to be exceeded. For example, you can have organizational units in your directory tree that you use for storing extranet customers. You can limit to 10,000 the number of customers with access to your extranet portal.

**Note:** The Container Limits feature counts the number of objects from the directory. If the number of objects is very large, performance can be affected.

To view and add container limits

1. From the Identity System Console, click the Org. Manager tab, then click Configuration, then click Container Limits.

   The Container Limits page appears.

   In this example, the Current Count table on this page indicates that the gensiteOrgPerson object class has 9 children stored at the current level of the DIT and 718 total children at or under this level.

2. In the Management Domain box, select a DIT entry you want to view.
The Current Count box displays all configured structural classes associated with the entry and the number of their children.

The Objectclass table displays the container limit, enforcement, and notification policies for the selected DIT entry, listed according to object class.

3. Select an object class and click Add to add a container limit, in the Objectclass list. A second Container Limits page appears showing the Management Domain and Object class you selected in the previous screen.

4. In the Container Limit box, specify the maximum number of children this object class can contain at this DIT level.

5. When you want to notify someone by email that your object class is nearing its container limit, select Notify if used up, and specify the limit percentage when you want the email sent.

6. Select Override subordinate policies to create a container limit that cannot be overridden by a lower policy on the DIT.

7. Use one or more of the following to specify the persons to receive container limit warnings:
   - Select Build Filter, then use the Query Builder to create a rule.
   - Click Select User, then use the Selector to specify one or more users.
   - Click Select Group, then use the Selector to specify one or more groups.

The Users, Roles, and Rules fields have an or relationship. Users specified in any of the fields are notified.
8. Click Save to save your container limit and add it to the Objectclass table.

**Copying Container Limits**
You can copy container limits from one domain to another.

**To copy container limits from one domain to another**
1. From the Organization Manager, click Configuration, then click Container Limits.
   The Container Limit screen appears (as shown on
2. In the Management Domain box, select the directory information tree (DIT) entry you want to view.
   The Current Count box displays the structural classes associated with the entry and the number of their children.
   The table Add Container Limit to Objectclass displays the container limit, enforcement, and notification policies for the currently selected DIT entry, listed according to object class.
3. Click Copy.
4. In the Management Domain box, locate the destination entry where you want to add the container limits.
5. Click Paste.
   The container limit policies are added to the selected DIT entry.

**Modifying Container Limits**
You can change container limits. See "Setting Container Limits in Organization Manager" on page 4-50.

**To modify a container limit**
1. In the Organization Manager, click Configuration.
   The Configuration screen appears.
2. Click Container Limits.
   The Container Limits screen appears.
3. In the Management Domain box, select the DIT entry you want to view.
   The Current Count box displays all configured structural classes associated with the entry and the number of their children.
4. In the Add Container Limit to Objectclass panel, select an object class from the Objectclass column.
5. Click Modify.
   The second Container Limits screen appears.
6. Make your changes.
   See "Setting Container Limits in Organization Manager" on page 4-50 for information about these fields.
7. Click Save.
   You can delete a container limit.
To delete a container limit

1. In the Organization Manager, click Configuration, then click Container Limits.

2. In the Management Domain box, select a directory information tree (DIT) entry.
   The Current Count box displays all configured structural classes associated with
   the entry and the number of their children.

3. In the Add Container Limit to Objectclass panel, select an object class.

4. Click Delete.
   The object class container limit is deleted.

---

**Note:** Click Delete All to delete all container limits for a DIT entry.
Chaining Identity Functions Into Workflows

This chapter includes the following topics:

- About Workflows
- Using the QuickStart Tool
- Using the Workflow Applet
- Defining a Subflow
- Advanced Workflow Ticket Routing
- Performing Asynchronous Operations
- Using a Workflow
- Managing Workflows
- Advanced Workflow Options
- Creating a Self-Registration Workflow
- Creating a Location Workflow

About Workflows

An Identity System workflow enables Master Identity Administrators and Delegated Identity Administrators to apply business logic to Identity System functions. A workflow organizes and automates complex procedures, for example, creating benefits and email accounts for new employees or changing user profile attributes in the directory.

Each workflow consists of a sequenced chain of actions. Rather than making a single person responsible for completing all the tasks in the workflow, you can assign each step to the specialist most appropriate to perform that step. When a step is completed, the workflow engine can send the workflow ticket to the person responsible for the next step in the sequence.

In sum, workflows enable you to:

- Automate and standardize processes for creating objects, deleting objects, and modifying attributes in the directory.
- Apply data integrity and rule checking when creating objects, deleting objects, and modifying attributes.
- Configure the Identity System as a data entry system for provisioning back-end applications.
How Workflows Are Initiated

Workflows can be initiated by a user. For example, a new employee can initiate a self-registration workflow.

Workflows can also be initiated programmatically. For example, you can initiate the workflowSaveCreateProfile function in IdentityXML to initiate a create user workflow. See Oracle Access Manager Developer Guide for details.

You can also copy a link to a URL for the workflow and embed it in a page from another application, and access it as a portal insert. See the Oracle Access Manager Customization Guide for details.

Typical Workflow Examples

Workflows are appropriate for just about any frequently repeated, multi-step task involving any combination of user actions or automated data retrieval. Each workflow is associated with one of the Identity System applications. The following list covers some common workflows:

- **User Manager**: You can define a workflow to permit users to change their department number and phone number pending approval by a manager. You can ensure that when a new user is created, the appropriate people obtain information about this person programmatically from an external system.

A different workflow can add new users to your corporate email application. If you have defined an object template schema, you can use a workflow to send data from an Identity System application to a back-end application for provisioning. See “Sending Non-LDAP Data to External Applications” on page 6-1 for details on object templates.

- **Group Manager**: You can create a workflow to route group registration requests to a manager for approval.

- **Organization Manager**: You can give a supplier the ability to create entries for parts, pending manager approval of each entry the supplier adds. You can also create a workflow that first enables a user to add a new part entry, then routes the request to add the data to an appropriate person for approval, and finally, permits the person giving approval to commit the new data to the directory.

Advanced Workflow Options

The Identity System workflows support the following advanced features:

- **Subflows** enable certain workflow activities to occur in parallel.

  For instance, if a request to create a new user requires approvals from two different departments, both parties can receive approval requests simultaneously. See “Defining a Subflow” on page 5-30 for details.

- You can route specific workflow steps to different *dynamic participants*, who are selected based on attribute values or business logic evaluated at runtime.

  See “Specifying Dynamic Participants” on page 5-33 for details.

- You can designate *surrogates* to assume responsibility for a step when the primary participant assigned to that task is out of the office or otherwise unavailable to process incoming tickets.

  See “Specifying Surrogates” on page 5-39 for details.
You can configure *time-based escalation* so that a workflow ticket is routed to a different participant if the original participant does not complete the assigned step within a specific period.

See "Enabling Time-based Escalation" on page 5-41 for details.

You can invoke a workflow from any Web page as a portal insert or application using IdentityXML.

See the *Oracle Access Manager Developer Guide* for details.

Workflow *auditing* enables you to monitor the state of a workflow and to determine exactly who performed particular actions at each step in the process.

See "Monitoring a Workflow" on page 5-49 for details.

For actions that do not require human intervention, you can configure workflow steps so that the Identity System automatically obtains the required data from external sources.

See the *Oracle Access Manager Developer Guide* for details.

**Workflow Types**

Workflows come in various types. For instance, one type of workflow enables you to change one or more attributes for an existing object. Another type of workflow enables you to create a new object. Figure 5–1 illustrates a Create User workflow:

**Figure 5–1 Create User Workflow**

Creating Workflows

The following overview summarizes the high-level steps for creating a workflow. The actual steps vary slightly for Change Attribute workflows and Create User (or Group, or Object) workflows:

**Task overview: Creating a workflow definition**

1. Add objects to the tab for the relevant Identity System application.
2. Configure attributes for the objects.
3. Configure read and write permissions for LDAP attributes.
Participants in a workflow must have appropriate read and write permissions for LDAP attributes that are viewed and changed during the processing of the workflow. See "Allowing Users to View and Change LDAP Data" on page 4-21 for details.

4. Add the attributes to the application panels.

This applies to both LDAP and template attributes. For Change Attribute workflows, users will not see the attributes from template objects on the profile page that contains the panel. However, the template attributes must be added for the workflow to operate properly.

5. Configure the workflow.

As discussed in "Defining Step Attributes" on page 5-25 for details, when you add attributes for a step in a Change Attribute workflow, the topmost attribute in the list must have been configured on a profile page. The subsequent attributes in the list will be added to the page automatically as long as the topmost attribute has been configured correctly.

A workflow definition changes the appearance of its related profile page in the Identity System application for which the workflow was created. For example, when a Modify Attribute workflow has been configured correctly, a Modify button appears next to the attribute on the Modify Profile page for the target object. When a Create User workflow has been configured correctly, the desired attributes appear when you select Create User Identity in the User Manager.

**How Users Access Workflows in an Identity System Application**

After a workflow definition has been created, an instance of the workflow is initiated in one of several ways, depending on the type of workflow that is being used:

<table>
<thead>
<tr>

<tr>
<td>Delete Group</td>
</tr>
<tr>
<td>Create Object</td>
</tr>
<tr>
<td>Delete Object</td>
</tr>
</tbody>
</table>
About Workflow Tickets

As program execution reaches a given step in a workflow, the workflow engine creates a ticket for that step instance. During a Create User workflow, for example, a ticket is typically sent to specific participants in IT as soon as the user selects the Create User function in the User Manager.

Each workflow ticket is initially displayed in the form of a link. When the participant clicks this link, he or she is prompted to perform the action associated with that step in the workflow. For example, when someone in IT processes a ticket for a Create User workflow, he or she is typically prompted to supply a login id and password for the new user.

A workflow log is created upon completion of each step in the workflow.

See "Using a Workflow" on page 5-46 for more information.

For example, the contents of a Create User Identity page may be based on attributes configured in a Create User workflow.

Once information about a new user is saved on this page, the initiate step of the workflow is complete. The workflow definition generates a ticket for this workflow instance, as illustrated in the following screen shot:

A participant in this workflow can view the ticket generated for this workflow step, and can approve the addition of the new user. You display ticket information by clicking on the ticket number next to the approval label.

A Workflow Scenario

Suppose you create a workflow for adding a user in the Identity System. You could define a Create User workflow that performs the following steps:

Process overview: Creating and using a Create User workflow

1. From the User Manager application, you create a new workflow definition.

   In this example, the workflow definition has three steps and specifies that anyone in IT who has logged in to the User Manager can create a new user workflow:

   Step 1. Initiate: This step allows anyone who has logged in to the User Manager to input data for a new user.
Step 2. Provide Information and Approval: This step allows the user’s manager to approve the data entered for the user.

Step 3. Activate: This step activates the new user.

2. A user logs in to the User Manager.
3. The user selects a Create User button.

   The workflow instance prompts the user to supply a name, user ID, and password for the new user, plus the user ID and email of the new user’s manager.
4. The workflow instance then routes a request to create the new user, along with information about the new user, to the manager of that user.
5. The manager clicks the Requests function in the User Manager application to display the request in the form of a link to a job ticket.
6. The manager clicks the link for the ticket to display the request.
7. To approve the request, the manager clicks a Process Request button.
8. In the Process Requests page, the manager clicks an Approve button.
9. The request is processed and the new user is enabled in the Identity System.

   The user is now allowed to log in and use the functions they are entitled to as defined by their directory profile and the rights assigned to attributes in that profile by a Master administrator. See “Allowing Users to View and Change LDAP Data” on page 4-21 for details.

LDAP Versus Template Attributes in a Workflow

When you define a workflow, you have a choice of using two types of objects and attributes in most workflow steps:

- **LDAP Objects and Attributes:** You can use a workflow to modify objects and attributes that you have configured for an application profile page. The people who participate in the workflow must have appropriate privileges for viewing and modifying these objects and attributes.

- **Template Attributes:** If you are using a workflow to provision a back-end application, you configure workflow steps for adding information based on a template schema. When template attribute values are committed during the workflow, an Identity Event API plug-in can intercept this data and send it to a back-end application for provisioning. See "Sending Non-LDAP Data to External Applications" on page 6-1 and the Oracle Access Manager Developer Guide for details.

As of version 7.0, provisioning allows only for a one-way flow of data from the Identity System to the back-end system. As a result, you might want to configure provisioning workflows to write data to both the LDAP directory and to the back-end system. This enables your users to view the data that has been configured for the workflow target. However, to see the current state of the target in the back-end application, you must access the application or its logs.

For provisioning workflows, you should have separate Commit, Activate, Enable, Delete, Disable, and Deactivate steps for each schema to which the workflow is written.
Workflow Types, Steps, and Actions

A workflow type determines the purpose of the workflow, for example, creating a user. A workflow step is a discreet segment of the workflow. Steps are performed in a series. A workflow action is an activity performed during a step, such as issuing a request for information.

For example, the Create User workflow type enables you to create a directory entry for a user. This type of workflow can have actions for requesting information about the user, actions for collecting the information, actions for approving the request, and so on.

The following table correlates the different types of workflows to the Identity System applications:

<table>
<thead>
<tr>
<th>Application</th>
<th>Workflow Type and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Manager</td>
<td>■ Create User: Adds a user to the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Self-Registration: Enables users to add themselves to the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Deactivate User: Makes a user unable to log in and unavailable for viewing in the Identity System. Deactivation takes effect once a user has logged out. It removes a user’s future access to the system. An administrator with sufficient access privileges can view deactivated users and either permanently delete them or reactivate them.</td>
</tr>
<tr>
<td></td>
<td>■ Reactivate User: Displays the Initiate User Reactivation button on the User Profile page and changes the status of a deactivated user, allowing the user to log in to and use the Identity System again.</td>
</tr>
<tr>
<td></td>
<td>■ Change Attribute: Changes an attribute value on a user profile. Attributes designated on this workflow will have a Request to Modify button on the target profile page.</td>
</tr>
<tr>
<td>Group Manager</td>
<td>■ Create Group: Adds a group to the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Delete Group: Deletes a group from the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Change Attribute: Changes an attribute value on a group profile. Attributes designated on this workflow will have a Request to Modify button on the target profile page.</td>
</tr>
<tr>
<td>Organization Manager</td>
<td>■ Create Object: Adds an object to the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Delete Object: Deletes an object from the directory.</td>
</tr>
<tr>
<td></td>
<td>■ Change Attribute: Changes an attribute value on an object profile. Attributes designated on this workflow will have a Request to Modify button on the target profile page.</td>
</tr>
<tr>
<td></td>
<td>■ Self-Registration: Enables users to add organization objects to the directory.</td>
</tr>
</tbody>
</table>

About Workflow Steps

You must define at least two steps for each workflow: one to initiate an instance of the workflow and one to finish it. A step consists of the following:

■ **A Number**: A unique identifier for this step.

■ **Actions**: An action is an activity can occur in the Identity System or in an outside system. Examples include starting the workflow, providing information, and requesting approval. See "About Step Actions" on page 5-9 for details.
About Workflows

- **Attributes**: An attribute value may be added or modified as part of a step.
  For example, you might define a step for changing the value of a user’s phone number attribute. Step attributes may be required, optional, or supplied by completion of another workflow step.
  For values that are used locally within the Identity System, you configure LDAP attributes as part of the workflow. For provisioning to a back-end application, you configure both LDAP and template attributes in a workflow step.

  **Note**: If Location ID has the Semantic type DN Prefix it is important to note Active Directory and ADAM do not allow multi-valued RDNs (although iPlanet/SunOne do). For Active Directory and ADAM, ensure that the Attribute Value(s) selection is Single in the meta-attribute configuration.

- **Participants**: A user or users who perform an action.
  For example, for a Create User workflow, you may create an Initiate step and configure this step so that anyone who is logged in to the User Manager can start the process for creating a new user. Or you may define a specific participant in a workflow who is responsible for approving a change request. Participants can be assigned based on their role, name, group membership, or another characteristic.
  For LDAP attributes, you can also define an LDAP filter that selects participants according to their DN.

- **Target**: The person, group, or other LDAP object that is being created, deleted, and so on.
  The target in the workflow definition is an LDAP object, not a template object.

- **Entry Conditions**: A step or subflow that must be completed before the present step.
  For example, the first step in a workflow may be the Initiate step. The second step in the workflow may have an entry condition of successful completion of the Initiate step. A typical entry condition is successful completion of the previous step.

- **Notifications**: Users who receive email notification before or after the execution of the step.
  Other participants can see pending tickets in their incoming request queues whether or not email notification is configured. See "Descriptions of Step Actions" on page 5-12 for details.

- **Pre and Post Processing**: External functions that are executed as part of the workflow.
  For example, in a create user workflow you might want to have a Java program that is called after an initiating step to assign a unique login ID.

A workflow process illustration is shown in Figure 5-2.
**Figure 5–2 Sample Workflow Process**

<table>

<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Participant: IT department manager</td>
<td></td>
</tr>
<tr>
<td>Action: Enable the new user in COREid</td>
<td></td>
</tr>
</tbody>
</table>

**About Step Actions**

You assign one action to each step in a workflow. Actions are performed by people or by an automated method.

For example, required actions in a workflow to create a user include:

- Initiating the request.
- Enabling or activating the user.

Available actions depend on the workflow type and the action defined in the previous step. For example, the Initiate action is available for only the first step of a workflow.

Table 5–3 lists the actions that you can associate with steps in User Manager workflows.

<table>
<thead>

### Descriptions of Step Actions

Table 5–6 describes the actions available in workflows.

### Table 5–6 Workflow Step Actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Activate</td>
<td>User Manager only. Activates a new user in the Identity System. An activated user is enabled, and can log in and perform operations granted by administrators. The obuseraccountcontrol attribute in the user’s entry controls activated/deactivated status. The Activate action requires a participant, such as a manager, to activate the user.</td>
</tr>
<tr>
<td>Approval</td>
<td>This action can be configured with required attributes. At run time, the values for the required attributes are presented to the participant for approval. No information can be changed by this action.</td>
</tr>
<tr>
<td>Change Information and Approval</td>
<td>Performs the same function as the Provide Info and Approval actions, but used only when deactivating users.</td>
</tr>
<tr>
<td>Change Information</td>
<td>Performs the same role as the Provide Info action, but is used only when deactivating users.</td>
</tr>
<tr>
<td>Commit</td>
<td>Writes the information collected in the previous steps to the directory. A commit operation writes information to the location of the e object in the directory. For example, during a Create operation, the Commit action adds a new entry to the directory. If the workflow contains additional Commit action, the information is written to the location in the directory that contains the newly created object. A Commit action can be used more than once in a workflow. No user action is required.</td>
</tr>
</tbody>
</table>

---

5-12  Oracle Access Manager Identity and Common Administration Guide
Deactivate User Manager only. Deactivation takes effect once the user’s current session has ended. A deactivated user cannot log in. Others cannot find a deactivated user in the Identity System except when searching for deactivated users. Deactivating does not delete the user from the directory. The obuseraccountcontrol attribute in user’s entry controls activated/deactivated status. A participant is required for a deactivate step in a workflow.

Note: To create an .ldif containing deleted users, use the Deactivate or Disable workflow steps instead of Delete. Go to the Deactivated User Identity page, and use the Archive option. This will delete the users from the directory and create a deactivateduser.ldif in the

IdentityServer_install_dir\oblx\data\common directory.

Delete The delete action in a Create User, Group, or Object workflow permanently removes the target entry from the directory. It is possible for a Create workflow to be rejected after a target entry is created. The Delete step cleans up the directory so that new attempts to create the same user can be made.

Disable User Manager only. Deactivates a user, which means the user cannot be recognized by the Identity System once the user’s current session has ended. Deactivation takes effect the next time the user attempts to log in. Deactivating does not delete the object from the directory. This action does not require a participant.

Enable User Manager only. An Enable action is a combination of a Commit and an Activate action. Automatically activates the new user, who is then recognized by the Identity System after the previous step is completed. This action does not require a person to activate the user.

Error Report When a background process encounters a processing error, you can configure an error report to send the error to particular users. You can also configure an error report when a step is rejected, for instance during the approval process.

External Action An action performed outside of Oracle Access Manager.

Initiate Starts the Create and Deactivate workflows. This action can be used once in a workflow. It must be the first action. The self-registration action can also be the initiating action of a workflow. All users see the Create Profile button or Initiate Deactivate option on their pages, regardless of whether they have been defined as a participant for this particular workflow. If a user clicks the button or link to the workflow but they have not been defined as a participant in the workflow, an error message will be displayed.

Provide Information and Approval Combines the Provide Info and Approval actions into one action.

Provide Information Collects information from the user. This action is similar to Initiate, but it cannot be the workflow’s first action.

Request A user’s request to change, add, or delete an attribute. Participants for this action see the Request to Modify or Request to Remove button on the Modify Profile page.

Self-Registration Lets users complete and submit a registration form. Other participants approve the request and activate the user. This action must be the first step in a workflow. The self-registration action does not necessarily require other participants to approve and activate the new user.

<table>
<thead>
<tr>
<th>Table 5–6 (Cont.) Workflow Step Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
</tr>
<tr>
<td>Deactivate</td>
</tr>
<tr>
<td>Delete</td>
</tr>
<tr>
<td>Disable</td>
</tr>
<tr>
<td>Enable</td>
</tr>
<tr>
<td>Error Report</td>
</tr>
<tr>
<td>External Action</td>
</tr>
<tr>
<td>Initiate</td>
</tr>
<tr>
<td>Provide Information and Approval</td>
</tr>
<tr>
<td>Provide Information</td>
</tr>
<tr>
<td>Request</td>
</tr>
<tr>
<td>Self-Registration</td>
</tr>
</tbody>
</table>
For self registration, these values are provided through globalparams.xml because the target is not yet created. In this case, you need to locate the parameters in the globalparams.xml, then modify the values to suit your environment. For example:

```xml
<SimpleList>
  <NameValPair
    ParamName="sendMailFromName"
    Value="SelfRegistration">)
</SimpleList>

<SimpleList>
  <NameValPair
    ParamName="sendMailFromEmail"
    Value="SelfRegistration@Oracle.com">)
</SimpleList>
```

If the target user has been created the values for `sendMailFromName` and `sendMailFromEmail` are obtained from the naming attribute and email attribute of logged in user's profile, respectively.

---

**About Workflows**

**Table 5-6 (Cont.) Workflow Step Actions**

<table>
<thead>
<tr>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select Groups</td>
<td>Enables the workflow participant to subscribe a target user to a group or groups during a create user workflow. The new user has to meet the subscription policy. Available only after an Enable or Activate step.</td>
</tr>
<tr>
<td>Subflow Approval</td>
<td>Reports the current status of a subflow that has been invoked from a main workflow step. It does not apply to subflows invoked from other subflows.</td>
</tr>
</tbody>
</table>

---

**Note:** Email post-notification for a self-registration step requires two parameters in the globalparams.xml, `sendMailFromName` and `sendMailFromEmail`. The values for these parameters are placed in the "mail From" or "sender's name" and "mail" or "sender's email" parts of the SMTP message respectively.

---

**Note:** A subflow is always a Change Attribute workflow.

**Process overview: A Create User workflow example**

1. The hiring manager initiates a Create User workflow.
2. A request is sent to Facilities for an employee number and badge number.
3. A request is sent to IT for the login and password.
4. A request is sent to the hiring manager for final approval and activation of the user.

By using subflows, some of the requests can occur in parallel. The approval waits until the subflows are complete, as illustrated in Figure 5–3.

**Figure 5–3  Order of step completion when using subflows**

A workflow does not move to the next step until a subflow is complete.

**Note:** For a subflow to launch, the target object or attribute must meet any filter criteria specified in the Workflow Domain filter.

---

**Using the QuickStart Tool**

For Master Administrators, the QuickStart tool enables the rapid creation of simple workflows based on default settings.

After completing a workflow definition using QuickStart, you can use workflow tools to modify the workflow definition, for example, you can specify dynamic participants or surrogates.

The QuickStart tool enables you to define the following workflows:

**Table 5–7  Workflows that Can Be Created with the QuickStart Tool**

<table>
<thead>
<tr>
<th>The workflow named . . .</th>
<th>Contains these steps . . .</th>
</tr>
</thead>
</table>
| Create User, Group or Object (Basic) | Self-Registration or Initiate  
| | Commit  
| | Error Report  
| | Note: For a simple Create User workflow, required attributes are Last Name and Name on most directory servers and Login ID if you use Active Directory.  
| Create User, Group or Object (Advanced: with Approval) | Initiate  
| | Approval  
| | Commit  
| | Error Report  

---
The QuickStart tool assigns anyone who is logged in to the Identity System as the participant for most steps. For the User Manager, the participant in a Change Attribute workflow is any person who has been assigned the role of Manager. For the Group Manager, any person assigned the role of Group Owner is the participant in the Approval step of a Change Attribute workflow.

Once you create a workflow using the QuickStart tool, you can view and modify the workflow steps, participants, affected attributes, and so on. Information on viewing a workflow definition is provided in "Viewing and Exporting a Workflow Summary" on page 5-51. Information on modifying a workflow is provided in "Modifying a Workflow" on page 5-53.

**Note:** Your ability to define a workflow depends on your administrative privileges.

### To define a workflow using the QuickStart tool

1. From the Identity System Console, select the User, Group, or Organization Manager.

2. Click Configuration, then click Workflow Definition.

   By default, only Master Administrators, Master Identity Administrators, and Delegated Identity Administrators have permission to view configuration information.

3. Click the link labeled "Click here".

### Table 5–7  (Cont.) Workflows that Can Be Created with the QuickStart Tool

<td>Change Attribute (Advanced: with Approval)</td>
<td>Request Approval Commit Error Report</td>
</tr>
</tbody>
</table>

The QuickStart tool assigns anyone who is logged in to the Identity System as the participant for most steps. For the User Manager, the participant in a Change Attribute workflow is any person who has been assigned the role of Manager. For the Group Manager, any person assigned the role of Group Owner is the participant in the Approval step of a Change Attribute workflow.

Once you create a workflow using the QuickStart tool, you can view and modify the workflow steps, participants, affected attributes, and so on. Information on viewing a workflow definition is provided in "Viewing and Exporting a Workflow Summary" on page 5-51. Information on modifying a workflow is provided in "Modifying a Workflow" on page 5-53.

**Note:** Your ability to define a workflow depends on your administrative privileges.
Using the QuickStart Tool

Chaining Identity Functions Into Workflows

This launches the QuickStart tool.

4. Select the type of workflow you want to create.

Note: You can define a Create workflow and a Change Attribute workflow from the same QuickStart page. Scroll to the bottom of the page to see the Change Attribute fields and options.

You can also provide a name for your workflow. A default name is provided, but it does not change if you use the QuickStart tool to create multiple workflows of this type.

5. If you select a Create workflow type, you can also specify one target location for the object the workflow creates.

The default target location is the searchbase for the Identity System.

6. Optionally, you can select additional attributes.

For a Create User, Create Group, or Create Object workflow, these attributes are entered during initiation or self registration steps.

For a Change Attribute workflow, these attributes are modified when running the workflow. A separate workflow is created for each attribute you select. For example, if you select five attributes, the QuickStart tool generates five change attribute workflows.

7. Click Generate.

8. View the summary report generated by the QuickStart tool.

Workflow Definition - QuickStart (2 of 2)

Summary report

The following workflows have been generated:

<table>
<thead>
<tr>
<th>Workflow name</th>
<th>Warning (if any)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create user - Basic</td>
<td></td>
</tr>
</tbody>
</table>

9. To test the workflow, click a link to one of the workflows on the summary report.
This initiates a workflow instance. For information on the process for using a workflow, see "How Users Access Workflows in an Identity System Application" on page 5-4.

**Note:** To use a workflow as a portal insert, copy the resulting URL from your browser. See the Oracle Access Manager Customization Guide for more information on creating portal inserts.

10. Click Done.

**Creating a Self-Registration Workflow Using the Quickstart Tool**

If you want to provide a user registration page for your Web portal, you can define a self-registration workflow and capture the resulting URL of the workflow. This URL can be used as a portal insert.

**To define a self-registration workflow using the Quickstart tool**

1. Create a self-registration workflow as described in "To define a workflow using the QuickStart tool" on page 5-16.
2. After clicking the Generate button, click the link for the newly-created workflow.
3. When the new workflow appears, copy the URL.
   
   You can use this URL when you set up the user registration page for your Web portal. This URL is the link to the first page of the workflow. See "Creating a Self-Registration Workflow" on page 5-60 for other methods of defining self-registration workflows.

**Using the Workflow Applet**

In addition to using the QuickStart tool, you can define workflows using configuration pages that allow you to specify multiple options and subflows.

You must have permissions to define workflows. See "About Delegating Administration" on page 2-5 for more information.

Typically, workflows contain at least two steps: one step to initiate the workflow and another step to commit the changes.

**Task overview: Defining a workflow using the workflow applet**

1. Invoke the Workflow Definition applet.
   
   See "To access the Workflow Definition applet" on page 5-19 for details.
2. Select New to start creating a new workflow definition.
   
   "Starting a New Workflow Definition" on page 5-19.
3. If you selected a Create workflow type, identify a workflow target.
   
   The target is the location in the directory tree where the object will be created. See "Defining an LDAP Target for Create Object Workflows" on page 5-21 for details.
4. Define a workflow step and action.
   
   For each step in a workflow, there is an action. Actions are performed by people or by an automated method. You assign one action to each step in a workflow. You
also assign participants to each step. See "Defining the First Step in a Workflow" on page 5-23 for details.

5. Associate attributes with the step.

Step actions are performed on one or more attribute values. These attributes may be taken from the directory or from an object template. See "Defining Step Attributes" on page 5-25 for details.

6. Define entry conditions for subsequent steps.

See "Defining Subsequent Steps" on page 5-27 for details.

7. Define the subsequent steps.

8. Define one or more subflows.

Subflows are conditions that must be satisfied for a particular step or workflow to complete. Like main workflow steps, subflows have associated actions, participants, and attributes. See "Defining a Subflow" on page 5-30 for details.

9. Define one or more commit steps to end the workflow.

If you are configuring a workflow using more than one schema (for example, an LDAP schema and a template schema), you should configure separate commit steps for each schema type.

---

**Note:** As of the 7.0 version of the Identity System, template attribute values can be sent to the back-end system, but these values cannot be read back in to the Identity System for display on profile pages. As a result, to check if a workflow configuration was done correctly and an instance of using the workflow was successful, you may have to examine the data in the back-end system.

---

**To access the Workflow Definition applet**

1. From the Identity System Console, select the User, Group, or Organization Manager.

   If the Organization Manager has more than one tab, select the appropriate tab.

2. Click Configuration, then click Workflow Definition.

   On some browsers, you may receive a prompt asking if you trust the certificate of the application. If you receive this prompt, select the Trust Always option.

   For the User Manager and Organization Manager, a Workflow Definition page is displayed.

3. If you are using the Group Manager, indicate the appropriate Group Type, if applicable. The available group types depend on your configuration, as described in "Adding Auxiliary and Template Object Classes to a Group Tab" on page 4-8.

4. If you are using the Group Manager, from the Workflow Definition page, select an appropriate group type if applicable and click Next.

   If you do not select a group type, the Basic group type is used for this workflow.

---

**Starting a New Workflow Definition**

You can create workflow definitions for different sets of users. For example, you can define different Create User workflows for Engineering and Sales.
To begin a new workflow definition

1. Invoke the workflow definition tool as described in "Using the Workflow Applet" on page 5-18.
2. Click New and wait for all buttons except the New button to become deactivated.
3. In the Workflow Name field, enter a name for your workflow.
4. From the Workflow Type list, select the type of workflow you want to create.
   For more information on workflow types, see "Workflow Types, Steps, and Actions" on page 5-7.
   If you are creating a subflow, see "Defining a Subflow" on page 5-30.
5. In the Workflow Description field, you can enter an optional description of this workflow.
6. In the Workflow Domain field, select the starting point in the directory tree from which this workflow is available.
   If you want the workflow domain to match a directory entry of the logged in user who initiates the workflow, use substitution syntax. For example, if you want the "ou" of the workflow domain to always match the "ou" of the person who is generating the workflow, you would enter the following:
   (ou=$ou$)
   See "Substitution Syntax: Returning Targets that Match the DN of the Logged In User" on page 3-25 for examples.
7. If you are in User or Organization Manager, click Next.
   Depending on your workflow type, you are prompted to select a target as described in "Defining an LDAP Target for Create Object Workflows" on page 5-21,
8. If you are in the Group Manager and you are working with an Advanced Group, specify the Subscription Type, if applicable.

For example, this might be the case when you define a step for selecting a group or for allowing a user to add themselves to a group. Subscription Type options are available to your participants if the obGroupSubscriptionType attribute was configured for the oblixAdvanced Group object class.

The following subscription types are available:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>No type selected</td>
<td>No subscription type is defined. Functionally equivalent to the Open policy.</td>
</tr>
<tr>
<td>Open</td>
<td>Enrollment is open to anyone who subscribes.</td>
</tr>
<tr>
<td>Open with Filter</td>
<td>Enrollment is open to any user who satisfies the Dynamic Filter (LDAP rule) for the group.</td>
</tr>
<tr>
<td>Controlled throughWorkflow</td>
<td>To subscribe or unsubscribe, the user must be the target of a select group step of a workflow.</td>
</tr>
<tr>
<td>Closed</td>
<td>Member list is closed. No changes are allowed. The default setting for the default_subscription policy parameter is SubscriptionPolicyClosed. This is located in IdentityServer_install_dir/identity/oblix/data/common/groupdbparams.xml where IdentityServer_install_dir is the directory where you installed the Identity System.</td>
</tr>
</tbody>
</table>

9. Click Add, then click Next.

Depending on your workflow type, you are either prompted to select a target as described in "Defining an LDAP Target for Create Object Workflows" on page 5-21, or you are prompted to define the first step as described in "Defining the First Step in a Workflow" on page 5-23.

**Defining an LDAP Target for Create Object Workflows**

If you selected Create as the type of workflow you are defining, for example, Create User, you need to define one or more targets. The target is the location in the directory tree where the object will be created. For example, a target of ou=bestmotors,o=company,c=us allows objects to be created under the ou=bestmotors container. When a user is created using a workflow with this target, the directory entry may look like cn=John Smith,ou=bestmotors,o=company,c=us.

You can also use substitution syntax when defining the workflow target. This would ensure, for example, that in a Create User workflow the "ou" entry of the new user would always match the "ou" entry of the logged in user who initiates the workflow. See "Substitution Syntax: Returning Targets that Match the DN of the Logged In User" on page 3-25 for examples. Note that when using substitution syntax, you may need to modify the ResourceFilterSearchScope parameter value in globalparams.xml. See the Oracle Access Manager Customization Guide for details.

If the logged in user has an "ou" entry with multiple values, and you want to provide the ability to create the new user under any of these "ou's," you need to modify the
ResourceFilterSearchScope parameter value to 2 in globalparams.xml. See the *Oracle Access Manager Customization Guide* for details. In this case, a list of all the possible targets is shown when the workflow is run. The user can then select the precise "ou" under which the new target user is to be created. The targets in the list are obtained from the multiple values of the "ou" attribute of the logged in user. You can restrict this list can be by having other filter components along with (ou=$ou$), such as (objectclass=organizationalUnit).

If you define more than one target, the participant is presented with a selection list when the workflow is run. Workflow targets are always based on the LDAP directory tree. Targets cannot be based on a template schema.

If you are defining another type of workflow, clicking Next on the initial workflow definition page brings you to the step definition page described in "Defining the First Step in a Workflow" on page 5-23.

---

**Note:** The default only displays immediate child nodes of the searchbase. See "Modifying the Default Searchbase Scope" on page 4-47 for details.

---

**To define a workflow target**

1. If you have not already done so, start a new workflow as described in "To begin a new workflow definition" on page 5-20.

2. From the first Workflow Definition page, click Next.

   The targets page appears, displaying fields for selecting characteristics of the target.

3. To define a new target, enter a name in the Target Name field.

   For example, if you are creating a target for a dealership, the target name may be Dealer Name.

4. In the Target Domain field, select the location in the directory tree where the object will be created and click Add to add the target domain to the Target(s) field.

   When you defined the workflow domain, you selected a branch of the directory tree that the workflow applies to. The target domain is a subset of the main workflow domain. You can use a filter to more closely specify the location for the target (any user object in the tree under the node you select).

---

**Note:** Do not use full LDAP URL while specifying the target domain (or workflow domain) while creating the workflow. Only the LDAP filter is expected. For example, cn=Shutterbug Canavan is expected rather than

See "Usage of Rules and Filters" on page 3-23 for more information.

---

**Note:** If you added a filter for the workflow domain, you cannot specify a filter for the target.

---

5. Click Add.
6. To apply the workflow to additional targets:
   - Click New.
   - Supply another name and domain.
   - Click Add.

7. When you are done supplying target domains, click Next.

**Defining the First Step in a Workflow**

After naming the workflow and defining a target, if required, you are prompted to create the first workflow step. You will see a page similar to the following.

**Workflow Definition**

Workflow Definition allows an administrator to define different workflows for different organizations. Different workflows pertain to different steps, attributes, and participants. To create a workflow using QuickStart, click here.

**To define the first step in a workflow**

1. If you have not already done so, start a new workflow as described in "To begin a new workflow definition" on page 5-20.

2. If you have not already done so, for a Create workflow type, define a target as described in "To define a workflow target" on page 5-22.

3. From the Select action to be performed list, select an action.
   
   For a Create Object workflow for the User or Organization Manager, the Initiate and Self Registration actions are available.
   
   For a Create Object workflow for the Group Manager, the Initiate action is available.

4. Click Participants.

   Most steps require participants to perform an action. The exception to this are steps with actions that occur automatically such as Commit and Enable, as well as External Action and the Self Registration action.

5. Use any of the following methods to specify participants.
   
   - **Roles**: Note that the role of Anyone refers to any user who is logged in to the Identity System.

     Roles are defined in the workflow parameter files gsc_wf_param.xml, usc_wf_param.xml, and osc_wf_param.xml. See "Customization of Data and Actions in a Workflow" on page 5-58 for details.
Participant roles (roles for people who can process a step) will only work after a commit, enable, or activate step has been completed. The commit, enable, or activate step creates the object’s DN from which notification information can be determined.

- **Select Person**: See “Search Functionality” on page 1-9 for details on using the Selector, and see “Search Filters for the Object Selector Display Type” on page 3-22 for information on how the Selector can be configured.
- **Select Group**: See “Search Functionality” on page 1-9 for details on using the Selector, and see “Search Filters for the Object Selector Display Type” on page 3-22 for information on how the Selector can be configured.
- **Build Filter**: See “Writing LDAP Filters Using Query Builder” on page 4-27 for information on creating an LDAP filter.

**Note**: If you chose Select Participants to Prenotify in the Select Participants field, do not choose Next Step Participants as the role. Also note that in the commit step for a Group Manager workflow, you should not check owner or member for post notification. There will be no email notifications for owner or member even if they are selected.

6. Click Save Step or Save Workflow, or select step attributes as described in the following paragraphs.
Defining Step Attributes

Step actions are performed on one or more attribute values. When you configure a step action, you indicate if certain attribute values are required, and other configuration options. For example, on a Provide Information action, you can specify the mail attribute to ensure that the step participant is prompted to supply an email address.

Defining step attributes consists of the following:

- Selecting the attributes that should be available in this step of the workflow.
- Configuring attribute properties.

For attributes based on an object template (.tpl file), when you configure the attribute in the Identity System Console, it may be helpful to indicate the type of schema that the attribute belongs to. For example, for a workflow that sends information to an application that can set up email accounts for new users, you may want to preface the attribute label with the application name. This will be helpful when users view this attribute. Since the flow of data is one-way for provisioned attributes, the attribute values will not be displayed on the Identity System profile page once the user submits the value. If your users have a question about this, the attribute label will help you determine if this is the expected behavior. See “Configuring Attributes” on page 3-17 for details.

To select attributes available for a step

1. If you have not already done so, start a new workflow as described in "To begin a new workflow definition" on page 5-20.

2. If you have not already done so, for a Create workflow type, define a target as described in "To define a workflow target" on page 5-22.

3. Begin defining a workflow step as described in "To define the first step in a workflow" on page 5-23.

4. After selecting participants for the workflow step, click Attributes.

5. From the Available Attributes panel, select one or more attributes to associate with the workflow step.

   For a Change Attribute workflow, be sure that the topmost selected attribute has already been added to a panel on a profile page. This ensures that a "Request to Modify" button will appear on the appropriate profile page, enabling users to run instances of this workflow.

   For information on making multiple selections, see "Keys for Selecting Multiple Attributes" on page 4-33.

6. Click the right arrow button (>>) to add the selected attributes to the Selected Attributes window.

   By default for a Create Object workflow, the attribute that defines the Relative Distinguished Name (RDN) appears in the Selected Attributes window.

   By default for a Change Attribute workflow, the attribute you selected as the basis for the workflow appears in the Selected Attributes window.
7. Save the step or configure attribute properties, if applicable, as described in the following paragraphs.

**Note:** You cannot save a workflow until all required attributes (as defined in the object class schema) are configured for the workflow.

**To configure attribute properties**

1. From the Selected Attributes window, select one or more attributes that you want to configure.

   For information on making multiple selections, see "Keys for Selecting Multiple Attributes" on page 4-33.

2. Click Properties.

   An Attribute Properties dialog appears:

   ![Attribute Properties Dialog]

3. Select one or more properties for these attributes:
   - Required: The workflow participant must provide a value for this attribute.
Using the Workflow Applet

Chaining Identity Functions Into Workflows

4. Click OK.
5. Click Save Step or Save Workflow.
You can now define Mail Notification participants, or you can define additional steps for this workflow.

Note: When you define Mail Notification participants, if you chose Select Participants to Prenotify in the Select Participants field, do not choose Next Step Participants as the role. Also note that in the Commit step for a Group Manager workflow, you should not check Owner or Member for post notification. There are no email notifications for owner or member even if they are selected.

A commit, enable, or activate step must be completed for a role selected for pre or post notification to work. Before the commit, enable, or activate step is completed, the object exists only in the workflow instance information in the directory tree. The commit, enable, or activate step creates the object's DN from which notification information can be determined.

Note: For information on customizing email notifications, see the Oracle Access Manager Customization Guide

Defining Subsequent Steps
A workflow consists of at least an initiating step and a completion step, and may have more steps and subflows. As part of the procedure for creating a second (or third, or more) step in a workflow, you define entry conditions for the step. Entry conditions consist of:

- Identifying what step precedes this one.
- Identifying the required outcome for the previous step.

To define subsequent steps in a workflow
1. After completing the first step in a workflow, as described in "To define the first step in a workflow" on page 5-23, click New in the Defined Steps area.
   New fields appear on this page appropriate for configuring subsequent steps in a workflow.
2. From the Previous Step list, select the step that should precede this action.
3. From the Return Value list, indicate whether the previous step should return a value of true or false in order for this action to execute.

You will want the previous step to return a value of True if it completes successfully. Select False to generate an error report when a previous step returns a value of false. Situations that return a value of false include:

- A participant rejects a workflow ticket
- The commit step fails
- The Identity Event Plug-in API or IdentityXML forces a return value of false.

4. In the Action list, select the action. You may choose enable, activate, and other actions.

The available actions depend on the action in the previous step. Examples:

- Provide Information cannot precede Initiate.
- An error report action usually provides a reason for a step failure. For example, rejection of an attribute value or denying a user activation request.
- Usually a condition of false is the entry condition for an error report step. For example, if a participant in the step prior to the error report step rejects an activation operation, the workflow may proceed to an error report step.

5. Select Wait for Subflows to delay execution of this action until all subflows from preceding steps are complete regardless of their return value.

Selecting this check box appends the return value entry condition with :true. If you do not select the checkbox, the return value entry condition is appended with :false. See "Defining a Subflow" on page 5-30 for details.

6. As needed, add participants and configure attributes as described in "Defining the First Step in a Workflow" on page 5-23.

7. Save the step or the workflow.

Note: Create user workflows must end with the Enable step or you will not be able to find users that are added with this workflow.

### Committing Workflow Steps

The last step of a workflow commits the data to a particular schema domain. By default, the schema domain is the LDAP directory that the Identity System communicates with. However, if you have configured template attributes in a workflow, you must configure a separate step to commit the data to the schema domain for the template attributes.

Commit steps for attributes in template schema domains can be processed by the Identity Event API and passed to back-end systems for provisioning.
Enabling a Workflow

After you create a workflow, by default it is disabled. When you are ready to allow other participants in the Identity System or external applications, you enable it.

To enable a workflow
1. Access the User, Group, or Organization Manager.
2. Click Configuration, then click Workflow Definition.
3. From the workflows menu, select the workflow.
4. Click Enable.

Note: if you receive a message that attributes are missing, examine the workflow steps. You must configure participants and attributes at each step.

Testing a Workflow

You must enable the workflow before you can test it. See "Enabling a Workflow" on page 5-29 for details. You must also be a workflow participant to be able to test it.

To test a workflow
1. From the Identity System Console, select the application in which this workflow can be run.
   For example, for a Create User workflow, you would open the User Manager.
2. Initiate the workflow.
   For example, if you defined a Create User workflow, the workflow that you want to test should appear in a list on the Create User page. To initiate the workflow, you select from the list.
   For Change User workflow, you would select the Request to Modify function in the User Manager, and so on.
3. Perform the functions indicated in the workflow steps.
   The workflow should behave as expected. For example, after completing the Create User workflow, you should be able to find the user that was added during the Create User operation.

To run a workflow in the Group Manager
1. From the Identity System Console, select Group Manager.
2. Select the group type panel corresponding to the group type in the workflow definition.
   For example, you may have different group type panels for the structural group object class and the oblixAdvancedGroup object class. See "Adding Auxiliary and Template Object Classes to a User or Org. Manager Tab" on page 4-7 for details.

Example of Defining a Workflow

The following is an example of defining a Create User workflow. In this example, you define a workflow that allows anyone who is logged in to the Identity System to create a user. This workflow generates a ticket requesting a name and email address to be provided for this user. When processed, the new user is enabled in the Identity System.
To create this workflow
1. From the User Manager, Click Configuration, then click Workflow Definition to go to the Workflow Definition page.
2. Click New.
3. Name this workflow Test New User Creation Workflow.
4. In the Workflow Type field, select Create User.
5. On the Target DN page, enter a name in the Target Name field and accept the default domain by clicking Add.
6. Click Next to proceed from the Target Domain page to the Workflow Definition Page.
7. Create an Initiate step for the workflow.
   Click the Participants tab and define the participants to be the role of Anyone.
   Click the Attributes tab and select the attributes that you want workflow participants to provide, for example, First Name and Last Name.
8. Click New to create a new step with the Enable action type.
   Click Add to add the Initiate step as an entry condition for the Enable step.
   Click Participants and select Anyone as a participant.
   Click Attributes and add an attribute that is presented during this step.
9. Save and enable the workflow.
10. Test the workflow by trying to create a new user in the User Manager.

Defining a Subflow

Only the Change Attribute workflow type can be a subflow. These workflows must also be explicitly configured as subflows in the workflow definition page. All subflows must also contain an approval step action.

Note: You must select Use as Subflow on the first page of the workflow definition for a workflow to be usable as a subflow.

To create a subflow
1. From the Identity System Console, click the User Manager, Group Manager, or Org. Manager application tab.
2. Click Configuration.
3. Click Workflow Definition.
4. Click New.
5. In the Workflow Name field, enter a name for your workflow.
6. Click the Use as Subflow checkbox.
7. From the Workflow Type list, select Change Attribute.
8. Click Next.
9. In the first step of the workflow, specify the attribute that the workflow is to change.
10. Complete the rest of the workflow as you would any other workflow.

**Note:** All subflow definitions must contain an approval step action.

### Associating a Subflow with a Workflow

You must associate a subflow with a specific workflow step in the main workflow. During workflow runtime, any subflows configured for a specific step will be invoked after the step action has executed.

**To associate a subflow with a workflow**

1. Invoke the workflow application, as described in “To access the Workflow Definition applet” on page 5-19.
2. Select a workflow to which you want to assign a subflow.
3. Click **Modify**.
   - The page refreshes and shows the step definitions page.
4. Click the **Subflows tab**.
5. In the Defined Steps area of the page, select the place in the workflow sequence where you want to insert a subflow.
6. In the Select Subflows area of the Subflows tab, select the subflow that you want to be a part of this workflow.
   - Select the subflow(s) you want to assign to this step and click the right arrow button (>>).

   **Note:** If you do not see your subflow here, verify that it is marked as a subflow, and it is enabled. The attribute that is the target of the subflow cannot also be used in the workflow to which the subflow is assigned.

7. Save the step.
8. On the subsequent step(s), you may optionally indicate whether or not you want to wait for subflows to complete.
   - a. Select the step that should be delayed until the subflow is complete and click **Modify**.
   - b. Click the **Wait for Subflows checkbox**.

### Approving Subflow Steps

The Subflow Approval step reports on the current status of subflows triggered from the main flow. By default, the status is set to Approved or Rejected during either an Approval step or a Provide Approval step. This step also allows for the configuration of attributes.

**Note:** You can set the subflow status programmatically using Identity Event Plug-in API or IdentityXML. See the *Oracle Access Manager Customization Guide* for information on the Identity Event Plug-in API.
Advanced Workflow Ticket Routing

Ordinarily, the static participants you specify when you create a workflow step are the users responsible for completing that step. To avoid processing bottlenecks or to ensure that each ticket reaches the participant most appropriate to process it, the following three advanced ticket routing features enable the replacement of static participants under specific circumstances:

- Instead of specifying static participants when you create a workflow, you can have a workflow plug-in or application choose dynamic participants according to runtime conditions.
- If a static or dynamic participant is going to be out of the office or otherwise unable to process workflow tickets, he or she can set an Out of Office flag in his or her user profile so that all incoming tickets are redirected to a surrogate participant for as long as the flag remains activated.
- If the participants receiving a given workflow ticket fail to process it within a specified interval, that ticket can be sent to an escalation participant, who assumes full responsibility for the ticket.

Configuring Workflow Actions for Advanced Ticket Routing

Not all workflow steps can be configured for advanced ticket routing. For instance, the first step in a workflow can never be rerouted. Fortunately, it is never necessary to reroute the first step, because the person who initiates the workflow is also the participant for the first step, which is always workflow initiation.

Steps that do not involve user action cannot be rerouted since, by definition, they do not involve user participants. For instance, a step involving the automatic retrieval of provisioning data from an external database involves no human participants, and therefore, participant replacement is moot.

The following table lists the user actions that can be associated with workflow steps:

<table>
<thead>
<tr>
<th>User Action</th>
<th>Availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>Approval</td>
<td>Available by default for dynamic participants, surrogates, and time-based escalation</td>
</tr>
<tr>
<td>Provide information with approval</td>
<td></td>
</tr>
<tr>
<td>Initiate</td>
<td></td>
</tr>
<tr>
<td>Self registration</td>
<td></td>
</tr>
<tr>
<td>Provide information</td>
<td></td>
</tr>
<tr>
<td>Subflow approval</td>
<td>Available by default for dynamic participants and surrogates; can be enabled for time-based escalation by modifying the appropriate workflow parameter file. For details, see &quot;To modify the workflow parameter files&quot; on page 5-44.</td>
</tr>
<tr>
<td>Activate</td>
<td></td>
</tr>
<tr>
<td>Deactivate</td>
<td></td>
</tr>
<tr>
<td>Error report</td>
<td></td>
</tr>
<tr>
<td>Select groups</td>
<td></td>
</tr>
<tr>
<td>Requests</td>
<td></td>
</tr>
<tr>
<td>Change information</td>
<td></td>
</tr>
<tr>
<td>Change information with approval</td>
<td></td>
</tr>
</tbody>
</table>
About Notifying Newly Assigned Step Participants

The Mail Notification tab in the workflow applet enables you to configure email notification for participants who are assigned tasks to complete when workflow tickets are rerouted. You can configure mail notification for each step to which ticket rerouting can apply.

To configure mail notification for any step involving advanced ticket rerouting, complete the following procedure:

To configure email notification for advanced workflow ticket rerouting
1. As appropriate for the workflow you are modifying, navigate to the User, Group, or Organization Manager, point to Configuration, then click Workflow Definitions.
2. Select the Workflow you wish to modify, then click Modify.
3. If you are modifying a Change Attribute workflow, click Next once. For any other type of workflow, click Next twice.
4. Select the step for which you wish to set mail notification, then click Modify.
5. Click the Mail Notification tab.
6. To enable notification for static, dynamic, and surrogate participants, click Select Participants to Prenotify or Select Participants to Postnotify.
   You cannot select Participants to Prenotify for the first step of a workflow.
7. Specify by Person, Group, Role, or Rule, the users to notify.
   You can use the Selector or the Filter Builder as the mechanism for specifying who should be notified.
8. If you also need to notify escalation participants, click Select Escalation Notifiees, then repeat step 7.
9. Click Save Step to commit your step-specific changes.
10. Click Save Workflow to save the entire workflow.

Specifying Dynamic Participants

The dynamic participants feature is one of the advanced workflow options that enable the automatic routing of workflow tickets to alternate participants, as determined by circumstances at runtime.

About Workflow Participants

the Identity System supports the following two types of workflow participants:

- **Static participants** are specified through the workflow applet, usually when you define a workflow step. For example, when you create a workflow to set up network accounts for new employees, you can include an approval step that routes all incoming tickets to the network security manager. Unless you later add a workflow plug-in or application, this pre-designated static participant serves as the primary recipient for all tickets generated by this workflow step.

- **Dynamic participants** must be specified in a workflow plug-in or application, rather than through the workflow applet. These conditional participants are selected based on runtime attribute values or external business logic. For example, your plug-in can specify that all purchase requests greater than $2,500 go to the accounting manager, all requests smaller than $50 go to the petty cash clerk, and all other requests go to any available staff accountant.
About Workflow Ticket Routing

As the following graphic illustrates, when a workflow is run and program execution reaches a step that has been enabled for dynamic participants, a workflow plug-in or application selects a set of dynamic participants and sends them a workflow ticket. In cases where the plug-in or application does not select any dynamic participants, the calling application sends the ticket to the original static participants, just as if the workflow plug-in or application had never intervened.

About Dynamic Participants

You designate dynamic participants using the same criteria you use to specify static participants. This includes specification by person, by group, by role, and by rule. For details, see the procedure step "Use any of the following methods to specify participants." on page 5-23.

You can define dynamic participants for every step in a workflow, except for the first step, which must be initiated by a static participant.

When step instances are assigned at runtime, dynamic participants inherit the same ticket-processing rights that static participants would normally receive. These rights extend only to tickets specifically assigned to the dynamic participant. In other words, the dynamic participant does not receive all the rights assigned to the original participant, as would be the case if the Substitute Rights feature were used to create a delegate. See "Adding Substitute Administrators" on page 2-10.

Since the identity of the dynamic participants is not known until the associated workflow step is run, they are not available for certain workflow services, such as post-action email generated by the previous workflow step. However, it is possible to notify dynamic participants through pre-action email generated by the workflow step that selects them. See the procedure "To prepare a workflow step for dynamic participants" on page 5-36.

About Static Participants

Under normal circumstances, workflow steps use static participants, whom you designate through the workflow applet.
In cases where the oblixpppcatalog catalog file specifies a plug-in or application for a given step, the plug-in or application receives the first opportunity to select dynamic participants according to the run-time values it evaluates. Only if the plug-in or application declines to specify a set of dynamic participants does control pass back to the main application, where the static participants are specified as the primary step participants.

**About the Static Participants Not Available Button**

If you know in advance that a workflow plug-in or application will always select dynamic participants for a given step, you don’t have to define static participants for that step. Remain aware, however, that if you do elect not to specify static participants, you must toggle the default Static Participants Available button to Static Participants Not Available. As the following graphic illustrates, these radio buttons appear on the Participants tab of the workflow applet, which is accessible through the User, Group or Organization Manager, as appropriate to the workflow you are configuring.

---

**Enabling Dynamic Participants**

The dynamic participants feature is not enabled by default. To activate this feature, you must complete the procedures listed in the following task overview:

**Task overview: Assigning dynamic participants to a workflow step**

1. Use either the QuickStart tool or the workflow applet to create a workflow containing the steps that will utilize dynamic participants.

   See "Using the QuickStart Tool" on page 5-15 and "Using the Workflow Applet" on page 5-18 for details.

2. If any possibility exists that a given step will use static participants, you must define static participants for that step as described in "Use any of the following methods to specify participants." on page 5-23.

   On the other hand, if you know in advance that a given step will always use dynamic participants, you don’t need to define static participants for that step. See "About the Static Participants Not Available Button" on page 5-35 for details.

3. If you wish, set up email notification for dynamic participants.

   See "To prepare a workflow step for dynamic participants" on page 5-36 for details.
4. Add a pointer to the oblixpppcatalog catalog file so that the proper plug-in or application is called at runtime to select dynamic participants. See "To modify oblixpppcatalog.lst" on page 5-37 for details.

5. Create a pre-action plug-in or application to select dynamic participants at runtime.

A typical plug-in or application might contain code sections to perform the following:

- Specify at least three sets of dynamic participants, the last of which always contains NULL values only
- Specify attributes or business logic to be evaluated at run time
- Select dynamic participants based on the evaluation
- Ensure that the selected participants actually exist in the Identity System directory; otherwise, the dynamic participant selection process will fail, but the workflow engine will not return an error message
- Pass the list of dynamic participants back to the calling the Identity System application

See "Task overview: Creating a plug-in or application to select dynamic participants" on page 5-38 for details.

---

**WARNING:** Plug-ins and applications that enable dynamic participants must be of type "pre-action." They can never be of type "post-action."

---

**To prepare a workflow step for dynamic participants**

1. In the User Manager, Group, Manager, or Organization Manager, navigate to Configuration, then click Workflow Definitions.

2. From the list marked Workflows, select the workflow containing the step being prepared for dynamic participants, then click Modify.

3. If any possibility exists that the current workflow step can ultimately use static participants, define static participants by Role, Rule, Persons, or Group, as described in "Use any of the following methods to specify participants." on page 5-23.

   If the preceding condition does not apply, or you previously defined static participants for this step, proceed directly to step 4.

4. If the current workflow step will use a plug-in or application to specify dynamic participants, and there are no conditions under which static participants can ultimately receive the workflow ticket for the current step, activate the Static Participants Not Available button, as described in "About the Static Participants Not Available Button" on page 5-35. Otherwise, proceed directly to step 5.

5. If you wish, set up email notification by clicking the Mail Notification tab, clicking the Select Participants to Prenotify button, then selecting Current Step Participants in the Select Role box. If they are ultimately selected, the dynamic participants will receive e-mail announcing that workflow tickets have been assigned to them.
6. Commit the step-specific information by clicking Save Step and then clicking OK to dismiss the prompt that asks you to confirm the operation.

7. Commit the information pertaining to the entire Workflow by clicking Save Workflow and then clicking OK to dismiss the prompt seeking to confirm the operation. If an additional prompt asks whether you want to enable the workflow, click Yes.

To modify oblixpppcatalog.lst

1. Complete the following sub-steps to determine the workflow ID of the workflow containing the step for which you wish to set dynamic participants:
   a. Launch the User, Group, or Organization Manager, as appropriate for the workflow you wish to modify.
   b. Click the Configuration tab, then click Workflow Definitions.
   c. Select the workflow you wish to modify, then click View.
   d. Make a note of the value reported in the Workflow Definition View for obworkflowid, which will appear in a string similar to the following:

   Workflow DN : obworkflowid=5985de47196a4a728a629a429b6a5194

2. Use any plain-text editor to open the file oblixpppcatalog.lst, which is located in the following directory:

   IdentityServer_install_dir\identity\oblix\apps\common\bin

   where IdentityServer_install_dir is the root installation folder for the Identity Server that runs your workflow.

3. Add one of the following strings to oblixpppcatalog.lst:

   | obworkflowid_workflowstep_preaction;lib;; |
   | Component_install_dir\identity\oblix\path\pluginName.dll; |
   | functionName; |
   
   Or

   | obworkflowid_workflowstep_preaction;exec;; |
   | Component_install_dir\identity\oblix\path\applicationName.exe; |
   | functionName; |

   where:
   - obworkflowid is the workflow identification number you noted in step 1d of this procedure
   - workflowstep is the step for which you wish to define dynamic participants
   - path is the path under Component_install_directory\identity\oblix\ leading to pluginName.dll or applicationName.exe, which are the code objects that select the dynamic participants at runtime

---

**Note:** The Select Participants to Prenotify button turns on email notification for static participants when the Static Participants Available switch is active. By contrast, it sends notifications to dynamic participants when the Static Participants Not Available switch is active.
functionName—If you specify a plug-in, you must also specify functionName, which is the function within the dynamic link library plug-in that sets the criteria for the dynamic participants.

You insert the first line of code if you are using a plug-in to specify the dynamic participants; you insert the second line if you are using an executable program, instead of a plug-in.

In any case, the line you insert must end with a semi-colon, and you may place it anywhere in the oblixpppcatalog.lst file, as long as that line does not interrupt an existing line.

The line you insert should be similar to the following:

```
wfqs20040901T1725193156_2_preact;lib;;
Component_install_dir\identity\oblix
\unsupported\ppp\ppp_dll\ppp_dll.dll;
WorkflowPreActionSetDynamicParticipantsTest;
```

4. Save oblixpppcatalog.lst in its original location.

See also Oracle Access Manager Developer Guide for details about the oblixpppcatalog.lst file.

**Task overview: Creating a plug-in or application to select dynamic participants**

1. Use C++ to create a plug-in or application that specifies the dynamic participants selected when program execution reaches the workflow step you specified in "To modify oblixpppcatalog.lst" on page 5-37.

2. You can use various conjunctions of LDAP attributes or proprietary business logic to specify the conditions under which one group of dynamic participants is chosen over the others at runtime.

3. Include in the plug-in or application, the following header files, which enable the pre-action processing necessary for dynamic participant selection:

   - obppp.h
   - obpppwf.h
   - obpppdata.h

4. Within the application or plug-in, define three or more sets of dynamic participants using any combination of roles, rules, persons, or groups. The final item in each array must always be NULL. For instance:

   a. If you wish to specify persons, insert lines similar to the following:

   ```
   PPPSetVals[0] = "cn=Van Oman, ou=Sales, ou=Dealer1k1,
                    ou=Latin America, ou=Ford, o=Company,c=US";
   PPPSetVals[1] = "cn=Fabien Esser, ou=Sales, ou=Dealer1k1,
                    ou=Latin America, ou=Ford, o=Company,c=US";
   PPPSetVals[2] = NULL;
   data->Set("DynamicParticipant.Persons", PPPSetVals);
   ```

   b. If you wish to specify groups, insert lines similar to the following:

   ```
   PPPSetVals[0] = "cn=Basic group1k1, ou=Groups, ou=Dealer1k1,
                    ou=Latin America, ou=Ford, o=Company,c=US";
   PPPSetVals[1] = "cn=Basic group1k2, ou=Groups, ou=Dealer1k1,
                    ou=Latin America, ou=Ford, o=Company,c=US";
   PPPSetVals[2] = NULL;
   data->Set("DynamicParticipant.Groups", PPPSetVals);
   ```
c. If you wish to specify roles, insert lines similar to the following:

PPPSetVals[0] = "ob_self";
PPPSetVals[1] = "manager";
PPPSetVals[2] = NULL;
data->Set("DynamicParticipant.Roles", PPPSetVals);
Remember, of course, that only certain roles are valid for particular workflow types. See page 200.

d. If you wish to specify rules, insert lines similar to the following:

PPPSetVals[0] = "(cn=rohit*)";
PPPSetVals[1] = "(cn=beth*)";
PPPSetVals[2] = NULL;
data->Set("DynamicParticipant.Rules", PPPSetVals);

Specifying Surrogates

You can configure the Identity System applications so that when a static or dynamic participant is not available to perform the actions assigned for a particular workflow step, that participant can set an Out of Office flag in his or her user profile, causing incoming workflow tickets to go to one or more designated surrogate participants. The surrogate is granted whatever rights the original participant had to process the rerouted tickets.

Only tickets created after activation of the Out of Office flag are rerouted to the surrogate. The original participant retains responsibility for processing all tickets created prior to activation of the Out of Office flag.

When the Out of Office flag is turned on, it applies to all of the steps in all of the workflows for which the participant has been designated as a static participant or potential dynamic participant.

When the Out of Office flag is reset to Off, newly created tickets are once again routed to the original participant. The surrogate retains responsibility for processing all tickets routed to him or her while the Out of Office flag was active, but no new tickets are routed to the surrogate unless the original participant once again activates his or her Out of Office flag.

The same workflow applet setting that sends ticket assignments to original participants also notifies surrogates and others that the workflow ticket has been rerouted because of the Out of Office flag.

Task overview: Enabling surrogates

1. Associate the attribute of your choice with the Out of Office semantic type through the Common Configuration tab of the Identity System Console.
   You only need to do this once. See "To associate an Out of Office attribute with the Out of Office semantic type" for details.

2. Specify one or more surrogates through the Out of Office tab in the workflow applet.
   See "Use any of the following methods to specify participants." on page 5-23 for details.

3. Individual users activate their Out of Office flags in their User Profiles.
   See "To make use of the Out of Office flag" on page 5-41 for details.
To associate an Out of Office attribute with the Out of Office semantic type

1. Choose an attribute in the LDAP directory to associate with the Out of Office semantic type.

   It must be an attribute with a boolean value that indicates whether the user is in or out of the office. For convenience, Oracle supplies the attribute obOutofOfficeIndicator, but you can use any suitable attribute in your directory.

2. Navigate to Identity System Console, select Common Configuration, select Object Class, select the person object class (for example, gensiteorgperson), then select Modify Attributes.

3. From the attribute list, select the attribute you wish to associate.

4. In the Semantic Type field, select "Out of Office - Indicator."

   Only some attributes will have this indicator. For example, for gensiteOrgPerson, the genuserid attribute will have this indicator.

5. In the Display Type box select Boolean, then click Done to commit the change.

---

**Note:** This procedure only needs to be performed once.

---

To specify a surrogate

1. As appropriate to the particular workflow containing the step for which you wish to specify one or more surrogates, log onto the User, Group, or Organization Manager, then navigate to Configuration, then select Workflow Definitions.

2. Select the workflow containing the step for which you wish to specify surrogates and click Modify.

3. Click Next once if you are modifying a Change Attribute workflow.

   Click Next twice if you are modifying any other type of workflow.

4. Select the step for which you wish to specify surrogates, then click Modify.

   The page is refreshed with information about this step. If the page does not refresh, be sure that the step is highlighted. If it is not, click it again, then click Modify.

   You can specify a surrogate for any workflow step associated with a user action.
5. Click the Out of Office tab.

6. Specify one or more Surrogates using any combination of the Person, Group, Role, and Rule tools.

   See "Use any of the following methods to specify participants." on page 5-23 for details.

   The Select Indirect Roles box provides check boxes to select whatever roles are currently defined in your directory. These roles are considered indirect, because they apply to the current participant, rather than the workflow target.

7. Click Save Step to commit the changes for that step.

   If you receive a warning to configure attributes, make sure that you have selected attributes for this step.

8. Repeat the preceding steps for each workflow step for which you wish to specify a surrogate.

9. Click Save Workflow to save the entire workflow.

**To make use of the Out of Office flag**

1. Verify that you, as a potential static or dynamic user, have been granted sufficient privileges (search, read, and write) to perform the operations described in this procedure.

2. Verify that the Out of Office flag has been configured for the attribute.

3. Navigate to User Manager, select My Profile, then click Modify.

4. In the Personal Information section, toggle the Out of Office Indicator to True. (This attribute is False, by default).

5. Click Save to commit the change, then click OK to dismiss the pop up that seeks to confirm the operation.

**Enabling Time-based Escalation**

If the participant or participants assigned to process a workflow ticket do not do so within a specified interval, you can have the Identity System escalate the ticket by rerouting it to a different participant. The original participant can no longer process the escalated ticket: it must now be processed by the escalation participant, who receives all rights previously given to the original participant for processing the ticket.

If the escalation participant does not process the ticket within the allotted time, the ticket is escalated again, and so on, until it is escalated to the Identity System administrator, who is the last possible participant to be assigned responsibility for the escalated ticket.

By default, you can enable time-based escalation on any workflow step, provided the following two conditions hold true:

- The escalated step is not the initial step in the workflow
- The action associated with the step has been enabled for escalation. By default, only Approval and Provide Information and Approval are enabled for escalation, but you can enable other actions by adding lines to the appropriate workflow parameter file. See the procedure “To modify the workflow parameter files” on page 5-44 for details.
To enable time-based escalation

1. As appropriate to the particular workflow for which you wish to set up time-based escalation, log onto the User, Group, or Organization Manager, then navigate to Configuration, then click Workflow Definitions.

2. Select the workflow for which you wish to set up escalation and click Modify.

   If a pop up appears to warn you that only certain settings can be modified while pending tickets exist for the workflow, dismiss it by clicking OK. If you modifying a Change Attribute workflow, click Next once; if you are modifying any other type of workflow, click Next twice.

3. Highlight the step for which you want to enable escalation, then click Modify.

   The page is refreshed with information about this step. If the page does not refresh, be sure that the step is highlighted. If it is not, click it again, then click Modify.

   The step you select must be associated with an action that is enabled for escalation. By default Approval and Provide Information and Approval are enabled. To enable additional actions to support time-based escalation, see the procedure "To modify the workflow parameter files" on page 5-44 for details.

4. Click the Escalation tab.

5. Specify the interval after which the ticket will be escalated. You can set the interval in days, minutes, or hours. This interval applies to all escalation levels.

6. Specify the participant or participants to whom the ticket will be escalated. Roles are indirect in the sense that they are evaluated not with respect to the workflow target, but with respect to the participant who did not process the ticket in time to prevent the most recent escalation. For instance, if Manager is checked in the Select Indirect Roles box, and the accountant who initially receives the ticket does not process it quickly enough, the ticket is escalated to that accountant's manager (and not the manager of the workflow target).
7. Specify the number of times (levels) a ticket can be escalated. This does not include the final escalation level, which always routes the ticket to the Identity System administrator.

You can only specify one set of escalation participants. This single set applies to all escalation levels. If you specify a unique user, for example, the ticket is escalated to that person each time escalation is triggered. If that escalation participant does not process the ticket at any level, the ticket is ultimately escalated to the Identity System Manager.

If, on the other hand, you specify a role that is held by a different person at each level, the ticket will be escalated to a different person at each level. For instance, if you specify Manager, the ticket will be escalated to the manager of the person to whom the ticket was originally issued, then to the manager of that manager, and then to that manager's manager, and so on.

8. Click Save Step to commit the setting you have entered on the escalation tab.

9. Specify the people who will be notified about the escalation by clicking the Mail Notification tab.

10. Click Select escalation notifees

11. Select the people to be notified by Person, Group, Role, or Rule. The available roles are the following:

   - **Previous step owners:** This is the participant who completed the previous step.
   - **Current step participants:** These are the people currently assigned to process the just-escalated ticket.
   - **Next step participants:** These are the people who will be assigned to process the next step. Only the static participants defined for the next step can be notified, since the email notifications are sent before the execution flow reaches the next step, and the identity of the dynamic participants is determined.
Initiator: This is the user who initiated the work flow.

To modify the workflow parameter files
1. Complete this procedure only if you want to enable time-based escalation for a user action other than Approval or Provide Information and Approval. For a list of the user actions that can be enabled for time-based escalation, see Table 5–9.

2. Using any plain text editor, launch the workflow parameter file appropriate to the workflow containing the actions for which you are enabling time-based escalation. Table 5–10 lists the workflow parameter files that apply to workflows associated with the various Identity System applications:

Table 5–10  Workflow parameter file names and paths

<table>
<thead>
<tr>
<th>Application</th>
<th>Workflow parameter file name and path</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Manager</td>
<td>IdentityServer_install_dir/identity/oblix/apps/userservcenter/bin/usc_wf_params.xml</td>
</tr>
<tr>
<td>Group Manager</td>
<td>IdentityServer_install_dir/identity/oblix/apps/groupservcenter/bin/gsc_wf_params.xml</td>
</tr>
<tr>
<td>Organization Manager</td>
<td>IdentityServer_install_dir/identity/oblix/apps/objservcenter/bin/osc_wf_params.xml</td>
</tr>
</tbody>
</table>

3. Locate the compound list for the action you want to support time-based escalation. The first half of this compound list should resemble the listing in Example 5–1:

Example 5–1  The workflow parameter compound list (partial listing only)

```
<CompoundList ListName='actionName'>
  <SimpleList>
    <NameValPair ParamName='occurrence' Value='n'/>
    <NameValPair ParamName='useraction' Value='true'/>
    <NameValPair ParamName='initialStep' Value='false'/>
    <NameValPair ParamName='time_based_escalation' Value='true'/>
  </SimpleList>
  ...
</CompoundList>
```

where actionName is the name of the action for which you want to enable time-based escalation. For a list of actions that can be enabled to support time-based escalation, see Table 5–9.

4. Add the following string in the position indicated by the preceding listing:

```
<NameValPair ParamName='time_based_escalation' Value='true'/>
```

5. Repeat the preceding steps for all the user actions you want to support time-based escalation.

6. Save and exit, the file.

Performing Asynchronous Operations

An asynchronous workflow moves from step to step without completing pending subflows. An asynchronous operation is pre and post processing code that is part of an
Identity Event, as described in the Oracle Access Manager Developer Guide. The async_user parameter determines who may resume the pending asynchronous action. The default is Anyone.

**To allow a user to perform an asynchronous operation**

1. Open the asynchparams.xml file in:

   \(\text{IdentityServer\_install\_dir/oblix/apps/asynch/bin/asynchparams.xml}\)

   where \(\text{IdentityServer\_install\_dir}\) is the directory where you installed the Identity Server.

2. Set the async_user parameter to one of the following:
   - **Anyone**: Anyone can perform asynchronous operations (default).
   - **DN**: A particular user can perform asynchronous operations. Provide the DN of a user.

   Only one DN can be accepted by the parameter.

**Notes on Asynchronous Workflows**

The User, Group, and Organization Managers are not automatically loaded when an asynchronous workflow is resumed. If there is a request to the Identity Server to resume an asynchronous workflow when the application is not loaded, the workflow engine may not register error conditions.

For example, suppose you create a Deactivate User workflow in the User Manager. This workflow only has Initiate and Disable steps. Suppose also that you create an event plug-in for the workflow that returns STATUS_PPP_WF_ASYNC code to make the workflow instance become asynchronous during the Initiate step, pending a command to instruct the workflow to resume and run the Disable step. If there is an IdentityXML request to resume this workflow while the Identity System is being restarted, the workflow engine would mistakenly return success. The Disable step would return with a status of complete when in fact the user was not disabled.

---

**Note:** Be sure the User Manager, Group Manager, and Organization Managers are pre-loaded when the Identity Server is restarted.

---

**To preload the User, Group, and Organization Managers**

1. Open the Identity System parameter file:

   \(\text{Identity\_install\_dir/identity/oblix/engine/obengineparams.xml}\)

2. In this file, find the configuration information for the Identity System applications:
   - \(<\text{ValNameList ListName="groupservcenter"}>\)
   - \(<\text{ValNameList ListName="userservcenter"}>\)
   - \(<\text{ValNameList ListName="objservcenter"}>\)

3. Change the Dll_Load parameter from 0 to 1 as in following example for Group Manager.

   \(<\text{ValNameList ListName="groupservcenter"}>\)
   \(<\text{NameValPair ParamName="Dll_Name" Value="groupservcenter"/>}\)
Using a Workflow

Once a workflow has been defined, users can invoke the workflow from the associated function in the User Manager, Group Manager, or Organization Manager. Participants in steps other than the Initiate step of the workflow can find and process tickets. Users can delete workflow requests, archive requests, and monitor the progress of a workflow.

Note that to be able to perform the actions specified in the workflow definition, participants in a workflow must be granted permission to view and modify the attributes affected by the workflow. See "Allowing Users to View and Change LDAP Data" on page 4-21.

Invoking a Workflow

Once a workflow is defined, it becomes a piece of embedded functionality in the User, Group, or Organization Manager. The workflow can be invoked by any user who has been defined as a participant in the Initiate step for this workflow. For example, suppose you define a Create User workflow. Users who are in the domain specified for the workflow can invoke this workflow from the Create User function in the User manager. If multiple workflows have been defined for a create operation, you will see a list on the create page for that object.

Users can also initiate a Change Attribute workflow. Change attribute workflows are available on profile pages that the user is permitted to access. For example, suppose a workflow has been defined for the manager attribute displayed on a profile page. When users change departments, they may need to issue a request to change the name of their manager. This request can be handled by a Change Attribute workflow.

To invoke a change attribute workflow

1. From the User Manager, click My Identity, then click Modify.
   
   Your user profile page is displayed using editable fields for all attributes that you can change.

2. For attributes on your profile page that have the Request to Remove or Request to Modify buttons, you may request to remove or change that attribute value.
   
   These buttons are displayed when a Change Attribute workflow or subflow with a Request to Remove or Request to Modify action has been created.
Your request is sent in the form of a ticket. The person who processes this ticket may approve or reject the request. See "Finding and Processing a Ticket" on page 5-47 for details.

Finding and Processing a Ticket

Once a workflow has been initiated, subsequent steps are generated by processing a ticket. You can find pending workflow tickets in the User Manager, Group Manager, and Organization Manager.

To find a workflow ticket

1. From the User Manager, Group Manager, or Organization Manager, click Requests.
2. From the Requests page, click either Incoming Requests, Outgoing Requests, or Monitor Requests.
   Note that outgoing requests are tickets that have already been processed.
3. In the Search list, select the application for which you want to view requests.
4. Specify a number of days in the text field, or leave this field blank to view all requests.
5. Click Go.
   A list of workflow tickets is displayed. The list will match your search criteria.

To process a ticket

1. From the User Manager, Group Manager, or Organization Manager, click Requests.
2. From the Requests page, click Incoming Requests.
3. In the Search list, select the application for which you want to view requests.
4. Specify a number of days in the text field, or leave this field blank to view all requests.
5. Click Go.
6. A list of workflow tickets is displayed. The list will match your search criteria.
7. Click a link for an incoming request.
8. On the details page for the request, click the Process button.
   If you are a participant for this workflow, a page is displayed showing the attributes configured for this step of the workflow.
9. Supply any required attributes for this workflow.
   For example, a Create User step may prompt you to supply an email address for the new user. Any information you need to supply on this page is determined by how this step of the workflow was configured.
10. Click the appropriate button for completing this step of the workflow.
    For example, on a Create User request, the detail page for this ticket may contain Approve and Reject buttons.
Deactivating and Reactivating Users

Once a user has been enabled in the Identity System, they can be deactivated and reactivated. Deactivation makes a user unable to log in and unavailable for viewing in the Identity System. It takes effect once the user logs out of the current session. An administrator with Monitor Requests privilege can view deactivated users and either permanently delete them or reactivate them.

**Note:** All configured directories will be searched to remove references to the Deactivated/Deleted user, including groups to which the user belongs. When you have stored user data and configuration data separately, both directories will be searched concurrently.

The steps for defining a workflow for deactivating a user are provided in "Using the Workflow Applet" on page 5-18. Once the workflow has been defined, users with sufficient privileges will see an Initiate User Deactivation button on a user's profile page.

Reactivating a Deactivated User

At times you may want to reactivate a deactivated user. For example, you may want to deactivate an employee during a leave of absence, and reactivate the employee when he or she returns to work.

**To reactivate a deactivated user**

1. Define a Reactivate User workflow for this purpose.
   
   For a summary of actions permitted on a reactivation workflow, see “Workflow Types, Steps, and Actions” on page 5-7. Once the workflow has been defined, users with sufficient privileges will see an Initiate User Reactivation button on a deactivated user's profile page.

2. In the User Manager, click the Deactivated User Identity sub-tab to display the Search Deactivated Users page.

3. Search for, then select the deactivated user name for the identity you want to reactivate.
   
   The View Profile page appears.
4. Click the Initiate User Reactivation button on the View Profile page.
   The user is reactivated.

**Note:** When you reactivate a user, you must manually add the user to any groups he or she belonged to, and re-set attribute policies and the searchbase for the user.

**Monitoring a Workflow**

Users who have the right to monitor a workflow can view the progress of a workflow, including request tickets owned by others.

Only requests within your management domain are listed. See "Delegating Administration" on page 2-5 for details.

**To monitor a workflow**

1. In User, Group, or Organization Manager, click Requests.
2. Click Monitor Requests.

**Note:** For subflows, if the first step has not been processed, the Date Processed field is empty.

3. In the Search fields, select your search criteria and click Go.
   The results appear after the search fields.
4. Click Next or Previous as necessary to see other results.
5. Click a ticket’s Request Number to open the Request page for that ticket. This page lists the workflow’s current step number.

To delete an incomplete workflow that is not responding, use the Monitor Requests function to locate the workflow and then click the Terminate button. To terminate a completed workflow, use the Delete button in the Monitor Workflow functionality.

Archiving Requests

You may want to archive workflows to keep a record of participants and times, and to prevent the Oblix tree from getting too large. Archived workflows are stored in LDIF format. The default storage file is oblix/data/common/wfinstance.ldif. Multiple archive operations add information to this file.

You can archive only completed workflows.

**To archive a workflow**
1. View workflow requests, as described in "Monitoring a Workflow" on page 5-49.
2. Select requests in the Select All column.
3. Click Archive.

You can change the default filename and location in the following files:

<table>
<thead>
<tr>
<th>Filename</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>usc_wf_params.xml</td>
<td>User Manager</td>
</tr>
<tr>
<td>gsc_wf_params.xml</td>
<td>Group Manager</td>
</tr>
<tr>
<td>osc_wf_params.xml</td>
<td>Org. Manager</td>
</tr>
</tbody>
</table>

4. When the archive confirmation page appears, click Back to return to the previous page.

---

**Note:** You must restart the Identity Server after changing parameter files.

Deleting Requests

You can remove workflow requests.

**To delete requests**
1. View requests as described in "Monitoring a Workflow" on page 5-49.
2. Select requests in the Select All column and click Delete.
3. When the delete confirmation page appears, click Back to return to the previous page.

Preventing Other Administrators from Working on a Workflow Ticket

At run time, multiple users may receive a workflow ticket. For example, suppose an IT group receives a ticket for a Create Workflow request. An administrator who processes this request can lock the ticket so that other users can view the information on the locked ticket but they cannot work on the ticket. Only the person who locked the
Ticket, the Master Identity Administrator, and people who have been granted permission to Monitor Requests can unlock the ticket.

**To lock or unlock a ticket**

1. Open a ticket as described in "To process a ticket" on page 5-47.
   
   The Lock and Unlock buttons are displayed on the workflow page when you process the workflow ticket.

2. Select Lock or Unlock, as appropriate.

**Managing Workflows**

Once you have defined workflows, you can view, copy, modify, delete, and export them.

**Viewing and Exporting a Workflow Summary**

You can view a summary of a workflow, including its steps, participants, and so on, and export this report to a comma-delimited value (CSV) file.

---

**Note:** The following is of interest if you use Microsoft Internet Explorer and you are protecting the Identity System interface (WebPass) with a WebGate. To enable the Export to CSV feature, you must configure the following two WebGate parameters as follows:

**CachePragmaHeader:** Leave blank

**CacheControlHeader:** Specify Private or leave blank

See *Oracle Access Manager Access System Administration Guide* for details.

---

**To view and export a workflow summary**

1. Access the User, Group, or Organization Manager.

2. Click Configuration, then click Workflow Definition.

3. From the workflows menu, select the workflow you want to view.

4. Select View.

   The Workflow Definition View page appears.
5. Enlarge the Workflow Definition View page or scroll to the right to see all of the workflow contents.

6. Click Export to CSV to save a comma-delimited value file of your workflow.

7. Click Close to close the page.

A sample CSV file, when opened in a spreadsheet, may appear as follows:

### Copying a Workflow

You can use a copy of a workflow as a starting point for a new workflow. You can also copy a workflow if you would like to modify a workflow that has too many pending tickets for the modify function to be practical.

**To copy a workflow as a starting point for a new workflow**

1. Access the User, Group, or Organization Manager.

2. Click Configuration and click Workflow Definition.
3. From the Workflows menu, select the workflow you want to copy.
4. Click Copy.
5. A copy of the workflow appears in the list.
   It is named Copy of original name. Oracle recommends renaming the copied workflow, although you are not required to do so.
6. Change information as necessary to create a new workflow.

To copy a workflow as an alternative to modifying it
1. Copy the workflow, as described in the previous procedure.
2. If the workflow has external actions, update the oblixpppcatalog catalog file to reference the new workflow.
   See Oracle Access Manager Developer Guide for details.
3. Modify the copy.
   If you intend the workflow to only be invoked from the Identity System, you are done.
4. If the workflow is embedded as a portal insert another application Web page, update the link for the workflow to point to the new workflow ID.

Modifying a Workflow

After creating a workflow, you can change its parameters. If the selected workflow has pending instances, you can only modify the list of Targets, the Participants for any step, or the Pre/Post Notification recipients for any step.

---

**Note:** Since only certain parts of a workflow can be modified when there are pending tickets, on a very active system you may need to copy the workflow and make changes to it. See “Copying a Workflow” on page 5-52 for details.

---

To modify a workflow
1. Access the User, Group, or Organization Manager.
2. Click Configuration and click Workflow Definition.
3. From the Workflows menu, select the workflow you want to modify.
4. Click Modify.
   The selected workflow information appears. Clicking Modify disables this workflow so that it cannot be used while being modified.
5. Change the workflow settings as necessary.
6. Click Save Workflow to save your changes.
7. Click Yes when prompted to enable the workflow.

Deleting a Workflow

You can delete a workflow unless the workflow has pending requests.
**To delete a workflow**
1. Access the User, Group, or Organization Manager.
2. Click Configuration and click Workflow Definition.
3. From the Workflows menu, select the workflow you want to delete.
4. Click Delete.
5. Click OK at the confirmation message.

**Exporting Workflows**

You can export all workflows to a comma-delimited value (CSV) file. This is a text file that can be printed.

---

**Note:** The following is of interest if you use Microsoft Internet Explorer and you are protecting the Identity System interface (WebPass) with a WebGate. To enable the Export to CSV feature, you must configure the following two WebGate parameters as follows:

- **CachePragmaHeader:** Leave blank
- **CacheControlHeader:** Specify Private or leave blank

See *Oracle Access Manager Access System Administration Guide* for details.

---

**To export workflows**
1. Access the User, Group, or Organization Manager.
2. Click Configuration, then click Workflow Definition.
3. From the workflows menu, select the workflow to export.
4. Click Export All to be prompted to save a comma-delimited value file that includes all of your workflows.

**Viewing Workflow Panel Settings**

As described in "About User, Group, and Organization Manager" on page 4-1, you configure what appears in the User, Group, and Organization Manager applications. The User and Group Manager applications consist of one tab and the Organization Manager consists of one or more tabs. Tabs are a collection of profile pages, which themselves are collections of panels. Panels are groups of attributes and values.

You can view and modify the workflow panels that appear on the profile pages for these applications.

**To view current workflow panel settings**
1. From the Identity System Console, click Common Configuration.
   The Common Configuration page appears.
2. Click Workflow Panels.
   The Workflow Panels page displays configured workflow panels.
The following table describes each panel.

<table>
<thead>
<tr>
<th>Panel</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workflow monitor table</td>
<td>The columns included in the results page when a user performs a workflow search from the Monitor Requests page.</td>
</tr>
<tr>
<td>Workflow profile panel</td>
<td>The information displayed about a workflow instance in the Monitor Requests page.</td>
</tr>
<tr>
<td>Workflow steps profile panel</td>
<td>The information displayed about a workflow instance’s steps in the Monitor Request page.</td>
</tr>
<tr>
<td>Ticket information panel</td>
<td>The information displayed in the Ticket Information page from the Incoming Requests or Outgoing Requests page.</td>
</tr>
<tr>
<td>Ticket search table</td>
<td>The information displayed in the results page when a user performs a workflow search from the Incoming Requests or Outgoing Requests page.</td>
</tr>
</tbody>
</table>

3. Click the panel you want to view.

The View Panel page displays the items that are displayed on the panel.

<table>
<thead>
<tr>
<th>Panel field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Panel Label</td>
<td>Name of the panel as displayed in the Identity System. This field can be localized.</td>
</tr>
<tr>
<td>Description</td>
<td>Description of what this panel does. This field can be localized.</td>
</tr>
<tr>
<td>Attributes</td>
<td>Attributes used for the panel columns and their display names. This field can be localized.</td>
</tr>
</tbody>
</table>

Modifying the Appearance of Workflow Panels

You can modify, but cannot delete, workflow panels.

**To modify a workflow panel**

1. From the Identity System Console, click Common Configuration.
   
   The Common Configuration page appears.

2. Click Configure Workflow Panels.
The Configure Workflow Panels page displays configured workflow panels.

3. Click the panel you want to view.
4. Click Modify.

The Modify Panel page appears.

5. In the Panel Label field, type a new name for this panel as it will appear in the application.
6. In the Description field, type a description.
7. In the Attributes fields, select attributes to display on the application in the order in which they will appear.
8. Click Save.

Localizing Workflow Panels

You can localize workflow panels if you want to display the panel information in more than one language. To do this, you must do the following:

- Install the appropriate language packs.
- Manually enter the panel display information in the Administration Console for each language that you installed.

See "Making Schema Data Available to the Identity System" on page 3-1 and "Configuring User, Group, and Organization Manager" on page 4-1 for information on localizing attributes.

To view language-specific workflow panel information

1. From the Identity System Console, click Common Configuration.
   
The Common Configuration page appears.
2. Click Configure Workflow Panels.
   
The Configure Workflow Panels page displays configured workflow panels.
3. Click the panel you want to view.
   The details of the workflow panel such as the panel name, description, and attributes are displayed on the page.

4. Click Translate.

---

Note: The Translate button appears only if more than one language pack is installed.

The Summary of Panel Display Names page appears. The language-specific display name for the panel fields and attributes are displayed. Fields that has not been translated for a language are marked as Not Configured.

To configure language-specific workflow panel information
1. In the Summary of Panel Display Names page, click Modify
   The Configure Panel Display Names page appears. This page contains panel information and links for the languages that you have installed
2. Click the language for which you want to configure the workflow panel.
   The Configure Panel Display Names page for the selected language appears.
3. Enter the following information:
   ■ Panel Label: Enter the language-specific display name for the panel.
   ■ Description: Enter a brief description of the panel. This is optional.
   ■ Attributes: Enter the language-specific text for each attribute display name.
4. Click Save to save your changes; click Cancel to exit the page without saving your changes.

---

Workflow Performance
Access to the directory server can be reduced by setting the WfInstanceNotRequired flag to true in the oblix/data/common/workflowdbparams.xml file. This flag indicates that no workflow instances should be written to the directory server unless necessary. It is set to false by default, which means workflow instances are written to the directory server.

For more information about workflow performance see Oracle Access Manager Deployment Guide.

---

The Identity Administrator’s Modify Rights
As defined in "Specifying Identity System Administrators" on page 2-1, only an Identity Administrator can manage the User, Group, and Organization Manager.

By default, an Identity Administrator bypasses attribute access controls. As a result, if you define a Change Attribute workflow, the attribute access controls in this workflow are not checked for Identity Administrators. These administrators automatically have modify rights where other users have only the right to request to modify an attribute.

The parameter to control this feature is BypassAccessControlForDirAdmin, located in IdentityServer_install_dir/identity/oblix/apps/common/bin/globalparams.xml. If you
want to not automatically provide modify rights to the Directory Administrator, set this flag to false and restart the Identity Server.

You can give the Identity Administrator the right to modify an attribute and request to modify an attribute in a Change Attribute workflow. In each application parameter file, for instance, `IdentityServer_install_dir/identity/oblix/apps/userservcenter/bin/userservcenter.xml`, you can set the parameter `checkChangeAttributeEvenAllowModify` to true. This setting provides that even if the administrator is allowed to modify an attribute, this person will see both input and workflow buttons. This parameter applies to administrators who have both modify and initiate workflow rights. Note that this feature can introduce performance overhead.

**Advanced Workflow Options**

The following advanced options are available:

- Attaching custom code to workflow actions
- Configuring the behavior of workflow actions

**Pre and Post Actions**

You can use the Identity Event Plug-in API to attach custom code to workflow actions. Common scenarios for using the Identity Event Plug-in API with workflows include:

- Automatically generating a value (such as a unique ID) from an external system
- Validating data for a workflow step
- Updating data in an external system

Once you write custom code, you must tell the Identity System to execute it either before the workflow action (pre action), or after the workflow action (post action) in the `oblixpppcatalog` file.

See the *Oracle Access Manager Developer Guide* for more information.

**External Actions**

An external action serves the same purpose as pre and post actions, but differ from Identity Event Plug-in API actions in two ways:

- An external action is not attached to an existing action.
- Routing paths can be fully configured based on the external action’s exit condition.

You implement the external action code as a hook in the `oblixpppcatalog` file. See the *Oracle Access Manager Developer Guide* for more information.

**Customization of Data and Actions in a Workflow**

The User, Group, and Organization Manager each have a workflow parameter file that controls the data displayed to participants and the actions that can be selected.

Each parameter file has three sections:

- Create Object
- Delete Object
- Change Attribute
The files are located in

IdentityServer_install_dir/identity/obl ix/apps/applicationname/bin/

where IdentityServer_install_dir is the Identity Server installation directory and applicationname is one of the following:

- usc_wf_params.xml: User Manager
- gsc_wf_params.xml: Group Manager
- osc_wf_params.xml: Org Manager

The following table describes each parameter:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Sample Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>occurrence</td>
<td>Indicates how many times this action may be used within a workflow.</td>
<td>[1] [n]</td>
</tr>
<tr>
<td></td>
<td>1: action can be used once.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>n: Action can be used multiple times.</td>
<td></td>
</tr>
<tr>
<td>useraction</td>
<td>Indicates whether or not the step is interactive.</td>
<td>[true] [false]</td>
</tr>
<tr>
<td></td>
<td>true: Action requires user interaction.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>false: This is a background step and requires no user interaction.</td>
<td></td>
</tr>
<tr>
<td>forceCommit</td>
<td>Indicates whether an implicit commit takes place for this step, even though this action is not a commit. An implicit commit writes all collected data to the specific target entry</td>
<td>[true][false]</td>
</tr>
<tr>
<td></td>
<td>true: Implicit commit takes place.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>false—Implicit commit does not take place.</td>
<td></td>
</tr>
<tr>
<td>pre_action</td>
<td>Indicates that the current action can be specified if the previous step’s action is in this list.</td>
<td>[list of actions]</td>
</tr>
<tr>
<td>exit_condition</td>
<td>Indicates the possible results for the given action.</td>
<td>[list of exit conditions]</td>
</tr>
<tr>
<td></td>
<td>For example:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>true: 1</td>
<td></td>
</tr>
<tr>
<td></td>
<td>false: 0</td>
<td></td>
</tr>
<tr>
<td>relevant_data</td>
<td>Indicates which types of relevant data can be configured for this step. Background steps do not contain any relevant data.</td>
<td>[list of relevant data]</td>
</tr>
<tr>
<td></td>
<td>Can be any combination of Required, Provisioned or Optional.</td>
<td></td>
</tr>
<tr>
<td>initialStep</td>
<td>A parameter you can apply to an initiate, self registration, or approval step.</td>
<td>Values are true and false.</td>
</tr>
</tbody>
</table>

**Adding Roles to a Workflow**

By default, only the role of Anyone is available in a workflow definition applet. To add the roles that have been defined in the directory to the workflow definition applet, you can modify the workflow parameter files for the User Manager, Group Manager, and Organization manager.

The following procedures cause all DN roles to show up in the workflow applet.
To configure a role
1. Open the Modify Attributes applet as described in "Configuring Attributes" on page 3-17.
2. For a person object class or an auxiliary object class associated with the person object class, select an attribute with a DN data type.
   For example, you might select the Manager attribute.
3. From the Display Type list, select the Object Selector display type for this attribute.
4. Select the person object class, for example, gensiteOrgPerson, in the Target Object Class list.
   The attribute will display as a role in the workflow applet, provided all roles are enabled as described in the following procedure.
5. Click Save.

To add roles to a workflow definition applet
1. Edit the WF parameter file in the following location:
   User Manager: Open usc_wf_params.xml.
   Group Manager: Open gsc_wf_params.xml.
   Organization Manager: Open osc_wf_params.xml.
2. Go to the section <CompoundList ListName="Roles">
3. Find the appropriate Workflow Type.
   For example, to modify a create object workflow, you would need to find <CompoundList ListName="CREATE_OBJECT">
4. Find the Participant or Notifee section in this file.
   For example, you could edit the section <ValNameList ListName="Participant" >
5. Add the following line:
   <NameValPair ParamName="dns" Value="dns"/>

Creating a Self-Registration Workflow

Self-registration enables users to add themselves or their organizations to the Identity System directly from a Web page. The Identity System does not provide a user interface for self-registration. You must configure a URL that displays a registration form.

When users self-register, they may be prompted to reset their passwords after their initial login attempt. This depends on settings provided for the Change On Reset field, as described in "Configuring Password Policies" on page 7-46. If more than one user self-registers using the same browser session and the Change On Reset option is chosen, all users after the first are prompted to change their passwords after their first login.

If you want users to be automatically logged in to the Identity System after self-registering, you must set the SelfRegGeneratesSSOCookie to true in the basedbparams.xml file. See the Oracle Access Manager Customization Guide for details.

Additional information on customizing self-registration pages is provided in the Oracle Access Manager Customization Guide.
Creating a Self-Registration Workflow

The following procedure illustrates a self-registration workflow for Basic authentication.

**To create a self-registration workflow**

1. From the Identity System Console, select the User, Group, or Organization Manager.
   
   If the Organization Manager has more than one tab, select the appropriate tab.

2. Click Configuration, then click Workflow Definition.

3. Define a Create User or a Create Organization workflow using self-registration as the first step.

4. Access this workflow and record the workflow’s Distinguished Name and the target domain.

   You will add this information to the self-registration URL.

5. Add the self-registration URL to an HTML document as follows:

   ```
   https://domain:port/identity/oblix/apps/userservcenter/bin/
   userservcenter.cgi?program=workflowSelfRegistration&ObWorkflowName=workflow_DN
   &ObDomainName=target_domain
   ```

   Variables are as follows:
   
   - **Domain_name:port**: host system’s domain name and port number.
   - **Workflow_DN**: the DN for the workflow.
   - **Target_domain**: the target path, without a name.

   The value of ObDomainName target_domain is a target domain that was defined in the self-registration workflow. See "Defining an LDAP Target for Create Object Workflows" on page 5-21 for details.

   For organization self-registration, use this format:

   ```
   https://domain_name:portnumber/identity/oblix/apps/objservcenter/
   bin/objservcenter.cgi?program=workflowSelfRegistration&tab_id=tab_name&ObWorkflowName=workflow_DN&ObDomainName=target_domain
   ```

   Variables are as follows:
   
   - **Domain_name:portnumber**: host system
   - **Tab_name**: the name of the tab
   - **Workflow DN**: the workflow’s DN
   - **Target_domain**: the target path, without name

   The URL for self-registration must be to a page that does not require authentication. The self-registration URL is not the usual /identity/oblix/apps/userservcenter/bin/userservcenter.cgi. Typically, when a user accesses the Identity System, the Access System asks the user to authenticate. However, the WebGate should be set up to not request authentication for people accessing self-registration and lost password pages.

6. Replace reserved characters with URL-compatible text substitutes.

   When providing a DN path in the dynamic expansion URL, you must encode URL-reserved characters (non-alphanumeric) with a % followed by the character’s ASCII hexadecimal equivalent, as follows:
Creating a Location Workflow

- %3D: Equal sign (=)
- %2C: Comma
- %20: Space

For example:

\text{cn=Engineering Team, ou=Engineering, o=Company, c=US}

is replaced by:

\text{cn%3DEngineering%20Team%2C%20ou%3DEngineering%2C%20o%3DCompany%2C%20c%3DUS}

7. Save the HTML file.

The following is an example of a self-registration URL:

\text{http://silicon/identity/oblix/apps/userservcenter/bin/userservcenter.cgi?program=workflowSelfRegistration\&obdomainname=ob%3DCompany%2Cc%3DUS\&obworkflowname=obworkflow\&obworkfid%3D20020605T1132216476\&obcontainerId%3Dworkflowdefinitions%2Co%3Doblix%2Co%3Dconfigdata}

\textbf{Note:} If you are using Sun's iPlanet directory, note that self-registration passwords cannot use UTF-8 characters. If the user supplies UTF-8 characters, the iPlanet directory default 7-bit plug-in fails the operation. By default the 7-bit plug-in requires the uid, mail, and userpassword attribute values to be 7-bit. To resolve this problem, turn off the plug-in or remove the userpassword attribute from the configuration. Note also that this issue applies as well to Create User and Modify Profile operations.

---

Creating a Location Workflow

In the Organization Manager, you can create workflows to manage business locations and allow specific users to manage those locations. You can select individual users or users who play a specific role such as Facilities Manager, or you can select specific groups such as IT Operations.

To enable users to view the location of the organization, you can attach .gif images of the location map to the workflow. When users click a location, the location profile displays a map of the area where building is located.

You can create a new location workflow and then create a location object using the new workflow. To do this, use the Create Org Profile feature in the Organization Manager. Alternatively, you can create a location object first and then link it to an existing workflow. Once you create a location object, you can assign other objects such as users to specific locations on the map.

\textbf{Note:} If Location ID has the Semantic type DN Prefix it is important to note Active Directory and ADAM do not allow multi-valued RDNs (although iPlanet/SunOne do). For Active Directory and ADAM, ensure that the Attribute Value(s) selection is Single in the meta-attribute configuration.

After you have created a location object, you must enable the Location functionality and enable users with the appropriate permissions to view the user or object's location.
Creating a Location Workflow

Task overview: Enabling Location functionality and users
1. Modify the Location tab for the Organization Manager, then add location attributes to the Profile pages for User Manager and the Organization Manager.
   See "Enabling the Location Tab in Organization Manager" on page 4-36 and "Configuring Tab Profile Pages and Panels" on page 4-11 for details.
2. Configure read permissions for location attributes.
   See "Allowing Users to View and Change LDAP Data" on page 4-21 for details.
3. Define a Create Location workflow as described in "Task overview: Defining a Create Location workflow" on page 5-63.
4. Create a new location and establish the location's hierarchy in relation to other locations if applicable.
   See "Adding Object Classes" on page 3-8 for details.
5. Assign a value for the Location attribute for a user or object profile.
   See "Using the Workflow Applet" on page 5-18 for details.

Note: Attribute values can also be added and modified on object profile pages as well as through a workflow.

Task overview: Defining a Create Location workflow
1. Initiate a workflow as described in "Starting a New Workflow Definition" on page 5-19.
2. Create one or more subflows, if necessary, as described in "About Subflows" on page 5-14.

Note: You must create subflows before you initiate the main workflow. This enables you to link a subflow to the main workflow.

3. Select the attributes that you want to associate with the workflow as described in "Defining Step Attributes" on page 5-25.

   The available default location attributes are Location ID, Location Name, Location Title, and Map Image. Location ID and Location Name are required attributes.
4. Specify participants as described in "Defining the First Step in a Workflow" on page 5-23.
5. Define the workflow process as described in "About Step Actions" on page 5-9.
6. Save the workflow.
7. Enable the workflow as described in "Enabling a Workflow" on page 5-29.
8. Test the workflow to ensure its validity as described in "Testing a Workflow" on page 5-29.
The User, Group, and Organization Manager are Identity System applications that enable users to view and modify information about themselves, other people, groups, inventory, and any other item that you, the administrator, choose to make available. As explained in the chapter, you can apply business logic to actions performed in the Identity System applications, so that, for example, review and approval must be performed before information about a user can be modified.

With the Identity System’s object template functionality, you can extend an Identity workflow so that information that is added, deleted, or changed is propagated to other applications. With templates non-LDAP schema can be managed in the Identity System, allowing for non-LDAP data to be made available to workflows and to the Identity Event API.

This chapter covers the following topics:

- About Configuring Non-LDAP Data
- Summary of Using Non-LDAP Data in a Workflow
- About Template Objects
- About Template Object Data and Workflows
- Object Template Configuration
- Sample Object Template File
- Creating an Identity Event Plug-In for Template Attributes

### About Configuring Non-LDAP Data

The User Manager, Group Manager, and Organization Manager applications rely on information in an LDAP directory or in an object template:

- **LDAP Directory**—You configure the information in the directory to display data on profile pages and to enable configuration of workflows that manipulate data about users, groups, and objects. The LDAP directory is the authoritative data source for the Identity System.

- **Object Template**—You can manually configure information in an object template to propagate data that is entered during an Identity workflow step to different target data sources. For example, you can configure an Add or Modify User workflow that uses non-LDAP data and makes this available to the Identity Event API (see Oracle Access Manager Developer Guide for details).
Summary of Using Non-LDAP Data in a Workflow

For sending non-LDAP data to a back-end system, the process is as follows:

Task overview: Configuring non-LDAP data for a back-end application

1. Configure an object template, as described in "Object Template Configuration" on page 6-4
   The template should contain objects and attributes that can be understood by the back-end application.

2. Store this file in:
   `IdentityServer_install_dir\oblix\config\template\xxx.tpl`
   where `IdentityServer_install_dir` is the directory where the Identity System is installed and `xxx` is the name of the .tpl file.

3. Configure the template objects and attributes in the Identity System Console, as described in "Making Schema Data Available to the Identity System" on page 3-1 and note the following:
   - Users can only specify values for template attributes in the context of a workflow step.
   - Template attributes are not searchable in the Identity System.
   - You cannot set View or Modify permissions for template attributes.
     You configure access control for template attributes by defining workflow step participants. Only individuals who are step participants have access to these attributes.
   - Template attributes cannot be configured as derived attributes.

---

**Note:** After you configure template objects and attributes in the Identity System Console, do not modify the template file. This restriction is the same as for an LDAP schema, which you also should not change after configuration. Such changes can cause unpredictable behavior and are not supported.

---

4. Associate one or more template attributes with panels on a tab in an Identity System application, for example, the User Manager, as described in "Configuring User, Group, and Organization Manager" on page 4-1.

5. Create a workflow and associate the template attribute with one or more workflow steps, as described in this chapter and "Chaining Identity Functions Into Workflows" on page 5-1.
   The attribute display name appears on the profile page associated with the workflow. However, the attribute value is not shown. This is because the data flow is only one-way from the Identity System to the target application. (In a future release, the data flow will be two-way, which will permit the display of these attribute values.) See "About Template Object Data and Workflows" on page 6-3 for details.

6. Ensure that the workflow has separate enable, commit, and other steps to write the data to each schema that is used in the workflow, as described in "Configuring User, Group, and Organization Manager" on page 4-1.
7. Configure an external action using the Identity Event API and IdentityXML to send the data in the object template to the back-end application, as described in the Oracle Access Manager Developer Guide.

---

**Note:** For non-LDAP attribute values, the IdentityXML actions of Add and Replace do not apply. The action Replace All is the only action that is used. If you create an IdentityXML statement using Add or Replace, the statement is processed as if you used Replace All.

---

The rest of this chapter discusses how object templates work and how to configure an object template.

**About Template Objects**

The Identity System provides a generic object template schema file, located in:

```
Identity_install_dir\oblix\config\template\n```

This is the required location for this file and for any other object template file that you configure.

Template objects created in this file are similar to LDAP objects. The primary difference is that you use LDAP objects and attributes to display data on user profile pages and to configure workflows, whereas template objects are only used in workflows.

You configure a workflow that contains one or more steps that perform actions on the template attributes. When a user invokes the workflow, the Identity System formats the data entered during the relevant step according to the requirements of the object template schema.

The workflow temporarily stores the template attribute values in the step instance. Once the commit step is performed, the data is written to the target back-end system. The data flow is one-way, so that the Identity System does not continue to store this data once it has been written to the back-end system.

Finally, you must create an Identity Event plug-in to send object template data to the target back-end system.

**About Template Object Data and Workflows**

As described in the previous discussion, you can configure a workflow step that uses template attributes to send non-LDAP data to back-end applications. Attribute values that the user enters as part of a workflow step, once committed, cannot be displayed on a profile page. This is because the Identity System sends data to, but does not retrieve the data from, the target application.

When you configure a workflow that uses an object template, you may want to configure commit steps that write both object template data and LDAP data. This would permit you to use your directory to display the LDAP attribute value on a profile page, and to use the template attribute value to send the data to the back-end application.

Since the flow of data from the Identity System to the back-end application is one-way, the user will not be able to verify the data in the Identity System. The user will need to view the target application or its logs to view the data created in the application from the workflow.
If there is an error writing the data to the back-end system, an Identity Event API plug-in can send a message back to the Identity System user.

---

**Note:** You cannot commit data for all data sources in one workflow step. You must configure one commit step for each domain.

---

**Object Template Configuration**

An object template file contains schema-like definitions for objects and attributes in XML format. The objects and attributes that you configure in an object template file correspond to values that can be understood by a back-end application to which you want to write data.

All object template files must reside in:

```
Identity_install_dir/oblix/config/template
```

where `Identity_install_dir` is the directory where the Identity System is installed. The file extension for any object template is `.tpl`.

The Identity Server reads the template file upon startup. If your installation uses multiple servers, you must copy the same template files to each server.

You can define multiple template object classes in a single file or in multiple files. If you create multiple files within the same domain, be aware that the Identity System enforces uniqueness of attributes and classes across files. If an attribute or a class already exists within a domain, the template file is not registered when the Identity Server starts up, and the objects cannot be shown in the System Console.

Similarly, the Identity Server cannot register the template file if it contains any syntax error. Instead, a log entry is generated.

**Format of the Object Template File**

The template file begins with a schema domain statement. The schema domain resolves ambiguity between object classes that have the same names but are used by different data sources, for example, the user object in LDAP and the user object in a back-end application.

The following is an example of a schema domain statement:

```
ObTemplateDefinition domain="exchange" version="1.0"/>
```

At startup time, the Identity Server reads the domain statement. For display purposes, template objects and attributes are shown in the Identity System Console in the following format:

```
attribute.class.domain
```

where the `domain` name is taken from the domain statement in the `.tpl` file.

Note that all domain statements must be unique. If the Identity System detects a non-unique domain, it fails to read the entire `.tpl` file. Note that the following domain names are reserved and cannot be used in your `.tpl` file:

- MIIS
- LDAP

The object template file enables you to define arbitrary name/value pairs. These name/value pairs must match those understood by the target application.
The template definition file is in XML format. The following is an example:

```xml
<?xml version="1.0" encoding="iso-8859-1"?>
<ObTemplateDefinition domain="ABC_APPLICATION" version=1.0">
    <!-- ObAttributeDefinition -->
    <ObAttributeDefinition name="cn" syntax="OB_CIS" maxlen="20"/>
    <ObAttributeDefinition name="sn" syntax="OB_CIS" maxlen="20"/>
    <ObAttributeDefinition name="mail" syntax="OB_CIS" maxlen="20"/>
    <ObAttributeDefinition name="phone" syntax="OB_CIS" maxlen="20"/>

    <!-- ObClassDefinition -->
    <ObClassDefinition name="User">
        <ObAttributeReference name="cn" required="true"/>
        <ObAttributeReference name="sn" required="false"/>
        <ObAttributeReference name="mail" required="false"/>
        <ObAttributeReference name="phone" required="false"/>
    </ObClassDefinition>
    <ObClassDefinition name="Group">
        <ObAttributeReference name="cn" required="true"/>
        <ObAttributeReference name="sn" required="false"/>
        <ObAttributeReference name="uniqueMember" required="false"/>
    </ObClassDefinition>
</ObTemplateDefinition>
```

How Template Objects Appear in the Identity System

Objects and attributes defined in the object template file appear as follows in the Identity System:

- Each object that you define in the .tpl file becomes selectable from the page displayed when you select the following from the Identity System Console:
  
  Common Configuration, Configure Object Class, Add.
  
  The name of the object class as displayed in the Identity System Console is in the format class.domain. The class is taken from the definition that you provide in the .tpl file.

- Each attribute that you associate with an object in the .tpl file becomes selectable from the page displayed when you select Common Configuration, Configure Object Class, object class link, Modify Attributes.
  
  The name of the attribute as displayed in the Identity System Console is in the format attribute.class.domain. The attribute name is taken from the definition that you provide in the .tpl file.

- In each attribute statement, the syntax element determines the attribute data type that is displayed in Common Configuration, Configure Object Class, object class link, Modify Attributes.
You cannot choose the data type for a template object attribute from the Identity System Console. You must configure the data type in the syntax element of the attribute definition.

- Whether this attribute is single- or multi-valued, as seen in Common Configuration, Configure Object Class, object class link, Modify Attributes, is determined by the attribute definition in the .tpl file.
- Other characteristics of the attribute, such as the display name and semantic type, are configured from the Identity System Console.

The Identity System enforces the use of only one semantic type for each domain. For example, you can only assign the Login and Password semantic types once each in a domain.
- Unlike LDAP attributes, the attributes you configure in the .tpl file are not searchable and cannot be configured as derived attributes.

Elements in an Object Template File

The elements of the object template file are as follows.

The object template file begins with a list of attribute definitions. These attributes are referenced in the object definitions later in the file:

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the attribute. This corresponds to the attribute name displayed in the Identity System Console. This parameter is required. Length: 32 (max.) Format: [(a-z)</td>
</tr>
<tr>
<td>syntax</td>
<td>This is the attribute syntax. It corresponds to the attribute Data Type in the Identity System Console. This parameter is required. Format:</td>
</tr>
<tr>
<td>OB_DN</td>
<td>This is synonymous with an LDAP DN attribute. This parameter enables you to configure an Object Selector display type in the Identity System Console. This parameter corresponds to an attribute data type of distinguished name in the Identity System Console.</td>
</tr>
<tr>
<td>OB_BIN</td>
<td>A binary. This corresponds to an attribute data type of binary in the Identity System Console.</td>
</tr>
<tr>
<td>OB_CES</td>
<td>Case Exact String. This corresponds to an attribute data type of string (case-sensitive) in the Identity System Console.</td>
</tr>
<tr>
<td>OB_CIS</td>
<td>Case Insensitive String. This corresponds to an attribute data type of string (case-insensitive) in the Identity System Console.</td>
</tr>
<tr>
<td>OB_INT</td>
<td>Integer. This corresponds to an attribute data type of integer in the Identity System Console.</td>
</tr>
<tr>
<td>OB_TEL</td>
<td>Telephone. This corresponds to an attribute data type of telephone in the Identity System Console.</td>
</tr>
<tr>
<td>OB_POSTAL_ADDRESS</td>
<td>This corresponds to an attribute data type of postal address in the Identity System Console.</td>
</tr>
</tbody>
</table>
Examples:

```
<ObAttributeDefinition name="c" syntax="OB_CIS" cardinality="single" />
<ObAttributeDefinition name="cn" syntax="OB_CIS" cardinality="single" />
```

In the .tpl file, a list of object classes occurs after the list of attribute definitions. Each object class contains an ObClassDefinition statement, followed by a list of ObAttributeReference statements.

### Table 6–2 Elements of ObClassDefinition

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the class. This must be a unique name within the domain. This parameter is required. Length: 32 (max.) Format: [(a-z)</td>
</tr>
</tbody>
</table>

Examples:

```
<ObClassDefinition name="User">
<ObClassDefinition name="Group">
```

You associate an attribute with an object by including the attribute in an AttributeReference statement in the object class definition in the .tpl file. Each ObAttributeReference statement must refer to an attribute defined in an ObAttributeDefinition statement:
The following is an example of an object template file:

```xml
<?xml version="1.0" encoding="iso-8859-1"?>

    <ObAttributeDefinition name="c" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="cn" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="department" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="l" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="location" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="mail" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="ou" syntax="OB_CIS" cardinality="single" />
    <ObAttributeDefinition name="uid" syntax="OB_CIS" cardinality="single" />

    <ObClassDefinition name="person">
        <ObAttributeReference name="c" required="false" />
        <ObAttributeReference name="cn" required="false" />
        <ObAttributeReference name="department" required="false" />
        <ObAttributeReference name="l" required="false" />
        <ObAttributeReference name="location" required="false" />
        <ObAttributeReference name="mail" required="false" />
        <ObAttributeReference name="ou" required="false" />
        <ObAttributeReference name="uid" required="false" />
    </ObClassDefinition>

    <ObClassDefinition name="organizationalUnit">
        <ObAttributeReference name="l" required="false" />
        <ObAttributeReference name="ou" required="false" />
    </ObClassDefinition>

    <ObClassDefinition name="locality">
        <ObAttributeReference name="l" required="false" />
    </ObClassDefinition>

    <ObClassDefinition name="country">
        <ObAttributeReference name="c" required="false" />
    </ObClassDefinition>
</ObTemplateDefinition>
```

### Table 6–3  Associations Between Attributes and Objects

<table>
<thead>
<tr>
<th>Element name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the template attribute. This parameter is required. The attribute reference must be unique within the object class. The 'name' must be the name of an existing attribute definition (ObAttributeDefinition) in this domain. Length: 32 (max.) Format: [(a-z)</td>
</tr>
<tr>
<td>required</td>
<td>Specifies whether the attribute is required or optional in the context of the class definition. This parameter is optional. Default: 'false'. Format: ['true'</td>
</tr>
</tbody>
</table>

Examples:

```
<ObAttributeReference name="cn" required='true'>
<ObAttributeReference name="mail" required='false'>
```
Creating an Identity Event Plug-In for Template Attributes

The Oracle Access Manager Developer Guide describes how to create a plug-in to send data from an Identity System workflow to a back-end application. Keep in mind the following when creating this plug-in:

- It is no longer possible to do bulk reactivations using the Identity Event API.
- When using IdentityXML and the Identity Event API, note that the only permitted action when sending attributes from the Identity System is Replace All. If you create an IdentityXML statement using Add or Replace, the statement is processed as if you used Replace All.
This chapter covers tasks that affect the basic functionality of Oracle Access Manager, including configuring multiple languages and directory and database server configuration.

This chapter also discusses how to control the appearance and functionality of Identity System applications. For example, through the searchbase and style sheet, you may want to control what users can view or the actions they can perform in Identity System applications. You may want to add additional Identity Servers or WebPasses for better performance.

To help you manage these tasks, you can specify other Oracle Access Manager Administrators and Master Identity Administrators, as described in "Specifying Identity System Administrators" on page 2-1.

This chapter contains the following topics:

- Configuring Styles for Identity System Applications
- Configuring Multiple Languages for Oracle Access Manager
- Configuring Identity Server Settings
- Managing Identity Servers
- Managing Directory Server Profiles
- Managing RDBMS Profiles
- Configuring WebPass
- Configuring Password Policies
- Configuring the Access Manager SDK for the Identity System
- Cloned and Synchronized Components

**Note:** You must be a Master Administrator to configure the Identity System. Most tasks in this chapter are performed through the Identity System Console.

See also "Changing Transport Security Modes" on page 8-1, "Implementing .NET Features" on page D-1, "Logging" on page 10-1, "Auditing" on page 11-1, and "SNMP Monitoring" on page 12-1.
Configuring Styles for Identity System Applications

You use styles to change the appearance or limit functionality across Identity System applications. A style is a named collection of style sheets, graphics files, and scripts that define a certain user interface for the system. A style is based on style sheets that define the appearance of elements in application pages, including the names of fields and functions, the GIF images used to specify the colors, shapes, and sizes of tabs and buttons, and the fonts used for tab and button names.

Styles can be cosmetic or functional. A cosmetic style determines the appearance of Identity System applications, such as color, or the appearance of tabs. A functional style determines the functionality of Identity System applications. That is, you can add, modify, or remove particular functions on an Identity System application page. For example, you can remove the Substitute Rights function from all three Identity System applications. The Identity System provides a default style named Classic Style but you can use PresentationXML to develop other styles to change the appearance of the Identity System.

You can use the Customize Styles option in the Identity System Console to set the default style, create styles, modify styles, or delete styles. However, when you create or modify a style through the Identity System Console, the system copies the existing style sheet and renames it. You must then open the style sheet and manually make the necessary changes.

See the information on designing the GUI with PresentationXML in the Oracle Access Manager Customization Guide for details about creating and modifying style sheets.

---

**Note:** You can change only the appearance of Identity System application pages. The System Console uses a style setting that cannot be modified.

---

This section discusses the following topics:

- Viewing a Style
- Adding a Custom Style Directory
- Deploying a Style
- Changing a Style Name
- Modifying a Style
- Deleting a Style
- Setting the Default Style

**Viewing a Style**

You can use the following procedure to view currently configured styles. This leads to the Customize Styles page, which is the starting point for style-related procedures.

**To view currently configured styles:**

1. From the Identity System Console, select System Configuration.
2. In the left navigation pane of the System Configuration page, select Styles.

   The Customize Styles page appears. The following example shows the Classic Style, which is the default provided by the Identity System.
3. Click the style’s link to view a style’s parameters.

You will see the style name, directory where style files are stored, and the source of those files (in the Copy from field).

Adding a Custom Style Directory

The Identity System out-of-the-box provides one default presentation style, known as Classic Style. The IdentityServer_install_dir/identity/oblix/lang/en-us/style0 directory contains XSL wrapper style sheet files for the Classic Style. Most of these files point to global shared style sheet template files for all languages in the IdentityServer_install_dir/identity/oblix/lang/shared directory.

The process of creating a custom style for presentation of Identity System pages for user applications begins by adding a new style to the Identity System, as described here. The result is a new custom style directory with XSL wrapper style sheet files. Then you may either copy and modify an existing style or create an entirely new style based on new style sheets.

**Note:** You may only change styles for user applications. The System Console always uses the default style.

In either case, adding a style (and custom style directory) to the Identity System follows the same method: you provide a style name and a directory name for your style files. You may also choose an existing style on which to base your new style. After selecting your new style as the default, you can begin customizing copies of Identity System style sheets or creating your own. To complete the process, you need to copy your new style sheets and GIFs to all Identity Servers and WebPass machines, respectively.

Before adding your first new style, there are a few things to take into account:

**Multiple Languages:** To support multiple languages, the Identity System provides a specific named directory for each installed language. For example, /lang/en-us is the default English language directory, /lang/fr-fr is the French language, and so on. Both the Identity System default and your custom style directories are stored within each installed language directory.

Suppose you have a French Language Pack installed. In this case, both lang/en-us and lang/fr-fr directories include the /style0 directory. When you add a style to the
Identity System, your new style directory is added in both the lang/en-us and lang/fr-fr directories:

- IdentityServer_install_dir/identity/oblix/lang/en-us/NewStyle
- IdentityServer_install_dir/identity/oblix/lang/en-us/style0
- IdentityServer_install_dir/identity/oblix/lang/fr-fr/NewStyle
- IdentityServer_install_dir/identity/oblix/lang/fr-fr/style0

Your Style Name: The Identity System uses the style name you supply internally. As a best practice, your style name should match your custom style directory name and should be easily recognizable. Do not include white spaces, &, *, or parentheses () in the name.

Your Style Directory Name: The directory name you specify will be used to create a directory for related wrapper style sheet files. This name should match your style name and follows the same rules for naming.

In addition, your custom style directory name is also assigned to an XML document (a duplicate of style0.xml) that is created to identify the status and origin of your new style. For example, if your new directory is named Pastel, a file is created and stored as:

- IdentityServer_install_dir/identity/oblix/config/style/Pastel.xml

No other files are created during this process. However, the styles.xml file will be updated to include a NameValPair specifying the directory and style name and directory name that you supply. For example:

- IdentityServer_install_dir/identity/oblix/config/style/styles.xml

The style information files in the config/style are not included on WebPass. For more information, see the Oracle Access Manager Customization Guide.

Copy from an Existing Style: You may copy style sheets from an existing style directory or select None to build a style that is not based on an existing style or to customize only selected style sheets.

Note: If this is the first style being added, the only available style is the default Classic Style.

Selecting None: If you select None, the directory that is created is empty and you must manually create a set of style sheets for your new style or selectively copy files from the /style0 directory to work with.

If you select None, your new style's status will appear as "Under Construction" within the Identity System until you select a style for it. An empty style directory is created automatically, and a duplicate of style0.xml is created in IdentityServer_install_dir/identity/oblix/config/style/style0.xml.

Selecting a Style: When you select a style to copy from, a duplicate of the directory you copied from is created under the custom directory name you specify. The copied files retain relative references to the directory you copied from (/style0 or a custom style that you chose to copy from).

During customization, you only change references that refer to the changed version of the style sheet in the your new style directory.

Results: Suppose you added a new style named Pastel in a directory named Pastel and you copied from the default Classic Style. In this case, the Pastel directory is created in
each langTag directory and populated with duplicate files from Classic Style's directory, /style0:

\[ \text{IdentityServer_install_dir/identity/oblix/lang/en-us/Pastel} \]

The Classic Style directory, /style0, remains intact as:

\[ \text{IdentityServer_install_dir/identity/oblix/lang/en-us/style0} \]

In addition, an XML document that duplicates style0.xml is created when the new style is selected as the default, named after the directory you created, and stored with style0.xml in config/style:

\[ \text{IdentityServer_install_dir/identity/oblix/config/style/Pastel.xml} \]

\[ \text{IdentityServer_install_dir/identity/oblix/config/style/Pastel.xml.lck} \]

For additional information and a look at the content of various files, see the Oracle Access Manager Customization Guide.

**To add a style**

1. From the Identity System Console, select System Configuration, then select Styles to display the Customize Styles page.

2. Click the Add Style button to display the Add Style page.

   **Note:** The style name you specify here is used internally by the Identity System and should match the directory name you supply.

3. Fill in the fields on the Add Style page, for example:
   - **Name:** Pastel
   - **Directory Name:** Pastel

4. In the Copy From field, select an existing style to use as a template for your new style.
   - For example:
     - Classic Style

5. Click Save to save the new style (or Cancel to exit this page without saving the style).
   - The new style name is listed in the Customize Styles page and one or more directories were created to hold the new wrapper style sheets.

6. Select the new style as your default style, as follows:
   - a. Click the Setup Default Style button to display the Set Default Style page.
   - b. Click the Make Default button beside your new style name, then click Save.

7. Check your file system for the new style directory name you specified.

Next, you will customize styles, as discussed in the Oracle Access Manager Customization Guide.

**Deploying a Style**

The following procedure enables you to make a style available to end users:
To deploy a style
Append the directory name containing the style sheets to the URL of the first page where users enter the Identity System, as follows:

```
&style=directory_name
```

where `directory_name` is the name of the directory that contains the style sheets for the Identity System.

Changing a Style Name
You can change the name of a style using the steps in the following procedure as a guide.

**To change a style name**
1. In the Customize Styles page, click the name of the style that you want to rename.
   The View Style page appears.
2. Click Modify.
   The Modify Style page appears.
3. Change the style name.
4. Click Save to save your changes (or Cancel to quit without saving your changes).
   The View Style page displays the style's new name.

Modifying a Style
You cannot modify Classic style, the default style provided by the Identity System, because it is used by the Identity System. However, you can modify any of the custom styles you have created.

**To change a style**
1. Modify the corresponding style sheets, as discussed in the chapter on designing the user interface with PresentationXML in the Oracle Access Manager Customization Guide.
2. When you have completed your changes, copy the style sheets to each Identity Server and to each WebPass linked to the Identity Server where the style sheets were modified.

Deleting a Style
You cannot delete the Classic Style, the default style provided by the Identity System, because it is used by the Identity System. However, you can delete any of the custom styles you have created.

**To delete a custom style**
1. In the Customize Styles page, click the name of a style.
   The View Style page appears.
2. Click Delete.
3. When prompted, confirm your deletion.
   The Customize Styles page reappears.
4. Delete the new style sheets from the new style directory in all the other Identity Servers, as well as the WebPass installation area.

**Setting the Default Style**

You use the Setup Default Style option to choose the default style for applications.

**Note:** You cannot select a style that has the *Under Construction status*.

**To set the default style**

1. In the Customize Styles page, click Setup Default style.
   
   The Set Default Style page appears.

2. Click Make Default beside your choice.

3. Click Save.

   In the Customize Styles page, the words "Available & Current Default” appear next to the style you selected.

**Configuring Multiple Languages for Oracle Access Manager**

As discussed in the *Oracle Access Manager Installation Guide*, the English language is installed automatically. However, you can install one or more Oracle-provided Language Packs. Language Packs enable you to provide localized information to end users and administrators in the languages identified in the *Oracle Access Manager Introduction*.

Some display names and attributes appear for end users in Identity System applications (User Manager, Group Manager, and Org. Manager), as well as in administrator applications (Identity System Console, Access System Console, and Policy Manager).

For end-users, Oracle Access Manager 10g (10.1.4.0.1) enables the display of static application data such as error messages, and display names for tabs, panels, and attributes in supported end-user languages. Administrative information can be displayed in only supported administrator languages.

After installation and setup, you must configure languages for use and localize attribute display names, which you can accomplish at the following levels:

- Object Class level
- Tab level
- Panel level
- Search Result Attributes level

**Note:** Oracle recommends that you configure display names at the Object Class level because this is the highest level. If you choose to configure display names at a lower level, ensure that you provide display names at each level for all languages.
Task overview: Configuring multi-language functionality

1. Install and set up Oracle Access Manager with one or more Oracle-provided Language Packs, as described in the Oracle Access Manager Installation Guide.

2. Enable the languages you have installed and want to use, as described in "Managing Multiple Languages" on page 7-14.

3. Configure the applications to use an installed language by manually entering the display names for labels and attributes. For example:
   - Localize object class attributes, as described in "Localizing Attribute Display Names" on page 3-20.
   - Localize display names for tabs, group type panels, search result attributes, and reports, as described in "Configuring User, Group, and Organization Manager" on page 4-1.
   - Localize workflow panel names, as described in "Localizing Workflow Panels" on page 5-56.
   - Localize tab names to display them in other languages, as described in "Localizing Tabs" on page 4-5.
   - Localize search result attributes, as described in "Viewing, Modifying, and Localizing Attributes that Appear in Search Results" on page 4-6.

Selecting a Language for Administrative Pages

If you have installed and configured more than one language, you can determine the language to use for administrative information in the Identity and Access System Consoles, and Policy Manager. You do this from your browser. See your browser’s documentation for details.

If administrative pages are requested in a language that is not supported for administrative information, the default language that was selected during product installation is used to display administrative pages.

Language Evaluation Order for End-User Applications

After enabling installed languages, and configuring attributes to use the installed languages, the language used to display application pages to an end user is chosen according to the following evaluation order.

Evaluation Order

1. The language specified in the URL.

   The user can specify a language in a URL. For instance, when a user selects the Create User function in the User Manager, he or she can append lang=fr-fr to display the User Manager page in French. The application first looks for a language preference specified in the URL for a resource. The user or the administrator can specify a language in the URL by appending lang=languageTag, where languageTag is a language tag in RFC 1766 format.

   The following example returns the Create User Profile page in French:

2. The language stored in a parameter called LangCookie in the ObTEM cookie.
Once you specify the language in a URL as in the previous step, this language is set in the LangCookie parameter. The ObTEM Cookie is created when the user logs in and is maintained for the duration of the user’s session. If a URL does not contain the language specification, The application checks the ObTEM Cookie, which lasts for the duration of the session. The ObTEM Cookie can also be set on a form or a page.

3. The language specified in the HTTP header variable, HTTP_OBLIX_LANG.
   You can create an authentication or authorization success header variable to contain this value, as explained in the chapters on authentication and authorization in Oracle Access Manager Access System Administration Guide. If you want to change the name of the HTTP_OBLIX_LANG header variable, you can do so in the following files:
   
   IdentityServer_install_dir/oblix/apps/common/bin/globalparams.xml
   
   PolicyManager_install_dir/access/oblix/apps/common/bin/globalparams.xml
   
   where IdentityServer_install_dir is the directory where the Identity Server is installed, and PolicyManager_install_dir is where the Policy Manager is installed.
   
   See the Oracle Access Manager Customization Guide for information on globalparams.xml.

4. The value set by the user’s Web browser determines the default language. This value is specified in the header variable, Accept-Language.
   If the application does not find the HTTP_OBLIX_LANG header variable, it looks for the Accept-Language header variable that is set in the user’s browser.

   **Note:** Both the HTTP_OBLIX_LANG and the Accept-Language header variables are configurable. See the Oracle Access Manager Customization Guide for information.

5. The default language of the Oracle Access Manager installation.
   If the Accept-Language header variable is not found in the user’s browser, the application looks in the obnls.xml configuration file for the default language of the Oracle Access Manager installation.
   
   The obnls.xml file is located in the IdentityServer_install_dir/identity/oblix/config directory. IdentityServer_install_dir is the directory where the Identity Server is installed.
   
   See “Managing Multiple Languages” on page 7-14 for details.

### Configuring Identity Server Settings

Configuring an Identity Server includes specifying the duration of user sessions, specifying email addresses for user feedback, configuring mail servers for notification events, managing the cache, and enabling multiple languages.

You use the Identity System Console to view and modify server settings.

This section discusses the following topics:

- Configuring Session Timeout
- Customizing Email Destinations
- Configuring a Mail Server
Managing Caches

Managing Multiple Languages

To view or modify server settings

1. In the Identity System Console, select System Configuration, then select Server Settings.

   The View Server Settings page appears, which looks something like the one in the following screen shot.

   ![View Server Settings](image)

   **View Server Settings**
   
   This page contains the list of all settings, used by the product. Click any link to change a particular value. You must restart every Identity server before the new values can take effect.

   **Configure session timeout**
   
   180 Minutes

   **Customize email destinations**
   
   Bug Reports
   Feedback
   Webmaster

   **Mail Server**
   
   Server Name: dd
   Server Port Number: 25
   Domain name: Asynch
   Mail Send Style: Async
   Mail Queue Size: 100
   Mail Style: Supports MHTML email

   **COREid URL Prefix**
   
   Cache
   Cache enabled: Yes

   **Multi Language**
   
   Multi-Language enabled: Yes

2. To view or modify a value for a setting, click the link for the setting (Mail Server or Multi-Language, for example).

3. Make the changes you want, if any.

4. Click Save to save your changes (or Cancel to exit without saving your changes).

5. Restart the Identity Server for the new values to take effect.

Configuring Session Timeout

Configuring session timeout enables you to specify user-idle session time (in minutes). The user session automatically ends when the specified idle time elapses.

The setting in this page applies to all users and all Identity System applications. You cannot have different settings for different users and applications.

A session timeout does not apply if you are using a Web-server-based login, such as through a WebGate, because the WebGate instance handles the timeout.

**Note:** Resources protected by Web single sign-on always ignore idle session timeout settings.
To configure the length of a user’s Identity System session

1. In the Identity System Console, select System Configuration, then select Server Settings, then click Configure session timeout to display this page.

2. Choose the timeout option:
   - **No Timeout**: User sessions continue indefinitely as long as the browser is active.
   - **Idle Session Timeout**: The number of minutes to wait before ending an idle session. After this period of inactivity elapses, the user must log in to the application to continue.

   There are several reasons for ending an idle session after a predetermined time period. A short session protects users who leave their workstations without locking them, making them vulnerable to unauthorized use.

   - **Refresh Period**: Configures how often to update the user session time stamp. A value of 0 (zero) means the session time stamp is updated on every request. Oracle recommends you set this value to 1/4 of the Idle Session Timeout value.

3. Click Save to save your changes (or Cancel to exit the page without saving).

### Customizing Email Destinations

Use the Customize Email function to specify email addresses for user feedback. End users access these addresses by clicking About on the side navigation bar, then clicking Submit Admin Feedback or Submit Oracle Feedback.

To customize email destinations

1. In the Identity System Console, select System Configuration, Server Settings.

2. In the Server Settings page, click Customize Email Destinations to display this page.
3. Type email addresses for the following fields:
   - **Email address for Bug Reports**: You must change this address if you plan to send it to a person or alias in your organization. This person or department can either solve the problem or contact Oracle for help.
   - **Email address for User Feedback**: If users in your company cannot send email outside the local network, you can type an internal address in the Bugs and Feedback fields. Provide the address of a user who is responsible for forwarding the information to Oracle.
   - **Webmaster's email address**: Type the email address of the user in your company responsible for administering Oracle Access Manager.

4. Click Save to save your changes (or Cancel to exit the page without saving).

**Configuring a Mail Server**

The Identity System can issue email alerts during request ticket processing and group management, notification of password expiration, or modification of a Profile attribute. Use the SMTP server configuration function to configure how the Identity System handles these emails.

When configuring a mail server, one of your options is Supports MHTML email. MHTML stands for MIME encapsulation of aggregate documents, such as HTML.

MHTML lets you send an HTML document with in-line graphics, applets, and linked documents in a MIME multipart/related body format. You can provide links to other parts included in the HTML document by using the CID (content-ID) URLs or any other kind of URL. The linked body part is identified in its header by either a content-ID (linked to by CID URLs) or a content-location (linked to by any other kind of URL).

The main difference between HTML and MHTML is that with MHTML, graphics are in-line in the email instead of referenced with a link as in HTML format.

**To configure a mail server**

1. In Identity System Console, select System Configuration, then select Server Settings.
2. In the Server Settings page, click Mail Server to display this page.
Configuring Identity Server Settings

3. In the Server Name field, enter your SMTP server name.
4. In the Server Port Number field, type the mail server's port number.
5. In the Domain name field, type the Web server's domain name.

**Note:** This field is optional, but specifying the domain name allows the SMTP connection to be set up according to RFC 821.

6. Select an option under Mail Send Style:
   - **Synchronous Mail**—Sent from the process, such as Modify Attribute, that triggered the email. If an error occurs connecting to the mail server or the server is down, the email is not sent and cannot be regenerated.
   - **Asynchronous Mail**—Uses a thread to queue emails from all applications and sends them one at a time. If the mail server cannot be reached, the thread re-sends the email. Queued mails are saved to disk. If you select Asynchronous Mailer, specify the mail queue size.

   Select an option under Mail Style.

   Click Save to save your changes (or Cancel to exit the page without saving).

Managing Caches

You can view the contents of the Identity Server cache, load the cache with new information, and clear the memory cache to resolve inconsistencies.

**To view Identity System cache details**

1. In the Identity System Console select System Configuration, then select Server Settings.
2. In the Server Settings page, click Cache to display the page.
3. Select the option you want to view the cache contents, or load or clear the memory cache.

See the *Oracle Access Manager Deployment Guide* for more information about managing caches.

### Managing Multiple Languages

In new installations, the Multi-Language feature is enabled by default. You can enable, disable, and specify preferred languages in the Identity System Console.

**Note:** When you upgrade from an older version, the Multi-Language feature is disabled. To enable this feature complete the steps in the following procedure.

To manage a language

1. From the Identity System Console, select System Configuration, then select Server Settings.
2. From the View Server Settings page, select Multi-Language.
   
   The Manage Multiple Languages page appears. Details such as available languages, the order of preference, and whether a language is enabled or not appear on this page.
3. Determine which languages to enable or disable.
   - Enable—Select a language and click Enable to enable it.
   - Disable—Select a language and click Disable to disable it.
4. Click Back to go back to the Server Settings page.

**See Also:** "Configuring Multiple Languages for Oracle Access Manager" on page 7-7

### Managing Identity Servers

Managing Identity Servers consists of tasks such as adding or deleting Identity Servers, and modifying an Identity Server’s parameter values. See the *Oracle Access Manager Installation Guide* for details about installing an Identity Server. To remove a server completely, you must un-install it.

This section includes the following topics:

- Setting Up Multiple Identity Servers
- Adding an Identity Server
- Viewing and Modifying Identity Server Parameters
- Deleting Identity Server Parameters
- Managing an Identity Server Service from the Command Line

### Setting Up Multiple Identity Servers

The following overview outlines how to set up multiple Identity Servers.
**Task overview: Setting up multiple Identity Servers**

1. Install the first Identity Server and a WebPass, then set up the Identity System as described in the *Oracle Access Manager Installation Guide*.

2. Add a new Identity Server instance in the Identity System Console, as described in the procedure "Viewing and Modifying Identity Server Parameters" on page 7-18.

3. Associate the new Identity Server instance with a WebPass and specify the priority as Primary, as described in "Managing Associations Between Identity Servers and WebPass" on page 7-44.

4. Modify the WebPass instance to set the maximum connections to the appropriate number to communicate with all primary Identity Servers, as described in "Adding or Modifying a WebPass" on page 7-40.
   
   You must wait at least one minute before step 5 to ensure that the WebPass configuration file, webpass.xml, is updated with the new instance information. Otherwise, the WebPass instance may not receive the new information and cannot connect to the new Identity Server instance.

5. Wait at least one minute before stopping all installed Identity Servers.

6. Install the new Identity Server and indicate that this is not the first Identity Server for this directory server, as described in the *Oracle Access Manager Installation Guide*.
   
   You do not need to update the schema again.

7. Set up the new Identity Server you installed, as explained in the *Oracle Access Manager Installation Guide*.

---

**Adding an Identity Server**

When you want to add a new Identity Server instance to your installation, use the following procedure.

**To add an Identity Server**

1. In the Identity System Console, click System Configuration, then select Identity Servers.
   
   The List all Identity Servers page appears with links to existing Identity Servers.

2. Click the Add button.
   
   The Add a New Identity Server page appears.
3. Fill in the Name through Number of Threads fields as follows:

- **Name**: Type the name of the Identity Server.
- **Hostname**: Type the name of the machine on which the Identity Server is running.
- **Port**: Type the port number of the Identity Server.
- **Debug**: Specify whether you want to store debug information on the low-level traffic between the Identity Server and the WebPass.
- **Debug File Name**: Type the name and path of the debug file. The default path is `IdentityServer_install_dir/oblix/logs/debugfile.lst`, where `IdentityServer_install_dir` is the directory where the Identity Server is installed.
- **Transport Security**: Select the security method used for communications between the WebPass and the Identity Server:
  - **Open**: Used if security is not required. No transport security.
  - **Simple**: Provides basic security. Communications are encrypted using TLS v1 (Transport Layer Security, RFC 2246). Communicating elements authenticate one another using a password-based mechanism. All elements that use simple security must use the same password throughout the installation. The Identity System provides the certificate that performs the authentication.
  - **Cert**: Used if you manage an internal Certificate Authority (CA). Communications are encrypted using TLS v1. In addition, each element, both client and server, must present an X.509 certificate when establishing a connection. The certificate must be provided by a third party such as VeriSign.
Managing Identity Servers

Configuring Global Settings

4. Complete the Audit information for your environment.

- **Maximun Session Time (Hours):** Type the maximum period of time that a connection between the WebPass and Identity Server can remain open. When the time expires, the connection closes and a new one is opened.
- **Number of Threads:** Type the maximum for number of concurrent requests that the Identity Server is allowed.

5. Fill in the Scope File Name field as follows:

**Note:** Cert—Used if you manage an internal Certificate Authority (CA). Communications are encrypted using TLS v1. In addition, each element, both client and server, must present an X.509 certificate when establishing a connection. The certificate must be provided by a third party such as VeriSign.

- **Audit File Maximum Size (Bytes):** Type the number of bytes an audit file can contain. When this amount is reached, the audit file is time stamped and saved, and a new file is created.

5. Complete the Audit information for your environment.

- **Audit to Database Flag (Auditing On/Off):** Selecting On directs audit information to a configured database. Off is the default.

- **Audit to File Flag (Auditing On/Off):** Selecting On directs audit information to a file whose name you specify in the next field. Off is the default.

- **Audit File Name:** Type the name of the auditing file where the Identity Server's auditing information is written.

You can specify an absolute or a relative path for the audit file for the Access or Identity Server. To specify a relative path, use either "." or ".." at the beginning of the path. For example, you can input the following relative path:

```
./auditfile.lst
```

This relative path creates an audit file in the following location:

```
Component_install_dir\oblix\apps\common\bin\auditfile.lst
```

Where `Component_install_dir` is the root installation directory for the associated Access or Identity Server.

The following relative path:

```
../logs/auditfile.lst
```

Creates `Component_install_dir\oblix\logs\auditfile.lst`.

**Note:** For IIS deployments, in order for your audit files to be visible, you must grant write permissions to the IIS user (the system user running the Web server) for the %TEMP% and %TMP% directories and to the audit file destination directory.

- **Audit File Rotation Interval (Seconds):** Type a number representing the number of seconds that elapse before audit file rotation occurs. Rotation means that the audit file is time stamped and a new file is created. The default is 7200. A setting of 0 means that the audit file never times out, and audit information continues to be added to the file.
Scope File Name: Type the name of the file that logs bug reports. When a bug report is generated, the information displayed on the page also is logged to a file. This parameter specifies the name of the file for Bug Report or OB_SCOPE messages.

6. Enter details for the SNMP state and agent registration port for your environment.

See “SNMP Monitoring” on page 12-1 for details.

- SNMP State: Selecting On enables SNMP monitoring. Off is the default.
- SNMP Agent Registration Port: The port that the SNMP agent listens on.

---

**Note:** Even if SNMP monitoring is On, to retrieve SNMP statistics you must configure your Network Management Station (NMS) to process the information defined in the Management Information Base (MIB). See details on the SNMP Agent MIB variables, later in this book.

---

7. Click Save to finish defining your new Identity Server (or Cancel to exit without saving).

**Viewing and Modifying Identity Server Parameters**

You use the following procedure in the Identity System Console to view or modify parameters.

**To view or modify an Identity Server’s parameters**

1. In the Identity System Console, select System Configuration, then select Identity Servers.

A list of existing Identity Servers appears, displaying each server’s name, hostname, and port number.

2. Click the name of an Identity Server to view its parameters.

The Details for Identity Server page appears. The server’s parameters are listed on this page.

3. Click Modify.

The Modify Identity Server page appears.

4. Modify the parameters as necessary.

See “To add an Identity Server” on page 7-15 for information about each parameter.

5. Click Save to save your changes (or Cancel to exit without saving).

**Deleting Identity Server Parameters**

You use the following procedure in the Identity System Console to delete Identity Server parameters.

---

**Note:** If you delete an Identity Server from the Console, an attempt to start that server from a command line will fail because the Identity Server’s parameters have been deleted from the Console.

---
To delete an Identity Server’s parameters

1. In the Identity System Console, click System Configuration, then select Identity Servers.

   A list of existing Identity Servers appears, displaying each server’s name, hostname, and port number.

2. In the List all Identity Servers page, select the Identity Server you want to delete.

3. Click Delete.

4. When asked to confirm your decision, click OK.

   The server’s name is removed from the list of servers.

Managing an Identity Server Service from the Command Line

You can use the command line tool config_ois to manage tasks related to the Identity Server Service in the Windows Service window.

You can install the Identity Server Service and perform other tasks such as starting or stopping the service with the following commands:

Table 7–1 Commands for config_ois

<table>
<thead>
<tr>
<th>Command</th>
<th>Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-i install_dir]</td>
<td>Specifies the installation directory for the Identity Server Service.</td>
</tr>
<tr>
<td>-v</td>
<td>Specifies the Service name.</td>
</tr>
<tr>
<td>[-a &lt;start, stop, query, install, remove&gt;]</td>
<td>Specifies the action to be performed.</td>
</tr>
</tbody>
</table>

C:\IdentityServer_install_dir\identity\oblix\apps\common\bin\config_ois.exe -q -i c:\IdentityServer_install_dir\identity -v Identity_ServiceName -a query

where IdentityServer_install_dir is the directory where Identity Server is installed and Identity_ServiceName is the name of the Identity Server Service.

The query displays the following information:

Sample Srv configuration:
Service Type: 0x110
   Start Type: 0x2
Err Control: 0x1
Binary path:
c:\COREid\identity\oblix\apps\common\bin\ois_server.exe
Load order group:
Dependencies:
    Dependencies: LocalSystem

Managing Directory Server Profiles

When installing components that communicate with a directory server, you specify the directory server with which the component communicates. Each component communicates with the directory for a specific purpose:

- Identity Server: When you install an Identity Server, you designate an LDAP directory server where configuration data is to be stored, and you designate where
user data is stored. The user data may be on the same directory server where the
configuration data is stored, or it may be a different directory server.

- Policy Manager and Access Server—When installing a Policy Manager or an
Access Server, you also designate where user data and configuration data are
stored. Additionally, you designate where access policy data is stored.

---

**Note:** As of release 7.0, you may have user data stored on one
directory server type and configuration and policy data stored
together on a different directory server type. For data storage details,
see the *Oracle Access Manager Installation Guide*.

---

The following topics provide more information:

- About LDAP Directory Server Profiles
- Creating an LDAP Directory Server Profile
- Viewing an LDAP Directory Server Profile
- Modifying an LDAP Directory Server Profile
- Rerunning Setup Manually
- Adding Database Instances to LDAP Directory Server Profiles
- Deleting an LDAP Directory Server Instance
- Working With Multiple Directory Searchbases

---

**About LDAP Directory Server Profiles**

For each type of data that Oracle Access Manager requires—configuration data, user
data, and policy data—an LDAP directory server profile identifies the precise location
of the data. The location of policy and configuration data is also stored in .xml files for
the Identity Server, Access Server, and Policy Manager. A directory server profile
contains the connection information for one or more directory servers that share the
same namespace and operational requirements for Read, Write, Search, and so on. The
connection information includes a name, a domain or namespace to which it applies, a
directory type, and a set of operations. A default directory server profile is created
automatically each time you install the Identity Server and specify new directory
server connection information.

You can create additional LDAP directory server profiles for load-balancing and
failover. You can create directory server profiles that correspond to the partitions of
your directory information tree (DIT). Partitioning can potentially increase
performance by freeing CPU cycles to perform read and write operations on a specific
portion of the DIT. This can be especially beneficial in installations with multiple
directory servers and machines.

You can also create LDAP directory server profiles that specify different operations for
master and replicated copies of the DIT. For example, you could specify that write
operations take place only in the master, and the replica can accept only read
operations.
Managing Directory Server Profiles

Creating an LDAP Directory Server Profile

Creating an LDAP Directory Server Profile

The following screen shot shows the Configure Profiles page in the Identity System Console.

The top portion of Configure Profiles page shows details for the directory server that contains user data and configuration data. The central portion of the page includes links you can use to configure LDAP Directory Server Profiles. The bottom portion of the page includes links to configure RDBMS profiles. For details about RDBMS profiles, see "Managing RDBMS Profiles" on page 7-35.

Creating an LDAP Directory Server Profile

Viewing an LDAP Directory Server Profile

Modifying an LDAP Directory Server Profile

Note: You must always support read, search, modify, create, and delete operations for the directory server profile containing the Oblix tree. You cannot create a read-only or write-only directory server profile for the Oblix tree. If you change settings for the configuration or policy data directory profile, you need to rerun Identity Server and Policy Manager setup and reconfigure the Access Server. For details, see "Rerunning Setup Manually" on page 7-28.
Managing Directory Server Profiles

Clicking the Directory Server link displays the Directory Server Configuration page. If you change the communication mode for the directory server, or hostname or port number, you must also change this information on the Directory Server Configuration page and rerun setup. See "Changing Transport Security Modes" on page 8-1 for details about this type of change.

The middle portion of the Configure Profiles page is titled "Configure LDAP Directory Server Profiles" followed by a list of links to LDAP directory server profiles for user data, configuration data, and policy data. You can click a profile link to review specifications and supported operations for the profile. You can specify all operations or specific operations, as listed in Table 7-2.

Table 7-2  Supported Directory Server Operations

<table>
<thead>
<tr>
<th>Category</th>
<th>Operation</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Operations</td>
<td>All operations are allowed (the default).</td>
<td></td>
</tr>
<tr>
<td>Search</td>
<td>Search Entries</td>
<td>The Authenticate User operation allows users to authenticate within the name space of the directory server profile. Selecting this option results in a list of the login pages for Authentication Domain.</td>
</tr>
</tbody>
</table>
The following procedure shows how to create a directory server profile.

**To create a directory server profile**

1. From the Identity System Console click System Configuration, then click Directory Profiles.

2. Click Add to create a new LDAP directory profile and display the Create Directory Server profile page.

---

**Note:** To modify a directory server profile, click the name of the profile in the list under Configure LDAP Directory Server Profiles. In this case, the Modify Directory Server Profile Page appears as described in "Modifying an LDAP Directory Server Profile" on page 7-28.
Managing Directory Server Profiles

3. In the Name field, enter a name for the directory server profile.
   This name is for informational purposes only. The Identity System uses the naming convention default `<Identity Server id>` for all default directory server profiles automatically created during Identity System installation.

4. In the Name Space field, enter the searchbase for the directory server profile.

   **Note:** Use caution that this namespace does not overlap with other directory server profile namespaces. Overlapping namespaces result in duplicate entries. Exceptions to overlapping name spaces include a directory server profile for a Microsoft Active Directory sub-domain, and the directory server profile containing the configuration DN.

5. Select the type of directory server.
Siemens DirX and Sun: When using either Siemens DirX or Sun (formerly iPlanet) exclusively, you have the option to store data either separately or together, as discussed in the Oracle Access Manager Installation Guide.

Oracle Data Anywhere: Requires integrating with the Oracle Virtual Directory Server (VDS).

Oracle Data Anywhere is a data management layer that aggregates and consolidates user data from multiple sources (including RDBMS and LDAP directories) into a virtual LDAP tree that can be managed by the Identity System and used to support authentication and authorization using the Access System.

The LDAP directory branches containing configuration and policy data must reside on one or more directory servers other than the one hosting VDS or user data. Identity System applications only recognize configuration and policy information that resides outside the VDS virtual directory.

**Caution:** Before installing for use with Oracle Data Anywhere and VDS, be sure to read the chapter about integrating with VDS in the Oracle Access Manager Integration Guide.

Active Directory: If you select Active Directory, specify whether to use ADSI (Active Directory Service Interfaces) for change password operations. Selecting the ADSI option implies you do not have to set up an LDAP/SSL connection for password changes. If you do not use ADSI, Oracle Access Manager uses an SSL connection to change the password. See "Configuring for ADSI" on page B-1.

If you have already set up LDAP/SSL for all other regular operations to the directory server, you do not need to set up the certificate server, import the CA certificate, and so forth. Otherwise, you need to configure LDAP/SSL for the password change.

See the Oracle Access Manager Installation Guide for more information.

Dynamic Auxiliary Classes—If you are using dynamic auxiliary classes with Active Directory, select Yes for Dynamic Auxiliary to associate a dynamic auxiliary class with a structural object class in Active Directory 2003.

See “Deploying with Active Directory” on page A-1 for more information.

**Note:** You can enable either dynamic or static auxiliary classes in Active Directory 2003.

6. Specify the supported operations for this directory server profile, as listed in Table 7–2.

7. Indicate which servers are to use this profile.
   - All Oracle Access Manager Components: Select this option if you want each component server in this installation to share the same profile.
   - Identity Servers: Select this option if you want only the Identity Servers to share this profile. If you want a particular Identity Server to use this profile, select the server name from the list box provided.
   - AAA Servers: The AAA Server option represents the configuration option for the Access Server. You are prompted to create a database profile whenever you
add a new Access Server. For details about adding an Access Server instance, see the Oracle Access Manager Access System Administration Guide.

8. Click Add to associate a directory server instance (database instance) with this profile, and assign the server type as primary or secondary.

See “To add or modify a database instance for an LDAP directory server profile” on page 7-31 for details.

9. Specify the number of maximum active servers you want (the number of primary and secondary database instances to connect to for load balancing).

   - A default value of 1 indicates that no load balancing takes place.
   - A value greater than 1 distributes database requests across all database instances, depending on which database instance has the shortest job queue. This ensures that the job is processed as quickly as possible.

For more information on load balancing, see the Oracle Access Manager Deployment Guide.

10. Specify the Failover Threshold.

    The value specifies the minimum number of primary servers that must be running. If the number of primary servers running is less than the specified number, a failover occurs. It is recommended that this value be the same as the number of maximum active servers. This ensures that failover to any secondary server happens immediately when a primary server goes down.

    The default value is 1. This indicates that failover to a secondary server only occurs when there are no primary directory servers to which the Identity Server can connect.

    Note: Oracle recommends that this value match the number of maximum active servers to ensure that failover to any secondary server happens immediately when a primary server goes down. For more information on failover and related parameters, see the Oracle Access Manager Deployment Guide.

11. In the Sleep For (Seconds) field, enter the number of seconds before the watcher thread wakes up and attempts to reestablish a connection to one or more downed primary servers.

    Note: If a primary server is available when failover occurs, the Identity Server will fail over to the primary server first.

12. In the Max. Session Time (Min.) field, specify the number of minutes that the Identity Server keeps a connection to the directory before attempting to reconnect.

    The default value is 0 (unlimited). If you see the memory usage rise for the Identity or Access Server or the Policy Manager, Oracle recommends to change this value to 600 (10 hours).

13. If this profile is ready for use, select Enable Profile.

    The following screen shot shows the lower half of the configuration page:
Managing Directory Server Profiles

Configuring Global Settings

14. Select Save, Cancel, or Reset as follows:
   - Click Save to save your changes.
   - Click Cancel to exit this page without saving.
   - Click Reset to reset all settings to the default settings.

15. Click OK to confirm your addition.

16. Restart your Identity Servers to enable the new profile.

Viewing an LDAP Directory Server Profile

The middle section of the Configure Profiles page, under the heading Configure LDAP Directory Server Profiles, contains a list of configured directory server profiles.

To view an LDAP directory server profile

1. From the Identity System Console, click System Configuration.
   The Configure Profiles page appears.
The middle section of the page, under the heading Configure LDAP Directory Server Profiles, contains a list of configured directory server profiles.

3. Click the link for the directory server profile that you want to view.

The Modify Directory Server Profile page appears.

Modifying an LDAP Directory Server Profile

There may be occasions when you need to modify an existing LDAP directory server profile.

To modify an LDAP Directory Server Profile

1. From the Identity System Console, select System Configuration.
3. On the Configure Profiles page, click the link for the directory server profile that you want to modify from those listed under the title 'Configure LDAP Directory Server Profiles'.
4. Refer to "Creating an LDAP Directory Server Profile" on page 7-21 for details about parameters.
5. Make the changes you need, then click Save to confirm them.
6. Restart your Identity Servers to enable the new profile.

Rerunning Setup Manually

You need to rerun the setup after completing any of the following operations on a directory server profile for configuration and policy data:

- Change directory server configuration options in the System Console.
- Create a new directory profile for configuration and policy data.
- Delete a directory profile belonging to configuration and policy data.
- Modify a directory profile for configuration and policy data.
- Add or change a directory instance within a profile.

**Note:** You also need to rerun setup when you make specific changes (those marked with an asterisk, *) on the Directory Server Configuration page.

Rerunning setup must occur in a specific sequence.

**Task overview: Rerunning system setup**

1. Rerun Identity System setup, as described in "Rerunning Identity System Setup" on page 7-29.
2. Rerun Policy Manager setup, as described in "Rerunning Policy Manager Setup" on page 7-29, if needed.
3. Reconfigure the Access Server, as described in "Reconfiguring the Access Server" on page 7-30.
Rerunning Identity System Setup
Modifying or removing the status parameter in setup.xml tells the Identity System that installation is not complete and permits you to rerun setup.

To rerun Identity System setup
1. Shut down all but one Identity Server if there is more than one running.
2. Go to the only remaining running Identity Server host and open the setup.xml file:
   \[\text{IdentityServer\_install\_dir/identity/oblix/config/setup.xml}\]
3. Remove the status parameter (or change the status parameter value from "done" to "incomplete"), as shown in the following example:
   \[<\text{NameValPair ParamName=\"status\" Value=\"incomplete\"}/NameValPair>\]
4. Save the file.
5. Restart the Identity Server.
6. From your Web browser, launch the Identity System Console.
   You will see a Setup page similar to the one that appears during the initial Identity System setup.
7. Initiate setup again and specify the new information.
8. After completing the setup, restart the other Identity Servers.
   The other Identity Servers should pick up the new information.
9. Complete the next procedure to rerun Policy Manager setup.

Rerunning Policy Manager Setup
After rerunning setup for the Identity System, if your implementation includes the Access System, you are ready to setup the Policy Manager manually. Modifying or removing the status parameter in setup.xml permits you to rerun Policy Manager setup.

To rerun Policy Manager setup
1. Shut down all but one Policy Manager Web server if there is more than one running.
2. Go to the only remaining running Policy Manager host and open the setup.xml file:
   \[\text{PolicyManager/oblix/config/setup.xml}\]
3. Remove the status parameter (or change the status parameter value from "done" to "incomplete"), and save the file as shown in the following example:
   \[<\text{NameValPair ParamName=\"status\" Value=\"incomplete\"}/NameValPair>\]
4. Restart the Policy Manager Web server.
5. From your Web browser, launch the Access System Console.
   You will see a Setup page similar to the one that appears during the initial Access System setup.
6. Initiate setup again and specify the new information.
7. After completing setup, restart the other Policy Manager Web servers.
The other Policy Managers should pick up the new information.

8. Rerun Access Server, as described in "Reconfiguring the Access Server" on page 7-30.

Reconfiguring the Access Server

After manually rerunning setup for the Policy Manager, you need to reconfigure the Access Server as indicated in the following procedure. For additional information on using the configureAAAServer tool, see the Oracle Access Manager Access System Administration Guide.

To reconfigure the Access Server

1. Locate the configureAAAServer tool.
   For example:
   ```
   AccessServer_install_dir/access/oblix/tools/configureAAAServer
   ```

2. Use the following command with the configureAAAServer tool to set up the Access Server:
   ```
   configureAAAServer install -i AccessServer_install_dir
   ```

Adding Database Instances to LDAP Directory Server Profiles

A directory server profile contains the bind information for a particular LDAP directory server, including the server name, the host machine, the port, the root DN, and the password. As part of a directory server profile, you can configure a database instance. When you define such a database instance, Oracle Access Manager validates the configured host and port against the supplied bind credential. The directory server corresponding to the database instance must be running when you configure it.

**Note:** A database instance within an LDAP directory server profile is distinct from a database instance within an RDBMS profile. An RDBMS profile is used to connect Oracle Access Manager to an external, ODBC 3.0-compatible relational database. See "Managing RDBMS Profiles" on page 7-35.

An LDAP directory server profile consists of one or more database instances, which are used for load balancing and failover. The directory server profile balances the load among its instances according to the maximum number of active servers; it experiences failover among its instances according to the failover threshold.

**Note:** Reconfiguring the Identity System to point the configuration directories to a new directory server causes /IdentityServer_install_dir/data/common to be reset. Specifically, in workflowdbparams.xml, the parameter wfinstancenotrequired=true is reset to false. After reconfiguring a directory server instance, manually reset the parameter wfinstancenotrequired to true.
LDAP Referrals
When you add a directory server instance, you can specify whether or not to enable LDAP referrals. A referral redirects a client request to another server, to find the requested information in another location. A referral contains the names and locations of objects.

If you choose to enable LDAP referrals when you add a directory server instance, you need to set the enableLDAPReferral parameter to true in the following file:

```
install-dir\oblix\data\common\ldapconfigdbparams.xml
```

Where `install_dir` is the installation directory for the Policy Manager, Access Server, or Identity Server.

The following is an example of this file for Active Directory:

```
BEGIN:vCompoundList
  specialAttrs:
    BEGIN:vNameList
    userPassword:( 2.5.4.35 NAME 'userPassword' DESC 'Standard Attribute' SYNTAX '1.3.6.1.4.1.1466.115.121.1.5' )
    sAMAccountName:( 1.2.840.113556.1.4.221 NAME 'sAMAccountName' DESC 'sAMAccountName' SYNTAX '1.3.6.1.4.1.1466.115.121.1.15' )
    END:vNameList
  useOIDNamingAttribute:false
  dynamicAuxiliary:false
  enableLDAPReferral:true
END:vCompoundList
```

To add or modify a database instance for an LDAP directory server profile

1. From the Identity System Console, click System Configuration.
3. Click the link for the directory server profile to which you want to add a database instance.
   The Modify Directory Server Profile page appears.
4. Scroll down to Database Instances and click the Add button (to edit/modify an existing database instance, select it from the list of database instances).
   The Create Database Instance (or Modify Database Instance) page appears.

**Note:** The fields for the Modify Database Instance page for an LDAP Directory Server Profile differ from those for the Modify Database Instance page for an RDBMS. See "Adding or Modifying an RDBMS Database Instance" on page 7-37 for details.
5. Fill in the fields as follows:

- **Name**: Enter a name for the directory server instance.
- **Machine**: Enter the name of the computer hosting the directory server instance.
- **Port Number**: Enter the port number for the directory server.
- **Root DN**: Enter the Root DN (bind DN) of the directory server user with administrative privileges.
- **Root Password**: Enter the password of the directory server user with administrative privileges.
- **Time Limit**: Specify the maximum amount of time allowed for a request to the directory server.
  The default value is 0 seconds, which means that the server determines the time. The database-instance setting takes precedence over this setting.
- **Size Limit**: Specify the maximum number of entries the directory server can return for a search operation.
  The default value is 0 entries, which indicates that the server determines the number.
- **Flags**: Select either of the following:
  - **SSL**: Directory server processes that use SSL. This requires initial certificate configuration. Refer to your directory server documentation for information.
  - **Referral**: Specifies whether the directory server profile should trace LDAP referrals for this directory server. The same bind credentials (Root DN and password) are used to log in to the referral server.
  - **Fast Bind (only for AD on Windows Server 2003)**: Authenticates a user name and password without returning a security token, unlike simple
Managing Directory Server Profiles

Configuring Global Settings

bind. This is faster than simple bind for applications that only perform authentication.

- Secure Port: Specify the port where you access the directory server.
  Leave this field blank if you are not using SSL or if you are using Active Directory with ADSI for change password.

- Initial Connections: Specify the initial number of connections used to connect to the directory server.
  These connections are shared among all user requests. The minimum is 1.

- Maximum Connections: Specify the maximum number of connections allowed to the directory server.
  The default is 1. A different DB agent is used for different types of operations.
  Note that the Maximum Connections field is implemented for a specific agent.
  The grand total of connections that can be opened can be much higher than the value specified in this field. See the information on configuring the directory connection pool in the *Oracle Access Manager Deployment Guide* for details.

6. Click Save to save your settings.

Clicking Cancel exits without saving, and clicking Reset reverts to the last saved settings.

Deleting an LDAP Directory Server Instance

You may want to remove an LDAP directory server instance.

**To delete a directory server instance for an LDAP directory server profile**

1. From the Identity System Console select System Configuration, then click Configure Directory Options.
   The Configure Directory Server Profiles page appears. All the directory server profiles are listed on this page.

2. Click the directory server profile to which you want to add an instance.
   The Modify Directory Server Profile page appears.

3. In the Modify Directory Server Profile page, select the Database Instance that you want to delete.

4. Click Delete.
   The directory server instance is deleted.

Working With Multiple Directory Searchbases

Some directories such as the Oracle Internet Directory allow you to configure multiple searchbases, sometimes referred to as disjoint searchbases or realms. These disjoint searchbases or realms consist of nonoverlapping directory trees, for example:

- o=company,c=us
- o=oracle,c=us

If you want Oracle Access Manager to manage data in more than one of these searchbases, you must configure the Identity and Access Systems separately for each searchbase.
The following procedures assume that you have already defined the disjoint searchbases (or realms) in your directory.

**Task overview: to configure the Identity System to work with a disjoint searchbase:**

1. From the Identity System Console click System Configuration, then click Directory Profiles.
2. Add a separate directory server profile for each new disjoint searchbase that you want to support.
   
   See "Creating an LDAP Directory Server Profile" on page 7-21 for details. Ensure that the name space that you provide matches exactly the name space in the directory.
4. Return to the Directory Profiles page—From the Identity System Console click System Configuration, then click Directory Profiles.
6. In the Disjoint Search Base field, enter the name space of the first disjoint searchbase.
   
   This must be identical to the name space provided in the directory server profile.
7. Click Add to configure additional disjoint searchbases.
8. For each new disjoint searchbase, configure new permissions for users who have entries in the searchbase.
   
   See "Allowing Users to View and Change LDAP Data" on page 4-21 for details.
9. Add Identity Administrators and Delegated Identity Administrators for each disjoint searchbase.
   
   See "Specifying Identity System Administrators" on page 2-1 for details.
10. Open the following file in a text editor and ensure that the value for the whichAttrIsLogin parameter in this file matches the user attribute in the directory:
    
    \[IdentityServer_install_dir/oblix/apps/common/bin/globalparams.xml\]

**Task overview: to configure the Access System to work with a disjoint searchbase:**

1. Complete the steps in "Task overview: to configure the Identity System to work with a disjoint searchbase:" on page 7-34.
2. Open the following file in a text editor and ensure that the value for the whichAttrIsLogin parameter in this file matches the user attribute in the directory:
    
    \[PolicyManager_install_dir/oblix/apps/common/bin/globalparams.xml\]
3. In the Access System Console, create an authentication scheme that uses the appropriate credential mapping parameters.
   
   For example, if your disjoint searchbases use the gensiteorgperson as the Person object class and genuserid as the login attribute, you might create an authentication scheme as follows:
Managing RDBMS Profiles

Oracle Access Manager connects to external, ODBC 3.0-compatible relational databases through RDBMS profiles. Currently user access profile reporting and the audit-to-database features make use of RDBMS profiles. Each profile can contain multiple database instances for failover if the primary instance of the database goes down.

Note: RDBMS profiles contain database instances. These database instances are distinct from database instances that are configured as part of LDAP directory server profiles. The latter are used to load balance and failover for LDAP directories.

This section discusses the following topics:

- Adding or Modifying an RDBMS Profile
- Adding or Modifying an RDBMS Database Instance

Adding or Modifying an RDBMS Profile

The steps to either add or modify an RDBMS profile are similar and are described in the following procedure. The fields you complete are described in Table 7–3.

Table 7–3 Field Descriptions for Adding or Modifying an RDBMS Profile

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Choose a self-explanatory name for your RDBMS profile.</td>
</tr>
</tbody>
</table>
To add or modify an RDBMS profile

1. From the Identity System Console select System Configuration, then click Directory Profiles.

The Configure Profiles page appears. All the directory server profiles are listed on this page.

### Table 7–3  (Cont.) Field Descriptions for Adding or Modifying an RDBMS Profile

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Connection Type</td>
<td>Choose the connection type that your database uses, if you have configured auditing to a database. See &quot;Auditing&quot; on page 11-1 for details.</td>
</tr>
<tr>
<td>Used By</td>
<td>Check the box corresponding to the feature for which you will be using the RDBMS profile. Currently, the choices are user access privilege reporting and auditing to database.</td>
</tr>
<tr>
<td>Database Instances</td>
<td>You can create multiple copies of the database for use in failover as follows:</td>
</tr>
<tr>
<td></td>
<td>■ To add a database instance and click Add. When the Create Database Instance page appears, complete the fields marked by asterisks. For field details, see &quot;To add or modify a database instance for an RDBMS profile&quot; on page 7-38.</td>
</tr>
<tr>
<td></td>
<td>■ To modify an existing database instance, select it from the database instance list.</td>
</tr>
<tr>
<td></td>
<td>■ To set the server type for the database instance, select Primary or Secondary from the list.</td>
</tr>
<tr>
<td></td>
<td>■ To delete a database instance, check the box next to the instance you want to delete, then click Delete.</td>
</tr>
<tr>
<td>Maximum Active Servers</td>
<td>This is the maximum number of servers that can be connected to the relational database at any given time.</td>
</tr>
<tr>
<td>Failover threshold</td>
<td>When the number of connected primary servers falls to this number, failover occurs.</td>
</tr>
<tr>
<td>Sleep For (Seconds)</td>
<td>Once a connection fails, this many seconds must elapse before failover takes place.</td>
</tr>
<tr>
<td>Max. Session Time (Min.)</td>
<td>The connection to the database is discarded after this many minutes, even if it is functioning, and a new connection is established.</td>
</tr>
<tr>
<td>Enable Profile</td>
<td>Make sure to check this box if you want the profile to be active.</td>
</tr>
</tbody>
</table>

To add or modify an RDBMS profile

1. From the Identity System Console select System Configuration, then click Directory Profiles.

The Configure Profiles page appears. All the directory server profiles are listed on this page.
The Configure RDBMS Profiles section is at the bottom of the Configure Profiles page.

2. Select from the RDBMS Profile list the name of the profile you want to edit (or click Add to create a new profile).

3. Complete or modify the fields on the Add RDBMS Profile (or Modify RDBMS Profile) page, as described in Table 7–3.

4. When you are satisfied with the information in the fields, click Save to commit the changes.

Adding or Modifying an RDBMS Database Instance

The steps to create or modify a database instance for an RDBMS database profile are so similar that they are combined in the following procedure. In either case, you must complete fields for the information in Table 7–4.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the database instance</td>
</tr>
</tbody>
</table>
Managing RDBMS Profiles

To add or modify a database instance for an RDBMS profile

1. From the Identity System Console select System Configuration, then click Directory Profiles.
   
   The Configure Directory Server Profiles page appears.

2. In the Configure RDBMS Profiles section, click Add to create a RDBMS profile, or select from the list the name of the RDBMS profile you want to modify.
   
   Depending on your selection, either the Add RDBMS Profile or Modify RDBMS Profile page appears.

3. In the Database Instances section, click the Add button to create a new instance (or select from the list the name of the instance you want to edit).

4. Complete the fields on the Modify Database Instance or Add Database Instance page.
   
   Field descriptions appear in Table 7–4.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSN Name or Global Database Name</td>
<td>If you configure database auditing with an ODBC connection type, the DSN Name field appears. It identifies a unique data-source definition to all the clients that access a given data source. (The term DSN is often used incorrectly to denote an entire ODBC data-source definition.) If you configure database auditing with an OCI connection type, you specify a Global Database Name (GDN) in the database instance definition. See &quot;About RDBMS Profiles for Database Auditing&quot; on page 11-12 for details.</td>
</tr>
<tr>
<td>User name</td>
<td>The name of the administrator with access privileges to this database instance</td>
</tr>
<tr>
<td>Password</td>
<td>The password for this database instance</td>
</tr>
<tr>
<td>Time Limit</td>
<td>The number of minutes after which the connection to the database is broken and then replaced with a fresh connection</td>
</tr>
<tr>
<td>Size Limit</td>
<td>The maximum size of the database</td>
</tr>
<tr>
<td>Initial Connections</td>
<td>The number of primary and secondary servers connected to this database instance when it is initialized</td>
</tr>
<tr>
<td>Maximum Connections</td>
<td>The total number of primary and secondary Access Servers that can be connected to this database instance</td>
</tr>
</tbody>
</table>
5. Click Save to commit the changes when you are satisfied with the information in the fields on the page.

Configuring WebPass

You first install WebPass after installing the Identity Server. After you set up the Identity System, you can install and configure multiple WebPass instances. Each WebPass instance is installed and configured separately. When a WebPass instance is installed, you supply several required parameters. A Master Administrator can modify these parameters and supply additional information, such as the failover threshold, in the Identity System Console.

When a user requests access to a Web server resource, WebPass redirects the request to an Identity Server, which then checks the user’s identity through the directory server. You must configure a WebPass plug-in for each Web server.

See the Oracle Access Manager Installation Guide for information about installing WebPass. Topics in this section include:

- Viewing a Configured WebPass
- Adding or Modifying a WebPass
- Removing a WebPass
- Modifying a WebPass from a Command Line
- Managing Associations Between Identity Servers and WebPass
- Disassociating a WebPass from an Identity Server

Viewing a Configured WebPass

WebPass configuration occurs using the Identity System Console, Configure WebPass function.

To view a configured WebPass

1. From the Identity System Console select System Configuration, then select WebPass.
The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. To view information about a WebPass, click the link for the WebPass.

The Details for WebPass page appears. All the information about the WebPass instance is listed on this page.

**Adding or Modifying a WebPass**

Adding a new WebPass involves adding the instance in the Identity System Console, installing WebPass on the Web server host, and updating the Web server configuration to establish communications between the WebPass and the Web server. Use the following procedure to add the instance. See the *Oracle Access Manager Installation Guide* for other details.

**To add a WebPass**

1. From the Identity System Console click the System Configuration sub-tab, then click WebPass in the left navigation pane.

   The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. From the Configure WebPass page, click Add.

   The Add a new WebPass page appears.

3. In the Name field, type a name for this WebPass instance.

   **Note:** You cannot change the name you save with this instance. To change the name, delete this instance and reconfigure it with a different name.

4. In the Hostname field, type the name of the Web server instance hosting this WebPass.

5. In the Web Server Port field, type the port number the Web server instance is listening to.

   The maximum value is 65535.

6. In the Maximum Connections field, specify the maximum number of connections this WebPass opens to Identity Servers.

   The minimum number of connections is 1. You may want to specify more connections for load balancing and failovers.

7. In the Transport Security field, you can modify the security mode that was specified when Oracle Access Manager was installed.

   The transport security mode specifies the degree of security during communications between the WebPass and the Identity Server. See "Changing Transport Security Modes" on page 8-1 for details.

   The supported transport security modes are as follows:

   - Open: No transport security.
   - Simple: Provides basic security. Communications are encrypted using Transport Layer Security, RFC 2246 (TLS v1). Communicating elements authenticate one another using a password-based mechanism. All elements
that use simple security must use the same password throughout the installation. Oracle Access Manager provides the certificate that performs the authentication.

- **Cert:** Used if you manage an internal certificate authority (CA).
  Communications are encrypted using TLS v1. Both client and server must present an X.509 certificate from a third party (such as VeriSign) when establishing a connection.

---

**Note:** Your Identity Servers and WebPasses must use the same transport security mode. Repeat these steps as necessary for each installed component.

---

8. In the **Maximum Session Time (hours)** field, specify the maximum period of time in hours before the connection between the WebPass and Identity Server is closed and a new one is opened.

9. In the **Failover Threshold** field, specify the minimum number of connections to Primary Identity Servers.

   If this number cannot be met using primary servers, WebPass attempts to do so using secondary servers. For example, if you type 4 in this field, and the number of available connections to primary Identity Servers falls to 3, WebPass attempts to open a connection to a secondary server.

   For details about configuring failover between WebPass and the Identity Server, see the Oracle Access Manager Deployment Guide.

10. In the **Identity Server Timeout Threshold** field, specify how long (in seconds) the WebPass attempts to contact a non-responsive Identity Server before it considers it unreachable and attempts to contact another.

    If a value is not specified, it indicates that there is no timeout.

11. In the **Sleep For (seconds)** field, specify the interval at which WebPass checks its connection with the Identity System.

    Along with checking for a minimum number of connections, the same check also tries to reestablish primary server connections when secondary connections are currently in use because the failover threshold was not met.

12. Click Save to add the WebPass plug-in (or Cancel to exit this page without saving).

    If you click Save, this WebPass plug-in appears on the List all WebPasses page.

13. Associate the WebPass plug-in with one or more Identity Servers, as described in "Managing Associations Between Identity Servers and WebPass" on page 7-44.

**To modify a WebPass**

1. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane.

   The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. In the List all WebPasses page, click the name of the WebPass that you want to modify.

   The Details for WebPass page appears.

3. Click Modify.
Configuring WebPass

The Modify WebPass page appears.

4. Modify the parameters as needed.

**Note:** See “Adding or Modifying a WebPass” on page 7-40 for more information on the parameters you will modify.

5. Click Save to save your changes (or Cancel to exit this page without saving).

Removing a WebPass

Removing a WebPass means that you remove it from the list of configured WebPass instances. To delete a WebPass from the Web server instance, you must uninstall it.

**To remove a WebPass**

1. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane.

   The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. In the List all WebPasses page, select the checkbox next to the WebPass instance that you want to remove.

3. Click Delete.

4. When prompted, click OK to confirm the action.

   The WebPass instance is removed from the list of configured WebPasses.

**Note:** If you remove a WebPass instance in the Identity System Console but do not run the uninstall program, it will be added to the directory server again when you restart the Web server.

Modifying a WebPass from a Command Line

Occasionally you may need to modify the parameters of a WebPass. You modify some parameters, such as Maximum Session Time and Failover Threshold, through the Identity System Console. You can use the command line tool setup_webpass to change other parameters, such as the host machine name and transport security mode.

Typically, you use the command-line tool to change the transport security mode. This tool can be used in both Windows and Solaris installations.

**To modify a WebPass through the command line**

1. Navigate to

   \WebPass_install_dir\identity\oblix\tools\setupWebPass

   where WebPass_install_dir is the directory where WebPass is installed.

2. From the setupWebPass directory, run the setup_webpass tool.

   You can specify parameters using the commands in Table 7-5.
To reconfigure transport security mode through the command line

1. To reconfigure a WebPass transport security mode, run the following command from the command line:
   ```
   setup_webpass -i WebPass_install_dir -m
   ```

2. Select the transport security mode for WebPass:

<table>
<thead>
<tr>
<th>Command Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>[-i install_dir] Specifies the installation directory for the WebPass</td>
</tr>
<tr>
<td>[-q] [-n WebPass_ID] Specifies the WebPass ID</td>
</tr>
<tr>
<td>[-h Identity_Server_Host_Name] Specifies the machine name where the Identity Server is installed</td>
</tr>
<tr>
<td>[-p Identity_Server_port_#] Specifies the port number of the machine where the Identity Server is installed</td>
</tr>
<tr>
<td>[-s open</td>
</tr>
<tr>
<td>[-P simple</td>
</tr>
<tr>
<td>[-c request</td>
</tr>
</tbody>
</table>

   **To reconfigure transport security mode through the command line**
   
   1. To reconfigure a WebPass transport security mode, run the following command from the command line:
      ```
      setup_webpass -i WebPass_install_dir -m
      ```
   
   2. Select the transport security mode for WebPass:

      If you select Open
      
      The transport security mode is reconfigured to run in Open mode.

      If you select Simple
      
      The system prompts you for the password.

      If you select Cert
      
      - The system prompts you for the certificate password.
        Enter the password at the prompt.
      - The system prompts you to specify whether you want to request a certificate or install a certificate.
      - If you specify a certificate request, the system prompts you for the following organization information:
        - Country name
        - State or Province
        - Locality
        - Organization name
        - Organizational unit
        - Common name (for example, HostName.DomainName.com)
        - Email address

      - For Cert mode, after you enter the information, a certificate request is generated and placed in Identity Server_install_dir\identity\oblix\config\ois_req.pem file, where IdentityServer_install_dir is the directory where the Identity System is installed.
        You must have this certificate request signed by the Certificate Authority.
      - If you specify a certificate installation, the system prompts you for the full paths to the location of the Certificate Key file, the Certificate file, and the Certificate Chain file.
After you specify the paths, the transport security mode is reconfigured. See "Changing Transport Security Modes" on page 8-1 for details.

To change the transport security mode password
1. Run the following command from the command line:
   
   ```bash
   setup_webpass -i WebPass_install_dir -k
   ```

2. Enter the following information:
   - The old password
   - The new password
   - Reconfirm the new password

   The password is changed.

Managing Associations Between Identity Servers and WebPass
You must select one or more Identity Servers to receive requests from a WebPass. A single Identity Server can be associated with multiple WebPasses. You can view a list of primary and secondary Identity Servers that are associated with a WebPass instance. You can also modify the number of connections that have been configured between an Identity Server and a WebPass for load balancing and failover purposes, as described in the following procedures:

- To view Identity Servers associated with a WebPass
- To modify an Identity Server's connections to a WebPass
- To associate an Identity Server with a WebPass

To view Identity Servers associated with a WebPass
1. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane.
   
   The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. Click the link for a WebPass.
   
   The Details for WebPass page appears.

3. Click the List Identity Servers button.
   
   A page appears that lists the primary and secondary servers configured for the WebPass.

4. Click the link for an Identity Server to view details for it.
   
   The Details for Identity Server page appears.

To modify an Identity Server's connections to a WebPass
1. From the Identity System Console click the System Configuration sub-tab, then click Identity Servers in the left navigation pane.
   
   The List all Identity Servers page appears. From this page you can add, modify, or delete a WebPass.

2. Click the link for the appropriate server.
   
   The Details for Identity Server page appears.

4. Change the value in the Number of Threads field, as needed.

5. Click Save to save your changes.

6. Restart the Identity Server.

To associate an Identity Server with a WebPass
1. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane. The List all WebPasses page appears. From this page you can add, modify, or delete a WebPass.

2. Click a link for the appropriate WebPass.

3. In the Details for WebPass page, click List Identity Servers. The next page lists the Primary and Secondary servers associated with the WebPass.

5. In the Select Server list, select an Identity Server.

6. Indicate whether this Identity Server is a Primary or Secondary server. This information is required for load balancing and failovers.

7. In the Number of connections box, specify the maximum number of connections the WebPass instance opens to this Identity Server. The minimum is 1. You may want to add more connections for load balancing and failover.

8. Click Add to associate this Identity Server with the WebPass.

Disassociating a WebPass from an Identity Server
Occasionally, you may need to disassociate a WebPass instance from an Identity Server. For example, the machine resources in your division may be reallocated. In this scenario, the associations between WebPass and an Identity Server may no longer be valid. So you must disassociate them from each other. If you do not disassociate them, WebPass continues to poll for the Identity Server and slows down the Web server’s performance.

**Note:** You cannot disassociate an Identity Server if it is the only primary server configured for a WebPass.

To disassociate an Identity Server from a WebPass
1. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane.

2. Click an existing WebPass.

3. Click List Identity Servers.

4. Select the check box next to the Identity Server you want to disassociate.
5. Click Delete.

6. When prompted, click OK to confirm your decision.

The WebPass instance will no longer communicate with the Identity Server.

**Configuring Password Policies**

Password policies consist of a set of rules that govern the kinds of passwords that users create and the validity period for passwords. Password policies also govern how users are notified of password expiry, how users reset expired passwords, and how users retrieve lost passwords.

You create password policies in the Identity System. These policies apply to users who try to log in to the Identity and Access Systems. These policies also apply to users who try to access resources protected by the Access System, as described in “Implementing Password Policies in the Access System” on page 7-60.

Password policies control the characteristics and life cycle of a password, including the following:

- **Rules for legal passwords.**
  
  This includes the minimum number of characters that can be used in a password and what types of characters must be used. For example, you can require both numbers and letters.

  You configure password properties from the Identity System Console.

  If you want to define additional rules for forming a legal password, an Identity Event API provides an external hook for password policy implementation. See the Oracle Access Manager Developer Guide for details.

- **Challenge phrases and responses for lost password management.**
  
  You can require users to respond to one or more challenge phrases when retrieving a lost password. You can also configure rules for challenge phrases, for example, you can prevent users from providing the same response to more than one challenge. Upon successfully responding to the challenge phrase or phrases, the user is redirected to a password reset page. After resetting the password, the user is logged in.

- **Settings for password expiry and password reset.**
  
  You can specify a password validity period and notify users of pending password expiration through email or at login time. You can also configure a URL redirect to return users to the originally requested resource after resetting a password.

- **Account lockout after incorrect password entry.**
  
  You can configure how many times a user can enter an incorrect password in a particular time interval before being locked out.

  For the Access System, you can also configure a lockout URL that has no user ID or requested resource information.

- **Style sheets for password reset and lost password management pages.**
  
  Although the Access System can redirect users to these pages, the pages themselves reside on the Identity System. You can configure different Identity System-provided style sheets for these pages.

- **Unique password policies for individual domains in the directory.**
You can create separate sets of password policies for different branches of the directory tree.

- Logs of the most recent successful and unsuccessful login attempts.

These are easily accessed logs written to the directory. They are provided in addition to the historical data provided in the audit logs.

This section discusses the following topics:

- Order of Password Policy Evaluation
- Managing Password Policies
- Lost Password Management
- Implementing Password Policies in the Access System
- Configuring Password Redirect URLs
- Updates to the Access Server Cache

Order of Password Policy Evaluation

You can configure different password policies for different domains. A domain is an area under a particular node in the directory tree.

A user can qualify under more than one policy in a domain. In this situation, password policies are evaluated in a bottom-to-top order. The first policy that applies to the user is selected, as illustrated in Figure 7–1.

![Figure 7–1 Password Policy Evaluation Order]

In this example, four password policies apply to John Smith. Password Policy 4 is implemented because it is at the lowest (cn) level of the directory tree, so it is evaluated first.

Managing Password Policies

You configure password policies in the Identity System Console. You can create default password policies that apply to all domains. You can also define password policies for specific directory domains, and you can define multiple policies within a domain.

This section discusses the following topics:

- Viewing Password Policies
- Setting the Defaults for Different Types of Password Policies
- Creating Password Policies for a Specific Domain
- Modifying Password Policies
Deleting a Password Policy

Viewing Password Policies
You view password policies from the Password Policy Management page.

To view a list of password policies
1. From the Identity System Console, click the System Configuration sub-tab.
2. Click Password Policy in the left navigation pane.
3. Click the policy’s link to view its settings.

The Password Policy Management page appears. This page displays default password policies and a list of domain-specific password policies.

Setting the Defaults for Different Types of Password Policies
You can set defaults for password policies. These defaults are overridden by any domain-specific policies that you create.

You can create defaults for the following:

- **Password expiry warning URL**: This applies only to resources protected by the Access System.
  
  This URL directs the user to an expiry notice form. Optionally, this URL can also redirect the user to a password change form. Another option for this URL is to return the user to the originally requested resource after changing the password.
  
  See “To set up a default password expiry warning redirect URL” on page 7-63 for details.

- **Password change redirect URL**: This setting applies only to resources protected by the Access System.
  
  It is similar to the password expiry warning URL. This URL points to a password change page. Optionally, this URL can redirect the user to the originally requested resource.
  
  See “Configuring Redirection to a Password Reset Page After Password Expiry” on page 7-62 for details.

- **Lost password redirect URL**: To be useful as part of your password management system, this URL must exist as a portal insert on a Web page.
  
  In the Identity System Console, you record this URL for informational purposes.
  
  See “Lost Password Management” on page 7-53 for details.

- **Custom account lockout redirect URL**: This URL is applicable only to resources protected by the Access System.
  
  See "Setting Up Redirect URLs for Account Lockout" on page 7-64 for details.
  
  By default, the Identity Server has a mechanism for displaying lockout information. If you want to customize account lockout behavior, the Identity System also returns an error code that you can use in an IDXML program. See the *Oracle Access Manager Developer Guide* for details.

- **Successful authentication events**: This writes the time of the user’s latest successful login attempts to the user directory server.
  
  By default, the information is written to the oblastSuccessfulLogin attribute of the OblixPersonPasswordPolicy object class. This feature enables quick access to the
most relevant login information. Historical information is provided in the audit logs.

- **Unsuccessful authentication events**: This writes the time of the user’s last failed login attempts to the user directory server.

  By default, the log authentication information is written to the oblastFailedLogin attribute of the OblixPersonPasswordPolicy object class. This feature enables quick access to the most relevant login information. Historical information is provided in the audit logs.

**To create the default password policy**

1. From the Identity System Console, click the System Configuration sub-tab.
2. In the left navigation pane, click Password Policy.
   The Password Policy Management page appears.
3. Enter the following information:
   - **Lost Password Redirect URL**: This is the URL that points users to a lost password management page in the Identity System. When entered in this field, this URL is for informational purposes only. The actual URL is provided in a portal insert. See "Lost Password Management" on page 7-53 for details.
   - **Password Change Redirect URL**: This is a URL to a password change form. See "Configuring Redirection to a Password Reset Page After Password Expiry" on page 7-62 for details.
   - **Password Expiry Warning Redirect URL**: Enter the URL to the password expiry warning form. See "Setting Up Password Expiry Warning Redirect URLs" on page 7-63 for details.
   - **Custom Account Lockout Redirect URL**: Enter the URL to a lockout notification page. See "Setting Up Redirect URLs for Account Lockout" on page 7-64 for details.
4. Set the logging of authentication attempts as follows:
   - **Successful Attempts Attribute**: By default, this value is oblastSuccessfulLogin. This is the recommended value. To change this value, enter any string attribute of the Person object class, or any string attribute of an auxiliary class that is attached to the Person object class.
   - **Failed Attempts Attribute**: By default, this value is oblastFailedLogin. This is the recommended value. To change this value, enter any string attribute of the Person object class, or any string attribute of an auxiliary class this is attached to the Person object class.
5. Click Enable to enable the logging features.
6. Click Save.

**Creating Password Policies for a Specific Domain**

You can configure password policies for specific domains. These settings override any global defaults.

You also can configure style sheets for the lost password management and password change pages for a specific policy. These Identity System style sheets named lpm_cr.xsl and lpm_changepwd.xsl are the original style sheets that you can use. You can copy these style sheets and customize them. For more information on style sheets, see the *Oracle Access Manager Customization Guide*. 
By default, these style sheets are stored in `IdentityServer_install_dir/identity/oblix/lang/language_id/style0`, where `IdentityServer_install_dir` is the directory where the Identity Server is installed and `language_id` is the directory where the language pack that is being used. The default language pack is en-us.

In the following procedure, the Defaults button at the bottom of the page populates all fields except the Password Policy Name, Password Policy Domain, and Password Policy Filter field.

**To create a password policy**

1. From the Identity System Console, click the System Configuration sub-tab, click Password Policy in the left navigation pane, then click Add in the Password Policy Management page.

2. In the Password Policy Name field, type the name of your policy.

3. In the Password Policy Domain field, type the domain of the LDAP directory to which this policy applies. For example:

   `ou=corporate,o=company,c=us`

4. In the Password Policy Filter field, you can optionally add an LDAP filter to further define the part of the domain to which this password policy applies. For example, `(title=System Administrator)` would restrict this password policy to a subset of people.

5. In the Lost Password Policy list, select the name of the lost password policy that you want to implement.

   See "Lost Password Management" on page 7-53 for details. If you leave this field blank, a single challenge-response model is used.

6. In the Password Minimum Length field, type the minimum number of characters the password must have.

   The default is 8.

7. In the Minimum Number of Uppercase Characters field, type the minimum number of uppercase characters the password must have.

   The default is 2.

8. In the Minimum Number of Lowercase Characters field, type the minimum number of lowercase characters the password must have.

   The default is 2.

9. In the Minimum Number of Nonalphanumeric Characters field, type the minimum number of nonalphanumeric characters the password must have.

   A nonalphanumeric character is any printable character that is not a letter or a number. Examples are +, !, and @.

   The default is 1.

10. In the Minimum Number of Numeric Characters field, enter the minimum number of numeric characters the password must have.

11. If external rules apply to this password policy, check Externally specified validation rules.

    Oracle Access Manager provides an external hook for password policy implementation. See Oracle Access Manager Developer Guide for details.
12. In the Password Validity Period field, select one of the options:
   - Password Never Expires.
   - Number of Days in which Password expires: Enter the number of days this password is valid. There is no default. You must supply a value if you select this option.

13. In the Password Expiry Notice Period, specify the number of days prior to password expiration that users are notified.

14. In the Mode of Conveying the Expiry Notice field, select one or both options:
   - At Login—When users log in, a message informs them of the number of days remaining until their password expires.
     If the Identity System is protected by the Access System, you must enter a Password Expiry Warning Redirect URL. See “Setting Up Password Expiry Warning Redirect URLs” on page 7-63 for details.
   - E-mail—Users are notified through email of the number of days remaining before their passwords expire. You cannot customize the message.

15. In the Password Minimum Age field, enter number of days the password must last before users can change it.

16. Select Change on Reset if you want to force users to change the password the first time they log in to the system after an administrator resets the password.

   By default, the Change on Reset flag is not set. During self-registration, the Change on Reset flag is not set.

   This field is applicable to both the Identity and Access Systems. For the Access System only, you can also configure a redirect URL for password change. See “Configuring Password Redirect URLs” on page 7-61 for details.

17. In the Password History field, indicate whether or not you want to maintain a password history.

   Select Do not Keep Password History or enter the number of passwords to be saved for each user. Saved passwords are stored in the directory and cannot be re-used. The default is 5.

   Oracle Access Manager can determine the latest passwords saved in the directory. If you delete one, Oracle Access Manager determines which remaining one is the oldest.

18. In the Number of Login Tries Allowed field, specify the number of login attempts allowed before the user's account is locked.

   The default value is 3. This means that if a user attempts to login three times using an incorrect login credential, they will be locked out after the third attempt that occurs within the lockout interval specified by “Lockout Duration value”. An incorrect login credential consists of a correct username but incorrect password. During the lockout interval, the user cannot login even with correct credentials.

   __________
   **Note:** This also applies to the number of attempts for a challenge response during Lost-Password Management.

   __________

19. In the Lockout Duration field, specify the number of hours an account remains locked after a user exceeds the number of failed logins specified in the previous step.
The default is 24 hours. To clear a lockout before the lockout duration expires, an administrator can reset the user's password from the Identity System. Upon login the user is redirected to a page where he or she can choose a new password—if Change on Reset was selected in the Password Policy Management page before the administrator reset the password.

If Change on Reset was not selected when the administrator assigned a new password, the user can log in to the system with the administrator-assigned password.

20. In the Login Tries Reset field, specify the number of days to store the failed login attempts that are uninterrupted by a successful login.

For example, if this value is set to 3, and a user fails to log in once, the application keeps track of that failure for 3 days before clearing it.

21. In the Lost Password Redirect Style Sheet, you can optionally enter the path to an XSL style sheet.

22. In the Password Change Redirect Style Sheet you can optionally enter the path to an XSL style sheet.

See the Oracle Access Manager Customization Guide for details on style sheet configuration. See "Configuring Redirection to a Password Reset Page After Password Expiry" on page 7-62 for details on the change password form.

23. In the Password Expiry Warning Redirect URL, you can optionally specify a URL to override the default.

This applies only to the Access System. See “Setting Up Password Expiry Warning Redirect URLs” on page 7-63 for details on this URL.

24. In the Custom Account Lockout Redirect URL, specify the redirect URL for users who have exceeded the number of login attempts.

This applies only to the Access System. See “Setting Up Redirect URLs for Account Lockout” on page 7-64 for details.

25. Select Password Policy Enable to enable this password policy.

If you later change the setting of this field or make any other change to this password policy, you have to flush the password policy cache. You can flush the password policy cache in the Access System Console. From the Access System Console, click Common Information Configuration, and click the Flush Password Policy Cache tab. For more information, see Oracle Access Manager Access System Administration Guide.

26. Click Save to save this policy and return to the Password Policy Management page.

The new policy appears in the list on the page.

---

**Note:** The Redirect URLs shown on this page apply to the Access System. For more information, see “Implementing Password Policies in the Access System” on page 7-60.
Modifying Password Policies
During this operation, you can click the Defaults button to populate all fields with default values, except the Password Policy Name, Password Policy Domain, and Password Policy Filter. See "Order of Password Policy Evaluation" on page 7-47 for information about each parameter.

**To modify a password policy's parameters**
- From the Identity System Console, click the System Configuration sub-tab, then click Password Policy in the left navigation pane. The Password Policy Management page displays a list of password policies.
- In the Password Policy Management page, click the policy you want to modify. The page with the policy’s parameters appears.
- Modify the parameters as necessary.
- Click Save.

Deleting a Password Policy
The Password Policy Management page displays a list of password policies. Saved passwords are stored in your LDAP directory. Oracle Access Manager can determine the latest passwords. If you choose to delete one, Oracle Access Manager determines which is the oldest.

**To delete a password policy**
1. From the Identity System Console, click the System Configuration sub-tab, then click Password Policy in the left navigation pane.
2. In the Password Policy Management page, select the check box next to the policy you want to delete.
3. Click Delete.
4. Click OK when prompted to confirm your deletion.

Lost Password Management
Lost password management enables users to reset their passwords if they forget them. Lost password management is a process that consists of the following:
- An "I lost my password" link that directs users to a page where they can respond to challenge phrases.
  You implement lost password management by creating a URL to a lost password management page, and placing this link on Web pages where you want users to be able to access this functionality. These URLs are known as portal inserts. See the Oracle Access Manager Customization Guide for details.
- A lost password management page that contains challenge phrases and response fields.
  The lost password management URL routes the users to an Identity System page that contains one or more challenge questions.
- A password reset page that is displayed if the user answers the challenges correctly.
  After giving the correct response, users can set a new password in the Identity System.
Configuring Password Policies

- Additional functionality to allow the user to be redirected back to the originally requested page.

For record-keeping purposes, you record the lost password management URL in a password policy in the Identity System Console. You can configure a lost password management policy for a particular domain.

The Identity System encrypts response values using an encryption scheme licensed from RSA. This encryption scheme is different from secure hash algorithm (SHA). You can replace the default encryption with your own by writing a custom action using the Identity Event Plug-in API. This is useful if you have existing challenge and response attributes that you want to import into the Identity System. See the Oracle Access Manager Developer Guide for details.

Lost password management is enabled by default.

---

**Note:** Unlike other redirect URLs that you enter in the Identity System, you enter the lost password management redirect URL for informational purposes only. Its primary location is in the portal insert.

---

**Task overview: Implementing Lost Password Management**

1. In your directory, create two new attributes: one to be used for challenges that are presented to users, and one for responses that users provide to the challenges.

   To support lost password management, you define an attribute pair to store values for challenges that are presented to users and for responses to those values. For example, you can define a pair of attributes named Challenge and Response. From the Identity System Console, you assign the Challenge and Response semantic types to these attributes. See “To configure challenge and response-type attributes in your directory” on page 7-57 for details.

2. From the Identity System Console, modify the attributes in your Person object class.

   Configure the attribute that is to store the challenge phrases, and the attribute that is to store the user’s responses to the challenge phrases.

   See "To configure the Lost Password Management attributes" on page 7-57 for details.

3. From User Manager, configure attribute access controls for these attributes.

   To be able to view and view and modify challenges and responses on profile pages, users need read and modify rights for the challenge and response. See "Allowing Users to View and Change LDAP Data" on page 4-21 for details.

4. Add the challenge and response attributes to user profile pages so that they appear when users view or modify these pages.

   During lost password management, users are directed to a page that presents them with challenge phrases. The page that contains the challenge phrases and response input fields is a profile page that you configure in the User Manager. See “Configuring Tab Profile Pages and Panels” on page 4-11 for details. Note that users can configure challenges during login, even if the associated attributes have no "self" read or modify rights.

5. Configure workflow step pages to use these attributes.
The challenge phrases and responses need to be configured during self-registration so that they can be used later for password retrieval. It is less likely, but possible, that a Create User workflow could also be useful to enable participants in the workflow to configure challenge phrases for new users. See "Chaining Identity Functions Into Workflows" on page 5-1 for details. The workflow step page does not require read or write permissions for challenge parameters.

6. Configure lost password management policies from the Identity System Console. See the "Managing Password Policies" on page 7-47 for details.

7. Insert a lost password management URL in a third-party application or portal page.

   See the information in this section for details. Also see the information on portal inserts in the Oracle Access Manager Customization Guide.

**Syntax for the Lost Password Management URL**

The format of a lost password management URL is as follows:

http://machinename:portnumber/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?program=passwordChallengeResponse&login=%scheme1_uid_parameter_value%scheme2_uid_parameter_value%schemeN_uid_parameter_value%&target=top

This is similar to a password expiry reset URL, as described in "Configuring Redirection to a Password Reset Page After Password Expiry" on page 7-62. One difference between the two types of URL is the following parameter:

```
program=passwordChallengeResponse
```

Another difference is that if you supply variables such as the user ID on this URL, you will need to modify the corresponding cgi script to pass in the user’s login ID. Alternatively, you can use the following URL syntax and require the user to re-enter a user ID after being redirected to the lost password reset page:

http://machinename:portnumber/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?program=passwordChallengeResponse&target=top

In the preceding URL, lost_pwd_mgmt.cgi is provided with Oracle Access Manager.

**About Presenting Challenge Phrases to Users**

Lost password management can be configured as either a single or a multiple challenge-response system. Challenge-response pairs are displayed in the following locations:

- During a create user account workflow, a workflow step will contain entries for challenge and response attributes.
- On View and Modify Profile pages, challenge and response pairs are displayed.
- During lost password management, users must respond to one or more challenge phrases.
- When logging in to Oracle Access Manager, users are prompted to provide additional challenges if the configured number of challenges is lower than the number required in the lost password policy that applies to the user.
About Other Aspects of the Challenge and Response Page

In addition to providing challenge and response prompts on the lost password management page, you may want to provide additional information on the page. For example, you may want to configure a link (or a workflow step) that sends the user to the password reset page after the user successfully responds to the lost password management challenges.

How the User Experiences Lost Password Management with Multiple Challenges

If a lost password management policy applies to the user, when the user clicks the lost password management URL, multiple challenges and response fields are displayed. The number of challenges that the user sees is determined by the Minimum Challenges to be Answered field. See "To configure lost password management for a password policy domain" on page 7-59 for details.

As noted in "Creating Password Policies for a Specific Domain" on page 7-49, password policies apply to particular domains or groups of users. If no lost password policy applies to a user, only one challenge phrase and one response entry field are displayed. If multiple challenge and responses are configured, but no lost password policy applies to a user, the first configured challenge phrase and response are displayed.

Users are prompted to configure additional challenge phrases during login if the number of configured challenge phrases and responses falls short of the minimum configured in the lost password policy. For example, suppose that you increase the minimum number of challenges to be configured after establishing the initial lost password management policy. In this case, during login the user is presented with an additional challenge phrase, displayed as one of the following:

- A text box: This appears if the User setting was selected in the lost password management policy.
- A select box with predefined phrases: This appears if the Predefined setting was selected in the lost password management policy.
- A combo box with predefined phrases: This appears if the User or Predefined setting was selected in the lost password management policy.

See "To configure lost password management for a password policy domain" on page 7-59 for details.

If you change the source type in the lost password management policy, for example, if you change the source from User to Predefined, or you change the minimum length, or change the Allow Duplicate Responses flag, these changes are enforced when the user modifies his or her own profile.

When being prompted to configure additional challenges, the type of message that the user receives depends on what has changed in the lost password management policy. For example, suppose that you change the minimum length of a response from 3 characters to 8 characters. When the user tries to save a change to his or her profile, an error message, "response does not meet the minimum length requirement" appears. If you increase the minimum number of challenges in the policy, the user is prompted to supply the required information during login.

Viewing and Configuring Lost Password Management Policies

The following procedures describe how to configure lost password management.
Configuring Password Policies

Configuring Global Settings

To configure challenge and response-type attributes in your directory

1. Ensure that there are two unused, empty attributes in your directory to be used for user challenges and responses.

   If two appropriate attributes are available, continue to the following procedure.

2. If you need to add new attributes, you can do so using whatever method you prefer.

   The following is an example of creating an LDIF schema file with a new auxiliary object class and two new attributes. You could create attributes that are similar to the following using the syntax appropriate for your directory server type:

   # ----------- Attributes ---------------
   #
   dn: cn=schema
   changetype: modify
   add: attributetypes
   attributetypes: ( 1.3.6.1.4.1.9999.1.1094.204 NAME 'Challenge2' SYNTAX
   1.3.6.1.4.1.1466.115.121.1.15 )

   dn: cn=schema
   changetype: modify
   add: attributetypes
   attributetypes: ( 1.3.6.1.4.1.9999.1.1094.205 NAME 'Response2' SYNTAX
   1.3.6.1.4.1.1466.115.121.1.15 )

   # ----------- Object class ---------------
   #
   dn: cn=schema
   changetype: modify
   add: objectclasses
   objectclasses: ( 1.3.6.1.4.1.9999.1.1094.206 NAME 'oblixAuxPerson4LPM' DESC
   'User defined objectclass' SUP top AUXILIARY MAY ( Challenge2 $ Response2 ) )

3. Import the LDIF file into the directory.

4. To configure the new auxiliary object class in Oracle Access Manager, in the Identity System Console, click Common Configuration.

5. Click Object Classes in the left navigation pane.

6. Click Add.

7. Select the name of the new object class from the list.

8. Select the option button for the Person structural object class.

   The new auxiliary object class is now associated with the Person structural object class. You can now configure the new challenge and response-type attributes in this object class, as described in "To configure the Lost Password Management attributes" on page 7-57.

To configure the Lost Password Management attributes

1. To configure an attribute from your Person object class to store the challenge phrases, from the Identity System Console, click Common Configuration.

---

**Note:** You cannot delete challenge parameters from profile or workflow pages if there is a lost password management policy in effect.
2. Click Object Classes in the left navigation pane.

3. Click the link for the Person object class.

4. Click Modify Attributes.

5. In the Attribute list, select the attribute that you want to use for the challenge phrase.
   This must be a new, empty attribute.

6. Configure the following.

   See "About Object Class Attributes" on page 3-9 and "Configuring Attributes" on page 3-17 for details:
   ■ Set the Semantic Type of this attribute to Challenge.
   ■ Set the Data Type to case-insensitive string.
   ■ Set the Attribute Value(s) field to Single
   ■ The Display Type is configured automatically, depending on the type of policy you configure.
   ■ Assign an appropriate Display Name, for example, Challenge.

   If you configure multiple challenge phrases, these are stored as a single value in the user’s directory entry for the challenge attribute. The values are stored in encoded format.

7. From the Attribute list, select a second attribute from your Person object class to store the user’s responses to the challenge phrases.
   This must be a new, empty attribute.

8. Configure this attribute as follows:
   ■ Set the Semantic Type of this attribute to Response.
   ■ Set the Data Type to case-insensitive string.
   ■ Set the Display Type to Password.
   ■ Set the Attribute Value(s) field to Single.
   ■ Assign an appropriate Display Name, for example, Response.

   See "About Object Class Attributes" on page 3-9 and "Configuring Attributes" on page 3-17 for details:

   If you configure multiple challenges and responses as part of your lost password management policy, the values that the user provides for the responses are stored as a single value in the user’s directory entry for the response attribute. The values are stored in encoded and encrypted format.

9. Add these attributes to user profile pages or workflow step panels, depending on where you want them to be displayed.

To view lost password policies

1. In the Identity System Console, click the System Configuration sub-tab, then click Lost Password Policy in the left navigation pane.

2. In the Lost Password Policy Management page, click the link for the policy that you want to view.
To enable or disable Lost Password Management
1. Locate the oblixbaseparams.xml file.
   The default path for the file is as follows:
   
   IdentityInstall_dir/identity/oblix/apps/common/bin/oblixbaseparams.xml

   where IdentityInstall_dir is the directory where the Identity System is installed.

2. Make sure Yes is entered for the Apply_LostPwdMgmt parameter.
   Yes is the default. Otherwise type No to disable this feature.

3. Save and close the file.

To configure lost password management for a password policy domain
1. From the Identity System Console, click the System Configuration sub-tab, then click Lost Password Policy.

2. In the Lost Password Policy page, click Add.
   The Add Lost Password Policy Page appears.

3. In the Lost Password Policy Name field, enter a name.

4. For Challenge Phrase Source, select who is to provide the challenge phrase:
   ■  **User**: When creating an account, the user must supply the challenge phrases.
   ■  **Predefined**: When creating a user account, a list of predefined challenges are shown to the user. The user must select from among the supplied challenge phrases.
   ■  **User or Predefined**: When creating a user account, a list of predefined phrases are shown to the user. The user can either select from among the supplied challenge phrases, or supply new challenge phrases.

5. In the Predefined Challenge Phrases field, enter a challenge phrase and click Add.
   The phrase is added to a selection list. Use the Delete button to remove selected phrases from the list.
   After completing the definition of this lost password policy, you can add predefined challenge phrases or delete existing ones at any time.

6. In the Minimum Challenges to be Configured field, enter the number of challenges that are to be configured when creating the user account or modifying the user profile.

7. In the Challenge Response Minimum Length field, enter the minimum number of characters permitted in the responses that a user configures.

8. The Allow Duplicate Responses checkbox configures the following:
   ■  Unchecked: False. If the user provides the same response for more than one challenge phrase, an error is displayed.
   ■  Checked: True. Turns off duplicate checking.

9. In the Minimum Challenges to be Answered field, enter the number of challenges that you want the user to respond to when resetting the password using the lost password management application.
   This value must be the same or less than the one in the Minimum Challenges to be Configured field. For example, if you set the value of this field to 3 and you configure four challenge-response pairs, the user must respond to three
challenges. Note that the actual number of responses that the user must provide depends on the number of correctly configured challenges and responses as well as the value of this field. For example, if you enter 2 in this field, but only one of the two challenge-response pairs is configured correctly, the user is prompted to respond to only one challenge.

10. In the Challenge Pose Type field, select whether challenges are to be displayed all at once or sequentially.
   - All at once: Challenges are displayed at one time. The order in which they are displayed changes each time. The user must respond correctly to all challenges.
   - One after the other: The user must respond to one challenge phrase before the next is displayed.

11. Select the Send Email After Password Change box if you want email to be sent to the user after the password has been reset.
    By sending email to the user, if an intruder has reset the password, the user can notice that something unexpected has happened and can contact the administrator.

12. Select the Lost Password Policy Enable box if you want administrators to be able to use this policy.

13. Click Save.

14. Add the name of this policy to a password policy domain.
    See “Creating Password Policies for a Specific Domain” on page 7-49 for details.

### Implementing Password Policies in the Access System

You can apply the password policies configured in the Identity System Console to resources that the Access System protects. To do this, you modify the authentication scheme that protects those resources. When users authenticate to a resource protected by the Access System, the password policy is invoked for the users if they are in the password policy domain.

The rest of this section discusses the following topics:

- Modifying Authentication Schemes to Include a Password Policy
- Configuring Redirection to a Password Reset Page After Password Expiry
- Setting Up Password Expiry Warning Redirect URLs
- Setting Up Redirect URLs for Account Lockout
- Updates to the Access Server Cache

See the section "Order of Password Policy Evaluation" on page 7-47 for more information. See the Oracle Access Manager Access System Administration Guide for instructions on creating an authentication scheme.

### Modifying Authentication Schemes to Include a Password Policy

The following procedure describes how to modify an authentication scheme to include a password policy.

#### To modify an authentication scheme to include a password policy

1. Log in to the Access System.
2. From the Access System Console, click Access System Configuration and then click Authentication Management in the left navigation pane.

The Authentication Management page appears, listing all the configured authentication schemes.

3. Click the link for an authentication scheme you want to change, and then click the Modify button on the page that appears.

The Modify Authentication Scheme appears.

4. Choose the validate_password plug-in, add the following information to the Plugin Parameters field, and click Save:

   \texttt{obReadPasswdMode="LDAP",obWritePasswdMode="LDAP"}

For example, suppose the original validate_password Plugin Parameters statement for the Basic Over LDAP scheme was the following:

   \texttt{obCredentialPassword=\textasciitilde\textasciitilde\textasciitilde}

The new parameter set would be as follows:

   \texttt{obCredentialPassword=\textasciitilde\textasciitilde\textasciitilde,obReadPasswdMode="LDAP",obWritePasswdMode="LDAP"}

The new parameters must be added for password change redirection.

5. Make a note of the uid parameter value for the credential_mapping plug-in.

You need this value when creating the password change redirect URL. For example, the uid parameter value may be \%userid\%.

6. Repeat this process for all authentication schemes for which you want to set up password change redirection.

---

**Note:** If you make any change to the password policy, be sure to flush the Access Server cache. See "Updates to the Access Server Cache" on page 7-64 for more information.

---

**Configuring Password Redirect URLs**

You can configure URLs that redirect users to the following pages:

- To a password reset page
- To a password expiration warning page
- To an error page stating that the user account is locked.

These redirect URLs apply only to cases where users log in to resources that are protected by a WebGate or AccessGate. In other words, if you have protected a resource as described in *Oracle Access Manager Access System Administration Guide*, you can configure one of these URLs. You can also configure these URLs to return the user to the originally requested resource when they are done with the target page specified in the redirection URL.

These URLs are explained in the following sections:

- Configuring Redirection to a Password Reset Page After Password Expiry
- Setting Up Password Expiry Warning Redirect URLs
- Setting Up Redirect URLs for Account Lockout
Configuring Password Policies

Configuring Redirection to a Password Reset Page After Password Expiry

When a password has gone beyond the validity period that you configured in a password policy, when the user attempts to log in, he or she is automatically redirected to a password reset page. You can configure the URL to this password reset page. Optionally, the password reset URL can redirect the user back to the originally requested resource after the password is reset.

To enter a password change redirect URL

1. From the Identity System Console, click the System Configuration sub-tab, then click Password Policy in the left navigation pane.

   The Password Policy Management page displays a list of password policies.

2. In the Password Change Redirect URL field, enter a URL with the following syntax:

   http://machinename:portnumber/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?program=redirectforchangepwd&login=%scheme1_uid_parameter_value%&target=top

   Where:

   ■ \textit{machinename:portnumber} are the host and port of the Web server on which a WebPass is installed, and

   ■ \%scheme1\_uid\_parameter\_value\% \%scheme2\_uid\_parameter\_value\% \%schemeN\_uid\_parameter\_value\% is the string of uid parameter values for all the authentication schemes for which you want to set up password change redirection

   For example, suppose that you have the following credential_mapping plug-in parameters for two authentication schemes:

   ■ \textbf{Form over LDAP}—\texttt{obMappingBase=\textbackslash \textbar o=company,c=us\textbackslash \textbar ,obMappingFilter=\textbackslash \textbackslash (\textbackslash \textbackslash (objectclass=genSiteOrgPerson) (uid=\%login\%))\textbackslash \textbar \textbackslash }\texttt{obMappingBase=\textbackslash \textbar o=company,c=us\textbackslash \textbar ,obMappingFilter=\textbackslash \textbackslash (\textbackslash \textbackslash (objectclass=genSiteOrgPerson) (uid=\%userid\%))}\texttt{)*}

   ■ \textbf{Basic over LDAP}—\texttt{obMappingBase=\textbackslash \textbar o=company,c=us\textbackslash \textbar ,obMappingFilter=\textbackslash \textbackslash (\textbackslash \textbackslash (objectclass=genSiteOrgPerson) (uid=\%userid\%))}\texttt{)*}

   The password change redirect URL that corresponds to these parameters would be the following:

   http://machinename:portnumber/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?program=redirectforchangepwd&login=%login%%userid%&target=top

3. To return the user to the originally requested resource after submitting the password change form, you can code a BackURL statement in the query string for this URL. The basic syntax is:

   http://machinename:portnumber/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?prtforchangepwd&login=%login%&backURL=%HostTarget%%RESOURCE%&target=top

   For example:

   http://130.35.46.141:99/identity/oblix/apps/lost_pwd_mgmt/bin/lost_pwd_mgmt.cgi?login=%login%&backUrl=%HostTarget%%RESOURCE%

   At runtime, the URL of the originally requested resource is substituted for the values enclosed in the percent delimiters, for example:
Configuring Password Policies

Setting Up Password Expiry Warning Redirect URLs
You configure a password expiry period in a password policy. When a user’s password is about to expire, a redirect URL sends the user to a warning page. Oracle Access Manager does not provide this warning page. You must create the actual landing page that contains the warning. Optionally, this warning page can also contain a URL that directs the user to the password reset page.

The password expiry redirect URL applies only to resources that are protected by the Access System. In other words, if you have protected a resource with a WebGate, you can configure this URL.

The password expiry URL is similar to the password change redirect URL. The URL directs the user to an expiry notice form, optionally redirects the user to a password change form, then optionally returns the user to the originally requested resource after the password is changed.

You can configure a default password expiry URL that applies to all password policies, and you can configure this URL for an individual policy.

Users may be redirected automatically to this URL, or they can be notified by email prior to expiry. See "Creating Password Policies for a Specific Domain" on page 7-49 for details.

There is no built-in page or portal to serve as a target for this URL. You must create this page. For example, you may want to provide a page that states, "Your password will expire soon and needs to be changed."

To set up a default password expiry warning redirect URL
1. From the Identity System Console, click the System Configuration sub-tab, then click Password Policy in the left navigation pane.

   The Password Policy Management page displays a list of password policies.

2. In the Password Expiry Warning Redirect URL, enter a URL with the following syntax:

   http://machinename:portnumber/path-to-custom-page

   Where:
   - machinename:portnumber are the host and port of the Web server on which a WebPass is installed, and
   - path-to-custom-page is the path of the custom Web page that warns them that their password is about to expire.

3. To return the user to the originally requested resource after authenticating, you can code a "back URL" (that is, a backURL statement) in the query string for this URL as follows:

   http://machinename:portnumber/notice.cgi?prtforchangepwd&login=%login%%userid%&backURL=%HostTarget%%RESOURCE%&target=top
For example, you could enter the following URL:

http://130.35.46.141:99/cgi-bin/notice.cgi?login=%login%&userid%&backUrl=%HostTarget%&RESOURCE%

In this example, notice.cgi contains logic to process the query parameters. You can create a simple Web page, or write a cgi or another script or JSP page to parse the parameters in the URL and display appropriate messages, process timeouts, and redirect the user to the backURL.

At runtime, the actual values of the user and the originally requested resource are substituted for the query strings. For example:

In this example, notice.cgi is a script that you have written that contains logic to process the query parameters.

The custom page can also retrieve the expiration date using an ExpiryDate query parameter. The following is an example of this parameter:

http://130.35.46.141:99/cgi-bin/notice.cgi?ExpiryDate=%PwdExpiryDate%&backUrl=%HostTarget%&RESOURCE%

4. Click Save.

Setting Up Redirect URLs for Account Lockout

As with the other redirect URLs, the redirect URL for account lockout is applicable only to the Access Server. You can configure a lockout URL that has no user ID or requested resource information.

To implement account lockout redirection, you need to create a Web page, or write a cgi or another script or JSP page to parse the parameters in the account lockout URL. The script or JSP should display messages regarding account lockout, process timeouts, and redirect the user to the originally requested resource.

To set up the account lockout URL

1. From the Identity System Console, click the System Configuration sub-tab, then click Password Policy in the left navigation pane.
   
   The Password Policy Management page displays a list of password policies.

2. In the Custom Account Lockout Redirect URL field, enter a URL for redirecting the user to an account lockout form.

3. Click Save.

Updates to the Access Server Cache

You can ensure that the Access Server is notified of changes made by the Identity System and that the Access System's cache is flushed automatically. However, if you choose to not implement automatic cache flush, you can still manually flush the cache when you make changes to the Password Policy Management page in the Identity System. This can be useful in avoiding a significant delay in applying password-policy management changes.
For more information about flushing the Access Server caches, see Oracle Access Manager Access System Administration Guide and the Oracle Access Manager Deployment Guide.

Configuring the Access Manager SDK for the Identity System

The Access Manager SDK consists of libraries, build instructions, and examples that you use to build an AccessGate for non-Web resources. The Access Manager SDK is automatically installed with the Identity System in IdentityServer_install_dir/AccessServerSDK.

The following functions in the Identity System require the Access Manager SDK. You must manually configure the Access Manager SDK for these functions:

- Automatic cache flush between the Identity System and Access System
- Automatic login to the Access System after self-registration.

Complete the following procedure if you protect WebPass with a WebGate. You do not have to repeat the procedure for each Identity System function previously mentioned.

To configure the Access Manager SDK

1. Install and set up the Identity System and Access System, as described in the Oracle Access Manager Installation Guide.

2. Windows: Set your path to point to the Access Manager SDK by modifying the systems PATH variable as shown below:

   set PATH = %PATH%;Identityserver_install_dir\AccessServerSDK\oblix\lib

3. From the Access System Console, click Access System Configuration, AccessGate Configuration.

4. Add an AccessGate.
   You do not need to configure a port.
   The Identity System uses the AccessGate to communicate with the Access Server for purposes of flushing the cache.
   For more information about flushing the Access Server caches, see Oracle Access Manager Access System Administration Guide and the Oracle Access Manager Deployment Guide.

5. Select Off for Access Management Service if you have upgraded your WebGates.
   A value of On is only appropriate for legacy systems.

6. Save the AccessGate.

7. Access the IdentityServer_install_dir\identity\AccessServerSDK\oblix\tools\configureAccessGate directory and run the configureAccessGate script.
   Where IdentityServer_install_dir is the directory where the Identity Server is installed.
   See the Oracle Access Manager Access System Administration Guide for details about modifying an AccessGate.
When running configureAccessGate, ensure that the AccessGate ID is the same as the AccessGate name you entered from the Access System Console in step 3.

8. From the IdentityServer_install_dir/identity/oblix/data/common directory, open the basedbparams.xml parameter catalog file in a text editor.

9. Change the value of the doAccessServerFlush flag to true as follows:

   ```xml
   <NameValPair ParamName="doAccessServerFlush" Value='true' />
   ```

10. Restart the Identity Server

## Cloned and Synchronized Components

Instead of using the command line or the installation GUI to install a Oracle Access Manager component, you can automatically install a component by cloning the configuration of an already-installed component. Cloning creates a copy of a component on a remote system using an already-installed component as a template.

_Synchronizing_ enables you to harmonize two installations of the same component when one is more up-to-date than the other. Synchronization can be used to upgrade or repair installations on similar platforms.

See the _Oracle Access Manager Installation Guide_ for details.
Certain functions and tasks are common to both the Oracle Access Manager Identity System and the Access System.

Part III explains how to perform tasks that are common to all Oracle Access Manager applications:

- Chapter 8, "Changing Transport Security Modes"
- Chapter 9, "Reporting"
- Chapter 10, "Logging"
- Chapter 11, "Auditing"
- Chapter 12, "SNMP Monitoring"
Setting up transport security is the subject of this chapter and is one of the administrative tasks that is common to both the Identity System and the Access System.

This chapter contains the following topics:

- About Transport Security Modes
- Changing Transport Security for the Identity System
- Changing Transport Security Modes for the Access System
- Transport Security Changes for Directory Servers
- Changing Transport Security Passwords
- Importing Multiple CA Certificates
- Changing Access Server Security Password

### About Transport Security Modes

A transport security mode is a method to protect communication between two points, such as a client and a server. To ensure protection, communication can be encrypted with a certificate authority (CA).

Oracle Access Manager offers the following three transport security modes for communication between components, as discussed in greater detail in the *Oracle Access Manager Installation Guide*:

- **Open**: Communication is not encrypted for protection. Use this mode when security is not an issue; for example, when testing communications between an AccessGate and the Access Server, as long as you consider your network secure. Open is the default setting.

- **Simple**: Communication is encrypted with Oracle Access Manager's internal CA. Simple mode encrypts communications using Transport Layer Security, RFC 2246 (TLS v1). This mode is less secure than Cert mode. Use this mode if you have some security concerns but do not want to manage your own CA.

- **Cert**: Communication is encrypted with an external CA. With Cert mode, communications are encrypted using TLS v1. In addition, each element, both client and server, must present an X.509 certificate (in base64 format) when establishing a connection. The certificate must be provided by you, perhaps from a third-party CA.
When you run the configureAAAServer, setup_ois, or setup_accessmanager utilities, the certificate store format and name is automatically modified to cert8.db. Version 7.0 and higher versions work with both the cert7.db (upgraded environments) and cert8.db (new installations) certificate store. On non-Windows systems, you use the following tools: start_configureAAAServer, start_setup_ois, start_setup_accessmanager.

The following two transport security modes are used for communication between a Oracle Access Manager component and the directory server:

- **Open**: Directory server communication is not encrypted for protection. Use this mode when security is not an issue; for example, when testing communications between an AccessGate and the Access Server, as long as you consider your network secure. Open is the default setting.
- **SSL**: Directory server communication using SSL.

Specifying transport security is part of the installation process. See the differences when installing the Identity System or Access System, in Table 8–1.

### Table 8–1 Specifying a Security Mode During Installation

<table>
<thead>
<tr>
<th>Identity System</th>
<th>Access System</th>
</tr>
</thead>
<tbody>
<tr>
<td>Install the Identity Server component. Specify the transport security mode used to communicate with WebPass.</td>
<td>Install Policy Manager. Specify the transport security mode used to communicate with the Access Server.</td>
</tr>
<tr>
<td>Install the WebPass component. Specify the transport security mode used to communicate with the Identity Server.</td>
<td>Create an Access Server instance in the Access System Console. Specify the transport security mode used to communicate with the Policy Manager.</td>
</tr>
<tr>
<td></td>
<td>Define a WebGate instance in the Access System Console. Specify the transport security mode used to communicate with the Access Server.</td>
</tr>
<tr>
<td></td>
<td>Install the Access Server component. Configure the transport security mode to communicate with WebGate.</td>
</tr>
<tr>
<td></td>
<td>Install the WebGate component. Configure the transport security mode to communicate with Access Server.</td>
</tr>
</tbody>
</table>

---

**Note**: As of version 7.0, the default certificate store format and name has changed from cert7.db to cert8.db. When you upgrade from a version earlier than version 7.0, you continue to use the old certificate store (cert7.db).

---

See also: See the *Oracle Access Manager Installation Guide* for more information on installing components.

### Transport Security Mode Between Components

Transport security can be configured between the following components:

- **Identity System**: Transport security between all Identity Servers and WebPass instances must match: either all open, all Simple mode, or all Cert.
- **Access System**: Transport security among all Policy Managers, Access Servers, and associated WebGates must match: either all open, all Simple mode, or all Cert.

**Access Cache Flushing Caveat**: When access cache flushing is enabled on the Identity Server, the Identity Server communicates with the Access Server. In this case, the
transport security mode among all five of the following components must be in the same mode.

- Identity Servers and WebPass instances
- Policy Managers, Access Servers, and associated WebGates

For details about managing caches, see both Managing Caches on page 7-13 of this manual and Oracle Access Manager Access System Administration Guide. For more information on caching, see the Oracle Access Manager Deployment Guide.

If you need to change the transport security mode after installation, you can change the security mode in the System Console:

**Identity System (WebPass and Identity Server):** You select a transport security mode for WebPass and Identity Server instances in the Identity System Console. Decide on the type of transport security mode you want to use before you configure WebPass and Identity Server instances. Again, transport security among all components must match. They must all be open, simple, or cert.

**Access System (Policy Manager, AccessGate, and Access Server):** You select a transport security mode for the Access System when configuring AccessGate and Access Server instances in the Access System Console. Decide on the type of transport security mode you want to use before you configure the AccessGate and Access Server instances. Again, transport security among all Access System components must match: either all open, all simple mode, or all cert.

After changing the mode in the System Console, follow the process described in:

- “Transport Security Mode Changes for the Access System” on page 8-10
- “Transport Security Changes for Directory Servers” on page 8-19

You may change the security mode between a component and the Directory server after installation:

**Identity or Access Server and the Directory Server:** Transport security between the directory server and an Identity or Access Server can be in Open or SSL mode. You specify this transport security mode during installation. If you select SSL, you also specify the location of the SSL certificate. The directory server is automatically updated with the specified security mode information.

When configuring SSL for the directory server, note that Oracle Access Manager supports server authentication only. Client authentication is not supported. Oracle Access Manager verifies the server certificate against the Root CA certificate that you imported during product setup.

The Policy Manager is a Web component that reads from and writes to the directory server. You also specify transport security between the Policy Manager and directory server. Figure 8–1 illustrates the supported transport security modes between Oracle Access Manager Web components and servers, and Oracle Access Manager components and the directory server.
You can share directory profiles for all components running in SSL mode, even if these components were initially configured in different modes. For example, suppose the Identity Server and Access Server were installed in open mode with the directory, and the Policy Manager was installed with SSL enabled for the directory server. In this case, the cert8.db and key3.db files must exist for each component that communicates with the directory server and must reside in the `component_install_dir\identity\access\oblix\config` directory. If these files do not exist, copy them from other existing component folders or run the genCert (Policy Manager) or other utilities to generate them, as described in this chapter.

**About CA Certificates**

This discussion explains the root certificate, request, and other certificate files.

If you select the cert transport security mode between components during installation, you need to create and install a root certificate. The root certificate file is a chain of certificates that is generated when you submit a certificate signing request, such as a CSR to a certificate authority. This request is in the form of an `xxx_req.pem` file. You store a root certificate as a file called `xxx_chain.pem`. You download the `xxx_chain.pem` file from the Certificate Server and store it in the following directory with the key and cert.pem files, then specify its location during product configuration:

```
Component_install_dir\identity\access\oblix\config
```

- Chain file (ois_chain.pem)
- Certificate file (ois_cert.pem)
- Key file (ois_key.pem) the installer may know where this is.

For most components, you install certificates during product setup. You install certificates in the Policy Manager using the genCert utility. The command for this utility is:

```
genCert -i <install Dir> -m <cert | simple> -P <password> -c <request | install>
```

For example:

```
genCert -i c:\COREid\webcomponent\access\oblix\tools\gencert -m cert -P <password> -c install
```

You can save an approved certificate to any location that is accessible to the component installer. For example, you can save it to `/oblix/config`. 
Changing Transport Security for the Identity System

All Identity Servers and WebPass instances in your installation must run in the same transport security mode. If you specified different modes for different components during your installation, you must change them.

Task overview: Changing transport security for the Identity System

1. If you are changing to simple or cert mode, complete the process for certificate preparation.
2. Perform the steps in “To change the Identity Server transport security mode” on page 8-5.
3. Perform the steps in “To change the WebPass transport security mode” on page 8-5.

Note: The WebPass and the Identity Server will not be able to communicate with each other until you have changed the transport security mode for both.

To change the Identity Server transport security mode

1. If you are changing to simple or cert mode, complete the certificate preparation process.
2. From the Identity System Console, click the System Configuration sub-tab, then click Identity Server in the left navigation pane.
3. Click the link for the server that you want to modify, then click Modify.
4. Click the appropriate button for the transport security mode of your choice. You can select Open, Simple, or Cert mode.
5. Click Save.
6. Restart the Identity Server.

To change the WebPass transport security mode

1. If you are changing to simple or cert mode, complete certificate preparation.
2. From the Identity System Console, click the System Configuration sub-tab, then click WebPass in the left navigation pane.
3. Select the WebPass you want to modify and click Modify.
4. Change the transport security mode
You can select Open, Simple, or Cert mode.

5. Click Save.

6. Stop the WebPass, restart the Identity Server, then restart the WebPass.

Transport Security Mode Changes for the Identity System

When changing the transport security mode after installation, specify the new mode in the Identity System Console, then change the mode in the appropriate configuration files. You repeat the steps shown in Table 8–2 as needed for each component.

Table 8–2 Transport Security Mode Changes for the Identity System

<table>
<thead>
<tr>
<th>New Security Mode</th>
<th>Process</th>
</tr>
</thead>
</table>
| Simple            | 1. Stop the Identity Server.  
|                   | 2. Generate the certificate through Oracle Access Manager’s internal CA (see "Changing to Simple Transport Security Mode" on page 8-6 for details).  
|                   | 4. Restart the Identity Server. |
| Cert              | 1. Stop the Identity Server.  
|                   | 2. Generate the certificate request (see "Changing to Cert Transport Security Mode" on page 8-7 for details).  
|                   | 3. Get the certificate approved through an external CA.  
|                   | 4. Install the certificate (see "To install a certificate for Cert mode" on page 8-8 for details).  
|                   | 6. Restart the Identity Server. |

Note: The clocks of computers running Identity System components must be synchronized, especially when the components are using open or cert mode. A difference of a few seconds is allowed as long as the Identity Server computer’s clock is ahead of the WebPass computer’s clock. Otherwise, certificate time stamps are invalid, and all requests are rejected. See the Oracle Access Manager Access System Administration Guide for details about synchronizing system clocks.

Changing to Simple Transport Security Mode

If you want to change to simple mode, you must first generate a certificate through Oracle Access Manager’s internal CA.

To generate a certificate through the CA

1. Open a Command Prompt window and go to:

   IdentityServer_install_dir/identity/oblix/tools/setup

   where IdentityServer_install_dir is the directory in which the Identity Server is installed.
2. Execute one of the following commands, depending on which component you are modifying.

### Table 8–3 Setup Commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| UNIX             | Identity Server:  
|                  | start_setup_ois -i IdentityServer_install_dir/identity -m  
|                  | WebPass:  
|                  | start_setup_webpass -i WebPass_install_dir/identity -m  |
| Windows          | Identity Server:  
|                  | setup_ois.exe -i IdentityServer_install_dir/identity -m  
|                  | WebPass:  
|                  | setup_webpass.exe -i WebPass_install_dir/identity -m  

You are prompted to enter simple or cert mode.

3. Type simple and press Enter.

4. Specify and confirm the Global Pass Phrase.
   This password must be the same across all Identity Servers and WebPass instances within an installation.

### Changing to Cert Transport Security Mode

If you want to change to cert mode, you must do the following after you install a Identity Server:

- Generate a certificate request to obtain a certificate from an external CA.
- Install the signed certificate after you receive it.

### To generate a certificate request for Cert mode

1. Open a Command Prompt window and change to

   

   IdentityServer_install_dir/identity/oblix/tools/setup

   

   where IdentityServer_install_dir is the directory in which the Identity System has been installed.

2. Run one of the commands in Table 8–4

### Table 8–4 Identity System Request Certificate Commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| UNIX             | Identity Server:  
|                  | start_setup_ois -i IdentityServer_install_dir/identity -m  
|                  | WebPass:  
|                  | start_setup_webpass -i WebPass_install_dir/identity -m  

   where WebPass_install_dir is the directory in which WebPass is installed.
You are prompted to enter simple or cert mode.

3. Type cert and press Enter.

4. Indicate that you are requesting a new certificate.

5. Enter information at the prompts for:
   - A two-letter country code (the default is US).
   - A state or province name.
   - Your city or other locality
   - An organization name (for example, your company)
   - An organizational unit name (for example, your department)
   - A common name (for example, your host name)
   - An email contact address

6. Press Enter.

   You see the message:

   "Your certificate request is in the file Identity_Server_install_dir/identity/oblix/config/ois_req.pem."

   The setup_ois utility creates two files in this directory: ois_key.pem, which contains your private key, and ois_req.pem.

7. Submit the ois_req.pem file to be signed by your Certificate Authority.

**To install a certificate for Cert mode**

1. Open a Command Prompt window and change to:

   `Identity_Server_install_dir/identity/oblix/tools/setup`

   where `IdentityServer_install_dir` is the directory in which the Identity Server is installed.

2. Run one of the commands in Table 8–5.
Changing Transport Security Modes for the Access System

Table 8–5  Identity System Install Certificate Commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| UNIX             | Identity Server:  
|                  | start_setup_ois -i IdentityServer_install_dir/identity -m  
|                  | WebPass:  
|                  | start_setup_webpass -i WebPass_install_dir/identity -m  
|                  | where WebPass_install_dir is the directory in which WebPass is installed. |
| Windows          | Identity Server:  
|                  | setup_ois.exe -i IdentityServer_install_dir\identity -m  
|                  | where IdentityServer_install_dir is the directory in which the Identity Server is installed  
|                  | WebPass:  
|                  | setup_webpass.exe -i WebPass_install_dir\identity -m  
|                  | where WebPass_install_dir is the directory in which WebPass is installed. |

You are prompted to enter simple or cert mode.

3. Type cert and press Enter.

4. Indicate that you are installing a certificate.

5. Specify the locations of the following files:
   - ois_key.pem
   - ois_cert.pem
   - ois_chain.pem

   If you have installed certificates for an earlier Oracle Access Manager-generated request, use the default value for ois_key.pem when prompted.

---

**Note:** When using certificates generated by a subordinate CA, the root CA's certificate must be present in the ois_chain.pem along with the subordinate CA certificate. Both certificates must be present to ensure appropriate verification and successful Identity System setup.

---

Your certificate is installed.

Changing Transport Security Modes for the Access System

Before you change the transport security mode for the AccessGate or Access Server, update the transport security modes for the components in the Access System Console.

You cannot update the transport security mode for Policy Manager from the Access System Console. If you are changing from Open mode to another mode, follow the instructions in Table 8–2. If you are changing to Open mode, you need not change the mode for Policy Manager because the Policy Manager automatically detects that the other AccessGate and Access Server are working in Open mode.
To specify transport security mode for Access Server
1. In the Access System Console, navigate to Access System Configuration, Access Server Configuration.
2. Select the Access Server you want to change, and click Modify.
3. Select the appropriate radio button for transport security, and click Save.
4. Restart the Access Server.

To specify transport security mode for AccessGate
1. In the Access System Console, go to Access System Configuration, AccessGate Configuration.
2. Select the AccessGate you want to change, and click Modify.
3. Select the appropriate radio button for transport security, and click Save.
4. Restart the Web server hosting the AccessGate.

Transport Security Mode Changes for the Access System
You can change the transport security mode for Access System components after you have specified the changes in the Access System Console. The process of changing modes depends on the security mode to which you are changing. If you change an Access Server's security mode, you must change the security mode of all Policy Managers and AccessGates pointing to this Access Server to match the new security mode.

If you change the security mode for one or more Access Servers, the Transport Security Mode Change Confirmation page may appear. This page notifies you of an incompatibility between the security modes used by the Access Server and one or more AccessGates.

Table 8–6 lists the process that you follow for each security mode. Repeat these steps as necessary for each installed component.
### Table 8–6  Transport Security Mode Changes for the Access System

<table>
<thead>
<tr>
<th>New Security Mode</th>
<th>Process</th>
</tr>
</thead>
</table>
| **Open**          | **Access Server:**  
|                   | 1. Move the appropriate directory or files to a new folder (see "Changing to Open Transport Security Mode" on page 8-12 for details). |
|                   | 2. Configure the Access Server instance in the Access System Console (see "To specify transport security mode for Access Server" on page 8-10 for details). |
|                   | 3. Run the configAAAServer program to specify the new mode. For details about using the ConfigureAAAServer Tool, see the Oracle Access Manager Access System Administration Guide. |
|                   | **AccessGate/WebGate:**  
|                   | 1. Move the appropriate directory or files to a new folder (see "Changing to Open Transport Security Mode" on page 8-12 for details). |
|                   | 2. Configure the AccessGate instance in the Access System Console (see "To specify transport security mode for AccessGate" on page 8-10 for details). |
|                   | 3. Run the configAccessGate or the configWebGate program, as appropriate, to specify the new mode. To modify an AccessGate through the command line, see the Oracle Access Manager Access System Administration Guide. |
|                   | **Policy Manager:**  
|                   | 1. Restart the Web server on which the Policy Manager is installed. |
| **Simple**        | **Access Server:**  
|                   | 1. Move the appropriate directory or files to a new folder (see "Changing to Simple Transport Security Mode" on page 8-6 for details). |
|                   | 2. Configure the Access Server instance in the Access System Console (see "To specify transport security mode for Access Server" on page 8-10 for details). |
|                   | 3. Run the configAAAServer program to specify the new mode. For details about using the ConfigureAAAServer Tool, see the Oracle Access Manager Access System Administration Guide. |
|                   | **AccessGate/WebGate:**  
|                   | 1. Move the appropriate directory or files to a new folder (see "Changing to Simple Transport Security Mode" on page 8-6 for details). You do not need to do this if you are changing over from Open mode. |
|                   | 2. Configure the new mode for the AccessGate instance in the Access System Console (see "To specify transport security mode for AccessGate" on page 8-10 for details). |
|                   | 3. Run the configAccessGate or the configWebGate program, as appropriate, to specify the new mode. To modify an AccessGate through the command line, see the Oracle Access Manager Access System Administration Guide. |
|                   | **Policy Manager:**  
|                   | Run the genCert utility to specify the new mode. The genCert utility is located in the directory  
|                   | PolicyManager_install_dir\access\oblix\tools\gencert  
|                   | where PolicyManager_install_dir is the directory in which the Policy Manager is installed. |
Changing Transport Security Modes for the Access System

</tbody>
</table>

Changing to Open Transport Security Mode

If you want to change transport security mode from Simple or Cert to Open, run the appropriate configuration program.

To change to Open security mode

1. Move the following directory to a new folder:

   AccessSystem_install_dir / access / oblix / config / simple (if in Simple mode)

   or

   AccessSystem_install_dir / access / oblix / config / * . pem and password.xml (if in Cert mode)

   where AccessSystem_install_dir is the directory in which the Access System components are installed. For example, the Policy Manager or Access Server or WebGate.

   This saves a previous configuration in case you want to revert to it.

2. Execute one of the commands in Table 8–7.
Changing to Simple Transport Security Mode

If you want to implement Simple mode, you do not need to request or install a certificate from an external CA. Oracle Access Manager ships with its own internal CA.

To change to Simple security mode

1. Move the following files to a new folder:
Changing Transport Security Modes for the Access System

AccessSystem_install_dir/access/oblix/config/*.pem

and

AccessSystem_install_dir/access/oblix/config/password.xml (if in Cert mode)

where AccessSystem_install_dir is the directory in which the Access System components are installed. For example, the Policy Manager or Access Server or WebGate.

This creates a backup file of your older configuration.

2. Generate a certificate through Oracle Access Manager's internal CA:
   a. Open a command prompt window and change to the appropriate AccessSystem_install_dir/access/oblix/tools/componentDirectory, Where:

      componentDirectory is the directory for the component you are modifying: configureAAAserver, configureWebGate, or genCert (genCert is the utility used by Policy Manager).

      For example:

      cd COREid/WebComponent/access/oblix/tools/configureWebGate

   b. Execute one of the commands in Table 8–8.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| UNIX             | Access Server:  
   start_configureAAAServer reconfig AccessServer_install_dir/access -R  
   where AccessServer_install_dir is the directory in which the Access Server is installed.  
   AccessGate:  
   start_configureAccessGate -i AccessGate_install_dir/access -t AccessGate -R  
   where AccessGate_install_dir is the directory in which the AccessGate is installed.  
   WebGate:  
   start_configureWebGate -i WebGate_install_dir/access -t WebGate -R  
   where WebGate_install_dir is the directory in which WebGate is installed.  
   Policy Manager:  
   Run the genCert utility to specify the new mode. The genCert utility is located in the directory AccessManager_install_  
   dir/access/oblix/tools/gencert  
   where PolicyManager_install_dir is the directory in which the Policy Manager is installed. |

Table 8–8  Access System Commands: Change to Simple Mode
Table 8–8 (Cont.) Access System Commands: Change to Simple Mode

<table>

</tr>
<tr>
<td></td>
<td>WARNING: You need to reinstall the Policy Manager if the Simple mode password for the Policy Manager is changed, or if the Access System is changed from Simple mode to Cert mode</td>
</tr>
</tbody>
</table>

Changing to Cert Transport Security Mode

The following procedure describes changing the transport security mode to Cert.

Note: The certificate request for WebGate generates the certificate-request file aaa_req.pem. You need to send this WebGate certificate request to a root CA that is trusted by the AAA server. The root CA returns the WebGate certificates, which can then be installed either during or after WebGate installation.

To change to Cert security mode

1. Move the following to a new folder: 

   AccessSystem_install_dir/\access/oblix/config/simple (if in Simple mode)

   This creates a backup of your old configuration
2. Generate a certificate request.

   a. Open a Command Prompt window and change to the following directory:

   \[\text{AccessSystem\_install\_dir}/access/oblix/tools/componentDirectory\]

   where \text{AccessSystem\_install\_dir} is directory in which the Access System
   components are installed and \text{componentDirectory} is the directory for the
   component you are modifying: configureAAAServer, configureWebGate, configureAccessGate, or genCert (genCert is used by Policy Manager)

   For example:

   \text{cd COREid/WebComponent/access/oblix/tools/genCert}

   b. Execute one of the commands in Table 44, depending on which component
   you are modifying.

\begin{table}[h]
\centering
\caption{Access System Request Certificate Commands}
\begin{tabular}{|l|l|}
\hline
\textbf{Operating System} & \textbf{Commands} \\
\hline
UNIX & Access Server:
\text{start\_configureAAAServer reconfig AccessServer\_install\_dir}/access -R \\
 & where \text{AccessServer\_install\_dir} is the directory in which the Access
 & Server is installed.

 & AccessGate:
 & \text{start\_configureAccessGate -i AccessGate\_install\_dir}/access -t \\
 & AccessGate -R \\
 & where \text{AccessGate\_install\_dir} is the directory in which the AccessGate is
 & installed.

 & where \text{WebGate\_install\_dir} is the directory in which WebGate is
 & installed.

 & Policy Manager:
 & Run the genCert utility to specify the new mode. The genCert utility is
 & located in the directory \text{PolicyManager\_install\_dir}/access/oblix/tools/gencert \\
 & where \text{PolicyManager\_install\_dir} is the directory in which the Policy
 & Manager is installed.
\hline
\end{tabular}
\end{table}
Changing Transport Security Modes for the Access System

Table 8-9 (Cont.) Access System Request Certificate Commands

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
| Windows          | **Access Server:**
|                  | configureAAAServer.exe reconfig AccessServer_install_dir\access -R |
|                  | where AccessServer_install_dir is the directory in which the Access Server is installed. |
|                  | **AccessGate:**
|                  | configureAccessGate.exe -i AccessGate_install_dir\access -t AccessGate -R |
|                  | where AccessGate_install_dir is the directory in which the AccessGate is installed. |
|                  | **WebGate:**
|                  | configureWebGate.exe -i WebGate_install_dir\access -t WebGate -R |
|                  | where WebGate_install_dir is the directory in which WebGate is installed. |
|                  | **Policy Manager:**
|                  | Run the genCert utility to specify the new mode. The genCert utility is located in the directory PolicyManager_install_dir\access\oblix\tools\gencert |
|                  | where PolicyManager_install_dir is the directory in which the Policy Manager is installed. |

**c.** When you are prompted for a mode, select Cert and press Enter.

**d.** Indicate that you are requesting a certificate.

**e.** Answer the prompts for information, including the following:
- A two-letter country code (the default is US)
- A state or province name
- Your city or other locality
- An organization name (your company, for example)
- An organizational unit name (your department, for example)
- A common name (must be your host machine name)
- An email contact address

**f.** Press Enter.

A message is displayed stating that your certificate request is in the file AccessServer_install_dir\access\oblix\config\aaa_req.pem.

The setup_aaa utility actually creates two files in this directory:
aaa_key.pem, which contains your private key, and aaa_req.pem.

**g.** Submit the aaa_req.pem file to the Certificate Authority to get your request signed.

3. Save the approved certificate to a file which the installer can access.

4. Save the CA chain in base64 code format to a .pem file that the installer can access.

5. After you receive the certificate from your CA, install the signed certificate.
To install the signed certificate for Cert mode

1. Open a Command Prompt window and change to the $AccessSystem_install_dir/access/oblix/tools/componentDirectory$

   where $AccessSystem_install_dir$ is the directory in which Access System is installed and $componentDirectory$ is the directory for the component you are modifying: configureAAAServer, configureWebGate, configureAccessGate, or genCert (genCert is the utility used by Policy Manager).

   For example:

   ```
cd COREid/access/oblix/tools/configureAAAServer
   ```

2. Execute one of the commands in

   **Table 8–10 Access System Install Certificate Commands**

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Commands</th>
</tr>
</thead>
</table>
   | UNIX              | Access Server:  
   |                   |   start_configureAAAServer reconfig $AccessServer_install_dir/access -R$  
   |                   |   AccessGate:  
   |                   |   start_configureAccessGate -i $AccessGate_install_dir/access -t $AccessGate -R$  
   |                   |   WebGate:  
   |                   |   start_configureWebGate -i $WebGate_install_dir/access -t $WebGate -R$  
   |                   |   Policy Manager:  
   |                   |   Run the genCert utility to specify the new mode. The genCert utility is located in the directory $PolicyManager_install_dir/access/oblix/tools/gencert$  
   |                   |   where $PolicyManager_install_dir$ is the directory in which the Policy Manager is installed. |
3. When you are prompted to enter Simple or Cert mode, type Cert and press Enter.
4. Indicate that you are installing a certificate.
5. Specify the locations of the key, server certificate, and CA chain files:
   - aaa_key.pem
   - aaa_cert.pem
   - aaa_chain.pem
   where aaa is the name you specify for the file (applicable only to Cert and chain files).

**WARNING:** The Webgate certificate request generates the certificate-request file aaa_req.pem. You need to send this certificate request to a root CA that is trusted by the AAA server. The root CA returns the WebGate certificates, which can then be installed either during or after WebGate installation.

If you have installed certificates for an earlier Oracle Access Manager-generated request, use the default value for aaa_key.pem when prompted.

Your certificate is installed.

6. Restart the AccessGate or Access Server, as appropriate.

**Transport Security Changes for Directory Servers**

When you install the Identity Server and the Access Server, you can specify Open or SSL mode between each of these servers and the directory server. To change the transport security mode after installation, you must reconfigure the Identity Server or
the Access Server, as appropriate. During reconfiguration, you can change the security mode between the directory server and the Identity or Access Server.

---

**Note:** See the *Oracle Access Manager Installation Guide* for additional information about adding directory certificates after installation.

---

**To change transport security between the Identity Server and directory server**

1. From a command line, find the appropriate setup_ois tool for your platform.
   
   On UNIX, for example:
   
   ```
   IdentityServer_install_dir/identity/oblix/tools/setup
   ```

2. At the command prompt, run the appropriate executable.
   
   On UNIX, for example:
   
   ```
   start_setup_ois -i
   ```
   
   You are guided through the steps required to set up the Identity Server.

3. When you are asked whether you want SSL between the Identity Server and the directory server, select either y (yes) or n (no).

   **Note:** If you select SSL, provide the full path to the location of the CA certificate when asked.

4. Complete the rest of the steps to finish the reconfiguration process.

**To change transport security to SSL between the Policy Manager and directory server**

1. From a command line, find the appropriate setup_access_manager tool for your platform.
   
   On UNIX, for example:
   
   ```
   PolicyManager/identity/oblix/tools/setup
   ```

2. At the command prompt, run the appropriate executable to create the cert8.db file.
   
   On UNIX, for example:
   
   ```
   start_setup_access_manager -i
   ```
   
   You are guided through the steps required to set up the Policy Manager.

3. When you are asked, provide the full path of the file containing the Root CA certificate for the directory server.

4. Complete the rest of the steps to finish the reconfiguration process.

**To change transport security between the Access Server and the directory server**

1. From a command line, navigate to the folder where the configureAAAServer tool is located.
   
   For example:
Changing Transport Security Passwords

When communicating with each other, components authenticate one another using a password-based mechanism.

- **Simple Mode:** In Simple mode, all components in an Identity or Access System must use the same password within the installation. Oracle Access Manager generates certificates that are required by Transport Layer Security (TLS). Any installation can generate valid certificates.
- You can store the password in a local file so that each component can start unattended. Or you may have the component prompt for the password when it starts. Prompting requires a system administrator to start each element manually and type the password.
- **Cert Mode:** Cert mode requires a password for each component's private key file. You can use a different password for each component.

As with Simple mode, you can store the password in a local file so that each component can start unattended, or you may have the component prompt for the password when it starts. Prompting requires a system administrator to start each component manually and type the password.

You can change the password for Cert or Simple transport security mode.

**To change the certificate password for the Identity System**

1. Open a Command Prompt window and change to the `IdentityServer_install_dir/identity/oblix/tools/setup` directory, where `IdentityServer_install_dir` is the directory in which the Identity Server is installed.

   For example:
   
   ```
   cd COREid/identity/oblix/tools/setup
   ```

2. Run one of the commands in Table 8–11.

### Changing Transport Security Modes

**Changing Transport Security Passwords**

When communicating with each other, components authenticate one another using a password-based mechanism.

- **Simple Mode:** In Simple mode, all components in an Identity or Access System must use the same password within the installation. Oracle Access Manager generates certificates that are required by Transport Layer Security (TLS). Any installation can generate valid certificates.
- You can store the password in a local file so that each component can start unattended. Or you may have the component prompt for the password when it starts. Prompting requires a system administrator to start each element manually and type the password.
- **Cert Mode:** Cert mode requires a password for each component's private key file. You can use a different password for each component.

As with Simple mode, you can store the password in a local file so that each component can start unattended, or you may have the component prompt for the password when it starts. Prompting requires a system administrator to start each component manually and type the password.

You can change the password for Cert or Simple transport security mode.

**To change the certificate password for the Identity System**

1. Open a Command Prompt window and change to the `IdentityServer_install_dir/identity/oblix/tools/setup` directory, where `IdentityServer_install_dir` is the directory in which the Identity Server is installed.

   For example:
   
   ```
   cd COREid/identity/oblix/tools/setup
   ```

2. Run one of the commands in Table 8–11.
Changing Transport Security Passwords

3. Specify the transport security mode this component is using.
4. Specify the old password.
5. Specify and confirm the new password.
6. Restart the Identity Server.

To change the certificate password for the Access System
1. Open a Command Prompt window and change to the AccessSystem_install_dir/access/oblix/tools/componentDirectory
   where AccessSystem_install_dir is the directory in which the Access System is installed and componentDirectory is the directory for the component you are modifying.
   For example:

   cd COREid/access/oblix/tools/configureAccessGate

2. Run one of the commands in Table 8–12.
3. Specify the transport security mode this component is using.

4. Specify the old password.

5. Specify and confirm the new password.

6. Restart the Access Server.

**Importing Multiple CA Certificates**

Oracle Access Manager recognizes one CA certificate for each directory server type for transport security between a component and the directory server for user data, configuration data, or policy data.

If your implementation has separate directory servers for user data, configuration data, or policy data, you can have separate CA certificates for each. Thus you can have up to three CA certificates in your implementation; one for the user directory, one for the configuration directory, and one for the policy directory.
Changing Access Server Security Password

You can change the Access Server transport security mode from the command line. For Simple mode, the AccessGate or WebGate and the Access Server must have the same password to allow them to communicate with each other.

To change the transport security mode password
1. Run the following executable:
   
   ```
   configureAAAserver chpasswd AccessServer_install_dir
   ```
   
   where `AccessServer_install_dir` is the directory in which the Access Server is installed.

2. Specify the following when prompted:
   - The transport security mode in which the Access Server is configured.
   - The old password
   - The new password

3. Restart the Access Server.

   See "About Transport Security Modes" on page 8-1 for more information.
This chapter provides an overview of reporting features, the information each feature presents, the types of output available, and possible uses for these reports. This chapter covers the following topics:

- About Reporting
- Summary of Reporting Features

About Reporting

Oracle Access Manager can collect and present a wide range of information related to the following:

- Users and resources in your Oracle Access Manager directory
- Activities on the Access and Identity Systems
- The operation, administration, and maintenance of your system

To help distinguish among the many report-related features built into Oracle Access Manager, this chapter reserves certain terms to describe specific functional areas, as explained in the following table:

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Monitoring</td>
<td>Refers exclusively to the SNMP data collected so that you can monitor the health and performance of the network components that host your system. For a complete discussion of SNMP Monitoring, see “SNMP Monitoring” on page 12-1.</td>
</tr>
<tr>
<td>Logging</td>
<td>Refers exclusively to program execution data collected so that you can diagnose the health of the components that make up your system, troubleshoot execution errors, and debug custom AccessGates and other plug-ins. For a complete discussion of logging, see “Logging” on page 10-1.</td>
</tr>
</tbody>
</table>
Report Types

The information collected and reported by the various reporting features falls into two broad categories:

- **Static reports**: Generally compiled from settings stored on Oracle Access Manager components or third-party related components. For example, policy and profile information stored on the Oracle Access Manager directory server is classified as static audit data. Connection settings (and states) fall into the Diagnostic category. Certain Audit Reports use static (stored) policy and profile information to compile a list of resources that are available to specified users during specified times.

- **Dynamic Reports**: Focus on events and changes in state at various levels throughout the Oracle Access Manager system. For example, the logging feature can record each function call (and outcome) originating from a given component. This low-level trace capability can be useful to developers. At the other end of the spectrum, the dynamic audit feature can reveal system intrusion threats by reporting patterns of failed authentication attempts on specific servers during a specific interval.
Data Sources

The reporting features can gather data from a variety of sources, the most important of which are covered in Table 9–2

<table>
<thead>
<tr>
<th>Data Source</th>
<th>Description</th>
</tr>
</thead>
</table>
| Oracle Access Manager        | Stores several types of static information, including the following:  
| directory                    |   ■ User, group, and organization profile settings  
|                               |   ■ Policy settings for protecting resources  
|                               |   ■ Connections settings such as those used to connect with Oracle Access Manager components or the various databases used by Oracle Access Manager  
|                               |   ■ Certain security settings  
|                               |   ■ Schema used to organize the LDAP directory at the heart of the Oracle Access Manager system  
| Component configuration files| Many key settings reside in configuration files stored within the directory structure of the Oracle Access Manager component they affect. This can range from the path to a database driver to the size of the buffer used for queuing log output.  
| System configuration files   | These settings for the machines that host the various Oracle Access Manager components can be environment variables that make components visible to each other, or they can be protocol settings that enable components to communicate at the same level. Generally, Oracle Access Manager does not report such system-level configurations directly, but it can sometimes report corresponding settings that must match the settings established at the host system level.  
| Access Servers               | In addition to providing configuration information about the settings they maintain to interact with other components, Access Servers can report Access System events such as authorization requests and their outcomes. This information is useful for determining who has gained (or tried to gain) access to what during a certain interval.  
| Identity Servers             | Identity Servers also store certain settings that govern how they interact with other components. Additionally, they report Identity System events such as who attempted to submit credentials at what time, and whether that authentication attempt succeeded.  
| Other components             | Components such as the Policy Manager can report changes to policies and certain other activities and settings.  

Data Output

Generally, the various types of reports can send data to one or more of the following destinations:

- The Oracle Access Manager graphical user interface
- A plain text file on the machine hosting the component that is sending the data
- A system file on the machine hosting the component that is sending the data
- A central database
Note: When data is sent to the audit database, it is generally filtered, compiled, and presented using special Crystal Reports templates that generate Audit Reports.

When a report is sent to the graphical user interface, it is likely to be somewhat less extensive than the equivalent type sent to a file or database. For instance, the on-screen Access Tester tool cannot report on the kind of complex user and resource groups that are available through the User Access Privilege tool, which sends output to a plain-text file or the audit database.

Output Configuration

Generally, you can format report output in one or both of the following ways:

- Through the Oracle Access Manager graphical user interface
- By manually editing a plain-text configuration file.

In a limited number of cases and to a limited extent, you can configure report output through a third-party GUI. For example, you can edit the templates used to generate the Audit Reports through the Crystal Reports interface.

Data Uses

Reports can prove useful to a variety of people, including the following:

- Administrators for Oracle Access Manager
- Network administrators
- Security administrators
- Compliance administrators
- Custom AccessGate and plug-in developers

Summary of Reporting Features

Table 9–3 provides an overview the reporting features, the information they present, and potential uses to which these features can be applied.

This chapter focuses on logging. It includes the following topics:

- About Logging and Log Levels
- About Log Configuration Files
- About Log Writers
- Log Configuration File Structure
- Controlling Logging Levels
- Log Configuration Parameters
- Configuring Logs in the Identity System Console

About Logging and Log Levels

The logging feature enables you to collect a wide range of program execution data so that you can troubleshoot system performance issues and diagnose component health problems.

Logging stands as just one of several features for collecting and presenting Oracle Access Manager-related information. For an overview of other reporting features, including system event auditing, Identity and Access System diagnostics, and SNMP monitoring, see “Reporting” on page 9-1.

The parameters that control logging activity reside in configuration files stored with each component. You customize log output for each component by manually editing the associated configuration file. For Identity Servers only, you have the option to set certain log parameters through the Identity System Console.

You can send the log data generated by a specific component to either of the following destinations, or neither, or both:

- A log file stored in the directory tree under the root installation directory of the component generating the data.
- The system file of the machine hosting the component logging data. (When more than one component resides on the same host, all components can send data to the system log file on that machine.)

For convenience, the many thousands of program events and states reportable through logging are classified within an eight-level, pyramidal hierarchy. At the highest level,
the Fatal category includes about 60 catastrophic events that usually force a component to exit. At the bottom of the pyramid, the Trace level reports about 900 Oracle Access Manager API and 150 third-party API calls and their outcomes. In most cases, these Trace level messages are meaningful only to developers and plug-in programmers.

Log Levels

The logging feature can collect logging data at one or more levels of detail. Since each level is activated individually, you can collect data from non-adjacent levels.

The following table lists the eight hierarchical levels that the LOG_THRESHOLD_LEVEL parameter uses to establish the levels to activate for logging. See Table 10–4 for details.

The ninth entry in this table, LOGLEVEL_ALL, encompasses all eight levels in the hierarchy.

<table>
<thead>
<tr>
<th>Level</th>
<th>Number of Events Reported</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGLEVEL_FATAL</td>
<td>&gt; 60</td>
<td>Critical errors are reported at this level. Generally, these events are serious enough to cause the component to exit.</td>
</tr>
<tr>
<td>LOGLEVEL_ERROR</td>
<td>&gt; 960</td>
<td>Events that may require corrective action are written to the log file. For example, an error-level entry is generated when the component is unavailable. An error log entry may also be generated for transient or self-correcting problems, such as failure to connect to another component.</td>
</tr>
<tr>
<td>LOGLEVEL_WARNING</td>
<td>&gt; 1200</td>
<td>Issues that may lead to an error or require corrective action at some point in the future are written to the log file.</td>
</tr>
<tr>
<td>LOGLEVEL_INFO</td>
<td>&gt; 400</td>
<td>Successfully completed actions or the current state of a component (if the component is initializing, for instance) are written to the log file.</td>
</tr>
<tr>
<td>LOGLEVEL_DEBUG1</td>
<td>&gt; 400</td>
<td>Basic debugging information is written to the log file. Typically, the information at this log level is only meaningful to a developer.</td>
</tr>
<tr>
<td>LOGLEVEL_DEBUG2</td>
<td>&gt; 100</td>
<td>Advanced (or rarely needed) debugging information is written to the log file. This log level augments the information provided in the Debug1 log level. Typically, the information at this log level is only meaningful to a developer.</td>
</tr>
<tr>
<td>LOGLEVEL_DEBUG3</td>
<td>&gt; 900</td>
<td>A large amount of debugging information (or data pertaining to an expensive section of the code) is written to the log file. This level is useful for debugging a tight loop or a performance-sensitive function. Typically, the information at this log level is only meaningful to a developer.</td>
</tr>
<tr>
<td>LOGLEVEL_TRACE</td>
<td>&gt; 900 Oracle Access Manager API; &gt; 150 3rd-party API</td>
<td>This log level is used to trace code path execution or to capture performance metrics. This information is captured at the entry and exit points for each component function. Typically, the information at this log level is only meaningful to a developer.</td>
</tr>
</tbody>
</table>
About Log Configuration Files

The parameters that control log output reside in XML-based log files that you can edit with any plain-text editor. Changes that you make to these files are effectively immediately.

Log Configuration File Paths

When you install a component, a default log configuration file is placed in the following location:

```
Component_install_dir\identity|access\oblix\config
```

where `Component_install_dir` is the directory where you are installing the component.

When you install more than one instance of a given component (such as multiple Identity Servers, for example), a logging configuration file is installed for each instance.

---

**Important:** To ensure that components can find the log configuration file, do not change the default path.

---

Be aware that a log configuration file is distinct from a log data file. For details on log data files, see Table 10–6.

Log Configuration File Names

The following table lists the names of the log configuration files for each type of component. To ensure that components can find this file, do not change the default name.

<table>
<thead>
<tr>
<th>Component</th>
<th>Logging Configuration File Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Server</td>
<td>oblog_config.xml</td>
</tr>
<tr>
<td>Identity Server</td>
<td>oblog_config.xml</td>
</tr>
<tr>
<td>Policy Manager</td>
<td>oblog_config_am.xml</td>
</tr>
<tr>
<td>WebGate</td>
<td>oblog_config_wg.xml</td>
</tr>
<tr>
<td>WebPass</td>
<td>oblog_config_wp.xml</td>
</tr>
<tr>
<td>Access Manager SDK (custom AccessGate)</td>
<td>oblog_config.xml</td>
</tr>
</tbody>
</table>

Table 10–1 (Cont.) Logging Levels

<table>
<thead>
<tr>
<th>Level</th>
<th>Number of Events Reported</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOGLEVEL_ALL</td>
<td>&gt; 5000</td>
<td>This amalgamated level includes all the events and states from all eight levels.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>Note:</strong> Even if you specify LOGLEVEL_ALL, logging may still not be activated at all levels, because the LOG_THRESHOLD_LEVEL takes precedence. See Figure 10–1 for details.</td>
</tr>
</tbody>
</table>
Modifying a Log Configuration File

The parameters set in the log configuration file associated with a given component determine the type of information that is logged for that component, the destination to which the data gets sent, and in certain cases, the size of the write buffer used for the log and the manner in which the target log file is rotated, among other specifics.

For all components, you edit the XML statements in the log configuration file with a plain text editor. For Identity Servers only, you can modify configuration parameters in the log file through the Identity System console, providing that the AUTOSYNC parameter in the configuration file has previously been set to the default value True. See "Configuring Logs in the Identity System Console" on page 10-15 for details.

About Embedded Comments

As installed, each log configuration file contains extensive embedded comments that explain the parameters you set to control log output. Comments, which can span one or multiple lines, begin with a left angle-bracket, an exclamation point, and two dashes, followed by two blank spaces ("<!-- "). They end with two spaces followed by two dashes, an exclamation point, and a closing angle-bracket (" --!>").

When you use the Identity System Console to modify the log parameters for a component, then commit those changes, the configuration file associated with that component is recorded to disk without the embedded comments. The presence or absence of these comments does not affect logging in any way; they are included solely to guide manual editing of the log configuration file.

In any case, you can view the original comments by opening the read-only duplicate of the original logging configuration file, which is named "oblog_config_original.xml" and located in the following directory:

Identity_Server_install_dir/oblix/config

Where IdentityServer_install_dir is the root installation folder for your Identity Server.

The following listing presents a typical log configuration file with comments embedded. For an example of a log file without embedded comments, see Example 10–7.

Example 10–1 The Default Log Configuration File (with Embedded Comments)

```xml
<<?xml version="1.0" encoding="ISO-8859-1" ?>
<!-------------------------------------------------------------------------- -->
<!-------------------------------------------------------------------------- -->
<!NetPoint Logging Configuration File -->
<!---->
<!--Changes to this file to take effect upon saving the file. -->
<!---->
<!---->
<!-------------------------------------------------------------------------- -->
<!-------------------------------------------------------------------------- -->
<!Set the Log Threshold -->
<!---->
<!--The log Threshold determines the amount of information to log. -->
<!--Selecting a lower level of logging includes the information -->
<!--logged at the higher levels. For example, LOGLEVEL_ERROR -->
<!--includes the information collected at LOGLEVEL_FATAL. -->
<!---->
<!--Choices are: -->
<!--LOGLEVEL_FATAL - serious error, possibly a program halt. -->
<!--LOGLEVEL_ERROR - a transient or self-correcting problem. -->
```
About Log Configuration Files

<!-- LOGLEVEL_WARNING - a problem that does not cause an error. -->
<!-- LOGLEVEL_INFO - reports the current state of the component. -->
<!-- LOGLEVEL_DEBUG1 - basic debugging information. -->
<!-- LOGLEVEL_DEBUG2 - advanced debugging information. -->
<!-- LOGLEVEL_DEBUG3 - logs performance-sensitive code. -->
<!-- LOGLEVEL_TRACE - used when you need to trace the code path -->
<!-- execution or capture metrics. Includes all previous levels. -->

<!-- If you do not specify a threshold, the default is WARNING. -->

<!-- In addition to specifying a threshold, you need to specify -->
<!-- the GUI overwrite the settings in this file. The -->
<!-- AutoSync parameter accomplishes this. This parameter takes a -->
<!-- value of True or False. If set to True, changes made in the -->
<!-- GUI overwrite changes in this config file. If False, changes -->
<!-- made in the GUI are only in effect until the server is -->
<!-- stopped or restarted. The default is True. -->

<!-- Configure the Log Level -->

<!-- To configure a log level, you specify a name for the -->
<!-- configuration (for instance, MyErrorLog1) and -->
<!-- the log level that you are configuring. You can create -->
<!-- more than one configuration per log level if you want -->
<!-- to output to more than one destination. You can output to -->
<!-- the system log or to a file, as specified on -->
<!-- the LOG_WRITER parameter. The value for the LOG_WRITER -->
<!-- parameter may only be SysLogWriter, FileLogWriter or -->
<!-- MPFileLogWriter. The MPFileLogWriter is a multi-process safe -->
<!-- FileLogWriter. It should be used to log in webcomponents i.e -->
<!-- WebGate, Policy Manager and WebPass loaded on multiprocess -->
<!-- webservers like Apache and IPlanet(Unix) -->

<!-- If you do not specify an output destination, the default is -->
<!-- SysLogWriter. -->

<!-- If outputting to a file, you also specify a file name and -->
<!-- other parameters. Default parameter values are: -->
<!-- FILE_NAME: <installdir>/oblix/log/oblog.log -->
<!-- BUFFER_SIZE: 32767 (number of bytes) -->
<!-- MAX_ROTATION_SIZE: 5242880 (bytes, equivalent to 5MB) -->
<!-- MAX_ROTATION_TIME: 86400 (seconds, equivalent to one day) -->

<!-- Configuring the log level does not ensure that the data is -->
<!-- actually collected. Data collection for a log is -->
<!-- determined by the LOG_THRESHOLD_LEVEL parameter, above, -->
<!-- and the LOG_STATUS parameter in the log configuration. -->
About Log Writers

In addition to controlling the content of component-specific logs (in other words, the levels of logging that are reported), you can send the output collected at any log level to the log "writer" of your choice. For instance, you can direct catastrophic errors to the system log, but send trace-level debugging information to a disk file of your choice.

You determine where log data gets sent by setting the value of the LOG_WRITER parameter in a log-handler definition in the log configuration file.

Each of the three log writers supplied formats log data into an appropriate format and directs the output to a specific destination such as a system log or a data file. These log writers are described in Table 10–3.
Log Configuration File Structure

The log configuration file conforms to a standard format, which is parsed during component start-up and at other key points. Although you can edit parameters and add or subtract certain sections known as log-handler definitions, you should not change the underlying format of the log configuration file, or else the configuration parameters may become unparsable.

**Example 10–2** lists the elements in a log configuration file with examples included as well. (The positions of elided content are indicated by ellipses.) For a listing of the default log configuration file, see **Example 10–1** or **Example 10–7**.

**Example 10–2  Log Configuration File Structure (with Sample Content)**

An XML file header that declares the relevant XML version, which is always 1.0, and the encoding format, which is always ISO-8859-1. Note that this header statement differs from the other XML statements in this file in that it begins with "<?" and ends with "?>"

```xml
<?xml version="1.0" encoding="ISO-8859-1" ?>
```
A compound list that contains:

```
<CompoundList...>...</CompoundList>
```

The relevant XML name space for the log configuration file (within the opening tag)

```
xmLns="http://www.example.com"
```

The name of the compound list (within the opening tag)

```
ListName="logframework.xml.staging"
```

A simple list that contains:

```
<SimpleList>...</SimpleList>
```

A name/value pair for the LOG_LEVEL_THRESHOLD parameter:

```
<NameValPair ParamName="LOG_THRESHOLD_LEVEL" Value="LOGLEVEL_WARNING" />
```

Another name/value pair for the AUTOSYNC parameter:

```
<NameValPair ParamName="AUTOSYNC" Value="True" />
```

One or more compound lists, which, at this particular level, are known as log-handler definitions. Each contains:

```
<CompoundList...>...</CompoundList>
```

The relevant XML name space (within the opening tag)

```
xmLns="http://www.example.com"
```

The name of the compound list (within the opening tag)

```
ListName="LOG_CONFIG"
```

And one or more value/name lists, each of which contains:

```
<ValNameList...>...</ValNameList>
```

The relevant XML name space (within the opening tag)

```
xmLns="http://www.example.com"
```

The name of the value/name list (within the opening tag)

```
ValNameList ListName='LogFatal2Sys'
```

The following three mandatory name/value pairs:

- The LOG_LEVEL parameter

```
<NameValPair ParamName='LOG_LEVEL' Value='LOGLEVEL_FATAL' />
```

- The LOG_WRITER parameter

```
<NameValPair ParamName='LOG_WRITER' Value='SysLogWriter' />
```

- The LOG_STATUS parameter

```
<NameValPair ParamName='LOG_STATUS' Value='On' />
```
And none, some, or all of the following four name/value pairs, which are relevant only if you specified FileLogWriter or MPFileLogWriter for the LOG_WRITER parameter:

The FILE_NAME parameter

<NameValPair ParamName="FILE_NAME" Value="oblog.log" />

The BUFFER_SIZE parameter

<NameValPair ParamName="BUFFER_SIZE" Value="65535" />

The MAX_ROTATION_SIZE parameter

<NameValPair ParamName="MAX_ROTATION_SIZE" Value="52428800" />

The MAX_ROTATION_TIME parameter

<NameValPair ParamName="MAX_ROTATION_TIME" Value="86400" />

About XML Element Order

The XML tag language employs a tree-like structure with lists of elements corresponding to the leaves on a branch.

Within a given list, parallel elements can be presented in any order as long as the elements themselves remain intact and entirely within the tags that originally bracketed them. For example, the name/value lists in Example 10–3 and Example 10–4 are equivalent:

Example 10–3  Name/Value List

<ValNameList xmlns="http://www.example.com" ListName="LogError2Sys">
  <NameValPair ParamName="LOG_LEVEL" Value="LOGLEVEL_ERROR" />
  <NameValPair ParamName="LOG_WRITER" Value="SysLogWriter" />
  <NameValPair ParamName="LOG_STATUS" Value="On" />
</ValNameList>

Example 10–4  Name/Value List

<ValNameList xmlns="http://www.example.com" ListName="LogError2Sys">
  <NameValPair ParamName="LOG_WRITER" Value="SysLogWriter" />
  <NameValPair ParamName="LOG_LEVEL" Value="LOGLEVEL_ERROR" />
  <NameValPair ParamName="LOG_STATUS" Value="On" />
</ValNameList>

Similarly, within a given tag, the attributes (except for the tag name, which must always be the first element within the tag brackets) can be reordered, as long as they remain intact and within the tag elements that originally bracketed them. The opening tags for a name-value list in Example 10–5 and Example 10–6 are equivalent:

Example 10–5  Opening tag for a Name/Value List

<ValNameList xmlns="http://www.example.com" ListName="LogError2Sys">

Example 10–6  Opening tag for a Name/Value List

<ValNameList ListName="LogError2Sys" xmlns="http://www.example.com">
Controlling Logging Levels

Up to four interconnected factors determine whether logging is active for a given component at a given log level. These factors are listed in the following table:

**Table 10–4 Factors that Determine Whether Logging Is Active**

<table>
<thead>
<tr>
<th>Factor</th>
<th>Importance</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LOG_THRESHOLD_LEVEL</td>
<td>Primary</td>
<td>This parameter provides a convenient means to limit log output through a single setting. It takes precedence over all other settings by setting an absolute threshold within the log level hierarchy described in Table 10–1. For levels that are more fine-grained than the threshold level, no logging takes place, regardless of the other settings. For Identity Servers only, see &quot;Configuring Logs in the Identity System Console&quot; on page 10-15 for details on the relationship between configuration file and GUI-based settings.</td>
</tr>
<tr>
<td>LOG_STATUS</td>
<td>Secondary</td>
<td>This parameter toggles logging on or off, providing it does not get overridden by the log threshold level. See the previous row for details.</td>
</tr>
<tr>
<td>AUTOSYNC</td>
<td>Secondary</td>
<td>When this parameter is set to True, changes that you make to logging parameters in the Identity System Console take effect immediately without a server restart and the changes are saved to the configuration file. When AUTOSYNC is False, the changes that you make in the Identity System Console also take effect immediately, but they are not saved to the configuration file and are discarded after the server is restarted.</td>
</tr>
</tbody>
</table>

About Log Handler Precedence

A single log-configuration file can contain as many as three log-handler definitions for a single log level. Three different log handlers are required if you wish to send output to each of the three log writers.

When the LOG_STATUS settings in these log handlers conflict, the setting in the log-handler definition closest to the physical end of the log configuration file is read last. Therefore, it takes precedence over the LOG_STATUS settings in all previous log-handler definitions for the same log level.

The state of the LOG_STATUS parameter in the "last read" log-handler definition for a given level takes effect for all the log-handler definitions for that level. For example, you can set LOG_STATUS to Off for the first two log handlers that aim at a certain level, yet logging can still occur for all three handlers, because LOG_STATUS happens to be On for the third and final log handler in the configuration file.

As previously mentioned, the LOG_STATUS settings at any given level become moot if that level is more fine-grained than the current LOG_THRESHOLD_LEVEL. In such a case, neither conflicting settings among the log handlers, nor the order in which the log handlers appear is of consequence, because logging cannot be activated at this level.
Ensuring That Your Edits Take Effect

A watcher thread picks up changes to the log file every minute (60 seconds) and ensures that changes take effect. It is unnecessary to restart the server.

**Note:** For Identity Servers, edits made through the Identity System Console are written to oblog_config.xml only if the AutoSync parameter in this file is set to True. If this parameter is set to False, the old configuration file settings take effect after the server is restarted.

---

**Log Configuration Parameters**

At minimum, each log-handler definition sets five parameters, as listed in Table 10–5.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>xmlns</td>
<td>This specifies the relevant XML namespace for the current list and is identical for all log-handler definitions in a given logging configuration file. Example: <a href="http://www.example.com">http://www.example.com</a></td>
</tr>
<tr>
<td>ListName</td>
<td>These names are required for all the lists in the logging configuration file. Wherever possible, preserve the default list names.</td>
</tr>
<tr>
<td></td>
<td>When creating a new log-handler definition, try to select a name for the associated name/value list that easily distinguishes the entry from all other entries in the logging configuration file. Examples:</td>
</tr>
<tr>
<td></td>
<td>WarningsAndAboveToSyslog sends Fatal, Error, and Warning messages to the system log file.</td>
</tr>
<tr>
<td></td>
<td>WarningsOnlyToFileLog128KBuffer sends messages from just the Warning level to a 128KB buffer, and hence to a disk file.</td>
</tr>
<tr>
<td></td>
<td>TraceOnlyToMPRotateDaily sends messages from just the Trace level to the multi-process file writer, which opens and closes the file each time it writes to disk. This file is replaced with a fresh (empty) file every day, regardless of the size of the file at the time of replacement.</td>
</tr>
<tr>
<td>LOG_LEVEL</td>
<td>This specifies one of the nine available log level settings. See Table 10–1. The default logging configuration file activates logging for three levels: Fatal, Error, and Warning. Output is sent to both the system log and the log data file for the component doing the logging.</td>
</tr>
<tr>
<td>LOG_WRITER</td>
<td>This specifies which log writer handles output for a given log-handler definition. See Table 10–3 for a list of the supported choices.</td>
</tr>
<tr>
<td>LOG_STATUS</td>
<td>This parameter turns the log handler on or off, as explained in the next section.</td>
</tr>
</tbody>
</table>

If you specify FileLogWriter or MPFileLogWriter as for the LOG_WRITER parameter, the four parameters detailed in the following table become relevant. The first becomes mandatory, while the other three are optional.
### Table 10–6 Log Data File Configuration Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILE_NAME</td>
<td>Used only for the FileLogWriter or MPFileLogWriter. It represents the name (and location) of the file to which logging information is written.</td>
<td>oblog.log</td>
</tr>
<tr>
<td></td>
<td>You can prepend an absolute path to the file name so as to store it somewhere other than the default location, which is:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Component_install_dir\oblix\logs</td>
<td></td>
</tr>
<tr>
<td></td>
<td>where Component_install_dir is the root installation directory for the component whose system events you are logging.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not specify a file name, the default applies.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>When you create more than one log-handler definition that sends output either to FileLogWriter or MPFileLogWriter, make sure that you specify different file names in each case so that multiple handlers do not attempt to write to the same file. This caution does not apply to log handlers accessing the SysLogWriter.</td>
<td></td>
</tr>
<tr>
<td>BUFFER_SIZE</td>
<td>This parameter represents the size of the buffer used to store logged data being written to the log file.</td>
<td>65535 (64KB)</td>
</tr>
<tr>
<td></td>
<td>If you set the buffer value to 0, no buffering is performed. (This ability to turn off buffering can be useful when a system failure occurs).</td>
<td></td>
</tr>
<tr>
<td></td>
<td>In the event of a system failure, Fatal-level messages are always flushed to the log file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not specify the buffer size, the default applies.</td>
<td></td>
</tr>
<tr>
<td>MAX_ROTATION_SIZE</td>
<td>When the log file reaches this size (in bytes), the file is renamed and a new file is created with the file name originally used by the just-renamed file. For example “oblog.log” becomes “oblog.log 1081303126.” The number represents the time when the file was created.</td>
<td>52428800 (512KB)</td>
</tr>
<tr>
<td></td>
<td>If you do not specify this parameter, the default is used.</td>
<td></td>
</tr>
<tr>
<td>MAX_ROTATION_TIME</td>
<td>The time interval, in seconds, when the log file is renamed, whether or not it has reached the maximum rotation size.</td>
<td>86400 (1 day, in seconds)</td>
</tr>
<tr>
<td></td>
<td>If the maximum log file size is not reach between two time-triggered file rotations, the numbers appended to the log files created differ by the number of seconds in the rotation interval. For example, “oblog.log 1081389526” and “oblog.log 1081303126” differ by 84,600, which is the number of seconds in 24 hours, the rotation interval set in the logging configuration file.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>If you do not specify this parameter, the default is used.</td>
<td></td>
</tr>
</tbody>
</table>
Default Log Settings

The default log configuration file installed with each component activates only the highest three levels (Fatal, Error, and Warning) in the hierarchy of logged events.

Also by default, all log output is directed to the system log.

On Windows machines, you can view the system log for the machine hosting the component you are logging by navigating to: My Computer, Manage, Event Viewer, Application. System event entries for the components being logged are interspersed among the system events reported for the operating system and non-Oracle Access Manager applications.

For the Solaris and Linux environments, the location of the system log is recorded in a system configuration file whose particulars can vary from machine to machine. For the name and location of this system file, consult the owner of the machine hosting the component whose system log you wish to examine.

The following listing presents the content of the default log-configuration file installed with each component. The embedded comments, which have no effect on the actual function of the file, have been removed in order to expose the underlying structure of the file:

Example 10–7  The Default Log Configuration File (without embedded comments)

```xml
<?xml version='1.0' encoding='ISO-8859-1' ?>
<CompoundList xmlns=http://www.example.com ListName="logframework.xml.staging">
  <SimpleList>
    <NameValPair ParamName="LOG_THRESHOLD_LEVEL" Value="LOGLEVEL_WARNING" />
    <NameValPair ParamName="AUTOSYNC" Value="True" />
  </SimpleList>
  <CompoundList xmlns=http://www.example.com ListName="LOG_CONFIG">
    <ValNameList xmlns=http://www.example.com ListName="LogFatal2Sys">
      <NameValPair ParamName="LOG_LEVEL" Value="LOGLEVEL_FATAL" />
      <NameValPair ParamName="LOG_WRITER" Value="SysLogWriter" />
      <NameValPair ParamName="LOG_STATUS" Value="On" />
    </ValNameList>
    <ValNameList xmlns=http://www.example.com ListName="LogError2Sys">

      <NameValPair ParamName="MAX_ROTATION_TIME" Value="86400" />
      <NameValPair ParamName="LOG_STATUS" Value="On" />
    </ValNameList>
  </CompoundList>
</CompoundList>
```
Parsing the Default Log Configuration File

The default log configuration file follows the abstract structure presented in "Log Configuration File Structure" on page 10-7.

The simple list near the top of the file sets LOG_THRESHOLD_LEVEL to the Warning level. Since the threshold parameter takes precedence over all others, none of the levels that are more fine-grained than Warning are logged, regardless of the settings in the rest of this file.

The simple list also sets the AUTOOSYNC parameter to True. This setting enables you to save the configuration values you set in the Identity System console to this configuration file so that they persist after you restart the Identity Server. Although the AUTOOSYNC setting appears in the default configuration files for all of the components, it is relevant only for Identity Servers.

The nested compound list contains four log-handler definitions. The first, named LogFatal2Sys, sets the LOG_LEVEL affected by this definition to Fatal and sets LOG_STATUS to On. As previously noted, the threshold level for this configuration file is Warning, which is more fine-grained than Fatal, so this definition is not overridden. The log output goes to the system log, because this is what the definition specifies through the LOG_WRITER parameter.

The LogError2Sys log-handler definition sends Error level messages to the system log. Error is located prior to the current threshold level (Warning), so this definition is in effect.

The LogWarning2Sys definition sends Warning level output to the system log. Like the two previous log-handler definitions, it is not overridden by the current LOG_THRESHOLD_LEVEL parameter.

LogAll2File, the final log-handler definition, appears to send output from all eight log levels to a disk file named oblog.log. However, LOG_THRESHOLD_LEVEL, which is currently set to Warning, takes precedence, so only the output from the Fatal, Error, and Warning levels gets recorded in the log file.
Figure 10–1 Log-Level Activation in the Default Log Configuration File

Since output from LogAll2File goes to the FileLogWriter, the parameters governing file name, buffer size, rotation size, and rotation interval all take effect.

In sum, the default configuration file sends Fatal, Error, and Warning messages to both the system log and a default log data file named oblog.log.

**Configuring Logs in the Identity System Console**

For Identity Servers only, you can modify certain log settings through the Identity System Console. Alternatively, you can edit the log configuration file manually.

**To view or modify log-handler definitions**

1. From the Identity System landing page, click the Identity System Console link. If you are already logged in, click the Identity System Console tab.
2. From the Identity System Console, click the System Configuration sub-tab, then click the Identity Servers link in the left navigation pane. The List of All Identity Servers page appears.
3. Click the link for the Identity Server whose activity you want to log.

The Details for Identity Server page appears with a list of log-handler definitions at the bottom of the page.

4. Examine the Log Threshold setting above the Log Handler Definitions table. This represents the current LOG_THRESHOLD_LEVEL.

If you want to change this setting, click Modify at the bottom of the page and proceed to "To modify the log threshold from the Identity System Console" on page 10-16. Otherwise, continue to the next step.

5. In the table of log-handler definitions, click the link for the log handler you wish to examine or change.

The Modify the Log Handler Definition page appears. From this page, you can specify values as described in Table 10–5. If you specify File in the Output To field, you must complete the fields described in Table 10–6.

You can change the defaults for the log file name, log file maximum size, log file rotation interval, and log buffer maximum size, as listed in Table 10–6.

6. Click Save.

To modify the log threshold from the Identity System Console
1. From the Identity System Console, click the System Configuration sub-tab, then click Identity Servers in the left navigation pane.

2. Click the name of the Identity Server whose settings you want to examine.

3. Click Modify at the bottom of the Details of the Identity Server page.
4. Use the list to set the Log Threshold Level to the value you want.

5. Click Save.

   The change takes effect immediately. If AUTOSYNC is True in the log configuration file, the change is written to the log configuration file so that the change persists after you restart the server.

To add or delete a log-handler definition

1. From the Identity System Console, click the System Configuration sub-tab, then click the Identity Server link in the left navigation pane.

2. Click the name of the Identity Server to which you wish to add a log-handler definition.

3. Click Modify at the bottom of the page.

   The Modify Identity Server page appears.

4. Under Log Handlers Definition, complete the appropriate action:

   ■ To delete a log output configuration, check the box next to the appropriate link, then click Delete.

   ■ To add a log writer, click Add.

   If you click Add, the Add a New Log Writer page appears.

5. Supply a name and a log level for the new log writer.

6. Verify that the log level is the same as or higher than the current log threshold level, as described in "To view or modify log-handler definitions" on page 10-15.

   If the new log level is lower than the current threshold level, set the threshold level to the new log level or lower, as detailed in "To modify the log threshold from the Identity System Console" on page 10-16.

7. If you choose to output to a file rather than the system log, you must supply a file name and path, as described in Table 10–6.

8. Click Save.
This chapter focuses on the auditing features and how to configure these using the Identity System console. The following topics are provided:

- About Auditing
- Audit Output Considerations
- Controlling Audit Output
- Auditing Requirements
- Audit-to-Database Architecture
- Setting Up File-Based Auditing
- Setting Up Database Auditing
- Setting up Audit Reports

**Note:** For details about installing audit-to-database components, see the *Oracle Access Manager Installation Guide*.

### About Auditing

The auditing feature collects and presents data pertaining to policy and profile settings, system events, and usage patterns. Oracle Access Manager can generate two types of audit reports:

- **Static:** These reports are derived from policy and profile information that is stored on the Oracle Access Manager directory server.
  
  See "Static Audit Reports" on page 11-3 for details.

- **Dynamic:** These reports are derived from Access System and Identity System events that are collected from the servers in your system.
  
  At the most detailed level, dynamic audit reports reveal when a system event was triggered and who triggered it. At a higher level, these reports can reveal component load levels, resource request patterns, system intrusion attempts, and overall system performance. See "Static Audit Reports" on page 11-3 for details.

In addition to auditing, Oracle Access Manager supports logging, SNMP monitoring, and other reporting features. See Chapter 9, "Reporting" on page 9-1 for details.
Audit Output Considerations

You can record all dynamic audit reports and some static audit reports to disk file, to a relational database, or both. Some static reports can also be displayed in limited form through the graphical user interface.

Audit Security Considerations

Database auditing provides the following advantages over file based auditing in the area of security:

- All audit information is stored in a central database that can be protected by any security methods that your database supports.

The audit-to-file option records data to a plain-text file on each server that collects audit data. Such files are not protected by database-level security.

---

**WARNING:** To take full advantage of database security, make sure you turn off the audit-to-file feature for all Access and Identity Servers in your system. You should also store the password to the default audit database user account in the RDBMS profile on the directory server rather than in the ODBC.ini file (if used) on each server host.

---

- Data can be sent to an audit database using the transport security methods supported by ODBC or OCI, as applicable to your database.

- Using the audit database, Crystal Reports can generate security-related statistics. For instance, you can track the number of resource requests that were refused during a given interval or compile a list of users who are locked out of the system.

- Auditing-to-database can assist in compliance reporting for regulatory acts such as Sarbanes-Oxley, Gramm-Leach-Billey, and HIPAA (the Health Information Privacy and Accountability Act of 1996).

Audit Performance Considerations

Auditing, whether to database or file, can slow the performance of your Oracle Access Manager System. You can control the impact of auditing as follows:

- Turn on auditing only for selected servers.

  See "To enable and configure auditing for each Identity Server" on page 11-33 and "To enable and configure auditing for each Access Server" on page 11-38 for details.

- Turn on auditing only for selected profile attributes, events, and Identity System applications.

  See "To specify global Identity System events and profile attributes for audit" on page 11-35 and "To specify User, Group, or Organization Manager events for audit" on page 11-36 for details.

- Increase the database audit retry interval so that whenever the connection to the database is broken, the server does not initiate thrashing by resending a failed write attempt before the connection is restored.

  You control this interval with the DBAuditRetryInterval parameter in the globalparams.xml file in the following directory:
Component_install_dir\apps\common\bin

where Component_install_dir is the installation directory of the server whose audit behavior you want to control. This parameter takes as a value the number of seconds to wait before initiating another attempt to write data to the audit database.

- For file-based auditing only, increase the size of the audit buffer.

  This measure reduces the number of times the audit feature accesses your hard disk. See "To enable and configure auditing for each Identity Server" on page 11-33 and "To enable and configure auditing for each Access Server" on page 11-38 for details.

- For file-based auditing only, lengthen the interval between buffer flushes.

  This reduces the number of times the auditing feature writes to disk, but it also increases the potential amount of audit data you lose in a system failure.

  **WARNING:** Only fatal errors are flushed to file if a server fails. All other audit items in the buffer at the moment of the failure are lost. Therefore, by increasing the buffer size or lengthening the interval between buffer flushes, you increase the potential volume of audit data lost in the event of a system failure.

### Static Audit Reports

Static audit reports are generated from policy and profile information stored on the Oracle Access Manager directory server. You can generate five types of static reports:

<table>
<thead>
<tr>
<th>Table 11–1 Static Audit Report Types</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Report Type</strong></td>
</tr>
<tr>
<td>User Access Privilege Report</td>
</tr>
<tr>
<td>Resource Access Privilege Report</td>
</tr>
<tr>
<td>Access Test</td>
</tr>
<tr>
<td>Access System Diagnostic Report</td>
</tr>
<tr>
<td>Identity System Diagnostic Report</td>
</tr>
</tbody>
</table>
Dynamic Audit Reports

To be able to send data to the audit database, you must install and configure one of the following databases on a host within your domain:

- Microsoft SQL Server for environments where the Oracle Access Manager servers all run on Windows.
  
  See "About installing SQL Server (Windows)" on page 11-19 for details.

- Oracle Database for environments where the computer hosting the Oracle Access Manager server contains either an Oracle database server or an Oracle database client that is configured to talk to an Oracle database server.

  The Oracle database client that resides on the computer hosting the Oracle Access Manager server can run on a different platform from the Oracle database server. For example, the Oracle Access Manager server and Oracle database client can run on a Linux host and the Oracle database server can be on a Windows host.

In addition, you can install and configure Crystal Reports presentation software on a Windows machine in your Oracle Access Manager domain. See "To install Crystal Reports" on page 11-42 for details.

Controlling Audit Output

You can control the type and amount of audit data collected by each server. For example, you can configure the Master Audit Rule on an Access Server to record authentication failures, but not authentication successes. See "To modify audit output formatting for the Access System" on page 11-39 for details. Or, you can configure the Application Auditing Policy on an Identity Server to record the time and date of each user logon, but not the time of logout or session expiration. See "To modify audit output formatting for the Identity System" on page 11-34 for details.

If you send data to the audit database, you can display the collected information in Crystal Reports templates that have been preconfigured to present audit data. The generated audit reports fall into the following categories:

- Global View Access
- Authentication
- Authorization
- Activity
- Identity Management

See "About Audit Reports" on page 11-13 for details.

About Audit Options

You set all audit options through configuration pages in Oracle Access Manager, as detailed in Table 11–2:
### Table 11–2  Where to Set Audit Options

<table>
<thead>
<tr>
<th>Audit-Related Functionality</th>
<th>Location in GUI</th>
<th>Scope</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable file-based auditing and database auditing, and modify audit file attributes on an individual Identity Server.</td>
<td>Identity System Console, System Configuration, Identity Server, ServerName, Modify where ServerName specifies the Identity Server you want to modify</td>
<td>Per server</td>
</tr>
<tr>
<td>Modify the default formatting used for file-based and database auditing, including date format, date separator, message format, escape character, record separator, and field separator. To enable database auditing, you must replace the default message format string. See &quot;To modify audit output formatting for the Identity System&quot; on page 11-34. If you modify any other attributes, you may have to reconfigure your Crystal Report templates and repository settings.</td>

</tbody>
</table>
Auditing Requirements

Displaying audit reports on-screen or sending audit output to disk files does not require the installation of special components.

Auditing to a database is restricted to certain Oracle Access Manager system configurations and requires the installation of special components, as detailed in the following sections.

Audit-to-Database Requirements

Database auditing requires special components, as outlined in the next section. Installation details are available in the Oracle Access Manager Installation Guide.

Special Components for Database Auditing

To enable auditing to a database, you must install the components listed in Table 11–3:
Table 11-3  Special Components Needed for Database Auditing

<table>
<thead>
<tr>
<th>Component</th>
<th>Installation Notes</th>
</tr>
</thead>
</table>
| Oracle Access Manager server hosts | All the machines hosting the Oracle Access Manager servers that are connected to the audit database must run on the same platform, as follows:  
  - For auditing to SQL Server, the Oracle Access Manager server platform can be Windows Advanced Server 2003 Enterprise Edition.  
  - For auditing to the Oracle Database, the platform can be Windows Server 2003 Enterprise Edition or Linux.  
  To obtain the latest platform support information, see "Updates to Supported Versions and Platforms" on page 11-8. |
| Database server                | Install the following database server application on a computer in your Oracle Access Manager domain:                                              
  - For SQL Server using an ODBC connection type, the database server machine can run Microsoft SQL Server 2000, Standard, Enterprise, or Developer edition for environments where all the servers connected to the audit database are running on Windows hosts.  
  - For an Oracle database, the computer hosting the Oracle Access Manager server should contain Oracle database server 9.2.0.7 or 10.1.0.5, or Oracle database client 10.1.0.5. If the computer hosting the Oracle Access Manager server contains Oracle database client 10.1.0.5, the Oracle database server could be either 10.1.0.5 or 10.2.0.2.  
  To obtain the latest platform support information, see "Updates to Supported Versions and Platforms" on page 11-8. |
| Crystal Reports                | You install Crystal Reports plus a required patch on a Windows machine that can access the ODBC database. See "Setting up Audit Reports" on page 11-41 for details. The Crystal Reports host must run Windows  
  The following Crystal Reports packages have been tested:  
| ODBC Drivers                   | If you use SQL Server, you do not have to install additional database drivers.                                                                       |
| OCI (Oracle Call Interface)    | The OCI connection type that can be used with the Oracle database is bundled with the Oracle Access Manager libraries. No additional configuration is required for this type of connection. |

Updates to Supported Versions and Platforms
To see the latest supported versions and platforms for this integration refer to Metalink, as follows.

To view information on Metalink
1. Go to the following URL:  
   http://metalink.oracle.com  
2. Click the Certify tab.  
3. Click View Certifications by Product.  
4. Select the Application Server option and click Submit.
5. Choose Oracle Application Server and click Submit.

Audit-to-Database Architecture

Note that if you use an ODBC connection type, all Identity and Access Servers must run on Windows. If some Identity or Access Servers run on Linux, you can only use an OCI connection type. For details about your environment, see the person who installed the database auditing components as described in the Oracle Access Manager Installation Guide.

The following diagrams show a distributed environment with Oracle Access Manager servers on one or more host machines, the OCI or ODBC-compatible database server on another host, and the Crystal Reports application on yet another host.

In a simpler deployment, you can install your entire Oracle Access Manager system and all database auditing components on one Windows computer. In a single-host scenario, if you install Oracle database with ODBC, you need only one table of ODBC data-source definitions (one ODBC.ini file) on your host.

Figure 11–1 and Figure 11–2 illustrate the components that you install and configure to enable auditing to database.

Figure 11–1 Audit-to-Database Architecture: SQL Server

Figure 11–1 shows an audit-to-database architecture on SQL Server that is distributed across four host machines. In this configuration, all Access and Identity Servers must run on Windows, and the database must run on Windows. The LDAP Server does not have to be Windows-based.
Figure 11–2 illustrates the architecture for auditing using the Oracle database. As shown, a Windows system can host OCI or ODBC, and Linux systems can host OCI. The LDAP directory can run on Windows or Linux. Different hosts can be used for OCI or ODBC data source definitions, the ODBC driver, and the Oracle Access Manager audit reports and the Crystal repository.

**Figure 11–2  Audit-to-Database Architecture: Oracle Database**

### About OCI Settings

If you are auditing to an Oracle database that uses an OCI connection type, little additional configuration is needed, with one exception. Users need to set the environment variable ORACLE_HOME.

### About ODBC Data Source Definitions

ODBC data-source definitions encapsulate all the information necessary for a client application such as an Oracle Access Manager server or Crystal Reports to connect with ODBC 3.0-compatible databases formatted for SQL Server or Microsoft Access (.MCPO).

ODBC data-source definitions are stored in a file named ODBC.ini on each Windows computer that hosts an application connected to the audit database. Only one such list of ODBC data-source definitions should exist on a given machine, and that file should be shared by all the applications that connect to the audit database.

- Users generally add or modify data source definitions through a Windows administration GUI.
  
  Because this GUI hides many configuration details, users may never become aware that ODBC.ini exists, much less learn its location.

- If you are auditing to an Oracle database that uses an ODBC connection type, users may also need to set the environment variable ORACLE_HOME. This is the case if the host machine for the Oracle Access Manager component being audited contains an Oracle database client that is configured to talk to an Oracle database client.
server on a different machine. If the Oracle Database server resides on the same machine as the component being audited, users do not have to set ORACLE_HOME.

The following table lists the most important attributes in a data source definition:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DSN (Data Source Name)</td>
<td>Identifies a unique data source definition to all the clients that access a given data source. (The term DSN is often used incorrectly to denote an entire ODBC data source definition.) A DSN must be unique within your Oracle Access Manager environment. Furthermore, all the ODBC.ini files and RDBMS profiles referencing a particular DSN must contain identical information related to that DSN, including login name, password, database, and so on.</td>
</tr>
<tr>
<td>User</td>
<td>Identifies the database user account authorized to access and modify the ODBC data source. When an Oracle Access Manager server or the Crystal Reports application needs to access the data source, it uses this account to supply credentials to the database security scheme. For SQL Server, the default user account is 'sa,' which stands for system administrator.</td>
</tr>
<tr>
<td>Password</td>
<td>This is the password associated with the account specified by User Name. You specify this password in the default user account for the audit database and again in either the RDBMS profile or the ODBC data source definition in the ODBC.ini file on each Oracle Access Manager server connected to the audit database. If you specify a password in both the ODBC data source definition and the RDBMS profile, you should know that the former stores the password string on each Oracle Access Manager host in unencrypted form in ODBC.ini, which is a plain text file, while the latter stores the string in encrypted form on just the Oracle Access Manager LDAP directory server.</td>
</tr>
</tbody>
</table>
| Database                | This is the name of the target data source, which, in the case of the audit-to-database feature, is one of the following:  
  - The name of the database containing the Oracle Access Manager audit data  
  - A Microsoft Access database (.mdb file) for the Crystal Repository containing .gif image files and SQL-compatible queries used by the Crystal Report templates preconfigured to present audit information |
| Server                  | This is the name of the machine on which the RDBMS server (SQL Server) resides. |
| Port                    | This is the port on which the RDBMS server listens for incoming requests. |
| Driver                  | The fully qualified path to the ODBC driver libraries on the local machine. |
| Description             | Details to help you identify the data source definition. |

**About ODBC Drivers**

An ODBC driver library is specific to the type of database server to which you are connecting and the platform on which the driver is installed.
Each ODBC driver provides libraries that facilitate connection to the audit database.

An ODBC driver must exist on each machine hosting an Oracle Access Manager server that connects to the audit database. When both an Access Server and an Identity Server reside on the same machine, only a single ODBC driver is required for that host.

**About the Windows ODBC Driver**

By default, Windows installs the ODBC driver for SQL Server in the \Windows\System32 directory. It is accessible through the ODBC Data Source Administrator, which you launch by navigating to Start, Programs, Administrative Tools, Data Sources (ODBC).

The About tab in the ODBC Data Source Administrator displays the driver version number. If, for any reason, the installed version is lower than 3.5, or the driver is damaged or missing, you can download a replacement from the following Web site:

http://www.microsoft.com/odbc

The self-installing file is named odbc35in.exe.

**About RDBMS Profiles for Database Auditing**

An RDBMS profile is a definition for an audit database where all Identity and Access servers send audit data. RDBMS profiles can be defined for primary and secondary database instances for use in the event of failover.

RDBMS profiles reside on the Oracle Access Manager directory server, where they are accessed by all the Access and Identity Servers that are connected to that directory server. You configure RDBMS profiles in the Access System Console or the Identity System Console. See "To create an RDBMS profile" on page 11-30 for details.

Generally, reporting (static reports) and auditing (dynamic reports) share a single RDBMS profile. All the Access and Identity Servers that use a particular feature (such as reporting and auditing) must use the same RDBMS profile.

LDAP database profiles are server- and operation-specific. They can be shared by Access and Identity Servers, but they do not need to be. Two or more Access or Identity Servers can each use a different LDAP database profile even though each LDAP database profile is set up for the same LDAP server and operation.

**About Profiles For Databases That Use an ODBC Connection Type**

Each RDBMS profile can be configured for an ODBC or an OCI connection type. The RDBMS profile contains a database instance definition that configures the connection between an Access or Identity Server and the audit database. For an ODBC connection type, the database instance includes the DSN (Data Source Name) for the ODBC data source definition that is used to connect to the audit database. It also includes a copy of the attributes listed in Table 11–4.

The same DSN appears in the ODBC.ini file of every machine that hosts an Access or Identity Server that is connected to the audit database. Details associated with the DSN stored in the RDBMS profile server must match exactly the details associated with every instance of that DSN in the ODBC.ini files throughout your Oracle Access Manager system.

If the associated attributes fail to match, the values for USER and PASSWORD recorded in the RDBMS profile take precedence over the corresponding values stored in ODBC.ini. On the other hand, the values for DATABASE and other attributes stored in ODBC.ini take precedence over the corresponding values in the RDBMS profile. The values in one location are never overwritten by the values stored in the other location.
About Profiles For Databases That Use an OCI Connection Type

Each RDBMS profile can be configured for an ODBC or an OCI connection type. The RDBMS profile contains a database instance definition that configures the connection between an Access or Identity Server and the audit database. For an OCI connection type, you specify a Global Database Name (GDN) in the database instance definition. The database instance also includes a copy of the attributes listed in Table 11–4.

About the Audit Database

The audit database collects data from all the Access Servers and Identity Servers in your system. Oracle Access Manager supports the following:

- ODBC 3.0-compliant databases on SQL Server, which runs on the Windows platform
- ODBC 3.0- and OCI-compliant Oracle Database running on Windows and Linux machines

About the Crystal Repository

Within the context of the auditing to a database, the Oracle Repository and the Crystal Repository are synonymous because you link them through the orMap.ini file. See the procedure “To edit orMap.ini” on page 11-43.

This repository is a Microsoft Access format (.mdb) database that contains the following resources:

- .gif files used in Audit Reports
- SQL queries and commands used in Audit Reports
- Custom functions
- Templates that give Audit Reports a consistent look and feel
- Sample reports

Figure 11–3 shows the organization of common, identity, and access resources in the repository.

Figure 11–3  Organization of resources in the repository

About Audit Reports

Table 11–4 describes the audit reports:
<table>
<thead>
<tr>
<th><strong>Audit Data Type</strong></th>
<th><strong>Audit Report Type</strong></th>
<th><strong>Description</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Authentication Statistics</td>
<td>Authentication/Dynamic</td>
<td>The number of authentication successes and failures that occurred on a given server or across the Oracle Access Manager system during a given interval.</td>
</tr>
<tr>
<td>Authorization Statistics</td>
<td>Authorization/Dynamic</td>
<td>The number of authorization successes and failures that occurred on a given server or across the Oracle Access Manager system during a given interval.</td>
</tr>
<tr>
<td>Access Failures by User</td>
<td>Authorization/Activity/Dynamic</td>
<td>The number of authorization requests from a given user that failed during a given interval.</td>
</tr>
<tr>
<td>Access Failures by Resource</td>
<td>Authorization/Activity/Dynamic</td>
<td>The number of authorization requests for a given resource that failed during a given interval.</td>
</tr>
<tr>
<td>Access Privileges</td>
<td>Filtered Query/Static</td>
<td>Two types of access privilege reports are supported:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- All the users allowed to access a list containing one or more resources.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- All the resources accessible by a list containing one or more users.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When this information is recorded to a file or database, it is referred to as a User Access Privilege Report or advanced Filtered Profile Query. See the procedure “To create and manage user access privilege reports” on page 11-40 for details.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When simpler queries are displayed through the GUI, they are referred to as Access Tester output.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>This type of audit information is static. It is derived from policy information that is stored on the directory server rather than collected on a historical, event-by-event basis from an Access Server or Identity Server.</td>
</tr>
<tr>
<td>User Profile History</td>
<td>Identity Management/Dynamic</td>
<td>Changes to password, policy, profile, and so on for all users.</td>
</tr>
<tr>
<td>Group History</td>
<td>Identity Management/Dynamic</td>
<td>A list of groups that a user has been added to or removed from in a given interval.</td>
</tr>
<tr>
<td>Revoked Users</td>
<td>Identity Management/Dynamic</td>
<td>A list of users who have been locked out of the system.</td>
</tr>
<tr>
<td>Deactivated Users</td>
<td>Identity Management/Dynamic</td>
<td>A list of users whose access accounts have been deactivated. Lists of reactivated users can also be generated.</td>
</tr>
<tr>
<td>Password Changes</td>
<td>Identity Management/Dynamic</td>
<td>The number of passwords that have been changed throughout the system during a given interval.</td>
</tr>
<tr>
<td>User Status Changes</td>
<td>Identity Management/Dynamic</td>
<td>The groups to which a given user or users has been added within a given interval.</td>
</tr>
<tr>
<td>Identity History</td>
<td>Identity Management/Dynamic</td>
<td>Changes to password, policy, profile, and so on for one or more individual users.</td>
</tr>
</tbody>
</table>
Setting Up File-Based Auditing

You turn file-based auditing on and off as well as change the name and location of the audit file generated by an individual Access Server or Identity Server through the Oracle Access Manager GUI. By default, the audit flag is off for all Oracle Access Manager Servers. The following two procedures detail the steps for activating and configuring file-based auditing for Identity Servers and Access Servers, respectively. Note that you must activate the auditing flag for each Oracle Access Manager server individually.

You can also modify the defaults for the following three categories of audit settings:

- **Common**: See "To specify global Identity System events and profile attributes for audit" on page 11-35 for details.
- **Oracle Access Manager server-specific**: See the procedures "To enable and configure auditing for each Identity Server" on page 11-33 and "To enable and configure auditing for each Access Server" on page 11-38 for details.
- **Identity System application-specific**: See the procedure "To specify User, Group, or Organization Manager events for audit" on page 11-36 for details.

The categories in the preceding list apply to both file-based and database auditing.

**To configure file-based auditing for an Identity Server**

1. From the Identity System landing page, click Identity System Console.

   If you are already logged in to the Identity System, click the Identity System Console tab.

2. Click the System Configuration sub-tab, then click Identity Servers in the left navigation pane.

3. From the list of identity servers, select the link for the server that you want to modify.

4. Review the Audit to File settings.

<table>
<thead>
<tr>
<th>Audit Data Type</th>
<th>Audit Report Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Workflow Execution Time</td>
<td>Identity Management/Dynamic</td>
<td>The average and maximum length of time it has taken to complete a workflow during a given period.</td>
</tr>
</tbody>
</table>
Table 11–6 describes the audit-to-file configuration parameters.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit to File Flag</td>
<td>The radio buttons turn the audit to file feature to On or Off</td>
<td>Off</td>
</tr>
<tr>
<td>Audit File Name</td>
<td>You can specify the absolute path and name of the audit file for the Access or Identity Server you are auditing. You may find it convenient to specify something similar to the following: <em>Component_install_dir</em>\oblix\log\auditfile.lst where <em>Component_install_dir</em> is the root installation directory for the associated Access or Identity Server.</td>
<td>[blank]</td>
</tr>
<tr>
<td>Audit File Maximum Size</td>
<td>The approximate size, in bytes, at which the existing audit file is closed and renamed to the following <em>AuditFileName</em>.lst <em>TimeStamp</em> where <em>AuditFileName</em> is the name of the audit file, and <em>TimeStamp</em> is a numerical representation, in seconds since midnight, January 1, 1971, of the moment when the file was created. By default, <em>AuditFileName</em> is AuditFile. Simultaneously, a new audit file named AuditFileName is created and opened for input.</td>
<td>100000</td>
</tr>
<tr>
<td>Audit File Rotation Interval</td>
<td>How often, in seconds, the audit file is renamed and a new one created to replace it. Time-based rotation occurs regardless of the current size of the audit file. See the previous row in this table for details.</td>
<td>7200</td>
</tr>
<tr>
<td>Audit Buffer Maximum Size</td>
<td>The amount of audit data, in bytes, that can be accumulated in a buffer before the entire buffer is written to disk.</td>
<td>[blank]</td>
</tr>
<tr>
<td>Audit Buffer Flush Interval</td>
<td>The number of seconds after which the content of the audit buffer is written to the audit file regardless of the amount of data in the buffer.</td>
<td>7200</td>
</tr>
</tbody>
</table>
**To configure file-based auditing for an Access Server**

1. From the landing page for the Access System, click the link for the Access System Console.
   
   If you are already logged in to the Access System and are working in the Policy Manager, click the Access System Console link at the top of the page.

2. Click the Access System Configuration tab, then click Access Server Configuration in the left navigation pane.

3. From the list in the Access Server Configuration page, select the Access Server you want to modify.

4. In the Details for Access Server page, examine the audit file settings.
   
   If you wish to change any of them, click the Modify button at the bottom of the page.

5. In the Modify Access Server page, modify the Audit File parameters.

---

**Setting Up Database Auditing**

The following are high-level tasks for setting up database auditing:

**Task overview: Enabling database auditing**

1. Set up and verify your Oracle Access Manager environment.
   
   See "Setting Up Your System for Database Auditing" on page 11-18 for details.

2. Install and configure your RDBMS application (SQL Server or the Oracle database), then create and configure the Oracle Access Manager audit database.
   
   See "Setting up the Audit Database" on page 11-18 for details.

3. Configure Oracle Access Manager for database auditing.
   
   For an OCI connection type, you create an RDBMS profile. For an ODBC connection type, this involves enabling your Oracle Access Manager servers to connect to the audit database by creating ODBC data source definitions and an RDBMS profile. You also need to configure and verify both your Identity and Access systems for auditing.
Setting Up Database Auditing

See "Configuring Auditing" on page 11-32 for details.

4. Install and configure Crystal Reports, then verify that the Oracle Access Manager audit templates can display audit database information.

See "Setting up Audit Reports" on page 11-41 for details.

Setting Up Your System for Database Auditing

Before you can use the audit-to-database feature, you must verify that all the Access Server and Identity Server hosts in your Oracle Access Manager system are running Windows, or that all are running Linux.

This prohibition against mixing platforms in an Oracle Access Manager environment applies to only the machines hosting Oracle Access Manager servers that connect to the database and to the machine hosting the database server. The machine(s) hosting the Oracle Access Manager LDAP server can run either Windows or Linux. The machine hosting Crystal Reports must run Windows, regardless of the type of database being used. Oracle Access Manager servers not connected to the audit database can run on any platform.

Setting up the Audit Database

The Oracle Access Manager audit database is an ODBC 3.0 compliant database running on SQL Server or the Oracle Database, or an OCI-compliant Oracle Database.

Task overview: Preparing for the audit database

1. If you are installing SQL Server, read "About installing SQL Server (Windows)" on page 11-19.

2. Create and configure the Oracle Access Manager audit database on the database server.

   See the procedures "SQL Server on Windows: To create the audit database" on page 11-20, "Oracle Database on Windows: To create the audit database" on page 11-20, or "Oracle Database on Linux: To create the audit database" on page 11-20.

   When creating the Oracle database, specify the Unicode character set (AL32UTF8). The SQL Server installation uses the Unicode character set UCS-2 by default. Select UTF-8 as the national character set.

3. Upload the auditing and reporting schema to the auditing database.

   See "Task overview: Uploading the audit schema" on page 11-20.

4. Create an ODBC data source definition (System DSN) on each Oracle Access Manager server that will send data to the audit database.

   See the procedures "To create an ODBC data source definition (Windows)" on page 11-27.

5. Create an RDBMS profile on the Oracle Access Manager LDAP directory server so that each Access or Identity Server that is connected to the directory server can recognize the ODBC data source definition on its host machine.

   See "To create an RDBMS profile" on page 11-30.

6. Restart all your Oracle Access Manager servers.
See "To make the RDBMS profile visible (Windows)" on page 11-32 or "To make the RDBMS profile visible (Linux)" on page 11-32.

**Installing the Database Server**
You install SQL Server or the Oracle Database if all the Oracle Access Manager server hosts in your system run Windows. You also can install the Oracle Database if all your Oracle Access Manager server hosts run Linux.

**About installing SQL Server (Windows)**
You can use the Standard, Enterprise, or Developer Edition of SQL Server 2000.

If you plan to implement other Oracle Access Manager features that use SQL Server (for example, the SharePoint Portal Server integration), the auditing feature can share a single SQL Server installation with the these other features, provided that SQL installation meets the minimum requirements dictated by each feature.

Follow the instructions supplied by Microsoft to install SQL Server. The installation wizard prompts you to specify setup options. In most cases, you should accept the defaults as you progress through the wizard pages, but first check the following table and enter any settings that differ from the defaults:

<table>
<thead>
<tr>
<th>Wizard Page Setting</th>
<th>What to Specify</th>
</tr>
</thead>
<tbody>
<tr>
<td>autorun.exe opening screen</td>
<td>SQL Server 2000 Components, Install Database Server</td>
</tr>
<tr>
<td>Installation target</td>
<td>&quot;Local Computer&quot;</td>
</tr>
<tr>
<td>Installation option</td>
<td>&quot;Create a new instance of SQL Server&quot;</td>
</tr>
<tr>
<td>Type of installation</td>
<td>&quot;Server and Client Tools&quot;</td>
</tr>
<tr>
<td>Instance name</td>
<td>&quot;Default&quot;</td>
</tr>
<tr>
<td>Type of setup</td>
<td>&quot;Typical&quot;</td>
</tr>
<tr>
<td>Services accounts</td>
<td>&quot;Use the same account for each service. Auto Start SQL User Service&quot;</td>
</tr>
<tr>
<td>Service settings</td>
<td>&quot;Use Local System account&quot;</td>
</tr>
</tbody>
</table>

The default login name, which is also referred to as the Login ID or User Name, is "sa," and the password can be blank if the box labeled "blank password" is checked. The password can be whatever you wish if "blank password" is not checked.

In any case, record the login name and associated password so that you can duplicate them exactly when you create your RDBMS profile and the ODBC data source definitions on each Oracle Access Manager server host.

Authentication mode          | "Mixed Mode"                                                                   |

After you have installed SQL Server, proceed to "SQL Server on Windows: To create the audit database" on page 11-20.

**Creating the Audit Database**
The procedure for creating the Oracle Access Manager audit database differs depending on whether you are using SQL Server or the Oracle Database.
SQL Server on Windows: To create the audit database

1. On the machine hosting SQL Server, navigate to:
   
   My Computer, Manage, Services and Applications, Microsoft SQL Servers, hostname

   where hostname is the Windows Services name for the machine hosting SQL Server.

2. In the left pane of the Computer Management window, right-click Databases in the branch beneath the host name of the machine on which SQL Server is installed, then click New Database.

3. Select a descriptive name for the database, then click OK.
   
   An icon representing the new database appears in the right hand pane of the Computer Management window.

Oracle Database on Windows: To create the audit database

1. Start the Oracle Database server.

2. Start the Database Configuration Assistant by clicking Start, Programs, Oracle - OraDb10g_home1, Configuration and Migration tools, Database configuration assistant.

3. When the wizard prompts you for a Global Database Name, record the name and use it in the database instance definition of the RDBMS profile in Oracle Access Manager.

4. In the Initialization Parameters screen, choose AL32UTF8 as the database character set, and choose UTF8 as the national character set.

5. Proceed to “Uploading the Audit Schema”.

Oracle Database on Linux: To create the audit database

1. Start the Oracle Database server located in the following directory:
   
   ORACLE_HOME/bin/dbca

2. Start the Database Configuration Assistant.

3. When the wizard prompts you for a Global Database Name, record the name and use it in the database instance definition of the RDBMS profile in Oracle Access Manager.

4. In the Initialization Parameters screen, choose AL32UTF8 as the database character set, and choose UTF8 as the national character set.

5. Proceed to “Uploading the Audit Schema”.

Uploading the Audit Schema

The audit schema enables you to import audit data from the Oracle Access Manager servers and export that data to the Crystal Repository, where it is presented in Oracle Access Manager audit reports.

Task overview: Uploading the audit schema

1. Copy the Oracle Access Manager audit schema and supporting resources from an Oracle Access Manager server host to the Oracle Access Manager audit database host.
The copy procedure differs depending whether you are performing a Windows-to-Windows or a Linux-to-Linux transfer. See: "To copy the audit and reporting schema to the audit database host" for details.

2. Upload the audit and reporting schema to your audit database and verify that the upload was successful, which differs depending on whether you are using SQL Server or the Oracle Database. See:
   - SQL Server on Windows: To upload the audit schema
   - SQL Server on Windows: To verify the audit schema
   - SQL Server on Windows: To upload and verify the access reporting schema
   - Oracle Database on Windows or Linux: To upload and verify the audit schema
   - Oracle Database on Windows or Linux: To upload and verify the access reporting schema

To copy the audit and reporting schema to the audit database host

1. On any machine hosting a Oracle Access Manager server, locate the directory containing the Oracle Access Manager audit schema by navigating to:

   Component_Install_dir\oblix\reports\crystal

   where Component_Install_dir is the root installation directory of your Oracle Access Manager server (IdentityServer_install_dir\identity\, for example).

2. Using any of the means available for your particular operating system and network domain, copy the file audit.sql to a directory on the machine hosting your Oracle Access Manager auditing database.

   This procedure isn’t necessary if you installed your audit database on the same machine as one of your Oracle Access Manager servers.

3. Continue with the following procedures as is appropriate for the database application you are using:
   - SQL Server on Windows: To upload the audit schema
   - SQL Server on Windows: To verify the audit schema
   - SQL Server on Windows: To upload and verify the access reporting schema
   - "Oracle Database on Windows or Linux: To upload and verify the audit schema"
   - "Oracle Database on Windows or Linux: To upload and verify the access reporting schema"

SQL Server on Windows: To upload the audit schema

1. On the machine hosting SQL Server, navigate to:

   Start, Programs, Microsoft SQL Server, Query Analyzer

2. If the "Connect to SQL Server" page is not already displayed in the SQL Query Analyzer window, navigate to:

   File, Connect
3. In the Connect to SQL Server page, verify that the Windows Service name of your SQL Server host is displayed in the field labeled SQL Server.

4. Check "Start SQL Server if it is stopped."

5. Set "Connect using" to "SQL Server authentication."

6. Enter the login name and password you selected when installing SQL Server, then click OK.

   A Query window will open in the SQL Query Analyzer window.

7. Launch the Oracle Access Manager audit database in the SQL Query Analyzer.

   In the SQL Query Analyzer menu, navigate to:
   File, Open

   Navigate to "audit.sql" which is located under the directory you copied from your Oracle Access Manager server to your audit database host in the preceding procedure.

   For details, see the procedure "To copy the audit and reporting schema to the audit database host" on page 11-21. The specific location of audit.sql is:
   ...eports\crystal\audit.sql

8. In the Query window, add the following line to the very beginning of the file audit.sql:

   ```sql
   use AuditDBName;
   ```

   where AuditDBName specifies the Oracle Access Manager audit database you created in the procedure "SQL Server on Windows: To create the audit database" on page 11-20. In our example, we named the database NPAuditDB.

   For all SQL statements, don’t forget to place a semi-colon at the end of the line.
10. Press F5 to execute the command. Alternatively, select Query, Execute from the SQL Query Analyzer menu.

The first time you do this, the application will return the following error message:
cannot drop the table 'oblix_audit_events', because it does not exist in the system catalog yet

This is both customary and logical, because the table did not exist when the "use" command was executed. If you save audit.sql and subsequently re-execute this command, the error message will not reappear, because the table now exists.

11. Minimize, but do not close the Query window; you will need to add another line to audit.sql when you verify that the schema have uploaded successfully. Proceed to: "SQL Server on Windows: To verify the audit schema" on page 11-23.

**SQL Server on Windows: To verify the audit schema**

1. Perform a "dummy" select from the oblix_audit_events table.

Add the following line immediately beneath the line you added to audit.sql in the procedure "SQL Server on Windows: To upload the audit schema" on page 11-25:

```sql
select * from oblix_audit_events;
```

Remember to include a semi-colon at the end of the line.

2. Click F5 to execute the command.
Column headings such as eventDateAndTime appear in a pane immediately beneath the code pane in the Query window. These indicate that the audit.sql schema uploaded successfully.

3. In the SQL Query Analyzer window, click File, Save to record the changes to your audit.sql, which is now linked to your Oracle Access Manager audit database.

4. Proceed to “SQL Server on Windows: To upload and verify the access reporting schema” next.

The next procedure is similar to the previous procedures (where you uploaded and verified the audit schema using the oblix_audit_events table. In the following procedure, you copy table definitions and commands for oblix_rpt_as_reports, oblix_rpt_as_resource, and oblix_rpt_as_users from the audit.sql file into the Query Analyzer workspace, and execute them.

**SQL Server on Windows: To upload and verify the access reporting schema**

1. On the machine hosting SQL Server, perform the following activities as needed to login:

   - Navigate to Start, Programs, Microsoft SQL Server, Query Analyzer
   - If the "Connect to SQL Server" page is not already displayed in the SQL Query Analyzer window, navigate to: File, Connect.
   - In the Connect to SQL Server page, verify that the Windows Service name of your SQL Server host is displayed in the field labeled SQL Server.
   - Check "Start SQL Server if it is stopped."
   - Set "Connect using" to "SQL Server authentication."
   - Enter the login name and password you selected when installing SQL Server, then click OK.

      A Query window will open in the SQL Query Analyzer window.

2. Launch the Oracle Access Manager audit database in the SQL Query Analyzer, as follows:

   - In the SQL Query Analyzer menu, navigate to File, Open
   - Navigate to the audit.sql file under the directory you copied from your Oracle Access Manager server to your audit database host earlier. For example:

      \IdentityServer_install_dir\identity\oblix\reports\crystal\audit.sql

3. In the Query window, add the following line to the very beginning of the file audit.sql:

   use AuditDBName;

   where AuditDBName specifies the Oracle Access Manager audit database you created in the procedure "SQL Server on Windows: To create the audit database" on page 11-20. In our example, we named the database NPAuditDB.

   For all SQL statements, don’t forget to place a semi-colon at the end of the line.

4. Add all drop and create commands for the three Oracle Access Manager tables (oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users) to the Query Analyzer window and execute these at one time, as follows:
Copy the drop table oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users information (3 drop commands followed by 3 create table commands) together from the audit.sql file and paste these into the Query Analyzer window at once.

**Note:** Copy all at one time and do not change the order of these commands. There are dependencies between the tables.

Press F5 to execute the commands at one time (or select Query, Execute from the SQL Query Analyzer menu).

Minimize, but do not close the Query window; you will need to add another line to audit.sql when you verify that the schema have uploaded successfully.

5. Verify information for the oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users tables as follows:

   - Perform a "dummy" select from the oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users tables (individually or all at once).

   - Add the following line immediately beneath the line you added from audit.sql in the procedure "SQL Server on Windows: To upload the audit schema" on page 11-25:

     ```
     select * from oblix_rpt_as_reports;
     select * from oblix_rpt_as_resources;
     select * from oblix_rpt_as_users;
     ```

   - Click F5 to execute the command.

6. Proceed to "Enabling Access and Identity Servers to Connect to the Audit Database".

The next two procedures are similar to the previous procedures. However, these are specific to the Oracle Database on Windows or Linux.

**Oracle Database on Windows or Linux: To upload and verify the audit schema**

1. Start the Oracle Database server and the iSQL*Plus application.

2. Connect to the iSQL*Plus web application of Oracle DB server.

   A typical URL for this is the following:

   ```
   http://oracle_DB_host_name:port/isqlplus/
   ```

   Where `oracle_DB_host_name` is the name of the Oracle Database instance and `port` is the port number that you have chose during the installation of the Oracle Database server.

3. Log in to iSQL*Plus by providing the user name, password and GDN of the database.

4. Copy the schema definition from the following file to the iSQL*Plus Workspace page:

   ```
   Identity_Server_install_dir\oblix\reports\crystal\audit_oracle.sql
   ```

5. Click the Execute button.

6. To verify the audit schema, enter the following command in iSQL*Plus:
desc oblix_audit_events
Alternatively, you can enter the select * command for oblix_audit_events; in iSQL*Plus.

7. Proceed to “Oracle Database on Windows or Linux: To upload and verify the access reporting schema” next.

The next procedure is similar to the previous procedures (where you uploaded and verified the audit schema using the oblix_audit_events table. In the following procedure, you copy table definitions for oblix_rpt_as_reports, oblix_rpt_as_resource, and oblix_rpt_as_users from the audit.oracle.sql file into the iSQL *Plus web application of Oracle DB server, and execute them.

**Oracle Database on Windows or Linux: To upload and verify the access reporting schema**

1. Login to the iSQL*Plus, as needed:
   - Start the Oracle Database server and the iSQL*Plus application
   - Connect to the iSQL *Plus web application of Oracle DB server.
   - Log in to iSQL *Plus by providing the user name, password and GDN of the database.

2. Add all drop and create commands for the three Oracle Access Manager tables (oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users), and execute as follows:
   - Add all drop and create commands for the three Oracle Access Manager tables (oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users) from the following file to the iSQL*Plus Workspace page:
     * Identity_Server_install_dir*\oblix\reports\crystal\audit_oracle.sql
   - Click the Execute button

3. Verify the schema for all three Oracle Access Manager tables (oblix_rpt_as_reports, oblix_rpt_as_resources, and oblix_rpt_as_users) individually or all at once with the following command in iSQL*Plus:
   - desc oblix_rpt_as_reports;
   - desc oblix_rpt_as_resources;
   - desc oblix_rpt_as_users;
   - Alternatively, you can enter the select * command for the three Oracle Access Manager tables oblix_rpt_as_reports, oblix_rpt_as_resources, oblix_rpt_as_users; in iSQL*Plus.

**Enabling Access and Identity Servers to Connect to the Audit Database**

You enable your servers to connect to the audit database by creating a RDBMS profile on the directory server and ODBC data source definitions on each machine hosting a server that connects to the audit database. A single, unique System DSN (System-wide Data Source Name) connects all of these objects.

It is extremely important that every attribute associated with a given DSN in both the RDBMS profile and the ODBC data source definitions on the server hosts match exactly. For details, see ”To create a primary RDBMS instance” on page 11-30.
Task overview: Enabling Oracle Access Manager servers to connect to the audit database

1. All—Set the value of the SQLDBType parameter in globalparams.xml.
2. Windows—create an ODBC data source definition (System DSN) on each Oracle Access Manager Server host.
3. All—Using either the Identity System Console or the Access System Console, create an RDBMS profile on the directory server.

See "Task overview: Setting up an RDBMS profile" on page 11-29. This includes the following tasks:

a. Create a primary RDBMS instance as described in "To create a primary RDBMS instance" on page 11-30.
b. Create optional secondary RDBMS instances for your RDBMS profile as described in "Task overview: To create a secondary RDBMS instance" on page 11-31.
c. Restart all Oracle Access Manager servers as described in "To make the RDBMS profile visible (Windows)" on page 11-32.

To set the SQLDBType parameter

1. Open the following file:

   Component_install_dir/identity/apps/common/bin/globalparams.xml

   where component_install_dir is the location where the Access or Identity Server was installed.

2. Set the value of the SQLDBType parameter in globalparams.xml as follows:

   Oracle: Indicates an Oracle Database that uses an ODBC connection type.
   Oracle_OCI: Indicates an Oracle Database that uses an OCI connection type.
   SQLServer: Indicates a SQL Server database.

To create an ODBC data source definition (Windows)

1. On a Oracle Access Manager server host you wish to connect to the audit database, navigate to: Start, Settings, Control Panel, Administrative Tools, Data Sources (ODBC).
2. Click the System DSN tab.
3. Click Add.
4. From the list of database drivers, select SQL Server, then click Finish.
5. In the Name field, type a descriptive name.

   For instance, AuditSysDSN stands for the System DSN for the audit database. Write this name down, because you will have to use this exact character string for the ODBC data source definitions on every other Oracle Access Manager Server host, and for the primary RDBMS instance in your RDBMS profile as well.
6. In the Description field enter notes to help users identify this object.

7. In the Server field, select the Windows Services name of the host on which the Oracle Access Manager audit database is running, then click Next.

8. When the next page appears, select "With SQL server authentication. . ."

9. Verify that “Connect to SQL server to obtain . . .” is selected.

10. Type the Login ID and password you specified when you installed SQL Server.

11. Leaving the default settings on the next two pages untouched, click Next, then click Finish.

12. After a page appears listing the settings for the new ODBC data source definition, click Test Data Source.
13. After a page appears to announce success, click OK three times to dismiss the open pages.

14. Repeat this procedure on every Oracle Access Manager server host you wish to connect to the audit database.

Make sure you use the exact same settings in every case, and for your RDBMS database instances as well. Proceed to "Task overview: Setting up an RDBMS profile".

**Task overview: Setting up an RDBMS profile**

1. Create an RDBMS profile.

   See "To create an RDBMS profile" on page 11-30 for details.

2. Create a primary RDBMS instance.

   See the procedure "To create a primary RDBMS instance" on page 11-30 for details.

3. Create (optional) secondary RDBMS instances.

   See "Task overview: To create a secondary RDBMS instance" on page 11-31 for details.

4. Make the RDBMS profile visible.
As appropriate for the database application you are using, see the procedure "To make the RDBMS profile visible (Windows)" on page 11-32 or "To make the RDBMS profile visible (Linux)" on page 11-32.

**To create an RDBMS profile**

1. From the Identity System Console, click System Configuration, then click the link for Directory Profiles in the left navigation pane, then click the Add button in the Configure RDBMS Profiles section of the Configure Profiles page.

   Alternatively, from the Access System Console, click System Configuration, then click Server Settings in the left navigation pane, then click the Add button in the Configure RDBMS Profiles section of the page.

   The Create RDBMS Profile page is identical for the Identity System Console and the Access System Console.

2. In the Name field, enter a descriptive name.

   For instance AuditDBSysDSN refers to the System DSN created for the audit database. You are creating an RDBMS profile on this page, but this name provides a convenient universal name to identify matching sets of data source definition values in the RDBMS profile and the ODBC.ini files on each Oracle Access Manager server host.

   The name of each RDBMS profile on a directory server must be unique.

3. In the Database Connection Type field, select the type of connection that your database uses.

4. In the Used By field, check the Reporting and Auditing options.

5. Verify that the Enable Profile box is selected.

6. Proceed to "To create a primary RDBMS instance" on page 11-30.

**To create a primary RDBMS instance**

1. Navigate to the Create RDMBS Profile page, as described in "To create an RDBMS profile" on page 11-30.
2. From the Create RDBMS Profile page, click the Add button next to the table labeled Database Instances.

3. In the Name field of the Create Database Instance page, enter a descriptive name. For convenience, you can use the universal name you gave to the RDBMS Profile, such as AuditDBSysDSN.

4. The following field will either be DSN Name or GDN, depending on whether you specified an ODBC or an OCI connection type for the database. For SQL Server, you can use the same name for the database instance and the RDBMS profile, for example AuditDBSysDSN. For the Oracle database, use the GDN that you specified when configuring the database. See "Oracle Database on Windows: To create the audit database" on page 11-20 or "Oracle Database on Linux: To create the audit database" on page 11-20 for details.

5. In the Database field, specify the name of the audit database. This example uses NBAuditDB.

6. In the User name field, enter the login name you specified when you created the audit database.

7. Enter the password associated with the audit database login name.

8. Leave the other fields at their default settings. You can change them later, if necessary.

9. Click Save to commit the database instance settings you have entered.

10. When the Modify RDBMS Profile page appears, click Save to commit the RDBMS profile settings you have entered.

11. If you wish to create a secondary RDBMS instance, proceed to the task overview immediately following. Otherwise, proceed to "To make the RDBMS profile visible (Windows)" on page 11-32 or "To make the RDBMS profile visible (Linux)" on page 11-32.

**Task overview: To create a secondary RDBMS instance**

1. Perform all the steps in "Creating the Audit Database" on page 11-19. For convenience, you may want to name the second instance of the audit database something like NPAuditDB_2.

2. Perform all the steps in "Uploading the Audit Schema" on page 11-20.

3. Perform steps 5 through 11 in "To create an RDBMS profile" on page 11-30. For convenience, you may want to specify the name of the RDBMS instance and the DSN name as something like AuditDBSysDSN_2.

**WARNING:** The character string you specify as the DSN for your RDBMS instance must match exactly the DSN you specify for the ODBC data source definition on each Oracle Access Manager server. Furthermore, the values for all other database instance attributes must be empty or match exactly the values for the corresponding attributes in the ODBC data source definitions throughout your Oracle Access Manager system.
4. After the Modify RDBMS Profile page appears, verify that the Server Type for your secondary RDBMS instance is set to secondary.

5. Add the ODBC data source definitions for the secondary RDBMS instance(s) to ODBC.ini on each Oracle Access Manager server host.
   As appropriate for the database application you are using, see "To create an ODBC data source definition (Windows)" on page 11-27.

6. As appropriate for the database application you are using, proceed to "To make the RDBMS profile visible (Windows)" on page 11-32 or "To make the RDBMS profile visible (Linux)" on page 11-32.

To make the RDBMS profile visible (Windows)
2. Right-click the icon representing the Oracle Access Manager server on the machine, then select Restart from the dropdown menu.
   If you installed both an Access Server and a Identity Server on the same machine, perform this procedure for both servers.
3. Repeat this procedure for all the Oracle Access Manager server hosts you wish to connect to the audit database.
4. Proceed to "Configuring Auditing" on page 11-32.

To make the RDBMS profile visible (Linux)
1. On a machine hosting a Oracle Access Manager server, run one of the following commands to stop your Oracle Access Manager server.
   - Access Servers: stop_access_server
   - Identity Servers: stop_ois_server
2. Run one of the following commands to start your Oracle Access Manager server.
   - Access Servers: start_access_server
   - Identity Servers: start_ois_server
3. Repeat this procedure for all the Oracle Access Manager server hosts you wish to connect to the audit database.
4. Proceed to "Configuring Auditing" on page 11-32.

Configuring Auditing
You can configure Oracle Access Manager for both file-based and database auditing.

By default, both file-based auditing and database auditing are turned off for all Oracle Access Manager servers. You can manually enable file-based and database auditing for each Oracle Access Manager server in your system.

You can configure audit options on a system-wide, server, event, and application basis. See "About Audit Options" on page 11-4 for a summary.

The defaults for auditing are optimal for most situations. You need to turn on the type or types of auditing you want on the Oracle Access Manager servers that you want to audit. If you send data to the audit database, you must also replace the default audit data format string on both the Identity and Access systems. See "To modify audit
output formatting for the Identity System” on page 11-34 and “To modify audit output formatting for the Access System” on page 11-39 for details.

Note that the global auditing settings that you configure in the Common Configuration sub-tab of the Identity System Console are different from the application-specific events that you audit from the sub-tabs for User, Group, and Org. Manager Configuration.

**Task overview: To configure auditing**

1. Turn on either or both file-based and database auditing for each Identity Server, and modify audit file attributes, if you wish.
   
   See "To enable and configure auditing for each Identity Server" on page 11-33.

2. Configure the audit output formatting for the Identity System.
   
   See "To modify audit output formatting for the Identity System" on page 11-34 for details.

3. Specify what data for which events will be audited.
   
   This includes the following categories:

   a. Events common to the User, Group, and Organization Manager applications.
      
      See "To specify global Identity System events and profile attributes for audit” on page 11-35 for details.

   b. User, Group, or Organization Manager events.
      
      See "To specify User, Group, or Organization Manager events for audit” on page 11-36 for details.

4. Verify that all Identity Servers can record data to the audit database.
   
   See "To verify that all Identity Servers can record data to the audit database (Windows)” on page 11-37 for details.

5. Turn on file-based or database auditing for individual Access Servers, and modify audit file attributes, if you wish.
   
   See "To enable and configure auditing for each Access Server" on page 11-38 for details.

6. Globally modify the audit output formatting for the Access system.
   
   See “To modify audit output formatting for the Access System” on page 11-39 for details.

7. Create and manage User access privilege reports.
   
   See "To create and manage user access privilege reports” on page 11-40 for details.

**To enable and configure auditing for each Identity Server**

1. From the Identity System Console, click the System Configuration sub-tab, then click Identity Servers in the left navigation pane.

2. Click the link for the server that you want to modify, then click Modify.
3. Set the file auditing and database auditing flags according to your preference, and change whichever audit file attributes you prefer. Click save to put your changes into effect.

4. For database auditing, open the globalparams.xml file in the following directory. For example:
   
   Component_install_dir/identity/apps/common/bin/globalparams.xml
   
   where component_install_dir is the location where the Access or Identity Server was installed.

   Set the value of the SQLDBType parameter in globalparams.xml as follows:
   
   Oracle: Indicates an Oracle Database that uses an ODBC connection type.
   
   Oracle_OCI: Indicates an Oracle Database that uses an OCI connection type.
   
   SQLServer: Indicates a SQL Server database. This is the default.

5. Repeat this for all Identity Servers in your Oracle Access Manager system, then proceed to "To modify audit output formatting for the Identity System" on page 11-34.

To modify audit output formatting for the Identity System
1. From the Identity System Console, click the Common Configuration sub-tab, then click Master Audit Policy in the left navigation pane, then click Modify.
2. Click anywhere within the Message Format text box, press Control-A to select everything within the text box, even the contents that are obscured, then press Delete.

3. In the empty text box, insert the following string:

```
%ob_datetime% - %ob_event% - %ob_operation% - %ob_serverid% - %ob_ip% - %ob_url% - %ob_target.uid% - %ob_app% - %ob_source.uid% - %ob_profileattrs% - %ob_auditapp%
```

Do not add a semi-colon or line return to the end of the string.

4. If you prefer, modify the default values in the Date Type, Date Separator, Escape Character, Record Separator, and Field Separator fields.

Note that if you change any of these values, you will need to reconfigure the Crystal report templates used to generate Audit Reports.

5. Click Save.

The new message format string and any other changes you made will display in the Configure Master Audit Policy page.

6. The new message format string applies across the Identity System, so you do not need to repeat the process for the other Identity Servers, but you do need to perform a similar procedure to set the format string for the Access system.

See "To modify audit output formatting for the Access System" on page 11-39 for details.

7. Proceed to "To specify global Identity System events and profile attributes for audit" on page 11-35.

**To specify global Identity System events and profile attributes for audit**

1. From the Identity System Console click the Common Configuration sub-tab, then click Global Auditing Policies in the left navigation pane, then click Modify.

2. Select up to five profile attributes to audit.

Profile attributes (Full Name, Employee Number, Department Number, and the like) are specific to the user performing the action/event being audited (Search or View Profile or Modify Profile, for example). The purpose of profile attributes is to help you identify the user performing the action/event.
3. Modify the default audit flag settings for the common User, Group, and Organization Manager application events you prefer.

4. Click Save to apply these settings to all the Identity Servers in your system.

5. Proceed to “To specify User, Group, or Organization Manager events for audit” on page 11-36.

To specify User, Group, or Organization Manager events for audit

1. From the Identity System Console, click the User, Group, or Org. Manager Configuration sub-tab, then click Audit Policies in the left navigation pane, then click Modify.

2. Select up to five profile attributes to audit.

Profile attributes (Full Name, Employee Number, Department Number, and the like) are specific to the user performing the action/event being audited (Search or View Profile or Modify Profile, for example). The purpose of profile attributes is to help you identify the user performing the action/event.

WARNING: To avoid exposing a challenge phrase or response attribute, Oracle recommends that you do not select these as profile attributes for auditing. If you add a challenge phrase or response as a profile attribute, it is audited in proprietary encoded format.

3. Modify the default audit flag settings for whichever common User Manager application events you prefer.Identity Server

4. Click Save to apply these settings to all the Identity Servers in your system.
To verify that all Identity Servers can record data to the audit database (Windows)

1. From any page in the Identity System Console for any Identity Server for which you have completed all the audit setup procedures up to this point, click Logout in the upper right corner of the application window.

2. Click OK when asked if you really want to log out.

3. Open the SQL Server Query Analyzer window on the machine hosting your audit base.

   You minimized this window when you completed the procedure "SQL Server on Windows: To verify the audit schema" on page 11-23.

   If, for any reason, the window is no longer open, re-launch it by navigating to:
   Start, Programs, Microsoft SQL Server, Query Analyzer, File, Open, Login_Credentials, OK, File, Open, audit_sql_path, OK

   where Login_Credentials is the user name and password you specified when installing SQL Server and audit_sql_path is the path to the audit.sql file you copied to the audit database host and subsequently modified in the procedure "SQL Server on Windows: To verify the audit schema" on page 11-23.

4. Press F5 to execute audit.sql.

   You previously saved audit.sql after adding the following lines:

   ```sql
   use AuditDBName;
   select * from oblix_audit_events;
   ```

   where AuditDBName specifies the audit database you created in the procedure "SQL Server on Windows: To create the audit database" on page 11-20.

   The column headings for the Oracle Access Manager schema appear at the bottom of the Query window with particulars for the logout under the appropriate columns.

5. Proceed to "To enable and configure auditing for each Access Server" on page 11-38.
To verify that all Identity Servers can record data to the audit database (Linux or Solaris)

1. From any page in the Identity System Console of any Identity Server for which you have completed all the audit setup procedures up to this point, click Logout in the upper right corner of the application window.

2. Click OK when asked if you really want to log out.

3. Perform the following in the iSQL *Plus Web application of the Oracle Database Server:
   Log in to iSQL *Plus by providing the user name, password, and GDN of the database.
   Enter following command in the iSQL *Plus Workspace:
   `select * from oblix_audit_events;`
   The columns headings for the Oracle Access Manager audit schema appear in the iSQL *Plus Workspace page. Information regarding logout appears under the appropriate column headings.

4. Proceed to "To enable and configure auditing for each Access Server" on page 11-38.

To enable and configure auditing for each Access Server

1. On any Access Server you plan to connect to the audit database, navigate to: Access System Console, Access System Configuration, Access Server Configuration, `ServerName`, Modify
   where `ServerName` specifies the Access Server you want to modify.

2. Set the file auditing and database auditing flags according to your preference.

3. Change whichever audit file attributes you prefer, then click Save to commit your changes.
   If you change any of the attributes marked with asterisks, you must restart your Access Server to make the changes take effect.

4. Repeat this for all Access Servers in your Oracle Access Manager system, then proceed to "To modify audit output formatting for the Access System".

5. For database auditing, open the `globalparams.xml` file in the following directory:
   `Component_install_dir/apps/common/bin/`
   where `component_install_dir` is the location where the Access or Identity Server was installed.
Set the value of the SQLDBType parameter in globalparams.xml as follows:

**SQLServer**: Indicates a SQL Server database. This is the default.

**Oracle**: Indicates an Oracle Database that uses an ODBC connection type.

**Oracle_OCI**: Indicates an Oracle Database that uses an OCI connection type.

**To modify audit output formatting for the Access System**

1. On any Access Server you plan to connect to the audit database, navigate to:
   Access System Console, Access System Configuration, Common Information Configuration, Master Audit Rule, Add (or Modify).

2. Click anywhere within the Audit Record Format text box, press Control-A to select everything within the text box, even the contents that are obscured, then press Delete.

3. In the empty text box, insert exactly what appears in the following string:
   
   %ob_datetime% - %ob_event% - %ob_operation% - %ob_serverid% - %ob_ip% - %ob_url% - %ob_userid% - %ob_time_no_offset% - %ob_resrc_scheme% - %ob_wgid% - %ob_wgcontext% - %ob_reason%
   
   Do not add a semi-colon or line return to the end of the string.

4. In the Profile Attributes box, type the name of a profile attribute you want to audit, then click the plus sign (+) to the right of the text box.
   
   Repeat this step to add other profile attributes.

5. Select the events you want to audit.
- If you prefer, modify the default event mappings.
- If you prefer, modify the default values in the Audit Date Type and Audit Escape Character fields. Remain aware that if you do change any of these values, you need to reconfigure the Crystal report templates used to generate Audit Reports.

6. Click Save.

The new message format string and any other changes you made appear in the Master Audit Rule page.

7. The new message format string applies across the Access System, so you do not need to repeat the process for the other Access Servers, but you do need to perform a similar procedure to replace the format string for the Identity System.

See “To modify audit output formatting for the Identity System” on page 11-34.

8. Proceed to “To create and manage user access privilege reports” on page 11-40.

To create and manage user access privilege reports

1. On any Access Server you plan to connect to the audit database, navigate to Access System Console, System Management, Manage Reports, Add.

2. In the Report Name field, type a descriptive name such as "Midnight Access."

3. In the Description field, type a longer explanation of the report content, such as "Who has night shift access to the loading dock shipping manifest URLs."

4. Specify whether to send the information to the audit database or the audit file on the local host. If you specify the audit file, you must provide a file name.

5. In the "From this IP Address field," type the IP of the host for a specific web browser whose access you want to test.

6. In the "Date/Time..." field, select the date, time, and time zone for which you wish to test access.

This can be a point in the future, because the audit feature does not actually report the historical results of a actual access attempt; rather, it consults the policy and profile information stored on the Oracle Access Manager directory server to
calculate whether the specified users currently have permission to access the specified resource at the specified time.

7. Click the Add button near the List of Resources label to add URLs to the list of resources to be tested.

The Add Resource Rule page appears.

8. Type the URL to be tested.

9. Set the Resource type to http or ejb.

10. Check the action(s) you want tested.

11. Click Save to return to the Add a New Report page.

12. Click Add again to add another resource to be tested, or proceed to the next step.

13. You can test access for all users, or you can use the Selector to test access for specific users.

   See “The Selector” on page 1-10 for details on the Selector.

14. When you are done with the Selector and the Add a new Report page reappears, click Save to commit your changes.

Setting up Audit Reports

To make use of the preconfigured Crystal Reports templates supplied with Oracle Access Manager, you must install the Crystal Reports application on a Windows machine within your Oracle Access Manager server domain. (Crystal Reports cannot be installed on Unix machines, but it can make use of information in a database generated by the Oracle Database installed on a Unix machine.)

In addition to installing Crystal Reports 9, you must also install a patch.

The Oracle Access Manager server installation directories are installed with certain templates, sample reports, database schema, and database drivers which are used by the Crystal Reports application. These are distinct from the Crystal Reports software itself. You must copy them from a Oracle Access Manager server install directory to the machine hosting your Crystal Reports software.

Task overview: To set up audit reports

1. Install Crystal Reports 9.22a on a Windows machine that can connect to the machine hosting SQL Server or the Oracle Database.

2. Install the mandatory patch for Crystal Reports 9.
3. Copy the Oracle Access Manager audit report templates, the Crystal Repository, and associated resources to the machine hosting Crystal Reports.
4. Connect Crystal Reports to the Oracle Access Manager audit database by creating an ODBC data source definition and editing orMap.ini.
5. Connect Crystal Reports to the Crystal database by creating an ODBC data source definition and editing orMap.ini.

To install Crystal Reports
1. Obtain a copy of the Crystal Reports 9.22 installation package from the vendor.
2. Launch setup.exe and follow the prompts.
3. Specify whichever installation directory you prefer.
4. When prompted, enter the product key, which is provided with the purchase of the reporting package.
5. When prompted, specify "typical" for the installation type.
6. Proceed to "To install the patch for Crystal Reports" on page 11-42.

To install the patch for Crystal Reports
1. Download the Crystal Reports 9 patch from the following Web site:
   
   http://support.businessobjects.com/communityCS/FilesAndUpdates/cr90dbexwin_en.zip.asp

2. Unzip cr90dbexwinen.zip into a temporary folder on your hard disk, then launch CR90DBEXWIN_EN_200403.EXE.
3. Follow the prompts to complete the patch installation.
4. Proceed to "To copy the Oracle Access Manager-specific Crystal resources" on page 11-42.

To copy the Oracle Access Manager-specific Crystal resources
1. Using whatever methods you are comfortable with, copy the following resources from a Oracle Access Manager server installation to a directory of your choice on the machine hosting Crystal Reports.

   Component_install_dir\oblix\reports

   Where Component_install_dir is the root installation directory for an Identity Server that is connected to the audit database.

   Make sure to copy everything in ".\reports" and its subdirectories. The following diagram shows the resources copied to the Crystal Reports machine.
Figure 11–4  Resources copied to the Crystal Reports machine

2. Proceed to "To connect Crystal Reports to the audit database" on page 11-43.

To connect Crystal Reports to the audit database
1. Follow the procedure described in "To create an ODBC data source definition (Windows)" on page 11-27 so that Crystal Reports can connect to the audit database.

Make sure that the DSN you specify and all associated details match exactly the values you specified for the RDBMS profile and the ODBC data source definitions you created for the Oracle Access Manager servers that connect to the audit database.

2. Proceed to "Task overview: To connect Crystal Reports to the Oracle Repository" on page 11-43.

Task overview: To connect Crystal Reports to the Oracle Repository
1. Create an ODBC data source definition to connect Crystal Reports to the Oracle/Crystal Repository (.mdb database).
2. Edit orMap.ini to equate the Oracle Repository with the Crystal Repository.

To create an ODBC data source definition to connect Crystal Reports to the Oracle/Crystal Repository
1. Follow the general procedure described in "To create an ODBC data source definition (Windows)" on page 11-27 so that Crystal Reports can connect to the audit database.

Except where noted in the steps that follow, use the values specified in the original procedure.

2. When prompted for a database driver, select "Microsoft Access driver (.mdb)."
3. For the Name parameter, choose some self-explanatory name such as OracleRepositorySysDSN.
4. Proceed to "To edit orMap.ini" on page 11-43.

To edit orMap.ini
1. On the machine hosting Crystal Reports, navigate to:

C:\Program Files\Common Files\Crystal Decisions\2.5\bin
2. Open the file orMap.ini in any plain text editor.

3. Replace the line "Crystal Repository=Crystal Repository" with the following:

\[\text{Crystal Repository} = \text{repository\_DSN}\]

where \text{repository\_DSN} is the System DSN you created for the OracleRepository.mdb file. We have been using OracleRepositorySysDSN in our example.
This chapter focuses on network monitoring through the Simple Network Management Protocol (SNMP).

SNMP monitoring is one of several methods of gathering information on your Oracle Access Manager system. Logging, auditing, and other reporting features, are described elsewhere in this guide.

This chapter includes the following topics:

- Prerequisites
- About Oracle Access Manager SNMP Monitoring and Agents
- About the Oracle Access Manager MIB and Objects
- Enabling and Disabling SNMP Monitoring
- Setting Up SNMP Agent and Trap Destinations
- Changing SNMP Configuration Settings
- Logging for SNMP
- SNMP Messages
- Discrepancies Between Netstat and SNMP Values

**Note:** For information about installing SNMP, refer to the Oracle Access Manager Installation Guide.

## Prerequisites

You need to have a network management station (NMS) installed, and you should be familiar with how to upload and display network statistics gathered from a Management Information Base (MIB). This chapter describes the Oracle Access Manager MIB objects and the Object Identifiers (OIDs) for these objects. However, this chapter does not provide information on how to use these OIDs in your NMS to collect statistics. For such information, refer to the documentation for your NMS.

## About Oracle Access Manager SNMP Monitoring and Agents

The Simple Network Management Protocol (SNMP) enables you to monitor component activity on the network that hosts your Oracle Access Manager system by collecting and displaying server-related SNMP data on a network management station. SNMP statistics commonly include data such as:
The hosts, routers, and servers on your network
■ The number of requests being processed on a particular device
■ Whether or not a particular device is running
■ Whether requests were processed successfully

SNMP data is displayed on a network management station (NMS). The NMS is a workstation running a network management application such as HP OpenView. You configure the NMS to display network statistics in a useful way, for instance, as a graph to show simple network statistics or to show whether the number of requests a device is processing falls within a set of defined limits.

You can capture SNMP statistics for the Identity Server and the Access Server running on any supported platform. Oracle Access Manager supports SNMP polling and trapping. Polling collects information such as:
■ The version number of a component
■ Configuration status
■ Connection status
■ Statistics on actions the component has processed

Event traps include information such as:
■ Component failure
■ Event failure
■ Connection status
■ Failure to complete actions

Note: Oracle Access Manager supports version 2 of the SNMP protocol.

The SNMP Agent

The Simple Network Management Protocol (SNMP) is an application-layer protocol that enables network devices to exchange information. By using SNMP-transported data (such as successful operations and failure conditions), administrators can monitor network performance and solve problems. The Oracle Access Manager’s SNMP Agent enables you to implement SNMP-based data collection for the Identity Server and Access Server. The SNMP Agent enables collection of information such as the number of successful authentications performed by the Access Server and the number of requests processed by the Identity Server.

The SNMP Agent is an optional installable component. The Agent collects information on the host where it is installed, so you must install an Agent on each host where you want to collect SNMP data. If installed, the Agent accesses information about the Identity or Access Server resident on the same server host on which the Agent was installed. The Agent is installed in SNMP_install_dir.

For information on installing the SNMP Agent, see the Oracle Access Manager Installation Guide.
About the Oracle Access Manager MIB and Objects

The Management Information Base (MIB) is a specification file that contains variables relevant to the status of different Oracle Access Manager components. The SNMP Agent collects values for fields in the MIB.

Figure 12–1 illustrates the Oracle Access Manager MIB hierarchy.

![MIB hierarchy diagram]

The Oracle Access Manager MIB can be expressed as a concatenation of branch and object identifiers (OIDs). The label from the MIB root to the top node of the MIB is as follows:

```
iso.org.dod.internet.private.enterprises.oblix.snmp
```

MIB files are located in `SNMP_install_dir/oblix/mibs`. These files conform to SNMP Version 2.

The following discussions describe the MIB objects that are provided with the Oracle Access Manager SNMP component.

**Note:** Refer to your NMS documentation for information on uploading the MIB files to your NMS.

**MIB Index Fields**

Each MIB table contains one or more index fields. The index field values help you identify a unique row in the table.

For example, the index fields for coreidInstanceTable described in "Identity Server MIB Objects" on page 12-4 are coreidHostname and coreidPort. These entries are used as
indexes because they uniquely identify an installation. Suppose that you have two
Identity Servers named Identity1 and Identity2, each with a host name of localhost
using ports 6023 and 6024, respectively. The indexes for these servers would be
localhost.6023 and localhost.6024.

To retrieve the first column value for Identity1, the object identifier you would request
from the SNMP Agent would take the following logical form:

1.3.6.1.4.1.3831.10.1.1.2.1.1.localhost.6023

where 1.3.6.1.4.1.3831.10.1.1.2.1.1 signals that you want the first column of
coreidInstanceTable, for the element with an index value of localhost.6023. The index
is represented in numeric notation (similar to specifying an OID) which actually
contains the length of the string followed by ascii codes for the characters in the string.
As a result, this example:

1.3.6.1.4.1.3831.10.1.1.2.1.1.localhost.6023

is actually represented as follows:

1.3.6.1.4.1.3831.10.1.1.2.1.1.9.108.111.99.97.108.104.111.115.
116.6023

**Note:** If you want the entire table to be returned in your SNMP
requests, it is not necessary to know the values of the index fields.

### Identity Server MIB Objects

Table 12–1 contains the Identity Server objects in the MIB. The path to this information
is the following:

iso.org.dod.internet.private.enterprises.oblix.snmp.coreid. versionone

The name of this table is coreidInstanceTable. Its index fields are coreidHostname and
coreidPort. It describes Identity Server instances.

<table>
<thead>

<td></td>
<td></td>
</tr>
</tbody>
</table>

Table 12–10 contains objects in the MIB for system events that can be mapped to SNMP traps. The SNMP Agent supports sending trap messages to multiple NMS systems. The path to this information is the following:

`iso.org.dod.internet.private.enterprises.oblix.snmp.aaa.versionone`

For example, to add the full path to the oblixAAAServerDown trap, you would specify:

`iso.org.dod.internet.private.enterprises.oblix.snmp.aaa.versionone.oblixAAAServerDown`

Table 12–10  Access Server Traps

<table>
<thead>

</table>

SNMP Monitoring   12-11
Enabling and Disabling SNMP Monitoring

You use the Identity and Access Servers configuration pages to enable SNMP and to indicate the TCP/IP port where contact will be established with the SNMP Agent.

To configure collection of SNMP statistics

1. From the Identity (or Access) System Console, select System Configuration, Identity Server (or Access Server.)
2. Click a link for a particular server.
3. Select the Modify button to display the page where you can turn SNMP monitoring on or off, as follows:
   - **Turn On:** Select the SNMP State On button at the bottom of the page.
   - **Turn Off:** Select the SNMP State Off button at the bottom of the page.
4. In the SNMP Agent Registration Port field, enter the port number to define or change the port on which the SNMP Agent listens.
5. Restart the Identity Server (or Access Server).

### Table 12–10 (Cont.) Access Server Traps

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Note:** Oracle Access Manager does not provide a configuration setting for a polling interval to retrieve SNMP statistics. However, most NMS systems provide a polling configuration parameter. This parameter is used by the NMS to periodically poll the Agent to retrieve MIB values.
Setting Up SNMP Agent and Trap Destinations

You use the following command to setup an SNMP Agent against an SNMP Manager:

```
setup_agent -i
```

The -i option is required.

Following procedures describe and illustrate how to configure the Oracle Access Manager SNMP Agent and trap destinations.

**To configure the SNMP Agent and trap destinations**

1. Change to the directory containing the SNMP setup_agent command.
   
   For example:
   
   ```
   > cd $SNMPDIR/oblix/tools/setup
   ```

   where SNMPDIR is the directory where you have installed the SNMP Agent.

2. Use the setup_agent command with the following options:
   
   ```
   -i <install_dir>
   -g Configure General Parameters
   -u <Agent SNMP UDP Port>
   -c <Agent Community String>
   -p <Agent TCP Port>
   -S <Run in silent mode>
   --help Prints help message
   ```

**To add a trap destination in silent mode**

1. Change to the directory containing the SNMP setup_agent command.

   For example:

   ```
   > cd $SNMPDIR/oblix/tools/setup
   ```

2. Use the setup_agent command with the following options:

   ```
   -a
   -m <Manager Station>
   -t <Trap port>
   ```

**To delete a trap destination in silent mode**

1. Change to the directory containing the SNMP setup_agent command.

   For example:

   ```
   > cd $SNMPDIR/oblix/tools/setup
   ```

2. Use the setup_agent command with the following options:

   ```
   -d
   -m <Manager Station>
   -t <Trap port>
   ```
To configure general parameters first
1. Change to the directory containing the SNMP setup_agent command.
   For example:
   > cd $SNMPDIR/oblix/tools/setup

2. Use the following setup_agent command:
   > ./setup_agent -i $SNMPDIR -g -u <UDP Port> -c public -p <TCP Port>

   This goes to the Manager Station Trap Configuration menu.

To add an SNMP Manager directly after general parameters
1. Change to the directory containing the SNMP setup_agent command.
   For example:
   > cd $SNMPDIR/oblix/tools/setup

2. Use the following setup_agent command:
   > ./setup_agent -i $SNMPDIR -a -m <Mgr M/c> -t <Mgr Port>

To delete an SNMP Manager directly after adding one
1. Change to the directory containing the SNMP setup_agent command.
   For example:
   > cd $SNMPDIR/oblix/tools/setup

2. Use the following setup_agent command:
   > ./setup_agent -i $SNMPDIR -d -m <Mgr M/c> -t <Mgr Port>

   You can add any number of Manager Stations. The Agent then sends all the traps to the configured SNMP Managers.

Changing SNMP Configuration Settings

A configuration file named obscoreboard_params.xml contains information that defines the collection of SNMP statistics. This file is located in:

Component_install_dir/identity|access/oblix/config

where Component_install_dir is the directory where the component is installed and identity | access represents either the Identity Server or Access Server, respectively.

Identity System File: obscoreboard_params.xml

Access System File: obscoreboard_params.xml

In this file, you can configure threshold levels to determine when various MIB counters are activated.

The following parameters are specified only in the Access Server file obscoreboard_params.xml:

- **NumberOfAuthenticationPlugins**: The maximum number of authentication plug-ins that may be loaded in the Access System. The Access Server maintains information on the number of plug-ins that are loaded. If the actual number of
plug-ins loaded by the Access Server exceeds the value specified for NumberOfAuthenticationPlugins, the difference is displayed as the counter aaaOverflowforAuthenticationPluginSlots.

- **NumberOfAuthorizationPlugins**: The maximum number of authorization plug-ins that may be loaded in the Access System. The Access Server maintains information on the number of plug-ins that are loaded. If the actual number of plug-ins loaded by the Access Server exceeds the value specified for NumberOfAuthorizationPlugins, the difference is displayed as the counter aaaOverflowforAuthorizationPluginSlots.

The following parameter is specified only in the Identity Server file obscoreboard_params.xml:

- **NumberOfPPPPluginActions**: The number of Identity Event API plug-in actions that may be connected with this Identity Server. When the Identity Server starts, it reads this value and monitors the actual number of Identity Event API plug-ins. If the number of active plug-ins exceeds the value for NumberOfPPPPluginActions, the difference is indicated by the counter coreidOverflowForPPPActionsSlots.

The following parameters are provided in both scoreboard files:

- **NumberOfServiceThreads**: The value for this parameter is read by the Identity or Access Server at startup. This parameter controls how many slots to allocate (one for each service thread) to maintain SNMP information for each service thread. The server monitors the number of service threads being used. The actual number of service threads is configured through the administration console, from the command line, or as part of a configuration file. This parameter does not control the number of threads to be started by the Identity Server. If the actual number used exceeds this value, there is no SNMP data generated regarding the extra threads.

- **NumberOfConfiguredDS**: The number of directory servers configured for this Identity or Access Server.

- **DsFailureTrapTimeSpan**: The amount of time to wait before sending the next failure trap to the same directory server.

- **NumOfSlotsInEventQueue**: The number of slots to be used in the event queue. This parameter must be updated if traps are not detected. However, the default value of five should be adequate for most installations.

- **SleepTimeInMilliSec**: The interval in milliseconds that the Identity or Access Server uses to check whether the SNMP Agent is up and running.

- **semaphore_filepath**: Information about the semaphore created by the Access Server. Semaphores are used for synchronization between the component (the Identity or Access Server) and the SNMP Agent. This information is used to automatically clean up the semaphore if the component fails.

- **semaphore_id**: The Agent semaphore identifier.

Changing these settings affect the memory map file used for SNMP data collection. On Unix, the memory map file is located in

```
/tmp/netpoint/scoreboard/component/process-id.osb
```

On Windows, this file is located in

```
Component_install_dir/oblix/scoreboard/process-id.osb
```
Logging for SNMP

The SNMP Agent supports logging. Once the SNMP Agent is enabled, it is always set to a certain log level. The SNMP logs can assist with troubleshooting. You can configure what is logged and the type of logs to generate in the Agent configuration file. This file resides in

SNMP_install_dir/oblix/config/snmp_agent_config_info.xml

where SNMP_install_dir is the directory where the SNMP Agent was installed.

The log_level parameter in the Agent configuration file may have one of the following values:

- 0: Debug
- 1: Information
- 2: Warning
- 3: Error
- 4: No logging (turns logging off)

SNMP Messages

The following are SNMP-related messages.

Message:

MErrNoConfigFile (Could not find agent configuration file at location (full path to the agent configuration file))

Description: The installation directory is not correct, or the configuration file is not present. Uninstall and reinstall the SNMP Agent.

Message:

MLogAgentStarted (Agent successfully started on port SNMP port number)

Description: Status message.

Message:

MErrAddressInUse (Agent was not able to bind to port port number, address already in use)

Description: The SNMP Agent is unable to bind to its configured TCP registration port. Reconfigure the Agent to use another TCP port, or make the port available by stopping the application using the port.

Note: If you change the Agent TCP registration port, you must also specify the new port when enabling SNMP for the Identity or Access Server using the appropriate System Console.

Message:

Agent was not able to bind to specified port, system lacked sufficient buffer space or queue was full.

Description: The SNMP Agent port is unavailable.
Message:
MErrTLUnsupported {Agent was not able to bind to specified port, address family not supported by protocol family}

Description: The specified port does not support SNMP. Configure a different port.

Message:
MErrRetriveIDs {Error: Unable to determine the uid/gid for which this snmp agent is installed.}

Description: The user who tried to start the SNMP Agent does not have the appropriate permissions. The user should start the SNMP Agent as root or as the user who installed the Agent.

Message:
MErrCouldNotSetIDs {Error: You don't have sufficient access rights to run this snmp agent.}

Description: You need to log in with administrative rights to be able to install the SNMP Agent. If you did not do this, the Agent is unable to run.

Message:
MLogAlreadyRunning {Agent is already running with process id (Process identifier of the agent).}

Description: The user is trying to start the Agent when it is already running.

Message:
MErrRegBindFailed {Error: Unable to bind to configured registration port (configured registration port number).}

Description: The SNMP Agent is unable to bind to the port configured on the Oracle Access Manager server configuration page. Specify a different port, as described in "Enabling and Disabling SNMP Monitoring" on page 12-12.

Message:
MErrRegListenFailed {Error: Unable to start listening on configured registration port (configured registration port number).}

Description: This message is displayed on Windows if the port is already in use by another application.

Message:
MErrReadingMsg {Error reading message sent by component.}

Description: The SNMP Agent and the Oracle Access Manager server talk over a TCP connection. If the Agent encounters a malformed message, it logs an error.

Message:
MErrNotRegMsg {Error: Agent expects only registration messages on the registration socket.}

Description: The Agent only expects registration messages on the TCP connection from a server that connects to it. If it finds that the message is not a registration message, it logs an error.

Message:
MErrMissingMmapFilename (Error: Registration message was missing the component scoreboard file name.)

**Description:** The scoreboard file is where the Identity or Access server stores the statistics that are read by the Agent. This name is communicated by the server to the Agent at registration time. If the registration request is missing the file information, this message is logged.

**Message:**

MErrMappingScoreboard (Error: Unable to memory map the scoreboard file (full path to the scoreboard file) registered by component.)

**Description:** This error can occur due to file permission issues, that is, the Agent cannot read or open the scoreboard file.

**Message:**

MErrUnknownComponent (Error: Unknown component type specified in scoreboard file.)

**Description:** The component type is specified in the registration request. The Agent processes information for the Identity Server and Access Server. If the component type is not either of these, this message is logged.

**Message:**

MErrIndexExists (Error: A component has already registered in table (OID for the table for that component) with index (index that is already in use by some other component).)

**Description:** The same instance of a component tried to register again. Each instance of a component is uniquely identified by a key or index by the same SNMP Agent. If another component instance tries to register using the same key or index, this message is logged.

**Message:**

MErrCreatingAgentSemaphore (Error: Unable to create named semaphore (full path to the agent semaphore file) for agent-component event dispatching.)

**Description:** The Agent and the component create one semaphore that is cleaned up at shutdown. In case of unclean shutdown, the semaphores are deleted on the next server/Agent startup. Probable causes are that the system has run out of semaphores or there are permission issues while creating the semaphore.

**Message:**

MErrOnSelect (Error: Select() call returned error code (error code returned for the select() call).)

**Description:** This is an error code returned directly from the function. This message is used for troubleshooting purposes.

**Message:**

MErrOnPoll (Error: Poll() call returned error code (error code returned for the poll() call).)

**Description:** This is an error code returned directly from the function. This message is used for troubleshooting purposes.

**Message:**

MErrNotDeregMsg (Error: Agent expected a de-registration message on the socket,
Description: The Agent only expects a de-registration message from a component once the component has registered.

Message:
MErrRemovingComponent (Error: Component with table oid (OID for the table for that component) and index (index which identifies the component in that table) could not be removed.)

Description: The component has already de-registered, and there has been another request to remove it.

Message:
MErrMissingEvent (Error: Unable to retrieve event from component with table oid (OID for the table for that component) and index (index which identifies the component in that table).)

Description: The component sends an event to the Agent, and the Agent converts this to an appropriate trap. The component also signals the Agent that it has dispatched an event. If the Agent is signaled but it does not find an event, this message is logged.

Message:
MErrMissingTrapData (Error: Missing trap meta-data for component from table oid (OID for the table) and index (index that identifies the component in that table) with event (event identifier supplied by the component).)

Description: The component did not deliver the complete data for an event.

Message:
MLogMappedScoreboard (Mapped scoreboard file (full path to the scoreboard file) for a component.)

Description: This is a status message.

Message:
MLogComponentRegistered (Component registered with table oid (OID for the table) and index (index that identifies the component).)

Description: This is a status message.

Message:
MLogComponentDeregistered (Component with table oid (OID for the table) and index (index that identifies the component) de-registered.)

Description: This is a status message.

Message:
MLogComponentFailed (Component with table oid (OID for the table) and index (index that identifies the component) failed.)

Description: This is a status message indicating that the Oracle Access Manager component did not deregister properly. This action is treated as a component failure by the SNMP Agent.

Message:
MLogSentTrap (Sent trap with trap oid (OID for the trap sent) for component with table oid (OID for the component table) and index (index that identifies the
Description: This is a status message.

Message:
MLogSemCleanup {Found left-over semaphore from previous run with key (key for the stale left-over semaphore) and file path (file path for the stale left-over semaphore), successfully cleaned up the semaphore.}

Description: Status message. The Agent and the component create one semaphore that is cleaned up at shutdown. In case of unclean shutdown, the semaphores are deleted on the next server/Agent startup.

Message:
MErrSemCleanup {Found left-over semaphore with key (key for the stale left-over semaphore) and file path (file path for the stale left-over semaphore). Encountered errors while removing it.}

Description: The Agent and the component create one semaphore that is cleaned up at shutdown. In case of unclean shutdown, the semaphores are deleted on the next server/Agent startup. This message would be logged if the Agent encountered errors while cleaning up the semaphores from a previous run. There may be permission issues.

Message:
MSBCreateFailed {Access Server: Could not create scoreboard file (full path for the file) with size file size.}

Description: The probable cause for this message is the system could not create the file due to insufficient space.

Message:
MCreateSemFailed {Access Server: Could not create event queue semaphore with path full path.}

Description: The Agent and the component create one semaphore that is cleaned up at shutdown. In case of unclean shutdown, the semaphores are deleted on the next server/Agent startup. This message is generated when the system has run out of semaphores or there are permission issues when creating the semaphore. Try increasing the semaphore limit on the machine.

Message:
MSSBDirCreateFailed {Access Server: Could not create scoreboard file file name.}

Description: The system could not create the required directory for the scoreboard file, probably due to insufficient permissions.

Discrepancies Between Netstat and SNMP Values

When using the netstat command, the value returned for this command may not always match the information collected for the MIB variables:

- aaaDirectoryServerNoOfLiveConnections
- coreIDirectoryServerNoOfLiveConnections

Table 12–11 explains the reason for this discrepancy and the chain of events that takes place.
Configuring the Shutdown Interval

To ensure that an Identity or Access component can perform a clean shutdown, enough time must be allocated to ensure that all cleanup activities can be completed. For the Identity Server, the Access Server, and the SNMP Agent, the shutdown_time parameter specifies the time allocated for the server to attempt a clean shutdown. This parameter is located in globalparams.xml. The default shutdown time is five seconds.

The globalparams file location is as follows:

For Access Server:

```
AccessServer_install_dir/access/oblix/apps/common/bin/globalparams.xml
```

For Identity Server:

```
Identity_install_dir/identity/oblix/apps/common/bin/globalparams.xml
```

The default shutdown time appears as follows in these files:

```
shutdown_time:5
```

You can change the value to any time, specified in seconds.
Configuring the Shutdown Interval
The information here is provided to help you configure Oracle Access Manager with Microsoft Active Directory and implement .NET features. An index is also provided.

Part IV contains the following information:

- Appendix A, "Deploying with Active Directory"
- Appendix B, "Configuring for ADSI"
- Appendix C, "Configuring for Active Directory with LDAP"
- Appendix D, "Implementing .NET Features"
Deploying with Active Directory

After you complete the activities in the Oracle Access Manager Installation Guide to install and set up Oracle Access Manager with Active Directory, you can complete activities here to configure these components for daily use and maintenance.

This appendix contains the following topics:

- Setting Up Directory Profiles and Searchbases
- Authentication and Authorization with Active Directory
- Configuring the credential_mapping Plug-In
- Configuring Single Sign-On for Use with Active Directory
- About Search Filters
- About the Length of the SAMAccountName
- Configuring for .NET Features
- Troubleshooting
- Microsoft Resources

For additional information and procedures, see the Oracle Access Manager Installation Guide. See also:

- Appendix B, "Configuring for ADSI"
- Appendix C, "Configuring for Active Directory with LDAP"

Setting Up Directory Profiles and Searchbases

The Active Directory forest shown in Figure A–1 includes three domains: Root_domain, Sub_domain, and Disjoint_domain. The configuration in Figure A–1 appears in the discussions that follow.

Figure A–1  Three Domains in a Single Active Directory Forest
When you have finished installation and set up for Active Directory, as described in the Oracle Access Manager Installation Guide, you are ready to complete the following tasks.

- Defining Directory Server Profiles for Remaining Domains
- Setting Up Disjoint Searchbases
- Configuring Group-Search Read Operations (Optional)

Defining Directory Server Profiles for Remaining Domains

A default directory server profile is created automatically each time you install the Identity Server and specify new directory server connection information. The directory server profile contains connection information for one or more directory servers that share the same namespace and operational requirements for read, write, search, and so on. The connection information includes a name, a domain or namespace to which it applies, a directory type, and a set of operations.

---

**Note:** The default directory server profile is created for only your Root_domain. You must set up directory profiles for the remaining domains in your installation: for example, Disjoint_domain and Sub_domain.

---

After installation, you can use the Identity System Console to modify the directory server profiles as outlined in the following procedure. When you finish the steps in the following procedure, you may set up the Disjoint Searchbases.

For more information, see "Managing Directory Server Profiles" on page 7-19.

**To set up additional directory server profiles**

1. Navigate to the Identity System Console.
   
   http://hostname:port/identity/Oblix

3. Add the profile for the Disjoint_domain, if you have one, as described in "Managing Directory Server Profiles" on page 7-19.

4. Add the profile for the Sub_domain.

5. Rename the Default Directory Profile if the default name generated during Identity System setup is not meaningful to you.

6. Set up disjoint searchbases, as described next.

Setting Up Disjoint Searchbases

After the domains are configured, you need to add a disjoint searchbase for the Disjoint_domain and verify that there is no value in the Tab Searchbase field.

---

**Note:** Depending on how you configured the Root_domain, you may want to add a disjoint searchbase for the Sub_Domain.

---
To add a disjoint searchbase for the Disjoint_domain
1. Navigate to the Identity System Console.
   
   http://hostname:port/identity/oblix
3. Add a disjoint searchbase for the Disjoint_domain and click Save.
4. Navigate to and select the Configure Tab function in the User Manager: Identity System Console, User Manager Configuration, Configure Tab.
5. Select a link on the Configure Tab page.
6. Confirm there is no value in the Tab Searchbase field.
7. Repeat these steps for the Sub_domain, if you have one.

About Deleting a Disjoint Searchbase
If there are searchbase policies for the disjoint searchbase, a user who has this searchbase on this node is able to create a filter with Query Builder whose base is this searchbase. It is advisable to remove all access control policies for this disjoint searchbase before deleting it.

If you remove a disjoint searchbase, you must disable all the database agents that use this searchbase.

Configuring Group-Search Read Operations (Optional)
Active Directory uses incremental retrieval of group members. This means that the Identity System must perform multiple reads to get the complete set of group members.

For Active Directory on Windows 2000, the maximum number of members that can be retrieved with one read is 1000. Unless you change the parameter, the Identity System uses a default value of 1000. For Active Directory on Windows .NET Server 2003 the maximum is 1500. The parameter maxForRangedMemberRetrieval located in globalparams.xml contains the maximum value that the Identity System uses.

Note: The notation install_dir refers to the directory where you installed the named component. For example, IdentityServer_install_dir refers to the directory where you installed the Identity Server.

To configure group-search read operations on Windows 2003
1. Locate the globalparams.xml file in \IdentityServer_install_dir\identity\oblix\apps\common\bin\globalparams.xml.
2. Add the maxForRangedMemberRetrieval entry with a value of 1500.
   For example:
   
   <SimpleList > <NameValPair ParamName='maxForRangedMemberRetrieval' Value='1500'/> </SimpleList>
3. Save the file.
4. Restart the Identity Server.
Authentication and Authorization with Active Directory

Two-forest configurations were introduced in the Oracle Access Manager Installation Guide. After installation, configuring the Access System for Active Directory can include setting up authentication and authorization in a parent-child domain.

This section contains the following topics:

- Parent-Child Authentication
- Parent-Child Authorization
- ObMyGroups Action Attribute

Parent-Child Authentication

In this case, you need to use the Access System’s credential mapping plug-in to authenticate users against both the parent and child domains. This plug-in obtains the user’s DN.

For example, suppose you have two domains, foo.goodwill.oracle.com and goodwill.oracle.com. In the Identity System, you have two directory profiles, one for foo.goodwill.oracle.com with a display name of foo and another for goodwill.oracle.com with a display name of goodwill:

Foo.goodwill.Oracle.com:
DisplayName=foo
Searchbase = dc=foo,dc=goodwill,dc=Oracle,dc=com
User:Alice

Goodwill.Oracle.com
DisplayName=goodwill
Searchbase=dc=goodwill,dc=Oracle,dc=com
User:Bob

Also suppose you are using a Oracle Access and Identity authentication mechanism that uses the filter in the credential_mapping plug-in shown in the previous example. When the user tries to log in to the Access System, a Basic Over LDAP dialog box appears.

The domain is the part of the login ID entered before the "\". From the domain name, the Access System can tell which searchbase to use to identify this user. When Alice logs in, she must specify a domain name of foo, and when Bob logs in he must specify a domain name of goodwill. Both users will be authenticated.
Parent-Child Authorization

You can define separate LDAP rules for each domain. For example, if you want all users who have the title of Manager to access a resource, you need to specify two LDAP rules, one for each domain. An example of these rules:

```
ldap:///dc=goodwill,dc=Oracle,dc=com??sub?(&(title=Manager)
(objectclass=user))
```

```
ldap:///dc=foo,dc=goodwill,dc=oracle,dc=com??sub?(&
(title=Manager)(objectclass=user))
```

Using these rules, managers who are in both foo and goodwill can be authorized.

ObMyGroups Action Attribute

You can use the ObMyGroups action attribute to return in a header variable all of the groups to which a user belongs. Specifying ObMyGroups in the attribute name uses the searchbase configured for the Access System. Access Server does not impose any limit on the number of groups that are returned. The returned groups are only limited by any size limit configured for the directory.

The Access System supports only one searchbase. Therefore, if the user chooses goodwill.Oracle.com as the product searchbase, then ObMyGroups results in a search for groups under goodwill.oracle.com. In this case, the Access System cannot follow referrals, and since the Access System does not have multiple searchbase capability, groups from foo.goodwill.oracle.com cannot be returned.

You can specify ObMyGroups with an LDAP URL. In this case, the searchbase is picked up from the LDAP URL. However, you can only associate one attribute with one header variable, so if you have two domains you need at least two header variables to obtain all of the groups a user belongs to.

For example, suppose you have two domains: dc=goodwill,dc=oracle,dc=com and dc=dilbert,dc=goodwill,dc=oracle,dc=com. To obtain groups from both these searchbases you must define two separate header variables, one for each domain, as shown in Table A–1.

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Return</th>
</tr>
</thead>
<tbody>
<tr>
<td>headervar</td>
<td>HTTP_PARENT_GROUP</td>
<td>&quot;obmygroups:ldap:///dc=goodwill,dc=Oracle,dc=com??sub?(group_type=role)&quot;</td>
</tr>
<tr>
<td>headervar</td>
<td>HTTP_CHILD_GROUP</td>
<td>&quot;obmygroups:ldap:///dc=dilbert,dc=goodwill,dc=Oracle,dc=com??sub?(group_type=role)&quot;</td>
</tr>
</tbody>
</table>

- In HTTP_PARENT_GROUP: all the groups in "dc=goodwill,dc=Oracle,dc=com" tree for which the logged-in user is a member and the group_type is role are returned.
In HTTP_CHILD_GROUP: all the groups in "dc=dilbert,dc=goodwill,dc=Oracle,dc=com" tree for which the logged-in user is a member and the group_type is role are returned.

The following procedures guide as you configure the credential_mapping authentication plug-in for Active Directory and set up SSO, if needed.

Configuring the credential_mapping Plug-In

Each policy domain requires an authentication scheme. Each authentication challenge method is supported by one or more plug-ins. For more information about plug-ins for authentication challenge methods, see the Oracle Access Manager Access System Administration Guide.

The credential_mapping plug-in maps the user's user ID to a valid distinguished name (DN) in the directory. You can configure the attribute to which the user ID is mapped. The most common attribute it is mapped to is uid. However, it is possible for a customer to map the user ID to a profile attribute other than uid by changing the obMappingFilter parameter.

The obmappingbase defines the user searchbase. In a single domain, the mapping base must be explicitly defined in the obMappingBase parameter of the credential_mapping plug-in. For example,

```
ou=company,dc=mydomain,dc=Oracle,dc=com).
```

With an Active Directory forest, the user needs to provide the domain plus the user ID during the login to validate the user credential against the specified domain. In this case, the mapping base should be set to obMappingBase="%domain%". The template for defining credential mapping for Oracle Access and Identity in an Active Directory forest should be

```
obmappingbase="%domain%",obmappingfilter=(&{objectclass=user} (sam accountname=%userid%))", obdomain="domain"
```

The domain information is maintained in the DB profiles in the Identity System Console. Be sure to create a DB profile for each domain. The login name for a multi-domain forest is the display name from the Access Server DB profile.

To configure the credential_mapping plug-in

1. Create a policy domain in the Policy Manager, as usual.

   **Note:** There is currently an upper limit of 350 policy domains when the Access System is deployed with Active Directory.

   where *link* is the name of the authentication scheme you want to alter.

3. Configure the credential_mapping plug-in for Active Directory.

   For example:

   - For Form Based:
     
     ```
     obmappingbase="%domain%",obmappingfilter=(&{objectclass=user} {samaccountname='%login%})
     ```
For Oracle Access and Identity:

obmappingbase="%domain%",obmappingfilter=(&(objectclass=user)(samaccountname=%userid"", obdomain="domain"

**Note:** To access a resource that is protected by an Oracle Access and Identity authentication scheme for an Active Directory forest, the user needs to enter the `domainname\username` as the user name in the Authentication dialog box. This `domainname` should be the display name for the DB profile created for the Access Server used to perform authentication for this user.

### Configuring Single Sign-On for Use with Active Directory

You may want to configure single sign-on for the Identity or Access System, as described in the following procedure. For more information, see about protecting resources with policy domains and configuring single sign-on, see the Oracle Access Manager Access System Administration Guide.

**To configure single sign-on with the Identity or the Access System**

1. Change actions in the policy domain authorization rules that need to pass the header variable `ObUniqueId` (rather than `uid`) `HTTP_OBLIX_UID`.

   **Note:** There is currently an upper limit of 350 policy domains with Active Directory. See "Troubleshooting" on page A-9 for details.

2. On the Web server, modify the value of the `WhichAttrIsLogin` parameter to `ObUniqueId` in the following files:

   \IdentityServer_install_dir\identity\oblix\apps\common\bin\globalparams.xml
   \PolicyManager_install_dir\access\oblix\apps\common\bin\globalparams.xml

   `WhichAttrIsLogin:ObUniqueId`

   The Configure Directory Server profiles page shows the associated directory profile, which specifies a number of attributes. For example:

   Machine:
   Port Number:
   Root DN:
   Root Password:
   Searchbase:
   Configuration base:
   Directory Server Security Mode:
   Disjoint Searchbase:
   ADSI enabled: Yes

   Following is resulting basic login window related to the single sign-on.
About Search Filters

If you are configuring for an Active Directory forest, the domain the user belongs to is determined by the directory profiles configured in the Identity System and used by the Access System. These directory profiles can be enabled or disabled through the Configure Directory Server Profile page accessible from the Identity System Console, Configure Directory Options function.

- If a directory profile is disabled and the user enters that domain name during login through the Access System, then the user is not allowed access.
- If a directory profile is enabled and user enters that name as the domain name, then the user is allowed access.

However, if a user is already authenticated and has a valid session token, after which the directory profile is disabled, then the user is allowed access based on the authorization rules, and so forth. The directory profile state (enabled/disabled) does not take affect during authorization. Only authentication honors the state of the profile.

About Search Filters

Active Directory does not invoke indexed searches when the filter contains constraints that evaluate to *which contains* --filters such as cn=*Smith, where the searched for value contains Smith. For indexed searches the following constraints are valid:

- Equals (cn=Smith)
- Begins with (cn=Smith*)

The myGroups tab on the Group Manager may take a long time to evaluate the result if the dynamic groups options is enabled and the dynamic filters specified contain the *which contains* search filter.

To prevent users from using the *which contains* search filter, restrict the available filters by modifying the catalog files. In the following directory:

```
Component_install_dir/identity|access/oblix/app//bin/application
```

where Component_install_dir is the directory where the component is installed and identity | access represents either the Identity or Access system, respectively

There are several xxxparams.xml files. In these files you can specify the type of valid filters allowed under vallist - ObEnhanceSearchList.

See also, *Resolving Ambiguous Names* on page D-1.
About the Length of the SAMAccountName

The attribute for the Security Access Manager account name (SAMAccountName) in the Active Directory schema is used for backward compatibility with versions of Windows prior to Windows 2000. If you do not need to support these older versions, you can run Active Directory in native mode.

If you need to run Active Directory in mixed mode, Active Directory limits the number of characters that can be specified as the value for the SAMAccountName. By default, Oracle Access Manager accommodates mixed mode and limits the length of SAMAccountName strings to 20 characters.

If you are running Active Directory in native mode, you should edit the value of the samAccountNameLength parameter in the globalparams.xml file. This file is located in the following directory:

```
Component_install_dir/apps/common/bin/globalparams.xml
```

Where `Component_install_dir` is the name of the directory where the Oracle Access Manager component is installed. You would edit the value of the following entry in this file:

```
<SimpleList>
 <NameValuePair
   ParamName="samAccountNameLength"
   Value="20">
 </NameValuePair>
</SimpleList>
```

For more information on globalparams.xml, see the Oracle Access Manager Customization Guide.

The user receives an error when defining a person or group with a name that exceeds the limit set for samAccountName in globalparams.xml. The default message is states that this parameter should not exceed 20 characters. The message tag is "MSamAccountNameExceeds20Error"

If you change the value of this parameter, you should also change the error message in the message catalog, globalmsg.xml.

Configuring for .NET Features

Oracle Access Manager provides support for .NET features with Windows Server 2003. See “Implementing .NET Features” on page D-1 for details.

For details about the following topics, see the Oracle Access Manager Integration Guide.

- Integrating with the Authorization Manager
- Integrating with Smart Card Authentication
- Integrating with the Security Connector for ASP.NET

Troubleshooting

For information on troubleshooting, see Troubleshooting Oracle Access Manager on page F-1.

Microsoft Resources

Active Directory Home Page
Both the Identity System and the Access System provide support for Active Directory Services Interface (ADSI) client applications. This chapter summarizes requirements and procedures when you are running Oracle Access Manager with Active Directory forests and the Active Directory Services Interface (ADSI).

This appendix contains the following sections:

- About ADSI with Oracle Access Manager
- Identity System ADSI Configurations
- Access System ADSI Configurations
- Configuring ADSI for the Identity System
- Enabling ADSI for a Default Directory Profile
- Enabling ADSI for Other Directory Profiles
- Configuring ADSI for the Access System
- Changing the pageSize Parameter

For additional information and procedures, see the Oracle Access Manager Installation Guide.

### About ADSI with Oracle Access Manager

Active Directory runs on Windows® 2000 and Windows Server 2003 domain controllers. Client applications using ADSI may be written and run on other windows platforms.

ADSI is a set of COM interfaces that enable tight integration with Active Directory. For example, ADSI:

- Abstracts the capabilities of different directory services from multiple vendors to present a single interface for managing network resources.
- Allows administrators and developers to manage the resources in a directory service, regardless of which network environment contains the resource.
- Enables administrators to automate common tasks such as adding users and groups, managing printers, and setting permissions on network resources.

**Important:** Enabling ADSI allows Oracle Access Manager to take advantage of Active Directory’s implicit failover and password-change capabilities.
With ADSI, Oracle Access Manager components do not have to bind to a specific host and port to access Active Directory data. Instead, ADSI allows Oracle Access Manager components to connect to the nearest available domain controller for accessing any user, group, or Oracle Access Manager configuration information.

As described in the Oracle Access Manager Installation Guide, the credentials for ADSI are used to bind to the entire forest. A forest can contain multiple Active Directory hosts. When user data and configuration data are stored on separate Active Directory hosts in separate forests, you cannot connect to these simultaneously using ADSI.

ADSI does not require specific host and port numbers for different domains in the forest. ADSI connects to Active Directory hosts using an LDAP URL like the following:

```
LDAP://domain.oblix.com/ou=oblix,dc=domain,dc=oblix,dc=com
```

For details about enabling ADSI during installation, see the Oracle Access Manager Installation Guide.

**Recommendation**

Active Directory replicates the entire tree structure. Due to potential replication delays, Oracle recommends you not replicate the directory tree containing Oracle configuration data. Changes to configuration data may not be immediately available.

For example, a change made to a user’s access permissions in the Policy Manager may not be available to the Access Server if they are talking to different domain controllers.

If you must replicate the Oblix tree, modify the replication frequency between the domain controllers on Active Directory.

**Identity System ADSI Configurations**

Oracle Access Manager supports a flexible combination of ADSI and LDAP that relates to your choice of authentication options and binding options.

---

**Note:** SSL is not required with ADSI and Oracle Access Manager. However, your business may require SSL for other reasons. For example, directory binds are in clear text and SSL is not automatically provided.

---

This section includes the following topics:

- Pure ADSI with ADSI Authentication
- Mixed ADSI with LDAP Authentication
- Oracle Access Manager ADSI Configuration Files
- Bind Mechanisms for the Identity Server

**Pure ADSI with ADSI Authentication**

With a pure ADSI setup, a single ADSI database agent is created during Identity System setup for the primary domain controller in your Active Directory tree. You must add additional agents for each child domain.

Additionally, if you have a noncontiguous forest of domain trees, you need to associate a separate ADSI database agent for each primary domain controller as shown in Figure B–1.
Figure B–1  Noncontiguous Forest with ADSI

See "Managing Directory Server Profiles" on page 7-19 for more information about multiple directory profiles and DB agents.

Mixed ADSI with LDAP Authentication

ADSI authentication may be slower than LDAP. For this reason, you may want to use LDAP for authentication when other operations, such as read, write, and search are handled by ADSI. An ADSI agent must be associated with every domain.

To associate an ADSI agent with every domain

1. Select the "Use LDAP for authentication" check box next to Microsoft Active Directory (using ADSI) on the Create Directory Profile page in the Identity System Console.
2. See "Managing Directory Server Profiles" on page 7-19 for more information about multiple directory profiles and DB agents.

Repeat as needed.

Note:  The Global Catalog is not required with this release.

For more information, see "Bind Mechanisms for the Access Server" on page B-6 and "Oracle Access Manager ADSI Configuration Files" on page B-4.

Bind Mechanisms for the Identity Server

ADSI provides several ways for the Identity Server to bind to Active Directory. There is no advantage to any particular method. Instead, it depends on which credentials you want to use. For example:

- **Implicitly**: Using the credential of the current process. This is the default for the Identity Server.

  This corresponds to the service logon credentials for the Identity Server. For implicit bind, the useImplicitBind flag in the adsi_params.xml file should be set to 0. See "Oracle Access Manager ADSI Configuration Files" on page B-4 for details.

  **Note:** You must create an account for the Identity Server to bind to Active Directory.

  The account that enables the Identity Server to bind to the Active Directory must be equivalent to the root DN that you specify during setup of the Identity Server. It should have all the administrative privileges for operations that are to be
performed using Oracle Access Manager. In an Active Directory forest, this user should be delegated control over all the other domains in the forest.

- **Explicitly Using the DN of the user**: The useImplicitBind flag in the adsi_params.xml file should be set to 1. The user DN should be specified with the adsiCredential parameter located in the adsi_params.xml file. See "Oracle Access Manager ADSI Configuration Files" on page B-4 for details.

- **Explicitly Using the userPrincipleName**: The useImplicitBind flag in the adsi_params.xml file should be set to 2. The UPN should be specified in the adsiUPN parameter in the adsi_params.xml file. See "Oracle Access Manager ADSI Configuration Files" on page B-4 for details.

### Oracle Access Manager ADSI Configuration Files

ADSI configuration parameters are maintained in two files:

```
\IdentityServer_install_dir\identity\oblix\apps\common\bin\globalparams.xml
\IdentityServer_install_dir\identity\oblix\config\adsi_params.xml
```

where `IdentityServer_install_dir` is the directory in which you installed the Identity Server.

#### About globalparams

This section shows a sample globalparams.xml file followed by a table of parameter values.

The install program in `\IdentityServer_install_dir\identity\oblix\apps\common\bin\globalparams.xml` creates the adsiEnable parameter and sets its value to true when you enable ADSI for the default directory profile. This parameter refers to a system level directory profile that contains Oracle configuration data.

```
<SimpleList>
  <NameValPair ParamName="ActiveDirectory" Value="true" />
</SimpleList>
<SimpleList>
  <NameValPair ParamName="ADSIEnabled" Value="true" />
</SimpleList>
```

**Note:** You must restart the Identity Server after changing any parameters. However, do not change the ADSIEnabled parameter value.

<table>
<thead>
<tr>
<th>Table B–1 Parameters and Values in globalparams Files</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>globalparams Parameters</strong></td>
</tr>
<tr>
<td>ActiveDirectory</td>
</tr>
<tr>
<td>ADSIEnabled</td>
</tr>
</tbody>
</table>

True when the Master Administrator selects Active Directory as the directory server type during Identity Server configuration

True when the Master Administrator enables ADSI during Identity Server configuration
About adsi_params
This section shows a sample adsi_params.xml file followed by a table of parameter values. By default, adsi_params.xml includes a value for the adsiCredential parameter and the password, as shown in the following example. This enables you to change the bind mechanism to be Explicit after initial setup.

The adsiPassword is encrypted and can only be generated by Oracle Access Manager during setup. The following is an example of this file:

```xml
<?xml version="1.0" ?>
<ParamsCtlg xmlns="http://www.oblix.com" CtlgName="adsi_params">
  <ValNameList ListName="adsi_params">
    <NameValPair ParamName="sizeLimit" Value="0" />
    <NameValPair ParamName="timeLimit" Value="0" />
    <NameValPair ParamName="pagesize" Value="100" />
    <NameValPair ParamName="useImplicitBind" Value="0" />
    <NameValPair ParamName="adsiCredential" Value="cn=Administrator,cn=users,dc=goodwill,dc=oblix,dc=com" />
    <NameValPair ParamName="adsiPassword" Value="0243455B5B5F5C4C5651595D41" />
    <NameValPair ParamName="useGCForAuthn" Value="false" />
    <NameValPair ParamName="encryption" Value="false" />
    <NameValPair ParamName="asynchronousSearch" Value="true" />
    <NameValPair ParamName="useDNSPrefixedLDAPPaths" Value="false" />
  </ValNameList>
</ParamsCtlg>
```

By default, encryption is set to false in adsi_params.xml. If you set it to true when running in open mode and restart the Identity Server, the Identity Server will not work.

---

**Note:** You must restart the Identity Server after changing any parameters.

Table B–2 describes parameters and values within the adsi_params files, next.

### Table B–2 Parameters and Values in adsi_params Files

<table>
<thead>
<tr>
<th><strong>adsi_params Parameters</strong></th>
<th><strong>Values</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>sizeLimit</td>
<td>Integer value that limits the number of query results returned for authentication.</td>
</tr>
<tr>
<td>timeLimit</td>
<td>Integer value that limits the number of seconds before a query times out.</td>
</tr>
<tr>
<td>pageSize</td>
<td>Page size of results that ADSI request from the server.</td>
</tr>
</tbody>
</table>
| useImplicitBind           | 0 = Implicit credentials  
                           | 1 = Explicit credentials  
                           | 2 = Use userPrincipalName |
| adsiCredential            | An LDAP specification of a user, such as cn=Administrator,cn=users,dc=myhost,dc=mydomain,dc=com |
| adsiPassword              | An encoded text string representing the LDAP user's password. |
| useGCForAuthn             | true/false  
                           | False |
Like the Identity System, the Access System provides the support for both ADSI and ADSI with LDAP authentication.

The Access System also supports multiple Active Directory domains and you must perform the steps for enabling ADSI for the default directory profile created during Oracle Access Manager setup.

This section includes the following topics:

- **Pure ADSI with ADSI Authentication**
- **Access System ADSI Configuration Files**

### Pure ADSI with ADSI Authentication

The Access Server authenticates to Active Directory using ADSI. This is the default when you enable ADSI on these components.

- The Policy Manager uses the same authentication mode as the Identity Server. Still, you must enable ADSI for the Policy Manager.

  See "Configuring ADSI for the Access System" on page B-11 for details.

- The Access Server can communicate directly with all directory servers in the forest and no longer requires the Global Catalog for LDAP authentication.

For a list of ADSI installation and setup considerations, see the Oracle Access Manager Installation Guide appendix on installing with Active Directory.

### Authentication Mechanisms

When users authenticate to Active Directory, the mechanism is the domain controller, which uses respective domain controllers for authentication with ADSI.

See "Access System ADSI Configuration Files" on page B-7 for details.

### Bind Mechanisms for the Access Server

ADSI provides several ways for the Access Server and Policy Manager to bind to Active Directory. There is no advantage to a particular method. Instead, it depends on which credentials you wish to use:

- **Implicitly**: Using the credential of the current process (default for the Access Server).
This corresponds to the service logon credentials for the Access Server. For implicit bind, the useImplicitBind flag in the adsi_params.xml file should be set to 0. See "Access System ADSI Configuration Files" on page B-7 for details.

Note: You need to create an account for the Access Service to bind to Active Directory. This account must be equivalent to the Root DN that you specify during setup of the Access Server. It should have all the administrative privileges for the operations that are to be performed using Oracle Access Manager. In an Active Directory Forest, this user should be delegated control over all the other domains in the forest.

- **Explicitly Using the DN of the User:** The useImplicitBind flag in the adsi_params.xml file should be set to 1.

The user DN should be specified with the adsiCredential parameter located in the adsi_params.xml file. See "Access System ADSI Configuration Files" on page B-7 for details.

- **Explicitly Using the userPrincipalName:** The useImplicitBind flag in the adsi_params.xml file should be set to 2.

The UPN should be specified in the adsiUPN parameter in the adsi_params.xml file. See "Access System ADSI Configuration Files" on page B-7 for details.

In a multi-domain Active Directory forest the only supported explicit bind mechanism is userPrincipalName. The Policy Manager supports only this mechanism.

**Access System ADSI Configuration Files**

Both the Policy Manager and Access Server each have two configuration files for modifying ADSI related parameters. Although the files are maintained in separate locations, and must be modified separately for each component, their contents are the same. The configuration files for the Policy Manager and Access Server are as follows:

- `\PolicyManager_install_dir\access\oblix\apps\common\bin\globalparams.xml`
- `\PolicyManager_install_dir\access\oblix\config\adsi_params.xml`

- `\AccessServer_install_dir\access\oblix\apps\common\bin\globalparams.xml`
- `\AccessServer_install_dir\access\oblix\config\adsi_params.xml`

These files are discussed in the following sections.

**Policy Manager ADSI Configuration**

This section shows a sample global-parameters configuration file, followed by a table of parameter values.

**Note:** When you install Policy Manager and Access Server, if you do not choose the ADSI option, you do not see the ADSIEnabled parameter in globalparams.xml. However, you do still see the useLDAPBind parameter, though it serves no purpose without ADSIEnabled.
The parameters and their values are described in Table B–3.

### Table B–3 Parameters and Values in globalparams Files

<table>
<thead>
<tr>
<th>globalparams Parameters</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>useLDAPBind</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td>True when the Master Administrator selects “Microsoft Active Directory using LDAP” during Policy Manager configuration. The ADSIEnabled flag must be true for this flag to have effect. The default is false.</td>
</tr>
<tr>
<td>ADSIEnabled</td>
<td>true</td>
</tr>
<tr>
<td></td>
<td>True when the Master Administrator enables ADSI during Policy Manager configuration.</td>
</tr>
<tr>

<td>True when the Master Administrator selects Active Directory as the Directory Server type during Policy Manager configuration.</td>
</tr>
</tbody>
</table>

### Access Server ADSI Configuration

This section shows a sample adsi parameters configuration file, followed by Table B–4 of parameter values.

### Table B–4 Parameters and Values in adsi_params Files

<table>
<thead>
<tr>
<th>adsi_params Parameters</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>sizeLimit</td>
<td>Integer value that limits the number of query results returned for authentication.</td>
</tr>
<tr>
<td>timeLimit</td>
<td>Integer value that limits the number of seconds before a query times out.</td>
</tr>
<tr>
<td>pageSize</td>
<td>Page size of results that adsi request from the server. The default is 0.</td>
</tr>
</tbody>
</table>
| useImplicitBind        | 0 = Implicit Credentials  
                         | 1 = Explicit Credentials  
                         | 2 = Use UserPrincipalName |
| adsiCredential         | An LDAP specification of a user, such as “cn=Administrator,cn=users,dc=myhost,dc=mydomain,dc=com” |
| adsiPassword           | An encoded text string representing the LDAP user’s password. |
| adsiUPN                | Text string of UserPrincipalName when useImplicitBind=2. A UPN string is typically an email address with the format: user@company.com |
| useGCForAuthn          | True/False  
                         | Change the useGCForAuthentication parameter to false. |
| asynchronousSearch     | True/False  
                         | By default, ADSI is enabled to perform asynchronous searches. If set to false, it does synchronous searches |
Configuring ADSI for Other Directory Profiles

---

### Enabling ADSI for Other Directory Profiles

If you have a noncontiguous forest of domain trees, you need to associate a separate ADSI database agent for each primary domain controller. Additional directory profiles are configured after Identity System installation and set up, as outlined in the following procedure and described in "Specifying Identity System Administrators" on page 2-1.

**To enable ADSI for additional directory profiles**

1. Navigate to the Identity System Console.
   
   http://hostname:port/identity/oblix

2. From the Identity System Console, click the System Configuration sub-tab, then click the Directory Profiles link in the left navigation pane.

---

### Enabling ADSI for a Default Directory Profile

The Identity System automatically creates a default directory profile during installation. You can enable ADSI for the default profile during Identity System setup.

The default database agent is automatically assigned a name using the convention default-ois-machine name. You should modify this name to the respective domain name because users must enter this name during authentication.

---

### Configuring ADSI for the Identity System

There are several tasks involved in configuring ADSI for the Identity System. Details are provided in the Oracle Access Manager Installation Guide.

#### Task overview: Configuring ADSI for the Identity System

- Prepare your Active Directory, as described in your Microsoft documentation and the Oracle Access Manager Installation Guide.

- Specify ADSI when you install and set up Oracle Access Manager, as described in the Oracle Access Manager Installation Guide. By default, this creates a pure ADSI configuration in which a single ADSI directory profile (DB agent) enables associated Identity Servers to perform all operations with a primary domain controller in your Active Directory tree using an Implicit Bind.

- Set up Active Directory attributes and enable change-password permissions, as described in the Oracle Access Manager Installation Guide.

- Configure the default directory profile, as described in "Enabling ADSI for a Default Directory Profile" on page B-9.

- Enable ADSI for additional directory profiles, if desired, as discussed under "Enabling ADSI for Other Directory Profiles" on page B-9.

---

### Enabling ADSI for Other Directory Profiles

If you have a noncontiguous forest of domain trees, you need to associate a separate ADSI database agent for each primary domain controller. Additional directory profiles are configured after Identity System installation and set up, as outlined in the following procedure and described in "Specifying Identity System Administrators" on page 2-1.

#### Table B–4 (Cont.) Parameters and Values in adsi_params Files

<table>
<thead>
<tr>
<th>adsi_params Parameters</th>
<th>Values</th>
</tr>
</thead>
<tbody>
<tr>
<td>asynchronousSearch</td>
<td>adsiUPN This parameter needs to be added if useImplicitBind is set to 2. The value of the parameter should be the UPN (userPrincipalName) of the user.</td>
</tr>
</tbody>
</table>
3. Click the Add button to display the Create Directory Server profile page.

Oracle recommends using the respective domain names as the profile names because users must enter this name during authentication.

4. Enter a name for this directory profile.

You must configure a directory profile for each Domain and Sub_domain controller. For more information, see "Configuring ADSI for the Identity System" on page B-9.

5. Enter a namespace for this directory profile.

There are multiple choices for the directory type. To use Active Directory without ADSI enabled, you should select Microsoft Active Directory.

**Note:** You still have the option to enable ADSI or SSL for changing passwords. Also, you can enable LDAP by selecting the secondary check box, Use LDAP for Authentication. When LDAP is enabled, an ADSI DB Agent associates with the primary domain controller. An LDAP agent needs to be configured for whichever Sub_domain controller you want to use to authenticate.

6. Select the appropriate directory type. For example:

   **Directory Type**
   - COREfd Data Anywhere
   - Microsoft Active Directory Application Mode
   - Microsoft Active Directory (using ADSI)
   - Use LDAP for Authentication
   - Microsoft Active Directory
   - AD-Change password using
   - ADSI
   - SSL

7. Select the operations supported for this directory profile, for example:
Configuring ADSI for the Access System

The Policy Manager uses the Identity Server for authentication. Therefore, the login operation uses the same mode (ADSI or LDAP) as the Identity Server it talks to. During Policy Manager setup, by default, you use an Explicit Bind to enable the Policy Manager and Access System Console to perform all operations except authentication in the Active Directory tree.

By default, enabling ADSI for the Access Server creates a pure ADSI configuration in which the Access Server performs all operations with a primary domain controller in your Active Directory tree using an Implicit Bind.

Configuring ADSI support in the Access System involves the following tasks.

**Task overview: Configure ADSI for the Access System**

1. Validate your setup, as described in the *Oracle Access Manager Installation Guide* appendix.
2. Install and set up the Policy Manager, as described in the *Oracle Access Manager Installation Guide*.
3. Install the Access Server and setup ADSI, as described in the *Oracle Access Manager Installation Guide*.
4. Install the WebGate, as described in the *Oracle Access Manager Installation Guide*.
5. Enable LDAP authentication for the Access Server, if desired, as described in "Enabling LDAP Authentication for the Access Server" on page B-11.

**Enabling LDAP Authentication for the Access Server**

ADSI authentication may be slower than LDAP. For that reason, you may wish to use LDAP for authentication while other operations such as authorization and auditing are handled by ADSI.
To enable LDAP authentication for the Access Server

1. Open `AccessServer_install_dir\access\oblx\apps\common\bin\globalparams.xml` with a text editor.
2. Change the value of useLDAPBind to true.
3. Save `globalparams.xml`.
4. Create a copy of `ConfigDBfailover.xml` located in `AccessServer_install_dir\access\oblx\config\` and name it `AppDBfailover.xml`.

   Both files should reside in the same directory.

5. Save.
6. Restart the Access Server.

Changing the pageSize Parameter

Based on your Active Directory forest deployment you may need to change the page-size parameter in the `adsi_params` file. For example, in Figure B–2 you have a parent-child relationship between your Active Directory domains, and you have user(s) in both the parent and child domain with the same `samaccountname`.

*Figure B–2  Users in Both the Parent and Child Domains*

Assume the authentication scheme is Oracle Access and Identity for an Active Directory forest. In this case:

- For user1k1 to log in to the Child1 domain, the user can enter their user ID as `Child1\user1k1`.
- For user1k2 to log in to the Child2 domain, the user can enter their user ID as `Child2\user1k2`.

However, if the `pageSize` parameter is set to 0, for user1k1 from the parent domain to log in entering `Parent\user1k1` produces an error: "The credentials Parent\user1k1 used in the login correspond to more than one user profile in the Identity System. The correspondence must be unique."

This is because when the page size is set to 0, ADSI searches the subdomains, therefore finding two users who satisfy the criteria. For user1k1 and user1k2 to log in to the parent domain you need to set the `pageSize` parameter to a finite value. Oracle recommends using 100.

Troubleshooting

For information on troubleshooting, see "Troubleshooting Oracle Access Manager" on page F-1.
This chapter summarizes procedures to set up Oracle Access Manager with Active Directory forests using LDAP as the communication protocol.

This appendix contains the following topics:

- Overview
- Setting Up the Policy Manager for LDAP
- Setting Up the Access Server for LDAP
- Setting Active Directory Timeouts for LDAP
- Enabling LDAP Authentication with ADSI

For additional information and procedures, see the Oracle Access Manager Installation Guide.

---

**Note:** The instructions here apply only if you are using LDAP as the protocol between the Access System and Active Directory. If your environment differs, skip this discussion.

---

**Overview**

The Access System supports Active Directory forests with some modifications.

---

**Note:** The Microsoft Global Catalog is no longer required for the Access System.

---

The steps in this section are based on the following example. In this case, the Identity System was configured using the two domains shown in Figure C–1. For example:

- `dc=maverick,dc=oblix,dc=com`
- `dc=iceman,dc=oblix,dc=com`
Complete the following procedures to set up the Access System for multiple domains using LDAP between the Access System and Active Directory:

- Setting Up the Policy Manager for LDAP
- Setting Up the Access Server for LDAP
- Setting Active Directory Timeouts for LDAP

**Note:** In the following discussions, install_dir refers to the installation directory you specified for the named component. For example, PolicyManager_install_dir is the directory where you installed the Policy Manager.

### Setting Up the Policy Manager for LDAP

The Oracle Access Manager-related configuration information is located in the PolicyManager_install_dir/access/oblix/config/ldap directory and must be accessed directly. The following are relevant files:

- AppDB.xml
- ConfigDB.xml
- WebResrcDB.xml

Suppose the Identity System was set up as shown earlier with the configuration data in the dc=iceman,dc=oblix,dc=com domain.

In this case, the Policy Manager must also be set up for this domain. To accomplish this, you must specify the same configuration DN for the Policy Manager and the Identity Server.

For more information about the configuration DN, see the Oracle Access Manager Installation Guide.

**To set up the Policy Manager for Active Directory**

1. Navigate to the Policy Manager setup page:
   ```
   http://hostname:port/access/oblix
   ```
2. Set up the Policy Manager with the same configuration DN as the Identity Server.
For example, against the machine containing the domain:
dc=iceman,dc=oblix,dc=com

3. Before starting the Web server, change the port to 3268 (open LDAP) to ensure that
users and groups are accessible from both domains.

4. See the appendix "Deploying with Active Directory" on page A-1 for information
about configuring the credential_mapping plug-in required in your authentication
schemes and setting up SSO.

Setting Up the Access Server for LDAP

This section only applies if you are using LDAP as the protocol between the Access
Server and Active Directory.

To set up the Access Server for Active Directory

1. Configure the Access Server using the same configuration DN as the Identity
Server.

   For example, against the machine containing the domain:
dc=iceman,dc=oblix,dc=com domain

2. Make sure Active Directory time out is handled correctly, as described under
"Setting Active Directory Timeouts for LDAP" on page C-3.

3. Create a copy of ConfigDBfailover.xml located in \AccessServer_install_dir\access\oblix\apps\config and name it AppDBfailover.xml.

   Both files should reside in the same directory.

Setting Active Directory Timeouts for LDAP

If you are using LDAP, you need to configure timeouts for the Access Server when it is
installed against Active Directory.

The Access Server, which runs as a service, opens connections to Active Directory.
Active Directory times out idle connections after a period of inactivity, which means
that the Access Server can try to access the directory and fail.

If you want to avoid this problem, you need to establish new connections before the
Active Directory Idle Session Time is reached. The failover information can be
specified when:

- You are prompted to specify failover information at the end of the Access Server
  installation.

- You reconfigure failover information after installation is complete, using the
  configureAAAServer application in AccessServer_install_dir/access/oblix/tools/configureAAAServer, as described in the following
  procedure.

The following files are created when you use the ConfigAAAServer.exe tool to
configure failover between a second directory server and the Access Server:

ConfigDBfailover
AppDBfailover
Web...DBfailover
To specify Access Server failover after installation

1. Locate the configureAAAServer application.
   
   AccessServer_install_dir\access\oblix\tools\configureAAAServer

2. Launch the configureAAAServer application using the following command.
   
   configureAAAServer install AS_install_dir

3. Answer No, when asked if you want to reconfigure Access Server.

4. Answer Yes, when asked if you want to specify failover information.

5. When asked where different types of data are stored, respond appropriately for your environment.
   
   For example:
   
   - **Separate Directory Servers, Choose Option 8**: If policy and Configuration DN are separate from user data, choose option 8 (Modify Common Parameters) and specify values appropriate for your system.
   
   - **Same Directory Server, Choose Option 4**: If policy, Configuration DN, and user information is on the same directory server, choose option 4 (Modify Common Parameters) and enter values appropriate for your system. For example:
     
     - Maximum Connections: 1
     - Sleep For (seconds): 60
     - Failover Threshold: 1
     - Maximum Session Time (seconds): 120

     After every Maximum Session Time, a new connection is created to Active Directory, and the old connection is dropped, whether the Access Server was idle or not.

   **Note**: Make sure the Maximum Session Time (in seconds) is less than the Active Directory Idle Timeout (typically less than 600 seconds).

6. Choose the option to quit.

7. When asked if you want to commit the changes, answer Yes.

   For more information about failover, see the Oracle Access Manager Deployment Guide.

Enabling LDAP Authentication with ADSI

ADSI authentication may be slower than LDAP. For that reason, you may wish to use LDAP for authentication while other operations such as authorization and auditing are handled by ADSI.

To enable LDAP authentication for the Access Server

1. Open globalparams.xml with a text editor.
   
   AccessServer_install_dir\access\oblix\apps\common\bin\globalparams.xml

2. Change the value of useLDAPBind to true.
3. Save globalparams.xml.
4. Create a copy of ConfigDBfailover.xml located in:

   AccesServer_install_dir\access\oblix\config\ldap\ConfigDBfailover.xml

5. Name it AppDBfailover.xml.
   Both files should reside in the same directory.
6. Save.
Oracle Access Manager provides support for .NET features with Windows Server 2003. For details about supported features and their implementation within Oracle Access Manager, see the following topics in this appendix:

- Resolving Ambiguous Names
- Configuring for Dynamically Linked Auxiliary Classes
- Enabling Fast Bind for Access System Authentication
- Enabling Impersonation
- Setting Up Integrated Windows Authentication
- Using Access System Password Management
- Using Managed Code and Helper Classes
- Integrating with Authorization Manager Services
- Integrating with Smart Card Authentication
- Integrating the Security Connector for ASP.NET
- Troubleshooting
- Microsoft Resources

Resolving Ambiguous Names

Active Directory running on Windows Server 2003 provides support for ambiguous name resolution (ANR).

ANR is a search algorithm associated with LDAP clients that must be enabled on both the LDAP client and the LDAP server. ANR allows objects to be bound without complex search filters and is useful when locating objects and attributes that may or may not be known by the client.

In Oracle Access Manager, ANR is a virtual attribute that does not physically exist in the directory server. Oracle Access Manager provides the virtual ANR attribute through the AD_anr.ldif file, which enables Oracle Access Manager to interpret ANR requests, map ANR requests to Boolean functions And and Or that expand to a directory-server filter to broaden the search, and send the query to Active Directory.

**Note:** The AD_anr.ldif file is included in the Oracle Access Manager schema installation and must be imported manually. See "Configuring for ANR" on page D-2 for details.
About ANR Attributes, Searches, and Results

By default, the attributes shown in Table D–1 are set for ANR.

<table>
<thead>
<tr>
<th>ANR Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>displayName</td>
</tr>
<tr>
<td>GivenName</td>
</tr>
<tr>
<td>LegacyExchangeDN</td>
</tr>
<tr>
<td>msExchMailNickname</td>
</tr>
<tr>
<td>name</td>
</tr>
<tr>
<td>physicalDeliveryOfficeName</td>
</tr>
<tr>
<td>proxyAddress</td>
</tr>
<tr>
<td>sAMAccountName</td>
</tr>
<tr>
<td>Surname</td>
</tr>
</tbody>
</table>

For a search filter such as (anr=von), the server would return objects that matched any of the previously listed attributes equal to von*. When a space is embedded in the search string, the search is divided at the space and an Or search is also performed on the attributes. The server attempts to perform first/last name processing. When there is only one space, the search divides only at the first space.

For example, if the search filter was (anr=Rob Al), the filter expansion would look like the following.

\[
(|(givenName=Rob\ Al*)\\
 (sn=Rob\ Al*)\\
 (displayName=Rob\ Al*)\\
 (LegacyExchangeDN=Rob\ Al*)\\
 (name=Rob\ Al*)\\
 (physicalDeliveryOfficeName=Rob\ Al*)\\
 (proxyAddress=Rob\ Al*)\\
 (sAMAccountName=Rob\ Al*)\\
 (&(givenName=Rob*)\{sn=Al*\})\\
 (&(givenName=Al*)\{sn=Rob*\})
\]

Configuring for ANR

The attributes used by ANR are configurable. You can specify other attributes to be included in ANR searches by using the Active Directory Schema Snap-in to check the Ambiguous Name Resolution box for the attribute. You can directly set the searchFlags attribute to 5 in the attributeSchema for the attribute you want to include. To include an attribute to be used for ANR, the attribute must also be indexed.

The following task overview outlines the procedures you must complete to enable ANR within Oracle Access Manager. After you upload the meta-attribute configuration for ANR into the configuration branch in the directory server, the ANR attribute should be configured on the profile page and defined as searchable. Attribute access control can also be configured on the same profile page.
Task overview: Preparing to use ANR during searches

1. Update Oracle configuration data to include the ANR meta-attribute details in the configuration branch of the schema, as described in "Updating Configuration Data" on page D-3.

2. Make the ANR attribute available to the Oracle Access Manager search function in the Identity Server, as described in "Configuring ANR in Identity System Panels" on page D-3.

3. Verify Access Control rights, as described in "Verifying ANR Attribute Access Control" on page D-4.

4. Use ANR-to-Oracle Access Manager authentication and authorization search filters, as described in "Using ANR in Identity System Searches" on page D-5.

Updating Configuration Data

You first need to update configuration data (Oracle Access Manager configuration data) to include the ANR meta-attribute configuration information in the configuration branch. During this procedure, the following AD_anr.ldif is executed.

```diff
# File to load ANR meta-attribute configuration to the directory tree.

dn: obattr=anr,obclass=user,OU=Oblix,<domain-dn>
  changetype: add
  instanceType: 4
  distinguishedName: obattr=anr,obclass=user,OU=Oblix,<domain-dn>
  objectClass: oblixmetaattribute
  name: anr
  obattr: anr
  obcardinality: ob_single
  obdisplayname: ANR
  obdisplaytype: ObDTextS
  obsearchable: true
  obvisible: true

When this procedure is complete, ANR appears as an attribute you can select when configuring Identity System panels.

To update Oracle configuration data

1. Locate the AD_anr.ldif file on the machine hosting the Identity Server:
   \IdentityServer_install_dir\identity\oblix\data.ldap\common\AD_anr.ldif.

2. Import the AD_anr.ldif file to the configuration directory.
   For example:
   ```bash
   D:\data>ldifde -i -f AD_anr.ldif -a
   "cn=administrator, cn=users, dc=name, dc=company, dc=net" password
   ```

3. Restart the Identity Server.

Configuring ANR in Identity System Panels

After you update the Oracle configuration data with ANR meta-attributes, you are ready to make the ANR attribute available to the Identity System search function on a Tab (panel) and in the list of searchable attributes in the User Manager Selector.

The following procedure guides you through configuring ANR in Identity System panels. For more information, see "Configuring User, Group, and Organization Manager" on page 4-1.
To configure ANR in Identity System Panels

1. From the Identity System landing page, click the link for the Identity System Console.
   
   If you are already logged in, click the Identity System Console tab.

2. Click the User Manager Configuration sub-tab, then click the Tabs link in the left navigation pane.

3. Click the link for the tab, then click View Object Profile.

4. Click Configure Panels, then click the link for the panel that you want to configure.
   
   A summary appears listing all attributes for the selected panel.

5. Click the Modify button at the bottom of the summary page.
   
   The Modify Panel page appears.

6. Click the Add button, then select ANR from the list in the Attributes column and click Save.
   
   The summary page appears listing all attributes, which should now include ANR.

   Next you need to confirm that ANR is a searchable attribute that will appear in the Query Builder’s search criteria list.

7. From the Identity System Console, click the User Manager Configuration sub-tab, then click the Tabs link in the left navigation pane.

8. Click the link for the tab.

9. Click the View Search Attributes button at the bottom of the page.
   
   A list of all search attributes appears.

10. Confirm that ANR is in the list. For example:

11. Restart the Identity Server.

Verifying ANR Attribute Access Control

By default, the attribute has read rights. The ANR attribute must not have modify rights. The following procedure shows the Access Control rights for the ANR attribute. See “Setting and Modifying LDAP Attribute Permissions” on page 4-30 for details.
To verify ANR attribute access control

1. From the Identity System landing page, click the link for the User Manager.
   If you are already logged in to the Identity System, click the tab for the User Manager application.

2. Click the Configuration sub-tab, then click the link for Attribute Access Control.

3. Select ANR from the Attribute list, then verify that it has read rights only.
   You are ready to use ANR in Identity System searches.

Using ANR in Identity System Searches

When a user invokes the User Manager, they can choose ANR from the search criteria list to perform a directory search.

To use ANR in a search

1. From the Identity System landing page, click the link for the User Manager.
   If you are already logged in to the Identity System, click the tab for the User Manager application.

2. Select ANR from the Search list, define other search criteria, then enter your condition.

3. Click Go and check your results.

Configuring for Dynamically Linked Auxiliary Classes

A structural object class can stand on its own and contains basic attributes required for use within Identity System applications. Structural object class examples include person and groupOfNames. The person object class may contain attributes such as name, department, employee ID, and email address. A structural object class must be assigned when you create a tab within an Identity System application.

Auxiliary object classes are mix-in classes that can be added to any structural class. You use an auxiliary object class to add a set of related attributes to an entry that already belongs to a structural class. Items such as a billing address, a challenge phrase, a response to a challenge phrase, and so on may be useful for definition in an auxiliary object class.

With Windows Server 2000, Active Directory supported only statically linked auxiliary classes. A statically-linked auxiliary class is one that is included in the auxiliaryClass or systemAuxiliaryClass attribute of an object class’s classSchema definition in the schema. It is part of every instance of the class with which it is associated. Using statically-linked auxiliary classes is the default with Oracle Access Manager is installed with Active Directory. All other directories support only dynamically linked auxiliary object classes.

With a Windows 2003 Server, Active Directory and Oracle Access Manager support dynamically linked auxiliary classes. With the schema defined for a particular user, group, or organization, dynamically linked auxiliary classes enable you to store additional attributes with an individual object without the forest-wide impact of extending the schema definition for an entire class. Dynamically linked auxiliary class attributes are mixed in only at runtime.

For example, you can use dynamic linking to attach a sales-specific auxiliary class to the user objects of sales people and other department-specific auxiliary classes to the
user objects of employees in other departments. Or you may want to convert a basic group to a mail group by adding specific attributes dynamically.

**Task overview: Setting up for dynamic auxiliary classes**

1. Install and set up Oracle Access Manager with dynamic-auxiliary classes enabled, as described in the *Oracle Access Manager Installation Guide*.

2. Specify additional structural object classes for the Organization Manager, as described in "About Object Classes" on page 3-1.

3. Configure attributes, as described in "About Object Class Attributes" on page 3-9.

4. Configure User, Group, and Organization application tabs, as described in "Configuring Tabs" on page 4-2.

5. Configure User, Group, and Organization profile pages, as described in "Configuring Tab Profile Pages and Panels" on page 4-11.

6. Define workflows, as described in "Chaining Identity Functions Into Workflows" on page 5-1.

7. Specify additional auxiliary object classes, as described in "Adding Attributes Dynamically" on page D-6.

**Adding Attributes Dynamically**

The following procedure provides an example only and assumes that you have created a Tab and Panel in the User Manager. Here you will add desired auxiliary attributes dynamically.

---

**Note:** This is only an example. You may be working in the Group Manager or Organization Manager. See also, "Adding Attributes for a Group" on page D-7.

---

**To specify additional auxiliary object classes in the User Manager**

1. From the Identity System Console, click User Manager Configuration, then click Tabs in the left navigation pane.

2. Click the link for the tab.

3. Click the View Object Profile button, then click the Configure Panels link.

4. Click the link for the panel that you want to modify.

5. Click the Modify button to display the Modify Panel page.

6. Click the Add button, select one or more attributes from the list, then click Save.

   The View Panel page appears with the attributes you added.
The entry in the directory server has changed, and the new attributes are included.

**Adding Attributes for a Group**

The example in this procedure dynamically converts a single basic group to a mail group by adding attributes, such as:

<table>
<thead>
<tr>
<th>Attribute 1</th>
<th>Attribute 2</th>
<th>Attribute 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>MailAlternateAddress</td>
<td>Mailhost</td>
<td>MailRoutingAddress</td>
</tr>
</tbody>
</table>

This example assumes that you have created a Group Panel and a workflow to create a Mail Group. Now you add desired attributes dynamically. This is only an example. You may be working in the User Manager or Organization Manager. See also "Adding Attributes Dynamically" on page D-6.

**To add attributes to a Group Profile panel**

1. From the Identity System landing page, click the link for the Identity System Console.

   If you are already logged in, click the Identity System Console tab.

2. Click the Group Manager Configuration sub-tab, then click the Tabs link in the left navigation pane.

3. Click View Object Profile, Configure Panels, then click the link for the panel that you want to modify.

   The View Panel page appears.

4. Click Modify.

   The Modify Panel page appears.

5. In the Attributes section of the page, click the Add button, select one or more attributes from the list, then click Save and verify that the attributes you added appear in the View Panel page.
6. Select Group Manager from the Select Application list in the upper right corner.

7. Enter your search criteria in the Selector and click Go.

The results are returned. When you select a Group to review you will notice that the attributes you added dynamically to one group are available only for that group.

8. Click Modify, click the + button, then add a specific value, and save, as usual.

The entry in the directory has also changed. For example, the following screen shot shows a sample entry before auxiliary classes were added.

Figure D–1 Sample Entry Before Dynamic Auxiliary Classes

The next screen shows the same entry after auxiliary classes were added.

Enabling Fast Bind for Access System Authentication

The Active Directory running on Windows Server 2003 provides a concurrent bind (also known as fast bind) feature that allows multiple authentications over the same LDAP connection.

The Access System supports and uses this feature, which provides the following advantages:

- Fast bind permits two threads to request a bind over one connection at the same time.
- Fast bind provides a faster authentication mechanism because it only validates the password and the account flag and does not build a ticket.

The Fast Bind option must be enabled for each database instance, and is located on individual database profiles in the Access System Console.

To configure the Access System to use a fast bind

1. From the Access System Console, click the System Configuration tab.
Enabling Impersonation

In a Windows environment, all processes and threads execute in a security context. Impersonation is the ability of a thread to execute in a security context that is different...
from that of the process that owns the thread. The primary purpose of impersonation is to trigger access checks against a client's identity.

For details about enabling impersonation in Oracle Access Manager, which overrides impersonation enabled with IIS, see Oracle Access Manager Access System Administration Guide.

Setting Up Integrated Windows Authentication

Oracle Access Manager provides support for integrated Windows authentication (IWA). Your environment may include:

- Windows 2000 Server or Windows Server 2003 or Solaris
- Internet Information Services (IIS) 5.5 or 6.x
- Active Directory or iPlanet directory server

If the user's directory server has, for example, an NT Logon ID, or if the user name is the same everywhere, then a user is able to authenticate into any directory server.

The most common authentication mechanism on Windows 2000 and Windows Server 2003 is Kerberos.

The use of IWA by Oracle Access Manager is seamless. The user won't notice any difference between a typical authentication and IWA when they log on to their desktop, open an Internet Explorer (IE) browser, request a protected web resource, and complete single sign-on.

To see the supported versions and platforms for this integration, refer to Metalink, as follows.

To view information on Metalink

1. Go to the following URL:

   http://metalink.oracle.com

2. Click the Certify tab.

3. Click View Certifications by Product.

4. Select the Application Server option and click Submit.

5. Choose Oracle Application Server and click Submit.

Process overview: Using IWA authentication

1. The user logs in to the desktop machine, and local authentication is completed using the Windows Domain Administrator authentication scheme.

2. The user opens an Internet Explorer (IE) browser and requests an Access System-protected Web resource.

3. The browser notes the local authentication and sends a token to the IIS Web server.

4. The IIS Web server uses the token to authenticate the user and set up the REMOTE_USER HTTP header variable that specifies the user name supplied by the client and authenticated by the server.

5. The WebGate installed on the IIS Web server uses the hidden feature of external authentication to get the REMOTE_USER header variable value and map it to a DN for the ObSSOCookie generation and authorization.
6. The WebGate creates an ObSSOCookie and sends it back to the browser.

7. The Access System authorization and other processes proceed as usual.
   
   The maximum session timeout period configured for the WebGate is applicable to
   the generated ObSSOCookie.

Task overview: Setting Up IWA authentication

1. Install a WebGate on the same IIS Web server or servers on which you will set up
   IWA, as described in the Oracle Access Manager Installation Guide.
   - If you installed the WebGate at the Site level, you should perform the tasks at
     the Site level.
   - If you have multiple WebGates installed at different virtual sites, you should
     perform the tasks for each virtual site.

2. Enable IWA on the WebGate, as described in "Enabling IWA on the WebGate Web
   Server" on page D-11.

3. Configure the WebGate to use IWA, as described in "Configuring the WebGate for
   IWA" on page D-12.

4. Create an authentication scheme for IWA in Oracle Access Manager, as described
   in "Creating an IWA Authentication Scheme in Oracle Access Manager" on
   page D-12.

5. Test the IWA implementation, as described in "Testing IWA Implementation" on

Enabling IWA on the WebGate Web Server

The first procedure is to enable IWA on the machine hosting the WebGate.

- If you have installed the WebGate at the Site level, you should perform the tasks at
  the Site level.
- If you have multiple WebGates installed at different virtual sites, you should
  perform the tasks for each virtual site.

To enable IWA on the machine hosting the WebGate

1. Start the Internet Services Manager on the machine hosting the WebGate: Start,
   Programs, Administrative Tools, Internet Services Manager

2. Right-click the Default Web site (or the name of Web server if you changed the
   name of the Default Web site), then select Properties.

   Note: If you installed WebGate at the Site level, right-click the Site then select Properties.

3. Click the Edit button beside Master Properties.

4. Click the Directory Security tab, then click Edit beside "Anonymous access and
   authentication control."

7. Click OK, then click OK again.
8. Restart the IIS Web server.

### Configuring the WebGate for IWA

To configure the WebGate for IWA, you must set the user-defined parameter UseIISBuiltinAuthentication to true in the Access System Console. See the chapter on configuring the Access System in Oracle Access Manager Access System Administration Guide for details.

#### To modify an AccessGate through the Access System Console

1. Launch the Access System Console, click the Access System Configuration tab, then click the AccessGate Configuration link in the left navigation pane.
   
   The Search for AccessGates page appears.

2. Select the search attribute and condition from the lists, or select All to find all AccessGates.
   
   The Search list is a selection list of attributes that can be searched. The remaining fields allow you to specify search criteria that are appropriate for the selected attribute.

3. Click Go.
   
   The search results are displayed on the page.

4. Click the name of the AccessGate or WebGate that you want to modify.
   
   The AccessGate Details page appears.

5. Click Modify.
   
   The Modify AccessGate page appears. You can enter new information on this page.
   
   You cannot change an AccessGate or WebGate name. To rename it, you must delete it from the Access System Console and then uninstall it. You then create a new AccessGate or WebGate.

6. Type new values as needed.

7. Click Save to save your changes.

### Creating an IWA Authentication Scheme in Oracle Access Manager

You must create an IWA authentication scheme for the Access System to use a specific challenge method, challenge parameter, and plug-in, as described in the following procedure.

#### To create an IWA authentication scheme in the Access System

1. Navigate to the Access System Console, as usual. For example:
   
   
   
   http://hostname:port/access/oblix

   
   For example:
   
   Name: Integrated Windows Authentication
   
   Description: This scheme is Integrated Windows Authentication, using the built-in Windows authentication mechanism.
4. Click the Plug-Ins tab, then click Modify.
5. Select the plug-in name from the list, enter your plug-in parameters and click Add, then save when you are finished.
For example:
Plugin(s)

<table>
<thead>
<tr>
<th>Plugin Name</th>
<th>Plugin Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>credential_mapping</td>
<td>obMappingBase=&quot;Domain name&quot;, obMappingFilter=&quot;(&amp;(objectclass=user)(samaccountname=%REMOTE_USER%))&quot;</td>
</tr>
</tbody>
</table>

6. Save the authentication scheme and protect resources using this scheme, as usual.

**Testing IWA Implementation**

It is always a good idea to test the implementation before you roll it out.

**To test IWA**
1. Log in to the machine as someone who is a user of both Oracle Access Manager and the Windows operating system.
2. Enter the URL of the protected resource.

**Using Access System Password Management**

When using the Access System Password Management feature with an Active Directory forest, note the following:
- The Change on Reset, Password Expiration, and Password ExpirationWarning features will work.
- The Number of Retrieves feature will not work.

This limitation applies only if you are using the LDAP mode for Password Management in the Access System and only if you are using Active Directory in a forest configuration.

**Using Managed Code and Helper Classes**

The .NET Framework provides an object-oriented programming environment to guarantee the safe execution of code and to eliminate performance problems in scripted environments. In the .NET Framework, code that targets the runtime is called managed code.

In addition, MANAGEDLIB actions offer the benefits of managed code, including:
- **Language Choice**—You can write your plug-ins in VisualBasic, C#, Managed C++ (MC++), Java, or PERL.
Integrating with Authorization Manager Services

The Access System provides an authorization plug-in that uses the Microsoft Windows Server 2003 Authorization Manager (AzMan) services to make authorization decisions for Access Server clients, including WebGates and callers of the Access Server API.

See the Oracle Access Manager Integration Guide for details about configuring a policy domain for the AzMan plug-in.

Integrating with Smart Card Authentication

Oracle Access Manager supports smart card authentication with Active Directory and IIS Web servers in homogeneous Windows environments. Using a smart card provides a stronger form of authentication than a user name and password alone because it is based on something the user knows and something the user has.

- **Something the user knows** is the user’s secret personal identification number (PIN), similar in concept to a personal bank code PIN.

- **Something the user has** is the cryptographically-based identification and proof-of-possession generated by the smart card device that you insert into the smart card reader attached to a computer.

See the Oracle Access Manager Integration Guide for details about configuring integrating with smart card authentication.

Integrating the Security Connector for ASP.NET

Oracle Access Manager supports the ASP.NET component of the Microsoft .NET Framework, which developers can use to build, deploy, and run Web applications and distributed applications. The Oracle Access Manager Security Connector for ASP.NET supports and enhances native .NET role-based security.

See the Oracle Access Manager Integration Guide for details about how to use the Oracle Access Manager Security Connector for ASP.NET to instantiate a new OblixPrincipal

Language Integration--You can combine MIL modules compiled from different source languages into one assembly or plug-in.

This provides the plug-in writer with a wider range of language choices for plug-in development.

Support for Memory Management--The common language runtime (CLR) provides garbage collection, freeing the plug-in writer from most memory management.

The garbage collector returns memory to the heap when that memory is no longer referenced. However, the plug-in writer should ensure that there are no dangling references to objects. If there are dangling references, garbage collection will not occur for the unused memory.

.NET Framework Support--The .NET framework SDK contains a wide range of functionality. This may reduce the need for third-party support in plug-in code.

Oracle Access Manager can use and call APIs in many languages, including managed code and languages such as C, Managed C++ (MC++), and Visual Basic.Net.

For more information about managed code and managed helper classes, see the Oracle Access Manager Developer Guide.
object and populate it with roles (Access System authorization rules) and the native WindowsPrincipal object.

**Troubleshooting**

For more information on troubleshooting, see "Troubleshooting Oracle Access Manager" on page F-1.

ADSI Programmers Page

Oracle Access Manager Parameter Files

Oracle Access Manager provides a simple means for users to modify the way it operates, by changing the content of specified parameter files, also called catalog files. This appendix describes the file format, provides a list of the files, and describes values within them that you can change to customize Oracle Access Manager system operation.

File Categories

All of the parameter files are located relative to the Identity System installation directory, which could be, for example:

on Windows:

\c:\COREid\identity\oblix

on Unix:

/\var/COREid/identity/oblix

The parameter files can be viewed as belonging to one of several categories, distinguished by the type of parameters they contain:

- Parameters that affect the administrative applications: User Manager Admin; Group Manager Admin; Organization Manager Admin.

- Parameters that affect the user applications: User Manager; Group Manager; Organization Manager; Asynch Mailer; Password Management; Query Builder; Selector.

- Parameters whose effect is common across many applications: the user applications, the administrative applications and the Comm Server (a binary streaming data module).

- Parameters that affect Oracle Access Manager interaction with the directory database (DB), further subcategorized as follows: user, group, organization, application, configuration, workflow, and LDAP referential integrity.

- Parameters that affect Oracle Access Manager multitier architecture (for example, the WebPass Web application, or the Identity Server engine).

For More Information on the Parameter Files

See the Oracle Access Manager Customization Guide for details.
Troubleshooting Oracle Access Manager

This appendix explains typical problems that you could encounter while running or installing Oracle Access Manager. It contains these sections:

- Problems and Solutions
- Need More Help?

Problems and Solutions

This section describes common Oracle Access Manager error messages, problems and solutions. It contains the following topics:

- Memory Usage Rises for an Identity Server After Configuring a Directory Server Profile
- Unable to Save a Directory Server Profile
- Active Directory: Adding Members Causes the Group Size to Shrink
- ADSI Cannot Be Enabled for a Directory Profile
- Database Validation Fails
- Simple Transport Security Mode Expires After One Year
- Style Sheet Validation Fails
- "Cannot Find xenroll.cab" Error Is Issued When Using a Workflow
- "Enable Failed" Error Is Issued When Using a Workflow
- JPEG Photo Images Are Not Updated

Memory Usage Rises for an Identity Server After Configuring a Directory Server Profile

After configuring a directory server profile, the memory usage for the Identity Server becomes too high. Note that this problem can also apply to an Access Server or Policy Manager.

Problem

When you configure a directory server profile, you are prompted to provide a maximum session time. The default value for the session time is 0 (unlimited). This may cause a performance issue, because the size of the caches for LDAP connections to the Identity Server increase over time. Oracle Access Manager does not control these caches directly.
Solution
To prevent the cache size from causing a performance problem, set the value of the Maximum Session Time (Minutes) for the directory server profile to a finite value, for example, 10 hours, as follows:

1. From the Identity System Console click System Configuration, then click Directory Profiles.
2. Click the link for the profile that you want to modify.
3. In the Max. Session Time (Min.) field, set the value to 600.

Unable to Save a Directory Server Profile
When saving a directory server profile for use by Identity System and Access System components, you may receive an error similar to the following:

"Unable to save the Directory Server Profile. The applications require a Directory Server Profile to access Policy base with search, modify, and delete operations to function properly. This Directory Server Profile cannot load balance between its servers as well."

Problem
When you install the Access System (at least the Policy Manager), you are asked to identify a location in the directory for policy information. This branch in the directory may or may not be the same as the branch where the Identity System configuration data is stored. Also during Policy Manager installation, a directory profile is created that provides the Identity Servers rights over the policy branch.

The Identity Servers require the ability to search, modify and delete objects in the Access System’s policy branch to ensure referential integrity between the Identity and Access Systems. For example, suppose that you allow a user access to a particular resource in the Allow Access page of a policy in the Access System. If you delete the user from the Identity System, referential integrity ensures that the user is also deleted from the policies in the Access System.

If there is no directory profile that provides referential integrity between the Identity and Access Systems, you receive the "Unable to save. . ." error. If you receive this message, you have probably deleted or edited this profile.

Solution
Create another directory server profile with access to the policy branch of the directory.

Active Directory: Adding Members Causes the Group Size to Shrink
Adding users to static groups works properly only up to a point.

Problem
Continuing to add members to static groups causes the group size to shrink.

Solution
Change the value for the parameter maxForRangedMemberRetrieval in globalparams.xml to a number higher than the desired group membership size:

- If you are using Active Directory on Windows 2003, set the parameter maxForRangedMemberRetrieval in globalparams.xml to 1500.
Problems and Solutions

Troubleshooting Oracle Access Manager

F-3

■ If you are using Active Directory on Windows 2000, set it to 1000.

**ADSI Cannot Be Enabled for a Directory Profile**

When using Active Directory, you can use the Identity System Console to change the directory profile for user data from ADSI to LDAP or LDAP to ADSI. However, you cannot do this for configuration or policy data.

**Problem**

When you attempt to change the directory profile for policy or configuration data from the Identity System Console, you get an error. For example, suppose that you store user data in an Active Directory forest using LDAP, and you store configuration and policy data in a different Active Directory forest using ADSI. If you use the Identity System Console to change the ADSI flag in the configuration data database profile to LDAP, after restarting the Oracle Access Manager servers and services, the ADSI flag remains enabled and the following message appears:

"ADSI can be enabled for either user or configuration DB Profile if they are in a separate forest. ADSI Cannot be Enabled for this DB Profile."

Any attempts to modify the directory profile for configuration or policy data to ADSI produces an error because Oracle Access Manager recognizes the profile as ADSI-enabled.

**Solution**

To modify the directory profile for configuration and policy data, rerun the setup program. See “Rerunning Setup Manually” on page 7-28 for details.

**Database Validation Fails**

In the Identity System Console, when you attempt to save a new database instance for an RDBMS profile you may receive a "Database Validation failed" message.

**Problem**

This problem occurs when creating an RDBMS profile, as described in "Managing RDBMS Profiles" on page 7-35. Usually, the problem arises because of an incorrect value for the SQLDBType parameter in the following file:

`Component_install_dir/identity/apps/common/bin/globalparams.xml`

Where `component_install_dir` is the location where the Identity Server was installed.

**Solution**

Set the value for the SQLDBType parameter as follows:

■ For an ODBC connection type, set the value to `Oracle`.
■ For an OCI connection type, set the value to `Oracle_OCI`.
■ For SQL Server database, set the value to `SQLServer`.

**Simple Transport Security Mode Expires After One Year**

The default value for validity period for Simple transport security mode certificates is 365 days.
Problem
When you configure transport security among Oracle Access Manager components, you can choose between Open, Simple, and Cert modes. See "Changing Transport Security Modes" on page 8-1 for details.

By default, Simple mode is only operational for one year.

Solution
You can extend the life of the Simple mode certificate as follows:

1. Open the following file:
   
   \$component_install_dir/identity\access/oblix/tools/openssl/openssl_silent.cnf
   
   Where \$component_install_dir is the directory where the Access or Identity System component was installed.

2. In this file, look for the parameter named default_days.
   
   By default, the value for this parameter is 365 days, as follows:
   
   default_days = 730 # Duration to certify for

3. You can extend the life of the certificate by increasing the default days.
   
   For example, you increase the life of the certificate to two years as follows:
   
   default_days = 730 # Duration to certify for

4. To regenerate the simple mode certificates with the duration you set in the openssl_silent.cnf file, reconfigure and restart the component using one of the following tools:
   
   - Access Server: use configureAAAServer.exe.
     See the Oracle Access Manager Access System Administration Guide for details.
   - WebGate: Use configureWebGate.
     See the Oracle Access Manager Access System Administration Guide for details.
   - WebPass: Use setup_webpass.exe
     See "Changing Transport Security Modes" on page 8-1 for details.
   - Identity Server: setup_ois.exe
     See "Changing Transport Security Modes" on page 8-1 for details.

Style Sheet Validation Fails
When you create or customize a style sheet using Presentation XML, the style sheet has compilation errors.

Problem
This problem occurs when you do the following:

1. Open a stylesheet in a text editor or (preferably) an XML editor.
2. Change some parameters in the file and save the changes.
3. Open an Identity application, for example, the User Manager, to see the changes.

Expected result: Changes appear as expected.
Actual result: The Identity System issues a bug report.

Solution
This problem can occur for any variety of reasons, but chances are good that there are errors in the way the style sheet is coded.

Open the XSL file in an Internet Explorer window. If there is an error in the code, the browser will show the line number that contains the error. For more information on Presentation XML, see Oracle Access Manager Customization Guide.

"Cannot Find xenroll.cab" Error Is Issued When Using a Workflow

When running a workflow, a user may receive a 404 error that states "Cannot find xenroll.cab."

Problem
This problem occurs when a user runs a workflow in an Identity System application, for example:
1. Open the User Manager.
2. View a user profile.
3. Click a Modify button on the profile that invokes an Enroll Certificate Workflow.

In older versions of Oracle Access Manager, the file xenroll.cab was used for certificate enrollment workflows and certificate revocation workflows. However, Oracle has removed support for these workflows. This file is not used anymore.

Solution
You can safely remove the references to xenroll.cab from the stylesheet. The following is an example of this reference. See the Oracle Access Manager Customization Guide for details:

    <head>
        ... <object id="cenroll" classid="clsid:43F8F289-7A20-11D0-8F06-00C04FC295E1" codebase="/identity/oblix/apps/common/bin/xenroll.cab" />
        ... <script src="http://km.oraclecorp.com/identity/oblix/apps/common/bin/installCert.vbx" language="VBScript" />
    </head>

"Enable Failed" Error Is Issued When Using a Workflow

The workflow fails when a user runs it.

Problem
This problem occurs when a user runs a workflow in an Identity System application, for example:
1. Open the User Manager.
2. View a user profile.
3. Click a Modify button on the profile that invokes a Change Attribute Workflow.

Expected result: The workflow behaves as expected.
Actual result: The user receives an "Enabled failed" error.
Solution
There is no definitive solution to this problem, since workflow configuration can fail for a number of reasons. However, a likely candidate is selecting an invalid searchbase during workflow configuration. Delete the searchbase and re-configure the workflow. See "About the Searchbase" on page 4-21 for details.

JPEG Photo Images Are Not Updated
When attempting to modify a photo in an Identity application, JPEG photo images are not being updated.

Problem
This problem occurs when a user who has write permission to the Photo attribute does the following:
1. Open the User Manager.
2. View a user profile that contains a photo.
3. Select Panel View.
4. Try to upload a new photo.

Expected result: The photo is updated.
Actual result: The photo does not change.

Solution
Modify JPEG photo images in the page view.

Need More Help?

Access Manager SDK
  To configure the Access Manager SDK, 7-65
Active Directory
  To add a disjoint searchbase for the Disjoint domain (AD), A-3
  To configure group-search read operations on Windows 2003, A-3
  To configure SSO with the Identity or Access System (AD), A-7
  To configure the credential_mapping plug-in (AD), A-6
  To enable LDAP authentication for the Access Server, C-4
  To set up additional directory server profiles, A-2
  To set up additional directory server profiles (AD), A-2
  To set up the Access Server for Active Directory, C-3
  To set up the Policy Manager for Active Directory, C-2
  To specify Access Server failover after installation, C-4
administrators
  To assign or remove a substitute, 2-10
  To assume an identity, 2-11
  To delegate administration, 2-8
  To delete an administrator, 2-4
  To revert to your own identity, 2-11
  To specify Master Administrators and Master Identity Administrators, 2-4
ADSI
  To associate an ADSI agent with every domain, B-3
  To enable ADSI for additional directory profiles, B-9
  To enable LDAP authentication for the Access Server, B-12
audits, logs, and reports
  To add an SNMP Manager directly after general parameters, 12-14
To add an SNMP trap destination in silent mode, 12-13
To add or delete a log-handler definition, 10-17
To add or delete log-handler definitions, 10-17
To change the formatting of a report, 4-45
To configure a collection of SNMP statistics, 12-12
To configure a report, 4-43
To configure collection of SNMP statistics, 12-12
To configure file-based auditing for an Access Server, 11-17
To configure file-based auditing for an Identity Server, 11-15
To configure general parameters first, 12-14
To configure the SNMP Agent and trap destinations, 12-13
To connect Crystal Reports to the audit database, 11-43
To copy the audit schema to the audit database host, 11-21
To copy the Oracle Access Manager-specific Crystal resources, 11-42
To create a primary RDBMS instance, 11-30
To create an ODBC data source definition (Windows), 11-27
To create an ODBC data source definition to connect Crystal Reports to the Oracle/Crystal Repository, 11-43
To create an RDBMS profile, 11-30
To create and manage user access privilege reports, 11-40
To create the audit database (Oracle Database on Linux), 11-20
To create the audit database (Oracle Database on Windows), 11-20
To create the audit database (SQL Server or Windows), 11-20
To delete an SNMP Manager directly after adding one, 12-14
To delete an SNMP trap destination in silent mode, 12-13
To delete reports, 4-46
To edit orMap.ini, 11-43
To enable and configure auditing for each Access Server, 11-38
To enable and configure auditing for each Identity Server, 11-33
To install Crystal Reports, 11-42
To install the patch for Crystal Reports, 11-42
To localize reports, 4-46
To make the RDBMS profile visible (Linux), 11-32
To make the RDBMS profile visible (Windows), 11-32
To modify audit output formatting for the Access System, 11-39
To modify audit output formatting for the Identity System, 11-34
To modify the log threshold from the Identity System Console, 10-16
To set or modify auditing policies, 4-42
To specify global Identity System events and profile attributes for audit, 11-35
To specify User, Group, or Org. Manager events for audit, 11-36
To upload and verify the audit schema (Oracle Database on Windows or Linux), 11-25, 11-26
To upload the audit schema (SQL Server on Windows), 11-21, 11-24
To verify that all Identity Servers can record data to the audit database (Linux or Solaris), 11-38
To verify that all Identity Servers can record data to the audit database (Windows), 11-37
To verify the audit schema (SQL Server on Windows), 11-23
To view auditing policies, 4-42
To view or modify log-handler definitions, 10-15
To view or modify reports, 4-45

Identity applications
To add a derived attribute to an application tab, 3-29
To add a disjoint searchbase for a disjoint domain, 4-26
To add a tab, 4-5
To add an auxiliary or template object class to a tab, 4-8
To add group members, 4-39
To add, modify, or delete a Group Type panel, 4-18
To build a complex filter, 4-29
To change the formatting of a report, 4-45
To change the order in which panels are displayed, 4-16
To configure a report, 4-43
To configure photos for importing to a directory, 4-35
To configure the header panel, 4-12
To copy container limits from one domain to another, 4-52
To create or add a panel, 4-14
To create, view, and modify localized tab configuration, 4-5
To delete a container limit, 4-53
To delete a disjoint searchbase, 4-26
To delete a tab, 4-10
To delete group members, 4-39
To delete reports, 4-46
To expand a dynamic group, 4-47
To import photos to the directory, 4-35
To localize a panel, 4-16
To localize attribute display names, 4-20
To localize panel display names, 4-18
To localize reports, 4-46
To localize search results, 4-7
To modify a container limit, 4-52
To modify attributes specific to the User, Group, or Org. Manager, 4-20
To order the tabs in the Organization Manager, 4-11
To reference photos that reside in a file system, 4-36
To select what users see in My Groups and View Member Profiles, 4-10
To set or modify attribute permissions, 4-31
To set or modify auditing policies, 4-42
To set the globalparams.xml file, 4-48
To set the searchbase, 4-23
To specify what attribute can be used in a search, 4-6
To subscribe to a group, 4-41
To subscribe to multiple groups, 4-41
To use the Query Builder, 4-27
To view a group, 4-38
To view a panel in an end user Identity System application, 4-13
To view and add container limits, 4-50
To view auditing policies, 4-42
To view group members, 4-38
To view Group Type panels, 4-17
To view or modify a panel’s configuration, 4-15
To view or modify reports, 4-45
To view or modify tab configuration information, 4-3
To view the search result attributes, 4-6

Identity System
To change a style, 7-6
To change a style name, 7-6
To delete a custom style, 7-6
To deploy a style, 7-6
To set the default style, 7-7
To view currently configured styles, 7-2

.NET
To add attributes to a Group Profile panel, D-7
To configure ANR in Identity System panels, D-4
To configure the Access System to use Fast Bind, D-8
To create an IWA authentication scheme in the Access System, D-12
To enable IWA on the machine hosting the WebGate, D-11
To modify an AccessGate through the Access System Console, D-12
To specify additional auxiliary object classes in the User Manager, D-6
To test IWA, D-13
To update configuration data, D-3

To use ANR in a search, D-5

Objects
To add a derived attribute to an application tab, 3-29
To add an object class, 3-8
To change user or group structural object classes, 3-7
To configure a derived attribute, 3-28
To configure a GIF image display type, 3-26
To configure an attribute, 3-17
To create a filter, 3-22
To create a static filter, 3-24
To create a static search filter using a wildcard, 3-24
To create, view, or modify localized attribute display names, 3-21
To define a list, 3-20
To define a rule, 3-19
To delete an auxiliary object class, 3-9
To modify an object class type, 3-6
To select the class attribute, 3-7
To view an application-specific Modify Attribute page, 3-17
To view configured object classes, 3-5
To view the Modify Attribute page from the System Console, 3-16

Passwords
To configure lost password management for a password policy domain, 7-59
To configure the Lost Password Management attributes, 7-57
To create the default password policy, 7-49
To enable or disable Lost Password Management, 7-59
To enter a password change redirect URL, 7-62
To modify a password policy’s parameters, 7-53
To modify an authentication scheme to include a password policy, 7-60
To set up a default password expiry warning redirect URL, 7-63
To set up the account lockout URL, 7-64
To view a list of password policies, 7-48
To view lost password policies, 7-58

Servers
To add a style, 7-5
To add or modify a database instance for an LDAP directory server profile, 7-31
To add or modify a database instance for an RDBMS profile, 7-38
To add or modify an RDBMS profile, 7-36
To change a style, 7-6
To change a style name, 7-6
To configure a mail server, 7-12
To configure the length of a user’s Identity System session, 7-11
To create a directory server profile, 7-23
To customize directory server profile, 7-11
To delete a custom style, 7-6
Index-12

To delete a directory server instance for an LDAP directory server profile, 7-33
To delete an Identity Server’s parameters, 7-19
To deploy a style, 7-6
To manage a language, 7-14
To modify an LDAP Directory Server Profile, 7-28
To reconfigure the Access Server, 7-30
To rerun Identity System setup, 7-29
To rerun Policy Manager setup, 7-29
To set the default style, 7-7
To view an LDAP directory server profile, 7-27
To view currently configured styles, 7-2
To view Identity System details, 7-13
To view or modify an Identity Server’s parameters, 7-18
To view or modify server settings, 7-10

transport security
To change the certificate password for the Access System, 8-22
To change the certificate password for the Identity System, 8-21
To change the Identity Server transport security mode, 8-5
To change the transport security mode password, 8-24
To change to Cert security mode, 8-15
To change to Open security mode, 8-12
To change to Simple security mode, 8-13
To change transport security between Access Server and the directory server, 8-20
To change transport security between the Identity Server and directory server, 8-20
To change transport security to SSL between Policy Manager and the directory server, 8-20
To install the signed certificate for Cert mode, 8-18

WebPass
To add a WebPass, 7-40
To change the transport security mode password, 7-44
To disassociate an Identity Server from a WebPass, 7-45
To modify a WebPass, 7-41
To modify a WebPass through the command line, 7-42
To reconfigure transport security mode through the command line, 7-43
To remove a WebPass, 7-42
To view a configured WebPass, 7-39

workflows
To access the Workflow Definition applet, 5-19
To add roles to a workflow definition, 5-60
To allow a user to perform an asynchronous operation, 5-45
To archive a workflow, 5-50
To associate a subflow with a workflow, 5-31
To associate an Out of Office attribute with a semantic type, 5-40
To begin a new workflow definition, 5-20
To configure a role, 5-60
To configure email notification for workflow steps, 5-33
To configure language-specific workflow panel information, 5-57
To configure workflow attribute properties, 5-26
To copy a workflow as a starting point for a new workflow, 5-52
To copy a workflow as an alternative to modifying it, 5-53
To create a self-registration workflow, 5-61
To create a subflow, 5-30
To create (example) workflow, 5-30
To define a self-registration workflow using the QuickStart tool, 5-18
To define a workflow target, 5-22
To define a workflow using the QuickStart tool, 5-16
To define subsequent steps in a workflow, 5-27
To define the first step in a workflow, 5-23
To delete a workflow, 5-54
To delete requests, 5-50
To enable a workflow, 5-29
To enable time-based escalation, 5-42
To export workflows, 5-54
To find a workflow ticket, 5-47
To invoke a change attribute workflow, 5-46
To lock or unlock a ticket, 5-51
To make use of the Out of Office flag, 5-41
To modify a workflow, 5-53
To modify a workflow panel, 5-55
To modify oblixpppcatalog.lst, 5-37
To modify the workflow parameter files, 5-44
To monitor a workflow, 5-49
To preload the User, Group, and Organization Managers, 5-45
To prepare a workflow step for dynamic participants, 5-36
To process a workflow ticket, 5-47
To reactivate a deactivated user, 5-48
To run a workflow in Group Manager, 5-29
To select attributes available for a workflow step, 5-25
To specify a surrogate, 5-40
To test a workflow, 5-29
To view and export a workflow summary, 5-51
To view current workflow panel settings, 5-54
To view language-specific workflow panel information, 5-56
