## 1 Ensuring Interoperable Web Services

**Why is Interoperability Necessary?**............................................................................. 1-1
**Web Service Interoperability Organizations** .......................................................... 1-2
**General Guidelines for Creating Interoperable Web Services**................................. 1-3
**Common Tips for Diagnosing and Solving Interoperability Issues** ....................... 1-4
  - Invalid or Improperly Formatted WSDL...................................................................... 1-6
  - WSDLs Containing Proprietary Data Binding Extensions........................................... 1-7
  - Illegal XML Characters .......................................................................................... 1-9
  - Out of Sync SOAPAction Values ............................................................................ 1-10
    - Understanding the soapAction WSDL Attribute.................................................... 1-11
      - Controlling the Value of soapAction in OracleAS Web Services ...................... 1-12
      - Controlling the Value of soapAction on the .NET Platform ................................ 1-12
  - Null Values in SOAP Messages ............................................................................. 1-13
  - Unsigned Schema Numeric Types .......................................................................... 1-15
  - Loss of Precision.................................................................................................... 1-17
**Tool Support for Interoperability**.............................................................................. 1-18
  - Capturing the Web Service Contract................................................................. 1-18
  - Replaying the Message Payload ............................................................................ 1-19
  - Analyzing the Interaction ..................................................................................... 1-20
  - Obtaining WS-I Tools ............................................................................................ 1-21
**Limitations**................................................................................................................. 1-21
**Additional Information**............................................................................................ 1-21

## 2 Working with Message Attachments

**Working with MIME Attachments**............................................................................ 2-1
  - How OracleAS Web Services Supports MIME Attachments ................................ 2-1
  - How to Assemble a Web Service Using swaRef MIME Attachments...................... 2-2
    - Steps for Assembling a Web Service Top Down.................................................. 2-3
      - Requirements for WSDLs with swaRef Attachments ...................................... 2-4
How to Implement a Service Endpoint Interface with Attachments ......................... 2-6
How to Create a New Instance of AttachmentPart ................................................... 2-7
Steps for Assembling a Web Service Bottom Up ...................................................... 2-7
How to Write a Service Endpoint Interface that Handles Attachments ................... 2-8
How to Assemble a WSDL File with swaRef Attachment References ...................... 2-8
How to Assemble a Web Service Using SWA MIME Attachments ............................. 2-9
Understanding SWA MIME Attachments ................................................................. 2-9
Steps for Assembling a Web Service with SWA Attachments Top Down ................. 2-10
Sample WSDL with SWA MIME References ......................................................... 2-10
Sample Generated Interface with Parameters that Can Pass SWA Attachments .... 2-12
How to Add MIME Attachments to SOAP Fault Messages ...................................... 2-12
Understanding SOAP Fault Messages with Attachments ....................................... 2-12
Steps for Assembling SOAP Faults with Attachments into a Web Service Top Down 2-13
How to Specify SOAP Faults with Attachments in the WSDL ................................. 2-14
How to Implement a Method that Throws Faults with Attachments ....................... 2-15
How to Retrieve SOAP Faults with Attachments on the Client ............................... 2-16

Working with Streaming Attachments ...................................................................... 2-16
Understanding Streaming Attachments ..................................................................... 2-17
Limitations on Streaming Attachments ..................................................................... 2-17
Understanding the Streaming Attachments API ...................................................... 2-18
Interface for Attachment Objects ............................................................................ 2-18
Factory Class for Attachment Objects ..................................................................... 2-19
Interface for Attachments ....................................................................................... 2-19
Interface for Incoming Attachments ....................................................................... 2-19
Interface for Outgoing Attachments ....................................................................... 2-19
WSDL Extensions for Streaming Attachments ....................................................... 2-19
How to Assemble Streaming Attachments into a Web Service ............................... 2-20
Steps for Assembling a Web Service that Supports Streaming Attachments Bottom Up 2-20
How to Write an Interface for Streaming Attachments .......................................... 2-21
How to Implement a Service Interface that Uses Streaming Attachments ............. 2-21
Sample Generated WSDL for a Service with Streaming Attachments .................. 2-21
How to Write Stub Code to Handle Streaming Attachments ................................ 2-22
Steps for Assembling a Web Service that Supports Streaming Attachments Top Down 2-23

Working with MTOM Encoded Attachments ............................................................ 2-23
Understanding MTOM Encoded Attachments ......................................................... 2-23
How to Assemble Support for MTOM Encoded Attachments into a Web Service ...... 2-24
Assembling Support for MTOM Encoded Attachments into a Web Service Bottom Up 2-25
Assembling Support for MTOM Encoded Attachments into a Web Service Top Down .... 2-27
Sample WSDL that Works with Binary Data ............................................................ 2-27
Assembling Support for MTOM Encoded Attachments into a Web Service Client .... 2-28
Programatically Overriding MTOM Support for a Web Service Client .................. 2-28
How to Work with MTOM Encoded Attachments Programatically .......................... 2-29
Understanding the OraSAAJ API for MTOM Encoded Attachments ....................... 2-29
MTOM_SUPPORT Property ..................................................................................... 2-29
3 Managing Web Services

Understand Web Service Management .......................................................... 3-1
Web Service Management Environment ...................................................... 3-2
Web Service Management Life Cycle .......................................................... 3-4

How to Pass Management Information to the Server ................................... 3-4

Working with Management Information in a J2SE Client ........................... 3-6
Understanding Data Flow for Management Information in a J2SE Client ...... 3-6
How to Pass Management Information to a J2SE Client ............................... 3-7

Working with Management Information in a J2EE Client ........................... 3-8
Understanding Data Flow for Management Information in a J2EE Client ...... 3-8
How to Pass Management Information to a J2EE Client ............................... 3-9

How to Pass a Management Configuration to a Client Programmatically ....... 3-10
How to Pass a Management Configuration to a DII Web Service Client Programatically ...... 3-11
How to Pass a Management Configuration to a Dynamic Proxy Web Service Client Programatically 3-12
How to Pass a Management Configuration to a Static Proxy Web Service Client Programatically 3-12
How to Pass a Management Configuration to a J2EE Web Service Client Programatically ...... 3-13

How to Pass a Static Management Configuration to a Client .......................... 3-14
How to Pass a Static Management Configuration to a Servlet or JSP Web Service Client ...... 3-15
How to Pass a Static Management Configuration to an EJB Web Service Client ........................................ 3-16
How to Pass a Static Management Configuration to an Application Client Web Service Client ...... 3-17

Working with Capability Assertions ............................................................... 3-18
### 4 Ensuring Web Services Security

Additional Information........................................................................................................................... 4-3

### 5 Ensuring Web Service Reliability

**Prerequisites for the Database Store** ........................................................................................................ 5-2
- Provide a Running Database .................................................................................................................. 5-2
- Install SQL Tables for the Client and Server .......................................................................................... 5-2
- How to Change the Widths of Database Columns .................................................................................. 5-3

**How to Add Reliable Messaging to a Web Service** .................................................................................. 5-3
- Steps to Assemble Reliability into a Web Service Bottom Up ................................................................. 5-4
- Steps to Assemble Reliability into a Web Service Top Down ................................................................. 5-5
- How to Assemble Capability Assertions into a Web Service Top Down .................................................. 5-6
- Steps to Assemble Reliability into a J2SE Web Service Client Proxy ...................................................... 5-6
- Steps to Assemble Reliability into a J2EE Web Service Client ................................................................. 5-8

**How to Configure Reliability on the Server** ........................................................................................... 5-8
- Server-Side Reliability Configuration Elements ..................................................................................... 5-9
- Port-Level Reliability Elements on the Server ....................................................................................... 5-9
- Operation Level Reliability Elements on the Server .............................................................................. 5-11
- Capability Assertions for Reliability ........................................................................................................ 5-12
- How to Add Capability Assertions for Reliability to a Web Service ....................................................... 5-12

**How to Configure Reliability on the Client** .......................................................................................... 5-12
- Client-Side Reliability Configuration Elements ...................................................................................... 5-13
- Port Level Reliability Elements on the Client ......................................................................................... 5-13
- Operation Level Reliability Elements on the Client ................................................................................ 5-15
- How to Configure Client-Side Database Support .................................................................................... 5-16
- How to Configure the Database to Store Messages from a J2SE Client ................................................ 5-17
- How to Configure the Database to Store Messages from a J2EE Client .................................................. 5-17
- How to Configure a Listener for a J2EE Client ....................................................................................... 5-18
- How to Configure Client-Side Reliability Programmatically ................................................................. 5-18
- Adding Reliable Messaging Support to Static Stub and DII Client Code .............................................. 5-19
- Implementing Message Ordering in Client Code .................................................................................... 5-20

**Tool Support for Web Services Reliability** ............................................................................................. 5-21
- Application Server Control Support for Web Service Reliability ............................................................ 5-21
- Oracle JDeveloper Support for Web Service Reliability ......................................................................... 5-21

**Limitations** .............................................................................................................................................. 5-22

**Additional Information** ........................................................................................................................... 5-22
6  Auditing and Tracing Messages

Understanding Auditing ................................................................. 6-1
   How Auditing Affects Performance ............................................. 6-1
   How the Runtime Handles Auditing ........................................... 6-2
      How the Runtime Audits Request Messages ......................... 6-3
      How the Runtime Audits Response Messages ....................... 6-3
      How the Runtime Audits Fault Messages .............................. 6-3
How to Configure Auditing on the Server ...................................... 6-3
   Server-Side Auditing Configuration Elements ......................... 6-4
How to Configure Auditing in a J2EE Client ................................... 6-4

Understanding Tracing ................................................................. 6-5
   How Tracing Affects Performance ............................................ 6-6
   How the Runtime Handles Tracing .......................................... 6-6
      How the Runtime Logs Request Messages ......................... 6-7
      How the Runtime Logs Response Messages ....................... 6-7
      How the Runtime Logs Fault Messages .............................. 6-7
How to Configure Tracing on the Server ....................................... 6-7
   Server-Side Tracing Configuration Elements .......................... 6-8
      Port-Level Tracing Elements on the Server ......................... 6-8
      Operation Level Tracing Elements on the Server ................. 6-8

Tool Support for Web Services Auditing and Tracing ....................... 6-9
   How to Use WebServicesAssembler to Add an Auditing and Tracing Configuration ... 6-10
      Steps to Assemble Auditing and Tracing into a Web Service Bottom Up ... 6-10
      Steps to Assemble Auditing and Tracing into a Web Service Top Down ... 6-12
      Steps to Assemble Auditing into a J2SE Web Service Client Proxy ... 6-13
      Steps to Assemble Auditing into a J2EE Web Service Client .......... 6-13
   How Application Server Control Supports Auditing and Tracing .......... 6-15
   How Oracle JDeveloper Supports Auditing and Tracing ................ 6-15

Understanding Diagnostic Loggers .............................................. 6-16
   Controlling the Output of Web Services Loggers ....................... 6-16
      Log Handlers ........................................................................ 6-16
      Loggers ............................................................................. 6-18
   Adding Configuration for Diagnostic Loggers .......................... 6-19
      Setting Levels of Diagnostic Logging in Application Server Control ... 6-20

Limitations ................................................................................. 6-20

Additional Information .............................................................. 6-20

7  Implementing Custom Serialization of Java Value Types

Understanding the Custom Serialization Framework API .................. 7-2

How to Use Custom Serialization in Web Service Development ........ 7-2
   How to Implement a Custom Serializer ..................................... 7-3
      How to Define a Custom Java Type Value Class .................. 7-3
      How to Define a Custom Serializer Implementation for a Java Type Value Class ... 7-4
      How to Define a Service Endpoint Interface that Uses a Java Type Value Class .... 7-5
      How to Create an oracle-webservices Type Mapping Configuration .......... 7-7
   How to Use Custom Types in Client Proxy Code ......................... 7-7
10 Using Web Service Providers

What is a Provider................................................................. 10-1
Understanding the Provider API......................................... 10-1
   Provider Interface.......................................................... 10-2
      init Method................................................................. 10-2
      processMessage Method............................................ 10-2
      destroy Method........................................................ 10-3
   ProviderConfig Class.................................................... 10-3
      addService and removeService Methods...................... 10-3
      PROPAGATE_DYNAMIC_ENDPOINTS Property............... 10-5
   MessageContext Class.................................................. 10-5
   HTTPConstants Class.................................................... 10-5

F  JAX-RPC Mapping File Descriptor

How to Produce a JAX-RPC Mapping File ...................................... F-1

Understanding Naming Conventions for the JAX-RPC Mapping File F-2

How to Customize the WSDL or Service Endpoint Interface Contents F-2

Scenarios for Editing the JAX-RPC mapping File ............................. F-2

How to Change Namespace-to-Java Mappings ............................... F-3

How to Change the Names of Java or WSDL Artifacts .................. F-3

How to Change a Java Class Associated with an XML Type .......... F-3

How to Generate Code into a Single Package from a WSDL with Multiple Namespaces ..... F-4

How to Wrap or Unwrap Mapping for Document-Literal Operations F-5

How to Map Between SOAP Headers and Java Method Parameters F-5
This book describes topics beyond basic Web service assembly. For example, it describes how to diagnose common interoperability problems, how to enable Web service management features (such as reliability, auditing, and logging), and how to use custom serialization of Java value types.

This book also describes how to employ the Web Service Invocation Framework (WSIF), the Web Service Provider API, message attachments, and management features (reliability, logging, and auditing). It also describes alternative Web service strategies, such as using JMS as a transport mechanism.

This preface contains these topics:

- Intended Audience
- Documentation Accessibility
- Related Documents
- Conventions

**Intended Audience**

Oracle Application Server Advanced Web Services Developer’s Guide is intended for application programmers and system administrators who perform the following tasks:

- Configure software installed on the Oracle Application Server.
- Create programs that implement Web services.
- Create programs that run as Web services Clients.

**Documentation Accessibility**

Our goal is to make Oracle products, services, and supporting documentation accessible, with good usability, to the disabled community. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at:

http://www.oracle.com/accessibility/
Accessibility of Code Examples in Documentation
Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

Accessibility of Links to External Web Sites in Documentation
This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

TTY Access to Oracle Support Services
Oracle provides dedicated Text Telephone (TTY) access to Oracle Support Services within the United States of America 24 hours a day, seven days a week. For TTY support, call 800.446.2398.

Related Documents
For more information, see these Oracle resources:

■ Oracle Application Server Web Services Developer’s Guide
   This book describes how to use the WebServicesAssembler tool to assemble Web services from a variety of resources: Java classes, EJBs, database resources, JMS destinations and J2SE 5.0 Annotations. You can also assemble REST-style Web services. The Developers Guide also describes how to assemble J2SE and J2EE clients to access these services. This book includes descriptions of the message formats and datatypes supported by OracleAS Web Services.

■ Oracle Application Server Web Services Java API Reference
   The Reference provides the output of the Javadoc tool for the OracleAS Web Services Java API.

■ Oracle Application Server Web Services Security Guide
   This book describes the different security strategies that can be applied to a Web service in Oracle Application Server Web Services. These strategies include username token, X.509 token, SAML token, XML encryption, and XML signature. The book describes the configuration options available for the client and the service, for inbound messages and outbound messages. It also describes how to configure these options for a number of different scenarios.

■ Oracle Containers for J2EE Security Guide
   This book describes security features and implementations particular to OC4J. This includes information about using JAAS, the Java Authentication and Authorization Service, as well as other Java security technologies.

■ Oracle Containers for J2EE Services Guide
   This book provides information about standards-based Java services supplied with OC4J, such as JTA, JNDI, JMS, JAAS, and the Oracle Application Server Java Object Cache.

■ Oracle Containers for J2EE Configuration and Administration Guide
   This book describes how to configure and administer applications for OC4J, including use of the Oracle Enterprise Manager 10g Application Server Control
Console, use of standards-compliant MBeans provided with OC4J, and, where appropriate, direct use of OC4J-specific XML configuration files.

- **Oracle Containers for J2EE Deployment Guide**
  This book covers information and procedures for deploying an application to an OC4J environment. This includes discussion of the deployment plan editor that comes with Oracle Enterprise Manager 10g.

- **Oracle Containers for J2EE Developer’s Guide**
  This book discusses items of general interest to developers writing an application to run on OC4J—issues that are not specific to a particular container such as the servlet, EJB, or JSP container. (An example is class loading.)

**Contents of the Oracle Application Server Web Services Developer’s Guide**

This book is designed to be used with the Oracle Application Server Web Services Developer’s Guide. The "Developer’s Guide" describes how to use the WebServicesAssembler tool to assemble Web services from a variety of resources: Java classes, EJBs, database resources, JMS destinations and J2SE 5.0 Annotations.

For your convenience, the contents of the Oracle Application Server Web Services Developer’s Guide are listed here.

- Chapter 1, "Web Services Overview"
- Chapter 2, "Development and Documentation Roadmap"
- Chapter 3, "Oracle Application Server Web Services Architecture and Life Cycle"
- Chapter 4, "Getting Started"
- Chapter 5, "Oracle Application Server Web Services Messages"
- Chapter 6, "Assembling a Web Service from a WSDL"
Chapter 7, "Assembling a Web Service with Java Classes"
Chapter 8, "Assembling a Web Service with EJBs"
Chapter 9, "Assembling Web Services with JMS Destinations"
Chapter 10, "Assembling Database Web Services"
Chapter 11, "Assembling Web Services with Annotations"
Chapter 12, "Assembling REST Web Services"
Chapter 13, "Testing Web Service Deployment"
Chapter 14, "Assembling a J2EE Web Service Client"
Chapter 15, "Assembling a J2SE Web Service Client"
Chapter 16, "Understanding JAX-RPC Handlers"
Chapter 17, "Processing SOAP Headers"
Chapter 18, "Using WebServicesAssembler"
Chapter 19, "Packaging and Deploying Web Services"
Appendix A, "Web Service Client APIs and JARs"
Appendix B, "Oracle Implementation of the WSDL 1.1 API"
Appendix C, "oracle-webservices.xml Deployment Descriptor Schema"
Appendix D, "service-ref-mapping Schema"
Appendix E, "Error Message Prefixes"
Appendix F, "Troubleshooting"
Appendix G, "Third Party Licenses"

<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td>monospace</td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
Ensuring Interoperable Web Services

This chapter contains the following sections.

■ Why is Interoperability Necessary?
■ Web Service Interoperability Organizations
■ General Guidelines for Creating Interoperable Web Services
■ Common Tips for Diagnosing and Solving Interoperability Issues
■ Tool Support for Interoperability

Why is Interoperability Necessary?

The goal of the Web service architecture is to allow heterogeneous business applications to smoothly work together. The architecture is loosely coupled and based on XML standards. Web services are designed to work with each other by defining Web Service Description Language (WSDL) files as service contracts, regardless of which operating system and development technology are behind them. However, because of the complexity involved in service contracts, standards like WSDL and SOAP leave room for ambiguous interpretations. In addition, vendor-specific enhancements and extensions work against universal interoperability.

Business applications must invoke each other’s services. These services are often implemented with different technologies. Interoperability failures tend to increase as Web service complexity increases. If you host a publicly available Web service, you will want to ensure that your clients from all over the world, using vastly different tool kits, can successfully invoke it. Likewise, your business application might need to integrate or interact with another vendor’s Web service that was built on top of an existing legacy system and has an unusual interface design.

Interoperability issues can originate from any layer of the protocol stack. On the transport level, both parties involved in exchanging messages must agree on a specific physical transport mechanism. For example, you cannot expect to use JMS transport from a non-Java platform. This is why using basic HTTP protocol increases your chance of interoperability. On the message level, because SOAP allows virtually any type of data encoding to be used, interoperability can become difficult. For example, a standard ArrayList on a Java platform will not be automatically translated into a System.Collections.ArrayList on the .NET platform. Also, interoperability issues arise at the basic WSDL and SOAP level: advanced Web service developers will find many more new challenges when they start implementing quality of service (QOS) features such as security, reliability, and transaction services.
Difficulties in interoperability do exist. However, with a few good guidelines, your Oracle Web service should work seamlessly with other J2EE vendor platforms or non-Java platforms like the Microsoft .NET platform.

**Web Service Interoperability Organizations**

As interoperability gains more and more importance in the Web service community, a number of organizations have been established to achieve this goal.

- **SOAPBuilders Community**
- **WS-Interoperability**

**SOAPBuilders Community**

SOAPBuilders is a loosely organized forum of developers working toward a test bed for interoperability testing between SOAP implementations. Interoperability is demonstrated by implementing a canonical set of tests that are collectively defined by the participants in the forum.

The tests developed by the SOAPBuilder community are, by and large, based on vendor practices. However, practices shift over time. Clean and well-defined rules organized in a formal manner are needed for Web service vendors, Web service developers, and Web service consumers.

**See Also:**

http://www.whitemesa.net/ for more information on SOAPBuilder tests.

**WS-Interoperability**

The Web Services Interoperability organization (WS-I) is an open industry organization that creates, promotes, and supports generic protocols for the interoperable exchange of messages between Web services. WS-I profiles are guidelines and recommendations for how the standards should be used. These profiles aim to remove ambiguities by adding constraints to the underlying specifications.

WS-I deliverables are profiles, common or best practices, scenarios, testing software, and testing materials.

You should design your Web service so that it adheres to WS-I basic profiles. WS-I compliant services agree to clear contracts and have a greater chance of interoperability.

For example, a WS-I basic profile-compliant Web service should use the following features.

- Use HTTP or HTTPS as the transport binding. HTTP 1.1 is preferred over HTTP 1.0.
- Use literal style encoding. Do not use SOAP encoding.
- Use stricter fault message syntax. When a MESSAGE contains a soap:Fault element, its element children must be unqualified.
- Use XML version 1.0.
- The service should not declare array wrapper elements using the convention ArrayOfXXX.
Oracle is a member of the WS-I organization and is fully committed to helping our customers achieve interoperability. The Oracle Application Server Web Services platform allows a high degree of flexibility to help you create interoperable Web services.

- The WebServicesAssembler tool and Oracle JDeveloper 10g generate WS-I compliant services when you create a bottom up, document-literal Web service. When receiving SOAP messages, the Oracle implementation is accommodating instead of strict so that your message exchanges with other SOAP stacks are more likely to succeed.
- Oracle JDeveloper 10g supports integrated testing of WSDL files and running Web services for WS-I Basic Profile conformance. It delivers an enhanced HTTP Analyzer for monitoring and logging, and provides a built-in analysis and reporting tool to better diagnose interoperability issues.

General Guidelines for Creating Interoperable Web Services

The first general guideline is to create Web services which are WS-I compliant, if possible.

The WS-I profiles, however, do not solve all interoperability problems. Many Web services were implemented before WS-I profiles existed. Also, the legacy systems that you are enabling as a Web service might have placed restrictions on your designs.

Thus, good practice in designing Web services should always be adopted from the beginning of the development process, whenever possible. The following sections describe these guidelines.

- Design your Web service top down
- Design data types using XSD first
- Keep data types simple
- Be careful with null values
- Use a compliance testing tool to validate the WSDL
- Understand the differences between platform native types
- Avoid using RPC-encoded message format

Design your Web service top down
The top down from WSDL approach enables you to design your Web service from service contracts that are not tied to any platform or language-specific characteristics. Your WSDL is less likely to be affected by existing legacy APIs.

Design data types using XSD first
If possible, use an XSD schema editor to design your data types with schema types. Resist using platform-specific data types such as the .NET DataSet data type, Java collections, and so on.

See Also:
http://www.ws-i.org/ for more information about WS-I profiles, and the rules defined within profiles.
Keep data types simple
Avoid unnecessarily complex schema data types such as xsd:choice. Simple types provide the best interoperability and have the added benefit of improved performance.

Be careful with null values
Decide what you want to do with null values. For example, should an array be allowed to be null? Should you use a null string or an empty string? If you are sending a null value across the platform, will it cause exceptions on the receiver side?

Avoid sending null values if possible. If you must use null values in your application, design your schema types to clearly indicate that a null value is allowed.

Use a compliance testing tool to validate the WSDL
If your Web service is designed to be WS-I compliant, use the WS-I monitor tool to log messages and the analyzer tool to validate for conformance.

See Also:
http://www.ws-i.org/deliverables/workinggroup.aspx?w
g=testingtools/ for free downloads of WS-I tools.

Understand the differences between platform native types
Some schema types, such as xsd:unsignedshort and xsd:unsignedint, do not always have a direct native type mapping. For example, there are no Java platform equivalent unsigned types. Schema numeric types such as xsd:double, xsd:float, and xsd:decimal might have different precisions once mapped to their platform native types. There are also limitations on the xsd:string type. The strings must not contain illegal XML characters and the \r (carriage return) character will typically be mapped to the \n (line feed) character.

Avoid using RPC-encoded message format
By itself, the RPC-encoded message format does not imply that you will not be able to interoperate with other platform and clients. In many cases, there are RPC-encoded Web services which are working today. The reason to move away from RPC-encoded message formats is to avoid some of the corner cases where different interpretations of the underlying specification and implementation choices break interoperability. Some examples of these corner cases include the treatment of sparse arrays, multi-dimensional arrays, custom fault code QNames, un-typed payloads, and so on.

Common Tips for Diagnosing and Solving Interoperability Issues
Many interoperability problems can be recognized and solved by understanding the relationship between the WSDL, the wire format, and the validity of the data representation. Once you can identify where the issue is, correcting it can be straightforward.

Figure 1–1 illustrates the interaction between the elements in a client stack and a service stack. The WSDL is used to generate the client artifacts. The client application, which could be implemented for either the JAX-RPC or .NET platform, forms an XML SOAP request message. The application serializes the request and passes it to the service over HTTP. The service, which could be implemented for either the JAX-RPC or .NET platform, deserializes the request and processes it.
After processing the client request, the service application forms the XML SOAP response message, serializes it, and passes it to the client over HTTP. The client application deserializes the response and processes the result.

**Figure 1–1 Points of Possible Interoperability Failures**

The numbers and letters in the illustration identify the points, from the client’s perspective, where interoperability failures can occur. On the server side, the failure points are similar. The following list describes these problem categories.

1. The utility which generates the client artifacts fails to consume the WSDL (the contract). The WSDL is either invalid, not compliant with a WS-I Profile, or not supported by the client platform. For example, .NET 1.1 does not support RPC-literal style of Web service.

   "Invalid or Improperly Formatted WSDL” on page 1-6 provides more information on this type of failure.

2. The utility which generates the client artifacts consumes the WSDL successfully, but the artifacts it generates cannot be used or are not very useful. For example, the WSDL might contain proprietary schema extensions that the tool cannot process.

   "WSDLs Containing Proprietary Data Binding Extensions” on page 1-7 provides more information on this type of failure.

3. At runtime, an exception is thrown to the client application before any payload is actually processed. Usually, the error will be converted into a SOAP fault with a fault code set as Client in SOAP 1.1 or Sender in SOAP 1.2. The reason could be that the service endpoint is unavailable or authentication negotiation is not successful.

   "Illegal XML Characters” on page 1-9 provides an example of this type of failure.

4. A SOAP fault is thrown from the server side due to one of the following reasons.
   a. The request is not routed to the correct operation. The SOAP fault code would be set as Client in SOAP 1.1 or Sender in SOAP 1.2.
"Out of Sync SOAPAction Values" on page 1-10 provides an example of this type of failure.

b. The request is not deserialized successfully. The SOAP fault code would be set as Client in SOAP 1.1 or Sender in SOAP 1.2.

"Null Values in SOAP Messages" on page 1-13 and "Unsigned Schema Numeric Types" on page 1-15 provides more information on this type of failure.

c. The request is not processed by the application code. The internal exception which is thrown could be an unhandled exception or an application-specific SOAP fault at the business logic level. The SOAP fault code will be set as Server or Receiver unless the server application considers the error to be related to the validation of input parameters.

d. The response is not serialized. The SOAP fault code will be set as Server or Receiver.

5. At runtime, an exception is thrown by the client when it tries to deserialize the response to convert the content of the SOAP envelope back into Java instances.

"Loss of Precision" on page 1-17 provides an example of this type of failure.

The following sections provide more information and examples of the failures that can occur at each of these points.

Invalid or Improperly Formatted WSDL

Interoperability failures can be caused by errors that arise in processing the WSDL. This is indicated in Point 1 in Figure 1–1. Different tool kits are not consistent in how they process WSDLs. For example, an improperly formatted WSDL might be graciously accepted by one tool kit but rejected by another.

Example

The following code samples illustrate how an improperly formatted WSDL can cause an interoperability failure.

Example 1–1 illustrates a fragment from an improperly formatted WSDL. The fragment contains an improperly named input parameter, getQuote. Notice that the portType operation has defined an input parameter named getQuote, but the corresponding binding operation does not provide input or output names. If you use the default naming pattern (<operationName>Request and <operationName>Response) to create the missing binding operation input and output names, then the WSDL will not be valid because the getQuote operation will have inconsistent input parameters.

Example 1–1 WSDL Fragment with an Improperly Named Input Parameter

```xml
<portType name="qotdPortType">
  <operation name="getQuote">
    <input name="getQuote" message="tns:getQuoteRequest"/>
    <output name="getQuoteResponse" message="tns:getQuoteResponse"/>
  </operation>
</portType>

<binding name="qotdBinding" type="tns:qotdPortType">
  <soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="getQuote">
    <soap:operation soapAction="urn:xmethods-qotd#getQuote"/>
  </operation>
</binding>
```
If you attempt to generate client proxy classes from this WSDL, problems will arise regardless of whether you are on the .NET or the OracleAS Web Services platforms. If you attempt to generate client proxy C# classes on the .NET platform, you will get errors rejecting the WSDL as not having a matching binding. On the Oracle Application Server Web Services platform, Java client proxy classes will be generated, however, you will get warnings about the improper input and output names used in the WSDL.

Unfortunately, the WSDL specification does not clearly specify that the default naming pattern for the portType operation should be used for the binding operation when input and output names are missing. It is not clear whether the WSDL should be rejected. The OracleAS Web Services tool kit will graciously accept this WSDL and output warnings.

The potential interoperability problem illustrated in this example can be corrected by specifying the name attribute for the input in the binding operation and in the portType.

WSDLs Containing Proprietary Data Binding Extensions

Point 2 in Figure 1–1 represents a failure point where the tool kit is unable to generate useful artifacts from the given WSDL. This problem can arise if the WSDL contains proprietary data binding extensions.

Example

The following code samples illustrate how working with a WSDL that contains proprietary data binding extensions can cause interoperability failures.

**Note:** The following code samples use the ADO.NET System.Data DataSet data type as an example of a proprietary data binding that can cause interoperability failures. However, because XML is extensible by nature, you will likely face this issue when dealing with other proprietary data bindings as well.

Assume that you are developing a Web service for the .NET platform and you have the following C# method that returns a System.Data DataSet data type.

```csharp
```

Example 1–2 illustrates an XML schema fragment that represents the response output element when the method is exposed as a .NET Web service.

```xml
<s:element name="ListBooksResponse">
```
Suppose you want to use the WebServicesAssembler tool to generate client proxy code based on this WSDL. WebServicesAssembler will consume the WSDL successfully and will generate a set of proxy classes including the client code that contains the following Java method.

```java
public javax.xml.soap.SOAPElement listBooks(ListBooks parameters) throws java.rmi.RemoteException
```

The response is returned as a SOAPElement because OracleAS Web Services cannot infer any more detailed information from the schema definition. Unfortunately, the schema in the .NET WSDL in Example 1–2 does not fully describe the payload you will receive on the wire representing the .NET DataSet data type. The schema describes only that the SOAP message contains two parts: the first part is the schema definition for the payload and the payload follows next.

Example 1–3 illustrates the SOAP message that the client receives. Notice that the first child of the `xs:schema` element (`<xs:element name="NewDataSet"...>` describes the payload of the message. The second child, (`<diffgr:diffgram ...>` contains the payload.

**Example 1–3  SOAP Message Generated from a .NET DataSet Data Type**

```xml
<soap:Body>
<ListBooksResponse xmlns="http://francisshanahan.com"/>
<ListBooksResult>
  <xs:schema id="NewDataSet" xmlns="http://www.w3.org/2001/XMLSchema"
            xmlns:xs="http://www.w3.org/2001/XMLSchema"
            xmlns:msdata="urn:schemas-microsoft-com:xml-msdata">
    <xs:element name="NewDataSet" msdata:IsDataSet="true">
      <xs:complexType>
        <xs:choice maxOccurs="unbounded">
          <xs:element name="bible_content">
            <xs:complexType>
              <xs:sequence>
                <xs:element name="Book" type="xs:string"
                minOccurs="0"/>
                <xs:element name="BookTitle" type="xs:string"
                minOccurs="0"/>
              </xs:sequence>
            </xs:complexType>
          </xs:element>
        </xs:choice>
      </xs:complexType>
    </xs:element>
  </xs:schema>
<diffgr:diffgram xmlns:msdata="urn:schemas-microsoft-com:xml-msdata"
```
Since the WebServicesAssembler tool is unable to provide you with Java type classes that capture the payload schema, how would you write a Java client to process the dataset records appropriately?

The solution is a two step process.

1. Obtain the schema. The code must parse the incoming SOAPElement, extract the schema child element and save the schema definition.

2. Process the actual payload based on the schema you have.

You can use tools such as JAXB and Oracle TopLink to process the payload. JAXB provides a Java API and command line tools to help you generate Java type-safe classes directly from the schema.

Oracle TopLink is an advanced object to relational persistence framework that includes support for JAXB. With TopLink, however, you also get a visual mapping editor and many other advanced features.

Once you have generated Java types based on the schema with your preferred tools, you can now process the actual SOAP payload and extract the any element that comes after the schema. This element has the tag name diffgr and the actual payload starts as the first child of the <diffgr> element.

Illegal XML Characters

Sometimes, even though you have a perfectly valid WSDL that can successfully generate client artifacts, an application might fail before reaching the server side. This is illustrated in Figure 1–1 as Point 3. Usually, this failure occurs because the service is currently unavailable. There are other, harder to detect, cases as well. For example, the application might have produced invalid XML data in the SOAP message. The
application could also be attempting to pass characters which are invalid in XML. In these cases, the server transport layer immediately rejects the message before it reaches the Web service.

If your application must send special characters or data in the SOAP Body that could cause XML parsing errors, then the application should be designed to use a basic encoding scheme such as BASE64Encoding.

**Example**
The following code samples illustrate how an attempt to pass an invalid XML character in a SOAP message can cause an interoperability failure.

Assume that your C# client application code sends a command string and the service executes the command for the client. Also assume that one of the commands uses the backspace character (\b).

```csharp
MyCommand request = new MyCommand("\b");
MyCommandResponse response = soapClient.runCommand(request);
```

If the client application tries to send a command string containing the backspace character (\b), OracleAS Web Services will reject it because the backspace character is an invalid XML character. This can return an HTTP transport error and a HTML reply similar to the following.

```html
<HTML><HEAD><TITLE>Web Service</TITLE></HEAD><BODY><H1>Bad Request</H1><PRE>Error parsing envelope: (2, 237) Invalid char in text.</PRE></BODY></HTML>
```

**Out of Sync SOAPAction Values**

In OracleAS Web Services, the value of the soapAction attribute of the WSDL operation element is a URI constructed from the target namespace and the operation name:

```
http://<target-namespace>/<operation-name>
```

This same value should also be used as the value of the SOAPAction HTTP header for this operation in the SOAP request message. If it is not, then unexpected behavior can occur. This type of failure is referred to as Point 4a in Figure 1–1.

Most SOAP processors use the SOAPAction HTTP header as a hint to route the request to the appropriate operation without having to decode the full body. Some implementations support the SOAPAction value of quoted string ("", that is, the empty string). The SOAPAction may even be missing from the HTTP header. You should always use a quoted string to avoid interoperability problems.

This problem indicates that the client is out of sync with the WSDL published by the service. To solve this problem, regenerate your client so that it is consistent with the WSDL for the service.

**Example**
The following code samples illustrate how a mismatch between the values of the soapAction attribute of the WSDL operation element and the SOAPAction HTTP header for this operation can cause an interoperability failure.

Assume that you have the following add operation defined in WSDL:

```
<soapbind:operation soapAction= "http://ws.oracle.com/demo/:add"/>
```

Example 1–4 illustrates a SOAP request that is sent at runtime. Note that the message sets a multiply SOAPAction for an add operation.
Example 1–4  SOAP Request Fragment, Illustrating Value of SOAPAction

POST http://localhost/khub/MathService.asmx HTTP/1.1

Host: localhost
Proxy-Connection: Keep-Alive
Connection: TE
TE: trailers, deflate, gzip, compress
User-Agent: Oracle HTTPClient Version 10h
SOAPAction: "http://ws.oracle.com/demo/:multiply"
Accept-Encoding: gzip, x-gzip, compress, x-compress
Content-type: text/xml; charset=\"UTF-8\"
Content-length: 347

<?xml version = '1.0' encoding = 'UTF-8'?>
<env:Envelope xmlns:env="http://schemas.xmlsoap.org/soap/envelope/">
  <ns0:addElement>
    <ns0:a>3</ns0:a>
    <ns0:b>2</ns0:b>
  </ns0:addElement>
</env:Envelope>

OracleAS Web Services will throw an error and quit processing because the server detects that there is a mismatch between the SOAPAction HTTP header value and the first child element of the SOAP body element (<ns0:addElement>). The error will look similar to the following:

unexpected element name: expected={http://ws.oracle.com/demo/}addElement, actual={http://ws.oracle.com/demo/}multiplyElement

In a .NET 1.1 implementation, because the SOAPAction header is used by default for dispatching SOAP messages, the multiply operation will be invoked by mistake instead of the add operation. A fault will not be generated. Example 1–5 illustrates the incorrect response that .NET returns from the multiply service. It should return a fault because the wrong Web service was invoked. Another possible behavior is to ignore the invalid value of the SOAPAction, and route the message to the add operation, based on the payload of the request.

Example 1–5  Incorrect Response Returned by .NET

<multiplyResponseElement xmlns="http://ws.oracle.com/demo/">
  <MultiplyResult>0</MultiplyResult>
</multiplyResponseElement>

The Apache Axis platform does not rely on the SOAPAction header to route the operation. It will always use the top element of the SOAP Body payload to find a matching operation.

Understanding the soapAction WSDL Attribute

To prevent unexpected behaviors from occurring in Web service interactions, it is useful to understand how the value of the soapAction attribute in the WSDL is set, and its effect on the value of the SOAPAction header in the SOAP message. The following sections describe how this attribute is set and used on the OracleAS Web Services and .NET platforms.
Controlling the Value of soapAction in OracleAS Web Services

When you use the Oracle WebServicesAssembler tool to assemble Web services from Java code, a unique soapAction attribute value is generated for each operation in the WSDL.

You can control the value of this attribute with the Boolean emptySoapAction argument. If you set the argument to true, then the soapAction attribute for each SOAP binding operation in the generated WSDL is set to an empty string and the SOAPAction header in the SOAP message is set to a quoted (""") string. Setting this argument to true increases the chances of interoperability with tools from other vendors.

The default value of the emptySoapAction argument is false. In this case, the value of the soapAction attribute is the concatenation of the targetNamespace and the operation name. This will also be the value of the SOAPAction header in the SOAP message.

Example

The following code samples illustrate how the value of the emptySoapAction argument can be used to control the value of the soapAction attribute in OracleAS Web Services.

Assume that you have the following TimeService Java interface that defines a getDateTime service.

```java
public interface TimeService extends Remote {
    public String getDateTime(String name) throws RemoteException;
}
```

This interface can be used as input to the WebServicesAssembler assemble command or Ant task without the emptySoapAction argument. Since the emptySoapAction argument will not be used in the command or task, it is assumed that its value is false by default. The resulting WSDL will have the following soapAction value:

`soapAction="http://timeService/getDateTime"`

This will also be the value of the SOAPAction header in the SOAP message.

Controlling the Value of soapAction on the .NET Platform

On the .NET platform, you can specify the RoutingStyle of the XML Web service as SoapAction. Then, depending on whether the Web service is document or RPC style, set the SoapAction by using the Action parameter of the SoapDocumentMethod or SoapRpcMethod attribute. By default, the value for the Action parameter is defined by the following URI:

`http://<web service namespace>/MethodName`

In this URI, `MethodName` is the name of the XML Web service method.
Example

The following code sample illustrates how you can use the RoutingStyle parameter to control the value of SoapAction for a .NET Web service.

In Example 1–6, the RoutingStyle of the XML Web service is set to SoapServiceRoutingStyle.SoapAction. The SoapDocumentMethod attribute identifies the service as being of document style, and the Action parameter identifies the URI of the Web services as myAddService and myMultiplyService.

Example 1–6 Setting the Routing Style of a Service on the .NET Platform

```csharp
<%@ WebService Language="C#" Class="MathService" %>

using System;
using System.Web.Services;

[SoapDocumentService(SoapBindingUse.Literal,
    SoapParameterStyle.Wrapped,
    RoutingStyle=SoapServiceRoutingStyle.SoapAction)]
public class MathService : WebService {
    [SoapDocumentMethod(Action="http://localhost/myAddService")]
    [WebMethod] public float Add(float a, float b) {
        return a + b;
    }
    
    [SoapDocumentMethod(Action="http://localhost/myMultiplyService")]
    [WebMethod] public float multiply(float a, float b) {
        return a * b;
    }
}
```

Null Values in SOAP Messages

Data type mismatch is by far the most common cause of interoperability failures. These failures usually appear when the server or the client tries to deserialize the SOAP message. This is shown in Figure 1–1 as Point 4b and Point 5.

Data type mismatch failure can occur when null values are sent across different platforms. If possible, you should avoid passing null values. If you must send null values from one Web service application to another, you should understand what the
data types are mapped to on the other system and whether the data type can handle the null value correctly.

For example, the xsd:dateTime schema type is mapped to System.DateTime on the .NET platform. On the Java platform, it is mapped to java.util.Calendar or java.util.Date. If the Calendar or Date object is initialized with a null value in a Java program, then a null xsd:dateTime is sent in the SOAP message. If a Web service built on the .NET platform receives the SOAP message, then it will not be able to correctly deserialize the message, because the System.DateTime type is not nillable.

Example
The following code samples illustrate how passing a null value between the sending and receiving platform can result in an interoperability failure.

An XML element is a null element when its nil attribute is set to true. The WSDL must account for this by setting the nillable attribute of the corresponding element to true (the default value of nillable is false).

In the WSDL in Example 1–7, the source element has omitted the nillable attribute. Thus, by default, it has a nillable=false attribute.

Example 1–7  WSDL Fragment, Where the Source Element is Not Nillable

```
<s:element name="Src2html">
  <s:complexType>
    <s:sequence>
      <s:element minOccurs="0" maxOccurs="1" name="login" type="s:string"/>
      <s:element minOccurs="0" maxOccurs="1" name="passe" type="s:string"/>
      <s:element minOccurs="0" maxOccurs="1" name="lan" type="s:string"/>
      <s:element minOccurs="0" maxOccurs="1" name="source" type="s:string"/>
    </s:sequence>
  </s:complexType>
</s:element>
```

Suppose the client application assigns a null value to the Java object representing the source element. Assuming that the Apache Axis platform generates the client proxy code from this WSDL, Example 1–8 illustrates the resulting request SOAP message on the wire. Note that the source element has the xsi:nil attribute set to true.

Example 1–8  Request Message, With xsi:nil Set to true

```
<soapenv:Envelope xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
 <soapenv:Body>
   <Src2html xmlns="http://www.dotnetisp.com/webservices/dotnetisp/src2html.asmx">
     <login>Gigi</login>
     <passe>oracle</passe>
     <lan>C#</lan>
     <source xsi:nil="true"/>
   </Src2html>
 </soapenv:Body>
</soapenv:Envelope>
```

Because the WSDL definition does not allow the source element to contain a nil value, the Web service built on the OracleAS Web Services platform will fail to deserialize the incoming SOAP message. Example 1–9 illustrates a sample SOAP fault response that OracleAS Web Services generates for the preceding request.
Example 1–9  Sample SOAP Fault Response from OracleAS Web Services

```xml
<env:Body>
<env:Fault>
  <faultcode>env:Client</faultcode>
  <faultstring>caught exception while handling request: unexpected null</faultstring>
</env:Fault>
<env:Body>
</env:Envelope>
```

On the other hand, if the same client application assigning a null source element is developed with OracleAS Web Services, it will omit the source element completely, because the schema defines it to be optional. Example 1–10 illustrates a request SOAP message on the wire sent by a client developed with OracleAS Web Services.

Example 1–10  Request Message, Omitting Optional Elements

```xml
<env:Envelope xmlns:env="http://schemas.xmlsoap.org/soap/envelope/"
               xmlns:xsd="http://www.w3.org/2001/XMLSchema"
               xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xmlns:ns0="http://www.dotnetisp.com/webservices/dotnetisp/src2html.asmx">
<env:Body>
  <ns0:Src2html>
    <ns0:login>Gigi</login>
    <ns0:passe>oracle</passe>
    <ns0:lan>C#</lan>
  </ns0:Src2html>
</env:Body>
</env:Envelope>
```

Because the request in Example 1–10 does not contain an invalid null element, the server returns a response without error. Example 1–11 illustrates a sample response to the request.

Example 1–11  Sample SOAP Message

```xml
<env:Envelope xmlns:env="http://schemas.xmlsoap.org/soap/envelope/"
               xmlns:xsd="http://www.w3.org/2001/XMLSchema"
               xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
               xmlns:ns0="http://www.dotnetisp.com/webservices/dotnetisp/src2html.asmx">
<env:Body>
  <ns0:Src2htmlResponse/>
</env:Body>
</env:Envelope>
```

Unsigned Schema Numeric Types

Another type of deserialization failure that occurs at Point 4b or Point 5 in Figure 1–1 involves using unsigned schema types. On the .NET platform, unsigned types are directly mapped to unsigned native types, while on the Java platform, unsigned types are not defined. As a result, using unsigned schema types in your WSDL can cause unexpected interoperability failures.

If possible, avoid using unsigned numeric data types, such as unsignedShort, unsignedInt, unsignedDouble, or unsignedFloat in your client applications. If you do use these data types, you must check their range and precision limit on each system.
Example
The following code samples illustrate how using unsigned data types in a client application can cause unexpected interoperability failures.

The following C# Web method takes an unsigned input argument, ui, and returns the same value back to the caller.

```csharp
[WebMethod]
public uint getUint(uint ui) {
    return ui;
}
```

Example 1–12 illustrates the WSDL fragment containing the input and output parameters for the getUint Web method. These parameters are directly mapped to the xsd:unsignedInt type.

**Example 1–12  WSDL Fragment, with Mappings for Input and Output Parameters**

```xml
...<s:element name="getUint">
    <s:complexType>
        <s:sequence>
            <s:element minOccurs="1" maxOccurs="1" name="ui" type="s:unsignedInt"/>
        </s:sequence>
    </s:complexType>
</s:element>
<s:element name="getUintResponse">
    <s:complexType>
        <s:sequence>
            <s:element minOccurs="1" maxOccurs="1" name="getUintResult" type="s:unsignedInt"/>
        </s:sequence>
    </s:complexType>
</s:element>
...```

Using the WebServicesAsmberger tool, you can generate JAX-RPC-compliant client code that consumes the getUint service. The generated client code maps the request input type to the Java native type long.

Now, assume that your Java client application, similar to the code fragment illustrated in Example 1–13, passes in a very large long value without knowing the type expected on the other end of the Web service.

**Example 1–13  Client Application Fragment that Passes a Large long Value**

```java
...stubs.Service1SoapClient myPort = new stubs.Service1SoapClient();
System.out.println("calling " + myPort.getEndpoint());
long l1 = 9223372036854775807L;
GetUint request = new GetUint(l1);
GetUintResponse response = myPort.getUint(request);
long l2 = response.getGetUintResult();
...
```

When the message is sent across the wire, the .NET platform will reject the value and return a SOAP fault similar to the one illustrated in Example 1–14.

**Example 1–14  Sample SOAP Fault Sent by the .NET Platform**

```xml
<soap:Envelope xmlns:soap="http://schemas.xmlsoap.org/soap/envelope/"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    ...```
Loss of Precision

Loss of precision can occur at the point where messages are deserialized. This is depicted as Point 4b and Point 5 in Figure 1–1. Failures of this kind are not always obvious, because SOAP faults are not always thrown.

Loss of precision can occur when translating values of XML data types to different platforms. For example, the value of an XML dateTime simple type might be different on the Java and .NET platforms. This is because these platforms use different precisions when interpreting the value of this XML type.

Example

The following code samples illustrate how passing the xsd:dateTime XML simple type between Java and .NET Web services can cause a loss of precision, which translates into a potential interoperability issue.

The following C# Web method returns a System.MAX_VALUE of the DateTime data type.

```csharp
[WebMethod]
Public DateTime getDateTime() {
    Return DateTime.MaxValue;
}
```

Example 1–15 illustrates a Java client code fragment that accesses the getDateTime .NET Web service.

```java
... GetDateTime request = new GetDateTime(); GetDateTimeResponse response = myPort.getDateTime(request); Calendar cal = response.getGetDateTimeResult(); ...
```

Example 1–16 illustrates the SOAP response that the Java client receives on the wire. Note the values given for the date (highlighted in bold).

```xml
<?xml version="1.0" encoding="utf-8" ?> <dateTime
xmlns="http://tempuri.org/">9999-12-31T23:59:59.9999999-08:00</dateTime>
```

The Java client deserializes the response into the java.util.Calendar class. Example 1–17 illustrates the printout of the contents of the Calendar object. Notice that the dateTime value is slightly later than the value passed over the wire. This is because the two native dateTime types have different precisions. On the .NET
platform, four digits are used for the year value and seven digits are used for the milliseconds. On the Java platform, five digits are used for the year value and three digits are for milliseconds. Moreover, the Java Web service maintains only three digits of milliseconds and rounds up the date. The new value, on the receiving side is January 1, 10000.

**Example 1–17  Printout of a Java Calendar Object**

```java
[java] ERA: 1
[java] YEAR: 10000
[java] MONTH: 0
[java] WEEK_OF_YEAR: 1
[java] WEEK_OF_MONTH: 1
[java] DATE: 1
[java] DAY_OF_MONTH: 1
[java] DAY_OF_YEAR: 1
[java] DAY_OF_WEEK: 7
[java] DAY_OF_WEEK_IN_MONTH: 1
[java] AM_PM: 0
[java] HOUR: 0
[java] HOUR_OF_DAY: 0
[java] MINUTE: 0
[java] SECOND: 0
[java] MILLISECOND: 0
[java] ZONE_OFFSET: -8
[java] DST_OFFSET: 0
```

**Tool Support for Interoperability**

The previous sections suggest that there are distinct steps which you can follow to investigate Web services interoperability. These steps can be summarized as the Capture, Replay, Analyze process:

- Capturing the Web Service Contract—capture the WSDL, the XSD files, and the data on the wire: the SOAP payload and the HTTP headers.
- Replaying the Message Payload—re-send the message payload to replay the interaction between proxy and service endpoint. You can also edit the payload to replay the interaction in a different context.
- Analyzing the Interaction—analyze the results of the interaction between the service consumer and provider. You need to make sense out of these broken interactions, sometimes by comparing them with a message payload that transmits successfully.

Oracle provides tools that can assist you in each step. Which tools you use will depend on the environment where you are developing the Web service endpoints and proxies. The following sections describe the tools which can assist you in each step.

**Capturing the Web Service Contract**

The Web service contract consists of the WSDL file, the SOAP message payload, and the HTTP headers.

To capture the WSDL and the XSD files, you can use the following tools:

- Oracle JDeveloper wizards provide an option that will make a local copy of the WSDL file in your project. Figure 1–2 illustrates the Oracle JDeveloper Copy WSDL Into Project option.
The WebServicesAssembler tool provides a command, fetchWsdl, that will copy the base (or top-level) WSDL file and all of its imported and included WSDLs and schemas into a specified output directory. You can run this command on the command line or as an Ant task.

See "fetchwsdl" in the Oracle Application Server Web Services Developer's Guide for more information on this argument.

The generic Ant task get can be used to return a WSDL. If you use this Ant task, you must make a local copy of all the remote resources that have been referenced using wsdl:import or xsd:import.

Figure 1–2 Oracle JDeveloper Option to Make a Local WSDL Copy

Capturing the SOAP Payload and HTTP Headers
To capture the SOAP payload and HTTP headers, you can use the following tools:

- The HTTP Analyzer tool which is included with Oracle JDeveloper 10g offers a convenient way to capture the HTTP traffic between the service consumer and the service provider. This technique assumes that you can easily introduce an HTTP proxy between the two nodes. To change the behavior of the client, you must use the http.proxyHost and http.proxyPort system properties, while running the client.

- If inserting an HTTP proxy is not practical, you can use an intermediary node, which will redirect the incoming traffic to the final destination. The WS-I monitor is an example of a tool that can do this. Unlike an HTTP proxy, using an intermediary node requires you to change the URL of the endpoint on the client side.

- If you cannot change the client code or route the HTTP traffic through a proxy, set up an TCP sniffer. Ethereal is an example of a network protocol analyzer for Unix and Windows that can be used in this context.

Replaying the Message Payload
Once you have captured the payload, you must be able to either re-send the same payload, or to edit the payload and send it to see the effects of your changes.

- JUnit can help you with the process of re-sending the same payload. You can take advantage of the test classes generated by the WebServicesAssembler genProxy command. You can also generate these test classes with Oracle JDeveloper 10g. Figure 1–3 illustrates the option to generate JUnit classes, as it appears in Oracle JDeveloper wizards.

- The HTTP Analyzer tool, included with Oracle JDeveloper 10g, offers a convenient way to re-send either the same payload, or the edited payload. Figure 1–4 illustrates the Resend Request command in the HTTP Analyzer tool included with Oracle JDeveloper.
Analyzing the Interaction

Analyze the interaction between the service consumer and the provider. To help you analyze the interaction, you can use the following tools.

- **Oracle JDeveloper 10g HTTP Analyzer** lets you use the WS-I Analyzer directly from the IDE. To use the Analyzer from the IDE, you must first download the Java version of the WS-I tools. The WS-I Analyzer generates the XML configuration files for you, and displays the progress as the reports are generated. Figure 1–5 illustrates the Oracle JDeveloper HTTP Analyzer with the focus on the integrated WS-I Analyzer command.

- The WebServicesAssembler tool provides an `analyze` command which performs a full scan of the WSDL and confirms whether the WSDL can be processed by this version of the WebServicesAssembler. The `genProxy` and `genInterface` commands perform the same task, but unlike these commands, `analyze` does not generate any code.

  **See Also:**

  "analyze" in the Oracle Application Server Web Services Developer's Guide.

The WSDL validation command is also integrated into the Oracle JDeveloper IDE. It is available from the Context menu, based on the type of resource selected. Figure 1–6 illustrates the Oracle JDeveloper command to compare files. In this case, the command compares two WSDL files.
Obtaining WS-I Tools

For more information on the tools mentioned in this section, see the following Web addresses.

Using WS-I Test Tools:

http://www.oracle.com/technology/products/jdev/howtos/10g/WS_WSII/WSI_HowTo.html

WS-I Basic Profile 1.0 Compliance Analyzer demo:

http://www.oracle.com/technology/products/jdev/viewlets/905p_j2ee_wsi/wsi_webservices_10g_viewlet.swf.html

Downloading the WS-I tool:

Limitations

See “Ensuring Interoperable Web Services” on page I-13.

- Working with DIME-Encoded Attachments
- Working with Attachments in WSIF

**Working with MIME Attachments**

This section contains the following subsections.

- How OracleAS Web Services Supports MIME Attachments
- How to Assemble a Web Service Using swaRef MIME Attachments
- How to Assemble a Web Service Using SWA MIME Attachments
- How to Add MIME Attachments to SOAP Fault Messages

**How OracleAS Web Services Supports MIME Attachments**

Oracle Application Server Web Services enables you to pass Multipurpose Internet Mail Extension (MIME) attachments with SOAP messages. The SOAP with Attachments (SWA) specification defines these messages.

In addition to the SOAP with Attachments specification, OracleAS Web Services also supports the Web Service-Interoperability (WS-I) Attachments Profile 1.0 that defines interoperable SOAP messages with attachments. In the interests of interoperability, the WS-I Attachments Profile adds certain constraints to the SWA specification. The profile also defines a new schema type, swaRef, for referencing MIME parts from within the SOAP message body. Using this schema type for sending interoperable SOAP messages with attachments is not mandated, nor does it guarantee conformance to the profile. The type is only an optional convenience mechanism. OracleAS Web Services support both the swaRef type and plain swa for sending SOAP messages with MIME attachments.

OracleAS Web Services supports both the swa and swaRef formats and their handling is transparent to the developer.
The following list describes the main differences between swaRef and SWA.

- **swaRef** attachments are uniquely identified MIME attachments, referenced in the SOAP body by a URL. SWA attachments are uniquely identified, but there is no standard way for referencing them from within a SOAP body.

- **SWA** MIME parts must be defined by a mime:content element in the corresponding mime:part. The following example illustrates a ClaimPhoto JPEG file, referenced as a SWA in a mime:content element.

  ```xml
  <mime:part>
    <mime:content part="ClaimPhoto" type="image/jpeg"/>
  </mime:part>
  ```

  In contrast, **swaRef** attachments should not be defined in the mime:content element. Instead, they should be referenced in the soapbind:body of the wsd1:binding. The following example illustrates the ClaimDetail file referenced as a swaRef in the soapbind:body element. Note that the file is referenced by a URL.

  ```xml
  <mime:part>
    <soapbind:body use="literal" parts="ClaimDetail"
                   namespace="http://example.com/mimetypes"/>
  </mime:part>
  ```

- **SWA** attachments are mapped to a corresponding Java type based on the MIME content type defined in the WSDL. For example, if the MIME content type is image/jpeg, a java.awt.Image will be used to represent the attachment. In contrast, **swaRef** will always be mapped to javax.xml.soap.AttachmentPart.

### How to Assemble a Web Service Using swaRef MIME Attachments

The **swaRef** type allows MIME attachments to be referenced by a URL within the SOAP body. WS-I publishes a public schema which defines the **swaRef** type. The public schema is defined by the following XSD:

http://ws-i.org/profiles/basic/1.1/xsd/

For more information on how to use this type to define attachments in a WSDL, see Section 4.4 of the WS-I Attachments Profile 1.0.

---

**Note:** Only RPC-literal and document-literal Web services are supported by the WS-I Attachments Profile 1.0. Thus, only those types of services can use **swaRef**.

---

OracleAS Web Services enables you to assemble Web services up that can pass MIME attachments with **swaRef**. This is described in the following sections.
Steps for Assembling a Web Service Top Down

You can use WebServicesAssembler to assemble a Web service top down that can process and generate swaRef MIME attachments. One of the ways in which you could do this is to provide a WSDL that contains swaRef references as input to the genInterface command. This command generates a service endpoint interface containing methods with parameters that will be passed as attachments.

Implementing the generated service endpoint interface includes working with classes and methods in the oracle.webservices.attachments package.

Steps for Assembling a Web Service Top Down

You can use WebServicesAssembler to assemble a Web service top down that can process and generate swaRef MIME attachments. One of the ways in which you could do this is to provide a WSDL that contains swaRef references as input to the genInterface command. This command generates a service endpoint interface containing methods with parameters that will be passed as attachments.

Implementing the generated service endpoint interface includes working with classes and methods in the oracle.webservices.attachments package.

See Also:
"Understanding the Streaming Attachments API" on page 2-18 for a description of this API.

The following general steps describe how to assemble a Web service top down that exposes methods that pass swaRef MIME attachments.

1. Provide a WSDL from which you want to assemble a Web service.
2. Enter the import statement for the swaRef XSD in the WSDL. The following is an example import statement.
   `<xsd:import namespace="http://ws-i.org/profiles/basic/1.1/xsd" schemaLocation="http://ws-i.org/profiles/basic/1.1/xsd"/>
   
3. For each part in the wsdl:message that needs to be a swaRef attachment, set the type attribute to the swaRef complex type in the imported schema. An example of setting swaRef to a complex type is type="wsi:swaRef".
   "Requirements for WSDLs with swaRef Attachments" on page 2-4 provides an example of a WSDL that references a swaRef attachment.

   Note: For document-literal services you should define an element in the schema with the type wsi:swaRef and reference that element in the wsdl:message part. This is because the Basic Profile requires document-literal message parts to reference elements, not types.

   In the following example, the wsdl:part name="status" in the message part references the xsd:element name="Status" of type swaRef in the schema section of the WSDL.
   <!--This is defined in the schema section of the WSDL-->
   <xsd:element name="Status" type="wsi:swaRef"/>
   
   <!--This is the message part that references the swaRef element-->
   <wsdl:message name="replacePhotoResponse">
   <wsdl:part name="status" type="types:Status"/>
   </wsdl:message>

4. Use the WSDL as input to the WebServicesAssembler genInterface command. Following is a sample genInterface command.

   java -jar wasa.jar genInterface -wsdl mySwaRefWsdl -output c:\appDir

Steps for Assembling a Web Service Bottom Up
This command generates a service endpoint interface with methods that handle swaRef attachments and a Java class for each complexType in the WSDL. The AttachmentPart class will be used for all instances of swaRef.

"How to Implement a Service Endpoint Interface with Attachments" on page 2-6 provides a sample generated service endpoint interface.

5. Implement the generated service endpoint interface.

In the implementation class, methods that receive attachments will have an AttachmentPart parameter while methods that send swaRef attachments will have AttachmentPart as the return type. As part of the implementation of the methods, create a new instance of the AttachmentPart and add an attachment using the setContent method.

See Also:
- "How to Create a New Instance of AttachmentPart" on page 2-7 for information on how to create an instance of AttachmentPart.
- Example 2–4 on page 2-6 for a sample implementation of a generated service endpoint interface, with code that creates a new instance of AttachmentPart.

Requirements for WSDLs with swaRef Attachments A WSDL that uses swaRef attachments must have the following characteristics.

- The WSDL must import the swaRef XSD file.
- Each part of the wsdl:message that must be a swaRef attachment must set its type attribute to the swaRef complex type in the imported schema (or the element attribute set to an element that is of type swaRef for document-literal services).
- The swaRef attachment should be referenced in the soapbind:body of the wsdl:binding. Example 2–1 illustrates the format of the swaRef reference. The soapbind:body element has these attributes:
  - use—indicates whether the message format is literal or encoded.
  - parts—indicates the part of the SOAP message that the attachment references.
  - namespace—indicates the URL of the attachment.

Example 2–1 swaRef Attachment Referenced in the soapbind:body Element

```xml
<mime:part>
  <soapbind:body use="literal|encoded" parts="string" namespace="URL"/>
</mime:part>
```

Example 2–2 illustrates a WSDL that contains a swaRef reference that can be used as input to genInterface. The ClaimDetailType complex type which is referenced by the ClaimDetail part of the ClaimIn message has an element ClaimForm that is of type swaRef. The ClaimDetail part is referenced in the soapbind:body of the binding as opposed to a mime:content element which is not referenced as part of the SOAP body. The elements described in the preceding list, as well as the xsd:import statement for the swaRef schema, are highlighted in bold.

Example 2–2 WSDL that References a swaRef Attachment

```xml
<?xml version="1.0"?>
```
<wsdl:definitions xmlns:types="http://example.com/mimetypes"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:soapbind="http://schemas.xmlsoap.org/wsdl/soap/"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:mime="http://schemas.xmlsoap.org/wsdl/mime/
    targetNamespace="http://example.com/mimewsdl"
    xmlns:tns="http://example.com/mimewsdl">
    <wsdl:types>
        <xsd:schema targetNamespace="http://example.com/mimetypes"
            xmlns:xsd="http://www.w3.org/2001/XMLSchema">
            <xsd:import namespace="http://ws-i.org/profiles/basic/1.1/xsd"
                schemaLocation="http://ws-i.org/profiles/basic/1.1/xsd"/>
            <xsd:complexType name="ClaimDetailType">
                <xsd:sequence>
                    <xsd:element name="Name" type="xsd:string"/>
                    <xsd:element name="ClaimForm" type="ref:swaRef"/>
                </xsd:sequence>
            </xsd:complexType>
        </xsd:schema>
    </wsdl:types>
    <wsdl:message name="ClaimIn">
        <wsdl:part name="ClaimDetail" type="types:ClaimDetailType"/>
    </wsdl:message>
    <wsdl:message name="ClaimOut">
        <wsdl:part name="ClaimRefNo" type="ref:swaRef"/>
    </wsdl:message>
    <wsdl:portType name="ClaimPortType">
        <wsdl:operation name="SendClaim">
            <wsdl:input message="tns:ClaimIn"/>
            <wsdl:output message="tns:ClaimOut"/>
        </wsdl:operation>
    </wsdl:portType>
    <wsdl:binding name="ClaimBinding" type="tns:ClaimPortType">
        <soapbind:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
        <wsdl:operation name="SendClaim">
            <soapbind:operation soapAction="http://example.com/soapaction"/>
            <wsdl:input>
                <mime:multipartRelated>
                    <mime:part>
                        <soapbind:body use="literal"
                            parts="ClaimDetail" namespace="http://example.com/mimetypes"/>
                    </mime:part>
                </mime:multipartRelated>
            </wsdl:input>
            <wsdl:output>
                <mime:multipartRelated>
                    <mime:part>
                        <soapbind:body use="literal"
                            namespace="http://example.com/mimetypes"/>
                    </mime:part>
                </mime:multipartRelated>
            </wsdl:output>
        </wsdl:operation>
    </wsdl:binding>
</wsdl:definitions>
From this WSDL, the `genInterface` command generates a service endpoint interface with `swaRef` attachments, and a Java class for each `complexType` in the WSDL. The `AttachmentPart` class will be used for all instances of `swaRef`.

For example, WebServicesAssembler will generate a Java class for the `ClaimDetail` complex type. Its `claimForm` parameter, which is of type `swaRef` in the WSDL, will be generated as type `AttachmentPart` in the Java code. The following code sample illustrates part of the class signature.

```java
public class ClaimDetail{
    private String name;
    private javax.xml.soap.AttachmentPart claimForm;
    ...
}
```

**How to Implement a Service Endpoint Interface with Attachments** Given a WSDL with references to `swaRef` attachments, WebServicesAssembler generates a service endpoint interface that contains a Java class for each `complexType` in the WSDL. It also contains Java methods that return a `java.xml.soap.AttachmentPart` for each WSDL operation that has a `swaRef` in the output method.

An implementation of a generated service endpoint interface must create a new instance of `AttachmentPart`. OracleAS Web Services uses the `AttachmentPart` class for creating and accessing `swaRef` attachments. Since `AttachmentPart` is an abstract class, it cannot be instantiated directly. You must create a new instance of `AttachmentPart` as a part of the implementation of methods that send attachments.

**See Also:**

"How to Create a New Instance of AttachmentPart" on page 2-7 for information on how to use the SAAJ API to create a new instance of `AttachmentPart`.

Example 2–3 illustrates a generated service endpoint interface with a `sendClaim` method that sends an attachment as a return parameter. Example 2–4 illustrates the implementation of the interface.

**Example 2–3 Sample Generated Service Endpoint Interface with an Attachment**

```java
package com.demo.attachments;

import java.xml.soap.AttachmentPart;
...
public interface claimPortType extends java.rmi.Remote{
    public AttachmentPart sendClaim(ClaimDetail claimDetail) throws java.rmi.RemoteException;
}
```

The implementation class in Example 2–4 creates a new instance of `AttachmentPart` in the `sendClaim` method. Once the `AttachmentPart` instance is created, an image or any other object can be added using the `setContent(Object obj, String mimeType)` method. The first parameter of the method takes the object to be attached and the second parameter specifies the MIME content type of that object. For example, if a GIF image is being sent, the `setContent` method would be `setContent(newPhoto,"image/gif").`

**Example 2–4 Implementation of a Service Endpoint Interface**

```java
public class ClaimPortTypeImpl implements ClaimPortType {
```
public AttachmentPart sendClaim(ClaimDetail claimDetail) throws RemoteException{
    AttachmentPart impl = null;
    try{
        MessageFactory factory = MessageFactory.newInstance();
        SOAPMessage message = factory.createMessage();
        impl = message.createAttachmentPart();
    } catch(SOAPException ex){
        return null;
    }
    return impl;
}

How to Create a New Instance of AttachmentPart

This section illustrates the basic code for creating a new instance of AttachmentPart. OracleAS Web Services uses the AttachmentPart class for creating and accessing swaRef attachments.

Example 2–5 illustrates sample code that uses the SAAJ API to create a new instance of AttachmentPart. Note that the createAttachmentPart method of javax.xml.soap.SOAPMessage takes an object and a MIME type as parameters.

Example 2–5 Creating a New Instance of AttachmentPart

javax.xml.soap.SOAPMessage message = mf.createMessage();
javax.xml.soap.AttachmentPart ap = message.createAttachmentPart(attachmentObj,"image/jpeg");

The generated service interface can now be implemented and swaRef attachments can be sent and received using AttachmentPart from the SAAJ API.

Steps for Assembling a Web Service Bottom Up

You can use WebServicesAssembler to assemble a Web service bottom up that can pass swaRef MIME attachments. One way to do this is to provide a Java class that contains method parameters that represent attachments to the assemble or genWsdl commands. These commands produce a WSDL with references to swaRef attachments.

See Also:

"Understanding the Streaming Attachments API" on page 2-18 for a description of this package.

Note: WebServicesAssembler will not be able to assemble a Web service that can pass swaRef MIME attachments if you specify an RPC-encoded message format. To assemble the service, you must select a different format.

The following general steps describe how to assemble a Web service bottom up that exposes elements in the WSDL that represent swaRef MIME attachments.

1. Provide the Java class you want to expose as a Web service.

In the class file, any methods that use parameters that represent attachments should be identified as type AttachmentPart. In your implementation of the methods that use attachments, create a new instance of AttachmentPart.
"How to Create a New Instance of AttachmentPart" on page 2-7 provides sample code that uses the SAAJ API to do this. "How to Write a Service Endpoint Interface that Handles Attachments" on page 2-8 provides a sample service endpoint interface with a method that passes attachments.

2. Use the WebServicesAssembler to generate a WSDL file.

   - Use the assemble command if you want to assemble the WSDL and all of the service artifacts for a Web service.
   - Use the genWsdl command if you want to generate only the WSDL file.

   The generated WSDL file will contain the following element for each parameter in the Java class identified as type AttachmentPart:

   ```xml
   <xsd:element name="..." type="ref:swaRef"/>
   ```

   "How to Assemble a WSDL File with swaRef Attachment References" provides a sample WSDL file generated with the genWsdl command that contains swaRef attachment references.

3. If you used the genWsdl command to generate the WSDL, you can now inspect the file.

4. If you used the assemble command to assemble the Web service, you can now deploy the service, generate a proxy, and write a client.

See Also:

"Assembling a Web Service with Java Classes" in the Oracle Application Server Web Services Developer's Guide for more information on the steps for assembling and deploying a Web service, and generating client code.

How to Write a Service Endpoint Interface that Handles Attachments If methods in your service endpoint interface pass attachments, and you want the attachments to be passed as a swaRef, then the parameters that represent the attachments must be of type AttachmentPart. In bottom up Web service assembly scenarios, WebServicesAssembler generates a swaRef type reference into the WSDL for every AttachmentPart type it encounters in an implementation class or interface.

Example 2–6 illustrates an interface that contains a parameter, claimDetail, of type AttachmentPart. When passed to WebServicesAssembler using the genWsdl or assemble command, this interface yields a WSDL file.

**Example 2–6 Service Endpoint Interface with a Method that Passes Attachments**

```java
public interface ClaimServicePortType extends java.rmi.Remote{
    public String sendClaim(int id, AttachmentPart claimDetail) throws RemoteException;
}
```

How to Assemble a WSDL File with swaRef Attachment References Example 2–7 illustrates a fragment of the WSDL file, displaying only the type definitions. The example assumes that the interface in Example 2–6 was used as input to the genWsdl command to generate the WSDL with document-wrapped style. The WSDL fragment identifies the claimDetail element as being of type swaRef (highlighted in bold).

Note that the same WSDL fragment would be created if the assemble command was used to generate the WSDL. This is the default behavior when WebServicesAssembler encounters the AttachmentPart data type.
Example 2–7  WSDL Fragment, Displaying only Type Definitions

```xml
... 
  <xsd:import namespace="http://ws-i.org/profiles/basic/1.1/xsd" />
  <xsd:complexType name="sendClaimType">
    <xsd:sequence>
      <xsd:element name="id" type="xsd:string"/>
      <xsd:element name="claimDetail" type="ref:swaRef"/>
    </xsd:sequence>
  </xsd:complexType>
</xsd:schema>
... 
```

How to Assemble a Web Service Using SWA MIME Attachments

This section contains the following subsections:

- Understanding SWA MIME Attachments
- Steps for Assembling a Web Service with SWA Attachments Top Down
- Sample WSDL with SWA MIME References
- Sample Generated Interface with Parameters that Can Pass SWA Attachments

Understanding SWA MIME Attachments

SWA attachments refer to attachments that conform to the SOAP With Attachments (SWA) specification. Currently, WebServicesAssembler supports only top down assembly of Web services with WSDL files that contain SWA attachments. SWA MIME parts are defined in the `<wsdl:binding>` clause of the WSDL. The attachment is defined by a `mime:content` element in the corresponding `mime:part`.

Example 2–8 illustrates the format of the `mime:content` element and its `part` and `type` attributes. The `part` attribute identifies the part of the SOAP message to which the attachment belongs. The `type` attribute identifies the content type in the attachment.

Example 2–8  SWA Attachment Referenced in the `mime:content` Element

```xml
<mime:part>
  <mime:content part="string"
    type="content type"/>
</mime:part>
```

WebServicesAssembler processes each `mime:content` element found in the WSDL file and maps it to a Java type that corresponds to the MIME-content type.

Table 2–1 displays the MIME content types and corresponding Java types to which they will be mapped. The default type for any MIME-content type that is not recognized is `javax.activation.DataHandler`.

<table>
<thead>
<tr>
<th>Content Type</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>image/jpeg, image/gif, image/tif</td>
<td><code>java.awt.Image</code> If these content types are used in combination, or if <code>image/*</code> is specified, then they are mapped to the <code>java.activation.DataHandler</code> Java type.</td>
</tr>
</tbody>
</table>
Steps for Assembling a Web Service with SWA Attachments Top Down

The following steps describe how to generate a service endpoint interface that can handle SWA attachments. In the steps, JPG content is used as an example of a content type that will be represented as a Java class in the interface. However, any content type described in Table 2–1 can be used.

1. Provide the WSDL from which you want to generate a Web service.

2. Ensure that each element that represents a SWA attachment appears in a `<mime:content...>` element in the `<wsdl:binding...>` clause of the WSDL.

   In Example 2–9, a photo JPEG attachment appears in a `<mime:content...>` element:
   ```xml
   <mime:part>
     <mime:content part="photo" type="image/jpeg"/>
   </mime:part>
   ```

3. Use the WSDL as input to the WebServicesAssembler `genInterface` command. Following is a sample `genInterface` command.

   ```
   java -jar wsa.jar genInterface -wsdl mySwaWsdl -output c:\appDir
   ```

   The `genInterface` command generates a service endpoint interface with parameters that represent SWA attachments and a Java class for each complexType in the WSDL. This Java class will be used for all instances of SWA attachments.

   Example 2–10 illustrates a generated service endpoint interface with a parameter that represents a SWA attachment as a `java.awt.Image` Java data type.

4. Implement the generated service endpoint interface.

Sample WSDL with SWA MIME References

Example 2–9 illustrates a WSDL that contains a SWA reference that can be used as input to `genInterface`. Note that this WSDL example omits the `wsdl:service` element for the sake of brevity.

### Example 2–9 WSDL that References a SWA Attachment

```xml
<wSDL:definitions
  name="PhotoCatalogService"
  targetNamespace="http://examples.com/PhotoCatalog"
  xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns:types="http://examples.com/PhotoCatalog/types"
  xmlns:mime="http://schemas.xmlsoap.org/wsdl/mime/
  xmlns:tns="http://examples.com/PhotoCatalog">
  <wsdl:message name="addPhotoRequest">
    <mime:content/>
  </wsdl:message>
  <wsdl:portType name="AddPhotoPortType">
    <wsdl:operation name="addPhoto">
      <wsdl:input message="wsdl:addPhotoRequest"/>
    </wsdl:operation>
  </wsdl:portType>
  <wsdl:binding name="AddPhotoSwaBinding" type="tns:AddPhotoPortType">
    <wsdl:operation name="addPhoto">
      <wsdl:input message="wsdl:addPhotoRequest"/>
      <mime:part/>
    </wsdl:operation>
  </wsdl:binding>
</wsdl:definitions>
```
<wsdl:part name="photo" type="xsd:hexBinary"/>
</wsdl:message>
<wsdl:message name="addPhotoResponse">
  <wsdl:part name="status" type="xsd:string"/>
</wsdl:message>
<wsdl:message name="replacePhotoRequest">
  <wsdl:part name="oldPhoto" type="xsd:string"/>
  <wsdl:part name="newPhoto" type="xsd:hexBinary"/>
</wsdl:message>
<wsdl:message name="replacePhotoResponse">
  <wsdl:part name="status" type="xsd:string"/>
</wsdl:message>
<wsdl:portType name="PhotoCatalog">
  <wsdl:operation name="addPhoto">
    <wsdl:input message="tns:addPhotoRequest"/>
    <wsdl:output message="tns:addPhotoResponse"/>
  </wsdl:operation>
  <wsdl:operation name="replacePhoto">
    <wsdl:input message="tns:replacePhotoRequest"/>
    <wsdl:output message="tns:replacePhotoResponse"/>
  </wsdl:operation>
</wsdl:portType>
<wsdl:binding name="PhotoCatalogBinding" type="tns:PhotoCatalog">
  <soap:binding style="document"
              transport="http://schemas.xmlsoap.org/soap/http"/>
  <wsdl:operation name="addPhoto">
    <wsdl:input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="literal"/>
        </mime:part>
        <mime:part>
          <mime:content part="photo" type="image/jpeg"/>
        </mime:part>
      </mime:multipartRelated>
    </wsdl:input>
    <wsdl:output>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="literal"/>
        </mime:part>
        <mime:part>
          <mime:content part="status" type="text/plain"/>
          <mime:content part="status" type="text/xml"/>
        </mime:part>
      </mime:multipartRelated>
    </wsdl:output>
  </wsdl:operation>
  <wsdl:operation name="replacePhoto">
    <wsdl:input>
      <mime:multipartRelated>
        <mime:part>
          <soap:body parts="oldPhoto" use="literal"/>
        </mime:part>
        <mime:part>
          <mime:content part="newPhoto" type="image/jpeg"/>
        </mime:part>
      </mime:multipartRelated>
    </wsdl:input>
    <wsdl:output>
      <mime:multipartRelated>
        <mime:part>
          <soap:body use="literal"/>
        </mime:part>
        <mime:part>
          <mime:content part="status" type="text/plain"/>
          <mime:content part="status" type="text/xml"/>
        </mime:part>
      </mime:multipartRelated>
    </wsdl:output>
  </wsdl:operation>
</wsdl:binding>
Sample Generated Interface with Parameters that Can Pass SWA Attachments

Given the WSDL displayed in Example 2–9, the WebServicesAssembler genInterface command generates the interface in Example 2–10. The photo and newPhoto parameters are generated with the Java data type java.awt.Image because their mime:content is defined with image/jpeg. An implementation of the interface can now pass JPEG files as attachments for the photo part. This is the same for RPC-literal and document-literal (wrapped and bare). The return for the addPhoto method is mapped to DataHandler because there was a mime:content binding in the WSDL for that operation.

Example 2–10  Generated Interface with a SWA Attachment

```java
public interface PhotoCatalog extends java.rmi.Remote{
    public javax.activation.DataHandler addPhoto (java.awt.Image photo) throws java.rmi.RemoteException;
    public String replacePhoto(java.awt.Image newPhoto, String oldPhoto) throws java.rmi.RemoteException;
}
```

How to Add MIME Attachments to SOAP Fault Messages

This section describes how to add MIME type attachments to SOAP fault messages. It contains the following subsections:

- Understanding SOAP Fault Messages with Attachments
- Steps for Assembling SOAP Faults with Attachments into a Web Service Top Down
- How to Specify SOAP Faults with Attachments in the WSDL
- How to Implement a Method that Throws Faults with Attachments
- How to Retrieve SOAP Faults with Attachments on the Client

**Note:** In OracleAS Web Services, you can add only MIME type attachments to SOAP fault messages.

Understanding SOAP Fault Messages with Attachments

In SOAP, an attachment is added to the fault message when the Web service implementation class throws an exception. The WS-I Attachments Profile 1.0 specifies that a SOAP fault can contain attachments only if a <mime:part> element appears in an operation’s output message in the WSDL. Thus, if custom faults appear in a WSDL operation that has an output message with an attachment, WebServicesAssembler generates a special exception class that handles attachments in the fault.

The WSDL fragment in Example 2–11 illustrates the <mime:part> in the <wsdl:operation> clause that declares that an operation can output MIME content. The namespace attribute is required only when you are working with RPC-literal
messages. The WSDL fragment also illustrates the `<wsdl:fault>` element that defines the fault that the operation can throw.

**Example 2–11  WSDL Fragment, that Defines a SOAP Fault**

```xml
<wsdl:operation>
...
<wsdl:output>
  <mime:multipartRelated>
    <mime:part>
      <soap:body parts="string" use="literal|encoded" [namespace="URL"]/>
    </mime:part>
  </mime:multipartRelated>
</wsdl:output>
<wsdl:fault name="string">
  <soap:fault name="string" use="literal|encoded"/>
</wsdl:fault>
</wsdl:operation>
```

When WebServicesAssembler encounters a `<wsdl:fault>` element, it generates a `com.examples.types.Fault_NameType` exception class (as defined in Example 2–9), where `Fault_Name` is the value of the `name` attribute in the `wsdl:fault` element.

An implementation of a method that throws a generated fault class must also include an implementation of a new instance of the class. It must also include code to add the attachment to the exception.

Writing and implementing the Java classes that contain attachments includes working with classes and methods in the `oracle.webservices.attachments` package.

**See Also:**

"Understanding the Streaming Attachments API" on page 2-18 for a description of this package.

**Note:** Faults with attachments can be added to a Web service only when you are assembling it from a WSDL (top down). They cannot be added when assembling a Web service bottom up.

**Steps for Assembling SOAP Faults with Attachments into a Web Service Top Down**

The following general steps describe how to add attachments to SOAP fault messages and generate them into the service endpoint interface.

1. Provide the WSDL that you want to work with.
2. Edit the WSDL operation that you want to throw a fault with attachment content.
   a. Declare the output element that will contain attachment content in the `<wsdl:output.../>` clause. The clause must contain `<mime:multipartRelated>` content.
   b. Define a `<wsdl:fault.../>` element.

"How to Specify SOAP Faults with Attachments in the WSDL" on page 2-14 provides a sample WSDL that has been edited to include the `wsdl:output` and `wsdl:fault` elements.
3. Use the WebServicesAssembler `genInterface` command to generate a service endpoint interface.

   java -jar wsa.jar genInterface -wsdl myWsdl -output c:\appDir

   The methods in the service endpoint interface that use the attachment data will have a parameter that takes an attachment data type. The methods will throw an exception that implements `oracle.webservices.attachments.AttachmentFault`.

4. Implement the interface.

   In the implementation, include code to perform the following tasks.

   a. Create a new instance of the exception that implements `oracle.webservices.attachments.AttachmentFault`

   b. Add an attachment to the exception with the `addAttachment` method.

      "How to Implement a Method that Throws Faults with Attachments" on page 2-15 provides sample code that creates a new instance of the exception and adds the attachment to it.

5. Compile the interface and the implementation, deploy the service, and assemble the client code.

   **See Also:**

   "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer's Guide for more detail on the steps for assembling and deploying a Web service, and assembling client code.

---

**How to Specify SOAP Faults with Attachments in the WSDL**

To specify a SOAP fault that can throw attachment content, the WSDL operation must identify the following attributes:

- the namespace of the attachment content
- whether the fault’s message use is literal or encoded
- the part of the SOAP message that the fault belongs to

The WSDL fault itself must identify its name and whether its message use is literal or encoded. The `<wsdl:faul`t> clause appears as a peer to the WSDL input and WSDL output clauses.

Example 2–12 illustrates a WSDL fragment for the `replacePhoto` binding operation with `wsdl:output` and `wsdl:faul`t elements. Because `wsdl:output` identifies MIME content, the fault message defined by `wsdl:faul`t will be able to contain attachments.

**Example 2–12  WSDL Fragment, Displaying only Port Types and Binding Declarations**

```xml
<wSDL:operation name="replacePhoto">
  <wSDL:input>
    <mime:multipartRelated>
      <mime:part>
        <soap:body parts="oldPhoto" use="literal" namespace="http://examples.com/PhotoCatalog"/>
      </mime:part>
      <mime:part>
        <mime:content part="newPhoto" type="image/jpeg"/>
      </mime:part>
    </mime:multipartRelated>
  </wSDL:input>
</wSDL:operation>
```
How to Implement a Method that Throws Faults with Attachments

A method in the generated service endpoint interface that can throw a fault with attachment content contains a parameter that takes an attachment data type and throws an exception that implements oracle.webservices.attachments.AttachmentFault. An implementation of the method must create a new instance of the exception. It must also add the attachment to the exception. The oracle.webservices.attachments package provides an FaultWithAttachments.addAttachment method to do this.

See Also:

"Understanding the Streaming Attachments API" on page 2-18 for more information on the addAttachment method.

Example 2–13 illustrates an implementation of the replacePhoto operation defined by the WSDL fragment in Example 2–12. The InvalidPhoto fault defined in the WSDL is mapped to the com.examples.types.InvalidPhotoType exception class.

As required, the implementation of replacePhoto creates a new instance of the InvalidPhotoType exception. It also adds the attachment to the exception with the FaultWithAttachments.addAttachment method. The InvalidPhotoType can then be thrown as an exception which causes it to be transmitted as a SOAP fault with attachments.

Example 2–13  Implementing a Method that Throws Faults with Attachments

```java
public AttachmentPart replacePhoto(PhotoInfoType oldPhoto, Image newPhoto) throws RemoteException, com.examples.types.InvalidPhotoType {
    if (newPhoto == null) {
        return null;
    }
    if (oldPhoto.getPhotoID() == -1) {
        InvalidPhotoType typeException = new InvalidPhotoType(-1, "InvalidPhotoType","The PhotoId specified is invalid");
        try{
            Image image = javax.imageio.ImageIO.read(new File("myImage"));
            typeException.addAttachment(image,"image/jpeg");
        }catch(Exception e){
            throw new RemoteException("unexpected exeption",e);
        }
        throw typeException;
    }
    AttachmentPart impl = null;
```
try{
    MessageFactory factory = MessageFactory.newInstance();
    SOAPMessage message = factory.createMessage();
    impl = message.createAttachmentPart();
}catch(SOAPException ex){
    return null;
}
return impl;

How to Retrieve SOAP Faults with Attachments on the Client

A J2SE or J2EE Web service client can be coded to retrieve SOAP faults with attachments thrown by the service. The oracle.webservices.attachments package provides methods that can use retrieve attachment content from the fault. For example, the getAttachments method can be used to get an iterator of the list of attachments in the fault. The hasAttachments method can be used to query if a fault has an attachment.

Example 2–14 illustrates a client stub, photoCatalog, that can retrieve attachment content. The example assumes that the oldPhoto and newPhoto parameters have been previously defined, and the InvalidPhotoType exception implements oracle.webservices.attachments.AttachmentFault. Since InvalidPhotoType implements AttachmentFault, it is a SOAP fault that can contain attachments.

The hasAttachments method tests for attachments in the fault. If this method returns true, the SOAP fault has attachments. The getAttachments method retrieves all of the attachments in a SOAP fault. This method returns an iterator containing an AttachmentPart object for each attachment in the SOAP fault.

Example 2–14  Web Service Client with Code for Retrieving Attachments

```java
public class MyClientExample{

    PhotoCatalog photoCatalog = getPhotoCatalogPortType(); //create a client stub for the web service
    try{
        //assuming oldPhoto and newPhoto are defined
        photoCatalog.replacePhoto(oldPhoto, newPhoto);

        // assuming InvalidPhotoType implements AttachmentFault
        }catch(InvalidPhotoType type){
            if(type.hasAttachments()){
                java.util.Iterator it = type.getAttachments();
                AttachmentPart p = (AttachmentPart)it.next();
                //do something useful with the attachment.
            }
    }
}
```

Working with Streaming Attachments

This section contains the following subsections:

- Understanding Streaming Attachments
- Understanding the Streaming Attachments API
- WSDL Extensions for Streaming Attachments
- How to Assemble Streaming Attachments into a Web Service
Understanding Streaming Attachments

OracleAS Web Services enables you to pass large attachments as a stream. As opposed to the JAX-RPC API, which requires attachments to be materialized entirely in memory, streams make the programming model more efficient to use. Streaming attachments also enhance performance and scalability in that there is no need to load the entire attachment into memory before service execution.

Like embedded attachments, streamed attachments conform to the multipart-MIME binary format. On the wire, messages with streamed attachments are identical to any other SOAP message with attachments.

Example 2–15 provides a sample message with a streamed attachment. The first "part" in the message is the SOAP envelope (<SOAP-ENV:Envelope...). The second "part" is the attachment, in this case, myImage.gif.

Example 2–15 Sample Message with a Streamed Attachment

MIME-Version: 1.0
Content-Type: Multipart/Related; boundary=MIME_boundary; type=text/xml;
Content-Description: This is the optional message description.

--MIME_boundary
Content-Type: text/xml; charset=UTF-8
Content-Transfer-Encoding: 8bit
Content-ID: NotSure/DoesntMatter

<?xml version='1.0' ?>
<SOAP-ENV:Envelope
xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/"
<SOAP-ENV:Body>
..
<DocumentName>MyImage.gif</DocumentName>
..
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

--MIME_boundary
Content-Type: image/gif
Content-Transfer-Encoding: binary
Content-ID: AnythingYoudLike

...binary GIF image...
--MIME_boundary--

Limitations on Streaming Attachments

There are some limitations on streamed attachments in OracleAS Web Services.

- A Web service port can send only embedded attachments or streamed attachments; not both.
- Handlers cannot obtain access to streamed attachments.
Any message with streamed attachments will appear to all handlers as a SOAP message without attachments.

See Also:
"Understanding the Streaming Attachments API" for more information on the Attachments interface.

Understanding the Streaming Attachments API

The Attachments API provides a programmatic interface to streaming attachments. Streamed attachments are directional; they can be classified as "incoming" (service requests or client responses) and "outgoing" (service responses or client requests). Incoming streams can only be read and outgoing streams can only be written to.

Streaming is enabled by adding an extra parameter to each service or stub operation that wants to stream attachments. This parameter must be of type Attachments (oracle.webservices.attachments.Attachments). The Attachments interface provides methods for reading incoming attachment streams and for adding outgoing attachment streams.

The API resides in the oracle.webservices.attachments package. Table 2–2 summarizes the interfaces and classes in the Attachments API. The sections following the table provide more detail.

<table>
<thead>
<tr>
<th>Interface or Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attachment interface</td>
<td>The Attachment object consists of a String ID to identify the attachment and a data handler to retrieve the data. See &quot;Interface for Attachment Objects&quot; on page 2-18 for more information.</td>
</tr>
<tr>
<td>AttachmentFactory class</td>
<td>This factory class creates instances of Attachments and Attachment objects. See &quot;Factory Class for Attachment Objects&quot; on page 2-18 for more information.</td>
</tr>
<tr>
<td>Attachments interface</td>
<td>Root interface for managing attachments. This interface contains methods for storing attachments as either incoming or outgoing attachments. See &quot;Interface for Attachments&quot; for more information.</td>
</tr>
<tr>
<td>IncomingAttachments interface</td>
<td>Provides iterators to process incoming attachments. These can be request attachments on the server or response attachments on the client. See &quot;Interface for Incoming Attachments&quot; on page 2-19 for more information.</td>
</tr>
<tr>
<td>OutgoingAttachments interface</td>
<td>Collects outgoing attachments for streaming after the message is serialized. These can be request attachments on the client or response attachments on the server. See &quot;Interface for Outgoing Attachments&quot; on page 2-19 for more information.</td>
</tr>
</tbody>
</table>

Interface for Attachment Objects

The Attachment object consists of a String ID to identify the attachment and a data handler to retrieve the data. It is used by the addAttachment method in the OutgoingAttachments interface to add an attachment to the output stream.

```java
interface Attachment {
    public String getId();
    public DataHandler getDataHandler();
}
```
Factory Class for Attachment Objects

The package provides a factory class for creating instances of Attachments and Attachment objects. When you are using streaming attachments in a stub, you must create the Attachments object before you call the service.

```java
abstract class AttachmentFactory {
    public Attachments createAttachments();
    public Attachment createAttachment (String id,
                                       String contentType, InputStream attachmentStream);
    public Attachment createAttachment (String id, DataHandler handler);
    public static AttachmentFactory newInstance();
}
```

Interface for Attachments

Attachments is the root interface for managing attachments. The getIncomingAttachments method returns an IncomingAttachments object. It returns null if there are no incoming attachments. The getOutgoingAttachments method always returns an OutgoingAttachments object.

```java
public interface Attachments {
    IncomingAttachments getIncomingAttachments();
    OutgoingAttachments getOutgoingAttachments();
}
```

Interface for Incoming Attachments

The IncomingAttachments interface is used for request attachments on the server and for response attachments on the client. It is, essentially, an iterator over attachments. The interface includes a close method that tells the runtime to flush any remaining attachments from the stream. This must be called after all attachments have been processed so the connection can be cleared for the next request.

```java
interface IncomingAttachments {
    public boolean hasNextAttachment() throws IOException;
    public Attachment nextAttachment() throws IOException;
    public void close() throws IOException;
}
```

Interface for Outgoing Attachments

The OutgoingAttachments interface is used for request attachments on the client and for response attachments on the server. It collects attachments for streaming after the message is serialized. The interface includes an addAttachment method to add attachments to the output stream. You can create attachments using the methods described in "Factory Class for Attachment Objects".

```java
interface OutgoingAttachments {
    public void addAttachment (Attachment attachment);
}
```

WSDL Extensions for Streaming Attachments

Streaming attachments use a WSDL extension, <stream-attachments>, to notify the WebServicesAssembler tool that attachment data will be streamed. The element takes a required string attribute, name, as the parameter name for the generated Java classes and interfaces. The element is specified in an Oracle namespace:

http://oracle.com/schemas/webservices/streaming-attachments

The element can be used only at the binding operation level.
Example 2–19 illustrates a WSDL that contains the `<stream-attachments>` element. Example 2–16 illustrates the `<stream-attachments>` schema.

**Example 2–16 XML Schema for Streaming Attachments**

```xml
<schema
  xmlns="http://www.w3.org/2000/10/XMLSchema"
  xmlns:sa="http://oracle.com/schemas/webservices/streaming-attachments"
  targetNamespace="http://oracle.com/schemas/webservices/streaming-attachments">
  <element name="stream-attachments" type="sa:streamAttachmentsType"/>
  <complexType name="streamAttachmentsType">
    <attribute name="name" type="string" use="required"/>
  </complexType>
</schema>
```

**How to Assemble Streaming Attachments into a Web Service**

This section describes how to assemble a Web Service that uses streaming attachments.

- Steps for Assembling a Web Service that Supports Streaming Attachments Bottom Up
- Steps for Assembling a Web Service that Supports Streaming Attachments Top Down

**Steps for Assembling a Web Service that Supports Streaming Attachments Bottom Up**

The model for assembling a Web service bottom up that supports streaming attachments is the same as any other service based on Java classes. "Assembling a Web Service with Java Classes" in the Oracle Application Server Web Services Developer’s Guide provides more information on assembling a Web service bottom up with Java classes.

1. Write a public interface that contains the remote methods that you want to expose as a service. In this case, one or more of the methods will use the Attachment API. "How to Write an Interface for Streaming Attachments” on page 2-21 provides more information on this step.

2. Write the implementation of the service. "How to Implement a Service Interface that Uses Streaming Attachments” on page 2-21 provides more information on this step.

3. Write the stub code for the Web service client. To use a stub to send or receive attachments, you must create the Attachments object before the call. "How to Write Stub Code to Handle Streaming Attachments” on page 2-22 provides more information on this step.

4. Generate the service artifacts by running the WebServicesAssembler with the assemble command. "Sample Generated WSDL for a Service with Streaming Attachments” on page 2-21 illustrates a sample generated WSDL.

5. Deploy the service and bind the application.

6. Generate the client-side code.

7. Compile and run the client.
**How to Write an Interface for Streaming Attachments**  If you want to stream attachments as a part of your Web service, then at least one of the methods within the service interface must contain a parameter of type `Attachments` (oracle.webservices.attachments.Attachments). The `Attachments` type indicates objects will be streamed by OracleAS Web Services.

Example 2–17 illustrates the service interface for a Web service that stores large image files in a local database. The request includes an image name, a description, and the image to be stored. Note that the `attachments` parameter of type `Attachments` indicates that the image will be streamed.

**Example 2–17  Service that Uses Streaming Attachments**

```java
public interface ImageStore extends java.rmi.Remote {
    public void storeImage (String name, String desc, Attachments attachments)
        throws java.rmi.RemoteException;
}
```

If you use this interface to generate a Web service bottom up, WebServicesAssembler will detect the parameter of type `Attachments`. Support for streaming attachments will automatically be generated into the Web service.

**See Also:**

Example 2–19 for an illustration of the relevant parts of the WSDL generated by WebServicesAssembler.

**How to Implement a Service Interface that Uses Streaming Attachments**  Implementations of interfaces that include data as streaming attachments use the methods and classes of the oracle.webservices.attachments API to work with the attachment data.

Example 2–18 illustrates the implementation of the interface in Example 2–17 for a Web service that stores large image files in a local database. The implementation uses the `getIncomingAttachments` method to capture the incoming streaming attachment as an `Attachment` object. The `getId` method retrieves the attachment’s metadata and `getInputStream` stores the stream image bytes.

**Example 2–18  Service Implementation that Employs Streaming Attachments**

```java
class ImageStoreImpl {
    public void storeImage(String name, String desc, Attachments attachments)
        throws Exception {
        IncomingAttachments incomingAtts = attachments.getIncomingAttachments();
        {
            if (incomingAtts == null || !incomingAtts.hasNextAttachment())
                throw new Exception("Expected request attachments");
            Attachment imageAtt = incomingAtts.nextAttachment();
            String id = imageAtt.getId();
            DataHandler dataHandler = imageAtt.getDataHandler();
            InputStream imageStream = dataHandler.getInputStream();
            //-- Store image metadata and stream image bytes
            if (incomingAtts.hasNextAttachment())
                throw new Exception("Expected only one attachment");
        }
    }
}
```

**Sample Generated WSDL for a Service with Streaming Attachments**  Example 2–19 illustrates the relevant parts of the WSDL that WebServicesAssembler generates from the
interface in Example 2–17. The presence of the <stream-attachments> extension in the WSDL indicates that the Web service supports streaming attachments.

See Also:
"WSDL Extensions for Streaming Attachments" on page 2-19 for more information about the <stream-attachments> element and its schema.

Example 2–19  WSDL Elements for a Streaming Attachment

```
<message name="storeImageRequest">
  <part name="name" type="string"/>
  <part name="desc" type="string"/>
</message>

<portType name="ImageStorePortType">
  <operation name="storeImage">
    <input name="storeImageRequest" message="tns:storeImageRequest"/>
    <output name="storeImageResponse" message="tns:storeImageResponse"/>
  </operation>
</portType>

<binding name="ImageStoreBinding" type="tns:ImageStorePortType">
  <soap:binding style="rpc" />
  <operation name="addPerson">
    <soap:operation style="encoded" wsdl:required="true" />
    <sa:stream-attachments name="attachments" />
    <input name="storeImageRequest">
      <soap:body use="encoded" />
    </input>
    <output name="storeImageResponse">
      <soap:body use="encoded" />
    </output>
  </operation>
</binding>
```

How to Write Stub Code to Handle Streaming Attachments  The stub is the client side of the Web service. If the service wants to receive streamed attachments, the client must send them. If the service sends streamed attachments, the client must read them.

To handle streaming attachments, client code must create a new instance of an AttachmentFactory and create an Attachments object. For a request attachment, the addAttachment method can be used to add the attachment to the output stream.

For a response attachment, the client code must create a new instance of an AttachmentFactory and create an Attachments object. The client can capture the attachments with the iterator methods in the IncomingAttachments interface.

Example 2–20 illustrates stub code to store a streaming attachment. In the example, an AttachmentFactory is instantiated with the newInstance method and an Attachments object is created with the createAttachments method. The addAttachment method adds the data to the output stream.

Example 2–20  Client Code to Store a Streaming Attachment

```java
public void storeImageFile (String fileName) {
 //--  Create the attachment objects
  AttachmentFactory factory = AttachmentFactory.newInstance();
  Attachments atts = factory.createAttachments();
  Attachment imageAtt = factory.createAttachment(fileName, "image/gif",
       new FileInputStream(fileName));
  atts.getOutgoingAttachments().addAttachment(imageAtt);
}
Steps for Assembling a Web Service that Supports Streaming Attachments Top Down

Assembling a Web service that supports streaming attachments follows the general steps described in “Assembling a Web Service from a WSDL” in the Oracle Application Server Web Services Developer’s Guide. This section summarizes these steps.

To support streaming attachments, you must also edit the WSDL to add the <stream-attachments> element. Example 2–19 illustrates a WSDL that contains the <stream-attachments> element.

1. Provide a WSDL from which the Web service will be generated.
2. Edit the WSDL to add the elements that allow the Web service to support streaming attachments.
   "WSDL Extensions for Streaming Attachments" on page 2-19 provides more information on the <stream-attachments> element and its schema.
3. Use the WSDL as input to the WebServicesAssembler genInterface command.
4. Compile the generated interface and type classes.
5. Write the Java Service Endpoint interface for the Web service you want to provide.
6. Compile the Java Service Endpoint interface.
7. Generate the service by running the WebServicesAssembler tool with the topDownAssemble command.
8. Deploy the service.
9. Generate the client code.

Working with MTOM Encoded Attachments

In the current release, OracleAS Web Services and clients have the ability to process messages that are encoded in MTOM, MIME, and DIME format. MTOM (SOAP Message Transmission Optimization Mechanism) encoding allows binary content to be efficiently passed between the client and service.

This section has the following subsections:

- Understanding MTOM Encoded Attachments
- How to Assemble Support for MTOM Encoded Attachments into a Web Service
- How to Work with MTOM Encoded Attachments Programatically

Understanding MTOM Encoded Attachments

Binary content, such as an image in JPEG format, can be passed between the client and the service. In order to be passed, the binary content is typically inserted into an XML document as an xsd:base64Binary string. Transmitting the binary content in this format greatly increases the size of the message sent over the wire and is expensive in terms of the required processing space and time.

Using MTOM, binary content can be sent as a MIME attachment, which reduces the transmission size on the wire. The binary content is semantically part of the XML.
document. This is an advantage over SWA (SOAP Messages with Attachments), in that it enables you to apply operations such as WS-Security signature on the message.

Using MTOM to pass binary content as an attachment improves the performance of the Web services stack. Performance is not affected if an MTOM-encoded message does not contain binary content. For better interoperability, messages that do not contain binary content should not be MTOM encoded.

MTOM provides an optimized transmission mechanism for SOAP 1.2 messages with an envelope that contains elements of XML schema type xs:base64Binary. MTOM makes use of data handling mechanisms described in the following specifications:

- **XOP (XML-binary Optimized Packaging)**—provides a mechanism to more efficiently serialize XML Infosets that have content of type xs:base64Binary.
- **DMCBDX (Describing Media Content of Binary Data in XML)**—provides content type information for the binary data in the XML instance and schema. This information can be used to optimize the processing of binary data.
- **RRSHB (Resource Representation SOAP Header Block)**—allows a SOAP message to carry a representation of a Web resource, such as a JPEG image, in a SOAP header block. When combined with MTOM and XOP, the Web resource contained in a RRSHB SOAP header block can be transmitted as a raw binary MIME attachment instead of an xs:base64Binary string in the SOAP header.

These specifications fulfill the requirements outlined in OSUCR (SOAP Optimized Serialization Use Cases and Requirements).

**How to Assemble Support for MTOM Encoded Attachments into a Web Service**

You can use the WebServicesAssembler tool to add support for MTOM encoded attachments to a Web service and client. To do this, include the boolean `mtomSupport` attribute set to `true` in the WebServicesAssembler Ant target for top down, bottom up, or client Web service assembly.
The `mtomSupport` attribute is available only for the WebServicesAssembler `topDownAssemble`, `assemble`, and `genProxy` Ant tasks. It is not available on the command line.

- Assembling Support for MTOM Encoded Attachments into a Web Service Bottom Up
- Assembling Support for MTOM Encoded Attachments into a Web Service Top Down
- Assembling Support for MTOM Encoded Attachments into a Web Service Client
- Programatically Overriding MTOM Support for a Web Service Client

Assembling Support for MTOM Encoded Attachments into a Web Service Bottom Up

Assembling support for MTOM encoded attachments into a Web service based on Java classes is similar to assembling any other service from Java classes. The only differences are that the Java classes work with binary data and you add the `mtomSupport` attribute to the `assemble` Ant task.

See Also:

- The Oracle Technology Network provides a "How To" which demonstrates how to assemble support for MTOM encoded attachments into a Web service bottom up from Java classes and how to assemble a client. You can find the "How To" at the following Web site:
  

- For a detailed description of the steps involved in assembling a Web service bottom up, see "Assembling a Web Service from Java Classes" in the Oracle Application Server Web Services Developer’s Guide.

- For more information on the `mtomSupport` Ant attribute, see the chapter "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer’s Guide.

The example in this section assumes that methods in the following Java interface and class files will be exposed as a Web service.

Example 2–21 illustrates the Java interface `MtomBottomupSEI` with methods to be exposed as a Web service. Note that this interface has a method that accepts a `byte[]` array as an input and returns the same byte array.

**Example 2–21 Java Interface to be Exposed as a Web Service**

```java
public interface MtomBottomupSEI extends Remote{
    public byte[] echoBase64Binary(byte[] text) throws RemoteException;
}
```

Example 2–22 illustrates the Java class `MtomBottomupImpl`, the implementation of the interface to be exposed as a Web service:

**Example 2–22 Java Class to be Exposed as a Web Service**

```java
public class MtomBottomupImpl {
    public byte[] echoBase64Binary(byte[] text) {
```
You can generate the Web service artifacts by running the WebServicesAssembler with the `assemble` Ant task. The following task exposes the interface and class to two ports, one for SOAP 1.2 and the other for SOAP 1.1. The port specification for SOAP 1.2 has `mtomSupport` enabled. The compiled implementation and class files reside in the `mtom-bottomup-impl.jar`.

```xml
<oracle:assemble
    appName="mtom-bottomup"
    serviceName="mtom-bottomup"
    input="mtom-bottomup-impl.jar"
    style="rpc"
    use="literal"
    ear="mtom-bottomup.ear">
    <oracle:porttype
        interfaceName="mtom.service.MtomBottomupSEI"
        className="mtom.service.MtomBottomupImpl">
        <oracle:
            port
                soapVersion="1.2"
                uri="MtomBottomupPort"
                name="MtomBottomupPort"
                mtomSupport="true"/>
        <oracle:
            port
                soapVersion="1.1"
                uri="MtomBottomupPortSoap11"
                name="MtomBottomupPortSoap11"/>
    </oracle:porttype>
</oracle:assemble>
```

Example 2–23 illustrates part of the generated WSDL for this Web service. Note that the byte array is mapped to `xsd:base64Binary` as before. There is no WSDL or schema extension for MTOM.

**Example 2–23  WSDL Fragment for a Web Service that Supports MTOM-Encoded Attachments**

```xml
...<message
    name="MtomBottomupSEI_echoBase64Binary">
    <part
        name="text"
        type="xsd:base64Binary"/>
</message>
...<message
    name="MtomBottomupSEI_echoBase64BinaryResponse">
    <part
        name="result"
        type="xsd:base64Binary"/>
</message>
...```

Example 2–24 illustrates part of the generated `oracle-webservices.xml` deployment descriptor for the Web service. Note that the port definition for `MtomBottomupPort` contains the line `<mtom-support>true</mtom-support>` while the other port, `MtomBottomupPortSoap11`, does not. The `<mtom-support>` element has a default value of `false`.

**Example 2–24  oracle-webservices.xml Fragment for MTOM Encoded Web Service**

```xml
...<port-component
    name="MtomBottomupPort">
    <mtom-support>true</mtom-support>
    <operations>
        <operation
            name="echoBase64Binary"
            input="[http://mtom.service/]echoBase64Binary"/>
    </operations>
</port-component>
<port-component
    name="MtomBottomupPortSoap11">
```
Assembling Support for MTOM Encoded Attachments into a Web Service Top Down

Assembling support for MTOM encoded attachments into a Web service top down is similar to any other top down assembly. The only differences are that the WSDL document is written to work with binary data and you add the `<mtomSupport>` attribute to the `<topDownAssemble>` Ant task.

See Also:

- For a detailed description of the steps involved in assembling a Web service top down, see "Assembling a Web Service from WSDL" in the Oracle Application Server Web Services Developer’s Guide.

- For more information on the `<mtomSupport>` Ant attribute, see the chapter "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer’s Guide.

For example, presume that you have already provided a WSDL that can work with binary data as input to the `<genInterface>` Ant task. Also presume that you have implemented and compiled the service endpoint interface generated by the Ant task.

In the following `<topDownAssemble>` Ant task example, the Web service artifacts are assembled from the `<echo-service.wsdl>` file (illustrated in Example 2–25) and stored in the `<echo-service.ear>` file. The `<mtomSupport>` attribute is set on the definition of `EchoTestPort` to allow MTOM encoded binary attachments to be passed through that port.

```xml
<oracle:topDownAssemble
    appName="mtom-echo-service"
    wsdl="echo-service.wsdl"
    ear="echo-service.ear">
    <oracle:portType name="EchoTestPortType"
        className="mtom.service.EchoTestImpl"
        classFileName="src/mtom/service/EchoTestImpl.java">
        <oracle:port
            uri="/EchoTestPort"
            name="EchoTestPort"
            mtomSupport="true"></oracle:port>
    </oracle:portType>
</oracle:topDownAssemble>
```

This Ant task creates the following method in the service endpoint interface:

```java
... public byte[] echoPicture(byte[] picture); ...
```

The following MTOM configuration is generated into the `oracle-webservices.xml` deployment descriptor:

```xml
<mtom-support>true</mtom-support>
```

Sample WSDL that Works with Binary Data  Example 2–25 illustrates a fragment of the `echo-service.wsdl` file. This WSDL defines a single `portType` with a single operation which accepts a `xs:base64Binary` request and returns a
xs:base64Binary response. On the wire, the xs:base64Binary content will be in a MIME attachment part in binary format when MTOM is enabled.

**Example 2–25 Sample WSDL that Works with Binary Data**

```xml
...<wsdl:message name="echo-picture-Request">
  <wsdl:part name="picture" type="xsd:base64Binary"/>
</wsdl:message>
<wsdl:message name="echo-picture-Response">
  <wsdl:part name="picture" type="xsd:base64Binary"/>
</wsdl:message>
<wsdl:portType name="echo-servicePortType">
  <wsdl:operation name="echo-picture">
    <wsdl:input message="tns:echo-picture-Request"/>
    <wsdl:output message="tns:echo-picture-Response"/>
  </wsdl:operation>
</wsdl:portType>
...```

**Assembling Support for MTOM Encoded Attachments into a Web Service Client**

Assembling support for MTOM encoded attachments into a Web service client proxy is similar to assembling any other client proxy. The only differences are that the client code works with binary data and you add the `mtomSupport` attribute to the `genProxy` Ant task.

**See Also:**

- For a detailed description of the steps involved in assembling a Web service client proxy, see "Assembling a J2SE Web Service Client" in the *Oracle Application Server Web Services Developer's Guide*.
- For more information on the `mtomSupport` Ant attribute, see the chapter "Using WebServicesAssembler" in the *Oracle Application Server Web Services Developer's Guide*.

In the following `genProxy` Ant task example, the client stub is assembled from the `echo-service.wsdl` file (illustrated in Example 2–25). The `mtomSupport` attribute is set to `true` on the definition of the `EchoPort` port. This will generate a proxy which has MTOM enabled: when request messages contain relevant content, they will be sent from the `EchoPort` encoded in MTOM format.

```xml
...<oracle:genProxy wsdl="echo-service.wsdl">
  <oracle:port name="EchoPort" mtomSupport="true"/>
</oracle:genProxy>
...```

**Programmatically Overriding MTOM Support for a Web Service Client**

You can enable or disable MTOM support in the client by using the boolean `MTOM_SUPPORT` property in the `oracle.webservices.ClientConstants` class. This property enables a client stub to specify whether requests will be packaged in MTOM/XOP encoding. For examples of how to use the `MTOM_SUPPORT` property, see "How to Pass MTOM Encoded Attachments in Static Stub and Dynamic Proxy Clients" on page 2-33.
How to Work with MTOM Encoded Attachments Programatically

The following sections describe how you can use the Oracle implementation of the SOAP with Attachments API for Java (OraSAAJ) to work with MTOM encoded attachments.

- Understanding the OraSAAJ API for MTOM Encoded Attachments
- How to Use the OraSAAJ API for Attachments with Binary Content in Client Code

Understanding the OraSAAJ API for MTOM Encoded Attachments

The OraSAAJ API provides methods and properties that enable clients and services to work with binary attachments in MTOM-encoded format. These methods and properties are described in the following sections.

- MTOM_SUPPORT Property
- PACKAGING_STYLE and ATTACHMENT_STYLE_PACKAGING Properties
- OracleSOAPElement getDataHandler and setDataHandler Methods

MTOM_SUPPORT Property

The oracle.webservices.ClientConstants class provides a boolean MTOM_SUPPORT property which allows a client stub to specify whether requests will be packaged in MTOM/XOP encoding. This property is set on the port that will be sending the requests.

```java
public static final String MTOM_SUPPORT="oracle.webservices.mtomSupport";
```

If the value of the property is set to true, then requests are encoded in MTOM/XOP format. The default value is false.

See Also:
"How to Pass MTOM Encoded Attachments in Static Stub and Dynamic Proxy Clients" on page 2-33 provides examples of how to use the MTOM_SUPPORT property.

PACKAGING_STYLE and ATTACHMENT_STYLE_PACKAGING Properties

The abstract oracle.j2ee.ws.saaj.soap.MessageImpl class is an Oracle proprietary extension of the javax.xml.soap.SOAPMessage class. Among other features, the MessageImpl class provides the PACKAGING_STYLE and ATTACHMENT_STYLE_PACKAGING properties to indicate the encoding format into which the message should be serialized.

```java
public abstract class MessageImpl extends SOAPMessage {
    ...
    public static final String ATTACHMENT_STYLE_PACKAGING="AttachmentStylePackaging";
    public static final String PACKAGING_STYLE = "PackagingStyle";
    public static final String MTOM = "MTOM";
    public static final String DIME = "DIME";
    public static final String MIME = "MIME";
    ...
}
```

The Oracle proprietary MessageImpl.PACKAGING_STYLE property enables you to serialize messages into a number of different encoding formats. The encoding format is applied to a SOAPMessage object. The possible values for MessageImpl.PACKAGING_STYLE are:

- MessageImpl.MTOM—serializes a SOAPMessage into MTOM format.
MessageImpl.MIME (default)—serializes a SOAPMessage into MIME format.

MessageImpl.DIME—serializes a SOAPMessage into DIME format.

For example, the following will encode the request message into MTOM format if it contains relevant content.

...  
request.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MTOM);  
...

See Also:

"How to Pass Attachments with Binary Content in Clients that Connect with SOAPConnection" on page 2-34 provides examples of how to use the MessageImpl.PACKAGING_STYLE property.

The boolean MessageImpl.ATTACHMENT_STYLE_PACKAGING property enables you to force a message to take the encoding style specified by the MessageImpl.PACKAGING_STYLE property. If the MessageImpl.ATTACHMENT_STYLE_PACKAGING property is set to true, the message will be encoded in the format specified by MessageImpl.PACKAGING_STYLE even if it does not contain relevant content. The default value for this property is false.

For example, the following code sample will force the contents of the msg message to be encoded into MTOM format.

...  
msg.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MTOM);  
msg.setProperty(MessageImpl.ATTACHMENT_STYLE_PACKAGING, "true");  
...

If the MessageImpl.ATTACHMENT_STYLE_PACKAGING property is set to true and the MessageImpl.PACKAGING_STYLE property is not present, then the message will be encoded in MIME format (the default value of MessageImpl.PACKAGING_STYLE).

See Also:

"How to Force a Message Encoding" on page 2-35 for examples of how to use the MessageImpl.ATTACHMENT_STYLE_PACKAGING property.

Table 2–3 describes the expected output when you use the MessageImpl.ATTACHMENT_STYLE_PACKAGING property with MessageImpl.PACKAGING_STYLE.
Working with MTOM Encoded Attachments

**OracleSOAPElement getDataHandler and setDataHandler Methods**

The `oracle.webservices.soap.OracleSOAPElement` interface is an Oracle proprietary extension of the `javax.xml.soap.SOAPElement` interface. The interface contains methods for working with attachments with binary content (MTOM/XOP).

The interface has the following signature:

```java
public interface OracleSOAPElement extends SOAPElement{
    public DataHandler getDataHandler() throws SOAPException;
    public void setDataHandler(DataHandler datahandler);
}
```

**Table 2–3  Resulting Message Formats for Different PACKAGING_STYLE and ATTACHMENT STYLE_.PACKAGING Values**

<table>
<thead>
<tr>
<th>PACKAGING_STYLE Property Value</th>
<th>ATTACHMENT STYLE_PACKAGING Property Value</th>
<th>Resulting Message Format</th>
</tr>
</thead>
</table>
| not present or MTOM           | not present (default) or false            | ■ If the MTOM attachment exists, then the user receives a message in MTOM format.  
|                                |                                          | ■ If SWA attachment, then the user receives a message in MIME format.  
|                                |                                          | ■ If the attachment is neither MTOM or SWA, or if there is no attachment, then the user receives a message in Envelope-only format.  |
| MIME                           | not present (default) or false            | ■ If the attachment is in SWA format, then the user receives a message in MIME format.  
|                                |                                          | ■ If there is no SWA attachment or if the attachment is in another format, then the user receives a message in Envelope-only format.  |
| DIME                           | not present (default) or false            | ■ If the attachment is in SWA format, then the user receives a message in DIME format.  
|                                |                                          | ■ If there is no SWA attachment or if the attachment is in another format, then the user receives a message in Envelope-only format.  |
| MTOM                           | true                                     | The user receives a message in MTOM format.  |
| MIME                           | true                                     | The user receives a message in MIME format.  |
| DIME                           | true                                     | The user receives a message in DIME format.  |
| not present                    | true                                     | The user receives a message in MIME format.  |

**Note:** You do not have to use the `OracleSOAPElement` API if you do not need to access the binary content directly. If you use the DOM or SAAJ APIs, then binary content in MTOM encoding can be accessed like any other message content.

For example, assume that you are using the DOM or SAAJ APIs and you receive a message with an MTOM-encoded attachment. You can use a method such as `SOAPElement.getValue` to get a base-64 encoded binary string instead of the binary object.
The `setDataHandler` method sets the given `DataHandler` object as the data handler for this `OracleSOAPElement` object. Typically, a data handler is automatically set on an incoming message. When a message is created and populated with content, the `setDataHandler` method can get information from various data sources and add them to the message.

When the `SOAPMessage` containing this element is serialized into MTOM/XOP format, a MIME part will be created out of this `DataHandler`. When this `SOAPMessage` is serialized into other formats, then the bytes read from this `DataHandler` will be encoded into a base-64 string and set as the only child of this `OracleSOAPElement`.

The `setDataHandler` method can throw an `IllegalArgumentException` if the data handler is invalid.

**See Also:**
See "PACKAGING_STYLE and ATTACHMENT_STYLE_ PACKAGING Properties" on page 2-29 for a description of the properties that can be set on the `SOAPMessage` to serialize it into various formats.

The `getDataHandler` method can return either the `DataHandler` object created from the MTOM/XOP attachment associated with this `OracleSOAPElement` object or text in base-64 binary format.

This method assumes that the element is of type `xsd:base64Binary`, either in native base-64 string form or MTOM/XOP attachment form. If you call this method on other types of elements, then the results are undefined. This method can be called regardless of whether the associated `SOAPMessage` is packaged in MTOM/XOP format.

The `getDataHandler` method throws a `SOAPException` if these conditions are not met. For example, an exception is thrown if this `OracleSOAPElement` object has no data or if it has child elements.

**See Also:**
"How to Use the OraSAAJ API to Work With MTOM Encoded Attachments" on page 2-35 provides information and examples of how to use the methods in the `OracleSOAPElement` interface.

**How to Use the OraSAAJ API for Attachments with Binary Content in Client Code**
This section describes how to use the Oracle extensions to the SAAJ (OraSAAJ) API for attachments with binary content in client code. These extensions allow a Web service to work with SOAP 1.2 messages.

- How to Pass MTOM Encoded Attachments in Static Stub and Dynamic Proxy Clients
- How to Pass Attachments with MTOM Encoded Content in J2EE Clients
- How to Pass Attachments with Binary Content in Clients that Connect with SOAPConnection
- How to Force a Message Encoding
- How to Use the OraSAAJ API to Work With MTOM Encoded Attachments
- How to Add Binary Content with the `OracleSOAPElement` API
- How to Access Binary Content with the `OracleSOAPElement` API
How to Pass MTOM Encoded Attachments in Static Stub and Dynamic Proxy Clients  To enable or disable the ability of a Web Service client to send MTOM encoded requests, the OraSAAJ API provides the boolean MTOM_SUPPORT property in the oracle.webservices.ClientConstants package:

```java
public static final String MTOM_SUPPORT = "oracle.webservices.mtomSupport";
```

Set this property on the port that will be sending the messages. If the property is set to `true`, then any messages sent from the port will be MTOM encoded. The default value is `false`.

The property can be used in client code to override MTOM support in a client that was assembled to send MTOM encoded requests, or to enable support in a client that was assembled without MTOM.

**See Also:**

- "How to Pass Attachments with MTOM Encoded Content in J2EE Clients" provides information on how to use this property to pass MTOM encoded attachments in J2EE clients.
- "Assembling Support for MTOM Encoded Attachments into a Web Service Client" on page 2-28 provides information on how to assemble MTOM support into Web service clients.

Example 2–26 illustrates a fragment of static stub client code. It is assumed that the client was originally assembled without MTOM support. In the code fragment, the MTOM_SUPPORT property is set on the EchoPort port before the client is invoked. Any messages sent from the EchoPort port will be in MTOM-encoded format.

**Example 2–26  MTOM_SUPPORT Property in Static Stub Client Code**

```java
... //obtain the service from the ServiceFactory ServiceFactory serviceFactory = ServiceFactory.newInstance(); EchoService service = (EchoService)serviceFactory.createService(null, EchoService.class);

// get the port Object port = service.getEchoPort();

// enable MTOM support ((OracleStub)port).setProperty(MTOM_SUPPORT, "true");

// invoke the stub byte[] response = ((EchoPort)port).echoPicture(new byte[picture]);
...```

How to Pass Attachments with MTOM Encoded Content in J2EE Clients J2EE clients can pass attachments with MTOM encoded content by setting the boolean property oracle.webservices.mtomSupport to `true` in any of the Oracle proprietary client deployment descriptor files. These files are:

- `orion-web.xml` for Web clients
- `orion-ejb-jar.xml` for EJB clients
- `orion-application-client.xml` for application clients

To make a J2EE client aware of MTOM support, enter the property in the deployment descriptor file as a stub property in a `<service-ref-mapping>` clause.
Example 2–27 illustrates a sample configuration in an orion* file that enables the client to send requests in MTOM encoded format. In the sample, *service_name* represents the Web service’s service name.

**Example 2–27  Enabling MTOM in a J2EE Client**

... <service-ref-mapping name="service_name">  
   <port-info>  
      <stub-property>  
         <name>oracle.webservices.mtomSupport</name>  
         <value>true</value>  
      </stub-property>  
   </port-info>  
</service-ref-mapping> ...

How to Pass Attachments with Binary Content in Clients that Connect with SOAPConnection  The SOAPConnection object establishes a point-to-point connection that a Web service client can use to send messages to a remote party, such as a URL. This type of connection does not require a messaging provider. For this reason, a client that uses a SOAPConnection in OraSAAJ directly must serialize the request SOAPMessage into the appropriate format before calling the SOAPConnection.call method.

To serialize the message, apply the Oracle proprietary MessageImpl.PACKAGING_STYLE property to the SOAPMessage. The value of the property indicates the format into which the message will be serialized. The possible values for MessageImpl.PACKAGING_STYLE are:

- MessageImpl.DIME—serializes a SOAPMessage into DIME format
- MessageImpl.MIME— (default) serializes a SOAPMessage into MIME format
- MessageImpl.MTOM—serializes a SOAPMessage into MTOM format

The MessageImpl.PACKAGING_STYLE property produces a message in the specified encoding only when the relevant content exists. If the content is not provided, then you might get a message in an unexpected format. To force a message into a particular encoding, see the following section, "How to Force a Message Encoding".

Example 2–28 illustrates the use of the MessageImpl.PACKAGING_STYLE property. The code sample creates a request of type SOAPMessage. After adding binary content to the request message, the setProperty method identifies the encoding into which the message should be serialized. In this case, the message is serialized into MTOM encoding. The connection is then made to the remote party and the call is made with the serialized request.

**Example 2–28  MessageImpl.PACKAGING_STYLE Property in Client Code**

... SOAPMessage request = MessageFactory.newInstance().createMessage(); ...

// add some binary content ...
request.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MTOM);
SOAPConnection conn = SOAPConnectionFactory.newInstance().createConnection(); SOAPMessage response = sc.call(request, endpoint); ...
How to Force a Message Encoding  The MessageImpl.PACKAGING_STYLE property produces a message in the specified encoding only when the relevant content exists. If the relevant content is not provided, then you might get a message in an unexpected format.

For example, assume that you provide binary content for a message msg, then call the MessageImpl.PACKAGING_STYLE property with the MessageImpl.MTOM value:

```java
msg.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MTOM);
```

You will get a message in MTOM encoding.

If you provide a regular MIME attachment instead of binary, then you will receive a SWA MIME message. If you do not provide an attachment, then you will receive a SOAP-only message.

If you want to force a specific encoding on a message even if the relevant content does not exist, use the boolean MessageImpl.ATTACHMENT_STYLE_PACKAGING property with the MessageImpl.PACKAGING_STYLE property. For example, the following code sample forces the message msg to be encoded in MIME format.

```java
... SOAPMessage msg = MessageFactory.newInstance().createMessage(); ...
// add content to the message ...
...
msg.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MIME);
msg.setProperty(MessageImpl.ATTACHMENT_STYLE_PACKAGING, "true");
... 
```

See Also:

"PACKAGING_STYLE and ATTACHMENT_STYLE_PACKAGING Properties" on page 2-29 provides more information on the ATTACHMENT_STYLE_PACKAGING property.

How to Use the OraSAAJ API to Work With MTOM Encoded Attachments  The OraSAAJ API enables a Web service to work with SOAP 1.2 messages. Artifacts that use this API and SOAP 1.2 messages, such as handlers, interceptors, provider services, and BPEL, can use the oracle.webservices.soap.OracleSOAPElement interface to work with attachments with binary content.

The OracleSOAPElement interface extends the javax.xml.soap.SOAPElement interface.

This section has the following subsections:

- How to Add Binary Content with the OracleSOAPElement API
- How to Access Binary Content with the OracleSOAPElement API
Working with MTOM Encoded Attachments

See Also:

- "OracleSOAPElement getDataHandler and setDataHandler Methods" on page 2-31 provides more information on this interface.
- "OraSAAJ APIs" in the Oracle Application Server Web Services Developer’s Guide provides more information on the OraSAAJ APIs and the contents of the oracle.webservices.soap package.

How to Add Binary Content with the OracleSOAPElement API To add binary content, such as xs:base64Binary type data to a message, use the OracleSOAPElement.setDataHandler method. To encode the message into MTOM format, use the MessageImpl.PACKAGING_STYLE property.

Example 2–29 illustrates adding binary content to a message then encoding it as an attachment in MTOM format. A picture element of type SOAPElement is added to body of a SOAP message. A BufferedImage image object is defined with a height and width of 10, and a color model of one bit for each pixel, eight pixels to a byte (TYPE_BYTE_BINARY). The picture element is cast to a OracleSOAPElement, so that the setDataHandler method can be applied. This method loads the file (image/jpeg is the MIME content type that corresponds to a java.awt.Image). The MessageImpl.PACKAGING_STYLE property indicates that the binary attachment will be encoded in MTOM format. The resulting message is written to the output stream baos.

Example 2–29 Adding Binary Content to a Message as an MTOM-Encoded Attachment

```java
SOAPElement picture = msg.getSOAPBody().addChildElement("Picture");
BufferedImage image = new BufferedImage(10, 10, BufferedImage.TYPE_BYTE_BINARY);
((OracleSOAPElement)picture).setDataHandler(new DataHandler(image, "image/jpeg"));
msg.setProperty(MessageImpl.PACKAGING_STYLE, MessageImpl.MTOM);
msg.writeTo(baos);
```

How to Access Binary Content with the OracleSOAPElement API To access content from an OracleSOAPElement, use the OracleSOAPElement.getDataHandler method. The method simply provides a handler for the message data; the data does not have to be encoded.

Example 2–30 illustrates using the OracleSOAPElement.getDataHandler method to get message content. The method assumes that the message msg has an attachment that contains xs:base64Binary content, in this case, a java.awt.Image. The code gets the contents of the child elements of a SOAPMessage and stores them in a OracleSOAPElement picture. The OracleSOAPElement.getDataHandler method is then used to get the content from picture and store it in the Image object.

Example 2–30 Accessing a Message Attachment that Contains Binary Content

```java
OracleSOAPElement picture =
    (OracleSOAPElement)msg.getSOAPBody().getChildElements().next();
Image image = (Image)picture.getDataHandler().getContent();
```
Working with DIME-Encoded Attachments

This section has the following subsections:
- Understanding DIME-Encoded Attachments
- How to Implement Interoperable DIME-Encoded Messages
- How to Implement Oracle Proprietary DIME-Encoded Messages

Understanding DIME-Encoded Attachments

Direct Internet Message Encapsulation (DIME) is a format for streaming multi-part message attachments over the wire. DIME can be applied to SOAP messages with attachments. DIME separates each record, such as a SOAP message or attachment, with a simple binary SOAP header that describes the size and type of the payload. DIME also allows a given piece of payload to be broken into multiple records. This allows the sender to stream data through a buffer of constrained size.

Compared to the multipart-MIME encoding format which OracleAS Web Services uses by default, DIME requires much less processing effort to encode or decode.

OracleAS Web Services lets you choose between supporting interoperable DIME-encoded messages and messages with Oracle proprietary DIME encoding.
- Interoperable DIME encoding for messages with attachments is implemented by adding extensions to the WSDL.
- Oracle proprietary DIME encoding is implemented by allowing WebServicesAssembler to generate code that applies DIME encoding to all SOAP messages with attachments.

How to Implement Interoperable DIME-Encoded Messages

WSDL extensions for DIME-encoded messages are an implementation of Microsoft's DIME support. This technique creates messages with attachments that are interoperable with other vendors, particularly Microsoft, who implement DIME extensions in the WSDL. The extensions cause any binary data in the envelope to be extracted and placed in attachments. These messages and their attachments are then encoded in DIME.

The "WSDL Extension for SOAP in DIME" specification defines a DIME element, `<dime:message>`. If this element is added to the WSDL, then any binary data in the SOAP message is automatically removed and put into attachments. The message and its attachments are then sent in DIME format instead of the default multipart-MIME format.

See Also:
- [http://schemas.xmlsoap.org/ws/2002/04/dime/wsl](http://schemas.xmlsoap.org/ws/2002/04/dime/wsl) for the schema that defines the WSDL extensions for SOAP in DIME.

The `<dime:message>` element can be inserted into the `<wsdl:input>` and/or `<wsdl:output>` elements of a Web service operation bindings definition. Table 2–4 describes the attributes that `<dime:message>` must include.
Example 2–31 illustrates a WSDL skeleton with the extensions for DIME encoding highlighted in bold.

Example 2–31  WSDL Skeleton, with the Extensions for DIME Encoding

```xml
<wsdl:definitions ...>
    <wsdl:binding ...>
        <soap:binding .../>
        <wsdl:operation ...>
            <soap:operation .../>
            <wsdl:input>
                <dime:message layout="uri" wsdl:required="true"/>
            </wsdl:input>
            <wsdl:output>
                <dime:message layout="uri" wsdl:required="true"/>
            </wsdl:output>
        </wsdl:operation>
    </wsdl:binding>
</wsdl:definitions>
```

Limitations on OracleAS Web Services Support for Interoperable Dime Encoded Messages

- Support for DIME encoding can be assembled into a Web service only from WSDL (top down). It cannot be assembled into a Web service bottom up.

- OracleAS Web Services does not support content type definition with DIME as specified by the following namespace:
  
  ```
  ```

How to Implement Oracle Proprietary DIME-Encoded Messages

The WebServicesAssembler supports the DIME-encoded format by providing a `useDimeEncoding` argument. This argument will apply DIME encoding to all streaming SOAP messages with attachments in a generated service or stub.

The messages generated with the `useDimeEncoding` argument are not interoperable and are incompatible with non-Oracle Web services or earlier versions of Oracle.
Application Server. Generating a Web service with this argument is useful for in-house projects where performance is key.

Managing Web Services

This chapter provides an overview of Web service management for Oracle Application Server Web Services.

- Understanding Web Service Management
- How to Pass Management Information to the Server
- Working with Management Information in a J2SE Client
- Working with Management Information in a J2EE Client
- Working with Capability Assertions
- Application Server Control Support for Web Service Management

Understanding Web Service Management

Web service management is a set of policies applied against a message en-route to a target. In the case of OracleAS Web Services, the messages are SOAP requests, responses and faults, and the targets are the client and the business logic on the server. OracleAS Web Services supports policies for the following management features.

- security—configures authentication, integrity with digital signatures, and confidentiality with encryption based on the WS-Security standard.
  
  See the Oracle Application Server Web Services Security Guide for more information on this topic.

- reliability—configures guaranteed message delivery and ordering, and eliminates duplicate messages based on the WS-Reliability standard.
  
  See Chapter 5, "Ensuring Web Service Reliability" for more information on this topic.

- auditing and logging—auditing keeps a complete, persistent record of SOAP requests and faults. Logging enables content-based logging by using XPath to query the inbound and outbound SOAP messages.
  
  See Chapter 6, "Auditing and Tracing Messages" for more information on this topic.

- life cycle management—enables and disables services and their managed capabilities.
  
  See "Web Service Management Life Cycle" on page 3-4 for more information on this topic.

- deployment—configures the OracleAS Web Services proprietary deployment descriptors based on J2EE 1.4 standards.
See the chapter, "Packaging and Deploying Web Services" in the *Oracle Application Server Web Services Developer’s Guide* for more information on this topic.

Figure 3–1 illustrates the passage of a SOAP request from the client to the business logic on the server. The SOAP request passes from the client through a layer of management for outbound messages before it is sent over the wire. When it reaches the server, the request must pass through a layer of management configuration for inbound messages before it is used by the business logic. The values given to the server-side management must be coordinated with the values in the client; otherwise, the request might be rejected before reaching the service implementation.

Similarly, the response from the business logic on the server reverses the process. The response must pass through a layer of management for outbound messages before it is sent over the wire. When it reaches the client, the response must pass through a layer of management for inbound messages before the client can use it.

![Web Services Message Flow with Management Enabled](image)

As Figure 3–1 suggests, Web service management can consist of as many as four separate configurations. The server can have separate configurations for inbound messages (requests) and outbound messages (responses). The client can have separate configurations for outbound messages (requests) and inbound messages (responses).

These management policies can be configured pre-deployment within Oracle JDeveloper. Post-deployment you can configure the policies within the Oracle Application Server Control management environment.

**See Also:**
- Oracle JDeveloper on-line help.
- “Overview of Managing Web Services” and “Enabling and Disabling Web Services Management Features” topics in the Application Server Control on-line help.

**Web Service Management Environment**

Figure 3–2 illustrates the management environment. Three major product components make up this solution: the design time with Oracle JDeveloper or
WebServicesAssembler, the runtime with OracleAS Web Services Release 10.1.3.1, and the management environment with Oracle Application Server Control.

**Figure 3–2  Web Services Management Data Flow in the Server**

The following steps correspond to the numbers in the figure:

1. A developer uses Oracle JDeveloper or its command-line counterpart, WebServicesAssembler, to author a Web service and to configure the Web service management information that will be applied at runtime.

2. Oracle JDeveloper (or WebServicesAssembler) can then be used to assemble the Web service and package it in an enterprise archive (EAR). Among other Web service artifacts, the EAR also contains the `oracle-webservices.xml` file that describes management policies. This file is the application server-specific binding to the Oracle infrastructure. The `oracle-webservices.xml` file can be considered to be an extension of the standard JAX-RPC `webservices.xml` file, which defines platform-independent Web service behavior.

3. Upon deployment to OC4J, the policies in the `oracle-webservices.xml` file are automatically copied to the runtime Web services management policy file, `wsmgmt.xml`. This file resides at `ORACLE_HOME\j2ee\OC4J_instance_name\config\wsmgmt.xml` where `ORACLE_HOME` is the installation directory for OC4J.

4. Application Server Control can be used to further manipulate the management policies in `wsmgmt.xml`.

5. The Web service clients can communicate with the Application Server through the OC4J runtime.

As this figure illustrates, the creation and administration of Web services management is completely separate from the Web service, business logic, and client implementation. The management configuration can be changed independently of the implemented business logic and does not require redeployment.
In addition to the server-side policy configuration, a symmetric policy configuration is often required on the client side. OC4J provides the option to have the server-side policy expressed in the WSDL in the form of capability assertions. By providing this information in the WSDL, client-generation tools can inspect this publicly available contract. The tools can use the capability assertions to know what questions to ask in order to create a configuration that will allow the client to communicate with the server.

**See Also:**

"Working with Capability Assertions" on page 3-18 for more information on how a Web service management configuration can be added to the WSDL.

### Web Service Management Life Cycle

An important part of managing a Web service is managing its life cycle. This includes the ability to enable or disable the service’s management configuration. Application Server Control provides the ability to enable and disable security, reliability, auditing, and logging. Application Sever Control can also be used to enable or disable the entire Web service.

**See Also:**

*Oracle Containers for J2EE Deployment Guide* for information on other aspects of life cycle management, specifically deployment and undeployment.

### How to Pass Management Information to the Server

There are a number of techniques that you can use to configure server-side management information for a Web service. For example, you can write the management information into an existing *oracle-webservices.xml* file by hand or you can allow Oracle JDeveloper or WebServicesAssembler to automate the process. If the Web service is already deployed, you can use Application Server Control to configure many of the management options. The following sections summarize the ways in which you can configure server-side management information:

- **By Hand**
- **With Oracle JDeveloper**
- **With WebServicesAssembler**
- **With Application Server Control and WebServicesAssembler**

**By Hand**

1. Examine the *oracle-webservices.xsd* schema and write the management information into an existing *oracle-webservices.xml* file by hand.
2. Run the appropriate WebServicesAssembler *Assemble command to assemble your Web service.
   - Use the ddFileName argument to specify the modified oracle-webservices.xml file.
   - Optionally, use the genQosWsdl argument to insert capability assertions into the WSDL if you are generating the Web service bottom up or use genQosWsdl if you are generating the Web service top down.

3. Deploy the Web service.

**With Oracle JDeveloper**
1. Use the wizards in Oracle JDeveloper to configure a Web service. This will produce an oracle-webservices.xml file.
2. Run the appropriate wizard in Oracle JDeveloper to configure management information in the Web service.
3. Select the "add capability assertions" option if you want to insert capability assertions into the WSDL.
4. Deploy the Web service.

**With WebServicesAssembler**
1. Run WebServicesAssembler with the genDDs command to create a generic oracle-webservices.xml file.
   This step will create a "skeleton" deployment descriptor file. This file will not contain any management configuration information. It will, however, provide the basic structure of the file and indicate where the management configuration should be placed.
2. Examine the oracle-webservices.xsd schema and write the management information into an existing oracle-webservices.xml file by hand.
3. Run the appropriate *Assemble command to assemble your Web service.
   - Use the ddFileName argument to specify the modified oracle-webservices.xml file.
   - Optionally, use the genQosWsdl argument to insert capability assertions into the WSDL.
4. Deploy the Web service.

**With Application Server Control and WebServicesAssembler**
This scenario enables you to establish a default server-side configuration without having to use Oracle JDeveloper or author the configuration by hand. The following steps describe how to use Application Server Control to define and populate a default management configuration for the server side. You then copy this configuration from the runtime configuration into the deployable EAR file.

1. Run WebServicesAssembler with the appropriate *Assemble command to create a Web service. Note that a Web service created by WebServicesAssembler will not have management information unless you explicitly build it in.
2. Deploy the Web service without management information. The deployment will cause a wsmgmt.xml file to be created in OC4J.
3. Use the Web services management screens in Application Server Control to configure server-side Web service management options. These values will be reflected in the wsmgmt.xml file.

4. Copy Web service management information in the wsmgmt.xml file into the oracle-webservices.xml file that was created in Step 1.
   a. Locate the <runtime> element and the <operations> element that appear under the <port> element in the wsmgmt.xml file. Note the value of the port attribute in the <port> element.
   b. Locate the <port-component> element in the oracle-webservices.xml file, whose name attribute has the same value as the port attribute of the <port> element in the wsmgmt.xml file.
   c. Copy the <runtime> element, the <operations> element, and all of their child elements in the wsmgmt.xml file.
   d. Paste these elements into the oracle-webservices.xml file, as a children of the <port-component> element located in Step 4b.
   e. Repeat Steps 4a to 4d for each port you want to expose as a Web service.

5. Re-run the appropriate *Assemble command for your Web service.
   - Use the ddFileName argument to specify the modified oracle-webservices.xml file.
   - Optionally, use the genQosWsd1 option to insert capability assertions into the WSDL.

6. Re-deploy the Web service.

Working with Management Information in a J2SE Client

This section has the following subsections:

- Understanding Data Flow for Management Information in a J2SE Client
- How to Pass Management Information to a J2SE Client

Understanding Data Flow for Management Information in a J2SE Client

Figure 3–3 presents an overview of how Web service management information is developed, transmitted, and manipulated in the J2SE client environment.

Figure 3–3  Web Services Management Data Flow in a J2SE Client

The data flow illustrated in Figure 3–3 is summarized in the following steps.

1. A developer creates a client-side configuration file. This can be done by using the wizards in Oracle JDeveloper, or by hand, using the
Working with Management Information in a J2SE Client

 oracle-webservices-client-10_0.xsd schema. The client-side configuration file contains the client-side configuration for Web services management features such as security, reliability, and auditing. (Note: logging is not available on the client.)

2. Use either Oracle JDeveloper or WebServicesAssembler to generate a J2SE client JAR file. If WebServicesAssembler is used, the ddFileName argument to the genProxy command specifies the configuration file.

Among the files contained in the J2SE client JAR are:

- proxy class file—this file can send invocations to the server. This file typically has a <generated_name>_Stub.java extension, where generated_name is derived from the target namespace and port name in the WSDL.

- client-side configuration file—this file typically resides in the same directory as the proxy class file. It has the same generated name as the proxy class file, but with a _Stub.xml extension.

For example, given a service endpoint interface, test\proxy\Test, you can use WebServicesAssembler to generate a proxy class file, test\proxy\runtime\Test_Stub.class. The client-side configuration file, specified with the ddFileName argument, will be copied to the same directory and will be called test\proxy\runtime\Test_Stub.xml.

"Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide provides more information on using WebServicesAssembler to generate J2SE Web service clients.

3. At runtime, the generated proxy class file will read the XML file and apply the management configuration settings to the messages.

4. Requests and responses can be passed between the client and server.

How to Pass Management Information to a J2SE Client

You can use Oracle JDeveloper or WebServicesAssembler to add a management configuration to the J2SE client.

- With Oracle JDeveloper

- With WebServicesAssembler

With Oracle JDeveloper

1. Given a WSDL belonging to a Web service, use the wizards in Oracle JDeveloper to create the proxy class file and the client-side configuration file.

2. Run the appropriate wizards in Oracle JDeveloper to configure management information for the client.

3. Run the client.

With WebServicesAssembler

"Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide provides more detailed information on using WebServicesAssembler to create J2SE Web service clients.

1. Create a client-side configuration file. You can refer to the oracle-webservices-client-10_0.xsd schema and write the file by hand.
2. Given a WSDL belonging to a Web service, run WebServicesAssembler with the genProxy command to create a proxy class file. Use the ddFileName argument to specify the client-side configuration file. For example:

```xml
<oracle:genProxy
    wsdl="HelloService.wsdl"
    output="src"
    packageName="oracle.demo.hello"
    ddFileName="clientConfig.xml"/>
```

This results in the generation of several Java source files beneath the directory specified by the output parameter. In this case, the Java source files are generated into the src directory. The generated Java source file that implements the port is `oracle/demo/hello/runtime/HttpSoap11Binding_Stub.java`. The name of this file is based on the way that Java class names are derived from the targetNamespaces and port names in the WSDL. In this example the WSDL targetNamespace is `http://oracle.demo.hello/` and the name of the port is `HttpSoap11Binding`.

You can modify this default behavior using additional inputs to WebServicesAssembler. The generated _Stub.xml file will always have the same root name as the generated Java source file which implements the port.

Note that since the _Stub.xml file is generated into the source directory, you must ensure that this file is also copied to the directory into which you compile the Java source files. The following example shows how you might do this in an Ant task.

```xml
<copy todir="classes">
    <fileset dir="src">
        <include name="**/*_Stub.xml"/>
    </fileset>
</copy>
```

3. Use the client utility class file created by genProxy as your application client, or use it as a template to write your own client code. The client utility class file is one of a number of files created by genProxy.

4. Run the client.

**Working with Management Information in a J2EE Client**

This section has the following subsections:

- Understanding Data Flow for Management Information in a J2EE Client
- How to Pass Management Information to a J2EE Client

**Understanding Data Flow for Management Information in a J2EE Client**

Figure 3–4 illustrates how Web service management data is transmitted in a J2EE client.
1. To access the Web service, the J2EE client performs a JNDI lookup for a reference to the service endpoint interface.

2. At runtime, the object implementing the interface will use the management configuration used in either orion-ejb-jar.xml, orion-web.xml, or orion-application-client.xml, depending on the type of client.

The orion-*.xml file which is contained in the deployment archive has a <service-ref-mapping> element which contains the information needed to generate the service endpoint interface at runtime. The Web service management information is contained within the <service-ref-mapping> element.

"Adding OC4J-Specific Platform Information" in the Oracle Application Server Web Services Developer’s Guide provides more information on the <service-ref-mapping> element.

How to Pass Management Information to a J2EE Client

You can use Oracle JDeveloper or WebServicesAssembler to pass a management configuration to the J2EE client.

- With Oracle JDeveloper
- With WebServicesAssembler

With Oracle JDeveloper

1. Given a WSDL belonging to a Web service, use Oracle JDeveloper to create the Java service endpoint interface file and the client component descriptor file. The configuration file will be either orion-ejb-jar.xml, orion-web.xml, or orion-application-client.xml, depending on the type of client.

2. Edit the <service-ref-mapping> tag in the orion-*.xml generated for your particular client. Enter the client-side Web service management configuration within this tag.

3. Assemble and deploy the client module.

"How to Assemble a J2EE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide provides more information on assembling and deploying J2EE Web service clients.
With WebServicesAssembler

1. Run WebServicesAssembler with the genInterface command to create a Java service endpoint interface file.

2. Edit the <service-ref-mapping> tag in the orion-*.xml generated for your particular Web service. Enter the client-side Web service management configuration within this tag.

3. Assemble the client deployment module:
   a. Compile all of the client files.
   b. Copy deployment descriptor files to their appropriate locations.
   c. Package the client deployment module.

   "Packaging Web Service Applications" in the Oracle Application Server Web Services Developer’s Guide describes where deployment descriptors should reside and how they should be packaged for servlet, EJB, or JSP Web service clients.

4. Deploy the client deployment module.

5. Run the client.

**How to Pass a Management Configuration to a Client Programatically**

In all of the client-side dynamic configuration scenarios described in the following sections, the client provides a configuration for each invocation. The client does this by setting the value for the following property either on the call or on the stub or port.

```java
oracle.webservices.ClientConstants.CLIENT_CONFIG
```

The value provided can be either an XML DOM element reference to the root node, or a `java.io.File` object of a document that conforms to the Web service management client-side configuration schema. If an XML DOM element reference is provided, the client must load and parse the configuration. If a `java.io.File` object is provided, the runtime will perform the loading and parsing.

The configuration provided by the `ClientConstants.CLIENT_CONFIG` attribute will override any static configuration. The following example sets the configuration for an XML DOM element reference.

```java
...setProperty(
    oracle.webservices.ClientConstants.CLIENT_CONFIG,
    parseAndReturnElement(config));
```

This example sets the configuration for a `java.io.File` object.

```java
...setProperty(
    oracle.webservices.ClientConstants.CLIENT_CONFIG,
    new java.io.File("config file path"));
```

The override is all or nothing: if a dynamic configuration is provided, then any static configuration is completely ignored.

The following sections provide code examples of passing a management configuration to DII, dynamic proxy, static proxy, and J2EE Web service clients. In all of these cases, the configuration is defined in the following lines.
String config =
$<$port-info$> 
... 
$</port-info$>;

This can be entered into the configuration file for J2SE clients or the deployment descriptors for J2EE clients.

- How to Pass a Management Configuration to a DII Web Service Client Programmatically
- How to Pass a Management Configuration to a Dynamic Proxy Web Service Client Programmatically
- How to Pass a Management Configuration to a Static Proxy Web Service Client Programmatically
- How to Pass a Management Configuration to a J2EE Web Service Client Programmatically

**How to Pass a Management Configuration to a DII Web Service Client Programmatically**

Example 3–1 displays management configuration being passed to a DII client. The `setProperty` statement is highlighted in bold. Note the presence of the `<call-property>` element in the example. You can use this element to pass information such as an endpoint address, a user name and password, and any other standard and proprietary properties.

**Example 3–1  Properties and Management Configuration Dynamically Passed to a DII Client**

... String config =
$<$port-info$> 
$<$call-property$> 
$<$name$>...</name$>

$<$value$>...</value$>

$</call-property$>

$<$runtime$>

$<$security$>

$</runtime$>

$<$operations$>

$<$operation name='echo'>

$<$runtime$>

$<$security$>

$</runtime$>

$</operation$>

$</operations$>

$</port-info$>;
call.setProperty(
    oracle.webservices.ClientConstants.CLIENT_CONFIG,
parseAndReturnElement(config))
call.invoke(params);
...
How to Pass a Management Configuration to a Dynamic Proxy Web Service Client Programmatically

Example 3-2 displays a management configuration being passed to a dynamic proxy. The `setProperty` statement is highlighted in bold. Note the presence of the `<stub-property>` element in the example. You can use this element to pass information such as an endpoint address, a user name and password, and any other standard and proprietary properties.

**Example 3-2  Management Configuration Dynamically Passed to a Dynamic Proxy**

```java
... String config =
    "<port-info>" +
    "<stub-property>" +
    "<name>...</name>" +
    "<value>...</value>" +
    "</stub-property>" +
    "<runtime>" +
    "<security>..." + ...
    "<security>" +
    "<reliability>" + ...
    "</reliability>" +
    "</runtime>" +
    "<operations>" +
    "<operation name='echo'>" +
    "<runtime>" +
    "<security>" + ...
    "<security>" +
    "<reliability>" + ...
    "</reliability>" +
    "<auditing>" + ...
    "</auditing>" +
    "</runtime>" +
    "</operations>" +
    "</port-info>
;
((Stub)port).setProperty(
    oracle.webservices.ClientConstants.CLIENT_CONFIG,
    parseAndReturnElement(config));
port.echo("Hello");
...```

How to Pass a Management Configuration to a Static Proxy Web Service Client Programmatically

Example 3-3 displays a management configuration being passed to a static proxy. The `setProperty` statement is highlighted in bold. Note the presence of the `<stub-property>` element in the example. You can use this element to pass information such as an endpoint address, a user name and password, and any other standard and proprietary properties.

**Example 3-3  Properties and Management Configuration Dynamically Passed to a Static Proxy**

```java
... String config =
    "<port-info>" +
    "<stub-property>" +
    "<name>...</name>" +
    "<value>...</value>" +
    "</stub-property>" +
    "<runtime>" +
```
How to Pass a Management Configuration to a Client Programmatically

Example 3–4 displays a management configuration being passed to a J2EE Web service client. The setProperty statement is highlighted in bold.

**Example 3–4 Management Configuration Dynamically Passed to a J2EE Web Service Client**

...  
String config =  
"<port-info>" +  
"<runtime>" +  
"<security>" + ... + "<security>" +  
"<reliability>" +...+"<reliability>" +  
"</runtime>" +  
"<operations>" +  
"<operation name='echo'>" +  
"<runtime>" +  
"<security>" + ... + "<security>" +  
"<reliability>"+...+"<reliability>" +  
"<auditing>" +...+ "<auditing>" +  
"</runtime>" +  
"</operation>" +  
"</operations>" +  
"</port-info>";  
Context ic = new InitialContext();  
Service service = (Service)ic.lookup("java:comp/env/service/MyTestServiceRef");  
TestInterface port = (TestInterface)service.getPort(port QName, j2ee.client.TestInterface.class);  
((Stub)port)._setProperty(oracle.webservices.ClientConstants.CLIENT_CONFIG, parseAndReturnElement(config));  
port.echo("Hello");  
...

Managing Web Services  3-13
How to Pass a Static Management Configuration to a Client

A static client-side configuration is supported only for J2SE and J2EE Web service clients. It is not supported for DII or dynamic proxies.

See Also:

"How to Pass a Management Configuration to a Static Proxy Web Service Client Programatically" on page 3-12 for a description of static proxies and how they are supported.

The Enterprise Web Services 1.1 specification defines a deployment descriptor for each J2EE component type. The deployment descriptor contains information that allows the component to access a Web service endpoint.

Each standard J2EE Web services deployment descriptor has a corresponding Oracle proprietary deployment descriptor. The purpose of an Oracle proprietary deployment descriptor is to provide deployment-specific configuration information. While the application developer might specify suitable defaults, the Oracle proprietary deployment descriptors allow the deployer to change deployment settings without affecting the application. The names of the Oracle proprietary deployment descriptors are identical to the standard descriptors, except they have an orion- prefix. Table 3–1 lists the standard deployment descriptor and Oracle proprietary deployment descriptor for each J2EE component.

<table>
<thead>
<tr>
<th>J2EE Component</th>
<th>Standard J2EE Web Services Deployment Descriptor</th>
<th>Oracle Proprietary Deployment Descriptor</th>
</tr>
</thead>
<tbody>
<tr>
<td>application client</td>
<td>application-client.xml</td>
<td>orion-application-client.xml</td>
</tr>
<tr>
<td>EJB</td>
<td>ejb-jar.xml</td>
<td>orion-ejb-jar.xml</td>
</tr>
<tr>
<td>JSP or Servlet</td>
<td>web.xml</td>
<td>orion-web.jar</td>
</tr>
</tbody>
</table>

The standard deployment descriptors contain a <service-ref> element. This element captures all of the Web service access information, such as the location of the WSDL and mapping file, the service interface, the service ports, and their related service endpoint interfaces.

One of the elements within <service-ref> is <service-ref-name>. The value of the <service-ref-name> element in the standard descriptor maps to the value of the name attribute in the <service-ref-mapping> element in the proprietary (that is, the orion-*) descriptor. This reference provides the JNDI path and service name assigned by the client.

The Oracle proprietary deployment descriptors contain structures that use the value of the <service-ref-mapping> element to map to its corresponding standard deployment descriptor. Within this element is a <port-info> element. This element provides all of the information, including Web service management information, for a port within a service reference. The structure and content of the <port-info> element is the same for every type of client.
The following sections describe how the standard and Oracle proprietary deployment descriptors are used to provide static configuration information to J2EE Web service clients.

- How to Pass a Static Management Configuration to a Servlet or JSP Web Service Client
- How to Pass a Static Management Configuration to an EJB Web Service Client
- How to Pass a Static Management Configuration to an Application Client Web Service Client

How to Pass a Static Management Configuration to a Servlet or JSP Web Service Client

Example 3–5 displays a fragment of a web.xml deployment descriptor for a Servlet or JSP Web service client. The <service-ref-name> element contains the reference to the static configuration for the client.

Example 3–6 displays the corresponding orion-web.xml file. The <service-ref-mapping name="..."/> element also contains the reference. The <port-info> element within <service-ref-mapping> contains the Web service management information.

The values for the <service-ref-name> and <service-ref-mapping> elements must match. These elements are highlighted in bold.

Example 3–5  web.xml—Static Configuration for a Servlet or JSP Web Service Client

```xml
<web-app>
  ...
  <service-ref>
    <service-ref-name>service/MyTestServiceRef</service-ref-name>
    ...
  </service-ref>
  ...
</web-app>
```

Example 3–6  orion-web.xml—Static Configuration and Management Information for a Servlet or JSP Web Service Client

```xml
<orion-web-app ...>
  <service-ref-mapping name="service/MyTestServiceRef">
    <port-info>
      ...
    </port-info>
    ...
  </service-ref-mapping>
  ...
</orion-web-app>
```

See Also:

- "Adding J2EE Web Service Client Information to Deployment Descriptors" in the Oracle Application Server Web Services Developer’s Guide for information on the <service-ref> element.
How to Pass a Static Management Configuration to an EJB Web Service Client

Example 3–7 displays a fragment of an ejb-jar.xml deployment descriptor for an EJB Web service client. The <service-ref-name> element contains the reference to the static configuration for the client.

Example 3–8 displays the corresponding orion-ejb-jar.xml file. The <service-ref-mapping name="..."> element also contains the reference. The <port-info> element within <service-ref-mapping> contains the Web service management information.

The values for the <service-ref-name> and <service-ref-mapping> elements must match. These elements are highlighted in bold.

**Example 3–7  ejb-jar.xml—Static Configuration for an EJB Web Service Client**

```xml
<ejb-jar ...>
  ...
  <enterprise-beans>
    <session>
      <ejb-name>EjbServiceConsumer</ejb-name>
      ...
      <service-ref>
        <service-ref-name>service/MyTestServiceRef</service-ref-name>
      </service-ref>
    </session>
  </enterprise-beans>
</ejb-jar>
```

**Example 3–8  orion-ejb-jar.xml—Static Configuration and Management Information for an EJB Web Service Client**

```xml
<orion-ejb-jar ...>
  ...
  <enterprise-beans>
    <session-deployment name="EjbServiceConsumer">
      <service-ref-mapping name="service/MyTestServiceRef">
        <port-info>
          ...
          <runtime>
            <security/>
          </runtime>
        </port-info>
      </service-ref-mapping>
    </session-deployment>
  </enterprise-beans>
</orion-ejb-jar>
```
How to Pass a Static Management Configuration to an Application Client Web Service Client

Example 3–9 displays a fragment of an application-client.xml deployment descriptor for an application client Web service client. The <service-ref-name> element contains the reference to the static configuration for the client.

Example 3–10 displays the corresponding orion-application-client.xml file. The <service-ref-mapping_name> element also contains the reference. The <port-info> element within <service-ref-mapping> contains the Web service management information.

The values for the <service-ref-name> and <service-ref-mapping> elements must match. These elements are highlighted in bold.

**Example 3–9 application-client.xml—Static Configuration for an Application Client Web Service Client**

```xml
<application-client>
  ...
  <service-ref>
    <service-ref-name>service/MyTestServiceRef</service-ref-name>
  ...
  </service-ref>
</application-client>
```

**Example 3–10 orion-application-client.xml—Static Configuration and Management Information for an Application Client Web Service Client**

```xml
<orion-application-client>
  <service-ref-mapping name="service/MyTestServiceRef">
    <port-info>
      ...
      <runtime>
        <security/>
      </runtime>
      <operations>
        <operation name="echo">
          <runtime>
            <security/>
          </runtime>
        </operation>
      </operations>
    </port-info>
  </service-ref-mapping>
</orion-application-client>
```
Working with Capability Assertions

This section contains the following subsections:

- Understanding Capability Assertions
- How to Assemble Capability Assertions into a Web Service

Understanding Capability Assertions

Capability assertions are descriptions of Web service management policies, such as security and reliability. They allow consumers of Web services to discover which management policies are enabled for the Web service.

For example, assume that you created a Web service that requires a security token, such as a user name and password. The client will not be able to access the service unless it is aware of this requirement. Capability assertions provide hints to the client that a user name and password must be placed in the message SOAP headers at runtime.

Capability assertions are derived from the server-side Web service management configuration in the `oracle-webservices.xml` deployment descriptor and generated into the WSDL. The generation can be performed either by Oracle JDeveloper wizards or WebServicesAssembler commands.

For the generation of an OracleAS Web Services client, a WSDL and configuration file are used as input. The configuration file describes some of the built-in behavior of the generated client and is based on the `oracle-webservices-client-10_0.xsd` schema. The configuration file can be written by hand or created by a tool, such as Oracle JDeveloper. The capability assertions from the WSDL are used as hints to help in the creation of the client-side configuration.

For a J2SE client, the client-side configuration file is automatically packaged with the proxy classes when they are generated. For a J2EE client, the client-side configuration is set up at deployment time.

How to Assemble Capability Assertions into a Web Service

You can use either the WebServicesAssembler or Oracle JDeveloper tool to assemble capability assertions into a Web service. For example, you can use either of these tools to assemble capability assertions into the WSDL that state that a user name and password are required to access the service.

If you use Oracle JDeveloper to assemble the client, it can take this information and prompt you for a user name and password. Oracle JDeveloper will create a client-side configuration file that will be used at runtime to place this user name and password into the message SOAP headers.

If you use WebServicesAssembler to assemble the client, you will have to understand the capability assertions in the WSDL and author the client-side configuration accordingly. You must then either pass the configuration to WebServicesAssembler with the `ddFileName` argument for packaging with the client proxy or pass it to the call or proxy at runtime.

The following generalized steps summarize the process of including capability assertions in your Web service:
1. Create the server-side Web service management configuration for security, reliability, auditing, and logging by hand or by using Oracle JDeveloper.

   ■ **By Hand:** enter the management configuration into the oracle-webservices.xml deployment descriptor by hand.

   ■ **Oracle JDeveloper:** use the Oracle JDeveloper wizards to choose the Web service management options. The wizards will enter this information into the oracle-webservices.xml deployment descriptor.

2. Assemble the capability assertions into the Web service, or simply assemble them into the WSDL by using either the WebServicesAssembler or Oracle JDeveloper tool.

   ■ **WebServicesAssembler:** to assemble capability assertions into an existing WSDL, use the genQosWsdl command, and specify the name of the file (typically the oracle-webservices.xml deployment descriptor) that contains the capability assertions.

   To assemble capability assertions into a Web service, call any of the top down or bottom up Web service assembly commands that support the genQos argument. This argument directs the WebServicesAssembler tool to derive the assertions from a specified file (typically the oracle-webservices.xml deployment descriptor) and insert them into the WSDL.

   See "How to Add Capability Assertions with WebServicesAssembler" for more information.

   ■ **Oracle JDeveloper:** select the "Capability Assertions" option in the Web service management configuration wizard to assemble capability assertions into the WSDL.

3. Generate the client code by using either WebServicesAssembler or Oracle JDeveloper.

   ■ **WebServicesAssembler:** supply a WSDL and client-side configuration file to the genProxy command (for a J2SE client) or genInterface command (for a J2EE client); use the ddFileName argument to specify the client-side configuration file.

   ■ **Oracle JDeveloper:** use the appropriate Oracle JDeveloper wizard to generate either J2SE or J2EE client code.

4. Run the client code:

   ■ for a J2SE client, compile and run the client

   ■ for a J2EE client, deploy, then run the client

**How to Add Capability Assertions with WebServicesAssembler**

WebServicesAssembler gives you the option of either assembling capability assertions for reliability into the Web service (bottom up or top down) or simply assembling them into the WSDL. This section has the following subsections:

■ **Steps to Assemble Capability Assertions into a Web Service**

**Steps to Assemble Capability Assertions into a WSDL**
WebServicesAssembler tool will derive the capability assertions from the contents of an oracle-webservices.xml deployment descriptor and enter them into the WSDL.

1. Enter the capability assertions into an oracle-webservices.xml deployment descriptor.

2. Call the appropriate WebServicesAssembler command to assemble the Web service. Set the genQos argument to true to assemble capability assertions into the WSDL. Use the ddFileName argument to specify the oracle-webservices.xml deployment descriptor that contains the assertions.

**See Also:**

- For complete instructions on top down and bottom up Web service assembly, see the Oracle Application Server Web Services Developer’s Guide.
- See "ddFileName" and "genQos" in the "WebServicesAssembler Arguments" section of the Oracle Application Server Web Services Developer’s Guide for more information on these arguments.

**Steps to Assemble Capability Assertions into a WSDL** The WebServicesAssembler tool provides a command, genQosWsdl, that enables you to assemble capability assertions into a WSDL without generating additional files.

1. Call the WebServicesAssembler tool with the genQosWsdl command.

2. Use the ddFileName argument to specify the name of the file that contains the capability assertions (typically, this will be the oracle-webservices.xml deployment descriptor) and the wsdl argument to specify the name of the WSDL into which they will be inserted.

**See Also:**

"genQosWsdl" in the Oracle Application Server Web Services Developer’s Guide

Example 3–11 provides an excerpt from a generated WSDL with capability assertion tags. You can edit the generated values in the WSDL to change their effect. Note, that if you edit the WSDL, then you will have to regenerate the endpoint and any clients.

**Example 3–11  WSDL Fragment, Containing Capability Assertions for Reliability**

```xml
...<binding name="HttpSoap11Binding" type="tns:Bank">
<soap:binding style="rpc" transport="http://schemas.xmlsoap.org/soap/http"/>
<operation name="deposit">
<soap:operation soapAction="http://www.oracle.com/bank/deposit"/>
<capability-assertions wsdl:required="true">
<guaranteed-delivery required="true">
<reply-patterns callback="true" poll="true" response="true"/>
</guaranteed-delivery>
<duplicate-elimination required="true"/>
</capability-assertions>
<input>
<soap:body use="encoded" namespace="http://www.oracle.com/bank" encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" parts="accountName amount"/>
</input>
</operation>
```
How to Add Capability Assertions with Oracle JDeveloper
To add capability assertions to a Web service with Oracle JDeveloper, select the "Capability Assertions" option in the Web service management configuration wizard.

Application Server Control Support for Web Service Management
The following sections briefly describe the functionality for managing a Web service that is available by using Application Server Control.

Configuring, Enabling, and Disabling Web Service Management Features
You can use the Application Server Control to manage the Web services you deploy. For example, you can deploy your Web service applications, perform configuration tasks, and monitor your Web service ports.

In addition, you can perform administration tasks associated with standard Web Service Management features, which include auditing, logging, reliability, and security. Web Service Management is a set of policies applied against a message en-route to a target. In the case of OracleAS Web Services, the messages are SOAP requests, responses, and faults, and the targets are the client and the business logic on the server.

See Also:
Overview of Web Services Management and Enabling and Disabling Web Service Management Features topics in the Application Server Control on-line help for instructions on how to configure, enable, and disable Web service management features.

Enabling and Disabling a Web Service
You can use Application Server Control to enable a disabled Web service or disable an enabled Web service for an OC4J instance.

See Also:
Enabling and Disabling a Web Service in the Application Server Control on-line help for instructions on how to enable and disable a Web service.

Configuring Auditing for a Web Service
The Auditing feature of Web Service Management enables you to keep a complete, persistent record of SOAP requests, responses, and faults. During development it is often very convenient to be able to inspect the contents of SOAP requests and responses to diagnose problems.

Auditing captures request, response, and fault messages and stores them in the following persistent file.

```
ORACLE_HOME\j2ee\OC4JInstanceName\log\instanceName_groupName_n\wsmgmt\auditing\log.xml
```

See Also:
Configuring Auditing for a Web Service in the Application Server Control on-line help for instructions on how to configure auditing.
Configuring Logging for a Web Service
When you configure logging for a Web service, you can identify the attributes you want logged from incoming, outgoing, and fault SOAP messages. Logging messages are stored in the following persistent file.

```
ORACLE_HOME\j2ee\OC4JInstanceName\log\instanceName_groupName_instanceName_groupName_wsmgmt\logging\log.xml
```

See Also:
Configuring Logging for a Web Service in the Application Server Control on-line help for instructions on how to configure logging for a Web service.

Configuring Reliability for a Web Service
You can use Application Server Control to configure your Web service with reliable messaging. Reliable messaging allows users of the Web services stack to exchange SOAP messages without duplicates and with guaranteed delivery and message ordering.

See Also:
Configuring Reliability for a Web Service in the Application Server Control on-line help for instructions on how to configure reliability for a Web service.

Configuring Security for a Web Service
You can use Application Server Control to configure your Web service with authentication, integrity with digital signatures, and confidentiality with encryption based on the WS-Security standard.

See Also:
Configuring Security for a Web Service in the Application Server Control on-line help for instructions on how to configure security for a Web service.

Viewing the WSDL for a Web Service
You can use Application Server Control to view the WSDL for a Web service. You cannot edit the contents of the WSDL file, but you can review the contents to verify the attributes and characteristics of the Web service.

See Also:
Specifying an XPath When Configuring Web Services Logging in the Application Server Control on-line help for instructions on how to view the WSDL.

Testing a Web Service
You can use Application Server Control to test a Web service. When you test the Web service, you display its Home Page. The Web Services Home Page URL is also the service endpoint that the Web service exposes to its clients. From this URL you can invoke the operations for values that you enter and verify that the Web service is responding appropriately.
Managing Web Services

Viewing Web Service Operations
You can use Application Server Control to view Web service operations and operation metrics.

See Also:
Viewing Web Service Operations in the Application Server Control on-line help for instructions on how to view Web service operations and operation metrics.

Additional Information
For more information on:
- adding security features to a Web service, see Chapter 4, "Ensuring Web Services Security" and the Oracle Application Server Web Services Security Guide.
- adding reliable messaging to a Web service, see Chapter 5, "Ensuring Web Service Reliability".
- adding logging and auditing to a Web service, see Chapter 6, "Auditing and Tracing Messages".
- assembling a Web service top down, see "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer’s Guide.
- using Java classes to assemble a Web service, see "Assembling a Web Service with Java Classes" in the Oracle Application Server Web Services Developer’s Guide.
- using EJBs to assemble a Web service, see "Assembling a Web Service with EJBs" in the Oracle Application Server Web Services Developer’s Guide.
- using JMS topics and destinations to assemble a Web service, see "Assembling Web Services with JMS Destinations" in the Oracle Application Server Web Services Developer’s Guide.
- using database resources, such as PL/SQL packages, SQL queries, DML statements, Oracle Streams AQ, or server-side Java classes, to assemble a Web service, see "Assembling Database Web Services" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2EE Web Service client, see "Assembling a J2EE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2SE Web service client, see "Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- packaging and deploying of Web services, see "Packaging and Deploying Web Services" in the Oracle Application Server Web Services Developer’s Guide.
- using WebServicesAssembler commands to assemble Web service artifacts, see "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer’s Guide.
- using Oracle JDeveloper to add management information to a Web service, see the Oracle JDeveloper on-line help.
■ using Application Server Control to add management information to a Web service, see the Application Server Control on-line help.
Ensuring Web Services Security

Web services security is described in the Oracle Application Server Web Services Security Guide. The Security Guide contains the following chapters:

- Chapter 1, "Introduction"
  This chapter introduces essential Web service security concepts, standards, and specifications. It is divided into the following sections:
  - Web Service Security Concepts
  - Web Services Security Support in OC4J
  - Tool Support for Web Services Security

- Chapter 2, "Configuring Web Services Security"
  This chapter describes the Web service security configuration elements that can be used to secure a Web service on the client and the server. It is divided into the following sections:
  - Keystore Elements
  - Signature and Encryption Key Elements
  - Nonce Configuration Elements
  - Security Elements for Inbound Messages
  - Security Elements for Outbound Messages

- Chapter 3, "Administering Web Services Security"
  This chapter describes administration tasks for Web services security. It is divided into the following sections:
  - Using Keystores
  - Integrating Security Tokens with Security Providers
  - Using a Username Token
  - Using an X.509 Token
  - Using a SAML Token
  - Configuring XML Encryption
  - Configuring XML Signature
  - Combining Tokens, Encryption, and Signature

- Chapter 4, "Building Secure Web Services"
This chapter provides the generalized steps for assembling a secure Web service. Oracle Application Server Web Services provides the WebServicesAssembler tool which enables you to assemble the service top down (from a WSDL) or bottom up (from Java classes, EJBs, or database resources).

– Assembling a Secure Web Service
– Creating a Server-Side Security Configuration File
– Creating a Client-Side Security Configuration File
– Client JAR Files
– Adding Transport-Level Security to a Web Service
– Ant Tasks and WebServicesAssembler
– Getting an Authenticated User Identity in a Web Service Application
– Performing JAAS Provider Authorization on a Web Service
– WS-Security and XML APIs
– Development Decisions

■ Chapter 5, "Secure Web Service Usage Scenarios"
This chapter discusses common scenarios for using Web service security. It begins with the simplest use case, then proceeds through increasingly more complex use cases. The first section of the chapter discusses use cases with no security implications; these are then modified to add security features. It contains the following sections:
– Non-Secured Web Services
– HTTP-Based Security
– WS-Security
– XML Signature
– XML Encryption
– Gateways
– Identity Management
– Interoperability

■ Chapter 6, "Troubleshooting"
This chapter describes solutions to some of the errors you might encounter when working with OracleAS Web Services Security. The errors are divided into these categories.
– General Errors
– Keystore-Related Errors
– Message Integrity Errors
– Message Confidentiality Errors
– Authentication Errors

■ Appendix A, "OracleAS Web Services Security Schema"
This appendix describes the contents of the OracleAS Web Services Security schema file, oracle-webservices-security-10_0.xsd.
Appendix B, "Security Threats and Solutions"

This appendix describes how the functionality in OracleAS Web Services can be used to address the threats to security that are present in today’s Web environment.

Additional Information

For more information on:

- securing a Web service, see the Oracle Application Server Web Services Security Guide
- adding Web service management information, including security, to a Web service, see Chapter 3, "Managing Web Services".
- adding reliability information to a Web service, see Chapter 5, "Ensuring Web Service Reliability".
- adding auditing and logging information to a Web service, see Chapter 6, "Auditing and Tracing Messages".
- assembling a Web service top down, see "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer’s Guide.
- using Java classes to assemble a Web service, see "Assembling a Web Service with Java Classes" in the Oracle Application Server Web Services Developer’s Guide.
- using EJBs to assemble a Web service, see "Assembling a Web Service with EJBs" in the Oracle Application Server Web Services Developer’s Guide.
- using JMS topics and destinations to assemble a Web service, see "Assembling Web Services with JMS Destinations" in the Oracle Application Server Web Services Developer’s Guide.
- using database resources, such as PL/SQL packages, SQL queries, DML statements, Oracle Streams AQ, or server-side Java classes, to assemble a Web service, see "Assembling Database Web Services" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2EE Web Service client, see "Assembling a J2EE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2SE Web service client, see "Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- using WebServicesAssembler commands to assemble Web service artifacts, see "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer’s Guide.
- the contents of the oracle-webservices.xml deployment descriptor which contains the Web services management configuration, see "Packaging and Deploying Web Services", in the Oracle Application Server Web Services Developer’s Guide.
- the contents of the wsmgmt.xml file which contains the security configuration, see Appendix A, "Understanding the Web Services Management Schema".
Ensuring Web Service Reliability

Message exchange in Web services can be inherently unreliable. It is not well-suited for long-running conversations in a reliable fashion without additional infrastructure. To use Web services for mission-critical, complex business processes, you must be able to exchange messages reliably. To this end, Oracle Application Server Web Services provides the ability to add quality of service (QOS) guarantees around reliable messaging according to the OASIS WS-Reliability 1.1 specification.

See Also:

WS-Reliability 1.1 is a specification for open, reliable Web service messaging including guaranteed delivery, duplicate message elimination and message ordering, enabling reliable communication between Web services. The reliability features are based on extensions to the Simple Object Access Protocol (SOAP), rather than being tied to the underlying transport protocol. The specification allows a variety of systems to interoperate reliably in a platform- and vendor-neutral manner.

Note: The Reliability 1.1 specification is different from the WS-Reliable Messaging specification proposed by Microsoft, BEA, IBM, and others. It is also different from the WS-Reliability Exchange (WS-Rx) specification. In the current release, OracleAS Web Services does not support these two specifications.

Reliability allows users of the Web services stack to exchange SOAP messages without duplicates and with guaranteed delivery and message ordering. The information that allows messages to be delivered in a reliable fashion is contained in extensions to the SOAP message headers. The SOAP header extensions, the details of the messaging model, and the semantics associated with it are defined by the WS-Reliability specification.

Reliability encompasses the following features.
- guaranteed delivery—ensures that a sent message will be received.
- duplication elimination—ensures that the receiver will not see any duplicate messages (messages with the same message ID are treated as duplicates).
- guaranteed message delivery and duplicate message elimination—ensures that all messages sent will be received, and any duplicate messages will be removed.
Prerequisites for the Database Store

The following sections describe the requirements you must satisfy before you can use reliable messaging between the server and client.

- Provide a Running Database
- Install SQL Tables for the Client and Server

Provide a Running Database

You can configure reliable messaging such that messages will be stored in the server-side memory store or in a database store. If you choose to use a database store, then a database must be accessible through JNDI from the server before the reliable service is deployed.

Install SQL Tables for the Client and Server

To enable reliable messaging, you must install certain SQL tables on both the client and the server. The SQL scripts that install these tables are stored in the \texttt{j2ee/home/database/webservices/reliability/oracle} directory.

- \texttt{clear-tables.sql}—can be used to delete all records from the server-side reliability tables. This script is provided as a convenience and should be used only by the database administrator if the tables are in an irreversibly inconsistent state.
- \texttt{drop-tables.sql}—can be used to drop all of the client and server reliability tables.
- \texttt{reliability-tables.sql}—creates reliability tables on both the client and server. The tables required on the server are \texttt{RM_SERVER_MESSAGE_INFO} and \texttt{RM_SERVER_GROUP_INFO}. The tables required on the client are \texttt{RM_CLIENT_MESSAGE_INFO} and \texttt{RM_CLIENT_GROUP_INFO}. If you are developing only a client or a server, then only its respective table has to be installed.

The scripts can be executed on the command line with the following SQL*Plus command.

\texttt{sqlplus username/password @sql_script}
In this command, *username* and *password* are your user name and password for executing SQL scripts; *sql_script* is the name of the SQL script.

### How to Change the Widths of Database Columns

By default, database column widths for fields such as GROUP_ID, REPLY_TO_URL, URL_PATTERN, and ENDPOINT_ADDRESS are set to 150. However, some applications might generate longer names. This is likely to happen if you are working with unusually long URLs or host names. If a generated name is longer than the specified column width, then a database error can be returned.

To avoid this problem, you can modify the reliability-tables.sql script to increase the column widths of the server-side and client-side tables. Example 5–1 illustrates a modified reliability-tables.sql script where the column width of the GROUP_ID, REPLY_TO_URL, URL_PATTERN and ENDPOINT_ADDRESS fields have been increased from 150 to 250.

**Example 5–1 reliability-tables.sql with Modified Column Widths**

```
CREATE TABLE RM_SERVER_MESSAGE_INFO (  
  GROUP_ID varchar(250),  
  SEQUENCE_NUM number,  
  TIMESTAMP number,  
  EXPIRY_TIME number,  
  RETRY_COUNT number,  
  ACK_STATUS varchar(50),  
  PROCESS_STATUS varchar(50),  
  REPLY_TO_URL varchar(250),  
  ENDPOINT_ADDRESS varchar(250),  
  URL_PATTERN varchar(250),  
  REPLY_PATTERN varchar(150),  
  FAULT_CODE varchar(50),  
  LAST_UPDATE number,  
  CONTENT_TYPE varchar(150),  
  SOAP_ACTION varchar(150),  
  MESSAGE BLOB,  
  PIPELINE_CONFIG BLOB,  
  CONSTRAINT RM_SERVER_MESSAGE_INFO_PK PRIMARY KEY (GROUP_ID, SEQUENCE_NUM));

CREATE TABLE RM_SERVER_GROUP_INFO (  
  GROUP_ID varchar(250) PRIMARY KEY,  
  SEQUENCE_NUM number,  
  LAST_UPDATE number,  
  TIMESTAMP number,  
  GROUP_EXPIRY_TIME number,  
  GROUP_MAX_IDLE number,  
  REPLY_TO_URL varchar(250),  
  ENDPOINT_ADDRESS varchar(250));
```

### How to Add Reliable Messaging to a Web Service

To enable reliable messaging, you have to configure it into the Web service on the server side and into the client. The following sections describe how to use the WebServicesAssembler tool to add a reliability configuration to a Web service. A configuration can be added in a top down or bottom up Web service assembly. The tool can also assemble a Web service client. In each case, the configuration is specified in an XML file and passed to the WebServicesAssembler command with the *ddFileName* argument.
For information on assembling static stub and DII clients that can support reliable messaging, see "How to Configure Reliability on the Client" on page 5-12.

- Steps to Assemble Reliability into a Web Service Bottom Up
- Steps to Assemble Reliability into a Web Service Top Down
- Steps to Assemble Reliability into a J2SE Web Service Client Proxy
- Steps to Assemble Reliability into a J2EE Web Service Client

Steps to Assemble Reliability into a Web Service Bottom Up

The following general steps describe how to assemble a reliability configuration into a Web service bottom up. The Oracle Application Server Web Services Developer’s Guide provides complete information on how you can assemble Web services bottom up from Java classes, EJBs, JMS queues, or database resources.

1. Create the XML file that provides settings for the reliability features.

   The file should be based on the oracle-webservices-10_0.xsd schema. Example 5–3 illustrates an XML file that contains a reliability configuration. "Server-Side Reliability Configuration Elements" on page 5-9 describes the port-level and operation-level reliability features that are available on the server.

2. Use the appropriate *Assemble command to assemble the Web service. Use the ddFileName argument to pass the name of the XML file that contains the reliability configuration to the command.

   See "Web Service Assembly Commands" in the Oracle Application Server Web Services Developer’s Guide for descriptions of the *Assemble commands.

   See "ddFileName" in the "Deployment Descriptor Arguments" section of the Oracle Application Server Web Services Developer’s Guide for a description of this argument.

   If you are also assembling capability assertions into the Web service, use the genQos argument set to true. For more information on capability assertions, see "Working with Capability Assertions" on page 3-18.

   Example 5–2 illustrates an assemble Ant task that uses the ddFileName argument to add the reliability configuration in wsmBankServiceConfig.xml to the Web service.

   **Example 5–2  Passing a Reliability Configuration in a Bottom Up Web Service Assembly**

   ```xml
   <oracle:assemble appName="bank"
   targetNamespace="http://www.oracle.com/bank"
   typeNamespace="http://www.oracle.com/bank"
   serviceName="Banking"
   interfaceName="oracle.ws.server.bank.Bank"
   className="oracle.ws.server.bank.BankImpl"
   input="./build/classes/service"
   output="build"
   genQos="true"
   ear="build/bank.ear"
   style="rpc"
   use="encoded"
   createOneWayOperations="true"
   ddFileName="wsmBankServiceConfig.xml"
   />
   </oracle:assemble>
   ```
Example 5–3 illustrates the contents of the wsmBankServiceConfig.xml for a server-side reliability configuration. Note that the contents of the file are enclosed in the <oracle-webservices> element. The reliability configuration is highlighted in bold.

**Example 5–3 Sample Server-Side Reliability Configuration**

```xml
<oracle-webservices xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:noNamespaceSchemaLocation="oracle-webservices-management-10_0.xsd" schema-major-version="10" schema-minor-version="0">
  <webservice-description name="Banking">
    <port-component name="HttpSoap11">
      <runtime enabled="reliability">
        <reliability>
          <repository name="bank-server-store" type="memory"/>
          <ack-interval value="60"/>
          <order-interval value="60"/>
          <cleanup-interval value="10000"/>
          <ack-limit value="10"/>
          <max-age value="86000"/>
        </reliability>
      </runtime>
      <operations>
        <operation name="deposit">
          <runtime>
            <reliability>
              <duplication-elimination-required value="true"/>
              <guaranteed-delivery-required value="true"/>
            </reliability>
          </runtime>
        </operation>
      </operations>
    </port-component>
  </webservice-description>
</oracle-webservices>
```

**Steps to Assemble Reliability into a Web Service Top Down**

The following general steps describe how to assemble a reliability configuration into a Web service top down. For a detailed description of top down Web service assembly, see "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer’s Guide.

1. Provide settings for the reliability features that you want to enable in an XML file. "Server-Side Reliability Configuration Elements" on page 5-9 describes the port-level and operation-level reliability features that are available on the server.

2. (Optional) Assemble capability assertions into the WSDL for the Web service.
   
   If you are assembling capability assertions into the Web service, you must assemble the assertions into the WSDL before assembling the service. This is described in "How to Assemble Capability Assertions into a Web Service Top Down" on page 5-6.

3. Assemble the Web Service top down by calling the topDownAssemble command.
   
   Use the ddFileName argument to pass the name of the XML file that contains the reliability configuration to the command.
If the WSDL contains capability assertions, use the genQos argument set to true. For more information on capability assertions, see "Working with Capability Assertions" on page 3-18.

See "ddFileName" and "genQos" in the "WebServicesAssembler Arguments" section of the Oracle Application Server Web Services Developer's Guide for more information on these arguments.

Example 5–4 illustrates a topDownAssemble Ant task that uses the ddFileName argument to add the reliability configuration in wsmLoggingServiceConfig.xml to the Web service. The ddFileName argument is highlighted in bold.

Example 5–4  Passing a Reliability Configuration in a Top Down Web Service Assembly

```xml
<oracle:topDownAssemble
    wsdl=" ./wsdl/LoggingFacility.wsdl"
    unwrapParameters="false"
    className="oracle.demo.topdowndoclit.service.DocLitLoggerImpl"
    input="build/classes/service"
    output="build"
    ears="dist/doclit_topdown.ear"
    mappingFileName="type-mapping.xml"
    packageName="oracle.demo.topdowndoclit.service"
    fetchWsdlImports="true"
    classpath="/build/classes/client"
    ddFileName="wsmLoggingServiceConfig.xml"
</oracle:topDownAssemble>
```

How to Assemble Capability Assertions into a Web Service Top Down

If you are assembling a Web service top down and want it to include capability assertions, then you must add the assertions to the WSDL before assembling the service.

The WebServicesAssembler command genQosWsdl allows you to add capability assertions for security and reliability to a specified WSDL. Typically, capability assertions are defined in the deployment descriptor file.

In the genQosWsdl command, use the following arguments:

- `ddFileName`—to specify a deployment descriptor file that contains the server-side reliability configuration elements.
- `wsdl`—to specify the name of the WSDL file into which they will be inserted.
- `output`—to specify where the modified WSDL will be stored. If you do not use this argument, the original WSDL will be overwritten.

You can then use the modified WSDL as input to the topDownAssemble command. The genQos argument to topDownAssemble must be set to true.

See Also:

See "genQosWsdl" in the Oracle Application Server Web Services Developer's Guide for more information on this command.

Steps to Assemble Reliability into a J2SE Web Service Client Proxy

The following general steps describe how to assemble a reliability configuration into a J2SE Web service client proxy. The reliability configuration values must be consistent for both the server side and the client side for reliable message communication to occur.
1. Provide settings for the reliability features that you want to enable in an XML file. This file can be written by hand or created by a tool, such as Oracle JDeveloper. The configuration file describes some of the built-in behavior of the generated client and is defined by the oracle-webservices-client-10_0.xsd schema. If there are certain quality of service properties marked as "required" (such as duplicate elimination or guaranteed delivery) on the server-side, then the client must also specify these properties.

"Client-Side Reliability Configuration Elements" on page 5-13 describes of the port-level and operation-level reliability features that can be set for the client.

2. Use the genProxy command to assemble the Web service client. Use the ddFileName argument to pass the name of the XML file that contains the reliability configuration to the command.

See "How to Pass Management Information to a J2SE Client" on page 3-7 for more detailed information on adding a management configuration to a J2SE client.

"Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide provides more information on creating J2SE Web service clients.

Example 5–5 illustrates a genProxy Ant task that uses the ddFileName argument to add the reliability configuration in wsmClientDD.xml to the Web service. The ddFileName argument is highlighted in bold.

**Example 5–5 Passing a Reliability Configuration in a Web Service Client Assembly**

```xml
<oracle:genProxy
    output="test/src"
    debug="true"
    packageName="oracle.generated"
    ddFileName="wsmClientDD.xml"/>
</oracle:genProxy>
```

Example 5–6 illustrates the contents of the wsmClientDD.xml for a client-side reliability configuration. Note that the contents of the file are enclosed in the <port-info> tag.

**Example 5–6 Sample Client-Side Reliability Configuration**

```
...<port-info>
  <runtime enabled="reliability">
    <reliability>
      <repository name="standalone-client-store" type="memory"/>
      <retry-interval value="60"/>
      <cleanup-interval value="10000"/>
      <poll-interval value="60"/>
      <retry-limit value="10"/>
      <max-age value="86000"/>
      <standalone-listener-port value="9876"/>
    </reliability>
  </runtime>
  <operations>
    <operation name="deposit">
      <runtime>
        <reliability>
          <guaranteed-delivery enabled="true"/>
        </reliability>
      </runtime>
    </operation>
  </operations>
</port-info>
```
Steps to Assemble Reliability into a J2EE Web Service Client

The following general steps describe how to assemble a reliability configuration into a J2EE Web service client. The reliability configuration values must be consistent for both the server side and the client side for reliable message communication to occur.

1. Provide settings for the reliability features that you want to enable in an XML file.

   This file can be written by hand or created by a tool, such as Oracle JDeveloper. The configuration file describes some of the built-in behavior of the generated client and is defined by the oracle-webservices-client-10_0.xsd schema. If there are certain quality of service properties marked as "required" (such as duplicate elimination or guaranteed delivery) on the server-side, then the client must also specify these properties.

   "Client-Side Reliability Configuration Elements" on page 5-13 describes the port-level and operation-level reliability features that can be set for the client.

2. Use the genInterface command to create the Web service client. Pass the reliability configuration to the command with the ddFileName argument.

   "How to Assemble a J2EE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide provides detailed instructions for creating and packaging the J2EE Web service client.

   "How to Pass Management Information to a J2EE Client" on page 3-9 for more detailed information on adding a management configuration to a J2EE client.

How to Configure Reliability on the Server

This section describes the configuration elements for reliability that can be found in the server-side oracle-webservices.xml file.

As with other files that are to be deployed, oracle-webservices.xml is typically stored in an EAR file. Once the EAR is deployed to OracleAS Web Services, the Web services management information in oracle-webservices.xml is extracted and stored in wsmgmt.xml. You can modify the management configuration post-deployment by using the Application Server Control tool.

This section contains the following subsections:

- Server-Side Reliability Configuration Elements
- Capability Assertions for Reliability
See Also:

"How to Pass Management Information to the Server" on page 3-4 for a description of how to add management information, including reliability, to oracle-webservices.xml.

Server-Side Reliability Configuration Elements

Reliability features can be assigned at the port level and at the operation level.

- Port-Level Reliability Elements on the Server
- Operation Level Reliability Elements on the Server

Note: Message ordering cannot be configured at the operation level or the port level. It cannot be configured at the operation level because message ordering can take place across operations. It cannot be configured at the port level because you might not want all operations to be reliable or sensitive to message ordering.

Port-Level Reliability Elements on the Server

This section describes the reliability elements that can be set at the port level. The port level configuration determines where messages are stored.

The value of the type attribute in the <repository> element determines whether the server will store messages in-memory or in a database store. If type="memory" then messages are stored in an in-memory store. If type="jdbc" then messages are stored in a database store.

Table 5–1 provides more information on <repository> and other port-level reliability elements that can appear in the oracle-webservices.xml file.

Note: The oracle-webservices-reliability-10_0.xsd schema file defines the reliability elements as a sequence. In any reliability configuration, they must appear in order.
Example 5–7 lists the reliability elements as they are used in oracle-webservices.xml to describe reliability for an in-memory store.

**Example 5–7  Port-Level Reliability Set for an In-Memory Store**

```xml
...<port-component name="...">
  <runtime enabled="reliability">
    <reliability>
      <repository name="bank-server-store" type="memory"/>
      <ack-interval value="60"/>
      <order-interval value="60"/>
      <cleanup-interval value="3600"/>
      <ack-limit value="10"/>
      <max-age value="86400"/>
    </reliability>
  </runtime>
  <operations>
    ...
  </operations>
...</port-component>
```
Example 5–8 lists the reliability elements for a configured datasource on the server.

**Example 5–8  Port Level Reliability Set for a Configured Datasource on the Server**

```xml
...<port-component name="...">
  <runtime enabled="reliability">
    <reliability>
      <repository type="jdbc" jndiLocation="jdbc/OracleManagedDS"/>
      <ack-interval value="60"/>
      <order-interval value="60"/>
      <cleanup-interval value="3600"/>
      <ack-limit value="10"/>
      <max-age value="86400"/>
    </reliability>
  </runtime>
</port-component>
```

**Operation Level Reliability Elements on the Server**

This section describes the reliability elements that can be set at the operation level. Example 5–9 lists the reliability elements as they are used in `oracle-webservices.xml`.

**Example 5–9  Operation-Level Reliability Elements in the Server-Side Configuration File**

```xml
...<port-component name="...">
  ...<operations>
    <operation name="deposit">
      <runtime>
        <reliability>
          <duplication-elimination-required value="true"/>
          <guaranteed-delivery-required value="true"/>
        </reliability>
      </runtime>
    </operation>
  </operations>
</port-component>
```

Table 5–2 describes the reliability elements that you can set at the operation level in the `oracle-webservices.xml` file. If the values of these assertions are `true`, but the client does not send the message according to the requirement, then a SOAP fault is returned, describing the assertion that was violated.

**Note:** The `oracle-webservices-reliability-10_0.xsd` schema file defines the reliability elements as a sequence. In any reliability configuration, they must appear in order.
Capability Assertions for Reliability

On the server, capability assertions for reliability are used to restrict the kinds of messages sent to the endpoint. Capability assertions for reliability can be added to the Web service either by Oracle JDeveloper wizards or WebServicesAssembler commands. Table 5–3 describes the capability assertions defined for WS-Reliability.

### Table 5–2 Operation-Level Reliability Elements in the Server-Side Configuration File

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;duplication-elimination-required&gt;</td>
<td>If set to true, it indicates that non-reliable clients will not be allowed to invoke this operation. Specifically, messages that do not have the SOAP header for duplicate elimination will be rejected. The default is false.</td>
</tr>
<tr>
<td>&lt;guaranteed-delivery-required&gt;</td>
<td>If set to true, it indicates that non-reliable clients will not be allowed to invoke this operation. Specifically, messages that do not have the SOAP header for guaranteed delivery will be rejected. The default is false.</td>
</tr>
</tbody>
</table>

### Table 5–3 Capability Assertions Defined for WS-Reliability

<table>
<thead>
<tr>
<th>Reliability Assertion</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;duplicate-elimination required=&quot;true&quot;/&gt;</td>
<td>This assertion indicates that only messages that have a duplicate elimination SOAP header element will be processed. Any messages that arrive at the reliable endpoint without the correct SOAP header in the message indicating duplicate elimination will be rejected with a SOAP fault.</td>
</tr>
<tr>
<td>&lt;guaranteed-delivery required=&quot;true&quot;/&gt;</td>
<td>This assertion indicates that only messages that have a guaranteed delivery SOAP header element will be processed. Any messages that arrive at the reliable endpoint without a SOAP header indicating guaranteed delivery will be rejected with a SOAP fault.</td>
</tr>
<tr>
<td>&lt;reply-patterns callback=&quot;true&quot; poll=&quot;true&quot; response=&quot;true&quot;/&gt;</td>
<td>This assertion indicates support for various reply patterns. These assertions are explicit advertisements of the capabilities of the endpoint. Clients can use these capabilities to determine how they want to interact with the endpoint.</td>
</tr>
</tbody>
</table>

How to Add Capability Assertions for Reliability to a Web Service

You can use the Oracle JDeveloper or WebServicesAssembler tools to add capability assertions to a Web service, or to simply insert the assertions into an existing WSDL. For more information, see "How to Assemble Capability Assertions into a Web Service" on page 3-18.

How to Configure Reliability on the Client

You can configure reliability for a client by using either an API or a configuration file.

- Client-Side Reliability Configuration Elements
- How to Configure Client-Side Database Support
- How to Configure Client-Side Reliability Programmatically
Client-Side Reliability Configuration Elements

The reliability configuration values must be consistent for both the server side and the client side for reliable message communication to occur. This section describes only the client-side configuration elements.

See Also:
“Server-Side Reliability Configuration Elements” on page 5-9 for information on server-side reliability elements

On the client, reliability elements are stored in a configuration file. The name of the file and where it resides depends on whether the client is J2EE or J2SE.

- For J2EE servlet, EJB, and Web application clients, the configuration file is:
  - META-INF/orion-ejb-jar.xml for an EJB client
  - WEB-INF/orion-web.xml for a JSP or servlet client
  - META-INF/orion-application-client.xml for a Web application client

- For J2SE clients, the configuration file is: `<generated_name>_Stub.xml`, where `generated_name` is derived from the `targetNamespace` and `port` name in the WSDL.

Reliability can be assigned at the port level and at the operation level.

Port Level Reliability Elements on the Client

This section describes the reliability elements that can be set at the port level for the client. Example 5–10 lists the reliability elements as they are used in the client-side configuration file.

Example 5–10  Port-Level Reliability Elements in the Client-Side Configuration File

```
...<port-info>
  <runtime enabled="reliability">
    <reliability>
      <repository name="standalone-client-store" type="memory"/>
      <retry-interval value="60"/>
      <retry-limit value="10"/>
      <poll-interval value="60"/>
      <cleanup-interval value="3600"/>
      <max-age value="86400"/>
      <standalone-listener-port value="8008"/>
      <async-poll-reply-to-url value="http://host:port"/>
    </reliability>
  </runtime>
...
</port-info>
```

Table 5–4 describes the reliability elements that can be set at the port level.

Note: The `oracle-webservices-reliability-10_0.xsd` schema file defines the reliability elements as a sequence. In any reliability configuration, they must appear in order.
### Table 5–4  Port-Level Reliability Elements in the Client-Side Configuration File

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;repository&gt;</td>
<td>Specifies the kind of store that will be used to store messages. This element has the following attributes:</td>
</tr>
<tr>
<td></td>
<td>■ connection-driver—the JDBC driver class name for this data source, used by some data sources that deal with java.sql.Connection. For most data sources, the driver is oracle.jdbc.driver.OracleDriver. This attribute applies only to emulated data sources for which the class attribute is com.evermind.sql.DriverManagerDataSource.</td>
</tr>
<tr>
<td></td>
<td>■ jndiLocation—Specifies the JNDI name of the datasource on the server. Required only if messages will be stored in the database.</td>
</tr>
<tr>
<td></td>
<td>■ name—A String that specifies the name of the repository.</td>
</tr>
<tr>
<td></td>
<td>■ password—Specifies the user’s password to the repository.</td>
</tr>
<tr>
<td></td>
<td>■ type—(required) Specifies whether a memory store or database store is being configured. The allowed values for type are memory for a memory store and jdbc for a database store. The default type of store is a memory store.</td>
</tr>
<tr>
<td></td>
<td>■ url—Specifies the URL for database connections.</td>
</tr>
<tr>
<td></td>
<td>■ username—Specifies the name of the user that can access the repository.</td>
</tr>
<tr>
<td>&lt;retry-interval&gt;</td>
<td>The value attribute specifies the interval after which an attempt will be made to retry sending of messages that have not yet received any acknowledgment or fault. The default value is 60 seconds.</td>
</tr>
<tr>
<td>&lt;retry-limit&gt;</td>
<td>The value attribute specifies a limit on the number of attempts that will be made to retry a message. The default value is 10. A value of -1 indicates no -limit, or infinite retries.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> If the value attribute is set to 0, then the client will not attempt to re-send messages. This, in effect, negates the guaranteed delivery quality of service. As an optimization, the reliability stack does retain messages in the database if the value attribute is set to 0. No polling will be performed for these messages since no guarantee can be made that the message will reach the destination and an acknowledgment returned.</td>
</tr>
<tr>
<td>&lt;poll-interval&gt;</td>
<td>The value attribute specifies the interval, in seconds, after which a poll message will be sent to the server for reliable messages that have not yet received any acknowledgment. Default value is 60 seconds.</td>
</tr>
<tr>
<td>&lt;cleanup-interval&gt;</td>
<td>The value attribute specifies the interval, in seconds, after which an attempt is made to purge the store of expired or invalid messages. The default is 3600 seconds (60 minutes).</td>
</tr>
</tbody>
</table>
How to Configure Reliability on the Client

Ensuring Web Service Reliability

Operation Level Reliability Elements on the Client

This section describes the reliability elements that can be set at the operation level for the client. Example 5–11 lists the reliability elements as they are used in the client-side configuration file.

Example 5–11  Operation-Level Reliability Elements in the Client-Side Configuration File

```xml
<port-info>
  ...
  <operations>
    <operation name="...">
      <runtime>
        <reliability>
          <guaranteed-delivery enabled="true"/>
          <duplicate-elimination enabled="true"/>
          <group-max-idle-time value="5"/>
          <group-expiry-time value="86400"/>
          <expiry value="3600"/>
          <reply-pattern value="Callback"/>
          <reply-to-url value="http://localhost:8008"/>
        </reliability>
      </runtime>
    </operation>
  </operations>
</port-info>
```

Table 5–5 describes the reliability elements that can be set on the operation level.

You should provide a value for either `<group-max-idle-time>` or `<group-expiry-time>`. If both elements are specified, then the value for `<group-expiry-time>` will take precedence.

Note: The `oracle-webservices-reliability-10_0.xsd` schema file defines the reliability elements as a sequence. In any reliability configuration, they must appear in order.
How to Configure Client-Side Database Support

OracleAS Web Services lets you choose whether to store messages sent to the client in memory or in a database. Storing your messages in a database has advantages over storing messages in memory. Messages stored in memory are not persistent: messages are lost once client processes exit (JVM termination) or if the server goes down.

If you choose to store client messages in a database, you must provide the database and connection details to the client. This information cannot be passed to the client by using client-side APIs. Instead, you must provide settings for the port-level <repository> element in the client-side management configuration file. This element is described in Table 5–4 on page 5-14.

The following sections describe the tasks involved in configuring the database to store client messages.

- How to Configure the Database to Store Messages from a J2SE Client
- How to Configure the Database to Store Messages from a J2EE Client
- How to Configure a Listener for a J2EE Client

Table 5–5 Operation-Level Reliability Elements in the Client-Side Configuration File

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;guaranteed-delivery&gt;</td>
<td>If the enabled attribute is true, guaranteed delivery of message is enabled. Default value is true.</td>
</tr>
<tr>
<td>&lt;duplicate-elimination&gt;</td>
<td>If the enabled attribute is true, duplicate elimination of the message is enabled. Default value is true.</td>
</tr>
<tr>
<td>&lt;group-max-idle-time&gt;</td>
<td>The value attribute specifies the maximum idle time, in seconds, for a group of messages. This element is optional.</td>
</tr>
<tr>
<td>&lt;group-expiry-time&gt;</td>
<td>The value attribute specifies the expiration time, in seconds, for all messages in the group. The value for &lt;group-expiry-time&gt; should be greater than the value set for &lt;expiry&gt;. Default value is 84600 seconds (1 day).</td>
</tr>
<tr>
<td>&lt;expiry&gt;</td>
<td>The value attribute specifies the expiry time for a single message in a group. For example, if a message, has not been acknowledged for a time duration longer than the expiration duration, then no further attempt will be made to deliver the message. The client will be notified of the failure. If a value is set for &lt;group-expiry-time&gt;, it should be greater than the value of &lt;expiry&gt;. Default value is 3600 seconds (60 minutes).</td>
</tr>
<tr>
<td>&lt;reply-pattern&gt;</td>
<td>The value attribute can be either Callback (asynchronous acknowledgment/fault), Response (synchronous acknowledgment/fault) or Polling (the acknowledgment or fault will be polled for). Default value is Polling. To use Callback, you must configure a listener. This is not possible on a J2SE client. The &lt;reply-pattern&gt; element must be set only if &lt;guaranteed-delivery&gt; is true.</td>
</tr>
<tr>
<td>&lt;reply-to-url&gt;</td>
<td>The value attribute specifies the URL to which acknowledgments and faults will be sent for messages that want asynchronous acknowledgments. The URL for this is typically the host name of the client along with the port that the listener is on. The &lt;reply-to-url&gt; element must be set only if &lt;guaranteed-delivery&gt; is true.</td>
</tr>
</tbody>
</table>
How to Configure the Database to Store Messages from a J2SE Client

For a J2SE client, you must provide all of the parameters that are required to establish a database connection. This information, such as the name of the database, its URI, connection type, the connection driver, and the user name and password, are all attributes of the repository element. Enter this information into the <generated_name>_Stub.xml file, where generated_name is derived from the target namespace and port name in the WSDL.

Example 5–12 illustrates the configuration of a database connection for a J2SE client. Note that the J2SE client requires all of the repository attributes to connect to the database.

Example 5–12 Database Connection for a J2SE Client

```xml
<reliability>
  <repository
    name="bank-client-store"
    type="jdbc"
    connection-driver="org.hsqldb.jdbcDriver"
    username="SCOTT"
    password="TIGER"
    url="jdbc:hsqldb:testdb" />
  <retry-interval value="60" />
  <retry-limit value="10" />
  <poll-interval value="60" />
  <cleanup-interval value="3600" />
  <max-age value="86400" />
  <standalone-listener-port value="9999" />
</reliability>
```

How to Configure the Database to Store Messages from a J2EE Client

A J2EE client typically interacts with a datasource in an application server. The client connects to the data source by performing a JNDI lookup on its location.

You enter the information into one of the following files, based on your client.

- META-INF/orion-ejb-jar.xml for an EJB client
- WEB-INF/orion-web.xml for a JSP or servlet client
- META-INF/orion-application-client.xml for a Web application client

Datasources used for reliable clients should be configured to use local transactioning. To declare local transactioning, add the attribute tx-level="local" to the <managed-data-source> element. For example:

```xml
...<managed-data-source name="OracleDS" tx-level="local"
  jndi-name="jdbc/OracleManagedDS" ... />
...```

In Example 5–13 the values for the repository attributes type and jndiLocation provide the datasource type and location details to the J2EE client. The repository elements are highlighted in bold.

Example 5–13 Database Connection for a J2EE Client

```xml
<reliability>
  <repository
    type="jdbc"```
How to Configure Reliability on the Client

The following code snippet demonstrates how to configure reliability settings within an application.

```
jndiLocation="jdbc/OracleManagedDS"/>
<retry-interval value="60" />
<retry-limit value="10" />
<poll-interval value="60" />
<cleanup-interval value="3600" />
<max-age value="86400" />
</reliability>
```

**How to Configure a Listener for a J2EE Client**

For a J2EE client where the reliability client runs inside of an application, a Servlet class, `oracle.j2ee.ws.reliability.AckFaultServlet`, is provided for use in the application.

Example 5–14 illustrates the code that must be added to the application's `web.xml` file.

**Example 5–14  Listener Configuration for a J2EE Client**

```
<servlet>
  <servlet-name>wsrm</servlet-name>
  <servlet-class>oracle.j2ee.ws.reliability.AckFaultServlet</servlet-class>
  <load-on-startup>1</load-on-startup>
</servlet>
<servlet-mapping>
  <servlet-name>wsrm</servlet-name>
  <url-pattern>/wsrm/*</url-pattern>
</servlet-mapping>
```

The replyTo URL must be set to the URL to which the `AckFaultServlet` is mapped. This is in contrast to the J2SE case, where the replyTo URL must correspond to the standalone listener's `host:port` value.

**How to Configure Client-Side Reliability Programmatically**

OracleAS Web Services provides the ability to programmatically configure reliability features and receive notifications for acknowledgments and faults at the application level. This functionality is provided by the `oracle.webservices.reliability` package, a client-level API for managing reliability features.

The functionality contained in this package lets you override any default configuration, or the configuration that was initially provided to the client.

You must use the API if you want to implement message ordering for your Web service. Currently, using the API is the only way to start and end groups of ordered messages.

You can also use this API if you want to enforce reliability policies on a per-message basis.

Table 5–6 summarizes the classes in the `oracle.webservices.reliability` package.

**See Also:**

More detailed information about the classes, such as fields and method-level descriptions, can be found in the Oracle Application Server Web Services Java API Reference.
The APIs in the reliability package can be used to create the reliability context for both static stub and DII clients.

The createContext() method in the ReliabilityClient class creates a reliability context. The context is where you can set, among other features, the reliability listeners, message acknowledgment type, duplicate message elimination, guaranteed delivery, message expiration time, and the reply URL.

For a static stub, the reliability context is set on the current thread. All operations invoked on the stub within the scope of a reliability context inherit their reliability characteristics from that context.

For a DII client, the details about the service are passed to the client by URIs.

**See Also:**

"How to Pass a Management Configuration to a DII Web Service Client Programmatically" on page 3-11 for more information on how to pass management details to a DII Web service client.

### Adding Reliable Messaging Support to Static Stub and DII Client Code

Example 5–15 illustrates the code to make a stub that is generated by genProxy reliable. In the code sample, a reliability context is created that is used over the lifetime of the client (client.createContext()). The context is set on ThreadContext when it is created. This allows operations on the banking stub to inherit their reliability characteristics from the context.

Reliability is set to return asynchronous acknowledgments of messages received (setAcknowledgmentType). The code guarantees that messages will be delivered (setGuaranteedDeliveryEnabled), and that duplicate messages will be eliminated (setDuplicateEliminationEnabled).

### Example 5–15  Reliability Code for a Static Stub Client

```java
ReliabilityClient client= ReliabilityClientFactory.getClientFactory().getClient();
ReliabilityContext reliabilityContext = client.createContext();
reliabilityContext.setAcknowledgmentType(ReliabilityContext.ACKNOWLEDGMENT_TYPE_
CALLBACK);
reliabilityContext.setDuplicateEliminationEnabled(true);
reliabilityContext.setGuaranteedDeliveryEnabled(true);

Banking banking = new Banking_Impl();
Bank bank = banking.getBankPort();
bank.deposit(new Deposit("checking", 100));

Example 5–16 illustrates the same client code, but for a DII client. In this case, the service name and deposit details are obtained dynamically with URIs.

**Example 5–16  Reliability Code for a DII Client**

```
ReliabilityClient client = ReliabilityContextFactory.getDefault().getClient();
ReliabilityContext reliabilityContext = client.createContext();

reliabilityContext.setAcknowledgmentType(ReliabilityContext.ACKNOWLEDGMENT_TYPE_CALLBACK);
reliabilityContext.setDuplicateEliminationEnabled(true);
reliabilityContext.setGuaranteedDeliveryEnabled(true);

Service service = ServiceFactory.newInstance().createService(new QName("http://oracle.com/test/wsdl","TestService","test") );
Call call = service.createCall(new QName("http://oracle.com/test/wsdl","TestServicePort" ),
   new QName("http://oracle.com/test/wsdl","deposit") );
call.setProperty(ClientConstants.CLIENT_CONFIG,
   new File("wsmClient.xml"));
```

**Implementing Message Ordering in Client Code**

Example 5–17 illustrates client code that performs message ordering. Like the previous examples, a reliability context is created that is used over the lifetime of the client (reliabilityClient.createContext()). To ensure that messages are received in the same order in which they are sent, embed the code which is capable of sending messages within the startMessageOrdering and endMessageOrdering methods. These methods are highlighted in bold.

Note that for message ordering to work, the methods setDuplicateEliminationEnabled and setGuaranteedDeliveryEnabled must also be present and set to true. These methods are also highlighted in bold.

**Example 5–17  Message Ordering on the Client**

```
reliabilityContext = reliabilityClient createContext();

reliabilityContext.setAcknowledgmentType(ReliabilityContext.ACKNOWLEDGMENT_TYPE_CALLBACK);
reliabilityContext.setDuplicateEliminationEnabled(true);
reliabilityContext.setGuaranteedDeliveryEnabled(true);
reliabilityContext.startMessageOrdering();

Banking banking = new Banking_Impl();
Bank bank = banking.getBankPort();
bank.deposit("Checking", 10.0);
bank.withdraw("Checking", 5.0);
reliabilityContext.endMessageOrdering();
```
Tool Support for Web Services Reliability

The following sections describe the support for reliability offered by Application Server Control and Oracle JDeveloper.

- Application Server Control Support for Web Service Reliability
- Oracle JDeveloper Support for Web Service Reliability

Application Server Control Support for Web Service Reliability

Application Server Control lets you view, enable, and disable the reliability configuration of a deployed Web service. Once the configuration has been modified and applied, the Web service will run with the new configuration values. Application Server Control can be used to set Web service reliability options on the port and operation level.

You cannot use Application Server Control to view or change the reliability configuration for clients.

The following steps provide a general description of how to deploy a Web service and use Application Server Control to read and modify its reliability configuration.

1. Deploy the Web service.

Web services are deployed in the standard manner into a running instance of OC4J. See Oracle Containers for J2EE Deployment Guide for more information on deploying Web service EAR files.

2. Use Application Server Control to configure reliable messaging for the deployed Web service.
   a. Log in to the Application Server Control tool.
   b. Click the Web services tab.
   c. Select the name of the Web service that was deployed.
   d. Click the Administration tab.
   e. Click Enable/Disable features.
   f. Move "Reliability" to the enabled column and click "OK".

The Web service will have reliable messaging enabled.

See Configuring Reliability for a Web Service in the Application Server Control on-line help for more information on this step.

Oracle JDeveloper Support for Web Service Reliability

Oracle JDeveloper can be used to develop OracleAS Web Services and client Web service management configuration files. Oracle JDeveloper can aid you in the initial creation of these files or it can be used to add management configuration to existing files.

The "Configure Management and Reliability" wizard helps you configure port and operation level reliability for inbound and outbound SOAP messages.
See Also:
"Port-Level Reliability Elements on the Server” on page 5-9 and
"Operation Level Reliability Elements on the Server” on page 5-11
describes the reliability elements that the wizard enables you to
configure.

Limitations
See "Ensuring Web Service Reliability” on page I-14.

Additional Information
For more information on:

- adding Web service management information, including security, to a Web service,
  see Chapter 3, "Managing Web Services”.
- adding security information to a Web service, see Chapter 4, "Ensuring Web
  Services Security” and the Oracle Application Server Web Services Security Guide.
- adding auditing and logging information to a Web Service, see Chapter 6,
  "Auditing and Tracing Messages”.
- the contents of the wsmgmt .xml file which contains the security configuration, see
  Appendix A, "Understanding the Web Services Management Schema”.
- assembling a Web service top down, see "Assembling a Web Service from a WSDL”
in the Oracle Application Server Web Services Developer’s Guide.
- using Java classes to assemble a Web service, see "Assembling a Web Service with
  Java Classes” in the Oracle Application Server Web Services Developer’s Guide.
- using EJBs to assemble a Web service, see "Assembling a Web Service with EJBs” in
  the Oracle Application Server Web Services Developer’s Guide.
- using JMS topics and destinations to assemble a Web service, see "Assembling Web
  Services with JMS Destinations” in the Oracle Application Server Web Services
  Developer’s Guide.
- using database resources, such as PL/SQL packages, SQL queries, DML
  statements, Oracle Streams AQ, or server-side Java classes, to assemble a Web
  service, see "Assembling Database Web Services” in the Oracle Application Server
  Web Services Developer’s Guide.
- assembling a J2EE Web Service client, see "Assembling a J2EE Web Service Client”
in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2SE Web service client, see "Assembling a J2SE Web Service Client”
in the Oracle Application Server Web Services Developer’s Guide.
- the contents of the oracle-webservices.xml deployment descriptor which
  contains the Web services management configuration, see “Packaging and
  Deploying Web Services” in the Oracle Application Server Web Services Developer’s
  Guide.
- using WebServicesAssembler commands to assemble Web service artifacts, see
  "Using WebServicesAssembler” in the Oracle Application Server Web Services
  Developer’s Guide.
This chapter describes the auditing and tracing (logging) functionality available for Oracle Application Server Web Services. Auditing enables you to keep a complete, persistent record of request, response, and fault SOAP messages. It records the entire message. Tracing enables you to extract and persistently store discrete portions of request, response, and fault SOAP messages.

- Understanding Auditing
- How to Configure Auditing on the Server
- Understanding Tracing
- How to Configure Tracing on the Server
- Tool Support for Web Services Auditing and Tracing
- Controlling the Output of Web Services Loggers

**Understanding Auditing**

Auditing enables you to keep a complete, persistent record of SOAP requests, responses, and faults. During development it is often very convenient to be able to inspect the contents of SOAP requests and responses to diagnose problems.

In a production environment, specific SOAP messages can be stored to support non-repudiation efforts. For example, an on-line retailer could record all received purchase order requests.

Auditing also enables you to design a strategy that records and analyzes security-related events. A history of audit records can produce an audit trail enabling the reconstruction and examination of a sequence of events. The audit trail can be used to detect attacks, confirm compliance with policy, deter abuse, and so on.

**How Auditing Affects Performance**

Auditing is initiated and performed by the server. It cannot be initiated or performed by the client. Adding auditing to your Web service does not require changes or extensions to the WSDL.

If you enable auditing, there will probably be a measurable impact upon the performance of the system. You should use it only during development and debugging, or when there is a clear need to persist the entire contents of a message during production. Auditing for non-repudiation is a good example. In this case, it is likely that you will have to audit only a small set of Web service operations, so the performance impact should be acceptable.
The size of the logged messages will effect how large the performance impact will be. Larger message will take more time and system resources to store.

**How the Runtime Handles Auditing**

Auditing can be applied at runtime to messages flowing into the platform (request messages), flowing out of the platform (response messages), and generated fault messages. The runtime stores these messages in the following persistent log file:

```
ORACLE_HOME\j2ee\OC4J_Instance_Name\log\group_name\n\wsmgmt\auditing\log.xml
```

This is a rolling file: after it reaches a certain size, it is renamed `log-[number].xml` and a new `log.xml` file is started. Over time, older versions of the file may be deleted. Application Server Control can read this file.

The location of the log file is determined by the configuration file `ORACLE_HOME\j2ee\OC4J_instance_name\config\j2ee-logging.xml`.

**See Also:**

- "Controlling the Output of Web Services Loggers" on page 6-16 for more information on how diagnostic logging for auditing and logging is configured in OracleAS Web Services.
- "Configuring OC4J Logging" in the Oracle Containers for J2EE Configuration and Administration Guide provides more information on the `j2ee-logging.xml` file.

The following sections describe how the runtime processes these messages.

- How the Runtime Audits Request Messages
- How the Runtime Audits Response Messages
- How the Runtime Audits Fault Messages

Example 6–1 illustrates a sample logged SOAP message. The original SOAP message appears in the `<MSG_TEXT>` element and is highlighted in bold in this example.

**Example 6–1  Sample SOAP Message in the Audit Log**

```

How to Configure Auditing on the Server

How the Runtime Audits Request Messages
When an inbound SOAP message is received, the runtime determines, based on the configuration, whether auditing is enabled for the port. The configuration also indicates whether request messages are to be audited. If auditing is enabled for both the port and operation, then the entire message is written to the audit log.

How the Runtime Audits Response Messages
When the Web service implementation creates outbound response SOAP messages, the management features are applied in reverse order. If auditing is enabled for the port and the configuration also indicates that response messages are to be audited, then the entire message is written to the audit log.

How the Runtime Audits Fault Messages
Fault messages can be generated by the Web service implementation or by any of the application handlers. If the auditing of fault messages is enabled for the port and operation by the configuration, then fault messages are written to the audit log.

How to Configure Auditing on the Server
The configuration information for auditing is located in the server-side Web services proprietary deployment descriptor oracle-webservices.xml. The contents of this file can be modified during packaging or deployment. At runtime, changes must be made using either Application Server Control or by editing the management configuration file:

ORACLE_HOME\j2ee\OC4J_Instance_Name\config\wsmgmt.xml file.

Auditing can be performed only at the operation level; you cannot configure auditing at the global or port-level.

See Also:
Configuring Auditing for a Web Service in the Application Server Control on-line help for more information about the log.xml file.
Server-Side Auditing Configuration Elements

An auditing configuration can be defined for each operation in a Web service port. The `<auditing>` element and its three attributes, `request`, `response`, and `fault`, define the auditing configuration. Each attribute can have a `true` or `false` value to indicate whether Web service management will store these messages. The following is a sample auditing configuration.

```
<auditing request="true" response="false" fault="false"/>
```

Example 6–2 illustrates the `<auditing>` element, highlighted in bold, as it appears in the `oracle-webservices.xml` deployment descriptor. Note that even though you cannot specify auditing for a port, a `<runtime enabled="auditing">` element is still required at the port level. The schema for this file is:

```
http://xmlns.oracle.com/oracleas/schema/oracle-webservices-10_0.xsd
```

Example 6–2  Operation-Level Auditing Element in the Server-Side Configuration File

```
...<port-component name="String">...<runtime enabled="auditing">...<operations><operation name="...">...<runtime><auditing request="true" response="true" fault="false"/></operation></operations><port-component>...
```

Table 6–1 describes the attributes of the auditing element.

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;auditing&gt;</code></td>
<td>Has attributes <code>request</code>, <code>response</code>, and <code>fault</code> that accept a Boolean value. If an attribute is <code>true</code>, then messages of that type will be audited.</td>
</tr>
<tr>
<td></td>
<td>❑ <code>fault</code>—Indicates whether fault messages will be audited. Default is <code>false</code>.</td>
</tr>
<tr>
<td></td>
<td>❑ <code>request</code>—Indicates whether request messages will be audited. Default is <code>true</code>.</td>
</tr>
<tr>
<td></td>
<td>❑ <code>response</code>—Indicates whether response messages will be audited. Default is <code>false</code>.</td>
</tr>
</tbody>
</table>

How to Configure Auditing in a J2EE Client

The configuration information for auditing is located in the J2EE client-side Web services proprietary deployment descriptor. Depending on the client application, this can be either `orion-web.xml`, `orion-ejb-jar.xml`, or `orion-application-client.xml`. The contents of this file can be modified during packaging or deployment.
Auditing can be performed only at the operation level. Hence, there is no global or port-level configuration.

Similar to the server-side, a client-side auditing configuration can be defined for each operation in a Web service port. The `<auditing>` element and its three attributes, `request`, `response`, and `fault`, define the auditing configuration. Each attribute can have a `true` or `false` value to indicate whether Web service management will store these messages. Table 6–1 provides a description of the `<auditing>` element and its attributes. The following is a sample auditing configuration.

```xml
<auditing request="true" response="false" fault="false"/>
```

The auditing configuration appears within the `<operation>` clause of the `<service-ref-mapping>` element. Each operation can have its own auditing configuration. Example 6–3 illustrates the skeleton of an `orion-web.xml` Oracle proprietary client-side deployment descriptor that indicates the position of the auditing configuration in the hierarchy. The auditing configuration is highlighted in bold. Note that the configuration occurs within the `<port-info>` element. The schema for this file is:

http://xmlns.oracle.com/oracleas/schema/orion-web-10_0.xsd

**Example 6–3 Sample Client-Side orion-web.xml with an Auditing Configuration**

```xml
<orion-web-app ...>
  <service-ref-mapping name="service/MyTestServiceRef">
    <port-info>
      ...
      <runtime>
        ...
        <security/>
        <reliability/>
        ...
      </runtime>
      <operations>
        ...
        <operation name="echo">
          <runtime enabled = "security,reliability,auditing">
            ...
            <security/>
            <reliability/>
            <auditing request="true" response="true" fault="false"/>
            ...
          </runtime>
        </operation>
        ...
      </operations>
    </port-info>
  </service-ref-mapping>
</orion-web-app>
```

**Understanding Tracing**

OracleAS Web Services includes basic SOAP message tracing (logging). This functionality lets you extract and persistently store discrete portions of request, response, and fault SOAP messages.

There are many situations where you might want to persistently capture information from SOAP messages. For example many large organizations deploying internal Web services may want to track which groups within the organization are using the service.
Understanding Tracing

Tracing could enable this by extracting and collecting group information from messages.

---

**Note:** Tracing is not available, nor can it be configured for Web service clients.

---

How Tracing Affects Performance

Tracing is likely to have a minor impact upon the performance of the system. Since only simple types can be extracted from messages, this impact should be limited. If the tracing mechanism is asked to extract large amounts of information from individual messages (for example, large text blocks) a proportional performance impact may occur.

How the Runtime Handles Tracing

Tracing can be applied at runtime to messages flowing into the platform (request messages), flowing out of the platform (response messages), and generated fault messages. Tracing information is stored in the following persistent log file:

```
ORACLE_HOME\j2ee\OC4J_Instance_Name\log\group_name\n\wsmgmt\logging\log.xml
```

This is a rolling file: after it reaches a certain size, it is renamed `log-[number].xml` and a new `log.xml` file is started.

The location of the log file is determined by the configuration file `ORACLE_HOME\j2ee\OC4J_instance_name\config\j2ee-logging.xml`.

See Also:

- "Controlling the Output of Web Services Loggers" on page 6-16 for more information on how diagnostic logging for auditing and logging is configured in OracleAS Web Services.
- "Configuring OC4J Logging" in the *Oracle Containers for J2EE Configuration and Administration Guide* provides more information on the `j2ee-logging.xml` file.

The following sections describe how the runtime processes these messages.

- How the Runtime Logs Request Messages
- How the Runtime Logs Response Messages
- How the Runtime Logs Fault Messages

Example 6-4 provides a sample of a log record derived from an inbound SOAP request message.

**Example 6-4 Sample Log File Entry**

```

```
How to Configure Tracing on the Server

The configuration elements for tracing are defined in the oracle-webservices-logging-10_0.xsd schema. This file can be found in the oc4j-schemas.jar file.

`OC4J_HOME\j2ee\home\lib\oc4j-schemas.jar`

The tracing configuration for the server-side is stored in the oracle-webservices.xml proprietary deployment descriptor. The contents of this file can be modified during packaging or deployment. At runtime, changes must be made either by using Application Server Control or by editing the management configuration file:

`ORACLE_HOME\j2ee\OC4J_Instance_Name\config\wsmgmt.xml`

Tracing must be configured at the port and operation levels. There is no global-level configuration.
Server-Side Tracing Configuration Elements

If tracing features are employed, they must be configured at both the port and the operation level. The port-level configuration contains information that is referenced by the operation level. Unlike security, operation-level configuration does not override port-level configuration.

Port-Level Tracing Elements on the Server

Example 6–5 displays the port-level tracing elements as they appear in the server-side Web services proprietary deployment descriptor, oracle-webservices.xml. These elements are used to create a set of namespace prefix and URI pairs that are referenced by the operation level configuration. The schema for this file is:

Example 6–5  Port-Level Tracing Elements in the Server-Side Configuration File

...<port-component name="...">
...<runtime enabled="logging">
<logging>
<namespaces>
<namespace prefix='env' uri='http://schemas.xmlsoap.org/soap/envelope'/>
<namespace prefix='ns0' uri='http://oracle.com/test/wsdl'/>
</namespaces>
</logging>
...<runtime>
</port-component>
...

Table 6–2 describes the port-level namespace elements that must be set for tracing information to be reported. The namespace prefix-URI pairs are used for processing xpath expressions.

Table 6–2  Namespace Elements for Tracing

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;namespace&gt;</td>
<td>Specifies a name-value pair of namespace prefixes and namespace URIs. The namespace URIs are implicitly referenced by the use of the prefixes in xpath expressions defined for tracing at the operation level.</td>
</tr>
</tbody>
</table>

Operation Level Tracing Elements on the Server

Example 6–6 illustrates the operation-level tracing elements as they appear in the server-side Web services proprietary deployment descriptor, oracle-webservices.xml. At the operation level, you can enable or disable tracing for request, response, and fault messages.

Example 6–6  Operation-Level Tracing Elements in the Server-Side Configuration File

...<port-component name="String">
...<operations>
<operation name="...">
<runtime>
...
<logging>
Table 6–3 describes the message tracing elements: request, response, and fault. Setting an element to true enables tracing for that message type. If tracing is enabled, you can specify one or more attributes you want to log for each message type. These attributes are indicated by its name and xpath.

If tracing for a message type is enabled, but no attributes are configured, then no tracing will occur. Similarly, if the xpath query returns no results, then no tracing will occur.

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;fault&gt;</td>
<td>If enabled=true, specify name-value pairs of message attributes. Each attribute is specified by an attribute name and xpath value. Default is true.</td>
</tr>
<tr>
<td>&lt;request&gt;</td>
<td>If enabled=true, specify name-value pairs of message attributes. Each attribute is specified by an attribute name and xpath value. Default is true.</td>
</tr>
<tr>
<td>&lt;response&gt;</td>
<td>If enabled=true, specify name-value pairs of message attributes. Each attribute is specified by an attribute name and xpath value. Default is true.</td>
</tr>
</tbody>
</table>

Tool Support for Web Services Auditing and Tracing

This section provides an overview of the parts of the Web service auditing and tracing configuration that can be set by the Oracle JDeveloper and Application Server Control tools. For detailed information of the individual auditing and tracing options that can be controlled by these tools, see the on-line help for Application Server Control and Oracle JDeveloper.

- How to Use WebServicesAssembler to Add an Auditing and Tracing Configuration
How Application Server Control Supports Auditing and Tracing
How Oracle JDeveloper Supports Auditing and Tracing

How to Use WebServicesAssembler to Add an Auditing and Tracing Configuration

This section describes how to use WebServicesAssembler commands to add an auditing and tracing configuration to a Web service. A configuration can be added in a top down or bottom up Web service assembly. Auditing can also be assembled into a J2EE Web service client (tracing is not available on the client). In each case, the configuration is specified in an XML file and passed to the WebServicesAssembler command with the ddFileName argument.

- Steps to Assemble Auditing and Tracing into a Web Service Bottom Up
- Steps to Assemble Auditing and Tracing into a Web Service Top Down
- Steps to Assemble Auditing into a J2SE Web Service Client Proxy
- Steps to Assemble Auditing into a J2EE Web Service Client

Steps to Assemble Auditing and Tracing into a Web Service Bottom Up

The following general steps describe how to assemble an auditing and tracing configuration into a Web service bottom up.

1. Create the XML file that provides settings for the auditing and tracing features you want to enable. There are two different ways in which you can do this.
   - Manually write the XML file that contains the auditing and tracing settings. Example 6–8 illustrates a sample XML file that contains these settings. Save the file.
   - Run the WebServicesAssembler tool with the appropriate *Assemble command for your Web service. One of the files it creates will be an oracle-webservices.xml file that contains a skeleton of the ports and operations. For example, you could run the Ant task in Example 6–7 without the ddFileName argument to obtain this file. Edit the oracle-webservices.xml file to enter the appropriate settings for the auditing and tracing features. Save the file under a different name.
   
   "Server-Side Auditing Configuration Elements" on page 6-4 and "Server-Side Tracing Configuration Elements" on page 6-8 provide descriptions of the port-level and operation-level auditing and tracing features that are available on the server.

2. Use the appropriate *Assemble command to assemble the Web service. Use the ddFileName argument to pass the file with the auditing and tracing configuration you created in Step 1 to the WebServicesAssembler tool.

   See "Web Service Assembly Commands" in the Oracle Application Server Web Services Developer’s Guide for descriptions of the *Assemble commands.

   See "ddFileName" in the "Deployment Descriptor Arguments" section of the Oracle Application Server Web Services Developer’s Guide for more information about the ddFileName command.

   Example 6–7 illustrates an assemble Ant task that uses the ddFileName argument to add the auditing and tracing configuration in wsmBankServiceConfig.xml to the Web service.
Example 6–7  Passing an Auditing and Tracing Configuration in a Bottom Up Web Service Assembly

```xml
<oracle:assemble appName="bank"
    targetNamespace="http://www.oracle.com/bank"
    typeNamespace="http://www.oracle.com/bank"
    serviceName="Banking"
    interfaceName="oracle.ws.server.bank.Bank"
    className="oracle.ws.server.bank.BankImpl"
    input="./build/classes/service"
    output="build"
    ear="build/bank.ear"
    style="rpc"
    use="encoded"
    ddFileName="wsmBankServiceConfig.xml"/>
</oracle:assemble>
```

Example 6–8 illustrates the contents of the `wsmBankServiceConfig.xml` for a server-side auditing and tracing configuration. While both auditing and tracing are enabled at the port level, only a tracing configuration is provided. At the operations level, an auditing configuration is provided for the `withdraw` operation and a tracing configuration is provided for the `deposit` operation. Note that the contents of the file are enclosed in the `<oracle-webservices>` element.

Example 6–8  Sample Server-Side Auditing and Tracing Configuration

```xml
<?xml version='1.0' encoding='UTF-8'?>
<oracle-webservices xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:noNamespaceSchemaLocation="http://xmlns.oracle.com/oracleas/schema/oracle-webservices-10_0.xsd">
    <webservice-description name="Bank">
        <port-component name="HttpSoap11">
            <runtime enabled="auditing, logging">
                <auditing/>
                <logging>
                    <namespaces>
                        <namespace prefix="target_ns" uri="http://oracle.com/bank/wsdl"/>
                        <namespace prefix="soap" uri="http://schemas.xmlsoap.org/soap/envelope/"/>
                    </namespaces>
                </logging>
            </runtime>
            <operations>
                <operation name="withdraw">
                    <runtime>
                        <auditing request="true" response="true" fault="false"/>
                    </runtime>
                </operation>
                <operation name="deposit">
                    <runtime>
                        <logging>
                            <request enabled="true">
                                <attributes>
                                    <attribute name="request_string" xpath="/soap:Envelope/soap:Body/target_ns:deposit/String_1/text()"/>
                                </attributes>
                            </request>
                            <response enabled="true">
                                <attributes>
                                    ...
                                </attributes>
                            </response>
                        </logging>
                    </runtime>
                </operation>
            </operations>
        </port-component>
    </webservice-description>
</oracle-webservices>
```
Steps to Assemble Auditing and Tracing into a Web Service Top Down

The following general steps describe how to assemble an auditing and tracing configuration into a Web service top down.

1. Create the XML file that provides settings for the auditing and tracing features that you want to enable. There are two different ways in which you can do this.

   - Manually write the XML file that contains the auditing and tracing settings. Example 6–8 illustrates an XML file that contains sample auditing and tracing settings.

   - Run the WebServicesAssembler tool with the topDownAssemble command. One of the files it creates is an oracle-webservices.xml file that contains a skeleton of the ports and operations. For example, you could run the Ant task in Example 6–9 without the ddFileName argument to obtain this file. Edit oracle-webservices.xml file to enter the appropriate settings for the auditing and tracing features. Save the file under a different name.

   "Server-Side Auditing Configuration Elements" on page 6-4 and "Server-Side Tracing Configuration Elements" on page 6-8 describe the port-level and operation-level auditing and tracing features that are available on the server.

2. Use the topDownAssemble command to assemble the Web service. Use the ddFileName argument to pass the file with the auditing and tracing configuration you created in Step 1 to the WebServicesAssembler tool.

   See "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer's Guide for more information on the topDownAssemble command.

   See "ddFileName" in the "Deployment Descriptor Arguments" section of the Oracle Application Server Web Services Developer's Guide for more information on this argument.

   Example 6–9 illustrates a topDownAssemble Ant task that uses the ddFileName argument to add the auditing and tracing configuration in wsmLoggingServiceConfig.xml to the Web service.

**Example 6–9  Passing an Auditing and Tracing Configuration in a Top Down Web Service Assembly**

```xml
<oracle:topDownAssemble
   wsdl="BankService.wsdl"
   input="build/classes/service"
   output="build"
   className="oracle.ws.server.bank.BankImpl"
   ear="dist/bank.ear"
   packageName="oracle.ws.server.bank"
   ddFileName="BankServiceWsmConfig.xml"/>
```
Steps to Assemble Auditing into a J2SE Web Service Client Proxy

The following general steps describe how to assemble an auditing configuration into a J2SE Web service client proxy. Tracing is not available for a Web service client.

1. Provide settings for the auditing features that you want to enable in an XML file.
   See “How to Configure Auditing in a J2EE Client” on page 6-4 for a description of the operation-level auditing features that can be set for the client.

2. Use the genProxy command to assemble the Web service proxy. Pass the auditing configuration to the command with the ddFileName argument.
   This will generate an XML file. For the genProxy command illustrated in Example 6–10, the file oracle\generated\runtime\BankPortBinding_Stub.xml will be generated into the test\src directory.
   See “How to Pass Management Information to a J2SE Client” on page 3-7 for more detailed information on adding a management configuration to a J2SE client.

Example 6–10 illustrates a genProxy Ant task that uses the ddFileName argument to add the auditing configuration in wsmClientDD.xml to the Web service.

Example 6–10 Passing an Auditing Configuration in a Web Service Client Assembly

```xml
<oracle:genProxy
    output="test\src"
    packageName="oracle.generated"
    ddFileName="wsmClientDD.xml"/>
</oracle:genProxy>
```

Example 6–11 illustrates the contents of the wsmClientDD.xml for a client-side auditing configuration. The auditing configuration is highlighted in bold. Note that the contents of the file are enclosed in the <port-info> tag.

Example 6–11 Sample Client-Side Auditing Configuration

```xml
<port-info>
    <runtime>
        <operations>
            <operation name="deposit">
                <runtime>
                    <auditing request="true" response="true" fault="false"/>
                </runtime>
            </operation>
        </operations>
    </runtime>
</port-info>
```

Steps to Assemble Auditing into a J2EE Web Service Client

J2EE Web service clients can be configured to perform auditing. Tracing is not available for Web service clients. The following general steps describe how you can add an auditing configuration to a J2EE Web service client. In addition to generating the client code, you must also edit both the standard and the Oracle proprietary Web service deployment descriptor.

1. Generate the J2EE client code by providing the WSDL and the service endpoint interface as input to the genInterface command.
"How to Assemble a J2EE Web Service Client" in the Oracle Application Server Web Services Developer's Guide provides more detailed information on using WebServicesAssembler to assemble J2EE client code.

2. Edit the deployment descriptor for the J2EE component (either web.xml, ejb-jar.xml, or application-client.xml) to add the code to the <service-ref> element that will allow the component to access the Web service endpoint. For examples of how auditing and other Web service management information can be added to a standard J2EE Web service client deployment descriptor, see the following examples.

■ Example 3–5, "web.xml—Static Configuration for a Servlet or JSP Web Service Client"
■ Example 3–7, "ejb-jar.xml—Static Configuration for an EJB Web Service Client"
■ Example 3–9, "application-client.xml—Static Configuration for an Application Client Web Service Client"

3. Edit the Oracle proprietary deployment descriptor for the J2EE component (either orion-web.xml, orion-ejb-jar.xml, or orion-application-client.xml) to add OC4J platform-specific information and the auditing configuration to the <service-ref-mapping> element.

For examples of how auditing and other Web service management information can be added to a J2EE Web service client, see the following examples.

■ Example 3–6, "orion-web.xml—Static Configuration and Management Information for a Servlet or JSP Web Service Client"
■ Example 3–8, "orion-ejb-jar.xml—Static Configuration and Management Information for an EJB Web Service Client"
■ Example 3–10, "orion-application-client.xml—Static Configuration and Management Information for an Application Client Web Service Client"

Example 6–12 illustrates a sample orion-web.xml file that has been edited to contain an auditing configuration. The configuration appears within the <service-ref-mapping> element, which is used to provide platform-specific information.

**Example 6–12 orion-web.xml File Edited to Contain an Auditing Configuration**

```xml
<?xml version="1.0"?>
<orion-web-app
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="http://xmlns.oracle.com/oracleas/schema/orion-web-1.0.0.xsd">
  <service-ref-mapping name="service/BankTeller">
    <port-info>
      <wsdl-port namespaceURI="http://oracle.com/bank"
        localpart="BankPort"/>
    </port-info>
    <service-endpoint-interface>oracle.ws.client.bank.BankService</service-endpoint-interface>
    <runtime enabled="auditing"/>
  </service-ref-mapping>
</orion-web-app>
```
<operations>
  <operation name="deposit">
    <runtime>
      <auditing request="true" response="true" fault="false"/>
    </runtime>
  </operation>
</operations>
</orion-web-app>

How Application Server Control Supports Auditing and Tracing

Application Server Control lets you enable and configure different auditing options at deployment and at runtime. Application Server Control lets you perform the following tasks.

- Modify at deployment time which Web service operations and messages to audit.
- Control at runtime which Web service operations and messages to audit.
- Browse the messages contained in the audit logs for services and J2EE clients.

Similarly, you can enable and configure different tracing options at deployment and at runtime. Application Server Control lets you perform the following tasks.

- Modify at deployment time the type of information to extract and log.
- Control at runtime the type of information to extract and log.
- Browse the messages contained within the logs.

How Oracle JDeveloper Supports Auditing and Tracing

Wizards in Oracle JDeveloper let you configure auditing and tracing (which is called "logging" in JDeveloper) for a Web service in a deployment module. The auditing and logging configuration is stored in the Oracle proprietary deployment descriptor, oracle-webservices.xml.

When Oracle JDeveloper performs the final packaging of a Web service module, it includes the deployment descriptor in the location required by the Web services runtime.

When Oracle JDeveloper is used as the deployment tool for deploying Web services, you have the option to override any auditing and logging configuration that was set during packaging.

The auditing and logging configuration created by Oracle JDeveloper can also be overridden after deployment by Application Server Control.

See Also:

- Oracle JDeveloper on-line help for more information on enabling logging and auditing.
- Edit Auditing Configuration Page and Edit Tracing Configuration Page in the Application Server Control on-line help for more information on overriding auditing and tracing features after deployment.
Understanding Diagnostic Loggers

The Oracle Diagnostic Logging (ODL) framework provides diagnostic logging for Web services auditing and logging. In the ODL framework, log files are formatted as XML documents, enabling logs to be parsed and reused by other Oracle Application Server components such as Application Server Control.

The various components of OC4J use Java loggers that direct log messages of a pre-determined severity to the OC4J log file.

The OC4J log file is generated in XML format using the Oracle Diagnostic Logging framework. It can be viewed and configured through the Logger Configuration page of the Application Server Control Console.

The j2ee-logging.xml file, also known as the "oracle logger", provides the configuration for diagnostic log handlers. This file is described in the following sections.

See Also:
"Using Oracle Diagnostic Logging (ODL)" in the Oracle Containers for J2EE Configuration and Administration Guide provides more information on the features of ODL and the contents of the j2ee-logging.xml file.

Controlling the Output of Web Services Loggers

The j2ee-logging.xml file, also known as the "oracle logger", provides the configuration for diagnostic log handlers. The file contains two sections. The log handler section is where you can define the output properties of a particular logger. The logger section links a particular logger with its handler.

Log Handlers

A log handler specifies the output properties of a particular logger. In the j2ee-logging.xml file, the <log_handler> element defines the handler. Attributes, such as the maximum log file size and its character encoding, are specified by <property> sub-elements. You can also direct the output to a file other than the OC4J log file.

Table 6–4 describes the properties that can be configured for log handlers.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>encoding</td>
<td>Specifies the character encoding for the log file. Default is UTF-8.</td>
</tr>
<tr>
<td>maxFileSize</td>
<td>Sets the maximum size, in bytes, that any log file in the directory will be allowed to grow to. Default is 104857600 bytes.</td>
</tr>
<tr>
<td>maxLogSize</td>
<td>Sets the maximum size, in bytes, for the log file directory. Default is 104857600 bytes.</td>
</tr>
</tbody>
</table>
Example 6–13 illustrates the log handler configuration for auditing and tracing in the j2ee-logging.xml file. The names of the handlers for auditing and logging are oracle-webservices-management-auditing-handler and oracle-webservices-management-logging-handler, respectively.

**Example 6–13  Configuration for Auditing and Tracing Log Handlers**

```xml
...<logging_configuration>
  <log_handlers>
    ...
    <!-- The log handler for the oracle.webservices.management.auditing logger. -->
    <log_handler name='oracle-webservices-management-auditing-handler'
      class='oracle.core.ojdl.logging.ODLHandlerFactory'>
      <property name='path' value='%ORACLE_HOME%/j2ee/OC4J_Instance_Name/log/group_name_n/wsmgmt/auditing/log.xml'/>
      <property name='maxFileSize' value='104857600'/>
      <property name='maxLogSize' value='104857600'/>
      <property name='encoding' value='UTF-8'/>
      <property name='supplementalAttributes' value='J2EE_APP.name,J2EE_MODULE.name,WEBSERVICE.name,WEBSERVICE_PORT.name'/>
    </log_handler>
    <!-- The log handler for the oracle.webservices.management.logging logger. -->
    <log_handler name='oracle-webservices-management-logging-handler'
      class='oracle.core.ojdl.logging.ODLHandlerFactory'>
      <property name='path' value='%ORACLE_HOME%/j2ee/OC4J_Instance_Name/log/group_name_n/wsmgmt/logging/log.xml'/>
      <property name='maxFileSize' value='104857600'/>
      <property name='maxLogSize' value='104857600'/>
      <property name='encoding' value='UTF-8'/>
      <property name='supplementalAttributes' value='J2EE_APP.name,J2EE_MODULE.name,WEBSERVICE.name,WEBSERVICE_PORT.name'/>
    </log_handler>
  </log_handlers>
...```

Example 6–13 illustrates the log handler configuration for auditing and tracing in the j2ee-logging.xml file. The names of the handlers for auditing and logging are oracle-webservices-management-auditing-handler and oracle-webservices-management-logging-handler, respectively.
Loggers
As described in "Understanding Diagnostic Loggers" on page 6-16, OC4J provides a number of Java loggers. In the <loggers> section of the j2ee-logging.xml file, separate <logger> elements define each individual component logger. In addition to linking the specified logger to its output properties in the log handler section, the <logger> element provides attributes that define the Java logging level, whether the logger can inherit the logging level of its parent logger, and the name of the log handler that it is associated with.

The level attribute specifies the Java log level for the logger. By default, the ODL message type and log level is set to NOTIFICATION:1, which maps to the Java log level INFO.

The Web services diagnostic log levels set in the j2ee-logging.xml file can be viewed and configured in the Logger Configuration page of Application Server Control. You can use Application Server Control to change the value of the log level, but these changes are not persistent; they are kept only for the duration of the JVM process.

Note:
- You can make changes to the <log-handler> section of the j2ee-logging.xml file, but changing the <loggers> section is not recommended.
- The "per Web service port" logging level that can be set through Application Server Control cannot currently be specified through the j2ee-logging.xml file.

See Also:
"Configuring OC4J Logging" in the Oracle Containers for J2EE Configuration and Administration Guide provides more information on the contents of the j2ee-logging.xml file.

Example 6-14 illustrates the <loggers> section of the j2ee-logging.xml file for auditing and tracing. The name of the auditing logger is oracle.webservices.management.auditing; the name of the tracing logger is oracle.webservices.management.logging. Their level attributes are set to their default value, NOTIFICATION:1, which maps to the Java Info log level. The
useParentHandlers attribute is set to false, to prevent the auditing and tracing loggers from inheriting the level set for its parent, root, logger.

**Example 6–14  Log Level Configuration for Auditing and Tracing**

...  
  ...<loggers>  
  ...  
  <logger name='oracle.webservices.management.auditing' level='NOTIFICATION:1' useParentHandlers='false'>  
    <handler name='oracle-webservices-management-auditing-handler'/>  
  </logger>  
  ...  
  <logger name='oracle.webservices.management.logging' level='NOTIFICATION:1' useParentHandlers='false'>  
    <handler name='oracle-webservices-management-logging-handler'/>  
  </logger>  
  ...  
  </loggers>  
...

**Adding Configuration for Diagnostic Loggers**

You can use the Diagnostic Logger Configuration page in the Application Server Control to change the log level for a Web service. However, it does not let you change the level for individual loggers and any changes you make are not persistent.

If you want to change the default configuration for a logger, such as the log level or the target file where it will store messages, you can add a configuration for it to the `j2ee-logging.xml` file.

To add a configuration, you must identify the logger in the `<loggers>` section of the file and define a handler for it in the `<log_handlers>` section.

**See Also:**

"Log Handlers" on page 6-16 and "Loggers" on page 6-18 for more information on the `<log_handlers>` and `<loggers>` sections of the `j2ee-logging.xml` file.

Example 6–15 provides a sample configuration for the Web services security logger `oracle.webservices.management.security`. The configuration specifies that the log messages will be stored in the `ORACLE_HOME\j2ee\OC4J_Instance_Name\log\group_name_n\wsmgmt\security\log.xml` file instead of the OC4J log file.

**Example 6–15  Sample Configuration for a Web Services Security Logger**

...  
  ...  
  <!-- The log handler for the oracle.webservices.management.security logger. -->  
  <log_handler name='oracle-webservices-management-security-handler' class='oracle.core.ojdl.logging.ODLHandlerFactory'>  
    <property name='path' value='%ORACLE_HOME%/j2ee/%OPMN_PROC_TYPE%/log/%OPMN_PROC_TYPE_%OPMN_PROC_SET_%OPMN_PROC_INDEX%/wsmgmt/security'/>  
    <property name='maxFileSize' value='10485760'/>  
    <property name='maxLogSize' value='104857600'/>  
    <property name='encoding' value='UTF-8'/>  
  </log_handler>  
...  
  ...  
  ...
Setting Levels of Diagnostic Logging in Application Server Control

Application Server Control enables you to set diagnostic logging levels for each Web service port. To set the logging level, click the Diagnostic Logger Configuration link on the Application Server Control Web Service Administration page. Follow that link to set a logging level for the Web service port.

The level that you set through Application Server Control will override the level of the individual oracle.webservice.* loggers if and only if a “finer” level is set.

For example:

- if the oracle.webservice.security logger is set to INFO and the "per port" level is set to FINE, then all diagnostic messages for the logger oracle.webservice.security that are SEVERE-FINE will be logged for that port.

- if the "per port" level is set to WARNING and the webservice.oracle.security logger is set to INFO, then all diagnostic messages for the logger oracle.webservice.security for the port at level SEVERE-WARNING will be logged and all oracle.webservice.security diagnostic messages of level SEVERE-INFO will be logged regardless of port.

This chapter describes the Custom Serialization Framework API. This API enables you to map and serialize Java value types between schema-defined XML types and Java value type classes that do not conform to the JAX-RPC value type requirements and cannot be handled by the default JAX-RPC serialization mechanism. This framework can also be used to implement custom mapping for the schema types that have default mappings. For example, you can use the framework to map xsd:dateTime to the custom class com.hello.MyDate instead of its default mapping java.util.Calendar.

The Custom Serialization Framework API can be used to serialize Java value types for publishing a Web service top down, bottom up, or for generating Java value types from a schema to publish a Web service endpoint.

OracleAS Web Services provides built in support for mapping certain Java data types. You do not need to create custom mappings for these Java value types.

See Also:

- "How OracleAS Web Services Supports Java Value Types" on page H-3 and Chapter 5.4 of the JAX-RPC 1.1 specification lists the requirements for Java value types. The JAX-RPC 1.1 specification can be found at the following Web site:
  http://java.sun.com/webservices/jaxrpc/index.jsp
- Appendix H, "Mapping Java Types to XML and WSDL Types" lists the built in support for Java value types offered by OracleAS Web Services.

This chapter has the following sections:

- Understanding the Custom Serialization Framework API
- How to Use Custom Serialization in Web Service Development
- How to Use Custom Serialization in Top Down Web Service Development
- How to Use Custom Serialization in Bottom Up Web Service Development
- How to Use Custom Serialization in Schema-Driven Web Service Development
- How to Assemble a Client for Custom Type Mapping and a Custom Serializer
Understanding the Custom Serialization Framework API

If you want to expose a custom or non-standard Java value type in your Web service, OracleAS Web Services provides an API that lets you serialize them into an XML representation. The SOAPElementSerializer interface in the oracle.webservices.databinding package defines the interface for pluggable custom serializers for the OracleAS Web Services JAX-RPC implementation.

public interface SOAPElementSerializer

An instance of SOAPElementSerializer serializes a Java object to an XML representation of a SOAPElement and deserializes a SOAPElement to a Java object. The interface has the following methods.

■ public SOAPElement serialize(QName tagName, Object object)
  Implements the serialize method to marshall a Java object to an XML fragment of a SAAJ SOAPElement instance. For this serializer implementation to be reusable, the implementation of serialize uses the value of the tagName parameter as the top level element tag name of the returned SOAPElement instance. This is because an XML schema complexType may be used for different element definitions.

■ public Object deserialize(SOAPElement element)
  Implements the deserialize method to unmarshal an XML fragment of a SAAJ SOAPElement instance to a Java object.

■ public void init(Map prop)
  Called by the OracleAS Web Services runtime to indicate that an instance of the SOAPElementSerializer implementation is being placed into service. The init method is called with an instance of Map created from the init-param elements specified under the corresponding serializer element in the Custom Type Mapping File. Both the key type and value type of the Map instance are java.lang.String.

The key and value values are defined by the user and obtained from the name and value attributes of the <init-param> element in the <serializer> section of the oracle-webservices.xml. For example, in the following oracle-webservices.xml fragment, myParam is the key type and myValue is the value.

...<serializer java-class="mySerializer">
  <init-param name="myParam" value="myValue"/>
</serializer>
...

An implementation of the interface requires a default no-argument constructor. For more information on the SOAPElementSerializer interface, see the Oracle Application Server Web Services Java API Reference.

How to Use Custom Serialization in Web Service Development

To use the custom serialization in your Web service, provide an implementation of the SOAPElementSerializer for your custom Java type value class. You must also provide the custom Java value type class and an XML configuration file that defines the mapping between the Java type value class and the XML schema type it should represent. This is described in the following sections.
How to Implement a Custom Serializer

This section describes the steps for implementing a custom serializer for a Java value type class.

1. Define the custom Java value type class that you want to express as an XML schema type.
2. Define a custom serializer implementation of the class.
3. Define the service endpoint interface, and its implementation.
   - If you are assembling a Web service top down, then WebServicesAssembler will generate the service endpoint interface from a WSDL. If you are assembling the Web Service bottom up, then you must provide a Java service endpoint interface.
4. Create an oracle-webservices type mapping configuration XML file that identifies the schema type that will be used to represent the custom Java type value class.
5. Include the custom type in the client code.

These steps are more completely described in the following sections:

- How to Define a Custom Java Type Value Class
- How to Define a Custom Serializer Implementation for a Java Type Value Class
- How to Define a Service Endpoint Interface that Uses a Java Type Value Class
- How to Create an oracle-webservices Type Mapping Configuration
- How to Use Custom Types in Client Proxy Code

How to Define a Custom Java Type Value Class

This section illustrates a custom Java type value class that can be used to map to an XML schema type.

Note:

- The custom Java type class does not have to be Serializable if the Web service is not going to be used with any J2EE features that require it (such as EJB or JMS).
- An empty constructor is not a requirement. The serializer implementation that you write programmatically constructs the instance of the corresponding Java type and populates the content of the Java object. This is why you want to use the custom serializer. It provides full control over the XML-to-Java and Java-to-XML mappings.
Example 7–1 illustrates a definition of a custom Java type value class. In JAX-RPC, xsd:dateTime can be represented by either java.util.Calendar or java.util.Date. However, instead of using either of these classes, assume that you want to implement your own data class. Example 7–1 illustrates a single user-defined Java type value class, oracle.demo.custom_type.MyDate. The class implements Serializable and contains methods to get and set String values.

Example 7–1 Sample Custom Java Type Value Class

```java
package oracle.demo.custom_type;

public class MyDate implements java.io.Serializable{
    private String string;
    public MyDate(String s) {
        string = s;
    }
    public String getString() {
        return string;
    }
    public void setString(String string) {
        this.string = string;
    }
}
```

How to Define a Custom Serializer Implementation for a Java Type Value Class

To use a Java type value class in a Web service implementation and to allow an XML schema type to represent the class in a WSDL, you must provide an implementation of SOAPElementSerializer for it. The implementation will handle the serialization and deserialization between the Java type value class and the XML schema type.

Example 7–2 illustrates MyDateSerializer. This is an implementation of SOAPElementSerializer for the MyDate value type class described in Example 7–1. The implementation will allow MyDate to be used in the Web service endpoint interface and to handle serialization and deserialization between MyDate and xsd:dateTime. It will also allow the xsd:dateTime schema type to represent the MyDate class in the generated WSDL.

Example 7–2 Sample SOAPElementSerializer Implementation

```java
package oracle.demo.custom_type;
import oracle.webservices.databindng.SOAPElementSerializer;
import javax.xml.soap.SOAPFactory;
import javax.xml.soap.SOAPException;
import javax.xml.soap.SOAPElement;
import javax.xml.namespace.QName;
import java.util.Iterator;
import java.util.Map;
public class MyDateSerializer implements SOAPElementSerializer {
    private Map initParams;
    protected SOAPFactory soapFactory;
    public MyDateSerializer() {
    }
    public void init(Map prop) {
```
### Implementing Custom Serialization of Java Value Types

```java
initParams = prop;
try {
    soapFactory = SOAPFactory.newInstance();
} catch (SOAPException e) {
    e.printStackTrace();
}

public Object deserialize(SOAPElement ele) {
    String str = "";
    for( Iterator i = ele.getChildElements(); i.hasNext(); ) {
        Object obj = i.next();
        if( obj instanceof Text ) {
            str += ((Text)obj).getValue();
        }
    }
    return new MyDate(str);
}

public SOAPElement serialize(QName qname, Object obj) {
    SOAPElement xml = null;
    try {
        xml = soapFactory.createElement(
            qname.getLocalPart(),
            qname.getPrefix(),
            qname.getNamespaceURI());
        xml.addTextNode( ((MyDate)obj).getString() );
    } catch (SOAPException e) {
        e.printStackTrace();
    }
    return xml;
}
```

### How to Define a Service Endpoint Interface that Uses a Java Type Value Class

This section illustrates how to expose a Java service endpoint interface that uses a user-defined bean as a Web service. Example 7–3 and Example 7–4 illustrate a Java service endpoint interface and implementation that use the `oracle.demo.custom_type.MyDate` class. Example 7–5 illustrates the definition of a user-defined bean type, `MyDateBean`, employed by the interface.

Note that to satisfy JAX-RPC requirements, the `MyDateServiceEndpoint` interface in Example 7–3 extends `java.rmi.Remote` and the methods throw `java.rmi.RemoteException`.

The interface also employs a user-defined bean type, `MyDateBean`, as a parameter. `MyDateBean` has two properties of type `MyDate`: `beginDate` and `endDate`. `WebServicesAssembler` will generate the schema for `MyDateBean` because `MyDate` is configured to use the custom serializer and `MyDateBean` conforms to the JAX-RPC Value Type (Bean) patterns.

#### Example 7–3  Sample Java Service Endpoint Interface

```java
package oracle.demo.custom_type;
import oracle.demo.custom_type.MyDate;
```
public interface MyDateServiceEndpoint extends java.rmi.Remote {

    public MyDate echoMyDate(MyDate date)
    throws java.rmi.RemoteException;

    public MyDateBean echoMyDateBean(MyDateBean bean)
    throws java.rmi.RemoteException;
}

Example 7–4 illustrates the implementation of MyDateServiceEndpoint. Note that the new methods defined in the implementation throw a java.rmi.RemoteException.

Example 7–4  Sample Implementation of a Java Service Endpoint Interface

```
package oracle.demo.custom_type;

public class MyDateServiceEndpointImpl implements MyDateServiceEndpoint {

    public MyDate echoMyDate(MyDate date) throws java.rmi.RemoteException {
        return date;
    }

    public MyDateBean echoMyDateBean(MyDateBean bean) throws java.rmi.RemoteException {
        return bean;
    }
}
```

Example 7–5 illustrates MyDateBean, a user-defined bean employed by the interface.

Example 7–5  Sample User-Defined Bean Type

```
package oracle.demo.custom_type;

public class MyDateBean implements java.io.Serializable{

    private MyDate beginDate;
    private MyDate endDate;

    public MyDate getBeginDate() {
        return beginDate;
    }

    public void setBeginDate(MyDate beginDate) {
        this.beginDate = beginDate;
    }

    public MyDate getEndDate() {
        return endDate;
    }

    public void setEndDate(MyDate endDate) {
        this.endDate = endDate;
    }
}
```
How to Create an oracle-webservices Type Mapping Configuration

The oracle-webservices type mapping configuration XML file specifies the XML schema type that represents the custom Java type value class. The file provides a <type-mapping> element to specify the XML schema type it will serialize to, the custom Java type value class, and the class that performs the custom serialization. Table 7–1 describes the contents of the <type-mapping> element.

Table 7–1 Contents of the <type-mapping> Element

<table>
<thead>
<tr>
<th>Attribute or Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>java-class</td>
<td>Attribute of the type-mapping element; identifies the Java type value class.</td>
</tr>
<tr>
<td>serializer-class</td>
<td>Subelement of the type-mapping element; identifies the class that performs the custom serialization.</td>
</tr>
<tr>
<td>xml-type</td>
<td>Attribute of the type-mapping element; identifies the XML schema type.</td>
</tr>
</tbody>
</table>

The schema files oracle-webservices-10_0.xsd and oracle-webservices-types-10_0.xsd can be found in the oc4j-schemas.jar file in the OC4J_HOME/j2ee/home/lib/ directory.

Example 7–6 illustrates an oracle-webservices type mapping configuration that instructs WebServicesAssembler to map the oracle.demo.custom_type.MyDate class to xsd:dateTime. The <serializer-class...> element identifies the MyDateSerializer class developed in Example 7–2.

Example 7–6 Sample oracle-webservices Type Mapping Configuration

```
<oracle-webservices>
  <webservice-description name="MyDateService">
    <type-mappings xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <type-mapping
        java-class="oracle.demo.custom_type.MyDate"
        xml-type="xsd:dateTime">
        <serializer class="oracle.demo.custom_type.MyDateSerializer"/>
      </type-mapping>
    </type-mappings>
  </webservice-description>
</oracle-webservices>
```

How to Use Custom Types in Client Proxy Code

By default, WebServicesAssembler does not configure custom types when assembling the Web service client proxy. The assembled proxy will use the default JAX-RPC Java value type-to-XML schema type mappings. For example, for the MyDate example presented in this section, this means that the default Java value type, java.util.Calendar, will be used to represent xsd:dateTime.

To configure custom types into your assembled client proxy code, use the ddFileName and classpath arguments to the genProxy command. The ddFileName argument specifies the oracle-webservices type mapping configuration XML file. The classpath argument must include the value types and custom serializer. This will allow you to use the custom Java classes in your client proxy code.

For the example in this section, you must provide the oracle-webservices type mapping configuration and its classpath when you generate the client proxy code. This will enable you to use MyDate instances for xsd:dateTime in the Web service client proxy.
Example 7–7 illustrates assembled client proxy code. The example assumes that the client proxy was generated with an oracle-webservices type mapping configuration XML file that describes the mapping of MyDate to xsd:dateTime. Note that the client proxy code uses instances of MyDate instead of the default mapping, Calendar.

Example 7–7  Client-Side Proxy Code, Using Custom Java Type Values

```java
ServiceFactory factory = ServiceFactory.newInstance();
MyDateService service = (MyDateService)factory.loadService(MyDateService.class);
MyDateServiceEndpoint proxy = service.getMyDateServiceEndpointPort();
((Stub)proxy)._setProperty( Stub.ENDPOINT_ADDRESS_PROPERTY, address );
MyDate req = new MyDate("Year:2004, Month:5, Date:24");
MyDate res = proxy.echoMyDate( req );
MyDate begin = new java.util.GregorianCalendar(1977, 5, 24);
MyDate end = new java.util.GregorianCalendar(2004, 5, 24);
...
```

How to Use Custom Serialization in Top Down Web Service Development

You can use the custom serializer to provide special Java value type-to-XML schema type mappings for a custom Java value type in the service endpoint interface. This enables you to substitute a custom Java value type for a type that has a defined, default JAX-RPC mapping in the WSDL. WebServicesAssembler will process the custom Java value type and generate the correct code for the interface.

For example, you can change the default mapping of the schema-defined XML type xsd:dateTime from java.util.Calendar, to a custom Java value type class, MyDate. The custom serializer will allow you to generate the correct code for the service endpoint interface.

Other than providing the custom Java value type class, the SOAPElementSerializer implementation, and the type mapping configuration file, this is very similar to the generic top down Web service development.

Developing a Web service that uses a custom serializer follows these general steps.

1. Run WebServicesAssembler with the genInterface command and the custom serializer to generate the service endpoint interface with the custom type mappings.
2. Implement the service endpoint interface.
3. Run WebServicesAssembler again with the toplevelAssemble command to assemble the Web service and package it in an EAR.

The following sections describe these steps in greater detail.

Prerequisites

Before you begin, provide the following files and information.

- the custom Java value type class(es)
  See "How to Define a Custom Java Type Value Class" on page 7-3 for more information on custom Java value type classes.
- the implementation of the SOAPElementSerializer interface for the custom Java value type class(es)
See "How to Define a Custom Serializer Implementation for a Java Type Value Class" on page 7-4 for more information on implementing the SOAPElementSerializer interface.

- the WSDL that employs the custom Java value class(es)
- the oracle-webservices type mapping configuration XML file

See "How to Create an oracle-webservices Type Mapping Configuration" on page 7-7 for more information on creating the oracle-webservices type mapping configuration.

**Steps for Using Custom Serialization in Top Down Web Service Development**

The following steps describe how to use custom serialization in top down Web service development.

1. Provide the files described in the Prerequisites section as input to the WebServicesAssembler genInterface command. For example:

   ```
   java -jar wasa.jar -genInterface
   -ddFileName myOracleWSDescriptor.xml
   -output build/src/service
   -wsdl wsdl/MyWSDL.wsdl
   -unwrapParameters false
   -packageName oracle.demo.customdoclit.service
   ```

   In this command:

   - genInterface—Creates a service endpoint interface for each port type and a Java value type class (beans) for any complex type defined in a WSDL. It also creates a JAX-RPC mapping file that describes the mapping between the XML schema types and the Java value type classes.
   - ddFileName—Specifies the oracle-webservices.xml deployment descriptor that contains the settings you want to assign to the Web service.
   - output—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
   - wsdl—Specifies the absolute file path, relative file path, or URL to a WSDL document.
   - unwrapParameters—This argument can be set only for document-literal operations and will be ignored for other message formats. When set to false the generated service endpoint interface will be generated with wrappers around the input parameter and the return type.
   - packageName—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.

   **See Also:**

   "Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

The major difference between using a custom serializer and standard top down Web services development, is the presence of the ddFileName argument. The myOracleWSDescriptor.xml file provides WebServicesAssembler with the mappings it will use to generate the service endpoint interface.
WebServicesAssembler will also use the custom mappings in this file to generate a Java interface for every port type specified in the WSDL and a Java Bean for each complex type.

The name of the directory that stores the generated interface is based on the values of the output and packageName arguments. For this example, the generated interface is stored in `build/src/service/oracle/demo/customdoclit/service`.

2. Compile the generated interface and type classes.

For example:

```
javac -destdir ${service.classes.dir}
    -excludes {javac.excludes}
    -path build/src/service
    -classpath ${wsdemo.common.class.path}
```

If you have set your CLASSPATH to include the referenced libraries described in "Web Service Client APIs and JARs" in the Oracle Application Server Web Services Developer's Guide, you can omit the classpath argument. Otherwise, ensure that all of these libraries are contained in the path represented by `${wsdemo.common.class.path}`. If you are running an Ant example, make the appropriate settings in the Ant build script.

3. Implement the service endpoint interface.

The implementation must have a method signature that matches every method in the generated Java interface.

4. Compile the service implementation.

For example, you can use the same command as in Step 2 if the interface source was generated in the same directory where the Impl class was saved. If it was not, you must change the value of the path argument.

5. Provide the service endpoint implementation, the WSDL, the custom Java value type class(es), the SOAPElementSerializer implementation(s), and the type mapping configuration XML file as input to the WebServicesAssembler `topdownAssemble` command. This command will generate and package a deployable EAR file.

```
java -jar wsa.jar -topDownAssemble
    -ddFileName myOracleWSDescriptor.xml
    -output ./build
    -wsdl wsdl/MyWSDL.wsdl
    -unwrapParameters false
    -packageName oracle.demo.customdoclit.service
    -className oracle.demo.customdoclit.service.MyEndpointImpl
    -appName MyWebService
    -ear ./build/MyWebService.ear
```

In this command and Ant task:

- **topDownAssemble**—Creates the required classes and deployment descriptors for a Web service based on a WSDL description. The files can be stored in either an EAR file, a WAR file, or a directory.
- **ddFileName**—Specifies the `oracle-webservices.xml` deployment descriptor that contains the settings you want to assign to the Web service.
- **output**—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
How to Use Custom Serialization in Top Down Web Service Development

- **wsdl**—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- **unwrapParameters**—When set to false the generated service endpoint interface will be generated with wrappers around the input parameter and the return type.
- **packageName**—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.
- **className**—Specifies the name of the class (including the package name) that is the implementation class for the Web service.
- **appName**—Specifies the name of an application. Usually, this name is used as a base value for other arguments like context and uri.
- **ear**—Specifies the name and location of the generated EAR.

**See Also:**

"Using WebServicesAssembler", in the *Oracle Application Server Web Services Developer's Guide* for more detailed information on these arguments.

6. Use WebServicesAssembler to generate the Web services client-side proxy.

- generate stubs (client proxies) for a J2SE Web service client by running the WebServicesAssembler tool with the genProxy command, or
- generate a service endpoint interface and a JAX-RPC mapping file for a J2EE Web service client by running the WebServicesAssembler tool with the genInterface command.

Assembling a J2EE Web Service Client" and "Assembling a J2SE Web Service Client" in the *Oracle Application Server Web Services Developer's Guide* provides more information on assembling client-side code.

To use `MyDate` to represent `xsd:dateTime` in your client-side proxy code, you must use `ddFileName` to specify the oracle-webservices type mapping configuration XML file and `classpath` to provide the path to the custom Java class `MyDate`.

For example, the following command generates client proxies (stubs) that can be used for a J2SE client.

```
java -jar wasa.jar -genProxy
   -wsdl http://localhost:8888/custom_type_mydate/custom_type_mydate?WSDL
   -packageName oracle.demo.custom_type.mydate_with_ser
   -output ./build/src/client
   -ddFileName MyClientSideDD.xml
   -classpath ./build/classes/service
```

In this command and Ant task:

- **genProxy**—Creates a static proxy stub that can be used by a J2SE Web service client.
- **wsdl**—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- **packageName**—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.
How to Use Custom Serialization in Bottom Up Web Service Development

You can use the custom serializer to provide special Java value type-to-XML schema type mappings of some specific Java value types used in the service endpoint interface. This means that you can use your own custom schema document which describes special Java value types-to-XML schema type mappings. When you provide special Java value type-to-XML schema type mappings, you do not want WebServicesAssembler to generate schema definitions for these types.

Because this is bottom up Web service development, WebServicesAssembler will generate a WSDL. In the WSDL, instead of generating the schema for the value types, WebServicesAssembler will import one or more schema documents you specify.

Prerequisites

Before you begin, provide the following files and information.

- the custom Java value type class(es). These classes must reside in the classpath
  See "How to Define a Custom Java Type Value Class" on page 7-3 for more information on custom Java value type classes.
- the schema document that describes the custom Java value type(s)
- the implementation of the SOAPElementSerializer interface for the custom Java value type class(es)
  See "How to Define a Custom Serializer Implementation for a Java Type Value Class" on page 7-4 for more information on implementing the SOAPElementSerializer interface.
- the Java service endpoint interface that uses special custom Java value type class(es)
  See "How to Define a Service Endpoint Interface that Uses a Java Type Value Class" on page 7-5 for more information on Service Implementation Endpoints.
- the oracle-webservices type mapping configuration XML file
  See "How to Create an oracle-webservices Type Mapping Configuration" on page 7-7 for more information on creating the oracle-webservices type mapping configuration file.

See Also:

- "How to Use Custom Types in Client Proxy Code" on page 7-7 for information on coding a client-side proxy to use custom types.
- "Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.
Steps to Use Custom Serialization in Bottom Up Web Service Development

The following instructions assemble a Web service bottom up, that requires custom type mapping.

1. Provide the files described in the Prerequisites section as input to WebServicesAssembler assemble command.

This command is similar to the standard bottom up Web services development except that the ddFileName argument is used to specify the oracle-webservices type mapping configuration XML file. The input argument contains the custom serializer implementation. WebServicesAssembler generates the WSDL and packages a deployable EAR file.

Command line:

```
java -jar wsa.jar -assemble
-targetNamespace http://oracle.com/ws_demo/custom_type_mydate
-typeNamespace http://oracle.com/ws_demo/custom_type_mydate
-input ./build/classes/service
-classpath ./build/classes/service
-output ./dist
-ddFileName ./MyOracleWSDescriptor.xml
-interfaceName oracle.demo.custom_type.MyDateServiceEndpoint
-className oracle.demo.custom_type.MyDateServiceEndpointImpl
-serviceName MyDateService
-appName custom_type_mydate
```

Ant task:

```
<oracle:assemble targetNamespace="http://oracle.com/ws_demo/custom_type_mydate"
    typeNamespace="http://oracle.com/ws_demo/custom_type_mydate"
    input="/build/classes/service"
    classpath="/build/classes/service"
    output="/dist"
    ddFileName="/custom_type_mydate_pdd.xml"
    serviceName="MyDateService"
    appName="custom_type_mydate"
    >
    <oracle:porttype
        interfaceName="oracle.demo.custom_type.MyDateServiceEndpoint"
        className="oracle.demo.custom_type.MyDateServiceEndpointImpl">
    </oracle:porttype>
</oracle:assemble>
```

In this command and Ant task:

- **assemble**—Generates a Web service from Java files bottom up. The command creates all of the files required to create a deployable archive.
- **targetNamespace**—Specifies the target namespace to be used in the generated WSDL. The value can be either a conforming HTTP URL, a non-conforming HTTP URL, or even a URI.
- **typeNamespace**—Specifies the type namespace to be used in the schema types in the generated WSDL. The name that you specify will always be used and it will not be reversed.
- **input**—Specifies the directory or JAR containing the classes that should be copied to WEB-INF/classes. This argument will be added to the classpath used by the WebServicesAssembler.
classpath—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

output—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

ddFileName—Specifies the oracle-webservices.xml deployment descriptor that contains the settings you want to assign to the Web service.

interfaceName—Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).

className—Specifies the name of the class (including the package name) that is the implementation class for the Web service.

serviceName—Specifies the service name.

appName—Specifies the name of an application. Usually, this name is used as a base value for other arguments like context and uri.

See Also:
"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

2. Use WebServicesAssembler to generate the Web service client-side proxy. To use MyDate to represent xsd:dateTime in your client-side proxy code, you must use ddFileName to specify the oracle-webservices type mapping configuration file and classpath to provide the path to the custom Java class MyDate.

Command line:
```
java -jar wsa.jar -genProxy
 -wsdl http://localhost:8888/custom_type_mydate/custom_type_mydate?WSDL
 -packageName oracle.demo.custom_type.mydate_with_ser
 -output ./build/src/client
 -ddFileName ./MyClientSideDD.xml
 -classpath ./build/classes/service
```

Ant task:
```
<oracle:genProxy
    wsdl="http://localhost:8888/custom_type_mydate/custom_type_mydate?WSDL"
    packageName="oracle.demo.custom_type.mydate_with_ser"
    output="/build/src/client"
    ddFileName="/MyOracleClientDD.xml"
    classpath="/build/classes/client"
/>
```

In this command and Ant task:
- genProxy—Creates a static proxy stub that can be used by a J2SE Web service client.
- wsd1—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- packageName—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.
How to Use Custom Serialization in Schema-Driven Web Service Development

In schema-driven Web service development, you invoke WebServicesAssembler with the schema document to generate the Java value type classes (beans) before you assemble the Web service.

Because the Java value classes generated from a schema complex type conform to the JAX-RPC value type (bean) pattern requirement, a custom serializer is not necessary. If you are satisfied with the default mapping provided by JAX-RPC, you do not need to implement the a custom serializer.

However, if you want to change the default marshaling between XML and Java, then you must implement the custom serializer for the generated Java value type classes.

Assembling a Web service from a schema follows these general steps.

1. Run WebServicesAssembler with the schema document to generate the Java Value Type classes, the standard JAX-RPC mapping file, and the oracle-webservices type mapping configuration XML file (custom-type-mappings.xml).

2. Develop your own service endpoint interface and its implementation. It is assumed that the interface and implementation use one or more custom Java data types that are not used in the schema document in Step 1.

3. If you are not satisfied with the default marshalling for one or more classes, write a custom serializer to implement your own marshalling logic.

4. Edit the oracle-webservices type mapping configuration XML file to include the custom serializer. You can also substitute an alternative Java class for any of the generated Java value type classes.

5. Run WebServicesAssembler again, this time, to generate a WSDL document. Input the JAX-RPC mapping file, the edited oracle-webservices type mapping configuration XML file, the schema document, the generated Java value types, and the service endpoint interface and its implementation. Also include the custom serializer, if one was created.

The generated WSDL will import the specified schema instead of generating one from the Java value types.

See Also:
- "How to Use Custom Types in Client Proxy Code" on page 7-7 for information on coding a client-side proxy to use custom types.
- "Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.
WebServicesAssembler will assemble a deployable EAR with a generated WSDL and all of the implementation files and deployment descriptors to enable a Web service.

Prerequisites

Before you begin, provide the following files and information.

- the schema document
  See "Sample Schema Document" on page 7-20 for an example of a schema document from which Java value type classes can be generated.

- the service endpoint interface and its implementation
  It is assumed that the interface and implementation use one or more custom Java data types that are not used in the schema document. See "Sample Service Endpoint Interface and Implementation" on page 7-20 for a sample service endpoint interface and implementation that use custom Java data types that do not appear in the schema document described in Step 1.

- the definition of a custom Java type that will represent the complex type in the schema
  "Sample Java Custom Type Implementation" on page 7-22 illustrates the implementation of a custom Java data type used in the sample interface and implementation.

- if you are providing custom default marshalling logic, you must also provide a custom serializer to implement your own marshalling logic
  "How to Implement a Serializer with Custom Marshalling Logic" on page 7-22 describes how to implement the serializer and marshalling logic.

See Also:

"Sample Schema Document" on page 7-20 for a schema document that defines types can be exposed through a service endpoint interface.

Steps for Schema-Driven Web Services Assembly with Custom Serialization

This section describes how to develop a Web service from an XML schema that contains complex types. It also describes how to provide a custom serializer to handle serialization and deserialization between the complex type and a Java custom type. "Sample Schema Document" on page 7-20 describes the schema used in this example. The schema contains two complex types: InitItem and StringItem.

The section assumes that you want to use the custom Java type oracle.webservices.examples.customtypes.MyInitItem, described in "Sample Java Custom Type Implementation" on page 7-22, to represent the InitItem complex type in the schema. To do this, you must provide a custom serializer to handle serialization and deserialization between the Java instance of MyInitItem and XML instance of InitItem.

For the complex schema type StringItem, the section assumes that you want to use the default JAX-RPC value type data binding mechanism to generate a value type class to represent the complex type. It also assumes that you want to do custom formatting on the XML instances of xsd:string. To do this, a custom serializer will be created to handle serialization and deserialization between Java instance of java.lang.String and the XML instance of xsd:string.

The following steps describe how to develop this Web service.
1. Run WebServicesAssembler with the schema document to generate the Java value types and the standard JAX-RPC mapping file.

   java -jar wsa.jar -genValueTypes
   -packageName oracle.webservices.examples.customtypes
   -schema ./MySchema.xsd
   -output ./build/src/types

   In this command:
   - genValueTypes—Creates JAX-RPC value type classes (beans) from the specified schemas.
   - packageName—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.
   - schema—Specifies the relative path or URL to an XML schema document. This argument enables you to specify a schema for value types instead of letting WebServicesAssembler generate them.
   - output—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

   See Also:

   "Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

   The schema document used in this command is described in "Sample Schema Document" on page 7-20. The genValueTypes command generates two classes from this schema InitItem and StringItem. The InitItem class is not needed since you will be replacing it with your custom type class.

   This command also generates a JAX-RPC mapping file, jaxrpc-mappings.xml, which describes the binding of the generated value types classes, and a custom-type-mappings.xml file to record which value type classes are generated from an existing schema file. The custom-type-mappings.xml file is a generated server-side instance of the OracleAS Web Services type mapping configuration XML file.

2. Compile the generated value types to the /build/classes/service directory.

   The genValueTypes command does not compile classes. You must perform this step yourself. Note that you can either delete the InitItem class or exclude it from your compilation. This is because you will be providing a custom serializer for it.

3. Implement the custom serializers. In this example, two custom serializers are required: a serializer to map between oracle.webservices.examples.customtypes.MyInitItem and InitItem and a serializer to map between java.lang.String and xsd:string.

   See "How to Implement a Serializer with Custom Marshalling Logic" on page 7-22 for a sample implementation of these serializers.

4. Develop the service endpoint interface and its implementation.

   See "Sample Service Endpoint Interface and Implementation" on page 7-20 for a sample implementation of a service endpoint interface that uses oracle.webservices.examples.customtypes.MyInitItem and the generated Java value type classes.
5. Edit the `custom-type-mappings.xml` file to include an alternative Java class and to include the custom serializer. In Step 1, the `custom-type-mappings.xml` file was generated into the output directory `/build/src/types`. Edit the file to use `oracle.webservices.examples.customtypes.MyInitItem` and its custom serializer, and to use the `oracle.webservices.examples.customtypes.MyStringSerializer` custom serializer.

See “How to Edit the Type Mapping Configuration XML File for Java Value Type Classes” on page 7-25 for details about adding the alternative Java class and custom serializers.

6. Run the WebServicesAssembler tool again, this time with the `assemble` command, to generate the WSDL and a deployable EAR file. Use the following items as input:

   - the XML schema document (`MySchema.xsd`) as the target of the `schema` argument.
   - the value type classes generated in Step 1. These classes should be stored in the directory specified by the `input` argument (`build/classes.service`).
   - the JAX-RPC mapping file (`jaxrpc-mappings.xml`) generated in Step 1.
   - the compiled custom serializer classes created in Step 2. These classes should be stored in the directory specified by the `input` argument (`build/classes.service`).
   - the service endpoint interface, `MyEndpointIntf`, and its implementation, `MyEndpointImpl`, created in Step 3. These files are targets of the `interfaceName` and `className` arguments.
   - the modified custom type mapping file, `MyCustomTypeMappings.xml`, created in Step 4. This file lists the class name of each custom serializer. Enter this file as the target of the `ddFileName` argument.
   - the `appName` argument identifies the name of the generated application.

   The WebServicesAssembler tool assembles a deployable EAR file in the `/dist` directory. The generated WSDL in the EAR file imports the schema document. Note that the following `assemble` command is similar to normal Java-to-WSDL, or bottom up Web services assembly.

```
java -jar wsa.jar -assemble
   -schema ./MySchema.xsd
   -mappingFileName ./build/src/types/jaxrpc-mappings.xml
   -input ./build/classes/service
   -classpath ./build/classes/service
   -output ./dist
   -ddFileName ./MyCustomTypeMappings.xml
   -interfaceName oracle.webservices.examples.customtypes.MyEndpointIntf
   -className oracle.webservices.examples.customtypes.MyEndpointImpl
   -appName MyCustomTypes
```

In this command:

- `assemble`—Generates a Web service from Java files bottom up. The command creates all of the files required to create a deployable archive.
- `schema`—Specifies the relative path or URL to an XML schema document. This argument enables you to specify a schema for value types instead of letting WebServicesAssembler generate them.
■ mappingFileName—Specifies a file location that points to a JAX-RPC mapping file.

■ input—Specifies the directory or JAR containing the classes that should be copied to WEB-INF/classes. This argument will be added to the classpath used by the WebServicesAssembler.

■ classpath—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

■ output—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

■ ddFileName—Specifies the oracle-webservices.xml deployment descriptor that contains the settings you want to assign to the Web service.

■ interfaceName—Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).

■ className—Specifies the name of the class (including the package name) that is the implementation class for the Web service.

■ appName—Specifies the name of an application. Usually, this name is used as a base value for other arguments like context and uri.

See Also:
"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

7. Deploy the service and bind the application.

Deploy EAR files in the standard manner into a running instance of OC4J. The following is a sample deployment command:

```
java -jar <OC4J_HOME>/j2ee/home/admin_client.jar deployer:oc4j:localhost:port <user> <password>
   -deploy
   -file ./dist/MyCustomTypes.ear
   -deploymentName MyCustomTypes
   -bindWebApp default-web-site
```

See Oracle Containers for J2EE Deployment Guide for more information on deploying EAR files.

8. Develop the client.

■ generate stubs (client proxies) for a J2SE Web service client by running the WebServicesAssembler tool with the genProxy command, or

■ generate a service endpoint interface and a JAX-RPC mapping file for a J2EE Web service client by running the WebServicesAssembler tool with the genInterface command

See "How to Assemble a Client for Custom Type Mapping and a Custom Serializer" on page 7-27 for an example of developing a J2SE client-side proxy that uses oracle.webservices.examples.customtypes.MyInitItem to represent InitItem and the custom serializer to handle the marshalling and unmarshaling of data between the client and server.
Sample Schema Document
Example 7–8 illustrates the MySchema.xsd schema document that provides types that will be exposed as a service endpoint interface. The InitItem and StringItem are complex types.

Example 7–8  Schema Definitions of InitItem and StringItem

```xml
<?xml version = '1.0' encoding = 'UTF-8'?>
<schema
    targetNamespace="http://examples.webservices.oracle/customtypes"
    xmlns:tns="http://ws.oracle.com/types"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://www.w3.org/2001/XMLSchema">

    <complexType name="IntItem">
        <sequence>
            <element name="name" type="xsd:string"/>
            <element name="value" type="xsd:int"/>
        </sequence>
    </complexType>

    <complexType name="StringItem">
        <sequence>
            <element name="name" type="xsd:string"/>
            <element name="value" type="xsd:string"/>
        </sequence>
    </complexType>

</schema>
```

Sample Service Endpoint Interface and Implementation
This section illustrates a service endpoint implementation that uses a different Java data type than the one in the schema document.

Example 7–10 provides a sample service endpoint interface, oracle.webservices.examples.customtypes.MyEndpointIntf, and Example 7–11 provides its implementation, oracle.webservices.examples.customtypes.MyEndpointImpl. Note that the interface extends java.rmi.Remote and its methods throw java.rmi.RemoteException. Also note that the getItems methods in the interface and implementation get items of type MyInitItem instead of the InitItem value type class generated from the schema document.

To assemble a Web service that will expose the methods that use oracle.webservices.examples.customtypes.MyInitItem data types, you must also replace the InitItem entry in the oracle-webservices type mapping configuration XML file with MyInitItem.

Optionally, if you want to provide custom marshalling and unmarshaling for MyInitItem data, you must implement a custom serializer for this class.

See Also:
- "How to Edit the Type Mapping Configuration XML File for Java Value Type Classes" on page 7-25 for more information on replace the InitItem entry in the oracle-webservices type mapping configuration XML file.
- "How to Implement a Serializer with Custom Marshalling Logic" on page 7-22 for more information on implementing a custom serializer to provide custom marshalling and unmarshaling logic.
Example 7–9 illustrates the definition of the Items custom type class. This class will be used in the service endpoint implementation. The Items class uses two value types, MyIntItem and StringItem. The MyIntItem class is a custom class that you need to provide a custom serializer. The StringItem class is generated from the schema with custom mapping of String. Both MyIntItem and StringItem are described by an existing schema document.

**Example 7–9  Definition of the Items Class**

```java
package oracle.webservices.examples.customtypes;

public class Items {
    private MyIntItem[] myIntItem;
    private StringItem[] stringItem;
    public Items() {
    }
    public Items(MyIntItem[] intItem, StringItem[] strItem) {
        myIntItem = intItem;
        stringItem = strItem;
    }
    public MyIntItem[] getMyIntItem() {
        return myIntItem;
    }
    public void setMyIntItem(MyIntItem[] intItem) {
        myIntItem = intItem;
    }
    public StringItem[] getStringItem() {
        return stringItem;
    }
    public void setStringItem(StringItem[] strItem) {
        stringItem = strItem;
    }
}
```

Example 7–10 illustrates the service endpoint interface for MyEndpointIntf. Notice that the getItems method uses the MyIntItem data type instead of the InitItem type defined by the schema. As required by JAX-RPC, the interface extends java.rmi.Remote and the methods throw java.rmi.RemoteException.

**Example 7–10  Service Endpoint Interface for MyEndpointIntf**

```java
package oracle.webservices.examples.customtypes;

import java.rmi.Remote;
import java.rmi.RemoteException;

public interface MyEndpointIntf extends Remote {
    public Items getItems( MyIntItem[] myInts, StringItem[] myStrings )
        throws RemoteException;
}
```

Example 7–11 illustrates the implementation of the MyEndpointIntf interface.

**Example 7–11  Service Endpoint Implementation**

```java
package oracle.webservices.examples.customtypes;

public class MyEndpointImpl {

    public Items getItems( MyIntItem[] myInts, StringItem[] myStrings ) {
```
Items items = new Items();
items.setMyIntItem(myInts);
items.setStringItem(myStrings);
return items;
}
}

Sample Java Custom Type Implementation
Example 7–12 illustrates an implementation of the Java custom type oracle.
webservices.examples.customtypes.MyIntItem. This type will be used to
represent the InitItem complexType used in the schema illustrated in Example 7–8.

Example 7–12 Implementation of the Custom Java Type InitItem
/**
 * MyIntItem does not have the JAXRPC Value type (Bean) pattern.
 */
package oracle.webservicesexamples.customtypes;
public class MyIntItem {
    private String name;
    private int value;
    public MyIntItem(String name, int value) {
        this.name = name;
        this.value = value;
    }
    public String itemName() {
        return name;
    }
    public int itemValue() {
        return value;
    }
}

How to Implement a Serializer with Custom Marshalling Logic
This section provides an example of a serializer implementation that contains custom
marshalling and unmarshalling logic. It assumes that you want to use the oracle.
webservices.examples.customtypes.MyInitItem custom Java data type in
your Web service to represent the InitItem complex type in the schema document. It
also assumes that you want to provide custom marshalling and unmarshaling logic for
the class. To provide the custom logic, you must implement a custom serializer.

Example 7–13 provides a sample custom serializer implementation for MyInitItem.
To provide serialization capabilities, the custom serializer, MyInitItemSerializer,
implements the SOAPElementSerializer class and implements its serialize and
deserialize methods.

Example 7–13 Custom Serializer Implementation to Map MyInitItem to InitItem
package oracle.webservices.examples.customtypes;
import java.util.Iterator;
import java.util.Map;
import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;
import javax.xml.soap.SOAPException;
import javax.xml.soap.SOAPFactory;
import javax.xml.soap.Text;
import oracle.webservices.databinding.SOAPElementSerializer;

public class MyIntItemSerializer implements SOAPElementSerializer {

    private Map config;
    private SOAPFactory soapFactory;
    public void init(Map initParams) {
        config = initParams;
        try {
            soapFactory = SOAPFactory.newInstance();
        } catch (SOAPException e) {
            e.printStackTrace();
        }
    }

    public SOAPElement serialize(QName tagName, Object object) {
        MyIntItem myIntItem = (MyIntItem) object;
        SOAPElement xml = null;
        try {
            xml = soapFactory.createElement(
                tagName.getLocalPart(), tagName.getPrefix(), tagName.getNamespaceURI());
            SOAPElement name = soapFactory.createElement(
                "name", tagName.getPrefix(), tagName.getNamespaceURI());
            name.addTextNode(myIntItem.itemName());
            SOAPElement value = soapFactory.createElement(
                "value", tagName.getPrefix(), tagName.getNamespaceURI());
            value.addTextNode(String.valueOf(myIntItem.itemValue()));
            xml.addChildElement(name);
            xml.addChildElement(value);
        } catch (SOAPException e) {
            e.printStackTrace();
        }
        return xml;
    }

    private String getTextContent(SOAPElement element) {
        String str = "";
        for (Iterator i = element.getChildElements(); i.hasNext();)
        {
            Object obj = i.next();
            if (obj instanceof Text) {
                str += (((Text) obj).getValue());
            }
        }
        return str;
    }

    public Object deserialize(SOAPElement element) {
        String name = null;
        int value = -1;
        for (Iterator i = element.getChildElements(); i.hasNext();)
        {
            Object obj = i.next();
            if (obj instanceof SOAPElement) {
                SOAPElement child = (SOAPElement) obj;
                if (child.getLocalName().equals("name")) {
                    name = MyStringSerializer;
                } else if (child.getLocalName().equals("value")) {
                    value = Integer.parseInt(child.getTextContent());
                }
            }
        }
        return new MyIntItem(name, value);
    }
}
createMyString(getTextContent(child));

    if (child.getLocalName().equals("value")) {
        value = Integer.parseInt(getTextContent(child));
    }

return new MyIntItem(name, value);

Example 7–14 provides a sample custom serialization implementation to map `java.lang.String` to `xsd:string`. To provide serialization capabilities, the custom serializer, `MyStringSerializer`, implements the `SOAPElementSerializer` class and implements its `serialize` and `deserialize` methods. It also provides a placeholder where you can enter your own string formatting or validation code.

**Example 7–14 Custom Serializer Implementation to Map java.lang.String to xsd:string**

```java
package oracle.webservices.examples.customtypes;

import java.util.Iterator;
import java.util.Map;

import javax.xml.namespace.QName;
import javax.xml.soap.SOAPElement;
import javax.xml.soap.SOAPException;
import javax.xml.soap.SOAPFactory;
import javax.xml.soap.Text;
import oracle.webservices.databinding.SOAPElementSerializer;

public class MyStringSerializer implements SOAPElementSerializer {

    private Map config;
    private SOAPFactory soapFactory;

    public void init(Map initParams) {
        config = initParams;
        try {
            soapFactory = SOAPFactory.newInstance();
        } catch (SOAPException e) {
            e.printStackTrace();
        }
    }

    public SOAPElement serialize(QName tagName, Object object) {
        String value = (object == null) ? "null" : object.toString();
        SOAPElement xml = null;
        try {
            xml = soapFactory.createElement(tagName.getLocalPart(),
                                             tagName.getPrefix(),
                                             tagName.getNamespaceURI());
            xml.addTextNode(value);
        } catch (SOAPException e) {
            e.printStackTrace();
        }
        return xml;
    }
}
```
public Object deserialize(SOAPElement element) {
    String value = "";
    for (Iterator i = element.getChildElements(); i.hasNext();) {
        Object obj = i.next();
        if (obj instanceof Text) {
            value += (((Text) obj).getValue());
        }
    }
    return createMyString(value);
}

static public String createMyString(String input) {
    // You can add your own formatting or validation logic here
    return input.trim().toUpperCase();
}

How to Edit the Type Mapping Configuration XML File for Java Value Type Classes

The genValueTypes command creates a generated instance of the oracle-webservices type mapping configuration XML file, custom-type-mappings.xml. This file records the Java value type classes that are generated from an existing schema document. When you generate a WSDL from a service endpoint interface, you can use this file as input to WebServicesAssembler to avoid regenerating the schema definition for these pre-generated classes.

If you want to use an alternative Java class to represent a complex type in the schema instead of the class generated from the schema document, then you must edit the contents of the appropriate <type-mapping> element in the custom type mapping file. You can also edit the element to include a custom serializer for the alternative class.

The sample custom type mapping file in Example 7–15 assumes that the genValueTypes command used the schema in Example 7–8 on page 7-20 to generate the Java value types.

Example 7–15  Custom Type Mapping File, with Pre-Generated Value Type Classes

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oracle-webservices>
  <webservice-description name="unknown">
    <type-mappings
      xmlns:typens0="http://examples.webservices.oracle/customtypes"
      xmlns:typens2="http://www.w3.org/2001/XMLSchema">
      <type-mapping
        java-class="oracle.webservices.examples.customtypes.StringItem"
        xml-type="typens0:StringItem">
      </type-mapping>
      <type-mapping
        java-class="oracle.webservices.examples.customtypes.IntItem"
        xml-type="typens0:IntItem">
      </type-mapping>
      <type-mapping
        java-class="int"
        xml-type="typens2:int">
      </type-mapping>
      <type-mapping
        java-class="java.lang.String"
        xml-type="typens0:long">
    </type-mappings>
  </webservice-description>
</oracle-webservices>
```
To use `oracle.webservices.examples.customtypes.MyInitItem` and its custom serializer `oracle.webservices.examples.customtypes.MyInitItemSerializer` instead of the generated `InitItem` class, and to use the custom serializer `oracle.webservices.examples.customtypes.MyStringSerializer` for `java.lang.String`, you must edit the custom-type-mappings.xml file.

1. Replace the instance of `InitItem`.
   a. Replace the instance of `InitItem` with `oracle.webservices.examples.customtypes.MyInitItem` in the appropriate `<type-mapping>` element.
   b. Add a `<serializer>` element to `<type-mapping>` to specify the custom serializer class, `oracle.webservices.examples.customtypes.MyInitItemSerializer` for `MyInitItem`.

   For example, the original `<type-mapping>` element in `custom-type-mappings.xml`:
   
   ```xml
   <type-mapping
     java-class="oracle.webservices.examples.customtypes.IntItem"
     xml-type="typens0:IntItem">
   </type-mapping>
   ```

   should now look like this:

   ```xml
   <type-mapping
     java-class="oracle.webservices.examples.customtypes.MyInitItem"
     xml-type="typens2:string">
     <serializer class="oracle.webservices.examples.customtypes.MyInitItemSerializer"/>
   </type-mapping>
   ```

2. Edit the `<type-mapping>` element for the mapping of `java.lang.String` to `xsd:string`. The entry should look like this:

   ```xml
   <type-mapping
     java-class="java.lang.String"
     xml-type="xsd:string">
     <serializer class="oracle.webservices.examples.customtypes.MyStringSerializer"/>
   </type-mapping>
   ```

3. Rename the file `MyCustomTypeMappings.xml` and copy it to the root directory of the project.

Example 7–16 illustrates the edited version of the type mapping file. The type-mapping element for `StringItem` is retained in the file in order to avoid regenerating the schema definition for this pre-generated class.

The namespace prefix declaration (`xmlns:xsd="http://www.w3.org/2001/XMLSchema"`) is added so that it can be used in the type mapping configuration file. In the edited type mapping configuration file, you must refer to the string schema type defined in the schema namespace (`http://www.w3.org/2001/XMLSchema`). Defining the prefix, `xsd`, enables you to use `xsd:string` as the "qualified name" of the schema type string.
Example 7–16  Custom Type Mapping File, with Edited Value Type Classes

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oracle-webservices>
  <webservice-description name="unknown">
    <type-mappings
      xmlns:typens0="http://examples.webservices.oracle/customtypes"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <type-mapping
        java-class="java.lang.String"
        xml-type="xsd:string">
        <serializer class="oracle.webservices.examples.customtypes.MyStringSerializer"/>
      </type-mapping>
      <type-mapping
        java-class="oracle.webservices.examples.customtypes.MyIntItem"
        xml-type="typens0:IntItem">
        <serializer class="oracle.webservices.examples.customtypes.MyIntItemSerializer"/>
      </type-mapping>
    </type-mappings>
  </webservice-description>
</oracle-webservices>
```

How to Assemble a Client for Custom Type Mapping and a Custom Serializer

To generate J2SE client-side proxy files, use the WebServicesAssembler `genProxy` command:

```bash
java -jar wsa.jar -genProxy
    -wsdl http://localhost:8888/MyCustomTypes/MyCustomTypes?WSDL
    -output ./build/src/client
```

In this command:

- `genProxy`—Creates a static proxy stub that can be used by a J2SE Web service client.
- `wsdl`—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- `output`—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

See Also:

"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

Because WebServicesAssembler does not configure custom types when generating the Web services client-side proxy, the generated proxy will try to generate value type (Bean) classes by default to represent the schema types `InitItem` and `StringItem`. Then you can write your client program using the generated proxy code.
Example 7–17 illustrates a client program that uses the Java value types that are present in the schema.

**Example 7–17  Client Program Using Default Generated Value Types**

```java
package oracle.webservices.examples.customtypes;
import javax.xml.rpc.ServiceFactory;
import javax.xml.rpc.Stub;
import examples.webservices.oracle.customtypes.*;
public class MyCustomTypesClient {
    public static final String DEFAULT_URL =
        "http://localhost:8888/MyCustomTypes/MyCustomTypes";

    public static void main(String[] args) throws Exception {
        String address = DEFAULT_URL;
        ServiceFactory factory = ServiceFactory.newInstance();
        MyCustomTypes service = (MyCustomTypes) factory.
            loadService(MyCustomTypes.class);
        MyEndpointIntf proxy = (MyEndpointIntf)service.getPort(MyEndpointIntf.
            class);

        ((Stub) proxy)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, address);
        IntItem int1 = new IntItem();
        int1.setName("int1");
        int1.setValue(123);
        IntItem int2 = new IntItem();
        int2.setName("int2");
        int2.setValue(456);
        IntItem[] ints = { int1, int2 };
        StringItem str1 = new StringItem();
        str1.setName("string1");
        str1.setValue("foo");
        StringItem str2 = new StringItem();
        str2.setName("string2");
        str2.setValue("coo");
        StringItem[] strings = { str1, str2 };
        Items items = proxy.getItems(ints, strings);
        System.out.println("items.getIntItem : "+ items.getIntItem().
            length);
        System.out.println("items.getStringItem: "+ items.getStringItem().
            length);
    }
}
```

The `MyIntItem` class was used in developing the `Items` class aforementioned. The `Items` type was developed to be a return value of the service endpoint implementation. The `MyIntItemSerializer` and `MyStringTypeSerializer` are used in the OracleAS Web Services runtime. While WebServicesAssembler is assembling the deployable EAR file, the edited type mapping configuration XML file is used to create a deployment descriptor inside the EAR so that these custom serializers will be correctly used in the runtime.

### Steps to Use Custom Serializers in Client Code

You can use a custom serializer in the Web service client-side proxy. This enables you to use the custom data types defined for the service in your client code. This section describes how to create a Web service client-side proxy that uses the `MyIntItemSerializer` (described in Example 7–13) to map `IntItem` to `MyIntItem` and `MyStringSerializer` (described in Example 7–14) to map the `string` type. To do this, you must use a client side version of the oracle-webservices
type mapping configuration file, MyCustomTypeMappings.xml (described in Example 7–16) as input to genProxy.

The following steps summarize the process of adding a custom serializer to a client proxy:

1. Provide a client version of the server-side custom type mapping file.
   For more information on this step, see "How to Edit the Custom Type Mapping File for the Client".

2. Generate the Web service client proxy with the WebServicesAssembler genProxy command.
   For more information on this step, see "How to Assemble the Web Service Client Side Proxy" on page 7-30.

3. Write the Web service client.
   For more information on this step, see "How to Write a Web Service Client with Custom Datatypes" on page 7-30.

**How to Edit the Custom Type Mapping File for the Client**

The custom type mapping file used on the client side must conform to the oracle-webservices-client-10_0.xsd schema. To provide a custom type mapping file for the client, you can use the service side custom type mapping file as a template. Edit the file to provide the appropriate client side root elements:

- Replace the <oracle-webservices> element with <oracle-webservices-clients>.
- Replace the <webservice-description> element and any attributes it might contain with <webservice-client>.

After making these edits, the client side custom type mapping file (in this case, MyCustomTypeMappings.xml) should look like the code in Example 7–18.

**Example 7–18 Client Side Custom Type Mapping File**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oracle-webservice-clients>
  <webservice-client>
    <type-mappings xmlns:typens0="http://examples.webservices.oracle/customtypes"
      xmlns:xsd="http://www.w3.org/2001/XMLSchema">
      <type-mapping java-class="java.lang.String"
        xml-type="xsd:string">
        <serializer class="oracle.webservices.examples.customtypes.MyStringSerializer"/>
    </type-mapping>
    <type-mapping java-class="oracle.webservices.examples.customtypes.MyIntItem"
      xml-type="typens0:IntItem">
        <serializer class="oracle.webservices.examples.customtypes.MyIntItemSerializer"/>
    </type-mapping>
    <type-mapping java-class="oracle.webservices.examples.customtypes.StringItem"
      xml-type="typens0:StringItem">
        </type-mapping>
    </type-mappings>
  </webservice-client>
</oracle-webservice-clients>
```
How to Assemble the Web Service Client Side Proxy

Generate the Web services client-side proxy with the WebServicesAssembler genProxy command. Use the ddFileName argument to provide the client side custom type mapping file as input. The genProxy command will create client proxy classes that will use your serializers.

The following sample genProxy command uses the client side custom type mapping file MyCustomTypeMappings.xml as input.

```
java -jar wsa.jar -genProxy
   -wsdl http://localhost:8888/MyCustomTypes/MyCustomTypes?WSDL
   -ddFileName ./MyCustomTypeMappings.xml
   -output ./build/src/client
```

In this command:
- **genProxy**—Creates a static proxy stub that can be used by a J2SE Web service client.
- **wsdl**—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- **ddFileName**—Specifies the oracle-webservices.xml deployment descriptor that contains the settings you want to assign to the Web service.
- **output**—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

See Also:

"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

How to Write a Web Service Client with Custom Datatypes

When you write your client program using the generated proxy code, you can call the custom data type instead of the default Java data type. Example 7–19 illustrates client code that employs the MyIntItem custom data type instead of the default IntItem data type.

**Example 7–19  Client Code Incorporating Custom Type Mapping and Custom Serializer**

```java
ServiceFactory factory = ServiceFactory.newInstance();
MyCustomTypes service = (MyCustomTypes) factory.loadService(MyCustomTypes.class);
MyEndpointInf proxy = (MyEndpointInf)service.getPort(MyEndpointInf.class);
((Stub) proxy)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, address);

MyIntItem int1 = new MyIntItem("int1", 123);
MyIntItem int2 = new MyIntItem("int2", 456);
MyIntItem [] ints = { int1, int2 };

StringItem str1 = new StringItem();
str1.setName("string1");
str1.setValue("foo");
StringItem str2 = new StringItem();
str2.setName("string2");
str2.setValue("coo");
```
StringItem[] strings = { str1, str2 };  

Items items = proxy.getItems(ints, strings);

**Limitations**

See "Custom Serialization of Java Value Types" on page I-15.

**Additional Information**

Using JMS as a Web Service Transport

This chapter describes how to employ JMS as an alternative transport mechanism for Web Services. It describes these major topics:

- Understanding JMS as a Transport Mechanism
- WSDL Extensions for JMS Transport
- How to Set Up JMS Queues
- How to Assemble a Web Service Bottom Up that Uses JMS Transport
- How to Assemble a Web Service Top Down that Uses JMS Transport
- How to Assemble a Proxy that Uses JMS as a Transport
- Writing Client Code to Support JMS Transport

Understanding JMS as a Transport Mechanism

Oracle Application Server Web Services can employ JMS as a transport mechanism to send messages in either one-way request messaging or two-way request and response messaging. One-way request messaging lets a Web service client unblock when the request message reaches a JMS queue. Two-way request and response messaging blocks a Web service client until the response message is received.

See Also:

For examples of one- and two-way messaging, see the following resources:

- "Assembling Web Services with JMS Destinations" in the Oracle Application Server Web Services Developer's Guide.
- "How to Assemble a Web Service from an Oracle Streams AQ" in the "Assembling Database Web Services" chapter in the Oracle Application Server Web Services Developer's Guide.

The SOAP protocol for exchanging XML messages is independent of any transport mechanism. Different mechanisms have different advantages. For example, HTTP provides a greater chance of interoperability with other Web services, since it follows standards developed by the Web Service Interoperability (WS-I) organization. In contrast, JMS provides support for asynchronous messaging and a greater degree of reliability and scalability.

When JMS is the transport mechanism, reliability is improved because messages sent by a service or client are placed on a queue and, optionally, in persistent storage. If
communications between the service and client fail, then the message can be retrieved from storage and re-sent.

**Note:** Reliability can also be enabled for SOAP messaging over HTTP. For more information, see Chapter 5, “Ensuring Web Service Reliability”.

JMS supports the asynchronous invocation of Web services. With asynchronous invocation, the client is free to pursue other tasks while waiting for a response. For example, it can send requests, poll to see the status of the request, and retrieve responses independently.

The scalability designed into JMS allows it to accommodate high-traffic services. This is an advantage over HTTP which has limited support for scalability.

**General Steps for Implementing JMS as a Transport Mechanism**

Enabling JMS as a transport mechanism follows these general steps.

1. Set up the queues that are to be used for sending and receiving SOAP messages. "How to Set Up JMS Queues" on page 8-4 provides more information on this step.

2. Assemble the Web service, specifying the JMS queue information for the SOAP transport.
   - If assembling bottom up, pass a descriptor containing the JMS transport details, or declare the JMS transport parameters on the command line or Ant task. "How to Assemble a Web Service Bottom Up that Uses JMS Transport" on page 8-5 provides more information on this process.
   - If assembling top down, edit the WSDL to add the JMS address. "How to Assemble a Web Service Top Down that Uses JMS Transport" on page 8-10 provides more information on this process.

3. Assemble the proxy (if necessary). When assembling the proxy, you must identify the return queue. The return queue is the JMS queue on which you want to receive responses to Web service invocations. You can do this by declaring the return queue on the command line or in Ant tasks.
   "How to Assemble a Proxy that Uses JMS as a Transport" on page 8-12 provides more information on this step.

**Understanding Data Flow for JMS Transport**

The following steps describe how data is passed between the Web service client and OracleAS Web Services when JMS is the transport mechanism. The WSDL elements and WebServicesAssembler arguments mentioned in the steps are described later in this chapter. Figure 8–1 illustrates the sequence of steps.

1. In the Web service client, the message is sent as a request to a JMS queue in OC4J. The `<jms:address>` element in the WSDL provides the location of the target endpoint to which the message will be served from the JMS queue in OC4J.

2. The client performs a JMS `send` operation to send the request to the sender queue in OC4J.

3. The sender queue in OC4J accepts the request. If WebServicesAssembler was used to assemble the Web service, then the location of the sender queue is provided by the `sendQueueLocation` argument.
4. The server runtime dequeues the request and serves it to the endpoint identified by the client’s request.

5. If the message has a reply (or response), the service puts the message on the reply-to queue. If WebServicesAssembler was used to assemble the Web service, then the location of the reply-to queue is provided by the replyToQueueLocation argument.

6. The client blocks on waiting to receive a response on the reply-to queue (in case of a request-response operation), thus simulating a synchronous request-response. If the message exchange pattern was one way, the client does not wait for a response.

Figure 8–1 Data Flow for JMS Transport

WSDL Extensions for JMS Transport

The following WSDL extensions define JMS transport for a Web service.

- JMS Address Element
- JMS Property Value Element

These are Oracle proprietary WSDL extensions and may not be interoperable. If you are using Oracle JDeveloper or WebServicesAssembler to develop and deploy the endpoint bottom up, then these extensions are generated into the WSDL. If you are manually writing the WSDL or developing and deploying the Web service top down, then you should add these extensions.

The following URI is the namespace for the extensions described in this section.

xmlns:jms="http://www.oracle.com/technology/oracleas/wsdl/jms"

JMS Address Element

Only one <jms:address> element should be used in a port-component definition. This element should be used in place of a <soap:address> declaration. This element has the following format:

<jms:address
  jndiConnectionFactoryName="xxx"
  jndiDestinationName="xxx"/>

Table 8–1 describes the attributes of the <jms:address> element.
Table 8–1  Attributes of the <jms:address> Element

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jndiConnectionFactoryName</td>
<td>The JNDI name of the connection factory that will be used. If you are generating the Web service bottom up, then this attribute is set by the sendConnectionFactoryLocation argument.</td>
</tr>
<tr>
<td>jndiDestinationName</td>
<td>The JNDI name of the JMS queue that messages will be sent to. If you are generating the Web service bottom up, then this attribute will be set by the sendQueueLocation argument.</td>
</tr>
</tbody>
</table>

JMS Property Value Element

The <jms:propertyValue> element must be added to the <jms:address> section of the binding operation to identify the endpoint location. This element has the following format:

```xml
<jms:propertyValue
   name="string"
   type="type"
   value="string"/>
```

Table 8–2 describes the attributes of the <jms:propertyValue> element.

Table 8–2  Attributes of the <jms:propertyValue> Element

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of a property defined by JMS, by the JMS implementation, or by the user.</td>
</tr>
<tr>
<td>type</td>
<td>The datatype of the attribute.</td>
</tr>
<tr>
<td>value</td>
<td>A value that hard codes the value of this property in the WSDL.</td>
</tr>
</tbody>
</table>

The WebServicesAssembler uri argument can provide the value for the propertyValue element in the WSDL. When the uri argument is specified, the name attribute is set to endpoint-location, the type attribute is set to string and the value attribute is set to the value of the uri argument.

```xml
<jms:propertyValue name="endpoint-location" type="string" value="value of uri argument"/>
```

How to Set Up JMS Queues

Queues must be set up in the OracleAS Web Services container to identify the sender queue and the receiver queue. Each queue is identified by a <queue> element and a <queue-connection-factory> element.

The <queue> element contains a name and a location attribute. The name attribute specifies the queue's JNDI name. The location attribute specifies the queue's JNDI location. The queue element can also contain an optional description element to provide a text description of the queue.

The queue-connection-factory element also contains a name and a location attribute. The name attribute specifies the JNDI name of the JMS connection factory used to produce connections for the send or receive operation. The location specifies the factory's JNDI location.
If the queues are set up in the OC4J/JMS jms.xml configuration file, you can add two clauses to that file: one for the sender queue and one for the reply-to queue.

See Also:
Oracle Containers for J2EE Services Guide for more information on using JMS in the OC4J environment.

Example 8–1 illustrates XML code that identifies the SOAP sender queue at the JNDI location jms/senderQueue. This queue uses jms/senderQueueConnectionFactory as the JMS connection factory to produce connections for the send operation. Similarly, the second clause identifies the SOAP receiver queue at the JNDI location jms/replyToQueue as the receiver queue. This queue uses jms/replyToQueueConnectionFactory as the JMS connection factory to produce connections for the response messages from the Web service endpoint.

Example 8–1  XML Code to Identify Sender Queue and Receiver Queue

...  
<queue name="SOAP sender" location="jms/senderQueue">
  <description>A queue for SOAP messages</description>
</queue>
<queue-connection-factory
  name="jms/senderQueueConnectionFactory"
  location="jms/senderQueueConnectionFactory"/>

<queue name="SOAP receiver" location="jms/replyToQueue">
  <description>A queue for SOAP response messages</description>
</queue>
<queue-connection-factory
  name="jms/replyToQueueConnectionFactory"
  location="jms/replyToQueueConnectionFactory"/>
...

How to Assemble a Web Service Bottom Up that Uses JMS Transport

To configure JMS transport into a Web service that you are generating bottom up, the extensions described in "WSDL Extensions for JMS Transport" on page 8-3 must be added to the WSDL to identify ports that have JMS transport enabled. WebServicesAssembler provides two arguments that will add this information to the WSDL.

- sendConnectionFactoryLocation—identifies the JNDI location of the JMS factory used to produce connections for the JMS send operation.
- sendQueueLocation—identifies the JNDI name of the JMS queue that messages will be sent to.

Steps to Assemble a Web Service Bottom Up that Uses JMS Transport

It is assumed that you have already configured the JMS queues for sending and receiving SOAP messages. The following steps describe how to assemble a Web service bottom up that uses JMS as its transport mechanism. The steps follow the standard procedure for assembling a Web service bottom up.
See Also:

- "How to Set Up JMS Queues" on page 8-4 provides more information on JMS queues.
- "Assembling a Web Service with Java Classes" and "Assembling a Web Service with EJBs" in the Oracle Application Server Web Services Developer’s Guide provide additional examples of bottom up Web service assembly.

1. Generate the service artifacts by running the WebServicesAssembler with the assemble command. Specify the queue location and queue connection factory with sendQueueLocation and sendConnectionFactoryLocation. The WSDL generated by this Ant task is illustrated in Example 8–2.

```xml
<oracle:assemble appName="echo"
    targetNamespace="http://www.oracle.com/echo"
    typeNamespace="http://www.oracle.com/echo"
    serviceName="EchoService"
    input="./build/classes/service"
    output="build"
    ear="build/echo.ear"
    style="rpc"
    use="encoded"
    createOneWayOperations="true"
>
<oracle:porttype
    interfaceName="oracle.j2ee.ws.jmstransport.Echo"
    className="oracle.j2ee.ws.jmstransport.EchoImpl"
>
<oracle:port
    uri="/echo"
    sendQueueLocation="jms/senderQueue"
    name="EchoPort"
    sendConnectionFactoryLocation="jms/senderQueueConnectionFactory">
</oracle:port>
</oracle:porttype>
</oracle:assemble>
```

In this Ant task:

- **assemble**—Generates a Web service from Java files bottom up. The command creates all of the files required to create a deployable archive.
- **appName**—Specifies the name of an application. Usually, this name is used as a base value for other arguments like context and uri.
- **targetNamespace**—Specifies the target namespace to be used in the generated WSDL. The value can be either a conforming HTTP URL, a non-conforming HTTP URL, or even a URI.

**Note:** Instead of specifying the queue location and queue connection factory on the command line or Ant task with sendQueueLocation and sendConnectionFactoryLocation, you can pass this information to WebServicesAssembler in a deployment descriptor file. For more information on this technique, see "How to Configure JMS Transport by using Deployment Descriptors" on page 8-9.
How to Assemble a Web Service Bottom Up that Uses JMS Transport

- **typeNamespace**—Specifies the type namespace to be used in the schema types in the generated WSDL. The name that you specify will always be used and it will not be reversed.
- **serviceName**—Specifies the service name.
- **input**—Specifies the directory or JAR containing the classes that should be copied to WEB-INF/classes. This argument will be added to the classpath used by the WebServicesAssembler.
- **output**—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- **ear**—Specifies the name and location of the generated EAR.
- **style**—For bottom up Web service assembly, this argument specifies the style attribute of the message format in the generated WSDL.
- **use**—For bottom up Web service assembly, this argument specifies the use attribute of the message format in the generated WSDL.
- **createOneWayOperations**—When this argument is set to true, methods that return void will have no response message. If it is not specified or set to false, the response message will be empty.
- **porttype**—This tag enables you to configure different interfaces to a Web service.
- **interfaceName**—Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).
- **className**—Specifies the name of the class (including the package name) that is the implementation class for the Web service.
- **uri**—Specifies the URI to use for the Web service.
- **sendQueueLocation**—Specifies the JNDI name of the JMS queue to be used for the JMS send operation.
- **sendConnectionFactoryLocation**—Specifies the JNDI name of the JMS ConnectionFactory used to obtain a connection for the JMS send operation.

**See Also:**

"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

2. **Deploy the service.**

Deploy the EAR file in the standard manner into a running instance of OC4J. For more information on deploying EAR files, see the Oracle Containers for J2EE Deployment Guide.

3. **Generate the client code.**

This step is described in "How to Assemble a Proxy that Uses JMS as a Transport" on page 8-12.
Sample Generated WSDL for JMS Transport

Example 8–2 illustrates the WSDL created by the Ant task in "How to Assemble a Web Service Bottom Up that Uses JMS Transport" on page 8-5. The JMS transport configuration is highlighted in bold.

Example 8–2  WSDL with a JMS Transport Configuration

```xml
<?xml version = '1.0' encoding = 'UTF-8'?>
<definitions xmlns="http://schemas.xmlsoap.org/wsdl/
xmlns:soap="http://schemas.xmlsoap.org/wsdl/
xmlns:http="http://schemas.xmlsoap.org/wsdl/http/
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:tns="http://www.oracle.com/echo"
xmlns:jms="http://www.oracle.com/technology/oracleas/wsdl/jms"
name="Echo" targetNamespace="http://www.oracle.com/echo">
  <types>
    <schema xmlns="http://www.w3.org/2001/XMLSchema"
      xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:soap11-enc="http://schemas.xmlsoap.org/soap/encoding/
      targetNamespace="http://www.oracle.com/echo"/>
  </types>
  <message name="Echo_echo">
    <part name="String_1" type="xsd:string"/>
  </message>
  <message name="Echo_echoInt">
    <part name="int_1" type="xsd:int"/>
  </message>
  <message name="Echo_echoIntResponse">
    <part name="result" type="xsd:int"/>
  </message>
  <message name="Echo_echoResponse">
    <part name="result" type="xsd:string"/>
  </message>
  <portType name="Echo">
    <operation name="echo" parameterOrder="String_1">
      <input message="tns:Echo_echo"/>
      <output message="tns:Echo_echoResponse"/>
    </operation>
    <operation name="echoInt" parameterOrder="int_1">
      <input message="tns:Echo_echoInt"/>
      <output message="tns:Echo_echoIntResponse"/>
    </operation>
  </portType>
  <binding name="EchoBinding" type="tns:Echo">
    <operation name="echo">
      <input>
        <soap:body use="encoded" namespace="http://www.oracle.com/echo"
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" parts="String_1"/>
      </input>
      <output>
        <soap:body use="encoded" namespace="http://www.oracle.com/echo"
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" parts="result"/>
      </output>
    </operation>
    <operation name="echoInt">
      <input>
        <soap:body use="encoded" namespace="http://www.oracle.com/echo"
          encodingStyle="http://schemas.xmlsoap.org/soap/encoding/" parts="result"/>
      </input>
    </operation>
  </binding>
</definitions>
```
How to Assemble a Web Service Bottom Up that Uses JMS Transport

Using JMS as a Web Service Transport

How to Configure JMS Transport by using Deployment Descriptors

A JMS transport configuration can be passed to the WebServicesAssembler by entering it into the oracle-webservices.xml deployment descriptor. This is an alternative to declaring the sendQueueLocation and sendConnectionFactoryLocation, arguments on the command line or Ant task.

When you enter the configuration into oracle-webservices.xml, use <jms-address> instead of <jms:address> and <jms-propertyValue> instead of <jms:propertyValue>. These elements should appear as subelements of the <port-component> element.

The <jms-address> and <jms-propertyValue> elements have the same attributes as described in "WSDL Extensions for JMS Transport" on page 8-3.

Example 8–3 illustrates an oracle-webservices.xml deployment descriptor that includes a JMS transport configuration. During assembly, a new WSDL will be created. The resulting WSDL will look like the one in Example 8–2. The JMS configuration is highlighted in bold.

**Example 8–3  oracle-webservices.xml with JMS Transport Configuration**

```xml
<oracle-webservices
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xsi:noNamespaceSchemaLocation="oracle-webservices-server-10_0.xsd"
 schema-major-version="10" schema-minor-version="0">
 <webservice-description name="Echo">
  <port-component name="EchoPort">
   <runtime enabled="true">
    <jms-address jndiDestinationName="jms/OracleSyndicateQueue"
 jndiConnectionFactoryName="jms/OracleSyndicateQueueConnectionFactory"/>
   </runtime>
  </port-component>
 </webservice-description>
</oracle-webservices>
```
How to Assemble a Web Service Top Down that Uses JMS Transport

For top down assembly, you must edit the WSDL to add the JMS address and property values for the endpoint.

The following steps describe how to generate a Web service that uses JMS as its transport mechanism. It is assumed that you have already configured the JMS queues for sending and receiving SOAP messages.

See Also:
- "WSDL Extensions for JMS Transport" on page 8-3 for descriptions of the <jms-address> element's jndiDestinationName and jndiConnectionFactoryName attributes.
- "How to Set Up JMS Queues" on page 8-4 for more information on JMS queues.
- "Generating the Web Service Top Down" in the Oracle Application Server Web Services Developer’s Guide. provides more detailed information on the required steps for assembling a Web service from a WSDL.

1. Provide a WSDL from which the Web service will be generated.
2. Edit the WSDL to add the elements that define JMS transport.
   "WSDL Extensions for JMS Transport" on page 8-3 describes the JMS transport elements.
3. Use the WSDL as input to the WebServicesAssembler genInterface command.
4. Compile the generated interface and type classes.
5. Write the Java service endpoint interface for the Web service you want to provide.
6. Compile the Java service endpoint interface.
7. Generate the service by running the WebServicesAssembler tool with the topDownAssemble command.

```xml
<oracle:topDownAssemble appName="bank"
    packageName="oracle.ws.server.bank"
    wsd1="./etc/Bank.wsdl"
    input="./build/classes/service"*
    output="build"
    ear="build/bank.ear"
    debug="true"
    fetchWsdlImports="true"/>
<oracle:classpath>
    <oracle:pathelement path="${build.impl.dir}*/
    <oracle:pathelement location="${wsa.jar}*/
</oracle:classpath>
<oracle:porttype
    classFileName="java/oracle/ws/server/bank/BankImpl.java"
>
<oracle:port name="BankPort" uri="/bank"/>
<oracle:port name="BankPortWithJMS" uri="/bank"/>
<oracle:port name="Soap12JmsEchoPort" uri="/soap12bank"/>
```

See Also:

"WSDL Extensions for JMS Transport" on page 8-3 for descriptions of the <jms-address> element's jndiDestinationName and jndiConnectionFactoryName attributes.

How to Assemble a Web Service Top Down that Uses JMS Transport

For top down assembly, you must edit the WSDL to add the JMS address and property values for the endpoint.

The following steps describe how to generate a Web service that uses JMS as its transport mechanism. It is assumed that you have already configured the JMS queues for sending and receiving SOAP messages.

See Also:
- "WSDL Extensions for JMS Transport" on page 8-3 for descriptions of the <jms-address> element's jndiDestinationName and jndiConnectionFactoryName attributes.
- "How to Set Up JMS Queues" on page 8-4 for more information on JMS queues.
- "Generating the Web Service Top Down" in the Oracle Application Server Web Services Developer’s Guide. provides more detailed information on the required steps for assembling a Web service from a WSDL.

1. Provide a WSDL from which the Web service will be generated.
2. Edit the WSDL to add the elements that define JMS transport.
   "WSDL Extensions for JMS Transport" on page 8-3 describes the JMS transport elements.
3. Use the WSDL as input to the WebServicesAssembler genInterface command.
4. Compile the generated interface and type classes.
5. Write the Java service endpoint interface for the Web service you want to provide.
6. Compile the Java service endpoint interface.
7. Generate the service by running the WebServicesAssembler tool with the topDownAssemble command.

```xml
<oracle:topDownAssemble appName="bank"
    packageName="oracle.ws.server.bank"
    wsd1="./etc/Bank.wsdl"
    input="./build/classes/service"*
    output="build"
    ear="build/bank.ear"
    debug="true"
    fetchWsdlImports="true"/>
<oracle:classpath>
    <oracle:pathelement path="${build.impl.dir}*/
    <oracle:pathelement location="${wsa.jar}*/
</oracle:classpath>
<oracle:porttype
    classFileName="java/oracle/ws/server/bank/BankImpl.java"
>
<oracle:port name="BankPort" uri="/bank"/>
<oracle:port name="BankPortWithJMS" uri="/bank"/>
<oracle:port name="Soap12JmsEchoPort" uri="/soap12bank"/>
```
<oracle:porttype>
</oracle:porttype>

In this Ant task:

- `topDownAssemble`—Creates the required classes and deployment descriptors for a Web service based on a WSDL description. The files can be stored in either an EAR file, a WAR file, or a directory.

- `packageName`—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.

- `wsdl`—Specifies the absolute file path, relative file path, or URL to a WSDL document.

- `input`—Specifies the directory or JAR containing the classes that should be copied to `WEB-INF/classes`. This argument will be added to the classpath used by the WebServicesAssembler.

- `output`—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.

- `ear`—Specifies the name and location of the generated EAR.

- `debug`—Indicates whether all detailed diagnostic messages should be printed for a given command.

- `fetchWsdlImports`—Indicates if you want to make a local copy of the WSDL and everything it imports.

- `classpath`—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

- `porttype`—This tag enables you to configure different interfaces to a Web service.

- `className`—Specifies the name of the class (including the package name) that is the implementation class for the Web service.

- `classFileName`—Identifies the Java file name of the implementation class specified in the `className` argument. If necessary, this file will be compiled during an assembly.

**See Also:**

"Using WebServicesAssembler", in the *Oracle Application Server Web Services Developer’s Guide* for more detailed information on these arguments.

8. Deploy the service.

   Deploy the EAR file in the standard manner into a running instance of OC4J. For more information on deploying EAR files, see the *Oracle Containers for J2EE Deployment Guide*.

9. Generate the client code.

   This step is described in "How to Assemble a Proxy that Uses JMS as a Transport".

10. Add the following client JAR files to the client classpath.
These client JAR files are required when the Web service client supports JMS as a transport mechanism. The J2EE_HOME environment variable in the paths represents the location where the Oracle Application Server or the standalone OC4J is installed.

- J2EE_HOME/j2ee/home/lib/oc4j-unsupported-apis.jar
- J2EE_HOME/j2ee/home/lib/oc4j-internal.jar

See Also:

"Web Service Client APIs and JARs" in the Oracle Application Server Web Services Developer's Guide, for a description of all of the available OracleAS Web Services client JARs.

How to Assemble a Proxy that Uses JMS as a Transport

When working with JMS as a transport mechanism you must ensure that the client code provides the JNDI names of the JMS queue and the connection factory for the reply-to queue which will be used for send operation JMS messages. The WebServicesAssembler arguments replyToQueueLocation and replyToConnectionFactoryLocation can provide these values. Used with the genProxy command, these arguments generate a proxy stub that can be used with JMS transport. The arguments will generate a stub configured with values for a queue that will receive response messages.

If you do not use the replyTo* arguments to generate a proxy stub, and the endpoint contains request/response operations, then you must set the replyTo* arguments programmatically so that response messages can be received.

See Also:

"How to Set the Send Queue Location and Connection Factory Programmatically" on page 8-14 describes how to add replyTo* arguments directly to your code.

It is assumed that you have already configured the JMS queues for sending and receiving SOAP messages. The following steps describe how to generate a proxy stub that uses JMS as its transport mechanism. The steps follow the standard procedure for assembling a proxy stub.

See Also:

- "How to Set Up JMS Queues" on page 8-4 provides more information on JMS queues.
- "How to Assemble a J2SE Web Service Client with a Static Stub" in the Oracle Application Server Web Services Developer's Guide, for more detailed information on the required steps for assembling a Web service proxy stub.

1. Provide the URI to the WSDL, the name of the output directory, the package name, and the locations of the JMS queue and connection factory as input to the WebServicesAssembler genProxy command.

   This Ant task generates the client proxy and stores it in the build/src/proxy directory. The client application uses the stub to invoke operations on a remote service.

   <oracle:genProxy
How to Assemble a Proxy that Uses JMS as a Transport

output="build/src/proxy"
packageName="oracle.ws.client.bank"
>
<oracle:port
   replyToConnectionFactoryLocation="jms/receiverQueueConnectionFactory"
   replyToQueueLocation="jms/receiverQueue"
</oracle:port>
 />

In this Ant task:

- `genProxy`—Creates a static proxy stub that can be used by a J2SE Web service client.
- `wsdl`—Specifies the absolute file path, relative file path, or URL to a WSDL document.
- `output`—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- `packageName`—Specifies the package name that will be used for generated classes if no package name is declared in the JAX-RPC mapping file.
- `replyToConnectionFactoryLocation`—Specifies the JNDI name of the JMS connection factory to be used as the default reply-to of all `send` operation JMS messages.
- `replyToQueueLocation`—Specifies the JNDI name of the JMS queue to be used as the default reply-to of all `send` operation JMS messages.

See Also:

"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

2. Use the client utility class file created by `genProxy` as your application client, or use it as a template to write your own client code. The client utility class file is one of a number of files created by `genProxy`.

3. Compile the client files and put them in the classpath.

   List the appropriate JARs on the classpath before compiling the client. As an alternative to listing individual JARs, you can include the client-side JAR, `wsclient_extended.jar` on the client classpath. This JAR file contains all the classes necessary to compile and run a Web service client.

   For JMS clients, you must also include the `oc4j-internal.jar` and `oc4j-unsupported-apis.jar` files on the classpath.

   To provide a JNDI configuration for the client, add the `jndi.properties` file to the client classpath.

4. Run the J2SE JMS client from the command line.
Writing Client Code to Support JMS Transport

The following sections describe how to write Web service clients that use JMS transport.

- How to Write Client Stub Code for JMS Transport
- How to Set the Send Queue Location and Connection Factory Programmatically
- How to Write DII Code for JMS Transport

How to Write Client Stub Code for JMS Transport

Stub code for a client that uses JMS transport is very similar to code for clients that use HTTP transport. The difference is that the endpoint address must be set to the unique URI that identifies the JMS endpoint.

Example 8–4 illustrates client stub code that uses JMS transport to send messages. The code that sets the endpoint address to the unique URI that identifies the JMS endpoint is highlighted in bold.

Example 8–4  Client Stub Code to Send Messages with JMS Transport

```java
...
ServiceFactory serviceFactory = ServiceFactory.newInstance();
Echo_Service echoService = (Echo_Service) serviceFactory.loadService(Echo_Service.class);
Echo_PortType echoPort = echoService.getEchoPort();
((Stub)echoPort)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, "/echo/echo");
String echo = echoPort.echo("Test echo");
...
```

See Also:

- "Classpath Components for Clients Using a Client Side Proxy” in the Oracle Application Server Web Services Developer’s Guide for lists all of the JAR files that can possibly be used on the client classpath.
- "Setting the Web Service Proxy Client Classpath” in the Oracle Application Server Web Services Developer’s Guide for a list of all of the classes that appear in wsclient_extended.jar. This appendix also provides more information on the client classpath.
- "JMS Transport-Related Client JAR File” in the Oracle Application Server Web Services Developer’s Guide for more information on the oc4j-internal.jar and oc4j-unsupported-apis.jar files.

How to Set the Send Queue Location and Connection Factory Programmatically

When you are working with JMS as a transport, client stub code requires you to identify the JNDI names of the JMS queue and the connection factory for the reply-to connection.

See Also:

- “Writing Web Service Client Applications” in the Oracle Application Server Web Services Developer’s Guide for more information on writing client code for J2SE client applications.
Writing Client Code to Support JMS Transport

Using JMS as a Web Service Transport

8-15

queue for send operation JMS messages. If you do not provide these values when you generate the proxy stub code, you can add them programmatically. OracleAS Web Services provides two properties in the oracle.webservices.OracleStub class that allow you to do this.

- JMS_TRANSPORT_REPLY_TO_FACTORY_NAME—specifies the JNDI name of the JMS connection factory to be used as the default reply-to of all send operation JMS messages. This property is comparable to the replyToConnectionFactoryLocation WebServicesAssembler argument.

- JMS_TRANSPORT_REPLY_TO_QUEUE_NAME—specifies the JNDI name of the JMS queue to be used as the default reply-to of all send operation JMS messages. This property is comparable to the replyToQueueLocation WebServicesAssembler argument.

Example 8–5 illustrates client stub code that uses these properties to set the JNDI name of the JMS queue and the connection factory for the reply-to queue for send operations. The code that sets the properties is highlighted in bold.

Example 8–5 Setting replyTo* Parameters Programmatically

ServiceFactory serviceFactory = ServiceFactory.newInstance();
    Echo_Service echoService = (Echo_Service)serviceFactory.loadService(Echo_Service.class);
    Echo_PortType echoPort = echoService.getEchoPort();
    ((Stub)echoPort)._setProperty(Stub.ENDPOINT_ADDRESS_PROPERTY, "/echo/echo");
    ((Stub)echoPort)._setProperty(OracleStub.JMS_TRANSPORT_REPLY_TO_FACTORY_NAME, 
        "jms/receiverQueueConnectionFactory");
    ((Stub)echoPort)._setProperty(OracleStub.JMS.TRANSPORT_REPLY_TO_QUEUE_NAME, 
        "jms/receiverQueue");
    String echo = echoPort.echo("Test echo");

How to Write DII Code for JMS Transport

If you are writing code for a Dynamic Invocation Interface (DII) client, you must create JmsAddress objects for the sender queue and the receiver queue. These objects are then used to declare an JmsClientTransportFactory object programmatically. This will allow the client to get response messages from a Web service invocation.

The JmsAddress and JmsClientTransportFactory classes belong to the oracle.webservices.transport package.

Example 8–6 illustrates DII client code for sending messages through JMS transport. The code which illustrates how JmsClientTransportFactory is created, set up, and used is highlighted in bold.

Example 8–6 DII Client Code to Send Messages Through JMS Transport

... QName operation = new QName("http://www.oracle.com/echo*, "echo");
    Call call = getCall(operation, SOAPVersion.SOAP_1_1);
    call.setTargetEndpointAddress("/echo/echo");
    JmsAddress jmsAddress = new JmsAddress("jms/senderQueue",
        "jms/senderQueueConnectionFactory");
    JmsAddress replyToAddress = new JmsAddress("jms/receiverQueue",
        "jms/receiverQueueConnectionFactory");
    JmsClientTransportFactory transportFactory = new JmsClientTransportFactory(jmsAddress, replyToAddress);
    ((OracleCall) call).setClientTransportFactory(transportFactory);
...
Limitations

See "Using JMS as a Web Service Transport" on page I-16.

This chapter describes Oracle Application Server Web Services support for the Web Services Invocation Framework (WSIF).

This chapter contains the following sections.

- Understanding WSIF
- Understanding WSIF Architecture
- WSIF and Java Classes
- WSIF and EJBs
- WSIF and Database Resources
- Writing a WSIF Client
- Tool Support for WSIF

### Understanding WSIF

WSIF provides a standard API for working with representations of different Web service messaging protocols as an alternative to working directly with a JAX-RPC SOAP client API. The WSIF API allows the client to use native protocols to communicate with the service.

The WSIF API allows a Web service to communicate with Web service components, such as Java classes, EJBs, or database resources, through a single interface. In addition to JAX-RPC which understands only SOAP, WSIF clients can directly use other protocols, such as RMI, IIOP, or JDBC.

To support different messaging protocols, you can add different WSIF bindings to the WSDL. This is in contrast to the SOAP protocol, where you add a SOAP binding. WSIF and SOAP bindings can co-exist in the same WSDL. This enables you to define both native and SOAP bindings for a particular service. For example, you can expose an EJB with a WSIF port and a SOAP port. Clients can access the same Web service even though they may be using different protocols. The protocol that is used to communicate with the service is determined by selecting a particular binding in the client: either a SOAP or a WSIF binding.

---

**Note:** WSIF invocations will map the primitive and nillable XML schema types to primitive Java types. This does not permit the representation of XML nil values.

As a work around, use SOAP-encoded XML types in the WSDL.
Understanding WSIF Architecture

In the WSIF architecture, communications between the client and Web services are enabled through the WSDL. The WSDL becomes the normalized description of the software interface.

Figure 9–1 illustrates the WSIF architecture for OracleAS Web Services. The following steps describe the data flow through the architecture.

1. Program the WSIF client according to the content of the abstract service description portion of the WSDL. This portion of the WSDL includes port types, operations, and message exchanges.
2. At runtime, the WSIF client selects a concrete binding in the WSDL that determines which provider the WSIF runtime will use. Providers are protocol-specific pieces of code that provide implementation of the different WSIF bindings in the WSDL.
3. The WSIF client makes calls into the WSIF API to invoke the Web service. This API is based on the abstract service description portion of the WSDL. By invoking the service based on its abstract description, you can work with a service regardless of how it was implemented, its protocol, or where it resides.
4. The WSIF runtime in the kernel determines which provider to use, based on the binding selected in Step 2.
5. The provider interacts with the Web service.

Services can be invoked dynamically and without the need for generating stubs.

Figure 9–1 WSIF Architecture for OracleAS Web Services
WSIF supports providers for clients of Web services that expose JAX-RPC (SOAP), Java classes, EJBs, and database resources. You can also define your own providers. Defining your own providers is beyond the scope of this manual. For information on this topic, see the Apache Software Group Web page for WSIF.

http://ws.apache.org/wsif/

The following sections describe the WebServicesAssembler commands and Ant tasks that insert WSIF information into the WSDL.

**WSIF and Java Classes**

This section has the following subsections:

- Providing WSIF Functionality for Java Classes
- How to Configure WSIF Endpoints for Java Ports
- WSIF Java Extensions to the WSDL

**Providing WSIF Functionality for Java Classes**

To insert WSIF Java extensions into the WSDL, OracleAS Web Services provides two arguments that can be used with the `assemble` or `genWsdl` WebServicesAssembler commands.

- `wsifJavaBinding`
- `wsifJavaPort`

If you assemble a Web service based on a Java class with the `assemble` or `genWsdl` commands, the `wsifJavaBinding` and `wsifJavaPort` arguments allow you to request a WSIF binding. These arguments add the appropriate WSDL extensions in the form of a WSIF binding that allow a WSIF client to access a Java class exposed as a Web service.

To configure the WSIF Java bindings for a single port, you can use either the `wsifJavaBinding` or `wsifJavaPort` argument. The `wsifJavaBinding` argument allows you to have a WSIF port and no additional SOAP ports in your WSDL. The `wsifJavaPort` argument enables you to specify multiple ports of different types within an Ant task.

While the `wsifJavaBinding` argument can be used either on the command line or in an Ant task, the `wsifJavaPort` can be used only in an Ant task.

**See Also:**

- "WSIF Java Extensions to the WSDL” on page 9-7 for lists of the schema definitions that can be added to the WSDL to support WSIF Java bindings.
- "Assembling a Web Service with Java Classes” in the *Oracle Application Server Web Services Developer’s Guide* for more information on creating a Web service based on a Java class.

**How to Configure WSIF Endpoints for Java Ports**

WSIF endpoints for Java ports can be configured with `wsifJavaBinding` or `wsifJavaPort`.

- How to Configure a Single Java Port with `wsifJavaBinding`
How to Configure a Single Java Port with wsifJavaPort

How to Configure Multiple Java Ports with wsifJavaPort

How to Configure a Single Java Port with wsifJavaBinding

The wsifJavaBinding argument is a flag that can be used by either the assemble or genWsdl command to specify the WSIF Java binding for a single port.

If you use the wsifJavaBinding argument, then you must also provide a value for the className argument. The className argument provides the value of the java:address element in the WSDL's <port> element.

Example 9–1 illustrates a WebServicesAssembler command line for genWsdl that calls wsifJavaBinding and Example 9–2 illustrates the corresponding Ant task. The argument populates the java:address element in the WSDL's <port> element with classname="oracle.demo.hello.HelloImpl". The variable \${wsdemo.common.class.path} represents the classpath.

Example 9–1 Command Line, Using wsifJavaBinding to Configure a Single Java Port

```
java -jar wsa.jar -genWsdl
   -output wsdl
   -style rpc
   -use literal
   -wsifJavaBinding true
   -interfaceName oracle.demo.hello.HelloInterface
   -className oracle.demo.hello.HelloImpl
   -classpath ${wsdemo.common.class.path}:build/classes
```

Example 9–2 Ant Task, Using wsifJavaBinding to Configure a Single Java Port

```
<oracle:genWsdl
   output="wsdl"
   style="rpc"
   use="literal"
   wsifJavaBinding="true"
>
   <oracle:porttype
      interfaceName="oracle.demo.hello.HelloInterface"
      className="oracle.demo.hello.HelloImpl"
   />
<oracle:classpath>
   <oracle:pathelement path="${wsdemo.common.class.path}"/>
   <oracle:pathelement location="build/classes"/>
</oracle:classpath>
</oracle:genWsdl>
```

In these command line and Ant task examples:

- **genWsdl**—Generates a WSDL and a JAX-RPC mapping file for assembling Web services bottom up from a Java interface.
- **output**—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- **style**—For bottom up Web service assembly, this argument specifies the style attribute of the message format in the generated WSDL.
- **use**—For bottom up Web service assembly, this argument specifies the use attribute of the message format in the generated WSDL.
- **wsifJavaBinding**—Used in bottom up Web services assembly to add WSIF Java bindings to the WSDL. If true, you must also specify the className of the Java implementation class. WebServicesAssembler will generate native WSIF Java bindings in addition to SOAP bindings in the WSDL.

- **interfaceName**—Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).

- **className**—Specifies the name of the class (including the package name) that is the implementation class for the Web service.

- **classpath**—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

**See Also:**
"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

### How to Configure a Single Java Port with wsifJavaPort

The wsifJavaPort argument can be used only in an Ant task. Although you typically use wsifJavaPort to specify WSIF Java bindings for multiple ports, you can also use it to specify a single port. The argument also has attributes that allow you to specify a WSIF port name, a Java class name for each port, and a custom class loader and its classpath. These attributes are passed to the java:address element in the WSDL's `<port>` element.

Table 9–1 describes the attributes that can be used by the wsifJavaPort argument. All of the attributes are optional.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>classLoader</td>
<td>Specifies the name of the Java class loader. If you do not provide a value for this attribute, the value for the system class loader will be used.</td>
</tr>
<tr>
<td>className</td>
<td>Specifies the name of the implementation class. If you do not provide a value for this attribute, WebServicesAssembler will use the class name for the parent Ant task if it was specified.</td>
</tr>
<tr>
<td>classPath</td>
<td>Specifies the class path for the Java class loader. If you do not provide a value for this attribute, the system class path will be used.</td>
</tr>
<tr>
<td>name</td>
<td>Specifies the name of the WSIF port in the Web service. This name will be used to identify the WSIF port in the WSDL's <code>&lt;port&gt;</code> element.</td>
</tr>
</tbody>
</table>

The Ant task for genWsdl in Example 9–3 inserts WSIF Java binding code into the WSDL's binding, binding operation, and port clauses. The HelloImpl class used as the className attribute to the wsifJavaPort argument, contains a sayHello method that takes a greeting parameter of type String. The variable `${additional.class.path}` represents the classpath.

### Example 9–3  Using wsifJavaPort to Configure a Single Java Port

```xml
<oracle:genWsdl
```
In this Ant task:

- `genWsdl` — Generates a WSDL and a JAX-RPC mapping file for assembling Web services bottom up from a Java interface.
- `output` — Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- `style` — For bottom up Web service assembly, this argument specifies the `style` attribute of the message format in the generated WSDL.
- `use` — For bottom up Web service assembly, this argument specifies the `use` attribute of the message format in the generated WSDL.
- `porttype` — This tag enables you to configure different interfaces to a Web service.
- `interfaceName` — Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).
- `wsifJavaPort` — Allows you to specify WSIF Java bindings for multiple ports.
- `className` — Specifies the name of the class (including the package name) that is the implementation class for the Web service.
- `classpath` — Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

**See Also:**

"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

Example 9–4 illustrates the WSIF Java binding code that the Ant task in the previous example inserts into the WSDL’s binding, binding operation, and port clauses.

**Example 9–4 WSDL Extensions for WSIF Java Bindings**

```xml
...<java:binding/>
<format:typeMapping encoding="Java" style="Java">
  <format:typeMap typeName="xsd:string" formatType="java.lang.String"/>
</format:typeMapping>
...```
<java:operation
    methodName="sayHello"
    parameterOrder="greeting"
    methodType="instance"
    returnType="result" />
...
<port name="HelloServiceJavaPort" binding="tns:JavaBinding">
    <java:address className="oracle.demo.hello.HelloImpl" />
</port>
...

How to Configure Multiple Java Ports with wsifJavaPort
You can use the wsifJavaPort argument with the assemble and genWsdl commands to define WSIF bindings for multiple Java ports. Example 9–5 illustrates an Ant task that creates a WSIF port named HelloServiceJavaPort and a SOAP port named HelloServiceSoapPort. The SOAP port is created by adding the <oracle:port name="...="/> subtask. Note that className is declared in the parent Ant task. The variable ${additional.class.path} represents the classpath. Table 9–1 on page 9-5 describes the attributes that can be used by wsifJavaPort.

Example 9–5  Using wsifJavaPort to Configure a WSIF Java Port and a SOAP Java Port
<oracle:genWsdl
    output="wsdl"
    style="rpc"
    use="literal"
>
    <oracle:porttype
        interfaceName="oracle.demo.hello.HelloInterface"
        className="oracle.demo.hello.HelloImpl">
        <oracle:wsifJavaPort name="HelloServiceJavaPort"/>
        <oracle:port name="HelloServiceSoapPort"/>
    </oracle:porttype>
    <oracle:classpath>
        <oracle:pathelement path="${additional.class.path}"/>
        <oracle:pathelement location="build/classes"/>
    </oracle:classpath>
</oracle:genWsdl>

WSIF Java Extensions to the WSDL
To comply with the WSIF Framework definition, OracleAS Web Services inserts binding information into the WSDL that allows a Java class to be represented as a Web service. Example 9–6 illustrates the XML schema definitions for these extensions.

Example 9–4 on page 9-6 illustrates how additional bindings, binding operations, and port clauses are added to the WSDL to describe a WSIF service.

Example 9–6  Schema Definitions to Support WSIF Java Bindings
...<!-- Java binding -->
<binding ... >
    <java:binding/>
    <format:typeMapping style="uri" encoding="..."/>
</format:typeMapping>
Providing WSIF Functionality for EJBs

To insert WSIF EJB extensions into the WSDL, the WebServicesAssembler tool provides two arguments that can be used with the ejbAssemble or genWsdl commands.

- wsifEjbBinding
- wsifEjbPort

As you assemble a Web service based on an EJB with the ejbAssemble command, the wsifEjbBinding or wsifEjbPort arguments allow you to request a WSIF binding. These arguments add the appropriate WSDL extensions that allow a WSIF client to access an EJB exposed as a Web service.

To configure the WSIF EJB binding for a single port, you can use either the wsifEjbBinding or wsifEjbPort argument. To configure WSIF EJB bindings for multiple ports, you must use the wsifEjbPort argument.

While the wsifEjbBinding argument can be used either on the command line or in an Ant task, the wsifEjbPort can be used only in an Ant task.
Providing WSIF Functionality for Version 3.0 EJBs

OracleAS Web Services enables you to assemble WSIF bindings for a version 3.0 EJB through the use of an Oracle proprietary addition to J2SE 5.0 Web Service Annotations. OracleAS Web Services defines an @WSIFEJBBinding annotation (oracle.webservices.annotations.@WSIFEJBBinding) that you can add to the interface file for an EJB. When the file is compiled, it generates an EJB WSIF binding in the WSDL, and an EJB port.

For more information on the @WSIFEJBBinding annotation and how to use it, see "Oracle Additions to the J2SE 5.0 JDK Annotations" in the Oracle Application Server Web Services Developer's Guide.

How to Configure WSIF Endpoints for EJB Ports

A WSIF endpoints for EJB ports can be configured with the wsifEjbBinding or wsifEjbPort argument.

How to Configure a Single EJB Port with wsifEjbBinding

How to Configure a Single EJB Port with wsifEjbPort

How to Configure Multiple EJB Ports with wsifEjbPort

How to Configure a Single EJB Port with wsifEjbBinding

The wsifEjbBinding argument can be used by either the ejbAssemble or genWsdl command to specify the WSIF EJB binding for a single port.

The wsifEjbBinding argument requires you to specify the name and jndiName arguments. The wsifEjbBinding argument passes these values to the ejb:address element in the WSDL's <port> element. The jndiProviderURL and initialContextFactory arguments provide the JNDI provider URL and JNDI initial context values. If you do not provide these arguments, then these values are obtained from the jndi.properties file.

See Also:

"wsifEjbBinding" in the Oracle Application Server Web Services Developer's Guide for more information on this argument.

Example 9–7 illustrates a WebServicesAssembler command line for genWsdl that calls wsifEjbBinding. Example 9–8 illustrates the corresponding Ant task. The argument causes the ejb:address element in the WSDL's <port> element to be populated with className="oracle.demo.hello.HelloImpl" and jndiName="HelloService2EJB". The variable ${additional.class.path} represents the classpath.
Example 9–7 Command Line, Using wsifEjbBinding to Configure a Single EJB Port

```java
java -jar wsa.jar -genWsdl
-output wsdl
-style rpc
-use literal
-wsifEjbBinding true
-jndiName HelloService2EJB
-interfaceName oracle.demo.ejb.HelloServiceInf
-jndiProviderUrl deployer:oc4j:localhost:23791/HelloService
-initialContextFactory oracle.j2ee.rmi.RMIInitialContextFactory
-className oracle.demo.hello.HelloImpl
-classpath ${additional.class.path}:build/classes
```

Example 9–8 Ant Task, Using wsifEjbBinding to Configure a Single EJB Port

```xml
<oracle:genWsdl
   output="wsdl"
   style="rpc"
   use="literal"
   wsifEjbBinding="true"
   jndiName="HelloService2EJB"
   jndiProviderUrl="deployer:oc4j:localhost:23791/HelloService"
   initialContextFactory="oracle.j2ee.rmi.RMIInitialContextFactory">
   <oracle:porttype
      interfaceName="oracle.demo.ejb.HelloServiceInf"
      className="oracle.demo.hello.HelloImpl">
   </oracle:porttype>
   <oracle:classpath>
      <pathelement path="${additional.class.path}"/>
      <pathelement location="build.ejb.dir"/>
   </oracle:classpath>
</oracle:genWsdl>
```

In these command line and Ant task examples:

- `genWsdl`—Generates a WSDL and a JAX-RPC mapping file for assembling Web services bottom up from a Java interface.
- `output`—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- `style`—For bottom up Web service assembly, this argument specifies the `style` attribute of the message format in the generated WSDL.
- `use`—For bottom up Web service assembly, this argument specifies the `use` attribute of the message format in the generated WSDL.
- `wsifEjbBinding`—Used in bottom up Web services assembly to add WSIF EJB bindings to the WSDL. If `true`, you must also specify the EJB’s home interface `className` and `jndiName`.
- `jndiName`—Specifies a JNDI name for an EJB.
- `jndiProviderUrl`—Specifies the URL for the JNDI Provider. This is an optional argument that can be called by the `genWsdl` or `ejbAssemble` command when configuring an EJB WSIF port with `wsifEjbBinding` or `wsifEjbPort`.
- `porttype`—This tag enables you to configure different interfaces to a Web service.
- **initialContextFactory**—Specifies the name of the factory that will provide the initial context. This is an optional argument that can be called by the `genWsdl` or `ejbAssemble` command when configuring an EJB WSIF port with `wsifEjbBinding` or `wsifEjbPort`.

- **interfaceName**—Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).

- **className**—Specifies the name of the class (including the package name) that is the implementation class for the Web service.

- **classpath**—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

**See Also:**
"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer's Guide for more detailed information on these arguments.

### How to Configure a Single EJB Port with `wsifEjbPort`

The `wsifEjbPort` argument can be used only in an Ant task. Although you typically use `wsifEjbPort` to specify WSIF EJB bindings for multiple ports, you can also use it to specify a single port. The argument has attributes that allow you to specify a WSIF port name, a class name, a JNDI name, a JNDI initial context, and a JNDI provider URL for each port. These attributes are passed to the `ejb:address` element in the WSDL. Table 9–2 describes the attributes that can be used by the `wsifEjbPort` argument. Except for `jndiName`, all of the attributes are optional.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>className</code></td>
<td>Specifies the class name of the EJB's home interface. If you do not provide a value for this attribute, WebServicesAssembler will use the class name for the parent Ant task if it was specified.</td>
</tr>
<tr>
<td><code>initialContextFactory</code></td>
<td>Specifies the name of the factory that will provide the initial context. If you do not provide a value for this attribute, the value in the <code>jndi.properties</code> file will be used.</td>
</tr>
<tr>
<td><code>jndiName</code></td>
<td>(required) Specifies the JNDI name for the EJB.</td>
</tr>
<tr>
<td><code>jndiProviderURL</code></td>
<td>Specifies the URL for the JNDI Provider. If you do not provide a value for this attribute, the value in the <code>jndi.properties</code> file will be used.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>Specifies the name of the WSIF Port in the Web service. This name will be used to identify the WSIF port in the WSDL's <code>port</code> element.</td>
</tr>
</tbody>
</table>

The Ant task for `genWsdl` in Example 9–9 inserts WSIF EJB binding code into the WSDL’s binding, binding operation, and port clauses. The `HelloHome` class used as the `className` attribute to the `wsifEjbPort` argument, contains a `sayHello` method that takes a `greeting` parameter of type `String`. The variable `${additional.class.path}` represents the classpath.

**Example 9–9  Using `wsifEjbPort` to Configure a Single EJB Port**

```xml
<oracle:genWsdl
```
In these command line and Ant task examples:

- `genWsdl` — Generates a WSDL and a JAX-RPC mapping file for assembling Web services bottom up from a Java interface.
- `output` — Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- `style` — For bottom up Web service assembly, this argument specifies the `style` attribute of the message format in the generated WSDL.
- `use` — For bottom up Web service assembly, this argument specifies the `use` attribute of the message format in the generated WSDL.
- `serviceName` — Specifies the service name.
- `porttype` — This tag enables you to configure different interfaces to a Web service.
- `interfaceName` — Specifies the name of a Java class (including the package name) that contains the service endpoint interface (SEI).
- `wsifEJBPort` — Allows you to specify WSIF Java bindings for multiple ports.
- `className` — Specifies the name of the class (including the package name) that is the implementation class for the Web service.
- `jndiName` — Specifies a JNDI name for an EJB.
- `jndiProviderUrl` — Specifies the URL for the JNDI Provider. This is an optional argument that can be called by the `genWsdl` or `ejbAssemble` command when configuring an EJB WSIF port with `wsifEjbBinding` or `wsifEjbPort`.
- `initialContextFactory` — Specifies the name of the factory that will provide the initial context. This is an optional argument that can be called by the `genWsdl` or `ejbAssemble` command when configuring an EJB WSIF port with `wsifEjbBinding` or `wsifEjbPort`.
- `classpath` — Specifies the classpath that contains any user-created classes given to `WebServicesAssembler`. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want `WebServicesAssembler` to overwrite them.
Example 9–10 illustrates the WSIF EJB binding code that the previous example inserts into the WSDL's binding, binding operation, and port clauses.

Example 9–10  WSDL Extensions for WSIF EJB Bindings

...  
<ejb:binding/>
  <format:typeMapping encoding="Java" style="Java">
    <format:typeMap typeName="xsd:string" formatType="java.lang.String"/>
  </format:typeMapping>
...  
<operation name="sayHello">
  <ejb:operation
    methodName="sayHello"
    interface="remote"
    parameterOrder="greeting"
    returnPart="result"/>
...  
<port name="EjbPort" binding="tns:EjbPortBinding">
  <ejb:address className="oracle.test.wsif.HelloHome"
    jndiName="HelloServiceBean"
    initialContextFactory="oracle.j2ee.rmi.RMIInitialContextFactory"
    jndiProviderURL="deployer:oc4j:localhost:23791/HelloService"/>
</port>
...  

How to Configure Multiple EJB Ports with wsifEjbPort

Use the wsifEjbPort argument to define WSIF bindings for multiple EJB ports. This argument can be used by the ejbAssemble and the genWsdl Ant tasks. Example 9–11 illustrates the Ant task that creates a WSIF port named EjbPort and a SOAP port named SoapPort. The SOAP port is created by adding the <oracle:port name="... "/> subtask. The variable ${additional.class.path} represents the classpath. Table 9–2 on page 9-11 describes the attributes that can be used by wsifEjbPort.

Example 9–11  Using wsifEjbPort to Configure Multiple EJB Ports

<oracle:genWsdl
  output="wsdl"
  style="rpc"
  use="literal"
  serviceName="${app.name}"
>
  <oracle:porttype interfaceName="oracle.test.wsif.HelloServiceInf"/>
  <oracle:port name="SoapPort" uri="TestWsdlService"/>
  <oracle:wsifEjbPort name="EjbPort"
    className="oracle.test.wsif.HelloHome"
    jndiName="HelloServiceBean"
    jndiProviderUrl="deployer:oc4j:localhost:23791/HelloService"
    initialContextFactory="oracle.j2ee.rmi.RMIInitialContextFactory"/>
</oracle:genWsdl>
WSIF EJB Extensions to the WSDL

To comply with the WSIF Framework definition, OracleAS Web Services inserts code into the WSDL that allows an EJB to be represented as a Web service. Example 9–10 on page 9-13 illustrates how additional bindings, binding operations, and port clauses are added to the WSDL to describe a WSIF service. Example 9–12 illustrates the corresponding XML schema definitions for these extensions.

Example 9–12  Schema Definitions to Support WSIF EJB Bindings

...  <!-- EJB binding -->
<binding ... >
  <ejb:binding/>
  <format:typeMapping style="uri" encoding="..."/>
    <format:typeMap typeName="qname" elementName="qname"
        formatType="nmtoken"/>
  </format:typeMapping>
  ...  <operation>*
    <ejb:operation
      methodName="nmtoken"
      parameterOrder="nmtoken"?
      returnPart="nmtoken"?
      interface="home|remote"?/>
      <input name="nmtoken"/>
      <output name="nmtoken"/>
      <fault name="nmtoken"/>
    </operation>
  </binding>
...  <service ... >
  <port>*
    <ejb:address
      className="nmtoken"
      jndiName="nmtoken"
      initialContextFactory="nmtoken"?
      jndiProviderURL="url"?/>
  </port>
</service>
...

WSIF and Database Resources

To insert WSIF extensions for database resources into the WSDL, OracleAS Web Services provides two arguments that can be used with the aqAssemble, dbJavaAssemble, plsqlAssemble, sqlAssemble and genWsdl WebServicesAssembler commands.

- wsifDbBinding
- wsifDbPort
As you assemble a Web service based on a database resource with the aqAssemble, dbJavaAssemble, plsqlAssemble, sqlAssemble, or genWsdl commands, the wsifDbBinding and wsifDbPort arguments allow you to create a direct invocation to the database by using a WSIF binding. Note that database WSIF clients must provide a JNDI setup where the data source for connecting to the database can be determined at runtime.

These arguments add the appropriate WSDL extensions that allow a WSIF client to access database resources exposed as a Web service.

See Also:

"WSIF SQL Extensions to the WSDL" on page 9-21 for lists of the schema definitions that can be added to the WSDL to support WSIF database resource bindings.

To configure the WSIF database resource binding for a single port, you can use either the wsifDbBinding or wsifDbPort argument. To configure WSIF database resource bindings for multiple ports, you must use the wsifDbPort argument.

While the wsifDbBinding argument can be used either on the command line or in an Ant task, wsifDbPort can be used only in an Ant task.

The following sections describe how to configure WSIF endpoints for single and multiple database resource ports.

- How to Configure a WSIF Endpoints Database Resource Ports
- How to Configure Multiple Database Resource Ports with wsifDbPort

How to Configure a WSIF Endpoints Database Resource Ports

The WSIF endpoint for a single database resource port can be configured with wsifDbBinding or wsifDbPort.

- How to Configure a Single Database Resource Port with wsifDbBinding
- How to Configure a Single Database Resource Port with wsifDbPort

How to Configure a Single Database Resource Port with wsifDbBinding

The wsifDbBinding argument can be used with aqAssemble, dbJavaAssemble, plsqlAssemble, sqlAssemble, and genWsdl WebServicesAssembler commands to specify the WSIF database resource bindings for a single port.

To establish the database connection, you must specify either dataSource or a combination of dbUser and dbConnection.

Table 9-3 Attributes for the wsifDbBinding and wsifDbPort Arguments

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>className</td>
<td>(required) Specifies the name of the Java class generated by Oracle JPublisher. If you do not provide a value for this attribute, WebServicesAssembler will derive a value based on the port name.</td>
</tr>
<tr>
<td>dataSource</td>
<td>Specifies the JNDI location of the data source used by the Web service. This attribute is required if you do not provide dbConnection and dbUser attributes. For more information on the dataSource argument, see &quot;dataSource&quot; in the &quot;Database Assembly Commands&quot; section of the Oracle Application Server Web Services Developer’s Guide.</td>
</tr>
</tbody>
</table>
If only the `dataSource` argument appears in an Ant task or on the command line, it will provide assembly time and runtime access to the database.

If only the `dbConnection` and `dbUser` arguments appear in an Ant task or on the command line, they will provide assembly time access to the database. In addition, the `dbConnection` attribute is used at runtime. See "How to Access the Database from a WSIF Client" on page 9-25 for information on how the user name and password is set at runtime.

If the `dbConnection`, `dbUser`, and `dataSource` arguments appear in an Ant task or on the command line, then `dbConnection` and `dbUser` will be used for assembly time access to the database. The `dataSource` argument will be used for runtime access.

Example 9–13 illustrates a WebServicesAssembler command line for `sqlAssemble` that calls `wsifDbBinding` to configure a single port for a database resource. Example 9–14 illustrates the corresponding Ant task. These examples provides values for `dbUser` and `dbConnection` which will be entered into the `<port>` element of the WSDL. The `useDataSource` argument is specified as false: the value of the `dataSource` argument will not be used in the WSDL `<port>` element. The variables `${wsdemo.common.class.path}`, `additional.class.path`, and `service.classes.dir` represent classpath elements.

Example 9–13 Command Line, Using wsifDbBinding to Configure a Single Database Resource Port

```
java -jar wsa.jar -sqlAssemble
  -dbUser scott/tiger
  -dbConnection jdbc:oracle:thin:@...
  -dataSource jdbc/OracleManagedDS
  -appName SqlWsifTest
  -serviceName sqlwsif
  -output build
  -ear dist/SqlWsifTest.ear
  -style rpc
  -use literal
  -wsifDbBinding true
  -sqlstatement "getEname=select ename from emp"
  -sqlstatement "updateSal=update emp SET sal=sal+500 where
```

### Table 9–3 (Cont.) Attributes for the `wsifDbBinding` and `wsifDbPort` Arguments

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dbConnection</code></td>
<td>Specifies the JDBC URL for the database. If you specify <code>dbConnection</code>, you must also provide a value for <code>dbUser</code>. The <code>dbConnection</code> attribute might also be used at runtime in certain cases. See &quot;dbConnection&quot; in the &quot;Database Assembly Commands&quot; section of the Oracle Application Server Web Services Developer’s Guide for more information on this attribute.</td>
</tr>
<tr>
<td><code>dbUser</code></td>
<td>Specifies the database schema and password in the form <code>user/password</code>. The value of this attribute is employed only at code generation time to access the database. If you specify <code>dbUser</code>, you must also provide a value for <code>dbConnection</code>. See &quot;dbUser&quot; in the &quot;Database Assembly Commands&quot; section of the Oracle Application Server Web Services Developer’s Guide for more information on this attribute.</td>
</tr>
<tr>
<td><code>name</code></td>
<td>(required for <code>wsifDbPort</code> only) Specifies the port name.</td>
</tr>
</tbody>
</table>

- If only the `dataSource` argument appears in an Ant task or on the command line, it will provide assembly time and runtime access to the database.
- If only the `dbConnection` and `dbUser` arguments appear in an Ant task or on the command line, they will provide assembly time access to the database. In addition, the `dbConnection` attribute is used at runtime. See "How to Access the Database from a WSIF Client" on page 9-25 for information on how the user name and password is set at runtime.
- If the `dbConnection`, `dbUser`, and `dataSource` arguments appear in an Ant task or on the command line, then `dbConnection` and `dbUser` will be used for assembly time access to the database. The `dataSource` argument will be used for runtime access.
Example 9–14  Ant Task, Using wsifDbBinding to Configure a Single Database Resource Port

```xml
<oracle:sqlAssemble
    dbUser="scott/tiger"
    dbConnection="jdbc:oracle:thin:@..."
    dataSource="jdbc/OracleManagedDS"
    appName="SqlWsifTest"
    serviceName="sqlwsif"
    output="build"
    ear="dist/SqlWsifTest.ear"
    style="rpc"
    use="literal"
    wsifDbBinding="true">
   <oracle:port name="sqlwsif" uri="SqlWsifTest" />
   <sqlstatement value="getEname=select ename from emp" />
   <sqlstatement value="updateSal=update emp SET sal=sal+500 where ename=:{myname VARCHAR}" />
<oracle:classpath>
   <oracle:pathelement path="${wsdemo.common.class.path}"/>
   <oracle:pathelement path="${additional.class.path}"/>
   <oracle:pathelement location="client/classes"/>
   <oracle:pathelement location="${service.classes.dir}"/>
</oracle:classpath>
</oracle:sqlAssemble>
```

In these command line and Ant task examples:

- `sqlAssemble`—Generates Web services from SQL statements, including SQL queries and DMLs (Data Manipulation Language). To use this command, you must connect to a database.
- `dbUser`—Specifies the database schema and password in the form of `user/password`.
- `dbConnection`—Specifies the JDBC URL for the database.
- `dataSource`—Specifies the JNDI location of the data source used by the Web services at runtime.
- `appName`—Specifies the name of an application. Usually, this name is used as a base value for other arguments like `context` and `uri`.
- `serviceName`—Specifies the service name.
- `output`—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- `ear`—Specifies the name and location of the generated EAR.
- `style`—For bottom up Web service assembly, this argument specifies the `style` attribute of the message format in the generated WSDL.
- `use`—For bottom up Web service assembly, this argument specifies the `use` attribute of the message format in the generated WSDL.
- `wsifDbBinding`—Used in bottom up Web services assembly to add WSIF SQL bindings to the WSDL. WebServicesAssembler will generate native WSIF SQL bindings in addition to SOAP bindings in the WSDL.
sqlStatement—Specifies the DML statement or SQL query to be published as a Web service.

classpath—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have already created some value type classes or exceptions and you do not want WebServicesAssembler to overwrite them.

See Also:
"Using WebServicesAssembler", in the Oracle Application Server Web Services Developer’s Guide for more detailed information on these arguments.

Example 9-15 illustrates the WSIF database resource binding code that the previous example inserts into the WSDL’s <port> element.

Example 9-15  WSDL Extensions for WSIF Database Resource Bindings

...<service name="sqlwsif">
  <port name="JavaPort" binding="tns:JavaPortBinding">
    <java:address className="...User"
      dataSource="jdbc/OracleManagedDS"/>
  </port>
</service>
...

How to Configure a Single Database Resource Port with wsifDbPort

The wsifDbPort argument can be used only in an Ant task. Although you typically use wsifDbPort to specify the WSIF database resource bindings for multiple ports, you can also use it to specify a single port. The argument has attributes that allow you to specify a WSIF port name, a class name for the Java files generated by Oracle JPublisher, and database connection information. These attributes are passed to the java:address element of the WSDL’s <port> element.

Table 9-3 describes the attributes that can be used by the wsifDbPort argument. Except for className and name, all of the attributes are optional.

- If only the dataSource argument appears in an Ant task or on the command line, it will provide assembly time and runtime access to the database.
- If only the dbConnection and dbUser arguments appear in an Ant task or on the command line, they will provide assembly time access to the database. In addition, the dbConnection attribute is used at runtime. See "How to Access the Database from a WSIF Client" on page 9-25 for information on how the user name and password is set at runtime.
- If the dbConnection, dbUser, and dataSource arguments appear in an Ant task or on the command line, then dbConnection and dbUser will be used for assembly time access to the database. The dataSource argument will be used for runtime access.

Example 9-13 illustrates the WebServicesAssembler command line for wsifDbPort which inserts WSIF database resource code into the WSDL’s binding, binding operation, and port clauses. Example 9-16 illustrates the corresponding Ant task. In the wsifDbPort argument, the name of the port is set to JavaPort and the name of the JPublisher-generated Java class is oracle.generated.sqlwsifUser.
Example 9–16  Ant Task, Using wsifDbPort to Configure a Single Database Resource Port

```xml
<oracle:sqlAssemble
    dataSource="jdbc/OracleManagedDS"
    appName="SqlWsifTest"
    portName="sqlwsif"
    serviceName="sqlwsif"
    output="build"
    ear="dist/SqlWsifTest.ear"
    style="rpc"
    use="literal" />
<oracle:port name="sqlwsif" uri="SqlWsifTest" /><
<sqlstatement value="getEname=select ename from emp" />
<sqlstatement value="updateSal=update emp SET sal=sal+500 where ename=:{myname} VARCHAR" />
<oracle:wsifDbPort
    name="JavaPort"
    className="oracle.generated.sqlwsifUser" />
<oracle:classpath>
    <oracle:pathelement path="${wsdemo.common.class.path}"/>
    <oracle:pathelement path="${additional.class.path}"/>
    <oracle:pathelement location="client/classes"/>
    <oracle:pathelement location="service/classes"/>
</oracle:classpath>
</oracle:sqlAssemble>
```

Example 9–17 illustrates the WSIF database resource binding code that the previous example inserts into the WSDL.

Example 9–17  WSDL Extensions for WSIF Database Resource Bindings

```xml
<service name="sqlwsif">
    <port name="JavaPort" binding="tns:JavaPortBinding">
        <java:address className="oracle.generated.sqlwsifUser"
                      dataSource="jdbc/OracleManagedDS"/>
    </port>
</service>
```

How to Configure Multiple Database Resource Ports with wsifDbPort

Use the wsifDbPort argument to define WSIF bindings for multiple database resource ports. This argument can be used in the Ant tasks for the aqAssemble, dbJavaAssemble, plsqlAssemble, sqlAssemble, and genWsdl commands.

Example 9–18 illustrates an Ant task that creates a SOAP port and a WSIF port. The port operations are based on the `<sqlstatement value="..."/>` subtasks. The wsifDbPort subtask creates the JavaPort port. The oracle:port subtask creates the SOAP port. The variables `${wsdemo.common.class.path}`, `${additional.class.path}`, and `${service.classes.dir}` represent classpath elements. Table 9–3 describes the attributes that can be used by wsifDbPort.

Example 9–18  Ant Task, Using wsifDbPort to Configure Multiple Database Resource Ports

```xml
<oracle:sqlAssemble
    dbUser="scott/tiger"
    dbConnection="jdbc:oracle:thin:@${DB_HOST}:${DB_PORT}:${DB_SID}"
dataSource="jdbc/OracleManagedDS"
appName="wsifTest"
portName="dbwsif"
serviceName="dbwsif"
output="build"
ear="dist/wsifDbTest.ear"
style="rpc"
use="literal"
>
<oracle:port name="dbwsif"  uri="wsifDbTest"/>
<sqlstatement value="getEname=select ename from emp" />
<sqlstatement value="updateSal=update emp SET sal=sal+500 where ename=:myname VARCHAR" />
<oracle:wsifDbPort name="JavaPort"
    className="oracle.generated.sqlwsifUser">
<oracle:classpath>
<oracle:pathelement path="${wsdemo.common.class.path}"/>
<oracle:pathelement path="${additional.class.path}"/>
<oracle:pathelement location="${client.classes.dir}"/>
<oracle:pathelement location="${service.classes.dir}"/>
</oracle:classpath>
</oracle:sqlAssemble>

In this Ant task example:

- **sqlAssemble**—Generates Web services from SQL statements, including SQL queries and DMLs (Data Manipulation Language). To use this command, you must connect to a database.
- **dbUser**—Specifies the database schema and password in the form of `user/password`.
- **dbConnection**—Specifies the JDBC URL for the database.
- **dataSource**—Specifies the JNDI location of the data source used by the Web services at runtime.
- **appName**—Specifies the name of an application. Usually, this name is used as a base value for other arguments like `context` and `uri`.
- **portName**—Specifies the name of a port in a WSDL document.
- **serviceName**—Specifies the service name.
- **output**—Specifies the directory where generated files will be stored. If the directory does not exist, it will be created.
- **ear**—Specifies the name and location of the generated EAR.
- **style**—For bottom up Web service assembly, this argument specifies the `style` attribute of the message format in the generated WSDL.
- **use**—For bottom up Web service assembly, this argument specifies the `use` attribute of the message format in the generated WSDL.
- **wsifDbPort**—Enables you to define WSIF bindings for multiple database resource ports.
- **sqlStatement**—Specifies the DML statement or SQL query to be published as a Web service.
- **classpath**—Specifies the classpath that contains any user-created classes given to WebServicesAssembler. One reason to specify this argument is if you have
already created some value type classes or exceptions and you do not want
WebServicesAssembler to overwrite them.

See Also:
"Using WebServicesAssembler", in the Oracle Application Server Web
Services Developer’s Guide for more detailed information on these
arguments.

**WSIF SQL Extensions to the WSDL**

To comply with the WSIF Framework definition, OracleAS Web Services inserts code
into the WSDL that allows a database resource to be represented as a Web service.
Example 9–15 on page 9-18 illustrates how additional database resource bindings are
placed in the WSDL. Specifically, the WSIF JavaPortBinding is further extended
with the optional dataSource attribute. The presence of this attribute indicates that
this is a database port and not a Java port. Example 9–19 illustrates the corresponding
XML schema definitions for this extension.

*Example 9–19  Schema Definitions to Support WSIF Database Resource Bindings*

```xml
...<definitions .... >

<!-- Java binding -->
<binding ... >
  <java:binding/>
  <format:typeMapping style="uri" encoding="..."/>
  <format:typeMap typeName="qname" elementName="qname" formatType="nmtoken"/>
</format:typeMapping>
<operation>*
  <java:operation
    methodName="nmtoken"
    parameterOrder="nmtoken"?
    returnPart="nmtoken"?
    methodType="instance|static|constructor"? />
  <input name="nmtoken" />
  <output name="nmtoken" />
  <fault name="nmtoken" />
</operation>
</binding>

<service ... >
  <port>*
    <java:address
      className="nmtoken"
      classPath="nmtoken"?
      classLoader="nmtoken"?
      dataSource="nmtoken"?

</port>
</service>
</definitions>
...

**Writing a WSIF Client**

A WSIF client is similar to a DII client in that it does not rely on any pre-generated
stub. The WSDL plays a central role for the WSIF client. Since the WSDL contains all of
the information to invoke the service, it must be available to the client at runtime. The
WSIF client must create the WSIF service, port, operation, and messages, before it
actually invokes the operation with the messages.

The WSIF API, which is based on the abstract service description portion of the WSDL,
contains methods for obtaining this information from the WSDL. The WSIF API is
available from the Apache Software Group Web site.

http://ws.apache.org/wsif/

---

**Note:** There is no WebServicesAssembler support for generating
WSIF clients.

---

This section contains the following subsections:

- Steps to Write a WSIF Client
- Steps to Write a WSIF Client Using a Dynamic Proxy
- How to Access the Database from a WSIF Client
- How to Add a Management Configuration to a WSIF Client
- How DII Clients of WSIF Services Can Get Message Headers
- How to Add Message Attachments in WSIF

**Steps to Write a WSIF Client**

To write a WSIF client, follow these general steps.

1. Create a new instance of a WSIF service factory.

   The `newInstance` method of the `org.apache.wsif.WSIFServiceFactory` class
   instantiates a new WSIF service factory. For example:

   ```java
   // create a service factory
   WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
   ```

2. Create a WSIF service.

   Information in the WSDL file is used to build the WSIF service. The
   `WSIFServiceFactory` class provides a variety of `getService` methods to
   obtain the service definition from the WSDL. The location of the WSDL file can be
   specified either as a URL location available over HTTP, or as a file-based location
   available through the classLoader. Additional parameters for service creation are
   service name/namespace and portType/namespace. For example:

   ```java
   WSIFService service = factory.getService( ... );
   ```

3. Create the WSIF port, operation, and messages.

   Use the WSIF service to create the WSIF port. Use one of the WSIF API
   `WSIFService.getPort` methods to get the WSIF port for the port type that this
   factory supports. For example:

   ```java
   WSIFPort port = service.getPort("portName");
   ```

4. Create the WSIF operation.

   Use the WSIF port to create the WSIF operation. An operation is created using a
   service name or a combination of service name and input and output messages.
   There must be exactly one operation in this port's `portType` with this name. The
Writing a WSIF Client

Using Web Services Invocation Framework

9-23

WSIF API supports a variety of createOperation methods, depending on the type of J2EE component you are exposing as a Web service. For example:

```java
WSIFOperation operation = port.createOperation("operationName");
```

5. Create the input, output, and fault messages.

Use the WSIF operation to create the messages. The WSIFOperation interface in the WSIF API supports a variety of methods to create input, output, and fault messages. For example:

```java
WSIFMessage input = operation.createInputMessage();
WSIFMessage output = operation.createOutputMessage();
WSIFMessage fault = operation.createFaultMessage();
```

6. Populate the input message.

There are two possible ways to populate the message, depending on whether you will be invoking an RPC or a document-literal Web service.

- To populate the input message for an RPC Web service, set the parts (defined in the WSDL) of the input message. For example, use one of the WSIFMessage.setObjectPart methods to allow the operation to pass a value to the service. You can also set message types using Java classes based on the type map, which is set by the service. In the following example, the name variable is taken from the WSDL's request message part for the operation.

```java
input.setObjectPart("name", "Duke");
```

- To populate the input message for a document-literal Web service, the client must construct the SOAPElement object before setting the parts. This is illustrated in the following example. The parameter variable is taken from the WSDL's request message part for the sayHello operation.

```java
SOAPFactory soapfactory = SOAPFactory.newInstance();
SOAPElement request = soapfactory.createElement("sayHelloElement", "ns0", "http://oracle.demo.hello/");
SOAPElement nameChild = soapfactory.createElement("name");
namChild.addTextNode("Duke");
request.addChildElement(nameChild);
input.setObjectPart("parameter", request)
```

7. Make the call to the service.

Use one of the WSIF API "execute" methods to execute the operation. The signature allows for input, output and fault messages. The WSIF API supports a variety of "execute" methods, depending on the type of J2EE component you are exposing as a Web service. For example:

```java
operation.executeRequestResponseOperation(...);
```

The call can return a Boolean variable that is equal to true if the operation succeeds, or false otherwise. If the call fails, a fault message can be examined to determine the exact reason for the failure. The fault message is populated based on the SOAPBody:Fault element defined in the SOAP specification. If the call succeeds, the content of the output message can be extracted into Java classes based on the output message parts (similar to the population of the input messages).

Example 9–20 illustrates a sample DII client. The client performs an invocation on the HelloService's sayHello method, and passes "Duke" as the value for the name
parameter. The WSDL that defines the service is deployed at http://localhost:8888/helloWSIFDii/helloWSIFDii?WSDL. The portType is the QName {http://hello.demo.oracle/}HelloInterface, where http://hello.demo.oracle/ is the portType namespace and HelloInterface is the port name. The name of the WSIF port is HelloServicePort and the name of the operation is sayHello. The executeRequestResponseOperation method makes the call to the service.

Example 9–20  Sample WSIF Client Code

import org.apache.wsif.*;
...
// create a service factory
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

// parse the WSDL
null, null, "http://hello.demo.oracle/", "HelloInterface");

// create WSIF port, operation, and messages
WSIFPort port = service.getPort("HelloServicePort");
WSIFOperation operation = port.createOperation("sayHello");
WSIFMessage input = operation.createInputMessage();
WSIFMessage output = operation.createOutputMessage();
WSIFMessage fault = operation.createFaultMessage();
input.setObjectPart("name", "Duke");

// make the actual call to the service
operation.executeRequestResponseOperation(input, output, fault);
...

Steps to Write a WSIF Client Using a Dynamic Proxy

A much simpler way of writing a WSIF client is to write it using a service endpoint interface. The WSIF runtime can create a corresponding implementation for you in the form of a dynamic proxy. This technique assumes that you already have a compiled service endpoint interface. The WSIF API provides a getStub method (org.apache.wsif.WSIFService.getStub) that gets the dynamic proxy that implements the interface.

The following steps summarize how to get the interface as a dynamic proxy.

1. Create a new instance of a WSIF service factory.
   For example:
   
   WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

2. Create a WSIF service.
   For example:
   
   WSIFService service = factory.getService( ... );

3. Pass the service port name and the service endpoint interface class to the getStub method. Cast the dynamic proxy which is returned to the service endpoint interface.
   For example:
   
   HelloInterface stub = (HelloInterface) service.getStub( ... );
4. Call methods directly on the proxy that implements the interface.

   For example:

   ```java
   String resp = stub.sayHello("Duke");
   ```

Example 9–21 illustrates using the WSIF client as a dynamic proxy. The port name HttpSoap11 and the service endpoint interface class HelloInterface.class are passed to the getStub method. The returned dynamic proxy is cast to the HelloInterface service endpoint interface. Note that the stub parameter is also declared as type HelloInterface. Using the stub, you can then call methods on the interface directly.

**Example 9–21 Using a WSIF Client as a Dynamic Proxy**

```java
// Create a service factory
WSIFServiceFactory factory = WSIFServiceFactory.newInstance();

// Parse the WSDL
WSIFService service = factory.getService(serviceURL + "?WSDL", null, null, 
    "http://hello.demo.oracle/", "HelloInterface");

// Call the getStub method with the port name and
//    the service endpoint interface class.
// Cast the returned dynamic proxy to the service endpoint interface.
HelloInterface stub = (HelloInterface) service.getStub("HttpSoap11", HelloInterface.class);

// Call methods directly on the interface
String resp = stub.sayHello("Duke");
```

**How to Use genInterface to Generate a Service Endpoint Interface**

The steps in the previous section assume that you have a WSDL and a service endpoint interface. If you do not have the service endpoint interface, one way to obtain it is to write it by hand, using the WSDL as a guide.

As an alternative to writing the interface by hand, you can pass the WSDL to the WebServicesAssembler genInterface command. The command will generate the service endpoint interface for you. This is especially convenient if the WSDL has a large number of operations that must be converted to methods.

When genInterface converts WSDL operations to Java methods, it will always make the first letter of the method name lowercase. If the original operation name in the WSDL begins with an uppercase character, this will cause a mismatch when you attempt to call methods on the proxy. Typically, a "Method does not exist" error will be returned.

To avoid this error, edit the service endpoint interface, if necessary, to ensure that method names exactly match the operation names in the WSDL, character-for-character.

**How to Access the Database from a WSIF Client**

The waifDbBinding and waifDBPort arguments add the appropriate bindings to the WSDL that allow a WSIF client to access database resources exposed as a Web service. The dataSource argument identifies the database that contains the resources.

If you omit the dataSource argument and only use dbConnection to identify the database URL at both code generation time and at runtime, then
WebServicesAssembler generates its value into the WSDL file. To access the database, the WSIF client must pass the user name and password values at runtime. The generated code provides two methods to do this.

```java
public void _setDataSourceUser(String);
public void _setDataSourcePassword(String);
```

The following are the complete paths of these methods. The `CLASSNAME` variable represents the value specified by the `className` argument. If `className` is not specified, it defaults to the value of `portName`.

```java
CLASSNAME.setDataSourceUser(String user);
CLASSNAME.setDataSourceUser(String password);
```

If the `dataSource` argument is specified in the command or Ant task, then these two methods are not needed. The client will already have the privileges of accessing the database.

Example 9–22 illustrates a client for the Web service assembled by the Ant task in Example 9–14. The `setDataSourceUser` and `setDataSourcePassword` methods, which pass the user name and password to the server, are highlighted in bold.

```java
Example 9–22 Client Code to Pass a User Name and Password to the Service

WSIFServiceFactory factory = WSIFServiceFactory.newInstance();
WSIFService service = factory.getService(wsdlPath1, null, null, 
    "http://generated.oracle/", "sqlwsif");
oracle.generated.sqlwsif stub = null;
stub = (oracle.generated.sqlwsif)
    service.getStub("JavaPort", oracle.generated.sqlwsif.class);
stub.setDataSourceUser("scott");
stub.setDataSourcePassword("tiger");
System.out.println("Run Sql...");
String[] names = stub.getEname();
```

**How to Add a Management Configuration to a WSIF Client**

You can add a Web service management configuration for security, reliability, and auditing to a WSIF client.

A Web service management configuration on the WSIF client is useful only when it invokes a SOAP port or operation that has a matching Web service management configuration.

OracleAS Web Services does not support Web service management configuration for Java and EJB ports on the Web service side.

If a WSIF client which has a Web service management configuration communicates with a Java or an EJB port, then the Web service management configuration is ignored. The Web service management is used, however, if SOAP port is used to invoke the service.

The `J2EE_HOME/config/wsif-wsm-config.xml` file provides a template where you can specify outgoing management policies for the client. The `wsif-wsm-config.xml` file is based on the `oracle-webservices-client-10_0.xsd` schema.

By default, the `wsif-wsm-config.xml` file resides in the `J2EE_HOME/config` directory. If you change the name of the file or call it from another location, you can use the `wsif.wsm.config.file` system property to override its default name and location.
To create the management configuration and make it available to the WSIF client, you can use the `wsif-wsm-config.xml` file in either of the following ways:

- edit the `wsif-wsm-config.xml` file in the `J2EE_HOME/config` directory, or
- use the `wsif-wsm-config.xml` file as a template and store it in the location of your choice. Specify the new name and location of the file with the following system property:

  ```
  -Dwsif.ws.config.file=<path to file>
  ```

Example 9–23 illustrates the contents of the `wsif-wsm-config.xml` file. Table 9–4 describes the elements in the file.

**Example 9–23  WSIF Client Configuration File**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<oracle-webservice-clients xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="/oracle-webservices-client-10_0.xsd">
  <webservice-client>
    <service-qname namespaceURI="" localpart=""/>
    <port-info>
      <wsdl-port namespaceURI="" localpart=""/>
      <service-endpoint-interface></service-endpoint-interface>
      <stub-property>
        <name></name>
        <value></value>
      </stub-property>
      <call-property>
        <name></name>
        <value></value>
      </call-property>
    </port-info>
    <runtime>
      <security>
        <!-- Port-level Security configuration. For more information on security configuration elements, see the Oracle Application Server Web Services Security Guide. -->
      </security>
      <reliability>
        <!-- Port-level Reliability configuration. See "Port Level Reliability Elements on the Client" on page 5-13 for a description of reliability configuration elements. -->
      </reliability>
    </runtime>
    <operations>
      <operation name="">
        <runtime>
          <security>
            <!-- Operation-level Security configuration. For more information on security configuration elements, see the Oracle Application Server Web Services Security Guide. -->
          </security>
          <!-- Operation level auditing configuration. See "How to Configure Auditing in a J2EE Client" on page 6-4 for a description of auditing configuration elements. -->
        </runtime>
      </operation>
    </operations>
  </webservice-client>
</oracle-webservice-clients>
```
Table 9–4 describes the subelements for the <port-info> element. This element provides all of the information for a port within a service reference. You can specify either a service-endpoint-interface or wsdl-port to indicate the port that the container will use for container-managed port selection. If you specify both, then the container will use the wsdl-port value. If you do not specify wsdl-port or service-endpoint-interface, then the <port-info> property values will apply to all available ports.

The <port-info> element also contains subelements that let you specify quality of service features that are available for the port and its operations.

Table 9–5 describes the subelements for the <port-info> element. This element provides all of the information for a port within a service reference. You can specify either a service-endpoint-interface or wsdl-port to indicate the port that the container will use for container-managed port selection. If you specify both, then the container will use the wsdl-port value. If you do not specify wsdl-port or service-endpoint-interface, then the <port-info> property values will apply to all available ports.

The <port-info> element also contains subelements that let you specify quality of service features that are available for the port and its operations.

Table 9–4 Subelements of the <port-info> Element

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;call-property&gt;</td>
<td>Defines the call property values applicable to the port defined by the &lt;port-info&gt; element. The name and value sub-elements of &lt;call-property&gt; are described in Table 9–5.</td>
</tr>
<tr>
<td>&lt;operations&gt;</td>
<td>Contains a sequence of elements, one for each operation. The &lt;operation&gt; subelement indicates an individual operation. Each of these subelements contain client-side quality of service configuration for a single operation provided by the referenced Web service. The &lt;operations&gt; element is a subelement of the &lt;port-info&gt; element. For a description of &lt;operations&gt;, and its subelements, see “Adding OC4J-Specific Platform Information” in the Oracle Application Server Web Services Developer’s Guide.</td>
</tr>
<tr>
<td>&lt;runtime&gt;</td>
<td>Contains client-side quality of service runtime information (security and/or reliability) applicable to all the operations provided by the referenced Web service. Each child element contains configuration for a specific feature.</td>
</tr>
<tr>
<td>&lt;service-endpoint-interface&gt;</td>
<td>Specifies the fully-qualified path to the service endpoint interface of a WSDL port. The container uses this port for container-managed port selection.</td>
</tr>
<tr>
<td>&lt;stub-property&gt;</td>
<td>Defines the stub property values applicable to the port defined by the &lt;port-info&gt; element. The name and value subelements of &lt;stub-property&gt; are described in Table 9–5.</td>

<td>Specifies the namespaceURI and localpart of a port in the WSDL that the container will use for container-managed port selection.</td>
</tr>
</tbody>
</table>

Table 9–5 describes the name and value subelements of the <stub-property> and <call-property> elements.
How DII Clients of WSIF Services Can Get Message Headers

DII clients in WSIF can use methods in `oracle.webservices.OracleCall`, `oracle.oc4j.wsif.providers.jaxrpc.WSIFPort_JaxRpc`, and the public WSIF WSIFOperation API to retrieve HTTP request and response headers.

To retrieve response headers, use the `WSIFOperation.executeRequestResponseOperation` method to make the call to the service and the `WSIFPort_JaxRpc.getCall` method to retrieve the `OracleCall` object. The `OracleCall.getResponseHeaders` method returns a `Vector` which contains the SOAP response headers.

To retrieve request headers use the `OracleCall.getHeaders` method. This method also returns a `Vector` where the elements are the SOAP response headers. Typically, the headers are added to the `Vector` with the `OracleCall.addHeaders` method.

Example 9–24 illustrates DII client code for getting the response headers.

```
...  
operation.executeRequestResponseOperation(input, output, fault);
OracleCall call = (OracleCall) ((WSIFPort_JaxRpc) port).getCall();
Vector headers = call.getResponseHeaders();
if (Vector != null) {
    for(int i = 0;i < headers.size();i++) {  
        Element header = (Element) headers.get(i);
        // do something with the header Element
        ...
    }
}...
```

How to Add Message Attachments in WSIF

You can enable WSIF clients to pass message attachments. By default, WSIF supports passing attachments in a MIME-format message. The attachment itself is an object of type `javax.activation.DataHandler`. The `mime:multipartRelated`, `mime:part` and `mime:content` tags are used to describe the attachment in the WSDL.

- Steps to Add Attachments in the WSIF Client with the WSIF API
- How to Add Attachments in a WSIF Client with the OracleCall API
- How to Retrieve Streamed Response Attachments in a WSIF Client
- How to Add DIME-Packaged Attachments in a WSIF Client
Steps to Add Attachments in the WSIF Client with the WSIF API

To enable a WSIF client to add an attachment to a message, follow these general steps:

1. Create a `DataHandler` object to encapsulate the attachment.
2. Use the WSIF API's `WSIFOperation.createInputMessage` method to create an input message on the desired operation.
3. Use the WSIF API's `WSIFMessage.setObjectPart` method to add the attachment to the message.

Example 9–25 illustrates how an attachment can be added to a message by using the WSIF API. In the code fragment, the `JohnDoe.jpg` attachment is saved as a `DataHandler` object. The `operationName` represents the operation that will be enabled to handle messages with attachments. The `WSIFOperation`'s `createInputMessage` method creates an input message on the operation. The `WSIFMessage`'s `setObjectPart` method attaches the attachment to the input message with the part name `myAttachment`.

```
Example 9–25 Adding an Attachment to a Message with the WSIF API
...
DataHandler dataHandler1 = new DataHandler(new URL("file:JohnDoe.jpg"));
WSIFOperation operation = port.createOperation(operationName);
WSIFMessage input = operation.createInputMessage();
input.setObjectPart("myAttachment", dataHandler1);
...
```

How to Add Attachments in a WSIF Client with the OracleCall API

The `oracle.webservices.OracleCall` API enables you to add attachments to messages that will be handled by WSIF clients. Using this technique, you save the attachment as a `DataHandler` object. You then add the attachment to the DII call object that you obtain from the WSIF port.

```
Example 9–26 Adding an Attachment to a Message with the WSIF API
...
DataHandler dataHandler1 = new DataHandler(new URL("file:JohnDoe.jpg"));
OracleCall call = (OracleCall) ((WSIFPort_JaxRpc) port).getCall();
call.addAttachment(dataHandler1, "BASE64", "<ID1@photo>");
...
```

How to Retrieve Streamed Response Attachments in a WSIF Client

A WSIF client can use methods from the `OracleCall` and `Attachments` APIs to retrieve streaming attachments from the service.
Example 9–27 illustrates sample WSIF client code to retrieve streamed response attachments from the server. In the sample, the getCall method gets the DII call from the WSIF port. This call must be cast to a SOAP port, then to an OracleCall object. The executeRequestResponseOperation method makes the call to the service. The OracleCall.getStreamedResponseAttachments method gets the streamed attachments from the OracleCall object. The getIncomingAttachments method captures the incoming streaming attachment as an Attachment object. The while loop iterates through the incomingAttachments IncomingAttachments objects. The getDataHandler method gets the data handler from the Attachment object, and the attachment is retrieved as an input stream (getInputStream).

Example 9–27  WSIF Client Code to Retrieve a Streamed Response

```java
OracleCall call = (OracleCall) ((WSIFPort_JaxRpc) port).getCall();
operation.executeRequestResponseOperation(input, output, fault);
Attachments atts = call.getStreamedResponseAttachments();
IncomingAttachments incomingAtts = atts.getIncomingAttachments();
while (incomingAtts.hasNextAttachment()) {
    Attachment att = incomingAtts.nextAttachment();
    InputStream is = att.getDataHandler().getInputStream();
    // read from InputStream is until no byte to read
    ...
}
```

How to Add DIME-Packaged Attachments in a WSIF Client

By default, attachments to messages sent by DII and WSIF API clients are packaged in MIME format. To send a message attachment packaged in DIME format, set the boolean property WSIFConstants.DIME_PACKAGING to true within the WSIF message context. This property can be set on the context with the setBooleanPart method.

If the property is set to false (default) or is not used, then the WSIF message attachment will be packaged in MIME format.

Example 9–28 illustrates the use of the DIME_PACKAGING property. In the example, a new context object of type WSIFMessage is created and the DIME_PACKAGING property is applied to it. The context is then applied to the operation. Any attachments added to the message will be added in DIME format. The operation object used in the example is an instance of WSIFOperation.

Example 9–28  Adding a DIME Attachment in a WSIF Client

```java
...
WSIFMessage context = new WSIFDefaultMessage();
context.setBooleanPart(WSIFConstants.DIME_PACKAGING, true);
operation.setContext(context);
...
```

Tool Support for WSIF

The Java J2EE Web Service wizard for Java classes in Oracle JDeveloper enables you to create WSIF bindings in addition to SOAP bindings for a Web service. Enter values for
the class loader and class path that let the WSIF clients locate the service implementation class. These values are comparable to the className and classPath parameters on the command line or Ant task.

The Web Service wizard for EJBs enables you to specify the initial context factory, JNDI provider URL, and JNDI name so that WSIF clients can locate the EJB through JNDI. These values are comparable to the initialContextFactory, jndiProviderUrl, and jndiName parameters on the command line or Ant task.

The Database Web Service wizard enables you to specify the user, connection, and datasource information necessary for defining WSIF bindings for a PL/SQL procedure.

Limitations
See "Using the Web Service Invocation Framework" on page I-16.

Additional Information
For more information on:
- using message attachments, see Chapter 2, "Working with Message Attachments"
- adding management configurations to a Web service, see Chapter 3, "Managing Web Services"
- adding security information to a Web service, see Chapter 4, "Ensuring Web Services Security" and the Oracle Application Server Web Services Security Guide.
- adding reliability information to a Web service, see Chapter 5, "Ensuring Web Service Reliability".
- the contents of the wsmgmt.xml file which contains the security configuration, see Appendix A, "Understanding the Web Services Management Schema".
- assembling a Web service top down, see "Assembling a Web Service from a WSDL" in the Oracle Application Server Web Services Developer’s Guide.
- using Java classes to assemble a Web service, see "Assembling a Web Service with Java Classes" in the Oracle Application Server Web Services Developer’s Guide.
- using EJBs to assemble a Web service, see "Assembling a Web Service with EJBs" in the Oracle Application Server Web Services Developer’s Guide.
- using JMS topics and destinations to assemble a Web service, see "Assembling Web Services with JMS Destinations" in the Oracle Application Server Web Services Developer’s Guide.
- using database resources, such as PL/SQL packages, SQL queries, DML statements, Oracle Streams AQ, or server-side Java classes, to assemble a Web service, see "Assembling Database Web Services" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2EE Web Service client, see "Assembling a J2EE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2SE Web service client, see "Assembling a J2SE Web Service Client" in the Oracle Application Server Web Services Developer’s Guide.
- using WebServicesAssembler commands to assemble Web service artifacts, see "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer’s Guide.
This chapter describes how to use the Oracle Application Server Web Services Provider API. The Provider API lets you define custom processing logic for a Web services endpoint that is not tied to any particular service endpoint implementation strategy, such as JAX-RPC. The Provider model can be used to provide common functionality to a number of endpoints. Rather than incorporating the same functions into many Web services, the Provider model enables you to add the logic into the runtime directly.

**What is a Provider?**

A Provider lets you bypass the JAX-RPC tie-based framework and enables you the flexibility of choosing your own mechanism for traversing and interpreting the message payload. Since it runs in the OC4J container, a Provider can take advantage of the container’s services such as schema validation, security, and reliability.

**When to Use a Provider**

You can choose to employ a Provider as your endpoint implementation if you find that your performance is lacking when using a standard JAX-RPC endpoint implementation. Because a Provider does not use the JAX-RPC framework, marshalling and unmarshalling of data is not performed. Therefore, based on your message traversal and interpretation mechanism, there may be less parsing and serialization effort before the message is processed.

Also, because a Provider enables you to process the SOAP message directly, you can perform much more sophisticated processing such as content-based routing. For example, inbound messages could be routed to a number of intermediate destinations (perhaps for some intermediate level of processing) before routing to a final destination.

**Understanding the Provider API**

The interfaces and classes in the oracle.webservices.provider package allow you to implement and use your own Provider to process SOAP messages.

- **Provider Interface**—your application must implement this interface to create your Provider.

- **ProviderConfig Class**—configuration class that is passed to the Provider during its initialization. This represents the information related to the Provider configuration. The Provider also uses this class to interact with the container.

- **MessageContext Class**—context class that is passed to the Provider’s processMessage method when an invocation is to be serviced by the Provider.
The Provider instance can use this class to obtain transport protocol-related information.

- **HTTPConstants Class**—provides a set of well-defined properties for the HTTP protocol that the container will set on the MessageContext.

## Provider Interface

Your Provider class must implement the `oracle.webservices.provider.Provider` interface. The following sections provide more information on the methods in the `Provider` interface that must be implemented.

- **init Method**
- **processMessage Method**
- **destroy Method**

### init Method

```java
public void init(ProviderConfig config) throws ProviderException;
```

The `init` method is called when the Provider is loaded and initialized. The method can be called only once during the lifecycle of the Provider. In response to the `init` method, the container passes an instance of `ProviderConfig` to the Provider. This instance provides configuration information related to the Provider. The `ProviderConfig` instance provides mechanisms to set and get properties and the `ServletContext`. The `init` and `destroy` methods provide the lifecycle mechanisms for the Provider much like the `ServiceLifecycle` interface provides the lifecycle mechanisms for JAX-RPC service endpoint implementation (SEI) classes.

The Provider uses the `ProviderConfig` instance to set or retrieve properties. If a property is set on the context, it will overwrite the corresponding static property set in the deployment descriptors. For example, the Provider can set the boolean `VALIDATION_SOAP_SCHEMA` property to `true` to let the container perform schema validation. Schema validation can be performed only if the WSDL is available; it cannot be performed in pass-through mode. In pass-through mode, the provider itself is not exposed as an endpoint. The default value of the `VALIDATION_SOAP_SCHEMA` property is `false`. Schema validation is based on the QName value of the child element of the SOAP Body.

If the appropriate load-on-startup directive is provided (for example, by using the `web.xml` file in the Provider application WAR file), then the `init` method will be called on application startup.

### processMessage Method

```java
public SOAPMessage processMessage(SOAPMessage request, MessageContext messageContext) throws ProviderException;
```

The `processMessage` method is the Provider's main access method: it is invoked every time a SOAP request is dispatched to the Provider instance. The `processMessage` method is where you provide the processing logic for the SOAP message. For the SOAP protocol, this method takes a `SOAPMessage` instance as an argument. From this `SOAPMessage` instance, the Provider can obtain access to other parts of the message payload, such as the SOAP body, headers, and attachments.

The `processMessage` method also takes a `MessageContext` object. The message context defines the properties that are valid for the particular message.
This method returns a SOAPMessage instance. If the instance is not null, then the Provider intends to return a response to the sender, assuming the underlying transport supports it. If the underlying transport is a one-way protocol, such as JMS, then an attempt to send a response will cause an error to be thrown in the server logs. The return must be null for pure one-way calls and must not be null for request-response calls.

**destroy Method**

```java
public void destroy() throws ProviderException;
```

The container invokes the `destroy` method to notify the Provider instance of its intent to remove the Provider from its working set. After the method is called, the Provider instance is destroyed and garbage collected.

**ProviderConfig Class**

This class contains the configuration-related information for the Provider instance. The information includes details that are also listed in the proprietary deployment descriptors.

The properties of the `ProviderConfig` are used to communicate with the container. For example, a policy object reference can be set as a `ProviderConfig` property inside `processMessage` (assuming the Provider implementation maintains a reference to the `ProviderConfig` instance as an attribute initialized during the `init` method invocation) or the `init` method of the Provider instance. The container can read this policy object and apply the appropriate management functions to the Provider instance.

The following section provides more information on the methods and properties in the `ProviderConfig` class.

**addService and removeService Methods**

These methods allow the Provider instance to dynamically provide or remove services to or from the container. The container can perform a variety of tasks on the services, such as test-page presentation, request message schema validation, and Web service management processing. The service registration process also allows the container to perform Web service management processing for the registered services.

```java
public void addService(String pathInfo, URL wsdlURL, QName wsdlPort, QName serviceName, Object policy) throws ProviderException;

public void addService(String pathInfo, InputStream wsdlStream, String wsdlBaseURI, QName wsdlPort, QName serviceName, Object policy) throws ProviderException;

public void addService(String pathInfo, Definition wsdl, QName wsdlPort, QName serviceName, Object policy) throws ProviderException;

public void removeService(String pathInfo);
```

The `addService` and `removeService` methods of the `ProviderConfig` class can be invoked in the Provider's `init` and `processMessage` methods to dynamically add and remove manageable service endpoints, each with a unique URI. Internally, the container maintains a repository of WSDLs and a map of the WSDLs with the URIs of the incoming requests. In addition, these dynamic endpoints can be managed by using the Application Server Control tool, allowing you to apply security, reliability,
auditing, and logging features. The Provider can make processing decisions for incoming requests based on the URI available from the Provider's MessageContext.

The addService and removeService methods both take a pathInfo parameter. This parameter contains the extra path information associated with the URL sent by the client when it invokes the endpoint. The extra path information follows the servlet path format, however, it precedes the query string and starts with a forward slash (/) character. While the pathInfo parameter cannot be null, it can be set to an empty string.

Three forms of the addService method are available; they differ only in how you provide the WSDL location for the service.

- **Providing the WSDL as a URL**—This form of the addService method enables you to provide the WSDL as a URL (URL wsdlURL).

- **Reading the WSDL From an Input Stream**—This form of the method enables the WSDL to be read from an input stream (InputStream wsdlStream). This method also provides a parameter where you can specify a URI for the WSDL file (String wsdlBaseURI). The value of this parameter is used to resolve relative imports in the Provider WSDL input stream.

- **Providing the WSDL as a Definition Object**—This form of the method enables you to provide the WSDL as a javax.wsdl.Definition object. Use this signature if you are constructing endpoints dynamically and already have a Definition object instantiated. For example, you may have created the Definition object in memory and it does not represent a WSDL in the file system.

The addService method can also take a policy parameter that defines the management features for the dynamic endpoint. The policy parameter must be an org.w3c.dom.Element that is compliant with the structure listed in Example 10–1.

The definition of this element is listed as a type in the oracle-webservices-10_0.xsd schema.

**Example 10–1 Definition of Provider-Policy-Type**

```xml
<xsd:complexType name="provider-policy-type">
  <xsd:all>
    <xsd:element name="runtime" type="serverPortRuntimeType" minOccurs="0"/>
    <xsd:element name="operations" type="serverOperationsType" minOccurs="0"/>
  </xsd:all>
</xsd:complexType>
```

Example 10–2 illustrates a structure defined by this type, as it would appear in an oracle-webservices.xml deployment descriptor.

**Example 10–2 XML Structure of the Policy Element**

```xml
<policy>
  <runtime enabled="logging,auditing,security,reliability">
    <logging>...</logging>
    <security>...</security>
    <reliability>...</reliability>
  </runtime>
  <operations>
    <operation name="..." inputName="..." outputName="..."/>
    <runtime>
      <logging>...</logging>
      <auditing>...</auditing>
      <reliability>...</reliability>
    </runtime>
  </operations>
</policy>
```
PROPAGATE_DYNAMIC_ENDPOINTS Property

To support clustered environments, the ProviderConfig class provides the boolean constant PROPAGATE_DYNAMIC_ENDPOINTS. This constant represents the following property:

oracle.webservices.provider.propagateDynamicEndpoints

This property enables a Provider to make a dynamic endpoint accessible from all instances of an application across a configuration group or cluster. For more information on how to use this property, see "How to Make Dynamic Endpoints Accessible in a Clustered Environment" on page 10-11.

MessageContext Class

This class contains the definitions of the transport-agnostic message properties. These properties are updated on each call to processMessage. A standard set of constants is defined for the HTTP transport. Properties of the same name are available from the MessageContext class. The MessageContext class also contains the definitions of constants defined for non-HTTP transports.

HTTPConstants Class

This class provides a set of well-defined properties for the HTTP protocol that the container will set on the MessageContext. The Provider instance should ensure that these properties are not overwritten.

ProviderServlet Class

The ProviderServlet (oracle.j2ee.ws.server.provider.ProviderServlet) handles the routing of requests to the Provider instance. Once deployed, a ProviderServlet listens to a URL for incoming SOAP over HTTP requests. When the servlet receives a SOAP message, ProviderServlet dispatches it to the processMessage method of the Provider instance.

If you are hosting the Provider in the servlet container, then specify this servlet in the <servlet-class> subelement of <servlet> in your Provider application's web.xml deployment descriptor. The servlet URL is specified in the <url-pattern> element.

Example 10–3 illustrates a fragment of a web.xml file. In the file, ProviderServlet is specified in the <servlet-class> element and the URL to which it listens, /LoggerService, is specified in the <url-pattern> element. This URL pattern is relative to the Web application's context root.

The <servlet-name> element provides the link between this entry and the Provider-specific information in oracle-webservices.xml illustrated in Example 10–5.

Example 10–3  web.xml Fragment, with ProviderServlet and the URL to Which it Listens

```xml
...  
<servlet>
   <servlet-name>LoggerProviderPort</servlet-name>
```
Extending ProviderServlet

You can extend ProviderServlet to tailor its functionality to a particular use case. Example 10-4 illustrates how you can extend the servlet's `doGet` method to allow for the retrieval of specific resources based on the HTTP query string. Note that in this case, if the query string is not processed by the extended servlet, the request should be passed to the parent servlet's `doGet` method. Note the call to `super` if the incoming GET request is not processed.

**Example 10–4 Extension of a ProviderServlet Method with a Call to super**

```java
public class ExtendedProviderServlet extends ProviderServlet{

    protected void doGet(HttpServletRequest request, HttpServletResponse response)
        throws ServletException, IOException {
        String queryString = request.getQueryString();
        if ((queryString != null) &&
            (queryString.equalsIgnoreCase("someotherquery"))) {
            response.setContentType("text/html; charset=UTF-8");
            response.setStatus(HttpServletResponse.SC_OK);
            OutputStream outputStream = response.getOutputStream();
            OutputStreamWriter writer = new OutputStreamWriter(outputStream);
            writer.write( "<HTML><BODY>TEST RESPONSE</BODY></HTML>" );
            writer.close();
        } else {
            super.doGet(request, response);
        }
    }
}
```

You can also extend ProviderServlet to use your own test-page generation mechanism instead of using the default test page provided by the servlet.

How to Make a Web Service Provider-Aware

For the Web service to recognize a Provider, you must edit the `oracle-webservices.xml` and `web.xml` deployment descriptors to add information about your Provider. The Oracle JDeveloper and Application Server Control tools do not provide support for adding this information; you must edit the files by hand.

- How to Edit the `oracle-webservices.xml` Deployment Descriptor
- How to Edit the `web.xml` Deployment Descriptor
How to Edit the oracle-webservices.xml Deployment Descriptor

To make the Web service Provider-aware, add the `<provider-description>` clause to the oracle-webservices.xml deployment descriptor. Example 10–5 illustrates a fragment of an oracle-webservices.xml deployment descriptor with this clause. "Provider Elements in oracle-webservices.xml" describes the elements that can appear in the `<provider-description>` clause.

Example 10–5  oracle-webservices.xml Fragment, with a `<provider-description>` Clause

```xml
<oracle-webservices>
  <provider-description>
    <provider-description-name> some name</provider-description-name>
    <wsdl-file>/file location</wsdl-file>
    <wsdl-service-name xmlns:ns_="urn:oracle-ws">ns_:PhotoService</wsdl-service-name>
    <provider-port>
      <provider-name>LoggerProviderPort</provider-name>
      <wsdl-port xmlns:ns_="urn:oracle-ws">ns_:PhotoIFPort</wsdl-port>
      <implementation-class>oracle.myprovider.JmsRetriever</implementation-class>
      <servlet-link>LoggerProviderPort</servlet-link>
      <property name="connection-factory-name">jms/ws/mdb/theQueueConnectionFactory</property>
      <property name="queue-name">jms/ws/mdb/theQueue</property>
      <policy>
        <runtime enabled="logging,auditing,security,reliability">
          <logging>...</logging>
          <security>...</security>
          <reliability>...</reliability>
        </runtime>
        <operations>
          <operation name="..." inputName="..." outputName="...">
            <runtime>
              <logging>...</logging>
              <auditing>...</auditing>
              <reliability>...</reliability>
            </runtime>
          </operation>
        </operations>
      </policy>
    </provider-port>
  </provider-description>
</oracle-webservices>
```

Provider Elements in oracle-webservices.xml

The top-level Provider element is `<provider-description>`. This element identifies a collection of Provider ports. Table 10–1 describes the subelements of `<provider-description>`. The `<provider-port>` subelement is required; all others are optional.

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;property&gt;</code></td>
<td>Specifies globally-defined properties; that is, properties that are available to all of the defined Provider ports. This element recognizes a name attribute.</td>
</tr>
<tr>
<td><code>&lt;provider-description-name&gt;</code></td>
<td>A name for the Provider description.</td>
</tr>
</tbody>
</table>
The `<provider-port>` element associates a WSDL port with a Web service interface and implementation. It defines the name of the port as a component. It also associates the port with a servlet endpoint. If a `wsdl-file` is not present, the `provider-port` defines a pass-through gateway. For information on the subelements of `<provider-port>`, see Table 10–2.

The `<wsdl-file>` specifies the location of an associated WSDL for the Provider.

The `<wsdl-service-name>` associates the WSDL's service name with the name of a Provider. This element should be provided if a WSDL has more than one service. This element is not required if the WSDL has only one service.

### Table 10–2 Subelements of the `<provider-port>` Element

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;expose-testpage&gt;</code></td>
<td>Indicates whether the test page should be exposed. Default is true.</td>
</tr>
<tr>
<td><code>&lt;expose-wsdl&gt;</code></td>
<td>Indicates whether the WSDL should be exposed. Default is true.</td>
</tr>
<tr>
<td><code>&lt;implementation-class&gt;</code></td>
<td>(required) Specifies the name of the class implementing the <code>oracle.webservices.provider.Provider</code> interface.</td>
</tr>
<tr>
<td><code>&lt;max-request-size&gt;</code></td>
<td>When a positive value is specified, the service will limit the size of requests to that value (in bytes). Any request that exceeds the maximum length will generate an error. Default is -1, which indicates no limit.</td>
</tr>
<tr>
<td><code>&lt;policy&gt;</code></td>
<td>Defines the Web service management policies for the Provider. Table 10–3 describes the subelements of <code>&lt;policy&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;property&gt;</code></td>
<td>A locally defined property. If a property with a particular name is defined both locally and globally, then the property defined locally overrides the one defined globally.</td>
</tr>
<tr>
<td><code>&lt;provider-name&gt;</code></td>
<td>(required) The name of the Provider. The <code>&lt;provider-name&gt;</code> within the <code>&lt;provider-port&gt;</code> must be unique within the deployment descriptor.</td>
</tr>
<tr>
<td><code>&lt;servlet-link&gt;</code></td>
<td>(required) Associates a <code>provider-port</code> value with a servlet endpoint defined in the <code>/WEB-INF/web.xml</code> file.</td>
</tr>
<tr>
<td><code>&lt;wsdl-port&gt;</code></td>
<td>Associates the Provider with a particular port of the WSDL defined by the <code>wsdl-file</code> element. This element is not required if no WSDL file is defined.</td>
</tr>
</tbody>
</table>

The `<policy>` element defines the Web service management policies for the Provider. Example 10–2 illustrates the structure of the element as it would appear in an `oracle-webservices.xml` deployment descriptor. Table 10–3 describes the subelements of the `<policy>` element.
**Table 10–3 Subelements of the <policy> Element**

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;operations&gt;</td>
<td>Contains a sequence of elements, one for each operation. The &lt;operation&gt; subelement describes the management policies applied to an individual operation. Table 10–4 describes the &lt;operation&gt; subelement.</td>
</tr>
<tr>
<td>&lt;runtime&gt;</td>
<td>Contains server-side quality of service runtime information (security, reliability, auditing, and logging) applicable to all the operations provided by the referenced Web service. Each child element contains configuration for a specific feature.</td>
</tr>
</tbody>
</table>

Table 10–4 describes the <operation> element, where you can define management policies for specific Provider operations.

**Table 10–4 Subelement of the <operations> Element**

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| <operation>  | Specifies client-side quality of service configuration for a particular operation provided by the referenced Web service. The configuration appears within this element's <runtime> subelement. This <operation> element has these attributes:  
  ■ input—contains the input name of the operation from the WSDL.  
  ■ name—(required) associates the contained quality of service configuration to a specific operation. The value of the attribute must match the operation name from the WSDL.  
  ■ output—contains the output name of the operation from the WSDL. |

## How to Edit the web.xml Deployment Descriptor

To make the Web service Provider-aware, add the <servlet-class> element to the <servlet> clause and the <url-pattern> element to the <servlet-mapping> clause. Example 10–6 illustrates a web.xml deployment descriptor with these elements. They are described in Table 10–5.

**Example 10–6 Provider Elements in the web.xml Deployment Descriptor**

```xml
<web-app>
  <display-name/>
  <description/>
  <servlet>
    <servlet-name>LoggerProviderPort</servlet-name>
    <display-name>LoggerProviderPort</display-name>
    <description>JAX-RPC endpoint Provider Port</description>
  </servlet>
</web-app>
```
Provider Elements in web.xml
Table 10–5 describes the elements which you must add to web.xml to make it Provider-aware.

<table>
<thead>
<tr>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;servlet-class&gt;</td>
<td>Specifies the name of the Provider servlet. The value can be either oracle.j2ee.ws.server.provider.ProviderServlet or a subclass as described in &quot;Extending ProviderServlet&quot; on page 10-6.</td>
</tr>
<tr>
<td>&lt;url-pattern&gt;</td>
<td>Specifies the URL pattern to use for the Web service. The Provider servlet will listen to URLs whose prefix is specified by this element. The URL pattern should be relative to the Provider servlet context for the Web module. For dynamic pass through mode, the &lt;url-pattern&gt; should be &quot;/*&quot;.</td>
</tr>
</tbody>
</table>

Registering a Provider-Managed Endpoint
The following sections describe how to register a Provider-managed endpoint for your Web service.

- How to Register a Static Provider-Managed Endpoint
- How to Register a Dynamic Provider-Managed Endpoint
- How to Make Dynamic Endpoints Accessible in a Clustered Environment

How to Register a Static Provider-Managed Endpoint
The following steps provide a general outline of how to register a static Provider-managed endpoint for your Web service. Follow the links for more detailed information on each step.

1. Write your Provider application so that it implements the Provider interface.
   The Provider methods init, processMessage, and destroy must be implemented. See "Provider Interface" on page 10-2 for more information on this interface and its methods.

2. Edit the oracle-webservices.xml and web.xml deployment descriptors.
   "How to Make a Web Service Provider-Aware" on page 10-6 provides more information on editing these descriptors.

3. (optional) Provide a management configuration.
   The configuration is specified as a policy clause in the oracle-webservices.xml deployment descriptor. Example 10–2 provides an example of the policy clause structure in the deployment descriptor.

4. Package the service.
"How to Package Provider Web Application Provider Classes" on page 10-12 provides more information on packaging a service which includes Provider classes.

How to Register a Dynamic Provider-Managed Endpoint

You can use the ProviderConfig.addService method to register additional Provider-managed endpoints and configure management features for them. For example, a Business Process Execution Language (BPEL) process manager might use this mechanism to register its processes.

The generation, packaging, and deployment of a dynamic Provider-managed endpoint follows the same steps outlined in "How to Register a Static Provider-Managed Endpoint". To register the endpoint, you must perform the following additional step:

- Register the service by invoking the addService method on the providerConfig reference. The implementation also has the option of passing the policy configuration by using the method's policy parameter.

Example 10–7 illustrates how a Provider can dynamically add an endpoint. In this example, the ADD_SERVICE_POLICY property declares the Web service management features for the dynamically-added endpoint (in this case, security auditing and reliability).

The addService invocation is made on the providerConfig reference (config) passed to the init method of the Provider. The policy parameter of the addService method uses the XMLUtil.elementFromString(ADD_SERVICE_POLICY) to pass the management features to the service. Note the WSDL is packaged as part of the WAR file and retrieved as a resource using the servletContext.

Example 10–7 Dynamically Registering a Provider-Managed Endpoint

```
private static final String ADD_SERVICE_POLICY = "<policy>
   <runtime enabled="security,auditing,reliability">
      <security>
         <inbound/>
      </security>
   </runtime>
</policy>";
```

```
public void init(ProviderConfig config) throws ProviderException {

   URL wsdlURL1 = ((ServletContext)config.getContainerContext()).
      getResource("/WEB-INF/wsdl/HelloService.wsdl");

   config.addService("/loanservice", wsdlURL1, new QName("http://hello.demo.
      oracle/","HttpSoap11"),null, XMLUtil.elementFromString( ADD_SERVICE_POLICY ));
}
```

How to Make Dynamic Endpoints Accessible in a Clustered Environment

To support clustered environments, the ProviderConfig class provides the boolean constant PROPAGATE_DYNAMIC_ENDPOINTS. This constant represents the following property:
oracle.webservices.provider.propagateDynamicEndpoints

This property enables you to make a dynamic endpoint accessible from all instances of an application across a configuration group or cluster.

If the property is set to true, then any addService invocation made after the dynamic endpoint is initialized at one OC4J instance causes the endpoint to be accessible to all instances of the application across the cluster or configuration group.

PROPAGATE_DYNAMIC_ENDPOINTS is an optional property that can be set as a <property> subelement of <provider-port> in the oracle-webservices.xml deployment descriptor. Example 10–8 illustrates how the property is used.

**Example 10–8  PROPAGATE_DYNAMIC_ENDPOINTS Property**

```
<oracle-webservices>
  <provider-description>
    ...
    <provider-port>
      ...
      <property name="oracle.webservices.provider.propagateDynamicEndpoints">true</property>
      ...
    </provider-port>
  </provider-description>
</oracle-webservices>
```

**How to Package Provider Web Application Provider Classes**

Provider Web applications are packaged like any standard Web application. If the Provider application has a WSDL file, store it in the /WEB-INF/wsdl directory in the WAR file. Store the Provider classes in the /classes directory which is a child of /WEB-INF. Example 10–9 illustrates the contents of an EAR file for a Provider Web application.

**Example 10–9  Package Structure for a Web Service with a Provider Application**

```
provider.ear
  __/META-INF/application.xml
  __ provider-web.war
    __/WEB-INF
      __web.xml
      __oracle-webservices.xml
      __/wsdl/<wsdl_name>.wsdl (optional)
      __/lib
      __/classes
```

**Deploying Provider Web Applications**

A Provider Web application is deployed (using standard deployment mechanisms) in a J2EE servlet container. The container must have the Provider system classes and the supporting classes available in its runtime.

**See Also:**

*Oracle Containers for J2EE Deployment Guide* for more information on deploying Provider Web applications.
Testing Provider Web Application Deployment

The endpoints of a Provider Web application can be exposed by using a statically configured endpoint or by adding one dynamically. If the endpoint provides an associated WSDL file, then you can invoke the Web Service Test Page to see whether deployment was successful. If the endpoint does not provide a WSDL file, a Test Page will not be available.

See Also:

Managing Provider Endpoints

If a static or a dynamically-added Provider endpoint provides an associated WSDL file, then it can be configured through the Web Services interface in Application Server Control. For more information see the topic ”Web Service Home Page” in the Application Server Control on-line help.

Assembling Clients for Provider Web Service Applications

A Provider Web Service application can be accessed by standard J2SE or J2EE static stub or DII clients.

See Also:

The following chapters provide more information on assembling Web service clients:

- "Assembling a J2EE Web Service Client” in the Oracle Application Server Web Services Developer’s Guide for information on assembling J2EE Web Service clients.

Troubleshooting

See "Using Web Service Providers” on page I-17.

Additional Information

For more information on:

- assembling a J2EE Web Service client, see "Assembling a J2EE Web Service Client” in the Oracle Application Server Web Services Developer’s Guide.
- assembling a J2SE Web service client, see "Assembling a J2SE Web Service Client” in the Oracle Application Server Web Services Developer’s Guide.
- testing whether the Provider Web service application deployed successfully, see "Testing Web Service Deployment” in the Oracle Application Server Web Services Developer’s Guide.
- using WebServicesAssembler commands to assemble Web service artifacts, see "Using WebServicesAssembler" in the Oracle Application Server Web Services Developer's Guide.
Understanding the Web Services Management Schema

The Web services management policy file, wsmgmt.xml, defines the security, reliability, logging, and auditing features that can be assigned to a Web service. On deployment, the contents of the oracle-webservices.xml deployment descriptor which relate to management, are extracted from the file and inserted to wsmgmt.xml.

The wsmgmt.xml file resides in the ORACLE_HOME\j2ee\OC4J_instance_name\config\directory.

Management features have scope: they can be assigned globally, to a port, and to an operation within a port.

This appendix has these sections.

- Levels of Web Service Management
- wsmgmt.xml Listing

Levels of Web Service Management

The schema for the wsmgmt.xml management policy file allows Web service management features to be set at these levels:

- Global Level
- Port Level
- Operation Level

The tags and elements described in the following sections are used in the Web service management schema.

See Also:

Example A-3, "Sample wsmgmt.xml File" on page A-4 for a listing of wsmgmt.xml, the XML version of the schema.

Global Level

The management features that are globally applied to a Web service appear between <runtime> elements at the top of wsmgmt.xml. If a feature is enabled, it will be
Levels of Web Service Management

applied at runtime. Only security features can be applied globally to all Web services. The security features are delimited by <security> elements.

See Also:

The XML fragment in Example A–1 illustrates the global elements of the wsmgmt.xml file, simplified for clarity. The ellipses indicate additional security elements.

Example A–1  Global Elements of the wsmgmt.xml File

```
<wsmgmt>
  <runtime>
    <security>
      ...
    </security>
  </runtime>
</wsmgmt>
```

Port Level

The management features that can be configured for a port are delimited by <port> elements. Each Web service can have a number of ports defined in the Web service management schema. A port is synonymous with a Java interface. For each port, security, reliability, and logging features can be set.

The security features that appear in the global level are repeated in the port level. Security features set at the port level override security features set at the global level.

The XML fragment in Example A–2 illustrates the port elements of the wsmgmt.xml file, simplified for clarity. The ellipses indicate additional elements.

Example A–2  Port Level Elements in the wsmgmt.xml File

```
<wsmgmt>
  ...
  <port app="my-ear" web="my-war" service="my-service" port="my-service-port">
    <runtime enabled="security">
      <security>
        ...
      </security>
      <reliability>
        ...
      </reliability>
      <logging>
        ...
      </logging>
    </runtime>
  </port>
  ...
</wsmgmt>
```

Table A–1 describes the settings for a port.

Table A–1  Attributes for the Port Element

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>app</td>
<td>Maps to the application name in server.xml.</td>
</tr>
</tbody>
</table>
The port component also has a <runtime> section where the port-level security, reliability, and logging features can be enabled or disabled. If a feature is enabled, it will be applied at runtime. This is done by including the name of the configuration element in the enabled attribute of the <port> element. The configuration of each feature (such as security or logging) can still be present even if it is disabled by virtue of not being present in the enabled attribute. The values of the enabled attribute are delimited by commas. The order of the features on the enabled attribute is currently ignored.

See Also:
- "Server-Side Reliability Configuration Elements" on page 5-9 for a description of the elements that appear in the <reliability> element.
- "Server-Side Tracing Configuration Elements" on page 6-8 for a description of the elements that appear in the <logging> element.

**Operation Level**

Each port can have multiple operations associated with it. In the <port> element, the <operations> element indicates the start of the list of operations belonging to a particular port. The <operation> element indicates the start of an individual operation.

Table A–2 describes the element for an operation.

<table>
<thead>
<tr>
<th>Table A–2 General Setting for Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element Name</strong></td>
</tr>
<tr>
<td>&lt;operation&gt;</td>
</tr>
</tbody>
</table>

For each operation, the wsmgmt.xml management policy file defines the available security, reliability, logging, and auditing.

The security, reliability, and logging features that are listed in the port level are repeated at the operation level. A security feature set at the operation level overrides the setting made at the port and global level. A reliability or logging feature set at the operation level, in contrast will be referenced by the corresponding feature set at the port level.
Example A–3 contains a skeleton listing of the server-side Web services management file \texttt{wsmgmt.xml}. See the cross references for the listings and description of the elements in the security, reliability, and logging components.

**Example A–3 Sample \texttt{wsmgmt.xml} File**

```xml

This appendix describes the oracle-webservices-client.xml file. This configuration file can be used to pass Oracle specific deployment and run-time information to a Web service client. It works in conjunction with the Oracle proprietary deployment descriptors orion-web.xml, orion-application-client.xml, and orion-ejb-jar.xml.

The configuration elements in this file are defined by the oracle-webservices-client-10_0.xsd schema file. This file can be found in the oc4j-schemas.jar file. 

OC4J_HOME\j2ee\home\lib\oc4j-schemas.jar

OC4J_HOME represents the directory where you installed Oracle Containers for J2EE (OC4J).

The information in a oracle-webservices-client.xml file can be assembled into a Web service client by the ddFileName argument to the WebServicesAssembler genInterface or genProxy command. For more information on using the oracle-webservices-client-10_0.xsd schema file in specifying a management configuration for clients, see Chapter 3, "Managing Web Services".

Hierarchy of XML Elements in oracle-webservices-client

The following conceptual code fragment illustrates the hierarchy of elements defined by the oracle-webservices-client.xsd schema file.

<oracle-webservice-clients>
  <webservice-client>
    <service-qname>
    <port-info>
    <type-mappings>

You can enter a client Web services management (security, reliability, and auditing) configuration here

You can define a custom serializer to map between WSDL types and custom Java types here

Elements and Attributes of oracle-webservices-client

This section is an alphabetical dictionary of the elements defined by the oracle-webservices.client-10_0.xsd schema file. See the preceding section, "Hierarchy of XML Elements in oracle-webservices-client" if you are interested in the hierarchy.
<oracle-webservice-clients>

Parent element: root element for a configuration that passes Oracle-specific information to a Web services client

Child element: <webservice-client>

Required? Optional

This element can be used to specify an Oracle-specific configuration for Web service clients.

<port-info>

Parent element: <webservice-client>

Child elements: Can have <wsdl-port>, <service-endpoint-interface>, <stub-property>, <call-property>, <runtime>, <operations> subelements

Required? Optional

This element corresponds to a port in the WSDL; the <wsdl-port> subelement provides the mapping. You can use this element to pass port-specific information to a Web service client.

For examples of using a <port-info> element to pass a management configuration to a client, see "How to Pass a Management Configuration to a Client Programmatically" on page 3-10.

This element is of type port-infoType which is defined in the service-ref-mapping-10_0.xsd schema. This file can be found in the oc4j-schemas.jar file.

<service-qname>

Parent element: <webservice-client>

Child element: None

Required? Optional

The value of this element maps the <webservice-client> configuration to a service in the WSDL definition.

The <service-qname> is a fully-qualified-nameType which consists of a namespaceURI and a localpart. The fully-qualified-nameType is defined in the service-ref-mapping-10_0.xsd. This file can be found in the oc4j-schemas.jar file.

<type-mappings>

Parent element: <webservice-client>

Child element: Can have one or more <type-mapping> subelements if there is a custom type mapping between a custom Java class and an XML type
Required?  Optional

This element can be used to specify sequence of zero or more `<type-mapping>` elements, each of which describes a non-default Java-to-XML type mapping for the web service client. For example:

```xml
<oracle-webservice-clients>
  <webservice-client>
    ... 
    <type-mappings>
      <type-mapping java-class="oracle.demo.custom_type.MyDate"
                    xml-type="xsd:dateTime">
        <serializer class="oracle.demo.custom_type.MyDateSerializer"/>
      </type-mapping>
    </type-mappings>
    ... 
  </webservice-client>
</oracle-webservice-clients>
```

The `<type-mappings>` element is of type `type-mappingsType`, which consists of a Java to XML type mapping and a custom serializer. The `type-mappingsType` is defined in the `oracle-webservices-types-10_0.xsd` file. This file can be found in the `oc4j-schemas.jar` file.

`<webservice-client>`

**Parent element:**  `<oracle-webservice-clients>`

**Child element:**  `<port-info>, <service-qname>, <type-mappings>`

**Required?**  Optional

This element can be used to set an Oracle specific configuration for a Web service client.
This appendix describes the Oracle Application Server Web Services reliability configuration elements defined by the reliability schema `oracle-webservices-reliability-10_0.xsd`. The schema can be found in the `oc4j-schemas.jar` file.

`OC4J_HOME\j2ee\home\lib\oc4j-schemas.jar`

`OC4J_HOME` represents the directory where you installed Oracle Containers for J2EE (OC4J).

The reliability elements are typically used as part of a larger Web services management configuration. To enable reliable messaging, you have to configure it into the Web service on the server side and into the client. The configuration is part of an XML configuration file that is passed to the Web service or client when it is assembled.

- For the server, the configuration is stored in the `oracle-webservices.xml` deployment descriptor file. This file is based on the `oracle-webservices-10_0.xsd` schema.
- For the client, the configuration is stored in the `<generated_name>_Stub.xml` deployment descriptor file. This file is based on the `oracle-webservices-client-10_0.xsd` schema.

If there are certain reliability properties marked as "required" (such as duplicate elimination or guaranteed delivery) on the server-side, then the client must also specify these properties.

Reliability elements can be set at the port level and at the operation level.

For more information about assembling reliability into a Web service and client, see Chapter 5, "Ensuring Web Service Reliability".

### Hierarchy of a Reliability Configuration

Here is an overview of the element hierarchy for reliability elements defined in the `oracle-webservices-reliability-10_0.xsd` schema file for reliability. Different elements can appear on the port and the operation level.

---

**Note:** The `oracle-webservices-reliability-10_0.xsd` schema file defines the reliability elements as a sequence. In any reliability configuration, they must appear in order.

---

**Server-Side Port-Level Hierarchy:**

`<reliability>`
Element and Attribute Descriptions for the Reliability Schema

This section is an alphabetical dictionary of the reliability elements that can be specified as part of a Web service management configuration. Reliability elements can be configured for the server and the client at the port level and the operation level. See the preceding section, “Hierarchy of a Reliability Configuration” if you are interested in the hierarchy.

<ack-interval>

**Parent element:**  &lt;reliability&gt;  

**Child element:** None  

**Required?** Optional  

**Server or Client?** Server  

**Port or Operation?** Port  

Specifies the interval, in seconds, after which an attempt is made to send acknowledgments or faults for messages that were processing asynchronously. The default value is 60 seconds.
<ack-limit>

Parent element: <reliability>
Child element: None
Required? Optional
Server or Client? Server
Port or Operation? Port
The value attribute specifies a limit on the number of attempts that will be made to acknowledge a message. The default value is -1. This indicates no-limit, or an infinite number of acknowledgment attempts. A value of 0 indicates no acknowledgment attempts.

<async-poll-reply-to-url>

Parent element: <reliability>
Child element: None
Required? Optional
Server or Client? Client
Port or Operation? Port
The value attribute specifies the URL to which acknowledgments and faults will be sent if asynchronous polling is desired. The URL for this is typically the host name of the client along with the port that the listener is on.

<cleanup-interval>

Parent element: <reliability>
Child element: None
Required? Optional
Server or Client? Both
Port or Operation? Port
Server:
The value attribute specifies the interval, in seconds, after which an attempt is made to purge the store of expired or invalid messages. The default is 3600 seconds (60 minutes).

Client:
The value attribute specifies the interval, in seconds, after which an attempt is made to purge the store of expired or invalid messages. The default is 3600 seconds (60 minutes).
<duplicate-elimination>

Parent element: <reliability>
Child element: None
Required? Required
Server or Client? Client
Port or Operation? Operation
If the enabled attribute is true, duplicate elimination of the message is enabled. Default value is true.

<duplication-elimination-required>

Parent element: <reliability>
Child element: None
Required? Required
Server or Client? Server
Port or Operation? Operation
If set to true, it indicates that non-reliable clients will not be allowed to invoke this operation. Specifically messages that do not have the SOAP header for duplicate elimination will be rejected. The default is false.

<expiry>

Parent element: <reliability>
Child element: None
Required? Optional
Server or Client? Client
Port or Operation? Operation
The value attribute specifies the expiry time for a single message in a group. For example, if a message has not been acknowledged for a time duration longer than the expiration duration, then no further attempt will be made to deliver the message. The client will be notified of the failure.

If a value is set for <group-expiry-time>, it should be greater than the value of <expiry>. Default value is 3600 seconds (60 minutes).

<group-expiry-time>

Parent element: <reliability>
Element and Attribute Descriptions for the Reliability Schema

**<group-expiry-time>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Optional
- **Server or Client?** Client
- **Port or Operation?** Operation

The `value` attribute specifies the expiration time, in seconds, for all messages in the group. The value for `<group-expiry-time>` should be greater than the value set for `<expiry>`. Default value is 84600 seconds (1 day).

**<group-max-idle-time>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Optional
- **Server or Client?** Client
- **Port or Operation?** Operation

The `value` attribute specifies the maximum idle time, in seconds, for a group of messages. This element is not required to be present.

**<guaranteed-delivery>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Required
- **Server or Client?** Client
- **Port or Operation?** Operation

If the `enabled` attribute is `true`, guaranteed delivery of message is enabled. Default value is `true`.

**<guaranteed-delivery-required>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Required
- **Server or Client?** Server
- **Port or Operation?** Operation

OracleAS Web Services Reliability Schema  C-5
If set to true, it indicates that non-reliable clients will not be allowed to invoke this operation. Specifically, messages that do not have the SOAP header for guaranteed delivery will be rejected. The default is false.

**<max-age>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Optional
- **Server or Client?** Both
- **Port or Operation?** Port

**Server:**
The `value` attribute specifies the maximum time the user would want the message to be stored. The default value is 86400 seconds (1 day).

**Client:**
The `value` attribute specifies the maximum time the user would want the message to be stored. The default value is 86400 seconds (1 day).

**<order-interval>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Optional
- **Server or Client?** Server
- **Port or Operation?** Port

The `value` attribute specifies the interval, in seconds, after which the unordered messages are processed. The default is 60 seconds.

**<poll-interval>**

- **Parent element:** `<reliability>`
- **Child element:** None
- **Required?** Optional
- **Server or Client?** Client
- **Port or Operation?** Port

The `value` attribute specifies the interval, in seconds, after which a poll message will be sent to the server for reliable messages that have not yet received any acknowledgment. Default value is 60 seconds.
<reliability>

Parent element: root element for reliability configuration

Child elements:

Server, port level: <ack-interval>, <ack-limit>, <cleanup-interval>, <max-age>, <order-interval>, <repository>

Server, operation level: <duplication-elimination-required>, <guaranteed-delivery-required>

Client, port level: <async-poll-reply-to-url>, <cleanup-interval>, <max-age>, <poll-interval>, <repository>, <retry-interval>, <retry-limit>, <standalone-listener-port>

Client, operation level: <duplicate-elimination>, <expiry>, <group-expiry-time>, <group-max-idle-time>, <guaranteed-delivery>, <reply-pattern>, <reply-to-url>

Required? Required to delimit a reliability configuration

Server or Client? Both

This element delimits the start and end of a reliability configuration.

<reply-pattern>

Parent element: <reliability>

Child element: None

Required? Required

Server or Client? Client

The value attribute can be either Callback (asynchronous acknowledgment/fault), Response (synchronous acknowledgment/fault) or Polling (the acknowledgment or fault will be polled for). Default value is Polling.

To use Callback, you must configure a listener. This is not possible on a J2SE client.

The <reply-pattern> element must be set only if <guaranteed-delivery> is true. See "<guaranteed-delivery>" on page C-5.

<reply-to-url>

Parent element: <reliability>

Child element: None

Required? Optional

Server or Client? Client

The value attribute specifies the URL to which acknowledgments and faults will be sent for messages that want asynchronous acknowledgments. The URL for this is typically the host name of the client along with the port that the listener is on.
The `<reply-to-url>` element must be set only if `<guaranteed-delivery>` is true. See "<guaranteed-delivery>" on page C-5.

```xml
<repository>

**Parent element:** `<reliability>`

**Child element:** None

**Required?** Required

**Server or Client?** Both

**Server:**
Describes the kind of store that the server will use to store messages.

For a memory store (memory), `name` is a required attribute. If the store with that name has been configured for another application in the server, then that store will be used. Otherwise a new store will be configured.

For a database store (jdbc), a datasource must be configured on the server and its location specified by `jndiLocation`.

**Table C–1 `<repository>` Attributes, Server-Side**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jndiLocation</td>
<td>Values: string</td>
</tr>
<tr>
<td></td>
<td>Default: n/a (Required if type=jdbc)</td>
</tr>
<tr>
<td></td>
<td>Specifies the JNDI name of the datasource on the server. Required only if messages will be stored in the database.</td>
</tr>
<tr>
<td>name</td>
<td>Values: string</td>
</tr>
<tr>
<td></td>
<td>Default: n/a</td>
</tr>
<tr>
<td></td>
<td>A String that specifies the name of the repository.</td>
</tr>
<tr>
<td>type</td>
<td>Values: memory</td>
</tr>
<tr>
<td></td>
<td>Default: memory</td>
</tr>
<tr>
<td></td>
<td>Determines the type of store being configured. The allowed values for type are memory for a memory store and jdbc for a database store. The default is memory.</td>
</tr>
</tbody>
</table>

**Client:**
Describes the kind of store that will be used to store messages.

**Table C–2 `<repository>` Attributes, Client-Side**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connection-driver</td>
<td>Values: string</td>
</tr>
<tr>
<td></td>
<td>Default: n/a</td>
</tr>
<tr>
<td></td>
<td>the JDBC driver class name for this data source, used by some data sources that deal with java.sql.Connection. For most data sources, the driver is oracle.jdbc.driver.OracleDriver. This attribute applies only to emulated data sources for which the class attribute is com.evermind.sql.DriverManagerDataSource.</td>
</tr>
</tbody>
</table>
Table C–2 (Cont.) <repository> Attributes, Client-Side

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| jndiLocation | Values: string  
  Default: n/a  
  Specifies the JNDI name of the datasource on the server. Required only if messages will be stored in the database. |
| name       | Values: string  
  Default: n/a  
  A String that specifies the name of the repository. |
| password   | Values: string  
  Default: n/a  
  Specifies the user’s password to the repository. |
| type       | Values: memory|jdbc  
  Default: memory  
  Determines the type of store being configured. The allowed values for type are memory for a memory store and jdbc for a database store. The default type of store is a memory store.  
  If memory is specified, then name is a required attribute. If a store with the same name has been configured for another server application, then that store will be used. If it has not, then a new store will be configured.  
  If jdbc is specified, then you must provide database support on the client side. For a J2EE client, a data source must be configured and its location specified with jndiLocation. |
| url        | Values: string  
  Default: n/a  
  Specifies the URL for database connections. |
| username   | Values: string  
  Default: n/a  
  Specifies the name of the user that can access the repository. |

<retry-interval>

**Parent element:** <reliability>

**Child element:** None

**Required?** Optional

**Server or Client?** Client

The value attribute specifies the interval after which an attempt will be made to retry sending of messages that have not yet received any acknowledgment or fault. The default value is 60 seconds.

<retry-limit>

**Parent element:** <reliability>
Reliability Configuration Listing

**Value**

The value attribute specifies a limit on the number of attempts that will be made to retry a message. The default value is 10. A value of -1 indicates no-limit, or infinite retries.

---

**Note:** If the value attribute is set to 0, then the client will not attempt to re-send messages. This, in effect, negates the guaranteed delivery quality of service. As an optimization, the reliability stack does retain messages in the database if the value attribute is set to 0. No polling will be performed for these messages since no guarantee can be made that the message will reach the destination and an acknowledgment returned.

---

### <standalone-listener-port>

**Parent element:** <reliability>

**Child element:** None

**Required?** Optional

**Server or Client?** Client

The value attribute specifies the port at which a listener will be started for receiving acknowledgments or faults. This is used for J2SE clients where there is no infrastructure to which acknowledgments can be sent. If the client is in a J2EE application, then a supplied servlet can be used.

**Reliability Configuration Listing**

You can find sample reliability configurations for a Web service and client in Chapter 5, "Ensuring Web Service Reliability."
This appendix describes the Oracle Application Server Web Services auditing configuration elements defined by the auditing schema oracle-webservices-auditing-10_0.xsd. This file can be found in the oc4j-schemas.jar file.

$OC4J_HOME\j2ee\home\lib\oc4j-schemas.jar$

$OC4J_HOME$ represents the directory where you installed Oracle Containers for J2EE (OC4J).

Auditing is typically used as part of a larger Web services management configuration. To enable auditing, you have to configure it into the Web service on the server side and into the client. The configuration is part of an XML configuration file that is passed to the Web service or client when it is assembled.

- For the server, the configuration is stored in the oracle-webservices.xml deployment descriptor file. This file is based on the oracle-webservices-10_0.xsd schema.
- For a J2SE client, the configuration is stored in the <generated_name>_Stub.xml deployment descriptor file. This file is based on the oracle-webservices-client-10_0.xsd schema.
- For a J2EE client, configuration information for auditing is located in the J2EE client-side Web services proprietary deployment descriptor. Depending on the client application, this can be either orion-web.xml, orion-ejb-jar.xml, or orion-application-client.xml.

Unlike other management features, auditing can be configured only at the operation level; you cannot configure auditing at the global or port-level.

For more information about auditing and assembling auditing in to a Web service and client see Chapter 6, "Auditing and Tracing Messages".

**Hierarchy of an Auditing Configuration**

Auditing is designated and defined by the single element <auditing>. In the oracle-webservices.xml server-side configuration file, this element appears in the <runtime> clause for an individual operation. Each operation can have its own auditing configuration. The following conceptual fragment illustrates where the <auditing> element appears in the hierarchy of an oracle-webservices.xml file.

```xml
... <port-component>
  ...
...<auditing>
```
For a J2EE client, the auditing configuration appears within the <operation> clause of the <service-ref-mapping> element. Like the server-side, auditing can be configured only for operations; the <auditing> element appears in the <runtime> clause for an individual operation. Each operation can have its own auditing configuration. The following fragment illustrates where the <auditing> element appears in the hierarchy of a orion-web-application.xml file:

```xml
<orion-web-app>
  ...
  <service-ref-mapping>
    <port-info>
      ...
      <runtime>
        ...
      </runtime>
    </port-info>
    ...
    <security>
      <reliability>
        ...
      </reliability>
      <operations>
        ...
      </operations>
    </security>
    <operations>
      ...
      <operation>
        <runtime>
          ...
        </runtime>
      </operation>
    </operations>
  </service-ref-mapping>
...<auditing>
```

### Elements and Attributes for the Auditing Schema

This section is an alphabetical dictionary of elements of the auditing schema, oracle-webservices-auditing-10_0.xsd. See the preceding section, "Hierarchy of an Auditing Configuration", if you are interested in the hierarchy.

The auditing schema defines the single element, <auditing>.

**<auditing>**

- **Parent element:** root element for auditing
- **Child element:** None
- **Required?** Optional

The <auditing> element designates the presence of an auditing configuration for an operation. Its attributes define whether auditing will be enabled for request messages, response messages, and fault messages.
Auditing Configuration Listing

You can find sample auditing configurations for a Web service and client in Chapter 6, "Auditing and Tracing Messages".

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>fault</td>
<td>Value: boolean</td>
</tr>
<tr>
<td></td>
<td>Default: false</td>
</tr>
<tr>
<td></td>
<td>Indicates whether fault messages will be audited.</td>
</tr>
<tr>
<td></td>
<td>Default is false.</td>
</tr>
<tr>
<td>request</td>
<td>Value: boolean</td>
</tr>
<tr>
<td></td>
<td>Default: true</td>
</tr>
<tr>
<td></td>
<td>Indicates whether request messages will be audited.</td>
</tr>
<tr>

<td>Default is false.</td>
</tr>
</tbody>
</table>
This appendix describes the Oracle Application Server Web Services tracing (logging) configuration elements defined by the tracing schema oracle-webservices-logging-10_0.xsd. This file can be found in the oc4j-schemas.jar file.

OC4J_HOME\j2ee\home\lib\oc4j-schemas.jar

OC4J_HOME represents the directory where you installed Oracle Containers for J2EE (OC4J).

Tracing is typically used as part of a larger Web services management configuration. To enable tracing, you must configure it into the Web service on the server side. The configuration is part of an XML configuration file that is passed to the Web service when it is assembled.

For the server, the configuration is stored in the oracle-webservices.xml deployment descriptor file. This file is based on the oracle-webservices-10_0.xsd schema.

**Note:** Tracing cannot be configured for a Web service client.

**Hierarchy of a Tracing Configuration**

Tracing features can be configured at both the port and the operation level in the oracle-webservices.xml server-side deployment descriptor. The port-level configuration contains information that is referenced by the operation level. Unlike security or reliability, an operation-level tracing configuration does not override a port-level configuration.

A tracing configuration is delimited by the `<logging>` element. At the port level in the oracle-webservices.xml file, this tracing configuration appears in the `<runtime>` clause beneath the `<port-component>` port description. At the operation level, the tracing configuration appears in the `<runtime>` clause beneath an individual `<operation>` description. Each operation can have its own tracing configuration.

The following fragment illustrates where a tracing configuration can appear in the hierarchy of an oracle-webservices.xml file.

```xml
<oracle-webservices>
  ...
  <port-component>
    ...
    <runtime>
      <logging>
```

OracleAS Web Services Tracing Schema  E-1
Elements and Attributes for the Tracing Schema

This section is an alphabetical dictionary of elements in the tracing schema, oracle-webservices-logging-10_0.xsd. See the preceding section, "Hierarchy of a Tracing Configuration", if you are interested in the hierarchy.

<attribute>

Parent element: <attributes>

Child element: None

Required? Optional

Port or Operation? Operation

This element enables you to specify one or more attributes you want to log for each message type. These attributes are indicated by its name and xpath. If tracing for a message type is enabled, but no attributes are configured, then no tracing will occur. Similarly, if the xpath query returns no results, then no tracing will occur.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| name | Value: string  
Default: n/a (Required)  
The name of the attribute. |
| xpath | Value: string  
Default: n/a (Required)  
The xpath query for attributes. |

<attributes>

Parent element: <fault>, <request>, <response>

Child element: <attribute>
Elements and Attributes for the Tracing Schema

OracleAS Web Services Tracing Schema

Required? Optional

Port or Operation? Operation

This element can occur no more than once in a configuration for a `<request>`, `<response>`, or `<fault>` element. It delimits a sequence of `<attribute>` elements.

`<fault>`

Parent element: `<logging>`

Child element: `<attributes>`

Required? Optional

Port or Operation? Operation

The presence of this element indicates that the tracing of request messages can be enabled or disabled for this operation. This element has the single attribute `enabled`.

If `enabled="true"`, then use the `<attribute>` element to specify name-value pairs of message attributes. Each attribute is specified by an attribute name and `xpath` value. The default for the `enabled` attribute is `true`.

`<logging>`

Parent element: Root element for a logging configuration

Child elements:

Port level: `<namespaces>`

Operation level: `<fault>`, `<request>`, `<response>`

Required? Optional

Port or Operation? Both

Delimits a port-level or operation-level tracing configuration.

`<namespace>`

Parent element: `<namespaces>`

Child element: None

Required? Optional

Port or Operation? Port

Specifies a name-value pair of namespace prefixes and namespace URIs. The namespace URIs are implicitly referenced by the use of the prefixes in `xpath` expressions defined for tracing at the operation level.
**Table E–2  `<namespace>` Attributes**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
</table>
| prefix | Value: string  
  Default: n/a (Required)  
  Used by the *xpath* expression defined at the operation level. |
| uri   | Value: anyURI  
  Default: n/a (Required)  
  Used by the *xpath* expression defined at the operation level. |

**<namespaces>**

**Parent element:**  `<logging>`

**Child element:**  `<namespace>`

**Required?**  Optional

**Port or Operation?**  Port

This element can occur no more than once in a port-level configuration. It delimits a sequence of `<namespace>` elements.

**<request>**

**Parent element:**  `<logging>`

**Child element:**  `<attributes>`

**Required?**  Optional

**Port or Operation?**  Operation

The presence of this element indicates that the tracing of request messages can be enabled or disabled for this operation. This element has the single attribute *enabled*. If *enabled*="true", then use the `<attribute>` element to specify name-value pairs of message attributes. Each attribute is specified by an attribute name and *xpath* value. The default for the *enabled* attribute is true.

**<response>**

**Parent element:**  `<logging>`

**Child element:**  `<attributes>`

**Required?**  Optional

**Port or Operation?**  Operation

The presence of this element indicates that the tracing of request messages can be enabled or disabled for this operation. This element has the single attribute *enabled*. 
If enabled="true", then use the <attribute> element to specify name-value pairs of message attributes. Each attribute is specified by an attribute name and xpath value. The default for the enabled attribute is true.

**Tracing Configuration Listing**

You can find sample tracing configurations for a Web service and client in Chapter 6, "Auditing and Tracing Messages".
The JAX-RPC mapping file is a standard XML file that describes the binding between the WSDL and the Java service endpoint interface(s). A number of WebServicesAssembler commands produce a JAX-RPC mapping file as part of their output. You can edit the contents of the file to customize the contents of the generated WSDL or service endpoint interface.

The JAX-RPC mapping file schema can be found at the following Web site.

http://java.sun.com/xml/ns/j2ee/j2ee_jaxrpc_mapping_1_1.xsd

This appendix has the following sections.

- How to Produce a JAX-RPC Mapping File
- Understanding Naming Conventions for the JAX-RPC Mapping File
- How to Customize the WSDL or Service Endpoint Interface Contents

How to Produce a JAX-RPC Mapping File

These WebServicesAssembler commands generate a JAX-RPC mapping file as part of their output. Note that many of these commands are used when assembling a Web service bottom up.

- aqAssemble
- assemble
- corbaAssemble
- dbJavaAssemble
- ejbAssemble
- jmsAssemble
- plsqlAssemble
- sqlAssemble
- genInterface
- genValueTypes (produces a “partial” JAX-RPC mapping file)
- genWsdl
F-2 Advanced Web Services Developer's Guide

Understanding Naming Conventions for the JAX-RPC Mapping File

The generated JAX-RPC mapping file has the following naming pattern. The prefix serviceName is the local part of the qname of the service.

<serviceName>java-wsdl-mapping.xml

The JAX-RPC mapping file is typically stored in the same directory as the webservices.xml file.

How to Customize the WSDL or Service Endpoint Interface Contents

Editing the JAX-RPC mapping file enables you to customize the contents of the generated WSDL (for bottom up Web services development) or the contents of the generated service endpoint interface (for top down Web services development).

"Scenarios for Editing the JAX-RPC mapping File" describes some common situations where you might want to customize the WSDL or service endpoint interface.

To produce a mapping file that you can edit, WebServicesAssembler provides two commands: genInterface and genWsdl.

- for general top down Web service development, the genInterface command takes a WSDL as input and produces a service endpoint interface and a JAX-RPC mapping file as output.
- for general bottom up Web service development, the genWsdl command takes a service endpoint interface as input and produces a WSDL and a JAX-RPC mapping file as output.

After modifying the mapping file, you can use it as input to any of the WebServicesAssembler commands that develop a Web service top down or bottom up. The resulting service endpoint interface or WSDL will reflect the changes that you specified in the mapping file.

This discussion can be summarized in these steps:

1. Generate a mapping file.
   To do this, use the genInterface command for top down Web service development or genWsdl command for bottom up Web service development.

2. Edit the mapping file.
   "Scenarios for Editing the JAX-RPC mapping File" describes some of the common ways in which you can edit the JAX-RPC mapping file.

3. Use the modified JAX-RPC mapping file as input to the appropriate WebServicesAssembler command to develop your Web service.

Scenarios for Editing the JAX-RPC mapping File

The following sections describe situations where you might want to edit the JAX-RPC mapping file to generate a custom WSDL or service endpoint interface.

- How to Change Namespace-to-Java Mappings
How to Customize the WSDL or Service Endpoint Interface Contents

- How to Change the Names of Java or WSDL Artifacts
- How to Change a Java Class Associated with an XML Type
- How to Generate Code into a Single Package from a WSDL with Multiple Namespaces
- How to Wrap or Unwrap Mapping for Document-Literal Operations
- How to Map Between SOAP Headers and Java Method Parameters

How to Change Namespace-to-Java Mappings

In the mapping file, the `<package-mapping>` element identifies the mapping between the namespace and the Java package. The `<namespaceURI>` sub-element identifies the namespace and the `<package-type>` sub-element identifies the Java package. A sample `<package-mapping>` element is displayed in Example F–1.

Example F–1 Package to Namespace Mapping Elements in the JAX-RPC Mapping File

```xml
<java-wsdl-mapping version="1.0">
  <package-mapping>
    <package-type>com.foo.mypackage</package-type>
    <namespaceURI>http://www.foo.com</namespaceURI>
  </package-mapping>
</java-wsdl-mapping>
```

You can change the mapping between the namespace and Java package by changing either of the values within the `<package-mapping>` element. The generated WSDL or service endpoint interface will use the new namespace or Java package value.

The `<package-mapping>` element can appear more than once in the mapping file.

How to Change the Names of Java or WSDL Artifacts

In the mapping file, you can change the names of Java or WSDL artifacts. For example, for top-down Web service development, assume that you want to change the mapping of the `wsdl-say-hello` operation in your given WSDL. You can use the WSDL as input to `genInterface`, then edit the resulting JAX-RPC mapping file to map the `wsdl-say-hello` WSDL operation from its default to a `javaSayHello` method that you provide.

Similarly, for bottom-up Web service development, you can use a given service endpoint interface, such as `MyServiceEndpoint`, as input to `genWsdl`. You can then edit the resulting JAX-RPC mapping file to map the service endpoint interface to a port-type, such as `my-service-port-type`, in the WSDL.

See the JAX-RPC mapping file schema for more information on where the names of the Java and WSDL artifacts can be changed.

http://java.sun.com/xml/ns/j2ee/j2ee_jaxrpc_mapping_1_1.xsd

How to Change a Java Class Associated with an XML Type

The Enterprise Web Services 1.1 specification defines the default mapping between Java classes and XML types. However, there may be situations where you might want to change the default mapping for your application. You can change the mapping by editing the contents of the `<java-xml-type-mapping>` element JAX-RPC mapping file.

For example, assume you are using the `genProxy` WebServicesAssembler command to assemble a client proxy. However, instead of mapping the XML `xsd:dateTime`
How to Customize the WSDL or Service Endpoint Interface Contents

type to java.util.Calendar objects (the default mapping) assume that you want to map them to java.util.Date objects instead. You can change the default mapping by editing the JAX-RPC mapping file.

Example F–2 illustrates a sample <java-xml-type-mapping> element. The <java-type> subelement lists the new Java object that you want to associate with the XML type. The <root-type-qname> subelement identifies the XML type.

Example F–2 Changing the Mapping of an XML Type to a Java Object

<java-wsdl-mapping>
...  
  <java-xml-type-mapping>
    <java-type>java.util.Date</java-type>
    <root-type-qname
      xmlns:qn="http://www.w3c.org/2001/XMLSchema">qn:dateTime</root-type-qname>
  </java-xml-type-mapping>
...  
</java-wsdl-mapping>

How to Generate Code into a Single Package from a WSDL with Multiple Namespaces

If you are working with a WSDL with multiple namespaces, WebServicesAssembler places all generated code into a package that corresponds to the namespace of the WSDL and schema value types. If the WSDL contains multiple namespaces, then one package will be created for each namespace. Importing multiple packages can be inconvenient when writing your implementation class.

WebServicesAssembler does not provide an argument that allows all code to be generated in the same package. For example, the packageName argument affects only the package name for service endpoint interface and any schema types that have the same target namespace as the WSDL. If there are schema value types in a different namespace, then WebServicesAssembler generates them into a different package by default.

You can direct WebServicesAssembler to generate a single package by editing the JAX-RPC mapping file. For each namespace, the file contains a <package-mapping> clause with a <package-type> and <namespaceURI> element. These elements identify the mapping between the namespace and a Java package. Edit each instance of the <package-type> element to enter the name of the single package where you want the generated code to reside.

Example F–3 illustrates the contents of a JAX-RPC mapping file that has been edited to place the generated code from three different namespaces into the package MyPackage. The <package-type> and <namespaceURI> elements are highlighted in bold.

Example F–3 Mapping File that Specifies a Single Package for Multiple Namespaces

<java-wsdl-mapping version="1.1">
  <package-mapping>
    <package-type>MyPackage</package-type>
    <namespaceURI>namespace1 in the WSDL</namespaceURI>
  </package-mapping>
  <package-mapping>
    <package-type>MyPackage</package-type>
    <namespaceURI>namespace2 in the WSDL</namespaceURI>
  </package-mapping>
  ...  
</java-wsdl-mapping>

F-4 Advanced Web Services Developer's Guide
How to Customize the WSDL or Service Endpoint Interface Contents

```xml
<package-type>MyPackage</package-type>
<namespaceURI>namespaceN in the WSDL</namespaceURI>
</package-mapping>
</java-wsdl-mapping>
```

How to Generate Code into a Single Package Using a WSDL with Multiple Namespaces

The following steps summarize how you can direct WebservicesAssembler to generate code into a single package when the WSDL contains multiple namespaces.

1. Generate a JAX-RPC mapping file for the Web service.
   
   Use the `genInterface` command if you are assembling a Web service top down or the `genWsdl` command if you are assembling a Web service bottom up. You can also write your own JAX-RPC mapping file by hand.

2. Edit the JAX-RPC mapping file so that each instance of the `<package-type>` element in the `<package-mapping>` clause contains the name of the single package where you want the generated code to reside.

3. Assemble the Web service using the appropriate `*Assemble` command.
   
   Use the `mappingFileName` argument to specify the edited JAX-RPC mapping file. All of the generated code will reside in the same package.

See Also:

"Default Algorithms to Map Between Target WSDL Namespaces and Java Package Names" in the Oracle Application Server Web Services Developer’s Guide for more information on how WebservicesAssembler constructs a default type namespace from the package name.

How to Wrap or Unwrap Mapping for Document-Literal Operations

The `<service-endpoint-method-mapping>` element defines the mapping of Java methods to WSDL operations. If a `<wrapped-element/>` is specified under this element and you are working with document-literal WSDL operations, then each Java method parameter that is not mapped to a SOAP header is mapped to a sub-element of a `complexType`. This `complexType` is used as the type of a wrapper element. Any Java method parameters that are not mapped to a SOAP header, must be mapped to a sub-element of a `complexType` (that is, they must be wrapped).

How to Map Between SOAP Headers and Java Method Parameters

The `<wsdl-message-mapping>` element defines the unique mapping from a specific Java method parameter to a specific message and its part. Parts within a message context are uniquely identified with their names.

If `<soap-header/>` is specified under a `<wsdl-message-mapping>` element, then:

- this Java method parameter is exposed as a SOAP header for bottom up development
- the corresponding SOAP header is mapped to a Java method parameter for top down development
Web Service MBeans

An MBean, or "managed bean", is a Java object that represents a manageable resource in a distributed environment, such as an application, a service, a component, or a device.

An MBean has an exposed interface that allows a management client to control the resource. The interface is comprised of:

- Attributes, values of any type that the management client can get or set. Attributes are analogous to properties set on a JavaBean.
- Operations, methods with any signature and any return type that the client can invoke.
- Notifications that can be generated when specific events occur.

The individual MBean descriptions provide more detailed information on the attributes, operations, and notifications that are available for them.

The following sections describe the MBeans that pertain to Oracle Application Server Web Services and how they are initialized within its environment.

- Web Services MBean Descriptions
- Initializing MBeans

Web Services MBean Descriptions

This section provides a description of the components that define the functionality of an MBean and a summary of the MBeans that are available for OracleAS Web Services.

- Understanding MBean Components
- WebServicePort
- WebServiceOperation
- WSMServiceConfig
- WSMOperationConfig
- WSMHandlerGlobalConfig
- WSMHandlerServiceConfig
- WSMHandlerOperationConfig
Understanding MBean Components

The name of an MBean consists of a number of components, such as J2EEApplication, WebServicePort, handler, and so on. The value of the components are set when the MBean is registered with the MBean server. The full name of an MBean will be displayed in Applications Server Control when you access it. Table G–1 describes the values of the MBean components.

<table>
<thead>
<tr>
<th>Component Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>{application}</td>
<td>The name given to the application (that is, the EAR file) when it was deployed. This value can be found in the &lt;application&gt; element in the ORACLE_HOME/j2ee/home/config/server.xml file.</td>
</tr>
<tr>
<td>{interceptor}</td>
<td>This value identifies the interceptor. The possible values currently are security, reliability, auditing, logging and owsm (Oracle Web Service Manager).</td>
</tr>
<tr>
<td>{operation}</td>
<td>The name of the Web service operation as described by the service's deployment descriptor. This value can be found in the WEB-INF/oracle-webservices.xml file of a deployed Web module. The operation name is the value of the name attribute of each &lt;operation&gt; element.</td>
</tr>
<tr>
<td>{port}</td>
<td>The name of the Web service port as described by the service's deployment descriptor. This value can be found in the WEB-INF/oracle-webservices.xml file of a deployed Web module. The port name is the value of the name attribute of each &lt;port-component&gt; element.</td>
</tr>
<tr>
<td>{service}</td>
<td>The name of the Web service as described by the service's deployment descriptor. This value can be found in the WEB-INF/oracle-webservices.xml file of a deployed Web module. The service name is the value of name attribute of each &lt;webservice-description&gt; element.</td>
</tr>
<tr>
<td>{web-module}</td>
<td>The name given to the Web module within the application’s deployment descriptor. This value can be found as the value of the ID attribute in the &lt;web-module&gt; element of the orion-application.xml file in the META-INF directory of an application.</td>
</tr>
</tbody>
</table>

WebServicePort

*:j2eeType=WebServicePort, J2EEApplication={application}, WebModule={web-module}, WebService={service}, name={port}, *

This MBean provides for the management of a Web service endpoint in the run-time. Specifically, this MBean provides information about the Web service port's structure, state, and performance. It also allows for the endpoint to be temporarily stopped and restarted.

Attributes: address, implementationType, path, serviceName, state, stats, style, wsdl

Operations: start, stop

Statistics: ActiveRange, TotalFault, ServiceTime

Notifications: j2ee.state.running, j2ee.state.stopped

WebServiceOperation

*:j2eeType=WebServiceOperation, J2EEApplication={application}, WebModule={web-module}, WebService={service}, WebServicePort={port}, name={operation}
This MBean provides for the observation and management of each operation of a Web service endpoint. Many of the attributes also provide information about the implementation of the operation.

Attributes: inputEncoding, outputEncoding, overloaded, sampleRequest, sampleResponse, stats, testPagePath, testPageURL

Statistics: RequestSize, ResponseSize, ActiveRange, FaultCount, ServiceTime

**WSMServiceConfig**

*:\j2eeType=WSMServiceConfig, J2EEApplication={application}, WebModule={web-module}, WebService={service}, WebServicePort={port}, *

This MBean is used only to create a hierarchy of MBeans within the system. It represents the port level configuration for all interceptors associated with each Web service port. There are however no useful attributes or operations provided by this MBean.

**WSMOperationConfig**

*:\j2eeType=WSMOperationConfig, J2EEApplication={application}, WebModule={web-module}, WebService={service}, WebServicePort={port}, operation={operation}, *

This MBean is used only to create a hierarchy of MBeans within the system. It represents the operation level configuration for all interceptors associated with each Web service operation. There are, however, no useful attributes or operations provided by this MBean.

**WSMHandlerGlobalConfig**

*:\j2eeType=WSMHandlerGlobalConfig, handler={interceptor}, *

This MBean provides the ability to get, set, and validate the global configuration settings for each individual interceptor. Currently only the security interceptor utilizes global configuration.

Attributes: stagedConfig, deployedConfig

Operations: validateConfig

**WSMHandlerServiceConfig**

*:\j2eeType=WSMHandlerServiceConfig, J2EEApplication={application}, WebModule={web-module}, WebService={service}, WebServicePort={port}, handler={interceptor}, *

This MBean provides access to the port level configuration of each interceptor. Each interceptor may also be enabled or disabled for the Web service port for the MBean by using the stagedEnabled attribute. The other attributes and operation allow the configuration to be retrieved, set, and validated.

Attributes: stagedEnabled, stagedConfig, deployedConfig

Operations: validateConfig
**WSMHandlerOperationConfig**

*: j2eeType=WSMHandlerOperationConfig, J2EEApplication={application}, WebModule={web-module}, WebService={service}, WebServicePort={port}, handler={interceptor}, operation={operation}, *

This MBean provides access to the operation level configuration of each interceptor. This MBean can be used to retrieve, set and validate the configuration.

Attributes: stagedConfig, deployedConfig

Operations: validateConfig

---

**Initializing MBeans**

The OracleAS Web Services runtime for the current release is implemented as a servlet; it relies upon the servlet container for the management of its life cycle. JMX MBeans are created and registered as part of the Servlet init method of the Web service runtime. Depending on the configuration of the web.xml deployment descriptor in the J2EE Web Archive (that is, the WAR file), the servlet container may not initialize the Web service servlet until the first request to the servlet is encountered.

To instruct the servlet container to initialize the servlet when the Web service is deployed or the container starts, set the load-on-startup element in the web.xml deployment descriptor to a nonzero value. For example:

```xml
<load-on-startup>1</load-on-startup>
```

This will result in the JMX MBean for the Web service being available as early as possible.

OracleAS Web Services recommends that all Web services deployed on the current release provide the `<load-on-startup>` setting in their web.xml deployment descriptor. This will ensure that the Application Server Control application works correctly.
This appendix describes the ways in which Oracle Application Server Web Services can map between Java and XML types.

- How OracleAS Web Services Maps Java Types to XML Types
- How OracleAS Web Services Maps Java Primitive Types to XML Types
- How OracleAS Web Services Supports Java Value Types
- How OracleAS Web Services Supports Array Mapping
- How OracleAS Web Services Maps Java Collection Classes to XML Types
- How OracleAS Web Services Supports Java Beans Components

### How OracleAS Web Services Maps Java Types to XML Types

Table H–1 describes the mapping between Java data types and XML data types that OracleAS Web Services can perform.

- **The Java Type** column lists the supported Java types recognized by OracleAS Web Services.
- **The XML Type: RPC-Literal, Document-Literal** column lists the mapping between the Java type and the corresponding XML type for RPC-literal and document-literal format.
- **The XML Type: RPC-Encoded** column lists the mapping between the Java type and the corresponding RPC-encoded format.

For example, `java.lang.String` is mapped to the `xsd:string` XML data type. You should note that not every Java type can be used as a method parameter or return type.

The namespace for the document-literal and RPC-literal formats uses an `xsd` prefix and has the following definition.

```xml
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
```

The SOAP 1.1 namespace for the RPC-encoded format uses a `soap-enc` prefix and has the following definition.

```xml
xmlns:soap-enc="http://schemas.xmlsoap.org/soap/encoding"
```
How OracleAS Web Services Maps Java Primitive Types to XML Types

How to Use Java Null Values in Bottom Up Mapping

It is good practice not to rely on any mapping from Java null values to XML nil values. Special care needs to be taken in the RPC case.

- In RPC-literal message format, null parameter values cannot be mapped to nil values.
- In RPC-encoded message format, SOAP-encoded type values can preserve nil.
- In all cases where a value type (Java Bean) is used as a parameter, you should not use Java null values.

See Also:

Chapter 1, "Ensuring Interoperable Web Services" for additional discussion on the use of Java null values.

How OracleAS Web Services Maps Java Primitive Types to XML Types

Table H–2 describes the mapping between Java primitive types and XML types that OracleAS Web Services can perform. The types listed in the XML Type column applies to RPC-encoded, RPC-literal, and document-literal formats.

Table H–2  Mapping Java Primitive Types to XML Types

<table>
<thead>
<tr>
<th>Java Primitive Type</th>
<th>XML Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>xsd:boolean</td>
</tr>
<tr>
<td>byte</td>
<td>xsd:byte</td>
</tr>
<tr>
<td>double</td>
<td>xsd:double</td>
</tr>
<tr>
<td>float</td>
<td>xsd:float</td>
</tr>
</tbody>
</table>
How OracleAS Web Services Supports Java Value Types

Java value types can contain a number of attributes. The following list describes the requirements on the Java class corresponding to the Java value type.

- the Java class must have an empty public constructor
- the Java class must not implement java.rmi.Remote
- the Java class must contain attributes of supported types
  - an attribute can be a public field that is not final or transient, or
  - an attribute can be represented by public getter and setter methods
- If the Java class contains a single array-valued attribute (such as int[] or String[]) then the name of the class must not contain the word "Array". You might want to rename the class to "Ary", "List", or something similar.

How to Represent a Java Value Type as a Schema Type

A Java value type can be represented by a schema type. The schema type that corresponds to a Java value type has the following general format.

```
<complexType name="classname of the value type">
  <sequence>
    ...attributes...
  </sequence>
</complexType>
```

How OracleAS Web Services Supports Array Mapping

The following sections describe the ways in which OracleAS Web Services can map arrays.

- All Message Formats
- Document-Literal and RPC-Literal Formats
- RPC-Encoded Format

All Message Formats

Byte arrays are a special case. The Java type byte[] maps to the XML type xsd:base64Binary for document-literal, RPC-literal, and RPC-encoded formats.

Document-Literal and RPC-Literal Formats

Table H–3 provides examples of how OracleAS Web Services can map arrays with members of supported types in the RPC-literal and document-literal formats. For example, an array containing elements of type int maps to the XML type xsd:int with the minOccurs and maxOccurs attributes. Table H–1 lists the supported type mappings for RPC-literal and document-literal formats.
How OracleAS Web Services Supports Array Mapping

Note: Byte arrays are an exception to the list of supported types. Table H–4 lists the XML type mapping for byte arrays.

Table H–3 Mapping Arrays Containing Java Types to XML Types for Document-Literal and RPC-Literal

<table>
<thead>
<tr>
<th>Java Type</th>
<th>XML Type: RPC-Literal, Document-Literal</th>
<th>Additional Properties for the XML Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>int[]</td>
<td>xsd:int</td>
<td>minOccurs=&quot;0&quot;, maxOccurs=&quot;unbounded&quot;</td>
</tr>
<tr>
<td>String[]</td>
<td>xsd:string</td>
<td>minOccurs=&quot;0&quot;, maxOccurs=&quot;unbounded&quot;</td>
</tr>
</tbody>
</table>

Multi-dimensional arrays, such as Double[][], are not supported for the document-literal or RPC-literal formats in the current release. However, it is possible to work around this limitation by wrapping the array in a Java value type and then using an array of these value types.

See Also:
“How OracleAS Web Services Supports Java Value Types” on page H-3 for a description of the requirements on Java value types. Note the restriction on the names for value types described in this section.

RPC-Encoded Format

For the RPC-encoded format, JAX-RPC defines mappings for arrays that contain members of supported types. Table H–1 lists the supported types for RPC-encoded.

Note: Byte arrays are an exception to the list of supported types. Table H–4 lists the XML type mapping for byte arrays.

Example H–1 illustrates how WSDL represents a String[] array. The String[] array is the target of the WSDL construct wsdl:arrayType, where wsdl is the namespace for the WSDL 1.1 schema prefix. This namespace has the following definition.

xmlns:wsdl=http://schemas.xmlsoap.org/wsdl/

Example H–1 WSDL Definition of an Array of Strings for the RPC-Encoded Format

```xml
<complexType name="ArrayOfString">
  <complexContent>
    <restriction base="soap-enc:Array">
      <attribute ref="soap-enc:arrayType" wsdl:arrayType="string[]"/>
    </restriction>
  </complexContent>
</complexType>
```

Example H–2 illustrates the definition of a multidimensional array. The array of strings (ArrayOfString[]) defined in the previous example is used in the wsdl:arrayType="tns:ArrayOfString[]" attribute (highlighted in bold) to create an array which contains arrays of strings. The tns is a WSDL construct that defines a local namespace.
How OracleAS Web Services Maps Java Collection Classes to XML Types

Table H–4 and Table H–5 describe the mapping between Java Collection and Map data types and the XML types that OracleAS Web Services supports. This is an Oracle proprietary mapping and may not be compatible with data type support provided by other vendors.

See Also:

"Definitions for Oracle Proprietary Collection Data Types" on page H-6 for more information on how these data types are defined.

Note that in OracleAS Web Services, you can nest Collections and Maps data types. For example, you can specify a Collection as an item within a Collection.

The Java Collection and Map data types are supported in RPC-literal, document-literal, and RPC-encoded formats. These data types map to the same XML types for the three formats. The Oracle proprietary collection types use the following proprietary namespace for RPC-literal and document-literal formats.

xmlns:owi="http://www.oracle.com/webservices/internal/literal"

The Oracle proprietary collection types use the following proprietary namespace for the RPC-encoded format.

xmlns:owi="http://www.oracle.com/webservices/internal"

</table>
Limitations on Using Collection and Map Data Types

This section describes the limitations on using Collection and Map data types in OracleAS Web Services.

- Instances of java.lang.Object cannot be used in Collections or Maps because there is no XML schema construct to describe the instances of java.lang.Object.

- If you use instances of non-built in types (such as Beans) in a Collection, then you must generate schemas for them. See "Oracle Specific Type Support" in the Oracle Application Server Web Services Developer's Guide for more information on this topic.

- In J2SE 5.0, Collections and Maps can be parameterized. For example, Collection<Integer>. However, the code generated by WebServicesAssembler does not support parameterized Collection and Map, because OracleAS Web Services does not preserve parameterized type metadata in the generated schema.

The following limitations apply to Collection and Map data types when you are working with document-literal and RPC-literal message formats.

- Object graph structure is NOT preserved between serialization and deserialization. See "Object Graph" on page I-15 for more information on limitations when working with object graphs.

- Recursive or circular reference structures return an error. This is illustrated in the following code samples.

  // the following lines of code will return an error
  ArrayList a = new ArrayList();
  a.add(a);

  The following code sample illustrates how Object is not supported as a Collection element.

  // the following lines of code will return an error
  ArrayList a = new ArrayList();
  a.add(new Object());

Definitions for Oracle Proprietary Collection Data Types

Table H–5 provides more information on how the Oracle proprietary XML types for collections are defined.

### Mapping J2SE 5.0 Collection and Map Data Types in Version 3.0 EJBs

In J2SE 5.0, the `Collection` and `Map` data types can be parameterized, for example `List<User>` and `Map<Integer, Bean>`. If you use a parameterized `Collection`
or Map data type in a version 3.0 EJB Web services implementation, and then generate the WSDL for the service at deployment time, then these types will have a distinct representation in the WSDL.

**Note:** The mappings of generic types described in this section is valid only for Web services assembled from version 3.0 EJBs, where the WSDL is generated at deployment time.

In the generated WSDL, a parameterized Collection type is represented as a repeated element sequence of the specific item type instead of xsd:anyType. For example, assume that you are assembling a Web service from a version 3.0 EJB that uses the following parameterized Collection type:

```java
ListOfUsers java.util.List<mypackage.User>
```

Example H–3 illustrates the schema representation of the ListOfUsers type, assuming that the WSDL is generated at deployment time.

**Example H–3  Schema Representation of a Parameterized Collection Data Type**

```xml
<complexType name="ListOfUsers">
  <sequence>
    <element maxOccurs="unbounded" minOccurs="0" name="item" type="tns:User"/>
  </sequence>
</complexType>
```

Similarly, a parameterized Map type is represented as a repeated element sequence of a specific map entry type. For example, assume that you are assembling a Web service from a version 3.0 EJB that uses the following parameterized Map type:

```java
MapOfIntToBean java.util.Map<java.lang.Integer, mypackage.Bean>
```

Example H–4 illustrates the schema representation of the MapOfIntToBean type, assuming that the WSDL is generated at deployment time.

**Example H–4  Schema Representation of a Parameterized Map Data Type**

```xml
<complexType name="MapOfIntToBean">
  <sequence>
    <element maxOccurs="unbounded" minOccurs="0" name="mapEntry" type="tns:MapEntryOfIntToBean"/>
  </sequence>
</complexType>
```

```xml
<complexType name="MapEntryOfIntToBean">
  <sequence>
    <element name="key" type="int"/>
    <element name="value" type="tns:Bean"/>
  </sequence>
</complexType>
```

Note: The mappings of generic types described in this section is valid only for Web services assembled from version 3.0 EJBs, where the WSDL is generated at deployment time.
How OracleAS Web Services Supports Java Beans Components

Java beans can have any number of properties. Each property must have a get ter and set ter method. The properties must belong to supported Java types.
Troubleshooting

This appendix provides solutions to possible problems that may occur when working with Oracle Application Server Web Services. The section titles in this appendix correspond to chapter titles in the Oracle Application Server Web Services Developer’s Guide and the Oracle Application Server Advanced Web Services Developer’s Guide.

OracleAS Web Services Messages

Cannot Serialize or Deserialize Array-Valued Elements to Collection Types

If you use a Java Collection type (such as java.util.Map, java.util.Collection, or a subclass of these) as a parameter or return type in your RPC-encoded Web service, then the runtime cannot properly serialize or deserialize array-valued elements to these collection parameters.

To ensure that serializers and deserializers are registered for Java array types when using the RPC-encoded message format, create a Java value type to represent each Java array.

1. Create a Java value type for each Java array type that you want to use.

   Note: Ensure that the Java value type does not contain the word "Array" in its name. "Array" is a recognized pattern.

   The following example represents the contents of the demo/StringAry.java file. A wrapper class, StringAry, represents the Java String[] array. Note that the name of the class uses the suffix "Ary".

   ```java
   package demo;
   public class StringAry
   { public StringAry() { } 
    public String[] getValue() { return m_value; }
    public void setValue(String[] value) { m_value=value; }
    private String[] m_value;
   }
   ```

2. Ensure that the proper serializers and deserializers are registered for all of your value types.

   To do this, use the `valueType` argument when you assemble the Web service. In the following example, the argument specifies the demo/StringAry.java file created in Step 1.

   ```bash
   java wsa.jar -assemble -valueType demo.StringAry ...
   ```
3. Use the value types you defined for setting and retrieving array-valued elements in your collection type parameter.

For example, assume that you have the following class definition.

```java
package demo;
public class Service extends java.rmi.Remote
{ java.util.Map getMap(String input)\nthrows java.rmi.RemoteException
{ ... }
}
```

You can write the following code to return a `String[]` value as one of the elements in the map.

```java
HashMap map = new HashMap();
String[] str_array = new String[] {"a","b","c");
StringAry sa = new StringAry();
sa.setValue(str_array);
map.put("myArray", sa);
return map;
```

Errors Occur When Publishing a Web Service that Uses Multi-Dimensional Arrays

An error occurs when attempting to publish a Web service that uses multidimensional arrays. For example, an error can be returned when you attempt to publish a Java class that contains a method which takes a multidimensional array as an input or as a return argument.

There are two possible solutions to this problem:

- Create a Java Bean for each dimension of the array
- Use RPC-encoded message format to publish the Web service

Creating a Java Bean for each Dimensional of the Array: You can wrap each dimension of the array into a Java value type and work around the limitation.

Note: Ensure that the Java value type does not contain the word "Array" in its name. "Array" is a recognized pattern.

In the following example, the `public static class StringAry` wraps the inner array of strings. The `public StringAry[]` represents an array of the inner array. That is, it contains an array of `String` Java value types. Note that the code sample uses the suffix "Ary".

```java
package demo;
public interface SampleItf extends java.rmi.Remote
// wrap the inner array as a Java value type
{ public static class StringAry
  { public StringAry() { }
  public String[] getValue() { return m_value; }
  public void setValue(String[] value) { m_value=value; }
  private String[] m_value;
  }

  // create an array of the inner array elements
  public StringAry[] echoString2(StringAry[] input)
  throws java.rmi.RemoteException;
}
The `Sample` class illustrates how you can then publish the `StringAry[]` array of `String` Java value types.

```java
package demo;
public class Sample implements java.rmi.Remote, SampleItf {
    public SampleItf.StringAry[] echoString2(SampleItf.StringAry[] input)
        throws java.rmi.RemoteException
    {
        return input;
    }
}
```

**Using RPC-Encoded Style to Publish a Web Service:** You can use the RPC-encoded style to publish a Web service that uses multidimensional arrays. For example:

```java
package demo;
public interface SampleItf extends java.rmi.Remote {
    public String[][] echoString2(String[][] input)
        throws java.rmi.RemoteException;
}
```

```java
package demo;
public class Sample implements java.rmi.Remote, SampleItf {
    public String[][] echoString2(String[][] input)
        throws java.rmi.RemoteException
    {
        return input;
    }
}
```

**Deserialization Errors Occur when Processing Responses or Requests**

This error can occur when OracleAS Web Services attempts to perform schema validation during the deserialization step. The cause of the error is a mismatch between the schema definition found in the `wsdl:types` element and the format of the SOAP payload on the wire.

The error can occur when a client proxy, assembled with `genProxy`, attempts to deserialize a response from the server. It can occur on the server when it attempts to deserialize the request.

The following example illustrates a mismatch between the order of the elements on the wire and in the WSDL. As the deserialization code processes `ParentItemId` on the wire, it skips over the `Quantity` and `PrePick` elements from the schema. Processing fails when encountering `PrePick` on the wire, as this element is not expected after `ParentItemId`.

**Wire format:**

```xml
...<ListOfProduct>
    <Product>
        <ParentItemId/></ParentItemId>
        <PrePick>Y</PrePick>
        <Quantity>1</Quantity>
    ...
```

**WSDL definition:**

```xml
...<xsd:complexType name="Product">
    <xsd:sequence>
        <xsd:element name="Quantity" maxOccurs="1" minOccurs="0" type="xsd:string"></xsd:element>
```
The following is an example deserialization error that can be thrown in this situation:

```java
unexpected element name:
expected={http://myCompany.com/Catalog/Data/CategoryProduct}Description,
actual={http://myCompany.com/Catalog/Data/CategoryProduct}PrePick.
at oracle.j2ee.ws.common.util.exception.JAXRPCExceptionBase.<init>(JAXRPCExceptionBase.java:93)
at oracle.j2ee.ws.common.util.exception.JAXRPCExceptionBase.<init>(JAXRPCExceptionBase.java:111)
at oracle.j2ee.ws.common.encoding.DeserializationException.<init>(DeserializationException.java:54)
```

The following are possible ways to work around the error:

- Change the service implementation so that the wire format matches the format described in the WSDL.
  
  You can employ this work around only if you have control over the service implementation and are working in a top down Web service assembly scenario. The mismatch between the schema definition and SOAP payload may have been caused by errors in formatting the response when you implemented the contract. This scenario is possible if you are using the SAAJ APIs (that is, you are either assembling the Web service top down with dataBinding=false, or writing custom code using the JAX-RPC handler chain or the Provider APIs).

- Edit the WSDL so that the schema definition matches the wire format.
  
  You can employ this work around on the server side if you own the service and made a mistake in authoring the XML schema definition. This work around is also possible on the client side when you do not own (or cannot change) the service implementation.

- Generate the Web service with dataBinding=false to avoid the XML to Java layer. Every schema type will be represented as a SOAPElement. Then, use the SAAJ APIs to write custom code to process the raw XML.

**Restrictions on RPC-Encoded Format and Data Binding**

OracleAS Web Services does not support the combination of RPC-encoded message formats and dataBinding=false. This combination is not considered a "best practice" within the industry.

**Document-Encoded Message Format is not Supported by OracleAS Web Services**

Even though the combination of style="document" and use="encoded" is valid according to the SOAP specification, it is not supported by any of the major Web Services platforms, including OracleAS Web Services.

**Document-Literal Bare Message Format is Limited to One Input Part**

OracleAS Web Services supports only one part as input in the bare case. All other input parameters must be mapped into SOAP header parts.
Serialization of BigDecimal Values May Introduce Rounding Errors

There are several constructors available for `java.Math.BigDecimal`. The constructors can take the following types of input.

- a double-precision floating point
- an integer and a scale factor
- a String representation of a decimal number

You should be careful when you use the `BigDecimal(double)` constructor. It can allow rounding errors to enter into your calculations. Instead, use the `int` or `String` based constructors.

For example, consider the following statements which take the value 123.45.

```java
... 
double d = 1234.45;
System.out.println(d);
System.out.println(new BigDecimal(d));
...
```

These statements produce the following output. The second value might not be the value you expected.

```
1234.45
1234.450000000000045474735088646411895751953125
```

Get NodeLists by Using `getFirstChild` and `getNextSibling` Instead of `getChildNode`

You may see a performance degradation when iterating over a `NodeList` obtained by using `node.getChildNode`. This degradation will only be significant for `NodeList`s with very long lengths.

Instead of using the `NodeList` obtained by `node.getChildNodes`, the current Oracle XDK implementation offers an optimization of navigating a list of child nodes by using `node.getFirstChild` and looping over `node getNextSibling`. The following code sample illustrates this technique.

```java
Node n = ...;
if (n.hasChildNodes()) {
    for (Node nd=n.getFirstChild(); nd!=null; nd=nd.getNextSibling()){
        nd.getValue(); // do something with nd
    }
}
```

Assembling Web Services from a WSDL

Restrictions on Using Document Literal Message Formats

If you attempt to assemble a Web service top down that uses a document-literal message format, WebServicesAssembler will return a warning if it detects two or more operations in the WSDL that use the same input message. This is because the OC4J runtime will not be able to distinguish which method is being invoked.

For example, the following WSDL fragment will cause WebServicesAssembler to return a warning. The fragment defines the `addRelationship` and `addRelationship3` operations. Each of these operations use the `addRelationshipRequest` input message.

```xml
... 
<operation name="addRelationship">
```
If you were to invoke the `addRelationship` operation from your client, then depending on the order in which the operations appear in your implementation class, either `addRelationship` or `addRelationship3` would be invoked.

Schema Features Limitations

Schema Features that are Mapped to a SOAPElement
If any of the following schema features are encountered in the WSDL, they will be mapped to a SOAPElement.

- any model group with multiple `xsd: any` elements
- `xsd: choice` elements
- mixed content
- substitution groups
- a type with multiple `xsd: any` attributes

If you are assembling Web Services top down or assembling Web service proxies, WebServicesAssembler cannot consume WSDLs that contain the `xsd: choice` or `xsd: group` XML types. If you want to consume a WSDL that contains these XML types, set the WebServicesAssembler dataBinding argument to `false` and code the SOAPElement so that the payload conforms to the schema definition in the WSDL file.

RPC Encoded Does Not Support Complex Types With Attributes
If the schema contains a binding with an RPC-encoded message format and WebServicesAssembler encounters a complexType with attributes, then it will throw an "unsupported type encountered" error message.

Assembling Web Services from Java Classes

Limitations on Stateful Web Services
The support that OracleAS Web Services offers for stateful Web services is limited to services based on Java classes. These services contain Oracle proprietary extensions and you should not consider them to be interoperable unless the service provider makes scopes with the same semantics available.

The support that OracleAS Web Services offers for stateful Web services is HTTP-based. Stateful Web services will work only for SOAP/HTTP endpoints and will not work for SOAP/JMS endpoints.
Assembling Web Services from Java Classes—Differences Between Releases 10.1.3.1 and 10.1.2
Note the following differences between Oracle Web Services release 10.1.2 (and earlier) and release 10.1.3.1.

- In release 10.1.2 there was no requirement to extend RemoteInterface or for methods to throw RemoteException. This is now required in release 10.1.3.1, unless you are using the J2SE 5.0 Web Service annotations feature.
- In release 10.1.2 it was possible to publish a class by itself without providing an interface. In release 10.1.3.1 you must provide an interface to publish a class, unless you are using the J2SE 5.0 Web Service annotations feature.

Assembling Web Services From EJBs

Setting the Transaction Demarcation for EJBs
An EJB exposed as a Web service should not have TX_REQUIRED or TX_MANDATORY set as its transaction demarcation.

Assembling Web Services with JMS Destinations

Supported Types for Message Payloads
For JMS endpoint Web services, OracleAS Web Services supports only instances of java.lang.String or javax.xml.soap.SOAPElement as the payload of JMS messages.

JMS Properties in the SOAP Message Header
Only a limited number of JMS properties can be transmitted by the SOAP header. If the value of the genJmsPropertyHeader argument is true (default), then the following JMS properties can be transmitted by the SOAP header.

- message-ID
- correlation-ID
- the reply-to-destination, including its name, type, and factory

Developing Web Services From Database Resources

Datatype Restrictions

- Streams are not supported in Oracle Streams AQ Web services.
- SQL Type SYS.ANYDATA is not supported in PL/SQL Web services.
- REF CURSOR as a parameter is not supported in PL/SQL Web services.
- REF CURSOR returned as Oracle WebRowSet and XDB RowSet does not support complex types in the result.
- Due to a limitation in JDBC, PL/SQL stored procedures do not support the following SQL types as OUT or INOUT parameters:
  - char types, including char, character, and nchar
  - long types including long and long raw
Differences Between Database Web Services for 10.1.3.1 and Earlier Releases

A Web service client written for a database Web service generated under release 9.0.4 or 10.1.2, will fail if you try to use it against a database Web service generated bottom up under release 10.1.3.1. This will be true even if the PL/SQL structures have remained the same.

One of the reasons for this is that the SQL collection type was mapped into a complex type with a single array property in releases 9.0.4 and 10.1.2. In release 10.1.3.1, it is mapped directly into array instead.

If you regenerate the Web service client, you will have to rewrite the client code. This is because the regenerated code will now be employing an array[] instead of a BeanWrappingArray.

Assembling Web Services with Annotations

Web Service Metadata Features that are Not Supported

There are parts of the Web Services Metadata for the Java Platform specification that OracleAS Web Services does not support. For example, OracleAS Web Services does not support the "Start With WSDL" or "Start With WSDL and Java" modes defined in sections 2.2.2 and 2.2.3 of the "Java Architecture for XML Binding" (JAXB) specification. OracleAS Web Services supports only the "Start With Java" mode.

If you use the assemble or the genWsdl WebServicesAssembler commands to generate a WSDL to use with J2SE 5.0 Web Service annotations, you must specify them differently than if you were using them to process files that do not contain annotations.

See Also:

See the "assemble" and "genWsdl" sections of the "Using WebServicesAssembler" chapter in the Oracle Application Server Web Services Developer's Guide for more information on using these commands to generate WSDLs for use with J2SE 5.0 Web Service annotations.

Annotated Classes Must be Listed in the classpath Argument for the WebServicesAssembler assemble Command

If you are using the WebServicesAssembler assemble command to assemble an annotated class into a Web service, then the class must be placed in both the input and the classpath arguments. The classpath should not be needed, as files listed in the input argument are implied to be part of the classpath for non-annotated classes.

Assembling REST Web Services

Restrictions on REST Web Services Support

The following list describes the limitations in OracleAS Web Services support for REST Web Services.

- REST support is available only for Web service applications with literal operations (both request and response should be literal).
- HTTP GET is supported only for Web service operations without (required) complex parameters.
- Some browsers limit the size of the HTTP GET URL, typically to 2000 characters or less. Try to keep the size of the URL small by using a limited number of parameters and short parameter values and names.
- REST Web services send only simple XML messages. You cannot send messages with attachments.
- Many management features, such as security and reliability, are not available with REST Web services. This is because SOAP headers, which are typically used to carry this information, cannot be used with REST invocations of services.
- REST invocations cannot be made from generated Stubs or DII clients. Invocations from those clients will be made in SOAP.
- There is no REST support for the Provider framework.
- Operation names in REST cannot contain multibyte characters.

**Testing Web Service Deployment**

The Web Service Test Page has the following limitations:

- The Web Service Test Page offers only basic support for WS-Security. The editors can enter only a username and password into the SOAP envelope. To enter any other complex or advanced WS-Security features, such as encryption and signing, in the SOAP request, you must edit the request directly in the Invocation Page.
- The Web Service Test Page does not allow you to upload attachments.
- You cannot invoke WSIF services using the Test Page.
- WSDL files that contain proprietary extensions may not work properly in the Web Service Test Page. For example, services that use JMS as a transport cannot be tested by using the Test Page.

**Assembling a J2EE Web Service Client**

**Client Applications and Thread Usage**

If the client application creates its own threads for its processing (for example, if it enables an asynchronous call using a separate thread), the application server must be started with the `-userThreads` option.

```
java -jar oc4j.jar -userThreads
```

The `-userThreads` option enables context lookup and class loading support from user-created threads.

**Understanding JAX-RPC Handlers**

WebServicesAssembler provides Ant tasks that let you configure JAX-RPC message handlers. Handlers cannot be configured by using the WebServicesAssembler command line.
Processing SOAP Headers

Strong Typing and the ServiceLifecycle Interface

Although the ServiceLifecycle interface enables you to access SOAP header blocks that may not have been declared in the WSDL file, the blocks are not strongly typed. You may also need to know the XML structure of a SOAP header in order to process it. For strong typing of SOAP header blocks, make sure that the mapHeadersToParameters argument for WebServicesAssembler is set to true (true is the default value). This is only possible if the SOAP header has been declared in the WSDL file and the type of the SOAP header is a supported JAX-RPC type.

Using WebServicesAssembler

Long file names cause deployment to fail

If the combined length of the generated file and directory names passes a certain size limit, then deployment will fail and throw an error. This size limit varies for different operating systems. For example, on the Windows operating system, the size limit is 255 characters.

The length of the names is controlled by WebServicesAssembler and the deployment code. WebServicesAssembler generates file names based on the method name in the Java class or the operation name in the WSDL. The deployment code creates directories for code generation based on the names of the EAR and the WAR files.

To avoid the generation of file and directory names that are too long, limit the number of characters in the following names to a reasonable length.

- method names in Java classes
- operation names in the WSDL
- directory name for the location of the OC4J installation
- file name for a WAR file
- file name for a EAR file

You can also avoid this problem by upgrading to a more recent version of the J2SE 5.0 JDK (jdk-1_5_0_06 or later).

Getting More Information on WebServicesAssembler Errors

You can get detailed diagnostic information on errors returned by WebServicesAssembler by including the debug argument in the command line or Ant task.

See Also:

"debug" in the "Using WebServicesAssembler" chapter in the Oracle Application Server Web Services Developer’s Guide for more information on this argument.

WebServicesAssembler Cannot Compile Files

If WebServicesAssembler cannot compile files successfully, it will return the error:

java? java.io.IOException: CreateProcess: javac -encoding UTF-8 -classpath

The javac compiler must be available so that WebServicesAssembler can compile your Java files. Make sure that JAVA_HOME/bin is in your path.
WebServicesAssembler Cannot Find Required Classes

You may need to use some classes that are common to all J2EE 1.4 applications. All standard J2EE 1.4 classes and Oracle database classes are included automatically. When using Ant tasks, WebServicesAssembler must search for the JARs that contain these classes.

A WebServicesAssembler Ant task tries to load these extra classes by searching for wsa.jar. The task searches for the following Ant properties or environment variables in the following order. If the task does not find wsa.jar, or if a property is not defined, it searches the next property.

1. oc4j.home—an Ant property that specifies the root installation directory for OC4J. This property can be used instead of an environment variable.
2. OC4J_HOME—an environment variable that specifies the root installation directory for OC4J.
3. oracle.home—an Ant property that specifies the root installation directory for Oracle products. This property can be used instead of an environment variable.
4. ORACLE_HOME—an environment variable that specifies the root installation directory for Oracle products.

When the Ant task finds wsa.jar, it loads all of the classes listed in its manifest file, relative to the location of wsa.jar.

Web Service and Message Parts are Generated into Separate Directories

It is possible, either intentionally or unintentionally, to generate the Web service and the message parts into separate directories. One of the ways this can happen is by setting the targetNamespace argument incorrectly.

The value of targetNamespace can be either a conforming HTTP URL, a non-conforming HTTP URL, or even a URI. The value of targetNamespace maps to a package name in the following ways:

- When the target namespace is a conforming HTTP URL, then the order of the elements in it will be reversed when mapping to a Java package name. For example:
  
  The target namespace http://hello.demo.oracle.com will map to the package name com.oracle.demo.hello.

- When the target namespace is a non-conforming HTTP URL, then the order of the elements in it will be unchanged. For example:
  
  The target namespace http://hello.demo.oracle will map to the package name hello.demo.oracle.

- When the target namespace is a URN, then the value is mapped into a single identifier, with components separated by underscores ("_ "). For example:
  
  The target namespace urn:oracle.demo.hello will map to the identifier oracle_demo_hello.

For example, assume you are assembling a Web service with a package path oracle/demo/hello. If you set the targetNamespace argument to http://hello.demo.oracle (a non-conforming URL), then the target namespace in the WSDL will be http://hello.demo.oracle, but the message parts will still use the namespace oracle.demo.hello (from the service package name). If you then generate a proxy with this WSDL, then the service will be generated into hello.demo.oracle and the message parts will be generated into oracle.demo.hello.
In this case, you should use http://oracle.demo.hello as the value of the targetNamespace argument. As an alternative, if the Java code resides in com/oracle/demo/hello, then use http://hello.demo.oracle.com as the value of the targetNamespace argument. This ensures that the generated code will be placed in the expected Java package.

**See Also:**

- "targetNamespace" for more information on how this argument responds to different URI values.
- "packageName" for more information on the behavior of this argument.

**genInterface, genProxy, and topDownAssemble Cannot Process WSDL Files Correctly that Contain Multibyte Characters in Element Names**

The genInterface, genProxy, and topDownAssemble commands cannot process a WSDL file correctly if it uses multibyte characters in element names. The commands will produce Java source files, but they will not compile.

To work around this limitation, set the dataBinding argument to false when generating the interface.

---

### Packaging and Deploying Web Services

#### Packaging for J2EE Clients

The current tool set cannot package J2EE Web service clients. You must package the client manually.

**See Also:**

"Packaging a J2EE Client" in the Oracle Application Server Web Services Developer’s Guide provides more information on how to package a J2EE Web service client.

#### Getting the Correct Endpoint Address when the WSDL Has More than One HTTP Port

If you want to enter values for the <web-site> or <wsdl-publish-location> elements in oracle-webservices.xml, then the returned WSDL may not have the correct endpoint addresses if the WSDL has more than one HTTP port.

The WebServicesAssembler tool does not insert the <web-site> or <wsdl-publish-location> elements into the oracle-webservices.xml file that it creates. You must insert these elements manually.

**OWS-04005 Error Returned when Generated Client and Service Classes Appear in the Same EAR File**

If you generate client and Web service classes into the same directory, WebServicesAssembler might package client classes in the Web service EAR file. When you deploy the EAR file to the server, the deployment will fail with an OWS-04005 error from OracleAS Web Services:

OWS-04005 An error occurred for port: ... 

For example, using Application Server Control to deploy an EAR file that contains generated client classes might return an error similar to the following:
Ensuring Interoperable Web Services

Troubleshooting

I-13

ERROR OWS-04005 An error occurred for port: {http://ws.myservice.org/}HttpSoap11:
no serializer is registered for (class org.myservice.ws.MyWebService_sayHello_
ResponseStruct, {http://ws.myservice.org/}sayHelloResponse)

If an attempt to invoke this service in the Web Services Test Page, the page will respond with a diagnostic message. For example, a response message similar to the following can be displayed on the Test Page:

```xml
<env:Envelope xmlns:env="http://schemas.xmlsoap.org/soap/envelope/">
  <env:Body>
      <faultcode>env:Server</faultcode>
      <faultstring>no serializer is registered for (class org.myservice.ws.MyWebService_sayHello_ResponseStruct, {http://ws.myservice.org/}sayHelloResponse)</faultstring>
    </env:Fault>
  </env:Body>
</env:Envelope>
```

To work around this problem, generate your client and Web service classes into separate directories.

Ensuring Interoperable Web Services

Leading Underscores in WebServicesAssembler Generated Names

The default behavior of the WebServicesAssembler tool is to generate namespaces from the Java package name. If the Java package name begins with a leading underscore ("_"), then the generated namespace URI will contain an underscore. Some versions of the .NET WSDL tool may not be able to consume these namespaces, even though the generated namespace is valid.

To work around this .NET issue, use the WebServicesAssembler arguments targetNamespace and/or mappingFileName to avoid the default package-derived namespace.

AXIS Platform Cannot Deserialize "0" as the Value of a URI Response

According to the JAX-RPC specification, the xsd:anyURI type must be mapped to the java.net.URI class in applications that are intended to run on J2SE 1.4 or later. For compatibility with pre-1.4 environments, JAX-RPC implementations are allowed to map this type to java.lang.String.

The AXIS platform, however, maps xsd:anyURI to the proprietary class org.apache.axis.types.URI. This can cause problems if "0" is passed to instantiate a new URI.

For example, when the AXIS platform consumes the value "0" in the following code sample, the URI-parser assigns "0" to the port and calls the constructor for instantiation.

```java
java.net.URI ret = new java.net.URI("0"); // <wsdl:part
name="inUri" type="xsd:anyURI"/>
return ret;
```

This situation will cause the setPort method on AXIS platform to throw an error such as the following:
org.apache.axis.types.URI$MalformedURIException: Port cannot be set when host is null!

As a workaround, use xsd:string instead of xsd:anyURI on the AXIS platform.

.NET Clients Cannot Correctly Deserialize Multi-dimensional soapenc:array Responses from OracleAS Web Services

.NET clients incorrectly represent the multi-dimensional SOAP-encoded array (soapenc:array) as an array of arrays. When these clients receive a response from OracleAS Web Services that contains a soapenc:array, they return an error similar to the following:

To work around this limitation in .NET clients, do not use multi-dimensional soapenc:array if interoperability with .NET is required. Use single dimensional arrays, or an array of arrays instead.

Working with Message Attachments

Adding Faults with swaRef Attachments to a Web Service

In OracleAS Web Services, you can add only swaRef MIME type attachments to SOAP fault messages. It does not support the adding of SWA type attachments.

Faults with attachments can be added to a Web service only when you are assembling it from a WSDL (top down). They cannot be added when assembling a Web service bottom up.

Supported Message Formats for Attachments

Only RPC-literal and document-literal Web services are supported by the WS-I Attachments Profile 1.0. Thus, only those types of services can use swaRef MIME type.

WebServicesAssembler will not be able to assemble a Web service that can pass swaRef MIME attachments if you specify an RPC-encoded message format. To assemble the service, you must select a different format.

Managing Web Services

Limitations on Application Server Control

Application Server Control cannot modify everything that can be expressed in the wsmgmt.xml file. For example, it cannot be used to change parts of the reliability configuration.

Ensuring Web Service Reliability

Reliability Limitations for OracleAS Web Services

- The reliability process on the client lives only as long as the client process. If the client process becomes permanently unavailable, then any messages that needed to be retried will be ignored.
Asynchronous polling capabilities can be enabled only at the port level and only by using a configuration.

## Auditing and Logging Messages

### Limitations on xpath Queries

An xpath query must return a primitive type. This means that the query must return the context of text nodes or attribute values.

The primitive type that the xpath query returns should have a small number of characters. For example, it should not exceed 120 characters.

## Custom Serialization of Java Value Types

This section describes limitations on the custom serialization of non-standard data types.

### Literal Use

This release supports only literal as the use part of the message format. This includes RPC-literal and document-literal. RPC-encoded is not supported in this release.

### Object Graph

Because RPC-encoded is not supported in this release, the initial support of serialization and deserialization does not allow object graph marshalling using href. If a Java Object has multiple references either in the parameters of a request or in the return value of a response, then serialization and deserialization might not preserve the object graph.

### WSDL- and Service-Level Configuration

SoapElementSerializer is configured for each Service or for each WSDL. For example, a SoapElementSerializer implementation representing the mapping of dateTime to oracle.sql.DATE can be configured to replace the default mapping of dateTime to java.util.Calendar. Under this configuration, every instance of the mapping is replaced. Configuration for each operation or message level is not supported in this release.

### Sub Tree Serialization

Each custom serializer gets the full XML sub-tree, and performs the serialization and deserialization of the entire XML element object model. For example, assume you have two custom serializers developed and configured for two top-level complexTypes, TypeA and TypeB. TypeA has a subelement of TypeB. Even though a custom serializer has been configured for TypeB, this custom serializer cannot be automatically invoked by the OC4J runtime when the subelement of TypeB is serialized inside the custom serializer for TypeA. The custom serializer of TypeA must handle the subelement of TypeB by itself. The custom serializer of TypeA can, in turn, call the custom serializer of TypeB, but it is up to the implementation strategy.

### Document-Literal Wrapper

Assume that a custom serializer is used to handle a global complexType that is referred by a global element to define the single part of a document-literal operation. If you use the unwrapParameters argument to unwrap the return type and response
Using JMS as a Web Service Transport

Interoperability of Messages when using JMS as a Transport Mechanism
The WSDL extensions that enable JMS as a transport mechanism are Oracle proprietary. The messages produced by the Web service may not be interoperable with applications or services provided by other vendors.

Retrieving Client Responses from JMS Web Service Transport
If the client process becomes unavailable without receiving its response and later returns, there is no facility provided for it to retrieve its old responses from the queue.

Changing JMS Properties
If you need to change the properties of your JMS binding after Web service deployment, you must manually edit the WSDL document to enter the correct values for the JMS address (<jms:address>) and JMS property value (<jms:propertyValue>) elements. After editing the WSDL document, redeploy the service.

Do not try to solve the problem by editing the JMS values in the oracle-webservices.xml file. The JMS part of this file is not reloaded when the service is redeployed. If you want to use the oracle-webservices.xml file to resolve the problem, then you must use WebServicesAssembler to regenerate the service.

See Also:
The JMS address and JMS property value WSDL elements are described in "WSDL Extensions for JMS Transport" on page 8-3 in the Oracle Application Server Advanced Web Services Developer's Guide.

Using the Web Service Invocation Framework
This section describes limitations in the OracleAS Web Services support for the Web Services Invocation Framework (WSIF).

- Database WSIF can pass only the data source, not the JDBC connection, to the provider for database access.
- Database WSIF is stateless. Each operation obtains a JDBC connection when it begins and closes it when it ends. Autocommit is always on for the JDBC connection. It is recommended that you use connection pooling when setting up data sources to reduce database overhead.
- Oracle’s Application Server Control Web Services Management and Monitoring can only directly monitor SOAP services; it cannot monitor any service interactions that utilize WSIF bindings, such as Java, EJB, or database WSIF bindings. By bypassing the SOAP protocol entirely, you are also bypassing the management infrastructure for Web services provided by Oracle Application Server Control.
Using Web Service Providers

**Duplicate MBeans Appear for Web Service Provider Operations**

If you are using a dynamic provider endpoint and notice duplicate MBeans appearing for an operation in Application Server Control, then ensure that the `inputName` and `outputName` attributes are specified for the operation in the `oracle-webvservices.xml` file.
This appendix includes the Third Party License for all the third party products included with Oracle Application Server Web Services Security.

Apache

This program contains third-party code from the Apache Software Foundation (“Apache”). Under the terms of the Apache license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the Oracle program, including the Apache software, and the terms contained in the following notices do not change those rights.

The Apache license agreements apply to the following included Apache components:

- Apache HTTP Server
- Apache JServ
- mod_jserv
- Regular Expression package version 1.3
- Apache Expression Language packaged in commons-el.jar
- mod_mm 1.1.3
- Apache XML Signature and Apache XML Encryption v. 1.4 for Java and 1.0 for C++
- log4j 1.1.1
- BCEL v. 5
- XML-RPC v. 1.1
- Batik v. 1.5.1
- ANT 1.6.2 and 1.6.5
- Crimson v. 1.1.3
- ant.jar
- wsif.jar
- bcel.jar
- soap.jar
- Jakarta CLI 1.0
- jakarta-regexp-1.3.jar
Apache J-2 Advanced Web Services Developer's Guide

- JSP Standard Tag Library 1.0.6 and 1.1
- Struts 1.1
- Velocity 1.3
- svnClientAdapter
- commons-logging.jar
- wsif.jar
- commons-el.jar
- standard.jar
- jstl.jar

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION
1. Definitions.

"License" shall mean the terms and conditions for use, reproduction,
and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by
the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all
other entities that control, are controlled by, or are under common
control with that entity. For the purposes of this definition,
"control" means (i) the power, direct or indirect, to cause the
direction or management of such entity, whether by contract or
otherwise, or (ii) ownership of fifty percent (50%) or more of the
outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity
exercising permissions granted by this License.

"Source" form shall mean the preferred form for making modifications,
including but not limited to software source code, documentation
source, and configuration files.

"Object" form shall mean any form resulting from mechanical
transformation or translation of a Source form, including but
not limited to compiled object code, generated documentation,
and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable (except as stated in this section) patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses granted to You under this License for that Work shall terminate as of the date such litigation is filed.

4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:
(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

(b) You must cause any modified files to carry prominent notices stating that You changed the files; and

(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement you may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS, WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.
8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

Apache SOAP

This program contains third-party code from the Apache Software Foundation ("Apache"). Under the terms of the Apache license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the Oracle program, including the Apache software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the Apache software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or Apache.

Apache SOAP License

Apache SOAP license 2.3.1

Copyright (c) 1999 The Apache Software Foundation. All rights reserved.

TERMS AND CONDITIONS FOR USE, REPRODUCTION, AND DISTRIBUTION

1. Definitions.

"License" shall mean the terms and conditions for use, reproduction, and distribution as defined by Sections 1 through 9 of this document.

"Licensor" shall mean the copyright owner or entity authorized by the copyright owner that is granting the License.

"Legal Entity" shall mean the union of the acting entity and all other entities that control, are controlled by, or are under common control with that entity. For the purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

"You" (or "Your") shall mean an individual or Legal Entity exercising permissions granted by this License.
"Source" form shall mean the preferred form for making modifications, including but not limited to software source code, documentation source, and configuration files.

"Object" form shall mean any form resulting from mechanical transformation or translation of a Source form, including but not limited to compiled object code, generated documentation, and conversions to other media types.

"Work" shall mean the work of authorship, whether in Source or Object form, made available under the License, as indicated by a copyright notice that is included in or attached to the work (an example is provided in the Appendix below).

"Derivative Works" shall mean any work, whether in Source or Object form, that is based on (or derived from) the Work and for which the editorial revisions, annotations, elaborations, or other modifications represent, as a whole, an original work of authorship. For the purposes of this License, Derivative Works shall not include works that remain separable from, or merely link (or bind by name) to the interfaces of, the Work and Derivative Works thereof.

"Contribution" shall mean any work of authorship, including the original version of the Work and any modifications or additions to that Work or Derivative Works thereof, that is intentionally submitted to Licensor for inclusion in the Work by the copyright owner or by an individual or Legal Entity authorized to submit on behalf of the copyright owner. For the purposes of this definition, "submitted" means any form of electronic, verbal, or written communication sent to the Licensor or its representatives, including but not limited to communication on electronic mailing lists, source code control systems, and issue tracking systems that are managed by, or on behalf of, the Licensor for the purpose of discussing and improving the Work, but excluding communication that is conspicuously marked or otherwise designated in writing by the copyright owner as "Not a Contribution."

"Contributor" shall mean Licensor and any individual or Legal Entity on behalf of whom a Contribution has been received by Licensor and subsequently incorporated within the Work.

2. Grant of Copyright License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a perpetual, worldwide, non-exclusive, no-charge, royalty-free, irrevocable copyright license to reproduce, prepare Derivative Works of, publicly display, publicly perform, sublicense, and distribute the Work and such Derivative Works in Source or Object form.

3. Grant of Patent License. Subject to the terms and conditions of this License, each Contributor hereby grants to You a patent license to make, have made, use, offer to sell, sell, import, and otherwise transfer the Work, where such license applies only to those patent claims licensable by such Contributor that are necessarily infringed by their Contribution(s) alone or by combination of their Contribution(s) with the Work to which such Contribution(s) was submitted. If You institute patent litigation against any entity (including a cross-claim or counterclaim in a lawsuit) alleging that the Work or a Contribution incorporated within the Work constitutes direct or contributory patent infringement, then any patent licenses
4. Redistribution. You may reproduce and distribute copies of the Work or Derivative Works thereof in any medium, with or without modifications, and in Source or Object form, provided that You meet the following conditions:

(a) You must give any other recipients of the Work or Derivative Works a copy of this License; and

(b) You must cause any modified files to carry prominent notices stating that You changed the files; and

(c) You must retain, in the Source form of any Derivative Works that You distribute, all copyright, patent, trademark, and attribution notices from the Source form of the Work, excluding those notices that do not pertain to any part of the Derivative Works; and

(d) If the Work includes a "NOTICE" text file as part of its distribution, then any Derivative Works that You distribute must include a readable copy of the attribution notices contained within such NOTICE file, excluding those notices that do not pertain to any part of the Derivative Works, in at least one of the following places: within a NOTICE text file distributed as part of the Derivative Works; within the Source form or documentation, if provided along with the Derivative Works; or, within a display generated by the Derivative Works, if and wherever such third-party notices normally appear. The contents of the NOTICE file are for informational purposes only and do not modify the License. You may add Your own attribution notices within Derivative Works that You distribute, alongside or as an addendum to the NOTICE text from the Work, provided that such additional attribution notices cannot be construed as modifying the License.

You may add Your own copyright statement to Your modifications and may provide additional or different license terms and conditions for use, reproduction, or distribution of Your modifications, or for any such Derivative Works as a whole, provided Your use, reproduction, and distribution of the Work otherwise complies with the conditions stated in this License.

5. Submission of Contributions. Unless You explicitly state otherwise, any Contribution intentionally submitted for inclusion in the Work by You to the Licensor shall be under the terms and conditions of this License, without any additional terms or conditions. Notwithstanding the above, nothing herein shall supersede or modify the terms of any separate license agreement You may have executed with Licensor regarding such Contributions.

6. Trademarks. This License does not grant permission to use the trade names, trademarks, service marks, or product names of the Licensor, except as required for reasonable and customary use in describing the origin of the Work and reproducing the content of the NOTICE file.

7. Disclaimer of Warranty. Unless required by applicable law or agreed to in writing, Licensor provides the Work (and each Contributor provides its Contributions) on an "AS IS" BASIS,
WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied, including, without limitation, any warranties or conditions of TITLE, NON-INFRINGEMENT, MERCHANTABILITY, or FITNESS FOR A PARTICULAR PURPOSE. You are solely responsible for determining the appropriateness of using or redistributing the Work and assume any risks associated with Your exercise of permissions under this License.

8. Limitation of Liability. In no event and under no legal theory, whether in tort (including negligence), contract, or otherwise, unless required by applicable law (such as deliberate and grossly negligent acts) or agreed to in writing, shall any Contributor be liable to You for damages, including any direct, indirect, special, incidental, or consequential damages of any character arising as a result of this License or out of the use or inability to use the Work (including but not limited to damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses), even if such Contributor has been advised of the possibility of such damages.

9. Accepting Warranty or Additional Liability. While redistributing the Work or Derivative Works thereof, You may choose to offer, and charge a fee for, acceptance of support, warranty, indemnity, or other liability obligations and/or rights consistent with this License. However, in accepting such obligations, You may act only on Your own behalf and on Your sole responsibility, not on behalf of any other Contributor, and only if You agree to indemnify, defend, and hold each Contributor harmless for any liability incurred by, or claims asserted against, such Contributor by reason of your accepting any such warranty or additional liability.

END OF TERMS AND CONDITIONS

JSR 110

This program contains third-party code from IBM Corporation ("IBM"). Under the terms of the IBM license, Oracle is required to provide the following notices. Note, however, that the Oracle program license that accompanied this product determines your right to use the Oracle program, including the IBM software, and the terms contained in the following notices do not change those rights. Notwithstanding anything to the contrary in the Oracle program license, the IBM software is provided by Oracle "AS IS" and without warranty or support of any kind from Oracle or IBM.

  adding SOAP faults, 2-12
  MTOM encoded attachments, 2-23, 2-28
  ATTACHMENT_STYLE_PACKAGING property, 2-29
bottom up Web service assembly, 2-25
getDataHandler method, 2-31
MTOM_SUPPORT property, 2-29
PACKAGING_STYLE property, 2-29, 2-34

N
name
  attribute for wsifDbPort argument, 9-16
  attribute for wsifEjbPort argument, 9-11
  attribute for wsifJavaPort argument, 9-5
name attribute, 10-9
namespace mappings
  changing via the JAX-RPC mapping file, F-3
null values and interoperability, 1-13
null values, effects on interoperability, 1-4

O
operation level Web service management, A-3
oracle, 10-4
Oracle HTTP Server
  third party licenses, J-1
Oracle proprietary deployment descriptors, standard
  J2EE deployment descriptors, and J2EE components, 3-14
OracleCall API, 9-30
oracle.j2ee.ws.saaj.soap.MessageImpl class, 2-29
oracle.j2ee.ws.server.provider.ProviderServlet class, 10-5
extending, 10-6
OracleSOAPElement interface, 2-31, 2-35
  accessing binary content, 2-36
  adding binary content, 2-36
oracle-webservices-10_0.xsd schema, 10-4
oracle.webservicesattachments package, 2-18, 2-21
oracle.webservices-client-10_0.xsd schema, 3-7, 9-26
oracle-webservices-client.xml client deployment descriptor
described, B-1
oracle.webservices.OracleCall API, 9-30
oracle.webservices.provider package, 10-1
oracle.webservices.soap.OracleSOAPElement interface, 2-31, 2-35
oracle-webservices.xml provider elements, 10-7
oracle.webservices.xml deployment descriptor, C-1, D-1, E-1
OraSAAJ API
  using with MTOM encoded attachments, 2-35
OUT parameter
  limitations on SQL types, 1-7
OutgoingAttachments interface, 2-19
output attribute, 10-9
overriding support for, 2-28

P
packaging
limitations, I-12
Provider Web Application, 10-12
PACKAGING_STYLE property, 2-29, 2-34
platform native types and interoperability, 1-4
plsqlAssemble command, 9-15, 9-18, 9-19
port level Web service management, A-2
port, attribute for <port> element, A-3
PROPAGATE_DYNAMIC_ENDPOINTS property, 10-11
Provider defined, 10-1
Provider API, 10-1
dynamically adding a managable service endpoint, 10-3
dynamically removing a managable service endpoint, 10-3
HTTPConstants class, 10-5
initializing a provider, 10-2
MessageContext class, 10-5
Provider interface, 10-2
ProviderConfig class, 10-3
removing a Provider instance, 10-3
provider package, 10-1
ProviderServlet class, 10-5
extending, 10-6
proxy Web service client configuring management information dynamically, 3-12

R
REF CURSOR parameter, 1-7
reply-to-destination
JMS message property, 1-7
request attribute, auditing, 6-4, 6-5
request messages auditing, 6-3
logging, 6-7
Resource Representation SOAP Header Block specification, 2-24
response attribute, auditing, 6-4, 6-5
response messages auditing, 6-3
logging, 6-7
RPC-encoded message format and interoperability, 1-4

S
sample audit message, 6-2
sample log record, 6-6

service endpoint interface customizing, F-2
handling swaRef MIME attachments, 2-8
implementing with swaRef MIME attachments, 2-6
SWA attachments, 2-12
service, attribute for <port> element, A-3
Servlet clients, static
configuring management information, 3-15
setDataHandler method, 2-31
SOAP faults
adding to MIME attachments, 2-12
adding to swaRef MIME attachments in the WSDL, 2-14
generating the exception class, 2-13
with swaRef attachments, 2-15
with swaRef attachments on the client, 2-16
SOAP faults with attachments
top down Web service assembly, 2-13
SOAP headers
mapping to Java method parameters, F-5
SOAP Optimized Serialization Use Cases and Requirements specification, 2-24
soapAction attribute
controlling the value in ŽNET, 1-12
controlling the value in OC4J, 1-12
described, 1-11
SOAPAction values and interoperability issues, 1-10
SOAPBuilders community, 1-2
SOAPConnection clients
passing MTOM encoded attachments, 2-34
SOAPConnection objects, 2-34
SOAPElement interface, 2-31, 2-35
sqlAssemble command, 9-15, 9-18, 9-19
standard J2EE deployment descriptors, Oracle proprietary deployment descriptors, and J2EE components, 3-14
static clients configuring management information, 3-14
static proxy Web service client configuring management information dynamically, 3-12
static stub clients passing MTOM encoded attachments, 2-33
streaming attachments, 2-17
APIs, 2-18, 2-20
bottom up Web service assembly, 2-20
implementing an interface, 2-21
limitations, 2-17
sample generated WSDL, 2-21
size recommendations, 2-17
supported format, 2-17
top down Web service assembly, 2-23
writing an interface, 2-21
writing stub code, 2-22
WSDL extensions, 2-19
stub code for streaming attachments, 2-22
SWA attachments, 2-9
sample generated service endpoint interface, 2-12
sample WSDL, 2-10
top down Web service assembly, 2-10
swaRef attachments
  throwing faults with, 2-15
swaRef MIME attachments, 2-2
adding SOAP faults in the WSDL, 2-14
adding to a WSDL, 2-4
assembling a WSDL, 2-8
bottom up Web service assembly, 2-7
implementing a service endpoint interface, 2-6
top down Web service assembly, 2-3
writing service endpoint interfaces for, 2-8
WSDL requirements, 2-4
