This function returns a table of all properties for all path items in all mounts

Syntax

```sql
DBMS_DBFS_CONTENT.LISTALLPROPERTIES
RETURN PROP_ITEMS_T PIPELINED;
```

Return Values

- PROP_ITEMS_T Table Type
LISTALLCONTENT Function

This function lists all path items in all mounts.

Syntax

```sql
DBMS_DBFS_CONTENT.LISTALLCONTENT
  RETURN  PATH_ITEMS_T PIPELINED;
```

Return Values

`PATH_ITEMS_T` Table Type
LISTMOUNTS Function

This function lists all available mount points, their backing stores, and the store features.

Syntax

```
DBMS_DBFS_CONTENT.LISTMOUNTS
RETURN MOUNTS_T PIPELINED;
```

Return Values

MOUNTS_T Table Type

Usage Notes

A single mount results in a single returned row, with its store_mount field of the returned records set to NULL.
LISTSTORES Function

This function lists all available stores and their features.

Syntax

```sql
DBMS_DBFS_CONTENT.LISTSTORES
RETURN STORES_T PIPELINED;
```

Return Values

STORES_T Table Type

Usage Notes

The `store_mount` field of the returned records is set to NULL (since mount-points are separate from stores themselves).
LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

Syntax

```
DBMS_DBFS_CONTENT.LOCKPATH (
    path           IN     VARCHAR2,
    lock_type      IN     INTEGER     DEFAULT LOCK_READ_ONLY,
    lock_data      IN     VARCHAR2    DEFAULT NULL,
    store_name     IN     VARCHAR2    DEFAULT NULL,
    principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>lock_type</td>
<td>One of the available lock types (see DBMS_DBFS_CONTENT Constants - Lock Types)</td>
</tr>
<tr>
<td>lock_data</td>
<td>Optional user data to be associated with the lock</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
MOUNTSTORE Procedure

This procedure mounts a previously registered store and binds it to the mount point.

Syntax

```sql
DBMS_DBFS_CONTENT.MOUNTSTORE (
    store_mount    in      VARCHAR2   DEFAULT NULL,
    singleton      in      BOOLEAN    DEFAULT FALSE,
    principal      in      VARCHAR2   DEFAULT NULL,
    owner          in      VARCHAR2   DEFAULT NULL,
    acl            in      VARCHAR2   DEFAULT NULL,
    asof           in      TIMESTAMP  DEFAULT NULL,
    read_only      in      BOOLEAN    DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_mount</td>
<td>Path name to use to mount this store</td>
</tr>
<tr>
<td>singleton</td>
<td>Whether the mount is a single backend store on the system</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
<tr>
<td>owner</td>
<td>Owner for new elements created (implicitly or explicitly) by the current operation</td>
</tr>
<tr>
<td>acl</td>
<td>ACL for all new elements created (implicitly or explicitly) by the current operation</td>
</tr>
<tr>
<td>asof</td>
<td>The &quot;as of&quot; timestamp at which the underlying read-only operation (or its read-only sub-components) executes</td>
</tr>
<tr>
<td>read_only</td>
<td>Whether the mount is read-only</td>
</tr>
</tbody>
</table>

Usage Notes

- Once mounted, accesses to path names of the form `/store_mount/xyz...` are redirected to `store_name` and its content provider.
- Store mount points must be unique, and a syntactically valid path name component (specifically, a `NAME_T` with no embedded `/`).
- If a mount point is not specified (NULL), the invoked subprogram attempts to use the store name itself as the mount point name (subject to the uniqueness and syntactic constraints).
- A special empty mount point is available for single stores, specifically a scenario where the content interface manages a single backend store - in such cases, the client can directly deal with full path names of the form `/xyz...` since there is no ambiguity in how to redirect these accesses.
- Singleton mount points are indicated by the "singleton" boolean argument, and the `store_mount` argument is ignored.
- The same store can be mounted multiple times, obviously at different mount points.
- Mount properties can be used to specify the execution environment, specifically, the default values of the principal, owner, ACL, and `asof` for a particular mount.
point. Mount properties can also be used to specify a read-only mount. If a flashback mount is specified (through `asof`), it implies a read-only mount.
NORMALIZEPATH Functions

This function converts a store-specific or full-absolute path name into normalized form:

- verifies that the path name is absolute, and so starts with "/"
- collapses multiple consecutive "/" into a single "/"
- strips trailing "/"
- breaks up a store-specific normalized path name into 2 components - parent pathname, trailing component name
- breaks up a full-absolute normalized path name into 3 components - store name, parent pathname, trailing component name

Syntax

**DBMS_DBFS_CONTENT.NORMAIZPATH (**

<table>
<thead>
<tr>
<th>path</th>
<th>IN</th>
<th>VARCHAR2</th>
</tr>
</thead>
<tbody>
<tr>
<td>parent</td>
<td>OUT NOCOPY</td>
<td>VARCHAR2</td>
</tr>
<tr>
<td>tpath</td>
<td>OUT NOCOPY</td>
<td>VARCHAR2</td>
</tr>
</tbody>
</table>

RETURN VARCHAR2;

**DBMS_DBFS_CONTENT.NORMAIZPATH (**

<table>
<thead>
<tr>
<th>path</th>
<th>IN</th>
<th>VARCHAR2</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>OUT NOCOPY</td>
<td>VARCHAR2</td>
</tr>
<tr>
<td>parent</td>
<td>OUT NOCOPY</td>
<td>VARCHAR2</td>
</tr>
<tr>
<td>tpath</td>
<td>OUT NOCOPY</td>
<td>VARCHAR2</td>
</tr>
</tbody>
</table>

RETURN VARCHAR2;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>parent</td>
<td>Parent path name</td>
</tr>
<tr>
<td>tpath</td>
<td>Name of trailing path item</td>
</tr>
</tbody>
</table>

Return Values

The completely normalized store-specific or full-absolute path name
PROPANY Functions

This function provides constructors that take one of a variety of types and return a PROPERTY_T.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPANY (val IN NUMBER) RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (val IN VARCHAR2) RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (val IN TIMESTAMP) RETURN PROPERTY_T;

DBMS_DBFS_CONTENT.PROPANY (val IN RAW) RETURN PROPERTY_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Value</td>
</tr>
</tbody>
</table>

Return Values

PROPERTY_T Record Type
PROPERTIESH2T Function

This function converts a PROPERTY_T hash to a DBMS_DBFS_CONTENT_PROPERTIES_T table.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPERTIEST2H (
    pprops      IN      PROPERTIES_T)
RETURN DBMS_DBFSCONTENT_PROPERTIES_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pprops</td>
<td>A PROPERTIES_T hash</td>
</tr>
</tbody>
</table>

Return Values

DBMS_DBFSCONTENT_PROPERTIES_T Table Type
PROPERTIEST2H Function

This function converts a DBMS_DBFS_CONTENT_PROPERTIES_T table to a PROPERTY_T hash.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPERTIEST2H (
   sprops      IN      DBMS_DBFS_CONTENT_PROPERTIES_T)
RETURN properties_t;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sprops</td>
<td>A DBMS_DBFS_CONTENT_PROPERTIES_T table</td>
</tr>
</tbody>
</table>

Return Values

PROPERTIES_T Table Type
**PROPNUMBER Function**

This function is a constructor that takes a number and returns a `PROPERTY_T`.

**Syntax**

```sql
DBMS_DBFS_CONTENT.PROPNUMBER (
   val      IN      NUMBER)
RETURN PROPERTY_T;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Value</td>
</tr>
</tbody>
</table>

**Return Values**

`PROPERTY_T` Record Type
PROPRAW Function

This function is a constructor that takes a RAW and returns a PROPERTY_T.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPRAW (
    val IN RAW)
RETURN PROPERTY_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Value</td>
</tr>
</tbody>
</table>

Return Values

PROPERTY_T Record Type
PROPTIMESTAMP Function

This function is a constructor that takes a TIMESTAMP and returns a PROPERTY_T.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPTIMESTAMP (
    val    IN    TIMESTAMP)
RETURN PROPERTY_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Value</td>
</tr>
</tbody>
</table>

Return Values

PROPERTY_T Record Type
PROPVARCHAR2 Function

This function is a constructor that takes a VARCHAR2 and returns a PROPERTY_T.

Syntax

```sql
DBMS_DBFS_CONTENT.PROPVARCHAR2 (
    val      IN      VARCHAR2)
RETURN PROPERTY_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Value</td>
</tr>
</tbody>
</table>

Return Values

PROPERTY_T Record Type
PURGEALL Procedure

This procedure purges all soft-deleted entries matching the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT.PURGEALL (  
  path           IN      VARCHAR2,
  filter         IN      VARCHAR2    DEFAULT NULL,
  store_name     IN      VARCHAR2    DEFAULT NULL,
  principal      IN      VARCHAR2    DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied based on specified criteria</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
PURGEPATH Procedure

This procedure purges any soft-deleted versions of the given path item.

Syntax

```sql
DBMS_DBFS_CONTENT.PURGEPATH (  
    path           IN      VARCHAR2,  
    filter         IN      VARCHAR2    DEFAULT NULL,  
    store_name     IN      VARCHAR2    DEFAULT NULL,  
    principal      IN      VARCHAR2    DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>

47-90 Oracle Database PL/SQL Packages and Types Reference
PUTPATH Procedures

This procedure creates a new path item.

Syntax

```
DBMS_DBFS_CONTENT.PUTPATH {
    path INVARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    content IN OUT NOCOPY BLOB,
    item_type OUT INTEGER,
    prop_flags IN INTEGER DEFAULT (PROP_STD +
                                PROP_OPT +
                                PROP_DATA),
    store_name IN VARCHAR2 DEFAULT NULL,
    principal IN VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH {
    path INVARCHAR2,
    properties IN OUT NOCOPY PROPERTIES_T,
    content IN OUT NOCOPY BLOB,
    item_type OUT INTEGER,
    prop_flags IN INTEGER DEFAULT (PROP_STD +
                                PROP_OPT +
                                PROP_DATA),
    store_name IN VARCHAR2 DEFAULT NULL,
    principal IN VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH {
    path IN VARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    amount IN NUMBER,
    offset IN NUMBER,
    buffer IN RAW,
    prop_flags IN INTEGER DEFAULT (PROP_STD +
                                PROP_OPT),
    store_name IN VARCHAR2 DEFAULT NULL,
    principal IN VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH {
    path IN VARCHAR2,
    properties IN OUT NOCOPY PROPERTIES_T,
    amount IN NUMBER,
    offset IN NUMBER,
    buffer IN RAW,
    prop_flags IN INTEGER DEFAULT (PROP_STD +
                                PROP_OPT),
    store_name IN VARCHAR2 DEFAULT NULL,
    principal IN VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH {
    path IN VARCHAR2,
    properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,
    written OUT NUMBER,
    offset IN NUMBER,
    buffers IN DBMS_DBFS_CONTENT_RAW_T,
    prop_flags IN INTEGER DEFAULT (PROP_STD +
                                PROP_OPT),
    store_name IN VARCHAR2 DEFAULT NULL,
```
principal IN VARCHAR2 DEFAULT NULL);

DBMS_DBFS_CONTENT.PUTPATH (  
  path IN VARCHAR2,  
  properties IN OUT NOCOPY PROPERTIES_T,  
  written OUT NUMBER,  
  offset IN NUMBER,  
  buffers IN DBMS_DBFS_CONTENT_RAW_T,  
  prop_flags IN INTEGER DEFAULT (PROP_STD +  
       PROP_OPT),  
  store_name IN VARCHAR2 DEFAULT NULL,  
  principal IN VARCHAR2 DEFAULT NULL);

Parameters

Table 47–59  PUTPATH Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>content</td>
<td>BLOB holding data which populates the file (optional)</td>
</tr>
<tr>
<td>item_type</td>
<td>Type of the path item specified (see DBMS_DBFS_CONTENT Constants - Path Name Types)</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes to be read</td>
</tr>
<tr>
<td>offset</td>
<td>Byte offset from which to begin reading</td>
</tr>
<tr>
<td>buffer</td>
<td>Buffer to which to write</td>
</tr>
<tr>
<td>buffers</td>
<td>Buffers to which to write</td>
</tr>
<tr>
<td>prop_flags</td>
<td>Determines which properties are set. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
REGISTERSTORE Procedure

This procedure registers a new store backed by a provider that uses a store service provider (conforming to the DBMS_DBFS_CONTENT_SPI package signature). This method is to be used primarily by service providers after they have created a new store.

Syntax

```
DBMS_DBFS_CONTENT.REGISTERSTORE(
    store_name          IN      VARCHAR2,
    provider_name       IN      VARCHAR2,
    provider_package    IN      VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store, must be unique</td>
</tr>
<tr>
<td>provider_name</td>
<td>Name of provider</td>
</tr>
<tr>
<td>provider_package</td>
<td>Store service provider</td>
</tr>
</tbody>
</table>
RENAMEPATH Procedures

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

---

**Note:** See “Rename and Move Operations” on page 47-21

---

**Syntax**

```sql
DBMS_DBFS_CONTENT.RENAMEPATH (  
  oldPath     IN              VARCHAR2,  
  newPath     IN              VARCHAR2,  
  properties  IN OUT NOCOPY   DBMS_DBFS_CONTENT_PROPERTIES_T,  
  store_name  IN              VARCHAR2    DEFAULT NULL,  
  principal   IN              VARCHAR2    DEFAULT NULL);
```

- **oldPath** is the name of the path prior to renaming.
- **newPath** is the name of the path after renaming.
- **properties** is one or more properties and their values to be set depending on **prop_flags** (see `DBMS_DBFS_CONTENT_PROPERTIES_T` Table Type).
- **store_name** is the name of the store, which must be unique.
- **principal** is the agent (principal) invoking the current operation.

---

**Parameters**

**Table 47–61**  
**RENAMEPATH Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oldPath</td>
<td>Name of path prior to renaming</td>
</tr>
<tr>
<td>newPath</td>
<td>Name of path after renaming</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set depending on prop_flags (see <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> Table Type)</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store, must be unique</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT.RESTOREALL (
    path        IN      VARCHAR2,
    filter      IN      VARCHAR2 DEFAULT NULL,
    store_name  IN      VARCHAR2 DEFAULT NULL,
    principal   IN      VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

Syntax

```sql
DBMS_DBFS_CONTENT.RESTOREPATH (  
  path           IN      VARCHAR2,  
  filter         IN      VARCHAR2    DEFAULT NULL,  
  store_name     IN      VARCHAR2    DEFAULT NULL,  
  principal      IN      VARCHAR2    DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>

SEARCH Function

This function...

Syntax

```sql
DBMS_DBFS_CONTENT.SEARCH (  
    path           IN      VARCHAR2,  
    filter         IN      VARCHAR2    DEFAULT NULL,  
    recurse        IN      INTEGER     DEFAULT 0,  
    asof           IN      TIMESTAMP   DEFAULT NULL,  
    store_name     IN      VARCHAR2    DEFAULT NULL,  
    principal      IN      VARCHAR2    DEFAULT NULL)  
RETURN  DBMS_DBFS_CONTENT_LIST_ITEMS_T PIPELINED;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>recurse</td>
<td>If 0, do not execute recursively. Otherwise, recursively search the contents of directories and files below the given directory.</td>
</tr>
<tr>
<td>asof</td>
<td>The &quot;as of&quot; timestamp at which the underlying read-only operation (or its read-only sub-components) executes</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>

Return Values

`DBMS_DBFS_CONTENT_LIST_ITEMS_T`
SETDEFAULTACL Procedure

This procedure sets the ACL parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

DBMS_DBFS_CONTENT.SETDEFAULTACL ( acl IN VARCHAR2);

Parameters

Table 47–65  SETDEFAULTACL Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>ACL for all new elements created (implicitly or explicitly) by the current operation</td>
</tr>
</tbody>
</table>

Usage Notes

- NULL by default, this parameter be can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.
SETDEFAULTASOF Procedure

This procedure sets the "as of" parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```sql
DBMS_DBFS_CONTENT.SETDEFAULTASOF (  
    asof    IN     TIMESTAMP);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asof</td>
<td>The &quot;as of&quot; timestamp at which the underlying read-only operation (or its read-only sub-components) executes</td>
</tr>
</tbody>
</table>

Usage Notes

- **NULL** by default, this parameter be can be cleared by setting it to **NULL**.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.
SETDEFAULTCONTEXT Procedure

This procedure sets the default context. The information contained in the context can be inserted explicitly by way of arguments to the various method calls, allowing for fine-grained control over individual operations.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTCONTEXT (
  principal    IN     VARCHAR2,
  owner        IN     VARCHAR2,
  acl          IN     VARCHAR2,
  asof         IN     TIMESTAMP);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
<tr>
<td>owner</td>
<td>Owner for new elements created (implicitly or explicitly) by the current operation</td>
</tr>
<tr>
<td>acl</td>
<td>ACL for all new elements created (implicitly or explicitly) by the current operation</td>
</tr>
<tr>
<td>asof</td>
<td>The &quot;as of&quot; timestamp at which the underlying read-only operation (or its read-only sub-components) executes</td>
</tr>
</tbody>
</table>

Usage Notes

- All of the context parameters are `NULL` by default, and be can be cleared by setting them to `NULL`.
- The context parameters, once set, remain as defaults for the duration of the session, and are inherited by all operations for which the defaults are not explicitly overridden.
SETDEFAULTOWNER Procedure

This procedure sets the “owner” parameter of the default context. This information can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```
DBMS_DBFS_CONTENT.SETDEFAULTOWNER (principal IN VARCHAR2);
```

Parameters

Table 47–68  SETDEFAULTOWNER Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>Owner for new elements created (implicitly or explicitly) by the current operation</td>
</tr>
</tbody>
</table>

Usage Notes

- NULL by default, this parameter be can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.
SETDEFAULTPRINCIPAL Procedure

This procedure sets the "principal" parameter of the default context. This information contained can be inserted explicitly by way of argument into other method calls, allowing for a more fine-grained control.

Syntax

```sql
DBMS_DBFS_CONTENT.SETDEFAULTPRINCIPAL (principal IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>

Usage Notes

- NULL by default, this parameter can be cleared by setting it to NULL.
- The parameters, once set, remain as a default for the duration of the session, and is inherited by all operations for which the default is not explicitly overridden.
SETPATH Procedures

This procedure assigns a path name to a path item represented by contentID. Stores and their providers that support contentID-based access and lazy path name binding also support the SETPATH Procedure that associates an existing contentID with a new path.

Note: See "Rename and Move Operations" on page 47-21

Syntax

```
DBMS_DBFS_CONTENT.SETPATH (  
  store_name IN VARCHAR2,  
  contentID IN RAW,  
  path IN VARCHAR2,  
  properties IN OUT NOCOPY DBMS_DBFS_CONTENT_PROPERTIES_T,  
  principal IN VARCHAR2 DEFAULT NULL);
```

```
DBMS_DBFS_CONTENT.SETPATH (  
  store_name IN VARCHAR2,  
  contentID IN RAW,  
  path IN VARCHAR2,  
  properties IN OUT NOCOPY PROPERTIES_T,  
  principal IN VARCHAR2 DEFAULT NULL);
```

Parameters

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of the store</td>
</tr>
<tr>
<td>contentID</td>
<td>Unique identifier for the item to be associated</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path item</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
```
SETSTATS Procedure

This procedure enables and disables statistics collection. The client can optionally control the flush settings by specifying non-NULL values for the time, count or both parameters.

Syntax

```sql
DBMS_DBFS_CONTENT.SETSTATS (
    enable          IN    BOOLEAN,
    flush_time      IN    INTEGER,
    flush_count     IN    INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>enable</td>
<td>If TRUE, enable statistics collection. If FALSE, disable statistics collection.</td>
</tr>
<tr>
<td>flush_time</td>
<td>How often to flush the statistics to disk in centiseconds</td>
</tr>
<tr>
<td>flush_count</td>
<td>Number of operations to allow between statistics flushes</td>
</tr>
</tbody>
</table>

Usage Notes

The SETSTATS Procedure buffers statistics in-memory for a maximum of flush_time centiseconds or a maximum of flush_count operations (whichever limit is reached first), or both, at which time the buffers are implicitly flushed to disk.
SETTRACE Procedure

This procedure sets the DBMS_DBFS_CONTENT tracing severity to the given level, 0 being "off".

Syntax

```sql
DBMS_DBFS_CONTENT.SETTRACE(trclvl IN INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trclvl</td>
<td>Level of the tracing, higher values implying more tracing</td>
</tr>
</tbody>
</table>
SPACEUSAGE Procedure

This procedure queries file system space usage statistics. Providers are expected to support this subprogram for their stores (and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on).

Syntax

```sql
DBMS_DBFS_CONTENT.SPACEUSAGE (  
    path IN VARCHAR2,  
    blksize OUT INTEGER,  
    tbytes OUT INTEGER,  
    fbytes OUT INTEGER,  
    nfile OUT INTEGER,  
    ndir OUT INTEGER,  
    nlink OUT INTEGER,  
    nref OUT INTEGER,  
    store_name IN VARCHAR2 DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>blksize</td>
<td>Natural tablespace blocksize that holds the store. If multiple tablespaces with different blocksizes are used, any valid blocksize is acceptable.</td>
</tr>
<tr>
<td>tbytes</td>
<td>Total size of the store in bytes computed over all segments that comprise the store</td>
</tr>
<tr>
<td>fbytes</td>
<td>Free or unused size of the store in bytes computed over all segments that comprise the store</td>
</tr>
<tr>
<td>nfile</td>
<td>Number of currently available files in the store</td>
</tr>
<tr>
<td>ndir</td>
<td>Number of currently available directories in the store</td>
</tr>
<tr>
<td>nlink</td>
<td>Number of currently available links in the store</td>
</tr>
<tr>
<td>nref</td>
<td>Number of currently available references in the store</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.
TRACE Procedure

This procedure outputs tracing to the current foreground trace file.

Syntax

```sql
DBMS_DBFS_CONTENT.TRACE
sev         IN              INTEGER,
msg0        IN              VARCHAR2,
msg1        IN              VARCHAR DEFAULT ' ',
msg2        IN              VARCHAR DEFAULT ' ',
msg3        IN              VARCHAR DEFAULT ' ',
msg4        IN              VARCHAR DEFAULT ' ',
msg5        IN              VARCHAR DEFAULT ' ',
msg6        IN              VARCHAR DEFAULT ' ',
msg7        IN              VARCHAR DEFAULT ' ',
msg8        IN              VARCHAR DEFAULT ' ',
msg9        IN              VARCHAR DEFAULT ' ',
msg10       IN              VARCHAR DEFAULT ''
);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sev</td>
<td>Severity at which trace message is output</td>
</tr>
<tr>
<td>msg*</td>
<td>One or more message strings to be output. If more than one message is specified, all are output.</td>
</tr>
</tbody>
</table>

Usage Notes

- Trace information is written to the foreground trace file, with varying levels of detail as specified by the trace level arguments.
- The global trace level consists of 2 components: "severity" and "detail". These can be thought of as additive bitmasks.

  The "severity" allows the separation of top level as compared to low-level tracing of different components, and allows the amount of tracing to be increased as needed. There are no semantics associated with different levels, and users are free to set trace at any severity they choose, although a good rule of thumb would use severity "1" for top level API entry and exit traces, "2" for internal operations, and "3" or greater for very low-level traces.

  The "detail" controls how much additional information: timestamps, short-stack, etc. is dumped along with each trace record.
TRACEENABLED Function

This function determines if the current trace "severity" set by the SETTRACE Procedure is at least as high as the given trace level.

Syntax

```sql
DBMS_DBPS_CONTENT.TRACEENABLED(
  sev        IN              INTEGER)
RETURN  INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sev</td>
<td>Severity at which trace message is output</td>
</tr>
</tbody>
</table>

Return Values

Returns 0 if the requested severity level is lower than the currently set trace severity level; 1 otherwise.
UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

Syntax

```
DBMS_DBFS_CONTENT.UNLOCKPATH (  
    path           IN     VARCHAR2,  
    store_name     IN     VARCHAR2    DEFAULT NULL,  
    principal      IN     VARCHAR2    DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>principal</td>
<td>Agent (principal) invoking the current operation</td>
</tr>
</tbody>
</table>
UNMOUNTSTORE Procedure

This procedure unmounts a registered store, either by name or by mount point.

Syntax

```sql
DBMS_DBFS_CONTENT.UNMOUNTSTORE (  
    store_name       IN      VARCHAR2   DEFAULT NULL,  
    store_mount      IN      VARCHAR2   DEFAULT NULL,  
    ignore_unknown   IN      BOOLEAN    DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>store_mount</td>
<td>Location at which the store instance is mounted</td>
</tr>
<tr>
<td>ignore_unknown</td>
<td>If TRUE, attempts to unregister unknown stores will not raise an exception.</td>
</tr>
</tbody>
</table>

Usage Notes

- Single stores can be unmounted only by store name (since they have no mount-points).
- Attempting to unmount a store by name unmounts all mount points associated with the store.
- Once unmounted all access to the store (or mount point) are not guaranteed to work.
- If the `ignore_unknown` argument is TRUE, attempts to unregister unknown stores or mounts do not raise an exception.
UNREGISTERSTORE Procedure

This procedure unregisters a previously registered store (invalidating all mount points associated with it).

Syntax

```sql
DBMS_DBFS_CONTENT.UNREGISTERSTORE (  
    store_name          IN      VARCHAR2,  
    ignore_unknown      IN      BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>ignore_unknown</td>
<td>If TRUE, attempts to unregister unknown stores will not raise an exception.</td>
</tr>
</tbody>
</table>

Usage Notes

- Once unregistered all access to the store (and its mount points) are not guaranteed to work
- If the `ignore_unknown` argument is TRUE, attempts to unregister unknown stores do not raise an exception.
UNREGISTERSTORE Procedure
The `DBMS_DBFS_CONTENT_SPI` package provides the Application Programming Interface (API) specification for `DBMS_DBFS_CONTENT` service providers. Application designers can create PL/SQL packages conforming to this API to extend `DBMS_CONTENT` to utilize custom service providers.

- Summary of `DBMS_DBFS_CONTENT_SPI` Subprograms
Using DBMS_DBFS_CONTENT_SPI

- Overview
- Security Model
- Operational Notes
Overview

The DBMS_DBFS_CONTENT_SPI package describes an internal contract between the implementation of the DBMS_DBFS_CONTENT interface and individual service providers, and whichever package contains their code.

Since PL/SQL does not allow a compile-time, declarative type-conformance between package signatures, store providers should informally conform to the SPI, which is to say, they should implement the SPI by means of a package that contains all of the methods specified in package DBMS_DBFS_CONTENT_SPI, with the same method signatures and semantics.

Obviously, these provider packages can implement other methods and expose other interfaces, however, these interfaces are not to be used by the DBMS_CONTENT interface itself.

Since the provider SPI is merely a contract specification, there is no package body for DBMS_DBFS_CONTENT_SPI, and it is not possible to actually invoke any methods using this package.

The SPI references various elements (constants, types, exceptions) defined by the DBMS_CONTENT interface.

Additionally, there is an almost one-to-one correspondence between the client API exported by the DBMS_CONTENT interface and the provider interface that the DBMS_CONTENT interface itself expects to work against.

The main distinction in the method naming conventions is that all path name references are always store-qualified. That is, the notion of mount-points and full-absolute path names have been normalized and converted to store-qualified path names by the DBMS_CONTENT interface before it invokes any of the provider SPI methods.

Since the interconnection of the DBMS_DBFS_CONTENT interface and the provider SPI is a 1-to-many pluggable architecture, and the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.
Security Model

Implementations of the `DBMS_DBFS_CONTENT_SPI` package should be created as `AUTHID CURRENT_USER`. 
Operational Notes

- Implementation
- Path Names
- Creation Operations
- Deletion Operations
- Get (Retrieve) and Put (Insert) Operations
- Rename and Move Operations
- Directory Navigation and Search
- Locking Operations
- Access Check Operation

Implementation

Since the interconnection of the DBMS_DBFS_CONTENT interface and the provider SPI is a 1-to-many pluggable architecture, the interface uses dynamic SQL to invoke methods in the provider SPI, this can lead to runtime errors.

There are no explicit INIT or FINI methods to indicate when the DBMS_DBFS_CONTENT interface plugs or unplugs a particular provider SPI. Provider SPIs must be willing to auto-initialize themselves at any SPI entry-point.

All operations performed by a service provider are "stateless" in that they are complete operations unto themselves. If state is necessary to be maintained for some reason, then the state must be maintained in data structures such as auxiliary tables that can be queried as needed.

Path Names

All path names used in the provider SPI are store-qualified in pair form (store_name, pathname) where the path name is rooted within the store namespace.

Stores and their providers that support contentID-based access (see FEATURE_CONTENT_ID in DBMS_DBFS_CONTENT Constants - Store Features) also support a form of addressing that is not based on path names. Content items are identified by an explicit store name, a NULL path name, and possibly a contentID specified as a parameter or by way of the OPT_CONTENT_ID (see DBMS_DBFS_CONTENT Constants - Optional Properties) property.

Not all operations are supported with contentID-based access, and applications should depend only on the simplest create or delete functionality being available.

Creation Operations

The provider SPI must allow the DBFS content API to create directory, file, link, and reference elements subject to store feature support.

All of the creation subprograms require a valid path name, but note the special exemption for contentID-based access. Creation subprograms can optionally specify properties to be associated with the path name as it is created. It is also possible for clients to returns item properties after the creation completes so that automatically generated properties, such as STD_CREATION_TIME (see DBMS_DBFS_CONTENT Constants - Standard Properties) are immediately available to clients. The exact set of properties fetched back is controlled by the various PROP_XXX bitmasks in the prop_flags parameter.
Links and references require an additional path name to associate with the primary path name.

File path names can optionally specify a BLOB value to use to initially populate the underlying file content (the provided BLOB may be any valid LOB). On creation, the underlying LOB is returned to the client, provided that PROP_DATA is specified in the prop_flags parameter.

Non-directory path names require that their parent directory be created first. Directory path names themselves can be recursively created with the path name hierarchy leading up to a directory created in one call.

Attempts to create paths that already exist is an error; the sole exception is path names that are “soft-deleted” (as discussed in the context of Deletion Operations) In these cases, the soft-deleted item is implicitly purged, and the new item creation is attempted.

Stores and their providers that support contentID-based access accept an explicit store name and a NULL path to create a new content element. The contentID generated for this element is available by means of the OPT_CONTENT_ID property (see DBMS_DBFS_CONTENT Constants - Optional Properties), contentID-based creation being automatically implied by PROP_OPT property in the prop_flags parameter).

The newly created element may also have an internally generated path name if FEATURE_LAZY_PATH property is not supported (see DBMS_DBFS_CONTENT Constants - Store Features) and this path is available by way of the STD_CANONICAL_PATH property (see DBMS_DBFS_CONTENT Constants - Standard Properties).

Only file elements are candidates for contentID-based access.

Deletion Operations

The provider SPI must allow the DBFS content API to delete directory, file, link, and reference elements (subject to store feature support).

By default, the deletions are permanent, removing the successfully deleted items on transaction commit, but stores may also support “soft-delete” features. If requested by the client, soft-deleted items are retained by the store, although they are not typically visible in normal listings or searches.

Soft-deleted items can be restored, or explicitly purged.

Directory path names can be recursively deleted, with the path name hierarchy below a directory deleted in one call. Non-recursive deletions can be performed only on empty directories. Recursive soft-deletions apply the soft-delete to all of the items being deleted.

Individual path names, as well as all soft-deleted path names under a directory, can be restored or purged by means of the various restore and purge subprograms.

Providers that support filtering can use the provider filter to identify subsets of items to delete. This makes most sense for bulk operations such as the DELETEDIRECTORY Procedure, PURGEALL Procedure, and RESTOREALL Procedure, but all of the deletion-related operations accept a filter argument.

Stores and their providers that support contentID-based access can also allow file items to be deleted by specifying their contentID.

Get (Retrieve) and Put (Insert) Operations

Existing path items can be accessed (for query or for update) and modified using simple get and put subprograms. All path names allow their metadata (properties) to
be read and modified. On completion of the call, the client can request specific properties to be fetched by means of the prop_flags parameter.

File path names allow their data (content) to be read and modified. On completion of the call, the client can use the PROP_DATA bitmasks in the prop_flags parameter to request a new BLOB locator to continue data access.

Files can also be read or written without using BLOB locators by explicitly specifying logical offsets or buffer-amounts and a suitably sized buffer.

Update accesses must specify the forUpdate flag. Access to link path names can be implicitly and internally de-referenced by stores (subject to feature support) if the deref flag is specified, however, this may have undetermined outcomes since symbolic links are not always resolvable.

The read methods, such as the GETPATH Procedures where forUpdate is specified as 0, also accepts a valid asof timestamp in the ctx parameter that can be used by stores to implement "as of" style flashback queries. Mutating versions of the GETPATH Procedures and the PUTPATH Procedures methods do not support "as of" modes of operation.

The GETPATHNOWAIT Procedure implies that the operation is for an update, and, if implemented (see FEATURE_NOWAIT in DBMS_DBFS_CONTENT Constants - Store Features), this allows providers to return an exception (ORA-00054) rather than wait for row locks.

**Rename and Move Operations**

Path names can be renamed or moved, possibly across directory hierarchies and mount-points, but within the same store.

Non-directory path names previously accessible by way of specifying the oldPath parameter are renamed as a single item subsequently accessible by specifying newPath, assuming that newPath does not already exist.

If newPath exists and is not a directory, the action of renaming implicitly deletes the existing item before renaming oldPath. If the newPath exists and is a directory, oldPath is moved into the target directory.

Directory path names previously accessible by way of oldPath are renamed by moving the directory and all of its children to newPath (if it does not already exist) or as children of newPath (if it exists and is a directory).

Stores and their providers that support contentID-based access and lazy path name binding also support the SETPATH Procedure that associates an existing contentID with a new "path".

**Directory Navigation and Search**

The DBMS_CONTENT interface can list or search the contents of directory path names, with the option of doing so recursively into sub-directories, optionally seeing soft-deleted items, optionally using flashback "as of" a provided timestamp, and optionally filtering items in or out within the store based on list or search predicates.

**Locking Operations**

Clients of the DBMS_CONTENT interface can apply user-level locks to any valid path name (subject to store feature support), associate the lock with user-data, and subsequently unlock these path names.

The status of locked items is available using various optional properties (note the previous discussion regarding opt_lock).
It is the responsibility of the store (assuming it supports user-defined lock checking) to ensure that lock and unlock operations are performed in a consistent manner.

**Access Check Operation**

This operation ascertains if a given path name (store_name, path, pathtype) can be manipulated by operation (see the various DBMS_CONTENT.OP_XXX opcodes in DBMS_DBFS_CONTENT Constants - Optional Properties) by the user acting on the store utilizing the principal parameter. This is a convenience function for the DBMS_CONTENT interface; a store that supports access control still internally performs these checks to guarantee security.
## Summary of DBMS_DBFS_CONTENT_SPI Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>

</tbody>
</table>
CHECKACCESS Function

This function reports if the user (principal) can perform the specified operation on the given path. This enables verifying the validity of an operation without attempting to perform the operation. If CHECKACCESS returns 0, then the subprogram invoked to implement that operation should fail with an error.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.CHECKACCESS (    store_name IN VARCHAR2 DEFAULT NULL,    path IN VARCHAR2,    pathtype IN INTEGER,    operation IN VARCHAR2,    principal IN VARCHAR2)    RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to check for access</td>
</tr>
<tr>
<td>pathtype</td>
<td>Type of object path represents (see DBMS_DBFS_CONTENT Constants - Path Name Types)</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to be checked (see DBMS_DBFS_CONTENT Constants - Optional Properties)</td>
</tr>
<tr>
<td>principal</td>
<td>File system user for whom the access check is made</td>
</tr>
</tbody>
</table>

Usage Notes

Whether or not the user invokes this function, a store that supports access control internally performs these checks to guarantee security.
CREATEDIRECTORY Procedure

This procedure creates a directory.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.CREATEDIRECTORY (  
  store_name  IN              VARCHAR2,
  path        IN              VARCHAR2,
  properties  IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
  prop_flags  IN              INTEGER,
  recurse     IN              INTEGER,
  ctx         IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to the directory</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set, returned, or both, depending on <code>prop_flags</code> (see <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> Table Type)</td>
</tr>
<tr>
<td>prop_flags</td>
<td>Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting PROP_SPC (see <code>DBMS_DBFS_CONTENT_CONSTANTS - Property Access Flags</code>), and providing an instance of the <code>DBMS_DBFS_CONTENT_PROPERTIES_T</code> Table Type with properties whose values are of interest.</td>
</tr>
<tr>
<td>recurse</td>
<td>If 0, do not execute recursively; otherwise, recursively create the directories above the given directory</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to create the directory (see <code>DBMS_DBFS_CONTENT_CONTEXT_T</code> Object Type)</td>
</tr>
</tbody>
</table>
CREATEFILE Procedure

This procedure creates a file.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.CREATEFILE (
    store_name    IN              VARCHAR2,
    path          IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    content       IN OUT NOCOPY   BLOB,
    prop_flags    IN              INTEGER,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

### Table 48–4 CREATEFILE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to the file</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set, returned or both depending, or both on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>content</td>
<td>BLOB holding data with which to populate the file (optional)</td>
</tr>
<tr>
<td>prop_flags</td>
<td>Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to create the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
CREATELINK Procedure

This procedure creates a physical link to an already existing file system element (such as file or directory). The resulting entry shares the same metadata structures as the value of the srcPath parameter, and so is similar to incrementing a reference count on the file system element. This is analogous to a UNIX file system hard link.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.CREATELINK (
    store_name    IN              VARCHAR2,
    srcPath       IN              VARCHAR2,
    dstPath       IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    prop_flags    IN              INTEGER,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>srcPath</td>
<td>File system entry with which to link</td>
</tr>
<tr>
<td>dstPath</td>
<td>Path of the new link element to be created</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>prop_flags</td>

</tbody>
</table>
CREATEREFERENCE Procedure

This procedure creates a new reference to the source file system element (such as a file, or directory). The resulting reference points to the source element but does not directly share metadata with the source element. This is analogous to a UNIX file system symbolic link.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.CREATEREFERENCE (  
    srcPath       IN              VARCHAR2,  
    dstPath       IN              VARCHAR2,  
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,  
    prop_flags    IN              INTEGER,  
    store_name    IN              VARCHAR2,  
    ctx           IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>srcPath</td>
<td>File system entry with which to link</td>
</tr>
<tr>
<td>dstPath</td>
<td>Path of the new link element to be created</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set, returned, or both, depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>prop_flags</td>
<td>Determines which properties are set, returned, or both. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to create the reference (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
DELETECONTENT Procedure

This procedure deletes the file specified by the given contentID.

Syntax

DBMS_DBFS_CONTENT_SPI.DELETECONTENT (  
  store_name IN VARCHAR2,  
  contentID IN RAW,  
  filter IN VARCHAR2,  
  soft_delete IN INTEGER,  
  ctx IN DBMS_CONTENT_CONTEXT_T);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>contentID</td>
<td>Unique identifier for the file to be deleted</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>soft_delete</td>
<td>If 0, execute a hard (permanent) delete. For any value other than 0, perform</td>
</tr>
<tr>
<td></td>
<td>a soft delete (see &quot;Deletion Operations&quot; on page 48-6).</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to delete the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
DELETEDIRECTORY Procedure

This procedure deletes a directory. If `recurse` is nonzero, it recursively deletes all elements of the directory. A filter, if supplied, determines which elements of the directory are deleted.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.DELETEDIRECTORY (
    store_name IN VARCHAR2,
    path     IN VARCHAR2,
    filter   IN VARCHAR2,
    soft_delete IN INTEGER,
    recurse  IN INTEGER,
    ctx      IN DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>store_name</code></td>
<td>Name of store</td>
</tr>
<tr>
<td><code>path</code></td>
<td>Name of path to the directory</td>
</tr>
<tr>
<td><code>filter</code></td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td><code>soft_delete</code></td>
<td>If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see “Deletion Operations” on page 48-6).</td>
</tr>
<tr>
<td><code>recurse</code></td>
<td>If 0, do not execute recursively. Otherwise, recursively delete the directories and files below the given directory.</td>
</tr>
<tr>
<td><code>ctx</code></td>
<td>Context with which to delete the directory (see <code>DBMS_DBFS_CONTENT_CONTEXT_T Object Type</code>)</td>
</tr>
</tbody>
</table>
DELETEFILE Procedure

This procedure deletes the specified file.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.DELETEFILE (  
    store_name     IN     VARCHAR2,  
    path           IN     VARCHAR2,  
    filter         IN     VARCHAR2,  
    soft_delete    IN     BOOLEAN,  
    ctx            IN     DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to the file</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>soft_delete</td>
<td>If 0, execute a hard (permanent) delete. For any value other than 0, perform a soft delete (see &quot;Deletion Operations&quot; on page 48-6).</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to delete the file (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
GETFEATURES Function

This function returns the features of a store.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.GETFEATURES (   store_name IN VARCHAR2)   RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Return Values

DBMS_CONTENT.FEATURE_* features supported by the Service Provider
GETPATH Procedures

This procedure returns existing path items (such as files and directories). This includes both data and metadata (properties).

The client can request (using `prop_flags`) that specific properties be returned. File path names can be read either by specifying a BLOB locator using the `prop_data` bitmask in `prop_flags` (see DBMS_DBFS_CONTENT Constants - Property Access Flags) or by passing one or more RAW buffers.

When `forUpdate` is 0, this procedure also accepts a valid "as of" timestamp parameter as part of `ctx` that can be used by stores to implement "as of" style flashback queries. Mutating versions of the GETPATH Procedures do not support these modes of operation.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name  IN              VARCHAR2,
    path        IN              VARCHAR2,
    properties  IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    content     OUT    NOCOPY   BLOB,
    item_type   OUT             INTEGER,
    prop_flags  IN              INTEGER,
    forUpdate   IN              INTEGER,
    deref       IN              INTEGER,
    ctx         IN              DBMS_CONTENT_CONTEXT_T);
```

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name  IN              VARCHAR2,
    path        IN              VARCHAR2,
    properties  IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    amount      IN OUT          NUMBER,
    offset      IN              NUMBER,
    buffer      OUT    NOCOPY   RAW,
    prop_flags  IN              INTEGER,
    ctx         IN              DBMS_CONTENT_CONTEXT_T);
```

```
DBMS_DBFS_CONTENT_SPI.GETPATH (
    store_name  IN              VARCHAR2,
    path        IN              VARCHAR2,
    properties  IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    amount      IN OUT          NUMBER,
    offset      IN              NUMBER,
    buffers     OUT    NOCOPY   DBMS_CONTENT_RAW_T,
    prop_flags  IN              INTEGER,
    ctx         IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

**Table 48–11 GETPATH Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path items</td>
</tr>
</tbody>
</table>
**Summary of DBMS_DBFS_CONTENT_SPI Subprograms**

**properties**
One or more properties and their values to be returned depending on `prop_flags` (see `DBMS_DBFS_CONTENT_PROPERTIES_T Table Type`)

**content**
BL0B holding data which populates the file (optional)

**item_type**
Type of the path item specified (see `DBMS_DBFS_CONTENTConstants - Path Name Types`)

**amount**
On input, number of bytes to be read. On output, number of bytes read

**offset**
Byte offset from which to begin reading

**buffer**
Buffer to which to write

**buffers**
Buffers to which to write

**prop_flags**
Determines which properties are set, returned, or both. Default is `PROP_STD`. Specify properties to be returned by setting `prop_spec`, and providing an instance of the `DBMS_DBFS_CONTENT_PROPERTIES_T Table Type` with properties whose values are of interest.

**forUpdate**
Specifies that a lock should be taken to signify exclusive write access to the path item

**deref**
If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link)

**ctx**
Context with which to access the path items (see `DBMS_DBFS_CONTENT_CONTEXT_T Object Type`)

---

</tbody>
</table>
GETPATHBystoreid Function

If the underlying GUID is found in the underlying store, this function returns the store-qualified path name.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.GETPATHBystoreid (
    store_name          IN      VARCHAR2,
    guid                IN      INTEGER)
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>guid</td>
<td>Unique ID representing the desired path item</td>
</tr>
</tbody>
</table>

Return Values

Store-qualified path name represented by the GUID

Usage Notes

If the STD_GUID is unknown, a NULL value is returned. Clients are expected to handle this as appropriate.
GETPATHNOWAIT Procedure

This procedure implies that the operation is for an update, and, if implemented (see FEATURE_NOWAIT in DBMS_DBFS_CONTENT Constants - Store Features), allows providers to return an exception (ORA-00054) rather than wait for row locks.

Syntax

```
DBMS_DBFS_CONTENT_SPI.GETPATHNOWAIT (
    store_name  IN              VARCHAR2,
    path        IN              VARCHAR2,
    properties  IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    content     OUT    NOCOPY   BLOB,
    item_type   OUT             INTEGER,
    prop_flags  IN              INTEGER,
    deref       IN              INTEGER,
    ctx         IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

*Table 48–13 GETPATHNOWAIT Procedure Parameters*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path items</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be returned depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>content</td>
<td>BLOB holding data which populates the file (optional)</td>
</tr>
<tr>
<td>item_type</td>
<td>Type of the path item specified (see DBMS_DBFS_CONTENT Constants - Path Name Types)</td>
</tr>
<tr>
<td>prop_flags</td>
<td>Determines which properties are returned. Default is PROP_STD. Specify properties to be returned by setting prop_spec, and providing an instance of the DBMS_DBFS_CONTENT_PROPERTIES_T Table Type with properties whose values are of interest.</td>
</tr>
<tr>
<td>deref</td>
<td>If nonzero, attempts to resolve the given path item to actual data provided it is a reference (symbolic link)</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
GETSTOREID Function

This function returns the ID of a store.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.GETSTOREID (  
    store_name          IN      VARCHAR2)  
RETURN  NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Return Values

ID of the Store

Usage Notes

A store ID identifies a provider-specific store, across registrations and mounts, but independent of changes to the store contents. For this reason, changes to the store table or tables should be reflected in the store ID, but re-initialization of the same store table or tables should preserve the store ID.
GETVERSION Function

This function returns the version associated with a store.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.GETVERSION (
    store_name          IN      VARCHAR2)
RETURN  VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Return Values

A "version" (either specific to a provider package, or to an individual store) based on a standard `a.b.c` naming convention (for `major`, `minor`, and `patch` components)
LIST Function

This function lists the contents of a directory path name.

The invoker of the subprogram has the option to investigate recursively into sub-directories, to make soft-deleted items visible, to use a flashback "as of" a specified timestamp, and to filter items within the store based on list predicates.

Syntax

DBMS_DBFS_CONTENT_SPI.LIST (  
  store_name    IN     VARCHAR2,  
  path          IN     VARCHAR2,  
  filter        IN     VARCHAR2,  
  recurse       IN     INTEGER,  
  ctx           IN     DBMS_CONTENT_CONTEXT_T)  
RETURN  DBMS_CONTENT_LIST_ITEMS_T PIPELINED;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of repository</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to directories</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>recurse</td>
<td>If 0, do not execute recursively. Otherwise, recursively list the contents of directories and files below the given directory.</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTEXT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>

Return Values

Path items found that match the path, filter and criteria for executing recursively (see DBMS_DBFS_CONTENT_LIST_ITEMS_T Table Type)

Usage Notes

This function returns only list items; the client is expected to explicitly use one of the GETPATH Procedures to access the properties or content associated with an item.
LOCKPATH Procedure

This procedure applies user-level locks to the given valid path name (subject to store feature support), and optionally associates user-data with the lock.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.LOCKPATH (
    store_name     IN     VARCHAR2,
    path           IN     VARCHAR2,
    lock_type      IN     INTEGER,
    lock_data      IN     VARCHAR2,
    ctx            IN     DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Path name of items to be locked</td>
</tr>
<tr>
<td>lock_type</td>
<td>One of the available lock types (see DBMS_DBFS_CONTENT Constants - Lock Types)</td>
</tr>
<tr>
<td>lock_data</td>
<td>Optional user data to be associated with the lock</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>

Usage Notes

- It is the responsibility of the store and its providers (assuming it supports user-defined lock checking) to ensure that lock and unlock operations are performed in a consistent manner.
- The status of locked items is available by means of various optional properties (see OPT_LOCK* in DBMS_DBFS_CONTENT Constants - Optional Properties).
PURGEALL Procedure

This procedure purges all soft.deleted entries matching the path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.PURGEALL (  
    store_name     IN      VARCHAR2,  
    path           IN      VARCHAR2,  
    filter         IN      VARCHAR2,  
    ctx            IN      DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied based on specified criteria</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
**PURGE PATH Procedure**

This procedure purges any soft-deleted versions of the given path item.

**Syntax**

```sql
DBMS_DBFS_CONTENT_SPI.PURGEPATH (
    path           IN      VARCHAR2,
    filter         IN      VARCHAR2,
    store_name     IN      VARCHAR2,
    ctx            IN      DBMS_CONTENT_CONTEXT_T);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to file items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
This procedure creates a new path item.

Syntax

DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name IN              VARCHAR2,
    path          IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    content       IN OUT NOCOPY   BLOB,
    item_type     OUT             INTEGER,
    prop_flags    IN              INTEGER,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name    IN              VARCHAR2,
    path          IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    amount        IN              NUMBER,
    offset        IN              NUMBER,
    buffer        IN              RAW,
    prop_flags    IN              INTEGER,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);

DBMS_DBFS_CONTENT_SPI.PUTPATH (
    store_name    IN              VARCHAR2,
    path          IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    written       OUT             NUMBER,
    offset        IN              NUMBER,
    buffers       IN              DBMS_CONTENT_RAW_T,
    prop_flags    IN              INTEGER,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);

Parameters

</tbody>
</table>
Summary of DBMS_DBFS_CONTENT_SPI Subprograms

Usage Notes

- All path names allow their metadata (properties) to be read and modified. On completion of the call, the client can access specific properties using `prop_flags` (see DBMS_DBFS_CONTENT Constants - Property Access Flags).
- On completion of the call, the client can request a new BLOB locator that can be used to continue data access using the `prop_data` bitmask in `prop_flags` (see DBMS_DBFS_CONTENT Constants - Property Access Flags).
- Files can also be written without using BLOB locators, by explicitly specifying logical offsets or buffer-amounts, and a suitably sized buffer.

Table 48–20 (Cont.) PUTPATH Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>prop_flags</code></td>

</tr>
</tbody>
</table>
RENAMEPATH Procedure

This procedure renames or moves a path. This operation can be performed across directory hierarchies and mount-points as long as it is within the same store.

---

**Note:** See “Rename and Move Operations” on page 48-7

---

**Syntax**

```
DBMS_DBFS_CONTENT_SPI.RENAMEPATH (
    store_name    IN              VARCHAR2,
    oldPath       IN              VARCHAR2,
    newPath       IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store, must be unique</td>
</tr>
<tr>
<td>oldPath</td>
<td>Name of path prior to renaming</td>

</table>
RESTOREALL Procedure

This procedure restores all soft-deleted path items meeting the path and optional filter criteria.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.RESTOREALL (  
  store_name IN VARCHAR2,  
  path IN VARCHAR2,  
  filter IN VARCHAR2,  
  ctx IN DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see <code>DBMS_DBFS_CONTENT_CONTEXT_T Object Type</code>)</td>
</tr>
</tbody>
</table>
RESTOREPATH Procedure

This procedure restores all soft-deleted path items that match the given path and optional filter criteria.

Syntax

```
DBMS_DBFS_CONTENT_SPI.RESTOREPATH (  
  store_name IN VARCHAR2,  
  path IN VARCHAR2,  
  filter IN VARCHAR2,  
  ctx IN DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>

SEARCH Function

This function searches for path items matching the given path and filter criteria.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.SEARCH (  
    store_name      IN      VARCHAR2,  
    path            IN      VARCHAR2,  
    filter          IN      VARCHAR2,  
    recurse         IN      INTEGER,  
    ctx             IN      DBMS_CONTENT_CONTEXT_T)  
RETURN  DBMS_CONTENT_LIST_ITEMS_T PIPELINED;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to the path items</td>
</tr>
<tr>
<td>filter</td>
<td>A filter, if any, to be applied</td>
</tr>
<tr>
<td>recurse</td>
<td>If 0, do not execute recursively. Otherwise, recursively search the contents of directories and files below the given directory.</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>

Return Values

Path items matching the given path and filter criteria (see DBMS_DBFS_CONTENT_LIST_ITEMS_T Table Type)
SETPATH Procedure

This procedure assigns a path name to a path item represented by contentID. Stores and their providers that support contentID-based access and lazy path name binding also support the SETPATH Procedure that associates an existing contentID with a new path.

Note: See "Rename and Move Operations" on page 48-7

Syntax

```
DBMS_DBFS_CONTENT_SPI.SETPATH (
    store_name    IN              VARCHAR2,
    contentID     IN              RAW,
    path          IN              VARCHAR2,
    properties    IN OUT NOCOPY   DBMS_CONTENT_PROPERTIES_T,
    ctx           IN              DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of the store</td>
</tr>
<tr>
<td>contentID</td>
<td>Unique identifier for the item to be associated</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to path item</td>
</tr>
<tr>
<td>properties</td>
<td>One or more properties and their values to be set depending on prop_flags (see DBMS_DBFS_CONTENT_PROPERTIES_T Table Type)</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
SPACEUSAGE Procedure

This procedure queries file system space usage statistics. Providers are expected to support this subprogram for their stores and to make a best effort determination of space usage, especially if the store consists of multiple tables, indexes, LOBs, and so on.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.SPACEUSAGE (  
    store_name    IN        VARCHAR2,
    blksize       OUT       INTEGER,
    tbytes        OUT       INTEGER,
    fbytes        OUT       INTEGER,
    nfile         OUT       INTEGER,
    ndir          OUT       INTEGER,
    nlink         OUT       INTEGER,
    nref          OUT       INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>blksize</td>
<td>Natural tablespace blocksize that holds the store. If multiple tablespaces with different block sizes are used, any valid blocksize is acceptable.</td>
</tr>
<tr>
<td>tbytes</td>
<td>Total size of the store in bytes computed over all segments that comprise the store</td>
</tr>
<tr>
<td>fbytes</td>
<td>Free or unused size of the store in bytes computed over all segments that comprise the store</td>
</tr>
<tr>
<td>nfile</td>
<td>Number of currently available files in the store</td>
</tr>
<tr>
<td>ndir</td>
<td>Number of currently available directories in the store</td>
</tr>
<tr>
<td>nlink</td>
<td>Number of currently available links in the store</td>
</tr>
<tr>
<td>nref</td>
<td>Number of currently available references in the store</td>
</tr>
</tbody>
</table>

Usage Notes

- A space usage query on the top-level root directory returns a combined summary of the space usage of all available distinct stores under it (if the same store is mounted multiple times, it is still counted only once).
- Since database objects are dynamically expandable, it is not easy to estimate the division between "free" space and "used" space.
UNLOCKPATH Procedure

This procedure unlocks path items that were previously locked with the LOCKPATH Procedure.

Syntax

```sql
DBMS_DBFS_CONTENT_SPI.UNLOCKPATH (
    store_name     IN     VARCHAR2,
    path           IN     VARCHAR2,
    ctx            IN     DBMS_CONTENT_CONTEXT_T);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>path</td>
<td>Name of path to the path items</td>
</tr>
<tr>
<td>ctx</td>
<td>Context with which to access the path items (see DBMS_DBFS_CONTENT_CONTEXT_T Object Type)</td>
</tr>
</tbody>
</table>
The Oracle Database File System Hierarchical Store is implemented in the `DBMS_DBFS_HS` package. This package provides users the ability to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management for their database tables.

Using DBMS_DBFS_HS

- Overview
- Security Model
- Constants
- Operational Notes
Overview

The DBMS_DBFS_HS package is a service provider underneath the DBMS_DBFS_CONTENT package that enables use of tape or Amazon S3 Web service as storage for data.

The data on tape or Amazon S3 Web service is part of the Oracle Database and can be accessed through all standard interfaces, but only through the database. The package allows users to use tape or Amazon S3 Web service as a storage tier when doing Information Lifecycle Management of their content.

The package initially stores all content files in level-1 cache. As the level-1 cache fills up, content files are moved to level-2 cache and then to an external storage device using bulk writes.
Security Model

The DBMS_DBFS_HS package runs with invoker’s rights.
Constants

The `DBMS_DBFS_HS` package uses the constants shown in following tables:

- **DBMS_DBFS_HS Constants - Used by the CREATESTORE Procedure**
- **DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function**
- **DBMS_DBFS_HS Constants - Used by the REGISTERSTORECOMMAND Function**
- **DBMS_DBFS_HS Constants - Failure/Success/Error**

**Table 49–1 **DBMS_DBFS_HS Constants - Used by the CREATESTORE Procedure

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STORETYPE_TAPE</td>
<td>VARCHAR2(50)</td>
<td>'HS_TAPE'</td>
<td>Use tape as a storage tier</td>
</tr>
<tr>
<td>STORETYPE_AMAZONS3</td>
<td>VARCHAR2(50)</td>
<td>'HS_S3'</td>
<td>Use Amazon S3 Web service as a storage tier</td>
</tr>
</tbody>
</table>

**Table 49–2 **DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROPNAME_BUCKET</td>
<td>VARCHAR2(50)</td>
<td>'BUCKET'</td>
<td>Specifies the AWS bucket to be used as a storage tier by the Hierarchical Store. Restrictions on bucket name are: 1) Bucket names can only contain lowercase letters, numbers, periods (.) and dashes(-). Note that underscores (_) are invalid. 2) Bucket names must start with a number or letter. 3) Bucket names cannot be in an IP address style (192.168.5.4). 4) Bucket names must be between 3 and 63 characters long. 5) Bucket names should not end with a dash. 6) Dashes cannot appear next to periods. For example, my-.bucket.com is invalid.</td>
</tr>
<tr>
<td>PROPNAME_CACHESIZE</td>
<td>VARCHAR2(50)</td>
<td>'CACHE_SIZE'</td>
<td>Specifies the cumulative cache size used for the Hierarchical Store. This property is set by the CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure. It cannot be modified by the SETSTOREPROPERTY Procedure, though its value can be queried by the GETSTOREPROPERTY Function.</td>
</tr>
<tr>
<td>Constant</td>
<td>Type</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>---------------</td>
<td>----------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PROPNAME_COMPRESSLEVEL</td>
<td>VARCHAR2(50)</td>
<td>&quot;COMPRESSION_LEVEL&quot;</td>
<td>Use to enable compression of files stored in the DBFS hierarchical store. It specifies the compression level to be used for compressing the files.</td>
</tr>
<tr>
<td>PROPNAME_ENABLECLEANUPONDDELETE</td>
<td>VARCHAR2(50)</td>
<td>&quot;ENABLE_CLEANUP_ON_DELETE&quot;</td>
<td>If this property is set to 'TRUE', whenever the user invokes the DELETEFILE Procedure in the DBMS_DBFS_CONTENT interface on a file residing in the DBMS_DBFS_HS store, the DBMS_DBFS_HS removes the file on the external storage that contains this user file provided that the file has no other useful data. By default, the property is set to 'TRUE' for STORETYPE_AMAZONS3 and 'FALSE' for STORETYPE_TAPE.</td>
</tr>
<tr>
<td>PROPNAME_HTTPPROXY</td>
<td>VARCHAR2(50)</td>
<td>&quot;HTTP_PROXY&quot;</td>
<td>Specifies the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service.</td>
</tr>
<tr>
<td>PROPNAME_LICENSEID</td>
<td>VARCHAR2(50)</td>
<td>&quot;LICENSE_ID&quot;</td>
<td>Specifies the license ID associated with the library libosbws11.so.</td>
</tr>
<tr>
<td>PROPNAME_LOBCACHE_QUOTA</td>
<td>VARCHAR2(50)</td>
<td>&quot;LOBCACHE QUOTA&quot;</td>
<td>Specifies fraction of the cache_size which is allocated for level 1 cache. The default value of this parameter is NULL which means that 0.8 (= 80%) of the cache_size is used for level 1 cache.  This property cannot be modified by the SETSTOREPROPERTY Procedure though its value can be queried by the GETSTOREPROPERTY Function. Its value is set by CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure.</td>
</tr>
<tr>
<td>PROPNAME_MEDIAPOOL</td>
<td>VARCHAR2(50)</td>
<td>&quot;MEDIA_POOL&quot;</td>
<td>Specifies the media pool number to use for storing the content.</td>
</tr>
<tr>
<td>PROPVAL_COMPLVL_NONE</td>
<td>VARCHAR2(50)</td>
<td>&quot;NONE&quot;</td>
<td>Indicates no compression</td>
</tr>
<tr>
<td>PROPVAL_COMPLVL_LOW</td>
<td>VARCHAR2(50)</td>
<td>&quot;LOW&quot;</td>
<td>Use to set the compression level to LOW. This is expected to have the best performance while still providing a good compression ratio.</td>
</tr>
<tr>
<td>PROPVAL_COMPLVL_MEDIUM</td>
<td>VARCHAR2(50)</td>
<td>&quot;MEDIUM&quot;</td>
<td>Use to set the compression level to MEDIUM. This compression level is expected to provide better compression ratio than LOW but the time required for compression will be higher than compression level LOW.</td>
</tr>
</tbody>
</table>
Table 49–2 (Cont.) DBMS_DBFS_HS Constants - Used by the SETSTOREPROPERTY Procedure and the GETSTOREPROPERTY Function

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROPVAL_COMPLVL_HIGH</td>
<td>VARCHAR2(50)</td>
<td>'HIGH'</td>
<td>Use to set the compression level to HIGH. This compression level is expected to provide the best compression ratio but compression time will in general be highest among the 3 compression levels.</td>
</tr>
<tr>
<td>PROPNAME_OPTTARBALLSIZE</td>
<td>VARCHAR2(50)</td>
<td>'OPTIMAL_TARBALL_SIZE'</td>
<td>Specifies optimal_tarbball_size as the maximum possible size of an archive file. Multiple content files are bundled together into one archive file and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation. This property cannot be modified by the SETSTOREPROPERTY Procedure though its value can be queried by the GETSTOREPROPERTY Function. Its value is set by CREATESTORE Procedure and can be modified by the RECONFIGCACHE Procedure.</td>
</tr>
<tr>
<td>PROPNAME_READCHUNKSIZE</td>
<td>VARCHAR2(50)</td>
<td>'READ_CHUNK_SIZE'</td>
<td>Specifies the size used by the SBT protocol to transfer data from tape or S3. This chunk is allocated in memory per transaction for retrieval of content files from an archive store, so the value of this property should be conservative. The default size of 1MB is typically good for most users.</td>
</tr>
<tr>
<td>PROPNAME_S3HOST</td>
<td>VARCHAR2(50)</td>
<td>'S3_HOST'</td>
<td>Specifies the HOST name of the Amazon S3 storage service. It must be s3.amazonaws.com.</td>
</tr>
<tr>
<td>PROPNAME_SBT_LIBRARY</td>
<td>VARCHAR2(50)</td>
<td>'SBT_LIBRARY'</td>
<td>Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named libosbws11.so and is available in rdbms/lib directory.</td>
</tr>
<tr>
<td>PROPNAME_STREAMABLE</td>
<td>VARCHAR2(50)</td>
<td>'STREAMABLE'</td>
<td>Indicates whether buffer-based PUT or GET should be done on this store. Valid values for are TRUE and FALSE. The default value of this property is TRUE.</td>
</tr>
</tbody>
</table>
The value of this property should be of the form:
LOCATION=file:filename
CREDENTIAL_ALIASES=access/secret_alias
PROXY_AUTH_ALIASES=proxyusername/password_alias
Defines the Oracle Wallet which contains the credentials of the Amazon S3 account associated with the store under consideration.
LOCATION: The directory path that contains the Oracle wallet. The format is file:directory-path
The format of wallet_path in Windows is, for example:
file:c:\WINNT\Profiles\username\WALLETS
In UNIX or Linux it is, for example:
file:/home/username/wallets
When the package is executed in the Oracle database server, the wallet is accessed from the database server.
PASSWORD: Defines the wallet password. If auto-login is enabled in wallet (this can be changed using the OWM utility), this parameter does not have to be specified. By default, the mkstore utility enables auto-login.
CREDENTIAL_ALIASES: Defines the credential alias for ACCESS_KEY and SECRET_KEY

<table>

<td>'2'</td>
<td>Specified operation must be performed before a retrieval operation such as reading a SECUREFILE from the remote device.</td>
</tr>
</tbody>
</table>

### Table 49–4  DBMS_DBFS_HS Constants - Failure/Success/Error

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FAIL</td>
<td>NUMBER</td>
<td>'0'</td>
<td>Procedure or function did not execute successfully</td>
</tr>
<tr>
<td>SUCCESS</td>
<td>NUMBER</td>
<td>'1'</td>
<td>Procedure or function completed successfully</td>
</tr>
<tr>
<td>ERROR</td>
<td>NUMBER</td>
<td>'2'</td>
<td>Procedure or function returned an error</td>
</tr>
</tbody>
</table>
Operational Notes

When the `DBMS_DBFS_HS` package is executed in the Oracle database server, the wallet is accessed from the database server.
Summary of DBMS_DBFS_HS Subprograms

<table>
<thead>
<tr>

</tbody>
</table>
CLEANUPUNUSEDBACKUPFILES Procedure

This procedure removes files created on the external storage device that hold no currently used data in them.

Syntax

```sql
DBMS_DBFS_HS.CLEANUPUNUSEDBACKUPFILES (store_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Usage Notes

- The action of removing files from external storage device can not be rolled back.
- This method can be executed periodically to clear space on the external storage device. Asynchronously deleting content from the external storage device is useful because it has minimal impact on the OLTP performance. The periodic scheduling can be accomplished using the DBMS_SCHEDULER package.
CREATEBUCKET Procedure

This procedure creates an AWS bucket, associated with a store of type STORETYPE_AMAZONS3 into which the Hierarchical Store can then move data.

Syntax

```
DBMS_DBFS_HS.CREATEBUCKET  (  
    store_name  IN  VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

Usage Notes

- The PROPNAME_BUCKET property of the store should be set before this subprogram is called.
- Once this procedure has successfully created a bucket in Amazon S3, the bucket can only be deleted using out-of-band methods, such as logging-in to S3 and deleting data (directories, files, and other items) for the bucket.
CREATESTORE Procedure

This procedure creates a new hierarchical store `store_name` of type `STORE_TYPE` (STORETYPE_TAPE or STORETYPE_AMAZONS3) in schema `schema_name` (defaulting to current schema) under the ownership of the invoking session user.

Syntax

```sql
DBMS_DBFS_HS.CREATESTORE  (
    store_name              IN     VARCHAR2,
    store_type              IN     VARCHAR2,
    tbl_name                IN     VARCHAR2,
    tbs_name                IN     VARCHAR2,
    cache_size              IN     NUMBER,
    lob_cache_quota         IN     NUMBER DEFAULT NULL,
    optimal_tarball_size    IN     NUMBER DEFAULT NULL,
    schema_name             IN     VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>store_type</td>
<td>STORETYPE_TAPE or STORETYPE_AMAZONS3</td>
</tr>
<tr>
<td>tbl_name</td>
<td>Table for store entries</td>
</tr>
<tr>
<td>tbs_name</td>
<td>Tablespace for the store</td>
</tr>
<tr>
<td>cache_size</td>
<td>Amount of space used by the store to cache content in given tablespace</td>
</tr>
<tr>
<td>lob_cache_quota</td>
<td>Fraction of the cache_size which is allocated for level 1 cache.</td>
</tr>
<tr>
<td>optimal_tarball_size</td>
<td>Maximum possible size of the archive file.</td>
</tr>
<tr>
<td></td>
<td>Multiple content files are bundled together into one archive file, and then the archive file is transferred to tape or Amazon S3. This is because creating one file on tape or Amazon S3 for every content file in the store is a prohibitively expensive operation.</td>
</tr>
<tr>
<td></td>
<td>The value of is set by default to 10GB for tape and to 100MB for Amazon S3.</td>
</tr>
<tr>
<td>schema_name</td>
<td>Schema for the store</td>
</tr>
</tbody>
</table>

Usage Notes

- Store names must be unique for an owner. The same store names can be used for different stores owned by different owners.
- Once a table space has been specified to store the store's content in a database, it cannot be changed later.
- This subprogram will execute like a DDL statement, performing an automatic `COMMIT` before and after execution.
Stores using DBMS_DBFS_HS must not use singleton mount. This means that the singleton parameter should be FALSE and the store_mount parameter should have a non-NULL value in a call to the DBMS_DBFS_CONTENT.MOUNTSTORE Procedure.
DEREGSTORECOMMAND Function

This procedure removes a command that had been previously associated with a store through the RECONFIGCACHE Procedure.

Syntax

```sql
DBMS_DBFS_HS.DEREGSTORECOMMAND (  
  store_name      IN     VARCHAR2,  
  message         IN     VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>message</td>
<td>Message to be deregistered</td>
</tr>
</tbody>
</table>

Usage Notes

If this subprogram successfully executes, its actions cannot be rolled back by the user. If the user wants to restore the previous state, the user must call the REGISTERSTORECOMMAND Procedure.
DROPSTORE Procedure

This procedure deletes a previously created hierarchical store specified by name and owned by the invoking session user.

Syntax

```sql
DBMS_DBFS_HS.DROPSTORE  (
  store_name   IN     VARCHAR2,
  opt_flags    IN     INTEGER DEFAULT 0);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store owned by the invoking session user</td>
</tr>
<tr>
<td>opt_flags</td>
<td>User can specify optional flags. If DISABLE_CLEANUPBACKUPFILES is specified as one of the optional flags, the call to the CLEANUPUNUSEDBACKUPFILES Procedure is not issued. By default, when this flag is not set, the procedure implicitly cleans-up all unused backup files.</td>
</tr>
</tbody>
</table>

Usage Notes

- The procedure executes like a DDL in that it auto-commits before and after its execution.
- If CLEANUPBACKUPFILES is disabled during the procedure, the user must resort to out-of-band techniques to cleanup unused backup files. No further invocations of CLEANUPBACKUPFILES for a dropped store are possible through hierarchical store.
- This subprogram will un-register the store from DBMS_DBFS_CONTENT package. All files in the given store are deleted from the store (Tape or Amazon S3 Web service). The database table holding the store's entries in the database, is also dropped by this subprogram.
FLUSHCACHE Procedure

This procedure flushes out dirty contents from level-1 cache, which can be locked, to level-2 cache, thereby freeing-up space in level 1 cache.

Syntax

```sql
DBMS_DBPS_HS.FLUSHCACHE(
    store_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>
GETSTOREPROPERTY Function

This function retrieves the values of a property.

Syntax

```
DBMS_DBFS_HS.GETSTOREPROPERTY  
    (store_name   IN     VARCHAR2,
     property_name   IN     VARCHAR2,
     noexcp          IN     BOOLEAN DEFAULT FALSE) RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>property_name</td>
<td>Name of property</td>
</tr>
<tr>
<td>noexcp</td>
<td>If set to FALSE, raises an exception if the property does not exist in the database. If noexcp is set to TRUE, returns NULL if the property does not exist.</td>
</tr>
</tbody>
</table>

Return Values

The values of a property.

Usage Notes

The specified store must already have been created.
RECONFIGCACHE Procedure

This procedure reconfigures the parameters of the database cache being used by the store.

Syntax

```sql
DBMS_DBFS_HS.RECONFIGCACHE (  
store_name              IN    VARCHAR2,  
cache_size              IN    NUMBER DEFAULT NULL,  
lobcache_quota          IN    NUMBER DEFAULT NULL,  
optimal_tarball_size    IN    NUMBER DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>cache_size</td>
<td>Cumulative cache size used for the Hierarchical Store</td>
</tr>
<tr>
<td>lobcache_quota</td>
<td>Fraction of the cache size that are assigned to level 1 cache</td>
</tr>
<tr>
<td>optimal_tarball_size</td>
<td>Maximum possible size of an archive file. Since creating one file for every content file in the store is prohibitively expensive operation, multiple content files are bundled together into one archive file for transfer to tape or Amazon S3.</td>
</tr>
</tbody>
</table>

Usage Notes

- The specified store must already have been created before reconfiguration.
- The Hierarchical Store uses a level 1 cache and a level 2 cache. The level 1 cache subsumes most of the working set and the level 2 cache is used to perform bulk writes to the backend device.
- If any of the last 3 parameters is `NULL`, its value specified during store creation is used. If the parameter was `NULL` when the call to the `CREATESTORE` Procedure was issued, the `DBMS_DBFS_HS` package assigns a default value.
- The `DBMS_DBFS_HS` package optimistically tries to allocate more than 1 tarball’s worth of size for level 2 cache to facilitate concurrency, though a minimum of 1 tarball size is necessary for level 2 cache.
- The values for cumulative cache size and LOB cache quota decide allocation of space for the two caches. If values are not provided, a user might see an `INSUFFICIENT_CACHE` exception. In that case, it is better to revise the cache parameters in order to have a working store.
- If this subprogram successfully executes, its actions cannot be rolled back by the user. In that case, the user should call `RECONFIGCACHE` again with new or modified parameters.
REGISTERSTORECOMMAND Procedure

This procedure registers commands for a store with the Hierarchical Store. These commands are sent to the Media Manager for the external storage device associated with the store.

Syntax

```sql
DBMS_DBFS_HS.REGISTERSTORECOMMAND (  
    store_name      IN     VARCHAR2,  
    message         IN     VARCHAR2,  
    flags           IN     NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>message</td>
<td>Message to be sent to the Media Manager of the external store</td>
</tr>
<tr>
<td>flags</td>
<td>Valid values:</td>
</tr>
<tr>
<td></td>
<td>• BEFORE_PUT CONSTANT NUMBER := 1;</td>
</tr>
<tr>
<td></td>
<td>• BEFORE_GET CONSTANT NUMBER := 2;</td>
</tr>
</tbody>
</table>

Usage Notes

- These commands are sent before the next read or write of content. When the Hierarchical Store wants to push (or get) data to (or from) the storage device, it begins a session (to communicate with the device). After beginning the session, it sends all registered commands for the to the relevant device before writing (or getting) any data.

- If this method successfully executes, its actions cannot be rolled back by the user. To restore the previous state the user must call the DEREGSTORECOMMAND Function.
SENDCOMMAND Procedures

This procedure sends a command to be executed on the external storage device’s Media Manager.

Syntax

```
DBMS_DBFS_HS.SENDCOMMAND (  
    store_name    IN       VARCHAR2,  
    message       IN       VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>message</td>
<td>Message string to be executed</td>
</tr>
</tbody>
</table>
**SETSTOREPROPERTY Procedure**

This procedure stores properties of a store in the database as name-value pairs.

**Syntax**

```sql
DBMS_DBFS_HS.SETSTOREPROPERTY (  
    store_name      IN     VARCHAR2,  
    property_name   IN     VARCHAR2,  
    property_value  IN     VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>property_name</td>
<td>For a store using Tape device, there are three properties whose values must be set by the user, and four properties that have default values. Stores of type STORETYPE_AMAZONS3 have properties with default values. The various options for both types of stores are detailed under property_value.</td>
</tr>
</tbody>
</table>
| property_value  | Stores using a Tape Device  

The values for the following properties must be set by the user:  

- PROPNAME_SETLIBRARY - This should point to the shared library used by RMAN to communicate with the external tape device. It is usually named libobk.so.  
- PROPNAME_MEDIAPool - Media pool number for storing content  
- PROPNAME_CACHE_SIZE - Amount of space, in bytes, used for the cache of this store  

The following properties, which have default values assigned to them when a store is created, benefit from tuning:  

- PROPNAME_READCHUNKSIZE and PROPNAME_WRITECHUNKSIZE - These are the sizes used by the SBT protocol to transfer data to and from the tapes. These chunks are allocated in memory per transaction, so the values should be conservative. The default size is 1MB.  
- PROPNAME_STREAMABLE - Indicates whether DBFS_LINKS can perform read operations (for example SELECT or DBMS_LOB.READ) directly from the store, or if the data must be copied back into the database before it can be read  
- PROPNAME_ENABLECLEANUPONDELETE - Indicates if unused files on the external storage device should be deleted by DBMS_DBFS_HS. Valid values for this property are 'FALSE' for STORETYPE_TAPE.  
- PROPNAME_COMPRESSLEVEL - Describes how files written to Tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.
It is mandatory that the following properties have assigned values, and default values are provided:

- **PROPNAME_SBTLIBRARY** - Specifies the path of the shared library used by RMAN to communicate with Amazon S3. It is named `libosbws11.so` and is available in `rdbms/lib` directory.
- **PROPNAME_S3HOST** - Defines the HOST name of the Amazon S3 storage service. It must be `s3.amazonaws.com`.
- **PROPNAME_BUCKET** - Defines the AWS bucket used as a storage tier by the Hierarchical Store. Restrictions on bucket names are:
  -- Bucket names can only contain lowercase letters, numbers, periods (.) and dashes (-). Use of an underscore (_) is invalid.
  -- Bucket names must start with a number or letter
  -- Bucket names cannot be in an IP address style ("192.168.5.4")
  -- Bucket names must be between 3 and 63 characters in length
  -- Bucket names should not end with a dash
  -- Dashes cannot appear next to periods. For example, "my-.bucket.com" is invalid.
- **PROPNAME_LICENSEID** - Specifies the license ID associated with the library `libosbws11.so`.
- **PROPNAME_WALLET** - Has the form:
  
  'LOCATION=filename CREDENTIAL_ALIAS=access/secret_alias PROXY_AUTH_ALIAS=proxyusername/password alias'

  -- LOCATION - Directory path that contains the Oracle wallet. The format is `file:directory-path`. See Examples for variations in format.
  -- PASSWORD - Defines the wallet password. If auto-login is enabled in the wallet (this can be changed using the user's own utility), and does not have to be specified. By default, the `mkstore` utility enables auto-login.
  -- CREDENTIAL_ALIAS - Defines the credential alias for `ACCESS_KEY` and `SECRET_KEY`
  -- PROXY_AUTH_ALIAS - Defines authentication credentials for the proxy server, if applicable.
Summary of DBMS_DBFS_HS Subprograms

Usage Notes

- The specified store must already have been created.
- If this subprogram successfully executes, its actions cannot be rolled back by the user.
- The same property can be set multiple times to the same or different values using this subprogram

Examples

Format

The format of wallet_path in Windows is, for example:

file:c:\WINNT\Profiles\<username>\WALLETS

The format of wallet_path in UNIX or Linux is, for example:

file:/home/username/wallets

Table 49–16 (Cont.) SETSTOREPROPERTY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(property_value (contd.)</td>
<td>The following properties are optional:</td>
</tr>
<tr>
<td></td>
<td>- PROPNAME_HTTPPROXY - Defines the DNS name of the HTTP proxy, if any, that is needed to access the Amazon S3 storage service.</td>
</tr>
<tr>
<td></td>
<td>- PROPNAME_STREAMABLE - Indicates whether buffer-based PUT or GET operation should be done on this store. Valid values for this property are TRUE (default) and FALSE.</td>
</tr>
<tr>
<td></td>
<td>- PROPNAME_ENABLECLEANUPONDELETE - Indicates if unused files on the external storage device should be deleted by DBMS_DBFS_HS. Valid values for this property are 'FALSE' for STORETYPE_TAPE.</td>
</tr>
<tr>
<td></td>
<td>- PROPNAME_COMPRESSLEVEL - Describes how files written to Tape should be compressed. It can be set to PROPVAL_COMPLVL_NONE, PROPVAL_COMPLVL_LOW, PROPVAL_COMPLVL_MEDIUM or PROPVAL_COMPLVL_HIGH. By default it is set to PROPVAL_COMPLVL_NONE.</td>
</tr>
</tbody>
</table>
STOREPUSH Procedure

This procedure pushes locally staged data to the remote storage.

Syntax

```sql
DBMS_DBFS_HS.STOREPUSH (  
    store_name   IN        VARCHAR2,  
    path         IN        VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store whose content the client writes from local cache to the external store</td>
</tr>
<tr>
<td>path</td>
<td>A non-mount qualified (without mount point) path within the store. By default, its value is NULL which corresponds to the root path of the store.</td>
</tr>
</tbody>
</table>

Usage Notes

- The Hierarchical Store caches the content files locally in database tables. When enough content is amassed in the cache to make it efficient to write to the external storage device (or the cache is completely filled), the Hierarchical Store creates a tarball out of the local content and writes these tarballs as files on the external device. The size of the tarball created by the Hierarchical Store is controlled by the store property `PROPNAME_OPTTARBALLSIZE`.

- When the amount of free space in the cache is such that the caching of a content file will push the space used above `cache_size`, the Hierarchical Store will internally call `STOREPUSH`. The `STOREPUSH` Procedure creates tarball(s) out of the existing dirty or modified content files in the cache and writes them out to the external device. A `STOREPUSH` call is not guaranteed to write all the dirty content from local cache to the external storage, since some files may be locked by other sessions.

- `STOREPUSH` has a built-in ability feature allowing it to automatically resume operation. If a `STOREPUSH` call is interrupted (say by a network outage) after it has transferred some tarballs to the external device, it can be restarted after the outage and will then resume transferring data from the point it was interrupted. In other words, work done before the outage is not lost. `STOREPUSH` can safely be restarted and the effect is such as if the outage never occurred.

- If this method successfully executes, its actions cannot be rolled back by the user.

- By default, when `path` is `NULL`, all files in the store are candidates for `STOREPUSH`. If `path` has a valid input value, all files which are under the namespace of given path are written from the local cache to the external store. If a given path is an existing file, it is pushed out again to the remote store.
The DBMS_DBFS_SFS package provides an interface to operate a SecureFile-based store (SFS) for the content interface described in the DBMS_DBFS_CONTENT package.

- Constants
Overview

The DBMS_DBFS_SFS package is a sample implementation of a package that implements and extends the DBMS_DBFS_CONTENT_SPI interface. It provides a POSIX-compliant file system stored in the RDBMS.
Security Model

The DBMS_DBFS_SFS package runs with AUTHID CURRENT_USER.
**Constants**

The `DBMS_DBFS_SFS` package uses the constants shown in the following tables:

- `DBMS_DBFS_SFS` Constants - Compression Levels
- `DBMS_DBFS_SFS` Constants - Used by the encryption Parameter
- `DBMS_DBFS_SFS` Constants - Used by the npartitions Parameter
- `DBMS_DBFS_SFS` Constants - Used by the partition_key Parameter

</tbody>
</table>
CREATEFILESYSTEM Procedure

This procedure creates a file system store.

Syntax

```
DBMS_DBFS_SFS.CREATEFILESYSTEM (  
    store_name         IN     VARCHAR2,  
    schema_name        IN     VARCHAR2 DEFAULT NULL,  
    tbl_name           IN     VARCHAR2 DEFAULT NULL,  
    tbl_tbs            IN     VARCHAR2 DEFAULT NULL,  
    lob_tbs            IN     VARCHAR2 DEFAULT NULL,  
    use_bf             IN     BOOLEAN DEFAULT FALSE,  
    properties         IN     DBMS_DBFS_CONTENT_PROPERTIES_T DEFAULT NULL,  
    create_only        IN     BOOLEAN FALSE,  
    use_objects        IN     BOOLEAN DEFAULT FALSE,  
    with_grants        IN     BOOLEAN DEFAULT FALSE,  
    do_dedup           IN     BOOLEAN DEFAULT FALSE,  
    do_compress        IN     BOOLEAN DEFAULT FALSE,  
    compression        IN     VARCHAR2 DEFAULT COMPRESSION_DEFAULT,  
    do_encrypt         IN     BOOLEAN DEFAULT FALSE,  
    encryption         IN     VARCHAR2 DEFAULT ENCRYPTION_DEFAULT,  
    do_partition       IN     BOOLEAN DEFAULT FALSE,  
    npartitions        IN     NUMBER DEFAULT DEFAULT_PARTITIONS,  
    partition_key      IN     NUMBER DEFAULT PARTITION_BY_ITEM,  
    partition_guidi    IN     BOOLEAN DEFAULT FALSE,  
    partition_pathi    IN     BOOLEAN DEFAULT FALSE,  
    partition_prop     IN     BOOLEAN DEFAULT TRUE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>schema_name</td>
<td>Schema for the store, defaulting to the current schema</td>
</tr>
<tr>
<td>tbl_name</td>
<td>Table for store entries. If not specified, an internally generated name is used.</td>
</tr>
<tr>
<td>tbl_tbs</td>
<td>Tablespace for the store, defaulting to the schema's default tablespace</td>
</tr>
<tr>
<td>lob_tbs</td>
<td>Tablespace in which to create the LOB segment. It defaults to the user's default tablespace.</td>
</tr>
<tr>
<td>use_bf</td>
<td>If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used.</td>
</tr>
<tr>
<td>properties</td>
<td>Table of (name, value, typecode) tuples used to configure the store properties. Currently no such properties are defined or used.</td>
</tr>
<tr>
<td>create_only</td>
<td>If TRUE, the file system is created, but not registered with the current user</td>
</tr>
<tr>
<td>use_objects</td>
<td>If TRUE, a single base-table with an object-type column (using a nested table) is created to backup the new file system. Otherwise, a pair of (parent, child) tables is used to backup the file system. In both cases, the object type nested table or the child table is used only for user-defined properties.</td>
</tr>
</tbody>
</table>
### Usage Notes

The procedure executes like a DDL in that it auto-commits before and after its execution.

---

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>with_grants</td>
<td>If TRUE, DML and query access permissions are granted to the DBFS_ROLE as part of creating the file system. Otherwise, explicit grants (or existing permissions) are required to access the file system.</td>
</tr>
<tr>
<td>do_dedup</td>
<td>If TRUE, do deduplication the underlying SecureFile column</td>
</tr>
<tr>
<td>do_compress</td>
<td>If TRUE, do compression the underlying SecureFile column</td>
</tr>
<tr>

</tr>
<tr>
<td>do_partition</td>
<td>If TRUE, partition the table used for storage</td>
</tr>
<tr>
<td>npartitions</td>
<td>Number of partitions to create for the table (see DBMS_DBFS_SFS Constants - Used by the npartitions Parameter).</td>
</tr>
<tr>
<td>partition_key</td>
<td>How to partition the table: by item name, by path name, or by GUID (see DBMS_DBFS_SFS Constants - Used by the partition_key Parameter).</td>
</tr>
<tr>
<td>partition_guidi</td>
<td>If TRUE, build an index on GUID</td>
</tr>
<tr>
<td>partition_pathi</td>
<td>If TRUE, build an index on path name</td>
</tr>
<tr>
<td>partition_prop</td>
<td>If TRUE, partition the properties table</td>
</tr>
</tbody>
</table>
CREATESTORE Procedure

This procedure creates a new DBFS SFS store owned by the invoking session user.

Syntax

```
DBMS_DBFS_SFS.CREATESTORE  (
    store_name     IN     VARCHAR2,
    tbl_name       IN     VARCHAR2  DEFAULT NULL,
    tbs_name       IN     VARCHAR2  DEFAULT NULL,
    use_bf         IN     BOOLEAN   DEFAULT FALSE,
    stgopts        IN     VARCHAR2 DEFAULT '');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
<tr>
<td>store_type</td>
<td>STORETYPE_TAPE or STORETYPE_AMAZONS3</td>
</tr>
<tr>
<td>tbl_name</td>
<td>Placeholder for the store content cached in database</td>
</tr>
<tr>
<td>tbs_name</td>
<td>Named tablespace</td>
</tr>
<tr>
<td>use_bf</td>
<td>If TRUE, a BasicFile LOB is used; otherwise a SecureFile LOB is used.</td>
</tr>
<tr>
<td>stgopts</td>
<td>Currently non-operational, reserved for future use</td>
</tr>
</tbody>
</table>
DROPFILESYSTEM Procedures

This procedure drops the DBFS SFS store, purging all dictionary information associated with the store, and dropping the underlying file system table.

Syntax

```sql
DBMS_DBFS_SFS.DROPFILESYSTEM
(schema_name IN VARCHAR2 DEFAULT NULL,
tbl_name IN INTEGER);

DBMS_DBFS_SFS.DROPFILESYSTEM
(store_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Name of schema</td>
</tr>
<tr>
<td>tbl_name</td>
<td>Name of tablespace</td>
</tr>
<tr>
<td>store_name</td>
<td>Name of store path</td>
</tr>
</tbody>
</table>

Usage Notes

- If the specified store table is registered by the current user, it will be unregistered from the content interface described in the DBMS_DBFS_CONTENT package and the POSIX metadata tables.
- Subsequent to unregistration, an attempt will be made to store table(s). This operation may fail if other users are currently using this store table.
- The user attempting a drop of the tables underlying the store must actually have the privileges to complete the drop operation (either as the owner of the tables, or as a sufficiently privileged user for cross-schema operations).
- The procedure executes like a DDL in that it auto-commits before and after its execution.
**INITFS Procedure**

This procedure initialize a POSIX file system store. The table associated with the POSIX file system store `store_name` is truncated and reinitialized with a single "root" directory entry.

**Syntax**

```sql
DBMS_DBFS_SFS.INITFS (store_name IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>store_name</td>
<td>Name of store</td>
</tr>
</tbody>
</table>

**Usage Notes**

The procedure executes like a DDL in that it auto-commits before and after its execution.
The DBMS_DB_VERSION package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

**See Also:** PL/SQL Users Guide and Reference regarding conditional compilation

This package contains the following topics

- **Using DBMS_DB_VERSION**
  - Overview
  - Constants
  - Examples
Using DBMS_DB_VERSION

- Overview
- Constants
Overview

The DBMS_DB_VERSION package specifies the Oracle version numbers and other information useful for simple conditional compilation selections based on Oracle versions.

The package for the Oracle Database 11g Release 1 version is shown below.

```plsql
PACKAGE DBMS_DB_VERSION IS
  VERSION CONSTANT PLS_INTEGER := 11;  -- RDBMS version number
  RELEASE CONSTANT PLS_INTEGER := 1;   -- RDBMS release number
  ver_le_9_1 CONSTANT BOOLEAN := FALSE;
  ver_le_9_2 CONSTANT BOOLEAN := FALSE;
  ver_le_9 CONSTANT BOOLEAN := FALSE;
  ver_le_10_1 CONSTANT BOOLEAN := FALSE;
  ver_le_10_2 CONSTANT BOOLEAN := FALSE;
  ver_le_10 CONSTANT BOOLEAN := FALSE;
  ver_le_11_1 CONSTANT BOOLEAN := TRUE;
  ver_le_11 CONSTANT BOOLEAN := TRUE;
END DBMS_DB_VERSION;
```

The boolean constants follow a naming convention. Each constant gives a name for a boolean expression. For example:

- `VER_LE_9_1` represents version <= 9 and release <= 1
- `VER_LE_10_2` represents version <= 10 and release <= 2
- `VER_LE_10` represents version <= 10

A typical usage of these boolean constants is:

```plsql
$IF DBMS_DB_VERSION.VER_LE_10 $THEN
  version 10 and earlier code
$ELSIF DBMS_DB_VERSION.VER_LE_11 $THEN
  version 11 code
$ELSE
  version 12 and later code
$END
```

This code structure will protect any reference to the code for hypothetical version 12. It also prevents the controlling package constant `DBMS_DB_VERSION.VER_LE_11` from being referenced when the program is compiled under version 10. A similar observation applies to version 11. This scheme works even though the static constant `VER_LE_11` is not defined in version 10 database because conditional compilation protects the `$ELSIF` from evaluation if `DBMS_DB_VERSION.VER_LE_10` is TRUE.
The DBMS_DB_VERSION package contains different constants for different Oracle Database releases. The Oracle Database 11g Release 1 version of the DBMS_DB_VERSION package uses the constants shown in Table 51–1.

**Table 51–1  DBMS_DB_VERSION Constants**

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VERSION</td>
<td>PLS_INTEGER</td>
<td>10</td>
<td>Current version</td>
</tr>
<tr>
<td>RELEASE</td>
<td>PLS_INTEGER</td>
<td>2</td>
<td>Current release</td>
</tr>
<tr>
<td>VER_LE_9</td>
<td>BOOLEAN</td>
<td>FALSE</td>
<td>Version &lt;= 9</td>
</tr>
<tr>
<td>VER_LE_9_1</td>
<td>BOOLEAN</td>
<td>FALSE</td>
<td>Version &lt;= 9 and release &lt;= 1</td>
</tr>
<tr>
<td>VER_LE_9_2</td>
<td>BOOLEAN</td>
<td>FALSE</td>
<td>Version &lt;= 9 and release &lt;= 2</td>
</tr>
<tr>

DBMS_DEBUG is a PL/SQL interface to the PL/SQL debugger layer, Probe, in the Oracle server.

This API is primarily intended to implement server-side debuggers and it provides a way to debug server-side PL/SQL program units.

Note: The term *program unit* refers to a PL/SQL program of any type (procedure, function, package, package body, trigger, anonymous block, object type, or object type body).

This chapter contains the following topics:

- **Using DBMS_DEBUG**
  - Overview
  - Constants
  - Variables
  - Exceptions
  - Operational Notes

- **Data Structures**
  - RECORD Types
  - TABLE Types

- **Summary of DBMS_DEBUG Subprograms**
Using DBMS_DEBUG

- Overview
- Constants
- Variables
- Exceptions
- Operational Notes
Overview

To debug server-side code, you must have two database sessions: one session to run the code in debug mode (the target session), and a second session to supervise the target session (the debug session).

The target session becomes available for debugging by making initializing calls with DBMS_DEBUG. This marks the session so that the PL/SQL interpreter runs in debug mode and generates debug events. As debug events are generated, they are posted from the session. In most cases, debug events require return notification: the interpreter pauses awaiting a reply.

Meanwhile, the debug session must also initialize itself using DBMS_DEBUG: This tells it which target session to supervise. The debug session may then call entry points in DBMS_DEBUG to read events that were posted from the target session and to communicate with the target session.

The following subprograms are run in the target session (the session that is to be debugged):

- SYNCHRONIZE Function
- DEBUG_ON Procedure
- DEBUG_OFF Procedure

DBMS_DEBUG does not provide an interface to the PL/SQL compiler, but it does depend on debug information optionally generated by the compiler. Without debug information, it is not possible to examine or modify the values of parameters or variables.
A breakpoint status may have the following value:

- `breakpoint_status_unused`—breakpoint is not in use

Otherwise, the status is a mask of the following values:

- `breakpoint_status_active`—a line breakpoint
- `breakpoint_status_disabled`—breakpoint is currently disabled
- `breakpoint_status_remote`—a shadow breakpoint (a local representation of a remote breakpoint)
Variables

The DBMS_DEBUG uses the variables shown in Table 52–1.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>default_timeout</td>
<td>The timeout value (used by both sessions). The smallest possible timeout is 1 second. If this value is set to 0, then a large value (3600) is used.</td>
</tr>
</tbody>
</table>
Exceptions

These values are returned by the various functions called in the debug session (SYNCHRONIZE, CONTINUE, SET_BREAKPOINT, and so on). If PL/SQL exceptions worked across client/server and server/server boundaries, then these would all be exceptions rather than error codes.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>Normal termination</td>
</tr>
</tbody>
</table>

Statutes returned by GET_VALUE and SET_VALUE:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_bogus_frame</td>
<td>No such entrypoint on the stack</td>
</tr>
<tr>
<td>error_no_debug_info</td>
<td>Program was compiled without debug symbols</td>
</tr>
<tr>
<td>error_no_such_object</td>
<td>No such variable or parameter</td>
</tr>
<tr>
<td>error_unknown_type</td>
<td>Debug information is unreadable</td>
</tr>
<tr>
<td>error_indexed_table</td>
<td>Returned by GET_VALUE if the object is a table, but no index</td>
</tr>
<tr>
<td></td>
<td>was provided</td>
</tr>
<tr>
<td>error_illegal_index</td>
<td>No such element exists in the collection</td>
</tr>
<tr>
<td>error_nullcollection</td>
<td>Table is atomically NULL</td>
</tr>
<tr>
<td>error_nullvalue</td>
<td>Value is NULL</td>
</tr>
</tbody>
</table>

Statutes returned by SET_VALUE:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_illegal_value</td>
<td>Constraint violation</td>
</tr>
<tr>
<td>error_illegal_null</td>
<td>Constraint violation</td>
</tr>
<tr>
<td>error_value_malformed</td>
<td>Unable to decipher the given value</td>
</tr>
<tr>
<td>error_other</td>
<td>Some other error</td>
</tr>
<tr>
<td>error_name_incomplete</td>
<td>Name did not resolve to a scalar</td>
</tr>
</tbody>
</table>

Statutes returned by the breakpoint functions:

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_no_such_breakpt</td>
<td>No such breakpoint</td>
</tr>
<tr>
<td>error_idle_breakpt</td>
<td>Cannot enable or disable an unused breakpoint</td>
</tr>
<tr>
<td>error_bad_handle</td>
<td>Unable to set breakpoint in given program (nonexistent or</td>
</tr>
<tr>
<td></td>
<td>security violation)</td>
</tr>
</tbody>
</table>

General error codes (returned by many of the DBMS_DEBUG subprograms):

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_unimplemented</td>
<td>Functionality is not yet implemented</td>
</tr>
</tbody>
</table>
The following exceptions are raised by procedure `SELF_CHECK`:

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>pipe_creation_failure</code></td>
<td>Could not create a pipe</td>
</tr>
<tr>
<td><code>pipe_send_failure</code></td>
<td>Could not write data to the pipe</td>
</tr>
<tr>
<td><code>pipe_receive_failure</code></td>
<td>Could not read data from the pipe</td>
</tr>
<tr>
<td><code>pipe_datatype_mismatch</code></td>
<td>Datatype in the pipe was wrong</td>
</tr>
<tr>
<td><code>pipe_data_error</code></td>
<td>Data got garbled in the pipe</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Status</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>error_deferred</code></td>
<td>No program running; operation deferred</td>
</tr>
<tr>
<td><code>error_exception</code></td>
<td>An exception was raised in the <code>DBMS_DEBUG</code> or <code>Probe</code> packages on the server</td>
</tr>
<tr>
<td><code>error_communication</code></td>
<td>Some error other than a timeout occurred</td>
</tr>
<tr>
<td><code>error_timeout</code></td>
<td>Timeout occurred</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>illegal_init</code></td>
<td><code>DEBUG_ON</code> was called prior to <code>INITIALIZE</code></td>
</tr>
</tbody>
</table>
Operational Notes

There are two ways to ensure that debug information is generated: through a session switch, or through individual recompilation.

To set the session switch, enter the following statement:

```
ALTER SESSION SET PLSQL_DEBUG = true;
```

This instructs the compiler to generate debug information for the remainder of the session. It does not recompile any existing PL/SQL.

To generate debug information for existing PL/SQL code, use one of the following statements (the second recompiles a package or type body):

```
ALTER [PROCEDURE | FUNCTION | PACKAGE | TRIGGER | TYPE] <name> COMPILE DEBUG;
ALTER [PACKAGE | TYPE] <name> COMPILE DEBUG BODY;
```

Figure 52–1 and Figure 52–2 illustrate the flow of operations in the session to be debugged and in the debugging session.

**Figure 52–1 Target Session**

1. Initialize session for debugging, and generate/specify unique debugID. DBMS_DEBUG.initialize()
2. Start debugging DBMS_DEBUG.debug_on()
3. Execute PL/SQL programs
4. Stop debugging DBMS_DEBUG.debug_off()

This illustration shows the first steps in the target session:

First, initialize the session for debugging, and generate or specify the unique debugID. DBMS_DEBUG.initialize()

Then, start debugging using DBMS_DEBUG.debug_on() or stop debugging using DBMS_DEBUG.debug_off(). Then, execute the PL/SQL program.

*******************************************************************************
Using DBMS_DEBUG

Figure 52–2  Debug Session

This illustration shows the continuation of steps in the target session:

- Initialize using DBMS_DEBUG.attach_session()
- Manipulate the breakpoints using:
  - DBMS_DEBUG.set_breakpoint()
  - DBMS_DEBUG.delete_breakpoint()
  - DBMS_DEBUG.disable_breakpoint()
  - DBMS_DEBUG.enable_breakpoint()
  - DBMS_DEBUG.show_breakpoints()
- Read first event from the target session using DBMS_DEBUG.synchronize()
- Show the stack using DBMS_DEBUG.print_backtrace()
- Get/set values
  - DBMS_DEBUG.get_value()
  - DBMS_DEBUG.set_value()
- Show source
  - DBMS_DEBUG.show_source()
Operational Notes

- Get/set values using:
  - DBMS_DEBUG.get_value()
  - DBMS_DEBUG.set_value()
- Manipulate the breakpoints
- Show the source by using DBMS_DEBUG.show_source().

Figure 52–3  Debug Session (Cont.)

This illustration shows the final steps in the target session:
- Continue execution and wait for next event DBMS_DEBUG.continue()
- If the program terminated, detach the session using DBMS_DEBUG.detach_session()
- If it did not terminate, resume the process by showing the stack.

Control of the Interpreter

The interpreter pauses execution at the following times:
1. At startup of the interpreter so any deferred breakpoints may be installed prior to execution.
2. At any line containing an enabled breakpoint.
3. At any line where an interesting event occurs. The set of interesting events is specified by the flags passed to DBMS_DEBUG.CONTINUE in the breakflags parameter.

Session Termination

There is no event for session termination. Therefore, it is the responsibility of the debug session to check and make sure that the target session has not ended. A call to DBMS_DEBUG.SYNCHRONIZE after the target session has ended causes the debug session to hang until it times out.
Deferred Operations

The diagram suggests that it is possible to set breakpoints prior to having a target session. This is true. In this case, Probe caches the breakpoint request and transmits it to the target session at first synchronization. However, if a breakpoint request is deferred in this fashion, then:

- `SET_BREAKPOINT` does not set the breakpoint number (it can be obtained later from `SHOW_BREAKPOINTS` if necessary).
- `SET_BREAKPOINT` does not validate the breakpoint request. If the requested source line does not exist, then an error silently occurs at synchronization, and no breakpoint is set.

Diagnostic Output

To debug Probe, there are `diagnostics` parameters to some of the calls in `DBMS_DEBUG`. These parameters specify whether to place diagnostic output in the RDBMS tracefile. If output to the RDBMS tracefile is disabled, these parameters have no effect.

Common and Debug Session Sections

- Common Section
- Target Session
- Debug Session Section

Common Section

The following subprograms may be called in either the target or the debug session:

- `PROBE_VERSION` Procedure
- `SELF_CHECK` Procedure
- `SET_TIMEOUT` Function

Target Session

The following subprograms may be called only in the target session:

- `INITIALIZE` Function
- `DEBUG_ON` Procedure
- `SET_TIMEOUT_BEHAVIOUR` Procedure
- `GET_TIMEOUT_BEHAVIOUR` Function

Debug Session Section

The following subprograms should be run in the debug session only:

- `ATTACH_SESSION` Procedure
- `SYNCHRONIZE` Function
- `SHOW_FRAME_SOURCE` Procedure
- `SHOW_SOURCE` Procedures
- `GET_MORE_SOURCE` Procedure
- `PRINT_BACKTRACE` Procedure
- `CONTINUE` Function
- `SET_BREAKPOINT` Function
OER Breakpoints

Exceptions that are declared in PL/SQL programs are known as user-defined exceptions. In addition, there are Oracle Errors (OERs) that are returned from the Oracle kernel. To tie the two mechanisms together, PL/SQL provides the `exception_init` pragma that turns a user-defined exception into an OER, so that a PL/SQL handler may be used for it, and so that the PL/SQL engine can return OERs to the Oracle kernel. As of the current release, the only information available about an OER is its number. If two user-defined exceptions are `exception_init`d to the same OER, they are indistinguishable.

Namespaces

Program units on the server reside in different namespaces. When setting a breakpoint, specify the desired namespace.

1. `Namespace_cursor` contains cursors (anonymous blocks).
2. `NamespacePgkspec_or_toplevel` contains:
   - Package specifications.
   - Procedures and functions that are not nested inside other packages, procedures, or functions.
   - Object types.
3. `Namespace_pkg_body` contains package bodies and type bodies.
Libunit Types

These values are used to disambiguate among objects in a given namespace. These constants are used in `PROGRAM_INFO` when Probe is giving a stack backtrace.

- `LibunitType_cursor`
- `LibunitType_procedure`
- `LibunitType_function`
- `LibunitType_package`
- `LibunitType_package_body`
- `LibunitType_trigger`
- `LibunitType_Unknown`

Breakflags

These are values to use for the `breakflags` parameter to `CONTINUE`, in order to tell Probe what events are of interest to the client. These flags may be combined.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>break_next_line</td>
<td>Break at next source line (step over calls)</td>
</tr>
<tr>
<td>break_any_call</td>
<td>Break at next source line (step into calls)</td>
</tr>
<tr>
<td>break_any_return</td>
<td>Break after returning from current entrypoint (skip over any entrypoints called from the current routine)</td>
</tr>
<tr>
<td>break_return</td>
<td>Break the next time an entrypoint gets ready to return. (This includes entrypoints called from the current one. If interpreter is running Proc1, which calls Proc2, then break_return stops at the end of Proc2.)</td>
</tr>
<tr>
<td>break_exception</td>
<td>Break when an exception is raised</td>
</tr>
<tr>
<td>break_handler</td>
<td>Break when an exception handler is executed</td>
</tr>
<tr>
<td>abort_execution</td>
<td>Stop execution and force an 'exit' event as soon as DBMS_DEBUG.CONTINUE is called.</td>
</tr>
</tbody>
</table>

Information Flags

These are flags which may be passed as the `info_requested` parameter to `SYNCHRONIZE`, `CONTINUE`, and `GET_RUNTIME_INFO`.

<table>
<thead>
<tr>
<th>Flag</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>info_getStackDepth</td>
<td>Get the current depth of the stack</td>
</tr>
<tr>
<td>info_getBreakpoint</td>
<td>Get the breakpoint number</td>
</tr>
<tr>
<td>info_getLineinfo</td>
<td>Get program unit information</td>
</tr>
</tbody>
</table>

Reasons for Suspension

After `CONTINUE` is run, the program either runs to completion or breaks on some line.

<p>| Reason       | Description |
|--------------|-------------|-------------|</p>
<table>
<thead>
<tr>
<th>Reason</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reason_interpreter_starting</td>
<td>Interpreter is starting</td>
</tr>
<tr>
<td>reason_breakpoint</td>
<td>Hit a breakpoint</td>
</tr>
<tr>
<td>reason_enter</td>
<td>Procedure entry</td>
</tr>
<tr>
<td>reason_return</td>
<td>Procedure is about to return</td>
</tr>
<tr>
<td>reason_finish</td>
<td>Procedure is finished</td>
</tr>
<tr>
<td>reason_line</td>
<td>Reached a new line</td>
</tr>
<tr>
<td>reason_interrupt</td>
<td>An interrupt occurred</td>
</tr>
<tr>
<td>reason_exception</td>
<td>An exception was raised</td>
</tr>
<tr>
<td>reason_exit</td>
<td>Interpreter is exiting (old form)</td>
</tr>
<tr>
<td>reason_knl_exit</td>
<td>Kernel is exiting</td>
</tr>
<tr>
<td>reason_handler</td>
<td>Start exception-handler</td>
</tr>
<tr>
<td>reason_timeout</td>
<td>A timeout occurred</td>
</tr>
<tr>
<td>reason_instantiate</td>
<td>Instantiation block</td>
</tr>
<tr>
<td>reason_abort</td>
<td>Interpreter is aborting</td>
</tr>
</tbody>
</table>
Data Structures

The `DBMS_DEBUG` package defines RECORD types and TABLE types.

**RECORD Types**
- BREAKPOINT_INFO Record Type
- PROGRAM_INFO Record Type
- RUNTIME_INFO Record Type

**TABLE Types**
- BACKTRACE_TABLE Table Type
- BREAKPOINT_TABLE Table Type
- INDEX_TABLE Table Type
- VC2_TABLE Table Type
BREAKPOINT_INFO Record Type

This type gives information about a breakpoint, such as its current status and the program unit in which it was placed.

Syntax

```sql
TYPE breakpoint_info IS RECORD {
  name        VARCHAR2(30),
  owner       VARCHAR2(30),
  dblink      VARCHAR2(30),
  line#       BINARY_INTEGER,
  libunittype BINARY_INTEGER,
  status      BINARY_INTEGER);
```

Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the program unit</td>
</tr>
<tr>
<td>owner</td>
<td>Owner of the program unit</td>
</tr>
<tr>
<td>dblink</td>
<td>Database link, if remote</td>
</tr>
<tr>
<td>line#</td>
<td>Line number</td>
</tr>
<tr>
<td>libunittype</td>
<td>NULL, unless this is a nested procedure or function</td>
</tr>
<tr>
<td>status</td>
<td>See Constants on page 52-4 for values of breakpoint_status_*</td>
</tr>
</tbody>
</table>

...
PROGRAM_INFO Record Type

This type specifies a program location. It is a line number in a program unit. This is used for stack backtraces and for setting and examining breakpoints. The read-only fields are currently ignored by Probe for breakpoint operations. They are set by Probe only for stack backtraces.

Syntax

```plaintext
TYPE program_info IS RECORD(
    -- The following fields are used when setting a breakpoint
    namespace        BINARY_INTEGER,
    name             VARCHAR2(30),
    owner            VARCHAR2(30),
    dblink           VARCHAR2(30),
    line#            BINARY_INTEGER,
    -- Read-only fields (set by Probe when doing a stack backtrace)
    libunittype      BINARY_INTEGER,
    entrypointname   VARCHAR2(30));
```

Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>namespace</td>
<td>See Namespaces on page 52-12</td>
</tr>
<tr>
<td>name</td>
<td>Name of the program unit</td>
</tr>
<tr>
<td>owner</td>
<td>Owner of the program unit</td>
</tr>
<tr>
<td>dblink</td>
<td>Database link, if remote</td>
</tr>
<tr>
<td>line#</td>
<td>Line number</td>
</tr>
<tr>
<td>libunittype</td>
<td>A read-only field, NULL, unless this is a nested procedure or function</td>
</tr>
<tr>
<td>entrypointname</td>
<td>A read-only field, to disambiguate among objects that share the same namespace (for example, procedure and package specifications). See the Libunit Types on page 52-13 for more information.</td>
</tr>
</tbody>
</table>
RUNTIME_INFO Record Type

This type gives context information about the running program.

**Syntax**

```plsql
TYPE runtime_info IS RECORD(
    line#            BINARY_INTEGER,
    terminated       binary_integer,
    breakpoint       binary_integer,
    stackdepth       BINARY_INTEGER,
    interpreterdepth BINARY_INTEGER,
    reason           BINARY_INTEGER,
    program          program_info);
```

**Fields**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>line#</td>
<td>Duplicate of program.line#</td>
</tr>
<tr>
<td>terminated</td>
<td>Whether the program has terminated</td>
</tr>
<tr>
<td>breakpoint</td>
<td>Breakpoint number</td>
</tr>
<tr>
<td>stackdepth</td>
<td>Number of frames on the stack</td>
</tr>
<tr>
<td>interpreterdepth</td>
<td>[A reserved field]</td>
</tr>
<tr>
<td>reason</td>
<td>Reason for suspension</td>
</tr>
<tr>
<td>program</td>
<td>Source location</td>
</tr>
</tbody>
</table>
BACKTRACE_TABLE Table Type

This type is used by PRINT_BACKTRACE.

Syntax

```plaintext
TYPE backtrace_table IS TABLE OF program_info INDEX BY BINARY_INTEGER;
```
BREAKPOINT_TABLE Table Type

This type is used by `SHOW BREAKPOINTS`.

Syntax

```sql
TYPE breakpoint_table IS TABLE OF breakpoint_info INDEX BY BINARY_INTEGER;
```
INDEX_TABLE Table Type

This type is used by GET_INDEXES to return the available indexes for an indexed table.

Syntax

```sql
TYPE index_table IS table of BINARY_INTEGER INDEX BY BINARY_INTEGER;
```
VC2_TABLE Table Type

This type is used by SHOW_SOURCE.

Syntax

TYPE vc2_table IS TABLE OF VARCHAR2(90) INDEX BY BINARY_INTEGER;
# Summary of DBMS_DEBUG Subprograms

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>SET_TIMEOUT</strong> Function on page 52-52</td>
<td>Sets the timeout value</td>
</tr>
<tr>
<td><strong>SET_TIMEOUT_BEHAVIOUR</strong> Procedure on page 52-53</td>
<td>Tells Probe what to do with the target session when a timeout occurs</td>
</tr>
<tr>
<td><strong>SET_VALUE</strong> Function on page 52-54</td>
<td>Sets a value in the currently-running program</td>
</tr>
<tr>
<td><strong>SHOW_BREAKPOINTS</strong> Procedures on page 52-56</td>
<td>Returns a listing of the current breakpoints</td>
</tr>
<tr>
<td><strong>SHOW_FRAME_SOURCE</strong> Procedure on page 52-57</td>
<td>Fetches the frame source</td>
</tr>
<tr>
<td><strong>SHOW_SOURCE</strong> Procedures on page 52-58</td>
<td>Fetches program source</td>
</tr>
<tr>
<td><strong>SYNCHRONIZE</strong> Function on page 52-60</td>
<td>Waits for program to start running</td>
</tr>
<tr>
<td><strong>TARGET_PROGRAM_RUNNING</strong> Procedure on page 52-61</td>
<td>Returns <strong>TRUE</strong> if the target session is currently executing a stored procedure, or <strong>FALSE</strong> if it is not</td>
</tr>
</tbody>
</table>

ATTACH_SESSION Procedure

This procedure notifies the debug session about the target program.

Syntax

```sql
DBMS_DEBUG.ATTACH_SESSION (  
    debug_session_id  IN VARCHAR2,  
    diagnostics       IN BINARY_INTEGER := 0);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug_session_id</td>
<td>Debug ID from a call to INITIALIZE in target session</td>
</tr>
<tr>
<td>diagnostics</td>
<td>Generate diagnostic output if nonzero</td>
</tr>
</tbody>
</table>
CONTINUE Function

This function passes the given breakflags (a mask of the events that are of interest) to Probe in the target process. It tells Probe to continue execution of the target process, and it waits until the target process runs to completion or signals an event.

If infoRequested is not NULL, then calls GET_RUNTIME_INFO.

Syntax

DBMS_DEBUG.CONTINUE (  
  run_info       IN OUT runtime_info,  
  breakflags     IN     BINARY_INTEGER,  
  info_requested IN     BINARY_INTEGER := NULL)  
RETURN BINARY_INTEGER;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>run_info</td>
<td>Information about the state of the program</td>
</tr>
<tr>
<td>breakflags</td>
<td>Mask of events that are of interest (see &quot;Breakflags&quot; on page 52-13)</td>
</tr>
<tr>
<td>info_requested</td>
<td>Which information should be returned in run_info when the program stops (see &quot;Information Flags&quot; on page 52-13)</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>Timed out before the program started running</td>
</tr>
<tr>
<td>error_timeout</td>
<td>Other communication error</td>
</tr>
<tr>
<td>error_communication</td>
<td>Other communication error</td>
</tr>
</tbody>
</table>
DEBUG_OFF Procedure

Caution: There must be a debug session waiting if immediate is TRUE.

This procedure notifies the target session that debugging should no longer take place in that session. It is not necessary to call this function before ending the session.

Syntax

DBMS_DEBUG.DEBUG_OFF;

Usage Notes

The server does not handle this entrypoint specially. Therefore, it attempts to debug this entrypoint.
DEBUG_ON Procedure

This procedure marks the target session so that all PL/SQL is run in debug mode. This must be done before any debugging can take place.

Syntax

```sql
DBMS_DEBUG.DEBUG_ON (
    no_client_side_plsql_engine BOOLEAN := TRUE,
    immediate                   BOOLEAN := FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>no_client_side_plsql_engine</td>
<td>Should be left to its default value unless the debugging session is taking place from a client-side PL/SQL engine</td>
</tr>
<tr>
<td>immediate</td>
<td>If this is TRUE, then the interpreter immediately switches itself into debug-mode, instead of continuing in regular mode for the duration of the call.</td>
</tr>
</tbody>
</table>
DELETE_BREAKPOINT Function

This function deletes a breakpoint.

Syntax

DBMS_DEBUG.DELETE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>breakpoint</td>
<td>Breakpoint number from a previous call to SET_BREAKPOINT</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>No such breakpoint exists</td>
</tr>
<tr>
<td>error_no_such_breakpt</td>
<td>Cannot delete an unused breakpoint</td>
</tr>
<tr>
<td>error_idle_breakpt</td>
<td>The program unit was redefined since the breakpoint was set</td>
</tr>
</tbody>
</table>
DELETE_OER_BREAKPOINT Function

This function deletes an OER breakpoint.

Syntax

```
DBMS_DEBUG.DELETE_OER_BREAKPOINT (  
oer  IN PLS_INTEGER)  
RETURN PLS_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oer</td>
<td>The OER (positive 4-byte number) to delete</td>
</tr>
</tbody>
</table>
DETACH_SESSION Procedure

This procedure stops debugging the target program. This procedure may be called at any time, but it does not notify the target session that the debug session is detaching itself, and it does not terminate execution of the target session. Therefore, care should be taken to ensure that the target session does not hang itself.

Syntax

DBMS_DEBUG.DETACH_SESSION;
DISABLE_BREAKPOINT Function

This function makes an existing breakpoint inactive but leaves it in place.

Syntax

```plsql
DBMS_DEBUG.DISABLE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>breakpoint</td>
<td>Breakpoint number from a previous call to SET_BREAKPOINT</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Returns</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td></td>
</tr>
<tr>
<td>error_no_such_breakpt</td>
<td>No such breakpoint exists</td>
</tr>
<tr>
<td>error_idle_breakpt</td>
<td>Cannot disable an unused breakpoint</td>
</tr>
</tbody>
</table>
ENABLE_BREAKPOINT Function

This function is the reverse of disabling. This enables a previously disabled breakpoint.

Syntax

```sql
DBMS_DEBUG.ENABLE_BREAKPOINT (  
    breakpoint IN BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>breakpoint</td>
<td>Breakpoint number from a previous call to SET_BREAKPOINT</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>Success</td>
</tr>
<tr>
<td>error_no_such_breakpt</td>
<td>No such breakpoint exists</td>
</tr>
<tr>
<td>error_idle_breakpt</td>
<td>Cannot enable an unused breakpoint</td>
</tr>
</tbody>
</table>
EXECUTE Procedure

This procedure executes SQL or PL/SQL code in the target session. The target session is assumed to be waiting at a breakpoint (or other event). The call to DBMS_DEBUG.EXECUTE occurs in the debug session, which then asks the target session to execute the code.

Syntax

```
DBMS_DEBUG.EXECUTE (  
    what         IN VARCHAR2,  
    frame#       IN BINARY_INTEGER,  
    bind_results IN BINARY_INTEGER,  
    results      IN OUT NOCOPY dbms_debug_vc2coll,  
    errm         IN OUT NOCOPY VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>what</td>
<td>SQL or PL/SQL source to execute</td>
</tr>
<tr>
<td>frame#</td>
<td>The context in which to execute the code. Only -1 (global context) is supported at this time.</td>
</tr>
<tr>
<td>bind_results</td>
<td>Whether the source wants to bind to results in order to return values from the target session:</td>
</tr>
<tr>
<td></td>
<td>0 = No</td>
</tr>
<tr>
<td></td>
<td>1 = Yes</td>
</tr>
<tr>
<td>results</td>
<td>Collection in which to place results, if bind_results is not 0</td>
</tr>
<tr>
<td>errm</td>
<td>Error message, if an error occurred; otherwise, NULL</td>
</tr>
</tbody>
</table>

Examples

Example 1
This example executes a SQL statement. It returns no results.

```
DECLARE  
    coll sys.dbms_debug_vc2coll; -- results (unused)  
    errm VARCHAR2(100);  
BEGIN  
    dbms_debug.execute ('insert into emp (ename,empno,deptno) ' ||  
        'values (''LJE'', 1, 1)' ,  
    -1, 0, coll, errm);  
END;
```

Example 2
This example executes a PL/SQL block, and it returns no results. The block is an autonomous transaction, which means that the value inserted into the table becomes visible in the debug session.

```
DECLARE  
    coll sys.dbms_debug_vc2coll;  
    errm VARCHAR2(100);  
BEGIN  
```

52-34 Oracle Database PL/SQL Packages and Types Reference
Example 3
This example executes a PL/SQL block, and it returns some results.

```plsql
DECLARE
coll sys.dbms_debug_vc2coll;
ero VARCHAR2(100);
BEGIN
dbms_debug.execute(
   'DECLARE pp SYS.dbms_debug_vc2coll := SYS.dbms_debug_vc2coll(); ' ||
   '   x PLS_INTEGER; ' ||
   '   i PLS_INTEGER := 1; ' ||
   'BEGIN ' ||
   '   SELECT COUNT(*) INTO x FROM emp; ' ||
   '   pp.EXTEND(x * 6); ' ||
   '   FOR c IN (SELECT * FROM emp) LOOP ' ||
   '      pp(i) := ''Ename: '' || c.ename; i := i+1; ' ||
   '      pp(i) := ''Empno: '' || c.empno; i := i+1; ' ||
   '      pp(i) := ''Job:   '' || c.job;   i := i+1; ' ||
   '      pp(i) := ''Mgr:   '' || c.mgr;   i := i+1; ' ||
   '      pp(i) := ''Sal:   '' || c.sal;   i := i+1; ' ||
   '      END LOOP; ' ||
   '   :1 := pp;' ||
   'END;',
   -1, 1, coll, erro);
each := coll.FIRST;
   WHILE (each IS NOT NULL) LOOP
      dosomething(coll(each));
each := coll.NEXT(each);
   END LOOP;
END;
```
GET_INDEXES Function

Given a name of a variable or parameter, this function returns the set of its indexes, if it is an indexed table. An error is returned if it is not an indexed table.

Syntax

```sql
DBMS_DEBUG.GET_INDEXES (  
  varname   IN  VARCHAR2,  
  frame#    IN  BINARY_INTEGER,  
  handle    IN  program_info,  
  entries   OUT index_table)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>varname</td>
<td>Name of the variable to get index information about</td>
</tr>
<tr>
<td>frame#</td>
<td>Number of frame in which the variable or parameter resides; NULL for a package variable</td>
</tr>
<tr>
<td>handle</td>
<td>Package description, if object is a package variable</td>
</tr>
<tr>
<td>entries</td>
<td>1-based table of the indexes: if non-NULL, then entries(1) contains the first index of the table, entries(2) contains the second index, and so on.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_no_such_object</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>- The package does not exist</td>
</tr>
<tr>
<td></td>
<td>- The package is not instantiated</td>
</tr>
<tr>
<td></td>
<td>- The user does not have privileges to debug the package</td>
</tr>
<tr>
<td></td>
<td>- The object does not exist in the package</td>
</tr>
</tbody>
</table>
GET_MORE_SOURCE Procedure

When source does not fit in the buffer provided by that version of the SHOW_SOURCE Procedures which produce a formatted buffer, this procedure provides additional source.

Syntax

DBMS_DEBUG.GET_MORE_SOURCE (buffer IN OUT VARCHAR2,
buflen IN BINARY_INTEGER,
piece# IN BINARY_INTEGER);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buffer</td>
<td>The buffer</td>
</tr>
<tr>
<td>buflen</td>
<td>The length of the buffer</td>
</tr>
<tr>
<td>piece#</td>
<td>A value between 2 and the value returned in the parameter pieces from the call to the relevant version of the SHOW_SOURCE Procedures</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure should be called only after the version of SHOW_SOURCE that returns a formatted buffer.
GET_LINE_MAP Function

This function finds line and entrypoint information about a program so that a debugger can determine the source lines at which it is possible to place breakpoints.

Syntax

```
DBMS_DEBUG.GET_LINE_MAP (
    program                IN   program_info,
    maxline                OUT  BINARY_INTEGER,
    number_of_entry_points OUT  BINARY_INTEGER,
    linemap                OUT  RAW)
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program</td>
<td>A top-level program unit (procedure / package / function / package body, and so on). Its Namespace, Name, and Owner fields must be initialized, the remaining fields are ignored.</td>
</tr>
<tr>
<td>maxline</td>
<td>The largest source code line number in 'program'</td>
</tr>
<tr>
<td>number_of_entry_points</td>
<td>The number of subprograms in 'program'</td>
</tr>
<tr>
<td>linemap</td>
<td>A bitmap representing the executable lines of 'program'. If line number N is executable, bit number N MOD 8 will be set to 1 at linemap position N / 8. The length of returned linemap is either maxline divided by 8 (plus one if maxline MOD 8 is not zero) or 32767 in the unlikely case of maxline being larger than 32767 * 8.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>A successful completion</td>
</tr>
<tr>
<td>error_no_debug_info</td>
<td>The program unit exists, but has no debug info</td>
</tr>
<tr>
<td>error_bad_handle</td>
<td>No such program unit exists</td>
</tr>
</tbody>
</table>
**GET_RUNTIME_INFO Function**

This function returns information about the current program. It is only needed if the `info_requested` parameter to `SYNCHRONIZE` or `CONTINUE` was set to 0.

---

**Note:** This is currently only used by client-side PL/SQL.

---

**Syntax**

```sql
DBMS_DEBUG.GET_RUNTIME_INFO (
    infoRequested  IN  BINARY_INTEGER,
    run_info        OUT runtime_info)
RETURN BINARY_INTEGER;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>info_requested</td>
<td>Which information should be returned in <code>run_info</code> when the program stops (see &quot;Information Flags&quot; on page 52-13)</td>
</tr>
<tr>
<td>run_info</td>
<td>Information about the state of the program</td>
</tr>
</tbody>
</table>
GET_TIMEOUT_BEHAVIOUR Function

This procedure returns the current timeout behavior. This call is made in the target session.

Syntax

```sql
DBMS_DEBUG.GET_TIMEOUT_BEHAVIOUR
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oer</td>
<td>The OER (a 4-byte positive number)</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>A successful completion</td>
</tr>
</tbody>
</table>

Information Flags

```sql
info_getOerInfo CONSTANT PLS_INTEGER:= 32;
```

Usage Notes

Less functionality is supported on OER breakpoints than on code breakpoints. In particular, note that:

- No "breakpoint number" is returned - the number of the OER is used instead. Thus it is impossible to set duplicate breakpoints on a given OER (it is a no-op).
- It is not possible to disable an OER breakpoint (although clients are free to simulate this by deleting it).
- OER breakpoints are deleted using `delete_oer_breakpoint`. 
**GET_VALUE Function**

This function gets a value from the currently-running program. There are two overloaded GET_VALUE functions.

**Syntax**

```sql
DBMS_DEBUG.GET_VALUE (
    variable_name  IN  VARCHAR2,
    frame#         IN  BINARY_INTEGER,
    scalar_value   OUT VARCHAR2,
    format         IN  VARCHAR2 := NULL)
RETURN BINARY_INTEGER;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variable_name</td>
<td>Name of the variable or parameter</td>
</tr>
<tr>
<td>frame#</td>
<td>Frame in which it lives; 0 means the current procedure</td>
</tr>
<tr>
<td>scalar_value</td>
<td>Value</td>
</tr>
<tr>
<td>format</td>
<td>Optional date format to use, if meaningful</td>
</tr>
</tbody>
</table>

**Return Values**

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>A successful completion</td>
</tr>
<tr>
<td>error_bogus_frame</td>
<td>Frame does not exist</td>
</tr>
<tr>
<td>error_no_debug_info</td>
<td>Entry point has no debug information</td>
</tr>
<tr>
<td>error_no_such_object</td>
<td>variable_name does not exist in frame#</td>
</tr>
<tr>
<td>error_unknown_type</td>
<td>The type information in the debug information is illegible</td>
</tr>
<tr>
<td>error_nullvalue</td>
<td>Value is NULL</td>
</tr>
<tr>
<td>error_indexed_table</td>
<td>The object is a table, but no index was provided</td>
</tr>
</tbody>
</table>

This form of GET_VALUE is for fetching package variables. Instead of a frame#, it takes a handle, which describes the package containing the variable.

**Syntax**

```sql
DBMS_DEBUG.GET_VALUE (
    variable_name  IN  VARCHAR2,
    handle         IN  program_info,
    scalar_value   OUT VARCHAR2,
    format         IN  VARCHAR2 := NULL)
RETURN BINARY_INTEGER;
```
GET_VALUE Function

Parameters

Table 52–28  GET_VALUE Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>variable_name</td>
<td>Name of the variable or parameter</td>
</tr>
<tr>
<td>handle</td>
<td>Description of the package containing the variable</td>
</tr>
<tr>
<td>scalar_value</td>
<td>Value</td>
</tr>
<tr>
<td>format</td>
<td>Optional date format to use, if meaningful</td>
</tr>
</tbody>
</table>

Return Values

Table 52–29  GET_VALUE Function Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_no_such_object</td>
<td>One of the following:</td>
</tr>
<tr>
<td></td>
<td>- Package does not exist</td>
</tr>
<tr>
<td></td>
<td>- Package is not instantiated</td>
</tr>
<tr>
<td></td>
<td>- User does not have privileges to debug the package</td>
</tr>
<tr>
<td></td>
<td>- Object does not exist in the package</td>
</tr>
<tr>
<td>error_indexed_table</td>
<td>The object is a table, but no index was provided</td>
</tr>
</tbody>
</table>

Examples

This example illustrates how to get the value with a given package PACK in schema SCOTT, containing variable VAR:

```
DECLARE
    handle     dbms_debug.program_info;
    resultbuf  VARCHAR2(500);
    retval     BINARY_INTEGER;
BEGIN
    handle.Owner     := 'SCOTT';
    handle.Name      := 'PACK';
    handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;
    retval           := dbms_debug.get_value('VAR', handle, resultbuf, NULL);
END;
```
### INITIALIZE Function

This function initializes the target session for debugging.

### Syntax

```sql
DBMS_DEBUG.INITIALIZE (  
    debug_session_id  IN VARCHAR2       := NULL,  
    diagnostics       IN BINARY_INTEGER := 0)  
RETURN VARCHAR2;
```

### Parameters

#### Table 52–30 INITIALIZE Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>debug_session_id</td>
<td>Name of session ID. If NULL, then a unique ID is generated.</td>
</tr>
<tr>
<td>diagnostics</td>
<td>Indicates whether to dump diagnostic output to the tracefile:</td>
</tr>
<tr>
<td></td>
<td>0 = (default) no diagnostics</td>
</tr>
<tr>
<td></td>
<td>1 = print diagnostics</td>
</tr>
</tbody>
</table>

### Return Values

The newly-registered debug session ID (debugID)

### Usage Notes

You cannot use `DBMS_DEBUG` and the JDWP-based debugging interface simultaneously. This call will either fail with an ORA-30677 error if the session is currently being debugged with the JDWP-based debugging interface or, if the call succeeds, any further use of the JDWP-based interface to debug this session will be disallowed.

Calls to `DBMS_DEBUG` will succeed only if either the caller or the specified debug role carries the `DEBUG CONNECT SESSION` privilege. Failing that, an ORA-1031 error will be raised. Other exceptions are also possible if a debug role is specified but the password does not match, or if the calling user has not been granted the role, or the role is application-enabled and this call does not originate from within the role-enabling package.

The `CREATE ANY PROCEDURE` privilege does not affect the visibility of routines through the debugger. A privilege `DEBUG` for each object has been introduced with a corresponding `DEBUG ANY PROCEDURE` variant. These are required in order to see routines owned by users other than the session’s login user.

Authentication of the debug role and the check for `DEBUG CONNECT SESSION` privilege will be done in the context of the caller to this routine. If the caller is a definer’s rights routine or has been called from one, only privileges granted to the defining user, the debug role, or `PUBLIC` will be used to check for `DEBUG CONNECT SESSION`. If this call is from within a definer’s rights routine, the debug role, if specified, must be one that has been granted to that definer, but it need not also have been granted to the session login user or be enabled in the calling session at the time the call is made.

The checks made by the debugger after this call is made looking for the `DEBUG` privilege on individual procedures will be done in the context of the session’s login user, the roles that were enabled at session level at the moment this call was made.
(even if those roles were not available within a definer's rights environment of the call), and the debug role.
PING Procedure

This procedure pings the target session to prevent it from timing out. Use this procedure when execution is suspended in the target session, for example at a breakpoint.

If the timeout_behaviour is set to retry_on_timeout then this procedure is not necessary.

Syntax

```
DBMS_DEBUG.PING;
```

Exceptions

Oracle will display the no_target_program exception if there is no target program or if the target session is not currently waiting for input from the debug session.

Usage Notes

Timeout options for the target session are registered with the target session by calling set_timeout_behaviour:

- retry_on_timeout - Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.
- continue_on_timeout - Continue execution, using same event flags.
- nodebug_on_timeout - Turn debug-mode OFF (in other words, call debug_off) and then continue execution. No more events will be generated by this target session unless it is re-initialized by calling debug_on.
- abort_on_timeout - Continue execution, using the abort_execution flag, which should cause the program to terminate immediately. The session remains in debug-mode.

```
retry_on_timeout CONSTANT BINARY_INTEGER:= 0;
continue_on_timeout CONSTANT BINARY_INTEGER:= 1;
nodebug_on_timeout CONSTANT BINARY_INTEGER:= 2;
abort_on_timeout CONSTANT BINARY_INTEGER:= 3;
```
PRINT_BACKTRACE Procedure

This procedure prints a backtrace listing of the current execution stack. This should only be called if a program is currently running.

There are two overloaded PRINT_BACKTRACE procedures.

Syntax

```sql
DBMS_DEBUG.PRINT_BACKTRACE (
    listing IN OUT VARCHAR2);

DBMS_DEBUG.PRINT_BACKTRACE (
    backtrace OUT backtrace_table);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>listing</td>
<td>A formatted character buffer with embedded newlines</td>
</tr>
<tr>
<td>backtrace</td>
<td>1-based indexed table of backtrace entries. The currently-running procedure is the last entry in the table (that is, the frame numbering is the same as that used by GET__VALUE). Entry 1 is the oldest procedure on the stack.</td>
</tr>
</tbody>
</table>
PRINT_INSTANTIATIONS Procedure

This procedure returns a list of the packages that have been instantiated in the current session.

Syntax

```
DBMS_DEBUG.PRINT_INSTANTIATIONS ( 
    pkgs   IN OUT NOCOPY backtrace_table, 
    flags  IN BINARY_INTEGER);
```

Parameters

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pkgs</td>
<td>The instantiated packages</td>
</tr>
<tr>
<td>flags</td>
<td>Bitmask of options:</td>
</tr>
<tr>
<td></td>
<td>■ 1 - show specs</td>
</tr>
<tr>
<td></td>
<td>■ 2 - show bodies</td>
</tr>
<tr>
<td></td>
<td>■ 4 - show local instantiations</td>
</tr>
<tr>
<td></td>
<td>■ 8 - show remote instantiations (NYI)</td>
</tr>
<tr>
<td></td>
<td>■ 16 - do a fast job. The routine does not test whether debug information exists or whether the libunit is shrink-wrapped.</td>
</tr>
</tbody>
</table>
```

Exceptions

- no_target_program - target session is not currently executing

Usage Notes

On return, pkgs contains a program_info for each instantiation. The valid fields are: Namespace, Name, Owner, and LibunitType.

In addition, Line# contains a bitmask of:

- 1 - the libunit contains debug info
- 2 - the libunit is shrink-wrapped
PROBE_VERSION Procedure

This procedure returns the version number of DBMS_DEBUG on the server.

Syntax

```
DBMS_DEBUG.PROBE_VERSION (    major out BINARY_INTEGER,    minor out BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>major</td>
<td>Major version number</td>
</tr>
<tr>
<td>minor</td>
<td>Minor version number: increments as functionality is added</td>
</tr>
</tbody>
</table>
SELF_CHECK Procedure

This procedure performs an internal consistency check. SELF_CHECK also runs a communications test to ensure that the Probe processes are able to communicate.

If SELF_CHECK does not return successfully, then an incorrect version of DBMS_DEBUG was probably installed on this server. The solution is to install the correct version (pbload.sql loads DBMS_DEBUG and the other relevant packages).

Syntax

```sql
DBMS_DEBUG.SELF_CHECK (
    timeout IN binary_integer := 60);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>The timeout to use for the communication test. Default is 60 seconds.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OER-6516</td>
<td>Probe version is inconsistent</td>
</tr>
<tr>
<td>pipe_creation_failure</td>
<td>Could not create a pipe</td>
</tr>
<tr>
<td>pipe_send_failure</td>
<td>Could not write data to the pipe</td>
</tr>
<tr>
<td>pipe_receive_failure</td>
<td>Could not read data from the pipe</td>
</tr>
<tr>
<td>pipe_datatype_mismatch</td>
<td>Datatype in the pipe was wrong</td>
</tr>
<tr>
<td>pipe_data_error</td>
<td>Data got garbled in the pipe</td>
</tr>
</tbody>
</table>

All of these exceptions are fatal. They indicate a serious problem with Probe that prevents it from working correctly.
SET BREAKPOINT Function

This function sets a breakpoint in a program unit, which persists for the current session. Execution pauses if the target program reaches the breakpoint.

Syntax

```sql
DBMS_DEBUG.SET_BREAKPOINT (
    program     IN  program_info,
    line#       IN  BINARY_INTEGER,
    breakpoint# OUT BINARY_INTEGER,
    fuzzy       IN  BINARY_INTEGER := 0,
    iterations  IN  BINARY_INTEGER := 0)
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program</td>
<td>Information about the program unit in which the breakpoint is to be set. (In version 2.1 and later, the namespace, name, owner, and dblink may be set to NULL, in which case the breakpoint is placed in the currently-running program unit.)</td>
</tr>
<tr>
<td>line#</td>
<td>Line at which the breakpoint is to be set</td>
</tr>
<tr>
<td>breakpoint#</td>
<td>On successful completion, contains the unique breakpoint number by which to refer to the breakpoint</td>
</tr>
<tr>
<td>fuzzy</td>
<td>Only applicable if there is no executable code at the specified line:</td>
</tr>
<tr>
<td></td>
<td>- 0 means return error_illegal_line</td>
</tr>
<tr>
<td></td>
<td>- 1 means search forward for an adjacent line at which to place</td>
</tr>
<tr>
<td></td>
<td>the breakpoint</td>
</tr>
<tr>
<td></td>
<td>- -1 means search backward for an adjacent line at which to place</td>
</tr>
<tr>
<td></td>
<td>the breakpoint</td>
</tr>
<tr>
<td>iterations</td>
<td>Number of times to wait before signalling this breakpoint</td>
</tr>
</tbody>
</table>

Return Values

- **success**: A successful completion
- **error_illegal_line**: Cannot set a breakpoint at that line
- **error_bad_handle**: No such program unit exists

---

**Note**: The `fuzzy` and `iterations` parameters are not yet implemented
SET_OERBREAKPOINT Function

This function sets an OER breakpoint.

Syntax

DBMS_DEBUG.SET_OERBREAKPOINT (oer IN PLS_INTEGER)
RETURN PLS_INTEGER;

Parameters

Table 52–38  SET_OERBREAKPOINT Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oer</td>
<td>The OER (positive 4-byte number) to set</td>
</tr>
</tbody>
</table>

Return Values

Table 52–39  SET_OERBREAKPOINT Function Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>A successful completion</td>
</tr>
<tr>
<td>error_no_such_breakpt</td>
<td>No such OER breakpoint exists</td>
</tr>
</tbody>
</table>
SET_TIMEOUT Function

This function sets the timeout value and returns the new timeout value.

Syntax

```sql
DBMS_DEBUG.SET_TIMEOUT (  
    timeout BINARY_INTEGER)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>The timeout to use for communication between the target and debug sessions</td>
</tr>
</tbody>
</table>
SET_TIMEOUT_BEHAVIOUR Procedure

This procedure tells Probe what to do with the target session when a timeout occurs. This call is made in the target session.

Syntax

```plaintext
DBMS_DEBUG.SET_TIMEOUT_BEHAVIOUR (behavior IN PLS_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>behaviour</td>
<td>One of the following:</td>
</tr>
<tr>
<td>retry_on_timeout</td>
<td>Retry. Timeout has no effect. This is like setting the timeout to an infinitely large value.</td>
</tr>
<tr>
<td>continue_on_timeout</td>
<td>Continue execution, using same event flags</td>
</tr>
<tr>
<td>nodebug_on_timeout</td>
<td>Turn debug-mode OFF (in other words, call <code>debug_off</code>) and continue execution. No more events will be generated by this target session unless it is re-initialized by calling <code>debug_on</code>.</td>
</tr>
<tr>
<td>abort_on_timeout</td>
<td>Continue execution, using the <code>abort_execution</code> flag, which should cause the program to terminate immediately. The session remains in debug-mode.</td>
</tr>
</tbody>
</table>

Exceptions

unimplemented - the requested behavior is not recognized

Usage Notes

The default behavior (if this procedure is not called) is continue_on_timeout, since it allows a debugger client to reestablish control (at the next event) but does not cause the target session to hang indefinitely.
SET_VALUE Function

This function sets a value in the currently-running program. There are two overloaded SET_VALUE functions.

Syntax

```sql
DBMS_DEBUG.SET_VALUE (
    frame#               IN binary_integer,
    assignment_statement IN varchar2
) RETURN BINARY_INTEGER;

DBMS_DEBUG.SET_VALUE (
    handle               IN program_info,
    assignment_statement IN VARCHAR2
) RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>frame#</code></td>
<td>Frame in which the value is to be set; 0 means the currently executing frame.</td>
</tr>
<tr>
<td><code>handle</code></td>
<td>Description of the package containing the variable</td>
</tr>
<tr>
<td><code>assignment_statement</code></td>
<td>An assignment statement (which must be legal PL/SQL) to run in order to set the value. For example, 'x := 3;'. Only scalar values are supported in this release. The right side of the assignment statement must be a scalar.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>success</code></td>
<td>-</td>
</tr>
<tr>
<td><code>errorillegal_value</code></td>
<td>Not possible to set it to that value</td>
</tr>
<tr>
<td><code>errorillegal_null</code></td>
<td>Cannot set to NULL because object type specifies it as 'not NULL'</td>
</tr>
<tr>
<td><code>errorvalue_malformed</code></td>
<td>Value is not a scalar</td>
</tr>
<tr>
<td><code>errorno_such_object</code></td>
<td>The assignment statement does not resolve to a scalar. For example, 'x := 3;' if x is a record.</td>
</tr>
</tbody>
</table>

Usage Notes

In some cases, the PL/SQL compiler uses temporaries to access package variables, and does not guarantee to update such temporaries. It is possible, although unlikely, that
modification to a package variable using `SET_VALUE` might not take effect for a line or two.

Examples

To set the value of `SCOTT.PACK.var` to 6:

```sql
DECLARE
    handle   dbms_debug.program_info;
    retval   BINARY_INTEGER;
BEGIN
    handle.Owner     := 'SCOTT';
    handle.Name      := 'PACK';
    handle.namespace := dbms_debug.namespace_pkgspec_or_toplevel;
    retval           := dbms_debug.set_value(handle, 'var := 6;');
END;
```
SHOW_BREAKPOINTS Procedures

There are two overloaded procedures that return a listing of the current breakpoints. There are three overloaded SHOW_BREAKPOINTS procedures.

Syntax

```sql
DBMS_DEBUG.SHOW_BREAKPOINTS (
    listing    IN OUT VARCHAR2);

DBMS_DEBUG.SHOW_BREAKPOINTS (
    listing    OUT breakpoint_table);

DBMS_DEBUG.SHOW_BREAKPOINTS (
    code_breakpoints  OUT breakpoint_table,
    oer_breakpoints   OUT oer_table);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>listing</td>
<td>A formatted buffer (including newlines) of the breakpoints. Indexed table of breakpoint entries. The breakpoint number is indicated by the index into the table. Breakpoint numbers start at 1 and are reused when deleted.</td>
</tr>
<tr>
<td>code_breakpoints</td>
<td>The indexed table of breakpoint entries, indexed by breakpoint number</td>
</tr>
<tr>
<td>oer_breakpoints</td>
<td>The indexed table of OER breakpoints, indexed by OER</td>
</tr>
</tbody>
</table>
SHOW_FRAME_SOURCE Procedure

The procedure gets the source code. There are two overloaded SHOW_SOURCE procedures.

Syntax

```
DBMS_DEBUG.SHOW_FRAME_SOURCE (  
    first_line IN            BINARY_INTEGER,  
    last_line   IN            BINARY_INTEGER,  
    source      IN OUT NOCOPY vc2_table,  
    frame_num   IN            BINARY_INTEGER);
```

Parameters

Table 52–45  SHOW_FRAME_SOURCE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>first_line</td>
<td>Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes)</td>
</tr>
<tr>
<td>last_line</td>
<td>Line number of last line to fetch. No lines are fetched past the end of the program.</td>
</tr>
<tr>
<td>source</td>
<td>The resulting table, which may be indexed by line#</td>
</tr>
<tr>
<td>frame_num</td>
<td>1-based frame number</td>
</tr>
</tbody>
</table>

Usage Notes

- You use this function only when backtrace shows an anonymous unit is executing at a given frame position and you need to view the source in order to set a breakpoint.
- If frame number is top of the stack and it’s an anonymous block then SHOW_SOURCE can also be used.
- If it’s a stored PLSQL package/function/procedure then use SQL as described in the Usage Notes to SHOW_SOURCE Procedures.
SHOW_SOURCE Procedures

The procedure gets the source code. There are two overloaded SHOW_SOURCE procedures.

Syntax

```sql
DBMS_DEBUG.SHOW_SOURCE (  
    first_line  IN   BINARY_INTEGER,  
    last_line   IN   BINARY_INTEGER,  
    source      OUT  vc2_table);

DBMS_DEBUG.SHOW_SOURCE (  
    first_line   IN     BINARY_INTEGER,  
    last_line    IN     BINARY_INTEGER,  
    window       IN     BINARY_INTEGER,  
    print_arrow  IN     BINARY_INTEGER,  
    buffer       IN OUT VARCHAR2,  
    buflen       IN     BINARY_INTEGER,  
    pieces       OUT    BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>first_line</td>
<td>Line number of first line to fetch (PL/SQL programs always start at line 1 and have no holes)</td>
</tr>
<tr>
<td>last_line</td>
<td>Line number of last line to fetch. No lines are fetched past the end of the program.</td>
</tr>
<tr>
<td>source</td>
<td>The resulting table, which may be indexed by line#</td>
</tr>
<tr>
<td>window</td>
<td>'Window' of lines (the number of lines around the current source line)</td>
</tr>
<tr>
<td>print_arrow</td>
<td>Nonzero means to print an arrow before the current line</td>
</tr>
<tr>
<td>buffer</td>
<td>Buffer in which to place the source listing</td>
</tr>
<tr>
<td>buflen</td>
<td>Length of buffer</td>
</tr>
<tr>
<td>pieces</td>
<td>Set to nonzero if not all the source could be placed into the given buffer</td>
</tr>
</tbody>
</table>

Return Values

An indexed table of source-lines. The source lines are stored starting at first_line. If any error occurs, then the table is empty.

Usage Notes

The best way to get the source code (for a program that is being run) is to use SQL. For example:

```sql
DECLARE  
    info DBMS_DEBUG.runtime_info;
BEGIN  
    -- call DBMS_DEBUG.SYNCHRONIZE, CONTINUE,  
    -- or GET_RUNTIME_INFO to fill in 'info'  
    SELECT text INTO <buffer> FROM all_source
```
WHERE owner = info.Program.Owner
    AND name = info.Program.Name
    AND line = info.Line#;
END;

However, this does not work for nonpersistent programs (for example, anonymous blocks and trigger invocation blocks). For nonpersistent programs, call `SHOW_SOURCE`. There are two flavors: one returns an indexed table of source lines, and the other returns a packed (and formatted) buffer.

The second overloading of `SHOW_SOURCE` returns the source in a formatted buffer, complete with line-numbers. It is faster than the indexed table version, but it does not guarantee to fetch all the source.

If the source does not fit in `bufferlength` (`buflen`), then additional pieces can be retrieved using the `GET_MORE_SOURCE` procedure (`pieces` returns the number of additional pieces that need to be retrieved).
SYNCHRONIZE Function

SYNCHRONIZE Function

This function waits until the target program signals an event. If `info_requested` is not `NULL`, then it calls `GET_RUNTIME_INFO`.

Syntax

```
DBMS_DEBUG.SYNCHRONIZE (  
    run_info       OUT  runtime_info,  
    info_requested IN   BINARY_INTEGER := NULL)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>run_info</td>
<td>Structure in which to write information about the program. By default, this includes information about what program is running and at which line execution has paused.</td>
</tr>
<tr>
<td>info_requested</td>
<td>Optional bit-field in which to request information other than the default (which is <code>info_getStackDepth + info_getLineInfo</code>). 0 means that no information is requested at all (see &quot;Information Flags&quot; on page 52-13).</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>success</td>
<td>A successful completion</td>
</tr>
<tr>
<td>error_timeout</td>
<td>Timed out before the program started execution</td>
</tr>
<tr>
<td>error_communication</td>
<td>Other communication error</td>
</tr>
</tbody>
</table>
TARGET_PROGRAM_RUNNING Procedure

This procedure returns TRUE if the target session is currently executing a stored procedure, or FALSE if it is not.

Syntax

```
DBMS_DEBUG.TARGET_PROGRAM_RUNNING
RETURN BOOLEAN;
```
This package provides access to some SQL data definition language (DDL) statements from stored procedures. It also provides special administration operations that are not available as Data Definition Language statements (DDLs).

This chapter contains the following topics:

- **Using DBMS_DDL**
  - Deprecated Subprograms
  - Security Model
  - Operational Notes
- **Summary of DBMS_DDL Subprograms**
Using DBMS_DDL

This section contains topics which relate to using the DBMS_DDL package.

- Deprecated Subprograms
- Security Model
- Operational Notes
Deprecated Subprograms

Oracle recommends that you do not use deprecated subprograms in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with release Release 10gR2:

- ALTER_COMPILE Procedure
Security Model

This package runs with the privileges of the calling user, rather than the package owner SYS.
Operational Notes

The `ALTER_COMPILE` procedure commits the current transaction, performs the operation, and then commits again.
## Table 53–1  DBMS_DDL Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER_COMPILE Procedure on page 53-7</td>
<td>Compiles the PL/SQL object</td>
</tr>
<tr>
<td>ALTER_TABLE_NOT_REFERENCEABLE Procedure on page 53-8</td>
<td>Reorganizes object tables</td>
</tr>
<tr>
<td>ALTER_TABLE_REFERENCEABLE Procedure on page 53-9</td>
<td>Reorganizes object tables</td>
</tr>
<tr>
<td>CREATE_WRAPPED Procedures on page 53-10</td>
<td>Takes as input a single CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body, generates a CREATE OR REPLACE statement with the PL/SQL source text obfuscated and executes the generated statement</td>
</tr>
<tr>
<td>IS_TRIGGER_FIRE_ONCE Function on page 53-12</td>
<td>Returns TRUE if the specified DML or DDL trigger is set to fire once. Otherwise, returns FALSE</td>
</tr>
<tr>
<td>SET_TRIGGER_FIRING_PROPERTY Procedures on page 53-13</td>
<td>Sets the specified DML or DDL trigger’s firing property</td>
</tr>
<tr>
<td>WRAP Functions on page 53-15</td>
<td>Takes as input a CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a CREATE OR REPLACE statement where the text of the PL/SQL unit has been obfuscated</td>
</tr>
</tbody>
</table>
ALTER_COMPILE Procedure

This procedure is equivalent to the following SQL statement:

```
ALTER PROCEDURE|FUNCTION|PACKAGE [<schema>.]<name> COMPILE [BODY]
```

**Note:** This procedure is deprecated in Release 10gR2. While the procedure remains available in the package, Oracle recommends using the DDL equivalent in a dynamic SQL statement.

**Syntax**

```
DBMS_DDL.ALTER_COMPILE {
  type             VARCHAR2,
  schema           VARCHAR2,
  name             VARCHAR2
  reuse_settings   BOOLEAN := FALSE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Must be either PROCEDURE, FUNCTION, PACKAGE, PACKAGE BODY or TRIGGER</td>
</tr>
<tr>
<td>schema</td>
<td>Schema name</td>
</tr>
<tr>
<td>name</td>
<td>If NULL, then use current schema (case-sensitive)</td>
</tr>
<tr>
<td>reuse_settings</td>
<td>Indicates whether the session settings in the objects should be reused, or whether the current session settings should be adopted instead</td>
</tr>
</tbody>
</table>

**Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-20000:</td>
<td>Insufficient privileges or object does not exist</td>
</tr>
<tr>
<td>ORA-20001:</td>
<td>Remote object, cannot compile</td>
</tr>
<tr>
<td>ORA-20002:</td>
<td>Bad value for object type: should be either PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, or TRIGGER</td>
</tr>
</tbody>
</table>
ALTER_TABLE_NOT_REFERENCEABLE Procedure

This procedure alters the given object table table_schema.table_name so it becomes not the default referenceable table for the schema affected_schema. This is equivalent to SQL

```
ALTER TABLE [<table_schema>.]<table_name> NOT REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

Syntax

```sql
DBMS_DDL.ALTER_TABLE_NOT_REFERENCEABLE (
    table_name        IN           VARCHAR2,
    table_schema      IN  DEFAULT  NULL,
    affected_schema   IN  DEFAULT  NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of the table to be altered. Cannot be a synonym. Must not be NULL. Case sensitive.</td>
</tr>
<tr>
<td>table_schema</td>
<td>Name of the schema owning the table to be altered. If NULL then the current schema is used. Case sensitive.</td>
</tr>
<tr>
<td>affected_schema</td>
<td>Name of the schema affected by this alteration. If NULL then the current schema is used. Case sensitive.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure simply reverts for the affected schema to the default table referenceable for PUBLIC; that is, it simply undoes the previous ALTER_TABLE_REFERENCEABLE call for this specific schema. The affected schema must have a particular schema (cannot be PUBLIC).

The user that executes this procedure must own the table (that is, the schema is the same as the user), and the affected schema must be the same as the user.

If the user executing this procedure has ALTER ANY TABLE and SELECT ANY TABLE and DROP ANY TABLE privileges, the user doesn’t have to own the table and the affected schema can be any valid schema.
**ALTER_TABLE_REFERENCEABLE Procedure**

This procedure alters the given object table `table_schema.table_name` so it becomes the referenceable table for the given schema `affected_schema`. This is equivalent to SQL:

```
ALTER TABLE [<table_schema>.]<table_name>  REFERENCEABLE FOR <affected_schema>
```

which is currently not supported or available as a DDL statement.

**Syntax**

```
DBMS_DDL.ALTER_TABLE_REFERENCEABLE
    table_name       IN  VARCHAR2,
    table_schema     IN  DEFAULT  NULL,
    affected_schema  IN  DEFAULT  NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of the table to be altered. Cannot be a synonym. Must not be NULL. Case sensitive.</td>
</tr>
<tr>
<td>table_schema</td>
<td>Name of the schema owning the table to be altered. If NULL then the current schema is used. Case sensitive.</td>
</tr>
<tr>
<td>affected_schema</td>
<td>Name of the schema affected by this alteration. If NULL then the current schema is used. Case sensitive.</td>
</tr>
</tbody>
</table>

**Usage Notes**

When you create an object table, it automatically becomes referenceable, unless you use the `OID AS` clause when creating the table. The `OID AS` clause makes it possible for you to create an object table and to assign to the new table the same EOID as another object table of the same type. After you create a new table using the `OID AS` clause, you end up with two object tables with the same EOID; the new table is not referenceable, the original one is. All references that used to point to the objects in the original table still reference the same objects in the same original table.

If you execute this procedure on the new table, it makes the new table the referenceable table replacing the original one; thus, those references now point to the objects in the new table instead of the original table.
The procedure takes as input a single CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body. It then generates a CREATE OR REPLACE statement with the PL/SQL source text obfuscated and executes the generated statement. In effect, this procedure bundles together the operations of wrapping the text and creating the PL/SQL unit.

**See Also:** WRAP Functions on page 53-15

This procedure has 3 overloads. Each of the three functions provides better performance than using a combination of individual WRAP Functions and DBMS_SQL.PARSE (or EXECUTE IMMEDIATE) calls. The different functionality of each form of syntax is presented with the definition.

**Syntax**

Is a shortcut for EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP(ddl):

```sql
DBMS_DDL.CREATE_WRAPPED (ddl VARCHAR2);
```

Is a shortcut for DBMS_SQL.PARSE(cursor, SYS.DBMS_DDL.WRAP (input, lb, ub)):

```sql
DBMS_DDL.CREATE_WRAPPED (ddl DBMS_SQL.VARCHAR2A, lb PLS_INTEGER, ub PLS_INTEGER);
```

Is a shortcut for DBMS_SQL.PARSE(cursor, SYS.DBMS_DDL.WRAP (input, lb, ub)):

```sql
DBMS_DDL.CREATE_WRAPPED (ddl DBMS_SQL.VARCHAR2S, lb PLS_INTEGER, ub PLS_INTEGER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ddl</code></td>
<td>A CREATE OR REPLACE statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body.</td>
</tr>
<tr>
<td><code>lb</code></td>
<td>Lower bound for indices in the string table that specify the CREATE OR REPLACE statement.</td>
</tr>
<tr>
<td><code>ub</code></td>
<td>Upper bound for indices in the string table that specify the CREATE OR REPLACE statement.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- The CREATE OR REPLACE statement is executed with the privileges of the user invoking DBMS_DDL.CREATE_WRAPPED.
- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name SYS.DBMS_DDL to avoid the possibility that the name DBMS_
DDL is captured by a locally-defined unit or by redefining the DBMS_DDL public synonym.

- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL wrap utility accepts a entire SQL*Plus file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL’s dynamic SQL interfaces (EXECUTE IMMEDIATE and DBMS_SQL.PARSE). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL*Plus "/*" termination character), both the CREATE_WRAPPED Procedures and the WRAP Functions require input to be a single unit.

**Exceptions**

ORA-24230: If the input is not a CREATE OR REPLACE statement specifying a PL/SQL unit, exception DBMS_DDL.MALFORMED_WRAP_INPUT is raised.

**Examples**

DECLARE
    ddl VARCHAR2(32767);
BEGIN
    ddl := GENERATE_PACKAGE(...);
    SYS.DBMS_DDL.CREATE_WRAPPED(ddl); -- Instead of EXECUTE IMMEDIATE ddl
END;
IS_TRIGGER_FIRE_ONCE Function

This function returns TRUE if the specified DML or DDL trigger is set to fire once. Otherwise, it returns FALSE.

A fire once trigger fires in a user session but does not fire in the following cases:

- For changes made by a Streams apply process
- For changes made by executing one or more Streams apply errors using the EXECUTE_ERROR or EXECUTE_ALL_ERRORS procedure in the DBMS_APPLY_ADM package
- For changes made by a Logical Standby apply process

---

**Note:** Only DML and DDL triggers can be fire once. All other types of triggers always fire.

---

**See Also:** "SET_TRIGGER_FIRING_PROPERTY Procedures" on page 53-13

Syntax

```sql
DBMS_DDL.IS_TRIGGER_FIRE_ONCE
    trig_owner   IN  VARCHAR2,
    trig_name    IN  VARCHAR2)
RETURN BOOLEAN;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>trig_owner</td>
<td>Schema of trigger</td>
</tr>
<tr>
<td>trig_name</td>
<td>Name of trigger</td>
</tr>
</tbody>
</table>

SET_TRIGGER_FIRING_PROPERTY Procedures

This procedure sets the specified DML or DDL trigger's firing property whether or not the property is set for the trigger. Use this procedure to control a DML or DDL trigger's firing property for changes:

- Applied by a Streams apply process
- Made by executing one or more Streams apply errors using the `EXECUTE_ERROR` or `EXECUTE_ALL_ERRORS` procedure in the `DBMS_APPLY_ADM` package.
- Applied by a Logical Standby apply process

Syntax

```
DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (  
  trig_owner   IN  VARCHAR2,  
  trig_name    IN  VARCHAR2,  
  fire_once    IN  BOOLEAN);
```

```
DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY (  
  trig_owner   IN  VARCHAR2,  
  trig_name    IN  VARCHAR2,  
  property     IN  INTEGER,  
  setting      IN  BOOLEAN);
```

Parameters

### Table 53–8  SET_TRIGGER_FIRING_PROPERTY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>trig_owner</code></td>
<td>Schema of the trigger to set</td>
</tr>
<tr>
<td><code>trig_name</code></td>
<td>Name of the trigger to set</td>
</tr>
</tbody>
</table>
| `fire_once`   | - If `TRUE`, the trigger is set to fire once. By default, the `fire_once` parameter is set to `TRUE` for DML and DDL triggers.  
  - If `FALSE`, the trigger is set to always fire unless `apply_server_only` property is set to `TRUE`, which overrides `fire_once` property setting. |
| `property`    | - `DBMS_DDL.fire_once` to set the `fire_once` property of the trigger  
  - `DBMS_DDL.apply_server_only` to indicate whether trigger fires only in the context of SQL apply processes maintaining a logical standby database or Streams apply processes |
| `setting`     | Value of property being set                                                |

Usage Notes

DML triggers created on a table have their fire-once property set to `TRUE`. In this case, the triggers only fire when the table is modified by an user process, and they are automatically disabled inside Oracle processes maintaining either a logical standby database (SQL Apply) or Oracle processes doing replication (Streams Apply) processes, and thus do not fire when a SQL Apply or a Streams Apply process modifies the table. There are two ways for a user to fire a trigger as a result of SQL Apply or a Streams Apply process making a change to a maintained table: (a) setting the fire-once property of a trigger to `FALSE`, which allows it fire both in the context of a user process or a SQL or Streams Apply process, or (b) by setting the
apply-server-only property to TRUE and thus making the trigger fire only in the context of a SQL Apply or a Streams Apply process and not in the context of a user process.

- **FIRE_ONCE=TRUE, APPLY_SERVER_ONLY=FALSE**
  This is the default property setting for a DML trigger. The trigger only fires when user process modifies the base table.

- **FIRE_ONCE=TRUE or FALSE, APPLY_SERVER_ONLY=TRUE**
  The trigger only fires when SQL Apply or Streams Apply process modifies the base table. The trigger does not fire when a user process modifies the base table. Thus the apply-server-only property overrides the fire-once property of a trigger.

---

**Note:**

- If you dequeue an error transaction from the error queue and execute it without using the DBMS_APPLY_ADM package, then relevant changes resulting from this execution cause a trigger to fire, regardless of the trigger firing property.

- Only DML and DDL triggers can be fire once. All other types of triggers always fire.

---

**See Also:** Oracle Streams Concepts and Administration for more information about the apply process and controlling a trigger’s firing property
**WRAP Functions**

This function takes as input a single `CREATE OR REPLACE` statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body and returns a `CREATE OR REPLACE` statement where the text of the PL/SQL unit has been obfuscated.

The function has 3 overloads to allow for the different ways in which DDL statements can be generated dynamically and presented to `DBMS_SQL` or `EXECUTE IMMEDIATE`. The different functionality of each form of syntax is presented with the definition.

See Also:  [CREATE_WRAPPED Procedures on page 53-10](#)

**Syntax**

Provides basic functionality:

```sql
DBMS_DDL.WRAP(
    dd1     VARCHAR2)
RETURN VARCHAR2;
```

Provides the same functionality as the first form, but allows for larger inputs. This function is intended to be used with the `PARSE Procedures` in the `DBMS_SQL` package and its argument list follows the convention of `DBMS_SQL.PARSE`:

```sql
DBMS_DDL.WRAP(
    dd1     DBMS_SQL.VARCHAR2S,
    lb      PLS_INTEGER,
    ub      PLS_INTEGER)
RETURN DBMS_SQL.VARCHAR2S;
```

Provides the same functionality as the second form and is provided for compatibility with multiple forms of the `PARSE Procedures` in the `DBMS_SQL` package:

```sql
DBMS_DDL.WRAP(
    dd1     DBMS_SQL.VARCHAR2A,
    lb      PLS_INTEGER,
    ub      PLS_INTEGER)
RETURN DBMS_SQL.VARCHAR2A;
```

**Parameters**

<table>
<thead>
<tr>
<th>Table 53–9</th>
<th>WRAP Function Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>dd1</td>
<td>A <code>CREATE OR REPLACE</code> statement that specifies creation of a PL/SQL package specification, package body, function, procedure, type specification or type body</td>
</tr>
<tr>
<td>lb</td>
<td>Lower bound for indices in the string table that specify the <code>CREATE OR REPLACE</code> statement</td>
</tr>
<tr>
<td>ub</td>
<td>Upper bound for indices in the string table that specify the <code>CREATE OR REPLACE</code> statement.</td>
</tr>
</tbody>
</table>

**Return Values**

A `CREATE OR REPLACE` statement with the text obfuscated. In the case of the second and third form, the return value is a table of strings that need to be concatenated in order to construct the `CREATE OR REPLACE` string containing obfuscated source text.
Usage Notes

- Any PL/SQL code that attempts to call these interfaces should use the fully qualified package name `SYS.DBMS_DDL` to avoid the possibility that the name `DBMS_DDL` is captured by a locally-defined unit or by redefining the `DBMS_DDL` public synonym.

- Each invocation of any accepts only a single PL/SQL unit. By contrast, the PL/SQL `wrap` utility accepts a full SQL file and obfuscates the PL/SQL units within the file leaving all other text as-is. These interfaces are intended to be used in conjunction with or as a replacement for PL/SQL’s dynamic SQL interfaces (`EXECUTE IMMEDIATE` and `DBMS_SQL.PARSE`). Since these dynamic SQL interfaces only accept a single unit at a time (and do not understand the SQL*Plus “/” termination character), both the `CREATE_WRAPPED Procedures` and the `WRAP Functions` require input to be a single unit.

Exceptions

ORA-24230: If the input is not a CREATE OR REPLACE statement specifying a PL/SQL unit, exception `DBMS_DDL.MALFORMED_WRAP_INPUT` is raised.

Examples

```sql
DECLARE
    ddl VARCHAR2(32767);
BEGIN
    ddl := GENERATE_PACKAGE(...);
    EXECUTE IMMEDIATE SYS.DBMS_DDL.WRAP(ddl);  -- Instead of EXECUTE IMMEDIATE ddl
END;
```
DBMS_DEFER is the user interface to a replicated transactional deferred remote procedure call facility. Replicated applications use the calls in this interface to queue procedure calls for later transactional execution at remote nodes.

These procedures are typically called from either after row triggers or application specified update procedures.

- Documentation of DBMS_DEFER
For a complete description of this package within the context of Replication, see DBMS_DEFER in the *Oracle Database Advanced Replication Management API Reference*. 
DBMS_DEFER_QUERY enables you to query the deferred transactions queue data that is not exposed through views.

- Documentation of DBMS_DEFER_QUERY
Documentation of DBMS_DEFER_QUERY

For a complete description of this package within the context of Replication, see DBMS_DEFER_QUERY in the Oracle Database Advanced Replication Management API Reference.
DBMS_DEFER_SYS subprograms manage default replication node lists. This package is the system administrator interface to a replicated transactional deferred remote procedure call facility. Administrators and replication daemons can execute transactions queued for remote nodes using this facility, and administrators can control the nodes to which remote calls are destined.

- Documentation of DBMS_DEFER_SYS
For a complete description of this package within the context of Replication, see DBMS_DEFER_SYS in the Oracle Database Advanced Replication Management API Reference.
You can use the DBMS_DESCRIBE package to get information about a PL/SQL object. When you specify an object name, DBMS_DESCRIBE returns a set of indexed tables with the results. Full name translation is performed and security checking is also checked on the final object.

This chapter contains the following topics:

- Using DBMS_DESCRIBE
  - Overview
  - Security Model
  - Types
  - Exceptions
  - Examples

- Summary of DBMS_DESCRIBE Subprograms
Using DBMS_DESCRIBE

- Examples
Overview

This package provides the same functionality as the Oracle Call Interface
OCIDescribeAny call.

See Also:  Oracle Call Interface Programmer’s Guide
Security Model

This package is available to PUBLIC and performs its own security checking based on the schema object being described.
Types

The DBMS_DESCRIBE package declares two PL/SQL table types, which are used to hold data returned by DESCRIBE_PROCEDURE in its OUT parameters. The types are:

```plsql
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(30)
   INDEX BY BINARY_INTEGER;

TYPE NUMBER_TABLE IS TABLE OF NUMBER
   INDEX BY BINARY_INTEGER;
```
### Exceptions

DBMS_DESCRIBE can raise application errors in the range -20000 to -20004.

**Table 57–1  DBMS_DESCRIBE Errors**

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-20000</td>
<td>ORU 10035: cannot describe a package (‘X’) only a procedure within a package.</td>
</tr>
<tr>
<td>ORA-20001</td>
<td>ORU-10032: procedure ‘X’ within package ‘Y’ does not exist.</td>
</tr>
<tr>
<td>ORA-20002</td>
<td>ORU-10033: object ‘X’ is remote, cannot describe; expanded name ‘Y’.</td>
</tr>
<tr>
<td>ORA-20003</td>
<td>ORU-10036: object ‘X’ is invalid and cannot be described.</td>
</tr>
<tr>
<td>ORA-20004</td>
<td>Syntax error attempting to parse ‘X’.</td>
</tr>
</tbody>
</table>
Examples

One use of the DESCRIBE.PROCEDURE procedure is as an external service interface.

For example, consider a client that provides an OBJECT_NAME of SCOTT.ACCOUNT_UPDATE, where ACCOUNT_UPDATE is an overloaded function with specification:

```sql
TABLE account (accnt_no NUMBER, person_id NUMBER,
               balance NUMBER(7,2))
TABLE person  (person_id number(4), person_nm varchar2(10))

CREATE OR REPLACE PACKAGE ACCOUNT_PKG is
  FUNCTION ACCOUNT_UPDATE (accnt_no NUMBER,
                           person      person%rowtype,
                           amounts     DBMS_DESCRIBE.NUMBER_TABLE,
                           trans_date  DATE)
  return       account.balance%type;

  FUNCTION ACCOUNT_UPDATE (accnt_no     NUMBER,
                           person       person%rowtype,
                           amounts      DBMS_DESCRIBE.NUMBER_TABLE,
                           trans_no     NUMBER)
  return       account.balance%type;
END;
```

This procedure might look similar to the following output:

```
<table>
<thead>
<tr>
<th>overload position</th>
<th>argument level</th>
<th>datatype length prec scale rad</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>ACCT_NO</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>PERSON</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>PERSON_ID</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>PERSON_NM</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>AMOUNTS</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>4</td>
<td>TRANS_DATE</td>
</tr>
<tr>
<td>2</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>ACCT_NO</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>PERSON</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>AMOUNTS</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>TRANS_NO</td>
</tr>
</tbody>
</table>
```

The following PL/SQL procedure has as its parameters all of the PL/SQL datatypes:

```sql
CREATE OR REPLACE PROCEDURE p1 (
  pvc2 IN VARCHAR2,
  pvc OUT VARCHAR,
  pstr IN OUT STRING,
  plong IN LONG,
  prowid IN ROWID,
  pchara IN CHARACTER,
  pchar IN CHAR,
  praw IN RAW,
  plraw IN LONG RAW,
  pbinint IN BINARY_INTEGER,
  ppilsint IN PLS_INTEGER,
  pbool IN BOOLEAN,
  pnat IN NATURAL,
  ppos IN POSITIVE,
...
If you describe this procedure using the following:

```sql
CREATE OR REPLACE PACKAGE describe_it AS
  PROCEDURE desc_proc (name VARCHAR2);
END describe_it;
CREATE OR REPLACE PACKAGE BODY describe_it AS
  PROCEDURE prt_value(val VARCHAR2, isize INTEGER) IS
    n INTEGER;
    BEGIN
      n := isize - LENGTHB(val);
      IF n < 0 THEN
        n := 0;
      END IF;
      DBMS_OUTPUT.PUT(val);
      FOR i in 1..n LOOP
        DBMS_OUTPUT.PUT(' ');
      END LOOP;
    END prt_value;
  PROCEDURE desc_proc (name VARCHAR2) IS
    overload     DBMS_DESCRIBE.NUMBER_TABLE;
    position     DBMS_DESCRIBE.NUMBER_TABLE;
    c_level      DBMS_DESCRIBE.NUMBER_TABLE;
    arg_name     DBMS_DESCRIBE.VARCHAR2_TABLE;
    dty          DBMS_DESCRIBE.NUMBER_TABLE;
    def_val      DBMS_DESCRIBE.NUMBER_TABLE;
    p_mode       DBMS_DESCRIBE.NUMBER_TABLE;
    length       DBMS_DESCRIBE.NUMBER_TABLE;
    precision    DBMS_DESCRIBE.NUMBER_TABLE;
    scale        DBMS_DESCRIBE.NUMBER_TABLE;
    radix        DBMS_DESCRIBE.NUMBER_TABLE;
    spare        DBMS_DESCRIBE.NUMBER_TABLE;
    idx          INTEGER := 0;
    BEGIN
      DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
        name, null,
```

```sql
BEGIN
  NULL;
END;
```

```sql
END;
```

```sql
If you describe this procedure using the following:

CREATE OR REPLACE PACKAGE describe_it AS
  PROCEDURE desc_proc (name VARCHAR2);
END describe_it;
CREATE OR REPLACE PACKAGE BODY describe_it AS
  PROCEDURE prt_value(val VARCHAR2, isize INTEGER) IS
    n INTEGER;
    BEGIN
      n := isize - LENGTHB(val);
      IF n < 0 THEN
        n := 0;
      END IF;
      DBMS_OUTPUT.PUT(val);
      FOR i in 1..n LOOP
        DBMS_OUTPUT.PUT(' ');
      END LOOP;
    END prt_value;
  PROCEDURE desc_proc (name VARCHAR2) IS
    overload     DBMS_DESCRIBE.NUMBER_TABLE;
    position     DBMS_DESCRIBE.NUMBER_TABLE;
    c_level      DBMS_DESCRIBE.NUMBER_TABLE;
    arg_name     DBMS_DESCRIBE.VARCHAR2_TABLE;
    dty          DBMS_DESCRIBE.NUMBER_TABLE;
    def_val      DBMS_DESCRIBE.NUMBER_TABLE;
    p_mode       DBMS_DESCRIBE.NUMBER_TABLE;
    length       DBMS_DESCRIBE.NUMBER_TABLE;
    precision    DBMS_DESCRIBE.NUMBER_TABLE;
    scale        DBMS_DESCRIBE.NUMBER_TABLE;
    radix        DBMS_DESCRIBE.NUMBER_TABLE;
    spare        DBMS_DESCRIBE.NUMBER_TABLE;
    idx          INTEGER := 0;
    BEGIN
      DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
        name, null,
```
null,
overload,
position,
c_level,
arg_name,
dty,
def_val,
p_mode,
length,
precision,
scale,
radix,
spare);

DBMS_OUTPUT.PUT_LINE('Position    Name        DTY  Mode');
LOOP
  idx := idx + 1;
  prt_value(TO_CHAR(position(idx)), 12);
  prt_value(arg_name(idx), 12);
  prt_value(TO_CHAR(dty(idx)), 5);
  prt_value(TO_CHAR(p_mode(idx)), 5);
  DBMS_OUTPUT.NEW_LINE;
END LOOP;
EXCEPTION
  WHEN NO_DATA_FOUND THEN
    DBMS_OUTPUT.NEW_LINE;
    DBMS_OUTPUT.NEW_LINE;
END desc_proc;
END describe_it;

Then the results list all the numeric codes for the PL/SQL datatypes:

<tr>
<td>DESCRIBE_PROCEDURE Procedure on page 57-11</td>
<td>Provides a brief description of a PL/SQL stored procedure</td>
</tr>
</tbody>
</table>
DESCRIBE_PROCEDURE Procedure

The procedure DESCRIBE_PROCEDURE provides a brief description of a PL/SQL stored procedure. It takes the name of a stored procedure and returns information about each parameter of that procedure.

Syntax

```
DBMS_DESCRIBE.DESCRIBE_PROCEDURE(
    object_name           IN  VARCHAR2,
    reserved1             IN  VARCHAR2,
    reserved2             IN  VARCHAR2,
    overload              OUT NUMBER_TABLE,
    position              OUT NUMBER_TABLE,
    level                 OUT NUMBER_TABLE,
    argument_name         OUT VARCHAR2_TABLE,
    datatype              OUT NUMBER_TABLE,
    default_value         OUT NUMBER_TABLE,
    in_out                OUT NUMBER_TABLE,
    length                OUT NUMBER_TABLE,
    precision             OUT NUMBER_TABLE,
    scale                 OUT NUMBER_TABLE,
    radix                 OUT NUMBER_TABLE,
    spare                 OUT NUMBER_TABLE,
    include_string_constraints OUT BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_name</td>
<td>Name of the procedure being described.</td>
</tr>
<tr>
<td>reserved1</td>
<td>Reserved for future use -- must be set to NULL or the empty string.</td>
</tr>
<tr>
<td>reserved2</td>
<td>A unique number assigned to the procedure’s signature.</td>
</tr>
<tr>
<td>overload</td>
<td>If a procedure is overloaded, then this field holds a different value for</td>
</tr>
<tr>
<td>position</td>
<td>Position of the argument in the parameter list.</td>
</tr>
<tr>
<td>level</td>
<td>Position 0 returns the values for the return type of a function.</td>
</tr>
<tr>
<td>argument_name</td>
<td></td>
</tr>
<tr>
<td>datatype</td>
<td></td>
</tr>
<tr>
<td>default_value</td>
<td></td>
</tr>
<tr>
<td>in_out</td>
<td></td>
</tr>
<tr>
<td>length</td>
<td></td>
</tr>
<tr>
<td>precision</td>
<td></td>
</tr>
<tr>
<td>scale</td>
<td></td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>spare</td>
<td></td>
</tr>
<tr>
<td>include_string_constraints</td>
<td></td>
</tr>
</tbody>
</table>
If the argument is a composite type, such as record, then this parameter returns the level of the datatype. See the Oracle Call Interface Programmer’s Guide for a description of the ODESSP call for an example.

**Argument Name**

Name of the argument associated with the procedure that you are describing.

**Datatype**

Oracle datatype of the argument being described. The datatypes and their numeric type codes are:

- 0  placeholder for procedures with no arguments
- 1  VARCHAR, VARCHAR, STRING
- 2  NUMBER, INTEGER, SMALLINT, REAL, FLOAT, DECIMAL
- 3  BINARY_INTEGER, PLS_INTEGER, POSITIVE, NATURAL
- 8  LONG
- 11  ROWID
- 12  DATE
- 23  RAW
- 24  LONG RAW
- 58  OPAQUE TYPE
- 96  CHAR (ANSI FIXED CHAR), CHARACTER
- 106  MLSLABEL
- 121  OBJECT
- 122  NESTED TABLE
- 123  VARRAY
- 178  TIME
- 179  TIME WITH TIME ZONE
- 180  TIMESTAMP
- 181  TIMESTAMP WITH TIME ZONE
- 231  TIMESTAMP WITH LOCAL TIME ZONE
- 250  PL/SQL RECORD
- 251  PL/SQL TABLE
- 252  PL/SQL BOOLEAN

**Default Value**

1 if the argument being described has a default value; otherwise, the value is 0.

**In-Out**

Describes the mode of the parameter:

- 0 IN
- 1 OUT
- 2 IN OUT

**Length**

For %rowtype formal arguments, the length constraint is returned, otherwise 0 is returned. If the include_string_constraints parameter is set to TRUE, the argument’s formal length constraint is passed back if it is of the appropriate type. Those are the string types: 1,8,23,24,96

**Precision**

If the argument being described is of datatype 2 (NUMBER), then this parameter is the precision of that number.

**Scale**

If the argument being described is of datatype 2 (NUMBER), then this parameter is the scale of that number.

**Radix**

If the argument being described is of datatype 2 (NUMBER), then this parameter is the radix of that number.

**Spare**

Reserved for future functionality.

**Include String Constraints**

The default is FALSE. If the parameter is set to TRUE, the arguments’ formal type constraints is passed back if it is of the appropriate type. Those are the string types: 1,8,23,24,96
Return Values

All values from \texttt{DESCRIBE\_PROCEDURE} are returned in its \texttt{OUT} parameters. The datatypes for these are PL/SQL tables, to accommodate a variable number of parameters.
The **DBMS_DG** package allows applications to notify the primary database in an Oracle Data Guard broker environment to initiate a fast-start failover when the application encounters a condition that warrants a failover.

**See Also:** *Oracle Data Guard Broker* for more information about performing a fast-start failover in a broker configuration

This chapter contains the following topics:

- **Using DBMS_DG**
  - Security Model
- **Summary of the DBMS_DG Subprogram**
There are conditions detectable by applications running outside of the Oracle database that may warrant the Oracle Data Guard broker to perform a fast-start failover. Because the range of possible conditions is virtually unlimited, it is left to the applications to determine which conditions warrant a fast-start failover.

When such conditions occur, the application calls the `DBMS_DG.INITIATE_FS_FAILOVER` procedure to alert the primary database that the application wants a fast-start failover to occur immediately. The primary database then notifies the observer, which immediately initiates a fast-start failover as long as the standby database is in a valid fast-start failover state ("observed" and either "synchronized" or "within lag") to accept a failover.

If the configuration is not in a valid fast-start failover state, the `INITIATE_FS_FAILOVER` subprogram returns an ORA error message (it will not signal an exception) to inform the calling application that a fast-start failover could not be performed.
Security Model

The DBMS_DG package runs with invoker's rights and requires the SYSDBA privilege.
Summary of the DBMS_DG Subprogram

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITIATE_FS_FAIOVER Procedure on page 58-5</td>
<td>Enables an application to notify the primary database that a fast-start failover is necessary when the application encounters conditions that warrant a failover.</td>
</tr>
</tbody>
</table>
INITIATE_FS_FAILOVER Procedure

Use this procedure to specify a condition string that, when encountered by an application, allows the application to request the primary database to immediately invoke a fast-start failover.

Syntax

```
DBMS_DG.INITIATE_FS_FAILOVER (condstr IN VARCHAR2) RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>condstr</td>
<td>Specifies the condition string for which a fast-start failover should be requested. If no condition string argument is supplied, the default string of &quot;Application Failover Requested&quot; will be logged in the broker log file and in the database alert log of the primary database.</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure returns a binary integer.
- Query the V$FS_FAILOVER_STATS view to see the time of the last fast-start failover and the reason it was performed.

Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-00000: normal, successful completion</td>
<td>The request to initiate a fast-start failover has been posted to the observer.</td>
</tr>
<tr>
<td>ORA-16646: fast-start failover is disabled</td>
<td>Either a broker configuration does not exist or fast-start failover has not been enabled.</td>
</tr>
<tr>
<td>ORA-16666: unable to initiate fast-start failover on a standby database</td>
<td>DBMS_DG.INITIATE_FS_FAILOVER was invoked on a standby site.</td>
</tr>
<tr>
<td>ORA-16817: unsynchronized fast-start failover configuration</td>
<td>DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum available fast-start failover configuration when the configuration was not synchronized.</td>
</tr>
<tr>
<td>ORA-16819: fast-start failover observer not started</td>
<td>DBMS_DG.INITIATE_FS_FAILOVER was invoked but an observer had not yet been started.</td>
</tr>
<tr>
<td>ORA-16820: fast-start failover observer is no longer observing this database</td>
<td>DBMS_DG.INITIATE_FS_FAILOVER was invoked but the configuration detects that the observer may not be running.</td>
</tr>
<tr>
<td>ORA-16829: lagging fast-start failover configuration</td>
<td>DBMS_DG.INITIATE_FS_FAILOVER was invoked in a maximum performance fast-start failover configuration when the configuration was not in the user-specified redo lag limit.</td>
</tr>
</tbody>
</table>
Example

In this example, the program attempts to initiate a fast-start failover when fast-start failover is disabled. To use this example, connect as user SYS with SYDBBA privileges.

```
set serveroutput on

declare
status integer;

begin
status := dbms_dg.initiate_fs_failover('Failover Requested');

dbms_output.put_line('Fast-Start Failover is disabled: Expected status = ORA-16646');
dbms_output.put_line('Actual Status = ORA-' || status);
end;
/
exit;
```
DBMS_DIMENSION enables you to verify dimension relationships and provides an alternative to the Enterprise Manager Dimension Wizard for displaying a dimension definition.

See Also: Oracle Database Data Warehousing Guide for detailed conceptual and usage information about the DBMS_DIMENSION package

This chapter contains the following topics:

- Using DBMS_DIMENSION
  - Security Model
- Summary of DBMS_DIMENSION Subprograms
Using DBMS_DIMENSION

This section contains topics which relate to using the DBMS_DIMENSION package.

- Security Model
Security Model

Security on this package can be controlled by granting `EXECUTE` to selected users or roles.

A user can validate or describe all the dimensions in his own schema. To validate or describe a dimension in another schema, you must have either an object privilege on the dimension or one of the following system privileges: `CREATE ANY DIMENSION`, `ALTER ANY DIMENSION`, and `DROP ANY DIMENSION`. 

Summary of DBMS_DIMENSION Subprograms

Table 59–1  DBMS_DIMENSION Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DESCRIBE_DIMENSION Procedure on page 59-5</td>
<td>Prints out the definition of the input dimension, including dimension owner and name, levels, hierarchies, and attributes</td>
</tr>
<tr>
<td>VALIDATE_DIMENSION Procedure on page 59-6</td>
<td>Verifies that the relationships specified in a dimension are correct</td>
</tr>
</tbody>
</table>
**DESCRIBE_DIMENSION Procedure**

This procedure displays the definition of the dimension, including dimension name, levels, hierarchies, and attributes. It displays the output using the `DBMS_OUTPUT` package.

**Syntax**

```sql
DBMS_DIMENSION.DESCRIBE_DIMENSION (dimension IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dimension</td>
<td>The owner and name of the dimension in the format of <code>owner.name</code>.</td>
</tr>
</tbody>
</table>
VALIDATE_DIMENSION Procedure

This procedure verifies that the relationships specified in a dimension are valid. The rowid for any row that is found to be invalid will be stored in the table `DIMENSION_EXCEPTIONS` in the user's schema.

Syntax

```
DBMS_DIMENSION.VALIDATE_DIMENSION (  
   dimension               IN VARCHAR2,  
   incremental             IN BOOLEAN := TRUE,  
   check_nulls             IN BOOLEAN := FALSE,  
   statement_id            IN VARCHAR2 := NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dimension</td>
<td>The owner and name of the dimension in the format of <code>owner.name</code>.</td>
</tr>
<tr>
<td>incremental</td>
<td>If TRUE, check only the new rows for tables of this dimension. If FALSE, check all the rows.</td>
</tr>
<tr>
<td>check_nulls</td>
<td>If TRUE, then all level columns are verified to be non-null. If FALSE, this check is omitted. Specify FALSE when non-NULLness is guaranteed by other means, such as NOT NULL constraints.</td>
</tr>
<tr>
<td>statement_id</td>
<td>A client-supplied unique identifier to associate output rows with specific invocations of the procedure.</td>

This chapter contains the following topics:
- Using DBMS_DST
  - Overview
  - Security Model
  - Views
- Summary of DBMS_DST Subprograms
Using DBMS_DST

- Overview
- Security Model
- Views
Overview

The transition period during which Daylight Saving Time comes into effect, or stops being in effect, has the potential for problems, such as data loss, when handling timestamps with time zone data. The DBMS_DST package enables working with these transitions in the context of a set of rules.
Security Model

The DBMS_DST package is an invoker's rights package.

See Also: Oracle Database PL/SQL Language Reference for more information about using Invoker Rights or Definer Rights

The execute privilege on the package is granted to the EXECUTE_CATALOG_ROLE role. This role is normally granted to selected users to allow EXECUTE privileges for packages and procedures in the data dictionary.

The user that invokes the package must have the following privileges:

- CREATE ANY TABLE
- ALTER ANY TABLE
- DROP ANY TABLE
- SELECT ANY TABLE
- LOCK ANY TABLE
- ALTER ANY INDEX
- ALTER ANY TRIGGER
- UPDATE ANY TABLE
- EXECUTE ANY TYPE
Views

The DBMS_DST package uses the views shown in Table 60–1, "Views used by DBMS_DST", further described in the Oracle Database Reference:

Table 60–1 Views used by DBMS_DST

<table>
<thead>
<tr>
<th>View</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBA_TSTZ_TABLES</td>
<td>Displays information about all tables in the database, which have columns defined on TIMESTAMP WITH TIME ZONE data types or object types containing attributes of TIMESTAMP WITH TIME ZONE data types. Its columns are the same as those in ALL_TSTZ_TABLES.</td>
</tr>
<tr>
<td>USER_TSTZ_TABLES</td>
<td>Displays information about the tables owned by the current user, which have columns defined on TIMESTAMP WITH TIME ZONE data types or object types containing attributes of TIMESTAMP WITH TIME ZONE data types. Its columns (except for OWNER) are the same as those in ALL_TSTZ_TABLES.</td>
</tr>
<tr>
<td>ALL_TSTZ_TABLES</td>
<td>Displays information about the tables accessible to the current user, which have columns defined on TIMESTAMP WITH TIME ZONE data types or object types containing attributes of TIMESTAMP WITH TIME ZONE data types.</td>
</tr>
</tbody>
</table>
## Summary of DBMS_DST Subprograms

<table>

</tbody>
</table>
BEGIN_PREPARE Procedure

This procedure starts a prepare window. Once a prepare window is started successfully, the database property 'DST_UPGRADE_STATE' is set to 'PREPARE', and the database property 'SECONDARY_TT_VERSION' is set to a new timezone version.

The prepare window lets a DBA investigate data affected by the upgrade, and so judge when it is optimal to perform the upgrade. The prepare window can overlap normal database operation.

Syntax

```sql
DBMS_DST.BEGIN_PREPARE (
    new_version                IN  BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_version</td>
<td>New timezone version to which the database is to be prepared to upgrade</td>
</tr>
</tbody>
</table>
BEGIN_UPGRADE Procedure

This procedure starts an upgrade window. When an upgraded window is started successfully, the TSTZ data in the dictionary tables is upgraded to reflect the new timezone version, and the database property 'DST_UPGRADE_STATE' is set to 'UPGRADE'. Once BEGIN_UPGRADE has been performed successfully, the user must re-start the database. After a successful restart, the database property 'PRIMARY_TT_VERSION' is the new timezone version, and 'SECONDARY_TT_VERSION' is the old timezone version.

The procedure operates atomically, and upgrades all or none of the dictionary tables and the database properties. It must be called in the database in OPEN MIGRATE mode.

Syntax

```
DBMS_DST.BEGIN_UPGRADE (  
  new_version       IN  BINARY_INTEGER, 
  error_on_overlap_time IN BOOLEAN := FALSE, 
  error_on_nonexisting_time IN BOOLEAN := FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>new_version</td>
<td>New timezone version to which the database is to be upgraded</td>
<td></td>
</tr>
<tr>
<td>error_on_overlap_time</td>
<td>Boolean flag indicating whether to report errors on the 'overlap' time semantic conversion error. The default is TRUE. For more information about boundary cases, see Oracle Database SQL Language Reference.</td>
<td></td>
</tr>
<tr>
<td>error_on_nonexisting_time</td>
<td>Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error. The default is TRUE.</td>
<td></td>
</tr>
</tbody>
</table>
**CREATE_AFFECTED_TABLE Procedure**

This procedure creates a table that has the schema shown in the comments for the `FIND_AFFECTED_TABLES` Procedure.

**Syntax**

```sql
DBMS_DST.CREATE_AFFECTED_TABLE (table_name IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of the table created</td>
</tr>
</tbody>
</table>

**Usage Notes**

This procedures takes a `table_name` without schema qualification, creating a table within the current user schema.
CREATE_ERROR_TABLE Procedure

This procedure creates a log error table which has the following schema:

```sql
CREATE TABLE dst$error_table(
    table_owner     VARCHAR2(30),
    table_name      VARCHAR2(30),
    column_name     VARCHAR2(4000),
    rid             ROWID,
    error_number    NUMBER)
```

Syntax

```sql
DBMS_DST.CREATE_ERROR_TABLE (  
    table_name      IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of the table created</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedures takes a `table_name` without schema qualification, creating a table within the current user schema.
- The error number is found when upgrading time zone file and timestamp with time zone data. For more information about error handling when upgrading time zone file and timestamp with time zone data, see Oracle Database Globalization Support Guide.
CREATE_TRIGGER_TABLE Procedure

This procedure creates a table that has the following schema.

```sql
CREATE TABLE dst_trigger_table (
    trigger_owner    VARCHAR2(30),
    trigger_name     VARCHAR2(30));
```

This table is used to record active triggers that are disabled before performing upgrade on the table, having not been enabled due to fatal failure during the upgrading process.

Syntax

```sql
DBMS_DST.CREATE_TRIGGER_TABLE (
    table_name     IN    VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of table to be created</td>
</tr>
</tbody>
</table>

Usage Notes

This procedures takes a `table_name` without schema qualification, creating a table within the current user schema.
END_PREPARE Procedure

This procedure ends a prepare window.

Syntax

```
DBMS_DST.BEGIN_PREPARE;
```
**END_UPGRADE Procedure**

This procedure ends an upgrade window. An upgraded window is ended if all the affected user tables have been upgraded. Otherwise, the OUT parameter `num_of_failures` indicates how many tables have not been converted.

**Syntax**

```plsql
DBMS_DST.END_UPGRADE (
    num_of_failures OUT  BINARY_INTEGER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_of_failures</td>
<td>Number of tables that fail to complete</td>
</tr>
</tbody>
</table>
FIND_AFFECTED_TABLES Procedure

This procedure finds all the tables which have affected TSTZ data due to the new timezone version. This procedure can only be invoked during a prepare window. The tables which have affected TSTZ data are recorded into a table indicated by parameter affected_tables. If semantic errors must be logged, they are recorded into a table indicated by parameter log_errors_table.

Syntax

```sql
DBMS_DST.FIND_AFFECTED_TABLES (  
  affected_tables IN VARCHAR2 := 'sys.dst$affected_tables',  
  log_errors IN BOOLEAN := FALSE,  
  log_errors_table IN VARCHAR2 := 'sys.dst$error_table');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| affected_tables | Name of table with the following schema:  
  CREATE TABLE dst$affected_tables (  
    table_owner VARCHAR2(30),  
    table_name VARCHAR2(30),  
    column_name VARCHAR2(4000),  
    row_count NUMBER,  
    error_count NUMBER)  
  The table can be created with the CREATE_AFFECTED_TABLE Procedure. |
| log_errors      | Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table. The default is FALSE. |
| log_errors_table | Table name with the following schema:  
  CREATE TABLE dst$error_table (  
    table_owner VARCHAR2(30),  
    table_name VARCHAR2(30),  
    column_name VARCHAR2(4000),  
    rid ROWID,  
    error_number NUMBER)  
  The table can be created with the CREATE_ERROR_TABLE Procedure. The rid column records the rowids of the offending rows, and the error_number column records the corresponding error number. |
UPGRADE_DATABASE Procedure

This procedure upgrades all tables in the database, which have one or more columns defined on the TSTZ type or an ADT containing the TSTZ type. This procedure can only be invoked after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that, a base table and its materialized view log table are upgraded in an atomic transaction.

Syntax

```sql
DBMS_DST.UPGRADE_DATABASE  (
    num_of_failures             OUT BINARY_INTEGER,
    upgrade_data                IN  BOOLEAN := TRUE,
    parallel                    IN  BOOLEAN := FALSE,
    continue_after_errors       IN  BOOLEAN := TRUE,
    log_errors                  IN  BOOLEAN := FALSE,
    log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
    error_on_overlap_time       IN  BOOLEAN := FALSE,
    error_on_nonexisting_time   IN  BOOLEAN := FALSE,
    log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_of_failures</td>
<td>Number of tables that fail to complete</td>
</tr>
<tr>
<td>upgrade_data</td>
<td>Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave it unconverted (FALSE). The default is TRUE.</td>
</tr>
<tr>
<td>parallel</td>
<td>Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML. The default is FALSE.</td>
</tr>
<tr>
<td>continue_after_errors</td>
<td>Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.</td>
</tr>
<tr>
<td>log_errors</td>
<td>Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, errors are logged to the log_errors_table. The default is FALSE.</td>
</tr>
<tr>
<td>log_errors_table</td>
<td>Table name with the following schema:</td>

</tr>
<tr>
<td>log_triggers_table</td>
<td>Table to log triggers which are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade</td>
</tr>
</tbody>
</table>
UPGRADE_SCHEMA Procedure

This procedure upgrades tables in a specified list of schemas that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type. This procedure can be invoked only after an upgrade window has been started. Each table is upgraded in an atomic transaction. Note that a base table and its materialized view log table are upgraded in an atomic transaction.

Syntax

```
DBMS_DST.UPGRADE_SCHEMA (
    num_of_failures             OUT BINARY_INTEGER,
    schema_list                 IN  VARCHAR2,
    upgrade_data                IN  BOOLEAN := TRUE,
    parallel                    IN  BOOLEAN := FALSE,
    continue_after_errors       IN  BOOLEAN := TRUE,
    log_errors                  IN  BOOLEAN := FALSE,
    log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
    error_on_overlap_time       IN  BOOLEAN := FALSE,
    error_on_nonexisting_time   IN  BOOLEAN := FALSE,
    log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_of_failures</td>
<td>Number of tables that fail to complete</td>
</tr>
<tr>
<td>schema_list</td>
<td>Schema name list (comma separated strings)</td>
</tr>
<tr>
<td>upgrade_data</td>
<td>Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE) or to leave unconverted (FALSE). The default is TRUE.</td>
</tr>
<tr>
<td>parallel</td>
<td>Boolean flag indicating whether to convert tables using PDML (Parallel DML) or Serial DML. The default is FALSE.</td>
</tr>
<tr>
<td>continue_after_errors</td>
<td>Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.</td>
</tr>
<tr>
<td>log_errors</td>

<tr>
<td>error_on_nonexisting_time</td>
<td>Boolean flag indicating whether to report errors on the 'non-existing' time semantic conversion error.                                                                                                          The default is TRUE.</td>
</tr>
<tr>
<td>log_triggers_table</td>
<td>Table to log triggers that are disabled before upgrade, having not been enabled due to a fatal failure when performing an upgrade</td>
</tr>
</tbody>
</table>
UPGRADE_TABLE Procedure

This procedure upgrades a specified list of tables that have one or more columns defined on the TSTZ type, or an ADT containing the TSTZ type.

Syntax

```
DBMS_DST.UPGRADE_TABLE  (
    num_of_failures             OUT BINARY_INTEGER,
    table_list                  IN  VARCHAR2,
    upgrade_data                IN  BOOLEAN := TRUE,
    parallel                    IN  BOOLEAN := FALSE,
    continue_after_errors       IN  BOOLEAN := TRUE,
    log_errors                  IN  BOOLEAN := FALSE,
    log_errors_table            IN  VARCHAR2 =: 'sys.dst$error_table' ,
    error_on_overlap_time       IN  BOOLEAN := FALSE,
    error_on_nonexisting_time   IN  BOOLEAN := FALSE,
    log_triggers_table          IN  VARCHAR2 := 'sys.dst$trigger_table',
    atomic_upgrade              IN  BOOLEAN := FALSE);
```

Parameters

**Table 60–12 UPGRADE_TABLE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_of_failures</td>
<td>Number of tables that fail to complete</td>
</tr>
<tr>
<td>table_list</td>
<td>Table name list (comma separated strings)</td>
</tr>
<tr>
<td>upgrade_data</td>
<td>Boolean flag indicating whether to convert TSTZ data using the new Time Zone patch File (TRUE), or to leave unconverted (FALSE). The default is TRUE.</td>
</tr>
<tr>
<td>parallel</td>
<td>Boolean flag indicating whether to convert tables using PDML (Parallel DML), or Serial DML. The default is FALSE.</td>
</tr>
<tr>
<td>continue_after_errors</td>
<td>Boolean flag indicating whether to continue after upgrade fails on the current table. The default is TRUE.</td>
</tr>
<tr>
<td>log_errors</td>
<td>Boolean flag indicating whether to log errors during upgrade. If FALSE, no error is logged into the log_errors_table after aborting conversion of the current table. If TRUE, the error is logged to the log_errors_table. The default is FALSE.</td>
</tr>
<tr>
<td>log_errors_table</td>
<td>Table name with the following schema:</td>
</tr>
</tbody>
</table>

```
CREATE TABLE dst$error_table (  
table_owner VARCHAR2(30),  
table_name VARCHAR2(30),  
column_name VARCHAR2(4000),  
rid ROWID,  
error_number NUMBER)
```

The table can be created with the CREATE_ERROR_TABLE Procedure. The rid parameter records the rowids of the offending rows and the corresponding error number.
Usage Notes

This procedure can only be invoked after an upgrade window has been started. The table list has to satisfy the following partial ordering:

1. If a base table has a materialized view log table, the log table must be the next item in the list.

2. If the container table for a materialized view appears in the list, the materialized view’s ‘non-upgraded’ base tables and log tables must appear in the table list and before the container table.

A base table and its materialized view log table need to be upgraded in an atomic transaction by specifying `atomic_upgrade` to `TRUE`.

</table>
DBMS_DISTRIBUTED_TRUST_ADMIN procedures maintain the Trusted Servers List. Use these procedures to define whether a server is trusted. If a database is not trusted, Oracle refuses current user database links from the database.

This chapter contains the following topics:

- Using DBMS_DISTRIBUTED_TRUST_ADMIN
  - Overview
  - Security Model
  - Examples
- Summary of DBMS_DISTRIBUTED_TRUST_ADMIN Subprograms
Using DBMS_DISTRIBUTED_TRUST_ADMIN

- Overview
- Security Model
- Examples
Overview

Oracle uses local Trusted Servers Lists, along with enterprise domain membership lists stored in the enterprise LDAP directory service, to determine if another database is trusted. The LDAP directory service entries are managed with the Enterprise Security Manager Tool in Oracle Enterprise Manager.

Oracle considers another database to be "trusted" if it meets the following criteria:

1. It is in the same enterprise domain in the directory service as the local database.
2. The enterprise domain is marked as trusted in the directory service.
3. It is not listed as untrusted in the local Trusted Servers List. Current user database links will only be accepted from another database if both databases involved trust each other.

You can list a database server locally in the Trusted Servers List regardless of what is listed in the directory service. However, if you list a database that is not in the same domain as the local database, or if that domain is untrusted, the entry will have no effect.

This functionality is part of the Enterprise User Security feature of the Oracle Advanced Security Option.
Security Model

To execute DBMS_DISTRIBUTED_TRUST_ADMIN, the EXECUTE_CATALOG_ROLE role must be
granted to the DBA. To select from the view TRUSTED_SERVERS, the SELECT_CATALOG_ROLE role must be granted to the DBA.

It is important to know whether all servers are trusted or not trusted. Trusting a particular server with the ALLOW_SERVER procedure does not have any effect if the database already trusts all databases, or if that database is already trusted. Similarly, denying a particular server with the DENY_SERVER procedure does not have any effect if the database already does not trust any database or if that database is already untrusted.

The procedures DENY_ALL and ALLOW_ALL delete all entries (in other words, server names) that are explicitly allowed or denied using the ALLOW_SERVER procedure or DENY_SERVER procedure respectively.
Examples

If you have not yet used the package DBMS_DISTRIBUTED_TRUST_ADMIN to change the trust listing, by default you trust all databases in the same enterprise domain if that domain it listed as trusted in the directory service:

```
SELECT * FROM TRUSTED_SERVERS;
TRUST    NAME
--------- ---------------------
Trusted   All
```

Because all servers are currently trusted, you can execute the DENY_SERVER Procedure and specify that a particular server is not trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;
TRUST    NAME
--------- -----------------------------------------------
Untrusted SALES.US.AMERICAS.ACME_AUTO.COM
```

By executing the DENY_ALL Procedure, you can choose to not trust any database server:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;
PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;
TRUST    NAME
--------- -----------------------------------------------
Untrusted All
```

The ALLOW_SERVER Procedure can be used to specify that one particular database is to be trusted:

```
EXECUTE DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER ('SALES.US.AMERICAS.ACME_AUTO.COM');
PL/SQL procedure successfully completed.
```

```
SELECT * FROM TRUSTED_SERVERS;
TRUST    NAME
--------- ------------------------------------------------
Trusted   SALES.US.AMERICAS.ACME_AUTO.COM
```
Summary of DBMS_DISTRIBUTED_TRUST_ADMIN Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ALLOW_ALL Procedure</strong> on page 61-7</td>
<td>Empties the list and inserts a row indicating that all servers should be trusted</td>
</tr>
<tr>
<td><strong>ALLOW_SERVER Procedure</strong> on page 61-8</td>
<td>Enables a specific server to be allowed access even though deny all is indicated in the list</td>
</tr>
<tr>
<td><strong>DENY_ALL Procedure</strong> on page 61-9</td>
<td>Empties the list and inserts a row indicating that all servers should be untrusted</td>
</tr>
<tr>
<td><strong>DENY_SERVER Procedure</strong> on page 61-10</td>
<td>Enables a specific server to be denied access even though allow all is indicated in the list</td>
</tr>
</tbody>
</table>
ALLOW_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers that are members of a trusted domain in an enterprise directory service and that are in the same domain are allowed access.

The view TRUSTED_SERVERS will show "TRUSTED ALL" indicating that the database trusts all servers that are currently trusted by the enterprise directory service.

Syntax

DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_ALL;

Usage Notes

ALLOW_ALL only applies to servers listed as trusted in the enterprise directory service and in the same enterprise domain.
ALLOW_SERVER Procedure

This procedure ensures that the specified server is considered trusted (even if you have previously specified "deny all").

Syntax

```
DBMS_DISTRIBUTED_TRUST_ADMIN.ALLOW_SERVER (server IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>Unique, fully-qualified name of the server to be trusted.</td>
</tr>
</tbody>
</table>

Usage Notes

If the Trusted Servers List contains the entry "deny all", then this procedure adds a specification indicating that a specific database (for example, DBx) is to be trusted.

If the Trusted Servers List contains the entry "allow all", and if there is no "deny DBx" entry in the list, then executing this procedure causes no change.

If the Trusted Servers List contains the entry "allow all", and if there is a "deny DBx" entry in the list, then that entry is deleted.
DENY_ALL Procedure

This procedure empties the Trusted Servers List and specifies that all servers are denied access. The view TRUSTED_SERVERS will show "UNTRUSTED ALL" indicating that no servers are currently trusted.

Syntax

DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_ALL;
DENY_SERVER Procedure

This procedure ensures that the specified server is considered untrusted (even if you have previously specified allow all).

Syntax

```sql
DBMS_DISTRIBUTED_TRUST_ADMIN.DENY_SERVER (server IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>server</td>
<td>Unique, fully-qualified name of the server to be untrusted.</td>
</tr>
</tbody>
</table>

Usage Notes

If the Trusted Servers List contains the entry allow all, then this procedure adds an entry indicating that the specified database (for example, DBx) is not to be trusted.

If the Trusted Servers List contains the entry "deny all", and if there is no "allow DBx" entry in the list, then this procedure causes no change.

If the Trusted Servers List contains the entry "deny all", and if there is an "allow DBx" entry, then this procedure causes that entry to be deleted.
The DBMS_EDITIONS_UTILITIES package implements the Edition API which provides helper functions for edition-related operations.

The chapter contains the following topics:

- Using DBMS_EDITIONS_UTILITIES
  - Overview
  - Security Model
  - Exceptions
- Summary of DBMS_EDITIONS_UTILITIES Subprograms
Using DBMS_EDITIONS_UTILITIES

- Overview
- Security Model
- Exceptions
Overview

The DBMS_EDITIONS_UTILITIES package implements the Edition API which provides helper functions for edition-related operations.
Security Model

This package is owned by SYS with execute access granted to PUBLIC. It runs with invokers rights, that is, with the security profile of the caller.
Exceptions

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-38817</td>
<td>Insufficient privileges</td>
</tr>
<tr>
<td>ORA-942</td>
<td>Missing table</td>
</tr>
</tbody>
</table>
## Summary of DBMS_EDITIONS_UTILITIES Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SET_EDITIONING_VIEWS_READ_ONLY Procedure</strong></td>
<td>Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to READ ONLY or READ/WRITE.</td>
</tr>
</tbody>
</table>

---
SET_EDITIONING_VIEWS_READ_ONLY Procedure

Given the schema name and table name, this procedure sets the corresponding editioning views in all editions to READ ONLY or READ/WRITE.

Syntax

DBMS_EDITIONS_UTILITIES.SET_EDITIONING_VIEWS_READ_ONLY (  
  table_name IN VARCHAR2,  
  owner      IN VARCHAR2 DEFAULT NULL,  
  read_only  IN BOOLEAN  DEFAULT TRUE);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Base table of the editioning views</td>
</tr>
<tr>
<td>owner</td>
<td>Base table schema. The default (or NULL) is the current schema.</td>
</tr>
<tr>
<td>read_only</td>
<td>TRUE to set the views to read-only; FALSE (or NULL) sets the views to READ/WRITE. Default is TRUE.</td>
</tr>
</tbody>
</table>

Usage Notes

The user must have the following privileges:

- Owner of the table, or have the ALTER ANY TABLE system privileges
- USE object privilege on all the editions for which the views are defined
The `DBMS_EPG` package implements the embedded PL/SQL gateway that enables a Web browser to invoke a PL/SQL stored procedure through an HTTP listener.

This chapter contains the following topics:

- **Using DBMS_EPG**
  - Overview
  - Security Model
  - Exceptions

- **Data Structures**
  - `VARCHAR2_TABLE` Table Type

- **Subprogram Groups**
  - Configuration Subprograms
  - Authorization Subprograms

- **Summary of DBMS_EPG Subprograms**
Using DBMS_EPG

- Overview
- Security Model
- Exceptions
Overview

The DBMS_EPG package is a platform on which PL/SQL users develop and deploy PL/SQL Web applications. The embedded PL/SQL gateway is an embedded version of the gateway that runs in the XML database HTTP server in the Oracle database. It provides the core features of mod_plsql in the database but does not require the Oracle HTTP server powered by Apache.

In order to make a PL/SQL application accessible from a browser by way of HTTP, a Database Access Descriptor (DAD) must be created and mapped to a virtual path. A DAD is a set of configuration values used for database access and the virtual path mapping makes the application accessible under a virtual path of the XML DB HTTP Server. A DAD is represented as a servlet in XML DB HTTP Server.
The `XDBADMIN` role is required to invoke the configuration interface. It may invoked by the database user "XDB".

The authorization interface can be invoked by any user.
Exceptions

The following table lists the exceptions raised by the DBMS_EPG package.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DAD_NOT_FOUND</td>
<td>20000</td>
<td>Database Access Descriptor (DAD) %s not found. Ensure that the name of the DAD is correct and that it exists.</td>
</tr>
</tbody>
</table>
The DBMS_EPG package defines a TABLE type.

**VARCHAR2_TABLE Table Type**

This type is used by the procedures GET_ALL_GLOBAL_ATTRIBUTES, GET_ALL_DAD_ATTRIBUTES, GET_ALL_DAD_MAPPINGS, and GET_DAD_LIST to return lists of attribute names, attribute values, virtual paths, and database access descriptors (DAD).

```
TYPE VARCHAR2_TABLE IS TABLE OF VARCHAR2(4000) INDEX BY BINARY_INTEGER;
```
Subprogram Groups

The DBMS_EPG consists of two interfaces:

- Configuration Subprograms
- Authorization Subprograms
The Configuration subprogram group contain the subprogram interfaces to examine and modify the global and database access descriptor (DAD) specific settings of the embedded PL/SQL gateway.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE_DAD Procedure on page 63-12</td>
<td>Creates a new DAD</td>
</tr>
<tr>

</tr>
<tr>
<td>MAP_DAD Procedure on page 63-23</td>
<td>Maps a DAD to the specified virtual path.</td>
</tr>
<tr>
<td>SET_DAD_ATTRIBUTE Procedure on page 63-24</td>
<td>Sets the value for a DAD</td>
</tr>
<tr>
<td>SET_GLOBAL_ATTRIBUTE Procedure on page 63-26</td>
<td>Sets the value of a global attribute</td>
</tr>
<tr>
<td>UNMAP_DAD Procedure on page 63-27</td>
<td>Unmaps a DAD from the specified virtual path</td>
</tr>
</tbody>
</table>
AUTHORIZE_DAD Procedure

This procedure authorizes a DAD to invoke procedures and access document tables with a database user’s privileges. The invoker can always authorize the use of her/his own privileges.

See Also: Authorization Subprograms on page 63-9 for other subprograms in this group

Syntax

```sql
DBMS_EPG.AUTHORIZE_DAD (    dad_name  IN  VARCHAR2,    path     IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD to create</td>
</tr>
<tr>
<td>user</td>
<td>The user whose privileges to deauthorize. If use, the invoker is assumed.</td>
</tr>
</tbody>
</table>

Usage Notes

- To authorize the use of another user’s privileges, the invoker must have the ALTER USER system privilege.
- The DAD must exist but its "database-username" DAD attribute does not have to be set to user to authorize.
- Multiple users can authorize the same DAD and it is up to the DAD’s "database-username" setting to decide which user's privileges to use.

Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

Examples

```sql
DBMS_EPG.AUTHORIZE_DAD('HR');
```
CREATE_DAD Procedure

This procedure creates a new DAD.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

```
DBMS_EPG.CREATE_DAD (  
dad_name  IN  VARCHAR2,  
path      IN  VARCHAR2 DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD to create</td>
</tr>
<tr>
<td>path</td>
<td>The virtual path to which to map the DAD</td>
</tr>
</tbody>
</table>
DEAUTHORIZE_DAD Procedure

This procedure deauthorizes a DAD with regard to invoking procedures and accessing document tables with a database user's privileges. The invoker can always deauthorize the use of his own privileges.

**See Also:** Authorization Subprograms on page 63-9 for other subprograms in this group

Syntax

```sql
DBMS_EPG.DEAUTHORIZE_DAD (
    dad_name  IN  VARCHAR2,
    path      IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD for which to deauthorize use</td>
</tr>
<tr>
<td>user</td>
<td>The user whose privileges to deauthorize. If use, the invoker is assumed.</td>
</tr>
</tbody>
</table>

Usage Notes

To deauthorize the use of another user's privileges, the invoker must have the **ALTER USER** system privilege.

Exceptions

Raises an error if the DAD or user does not exist, or the invoker does not have the needed system privilege.

Examples

```sql
DBMS_EPG.DEAUTHORIZE_DAD('HR');
```
DELETE_DAD_ATTRIBUTE Procedure

This procedure deletes a DAD attribute.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.DELETE_DAD_ATTRIBUTE (  
dad_name     IN  VARCHAR2,  
attr_name     IN  VARCHAR2);  

Parameters

Table 63–8  DELETE_DAD_ATTRIBUTE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD for which to delete a DAD attribute</td>
</tr>
<tr>
<td>attr_name</td>
<td>The name of the DAD attribute to delete</td>
</tr>
</tbody>
</table>

Exceptions

Raises an error if DAD does not exist
DELETE_GLOBAL_ATTRIBUTE Procedure

This procedure deletes a global attribute.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.DELETE_GLOBAL_ATTRIBUTE ( attr_name IN VARCHAR2 );

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_name</td>
<td>The global attribute to delete</td>
</tr>
</tbody>
</table>
DROP_DAD Procedure

This procedure drops a DAD. All the virtual-path mappings of the DAD will be dropped also.

**See Also:** Configuration Subprograms on page 63-8 for other subprograms in this group

**Syntax**

```sql
DBMS_EPG.DROP_DAD (  
    dadname  IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The DAD to drop</td>
</tr>
</tbody>
</table>

**Exceptions**

Raises an error if the DAD does not exist.
**GET_ALL_DAD_ATTRIBUTES Procedure**

This procedure retrieves all the attributes of a DAD. The outputs are 2 correlated index-by tables of the name/value pairs.

*See Also:* [Configuration Subprograms](#) on page 63-8 for other subprograms in this group

**Syntax**

```sql
DBMS_EPG.GET_ALL_DAD_ATTRIBUTES (
    dad_name      IN          VARCHAR2,
    attr_names    OUT NOCOPY  VARCHAR2_TABLE,
    attr_values   OUT NOCOPY  VARCHAR2_TABLE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_names</td>
<td>The name of the DAD</td>
</tr>
<tr>
<td>attr_names</td>
<td>The attribute names</td>
</tr>
<tr>
<td>attr_values</td>
<td>The attribute values</td>
</tr>
</tbody>
</table>

**Exceptions**

 Raises an error if DAD does not exist.

**Usage Notes**

If the DAD has no attributes set, then `attr_names` and `attr_values` will be set to empty arrays.
**GET_ALL_DAD_MAPPINGS Procedure**

This procedure retrieves all virtual paths to which the specified DAD is mapped.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

**Syntax**

```sql
DBMS_EPG.GET_ALL_DAD_MAPPINGS (  
    dad_name IN VARCHAR2,  
    paths OUT NOCOPY VARCHAR2_TABLE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD</td>
</tr>
<tr>
<td>paths</td>
<td>The virtual paths to which the DAD is mapped</td>
</tr>
</tbody>
</table>

**Exceptions**

Raises an error if DAD does not exist.

**Usage Notes**

If the DAD is not mapped to any virtual path, `paths` will be set to empty arrays.
GET_ALL_GLOBAL_ATTRIBUTES Procedure

This procedure retrieves all global attributes and values. The outputs are 2 correlated index-by tables of the name/value pairs.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.GET_ALL_GLOBAL_ATTRIBUTES (  
    attr_names  OUT  NOCOPY  VARCHAR2_TABLE,  
    attr_values OUT  NOCOPY  VARCHAR2_TABLE);  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_names</td>
<td>The global attribute names</td>
</tr>
<tr>
<td>attr_values</td>
<td>The values of the global attributes</td>
</tr>
</tbody>
</table>

Usage Notes

If the gateway instance has no global attributes set, then `attr_names` and `attr_values` will be set to empty arrays.
GET_DAD_ATTRIBUTE Function

This procedure retrieves the value of a DAD attribute.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.GET_DAD_ATTRIBUTE (  
dad_name   IN  VARCHAR2,  
attr_name   IN  VARCHAR2)  
RETURN VARCHAR2;

Parameters

Parameter Description

dad_name The name of the DAD for which to delete an attribute
attr_name The name of the attribute to delete

Return values

Returns the DAD attribute value. Returns NULL if attribute is unknown or has not been set.

Exceptions

Raises an error if DAD does not exist.
GET_DAD_LIST Procedure

This procedure retrieves a list of all DADs for an Embedded Gateway instance.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.GET_DAD_LIST (  
dad_names     OUT NOCOPY  VARCHAR2_TABLE);

Parameters

Table 63–15 GET_DAD_LIST Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_names</td>
<td>The list of all DADs</td>
</tr>
</tbody>
</table>

Usage Notes

If no DADs exist then dad_names will be set to an empty array.
GET_GLOBAL_ATTRIBUTE Function

This function retrieves the value of a global attribute.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

```
DBMS_EPG.GET_GLOBAL_ATTRIBUTE (   attr_name  IN  VARCHAR2)   RETURN VARCHAR2;
```

Parameters

Table 63–16 GET_GLOBAL_ATTRIBUTE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_name</td>
<td>The global attribute to retrieve</td>
</tr>
</tbody>
</table>

Return Values

Returns the global attribute value. Returns NULL if attribute has not been set or is not a valid attribute.
MAP_DAD Procedure

This procedure maps a DAD to the specified virtual path. If the virtual path exists already, the old virtual-path mapping will be overridden.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

DBMS_EPG.MAP_DAD (  
    dad_name  IN  VARCHAR2,  
    path      IN  VARCHAR2);  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD to map</td>
</tr>
<tr>
<td>path</td>
<td>The virtual path to map</td>
</tr>
</tbody>
</table>

Exceptions

Raises and error if the DAD does not exist.
SET_DAD_ATTRIBUTE Procedure

This procedure sets the value for a DAD.

**See Also:** Configuration Subprograms on page 63-8 for other subprograms in this group

**Syntax**

```sql
DBMS_EPG.SET_DAD_ATTRIBUTE (  
dad_name    IN  VARCHAR2,  
attr_name   IN  VARCHAR2,  
attr_value  IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD for which to set the attribute</td>
</tr>
<tr>
<td>attr_name</td>
<td>The name of the attribute to set</td>
</tr>
<tr>
<td>attr_value</td>
<td>The attribute value to set</td>
</tr>
</tbody>
</table>

<td>No</td>
<td>Enumeration of Char, Raw</td>
</tr>
<tr>
<td>PlsqlUploadAsLongRaw</td>
<td>upload-as-long-raw</td>
<td>No</td>
<td>String</td>
</tr>
</tbody>
</table>

Exceptions

Raises an error if DAD does not exist or the attribute is unknown.

Usage Notes

- If attr_name attribute has been set before, then the old value will be overwritten with the new attr_value argument.
- The embedded gateway assumes default values when the attributes are not set. The default values of the DAD attributes should be sufficient for most users of the embedded gateway. mod_plsql users should note the following:
  - The PlsqlDatabasePassword attribute is not needed.
  - The PlsqlDatabaseConnectString attribute is not needed because the embedded gateway does not support logon to external databases.

Examples

DBMS_EPG.SET_DAD_ATTRIBUTE('HR', 'default-page', 'HRApp.home');
SET_GLOBAL_ATTRIBUTE Procedure

This procedure sets the value of a global attribute.

**See Also:** Configuration Subprograms on page 63-8 for other subprograms in this group

**Syntax**

```sql
DBMS_EPG.SET_GLOBAL_ATTRIBUTE (    attr_name    IN VARCHAR2,    attr_value   IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_name</td>
<td>The global attribute to set</td>
</tr>
<tr>
<td>attr_value</td>
<td>The attribute value to set</td>
</tr>
</tbody>
</table>

**Usage Notes**

- The attribute name is case sensitive. The value may or may not be case-sensitive depending on the attribute.
- If `attr_name` attribute has been set before, then the old value will be overwritten with the new `attr_value` argument.

**Exceptions**

Raises an error if the attribute is unknown.

**Examples**

```sql
dbms_epg.set_global_attribute('max-parameters', '100');
```

**Table 63–20  SET_GLOBAL_ATTRIBUTE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_name</td>
<td>The global attribute to set</td>
</tr>
<tr>
<td>attr_value</td>
<td>The attribute value to set</td>
</tr>
</tbody>
</table>

**Table 63–21  Mapping Between mod_plsql and Embedded PL/SQL Gateway Global Attributes**

<td>No</td>
<td>Unsigned integer</td>
</tr>
<tr>
<td>PlsqlMaxParameters</td>
<td>max-parameters</td>
<td>No</td>
<td>Unsigned integer</td>
</tr>
</tbody>
</table>
UNMAP_DAD Procedure

This procedure unmaps a DAD from the specified virtual path. If path is NULL, the procedure removes all virtual-path mappings for the DAD but keeps the DAD.

See Also: Configuration Subprograms on page 63-8 for other subprograms in this group

Syntax

```
DBMS_EPG.UNMAP_DAD (
    dad_name IN VARCHAR2,
    path     IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dad_name</td>
<td>The name of the DAD to unmap</td>
</tr>
<tr>
<td>path</td>
<td>The virtual path to unmap</td>
</tr>
</tbody>
</table>

Usage Notes

Raises and error if the DAD does not exist.
The DBMS_ERRLOG package provides a procedure that enables you to create an error logging table so that DML operations can continue after encountering errors rather than abort and roll back. This enables you to save time and system resources.

See Also: Oracle Database Data Warehousing Guide for more information regarding how to use DBMS_ERRLOG and Oracle Database SQL Language Reference for error_logging_clause syntax

This chapter contains the following topics:

- Using DBMS_ERRLOG
  - Security Model
- Summary of DBMS_ERRLOG Subprograms
Using DBMS_ERRLOG

This section contains topics which relate to using the DBMS_ERRLOG package.

- Security Model
Security Model

Security on this package can be controlled by granting EXECUTE on this package to selected users or roles. The EXECUTE privilege is granted publicly. However, to create an error logging table, you need SELECT access on the base table or view, the CREATE TABLE privilege, as well as tablespace quota for the target tablespace.
### Summary of DBMS_ERRLOG Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CREATE_ERROR_LOG</td>
<td>Procedure on page 64-5. Creates the error logging table used in DML error logging</td>
</tr>
</tbody>
</table>
CREATE_ERROR_LOG Procedure

This procedure creates the error logging table needed to use the DML error logging capability.

LONG, CLOB, BLOB, BFILE, and ADT datatypes are not supported in the columns.

Syntax

```
DBMS_ERRLOG.CREATE_ERROR_LOG (
    dml_table_name            IN VARCHAR2,
    err_log_table_name        IN VARCHAR2 := NULL,
    err_log_table_owner       IN VARCHAR2 := NULL,
    err_log_table_space       IN VARCHAR2 := NULL,
    skip_unsupported          IN BOOLEAN := FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>dml_table_name</code></td>
<td>The name of the DML table to base the error logging table on. The name can be fully qualified (for example, <code>emp</code> or <code>emp.ERROR_LOADING</code>). If a name component is enclosed in double quotes, it will not be upper cased.</td>
</tr>
<tr>
<td><code>err_log_table_name</code></td>
<td>The name of the error logging table you will create. The default is the first 25 characters in the name of the DML table prefixed with 'ERR$_'. Examples are the following: <code>dml_table_name: 'EMP', err_log_table_name: 'ERR$_EMP'</code></td>
</tr>
<tr>
<td><code>err_log_table_owner</code></td>
<td>The name of the owner of the error logging table. You can specify the owner in <code>dml_table_name</code>. Otherwise, the schema of the current connected user is used.</td>
</tr>
<tr>
<td><code>err_log_table_space</code></td>
<td>The tablespace the error logging table will be created in. If not specified, the default tablespace for the user owning the DML error logging table will be used.</td>
</tr>
<tr>
<td><code>skip_unsupported</code></td>
<td>When set to <code>TRUE</code>, column types that are not supported by error logging will be skipped over and not added to the error logging table. When set to <code>FALSE</code>, an unsupported column type will cause the procedure to terminate. The default is <code>FALSE</code>.</td>
</tr>
</tbody>
</table>

Examples

First, create an error log table for the `channels` table in the `SH` schema, using the default name generation.

Then, see all columns of the table `channels`:

```
SQL> DESC channels
Name                     Null?     Type
------------------------ -------- -------
CHANNEL_ID               NOT NULL  CHAR(1)  
CHANNEL_DESC             NOT NULL  VARCHAR2(20) 
CHANNEL_CLASS            NOT NULL  VARCHAR2(20) 
```
Finally, see all columns of the generated error log table. Note the mandatory control columns that are created by the package:

```
SQL> DESC ERR$_CHANNELS
Name           Null?  Type
----------------- ---- ----
ORA_ERR_NUMBER$  ----   NUMBER
ORA_ERR_MESG$    ----   VARCHAR2(2000)
ORA_ERR_ROWID$   ----   ROWID
ORA_ERR_OPTYP$   ----   VARCHAR2(2)
ORA_ERR_TAG$     ----   VARCHAR2(2000)
CHANNEL_ID       ----   VARCHAR2(4000)
CHANNEL_DESC     ----   VARCHAR2(4000)
CHANNEL_CLASS    ----   VARCHAR2(4000)
```

See Oracle Database Administrator’s Guide for more information regarding control columns.
The DBMS_EXPFIL package contains all the procedures used to manage attribute sets, expression sets, expression indexes, optimizer statistics, and privileges by Expression Filter.

**Note:** This functionality is deprecated with Oracle Database Release 11.2 and obsoleted with Release 12.1. For details regarding obsolescence, see My Oracle Support Note ID 1244535.1

**See Also:** Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information.

This chapter contains the following topics:

- Using DBMS_EXPFIL
- Summary of Expression Filter Subprograms
Using DBMS_EXPFWL

This section contains topics that relate to using the Rules Manager DBMS_EXPFWL package.

- Security Model
Security Model

The Oracle Database installation runs the `catexf.sql` script to load the `DBMS_EXPFIL` package and create the required Expression Filter schema objects in the `EXFSYS` schema.

`DBMS_EXPFIL` is an `EXFSYS`-owned package compiled with `AUTHID CURRENT_USER`. Any `DBMS_EXPFIL` subprogram called from an anonymous PL/SQL block is run using the privileges of the current user.

Before you issue `COPY_ATTRIBUTE_SET` procedure, the user must have the `EXECUTE` privilege for the object type associated with the original attribute set.

A user requires `SELECT` privileges on a table storing expressions to evaluate them. The `SQL EVALUATE` operator evaluates expressions with the privileges of the owner of the table that stores the expressions. The privileges of the user issuing the query are not considered. The owner of the table can insert, update, and delete expressions. Other users must have `INSERT` and `UPDATE` privileges for the table and `INSERT EXPRESSION` and `UPDATE EXPRESSION` privilege for a specific Expression column in the table to be able to make modifications to it.

Using the `GRANT_PRIVILEGE` procedure, the owner of the table can grant `INSERT EXPRESSION` or `UPDATE EXPRESSION` privileges on one or more Expression columns to other users. Both privileges can be granted to a user by specifying `ALL` for the privilege type.

A user with `CREATE_INDEX` privileges on a table cannot create an Expression Filter index unless the user is the owner of the table.

A user must have `EXECUTE` privilege on the `CTX_DDL` package for successful synchronization of the text indexes using the `DBMS_EXPFIL.SYNC_TEXT_INDEXES` procedure.

The `USER_EXPFIL_PRIVILEGES` view lists the privileges of the current user on expression sets belonging to other schemas and the privileges of other users on the expression sets owned by the current user.
Summary of Expression Filter Subprograms

Table 65–1 describes the subprograms in the DBMS_EXPFIL package.

All the values and names passed to the procedures defined in the DBMS_EXPFIL package are not case sensitive, unless otherwise mentioned. To preserve the case, you use double quotation marks around the values.

</tbody>
</table>
ADD_ELEMENTARY_ATTRIBUTE Procedures

This procedure adds the specified attribute to the attribute set. The procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Adds the specified elementary attribute to the attribute set:

```sql
DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (
    attr_set   IN   VARCHAR2,
    attr_name  IN   VARCHAR2,
    attr_type  IN   VARCHAR2,
    attr_defv1 IN   VARCHAR2 DEFAULT NULL);
```

Identifies the elementary attributes that are table aliases and adds them to the attribute set:

```sql
DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (
    attr_set   IN   VARCHAR2,
    attr_name  IN   VARCHAR2,
    tab_alias  IN   exf$table_alias);
```

Allows addition of text attributes to the attribute set:

```sql
DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (
    attr_set       IN   VARCHAR2,
    attr_name      IN   VARCHAR2,
    attr_type      IN   VARCHAR2,
    text_pref      IN   EXF$TEXT);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set to which this attribute is added</td>
</tr>
<tr>
<td>attr_name</td>
<td>Name of the elementary attribute to be added. No two attributes in a set can have the same name.</td>
</tr>
<tr>
<td>attr_type</td>
<td>Datatype of the attribute. This argument accepts any standard SQL datatype or the name of an object type that is accessible to the current user.</td>
</tr>
<tr>
<td>attr_defv1</td>
<td>Default value for the elementary attribute</td>
</tr>
<tr>
<td>tab_alias</td>
<td>Type that identifies the database table to which the attribute is aliased</td>
</tr>
<tr>
<td>text_pref</td>
<td>Text preferences such as LEXER and WORDLIST specification.</td>
</tr>
</tbody>
</table>

Usage Notes

- If the attribute set receiving the elementary attribute was originally created from an existing object type, then additional attributes cannot be added.
- One or more, or all elementary attributes in an attribute set can be table aliases. If an elementary attribute is a table alias, then the value assigned to the elementary attribute is a ROWID from the corresponding table. An attribute set with one or
more table alias attributes cannot be created from an existing object type. For more information about table aliases, see Oracle Database Rules Manager and Expression Filter Developer’s Guide.

- Elementary attributes cannot be added to an attribute set that is already assigned to a column storing expressions.

- The default value specification for an attribute is similar to a default value specification for a table column. The resulting default values should agree with the datatype of the attribute. For example, valid default values for an attribute of DATE datatype are SYSDATE and to_date('01-01-2004','DD-MM-YYYY').

- See the section on defining attribute sets in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about adding elementary attributes.

- Related views: USER_EXPFIL_ATTRIBUTE_SETS and USER_EXPFIL_ATTRIBUTES.

- This procedure with a text preference bound to the text_pref argument creates a text attribute in the attribute set. The data type for such an attribute should be a VARCHAR2 or a CLOB. The preferences specified with this procedure are validated only when an Expression Filter index is created using this attribute set.

- These preferences are used in the creation of the CTXRULE index that processes the predicates involving CONTAINS operator. The valid preferences are those that are valid in the PARAMETERS clause of CTXRULE index creation. See Oracle Text Application Developer’s Guide for the syntax.

Examples

The following commands add two elementary attributes to an attribute set:

```sql
BEGIN
  DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (  
    attr_set   => 'HRAttrSet',  
    attr_name  => 'HRREP',  
    attr_type  => 'VARCHAR2(30)'  
    attr_defv1 => 'Betty Smith');
  DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (  
    attr_set   => 'HRAttrSet',  
    attr_name  => 'DEPT',  
    tab_alias => exf$table_alias('DEPT'));
END;
/
```

The following commands define a CreationTime elementary attribute that takes the database time as the default value.

```sql
BEGIN
  DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (  
    attr_set   => 'PurchaseOrder',  
    attr_name  => 'CreationTime',  
    attr_type  => 'DATE',  
    attr_defvl => 'SYSDATE');
END;
/
```

Alternately, the following commands initialize the CreationTime attribute to a specific value when it is not explicitly specified in the data item passed to the EVALUATE operator.

```sql
BEGIN
  DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE (  
    attr_set   => 'PurchaseOrder',  
    attr_name  => 'CreationTime',  
    attr_type  => 'DATE',  
    attr_defvl => 'SYSDATE');
END;
/
```
attr_set => 'PurchaseOrder',
attr_name => 'CreationTime',
attr_type => 'DATE',
attr_defvl => 'to_date(''01-01-2004'',''DD-MM-YYYY'')');

END;
/

The following commands create an attribute set with a Model attribute of VARCHAR2 data type and an InsReport attribute configured for text predicates.

BEGIN
   DBMS_EXPFIL.CREATE_EVENT_STRUT(event_struct => 'Car4Sale');
   // create scalar attributes
   DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE{
      attr_set => 'Car4Sale',
      attr_name => 'Model',
      attr_type => 'VARCHAR2(30)');

   //create text attribute
   DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE{
      attr_set => 'Car4Sale',
      attr_name => 'InsReport',
      attr_type => 'CLOB',
      attr_type => exf$text(
         'LEXER insrpt_lexer
         WORDLIST insrpt_wordlist'));

END;
/
ADD_FUNCTIONS Procedure

This procedure adds a user-defined function, package, or type representing a set of functions to the attribute set.

Syntax

```
DBMS_EXPFIL.ADD_FUNCTIONS (
    attr_set IN VARCHAR2,
    funcs_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set to which the functions are added</td>
</tr>
<tr>
<td>funcs_name</td>
<td>Name of a function, package, or type (representing a function set) or its synonyms</td>
</tr>
</tbody>
</table>

Usage Notes

- By default, an attribute set implicitly allows references to all Oracle Database supplied SQL functions for use by the expression set. If the expression set refers to a user-defined function, the function must be explicitly added to the attribute set.
- The ADD_FUNCTIONS procedure adds a user-defined function or a package (or type) representing a set of functions to the attribute set. Any new or modified expressions are validated using this list. The function added to the attribute set, and thus used in the stored expressions, should not perform any DML or DDL (database state changing) operations. Oracle Database catches violations to this rule only at run-time while evaluating the expressions. Violations are not checked during the ADD_FUNCTIONS procedure call.
- The function or the package name can be specified with a schema extension. If a function name is specified without a schema extension, only such references in the expression set are considered valid. The expressions in a set can be restricted to use a synonym to a function or a package by adding the corresponding synonym to the attribute set. This preserves the portability of the expression set to other schemas.
- See the section on defining attribute sets in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about adding functions to an attribute set.
- Related views: USER_EXPFIL_ATTRIBUTE_SETS and USER_EXPFIL_EXPRESSION_SETS

Examples

The following commands add two functions to the attribute set:

```
BEGIN
    DBMS_EXPFIL.ADD_FUNCTIONS (
        attr_set => 'Car4Sale',
        funcs_name => 'HorsePower');
    DBMS_EXPFIL.ADD_FUNCTIONS (
        attr_set => 'Car4Sale',
        funcs_name => 'Scott.CrashTestRating');
END;
```
END;
/

ASSIGN_ATTRIBUTE_SET Procedure

This procedure assigns an attribute set to a VARCHAR2 column in a user table to create an Expression column.

Syntax

```sql
DBMS_EXPFIL.ASSIGN_ATTRIBUTE_SET (attr_set => 'Car4Sale',
expr_tab IN VARCHAR2,
expr_col IN VARCHAR2,
force IN VARCHAR2 DEFAULT 'FALSE');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set</td>
</tr>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
<tr>
<td>force</td>
<td>Argument used to trust the existing expressions in a table (and skip validation)</td>
</tr>
</tbody>
</table>

Usage Notes

- The ASSIGN_ATTRIBUTE_SET procedure assigns an attribute set to a VARCHAR2 column in a user table to create an Expression column. The attribute set contains the elementary attribute names and their data types and any functions used in the expressions. The Expression column, the column named by the `expr_col` parameter to store the expression, uses the attribute set to validate changes and additions to the expression set.

- An attribute set can be assigned only to a table column in the same schema as the attribute set. An attribute set can be assigned to one or more table columns. Assigning an attribute set to a column storing expressions implicitly creates methods for the associated object type. For this operation to succeed, the object type cannot have any dependent objects before the attribute set is assigned.

- By default, the column should not have any expressions at the time of association. However, if the values in the column are known to be valid expressions, you can use a value of 'TRUE' for the `force` argument to assign the attribute set to a column containing expressions.

- See the information about defining Expression columns in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about adding elementary attributes.

- Related views: USER_EXPFL_ATTRIBUTE_SETS and USER_EXPFL_EXPRESSION_SETS

Examples

The following command assigns the attribute set to a column storing expressions. The expression set should be empty at the time of association.

```sql
BEGIN
    DBMS_EXPFIL.ASSIGN_ATTRIBUTE_SET (attr_set => 'Car4Sale',
```
expr_tab => 'consumer',
expr_col => 'interest');
END;
/

BUILD_EXCEPTIONS_TABLE Procedure

This procedure creates the exception table, used in validation, in the current schema.

Syntax

DBMS_EXPRIL.BUILD_EXCEPTIONS_TABLE (exception_tab IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exception_tab</td>
<td>Name of the exception table</td>
</tr>
</tbody>
</table>

Usage Notes

- During expression validation, you can optionally provide the name of the exception table in which the references to the invalid expressions are stored. The BUILD_EXCEPTIONS_TABLE procedure creates the exception table in the current schema.
- See the section on evaluation semantics in Oracle Database Rules Manager and Expression Filter Developer’s Guide and VALIDATE_EXPRESSIONS Procedure for more information.
- Related view: USER_TABLES

Examples

The following command creates the exception table, InterestExceptions, in the current schema:

```
BEGIN
    DBMS_EXPRIL.BUILD_EXCEPTIONS_TABLE (exception_tab => 'InterestExceptions');
END;
/
```
CLEAR_EXPRSET_STATS Procedure

This procedure clears the predicate statistics for the expression set stored in a table column.

Syntax

```sql
DBMS_EXPFIL.CLEAR_EXPRSET_STATS (  
   expr_tab   IN   VARCHAR2,  
   expr_col   IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
</tbody>
</table>

Usage Notes

- See also GET_EXPRSET_STATS Procedure for information about gathering the statistics.
- Related views: USER_EXPFIL_EXPRESSION_SETS and USER_EXPFIL_EXPRSET_STATS

Examples

The following command clears the predicate statistics for the expression set stored in `interest` column of the `consumer` table:

```sql
BEGIN
   DBMS_EXPFIL.CLEAR_EXPRSET_STATS (expr_tab => 'consumer',
                                      expr_col => 'interest');
END;
/
COPY_ATTRIBUTE_SET Procedure

This procedure copies an attribute set along with its user-defined function list and default index parameters to another set.

Syntax

```sql
DBMS_EXPFIL.COPY_ATTRIBUTE_SET (from_set IN VARCHAR2, to_set IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>from_set</code></td>
<td>Name of an existing attribute set to be copied</td>
</tr>
<tr>
<td><code>to_set</code></td>
<td>Name of the new attribute set</td>
</tr>
</tbody>
</table>

Usage Notes

- A schema-extended name can be used for the `from_set` argument to copy an attribute set across schemas. Before you issue this command, you must have the `EXECUTE` privilege for the object type associated with the original attribute set. Ensure that any references to schema objects (user-defined functions, tables, and embedded objects) are valid in the new schema.
- The default index parameters and the user-defined function list of the new set can be changed independent of the original set.
- Related views: `ALL_EXPFIL_ATTRIBUTE_SETS` and `ALL_EXPFIL_ATTRIBUTES`.

Examples

The following command makes a copy of the `Car4Sale` attribute set:

```sql
BEGIN
  DBMS_EXPFIL.COPY_ATTRIBUTE_SET (from_set => 'Car4Sale',
                                   to_set   => 'Vehicle');
END;
/
```
CREATE_ATTRIBUTE_SET Procedure

This procedure creates an empty attribute set or an attribute set with a complete set of elementary attributes derived from an object type with a matching name.

Syntax

```
DBMS_EXPFIL.CREATE_ATTRIBUTE_SET (  
    attr_set   IN   VARCHAR2,  
    from_type  IN   VARCHAR2 DEFAULT 'NO');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set to be created</td>
</tr>
<tr>
<td>from_type</td>
<td>YES, if the attributes for the attribute set should be derived from an existing object type</td>
</tr>
</tbody>
</table>

Usage Notes

- The object type used for an attribute set cannot contain any user methods, and it should not be an evolved type (with the use of `ALTER TYPE` command). This object type should not have any dependent objects at the time of the attribute set creation. If the attribute set is not derived from an existing object type, this procedure creates an object type with a matching name.
- An attribute set with one or more table alias attributes cannot be derived from an object type. For this purpose, create an empty attribute set and add one elementary attribute at a time using the `DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE` procedure. (See Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information.)
- See the section on defining attribute sets in Oracle Database Rules Manager and Expression Filter Developer’s Guide and ADD_ELEMENTARY_ATTRIBUTE Procedures for more information.
- Related views: USER_EXPFIL_ATTRIBUTE_SETS and USER_EXPFIL_ATTRIBUTES.

Examples

The following commands create an attribute set with all the required elementary attributes derived from the Car4Sale type:

```
CREATE OR REPLACE TYPE Car4Sale AS OBJECT  
(Model  VARCHAR2(20),  
Year   NUMBER,  
Price  NUMBER,  
Mileage NUMBER);  
/
BEGIN  
    DBMS_EXPFIL.CREATE_ATTRIBUTE_SET(  
        attr_set => 'Car4Sale',  
        from_type => 'YES');  
END;
/
```
Assuming that the Car4Sale type does not exist, the attribute set can be created from scratch as shown in the following example:

```sql
BEGIN
    DBMS_EXPFIL.CREATE_ATTRIBUTE_SET(attr_set => 'Car4Sale');
    DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE(
        attr_set => 'Car4Sale',
        attr_name => 'Model',
        attr_type => 'VARCHAR2(20)');
    DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE(
        attr_set => 'Car4Sale',
        attr_name => 'Year',
        attr_type => 'NUMBER');
    DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE(
        attr_set => 'Car4Sale',
        attr_name => 'Price',
        attr_type => 'NUMBER');
    DBMS_EXPFIL.ADD_ELEMENTARY_ATTRIBUTE(
        attr_set => 'Car4Sale',
        attr_name => 'Mileage',
        attr_type => 'NUMBER');
END;
/
```
**DEFAULT_INDEX_PARAMETERS Procedure**

This procedure assigns default index parameters to an attribute set. It also adds or drops a partial list of stored and indexed attributes to or from the default list associated with the attribute list.

**Syntax**

```sql
DBMS_EXPFIL.DEFAULT_INDEX_PARAMETERS(
    attr_set IN VARCHAR2,
    attr_list IN EXF$ATTRIBUTE_LIST,
    operation IN VARCHAR2 DEFAULT 'ADD');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set</td>
</tr>
<tr>
<td>attr_list</td>
<td>An instance of EXF$ATTRIBUTE_LIST with a partial list of (default) stored and indexed attributes for an Expression Filter index</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to be performed on the list of index parameters. Default value: ADD. Valid values: ADD and DROP.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- Existing Expression Filter indexes are not modified when the default parameters for the corresponding attribute set are changed. The new index defaults are used when a new Expression Filter index is created and when an existing index is rebuilt. (See the section on alter index rebuild in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about rebuilding indexes.)
- See the section on creating an index from default parameters in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about assigning default index parameters to an attribute set.
- Related views: `USER_EXPFIL_ATTRIBUTE_SETS` and `USER_EXPFIL_DEF_INDEX_PARAMS`

**Examples**

The following command adds the specified stored and indexed attributes to the attribute set’s default index parameters list:

```sql
BEGIN
    DBMS_EXPFIL.DEFAULT_INDEX_PARAMETERS(
        attr_set => 'Car4Sale',
        attr_list => exf$attribute_list(
            exf$attribute (attr_name => 'Model',
                attr_oper => exf$indexoper('='),
                attr_indexed => 'TRUE'),
            exf$attribute (attr_name => 'Price',
                attr_oper => exf$indexoper('all'),
                attr_indexed => 'TRUE'),
            exf$attribute (attr_name => 'HorsePower(Model, Year)',
                attr_oper => exf$indexoper('=','<','>','>='),'<='),
                attr_indexed => 'FALSE'));
END;
```
exf$attribute (attr_name => 'CrashTestRating(Model, Year)'),
  attr_oper => exf$indexoper('=','<','>','>=','<='),
  attr_indexed => 'FALSE')),
  operation => 'ADD');
END;
/

The following command drops the CrashTestRating(Model, Year) attribute (stored or indexed) from the previous list.

BEGIN
  DBMS_EXPFIL.DEFAULT_INDEX_PARAMETERS(
    attr_set  => 'Car4Sale',
    attr_list => exf$attribute_list {
      exf$attribute (attr_name => 'CrashTestRating(Model, Year)'),
      operation => 'DROP'});
END;
/
**DEFAULT_XPINDEX_PARAMETERS Procedure**

This procedure adds (or drops) a partial list of XPath parameters to the default index parameters associated with the attribute set.

**Syntax**

```sql
DBMS_EXPFIL.DEFAULT_XPINDEX_PARAMETERS (
    attr_set   IN   VARCHAR2,
    xmlt_attr  IN   VARCHAR2,
    xptag_list IN   EXF$XPATH_TAGS,
    operation  IN   VARCHAR2 DEFAULT 'ADD');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set</td>
</tr>
<tr>
<td>xmlt_attr</td>
<td>Name of the attribute with the XMLType datatype</td>
</tr>
<tr>
<td>xptag_list</td>
<td>An instance of EXF$XPATH_TAGS type with a partial list of XML elements and attributes to be configured for the Expression Filter index</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to be performed on the list of index parameters. Default value: ADD. Valid values: ADD and DROP.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- The attribute set used for an expression set may have one or more XML type attributes (defined with XMLType datatype) and the corresponding expressions may contain XPath predicates on these attributes. The Expression Filter index created for the expression set can be tuned to process these XPath predicates efficiently by using some XPath-specific index parameters (in addition to some non-XPath index parameters).

- The `DEFAULT_XPINDEX_PARAMETERS` procedure adds (or drops) a partial list of XPath parameters to the default index parameters associated with the attribute set. The XPath parameters are assigned to a specific XMLType attribute in the attribute set and this information can be viewed using the `USER_EXPFIL_DEF_INDEX_PARAMS` view. The `DEFAULT_INDEX_PARAMETERS` procedure and the `DEFAULT_XPINDEX_PARAMETERS` procedure can be used independent of each other. They maintain a common list of default index parameters for the attribute set.

- See the section on index tuning for XPath predicates in *Oracle Database Rules Manager and Expression Filter Developer’s Guide* for more information about XPath parameters to the default index parameters of an attribute set. See also `DEFAULT_INDEX_PARAMETERS Procedure` for more information about default index parameters.

- Related views: `USER_EXPFIL_ATTRIBUTES` and `USER_EXPFIL_DEF_INDEX_PARAMS`.

---

**Note:** The values assigned to the `tag_name` argument of `exf$xpath_tag` type are case sensitive.
The following command adds the specified XML tags to the default index parameters list along with their preferences such as positional or value filter and indexed or stored predicate group:

```sql
BEGIN
    DBMS_EXPFIL.DEFAULT_XPINDEX_PARAMETERS(
        attr_set => 'Car4Sale',
        xmlt_attr => 'Details',
        xptag_list => 
            exf$xpath_tags(
                exf$xpath_tag(tag_name => 'stereo@make',  --- XML attribute
                    tag_indexed => 'TRUE',
                    tag_type => 'VARCHAR(15)'), --- value filter
                exf$xpath_tag(tag_name => 'stereo',     --- XML element
                    tag_indexed => 'FALSE',
                    tag_type => null),          --- positional filter
                exf$xpath_tag(tag_name => 'memory',      --- XML element
                    tag_indexed => 'TRUE',
                    tag_type => 'VARCHAR(10)'), --- value filter
                exf$xpath_tag(tag_name => 'GPS',
                    tag_indexed => 'TRUE',
                    tag_type => null)
            )
    );
END;
/
```

The following command drops the `stereo@make` tag from the default index parameters:

```sql
BEGIN
    DBMS_EXPFIL.DEFAULT_XPINDEX_PARAMETERS(
        attr_set => 'Car4Sale',
        xmlt_attr => 'Details',
        xptag_list => 
            exf$xpath_tags(
                exf$xpath_tag(tag_name => 'stereo@make')
            )
    )
    operation => 'DROP'
);;
END;
/
```
**DEFRAG_INDEX Procedure**

This procedure rebuilds the bitmap indexes online and thus reduces the fragmentation.

**Syntax**

```sql
DBMS_EXPFIL.DEFRAG_INDEX (
    idx_name   IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>idx_name</td>
<td>Name of the Expression Filter index</td>
</tr>
</tbody>
</table>

**Usage Notes**

- The bitmap indexes defined for the indexed attributes of an Expression Filter index become fragmented as additions and updates are made to the expression set. This can affect performance. The `DEFRAG_INDEX` procedure rebuilds the bitmap indexes online and thus reduces the fragmentation.

- Indexes can be defragmented when the expression set is being modified. However, you should schedule defragmentation when the workload is relatively light, such as 2 a.m.

- See the section on index storage and maintenance in *Oracle Database Rules Manager and Expression Filter Developer’s Guide* for more information about rebuilding indexes.

- Related views: `USER_EXPFIL_INDEXES` and `USER_INDEXES`.

**Examples**

The following command is issued to defragment the bitmap indexes associated with the Expression Filter index:

```sql
BEGIN
    DBMS_EXPFIL.DEFRAG_INDEX (idx_name => 'InterestIndex');
END;
/
```
DROP_ATTRIBUTE_SET Procedure

This procedure drops an attribute set not being used for any expression set.

Syntax

```sql
DBMS_EXPFIL.DROP_ATTRIBUTE_SET (
    attr_set   IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set to be dropped</td>
</tr>
</tbody>
</table>

Usage Notes

- The `DROP_ATTRIBUTE_SET` procedure drops an attribute set not being used for any expression set. If the attribute set was initially created from an existing object type, the object type remains after dropping the attribute set. Otherwise, the object type is dropped with the attribute set.
- Related views: `USER_EXPFIL_ATTRIBUTE_SETS` and `USER_EXPFIL_EXPRESSION_SETS`.

Examples

Assuming that the attribute set is not used by an Expression column, the following command drops the attribute set:

```sql
BEGIN
    DBMS_EXPFIL.DROP_ATTRIBUTE_SET(attr_set => 'Car4Sale');
END;
/
**GET_EXPRSET_STATS Procedure**

This procedure computes the predicate statistics for an expression set and stores them in the expression filter dictionary.

**Syntax**

```sql
DBMS_EXPFIL.GET_EXPRSET_STATS (  
    expr_tab   IN   VARCHAR2,  
    expr_col   IN   VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
</tbody>
</table>

**Usage Notes**

- When a representative set of expressions are stored in a table column, you can use predicate statistics for those expressions to configure the corresponding Expression Filter index (using the TOP parameters clause). The GET_EXPRSET_STATS procedure computes the predicate statistics for an expression set and stores them in the expression filter dictionary.

- See the section on creating an index from statistics in *Oracle Database Rules Manager and Expression Filter Developer’s Guide* for more information about using predicate statistics.

- Related views: USER_EXPFIL_EXPRESSION_SETS and USER_EXPFIL_EXPRSET_STATS.

**Examples**

The following command computes the predicate statistics for the expressions stored in the interest column of the consumer table:

```sql
BEGIN
    DBMS_EXPFIL.GET_EXPRSET_STATS (expr_tab => 'consumer',
                                    expr_col => 'interest');
END;
/
```
GRANT_PRIVILEGE Procedure

This procedure grants privileges on one or more Expression columns to other users.

Syntax

```sql
DBMS_EXPFIL.GRANT_PRIVILEGE (  
  expr_tab IN VARCHAR2,  
  expr_col IN VARCHAR2,  
  priv_type IN VARCHAR2,  
  to_user IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
<tr>
<td>priv_type</td>
<td>Type of the privilege to be granted. Valid values: INSERT EXPRESSION, UPDATE EXPRESSION, ALL.</td>
</tr>
<tr>
<td>to_user</td>
<td>User to whom the privilege is to be granted</td>
</tr>
</tbody>
</table>

Usage Notes

- The SQL EVALUATE operator evaluates expressions with the privileges of the owner of the table that stores the expressions. The privileges of the user issuing the query are not considered. The owner of the table can insert, update, and delete expressions. Other users must have INSERT and UPDATE privileges for the table and INSERT EXPRESSION and UPDATE EXPRESSION privilege for a specific Expression column in the table.
- Using the GRANT_PRIVILEGE procedure, the owner of the table can grant INSERT EXPRESSION or UPDATE EXPRESSION privileges on one or more Expression columns to other users. Both the privileges can be granted to a user by specifying ALL for the privilege type.
- See REVOKE_PRIVILEGE Procedure and the section on granting and revoking privileges in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about granting and revoking privileges.
- Related views: USER_EXPFIL_EXPRESSION_SETS and USER_EXPFIL_PRIVILEGES.

Examples

The owner of consumer table can grant INSERT EXPRESSION privileges to user SCOTT with the following command. User SCOTT should also have INSERT privileges on the table so that he can add new expressions to the set.

```sql
BEGIN
  DBMS_EXPFIL.GRANT_PRIVILEGE (expr_tab => 'consumer',
                                expr_col => 'interest',
                                priv_type => 'INSERT EXPRESSION',
                                to_user => 'SCOTT');
END;
```
INDEX_PARAMETERS Procedure

This procedure fine-tunes the index parameters for each expression set before index creation.

Syntax

```sql
DBMS_EXPFIL.INDEX_PARAMETERS (  
  expr_tab   IN   VARCHAR2,  
  expr_col   IN   VARCHAR2,  
  attr_list  IN   EXF$ATTRIBUTE_LIST,  
  operation  IN   VARCHAR2 DEFAULT 'ADD');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions.</td>
</tr>
<tr>
<td>attr_list</td>
<td>An instance of EXF$ATTRIBUTE_LIST with a partial list of stored and indexed attributes</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to be performed on the list of index parameters. Default value: ADD. Valid values: ADD and DROP.</td>
</tr>
</tbody>
</table>

Usage Notes

- An attribute set can be used by multiple expression sets stored in different columns of user tables. By default, the index parameters associated with the attribute set are used to define an Expression Filter index on an expression set. If you need to fine-tune the index for each expression set, you can specify a small list of the index parameters in the PARAMETERS clause of the CREATE INDEX statement. However, when an Expression Filter index uses a large number of index parameters or if the index is configured for XPath predicates, fine-tuning the parameters with the CREATE INDEX statement is not possible.

- The INDEX_PARAMETERS procedure fine-tunes the index parameters for each expression set before index creation. This procedure can be used to copy the defaults from the corresponding attribute set and selectively add (or drop) additional index parameters for the expression set. (You use the XPINDEX_PARAMETERS procedure to add and drop XPath index parameters.) The Expression Filter index defined for an expression set with a non-empty list of index parameters always uses these parameters. The INDEX_PARAMETERS procedure cannot be used when the Expression Filter index is already defined for the column storing expressions.

- The operations allowed with this procedure include:
  - Deriving the current list of default index parameters (including any XPath-specific parameters) from the corresponding attribute set and assigning them to the specified expression set (a value of DEFAULT for the operation argument).
  - Adding (or dropping) one or more attributes to (or from) the current list of parameters assigned to the expression set (values of ADD or DROP for the operation argument).
Clearing the index parameters assigned to the expression set. This enables the user to start using default parameters or tune the parameters from scratch (a value of CLEAR for the operation argument).

Note: This procedure is useful only when an attribute set is shared across multiple expression sets. In all other cases, the defaults assigned to the attribute set can be tuned for the expression set using it.

See the section on creating an index from exact parameters in Oracle Database Rules Manager and Expression Filter Developer’s Guide and XPINDEX_PARAMETERS Procedure for more information.

Related views: USER_EXP FIL_EXPRESSION_SETS, USER_EXP FIL_DEF_INDEX_PARAMS and USER_EXP FIL_INDEX_PARAMS.

Examples

The following command synchronizes the expression set’s index parameters with the defaults associated with the corresponding attribute set:

```
BEGIN
  DBMS_EXP FIL.INDEX_PARAMETERS(expr_tab => 'consumer',
  expr_col => 'interest',
  attr_list => null,
  operation => 'DEFAULT');
END;
/
```

The following command adds a stored attribute to the expression set’s index parameters.

```
BEGIN
  DBMS_EXP FIL.INDEX_PARAMETERS(expr_tab => 'consumer',
  expr_col => 'interest',
  attr_list =>
    exf$attribute_list {
      exf$attribute {
        attr_name => 'CrashTestRating(Model, Year)',
        attr_oper => exf$indexoper('all'),
        attr_indexed => 'FALSE'),
      operation => 'ADD');
END;
/
```

The following command clears the index parameters associated with the expression set:

```
BEGIN
  DBMS_EXP FIL.INDEX_PARAMETERS(expr_tab => 'consumer',
  expr_col => 'interest',
  attr_list => null,
  operation => 'CLEAR');
END;
/
```

A subsequent index creation will use the default index parameters assigned to the corresponding attribute set.
MODIFY_OPERATOR_LIST Procedure

This procedure modifies the list of common operators associated with a certain attribute in the attribute set.

Syntax

```
DBMS_EXPFIL.MODIFY_OPERATOR_LIST (
    attr_set IN VARCHAR2,
    attr_name IN VARCHAR2,
    attr_oper IN EXF$INDEXOPER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attr_set</td>
<td>Name of the attribute set</td>
</tr>
<tr>
<td>attr_name</td>
<td>Name of the stored or indexed attribute being modified</td>
</tr>
<tr>
<td>attr_oper</td>
<td>New list of operators that are frequently used in the predicates with the attribute</td>
</tr>
</tbody>
</table>

Usage Notes

- The MODIFY_OPERATOR_LIST procedure modifies the operator list for the stored and indexed attributes defined in the default index parameters of the attribute set. Existing Expression Filter indexes are not affected when an attribute's operator list is modified. The updated index defaults are used when a new Expression Filter index is created or when an existing index is rebuilt.
- Related views: USER_EXPFIL_DEF_INDEX_PARAMS

Examples

The following command modifies the operator list associated with the HorsePower(Model, Year) attribute defined in the Car4Sale attribute set.

```
BEGIN
    DBMS_EXPFIL.MODIFY_OPERATOR_LIST (
        attr_set => 'Car4Sale',
        attr_name => 'HorsePower(Model, Year)',
        attr_oper => exf$indexoper('=', '<', '>','between'));
END;
/
```
REVOKE_PRIVILEGE Procedure

This procedure revokes an expression privilege previously granted by the owner.

Syntax

```sql
DBMS_EXPFIL.REVOKE_PRIVILEGE (  
    expr_tab   IN  VARCHAR2,
    expr_col   IN  VARCHAR2,
    priv_type  IN  VARCHAR2,
    from_user  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>Name of column in the table that stores the expressions</td>
</tr>
<tr>
<td>Type of privilege to be revoked</td>
</tr>
<tr>
<td>User from whom the privilege is to be revoked</td>
</tr>
</tbody>
</table>

Usage Notes

- See GRANT_PRIVILEGE Procedure and the section on granting and revoking privileges in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about granting and revoking privileges.
- Related views: USER_EXPFIL_EXPRESSION_SETS and USER_EXPFIL_PRIVILEGES.

Examples

The following command revokes the INSERT EXPRESSION privilege on the interest column of the consumer table from user SCOTT:

```sql
BEGIN
    DBMS_EXPFIL.REVOKE_PRIVILEGE (expr_tab => 'consumer',
                                   expr_col => 'interest',
                                   priv_type => 'INSERT EXPRESSION',
                                   from_user => 'SCOTT');
END;
/
```
SYNC_TEXT_INDEXES Procedure

This procedure synchronizes the indexes defined to process the predicates involving the CONTAINS operator in stored expressions.

Syntax

```sql
DBMS_EXPFIL.SYNC_TEXT_INDEXES (
   expr_tab IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table with expression columns containing text predicates</td>
</tr>
</tbody>
</table>

Usage Notes

- When an expression filter index is defined on a column storing expressions, any text predicates in the expressions are indexed using a CTXRULE index. Unlike the other types of indexes (bitmap for scalar and XML predicates or spatial for spatial predicates) used to process the predicates in the expression set, the CTXRULE index defined to process the text predicates is not transactional in nature. That is, when the text predicates are updated with DML operations on the table storing expressions, the new predicates are not automatically reflected in the corresponding CTXRULE index. This could result in inconsistent results until the CTXRULE index is synchronized. This procedure can be used to synchronize all the CTXRULE indexes associated with a table with one or more expression columns. This procedure identifies all the CTXRULE indexes and invokes the CTX_DDL.SYNC_INDEX procedure on each of these indexes.

You must have the EXECUTE privilege on the CTX_DDL package for successful synchronization of the text indexes.

Examples

The following command synchronizes the text indexes associated with the expression columns in the consumer table:

```sql
BEGIN
   DBMS_EXPFIL.SYNC_TEXT_INDEXES (expr_tab => 'consumer');
END;
/
UNASSIGN_ATTRIBUTE_SET Procedure

This procedure unassigns an attribute set from a column storing expressions.

Syntax

DBMS_EXPFIL.UNASSIGN_ATTRIBUTE_SET (  
expr_tab IN VARCHAR2,  
expr_col IN VARCHAR2);  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
</tbody>
</table>

Usage Notes

- A column of an expression data type can be converted back to a VARCHAR2 type by unassigning the attribute set. You can unassign an attribute set from a column storing expressions if an Expression Filter index is not defined on the column.
- See ASSIGN_ATTRIBUTE_SET Procedure for information about assigning attribute sets.
- Related views: USER_EXPFIL_EXPRESSION_SETS and USER_EXPFIL_INDEXES.

Examples

The following command unassigns the attribute set previously assigned to the interest column of the consumer table. (See the section on bulk loading of expression data in Oracle Database Rules Manager and Expression Filter Developer’s Guide.)

BEGIN
    DBMS_EXPFIL.UNASSIGN_ATTRIBUTE_SET (expr_tab => 'consumer',  
                                          expr_col => 'interest');  
END;
/

VALIDATE_EXPRESSIONS Procedure

This procedure validates all the expressions in a set.

Syntax

```sql
DBMS_EXPFIL.VALIDATE_EXPRESSIONS (  
    expr_tab      IN  VARCHAR2,  
    expr_col      IN  VARCHAR2,  
    exception_tab IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expr_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
<tr>
<td>exception_tab</td>
<td>Name of the exception table. This table is created using the BUILD_EXCEPTIONS_TABLE procedure.</td>
</tr>
</tbody>
</table>

Usage Notes

- The expressions stored in a table may have references to schema objects like user-defined functions and tables. When these schema objects are dropped or modified, the expressions could become invalid and the subsequent evaluation (query with EVALUATE operator) could fail.

- By default, the expression validation procedure fails on the first expression that is invalid. Optionally, the caller can pass an exception table to store references to all the invalid expressions. In addition to validating expressions in the set, this procedure validates the parameters (stored and indexed attributes) of the associated index and the approved list of user-defined functions. Any errors in the index parameters or the user-defined function list are immediately reported to the caller.

- See the section on evaluation semantics in Oracle Database Rules Manager and Expression Filter Developer’s Guide and BUILD_EXCEPTIONS_TABLE Procedure for more information.

- Related views: USER_EXPFIL_EXPRESSION_SETS, USER_EXPFIL_ASET_FUNCTIONS, and USER_EXPFIL_PREDTAB_ATTRIBUTES.

Examples

The following command validates the expressions stored in the interest column of the consumer table.

```sql
BEGIN
    DBMS_EXPFIL.VALIDATE_EXPRESSIONS (expr_tab => 'consumer',
                                       expr_col => 'interest');
END;
/
XPINDEX_PARAMETERS Procedure

This procedure is used in conjunction with the INDEX_PARAMETERS procedure to fine-tune the XPath-specific index parameters for each expression set.

Syntax

```sql
DBMS_EXPFIL.XPINDEX_PARAMETERS (  
  expr_tab   IN   VARCHAR2,  
  expr_col   IN   VARCHAR2,  
  xmlt_attr  IN   VARCHAR2,  
  xptag_list IN   EXP$XPATH_TAGS,  
  operation  IN   VARCHAR2 DEFAULT 'ADD');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exp_tab</td>
<td>Name of table storing the expression set</td>
</tr>
<tr>
<td>expr_col</td>
<td>Name of column in the table that stores the expressions</td>
</tr>
<tr>
<td>xmlt_attr</td>
<td>Name of the attribute with the XMLType datatype</td>
</tr>
<tr>
<td>xptag_list</td>
<td>An instance of EXP$XPATH_TAGS type with a partial list of XML elements and attributes</td>
</tr>
<tr>
<td>operation</td>
<td>Operation to be performed on the list of index parameters. Default value: ADD. Valid values: ADD and DROP.</td>
</tr>
</tbody>
</table>

Usage Notes

- When an attribute set is shared by multiple expression sets, the INDEX_PARAMETERS procedure can be used to tune the simple (non-XPath) index parameters for each expression set. The XPINDEX_PARAMETERS procedure is used in conjunction with the INDEX_PARAMETERS procedure to fine-tune the XPath-specific index parameters for each expression set.
- See also INDEX_PARAMETERS Procedure and the section on index tuning for XPath predicates in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information.
- Related views: USER_EXPFIL_ATTRIBUTES, USER_EXPFIL_DEF_INDEX_PARAMS, and USER_EXPFIL_INDEX_PARAMS.

Note: The values assigned to the tag_name argument of exp$xpath_tag type are case-sensitive.

Examples

The following command synchronizes the index parameters of the expression set (XPath and non-XPath) with the defaults associated with the corresponding attribute set:

```sql
BEGIN  
  DBMS_EXPFIL.INDEX_PARAMETERS(expr_tab => 'consumer',  
                                expr_col => 'interest',  
                                attr_list => null,
```
The following command adds an XPath-specific index parameter to the expression set:

```
BEGIN
   DBMS_EXPFIL.XPINDEX_PARAMETERS(expr_tab   => 'consumer',
                                   expr_col   => 'interest',
                                   xmlt_attr  => 'details',
                                   xptag_list =>
                                   exf$xpath_tags(
                                    exf$xpath_tag(tag_name    => 'GPS',
                                                  tag_indexed => 'TRUE',
                                                  tag_type    => NULL),
                                   operation  => 'ADD');
END;
```

The `DBMS_EXPFIL.XPINDEX_PARAMETERS` function allows you to add a specific index parameter to the expression set. In this example, it adds an XPath-specific parameter named 'details' for the consumer and interest columns, with the tag 'GPS' indexed as 'TRUE' and not having a specific tag type.

```sql
DBMS_EXPFIL.XPINDEX_PARAMETERS(expr_tab => 'consumer',
                                expr_col => 'interest',
                                xmlt_attr => 'details',
                                xptag_list =>
                                exf$xpath_tags(
                                   tag_name => 'GPS',
                                   tag_indexed => 'TRUE',
                                   tag_type => NULL),
                                operation => 'ADD');
```
The DBMS_FGA package provides fine-grained security functions.

This chapter contains the following topics:

- Using DBMS_FGA
  - Security Model
  - Operational Notes
- Summary of DBMS_FGA Subprograms
Using DBMS_FGA

- Security Model
- Operational Notes
Security Model

Execute privilege on DBMS_FGA is needed for administering audit policies. Because the audit function can potentially capture all user environment and application context values, policy administration should be executable by privileged users only. The policy event handler module will be executed with the module owner’s privilege.
Operational Notes

This package is available for only cost-based optimization. The rule-based optimizer may generate unnecessary audit records since audit monitoring can occur before row filtering. For both the rule-based optimizer and the cost-based optimizer, you can refer to `DBA_FGA_AUDIT_TRAIL` to analyze the SQL text and corresponding bind variables that are issued.
### Summary of DBMS_FGA Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD_POLICY Procedure on page 66-6</td>
<td>Creates an audit policy using the supplied predicate as the audit condition</td>
</tr>
<tr>
<td>DISABLE_POLICY Procedure on page 66-11</td>
<td>Disables an audit policy</td>
</tr>
<tr>

<td>Drops an audit policy</td>
</tr>
<tr>
<td>ENABLE_POLICY Procedure on page 66-13</td>
<td>Enables an audit policy</td>
</tr>
</tbody>
</table>
ADD_POLICY Procedure

This procedure creates an audit policy using the supplied predicate as the audit condition. The maximum number of FGA policies on any table or view object is 256.

Syntax

```sql
DBMS_FGA.ADD_POLICY(
    object_schema VARCHAR2,
    object_name VARCHAR2,
    policy_name VARCHAR2,
    audit_condition VARCHAR2,
    audit_column VARCHAR2,
    handler_schema VARCHAR2,
    handler_module VARCHAR2,
    enable BOOLEAN,
    statement_types VARCHAR2,
    audit_trail BINARY_INTEGER IN DEFAULT,
    audit_column_opts BINARY_INTEGER IN DEFAULT);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema of the object to be audited. (If NULL, the current log-on user schema is assumed.)</td>
<td>NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object to be audited.</td>
<td>-</td>
</tr>
<tr>
<td>policy_name</td>
<td>The unique name of the policy.</td>
<td>-</td>
</tr>
<tr>
<td>audit_condition</td>
<td>A condition in a row that indicates a monitoring condition. NULL is allowed and acts as TRUE.</td>
<td>NULL</td>
</tr>
<tr>
<td>audit_column</td>
<td>The columns to be checked for access. These can include OLS hidden columns or object type columns. The default, NULL, causes audit if any column is accessed or affected.</td>
<td>NULL</td>
</tr>
<tr>
<td>handler_schema</td>
<td>The schema that contains the event handler. The default, NULL, causes the current schema to be used.</td>
<td>NULL</td>
</tr>
<tr>
<td>handler_module</td>
<td>The function name of the event handler; includes the package name if necessary. This function is invoked only after the first row that matches the audit condition in the query is processed. If the procedure fails with an exception, the user SQL statement will fail as well.</td>
<td>NULL</td>
</tr>
<tr>
<td>enable</td>
<td>Enables the policy if TRUE, which is the default.</td>
<td>TRUE</td>
</tr>
<tr>
<td>statement_types</td>
<td>The SQL statement types to which this policy is applicable: INSERT, UPDATE, DELETE, or SELECT only.</td>
<td>SELECT</td>
</tr>
<tr>
<td>audit_trail</td>
<td>Destination (DB or XML) of fine grained audit records. Also specifies whether to populate LSQLTEXT and LSQLBIND in fga_log$.</td>
<td>DB+EXTENDED</td>
</tr>
<tr>
<td>audit_column_opts</td>
<td>Establishes whether a statement is audited when the query references any column specified in the audit_column parameter or only when all such columns are referenced.</td>
<td>ANY_COLUMNS</td>
</tr>
</tbody>
</table>

Usage Notes

- If object_schema is not specified, the current log-on user schema is assumed.
- An FGA policy should not be applied to out-of-line columns such as LOB columns.

- Each audit policy is applied to the query individually. However, at most one audit record may be generated for each policy, no matter how many rows being returned satisfy that policy's audit_condition. In other words, whenever any number of rows being returned satisfy an audit condition defined on the table, a single audit record will be generated for each such policy.

- If a table with an FGA policy defined on it receives a Fast Path insert or a vectored update, the hint is automatically disabled before any such operations. Disabling the hint allows auditing to occur according to the policy's terms. (One example of a Fast Path insert is the statement `INSERT-WITH-APPEND-hint`.)

- The audit_condition must be a boolean expression that can be evaluated using the values in the row being inserted, updated, or deleted. The expression can also use functions, such as the `USER` or `SYS_CONTEXT` functions.

  The expression must not combine conditions using operators such as `AND` and `OR`. audit_condition can be `NULL` (or omitted), which is interpreted as `TRUE`, but it cannot contain the following elements:

  - Subqueries or sequences
  - The following attributes of the `USERENV` namespace when accessed using the `SYS_CONTEXT` function:
    - `CURRENT_SQL`  
    - `CURRENT_SQL_LENGTH`  
    - `CURRENT_BIND`  
  - Any use of the pseudo columns `LEVEL`, `PRIOR`, or `ROWNUM`.

  Specifying an audit condition of "1=1" to force auditing of all specified statements ("statement_types") affecting the specified column ("audit_column") is no longer needed to achieve this purpose. A NULL value for audit_condition causes audit to happen even if no rows are processed, so that all actions on a table with this policy are audited.

- The audit_condition is evaluated using the privileges of the user who creates the policy.

- The audit function (handler_module) is an alerting mechanism for the administrator. The required interface for such a function is as follows:

  ```
  PROCEDURE fname ( object_schema VARCHAR2, object_name VARCHAR2, policy_name VARCHAR2 ) AS ...
  ```

  where `fname` is the name of the procedure, `object_schema` is the name of the schema of the table audited, `object_name` is the name of the table to be audited, and `policy_name` is the name of the policy being enforced. The audit function will be executed with the function owner's privilege.

  **See Also:** "Tutorial: Adding an E-Mail Alert to a Fine-Grained Audit Policy" in *Oracle Database Security Guide* for an example of creating an e-mail alert handler for a fine-grained audit policy

- The audit_trail parameter specifies both where the fine-grained audit trail will be written and whether it is to include the query's SQL Text and SQL Bind variable information (typically in columns named `LSQLTEXT` and `LSQLBIND`):
If audit_trail includes XML, then fine-grained audit records are written to
XML-format operating system files stored in the directory specified by an
AUDIT_FILE_DEST statement in SQL. (The default AUDIT_FILE_DEST is
$ORACLE_BASE/admin/$DB_UNIQUE_NAME/adump on Unix-based systems, and
$ORACLE_BASE/admin/$DB_UNIQUE_NAME\adump on Windows systems.)

If audit_trail includes DB instead, then the audit records are written to the
SYS.FGA_LOG$ table in the database. However, for read-only databases, Oracle
Database writes the fine-grained audit records to XML files, regardless of the
audit_trail settings.

If audit_trail includes EXTENDED, then the query’s SQL Text and SQL Bind
variable information are included in the audit trail.

Note that the SQL Text information could include sensitive data, such as credit
card numbers, in the audit trail. See "Auditing Sensitive Information" in Oracle
Database Security Guide for ways in which you can handle this.

For example:

* Setting audit_trail to DBMS_FGA.DB sends the audit trail to the SYS.FGA_
  LOG$ table in the database and omits SQL Text and SQL Bind.

* Setting audit_trail to DBMS_FGA.DB + DBMS_FGA.EXTENDED sends the
  audit trail to the SYS.FGA_LOG$ table in the database and includes SQL
  Text and SQL Bind.

* Setting audit_trail to DBMS_FGA.XML writes the audit trail in XML files
  sent to the operating system and omits SQL Text and SQL Bind.

* Setting audit_trail to DBMS_FGA.XML + DBMS_FGA.EXTENDED writes the
  audit trail in XML files sent to the operating system and includes SQL Text
  and SQL Bind.

The audit_trail parameter appears in the ALL_AUDIT_POLICIES view.

You can change the operating system destination using the following command:

ALTER SYSTEM SET AUDIT_FILE_DEST = ‘<New Directory>’ DEFERRED

On many platforms, XML audit files are named
<process_name>_<processId>.xml, for example, ora_2111.xml, or
s002_11.xml. On Windows, the XML audit files are named <process_name>_
<ThreadId>.xml (or <process_name>_ProcessId>.xml if the process is not running
as a thread).

The audit_column_opts parameter establishes whether a statement is audited

- when the query references any column specified in the audit_column
  parameter (audit_column_opts = DBMS_FGA.ANY_COLUMNS), or

- only when all such columns are referenced (audit_column_opts = DBMS_
  FGA.ALL_COLUMNS).

The default is DBMS_FGA.ANY_COLUMNS.

The ALL_AUDIT_POLICIES view also shows audit_column_opts.

When audit_column_opts is set to DBMS_FGA.ALL_COLUMNS, a SQL statement is
audited only when all the columns mentioned in audit_column have been
explicitly referenced in the statement. And these columns must be referenced in
the same SQL-statement or in the sub-select.

Also, all these columns must refer to a single table/view or alias.
Thus, if a SQL statement selects the columns from different table aliases, the statement will not be audited.

**V$XML_AUDIT_TRAIL View**

The new values for the audit_trail parameter (XML and XML+EXTENDED) cause fine-grained auditing records to be written to operating system files in XML format.

Audit records stored in operating system files can be more secure than database-stored audit records because access can require file permissions that DBAs do not have. Operating system storage for audit records also offers higher availability, since such records remain available even if the database is temporarily inaccessible.

A new dynamic view, V$XML_AUDIT_TRAIL, makes such audit records from XML files available to DBAs through SQL query, providing enhanced usability. Querying this view causes all XML files (all files with an .xml extension) in the AUDIT_FILE_DEST directory to be parsed and presented in relational table format.

The DBA_COMMON_AUDIT_TRAIL view includes the contents of the V$XML_AUDIT_TRAIL dynamic view for standard and fine-grained audit records.

Since the audit XML files are stored in files with extension .xml on all platforms, the dynamic view presents audit information similarly on all platforms, using the following schema:

<table>
<thead>
<tr>
<th>Element Type</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>SESSION_ID</td>
<td>NUMBER</td>
</tr>
<tr>
<td>PROXY_SESSIONID</td>
<td>NUMBER</td>
</tr>
<tr>
<td>STATEMENTID</td>
<td>NUMBER</td>
</tr>
<tr>
<td>ENTRYID</td>
<td>NUMBER</td>
</tr>
<tr>
<td>EXTENDED_TIMESTAMP</td>
<td>TIMESTAMP(6) WITH TIME ZONE</td>
</tr>
<tr>
<td>GLOBAL_UID</td>
<td>VARCHAR2(32)</td>
</tr>
<tr>
<td>DB_USER</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>CLIENT_ID</td>
<td>VARCHAR2(64)</td>
</tr>
<tr>
<td>EXT_NAME</td>
<td>VARCHAR2(4000)</td>
</tr>
<tr>
<td>OS_USER</td>
<td>VARCHAR2(255)</td>
</tr>
<tr>
<td>USERHOST</td>
<td>VARCHAR2(255)</td>
</tr>
<tr>
<td>OS_PROCESS</td>
<td>VARCHAR2(16)</td>
</tr>
<tr>
<td>TERMINAL</td>
<td>VARCHAR2(255)</td>
</tr>
<tr>
<td>INSTANCE_NUMBER</td>
<td>NUMBER</td>
</tr>
<tr>
<td>OBJECT_SCHEMA</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>OBJECT_NAME</td>
<td>VARCHAR2(128)</td>
</tr>
<tr>
<td>POLICY_NAME</td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>STATEMENT_TYPE</td>
<td>VARCHAR2(28)</td>
</tr>
<tr>
<td>TRANSACTIONID</td>
<td>RAW(8)</td>
</tr>
<tr>
<td>SCN</td>
<td>NUMBER</td>
</tr>
</tbody>
</table>
Table 66–3  (Cont.) Elements in the V$XML_AUDIT_TRAIL Dynamic View

<table>
<thead>
<tr>
<th>Element</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMENT_TEXT</td>
<td>VARCHAR2(4000)</td>
</tr>
<tr>
<td>SQL_BIND</td>
<td>VARCHAR2(4000)</td>
</tr>
<tr>
<td>SQL_TEXT</td>
<td>VARCHAR2(4000)</td>
</tr>
</tbody>
</table>

Usage Notes

- Every XML audit record contains the elements AUDIT_TYPE and EXTENDED_TIMESTAMP, with the latter printed in UTC zone (with no timezone information). Values retrieved using V$XML_AUDIT_TRAIL view are converted to session timezone and printed.
- For SQL_TEXT and SQL_BIND element values (CLOB type columns), the dynamic view shows only the first 4000 characters. The underlying XML file may have more than 4000 characters for such SQL_TEXT and SQL_BIND values.
- For large numbers of XML audit files, querying V$XML_AUDIT_TRAIL is faster when they are loaded into a database table using SQL*Loader or a similar tool. XML audit files are larger than the equivalent written to OS files when AUDIT_TRAIL=OS.
- Error handling is the same as when AUDIT_TRAIL=OS. If any error occurs in writing an audit record to disk, including the directory identified by AUDIT_FILE_DEST being full, the auditing operation fails. An alert message is logged.
- The policy event handler module will be executed with the module owner’s privilege.
- Do not create recursive fine-grained audit handlers. For example, suppose you create a handler that executes an INSERT statement on the HR.EMPLOYEES table. The policy that is associated with this handler is for INSERT statements (as set by the statement_types parameter). When the policy is used, the handler executes recursively until the system has run out of memory. This can raise the error ORA-1000: maximum open cursors exceeded or ORA-00036: maximum number of recursive SQL levels (50) exceeded. See also Oracle Database Security Guide

Examples

```
DBMS_FGA.ADD_POLICY (
  object_schema => 'scott',
  object_name   => 'emp',
  policy_name   => 'mypolicy1',
  audit_condition => 'sal < 100',
  audit_column => 'comm,sal',
  handler_schema => NULL,
  handler_module => NULL,
  enable => TRUE,
  statement_types => 'INSERT, UPDATE',
  audit_trail => DBMS_FGA.XML + DBMS_FGA.EXTENDED,
  audit_column_opts => DBMS_FGA.ANY_COLUMNS);
```
DISABLE_POLICY Procedure

This procedure disables an audit policy.

Syntax

```sql
DBMS_FGA.DISABLE_POLICY(
    object_schema  VARCHAR2,
    object_name    VARCHAR2,
    policy_name    VARCHAR2 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema of the object to be audited. (If NULL, the current log-on user schema is assumed.)</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object to be audited.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The unique name of the policy.</td>
</tr>
</tbody>
</table>

The default value for `object_schema` is NULL. (If NULL, the current log-on user schema is assumed.)

Examples

```sql
DBMS_FGA.DISABLE_POLICY ( 
    object_schema  => 'scott',
    object_name    => 'emp',
    policy_name    => 'mypolicy1');
```
DROP_POLICY Procedure

This procedure drops an audit policy.

Syntax

```sql
DBMS_FGA.DROP_POLICY(
    object_schema  VARCHAR2,
    object_name    VARCHAR2,
    policy_name    VARCHAR2 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema of the object to be audited. (If NULL, the current log-on user schema is assumed.)</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object to be audited.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The unique name of the policy.</td>
</tr>
</tbody>
</table>

Usage Notes

The `DBMS_FGA` procedures cause current DML transactions, if any, to commit before the operation unless they are inside a DDL event trigger. With DDL transactions, the `DBMS_FGA` procedures are part of the DDL transaction. The default value for `object_schema` is `NULL`. (If `NULL`, the current log-on user schema is assumed.)

Note: Oracle Database automatically drops the audit policy if you remove the object specified in the `object_name` parameter of the `DBMS_FGA.ADD_POLICY` procedure, or if you drop the user who created the audit policy.

Examples

```sql
DBMS_FGA.DROP_POLICY(
    object_schema => 'scott',
    object_name   => 'emp',
    policy_name   => 'mypolicy1');
```
ENABLE_POLICY Procedure

This procedure enables an audit policy.

Syntax

```sql
DBMS_FGA.ENABLE_POLICY(
    object_schema VARCHAR2,
    object_name VARCHAR2,
    policy_name VARCHAR2,
    enable BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema of the object to be audited. (If NULL, the current log-on user schema is assumed.)</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object to be audited.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The unique name of the policy.</td>
</tr>
<tr>
<td>enable</td>
<td>Defaults to TRUE to enable the policy.</td>
</tr>
</tbody>
</table>

Examples

```sql
DBMS_FGA.ENABLE_POLICY (
    object_schema => 'scott',
    object_name => 'emp',
    policy_name => 'mypolicy1',
    enable => TRUE);
```
The DBMS_FILE_GROUP package, one of a set of Oracle Streams packages, provides administrative interfaces for managing file groups, file group versions, and files. A file group repository is a collection of all of the file groups in a database and can contain multiple versions of a particular file group. You can use this package to create and manage file group repositories.

This chapter contains the following topics:

- Using DBMS_FILE_GROUP
  - Overview
  - Security Model
  - Constants
- Summary of DBMS_FILE_GROUP Subprograms
Using DBMS_FILE_GROUP

This section contains topics which relate to using the DBMS_FILE_GROUP package.

- Overview
- Security Model
- Constants
Overview

The following terms pertain to the DBMS_FILE_GROUP package:

**File**
A file is a reference to a file stored on hard disk. A file is composed of a file name, a directory object, and a file type. The directory object references the directory in which the file is stored on hard disk. For example, a file might have the following components:

- The file name is expdat.dmp.
- The directory object that contains the file is db_files.
- The file type is DBMS_FILE_GROUP.EXPORT_DUMP_FILE.

**Version**
A version is a collection of related files. For example, a version might consist of a set of datafiles and a Data Pump export dump file generated by a Data Pump transportable tablespace export. Only one Data Pump export dump file is allowed in a version.

**File Group**
A file group is a collection of versions. A file group can logically group a set of versions. For example, a file group named financial_quarters can keep track of quarterly financial data by logically grouping versions of files related to a tablespace set. The tablespaces containing the data can be exported at the end of each quarter and versioned under names such as Q1FY04, Q2FY04, and so on.

See Also: Oracle Streams Concepts and Administration
Security Model

Security on this package can be controlled in either of the following ways:

- Granting `EXECUTE` on this package to selected users or roles.
- Granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.
Constants

The DBMS_FILE_GROUP package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name. For example, DBMS_FILE_GROUP.EXPORT_DUMP_FILE.

Table 67–1 lists the parameters and enumerated constants.

<table>
<thead>
<tr>

---

**Note:** All subprograms commit unless specified otherwise.
ADD_FILE Procedure

This procedure adds a file to a version of a file group.

Syntax

```
DBMS_FILE_GROUP.ADD_FILE(
  file_group_name IN VARCHAR2,
  file_name        IN VARCHAR2,
  file_type        IN VARCHAR2 DEFAULT NULL,
  file_directory   IN VARCHAR2 DEFAULT NULL,
  version_name     IN VARCHAR2 DEFAULT NULL,
  comments         IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 67–3 ADD_FILE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group that contains the version, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of the file being added to the version. Each file name in a version must be unique.</td>
</tr>
<tr>
<td>file_type</td>
<td>The file type. The following are reserved file types:</td>
</tr>
<tr>
<td></td>
<td>■ If the file is a datafile, then enter the following:</td>
</tr>
<tr>
<td></td>
<td>'DATAFILE'</td>
</tr>
<tr>
<td></td>
<td>■ If the file is a Data Pump export dump file, then enter the following:</td>
</tr>
<tr>
<td></td>
<td>'DUMPSET'</td>
</tr>
<tr>
<td></td>
<td>Data Pump metadata is populated when a Data Pump export dump file is imported.</td>
</tr>
<tr>
<td></td>
<td>■ If the file is a Data Pump export log file, then enter the following:</td>
</tr>
<tr>
<td></td>
<td>'DATAPUMPLOG'</td>
</tr>
<tr>
<td></td>
<td>If the file type is not one of the reserved file types, then either enter a text description of the file type, or specify NULL to omit a file type description.</td>
</tr>
<tr>
<td></td>
<td>See &quot;Constants&quot; on page 67-5 for more information about the reserved file types.</td>
</tr>
<tr>
<td>file_directory</td>
<td>The name of the directory object that corresponds to the directory containing the file.</td>
</tr>
<tr>
<td></td>
<td>If NULL, then the procedure uses the default directory object for the version.</td>
</tr>
<tr>
<td></td>
<td>If NULL and no default directory object exists for the version, then the procedure uses the default directory object for the file group.</td>
</tr>
<tr>
<td></td>
<td>If NULL and no default directory object exists for the version or file group, then the procedure raises an error.</td>
</tr>
</tbody>
</table>
To run this procedure with either `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `'DUMPSET'` specified for the `file_type` parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have `READ` privilege on the directory object that contains the Data Pump export dump file

**See Also:** Oracle Database Utilities for more information about Data Pump privileges
ALTER_FILE Procedure

This procedure alters a file in a version of a file group.

Syntax

```sql
DBMS_FILE_GROUP.ALTER_FILE(
    file_group_name     IN  VARCHAR2,
    file_name           IN  VARCHAR2,
    version_name        IN  VARCHAR2  DEFAULT NULL,
    new_file_name       IN  VARCHAR2  DEFAULT NULL,
    new_file_directory  IN  VARCHAR2  DEFAULT NULL,
    new_file_type       IN  VARCHAR2  DEFAULT NULL,
    remove_file_type    IN  VARCHAR2  DEFAULT 'N',
    new_comments        IN  VARCHAR2  DEFAULT NULL,
    remove_comments     IN  VARCHAR2  DEFAULT 'N');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group that contains the version, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of the file being altered in the version</td>
</tr>
<tr>
<td>version_name</td>
<td>The name of the version that contains the file being altered. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then the file in version 1 of the file group is altered. If NULL, then the procedure uses the version with the latest creation time for the file group.</td>
</tr>
<tr>
<td>new_file_name</td>
<td>The new name of the file if the file name is being changed. Each file name in a version must be unique. If NULL, then the procedure does not change the file name. <strong>Note:</strong> When a non-NULL new file name is specified, this procedure changes the metadata for the file name in the data dictionary, but it does not change the file name on the hard disk.</td>
</tr>
<tr>
<td>new_file_directory</td>
<td>The new name of the directory object that corresponds to the directory containing the file, if the directory object is being changed. If NULL, then the procedure does not change the directory object name. <strong>Note:</strong> When a non-NULL new file directory is specified, this procedure changes the metadata for the file directory in the data dictionary, but it does not change the file directory on the hard disk.</td>
</tr>
<tr>
<td>new_file_type</td>
<td>The new type of the file if the file type is being changed.</td>
</tr>
<tr>
<td>remove_file_type</td>
<td>The type of the file that is being removed.</td>
</tr>
<tr>
<td>new_comments</td>
<td>The new comments for the file if the comments are being changed.</td>
</tr>
<tr>
<td>remove_comments</td>
<td>The comments that are being removed.</td>
</tr>
</tbody>
</table>
### Usage Notes

If the file type is changed to `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `DUMPSET`, then Data Pump metadata for the file is populated. If the file type is changed from `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `DUMPSET`, then Data Pump metadata for the file is purged.

To run this procedure with `DBMS_FILE_GROUP.EXPORT_DUMP_FILE` or `DUMPSET` specified for the `new_file_type` parameter, a user must meet the following requirements:

- Have the appropriate privileges to import the Data Pump export dump file
- Have `READ` privilege on the directory object that contains the Data Pump export dump file

**See Also:** *Oracle Database Utilities* for more information about Data Pump privileges
**ALTER_FILE_GROUP Procedure**

This procedure alters a file group.

**Syntax**

```
DBMS_FILE_GROUP.ALTER_FILE_GROUP(
    file_group_name           IN  VARCHAR2,
    keep_files                IN  VARCHAR2  DEFAULT NULL,
    min_versions              IN  NUMBER    DEFAULT NULL,
    max_versions              IN  NUMBER    DEFAULT NULL,
    retention_days            IN  NUMBER    DEFAULT NULL,
    new_default_directory     IN  VARCHAR2  DEFAULT NULL,
    remove_default_directory  IN  VARCHAR2  DEFAULT 'N',
    new_comments              IN  VARCHAR2  DEFAULT NULL,
    remove_comments           IN  VARCHAR2  DEFAULT 'N');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group being altered, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>keep_files</td>
<td>If Y, then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged. If N, then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged. If NULL, then this parameter is not changed. Note: If the file group is dropped because of a DROP USER CASCADE statement, then the setting of this parameter determines whether the files are dropped from the hard disk.</td>
</tr>
<tr>
<td>min_versions</td>
<td>The minimum number of versions to retain. The specified value must be greater than or equal to 1. If NULL, then the procedure does not change the min_versions setting for the file group.</td>
</tr>
<tr>
<td>max_versions</td>
<td>The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for min_versions. When the number of versions exceeds the specified max_versions, the oldest version is purged. Specify DBMS_FILE_GROUP.INFINITE for no limit to the number of versions. If NULL, then the procedure does not change the max_versions setting for the file group.</td>
</tr>
</tbody>
</table>
If `min_versions` is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set `min_versions` to at least 2 if a version of the file group must be available at all times.
ALTER_VERSION Procedure

This procedure alters a version of a file group.

Syntax

```
DBMS_FILE_GROUP.ALTER_VERSION(
    file_group_name           IN  VARCHAR2,
    version_name              IN  VARCHAR2  DEFAULT NULL,
    new_version_name          IN  VARCHAR2  DEFAULT NULL,
    remove_version_name       IN  VARCHAR2  DEFAULT 'N',
    new_default_directory     IN  VARCHAR2  DEFAULT NULL,
    remove_default_directory  IN  VARCHAR2  DEFAULT 'N',
    new_comments              IN  VARCHAR2  DEFAULT NULL,
    remove_comments           IN  VARCHAR2  DEFAULT 'N');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group that contains the version, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>version_name</td>
<td>The name of the version being altered. If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then version 1 of the file group is altered. If '*' is specified, then the procedure alters all versions, and the new_version_name parameter must be NULL. If NULL, then the procedure uses the version with the latest creation time for the file group.</td>
</tr>
<tr>
<td>new_version_name</td>
<td>The new name of the version. Do not specify a schema. The specified version name cannot be a positive integer or an asterisk ('*'). If NULL, then the procedure does not change the version name.</td>
</tr>
<tr>
<td>remove_version_name</td>
<td>If Y, then the procedure removes the version name. If the version name is removed, then the version number must be used to manage the version. If Y and the new_version_name parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the version name.</td>
</tr>
<tr>
<td>new_default_directory</td>
<td>The default directory object used when files are added to a version if no directory is specified when the files are added. If NULL, then the procedure does not change the default directory.</td>
</tr>
<tr>
<td>remove_default_directory</td>
<td>If Y, then the procedure removes the default directory. If Y and the new_default_directory parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the default directory.</td>
</tr>
</tbody>
</table>
### Table 67–6  (Cont.) ALTER_VERSION Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_comments</td>
<td>Comments about the version. If non-NULL, then the new comments replace the existing comments for the version. If NULL, then the procedure does not change the comments.</td>
</tr>
<tr>
<td>remove_comments</td>
<td>If Y, then the procedure removes the comments for the version. If Y and the new_comments parameter is set to a non-NULL value, then the procedure raises an error. If N, then the procedure does not remove the comments for the version.</td>
</tr>
</tbody>
</table>
CREATE_FILE_GROUP Procedure

This procedure creates a file group.

Syntax

```sql
DBMS_FILE_GROUP.CREATE_FILE_GROUP(
    file_group_name    IN  VARCHAR2,
    keep_files         IN  VARCHAR2  DEFAULT 'Y',
    min_versions       IN  NUMBER    DEFAULT 2,
    max_versions       IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
    retention_days     IN  NUMBER    DEFAULT DBMS_FILE_GROUP.INFINITE,
    default_directory  IN  VARCHAR2  DEFAULT NULL,
    comments           IN  VARCHAR2  DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group, specified as <code>[schema_name.]file_group_name</code>. For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code>, then specify <code>hq_dba.sales_tbs</code>. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>keep_files</td>
<td>If <code>Y</code>, then the files in the file group are retained on hard disk if the file group or a version of the file group is dropped or purged. If <code>N</code>, then the files in the file group are deleted from hard disk if the file group or a version of the file group is dropped or purged. <strong>Note:</strong> If the file group is dropped because of a <code>DROP USER CASCADE</code> statement, then the setting of this parameter determines whether the files are dropped from the hard disk.</td>
</tr>
<tr>
<td>min_versions</td>
<td>The minimum number of versions to retain. The specified value must be greater than or equal to 1.</td>
</tr>
<tr>
<td>max_versions</td>
<td>The maximum number of versions to retain. The specified value must be greater than or equal to the value specified for <code>min_versions</code>. When the number of versions exceeds the specified <code>max_versions</code>, the oldest version is purged. Specify <code>DBMS_FILE_GROUP.INFINITE</code> for no limit to the number of versions.</td>
</tr>
<tr>
<td>retention_days</td>
<td>The maximum number of days to retain a version. The specified value must be greater than or equal to 0 (zero). When the age of a version exceeds the specified <code>retention_days</code> and there are more versions than the number specified in <code>min_versions</code>, the version is purged. The age of a version is calculated by subtracting the creation time from the current time. A decimal value can specify a fraction of a day. For example, 1.25 specifies one day and six hours. Specify <code>DBMS_FILE_GROUP.INFINITE</code> for no limit to the number of days a version can exist.</td>
</tr>
<tr>
<td>default_directory</td>
<td>The default directory object used when files are added to a file group if no directory is specified when the files are added, and no default directory object is specified for the version.</td>
</tr>
<tr>
<td>comments</td>
<td>Comments about the file group being created.</td>
</tr>
</tbody>
</table>
Usage Notes

If `min_versions` is set to 1, then the only version of the file group can be purged when a new version is added. If the addition of the new version is not complete when the existing version is purged, then there can be a period of time when no version of the file group is available. Therefore, set `min_versions` to at least 2 if a version of the file group must be available at all times.
CREATE_VERSION Procedure

This procedure creates a version of a file group.

This procedure automatically runs the PURGE_FILE_GROUP procedure. Therefore, versions can be purged based on the file group's retention policy.

This procedure is overloaded. One version of the procedure contains the OUT parameter version_out, and the other does not.

See Also: PURGE_FILE_GROUP Procedure on page 67-22

Syntax

```
DBMS_FILE_GROUP.CREATE_VERSION(
    file_group_name    IN  VARCHAR2,
    version_name       IN  VARCHAR2 DEFAULT NULL,
    default_directory  IN  VARCHAR2 DEFAULT NULL,
    comments           IN  VARCHAR2 DEFAULT NULL);

DBMS_FILE_GROUP.CREATE_VERSION(
    file_group_name    IN   VARCHAR2,
    version_name       IN   VARCHAR2 DEFAULT NULL,
    default_directory  IN   VARCHAR2 DEFAULT NULL,
    comments           IN   VARCHAR2 DEFAULT NULL,
    version_out        OUT  VARCHAR2);
```

Parameters

Table 67–8  CREATE_VERSION Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group to which the new version is added, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>version_name</td>
<td>The name of the version being created. Do not specify a schema. The specified version name cannot be a positive integer because, when a version is created, a version number is generated automatically. The specified version name cannot be an asterisk ('*').</td>
</tr>
<tr>
<td>default_directory</td>
<td>The default directory object used when files are added to a version if no directory is specified when the files are added.</td>
</tr>
<tr>
<td>comments</td>
<td>Comments about the version being created</td>
</tr>
<tr>
<td>version_out</td>
<td>If the version_name parameter is set to a non-NULL value, then this parameter contains the specified version name. If the version_name parameter is set to NULL, then this parameter contains the generated version number.</td>
</tr>
</tbody>
</table>
DROP_FILE_GROUP Procedure

This procedure drops a file group.

Syntax

```
DBMS_FILE_GROUP.DROP_FILE_GROUP(
    file_group_name  IN  VARCHAR2,
    keep_files       IN  VARCHAR2  DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group being dropped, specified as [schema_name.]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>keep_files</td>
<td>If Y, then the procedure retains the files in the file group on hard disk. If N, then the procedure deletes the files in the file group from hard disk. If NULL, then the procedure uses the default keep files property of the file group.</td>
</tr>
</tbody>
</table>

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have WRITE privilege on the directory object that contains the files.
DROP_VERSION Procedure

This procedure drops a version of a file group.

Syntax

```sql
DBMS_FILE_GROUP.DROP_VERSION(
    file_group_name  IN  VARCHAR2,
    version_name     IN  VARCHAR2 DEFAULT NULL,
    keep_files       IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group that contains the version, specified as <code>{schema_name.}file_group_name</code>. For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code>, then specify <code>hq_dba.sales_tbs</code>. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>version_name</td>
<td>The name of the version being dropped.</td>
</tr>
<tr>
<td>keep_files</td>
<td>If <code>Y</code>, then the procedure retains the files in the version on hard disk.</td>
</tr>
</tbody>
</table>

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have `WRITE` privilege on the directory object that contains the files.
GRANT_OBJECT_PRIVILEGE Procedure

This procedure grants object privileges on a file group to a user.

Syntax

```sql
DBMS_FILE_GROUP.GRANT_OBJECT_PRIVILEGE(
    object_name   IN  VARCHAR2,
    privilege     IN  BINARY_INTEGER,
    grantee       IN  VARCHAR2,
    grant_option  IN  BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_name</td>
<td>The name of the file group on which the privilege is granted, specified as /[schema_name./]file_group_name. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>privilege</td>
<td>The constant that specifies the privilege. See &quot;Constants&quot; on page 67-5 for valid privileges.</td>
</tr>
<tr>
<td>grantee</td>
<td>The name of the user or role for which the privilege is granted. The specified user cannot be the owner of the object.</td>
</tr>
<tr>
<td>grant_option</td>
<td>If TRUE, then the specified user granted the specified privilege can grant this privilege to others. If FALSE, then the specified user granted the specified privilege cannot grant this privilege to others.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the object on which the privilege is granted
- Have the same privilege as the privilege being granted with the grant option
GRANT_SYSTEM_PRIVILEGE Procedure

This procedure grants system privileges for file group operations to a user.

Note: When you grant a privilege on "ANY" object (for example, ALTER_ANY_RULE), and the initialization parameter O7_DICTIONARY_ACCESSIBILITY is set to FALSE, you give the user access to that type of object in all schemas, except the SYS schema. By default, the initialization parameter O7_DICTIONARY_ACCESSIBILITY is set to FALSE.

If you want to grant access to an object in the SYS schema, then you can grant object privileges explicitly on the object. Alternatively, you can set the O7_DICTIONARY_ACCESSIBILITY initialization parameter to TRUE. Then privileges granted on "ANY" object allows access to any schema, including SYS. Set the O7_DICTIONARY_ACCESSIBILITY initialization parameter with caution.

Syntax

DBMS_FILE_GROUP.GRANT_SYSTEM_PRIVILEGE(
  privilege IN  BINARY_INTEGER,
  grantee  IN  VARCHAR2,
  grant_option IN BOOLEAN DEFAULT FALSE);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The constant that specifies the privilege. See &quot;Constants&quot; on page 67-5 for valid privileges.</td>
</tr>
<tr>
<td>grantee</td>
<td>The name of the user or role for which the privilege is granted. The user who runs the procedure cannot be specified.</td>
</tr>
</tbody>
</table>
| grant_option    | If TRUE, then the specified user granted the specified privilege can grant this privilege to others.  
                  If FALSE, then the specified user granted the specified privilege cannot grant this privilege to others. |
PURGE_FILE_GROUP Procedure

This procedure purges a file group using the file group’s retention policy.

A file group’s retention policy is determined by its settings for the max_versions, min_versions, and retention_days parameters. The following versions of a file group are removed when a file group is purged:

- All versions greater than the max_versions setting for the file group when versions are ordered in descending order by creation time. Therefore, the older versions are purged before the newer versions.
- All versions older than the retention_days setting for the file group unless purging a version would cause the number of versions to drop below the min_versions setting for the file group.

A job named SYS.FGR$AUTOPURGE_JOB automatically purges all file groups in a database periodically according to the job’s schedule. You can adjust this job’s schedule using the DBMS_SCHEDULER package. Alternatively, you can create a job that runs the PURGE_FILE_GROUP procedure periodically.

Syntax

```sql
DBMS_FILE_GROUP.PURGE_FILE_GROUP(
    file_group_name  IN  VARCHAR2);
```

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group, specified as [schema_name.][file_group_name]. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default. If NULL and this procedure is run by SYS user, then the procedure purges all file groups.</td>
</tr>
</tbody>
</table>

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have WRITE privilege on the directory object that contains the files. Files are deleted when a version is purged and the keep_files parameter is set to N for the version’s file group.
REMOVE_FILE Procedure

This procedure removes a file from a version of a file group.

Syntax

```sql
DBMS_FILE_GROUP.REMOVE_FILE(
    file_group_name  IN  VARCHAR2,
    file_name        IN  VARCHAR2,
    version_name     IN  VARCHAR2 DEFAULT NULL,
    keep_file        IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_group_name</td>
<td>The name of the file group that contains the version, specified as <code>{schema_name}.{file_group_name}</code>. For example, if the schema is hq_dba and the file group name is sales_tbs, then specify hq_dba.sales_tbs. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>file_name</td>
<td>The name of the file being removed from the version</td>
</tr>
<tr>
<td>version_name</td>
<td>The name of the version from which the file is removed.</td>
</tr>
<tr>
<td></td>
<td>If a positive integer is specified as a VARCHAR2 value, then the integer is interpreted as a version number. For example, if '1' is specified, then the file is removed from version 1 of the file group.</td>
</tr>
<tr>
<td></td>
<td>If NULL, then the procedure uses the version with the latest creation time for the file group.</td>
</tr>
<tr>
<td></td>
<td>If '*', then the procedure removes the file from all versions.</td>
</tr>
<tr>
<td>keep_file</td>
<td>If Y, then the procedure retains the file on hard disk.</td>
</tr>
<tr>
<td></td>
<td>If N, then the procedure deletes the file from hard disk.</td>
</tr>
<tr>
<td></td>
<td>If NULL, then the procedure uses the default keep files property of the file group.</td>
</tr>
</tbody>
</table>

Usage Notes

If this procedure deletes files on hard disk, then the user who runs the procedure must have WRITE privilege on the directory object that contains the files.
REVOKE_OBJECT_PRIVILEGE Procedure

This procedure revokes object privileges on a file group from a user.

Syntax

```sql
DBMS_FILE_GROUP.REVOKE_OBJECT_PRIVILEGE(  
  object_name IN VARCHAR2,  
  privilege IN BINARY_INTEGER,  
  revokee IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_name</td>
<td>The name of the file group on which the privilege is revoked, specified as <code>schema_name.file_group_name</code>. For example, if the schema is <code>hq_dba</code> and the file group name is <code>sales_tbs</code>, then specify <code>hq_dba.sales_tbs</code>. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>privilege</td>
<td>The constant that specifies the privilege. See &quot;Constants&quot; on page 67-5 for valid privileges.</td>
</tr>
<tr>
<td>revokee</td>
<td>The name of the user or role from which the privilege is revoked. The user who owns the object cannot be specified.</td>
</tr>
</tbody>
</table>
REVOKE_SYSTEM_PRIVILEGE Procedure

This procedure revokes system privileges for file group operations from a user.

Syntax

```
DBMS_FILE_GROUP.REVOKE_SYSTEM_PRIVILEGE(
    privilege IN BINARY_INTEGER,
    revokee IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The constant that specifies the privilege. See &quot;Constants&quot; on page 67-5 for valid privileges.</td>
</tr>
<tr>
<td>revokee</td>
<td>The name of the user or role from which the privilege is revoked. The user who runs the procedure cannot be specified.</td>
</tr>
</tbody>
</table>
The **DBMS_FILE_TRANSFER** package provides procedures to copy a binary file within a database or to transfer a binary file between databases.

**See Also:**
- *Oracle Database Administrator’s Guide* for instructions about using file transfer
- *Oracle Streams Concepts and Administration* for applications of file transfer.

This chapter contains the following topic:
- **Using DBMS_FILE_TRANSFER**
  - Operating Notes
- **Summary of DBMS_FILE_TRANSFER Subprograms**
Using DBMS_FILE_TRANSFER

- Operating Notes
Operating Notes

**Caution:** DBMS_FILE_TRANSFER supports online backup. You should therefore be careful in copying or transferring a file that is being modified by the database because this can result in an inconsistent file, and require recovery. To guarantee consistency, bring files offline when the database is in use.

If you want to use DBMS_FILE_TRANSFER for performing backups, note that you are implementing self-managed backups, and should therefore put the files in hot backup mode.
## Summary of DBMS_FILE_TRANSFER Subprograms

### Table 68–1  DBMS_FILE_TRANSFER Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COPY_FILE Procedure</td>
<td>Reads a file from a source directory and creates a copy of it in a destination directory. The source and destination directories can both be in a local file system, or both be in an Automatic Storage Management (ASM) disk group, or between local file system and ASM with copying in either direction.</td>
</tr>
<tr>
<td>GET_FILE Procedure</td>
<td>Contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM</td>
</tr>
<tr>
<td>PUT_FILE Procedure</td>
<td>Reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system</td>
</tr>
</tbody>
</table>
COPY_FILE Procedure

This procedure reads a file from a source directory and creates a copy of it in a
destination directory. The source and destination directories can both be in a local file
system, or both be in an Automatic Storage Management (ASM) disk group, or
between local file system and ASM with copying in either direction.

You can copy any type of file to and from a local file system. However, you can copy
only database files (such as datafiles, tempfiles, controlfiles, and so on) to and from an
ASM disk group.

The destination file is not closed until the procedure completes successfully.

Syntax

DBMS_FILE_TRANSFER.COPY_FILE(
    source_directory_object       IN  VARCHAR2,
    source_file_name              IN  VARCHAR2,
    destination_directory_object  IN  VARCHAR2,
    destination_file_name         IN  VARCHAR2);

Parameters

Table 68–2  COPY_FILE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_directory_object</td>
<td>The directory object that designates the source directory. The directory object must already exist. (You create directory objects with the CREATE DIRECTORY command).</td>
</tr>
<tr>
<td>source_file_name</td>
<td>The name of the file to copy. This file must exist in the source directory.</td>
</tr>
<tr>
<td>destination_directory_object</td>
<td>The directory object that designates the destination directory. The directory object must already exist. If the destination is ASM, the directory object must designate either a disk group name (for example, +diskgroup1) or a directory created for alias names. In the case of a directory, the full path to the directory must be specified (for example: +diskgroup1/dbs/control).</td>
</tr>
</tbody>
</table>
| destination_file_name    | The name to assign to the file in the destination directory. A file with the same name must not exist in the destination directory. If the destination is ASM:
  * The file is given a fully qualified ASM filename and created in the appropriate directory (depending on the database name and file type)
  * The file type tag assigned to the file is COPY_FILE
  * The value of the destination_file_name argument becomes the file’s alias name in the designated destination directory

The file name can be followed by an ASM template name in parentheses. The file is then given the attributes specified by the template.
Usage Notes

To run this procedure successfully, the current user must have the following privileges:

- **READ** privilege on the directory object specified in the `source_directory_object` parameter
- **WRITE** privilege on directory object specified in the `destination_directory_object` parameter

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.

Transferring the file is not transactional. The copied file is treated as a binary file, and no character set conversion is performed. To monitor the progress of a long file copy, query the `V$SESSION_LONGOPS` dynamic performance view.

**See Also:** Oracle Automatic Storage Management Administrator’s Guide for instructions about using file transfer

Examples

```sql
SQL> create directory DGROUP as '+diskgroup1/dbs/backup';
Directory created.

SQL> BEGIN
2    DBMS_FILE_TRANSFER.COPY_FILE('SOURCEDIR','t_xdbtmp.f', 'DGROUP',
3           't_xdbtmp.f');
3    END;
4  /

PL/SQL procedure successfully completed.

SQL> EXIT
$ASMCMD
ASMCMD> ls
DISKGROUP1/
ASMCMD> cd diskgroup1/dbs/backup
ASMCMD> ls
t_xdbtmp.f => +DISKGROUP1/ORCL/TEMPFILE/COPY_FILE.267.546546525
```

See Also: Oracle Automatic Storage Management Administrator’s Guide for instructions about using file transfer
## GET_FILE Procedure

This procedure contacts a remote database to read a remote file and then creates a copy of the file in the local file system or ASM. The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

### Syntax

```sql
DBMS_FILE_TRANSFER.GET_FILE
    source_directory_object      IN  VARCHAR2,
    source_file_name             IN  VARCHAR2,
    source_database              IN  VARCHAR2,
    destination_directory_object IN  VARCHAR2,
    destination_file_name        IN  VARCHAR2);
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_directory_object</td>
<td>The directory object from which the file is copied at the source site. This directory object must exist at the source site.</td>
</tr>
<tr>
<td>source_file_name</td>
<td>The name of the file that is copied in the remote file system. This file must exist in the remote file system in the directory associated with the source directory object.</td>
</tr>
<tr>
<td>source_database</td>
<td>The name of a database link to the remote database where the file is located.</td>
</tr>
<tr>
<td>destination_directory_object</td>
<td>The directory object into which the file is placed at the destination site. This directory object must exist in the local file system.</td>
</tr>
<tr>
<td>destination_file_name</td>
<td>The name of the file copied to the local file system. A file with the same name must not exist in the destination directory in the local file system.</td>
</tr>
</tbody>
</table>

### Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The connected user at the source database must have read privilege on the directory object specified in the `source_directory_object` parameter.
- The current user at the local database must have write privilege on the directory object specified in the `destination_directory_object` parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.
Transferring the file is not transactional. The copied file is treated as a binary file, and no character set conversion is performed. To monitor the progress of a long file transfer, query the `V$SESSION_LONGOPS` dynamic performance view.

**Examples**

```sql
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO 'user';
CREATE DIRECTORY DSK_FILES AS ''^t_work^'';
GRANT WRITE ON DIRECTORY dsk_files TO 'user';

-- assumes that dbs2 link has been created and we are connected to the instance.
-- dbs2 could be a loopback or point to another instance.
BEGIN
  -- asm file to an os file
  -- get an asm file from dbs1.asm/a1 to dbs2.^t_work^/oa5.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'df' , 'a1' , 'dbs1', 'dsk_files' , 'oa5.dat' );

  -- os file to an os file
  -- get an os file from dbs1.^t_work^/a2.dat to dbs2.^t_work^/a2back.dat
  DBMS_FILE_TRANSFER.GET_FILE ( 'dsk_files' , 'a2.dat' , 'dbs1', 'dsk_files' , 'a2back.dat' );
END ;
/```
PUT_FILE Procedure

This procedure reads a local file or ASM and contacts a remote database to create a copy of the file in the remote file system. The file that is copied is the source file, and the new file that results from the copy is the destination file. The destination file is not closed until the procedure completes successfully.

Syntax

```sql
DBMS_FILE_TRANSFER.PUT_FILE(
    source_directory_object       IN  VARCHAR2,
    source_file_name              IN  VARCHAR2,
    destination_directory_object  IN  VARCHAR2,
    destination_file_name         IN  VARCHAR2,
    destination_database          IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_directory_object</td>
<td>The directory object from which the file is copied at the local source site. This directory object must exist at the source site.</td>
</tr>
<tr>
<td>source_file_name</td>
<td>The name of the file that is copied from the local file system. This file must exist in the local file system in the directory associated with the source directory object.</td>
</tr>
<tr>
<td>destination_directory_object</td>
<td>The directory object into which the file is placed at the destination site. This directory object must exist in the remote file system.</td>
</tr>
<tr>
<td>destination_file_name</td>
<td>The name of the file placed in the remote file system. A file with the same name must not exist in the destination directory in the remote file system.</td>
</tr>
<tr>
<td>destination_database</td>
<td>The name of a database link to the remote database to which the file is copied.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure successfully, the following users must have the following privileges:

- The current user at the local database must have read privilege on the directory object specified in the source_directory_object parameter.
- The connected user at the destination database must have write privilege to the directory object specified in the destination_directory_object parameter.

This procedure converts directory object parameters to uppercase unless they are surrounded by double quotation marks, but this procedure does not convert file names to uppercase.

Also, the copied file must meet the following requirements:

- The size of the copied file must be a multiple of 512 bytes.
- The size of the copied file must be less than or equal to two terabytes.
Transferring the file is not transactional. The copied file is treated as a binary file, and no character set conversion is performed. To monitor the progress of a long file transfer, query the V$SESSION_LONGOPS dynamic performance view.

**Examples**

```sql
CREATE OR REPLACE DIRECTORY df AS '+datafile' ;
GRANT WRITE ON DIRECTORY df TO 'user';
CREATE OR REPLACE DIRECTORY ftl AS '+datafile/ft1' ;
GRANT READ,WRITE ON DIRECTORY ftl TO 'user';
CREATE OR REPLACE DIRECTORY ft1_1 AS '+datafile/ft1/ft1_1' ;

CONNECT user;
Enter password: password

-- - put a1.dat to a4.dat (using dbs2 dblink)
-- - level 2 sub dir to parent dir
-- - user has read privs on ft1_1 at dbs1 and write on df in dbs2
BEGIN
  DBMS_FILE_TRANSFER.PUT_FILE ( 'ft1_1' , 'a2.dat' , 'df' , 'a4.dat' ,
                               'dbs2' ) ;
END ;
```
Using DBMS_FLASHBACK, you can flash back to a version of the database at a specified wall-clock time or a specified system change number (SCN).

Using DBMS_FLASHBACK

- Overview
- Security Model
- Types
- Exceptions
- Operational Notes
- Examples
Overview

DBMS_FLASHBACK provides an interface for the user to view the database at a particular time in the past, with the additional capacity provided by transaction backout features that allow for selective removal of the effects of individual transactions. This should not be confused with a flashback database which actually moves the database back in time.

When DBMS_FLASHBACK is enabled, the user session uses the Flashback version of the database, and applications can execute against the Flashback version of the database.

You may want to use DBMS_FLASHBACK for the following reasons:

- Self-service repair: If you accidentally delete rows from a table, you can recover the deleted rows.
- Packaged applications such as e-mail and voicemail: You can use Flashback to restore deleted e-mail by re-inserting the deleted message into the current message box.
- Decision support system (DSS) and online analytical processing (OLAP) applications: You can perform data analysis or data modeling to track seasonal demand.
Security Model

To use this package, a database administrator must grant **EXECUTE** privileges for DBMS_FLASHBACK.
The following types are used by `DBMS_FLASHBACK` subprograms:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TXNAME_ARRAY</td>
<td>Creates a <code>VARRAY</code> for holding Transaction Names or Identifiers (XIDs)</td>
</tr>
</tbody>
</table>
### Table 69–2  DBMS_FLASHBACK Error Messages

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-08180</td>
<td>Time specified is too old</td>
</tr>
<tr>
<td>ORA-08181</td>
<td>Invalid system change number specified</td>
</tr>
<tr>
<td>ORA-08182</td>
<td>User cannot begin read-only or serializable transactions in Flashback mode</td>
</tr>
<tr>
<td>ORA-08183</td>
<td>User cannot enable Flashback within an uncommitted transaction</td>
</tr>
<tr>
<td>ORA-08184</td>
<td>User cannot enable Flashback within another Flashback session</td>
</tr>
<tr>
<td>ORA-08185</td>
<td>SYS cannot enable Flashback mode</td>
</tr>
</tbody>
</table>
**Operational Notes**

`DBMS_FLASHBACK` is automatically turned off when the session ends, either by disconnection or by starting another connection.

PL/SQL cursors opened in Flashback mode return rows as of the flashback time or SCN. Different concurrent sessions (connections) in the database can perform Flashback to different wall-clock times or SCNs. DML and DDL operations and distributed operations are not allowed while a session is running in Flashback mode. You can use PL/SQL cursors opened before disabling Flashback to perform DML.

Under Automatic Undo Management (AUM) mode, you can use retention control to control how far back in time to go for the version of the database you need.

If you need to perform a Flashback over a 24-hour period, the DBA should set the `undo_retention` parameter to 24 hours. This way, the system retains enough undo information to regenerate the older versions of the data.

You can set the `RETENTION GUARANTEE` clause for the undo tablespace to ensure that unexpired undo is not discarded. `UNDO_RETENTION` is not in itself a complete guarantee because, if the system is under space pressure, unexpired undo may be overwritten with freshly generated undo. In such cases, `RETENTION GUARANTEE` prevents this. For more information, see the Oracle Database Administrator’s Guide.

In a Flashback-enabled session, `SYSDATE` is not affected; it continues to provide the current time.

`DBMS_FLASHBACK` can be used within logon triggers to enable Flashback without changing the application code.
The following example illustrates how Flashback can be used when the deletion of a senior employee triggers the deletion of all the personnel reporting to him. Using the Flashback feature, you can recover and re-insert the missing employees.

```
DROP TABLE employee;
DROP TABLE keep_scn;

REM -- Keep_scn is a temporary table to store scns that we are interested in
CREATE TABLE keep_scn (scn number);
SET ECHO ON
CREATE TABLE employee (
  employee_no   number(5) PRIMARY KEY,
  employee_name varchar2(20),
  employee_mgr  number(5)
    CONSTRAINT mgr_fkey REFERENCES EMPLOYEE ON DELETE CASCADE,
  salary        number,
  hiredate      date
);

REM -- Populate the company with employees
INSERT INTO employee VALUES (1, 'John Doe', null, 1000000, '5-jul-81');
INSERT INTO employee VALUES (10, 'Joe Johnson', 1, 500000, '12-aug-84');
INSERT INTO employee VALUES (20, 'Susie Tiger', 10, 250000, '13-dec-90');
INSERT INTO employee VALUES (100, 'Scott Tiger', 20, 200000, '3-feb-86');
INSERT INTO employee VALUES (200, 'Charles Smith', 100, 150000, '22-mar-88');
INSERT INTO employee VALUES (210, 'Jane Johnson', 100, 100000, '11-apr-87');
INSERT INTO employee VALUES (220, 'Nancy Doe', 100, 100000, '18-sep-93');
INSERT INTO employee VALUES (300, 'Gary Smith', 210, 75000, '4-nov-96');
INSERT INTO employee VALUES (310, 'Bob Smith', 210, 65000, '3-may-95');
COMMIT;

REM -- Show the entire org
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;

REM -- Sleep for a short time (approximately 10 to 20 seconds) to avoid
REM -- querying close to table creation
EXECUTE DBMS_LOCK.SLEEP(10);

REM -- Store this snapshot for later access through Flashback
DECLARE
  I NUMBER;
BEGIN
  I := DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER;
  INSERT INTO keep_scn VALUES (I);
  COMMIT;
END;
/

REM -- Scott decides to retire but the transaction is done incorrectly
DELETE FROM EMPLOYEE WHERE employee_name = 'Scott Tiger';
COMMIT;
```
REM -- notice that all of scott's employees are gone
SELECT lpad(' ', 2*(level-1)) || employee_name Name
FROM EMPLOYEE
CONNECT BY PRIOR employee_no = employee_mgr

END IF;
END LOOP;
END;
/

REM -- Show the restored organization.
select lpad(' ', 2*(level-1)) || employee_name Name
FROM employee
CONNECT BY PRIOR employee_no = employee_mgr
START WITH employee_no = 1
ORDER BY LEVEL;
```
Summary of DBMS_FLASHBACK Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISABLE Procedure on page 69-12</td>
<td>Disables the Flashback mode for the entire session</td>
</tr>
<tr>
<td>ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure on page 69-13</td>
<td>Enables Flashback for the entire session. Takes an SCN as an Oracle number and sets the session snapshot to the specified number. Inside the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN</td>
</tr>
<tr>
<td>ENABLE_AT_TIME Procedure on page 69-14</td>
<td>Enables Flashback for the entire session. The snapshot time is set to the SCN that most closely matches the time specified in query_time</td>
</tr>
<tr>
<td>GET_SYSTEM_CHANGE_NUMBER Function on page 69-15</td>
<td>Returns the current SCN as an Oracle number. You can use the SCN to store specific snapshots</td>
</tr>
<tr>
<td>TRANSACTION_BACKOUT Procedures on page 69-16</td>
<td>Provides the mechanism to backout a transaction</td>
</tr>
</tbody>
</table>
DISABLE Procedure

This procedure disables the Flashback mode for the entire session.

Syntax

DBMS_FLASHBACK.DISABLE;

Examples

The following example queries the salary of an employee, Joe, on August 30, 2000:

EXECUTE dbms_flashback.enable_at_time('30-AUG-2000');
SELECT salary FROM emp where name = 'Joe'
EXECUTE dbms_flashback.disable;
ENABLE_AT_SYSTEM_CHANGE_NUMBER Procedure

This procedure takes an SCN as an input parameter and sets the session snapshot to the specified number. In the Flashback mode, all queries return data consistent as of the specified wall-clock time or SCN. It enables Flashback for the entire session.

Syntax

```sql
DBMS_FLASHBACK.ENABLE_AT_SYSTEM_CHANGE_NUMBER (
    query_scn IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query_scn</td>
<td>The system change number (SCN), a version number for the database that is incremented on every transaction commit.</td>
</tr>
</tbody>
</table>
ENABLE_AT_TIME Procedure

This procedure enables Flashback for the entire session. The snapshot time is set to the SCN that most closely matches the time specified in query_time. It enables Flashback for the entire session.

Syntax

DBMS_FLASHBACK.ENABLE_AT_TIME (
   query_time   IN TIMESTAMP);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query_time</td>
<td>This is an input parameter of type TIMESTAMP. A time stamp can be specified in the following ways:</td>
</tr>
<tr>
<td></td>
<td>■ Using the TIMESTAMP constructor</td>
</tr>
<tr>
<td></td>
<td>EXECUTE DBMS_FLASHBACK.ENABLE_AT_TIME(TIMESTAMP '2001-01-09 12:31:00').</td>
</tr>
<tr>
<td></td>
<td>Use the Globalization Support (NLS) format and supply a string. The format depends on the Globalization Support settings.</td>
</tr>
<tr>
<td></td>
<td>■ Using the TO_TIMESTAMP function:</td>
</tr>
<tr>
<td></td>
<td>EXECUTE DBMS_FLASHBACK.ENABLE_AT_TIME(TO_TIMESTAMP('12-02-2001 14:35:00', 'DD-MM-YYYY HH24:MI:SS'))</td>
</tr>
<tr>
<td></td>
<td>You provide the format you want to use. This example shows the TO_TIMESTAMP function for February 12, 2001, 2:35 PM.</td>
</tr>
<tr>
<td></td>
<td>■ If the time is omitted from query time, it defaults to the beginning of the day, that is, 12:00 A.M.</td>
</tr>
<tr>
<td></td>
<td>■ Note that if the query time contains a time zone, the time zone information is truncated.</td>
</tr>
</tbody>
</table>
GET_SYSTEM_CHANGE_NUMBER Function

This function returns the current SCN as an Oracle number datatype. You can obtain the current change number and store it for later use. This helps you retain specific snapshots.

Syntax

```sql
DBMS_FLASHBACK.GET_SYSTEM_CHANGE_NUMBER
RETURN NUMBER;
```
TRANSACTION_BACKOUT Procedures

This procedure provides a mechanism to backout a set of transactions. The user can call these procedures with either transaction names or transaction identifiers (XIDS).

The procedure analyzes the transactional dependencies, perform DML’s and generates an extensive report on the operation performed by the subprogram. This procedure does not commit the DML’s performed as part of transaction backout. However it holds all the required locks on rows and tables in the right form, so that no other dependencies can enter the system. To make the changes permanent the user needs to explicitly commit the transaction.

A report is generated in the system tables `DBA_FLASHBACK_TRANSACTION_STATE` and `DBA_FLASHBACK_TRANSACTION_REPORT`.

Syntax

```sql
DBMS_FLASHBACK.TRANSACTION_BACKOUT
numtxns NUMBER,
xids XID_ARRAY,
options NUMBER default NOCASCADE,
timeHint TIMESTAMP default MINTIME);
```

```sql
DBMS_FLASHBACK.TRANSACTION_BACKOUT
numtxns NUMBER,
xids XID_ARRAY,
options NUMBER default NOCASCADE,
scnHint TIMESTAMP default 0 );
```

```sql
DBMS_FLASHBACK.TRANSACTION_BACKOUT
numtxns NUMBER,
txnnames TXNAME_ARRAY,
options NUMBER default NOCASCADE,
timehint TIMESTAMP MINTIME );
```

```sql
DBMS_FLASHBACK.TRANSACTION_BACKOUT
numtxns NUMBER,
txnNames TXNAME_ARRAY,
options NUMBER default NOCASCADE,
scnHint NUMBER 0);}
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>numtxns</td>
<td>Number of transactions passed as input</td>
</tr>
<tr>
<td>xids</td>
<td>List of transaction IDs in the form of an array</td>
</tr>
<tr>
<td>txnnames</td>
<td>List of transaction names in the form of an array</td>
</tr>
</tbody>
</table>
Usage Notes

**Note:** For information about restrictions in using `TRANSACTION_BACKOUT`, see "Using Flashback Transaction" in the Oracle Database Advanced Application Developer’s Guide.

- If transaction name is used, a time hint must be provided. The time hint should be a time before the start of all the given transactions to back out.
- If the SCN hint is provided, it must be before the start of the earliest transaction in the specified input set, or this raises an error and terminate. If it is not provided and the transaction has committed within undo retention, the database system is able to determine the start time.
The DBMS_FLASHBACK_ARCHIVE package contains two simple procedures for disassociation and reassociation of a Flashback Data Archive (FDA) enabled table from/with its underlying FDA respectively.

Using DBMS_FLASHBACK_ARCHIVE

- Overview
- Security Model
- Examples
Overview

The Flashback Data Archive feature, which is available through the Total Recall option, provides strict protection on the internal history tables that it creates and maintains for users.

The read-only semantics provided prohibits users, including a DBA, from doing updates, deletes, and inserts on the Flashback Data Archive internal history tables. The feature also prohibits users from issuing any DDL statements on these tables. This strict security enforcement by Flashback Data Archive meets the requirements of regulatory-compliance type of applications. The feature supports a lot of common DDL statements, including some DDL statements that alter table definition or incur data movement, on user tables that are enabled for Flashback Data Archive. However, there are some DDL statements that are not supported on tables enabled for the feature. Since most applications schemas evolve as they release new versions of their software, the ability to perform DDL operations on the base table is a key customer requirement.

In order to support user applications' schema evolution during application upgrade and other table maintenance tasks beyond DDL statements supported by Flashback Data Archive, the DBMS_FLASHBACK_ARCHIVE package provides a set of simple-to-use PL/SQL procedures:

- To disassociate a Flashback Data Archive enabled base table from the underlying FDA.
- To reassociate a temporarily disassociated base table with its underlying FDA.

After a user has disassociated the base table from its FDA, it's possible to issue any DDL statements on the base table or the history tables in the FDA. Having finished with the schema changes, the user can then reassociate the base table with its FDA so that Flashback Data Archive protection is in operation and automatic tracking and archiving is resumed.
Security Model

Users with the `FLASHBACK ARCHIVE ADMINISTER` system privilege can execute the disassociation and reassociation PL/SQL procedures. Once a table is disassociated, normal users can perform DDL and DML statements as long as they have the necessary privileges on the tables.
Examples

Normally, users cannot perform any modification to the history table:

```sql
SQL> DELETE FROM scott.SYS_FBA_HIST_61527;
ERROR at line 1:
ORA-55622: DML, ALTER and CREATE UNIQUE INDEX operations are not allowed on table 'SCOTT'."SYS_FBA_HIST_61527"
```

Users also cannot issue DDL statements on history tables:

```sql
SQL> ALTER TABLE scott.SYS_FBA_HIST_61527 DROP COLUMN comm;
ERROR at line 1:
ORA-55622: DML, ALTER and CREATE UNIQUE INDEX operations are not allowed on table 'SCOTT'."SYS_FBA_HIST_61527"
```

Use the `DISASSOCIATE_FBA` Procedure to disassociate the `scott.emp_test` table:

```sql
SQL> EXEC DBMS_FLASHBACK_ARCHIVE.DISASSOCIATE_FBA('scott','emp_test');
PL/SQL procedure successfully completed.
```

Now a user can perform table structural modifications (through DDL statements) to the user base table:

```sql
SQL> ALTER TABLE scott.emp_test RENAME COLUMN sal TO salary;
Table altered.
```

Users can also modify the contents in the history table that they couldn't modify previously.

```sql
SQL> DELETE FROM scott.SYS_FBA_HIST_61527 WHERE empno=3968;
2 rows deleted.
```

If a user tries to reassociate the history table with the base table, this will fail as the user has not performed corresponding structural modifications (through DDL statements) to the history table:

```sql
SQL> EXEC DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA('scott','emp_test');
BEGIN DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA('scott','emp_test');
END;
ERROR at line 1:
ORA-55636: Flashback Data Archive enabled table "SCOTT"."EMP_TEST" has different definition from its history table
ORA-06512: at "SYS.DBMS_FLASHBACK_ARCHIVE", line 17
ORA-06512: at line 1
```

Disassociate the table and fix the table definition problem:

```sql
SQL> EXEC DBMS_FLASHBACK_ARCHIVE.DISASSOCIATE_FBA('scott','emp_test');
PL/SQL procedure successfully completed.
```

Perform the same rename column DDL on the history table to make its definition conform to its base table `scott.emp_test`:

```sql
SQL> ALTER TABLE scott.SYS_FBA_HIST_61527 RENAME COLUMN sal TO salary;
```
Table altered.

Finally, reassociate the base table with its history table successfully:

SQL> EXEC DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA('scott','emp_test')

PL/SQL procedure successfully completed.

The above example is used as an illustration. RENAME COLUMN is available as a supported DDL and you do not need to invoke disassociate/reassociate as a matter of course. You need to disassociate/reassociate only if the operation is not supported by flashback archive and produces a 55610 error message.

SQL> create table emp_test as select empno, sal from emp;

Table created.

SQL> alter table emp_test flashback archive;

Table altered.

Create a temporary history table with the same form as the base table but with the additional metadata columns.

SQL> EXEC DBMS_FLASHBACK_ARCHIVE.CREATE_TEMP_HISTORY_TABLE('scott','emp_test');

PL/SQL procedure successfully completed.

SQL> describe scott.temp_history

<table>
<thead>
<tr>
<th>Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>RID</td>
<td></td>
<td>VARCHAR2(4000)</td>
</tr>
<tr>
<td>STARTSCN</td>
<td></td>
<td>NUMBER</td>
</tr>
<tr>
<td>ENDSCN</td>
<td></td>
<td>NUMBER</td>
</tr>
<tr>
<td>XID</td>
<td></td>
<td>RAW(8)</td>
</tr>
<tr>
<td>OPERATION</td>
<td></td>
<td>VARCHAR2(1)</td>
</tr>
<tr>
<td>EMPNO</td>
<td></td>
<td>NUMBER(4)</td>
</tr>
<tr>
<td>SAL</td>
<td></td>
<td>NUMBER(7,2)</td>
</tr>
</tbody>
</table>

Do the following once per database. This will extend mappings to the past so that import of old history can be done. Goes back to 01-JAN-88.

SQL> EXEC DBMS_FLASHBACK_ARCHIVE.extend_mappings();

PL/SQL procedure successfully completed.

SQL> insert into scott.temp_history values (NULL, timestamp_to_scn(to_date('01-JAN-06')), timestamp_to_scn(to_date('31-DEC-06')), NULL, 'U', 1, 1000);

1 row created.

SQL> commit;

Commit complete.

SQL> EXEC DBMS_FLASHBACK_ARCHIVE.IMPORT_HISTORY('scott','emp_test');

PL/SQL procedure successfully completed.

Now flashback queries of the imported data are possible.

SQL> select * from scott.emp_test as of timestamp to_date('06-JUN-06') where empno=1;
<table>
<thead>
<tr>
<th>EMPNO</th>
<th>SAL</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1000</td>
</tr>
</tbody>
</table>

DISASSOCIATE_FBA Procedure

This procedure disassociates the given table from the flashback data archive.

Syntax

```sql
DBMS_FLASHBACK_ARCHIVE.DISASSOCIATE_FBA (
    owner_name      VARCHAR2,
    table_name      VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner_name</td>
<td>Schema of the Flashback Data Archive enabled base table</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the Flashback Data Archive enabled base table</td>
</tr>
</tbody>
</table>

Exceptions

<table>

</tr>
</thead>
<tbody>
<tr>
<td>ORA-55602</td>
<td>User table is not enabled for Flashback Data Archive</td>
</tr>
<tr>
<td>ORA-55634</td>
<td>Cannot acquire the lock on the table for disassociation</td>
</tr>
</tbody>
</table>
REASSOCIATE_FBA Procedure

This procedure reassociates the given table with the flashback data archive.

Syntax

```
DBMS_FLASHBACK_ARCHIVE.REASSOCIATE_FBA (
  owner_name      VARCHAR2,
  table_name      VARCHAR2);
```

Parameters

```

</tr>
<tr>
<td>ORA-55636</td>
<td>table definition validation failed</td>
</tr>
</tbody>
</table>
```

Usage Notes

- The procedure will signal an error if the base table and the history table do not have identical data definitions. For example when columns are added or table is split, the resulting base table and history table need to have the same schema.
- The FDA internal history table schema has some row versions metadata columns. The procedure will signal an error if any of the metadata columns is dropped by users.
The DBMS_FREQUENT_ITEMSET package enables frequent itemset counting. The two functions are identical except in the input cursor format difference.

This chapter contains the following topics:

- Summary of DBMS_FREQUENT_ITEMSET Subprograms
## Summary of DBMS_FREQUENT_ITEMSET Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>FI_HORIZONTAL Function</strong> on page 71-3</td>
<td>Counts all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded</td>

</tr>
</tbody>
</table>
**FI_HORIZONTAL Function**

The purpose of this table function is to count all frequent itemsets given a cursor for input data which is in 'HORIZONTAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total transactions counted.

In 'HORIZONTAL' row format, each row contains all of the item ids for a single transaction. Since all of the items come together, no transaction id is necessary.

The benefit of this table function is that if an application already has data in horizontal format, the database can skip the step of transforming rows that are in transactional format into horizontal format.

**Syntax**

```sql
DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL(
    tranx_cursor         IN    SYSREFCURSOR,
    support_threshold    IN    NUMBER,
    itemset_length_min   IN    NUMBER,
    itemset_length_max   IN    NUMBER,
    including_items      IN    SYS_REFCURSOR DEFAULT NULL,
    excluding_items      IN    SYS_REFCURSOR DEFAULT NULL)
RETURN TABLE OF ROW (
    itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
    support        NUMBER,
    length         NUMBER,
    total_tranx    NUMBER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tranx_cursor</td>
<td>The cursor parameter that the user will supply when calling the function. There is no limits on the number of returning columns. Each column of cursor represents an item. All columns of the cursor must be of the same data type. The item id must be number or character type (for example, VARCHAR2(n)).</td>
</tr>
<tr>
<td>support_threshold</td>
<td>A fraction number of total transaction count. An itemset is termed 'frequent' if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a NUMBER.</td>
</tr>
<tr>
<td>itemset_length_min</td>
<td>The minimum length for interested frequent itemset. The parameter must be a NUMBER between 1 and 20, inclusive.</td>
</tr>
<tr>
<td>itemset_length_max</td>
<td>The maximum length for interested frequent itemset. This parameter must be a NUMBER between 1 and 20, inclusive, and must not be less than itemset_length_min.</td>
</tr>
<tr>
<td>including_items</td>
<td>A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that are returned. The default is NULL.</td>
</tr>
<tr>
<td>excluding_items</td>
<td>A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that are returned. The default is NULL.</td>
</tr>
</tbody>
</table>
Return Values

Table 71–3  FI_HORIZONTAL Return Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>support</td>
<td>The number of transactions in which a frequent itemset occurs. This will be returned as a NUMBER.</td>
</tr>
<tr>
<td>itemset</td>
<td>A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor.</td>
</tr>
<tr>
<td>length</td>
<td>Number of items in a frequent itemset. This will be returned as a NUMBER.</td>
</tr>
<tr>
<td>total_tranx</td>
<td>The total transaction count. This will be returned as a NUMBER.</td>
</tr>
</tbody>
</table>

Example

Suppose you have a table horiz_table_in.

horiz_table_in(iid1 VARCHAR2(30), iid2 VARCHAR2(30), iid3 VARCHAR2(30), iid4 VARCHAR2(30), iid5 VARCHAR2(30));

and the data in horiz_table_in looks as follows:

('apple', 'banana', NULL, NULL, NULL)
('apple', 'milk', 'banana', NULL, NULL)
('orange', NULL, NULL, NULL, NULL)

Suppose you want to find out what combinations of items is frequent with a given support threshold of 30%, requiring itemset containing at least one of ('apple','banana','orange'), but excluding any of ('milk') in any itemset. You use the following query:

CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as FI_VARCHAR_NT)itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_HORIZONTAL(
    CURSOR(SELECT iid1, iid2, iid3, iid4, iid5
             FROM horiz_table_in),
    0.3,
    2,
    5,
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT('apple','banana','orange'))),
    CURSOR(SELECT * FROM table(FI_VARCHAR_NT('milk'))));
**FI_TRANSACTIONAL Function**

This procedure counts all frequent itemsets given a cursor for input data which is in 'TRANSACTIONAL' row format, support threshold, minimum itemset length, maximum itemset length, items to be included, items to be excluded. The result will be a table of rows in form of itemset, support, length, total number of transactions.

In 'TRANSACTIONAL' row format, each transaction is spread across multiple rows. All the rows of a given transaction have the same transaction id, and each row has a different item id. Combining all of the item ids which share a given transaction id results in a single transaction.

**Syntax**

```sql
DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL (
    tranx_cursor         IN    SYSREFCURSOR,
    support_threshold    IN    NUMBER,
    itemset_length_min   IN    NUMBER,
    itemset_length_max   IN    NUMBER,
    including_items      IN    SYS_REFCURSOR DEFAULT NULL,
    excluding_items      IN    SYS_REFCURSOR DEFAULT NULL)
RETURN TABLE OF ROW (
    itemset [Nested Table of Item Type DERIVED FROM tranx_cursor],
    support        NUMBER,
    length         NUMBER,
    total_tranx    NUMBER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tranx_cursor</td>
<td>The cursor parameter that the user will supply when calling the function. It should return two columns in its returning row, the first column being the transaction id, the second column being the item id. The item id must be number or character type (for example, VARCHAR2(n)).</td>
</tr>
<tr>
<td>support_threshold</td>
<td>A fraction number of total transaction count. An itemset is termed &quot;frequent&quot; if [the number of transactions it occurs in] divided by [the total number of transactions] exceed the fraction. The parameter must be a NUMBER.</td>
</tr>
<tr>
<td>itemset_length_min</td>
<td>The minimum length for interested frequent itemset. The parameter must be a NUMBER between 1 and 20, inclusive.</td>
</tr>
<tr>
<td>itemset_length_max</td>
<td>The maximum length for interested frequent itemset. This parameter must be a NUMBER between 1 and 20, inclusive, and must not be less than itemset_length_min.</td>
</tr>
<tr>
<td>including_items</td>
<td>A cursor from which a list of items can be fetched. At least one item from the list must appear in frequent itemsets that will be returned. The default is NULL.</td>
</tr>
<tr>
<td>excluding_items</td>
<td>A cursor from which a list of items can be fetched. No item from the list can appear in frequent itemsets that will be returned. The default is NULL.</td>
</tr>
</tbody>
</table>
**Return Values**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>support</td>
<td>The number of transactions in which a frequent itemset occurs. This will be returned as a NUMBER.</td>
</tr>
<tr>
<td>itemset</td>
<td>A collection of items which is computed as frequent itemset. This will be returned as a nested table of item type which is the item column type of the input cursor.</td>
</tr>
<tr>
<td>length</td>
<td>Number of items in a frequent itemset. This will be returned as a NUMBER.</td>
</tr>
<tr>
<td>total_tranx</td>
<td>The total transaction count. This will be returned as a NUMBER, and will be the same for all returned rows, similar to a reporting aggregate.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Applications must predefine a nested table type of the input item type and cast the output itemset into this predefined nested table type before further processing, such as loading into a table.

**Examples**

Suppose that the input table `tranx_table_in` looks as follows:

```sql
(1, 'apple')
(1, 'banana')
(2, 'apple')
(2, 'milk')
(2, 'banana')
(3, 'orange')
```

and the user is trying to find itemsets that satisfy a support-threshold of 60% and have the itemset-length greater than 1 (namely, (apple, banana)).

The output of this function would contain the following output row:

```sql
itemset=('apple','banana'), support=2, length=2, total_tranx=3
```

You need to create a nested table of item type before you submit a query to perform the frequent itemset counting. In this example, since item is of `VARCHAR2(30)`, you must create a nested table of `VARCHAR2(30)`:

```sql
CREATE TYPE fi_varchar_nt AS TABLE OF VARCHAR2(30);
SELECT CAST(itemset as fi_varchar_nt) itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
  cursor(SELECT tid, iid FROM tranx_table_in),
  0.6,
  2,
  5,
  NULL,
  NULL));
```

Here is another example to illustrate how to include certain items and exclude certain items in the counting:

```sql
SELECT CAST(itemset as FI_VARCHAR_NT) itemset, support, length, total_tranx
FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
  CURSOR(SELECT tid, iid FROM tranx_table_in),
  0.6,
  2,
  5,
  NULL,
  NULL));
```
Using the including/excluding items parameter, you are able to further optimize the execution by ignoring itemsets that are not expected by application.

You can also use transactional output through collection unnesting:

```sql
SELECT
    bt.setid, nt.*
FROM
    (SELECT cast(Itemset as FI_VARCHAR_NT) itemset, rownum setid
     FROM table(
         DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
             CURSOR(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
             NULL, NULL))) bt,
    table(bt.itemset) nt;
```

If you want to use an insert statement to load frequent itemsets into a nested table, it is better to use the `NESTED_TABLE_FAST_INSERT` hint for performance:

```sql
CREATE TABLE fq_nt (coll FI_VARCHAR_NT) NESTED TABLE coll STORE AS coll_nest;
 INSERT /*+ NESTED_TABLE_FAST_INSERT */ INTO fq_nt
 SELECT cast(itemset as FI_VARCHAR_NT)
 FROM table(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
     cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
     NULL, NULL));
```

Note that if you want to use the package inside a PL/SQL cursor, you must cast the return type of the table function:

```sql
CREATE TYPE fi_res AS OBJECT {
    itemset      FI_VARCHAR_NT,
    support      NUMBER,
    length       NUMBER,
    total_tranx  NUMBER
};
/
CREATE TYPE fi_coll AS TABLE OF fi_res;
/
DECLARE
    cursor freqC is
        SELECT Itemset
        FROM table(
            CAST(DBMS_FREQUENT_ITEMSET.FI_TRANSACTIONAL(
                cursor(SELECT tid, iid FROM tranx_table_in), 0.6, 2, 5,
                NULL, NULL) AS fi_coll));
    coll_nt  FI_VARCHAR_NT;
    num_rows int;
    num_itms int;
BEGIN
    num_rows := 0;
    num_itms := 0;
    OPEN freqC;
    LOOP
```
FETCH freqC INTO coll_nt;
EXIT WHEN freqC%NOTFOUND;
  num_rows := num_rows + 1;
  num_itms := num_itms + coll_nt.count;
END LOOP;
CLOSE freqC;
DBMS_OUTPUT.PUT_LINE(‘Totally ‘ || num_rows || ‘ rows ‘ || num_itms || ‘ items were produced.’);
END;
/

This package contains constants and procedure declarations for health check management. Health Monitor provides facilities to run a check store and retrieve the reports through `DBMS_HM` package.

**See Also:** *Oracle Database Administrator’s Guide* for more information about "Health Monitor"

This chapter contains the following topics:

- **Using DBMS_HM**
  - Security Model
- **Summary of DBMS_HM Subprograms**
Using DBMS_HM

- Security Model
Security Model

Users must have EXECUTE privilege to run the procedures of DBMS_HM package.
## Summary of DBMS_HM Subprograms

<table>
<thead>
<tr>
<th>Table 72–1 DBMS_HM Package Subprograms</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Subprogram</strong></td>
</tr>
<tr>
<td>GET_RUN_REPORT Function on page 72-5</td>
</tr>
<tr>
<td>RUN_CHECK Procedure on page 72-6</td>
</tr>
</tbody>
</table>
GET_RUN_REPORT Function

This function returns the report for the specified checker run.

Syntax

```
DBMS_HM.GET_RUN_REPORT (  
    run_name      IN  VARCHAR2,  
    type           IN  VARCHAR2 := 'TEXT',  
    level          IN  VARCHAR2 := 'BASIC',)  
RETURN CLOB;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>run_name</td>
<td>Name of the check's run</td>
</tr>
<tr>
<td>type</td>
<td>Report format type. Possible values are 'HTML', 'XML' and 'TEXT'. Default report type is 'TEXT'.</td>
</tr>
<tr>
<td>level</td>
<td>Details of report, possible value are 'BASIC' and 'DETAIL'. Caution: Currently only 'BASIC' level is supported.</td>
</tr>
</tbody>
</table>
RUN_CHECK Procedure

This procedure runs the specified checker with the given arguments. It lets user to specify a name for the run, inputs needed and maximum timeout for the run. The run’s report will be maintained persistently in database.

Syntax

```sql
DBMS_HM.RUN_CHECK (    
  check_name     IN  VARCHAR2,
  run_name       IN  VARCHAR2 := NULL,
  timeout        IN  NUMBER := NULL,
  input_params   IN  VARCHAR2 := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>check_name</td>
<td>Name of the check to be invoked. Check names and their parameters can be accessed from the V$HM_CHECK and V$HM_CHECK_PARAM views. Users can run all checks which are not internal in nature: SELECT name FROM V$HM_CHECK WHERE INTERNAL_CHECK = 'N' retrieves the list of checks that can be run manually by users.</td>
</tr>
<tr>
<td>run_name</td>
<td>Name with which external users can uniquely identify this check’s run. If NULL value is passed, then HM creates a unique name and associates with this check's run.</td>
</tr>
<tr>
<td>timeout</td>
<td>Maximum amount of time (in units of seconds), this checker run is allowed to run. HM will interrupt the run, if it the specified time elapses for the run. If NULL value is passed, HM doesn’t impose any timeout limits on the run.</td>
</tr>
</tbody>
</table>
| input_params | Input string: which consists of name, value pairs delimited by a special character '\'. Example ('Data Block Integrity Check' invocation may take following type of input parameters. 'BLC_DF_NUM=1;BLC_BL_NUM=23456' Input parameters BLC_DF_NUM and BLC_BL_NUM have values '1' and '23456' respectively. Every check will have well defined set of inputs associated with it. These Input parameters, their types, default values and descriptions can be obtained using V$HM_CHECK_PARAM view. Example: The following query gets the list of parameters, their default values and descriptions for a 'Data Block Integrity Check'

```sql
SELECT a.* FROM v$hm_check_param a, v$hm_check b
WHERE a.check_id = b.id
AND b.name = 'Data Block Integrity Check';
```
The DBMS_HPROF package provides an interface for profiling the execution of PL/SQL applications. It provides services for collecting the hierarchical profiler data, analyzing the raw profiler output and profiling information generation.

See Also: Oracle Database Advanced Application Developer’s Guide for more information about the "PL/SQL Hierarchical Profiler"

This chapter contains the following topic:

- Summary of DBMS_HPROF Subprograms
Summary of DBMS_HPROF Subprograms

This table lists the package subprograms in alphabetical order.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ANALYZE Function on page 73-3</td>
<td>Analyzes the raw profiler output and produces hierarchical profiler information in database tables</td>
</tr>

<td>Stops profiler data collection in the user’s session</td>
</tr>
</tbody>
</table>
ANALYZE Function

This function analyzes the raw profiler output and produces hierarchical profiler information in database tables.

Syntax

```
DBMS_HPROF.ANALYZE (
  location         VARCHAR2,
  filename         VARCHAR2,
  summary_mode     BOOLEAN     DEFAULT FALSE,
  trace            VARCHAR2    DEFAULT NULL,
  skip             PLS_INTEGER DEFAULT 0,
  collect          PLS_INTEGER DEFAULT NULL,
  run_comment      VARCHAR2    DEFAULT NULL)
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td>Name of a directory object. The raw profiler data file is read from the file system directory mapped to this directory object. Output files are also written to this directory.</td>
</tr>
<tr>
<td>filename</td>
<td>Name of the raw profiler data file to be analyzed. The file must exist in the directory specified by the location parameter.</td>
</tr>
<tr>
<td>summary_mode</td>
<td>By default (that is, when summary_mode is FALSE), the detailed analysis is done. When summary_mode is TRUE, only top-level summary information is generated into the database table.</td>
</tr>
<tr>
<td>trace</td>
<td>Analyze only the subtrees rooted at the specified trace entry. By default (when trace is NULL), the analysis/reporting is generated for the entire run. The trace entry must be specified in a special quoted qualified format (including the schema name, module name &amp; function name) as in for example, &quot;SCOTT.&quot;.PKG.&quot;FOO&quot; or &quot;.&quot;.<strong>plsql</strong>.vm&quot;. If multiple overloads exist for the specified name, all of them will be analyzed.</td>
</tr>
<tr>
<td>skip</td>
<td>Used only when trace is specified. Analyze only the subtrees rooted at the specified trace, but ignore the first skip invocations to trace. The default value for skip is 0.</td>
</tr>
<tr>
<td>collect</td>
<td>Used only when trace is specified. Analyze collect number of invocations of traces (starting from skip+1'th invocation). By default only 1 invocation is collected.</td>
</tr>
<tr>
<td>run_comment</td>
<td>User-provided comment for this run</td>
</tr>
</tbody>
</table>

Return Values

A unique run identifier for this run of the analyzer. This can then be used to look up the results corresponding to this run from the hierarchical profiler tables.
Usage Notes

- Use the `dbmshptab.sql` script located in the `rdbms/admin` directory to create the hierarchical profiler database tables and other data structures required for persistently storing the results of analyzing the raw profiler data.
- Running `dbmshptab.sql` drops the any previously created hierarchical profiler tables.

Examples

The following snippet installs the hierarchical profiler tables in HR schema.

```sql
connect HR/HR;
@?/rdbms/admin/dbmshptab.sql
```
**START_PROFILING Procedure**

This procedure starts hierarchical profiler data collection in the user’s session.

**Syntax**

```sql
DBMS_HPROF.START_PROFILING (
    location    VARCHAR2 DEFAULT NULL,
    filename    VARCHAR2 DEFAULT NULL,
    max_depth   PLS_INTEGER DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>location</td>
<td>Name of a directory object. The file system directory mapped to this directory object is where the raw profiler output is generated.</td>
</tr>
<tr>
<td>filename</td>
<td>Output filename for the raw profiler data. The file is created in the directory specified by the <code>location</code> parameter.</td>
</tr>
<tr>
<td>max_depth</td>
<td>By default (that is, when <code>max_depth</code> value is NULL) profile information is gathered for all functions irrespective of their call depth. When a non-NULL value is specified for <code>max_depth</code>, the profiler collects data only for functions up to a call depth level of <code>max_depth</code>.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Even though the profiler does not individually track functions at depth greater than `max_depth`, the time spent in such functions is charged to the ancestor function at depth `max_depth`. 
STOP PROFILING Procedure

This procedure stops profiler data collection in the user's session. This subprogram also has the side effect of flushing data collected so far in the session, and it signals the end of a run.

Syntax

```
DBMS_HPROF.STOP_PROFILING;
```
The DBMS_HS_PARALLEL PL/SQL package enables parallel processing for heterogeneous targets access. This package is designed to improve performance when retrieving data from a large foreign table.

This chapter discusses the following topics:

- Using DBMS_HS_PARALLEL
- Summary of DBMS_HS_PARALLEL Subprograms
Using DBMS_HS_PARALLEL

DBMS_HS_PARALLEL is compiled with the authorization ID of CURRENT_USER, which uses invoker’s rights. In other words, all procedures in this package are executed with the privileges of the calling user.
## Summary of DBMS_HS_PARALLEL Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CREATE_OR_REPLACE_VIEW</strong></td>

</tr>
<tr>
<td><strong>CREATE_TABLE_TEMPLATE</strong></td>
<td>Writes out a CREATE TABLE template based on information gathered from the remote table. You can use the information to add any optimal Oracle CREATE TABLE clauses.</td>
</tr>
<tr>
<td><strong>DROP_VIEW</strong></td>
<td>Drops the view and internal objects created by the CREATE_OR_REPLACE_VIEW procedure. If the view has not already been created by the CREATE_OR_REPLACE_VIEW procedure, an error message is returned.</td>
</tr>
<tr>
<td><strong>LOAD_TABLE</strong></td>
<td>Loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.</td>
</tr>
</tbody>
</table>
CREATE_OR_REPLACE_VIEW

This procedure creates (or replaces) a read-only view to be referenced for retrieving the data from a remote table in parallel.

Syntax

CREATE_OR_REPLACE_VIEW (remote_table, database_link, oracle_view, parallel_degree)

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote_table</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The name of the remote database table. It is specified as [remote_schema_name.]remote_table_name.</td>
</tr>
<tr>
<td>database_link</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The remote database link name. The call can only be applied to a heterogeneous services database link.</td>
</tr>
<tr>
<td>oracle_view</td>
<td>IN VARCHAR2</td>
<td>The name of the Oracle view. It is specified as [schema_name.]oracle_view_name. The default schema name is the current user. If the oracle_view parameter is not specified, the remote table name will be used as the view name.</td>
</tr>
<tr>
<td>parallel_degree</td>
<td>IN NUMBER</td>
<td>The number of parallel processes for the operation is computed based on the range-partition number if applicable, or the number of CPUs. The range of values is 2 to 16.</td>
</tr>
</tbody>
</table>

Usage Notes

- The specified Oracle view is created and future reference of this view utilizes internal database objects for parallel retrieval of remote non-Oracle table data. If the Oracle view already exists, the following Oracle error message is raised:

  ORA-00955: name is already used by an existing object

- This view is created as a read-only view. If you attempt to insert and update the view, the following Oracle error message is raised:

  ORA-01733: virtual column not allowed here

- If the remote table or the database link does not exist, one of the following Oracle error messages is raised:

  ORA-00942: table or view does not exist
  or
  ORA-02019: connection description for remote database not found

- You need the CREATE VIEW, CREATE TABLE, CREATE TYPE, CREATE PACKAGE, and CREATE FUNCTION privileges to execute the CREATE_OR_REPLACE_VIEW procedure.

- If you encounter either of the following Oracle error messages, increase the PROCESSES and SESSIONS parameter in the Oracle initialization parameter file:
ORA-12801: error signaled in parallel query server P003
or
ORA-00018: maximum number of session exceeded

- Because the CREATE_OR_REPLACE_VIEW procedure creates some internal objects, use the DROP_VIEW procedure to drop the view and the internal objects. The SQL DROP VIEW statement only drops the view and not the internal objects.
CREATE_TABLE_TEMPLATE

This procedure writes out a CREATE TABLE template based on information gathered from the remote table. You can use the information to add any optimal Oracle CREATE TABLE clauses.

Syntax

```sql
CREATE_TABLE_TEMPLATE (remote_table, database_link, oracle_table, create_table_template_string)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote_table</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The name of the remote database table. It is specified as [remote_schema_name.]remote_table_name.</td>
</tr>
<tr>
<td>database_link</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The remote database link name. The call can only be applied to a heterogeneous services database link.</td>
</tr>
<tr>
<td>oracle_table</td>
<td>IN VARCHAR2</td>
<td>The name of the local Oracle table the data will be loaded into. It is specified as [schema_name.]oracle_table_name. The default schema name is the current user. If the oracle_table parameter is not specified, the remote table name will be used as the local Oracle name.</td>
</tr>
<tr>
<td>create_table_template_string</td>
<td>OUT VARCHAR2</td>
<td>Contains the Oracle CREATE TABLE SQL template when the procedure is returned.</td>
</tr>
</tbody>
</table>
**DROP_VIEW**

This procedure drops the view and internal objects created by the `CREATE_OR_REPLACE_VIEW` procedure. If the view has not already been created by the `CREATE_OR_REPLACE_VIEW` procedure, an error message is returned.

**Syntax**

```
DROP_VIEW (oracle_view)
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>oracle_view</strong></td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The name of the Oracle view created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure. If the view has not been created by the <code>CREATE_OR_REPLACE_VIEW</code> procedure, an error is returned.</td>
</tr>
</tbody>
</table>
LOAD_TABLE

This procedure loads the data from a remote table to a local Oracle table in parallel. If the local Oracle table does not already exist, it is created automatically.

Syntax

```sql
LOAD_TABLE (remote_table, database_link, oracle_table, truncate, parallel_degree, row_count)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>remote_table</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The name of the remote database table. It is specified as [remote_</td>
</tr>
<tr>
<td></td>
<td></td>
<td>schema_name.]remote_table_name</td>
</tr>
<tr>
<td>database_link</td>
<td>IN VARCHAR2 NOT NULL</td>
<td>The remote database link name. The call can only be applied to a</td>
</tr>
<tr>
<td></td>
<td></td>
<td>heterogeneous services database link.</td>
</tr>
<tr>
<td>oracle_table</td>
<td>IN VARCHAR2</td>
<td>The name of the local Oracle table the data will be loaded into. It is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>specified as [schema_name.]oracle_table_name. The default schema name is</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the current user. If the oracle_table parameter is not specified, the</td>
</tr>
<tr>
<td></td>
<td></td>
<td>remote table name will be used as the local Oracle name.</td>
</tr>
<tr>
<td>truncate</td>
<td>IN BOOLEAN</td>
<td>Determines whether the Oracle table is truncated before the data is loaded.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The value is either TRUE or FALSE. The default value is TRUE which means</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the Oracle table is truncated first. When set to FALSE, the Oracle table</td>
</tr>
<tr>
<td></td>
<td></td>
<td>will not be truncated before the data is loaded.</td>
</tr>
<tr>
<td>parallel_degree</td>
<td>IN NUMBER</td>
<td>The number of parallel processes for the operation is computed based on</td>
</tr>
<tr>
<td></td>
<td></td>
<td>the range-partition number if applicable, or the number of CPUs. The</td>
</tr>
<tr>
<td></td>
<td></td>
<td>range of values is 2 to 16.</td>
</tr>
<tr>
<td>row_count</td>
<td>OUT NUMBER</td>
<td>Contains the number of rows just added with the load table operation.</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure only loads the remote table data into Oracle local table. It does not create a key, index, constraints or any other dependencies such as triggers. It is recommended that you create these dependencies after the table data is loaded as performance will improve greatly. You will need to decide whether to create the dependencies before or after the data is loaded based on your knowledge of the remote table data and dependencies.

- If the local table does not exist, the `LOAD_TABLE` procedure creates a simple (non-partitioned) local table based on the exact column matching of the remote table after which the data is inserted into the local table.
- If the remote table or the database link does not exist, an error message is returned.
- If the local table is incompatible with the remote table, an error message is returned.
- You need the `CREATE TABLE`, `CREATE TYPE`, `CREATE PACKAGE`, and `CREATE FUNCTION` privileges to execute the `LOAD_TABLE` procedure.
- If you encounter either of the following Oracle error messages, increase the `PROCESSES` and `SESSIONS` parameter in Oracle initialization parameter file:
  
  ORA-12801: error signaled in parallel query server P003
  or
  ORA-00018: maximum number of session exceeded

- One of the following is required for parallel processing:
  - The remote table is range partitioned.
  - Histogram information for a numeric column is available.
  - There is a numeric index or primary key.
- To drop the local table, use the `DROP TABLE` SQL statement.
The DBMS_HS_PASSTHROUGH PL/SQL package allows you to send a statement directly to a non-Oracle system without being interpreted by the Oracle server. This can be useful if the non-Oracle system allows operations in statements for which there is no equivalent in Oracle.

This chapter discusses the following topics:

- **Using DBMS_HS_PASSTHROUGH**
  - Overview
  - Operational Notes

- **Summary of DBMS_HS_PASSTHROUGH Subprograms**

**See Also:** *Oracle Database Heterogeneous Connectivity User’s Guide* for more information about this package.
Using DBMS_HS_PASSTHROUGH

This section contains topics which relate to using the DBMS_HS_PASSTHROUGH package.
Overview

You can execute passthrough SQL statements directly at the non-Oracle system using the PL/SQL package `DBMS_HS_PASSTHROUGH`. Any statement executed with this package is executed in the same transaction as standard SQL statements.

See Also: Oracle Database Heterogeneous Connectivity User’s Guide for information about this package
Operational Notes

The `DBMS_HS_PASSTHROUGH` package is a virtual package. It conceptually resides at the non-Oracle system. In reality, however, calls to this package are intercepted by Heterogeneous Services and mapped to one or more Heterogeneous Services calls. The driver, in turn, maps these Heterogeneous Services calls to the API of the non-Oracle system. The client application should invoke the procedures in the package through a database link in exactly the same way as it would invoke a non-Oracle system stored procedure. The special processing done by Heterogeneous Services is transparent to the user.
## Summary of DBMS_HS_PASSTHROUGH Subprograms

BIND_INOUT_VARIABLE Procedure

This procedure binds IN OUT bind variables.

Syntax

DBMS_HS_PASSTHROUGH.BIND_INOUT_VARIABLE (  
c     IN     BINARY_INTEGER NOT NULL,  
p     IN     BINARY_INTEGER NOT NULL,  
v     IN OUT <dty>,  
n     IN     VARCHAR2);  

<dty> is either DATE, NUMBER, or VARCHAR2.

See Also: For binding IN OUT variables of data type RAW see BIND_INOUT_VARIABLE_RAW Procedure on page 75-7.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
</tbody>
</table>
| v         | This value is used for two purposes:  
- To provide the IN value before the SQL statement is run.  
- To determine the size of the out value.  
(Optional) Name of the bind variable.  
For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable :ename is 1, the name is :ename.  
This parameter can be used if the non-Oracle system supports "named binds" instead of positional binds. Passing the position is still required. |
| n         | |

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28552</td>
<td>Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)</td>
</tr>
<tr>
<td>ORA-28553</td>
<td>The position of the bind variable is out of range.</td>
</tr>
<tr>
<td>ORA-28555</td>
<td>A NULL value was passed for a NOT NULL parameter.</td>
</tr>
</tbody>
</table>

BIND_INOUT_VARIABLE_RAW Procedure

This procedure binds IN OUT bind variables of data type RAW.

Syntax

```
DBMS_HS_PASSTHROUGH.BIND_INOUT_VARIABLE_RAW (c IN BINARY_INTEGER NOT NULL,
p IN BINARY_INTEGER NOT NULL,
v IN OUT RAW,
n IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>This value is used for two purposes: - To provide the IN value before the SQL statement is run. - To determine the size of the OUT value.</td>
</tr>
<tr>
<td>n</td>
<td>(Optional) Name the bind variable. For example, in <code>SELECT * FROM emp WHERE ename=:ename</code>, the position of the bind variable <code>ename</code> is 1, the name is <code>ename</code>. This parameter can be used if the non-Oracle system supports &quot;named binds&quot; instead of positional binds. Passing the position is still required.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>

BIND_OUT_VARIABLE Procedure

This procedure binds an OUT variable with a PL/SQL program variable.

Syntax

```sql
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE (  
c      IN  BINARY_INTEGER NOT NULL,  
p      IN  BINARY_INTEGER NULL,  
v      OUT <dty>,  
n      IN  VARCHAR2);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

See Also: For binding OUT variables of data type RAW, see BIND_OUT_VARIABLE_RAW Procedure on page 75-9.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>Variable in which the OUT bind variable stores its value. The package remembers only the &quot;size&quot; of the variable. After the SQL statement is run, you can use GET_VALUE to retrieve the value of the OUT parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using BIND_OUT_VARIABLE.</td>
</tr>
<tr>
<td>n</td>
<td>(Optional) Name of the bind variable. For example, in SELECT * FROM emp WHERE ename=:ename, the position of the bind variable ename is 1, the name is ename. This parameter can be used if the non-Oracle system supports &quot;named binds&quot; instead of positional binds. Passing the position is still required.</td>
</tr>
</tbody>
</table>

**BIND_OUT_VARIABLE_RAW Procedure**

This procedure binds an `OUT` variable of data type `RAW` with a PL/SQL program variable.

**Syntax**

```plaintext
DBMS_HS_PASSTHROUGH.BIND_OUT_VARIABLE_RAW (  
  c     IN  BINARY_INTEGER NOT NULL,  
  p     IN  BINARY_INTEGER NOT NULL,  
  v     OUT RAW,  
  n     IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>c</code></td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.</td>
</tr>
<tr>
<td><code>p</code></td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td><code>v</code></td>
<td>Variable in which the <code>OUT</code> bind variable stores its value. The package remembers only the &quot;size&quot; of the variable. After the SQL statement is run, you can use <code>GET_VALUE</code> to retrieve the value of the <code>OUT</code> parameter. The size of the retrieved value should not exceed the size of the parameter that was passed using <code>BIND_OUT_VARIABLE_RAW</code>.</td>
</tr>
<tr>
<td><code>n</code></td>
<td>(Optional) Name of the bind variable. For example, in <code>SELECT * FROM emp WHERE ename=:ename</code>, the position of the bind variable <code>ename</code> is 1, the name is <code>ename</code>. This parameter can be used if the non-Oracle system supports &quot;named binds&quot; instead of positional binds. Passing the position is still required.</td>
</tr>
</tbody>

</tr>
</tbody>
</table>

**Pragmas**

Purity level defined: WNDS, RNDS
BIND_VARIABLE Procedure

This procedure binds an IN variable positionally with a PL/SQL program variable.

Syntax

```sql
DBMS_HS_PASSTHROUGH.BIND_VARIABLE (  
c    IN BINARY_INTEGER NOT NULL,
  p    IN BINARY_INTEGER NOT NULL,
  v    IN <dty>,
  n    IN VARCHAR2);
```

<dty> is either DATE, NUMBER, or VARCHAR2.

**See Also:** To bind RAW variables use BIND_VARIABLE_RAW Procedure on page 75-11.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>Value that must be passed to the bind variable name.</td>
</tr>
<tr>
<td>n</td>
<td>(Optional) Name of the bind variable. For example, in <code>SELECT * FROM emp WHERE ename=:ename</code>, the position of the bind variable :ename is 1, the name is :ename. This parameter can be used if the non-Oracle system supports &quot;named binds&quot; instead of positional binds. Passing the position is still required.</td>
</tr>
</tbody>
</table>

**BIND_VARIABLE_RAW Procedure**

This procedure binds `IN` variables of type `RAW`.

**Syntax**

```sql
DBMS_HS_PASSTHROUGH.BIND_VARIABLE_RAW (
    c    IN BINARY_INTEGER NOT NULL,
    p    IN BINARY_INTEGER NOT NULL,
    v    IN RAW,
    n    IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>Value that must be passed to the bind variable.</td>
</tr>
<tr>
<td>n</td>
<td>(Optional) Name of the bind variable. For example, in <code>SELECT * FROM emp WHERE ename=:ename</code>, the position of the bind variable <code>ename</code> is 1, the name is <code>ename</code>. CLOSE_CURSOR Procedure

This function closes the cursor and releases associated memory after the SQL statement has been run at the non-Oracle system. If the cursor was not open, then the operation is a "no operation".

Syntax

```sql
DBMS_HS_PASSTHROUGH.CLOSE_CURSOR (c IN BINARY_INTEGER NOT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor to be released.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>

<tr>
<td>ORA-28555</td>
<td>A NULL value was passed for a NOT NULL parameter.</td>
</tr>
</tbody>
</table>

Pragmas

Purity level defined : WNDS, RNDS
EXECUTE_IMMEDIATE Procedure

This function runs a SQL statement immediately. Any valid SQL command except SELECT can be run immediately. The statement must not contain any bind variables. The statement is passed in as a VARCHAR2 in the argument. Internally the SQL statement is run using the PASSTHROUGH SQL protocol sequence of OPEN_CURSOR, PARSE, EXECUTE_NON_QUERY, CLOSE_CURSOR.

Syntax

```sql
DBMS_HS_PASSTHROUGH.EXECUTE_IMMEDIATE (  
    s IN VARCHAR2 NOT NULL)  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Table 75–16 EXECUTE_IMMEDIATE Procedure Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>s</td>
</tr>
</tbody>
</table>

Return Values

The number of rows affected by the execution of the SQL statement.

Exceptions

<table>
<thead>
<tr>
<th>Table 75–17 EXECUTE_IMMEDIATE Procedure Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception</td>
</tr>
<tr>
<td>-----------</td>
</tr>
<tr>
<td>ORA-28551</td>
</tr>
<tr>
<td>ORA-28554</td>
</tr>
<tr>
<td>ORA-28555</td>
</tr>
</tbody>
</table>
EXECUTE_NON_QUERY Function

This function runs a SQL statement. The SQL statement cannot be a `SELECT` statement. A cursor has to be open and the SQL statement has to be parsed before the SQL statement can be run.

Syntax

```
DBMS_HS_PASSTHROUGH.EXECUTE_NON_QUERY (
    c IN BINARY_INTEGER NOT NULL)
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines <code>OPEN_CURSOR</code> and <code>PARSE</code> respectively.</td>
</tr>
</tbody>
</table>

Return Values

The number of rows affected by the SQL statement in the non-Oracle system

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28552</td>
<td><code>BIND_VARIABLE</code> procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)</td>
</tr>
<tr>
<td>ORA-28555</td>
<td>A <code>NULL</code> value was passed for a <code>NOT NULL</code> parameter.</td>
</tr>
</tbody>
</table>
**FETCH_ROW Function**

This function fetches rows from a result set. The result set is defined with a SQL SELECT statement. When there are no more rows to be fetched, the exception NO_DATA_FOUND is raised. Before the rows can be fetched, a cursor has to be opened, and the SQL statement has to be parsed.

**Syntax**

```sql
DBMS_HS_PASSTHROUGH.FETCH_ROW (  
  c   IN BINARY_INTEGER NOT NULL,  
  f   IN BOOLEAN)  
RETURN BINARY_INTEGER;
```

**Parameters**

**Table 75–20 FETCH_ROW Function Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
</tbody>
</table>
| first     | (Optional) Reexecutes SELECT statement. Possible values:  
- TRUE: reexecute SELECT statement.  
- FALSE: fetch the next row, or if run for the first time, then execute and fetch rows (default). |

**Return Values**

The returns the number of rows fetched. The function returns "0" if the last row was already fetched.

**Exceptions**

**Table 75–21 FETCH_ROW Function Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28552</td>
<td>Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)</td>
</tr>
<tr>

Purity level defined : WND5
GET_VALUE Procedure

This procedure has two purposes:

- It retrieves the select list items of SELECT statements, after a row has been fetched.
- It retrieves the OUT bind values, after the SQL statement has been run.

Syntax

```sql
DBMS_HS_PASSTHROUGH.GET_VALUE (  
    c      IN  BINARY_INTEGER NOT NULL,  
    p    IN  BINARY_INTEGER NOT NULL,  
    v    OUT <dty>);  
```

<dty> is either DATE, NUMBER, or VARCHAR2.

See Also: For retrieving values of data type RAW, see GET_VALUE_RAW Procedure on page 75-17.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable or select list item in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>Variable in which the OUT bind variable or select list item stores its value.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-1403</td>
<td>Returns NO_DATA_FOUND exception when running the GET_VALUE after the last row was fetched (that is, FETCH_ROW returned &quot;0&quot;).</td>
</tr>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28552</td>
<td>Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)</td>
</tr>
<tr>
<td>ORA-28553</td>
<td>The position of the bind variable is out of range.</td>
</tr>
<tr>
<td>ORA-28555</td>
<td>A NULL value was passed for a NOT NULL parameter.</td>
</tr>
</tbody>
</table>

Purity level defined : WNDS
GET_VALUE_RAW Procedure

This procedure is similar to GET_VALUE, but for data type RAW.

Syntax

```sql
DBMS_HS_PASSTHRUGH.GET_VALUE_RAW (  
    c    IN  BINARY_INTEGER NOT NULL,  
    p    IN  BINARY_INTEGER NOT NULL,  
    v    OUT RAW);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened and parsed, using the routines OPEN_CURSOR and PARSE respectively.</td>
</tr>
<tr>
<td>p</td>
<td>Position of the bind variable or select list item in the SQL statement: Starts at 1.</td>
</tr>
<tr>
<td>v</td>
<td>Variable in which the OUT bind variable or select list item stores its value.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-1403</td>
<td>Returns NO_DATA_FOUND exception when running the GET_VALUE after the last row was fetched (that is, FETCH_ROW returned &quot;0&quot;).</td>
</tr>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28552</td>
<td>Procedure is not run in right order. (Did you first open the cursor and parse the SQL statement?)</td>
</tr>
<tr>
<td>ORA-28553</td>
<td>The position of the bind variable is out of range.</td>
</tr>
<tr>
<td>ORA-28555</td>
<td>A NULL value was passed for a NOT NULL parameter.</td>
</tr>
</tbody>
</table>

OPEN_CURSOR Function

This function opens a cursor for running a passthrough SQL statement at the non-Oracle system. This function must be called for any type of SQL statement. The function returns a cursor, which must be used in subsequent calls. This call allocates memory. To deallocate the associated memory, call the procedure CLOSE_CURSOR.

Syntax

```sql
DBMS_HS_PASSTHROUGH.OPEN_CURSOR
RETURN BINARY_INTEGER;
```

Return Values

The cursor to be used on subsequent procedure and function calls.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-28554</td>
<td>Maximum number of open cursor has been exceeded. Increase Heterogeneous Services' OPEN_CURSORS initialization parameter.</td>
</tr>
</tbody>
</table>

Purity level defined : WNDS, RNDS
PARSE Procedure

This procedure parses SQL statement at non-Oracle system.

Syntax

```
DBMS_HS_PASSTHROUGH.PARSE (    
   c       IN  BINARY_INTEGER NOT NULL,    
   stmt    IN  VARCHAR2 NOT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>Cursor associated with the passthrough SQL statement. Cursor must be opened using function OPEN_CURSOR.</td>
</tr>
<tr>
<td>stmt</td>
<td>Statement to be parsed.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-28550</td>
<td>The cursor passed is invalid.</td>
</tr>
<tr>
<td>ORA-28551</td>
<td>SQL statement is illegal.</td>
</tr>
<tr>
<td>ORA-28555</td>
<td>A NULL value was passed for a NOT NULL parameter.</td>
</tr>
</tbody>
</table>

The DBMS_IOT package creates a table into which references to the chained rows for an index-organized table can be placed using the ANALYZE command. DBMS_IOT can also create an exception table into which references to the rows of an index-organized table that violate a constraint can be placed during the enable_constraint operation.

DBMS_IOT is not loaded during database installation. To install DBMS_IOT, run dbmsiotc.sql, available in the ADMIN directory.

This chapter contains the following topics:

- Summary of DBMS_IOT Subprograms

**Note:** With the introduction of logical-rowids for IOTs with Oracle Database Release 8.1, you no longer need to use the procedures contained in this package which is retained for backward compatibility only. It is however required for servers running with Oracle Database Release 8.0.
Summary of DBMS_IOT Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUILD_CHAIN_ROWS_TABLE Procedure on page 76-3</td>
<td>Creates a table into which references to the chained rows for an index-organized table can be placed using the <code>ANALYZE</code> command</td>
</tr>
<tr>
<td>BUILD_EXCEPTIONS_TABLE Procedure on page 76-4</td>
<td>Creates an exception table into which rows of an index-organized table that violate a constraint can be placed</td>
</tr>
</tbody>
</table>
**BUILD_CHAIN_ROWS_TABLE Procedure**

This procedure creates a table into which references to the chained rows for an index-organized table can be placed using the `ANALYZE` command.

**Syntax**

```sql
DBMS_IOT.BUILD_CHAIN_ROWS_TABLE (
    owner               IN VARCHAR2,
    iot_name            IN VARCHAR2,
    chainrow_table_name IN VARCHAR2 default 'IOT_CHAINED_ROWS');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>Owner of the index-organized table.</td>
</tr>
<tr>
<td>iot_name</td>
<td>Index-organized table name.</td>
</tr>
<tr>
<td>chainrow_table_name</td>
<td>Intended name for the chained-rows table.</td>
</tr>
</tbody>
</table>

**Usage Notes**

You should create a separate chained-rows table for each index-organized table to accommodate its primary key.

**Examples**

```
CREATE TABLE l(a char(16), b char(16), c char(16), d char(240),
    PRIMARY KEY(a,b,c)) ORGANIZATION INDEX pctthreshold 10 overflow;
EXECUTE DBMS_IOT.BUILD_CHAIN_ROWS_TABLE('SYS','l','LC');
```

A chained-row table is created with the following columns:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>OWNER_NAME</td>
<td></td>
<td>VARCHAR2 (30)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td>VARCHAR2 (30)</td>
</tr>
<tr>
<td>CLUSTER_NAME</td>
<td></td>
<td>VARCHAR2 (30)</td>
</tr>
<tr>
<td>PARTITION_NAME</td>
<td></td>
<td>VARCHAR2 (30)</td>
</tr>
<tr>
<td>SUBPARTITION_NAME</td>
<td></td>
<td>VARCHAR2 (30)</td>
</tr>
<tr>
<td>HEAD_ROWID</td>
<td></td>
<td>ROWID</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td></td>
<td>DATE</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td>CHAR (16)</td>
</tr>
<tr>
<td>B</td>
<td></td>
<td>CHAR (16)</td>
</tr>
<tr>
<td>C</td>
<td></td>
<td>CHAR (16)</td>
</tr>
</tbody>
</table>
BUILD_EXCEPTIONS_TABLE Procedure

This procedure creates an exception table into which rows of an index-organized table that violate a constraint can be placed during the execution of the following SQL statements:

- ALTER TABLE ... ENABLE CONSTRAINT ... EXCEPTIONS INTO
- ALTER TABLE ... ADD CONSTRAINT ... EXCEPTIONS INTO

Syntax

```sql
DBMS_IOT.BUILD_EXCEPTIONS_TABLE (
    owner                 IN VARCHAR2,
    iot_name              IN VARCHAR2,
    exceptions_table_name IN VARCHAR2 default 'IOT_EXCEPTIONS');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>Owner of the index-organized table.</td>
</tr>
<tr>
<td>iot_name</td>
<td>Index-organized table name.</td>
</tr>
<tr>
<td>exceptions_table_name</td>
<td>Intended name for exception-table.</td>
</tr>
</tbody>
</table>

Usage Notes

You should create a separate exception table for each index-organized table to accommodate its primary key.

Examples

```sql
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE('SYS','L','LE');
```

An exception table for the preceding index-organized table with the following columns:

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Null?</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROW_ID</td>
<td></td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>OWNER</td>
<td></td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>TABLE_NAME</td>
<td></td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>CONSTRAINT</td>
<td></td>
<td>VARCHAR2(30)</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>B</td>
<td></td>
<td>CHAR(16)</td>
</tr>
<tr>
<td>C</td>
<td></td>
<td>CHAR(16)</td>
</tr>
</tbody>
</table>
The DBMS_JAVA package provides a PL/SQL interface for accessing database functionality from Java.

- Documentation of DBMS_JAVA
For a complete description of this package within the context of DBMS_JAVA, see DBMS_JAVA in the Oracle Database Java Developer’s Guide.
The DBMS_JOB package schedules and manages jobs in the job queue.

**Note:** The DBMS_JOB package has been superseded by the DBMS_SCHEDULER package. In particular, if you are administering jobs to manage system load, you should consider disabling DBMS_JOB by revoking the package execution privilege for users.

For more information, see Chapter 129, "DBMS_SCHEDULER" and "Moving from DBMS_JOB to DBMS_SCHEDULER" in Oracle Database Administrator’s Guide.

This chapter contains the following topics:

- **Using DBMS_JOB**
  - Security Model
  - Operational Notes
- **Summary of DBMS_JOB Subprograms**
Using DBMS_JOB

- Security Model
- Operational Notes
Security Model

No specific system privileges are required to use DBMS_JOB. No system privileges are available to manage DBMS_JOB. Jobs cannot be altered or deleted other than jobs owned by the user. This is true for all users including those users granted DBA privileges.

You can execute procedures that are owned by the user or for which the user is explicitly granted EXECUTE. However, procedures for which the user is granted the execute privilege through roles cannot be executed.

Note that, once a job is started and running, there is no easy way to stop the job.
Operational Notes

- Working with Oracle Real Application Clusters
- Stopping a Job

Working with Oracle Real Application Clusters

DBMS_JOB supports multi-instance execution of jobs. By default jobs can be executed on any instance, but only one single instance will execute the job. In addition, you can force instance binding by binding the job to a particular instance. You implement instance binding by specifying an instance number to the instance affinity parameter. Note, however, that in Oracle Database 10g Release 1 (10.1) instance binding is not recommended. Service affinity is preferred. This concept is implemented in the DBMS_SCHEDULER package.

The following procedures can be used to create, alter or run jobs with instance affinity. Note that not specifying affinity means any instance can run the job.

**DBMS_JOB.SUBMIT**

To submit a job to the job queue, use the following syntax:

```sql
DBMS_JOB.SUBMIT(
    job       OUT    BINARY_INTEGER,
    what      IN     VARCHAR2, NEXT_DATE IN DATE DEFAULT SYSDATE,
    interval  IN     VARCHAR2 DEFAULT 'NULL',
    no_parse  IN     BOOLEAN DEFAULT FALSE,
    instance  IN     BINARY_INTEGER DEFAULT ANY_INSTANCE,
    force     IN     BOOLEAN DEFAULT FALSE);
```

Use the parameters `instance` and `force` to control job and instance affinity. The default value of `instance` is 0 (zero) to indicate that any instance can execute the job. To run the job on a certain instance, specify the `instance` value. Oracle displays error ORA-23319 if the `instance` value is a negative number or NULL.

The `force` parameter defaults to false. If `force` is TRUE, any positive integer is acceptable as the job instance. If `force` is FALSE, the specified instance must be running, or Oracle displays error number ORA-23428.

**DBMS_JOB.INSTANCE**

To assign a particular instance to execute a job, use the following syntax:

```sql
DBMS_JOB.INSTANCE(  JOB IN BINARY_INTEGER,
    instance                IN BINARY_INTEGER,
    force                   IN BOOLEAN DEFAULT FALSE);
```

The `FORCE` parameter in this example defaults to FALSE. If the instance value is 0 (zero), job affinity is altered and any available instance can execute the job despite the value of force. If the `instance` value is positive and the `force` parameter is FALSE, job affinity is altered only if the specified instance is running, or Oracle displays error ORA-23428.

If the `force` parameter is TRUE, any positive integer is acceptable as the job instance and the job affinity is altered. Oracle displays error ORA-23319 if the `instance` value is negative or NULL.

**DBMS_JOB.CHANGE**

To alter user-definable parameters associated with a job, use the following syntax:
DBMS_JOB.CHANGE(  JOB IN BINARY_INTEGER,
    what   IN VARCHAR2 DEFAULT NULL,
next_date IN DATE DEFAULT NULL,
interval IN VARCHAR2 DEFAULT NULL,
instance IN BINARY_INTEGER DEFAULT NULL,
force   IN BOOLEAN DEFAULT FALSE );

Two parameters, instance and force, appear in this example. The default value of instance is null indicating that job affinity will not change.

The default value of force is FALSE. Oracle displays error ORA-23428 if the specified instance is not running and error ORA-23319 if the instance number is negative.

DBMS_JOB.RUN
The force parameter for DBMS_JOB.RUN defaults to FALSE. If force is TRUE, instance affinity is irrelevant for running jobs in the foreground process. If force is FALSE, the job can run in the foreground only in the specified instance. Oracle displays error ORA-23428 if force is FALSE and the connected instance is the incorrect instance.

DBMS_JOB.RUN(
    job  IN BINARY_INTEGER,
    force IN BOOLEAN DEFAULT FALSE);

Stopping a Job
Note that, once a job is started and running, there is no easy way to stop the job.
# Summary of DBMS_JOB Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BROKEN Procedure on page 78-7</td>
<td>Disables job execution</td>
</tr>
<tr>
<td>CHANGE Procedure on page 78-8</td>
<td>Alters any of the user-definable parameters associated with a job</td>
</tr>
<tr>
<td>INSTANCE Procedure on page 78-9</td>
<td>Assigns a job to be run by a instance</td>
</tr>
<tr>
<td>INTERVAL Procedure on page 78-10</td>
<td>Alters the interval between executions for a specified job</td>
</tr>
<tr>
<td>NEXT_DATE Procedure on page 78-11</td>
<td>Alters the next execution time for a specified job</td>
</tr>
<tr>
<td>REMOVE Procedure on page 78-12</td>
<td>Removes specified job from the job queue</td>
</tr>
<tr>
<td>RUN Procedure on page 78-13</td>
<td>Forces a specified job to run</td>
</tr>
<tr>
<td>SUBMIT Procedure on page 78-14</td>
<td>Submits a new job to the job queue</td>
</tr>
<tr>
<td>USER_EXPORT Procedures on page 78-16</td>
<td>Re-creates a given job for export, or re-creates a given job for export with instance affinity</td>
</tr>
<tr>
<td>WHAT Procedure on page 78-17</td>
<td>Alters the job description for a specified job</td>
</tr>
</tbody>
</table>
BROKEN Procedure

This procedure sets the broken flag. Broken jobs are never run.

Syntax

```sql
DBMS_JOB.BROKEN (
    job       IN  BINARY_INTEGER,
    broken    IN  BOOLEAN,
    next_date IN  DATE DEFAULT SYSDATE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>broken</td>
<td>Job broken: IN value is FALSE.</td>
</tr>
<tr>
<td>next_date</td>
<td>Date of the next refresh.</td>
</tr>
</tbody>
</table>

Note: If you set job as broken while it is running, Oracle resets the job’s status to normal after the job completes. Therefore, only execute this procedure for jobs that are not running.

Usage Notes

You must issue a COMMIT statement immediately after the statement.
CHANGE Procedure

This procedure changes any of the fields a user can set in a job.

Syntax

```
DBMS_JOB.CHANGE (  
  job       IN  BINARY_INTEGER,  
  what      IN  VARCHAR2,  
  next_date IN  DATE,  
  interval  IN  VARCHAR2,  
  instance  IN  BINARY_INTEGER DEFAULT NULL,  
  force     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>what</td>
<td>PL/SQL procedure to run.</td>
</tr>
<tr>
<td>next_date</td>
<td>Date of the next refresh.</td>
</tr>
<tr>
<td>interval</td>
<td>Date function; evaluated immediately before the job starts running.</td>
</tr>
<tr>
<td>instance</td>
<td>When a job is submitted, specifies which instance can run the job. This defaults to NULL, which indicates that instance affinity is not changed.</td>
</tr>
</tbody>
</table>
| force     | If this is FALSE, then the specified instance (to which the instance number change) must be running. Otherwise, the routine raises an exception.  
|           | If this is TRUE, then any positive integer is acceptable as the job instance. |

Usage Notes

- You must issue a COMMIT statement immediately after the statement.
- The parameters instance and force are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.
- If the parameters what, next_date, or interval are NULL, then leave that value as it is.

Example

```
BEGIN
  DBMS_JOB.CHANGE(14144, null, null, 'sysdate+3');
  COMMIT;
END;
```
INSTANCE Procedure

This procedure changes job instance affinity.

Syntax

DBMS_JOB.INSTANCE (
    job        IN BINARY_INTEGER,
    instance   IN BINARY_INTEGER,
    force      IN BOOLEAN DEFAULT FALSE);

Parameters

Table 78–4  INSTANCE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>instance</td>
<td>When a job is submitted, a user can specify which instance can run the job.</td>
</tr>
<tr>
<td>force</td>
<td>If this is TRUE, then any positive integer is acceptable as the job instance. If this is FALSE (the default), then the specified instance must be running; otherwise the routine raises an exception.</td>
</tr>
</tbody>
</table>

Usage Notes

You must issue a COMMIT statement immediately after the statement.
### INTERVAL Procedure

This procedure changes how often a job runs.

#### Syntax

```sql
DBMS_JOB.INTERVAL (  
    job       IN  BINARY_INTEGER,  
    interval  IN  VARCHAR2);
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>job</code></td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td><code>interval</code></td>
<td>Date function, evaluated immediately before the job starts running.</td>
</tr>
</tbody>
</table>

#### Usage Notes

- If the job completes successfully, then this new date is placed in `next_date`. `interval` is evaluated by plugging it into the statement `select interval into next_date from dual;`
- The `interval` parameter must evaluate to a time in the future. Legal intervals include:

<table>
<thead>
<tr>
<th>Interval</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>'sysdate + 7'</code></td>
<td>Run once a week.</td>
</tr>
<tr>
<td><code>'next_day(sysdate,'''TUESDAY'''</code></td>
<td>Run once every Tuesday.</td>
</tr>
<tr>
<td><code>'null'</code></td>
<td>Run only once.</td>
</tr>
</tbody>
</table>
- If `interval` evaluates to `NULL` and if a job completes successfully, then the job is automatically deleted from the queue.
- You must issue a `COMMIT` statement immediately after the statement.
NEXT_DATE Procedure

This procedure changes when an existing job next runs.

Syntax

```sql
DBMS_JOB.NEXT_DATE (  
    job       IN  BINARY_INTEGER,  
    next_date IN  DATE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>next_date</td>
<td>Date of the next refresh: it is when the job will be automatically run, assuming there are background processes attempting to run it.</td>
</tr>
</tbody>
</table>

Usage Notes

You must issue a COMMIT statement immediately after the statement.
REMOVE Procedure

This procedure removes an existing job from the job queue. This currently does not stop a running job.

Syntax

```
DBMS_JOB.REMOVE (
    job       IN  BINARY_INTEGER );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
</tbody>
</table>

Usage Notes

You must issue a COMMIT statement immediately after the statement.

Example

```
BEGIN
    DBMS_JOB.REMOVE(14144);
    COMMIT;
END;
```
RUN Procedure

This procedure runs job JOB now. It runs it even if it is broken.
Running the job recomputes next_date. See view user_jobs.

Syntax

DBMS_JOB.RUN ( 
    job       IN  BINARY_INTEGER, 
    force     IN  BOOLEAN DEFAULT FALSE);

Parameters

Table 78–8  RUN Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>force</td>
<td>If this is TRUE, then instance affinity is irrelevant for running jobs in the foreground process. If this is FALSE, then the job can be run in the foreground only in the specified instance.</td>
</tr>
</tbody>
</table>

Example

EXECUTE DBMS_JOB.RUN(14144);

Caution:  This re-initializes the current session's packages.

Exceptions

An exception is raised if force is FALSE, and if the connected instance is the wrong one.
SUBMIT Procedure

This procedure submits a new job. It chooses the job from the sequence sys.jobseq.

Syntax

```sql
DBMS_JOB.SUBMIT (  
  job       OUT BINARY_INTEGER,  
  what      IN  VARCHAR2,  
  next_date IN  DATE DEFAULT sysdate,  
  interval  IN  VARCHAR2 DEFAULT 'null',  
  no_parse  IN  BOOLEAN DEFAULT FALSE,  
  instance  IN  BINARY_INTEGER DEFAULT any_instance,  
  force     IN  BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>what</td>
<td>PL/SQL procedure to run.</td>
</tr>
<tr>
<td>next_date</td>
<td>Next date when the job will be run.</td>
</tr>
<tr>
<td>interval</td>
<td>Date function that calculates the next time to run the job. The default is NULL. This must evaluate to a either a future point in time or NULL.</td>
</tr>
<tr>
<td>no_parse</td>
<td>A flag. The default is FALSE. If this is set to FALSE, then Oracle parses the procedure associated with the job. If this is set to TRUE, then Oracle parses the procedure associated with the job the first time that the job is run. For example, if you want to submit a job before you have created the tables associated with the job, then set this to TRUE.</td>
</tr>
<tr>
<td>instance</td>
<td>When a job is submitted, specifies which instance can run the job.</td>
</tr>
<tr>
<td>force</td>
<td>If this is TRUE, then any positive integer is acceptable as the job instance. If this is FALSE (the default), then the specified instance must be running; otherwise the routine raises an exception.</td>
</tr>
</tbody>
</table>

Usage Notes

- You must issue a COMMIT statement immediately after the statement.
- The parameters instance and force are added for job queue affinity. Job queue affinity gives users the ability to indicate whether a particular instance or any instance can run a submitted job.

Example

This submits a new job to the job queue. The job calls the procedure DBMS_DDL.Analyze_Object to generate optimizer statistics for the table DQUON.ACCOUNTS. The statistics are based on a sample of half the rows of the ACCOUNTS table. The job is run every 24 hours:

```sql
VARIABLE jobno number;
```
BEGIN
    DBMS_JOB.SUBMIT(:jobno,
        'dbms_ddl.analyze_object(''TABLE'','
        ''DQUON'', ''ACCOUNTS'','
        ''ESTIMATE'', NULL, 50);'
        SYSDATE, 'SYSDATE + 1');
    COMMIT;
END;
/
Statement processed.
print jobno
JOBNO
----------
14144
USER_EXPORT Procedures

There are two overloaded procedures. The first produces the text of a call to re-create the given job. The second alters instance affinity (8i and after) and preserves the compatibility.

Syntax

```sql
DBMS_JOB.USER_EXPORT (    job IN BINARY_INTEGER,    mycall IN OUT VARCHAR2);

DBMS_JOB.USER_EXPORT (    job IN BINARY_INTEGER,    mycall IN OUT VARCHAR2,    myinst IN OUT VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>mycall</td>
<td>Text of a call to re-create the given job.</td>
</tr>
<tr>
<td>myinst</td>
<td>Text of a call to alter instance affinity.</td>
</tr>
</tbody>
</table>
WHAT Procedure

This procedure changes what an existing job does, and replaces its environment.

Syntax

```sql
DBMS_JOB.WHAT (
    job       IN  BINARY_INTEGER,
    what      IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job</td>
<td>Number of the job being run.</td>
</tr>
<tr>
<td>what</td>
<td>PL/SQL procedure to run.</td>
</tr>
</tbody>
</table>

Usage Notes

- You must issue a `COMMIT` statement immediately after the statement.
- Some legal values of `what` (assuming the routines exist) are:
  - `'myproc(''10-JAN-82'', next_date, broken)';`
  - `'scott.emppackage.give_raise(''JENKINS'', 30000.00)';`
  - `'dbms_job.remove(job);'`
The DBMS_LDAP package lets you access data from LDAP servers.

- Documentation of DBMS_LDAP
For a complete description of this package within the context of Oracle Internet Directory, see `DBMS_LDAP` in the *Oracle Fusion Middleware Application Developer’s Guide for Oracle Identity Management*. 
The DBMS_LDAP_UTL package contains the Oracle Extension utility functions.

- Documentation of DBMS_LDAP_UTL
Documentation of DBMS_LDAP_UTL

For a complete description of this package within the context of Oracle Internet Directory, see DBMS_LDAP_UTL in the Oracle Internet Directory Application Developer’s Guide.
The DBMS_LIBCACHE package consists of one subprogram that prepares the library cache on an Oracle instance by extracting SQL and PL/SQL from a remote instance and compiling this SQL locally without execution. The value of compiling the cache of an instance is to prepare the information the application requires to execute in advance of failover or switchover.

This chapter contains the following topics:

- Using DBMS_LIBCACHE
  - Overview
  - Security Model
- Summary of DBMS_LIBCACHE Subprograms
Using DBMS_LIBCACHE

- Overview
- Security Model
Overview

Compiling a shared cursor consists of open, parse, and bind operations, plus the type-checking and execution plan functions performed at the first execution. All of these steps are executed in advance by the package DBMS_LIBCACHE for SELECT statements. The open and parse functions are executed in advance for PL/SQL and DML. For PL/SQL, executing the parse phase has the effect of loading all library cache heaps other than the MCODE.
Security Model

To execute `DBMS_LIBCACHE` you must directly access the same objects as do SQL statements. You can best accomplish this by utilizing the same user id as the original system on the remote system.

When there are multiple schema users, `DBMS_LIBCACHE` should be called for each.

Alternatively, `DBMS_LIBCACHE` may be called with the generic user `PARSER`. However, this user cannot parse the SQL that uses objects with access granted though roles. This is a standard PL/SQL security limitation.
## Summary of DBMS_LIBCACHE Subprograms

<table>
<thead>
<tr>

</thead>
<tbody>
<tr>
<td>COMPILE_FROM_REMOTE Procedure on page 81-6</td>
<td>Extracts SQL in batch from the source instance and compiles the SQL at the target instance</td>
</tr>
</tbody>
</table>
COMPILE_FROM_REMOTE Procedure

This procedure extracts SQL in batch from the source instance and compiles the SQL at the target instance.

Syntax

```sql
DBMS_LIBCACHE.COMPILE_FROM_REMOTE (
  p_db_link                 IN     dbms_libcache$def.db_link%type,
  p_username                IN     VARCHAR2 default null,
  p_threshold_executions    IN     NATURAL  default 3,
  p_threshold_sharable_mem  IN     NATURAL  default 1000,
  p_parallel_degree         IN     NATURAL  default 1);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_db_link</td>
<td>Database link to the source name (mandatory). The database link pointing to the instance that will be used for extracting the SQL statements. The user must have the role SELECT_ON_CATALOG at the source instance. For improved security, the connection may use a password file or LDAP authentication. The database link is mandatory only for releases with <code>dbms_libcache$def.ACCESS_METHOD = DB_LINK_METHOD</code></td>
</tr>
<tr>
<td>p_instance_name</td>
<td>(Reserved for future use). The name of the instance that will be used for extracting the SQL statements. The instance name must be unique for all instances excluding the local instance. The name is not case sensitive.</td>
</tr>
<tr>
<td>p_username</td>
<td>Source username (default is all users). The name of the username that will be used for extracting the SQL statements. The username is an optional parameter that is used to ensure the parsing user id is the same as that on the source instance. For an application where users connect as a single user id, for example APPS, APPS is the parsing user id that is recorded in the shared pool. To select only SQL statements parsed by APPS, enter the string ‘APPS’ in this field. To also select statements executed by batch, repeat the executing the procedure with the schema owner, for example GL. If the username is supplied, it must be valid. The name is not case sensitive.</td>
</tr>
<tr>
<td>p_threshold_executions</td>
<td>The lower bound for the number of executions, below which a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with executions, for example, greater than 3. The default value is 1. This means SQL statements that have never executed, including invalid SQL statements, will not be extracted.</td>
</tr>
</tbody>
</table>
The lower bound for the size of the shared memory consumed by the cursors on the source instance. Below this value a SQL statement will not be selected for parsing. This parameter is optional. It allows the application to extract and compile statements with shared memory for example, greater than 10000 bytes.

The number of parallel jobs that execute to complete the parse operation. These tasks are spawned as parallel jobs against a sub-range of the SQL statements selected for parsing. This parameter is reserved for parallel compile jobs which are currently not implemented.

</tbody>
</table>
The DBMS_LOB package provides subprograms to operate on BLOBs, CLOBs, NCLOBs, BFILEs, and temporary LOBs. You can use DBMS_LOB to access and manipulation specific parts of a LOB or complete LOBs.

- Rules and Limits
- Exceptions
Overview

DBMS_LOB can read and modify BLOBs, CLOBs, and NCLOBs; it provides read-only operations for BFILEs. The bulk of the LOB operations are provided by this package.
Security Model

This package must be created under SYS. Operations provided by this package are performed under the current calling user, not under the package owner SYS.

Any DBMS_LOB subprogram called from an anonymous PL/SQL block is executed using the privileges of the current user. Any DBMS_LOB subprogram called from a stored procedure is executed using the privileges of the owner of the stored procedure.

When creating the procedure, users can set the AUTHID to indicate whether they want definer's rights or invoker's rights. For example:

CREATE PROCEDURE proc1 AUTHID DEFINER ...

or

CREATE PROCEDURE proc1 AUTHID CURRENT_USER ...

See Also: For more information on AUTHID and privileges, see Oracle Database PL/SQL Language Reference

You can provide secure access to BFILEs using the DIRECTORY feature discussed in BFILENAME function in the Oracle Database SecureFiles and Large Objects Developer’s Guide and the Oracle Database SQL Language Reference.

For information about the security model pertaining to temporary LOBs, see Operational Notes.
### Constants

The DBMS_LOB package uses the constants shown in following tables:

- Table 82–1, "DBMS_LOB Constants - Basic"
- Table 82–2, "DBMS_LOB Constants - Option Types"
- Table 82–3, "DBMS_LOB Constants - Option Values"
- Table 82–4, "DBMS_LOB Constants - DBFS State Value Types"
- Table 82–5, "DBMS_LOB Constants - DBFS Cache Flags"
- Table 82–6, "DBMS_LOB Constants - Maximum 1-Byte ASCII Characters for Contenttype"

<tr>
<td>BFILE</td>
<td>Large, binary object stored outside the database.</td>
</tr>
</tbody>
</table>

The DBMS_LOB package defines no special types.

An NCLOB is a CLOB for holding fixed-width and varying-width, multibyte national character sets.

The clause ANY_CS in the specification of DBMS_LOB subprograms for CLOBs enables the CLOB type to accept a CLOB or NCLOB locator variable as input.
Operational Notes

All DBMS_LOB subprograms work based on LOB locators. For the successful completion of DBMS_LOB subprograms, you must provide an input locator that represents a LOB that already exists in the database tablespaces or external file system. See also Chapter 1 of Oracle Database SecureFiles and Large Objects Developer’s Guide.

To use LOBs in your database, you must first use SQL data definition language (DDL) to define the tables that contain LOB columns.

- Internal LOBs
- External LOBs
- Temporary LOBs

Internal LOBs

To populate your table with internal LOBs after LOB columns are defined in a table, you use the SQL data manipulation language (DML) to initialize or populate the locators in the LOB columns.

External LOBs

For an external LOB (BFILE) to be represented by a LOB locator, you must:

- Ensure that a DIRECTORY object representing a valid, existing physical directory has been defined, and that physical files (the LOBs you plan to add) exist with read permission for the database. If your operating system uses case-sensitive path names, then be sure you specify the directory in the correct format.
- Pass the DIRECTORY object and the filename of the external LOB you are adding to the BFILENAME function to create a LOB locator for your external LOB.

Once you have completed these tasks, you can insert or update a row containing a LOB column using the specified LOB locator.

After the LOBs are defined and created, you can then SELECT from a LOB locator into a local PL/SQL LOB variable and use this variable as an input parameter to DBMS_LOB for access to the LOB value.

For details on the different ways to do this, you must refer to the section of the Oracle Database SecureFiles and Large Objects Developer’s Guide that describes "Accessing External LOBs (BFILES)."

Temporary LOBs

The database supports the definition, creation, deletion, access, and update of temporary LOBs. Your temporary tablespace stores the temporary LOB data. Temporary LOBs are not permanently stored in the database. Their purpose is mainly to perform transformations on LOB data.

For temporary LOBs, you must use the OCI, PL/SQL, or another programmatic interface to create or manipulate them. Temporary LOBs can be either BLOBS, CLOBs, or NCLOBs.

A temporary LOB is empty when it is created. By default, all temporary LOBs are deleted at the end of the session in which they were created. If a process dies unexpectedly or if the database crashes, then temporary LOBs are deleted, and the space for temporary LOBs is freed.
There is also an interface to let you group temporary LOBs together into a logical bucket. The duration represents this logical store for temporary LOBs. Each temporary LOB can have separate storage characteristics, such as CACHE/NOCACHE. There is a default store for every session into which temporary LOBs are placed if you don’t specify a specific duration. Additionally, you are able to perform a free operation on durations, which causes all contents in a duration to be freed.

There is no support for consistent read (CR), undo, backup, parallel processing, or transaction management for temporary LOBs. Because CR and rollbacks are not supported for temporary LOBs, you must free the temporary LOB and start over again if you encounter an error.

Because CR, undo, and versions are not generated for temporary LOBs, there is potentially a performance impact if you assign multiple locators to the same temporary LOB. Semantically, each locator should have its own copy of the temporary LOB.

A copy of a temporary LOB is created if the user modifies the temporary LOB while another locator is also pointing to it. The locator on which a modification was performed now points to a new copy of the temporary LOB. Other locators no longer see the same data as the locator through which the modification was made. A deep copy was not incurred by permanent LOBs in these types of situations, because CR snapshots and version pages enable users to see their own versions of the LOB cheaply.

You can gain pseudo-REF semantics by using pointers to locators in OCI and by having multiple pointers to locators point to the same temporary LOB locator, if necessary. In PL/SQL, you must avoid using more than one locator for each temporary LOB. The temporary LOB locator can be passed by reference to other procedures.

Because temporary LOBs are not associated with any table schema, there are no meanings to the terms in-row and out-of-row temporary LOBs. Creation of a temporary LOB instance by a user causes the engine to create and return a locator to the LOB data. The PL/SQL DBMS_LOB package, PRO/C/C++, OCI, and other programmatic interfaces operate on temporary LOBs through these locators just as they do for permanent LOBs.

There is no support for client side temporary LOBs. All temporary LOBs reside in the server.

Temporary LOBs do not support the EMPTY_BLOB or EMPTY_CLOB functions that are supported for permanent LOBs. The EMPTY_BLOB function specifies the fact that the LOB is initialized, but not populated with any data.

A temporary LOB instance can only be destroyed by using OCI or the DBMS_LOB package by using the appropriate FREETEMPORARY or OCIDurationEnd statement.

A temporary LOB instance can be accessed and modified using appropriate OCI and DBMS_LOB statements, just as for regular permanent internal LOBs. To make a temporary LOB permanent, you must explicitly use the OCI or DBMS_LOB COPY command, and copy the temporary LOB into a permanent one.

Security is provided through the LOB locator. Only the user who created the temporary LOB is able to see it. Locators are not expected to be able to pass from one user’s session to another. Even if someone did pass a locator from one session to another, they would not access the temporary LOBs from the original session. Temporary LOB lookup is localized to each user’s own session. Someone using a locator from somewhere else is only able to access LOBs within his own session that have the same LOB ID. Users should not try to do this, but if they do, they are not able to affect anyone else’s data.

The database keeps track of temporary LOBs for each session in a $ view called $TEMPORARY_LOBS, which contains information about how many temporary LOBs
exist for each session. V$ views are for DBA use. From the session, the database can determine which user owns the temporary LOBs. By using V$TEMPORARY_LOBS in conjunction with DBA_SEGMENTS, a DBA can see how much space is being used by a session for temporary LOBs. These tables can be used by DBAs to monitor and guide any emergency cleanup of temporary space used by temporary LOBs.

The following notes are specific to temporary LOBs:

1. All functions in DBMS_LOB return NULL if any of the input parameters are NULL. All procedures in DBMS_LOB raise an exception if the LOB locator is input as NULL.

2. Operations based on CLOBs do not verify if the character set IDs of the parameters (CLOB parameters, VARCHAR2 buffers and patterns, and so on) match. It is the user’s responsibility to ensure this.

3. Data storage resources are controlled by the DBA by creating different temporary tablespaces. DBAs can define separate temporary tablespaces for different users, if necessary.

**See Also:** Oracle Database PL/SQL Language Reference for more information on NOCOPY syntax
Rules and Limits

- General Rules and Limits
- Rules and Limits Specific to External Files (BFILEs)
- Maximum LOB Size
- Maximum Buffer Size

General Rules and Limits

- Oracle Database does not support constraints on columns or attributes whose type is a LOB, with the following exception: NOT NULL constraints are supported for a LOB column or attribute.

- The following rules apply in the specification of subprograms in this package:
  - length, offset, and amount parameters for subprograms operating on BLOBs and BFILEs must be specified in terms of bytes.
  - length, offset, and amount parameters for subprograms operating on CLOBs must be specified in terms of characters.

  In multi-byte character sets, it is not possible to interpret these offsets correctly. As a result, SUBSTR raises the following error: ORA-22998: CLOB or NCLOB in multibyte character set not supported.

- A subprogram raises an INVALID_ARGVAL exception if the following restrictions are not followed in specifying values for parameters (unless otherwise specified):
  1. Only positive, absolute offsets from the beginning of LOB data are permitted: Negative offsets from the tail of the LOB are not permitted.
  2. Only positive, nonzero values are permitted for the parameters that represent size and positional quantities, such as amount, offset, newlen, nth, and so on. Negative offsets and ranges observed in SQL string functions and operators are not permitted.
  3. The value of offset, amount, newlen, nth must not exceed the value lobmaxsize $18446744073709551615$ (264) in any DBMS_LOB subprogram.
  4. For CLOBs consisting of fixed-width multibyte characters, the maximum value for these parameters must not exceed (lobmaxsize/character_width_in_bytes) characters.

    For example, if the CLOB consists of 2-byte characters, such as:
    
    JA16SJISFIXED

    Then, the maximum amount value should not exceed:
    
    $18446744073709551615/2 = 9223372036854775807$

- PL/SQL language specifications stipulate an upper limit of 32767 bytes (not characters) for RAW and VARCHAR2 parameters used in DBMS_LOB subprograms. For example, if you declare a variable to be:

  charbuf VARCHAR2(3000)

  Then, charbuf can hold 3000 single byte characters or 1500 2-byte fixed width characters. This has an important consequence for DBMS_LOB subprograms for CLOBs and NCLOBs.
The `%CHARSET` clause indicates that the form of the parameter with `%CHARSET` must match the form of the `ANY_CS` parameter to which it refers.

For example, in `DBMS_LOB` subprograms that take a `VARCHAR2` buffer parameter, the form of the `VARCHAR2` buffer must match the form of the `CLOB` parameter. If the input `LOB` parameter is of type `NCLOB`, then the buffer must contain `NCHAR` data. Conversely, if the input `LOB` parameter is of type `CLOB`, then the buffer must contain `CHAR` data.

For `DBMS_LOB` subprograms that take two `CLOB` parameters, both `CLOB` parameters must have the same form; that is, they must both be `NCLOBs`, or they must both be `CLOBs`.

If the value of `amount` plus the `offset` exceeds the maximum `LOB` size allowed by the database, then access exceptions are raised.

Under these input conditions, read subprograms, such as `READ`, `COMPARE`, `INSTR`, and `SUBSTR`, read until the `End of Lob/File` is reached. For example, for a `READ` operation on a `BLOB` or `BFILE`, if the user specifies offset value of 3 GB and an amount value of 2 GB on a LOB that is 4GB in size, then `READ` returns only 1GB (4GB-3GB) bytes.

Functions with `NULL` or invalid input values for parameters return a `NULL`. Procedures with `NULL` values for destination `LOB` parameters raise exceptions.

Operations involving patterns as parameters, such as `COMPARE`, `INSTR`, and `SUBSTR` do not support regular expressions or special matching characters (such as `%` in the `LIKE` operator in SQL) in the `pattern` parameter or substrings.

The `End Of LOB` condition is indicated by the `READ` procedure using a `NO_DATA_FOUND` exception. This exception is raised only upon an attempt by the user to read beyond the end of the `LOB`. The `READ` buffer for the last read contains 0 bytes.

For consistent `LOB` updates, you must lock the row containing the destination `LOB` before making a call to any of the procedures (mutators) that modify `LOB` data.

Unless otherwise stated, the default value for an `offset` parameter is 1, which indicates the first byte in the `BLOB` or `BFILE` data, and the first character in the `CLOB` or `NCLOB` value. No default values are specified for the `amount` parameter — you must input the values explicitly.

You must lock the row containing the destination internal `LOB` before calling any subprograms that modify the `LOB`, such as `APPEND`, `COPY`, `ERASE`, `TRIM`, or `WRITE`. These subprograms do not implicitly lock the row containing the `LOB`.

**Rules and Limits Specific to External Files (BFILES)**

The subprograms `COMPARE`, `INSTR`, `READ`, `SUBSTR`, `FILECLOSE`, `FILECLOSEALL` and `LOADFROMFILE` operate only on an `opened` `BFILE` locator; that is, a successful `FILEOPEN` call must precede a call to any of these subprograms.

For the functions `FILEEXISTS`, `FILEGETNAME`, and `GETLENGTH`, a file’s open/close status is unimportant; however, the file must exist physically, and you must have adequate privileges on the `DIRECTORY` object and the file.

`DBMS_LOB` does not support any concurrency control mechanism for `BFILE` operations.

In the event of several open files in the session whose closure has not been handled properly, you can use the `FILECLOSEALL` subprogram to close all files opened in the session and resume file operations from the beginning.
If you are the creator of a DIRECTORY, or if you have system privileges, then use the CREATE OR REPLACE, DROP, and REVOKE statements in SQL with extreme caution.

If you, or other grantees of a particular directory object, have several open files in a session, then any of the preceding commands can adversely affect file operations. In the event of such abnormal termination, your only choice is to invoke a program or anonymous block that calls FILECLOSEALL, reopen your files, and restart your file operations.

All files opened during a user session are implicitly closed at the end of the session. However, Oracle strongly recommends that you close the files after both normal and abnormal termination of operations on the BFILE.

In the event of normal program termination, proper file closure ensures that the number of files that are open simultaneously in the session remains less than SESSION_MAX_OPEN_FILES.

In the event of abnormal program termination from a PL/SQL program, it is imperative that you provide an exception handler that ensures closure of all files opened in that PL/SQL program. This is necessary because after an exception occurs, only the exception handler has access to the BFILE variable in its most current state.

After the exception transfers program control outside the PL/SQL program block, all references to the open BFILEs are lost. The result is a larger open file count which may or may not exceed the SESSION_MAX_OPEN_FILES value.

For example, consider a READ operation past the end of the BFILE value, which generates a NO_DATA_FOUND exception:

```-- This assumes a directory 'DDD' whose path is already known
DECLARE
    fil BFILE := bfilename('DDD', 'filename.foo');
    pos INTEGER;
    amt BINARY_INTEGER;
    buf RAW(40);
BEGIN
    SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
    dbms_lob.open(fil, dbms_lob.lob_readonly);
    amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := '';
    dbms_lob.read(fil, amt, pos, buf);
    dbms_output.put_line('Read F1 past EOF: '||
        utl_raw.cast_to_varchar2(buf));
    dbms_lob.close(fil);
END;
```

ORA-01403: no data found
ORA-06512: at "SYS.DBMS_LOB", line 373
ORA-06512: at line 10

After the exception has occurred, the BFILE locator variable file goes out of scope, and no further operations on the file can be done using that variable. Therefore, the solution is to use an exception handler:

```DECLARE
    fil BFILE;
    pos INTEGER;
    amt BINARY_INTEGER;
    buf RAW(40);
BEGIN
    SELECT ad_graphic INTO fil FROM print_media WHERE product_id = 3106;
    dbms_lob.open(fil, dbms_lob.lob_readonly);
```
amt := 40; pos := 1 + dbms_lob.getlength(fil); buf := ''; 
dbms_lob.read(fil, amt, pos, buf);
dbms_output.put_line('Read F1 past EOF: ' ||
       utl_raw.cast_to_varchar2(buf));
dbms_lob.close(fil);
exception
WHEN no_data_found
THEN
   BEGIN
      dbms_output.put_line('End of File reached. Closing file');
      dbms_lob.fileclose(fil);
      -- or dbms_lob.filecloseall if appropriate
   END;
END;
/

Statement processed.
End of File reached. Closing file

In general, you should ensure that files opened in a PL/SQL block using DBMS_LOB are closed before normal or abnormal termination of the block.

**Maximum LOB Size**

The maximum size for LOBs supported by the database is equal to the value of the blocksize of the tablespace the LOB column resides in times the value $2^{32}-1$ (4294967295). This allows for a maximum LOB size ranging from 8 terabytes to 128 terabytes.

**Maximum Buffer Size**

The maximum buffer size, 32767 bytes.

</tbody>
</table>
### Table 82–9 (Cont.) DBMS_LOB Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRIM Procedures on page 82-79</td>
<td>Trims the LOB value to the specified shorter length</td>
</tr>
<tr>
<td>WRITE Procedures on page 82-81</td>
<td>Writes data to the LOB from a specified offset</td>
</tr>
<tr>
<td>WRITEAPPEND Procedures on page 82-83</td>
<td>Writes a buffer to the end of a LOB</td>
</tr>
</tbody>
</table>
APPEND Procedures

This procedure appends the contents of a source internal LOB to a destination LOB. It appends the complete source LOB.

Syntax

DBMS_LOB.APPEND (  
  dest_lob IN OUT NOCOPY BLOB,  
  src_lob IN BLOB);  

DBMS_LOB.APPEND (  
  dest_lob IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
  src_lob IN CLOB CHARACTER SET dest_lob%CHARSET);  

Parameters

Table 82–10  APPEND Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>Locator for the internal LOB to which the data is to be appended.</td>
</tr>
<tr>
<td>src_lob</td>
<td>Locator for the internal LOB from which the data is to be read.</td>
</tr>
</tbody>
</table>

Exceptions

Table 82–11  APPEND Procedure Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Either the source or the destination LOB is NULL.</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform a LOB write inside a query or PDML slave</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB</td>
</tr>
</tbody>
</table>

Usage Notes

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

  If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

- If APPEND is called on a LOB that has been archived, it implicitly gets the LOB before the first byte is written.

  See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
CLOSE Procedure

This procedure closes a previously opened internal or external LOB.

Syntax

DBMS_LOB.CLOSE (  
  lob_loc   IN OUT NOCOPY BLOB);  

DBMS_LOB.CLOSE (  
  lob_loc   IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);  

DBMS_LOB.CLOSE (  
  file_loc  IN OUT NOCOPY BFILE);  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
</tbody>
</table>

Exceptions

No error is returned if the BFILE exists but is not opened. An error is returned if the LOB is not open.

Usage Notes

CLOSE requires a round-trip to the server for both internal and external LOBs. For internal LOBs, CLOSE triggers other code that relies on the close call, and for external LOBs (BFILES), CLOSE actually closes the server-side operating system file.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
COMPARE Functions

This function compares two entire LOBs or parts of two LOBs.

Syntax

```
DBMS_LOB.COMPARE (   
  lob_1    IN BLOB,   
  lob_2    IN BLOB,   
  amount   IN INTEGER := DBMS_LOB.LOBMAXSIZE,   
  offset_1 IN INTEGER := 1,   
  offset_2 IN INTEGER := 1)   
RETURN INTEGER;
```

```
DBMS_LOB.COMPARE (   
  lob_1    IN CLOB  CHARACTER SET ANY_CS,   
  lob_2    IN CLOB  CHARACTER SET lob_1%CHARSET,   
  amount   IN INTEGER := DBMS_LOB.LOBMAXSIZE,   
  offset_1 IN INTEGER := 1,   
  offset_2 IN INTEGER := 1)   
RETURN INTEGER;
```

```
DBMS_LOB.COMPARE (   
  lob_1    IN BFILE,   
  lob_2    IN BFILE,   
  amount   IN INTEGER,   
  offset_1 IN INTEGER := 1,   
  offset_2 IN INTEGER := 1)   
RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(COMPARE, WNDS, WNPS, RNDS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_1</td>
<td>LOB locator of first target for comparison.</td>
</tr>
<tr>
<td>lob_2</td>
<td>LOB locator of second target for comparison.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs/NCLOBs) to compare.</td>
</tr>
<tr>
<td>offset_1</td>
<td>Offset in bytes or characters on the first LOB (origin: 1) for the comparison.</td>
</tr>
<tr>
<td>offset_2</td>
<td>Offset in bytes or characters on the second LOB (origin: 1) for the comparison.</td>
</tr>
</tbody>
</table>

Return Values

- INTEGER: 0 if the comparison succeeds, nonzero if not.
- NULL, if any of amount, offset_1 or offset_2 is not a valid LOB offset value. A valid offset is within the range of 1 to LOBMAXSIZE inclusive.
Usage Notes

- You can only compare LOBs of the same datatype (LOBs of BLOB type with other BLOBs, and CLOBs with CLOBs, and BFILEs with BFILEs). For BFILEs, the file must be already opened using a successful FILEOPEN operation for this operation to succeed.

- COMPARE returns 0 if the data exactly matches over the range specified by the offset and amount parameters. COMPARE returns -1 if the first CLOB is less than the second, and 1 if it is greater.

- For fixed-width \( n \)-byte CLOBs, if the input amount for COMPARE is specified to be greater than \( \text{DBMS_LOB.LOBMAXSIZE}/n \), then COMPARE matches characters in a range of size \( \text{DBMS_LOB.LOBMAXSIZE}/n \), or Max(length(clob1), length(clob2)), whichever is lesser.

- If COMPARE is called on any LOB that has been archived, it implicitly gets the LOB before the compare begins.

Exceptions

<table>
<thead>
<tr>
<th>Table 82–14</th>
<th>COMPARE Function Exceptions for BFILE operations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception</td>
<td>Description</td>
</tr>
<tr>
<td>UNOPENED_FILE</td>
<td>File was not opened using the input locator.</td>
</tr>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory does not exist.</td>
</tr>
<tr>
<td>NOPRIV_DIRECTORY</td>
<td>You do not have privileges for the directory.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
<tr>
<td>INVALID_OPERATION</td>
<td>File does not exist, or you do not have access privileges on the file.</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB.</td>
</tr>
</tbody>
</table>

See Also:  *Oracle Database SecureFiles and Large Objects Developer’s Guide* for additional details on usage of this procedure
CONVERTTOBLOB Procedure

This procedure reads character data from a source CLOB or NCLOB instance, converts the character data to the character set you specify, writes the converted data to a destination BLOB instance in binary format, and returns the new offsets. You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

Syntax

```sql
DBMS_LOB_CONVERTTOBLOB(
    dest_lob       IN OUT     NOCOPY  BLOB,
    src_clob       IN         CLOB CHARACTER SET ANY_CS,
    amount         IN         INTEGER,
    dest_offset    IN OUT     INTEGER,
    src_offset     IN OUT     INTEGER,
    blob_csid      IN         NUMBER,
    lang_context   IN OUT     INTEGER,
    warning        OUT        INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>LOB locator of the destination LOB instance.</td>
</tr>
<tr>
<td>src_clob</td>
<td>LOB locator of the source LOB instance.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of characters to convert from the source LOB.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>(IN) Offset in bytes in the destination LOB for the start of the write.</td>
</tr>
<tr>
<td></td>
<td>(OUT) The new offset in bytes after the end of the write.</td>
</tr>
<tr>
<td>src_offset</td>
<td>(IN) Offset in characters in the source LOB for the start of the read.</td>
</tr>
<tr>
<td></td>
<td>(OUT) Offset in characters in the source LOB right after the end of the read.</td>
</tr>
<tr>
<td>blob_csid</td>
<td>Desired character set ID of the converted data.</td>
</tr>
<tr>
<td>lang_context</td>
<td>(IN) Language context, such as shift status, for the current conversion.</td>
</tr>
<tr>
<td></td>
<td>(OUT) The language context at the time when the current conversion is done.</td>
</tr>
</tbody>
</table>

This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero.
Preconditions

Before calling the `CONVERTTOBLOB` procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked. To lock the row, select the LOB using the `FOR UPDATE` clause of the `SELECT` statement.

Constants and Defaults

All parameters are required. You must pass a variable for each `OUT` or `IN OUT` parameter. You must pass either a variable or a value for each `IN` parameter.

Table 82–16 gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values. These constants are defined in the `dbmslob.sql` package specification file.

### Table 82–16  DBMS_LOB.CONVERTTOBLOB Typical Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>LOBMAXSIZE (IN)</td>
<td>convert the entire file</td>
</tr>
<tr>
<td>dest_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>src_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>blob_csid</td>
<td>DEFAULT_CSID (IN)</td>
<td>default CSID, use same CSID as source LOB</td>
</tr>
<tr>
<td>lang_context</td>
<td>DEFAULT_LANG_CTX (IN)</td>
<td>default language context</td>
</tr>
<tr>
<td>warning</td>
<td>NO_WARNING (OUT)</td>
<td>no warning message, success</td>
</tr>
<tr>
<td></td>
<td>WARN_INCONVERTIBLE_CHAR</td>
<td>character in source cannot be properly converted</td>
</tr>
</tbody>
</table>

General Notes

- You must specify the desired character set for the destination LOB in the `blob_csid` parameter. You can pass a zero value for `blob_csid`. When you do so, the database assumes that the desired character set is the same as the source LOB character set.

- You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The `amount` and `src_offset`
values are in characters and the dest_offset is in bytes. To convert the entire LOB, you can specify LOBMAXSIZE for the amount parameter.

- `CONVERTTOBLOB` gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

### Exceptions

Table 82–17 gives possible exceptions this procedure can throw. The first column lists the exception string and the second column describes the error conditions that can cause the exception.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>One or more of the following:</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &lt; 1.</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &gt; LOBMAXSIZE.</td>
</tr>
<tr>
<td></td>
<td>- amount &lt; 1.</td>
</tr>
<tr>
<td></td>
<td>- amount &gt; LOBMAXSIZE.</td>
</tr>
</tbody>
</table>

**See Also:** Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on using LOBs in application development
CONVERTTOCLOB Procedure

This procedure takes a source BLOB instance, converts the binary data in the source instance to character data using the character set you specify, writes the character data to a destination CLOB or NCLOB instance, and returns the new offsets. You can use this interface with any combination of persistent or temporary LOB instances as the source or destination.

Syntax

```sql
DBMS_LOB.CONVERTTOCLOB(
    dest_lob       IN OUT NOCOPY  CLOB CHARACTER SET ANY_CS,
    src_blob       IN             BLOB,
    amount         IN             INTEGER,
    dest_offset    IN OUT         INTEGER,
    src_offset     IN OUT         INTEGER,
    blob_csid      IN             NUMBER,
    lang_context   IN OUT         INTEGER,
    warning        OUT            INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>LOB locator of the destination LOB instance.</td>
</tr>
<tr>
<td>src_blob</td>
<td>LOB locator of the source LOB instance.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes to convert from the source LOB. If you want to copy the entire BLOB, pass the constant DBMS_LOB.LOBMAXSIZE. If you pass any other value, it must be less than or equal to the size of the BLOB.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>(IN) Offset in characters in the destination LOB for the start of the write. Specify a value of 1 to start at the beginning of the LOB. (OUT) The new offset in characters after the end of the write. This offset always points to the beginning of the first complete character after the end of the write.</td>
</tr>
<tr>
<td>src_offset</td>
<td>(IN) Offset in bytes in the source LOB for the start of the read. (OUT) Offset in bytes in the source LOB right after the end of the read.</td>
</tr>
<tr>
<td>blob_csid</td>
<td>The character set ID of the source data</td>
</tr>
<tr>
<td>lang_context</td>
<td>(IN) Language context, such as shift status, for the current conversion. (OUT) The language context at the time when the current conversion is done. This information is returned so you can use it for subsequent conversions without losing or misinterpreting any source data. For the very first conversion, or if do not care, use the default value of zero.</td>
</tr>
</tbody>
</table>
Usage Notes

Preconditions
Before calling the CONVERTTOCLOB procedure, the following preconditions must be met:

- Both the source and destination LOB instances must exist.
- If the destination LOB is a persistent LOB, the row must be locked before calling the
  CONVERTTOCLOB procedure. To lock the row, select the LOB using the FOR UPDATE
  clause of the SELECT statement.

Constants and Defaults
All parameters are required. You must pass a variable for each OUT or IN OUT parameter. You must pass either a variable or a value for each IN parameter.

Table 82–19 gives a summary of typical values for each parameter. The first column lists the parameter, the second column lists the typical value, and the last column describes the result of passing the value. Note that constants are used for some values.

These constants are defined in the dbmslob.sql package specification file.

Table 82–19  DBMS_LOB.CONVERTTOCLOB Typical Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>LOBMAXSIZE (IN)</td>
<td>convert the entire file</td>
</tr>
<tr>
<td>dest_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>src_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>csid</td>
<td>DEFAULT_CSID</td>
<td>default CSID, use destination CSID</td>
</tr>
<tr>
<td>lang_context</td>
<td>DEFAULT_LANG_CTX (IN)</td>
<td>default language context</td>
</tr>
<tr>
<td>warning</td>
<td>NO_WARNING (OUT)</td>
<td>no warning message, success</td>
</tr>
<tr>
<td></td>
<td>WARN_INCONVERTIBLE_CHAR (OUT)</td>
<td>character in source cannot be properly converted</td>
</tr>
</tbody>
</table>

General Notes

- You must specify the desired character set for the destination LOB in the blob_csid parameter. You can pass a zero value for blob_csid. When you do so, the database assumes that the desired character set is the same as the source LOB character set.
You must specify the offsets for both the source and destination LOBs, and the number of characters to copy from the source LOB. The amount and src_offset values are in characters and the dest_offset is in bytes. To convert the entire LOB, you can specify LOBMAXSIZE for the amount parameter.

CONVERTTOCLOB gets the source and/or destination LOBs as necessary prior to conversion and write of the data.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>

<tr>
<td></td>
<td>- src_offset or dest_offset &gt; LOBMAXSIZE.</td>
</tr>
<tr>
<td></td>
<td>- amount &lt; 1.</td>
</tr>
<tr>
<td></td>
<td>- amount &gt; LOBMAXSIZE.</td>
</tr>
</tbody>
</table>

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for more information on using LOBs in application development
COPY Procedures

This procedure copies all, or a part of, a source internal LOB to a destination internal LOB. You can specify the offsets for both the source and destination LOBs, and the number of bytes or characters to copy.

Syntax

```sql
DBMS_LOB.COPY (    
  dest_lob    IN OUT NOCOPY BLOB,    
  src_lob     IN           BLOB,    
  amount      IN           INTEGER,    
  dest_offset IN           INTEGER := 1,    
  src_offset  IN           INTEGER := 1);
```

```sql
DBMS_LOB.COPY (    
  dest_lob    IN OUT NOCOPY CLOB  CHARACTER SET ANY_CS,    
  src_lob     IN           CLOB  CHARACTER SET dest_lob%CHARSET,    
  amount      IN           INTEGER,    
  dest_offset IN           INTEGER := 1,    
  src_offset  IN           INTEGER := 1);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>LOB locator of the copy target.</td>
</tr>
<tr>
<td>src_lob</td>
<td>LOB locator of source for the copy.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs) to copy.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>Offset in bytes or characters in the destination LOB (origin: 1) for the start of the copy.</td>
</tr>
<tr>
<td>src_offset</td>
<td>Offset in bytes or characters in the source LOB (origin: 1) for the start of the copy.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or invalid.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>Either:</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &lt; 1</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &gt; LOBMAXSIZE</td>
</tr>
<tr>
<td></td>
<td>- amount &lt; 1</td>
</tr>
<tr>
<td></td>
<td>- amount &gt; LOBMAXSIZE</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform a LOB write inside a query or PDML slave</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on either LOB.</td>
</tr>
</tbody>
</table>
Usage Notes

- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

- It is not an error to specify an amount that exceeds the length of the data in the source LOB. Thus, you can specify a large amount to copy from the source LOB, which copies data from the src_offset to the end of the source LOB.

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

- Prior to copy, the source and destination LOBs are gotten, if they are currently archived. For a complete over-write, the destination LOB is not be retrieved.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
COPY_DBFS_LINK Procedures

This procedure copies the DBFS link in the source LOB to the destination LOB.

Syntax

```sql
DBMS_LOB.COPY_DBFS_LINK (  
  lob_loc_dst    IN OUT BLOB,  
  lob_loc_src    IN     BLOB,  
  flags          IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);

DBMS_LOB.COPY_DBFS_LINK (  
  lob_loc_dst    IN OUT CLOB CHARACTER SET ANY_CS,  
  lob_loc_src    IN     CLOB CHARACTER SET ANY_CS,  
  flags          IN     PLS_INTEGER DEFAULT DBFS_LINK_NOCACHE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc_dst</td>
<td>LOB to be made to reference the same storage data as lob_loc_src</td>
</tr>
<tr>
<td>lob_loc_src</td>
<td>LOB from which to copy the reference</td>
</tr>
<tr>
<td>flags</td>
<td>Options to COPY_DBFS_LINK:</td>
</tr>
<tr>
<td></td>
<td>- DBFS_LINK_NOCACHE specifies to only copy the DBFS Link</td>
</tr>
<tr>
<td></td>
<td>- DBFS_LINK_CACHE specifies to copy the DBFS Link and read the data into the database LOB specified by lob_loc_dst so that the data is cached</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>Either lob_loc_src or lob_loc_dst is not a SECUREFILE</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>lob_loc_src LOB has not been archived</td>
</tr>
<tr>
<td>ORA-01555</td>
<td>If the source LOB has been retrieved, never archived, or if the LOB has been migrated in and out (modified or not) since the locator was gotten.</td>
</tr>
</tbody>
</table>
COPY_FROM_DBFS_LINK

This procedure reads the archived data from the DBFS store and writes it back into the LOB.

Syntax

DBMS_LOB.COPY_FROM_DBFS_LINK (lob_loc IN OUT BLOB);

DBMS_LOB.COPY_FROM_DBFS_LINK (lob_loc IN OUT CLOB CHARACTER SET ANY_CS);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be retrieved from the archive</td>
</tr>
</tbody>
</table>

Usage Note

Note that COPY_FROM_DBFS_LINK does not remove the underlying DBFS file.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
<tr>
<td>ORA-01555</td>
<td>If the LOB has already been retrieved and has been modified since retrieval, if the LOB has been migrated in and out (modified or not) since the locator was retrieved</td>
</tr>
</tbody>
</table>
**CREATETEMPORARY Procedures**

This procedure creates a temporary BLOB or CLOB and its corresponding index in your default temporary tablespace.

**Syntax**

```sql
DBMS_LOB.CREATETEMPORARY (
    lob_loc IN OUT NOCOPY BLOB,
    cache   IN            BOOLEAN,
    dur     IN            PLS_INTEGER := DBMS_LOB.SESSION);
```

```sql
DBMS_LOB.CREATETEMPORARY (
    lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    cache   IN            BOOLEAN,
    dur     IN            PLS_INTEGER := 10);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>cache</td>
<td>Specifies if LOB should be read into buffer cache or not.</td>
</tr>
<tr>
<td>dur</td>
<td>1 of 2 predefined duration values (SESSION or CALL) which specifies a hint as to whether the temporary LOB is cleaned up at the end of the session or call. If dur is omitted, then the session duration is used.</td>
</tr>
</tbody>
</table>

**See Also:**

DBFS_LINK_GENERATE_PATH Functions

This subprogram returns a unique file path name for use in creating a DBFS Link.

Syntax

DBMS_LOB.DBFS_LINK_GENERATE_PATH (    lob_loc       IN BLOB,    storage_dir   IN VARCHAR2)    RETURN VARCHAR2;

DBMS_LOB.DBFS_LINK_GENERATE_PATH (    lob_loc       IN CLOB CHARACTER SET ANY_CS,    storage_dir   IN VARCHAR2)    RETURN VARCHAR2;

Parameters

Table 82–28  DBFS_LINK_GENERATE_PATH Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be retrieved from DBFS</td>
</tr>
<tr>
<td>storage_dir</td>
<td>DBFS directory that will be the parent directory of the file</td>
</tr>
</tbody>
</table>

Exceptions

Table 82–29  DBFS_LINK_GENERATE_PATH Function Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_WRONGTYPE</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>
ERASE Procedures

This procedure erases an entire internal LOB or part of an internal LOB.

Syntax

```
DBMS_LOB.ERASE {
    lob_loc           IN OUT   NOCOPY   BLOB,
    amount            IN OUT   NOCOPY   INTEGER,
    offset            IN                INTEGER := 1);
}
```

```
DBMS_LOB.ERASE {
    lob_loc           IN OUT   NOCOPY   CLOB CHARACTER SET ANY_CS,
    amount            IN OUT   NOCOPY   INTEGER,
    offset            IN                INTEGER := 1);
}
```

Parameters

<table>
<thead>
<tr>
<th>Table 82–30 ERASE Procedure Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameter</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>lob_loc</td>
</tr>
<tr>
<td>amount</td>
</tr>
<tr>
<td>offset</td>
</tr>
</tbody>
</table>

Usage Notes

- When data is erased from the middle of a LOB, zero-byte fillers or spaces are written for BLOBs or CLOBs respectively.
- The actual number of bytes or characters erased can differ from the number you specified in the amount parameter if the end of the LOB value is reached before erasing the specified number. The actual number of characters or bytes erased is returned in the amount parameter.
- ERASE gets the LOB if it is archived, unless the erase covers the entire LOB.

**Note:** The length of the LOB is not decreased when a section of the LOB is erased. To decrease the length of the LOB value, see the "TRIM Procedures" on page 82-79.

Exceptions

<table>
<thead>
<tr>
<th>Table 82–31 ERASE Procedure Exceptions</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception</td>
</tr>
<tr>
<td>------------</td>
</tr>
<tr>
<td>VALUE_ERROR</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Usage Notes

It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

FILECLOSE Procedure

This procedure closes a `BFILE` that has already been opened through the input locator.

---

**Note:** The database has only read-only access to `BFILEs`. This means that `BFILEs` cannot be written through the database.

---

### Syntax

```
DBMS_LOB.FILECLOSE (  
    file_loc IN OUT NOCOPY BFILE);
```

### Parameters

**Table 82–32  FILECLOSE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>Locator for the <code>BFILE</code> to be closed.</td>
</tr>
</tbody>
</table>

### Exceptions

**Table 82–33  FILECLOSE Procedure Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>NULL input value for <code>file_loc</code>.</td>
</tr>
<tr>
<td>UNOPENED_FILE</td>
<td>File was not opened with the input locator.</td>
</tr>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory does not exist.</td>
</tr>
<tr>
<td>NOPRIV_DIRECTORY</td>
<td>You do not have privileges for the directory.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
<tr>
<td>INVALID_OPERATION</td>
<td>File does not exist, or you do not have access privileges on the file.</td>
</tr>
</tbody>
</table>

FILECLOSEALL Procedure

This procedure closes all BFILEs opened in the session.

Syntax

DBMS_LOB.FILECLOSEALL;

Exceptions

<table>
<thead>
<tr>
<th>Table 82–34 FILECLOSEALL Procedure Exception</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exception</td>
</tr>
<tr>
<td>----------------</td>
</tr>
<tr>
<td>UNOPENED_FILE</td>

**FILEEXISTS Function**

This function finds out if a specified **BFILE** locator points to a file that actually exists on the server's file system.

**Syntax**

```sql
DBMS_LOB.FILEEXISTS (
    file_loc    IN    BFILE)
RETURN INTEGER;
```

**Pragmas**

```sql
pragma restrict_references(FILEEXISTS, WNDS, RNDS, WNPS, RNPS);
```

**Parameters**

**Table 82–35  FILEEXISTS Function Parameter**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>Locator for the <strong>BFILE</strong>.</td>
</tr>
</tbody>
</table>

**Return Values**

**Table 82–36  FILEEXISTS Function Return Values**

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Physical file does not exist.</td>
</tr>
<tr>
<td>1</td>
<td>Physical file exists.</td>
</tr>
</tbody>
</table>

**Exceptions**

**Table 82–37  FILEEXISTS Function Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory does not exist.</td>
</tr>
<tr>
<td>NOPRIV_DIRECTORY</td>
<td>You do not have privileges for the directory.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
</tbody>
</table>

**See Also:**

- "FILEISOPEN Function" on page 82-41.
- *Oracle Database SecureFiles and Large Objects Developer’s Guide* for additional details on usage of this procedure.
FILEGETNAME Procedure

This procedure determines the directory object and filename, given a BFILE locator. This function only indicates the directory object name and filename assigned to the locator, not if the physical file or directory actually exists.

The maximum constraint values for the dir_alias buffer is 30, and for the entire pathname, it is 2000.

Syntax

```sql
DBMS_LOB.FILEGETNAME(
    file_loc   IN    BFILE,
    dir_alias  OUT   VARCHAR2,
    filename   OUT   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>Locator for the BFILE</td>
</tr>
<tr>
<td>dir_alias</td>
<td>Directory object name</td>
</tr>
<tr>
<td>filename</td>
<td>Name of the BFILE</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>dir_alias or filename are NULL.</td>
</tr>
</tbody>
</table>

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
FILEISOPEN Function

This function finds out whether a BFILE was opened with the specified FILE locator.

Syntax

```sql
DBMS_LOB.FILEISOPEN (  
    file_loc  IN    BFILE)  
RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(fileisopen, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>Locator for the BFILE.</td>
</tr>
</tbody>
</table>

Return Values

INTEGER: 0 = file is not open, 1 = file is open

Usage Notes

If the input FILE locator was never passed to the FILEOPEN procedure, then the file is considered not to be opened by this locator. However, a different locator may have this file open. In other words, openness is associated with a specific locator.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory does not exist.</td>
</tr>
<tr>
<td>NOPRIV_DIRECTORY</td>
<td>You do not have privileges for the directory.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
</tbody>
</table>

See Also:
- "FILEEXISTS Function" on page 82-39
- Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
FILEOPEN Procedure

This procedure opens a BFILE for read-only access. BFILE data may not be written through the database.

Syntax

```
DBMS_LOB.FILEOPEN (
    file_loc   IN OUT NOCOPY BFILE,
    open_mode  IN             BINARY_INTEGER := file_readonly);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>Locator for the BFILE.</td>
</tr>
<tr>
<td>open_mode</td>
<td>File access is read-only.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>file_loc or open_mode is NULL.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>open_mode is not equal to FILE_READONLY.</td>
</tr>
<tr>
<td>OPEN_TOOMANY</td>
<td>Number of open files in the session exceeds session_max_open_files.</td>
</tr>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory associated with file_loc does not exist.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
<tr>
<td>INVALID_OPERATION</td>
<td>File does not exist, or you do not have access privileges on the file.</td>
</tr>
</tbody>
</table>

- Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
FRAGMENT_DELETE Procedure

This procedure deletes the data at the specified offset for the specified length from the LOB without having to rewrite all the data in the LOB following the specified offset.

Syntax

DBMS_LOB.FRAGMENT_DELETE (  
    lob_loc     IN OUT NOCOPY BLOB,  
    amount      IN            INTEGER,  
    offset      IN            INTEGER);  

DBMS_LOB.FRAGMENT_DELETE (  
    lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    amount      IN            INTEGER,  
    offset      IN            INTEGER);  

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (BLOB) or characters (CLOB/NCLOB) to be removed from the LOB</td>
</tr>
<tr>
<td>offset</td>
<td>Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the deletion</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>A non-SECUREFILE LOB was used in a SECUREFILE LOB only call</td>
</tr>
<tr>
<td>SECUREFILE_OUTOFBOUNDS</td>
<td>Attempted to perform a FRAGMENT_* operation past LOB end</td>
</tr>
</tbody>
</table>
FRAGMENT_INSERT Procedures

This procedure inserts the specified data (limited to 32K) into the LOB at the specified offset.

Syntax

```sql
DBMS_LOB.FRAGMENT_INSERT (  
    lob_loc     IN OUT NOCOPY BLOB,  
    amount      IN            INTEGER,  
    offset      IN            INTEGER,  
    buffer      IN            RAW);
```

```sql
DBMS_LOB.FRAGMENT_INSERT (  
    lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    amount      IN            INTEGER,  
    offset      IN            INTEGER,  
    buffer      IN            VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (BLOB) or characters (CLOB/NCLOB) to be inserted into the LOB</td>
</tr>
<tr>
<td>offset</td>
<td>Offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to begin the insertion</td>
</tr>
<tr>
<td>buffer</td>
<td>Data to insert into the LOB</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>A non-SECUREFILE LOB was used in a SECUREFILE LOB only call</td>
</tr>
<tr>
<td>SECUREFILE_OUTOFBOUNDS</td>
<td>Attempted to perform a FRAGMENT_* operation past LOB end</td>
</tr>
</tbody>
</table>

Usage Notes

FRAGMENT_INSERT gets the LOB, if necessary, before performing operations on the LOB.
FRAGMENT_MOVE Procedure

This procedure moves the amount of bytes (BLOB) or characters (CLOB/NCLOB) from the specified offset to the new offset specified.

Syntax

DBMS_LOB.FRAGMENT_MOVE ( 
    lob_loc       IN OUT NOCOPY BLOB, 
    amount        IN            INTEGER, 
    src_offset    IN            INTEGER, 
    dest_offset   IN            INTEGER); 

DBMS_LOB.FRAGMENT_MOVE ( 
    lob_loc       IN OUT NOCOPY CLOB CHARACTER SET ANY_CS, 
    amount        IN            INTEGER, 
    src_offset    IN            INTEGER, 
    dest_offset   IN            INTEGER); 

Parameters

Table 82–48 FRAGMENT_MOVE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (BLOB) or characters (CLOB/NCLOB) to be moved in the LOB</td>
</tr>
<tr>
<td>src_offset</td>
<td>Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data</td>
</tr>
<tr>
<td>dest_offset</td>
<td>Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to remove the data</td>
</tr>
</tbody>
</table>

Exceptions

Table 82–49 FRAGMENT_MOVE Procedure Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>A non-SECUREFILE LOB was used in a SECUREFILE LOB only call</td>
</tr>
<tr>
<td>SECUREFILE_OUTOFBOUNDS</td>
<td>Attempted to perform a FRAGMENT_* operation past LOB end</td>
</tr>
</tbody>
</table>

Usage Notes

- All offsets are pre-move offsets.
- Offsets of more than 1 past the end of the LOB are not permitted.
- FRAGMENT_MOVE gets the LOB, if necessary, before performing operations on the LOB.
FRAGMENT_REPLACE Procedures

This procedure replaces the data at the specified offset with the specified data (not to exceed 32k).

Syntax

```sql
DBMS_LOB.FRAGMENT_REPLACE (
    lob_loc     IN OUT NOCOPY BLOB,
    old_amount  IN           INTEGER,
    new_amount  IN           INTEGER,
    offset      IN           INTEGER,
    buffer      IN           RAW);

DBMS_LOB.FRAGMENT_REPLACE (
    lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,
    old_amount  IN           INTEGER,
    new_amount  IN           INTEGER,
    offset      IN           INTEGER,
    buffer      IN           VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>old_amount</td>
<td>Number of bytes (BLOB) or characters (CLOB/NCLOB) to be replaced in the LOB</td>
</tr>
<tr>
<td>new_amount</td>
<td>Number of bytes (BLOB) or characters (CLOB/NCLOB) to be written to the LOB</td>
</tr>
<tr>
<td>offset</td>
<td>Beginning offset into the LOB in bytes (BLOB) or characters (CLOB/NCLOB) to put the data</td>
</tr>
<tr>
<td>buffer</td>
<td>Data to insert into the LOB</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>A non-SECUREFILE LOB was used in a SECUREFILE LOB only call</td>
</tr>
<tr>
<td>SECUREFILE_OUTOFBOUNDS</td>
<td>Attempted to perform a FRAGMENT_* operation past LOB end</td>
</tr>
</tbody>
</table>

Usage Notes

- Invoking this procedure is equivalent to deleting the old amount of bytes/characters at offset and then inserting the new amount of bytes/characters at offset.
- **FRAGMENT_REPLACE** gets the LOB, if necessary, before performing operations on the LOB.
**FREETEMPORARY Procedures**

This procedure frees the temporary BLOB or CLOB in the default temporary tablespace.

**Syntax**

```sql
DBMS_LOB.FREETEMPORARY (lob_loc  IN OUT NOCOPY BLOB);

DBMS_LOB.FREETEMPORARY (lob_loc  IN OUT NOCOPY CLOB CHARACTER SET ANY_CS);
```

**Parameters**

**Table 82–52 FREETEMPORARY Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- When a new temporary LOB is created, and there is currently no temporary LOB in use with the same duration (session, call), a new temporary LOB segment is created. When the temporary LOB is freed, the space it consumed is released to the temporary segment. If there are no other temporary LOBs for the same duration, the temporary segment is also freed.

- After the call to FREETEMPORARY, the LOB locator that was freed is marked as invalid.

- If an invalid LOB locator is assigned to another LOB locator using OCILobLocatorAssign in OCI or through an assignment operation in PL/SQL, then the target of the assignment is also freed and marked as invalid.

**See Also:** *Oracle Database SecureFiles and Large Objects Developer’s Guide* for additional details on usage of this procedure.
GET_DBFS_LINK Functions

This function returns the DBFS Link path associated with the specified SecureFile.

Syntax

```sql
DBMS_LOB.GET_DBFS_LINK (    lob_loc             IN     BLOB,    storage_path        OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),    lob_length          OUT NUMBER);

DBMS_LOB.GET_DBFS_LINK (    lob_loc             IN     CLOB CHARACTER SET ANY_CS,    storage_path        OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),    lob_length          OUT NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be retrieved from DBFS</td>
</tr>
<tr>
<td>storage_path</td>
<td>Path where the LOB is stored in DBFS</td>
</tr>
<tr>
<td>lob_length</td>
<td>LOB length at the time of write to DBFS</td>
</tr>
</tbody>
</table>

Return Values

The Archive ID

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
<tr>
<td>ORA-01555</td>
<td>If the LOB has already been retrieved and has been modified since retrieval, if the LOB has been migrated in and out (modified or not) since the locator was retrieved</td>
</tr>
</tbody>
</table>
GET_DBFS_LINK_STATE Procedures

This procedure retrieves the current DBFS Link state of the specified SecureFile.

Syntax

```sql
DBMS_LOB.GET_DBFS_LINK_STATE (
  lob_loc       IN BLOB,
  storage_path  OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  state         OUT NUMBER,
  cached        OUT BOOLEAN);

DBMS_LOB.GET_DBFS_LINK_STATE (
  lob_loc       IN CLOB CHARACTER SET ANY_CS,
  storage_path  OUT VARCHAR2(DBFS_LINK_PATH_MAX_SIZE),
  state         OUT NUMBER,
  cached        OUT BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be retrieved from the archive</td>
</tr>
<tr>
<td>storage_path</td>
<td>Path where the LOB is stored in DBFS</td>
</tr>
<tr>
<td>state</td>
<td>One of DBFS_LINK_NEVER, DBFS_LINK_NO or DBFS_LINK_YES</td>
</tr>
<tr>
<td>cached</td>
<td>If the LOB is archived and the data was specified to be cached on put</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>

Usage Notes

- If the LOB has never been archived, state is set to DBMS_LOB.DBFS_LINK_NEVER. If the LOB has been archived, state is set to DBMS_LOB.DBFS_LINK_YES. If the LOB has been previously retrieved from the archive, state is set to DBFS_LINK_NO.
- If the LOB was archived, but the data was left in the RDBMS, cached is set to TRUE. Cached is set to FALSE if the data was removed after the put, and NULL if state is DBMS_LOB.DBFS_LINK_NEVER.
GETCONTENTTYPE Functions

This procedure returns the content type string previously set by means of the SETCONTENTTYPE Procedure.

Syntax

```
DBMS_LOB.GETCONTENTTYPE (lob_loc  IN BLOB)
RETURN VARCHAR2;
```

```
DBMS_LOB.GETCONTENTTYPE (lob_loc  IN CLOB CHARACTER SET ANY_CS)
RETURN VARCHAR2;
```

Pragmas

PRAGMA RESTRICT_REFERENCES(getcontenttype, WNDS, RNDS, WNPS, RNPS);

Parameters

Table 82–57 GETCONTENTTYPE Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB whose content type is to be retrieved</td>
</tr>
</tbody>
</table>

Return Values

The returned content type.

Exceptions

Table 82–58 GETCONTENTTYPE Function Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>
GET_STORAGE_LIMIT Function

This function returns the LOB storage limit for the specified LOB.

Syntax

```
DBMS_LOB.GET_STORAGE_LIMIT (
   lob_loc  IN CLOB CHARACTER SET ANY_CS
) RETURN INTEGER;

DBMS_LOB.GET_STORAGE_LIMIT (
   lob_loc  IN BLOB
) RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(get_storage_limit, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
</tbody>
</table>

Return Value

The value returned from this function is the maximum allowable size for specified LOB locator. For BLOBs, the return value depends on the block size of the tablespace the LOB resides in and is calculated as $(2^{32})-1$ (4294967295) times the block size of the tablespace. For CLOBs/NCLOBs, the value returned is the $(2^{32})-1$ (4294967295) times the block size of the tablespace divided by the character width of the CLOB/NCLOB.

Usage

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for details on LOB storage limits
GETCHUNKSIZE Functions

When creating the table, you can specify the chunking factor, a multiple of tablespace blocks in bytes. This corresponds to the chunk size used by the LOB data layer when accessing or modifying the LOB value. Part of the chunk is used to store system-related information, and the rest stores the LOB value.

This function returns the amount of space used in the LOB chunk to store the LOB value.

Syntax

```sql
DBMS_LOB.GETCHUNKSIZE (  
    lob_loc IN BLOB)  
RETURN INTEGER;
```

```sql
DBMS_LOB.GETCHUNKSIZE (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
RETURN INTEGER;
```

Pragmas

```sql
PRAGMA RESTRICT_REFERENCES(getchunksize, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
</tbody>
</table>

Return Values

The return value is a usable chunk size in bytes.

Usage Notes

- With regard to basic LOB files, performance is improved if you enter read/write requests using a multiple of this chunk size. For writes, there is an added benefit, because LOB chunks are versioned, and if all writes are done on a chunk basis, then no extra or excess versioning is done or duplicated. You could batch up the WRITE until you have enough for a chunk, instead of issuing several WRITE calls for the same chunk.

  These tactics of performance improvement do not apply to SecureFiles.

- Note that chunk size is independent of LOB type (BLOB, CLOB, NCLOB, Unicode or other character set).

  See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB</td>
</tr>
</tbody>
</table>
GETLENGTH Functions

This function gets the length of the specified LOB. The length in bytes or characters is returned.

The length returned for a BFILE includes the EOF, if it exists. Any 0-byte or space filler in the LOB caused by previous ERASE or WRITE operations is also included in the length count. The length of an empty internal LOB is 0.

Syntax

```sql
DBMS_LOB.GETLENGTH (  
    lob_loc    IN  BLOB)  
RETURN INTEGER;

DBMS_LOB.GETLENGTH (  
    lob_loc    IN  CLOB   CHARACTER SET ANY_CS)  
RETURN INTEGER;

DBMS_LOB.GETLENGTH (  
    file_loc    IN  BFILE)  
RETURN INTEGER;
```

Pragmas

```sql
pragma restrict_references(GETLENGTH, WNDS, WNPS, RNDS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_loc</td>
<td>The file locator for the LOB whose length is to be returned.</td>
</tr>
</tbody>
</table>

Return Values

The length of the LOB in bytes or characters as an INTEGER. NULL is returned if the input LOB is NULL or if the input lob_loc is NULL. An error is returned in the following cases for BFILES:

- lob_loc does not have the necessary directory and operating system privileges
- lob_loc cannot be read because of an operating system read error

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB</td>
</tr>
</tbody>
</table>
GETOPTIONS Functions

This function obtains settings corresponding to the option_type field for a particular LOB.

Syntax

```sql
DBMS_LOB.GETOPTIONS (  
    lob_loc             IN     BLOB,  
    option_types        IN     PLS_INTEGER)  
RETURN PLS_INTEGER;

DBMS_LOB.GETOPTIONS (  
    lob_loc             IN     CLOB CHARACTER SET ANY_CS,  
    option_types        IN     PLS_INTEGER)  
RETURN PLS_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the LOB to be examined. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>option_type</td>
<td>See DBMS_LOB Constants - Option Types on page 82-5</td>
</tr>
</tbody>
</table>

Return Values

The return values are a combination of COMPRESS_ON, ENCRYPT_ON and DEDUPLICATE_ON (see DBMS_LOB Constants - Option Values on page 82-5) depending on which option types (see DBMS_LOB Constants - Option Types on page 82-5) are passed in.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>A non-SECUREFILE LOB was used in a SECUREFILE LOB only call</td>
</tr>
</tbody>
</table>

Usage Notes

You cannot turn compression or deduplication on or off for a SecureFile column that does not have those features on. The GetOptions Functions and SETOPTIONS Procedures work on individual SecureFiles. You can turn off a feature on a particular SecureFile and turn on a feature that has already been turned off by SetOptions, but you cannot turn on an option that has not been given to the SecureFile when the table was created.
INSTR Functions

This function returns the matching position of the $n$th occurrence of the pattern in the LOB, starting from the offset you specify.

Syntax

```sql
DBMS_LOB.INSTR (  
    lob_loc    IN   BLOB,  
    pattern    IN   RAW,  
    offset     IN   INTEGER := 1,  
    nth        IN   INTEGER := 1)  
RETURN INTEGER;
```

```sql
DBMS_LOB.INSTR (  
    lob_loc    IN   CLOB      CHARACTER SET ANY_CS,  
    pattern    IN   VARCHAR2  CHARACTER SET lob_loc%CHARSET,  
    offset     IN   INTEGER := 1,  
    nth        IN   INTEGER := 1)  
RETURN INTEGER;
```

```sql
DBMS_LOB.INSTR (  
    file_loc   IN   BFILE,  
    pattern    IN   RAW,  
    offset     IN   INTEGER := 1,  
    nth        IN   INTEGER := 1)  
RETURN INTEGER;
```

Pragmas

```sql
pragma restrict_references(INSTR, WNDS, WNPS, RNDS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the LOB to be examined. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>file_loc</td>
<td>The file locator for the LOB to be examined.</td>
</tr>
<tr>
<td>pattern</td>
<td>Pattern to be tested for. The pattern is a group of RAW bytes for BLOBs, and a character string (VARCHAR2) for CLOBs. The maximum size of the pattern is 16383 bytes.</td>
</tr>
<tr>
<td>offset</td>
<td>Absolute offset in bytes (BLOBs) or characters (CLOBs) at which the pattern matching is to start. (origin: 1)</td>
</tr>
<tr>
<td>nth</td>
<td>Occurrence number, starting at 1.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INTEGER</td>
<td>Offset of the start of the matched pattern, in bytes or characters. It returns 0 if the pattern is not found.</td>
</tr>
</tbody>
</table>
Usage Notes

The form of the VARCHAR2 buffer (the pattern parameter) must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

For BFILES, the file must be already opened using a successful FILEOPEN operation for this operation to succeed.

Operations that accept RAW or VARCHAR2 parameters for pattern matching, such as INSTR, do not support regular expressions or special matching characters (as in the case of SQL LIKE) in the pattern parameter or substrings.

Exceptions

Table 82–68  INSTR Function Exceptions for BFILES

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNOPENED_FILE</td>
<td>File was not opened using the input locator.</td>
</tr>
<tr>
<td>NOEXIST_DIRECTORY</td>
<td>Directory does not exist.</td>
</tr>
<tr>
<td>NOPRIV_DIRECTORY</td>
<td>You do not have privileges for the directory.</td>
</tr>
<tr>
<td>INVALID_DIRECTORY</td>
<td>Directory has been invalidated after the file was opened.</td>
</tr>
<tr>
<td>INVALID_OPERATION</td>
<td>File does not exist, or you do not have access privileges on the file.</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB</td>
</tr>
</tbody>
</table>

See Also:

- "SUBSTR Functions" on page 82-77
- Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
ISOPEN Functions

This function checks to see if the LOB was already opened using the input locator. This subprogram is for internal and external LOBs.

Syntax

```
DBMS_LOB.ISOPEN (  
    lob_loc IN BLOB)  
RETURN INTEGER;

DBMS_LOB.ISOPEN (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
RETURN INTEGER;

DBMS_LOB.ISOPEN (  
    file_loc IN BFILE)  
RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(isopen, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>file_loc</td>
<td>File locator.</td>
</tr>
</tbody>
</table>

Return Values

The return value is 1 if the LOB is open, 0 otherwise.

Usage Notes

For BFILES, openness is associated with the locator. If the input locator was never passed to OPEN, the BFILE is not considered to be opened by this locator. However, a different locator may have opened the BFILE. More than one OPEN can be performed on the same BFILE using different locators.

For internal LOBs, openness is associated with the LOB, not with the locator. If locator1 opened the LOB, then locator2 also sees the LOB as open. For internal LOBs, ISOPEN requires a round-trip, because it checks the state on the server to see if the LOB is indeed open.

For external LOBs (BFILES), ISOPEN also requires a round-trip, because that’s where the state is kept.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
ISTEMPORARY Functions

This function determines whether a LOB instance is temporary.

Syntax

```
DBMS_LOB.ISTEMPORARY (  
    lob_loc IN BLOB)  
RETURN INTEGER;
```

```
DBMS_LOB.ISTEMPORARY (  
    lob_loc IN CLOB CHARACTER SET ANY_CS)  
RETURN INTEGER;
```

Pragmas

```
PRAGMA RESTRICT_REFERENCES(istemporary, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
</tbody>
</table>

Return Values

The return value is 1 if the LOB is temporary and exists; 0 if the LOB is not temporary or does not exist; NULL if the given locator is NULL.

Usage Notes

When you free a Temporary LOB with FREETEMPORARY, the LOB locator is not set to NULL. Consequently, ISTEMPORARY will return 0 for a locator that has been freed but not explicitly reset to NULL.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
LOADBLOBFROMFILE Procedure

This procedure loads data from BFILE to internal BLOB. This achieves the same outcome as LOADFROMFILE, and returns the new offsets.

Syntax

```sql
DBMS_LOB.LOADBLOBFROMFILE (  
dest_lob    IN OUT NOCOPY BLOB,  
src_bfile   IN            BFILE,  
amount      IN            INTEGER,  
dest_offset IN OUT        INTEGER,  
src_offset  IN OUT        INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>BLOB locator of the target for the load.</td>
</tr>
<tr>
<td>src_bfile</td>
<td>BFILE locator of the source for the load.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes to load from the BFILE. You can also use DBMS_LOB.LOBMAXSIZE to load until the end of the BFILE.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>(IN) Offset in bytes in the destination BLOB (origin: 1) for the start of the write. (OUT) New offset in bytes in the destination BLOB right after the end of this write, which is also where the next write should begin.</td>
</tr>
<tr>
<td>src_offset</td>
<td>(IN) Offset in bytes in the source BFILE (origin: 1) for the start of the read. (OUT) Offset in bytes in the source BFILE right after the end of this read, which is also where the next read should begin.</td>
</tr>
</tbody>
</table>

Usage Notes

- You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The amount and src_offset, because they refer to the BFILE, are in terms of bytes, and the dest_offset is in bytes for BLOBs.
- If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB. If the offset is less than the current length of the destination LOB, then existing data is overwritten.
- There is an error if the input amount plus offset exceeds the length of the data in the BFILE (unless the amount specified is LOBMAXSIZE which you can specify to continue loading until the end of the BFILE is reached).
- It is not mandatory that you wrap the LOB operation inside the OPEN/CLOSE operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

---

Summary of DBMS_LOB Subprograms
If you do not wrap the LOB operation inside the OPEN/CLOSE, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

LOADFROMFILE gets the destination LOB prior to the load unless the load covers the entire LOB.

Constants and Defaults
There is no easy way to omit parameters. You must either declare a variable for IN/OUT parameter or provide a default value for the IN parameter. Here is a summary of the constants and the defaults that can be used.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>DBMS_LOB.LOBMAXSIZE</td>
<td>Load the entire file</td>
</tr>
<tr>
<td></td>
<td>(IN)</td>
<td></td>
</tr>
<tr>
<td>dest_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>src_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
</tbody>
</table>

Constants defined in DBMSLOB.SQL

lobmaxsize CONSTANT INTEGER := DBMS_LOB.LOBMAXSIZE;

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>Either:</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &lt; 1.</td>
</tr>
<tr>
<td></td>
<td>- src_offset or dest_offset &gt; LOBMAXSIZE.</td>
</tr>
<tr>
<td></td>
<td>- amount &lt; 1.</td>
</tr>
<tr>
<td></td>
<td>- amount &gt; LOBMAXSIZE.</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on the BLOB</td>
</tr>
</tbody>
</table>

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
LOADCLOBFROMFILE Procedure

This procedure loads data from a BFILE to an internal CLOB/NCLOB with necessary character set conversion and returns the new offsets.

Syntax

```sql
DBMS_LOB.LOADCLOBFROMFILE (
  dest_lob       IN OUT NOCOPY   NOCOPY CLOB CHARACTER SET ANY_CS,
  src_bfile      IN              BFILE,
  amount         IN              INTEGER,
  dest_offset    IN OUT          INTEGER,
  src_offset     IN OUT          INTEGER,
  bfile_csid     IN              NUMBER,
  lang_context   IN OUT          INTEGER,
  warning        OUT             INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>CLOB/NCLOB locator of the target for the load.</td>
</tr>
<tr>
<td>src_bfile</td>
<td>BFILE locator of the source for the load.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes to load from the BFILE. Use DBMS_LOB.LOBMAXSIZE of load until the end of the BFILE.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>(IN) Offset in characters in the destination CLOB (origin: 1) for the start of the write. (OUT) The new offset in characters right after the end of this load, which is also where the next load should start. It always points to the beginning of the first complete character after the end of load. If the last character is not complete, offset goes back to the beginning of the partial character.</td>
</tr>
<tr>
<td>src_offset</td>
<td>(IN) Offset in bytes in the source BFILE (origin: 1) for the start of the read. (OUT) Offset in bytes in the source BFILE right after the end of this read, which is also where the next read should begin.</td>
</tr>
<tr>
<td>bfile_csid</td>
<td>Character set id of the source (BFILE) file.</td>
</tr>
<tr>
<td>lang_context</td>
<td>(IN) Language context, such as shift status, for the current load.</td>
</tr>
<tr>
<td></td>
<td>(OUT) The language context at the time when the current load stopped, and what the next load should be using if continuing loading from the same source. This information is returned to the user so that they can use it for the continuous load without losing or misinterpreting any source data. For the very first load or if do not care, simply use the default 0. The details of this language context is hidden from the user. One does not need to know what it is or what's in it in order to make the call</td>
</tr>
</tbody>
</table>
Usage Notes

You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The amount and src_offset, because they refer to the BFILE, are in terms of bytes, and the dest_offset is in characters for CLOBs.

If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination CLOB. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

There is an error if the input amount plus offset exceeds the length of the data in the BFILE (unless the amount specified is LOBMAXSIZE which you can specify to continue loading until the end of the BFILE is reached).

Note the following requirements:

- The destination character set is always the same as the database character set in the case of CLOB and national character set in the case of NCLOB.
- csid=0 indicates the default behavior that uses database csid for CLOB and national csid for NCLOB in the place of source csid. Conversion is still necessary if it is of varying width.
- It is not mandatory that you wrap the LOB operation inside the OPEN/CLOSE operations. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the OPEN/CLOSE, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

The source BFILE can contain data in the Unicode character set. The Unicode standard defines many encoding schemes that provide mappings from Unicode characters to sequences of bytes. Table 82–75, "Supported Unicode Encoding Schemes" lists Unicode encodings schemes supported by this subprogram.

Table 82–75  Supported Unicode Encoding Schemes

<table>
<thead>
<tr>
<th>Encoding Scheme</th>
<th>Oracle Name</th>
<th>bfile_csid Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>UTF-8</td>
<td>AL32UTF8</td>
<td>873</td>
</tr>
<tr>
<td>UTF-16BE</td>
<td>AL16UTF16</td>
<td>2000</td>
</tr>
</tbody>
</table>

warning  (OUT) Warning message. This indicates something abnormal happened during the loading. It may or may not be caused by the user’s mistake. The loading is completed as required, and it’s up to the user to check the warning message. Currently, the only possible warning is the inconvertible character. This happens when the character in the source cannot be properly converted to a character in destination, and the default replacement character (for example, '?') is used in place. The message is defined the constant value DBMS_LOB.WARN_INCONVERTIBLE_CHAR.
All three UTF-16 encoding schemes encode Unicode characters as 2-byte unsigned integers. Integers can be stored in big-endian or in little-endian byte order. The UTF-16BE encoding scheme defines big-endian data. The UTF-16LE scheme defines little-endian data. The UTF-16 scheme requires that the source BFILE contains the Byte Order Mark (BOM) character in the first two bytes to define the byte order. The BOM code is 0xFEFF. If the code is stored as \{0xFE,0xFF\}, the data is interpreted as big-endian. If it is stored as \{0xFF,0xFE\}, the data is interpreted as little-endian.

In UTF-8 and in CESU-8 encodings the Byte Order Mark is stored as \{0xEF,0xBB,0xBF\}. With any of the Unicode encodings, the corresponding BOM sequence at the beginning of the file is recognized and not loaded into the destination LOB.

### Constants

Here is a summary of the constants and the suggested values that can be used.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Suggested Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>amount</td>
<td>DBMS_LOB.LOBMAXSIZE (IN)</td>
<td>Load the entire file</td>
</tr>
<tr>
<td>dest_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>src_offset</td>
<td>1 (IN)</td>
<td>start from the beginning</td>
</tr>
<tr>
<td>csid</td>

</tbody>
</table>

**See Also:** Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
LOADFROMFILE Procedure

This procedure copies all, or a part of, a source external LOB (BFILE) to a destination internal LOB.

Syntax

```sql
DBMS_LOB.LOADFROMFILE (  
dest_lob    IN OUT NOCOPY BLOB,  
src_file    IN            BFILE,  
amount      IN            INTEGER,  
dest_offset IN            INTEGER  := 1,  
src_offset  IN            INTEGER  := 1);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dest_lob</td>
<td>LOB locator of the target for the load.</td>
</tr>
<tr>
<td>src_file</td>
<td>BFILE locator of the source for the load.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes to load from the BFILE.</td>
</tr>
<tr>
<td>dest_offset</td>
<td>Offset in bytes or characters in the destination LOB (origin: 1) for the start of the load.</td>
</tr>
<tr>
<td>src_offset</td>
<td>Offset in bytes in the source BFILE (origin: 1) for the start of the load.</td>
</tr>
</tbody>
</table>

Usage Notes

You can specify the offsets for both the source and destination LOBs, and the number of bytes to copy from the source BFILE. The `amount` and `src_offset`, because they refer to the BFILE, are in terms of bytes, and the `dest_offset` is either in bytes or characters for BLOBs and CLOBs respectively.

**Note:** The input BFILE must have been opened prior to using this procedure. No character set conversions are performed implicitly when binary BFILE data is loaded into a CLOB. The BFILE data must already be in the same character set as the CLOB in the database. No error checking is performed to verify this.

If the offset you specify in the destination LOB is beyond the end of the data currently in this LOB, then zero-byte fillers or spaces are inserted in the destination BLOB or CLOB respectively. If the offset is less than the current length of the destination LOB, then existing data is overwritten.

There is an error if the input amount plus offset exceeds the length of the data in the BFILE.
LOADFROMFILE Procedure

**Note:** If the character set is varying width, UTF-8 for example, the LOB value is stored in the fixed-width UCS2 format. Therefore, if you are using `DBMS_LOB.LOADFROMFILE`, the data in the BFILE should be in the UCS2 character set instead of the UTF-8 character set. However, you should use `sql*loader` instead of `LOADFROMFILE` to load data into a CLOB or NCLOB because `sql*loader` provides the necessary character set conversions.

It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

### Exceptions

**Table 82–79  LOADFROMFILE Procedure Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of the input parameters are NULL or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>

</tr>
<tr>
<td></td>
<td>- amount &gt; LOBMAXSIZE.</td>
</tr>
</tbody>
</table>

See Also: *Oracle Database SecureFiles and Large Objects Developer’s Guide* for additional details on usage of this procedure.
MOVE_TO_DBFS_LINK Procedures

This procedure writes the specified SecureFile data to the DBFS store.

Syntax

```
DBMS_LOB.MOVE_TO_DBFS_LINK (  
   lob_loc       IN OUT BLOB,  
   storage_path  IN     VARCHAR2(dbfs_link_path_max_size),  
   flags         IN     BINARY INTEGER DEFAULT DBFS_LINK_NOCACHE);  

DBMS_LOB.MOVE_TO_DBFS_LINK (  
   lob_loc       IN OUT CLOB CHARACTER SET ANY_CS,  
   storage_path  IN     VARCHAR2(dbfs_link_path_max_size),  
   flags         IN     BINARY INTEGER DEFAULT DBFS_LINK_NOCACHE);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be archived</td>
</tr>
<tr>
<td>storage_path</td>
<td>Path where the LOB will be stored</td>
</tr>
<tr>
<td>flags</td>
<td>Either DBFS_LINK_CACHE or DBFS_LINK_NOCACHE. If DBFS_LINK_CACHE is specified, the LOB data continues to be stored in the RDBMS as well as being written to the DBFS store. DBFS_LINK_NOCACHE specifies that the LOB data should be deleted from the RDBMS once written to the DBFS.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>

Usage Notes

- If the LOB is already archived, the procedure silently returns as if the put was successful. In that case, if DBFS_LINK_NOCACHE is specified, or flags is defaulted, the LOB data is removed from the RDBMS.
- Calling this procedure multiple times on the same LOB with the same flags has no effect.
- Calling the procedure on a LOB that is already archived causes the LOB to be cached (DBFS_LINK_CACHE) or removed (DBFS_LINK_NOCACHE) according to the flag setting.
OPEN Procedures

This procedure opens a LOB, internal or external, in the indicated mode. Valid modes include read-only, and read/write.

Syntax

```sql
DBMS_LOB.OPEN (  
    lob_loc   IN OUT NOCOPY BLOB,  
    open_mode IN            BINARY_INTEGER);

DBMS_LOB.OPEN (  
    lob_loc   IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    open_mode IN            BINARY_INTEGER);

DBMS_LOB.OPEN (  
    file_loc  IN OUT NOCOPY BFILE,  
    open_mode IN            BINARY_INTEGER := file_readonly);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB locator. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>open_mode</td>
<td>Mode in which to open. For BLOB and CLOB types, the mode can be either: LOB_READONLY or LOB_READWRITE. For BFILE types, the mode must be FILE_READONLY.</td>
</tr>
</tbody>
</table>

Usage Notes

**Note:** If the LOB was opened in read-only mode, and if you try to write to the LOB, then an error is returned. BFILE can only be opened with read-only mode.

OPEN requires a round-trip to the server for both internal and external LOBs. For internal LOBs, OPEN triggers other code that relies on the OPEN call. For external LOBs (BFILES), OPEN requires a round-trip because the actual operating system file on the server side is being opened.

It is not mandatory that you wrap all LOB operations inside the Open/Close interfaces. However, if you open a LOB, you must close it before you commit the transaction; an error is produced if you do not. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

It is an error to commit the transaction before closing all opened LOBs that were opened by the transaction. When the error is returned, the openness of the open LOBs is discarded, but the transaction is successfully committed. Hence, all the changes made to the LOB and non-LOB data in the transaction are committed, but the domain and function-based indexes are not updated. If this happens, you should rebuild the functional and domain indexes on the LOB column.
See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
READ Procedures

This procedure reads a piece of a LOB, and returns the specified amount into the buffer parameter, starting from an absolute offset from the beginning of the LOB.

The number of bytes or characters actually read is returned in the amount parameter. If the input offset points past the End of LOB, then amount is set to 0, and a NO_DATA_FOUND exception is raised.

Syntax

```
DBMS_LOB.READ (    lob_loc   IN             BLOB,
                   amount    IN OUT  NOCOPY INTEGER,
                   offset    IN             INTEGER,
                   buffer    OUT            RAW);

DBMS_LOB.READ (    lob_loc   IN             CLOB CHARACTER SET ANY_CS,
                   amount    IN OUT  NOCOPY INTEGER,
                   offset    IN             INTEGER,
                   buffer    OUT            VARCHAR2 CHARACTER SET lob_loc%CHARSET);

DBMS_LOB.READ (    file_loc   IN             BFILE,
                   amount    IN OUT   NOCOPY INTEGER,
                   offset    IN              INTEGER,
                   buffer    OUT             RAW);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the LOB to be read. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>file_loc</td>
<td>The file locator for the LOB to be examined.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs) to read, or number that were read.</td>
</tr>
<tr>
<td>offset</td>
<td>Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1).</td>
</tr>
<tr>
<td>buffer</td>
<td>Output buffer for the read operation.</td>
</tr>
</tbody>
</table>

Exceptions

Table 82–84 lists exceptions that apply to any LOB instance. Table 82–85 lists exceptions that apply only to BFILES.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of lob_loc, amount, or offset parameters are NULL.</td>
</tr>
</tbody>
</table>
Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

- When calling DBMS_LOB.READ from the client (for example, in a BEGIN/END block from within SQL*Plus), the returned buffer contains data in the client’s character set. The database converts the LOB value from the server’s character set to the client’s character set before it returns the buffer to the user.

- READ gets the LOB, if necessary, before the read.

See Also: Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure.
SET_DBFS_LINK Procedures

This function links the specified SecureFile to the specified path name. It does not copy the data to the path.

Syntax

```sql
DBMS_LOB.SET_DBFS_LINK (    lob_loc        IN OUT BLOB,
    archive_id     IN     RAW(1024));

DBMS_LOB.SET_DBFS_LINK(    lob_loc_dst    IN OUT CLOB CHARACTER SET ANY_CS,
    archive_id     IN     RAW(1024));
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB for which to store the reference value</td>
</tr>
<tr>
<td>archive_id</td>
<td>Archive ID as returned by calling either of the GET_DBFS_LINK Functions</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>
SETCONTENTTYPE Procedure

This procedure sets the content type string for the data in the LOB.

Syntax

```sql
DBMS_LOB.SETCONTENTTYPE (    lob_loc      IN OUT NOCOPY BLOB,    contenttype IN VARCHAR2);    DBMS_LOB.SETCONTENTTYPE (    lob_loc     IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,    contenttype IN VARCHAR2);```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>LOB to be assigned the content type</td>
</tr>
<tr>
<td>contenttype</td>
<td>String to be assigned</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>lob_loc is not a SECUREFILE</td>
</tr>
</tbody>
</table>

Usage Notes

To clear an existing contenttype associated with a SECUREFILE, invoke SETCONTENTTYPE with contenttype set to empty string.
SETOPTIONS Procedures

This procedure enables/disables CSCE features on a per-LOB basis, overriding the default LOB column settings.

Syntax

```sql
DBMS_LOB.SETOPTIONS ( 
  lob_loc             IN     BLOB, 
  option_types        IN     PLS_INTEGER, 
  options             IN     PLS_INTEGER);

DBMS_LOB.SETOPTIONS ( 
  lob_loc             IN     CLOB CHARACTER SET ANY_CS, 
  option_types        IN     PLS_INTEGER, 
  options             IN     PLS_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the LOB to be examined. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>option_type</td>
<td>See DBMS_LOB Constants - Option Types on page 82-5</td>
</tr>
<tr>
<td>options</td>
<td>See DBMS_LOB Constants - Option Values on page 82-5</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SECUREFILE_BADLOB</td>
<td>Unsupported object type for the operation</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>A parameter value was invalid</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform operation during a query</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled</td>
</tr>
</tbody>
</table>

Usage Notes

- DBMS_LOB.SETOPTIONS cannot be used to enable or disable encryption on individual LOBs.

- You cannot turn compression or deduplication on or off for a SecureFile column that does not have those features on. The GETOPTIONS Functions and SetOptions Procedures work on individual SecureFiles. You can turn off a feature on a particular SecureFile and turn on a feature that has already been turned off by SetOptions, but you cannot turn on an option that has not been given to the SecureFile when the table was created.
SUBSTR Functions

This function returns amount bytes or characters of a LOB, starting from an absolute offset from the beginning of the LOB.

For fixed-width n-byte CLOBs, if the input amount for SUBSTR is greater than \((32767/n)\), then SUBSTR returns a character buffer of length \((32767/n)\), or the length of the CLOB, whichever is lesser. For CLOBs in a varying-width character set, \(n\) is the maximum byte-width used for characters in the CLOB.

Syntax

```sql
DBMS_LOB.SUBSTR ( lob_loc     IN    BLOB,
                   amount      IN    INTEGER := 32767,
                   offset      IN    INTEGER := 1)
RETURN RAW;

DBMS_LOB.SUBSTR ( lob_loc     IN    CLOB   CHARACTER SET ANY_CS,
                   amount      IN    INTEGER := 32767,
                   offset      IN    INTEGER := 1)
RETURN VARCHAR2 CHARACTER SET lob_loc%CHARSET;

DBMS_LOB.SUBSTR ( file_loc     IN    BFILE,
                   amount      IN    INTEGER := 32767,
                   offset      IN    INTEGER := 1)
RETURN RAW;
```

Pragmas

```sql
pragma restrict_references(SUBSTR, WNDS, WNPS, RNDS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the LOB to be read. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>file_loc</td>
<td>The file locator for the LOB to be examined.</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs) to be read.</td>
</tr>
<tr>
<td>offset</td>
<td>Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1).</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RAW</td>
<td>Function overloading that has a BLOB or BFILE in parameter.</td>
</tr>
<tr>
<td>VARCHAR2</td>
<td>CLOB version.</td>
</tr>
</tbody>
</table>
The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

When calling DBMS_LOB.SUBSTR from the client (for example, in a BEGIN/END block from within SQL*Plus), the returned buffer contains data in the client's character set. The database converts the LOB value from the server's character set to the client's character set before it returns the buffer to the user.

DBMS_LOB.SUBSTR will return 8191 or more characters based on the characters stored in the LOBs. If all characters are not returned as a consequence of the character byte size exceeding the available buffer, the user should either call DBMS_LOB.SUBSTR with a new offset to read the remaining characters, or call the subprogram on loop until all the data is extracted.

SUBSTR gets the LOB, if necessary, before read.

Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
TRIM Procedures

This procedure trims the value of the internal LOB to the length you specify in the newlen parameter. Specify the length in bytes for BLOBs, and specify the length in characters for CLOBs.

---

**Note:** The TRIM procedure decreases the length of the LOB to the value specified in the newlen parameter.

---

If you attempt to TRIM an empty LOB, then nothing occurs, and TRIM returns no error. If the new length that you specify in newlen is greater than the size of the LOB, then an exception is raised.

**Syntax**

```sql
DBMS_LOB.TRIM (lob_loc IN OUT NOCOPY BLOB, newlen IN INTEGER);

DBMS_LOB.TRIM (lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS, newlen IN INTEGER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the internal LOB whose length is to be trimmed. For more information, see Operational Notes.</td>
</tr>
<tr>
<td>newlen</td>
<td>New, trimmed length of the LOB value in bytes for BLOBs or characters for CLOBs.</td>
</tr>
</tbody>
</table>

**Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>lob_loc is NULL.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>Either:</td>
</tr>
<tr>
<td></td>
<td>- new_len &lt; 0</td>
</tr>
<tr>
<td></td>
<td>- new_len &gt; LOBMAXSIZE</td>
</tr>
<tr>
<td>QUERY_WRITE</td>
<td>Cannot perform a LOB write inside a query or PDML slave</td>
</tr>
<tr>
<td>BUFFERING_ENABLED</td>
<td>Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB</td>
</tr>
</tbody>
</table>

**Usage Notes**

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close.
it before you commit the transaction. When an internal \texttt{LOB} is closed, it updates the functional and domain indexes on the \texttt{LOB} column.

- If you do not wrap the \texttt{LOB} operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the \texttt{LOB}. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the \texttt{LOB} within the \texttt{OPEN} or \texttt{CLOSE} statement.

- \texttt{TRIM} gets the \texttt{LOB}, if necessary, before altering the length of the \texttt{LOB}, unless the new length specified is '0'

**See Also:**
- "\texttt{ERASE} Procedures" on page 82-35
- "\texttt{WRITEAPPEND} Procedures" on page 82-83
- \textit{Oracle Database SecureFiles and Large Objects Developer’s Guide}
  for additional details on usage of this procedure
WRITE Procedures

This procedure writes a specified amount of data into an internal LOB, starting from an absolute offset from the beginning of the LOB. The data is written from the buffer parameter.

WRITE replaces (overwrites) any data that already exists in the LOB at the offset, for the length you specify.

Syntax

```sql
DBMS_LOB.WRITE ( 
  lob_loc  IN OUT NOCOPY  BLOB,  
  amount   IN             INTEGER,  
  offset   IN             INTEGER,  
  buffer   IN             RAW);
```

```sql
DBMS_LOB.WRITE ( 
  lob_loc  IN OUT  NOCOPY CLOB   CHARACTER SET ANY_CS,  
  amount   IN             INTEGER,  
  offset   IN             INTEGER,  
  buffer   IN             VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the internal LOB to be written to. For more information, see Operational Notes</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs) to write</td>
</tr>
<tr>
<td>offset</td>
<td>Offset in bytes (for BLOBs) or characters (for CLOBs) from the start of the LOB (origin: 1) for the write operation.</td>
</tr>
<tr>
<td>buffer</td>
<td>Input buffer for the write</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of lob_loc, amount, or offset parameters are NULL, out of range, or INVALID.</td>
</tr>
<tr>
<td>INVALID_ARGVAL</td>
<td>Either:</td>
</tr>
<tr>
<td></td>
<td>- amount &lt; 1</td>
</tr>
<tr>
<td></td>
<td>- amount &gt; 32767 bytes</td>
</tr>

</tr>
<tr>
<td>SECUREFILE_OUTOFBOUNDS</td>
<td>Attempted to perform a write operation past the end of a LOB having FRAGMENT_* on it</td>
</tr>
</tbody>
</table>
Usage Notes

- There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer is written to the LOB. If the offset you specify is beyond the end of the data currently in the LOB, then zero-byte fillers or spaces are inserted in the BLOB or CLOB respectively.

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.

- When calling DBMS_LOB.WRITE from the client (for example, in a BEGIN/END block from within SQL*Plus), the buffer must contain data in the client's character set. The database converts the client-side buffer to the server's character set before it writes the buffer data to the LOB.

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the OPEN or CLOSE statement.

- WRITE gets the LOB, if necessary, before writing the LOB, unless the write is specified to overwrite the entire LOB.

- "COPY Procedures" on page 82-29
- Oracle Database SecureFiles and Large Objects Developer’s Guide for additional details on usage of this procedure
WRITEAPPEND Procedures

This procedure writes a specified amount of data to the end of an internal LOB. The data is written from the buffer parameter.

Syntax

```sql
DBMS_LOB.WRITEAPPEND (  
    lob_loc IN OUT NOCOPY BLOB,  
    amount IN INTEGER,  
    buffer IN RAW);

DBMS_LOB.WRITEAPPEND (  
    lob_loc IN OUT NOCOPY CLOB CHARACTER SET ANY_CS,  
    amount IN INTEGER,  
    buffer IN VARCHAR2 CHARACTER SET lob_loc%CHARSET);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lob_loc</td>
<td>Locator for the internal LOB to be written to. For more information, see Operational Notes</td>
</tr>
<tr>
<td>amount</td>
<td>Number of bytes (for BLOBs) or characters (for CLOBs) to write</td>
</tr>
<tr>
<td>buffer</td>
<td>Input buffer for the write</td>
</tr>
</tbody>
</table>

Usage Notes

There is an error if the input amount is more than the data in the buffer. If the input amount is less than the data in the buffer, then only amount bytes or characters from the buffer are written to the end of the LOB.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VALUE_ERROR</td>
<td>Any of lob_loc, amount, or offset parameters are NULL, out of range, or INVALID.</td>
</tr>
</tbody>
</table>
| INVALID_ARGVAL  | Either:  
  - amount < 1  
  - amount > 32767 bytes |
| QUERY_WRITE     | Cannot perform a LOB write inside a query or PDML slave |
| BUFFERING_ENABLED | Cannot perform operation with LOB buffering enabled if buffering is enabled on the LOB |

Usage Notes

- The form of the VARCHAR2 buffer must match the form of the CLOB parameter. In other words, if the input LOB parameter is of type NCLOB, then the buffer must contain NCHAR data. Conversely, if the input LOB parameter is of type CLOB, then the buffer must contain CHAR data.
WRITEAPPEND Procedures

- When calling `DBMS_LOB.WRITEAPPEND` from the client (for example, in a `BEGIN/END` block from within SQL*Plus), the buffer must contain data in the client’s character set. The database converts the client-side buffer to the server’s character set before it writes the buffer data to the LOB.

- It is not mandatory that you wrap the LOB operation inside the Open/Close interfaces. If you did not open the LOB before performing the operation, the functional and domain indexes on the LOB column are updated during the call. However, if you opened the LOB before performing the operation, you must close it before you commit the transaction. When an internal LOB is closed, it updates the functional and domain indexes on the LOB column.

- If you do not wrap the LOB operation inside the Open/Close API, the functional and domain indexes are updated each time you write to the LOB. This can adversely affect performance. Therefore, it is recommended that you enclose write operations to the LOB within the `OPEN` or `CLOSE` statement.

- WRITEAPPEND gets the LOB, if necessary, before appending to the LOB.

The **DBMS_LOCK** package provides an interface to Oracle Lock Management services. You can request a lock of a specific mode, give it a unique name recognizable in another procedure in the same or another instance, change the lock mode, and release it.

**See Also:** For more information, and an example of how to use the **DBMS_LOCK** package, see “About User Locks” in *Oracle Database Advanced Application Developer’s Guide*

This chapter contains the following topics:

- **Summary of DBMS_LOCK Subprograms**
Using DBMS_LOCK

- Overview
- Security Model
- Constants
- Rules and Limits
- Operational Notes
Overview

Some uses of user locks:

- Providing exclusive access to a device, such as a terminal
- Providing application-level enforcement of read locks
- Detecting when a lock is released and cleanup after the application
- Synchronizing applications and enforcing sequential processing
Security Model

There might be operating system-specific limits on the maximum number of total locks available. This must be considered when using locks or making this package available to other users. Consider granting the EXECUTE privilege only to specific users or roles.

A better alternative would be to create a cover package limiting the number of locks used and grant EXECUTE privilege to specific users. An example of a cover package is documented in the DBMS_LOCK.SQL package specification file. The abbreviations for these locks as they appear in Enterprise Manager monitors are in parentheses.
## Constants

The **DBMS_LOCK** package uses the constants shown in **Table 83–1**.

### Table 83–1 DBMS_LOCK Constants

<table>
<thead>
<tr>
<th>Name</th>
<th>Alternate Name(s)</th>
<th>Type</th>
<th>Value</th>
<th>OEM Abbreviation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NL_MODE</td>
<td>NuL1</td>
<td>INTEGER</td>
<td>1</td>
<td>-</td>
<td>-</td>
</tr>
<tr>
<td>SS_MODE</td>
<td>Sub Shared</td>
<td>INTEGER</td>
<td>2</td>
<td>ULRS</td>
<td>This can be used on an aggregate object to indicate that share locks are being acquired on subparts of the object.</td>
</tr>
<tr>
<td>SX_MODE</td>
<td>Sub eXclusive</td>
<td>INTEGER</td>
<td>3</td>
<td>ULRX</td>
<td>This can be used on an aggregate object to indicate that exclusive locks are being acquired on sub-parts of the object.</td>
</tr>
<tr>
<td></td>
<td>Row Exclusive Mode</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>S_MODE</td>

<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Intended Exclusive</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>SSX_MODE</td>
<td>Shared Sub eXclusive</td>
<td>INTEGER</td>
<td>5</td>
<td>-</td>
<td>This indicates that the entire aggregate object has a share lock, but some of the sub-parts may additionally have exclusive locks.</td>
</tr>
<tr>
<td></td>
<td>Share Row Exclusive</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Mode</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>X_MODE</td>
<td>Exclusive</td>
<td>INTEGER</td>
<td>6</td>
<td>ULX</td>
<td>-</td>
</tr>
</tbody>
</table>

These are the various lock modes (nl -> "NuL1", ss -> "Sub Shared", sx -> "Sub eXclusive", s -> "Shared", ssx -> "Shared Sub eXclusive", x -> "eXclusive").
Rules and Limits

When another process holds "held", an attempt to get "get" does the following:

<table>
<thead>
<tr>
<th>HELD MODE</th>
<th>GET NL</th>
<th>GET SS</th>
<th>GET SX</th>
<th>GET S</th>
<th>GET SSX</th>
<th>GET X</th>
</tr>
</thead>
<tbody>
<tr>
<td>NL</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
</tr>
<tr>
<td>SS</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Fail</td>
</tr>
<tr>
<td>SX</td>
<td>Success</td>
<td>Success</td>
<td>Success</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
</tr>
<tr>
<td>S</td>
<td>Success</td>
<td>Success</td>
<td>Fail</td>
<td>Success</td>
<td>Fail</td>
<td>Fail</td>
</tr>
<tr>
<td>SSX</td>
<td>Success</td>
<td>Success</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
</tr>
<tr>
<td>X</td>
<td>Success</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
<td>Fail</td>
</tr>
</tbody>
</table>

maxwait constant integer := 32767;

The constant maxwait waits forever.
Operational Notes

User locks never conflict with Oracle locks because they are identified with the prefix "UL". You can view these locks using the Enterprise Manager lock monitor screen or the appropriate fixed views. User locks are automatically released when a session terminates. The lock identifier is a number in the range of 0 to 1073741823.

Because a reserved user lock is the same as an Oracle lock, it has all the functionality of an Oracle lock, such as deadlock detection. Be certain that any user locks used in distributed transactions are released upon COMMIT, or an undetected deadlock may occur.

DBMS_LOCK is most efficient with a limit of a few hundred locks for each session. Oracle strongly recommends that you develop a standard convention for using these locks in order to avoid conflicts among procedures trying to use the same locks. For example, include your company name as part of your lock names.
## Summary of DBMS_LOCK Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALLOCATE_UNIQUE Procedure on page 83-9</td>
<td>Allocates a unique lock ID to a named lock</td>
</tr>
<tr>

<td>Converts a lock from one mode to another</td>
</tr>
<tr>
<td>RELEASE Function on page 83-12</td>
<td>Releases a lock</td>
</tr>
<tr>
<td>REQUEST Function on page 83-13</td>
<td>Requests a lock of a specific mode.</td>
</tr>
<tr>
<td>SLEEP Procedure on page 83-14</td>
<td>Puts a session to sleep for a specific time</td>
</tr>
</tbody>
</table>
**ALLOCATE_UNIQUE Procedure**

This procedure allocates a unique lock identifier (in the range of 1073741824 to 1999999999) to a specified lock name. Lock identifiers are used to enable applications to coordinate their use of locks. This is provided because it may be easier for applications to coordinate their use of locks based on lock names rather than lock numbers.

**Syntax**

```
DBMS_LOCK.ALLOCATE_UNIQUE (
    lockname         IN  VARCHAR2,
    lockhandle       OUT VARCHAR2,
    expiration_secs  IN  INTEGER   DEFAULT 864000);
```

**Parameters**

**Table 83–4  ALLOCATE_UNIQUE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lockname</td>
<td>Name of the lock for which you want to generate a unique ID. Do not use lock names beginning with ORA$; these are reserved for products supplied by Oracle.</td>
</tr>
</tbody>
</table>
| lockhandle      | Returns the handle to the lock ID generated by ALLOCATE_UNIQUE. You can use this handle in subsequent calls to REQUEST, CONVERT, and RELEASE.  
A handle is returned instead of the actual lock ID to reduce the chance that a programming error accidentally creates an incorrect, but valid, lock ID. This provides better isolation between different applications that are using this package.  
LOCKHANDLE can be up to VARCHAR2 (128).  
All sessions using a lock handle returned by ALLOCATE_UNIQUE with the same lock name are referring to the same lock. Therefore, do not pass lock handles from one session to another. |
| expiration_secs | Number of seconds to wait after the last ALLOCATE_UNIQUE has been performed on a specified lock, before permitting that lock to be deleted from the DBMS_LOCK_ALLOCATED table.  
The default waiting period is 10 days. You should not delete locks from this table. Subsequent calls to ALLOCATE_UNIQUE may delete expired locks to recover space. |

**Usage Notes**

If you choose to identify locks by name, you can use ALLOCATE_UNIQUE to generate a unique lock identification number for these named locks.

The first session to call ALLOCATE_UNIQUE with a new lock name causes a unique lock ID to be generated and stored in the dbms_lock_allocated table. Subsequent calls (usually by other sessions) return the lock ID previously generated.

A lock name is associated with the returned lock ID for at least expiration_secs (defaults to 10 days) past the last call to ALLOCATE_UNIQUE with the specified lock name. After this time, the row in the dbms_lock_allocated table for this lock name may be deleted in order to recover space. ALLOCATE_UNIQUE performs a commit.
Note: Named user locks may be less efficient, because Oracle uses SQL to determine the lock associated with a specified name.

Exceptions

ORA-20000, ORU-10003: Unable to find or insert lock <lockname> into catalog dbms_lock_allocated.
CONVERT Function

This function converts a lock from one mode to another. CONVERT is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the ALLOCATE_UNIQUE procedure.

Syntax

```
DBMS_LOCK.CONVERT(
    id         IN INTEGER ||
    lockhandle IN VARCHAR2,
    lockmode   IN INTEGER,
    timeout    IN NUMBER DEFAULT MAXWAIT)
RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id or lockhandle</td>
<td>User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by ALLOCATE_UNIQUE, of the lock mode you want to change</td>
</tr>
<tr>
<td>lockmode</td>
<td>New mode that you want to assign to the specified lock. For the available modes and their associated integer identifiers, see Constants on page 83-5.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number of seconds to continue trying to change the lock mode. If the lock cannot be converted within this time period, then the call returns a value of 1 (timeout).</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
<tr>
<td>1</td>
<td>Timeout</td>
</tr>
<tr>
<td>2</td>
<td>Deadlock</td>
</tr>
<tr>
<td>3</td>
<td>Parameter error</td>
</tr>
<tr>
<td>4</td>
<td>Don't own lock specified by id or lockhandle</td>
</tr>
<tr>
<td>5</td>
<td>Illegal lock handle</td>
</tr>
</tbody>
</table>
RELEASE Function

This function explicitly releases a lock previously acquired using the REQUEST function. Locks are automatically released at the end of a session. RELEASE is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the ALLOCATE_UNIQUE procedure.

Syntax

```sql
DBMS_LOCK.RELEASE (id IN INTEGER) RETURN INTEGER;
DBMS_LOCK.RELEASE (lockhandle IN VARCHAR2) RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id or lockhandle</td>
<td>User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by ALLOCATE_UNIQUE, of the lock mode you want to change</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
<tr>
<td>3</td>
<td>Parameter error</td>
</tr>
<tr>
<td>4</td>
<td>Do not own lock specified by id or lockhandle</td>
</tr>
<tr>
<td>5</td>
<td>Illegal lock handle</td>
</tr>
</tbody>
</table>
REQUEST Function

This function requests a lock with a specified mode. REQUEST is an overloaded function that accepts either a user-defined lock identifier, or the lock handle returned by the ALLOCATE_UNIQUE procedure.

Syntax

```sql
DBMS_LOCK.REQUEST(
    id                 IN  INTEGER ||
    lockhandle         IN  VARCHAR2,
    lockmode           IN  INTEGER DEFAULT X_MODE,
    timeout            IN  INTEGER DEFAULT MAXWAIT,
    release_on_commit  IN  BOOLEAN DEFAULT FALSE)
RETURN INTEGER;
```

The current default values, such as X_MODE and MAXWAIT, are defined in the DBMS_LOCK package specification.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id or lockhandle</td>
<td>User assigned lock identifier, from 0 to 1073741823, or the lock handle, returned by ALLOCATE_UNIQUE, of the lock mode you want to change</td>
</tr>
<tr>
<td>lockmode</td>
<td>Mode that you are requesting for the lock.</td>
</tr>
<tr>
<td></td>
<td>For the available modes and their associated integer identifiers, see Constants on page 83-5.</td>
</tr>
<tr>
<td>timeout</td>
<td>Number of seconds to continue trying to grant the lock.</td>
</tr>
<tr>
<td></td>
<td>If the lock cannot be granted within this time period, then the call returns a value of 1 (timeout).</td>
</tr>
<tr>
<td>release_on_commit</td>
<td>Set this parameter to TRUE to release the lock on commit or roll-back.</td>
</tr>
<tr>
<td></td>
<td>Otherwise, the lock is held until it is explicitly released or until the end of the session.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
<tr>
<td>1</td>
<td>Timeout</td>
</tr>
<tr>
<td>2</td>
<td>Deadlock</td>
</tr>
<tr>
<td>3</td>
<td>Parameter error</td>
</tr>
<tr>
<td>4</td>
<td>Already own lock specified by id or lockhandle</td>
</tr>
<tr>
<td>5</td>
<td>Illegal lock handle</td>
</tr>
</tbody>
</table>
SLEEP Procedure

This procedure suspends the session for a specified period of time.

Syntax

```plsql
DBMS_LOCK.SLEEP (
    seconds IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seconds</td>
<td>Amount of time, in seconds, to suspend the session. The smallest increment can be entered in hundredths of a second; for example, 1.95 is a legal time value.</td>
</tr>
</tbody>
</table>
The DBMS_LOGMNR package, one of a set of LogMiner packages, contains the subprograms you use to initialize the LogMiner tool and to begin and end a LogMiner session.

See Also: Oracle Database Utilities for information regarding LogMiner.

This chapter contains the following topics:

- Using DBMS_LOGMNR
  - Overview
  - Security Model
  - Constants
  - Views
  - Operational Notes
- Summary of DBMS_LOGMNR Subprograms
Using DBMS_LOGMNR

This section contains the following topics, which relate to using the `DBMS_LOGMNR` package:

- Overview
- Security Model
- Constants
- Views
- Operational Notes
Overview

Oracle LogMiner, which is part of Oracle Database, enables you to query online and archived redo log files through a SQL interface. The `DBMS_LOGMNR` package provides the majority of the tools needed to start and stop LogMiner and specify the redo log files of interest.

All changes made to user data or to the database dictionary are recorded in the Oracle redo log files so that database recovery operations can be performed. You can take advantage of the data recorded in the redo log files to accomplish other tasks, such as:

- Pinpointing when a logical corruption to a database, such as errors made at the application level, may have begun.
- Determining what actions you would have to take to perform fine-grained recovery at the transaction level.
- Performance tuning and capacity planning through trend analysis.
- Track any data manipulation language (DML) and data definition language (DDL) statements executed on the database, the order in which they were executed, and who executed them.

See Also: Chapter 85, "DBMS_LOGMNR_D" for information on the package subprograms that extract a LogMiner dictionary and re-create LogMiner tables in alternate tablespaces.
You must have the EXECUTE_CATALOG_ROLE role to use the DBMS_LOGMNR package.
The DBMS_LOGMNR package defines several enumerated constants for specifying parameter values. Enumerated constants must be prefixed with the package name, for example, DBMS_LOGMNR.NEW.

Table 84–1 describes the constants for the ADD_LOGFILE options flag in the DBMS_LOGMNR package.

Table 84–1 Constants for ADD_LOGFILE Options Flag

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEW</td>
<td>Implicitly calls the DBMS_LOGMNR.END_LOGMNR procedure to end the current LogMiner session and then creates a new session. The new session starts a new list of redo log files to be analyzed, beginning with the redo log file you specify.</td>
</tr>
<tr>
<td>ADDFILE</td>
<td>Adds the specified redo log file to the list of redo log files to be analyzed. Any attempt to add a duplicate file raises an exception (ORA-01289). This is the default if no options flag is specified.</td>
</tr>
</tbody>
</table>

Table 84–2 describes the constants for the START_LOGMNR options flag in the DBMS_LOGMNR package.

Table 84–2 Constants for START_LOGMNR Options Flag

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COMMITTED_DATA_ONLY</td>
<td>If set, DML statements corresponding to committed transactions are returned. DML statements corresponding to a committed transaction are grouped together. Transactions are returned in their commit order. Transactions that are rolled back or in-progress are filtered out, as are internal redo records (those related to index operations, management, and so on). If this option is not set, all rows for all transactions (committed, rolled back, and in-progress) are returned in the order in which they are found in the redo logs (in order of SCN values).</td>
</tr>
<tr>
<td>SKIP_CORRUPTION</td>
<td>Directs a select operation on the V$LOGMNR_CONTENTS view to skip any corruptions in the redo log file being analyzed and continue processing. This option works only when a block in the redo log file (and not the header of the redo log file) is corrupt. You should check the INFO column in the V$LOGMNR_CONTENTS view to determine the corrupt blocks skipped by LogMiner. When a corruption in the redo log file is skipped, the OPERATION column contains the value CORRUPTED_BLOCKS, and the STATUS column contains the value 1343.</td>
</tr>
<tr>
<td>DDL_DICT_TRACKING</td>
<td>If the LogMiner dictionary in use is a flat file or in the redo log files, LogMiner updates its internal dictionary if a DDL event occurs. This ensures that correct SQL_REDO and SQL_UNDO information is maintained for objects that are modified after the LogMiner internal dictionary is built. The database to which LogMiner is connected must be open. This option cannot be used in conjunction with the DICT_FROM_ONLINE_CATALOG option and cannot be used when the LogMiner dictionary being used is one that was extracted to a flat file prior to Oracle9i.</td>
</tr>
</tbody>
</table>
Constants

Table 84–2  (Cont.) Constants for START_LOGMNR Options Flag

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
</table>
| DICT_FROM_ONLINE_CATALOG                     | Directs LogMiner to use the current online database dictionary rather than a LogMiner dictionary contained in a flat file or in the redo log files being analyzed.  
This option cannot be used in conjunction with the DDL_DICT_TRACKING option. The database to which LogMiner is connected must be the same one that generated the redo log files.  
Expect to see a value of 2 in the STATUS column of the V$LOGMNR_CONTENTS view if the table definition in the database does not match the table definition in the redo log file. |
| DICT_FROM_REDO_LOGS                          | If set, LogMiner expects to find a LogMiner dictionary in the redo log files that were specified. The redo log files are specified with the DBMS_LOGMNR.ADD_LOGFILE procedure or with the DBMS_LOGMNR.START_LOGMNR procedure with the CONTINUOUS_MINE option. |
| NO_SQL_DELIMITER                              | If set, the SQL delimiter (a semicolon) is not placed at the end of reconstructed SQL statements. This is helpful for applications that open a cursor and then execute the reconstructed statements. |
| NO_ROWID_IN_STMT                              | If set, the ROWID clause is not included in the reconstructed SQL statements. The redo log file may already contain logically unique identifiers for modified rows if supplemental logging is enabled.  
When using this option, you must be sure that supplemental logging was enabled in the source database at the appropriate level and that no duplicate rows exist in the tables of interest. LogMiner does not make any guarantee regarding the uniqueness of logical row identifiers. |
| PRINTPRETTY_SQL                               | If set, LogMiner formats the reconstructed SQL statements for ease of reading. These reconstructed SQL statements are not executable.                                                                                     |
| CONTINUOUS_MINE                               | Directs LogMiner to automatically add redo log files, as needed, to find the data of interest. You only need to specify the first log to start mining, or just the starting SCN or date to indicate to LogMiner where to begin mining logs. You are not required to specify any redo log files explicitly. LogMiner automatically adds and mines the (archived and online) redo log files for the data of interest. This option requires that LogMiner is connected to the same database instance that is generating the redo log files. It also requires that the database be mounted and that archiving be enabled.  
Beginning with Oracle Database release 10.1, the CONTINUOUS_MINE options is supported for use in an Oracle Real Application Clusters (Oracle RAC) environment. |
| STRING_LITERALS_IN_STMT                       | If set, SQL_REDO and SQL_UNDO use literals for numbers and datetime and interval column types.                                                                                                               |
Views

The DBMS_LOGMNR package uses the views listed in the section on Accessing LogMiner Operational Information in Views in Oracle Database Utilities.
A LogMiner session begins with a call to `DBMS_LOGMNR.ADD_LOGFILE` or `DBMS_LOGMNR.START_LOGMNR` (the former if you plan to specify log files explicitly; the latter if you plan to use continuous mining). The session ends with a call to `DBMS_LOGMNR.END_LOGMNR`. Within a LogMiner session, you can specify the redo log files to be analyzed and the SCN or time range of interest; then you can issue SQL `SELECT` statements against the `V$LOGMNR_CONTENTS` view to retrieve the data of interest.
Summary of DBMS_LOGMNR Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ADD_LOGFILE Procedure</strong> on page 84-10</td>
<td>Adds a redo log file to the existing or newly created list of redo log files for LogMiner to process, so that if a new list is created, this marks the beginning of a LogMiner session.</td>
</tr>
<tr>
<td><strong>COLUMN_PRESENT Function</strong> on page 84-12</td>
<td>Call this function for any row returned from the <code>V$LOGMNR_CONTENTS</code> view to determine if undo or redo column values exist for the column specified by the <code>column_name</code> input parameter to this function.</td>
</tr>
<tr>
<td><strong>END_LOGMNR Procedure</strong> on page 84-14</td>
<td>Finishes a LogMiner session.</td>
</tr>
<tr>
<td><strong>MINE_VALUE Function</strong> on page 84-15</td>
<td>Call this function for any row returned from the <code>V$LOGMNR_CONTENTS</code> view to retrieve the undo or redo column value of the column specified by the <code>column_name</code> input parameter to this function.</td>
</tr>
<tr>
<td><strong>REMOVE_LOGFILE Procedure</strong> on page 84-17</td>
<td>Removes a redo log file from the list of redo log files for LogMiner to process.</td>
</tr>
<tr>
<td><strong>START_LOGMNR Procedure</strong> on page 84-18</td>
<td>Initializes the LogMiner utility and starts LogMiner (unless the session was already started with a call to <code>DBMS_LOGMNR.ADD_LOGFILE</code>).</td>
</tr>
</tbody>
</table>
ADD_LOGFILE Procedure

This procedure adds a file to an existing or newly created list of log files for LogMiner to process.

Syntax

```sql
DBMS_LOGMNR.ADD_LOGFILE (  
    LogFileName     IN VARCHAR2,  
    options         IN BINARY_INTEGER default ADDFILE );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogFileName</td>
<td>Specifies the name of the redo log file to add to the list of redo log files to be analyzed during this session.</td>
</tr>
<tr>
<td>options</td>
<td>Does one of the following:</td>
</tr>
<tr>
<td></td>
<td>■ Starts a new LogMiner session and a new list of redo log files for analysis (DBMS_LOGMNR.NEW)</td>
</tr>
<tr>
<td></td>
<td>■ Adds a file to an existing list of redo log files for analysis (DBMS_LOGMNR.ADDFILE)</td>
</tr>
<tr>
<td></td>
<td>See Table 84–1, &quot;Constants for ADD_LOGFILE Options Flag&quot;.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01284</td>
<td>Specified file cannot be opened.</td>
</tr>
<tr>
<td>ORA-01287</td>
<td>Specified file is from a different database incarnation.</td>
</tr>
<tr>
<td>ORA-01289</td>
<td>Specified file has already been added to the list. Duplicate redo log files cannot be added.</td>
</tr>
<tr>
<td>ORA-01290</td>
<td>Specified file is not in the current list and therefore cannot be removed from the list.</td>
</tr>
<tr>
<td>ORA-01324</td>
<td>Specified file cannot be added to the list because there is a DB_ID mismatch.</td>
</tr>
</tbody>
</table>

Usage Notes

- Before querying the V$LOGMNR_CONTENTS view, you must make a successful call to the DBMS_LOGMNR.START_LOGMNR procedure (within the current LogMiner session).
- Unless you specify the CONTINUOUS_MINE option, the LogMiner session must be set up with a list of redo log files to be analyzed. Use the ADD_LOGFILE procedure to specify the list of redo log files to analyze.
- If you are not using the CONTINUOUS_MINE option and you want to analyze more than one redo log file, you must call the ADD_LOGFILE procedure separately for each redo log file. The redo log files do not need to be registered in any particular order.
- Both archived and online redo log files can be mined.
After you have added the first redo log file to the list, each additional redo log file that you add to the list must be associated with the same database and database
\texttt{RESETLOGS SCN} as the first redo log file. (The database \texttt{RESETLOGS SCN} uniquely identifies each execution of an \texttt{ALTER DATABASE OPEN RESETLOGS} statement. When the online redo logs are reset, Oracle creates a new and unique incarnation of the database.)

To analyze the redo log files from a different database (or a database incarnation with a different database \texttt{RESETLOGS SCN}) than that with which the current list of redo log files is associated, use the \texttt{END_LOGMNR} procedure to end the current LogMiner session, and then build a new list using the \texttt{ADD_LOGFILE} procedure.

LogMiner matches redo log files by the log sequence number. Thus, two redo log files with different names but with the same log sequence number will return the \texttt{ORA-01289} exception. For instance, the online counterpart of an archived redo log file has a different name from the archived redo log file, but attempting to register it with LogMiner after registering the archived counterpart will result in the \texttt{ORA-01289} exception being returned.
COLUMN_PRESENT Function

This function is designed to be used in conjunction with the MINE_VALUE function. If the MINE_VALUE function returns a NULL value, it can mean either:

- The specified column is not present in the redo or undo portion of the data.
- The specified column is present and has a NULL value.

To distinguish between these two cases, use the COLUMN_PRESENT function, which returns a 1 if the column is present in the redo or undo portion of the data. Otherwise, it returns a 0.

Syntax

```sql
DBMS_LOGMNR.COLUMN_PRESENT (  
  sql_redo_undo   IN  RAW,  
  column_name     IN  VARCHAR2 default '') RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_redo_undo</td>
<td>Specifies either the REDO_VALUE or the UNDO_VALUE column in the V$LOGMNR_CONTENTS view from which to extract data values. See the Usage Notes for more information.</td>
</tr>
<tr>
<td>column_name</td>
<td>Specifies the fully qualified name (schema.table.column) of the column for which this function will return information.</td>
</tr>
</tbody>
</table>

Return Values

Table 84–7 describes the return values for the COLUMN_PRESENT function. The COLUMN_PRESENT function returns 1 if the self-describing record (the first parameter) contains the column specified in the second parameter. This can be used to determine the meaning of NULL values returned by the DBMS_LOGMNR.MINE_VALUE function.

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Specified column is not present in this row of V$LOGMNR_CONTENTS.</td>
</tr>
<tr>
<td>1</td>
<td>Column is present in this row of V$LOGMNR_CONTENTS.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01323</td>
<td>Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session.</td>
</tr>
<tr>
<td>ORA-00904</td>
<td>Value specified for the column_name parameter is not a fully qualified column name.</td>
</tr>
</tbody>
</table>
Usage Notes

- To use the `COLUMN_PRESENT` function, you must have successfully started LogMiner.
- The `COLUMN_PRESENT` function must be invoked in the context of a select operation on the `V$LOGMNR_CONTENTS` view.
- The `COLUMN_PRESENT` function does not support `LONG`, `LOB`, `ADT`, or `COLLECTION` datatypes.
- The value for the `sql_redo_undo` parameter depends on the operation performed and the data of interest:
  - If an update operation was performed and you want to know what the value was prior to the update operation, specify `UNDO_VALUE`.
  - If an update operation was performed and you want to know what the value is after the update operation, specify `REDO_VALUE`.
  - If an insert operation was performed, typically you would specify `REDO_VALUE` (because the value of a column prior to an insert operation will always be `NULL`).
  - If a delete operation was performed, typically you would specify `UNDO_VALUE` (because the value of a column after a delete operation will always be `NULL`).
END_LOGMNR Procedure

This procedure finishes a LogMiner session. Because this procedure performs cleanup operations that may not otherwise be done, you must use it to properly end a LogMiner session. This procedure is called automatically when you log out of a database session or when you call DBMS_LOGMNR.ADD_LOGFILE and specify the NEW option.

Syntax

```
DBMS_LOGMNR.END_LOGMNR;
```

Exceptions

<table>
<thead>
<tr>
<th>Exception Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01307</td>
<td>No LogMiner session is currently active. The END_LOGMNR procedure was called without adding any log files or before the START_LOGMNR procedure was called</td>
</tr>
</tbody>
</table>
MINE_VALUE Function

This function facilitates queries based on a column’s data value. This function takes two arguments. The first one specifies whether to mine the redo (REDO_VALUE) or undo (UNDO_VALUE) portion of the data. The second argument is a string that specifies the fully qualified name of the column to be mined. The MINE_VALUE function always returns a string that can be converted back to the original datatype.

Syntax

```sql
DBMS_LOGMNR.MINE_VALUE (  
    sql_redo_undo      IN  RAW,  
    column_name        IN  VARCHAR2 default '') RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sql_redo_undo</td>
<td>Specifies either the REDO_VALUE or the UNDO_VALUE column in the V$LOGMNR_CONTENTS view from which to extract data values. See the Usage Notes for more information.</td>
</tr>
<tr>
<td>column_name</td>
<td>Specifies the fully qualified name (schema.table.column) of the column for which this function will return information.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL</td>
<td>The column is not contained within the self-describing record, or the column value is NULL. To distinguish between the two different null possibilities, use the DBMS_LOGMNR.COLUMN_PRESENT function.</td>
</tr>
<tr>
<td>NON-NULL</td>
<td>The column is contained within the self-describing record; the value is returned in string format.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01323</td>
<td>Invalid state. Currently, a LogMiner dictionary is not associated with the LogMiner session. You must specify a LogMiner dictionary for the LogMiner session.</td>
</tr>
<tr>
<td>ORA-00904</td>
<td>Invalid identifier. The value specified for the column_name parameter was not a fully qualified column name.</td>
</tr>
</tbody>
</table>

Usage Notes

- To use the MINE_VALUE function, you must have successfully started LogMiner.
- The MINE_VALUE function must be invoked in the context of a select operation from the V$LOGMNR_CONTENTS view.
The `MINE_VALUE` function does not support `LONG`, `LOB`, `ADT`, or `COLLECTION` datatypes.

The value for the `sql_redo_undo` parameter depends on the operation performed and the data of interest:

- If an update operation was performed and you want to know what the value was prior to the update operation, specify `UNDO_VALUE`.
- If an update operation was performed and you want to know what the value is after the update operation, specify `REDO_VALUE`.
- If an insert operation was performed, typically you would specify `REDO_VALUE` (because the value of a column prior to an insert operation will always be null).
- If a delete operation was performed, typically you would specify `UNDO_VALUE` (because the value of a column after a delete operation will always be null).
REMOVE_LOGFILE Procedure

This procedure removes a redo log file from an existing list of redo log files for LogMiner to process.

---

**Note:** This procedure replaces the REMOVEFILE constant that was an option on the ADD_LOGFILE procedure prior to Oracle Database 10g.

---

Syntax

```
DBMS_LOGMNR.REMOVE_LOGFILE ( 
    LogFileName    IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LogFileName</td>
<td>Specifies the name of the redo log file to be removed from the list of redo log files to be analyzed during this session.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01290</td>
<td>Cannot remove unlisted log file</td>
</tr>
</tbody>
</table>

Usage Notes

- Before querying the V$LOGMNR_CONTENTS view, you must make a successful call to the DBMS_LOGMNR.START_LOGMNR procedure (within the current LogMiner session).
- You can use this procedure to remove a redo log file from the list of redo log files for LogMiner to process if you know that redo log file does not contain any data of interest.
- Multiple redo log files can be removed by calling this procedure repeatedly.
- The redo log files do not need to be removed in any particular order.
- To start a new list of redo log files for analysis, use the END_LOGMNR procedure to end the current LogMiner session, and then build a new list using the ADD_LOGFILE procedure.
- Even if you remove all redo log files from the list, any subsequent calls you make to the ADD_LOGFILE procedure must match the database ID and RESETLOGS SCN of the removed redo log files. Therefore, to analyze the redo log files from a different database (or a database incarnation with a different database RESETLOGS SCN) than that with which the current list of redo log files is associated, use the END_LOGMNR procedure to end the current LogMiner session, and then build a new list using the ADD_LOGFILE procedure.
START_LOGMNR Procedure

This procedure starts LogMiner by loading the dictionary that LogMiner will use to translate internal schema object identifiers to names.

Syntax

```sql
START_LOGMNR Procedure

DBMS_LOGMNR.START_LOGMNR (  
    startScn           IN NUMBER default 0,  
    endScn             IN NUMBER default 0,  
    startTime          IN DATE default '01-jan-1988',  
    endTime            IN DATE default '31-dec-2110',  
    DictFileName       IN VARCHAR2 default '',  
    Options            IN BINARY_INTEGER default 0 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>startScn</td>
<td>Directs LogMiner to return only redo records with an SCN greater than or equal to the startScn specified. This fails if there is no redo log file containing the specified startScn value. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)</td>
</tr>
<tr>
<td>endScn</td>
<td>Directs LogMiner to return only redo records with an SCN less than or equal to the endScn specified. If you specify an endScn value that is beyond the value in any redo log file, then LogMiner uses the greatest endScn value in the redo log file that contains the most recent changes. (You can query the FILENAME, LOW_SCN, and NEXT_SCN columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of SCN values contained in each redo log file.)</td>
</tr>
<tr>
<td>startTime</td>
<td>Directs LogMiner to return only redo records with a timestamp greater than or equal to the startTime specified. This fails if there is no redo log file containing the specified startTime value. (You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.) This parameter is ignored if startScn is specified. See the Usage Notes for additional information.</td>
</tr>
<tr>
<td>endTime</td>
<td>Directs LogMiner to return only redo records with a timestamp less than or equal to the endTime specified. If you specify an endTime value that is beyond the value in any redo log file, then LogMiner will use the greatest endTime in the redo log file that contains the most recent changes. (You can query the FILENAME, LOW_TIME, and HIGH_TIME columns in the V$LOGMNR_LOGS view for each redo log file to determine the range of time covered in each redo log file.) This parameter is ignored if endScn is specified. See the Usage Notes for additional information.</td>
</tr>
</tbody>
</table>
LogMiner can use a dictionary that you previously extracted to the redo log files or to a flat file, or you can specify that LogMiner use the online catalog if LogMiner is mining data from the source system. See Oracle Database Utilities and
Chapter 85, "DBMS_LOGMNR_D" in this manual for more information about the LogMiner dictionary.

- After executing the `START_LOGMNR` procedure, you can query the following views:
  - `V$LOGMNR_CONTENTS` - contains history of information in redo log files
  - `V$LOGMNR_DICTIONARY` - contains current information about the LogMiner dictionary file extracted to a flat file
  - `V$LOGMNR_PARAMETERS` - contains information about the LogMiner session

(You can query the `V$LOGMNR_LOGS` view after a redo log file list has been added to the list of files that LogMiner is to mine.)

- Parameters and options are not persistent across calls to `DBMS_LOGMNR.START_LOGMNR`. You must specify all desired parameters and options (including SCN and time ranges) each time you call `DBMS_LOGMNR.START_LOGMNR`.

- Be aware that specifying redo log files using a timestamp is not precise.

- The `CONTINUOUS_MINE` option directs LogMiner to automatically add redo log files, as needed, to find the data of interest. You need to specify only the first log to start mining, or just the starting SCN or date to indicate to LogMiner where to begin mining logs. Keep the following in mind when using the `CONTINUOUS_MINE` option:
  - The database control file will hold information about a limited number of archived redo log files, although the number of entries can be quite large. Query the `V$ARCHIVED_LOGS` view to determine which redo log file entries will be found by LogMiner.

  Even if an entry is listed in the database control file (and the `V$ARCHIVED_LOGS` view), the archived redo log file may not be accessible by LogMiner for various reasons. For example, the archived redo log file may have been deleted or moved from its location (maybe because of a backup operation to tape), or the directory where it resides may not be not available.

  - If you specify the `CONTINUOUS_MINE` option and an ending time or SCN that will occur in the future (or you do not specify an end time or SCN), a query of the `V$LOGMNR_CONTENTS` view will not finish until the database has generated redo log files beyond the specified time or SCN. In this scenario, LogMiner will automatically add archived redo log files to the LogMiner redo log file list as they are generated. In addition, in this scenario only, LogMiner may automatically remove redo log files from the list to keep it at 50 processed redo files. This is to save PGA memory as LogMiner automatically adds redo log files to the list. If LogMiner did not perform automated removal, memory could eventually be exhausted.

  - LogMiner can mine online redo logs. However, if the `CONTINUOUS_MINE` option is not specified, it is possible that the database is writing to the online redo log file at the same time that LogMiner is reading the online redo log file. If a log switch occurs while LogMiner is reading an online redo log file, the database will overwrite what LogMiner is attempting to read. The data that LogMiner returns if the file it is trying to read gets overwritten by the database is unpredictable.

- Keep the following in mind regarding starting and ending times or SCN ranges:
  - If you specify neither a `startTime` nor a `startScn` parameter, LogMiner will set the `startScn` parameter to use the lowest SCN value from the redo log file that contains the oldest changes.
- If you specify both time and SCN values, LogMiner uses the SCN value or values and ignores the time values.

- If you specify starting and ending time or SCN values and they are found in the LogMiner redo log file list, then LogMiner mines the logs indicated by those values.

- If you specify starting and ending times or SCN values that are not in the LogMiner redo log file list, and you specify DBMS_LOGMNR.START_LOGMNR without the CONTINUOUS_MINE option, and you specify:
  * 0 for the startTime or startScn value, then the lowest SCN in the LogMiner redo log file list will be used as the startScn
  * A nonzero number for the startTime or startScn value, then an error is returned
  * 0 or a nonzero number for the endTime or endScn value, then the highest SCN in the LogMiner redo log file list will be used as the endScn

- If you specify starting and ending times or SCN values and they are not found in the LogMiner redo log file list, and you specify DBMS_LOGMNR.START_LOGMNR with the CONTINUOUS_MINE option, and you specify:
  * 0 for the startTime or startScn value, then an error is returned
  * A startTime or startScn value that is greater than any value in the database's archived redo log files, then LogMiner starts mining in the online redo log file. LogMiner will continue to process the online redo log file until it finds a change at, or beyond, the requested starting point before it returns rows from the V$LOGMNR_CONTENTS view.
  * An endTime or endScn parameter value that indicates a time or SCN in the future, then LogMiner includes the online redo log files when it mines. When you query the V$LOGMNR_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until LogMiner sees a change beyond the requested ending point.
  * 0 for the endTime or endScn parameter value, then LogMiner includes the online redo log files when it mines. When you query the V$LOGMNR_CONTENTS view, rows will be returned from this view as changes are made to the database, and will not stop until you enter CTL+C or you terminate the PL/SQL cursor.
The DBMS_LOGMNR_D package, one of a set of LogMiner packages, contains two subprograms:

- The BUILD procedure extracts the LogMiner data dictionary to either the redo log files or to a flat file. This information is saved in preparation for future analysis of redo log files using the LogMiner tool.
- The SET_TABLESPACE procedure re-creates all LogMiner tables in an alternate tablespace.

The LogMiner data dictionary consists of the memory data structures and the database tables that are used to store and retrieve information about objects and their versions. It is referred to as the LogMiner dictionary throughout the LogMiner documentation.

See Also: Oracle Database Utilities for information regarding LogMiner.

This chapter contains the following topics:

- Using DBMS_LOGMNR_D
  - Overview
  - Security Model
- Summary of DBMS_LOGMNR_D Subprograms
This section contains the following topics, which relate to using the `DBMS_LOGMNR_D` package:

- Overview
- Security Model
Overview

LogMiner requires a dictionary to translate object IDs into object names when it returns redo data to you. LogMiner gives you three options for supplying the dictionary:

- Using the online catalog
- Extracting a LogMiner dictionary to the redo log files
- Extracting a LogMiner dictionary to a flat file

Use the BUILD procedure to extract the LogMiner dictionary to the redo log files or a flat file. If you want to specify the online catalog as the dictionary source, you do so when you start LogMiner with the DBMS_LOGMNR.START_LOGMNR package.

Use the SET_TABLESPACE procedure if you want LogMiner tables to use a tablespace other than the default SYSAUX tablespace.

See Also: DBMS_LOGMNR for information on the package subprograms used in running a LogMiner session.
Security Model

You must have the EXECUTE_CATALOG_ROLE role to use the DBMS_LOGMNR_D package.
### Summary of DBMS_LOGMNR_D Subprograms

**Table 85–1**  
DBMS_LOGMNR_D Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>BUILD Procedure</strong> on page 85-6</td>
<td>Extracts the LogMiner dictionary to either a flat file or one or more redo log files</td>
</tr>
<tr>
<td><strong>SET_TABLESPACE Procedure</strong> on page 85-9</td>
<td>Re-creates all LogMiner tables in an alternate tablespace</td>
</tr>
</tbody>
</table>
BUILD Procedure

This procedure extracts the LogMiner data dictionary to either the redo log files or to a flat file.

Syntax

```sql
DBMS_LOGMNR_D.BUILD (
    dictionary_filename  IN  VARCHAR2,
    dictionary_location  IN  VARCHAR2,
    options              IN  NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>dictionary_filename</td>
<td>Specifies the name of the LogMiner dictionary file.</td>
</tr>
<tr>
<td>dictionary_location</td>
<td>Specifies the path to the LogMiner dictionary file directory.</td>
</tr>
<tr>
<td>options</td>
<td>Specifies that the LogMiner dictionary is written to either a flat file (STORE_IN_FLAT_FILE) or the redo log files (STORE_IN_REDO_LOGS).</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ora-01302</td>
<td>Dictionary build options are missing or incorrect.</td>
</tr>
<tr>
<td></td>
<td>This error is returned under the following conditions:</td>
</tr>
<tr>
<td></td>
<td>■ If the value of the OPTIONS parameter is not one of the</td>
</tr>
<tr>
<td></td>
<td>supported values (STORE_IN_REDO_LOGS, STORE_IN_FLAT_FILE) or is not specified</td>
</tr>
<tr>
<td></td>
<td>■ If the STORE_IN_REDO_LOGS option is not specified and neither the dictionary_filename nor the dictionary_location parameter is specified</td>
</tr>
<tr>
<td></td>
<td>■ If the STORE_IN_REDO_LOGS option is specified and either the dictionary_filename or the dictionary_location parameter is specified</td>
</tr>
<tr>
<td>ora-01308</td>
<td>Initialization parameter UTL_FILE_DIR is not set.</td>
</tr>
<tr>
<td>ora-01336</td>
<td>Specified dictionary file cannot be opened.</td>
</tr>
<tr>
<td></td>
<td>This error is returned under the following conditions:</td>
</tr>
<tr>
<td></td>
<td>■ The specified value for the dictionary_location does not exist.</td>
</tr>
<tr>
<td></td>
<td>■ The UTL_FILE_DIR initialization parameter is not set to have access to the dictionary_location</td>
</tr>
<tr>
<td></td>
<td>■ The dictionary file is read-only.</td>
</tr>
</tbody>
</table>

Usage Notes

■ To extract the LogMiner dictionary to a flat file, you must supply a filename and location.
To extract the LogMiner dictionary to the redo log files, specify only the `STORE_IN_REDO_LOGS` option. The size of the LogMiner dictionary may cause it to be contained in multiple redo log files.

The combinations of parameters used result in the following behavior:

- If you do not specify any parameters, an error is returned.
- If you specify a filename and location, without any options, the LogMiner dictionary is extracted to a flat file with that name.
- If you specify a filename and location, as well as the `STORE_IN_FLAT_FILE` option, the LogMiner dictionary is extracted to a flat file with the specified name.
- If you do not specify a filename and location, but do specify the `STORE_IN_REDO_LOGS` option, the LogMiner dictionary is extracted to the redo log files.
- If you specify a filename and location, as well as the `STORE_IN_REDO_LOGS` option, an error is returned.
- If you do not specify a filename and location, but do specify the `STORE_IN_FLAT_FILE` option, an error is returned.

Ideally, the LogMiner dictionary file will be created after all database dictionary changes have been made and prior to the creation of any redo log files that are to be analyzed. As of Oracle9i release 1 (9.0.1), you can use LogMiner to dump the LogMiner dictionary to the redo log files or a flat file, perform DDL operations, and dynamically apply the DDL changes to the LogMiner dictionary.

- Do not run the `DBMS_LOGMNR_D.BUILD` procedure if there are any ongoing DDL operations.
- The database must be open when you run the `DBMS_LOGMNR_D.BUILD` procedure.
- When extracting a LogMiner dictionary to a flat file, the procedure queries the dictionary tables of the current database and creates a text-based file containing the contents of the tables. To extract a LogMiner dictionary to a flat file, the following conditions must be met:
  - You must specify a directory for use by the PL/SQL procedure. To do so, set the initialization parameter `UTL_FILE_DIR` in the initialization parameter file. For example:
    ```
    UTL_FILE_DIR = /oracle/dictionary
    ```
    After setting the parameter, you must shut down and restart the database for this parameter to take effect. If you do not set this parameter, the procedure will fail.
  - You must ensure that no DDL operations occur while the LogMiner dictionary build is running. Otherwise, the LogMiner dictionary file may not contain a consistent snapshot of the database dictionary.

Be aware that the `DDL_DICT_TRACKING` option to the `DBMS_LOGMNR START_LOGMNR` procedure is not supported for flat file dictionaries created prior to Oracle9i. If you attempt to use the `DDL_DICT_TRACKING` option with a LogMiner database extracted to a flat file prior to Oracle9i, the ORA-01330 error (problem loading a required build table) is returned.

To extract a LogMiner dictionary file to the redo log files, the following conditions must be met:
- The DBMS_LOGMNR_D.BUILD procedure must be run on a system that is running Oracle9i or later.
- Archivelog mode must be enabled in order to generate usable redo log files.
- The COMPATIBLE parameter in the initialization parameter file must be set to 9.2.0 or higher.
- The database to which LogMiner is attached must be Oracle9i or later.

In addition, supplemental logging (at least the minimum level) should be enabled to ensure that you can take advantage of all the features that LogMiner offers. See Oracle Database Utilities for information about using supplemental logging with LogMiner.

Examples

Example 1: Extracting the LogMiner Dictionary to a Flat File
The following example extracts the LogMiner dictionary file to a flat file named dictionary.ora in a specified path (/oracle/database).

```
SQL> EXECUTE dbms_logmnr_d.build('dictionary.ora', -
    '/oracle/database/', -
    options => dbms_logmnr_d.store_in_flat_file);
```

Example 2: Extracting the LogMiner Dictionary to the Redo Log Files
The following example extracts the LogMiner dictionary to the redo log files.

```
SQL> EXECUTE dbms_logmnr_d.build( -
    options => dbms_logmnr_d.store_in_redo_logs);
```
SET_TABLESPACE Procedure

By default, all LogMiner tables are created to use the SYSAUX tablespace. However, it may be desirable to have LogMiner tables use an alternate tablespace. Use this procedure to move LogMiner tables to an alternate tablespace.

Syntax

```
DBMS_LOGMNR_D.SET_TABLESPACE (    
    new_tablespace    IN VARCHAR2);    
```

Parameters

Table 85–4  SET_TABLESPACE Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_tablespace</td>
<td>A string naming a preexisting tablespace. To move all</td>
</tr>
<tr>
<td></td>
<td>LogMiner tables to employ this tablespace, supply this</td>
</tr>
<tr>
<td></td>
<td>parameter.</td>
</tr>
</tbody>
</table>

Usage Notes

- Users upgrading from earlier versions of Oracle Database may find LogMiner tables in the SYSTEM tablespace. Oracle encourages such users to consider using the SET_TABLESPACE procedure to move the tables to the SYSAUX tablespace once they are confident that they will not be downgrading to an earlier version of Oracle Database.
- Users of this routine must supply an existing tablespace.

See Also:  Oracle Database Concepts and Oracle Database SQL Language Reference for information about tablespaces and how to create them

Example: Using the DBMS_LOGMNR_D.SET_TABLESPACE Procedure

The following example shows the creation of an alternate tablespace and execution of the DBMS_LOGMNR_D.SET_TABLESPACE procedure.

```
SQL> CREATE TABLESPACE logmnrts$ datafile '/usr/oracle/dbs/logmnrts.f'    
    SIZE 25 M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;    
SQL> EXECUTE dbms_logmnr_d.set_tablespace('logmnrts$');    
```
The DBMS_LOGSTDBY package provides subprograms for configuring and managing the logical standby database environment.

**See Also:** Oracle Data Guard Concepts and Administration for more information about SQL Apply and logical standby databases

This chapter contains the following topics:

- **Using DBMS_LOGSTDBY**
  - Overview
  - Security Model
- **Summary of DBMS_LOGSTDBY Subprograms**
Using DBMS_LOGSTDBY

This section contains topics which relate to using the DBMS_LOGSTDBY package.

- Overview
- Security Model
Overview

The DBMS_LOGSTDBY package helps you manage the SQL Apply (logical standby database) environment. The subprograms in the DBMS_LOGSTDBY package help you to accomplish the following main objectives:

- Manage configuration parameters used by SQL Apply.
  For example, controlling how transactions are applied on the logical standby database, how much shared pool is used, and how many processes are used by SQL Apply to mine and apply the changes.

- Ensure an appropriate level of supplemental logging is enabled, and a LogMiner dictionary is built correctly for logical standby database creation.

- Provide a way to skip the application of changes to selected tables or entire schemas in the logical standby database, and specify ways to handle exceptions encountered by SQL Apply.

- Allow controlled access to tables in the logical standby database that may require maintenance.
You must have the **DBA** role to use the `DBMS_LOGSTDBY` package.

A prototype role, `LOGSTDBY_ADMINISTRATOR`, is created by default with `RESOURCE`, and `EXECUTE` privileges on `DBMS_LOGSTDBY`. If you choose to use this role, consider granting `ALTER_DATABASE` and `ALTER_SESSION` privileges to the role so that the grantee can start and stop SQL Apply and can enable and disable the database guard.

The procedures associated with skipping transactions (`SKIP` and `UNSKIP`, `SKIP_ERROR` and `UNSKIP_ERROR`, and `SKIP_TRANSACTION` and `UNSKIP_TRANSACTION`) all require `DBA` privileges to execute because their scope may contain wildcard schemas. Oracle recommends that where `SKIP` procedures are specified, these be owned by a secure account with appropriate privileges on the schemas they act on (for example, `SYS`).
Summary of DBMS_LOGSTDBY Subprograms

Table 86–1  DBMS_LOGSTDBY Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY_SET Procedure on page 86-7</td>
<td>Sets the values of various parameters that configure and maintain SQL Apply</td>
</tr>
<tr>
<td>APPLY_UNSET Procedure on page 86-10</td>
<td>Restores the default values of various parameters that configure and maintain SQL Apply</td>
</tr>
<tr>
<td>BUILD Procedure on page 86-11</td>
<td>Ensures supplemental logging is enabled properly and builds the LogMiner dictionary</td>
</tr>
<tr>
<td>INSTANTIATE_TABLE Procedure on page 86-12</td>
<td>Creates and populates a table in the standby database from a corresponding table in the primary database</td>
</tr>
<tr>
<td>IS_APPLY_SERVER Function on page 86-14</td>
<td>This function returns TRUE if it is executed from PL/SQL in the context of a logical standby apply server process. This function is used in conjunction with triggers that have the fire_once parameter in the DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY subprogram set to FALSE (the default is TRUE). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby.</td>
</tr>
<tr>
<td>MAP_PRIMARY_SCN Function on page 86-15</td>
<td>Maps an SCN relevant to the primary database to a corresponding SCN at the logical standby database. The mapped SCN is conservative in nature, and can thus be used to flash back the logical standby database to compensate for a flashback database operation performed at the primary database.</td>
</tr>
<tr>
<td>PREPARE_FOR_NEW_PRIMARY Procedure on page 86-16</td>
<td>Used after a failover, this procedure ensures a local logical standby database that was not involved in the failover has not processed more redo than the new primary database and reports the set of archive redo log files that must be replaced to ensure consistency</td>
</tr>
<tr>
<td>PURGE_SESSION Procedure on page 86-18</td>
<td>Identifies the archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply</td>
</tr>
<tr>
<td>REBUILD Procedure on page 86-19</td>
<td>Records relevant metadata (including the LogMiner dictionary) in the redo stream in case a database that has recently changed its role to a primary database following a failover operation fails to do so during the failover process</td>
</tr>
<tr>
<td>SET_TABLESPACE Procedure on page 86-20</td>
<td>Moves metadata tables required by SQL Apply to the user-specified tablespace. By default, the metadata tables are created in the SYSAUX tablespace.</td>
</tr>
<tr>
<td>SKIP Procedure on page 86-21</td>
<td>Specifies rules that control database operations that should not be applied to the logical standby database</td>
</tr>
<tr>
<td>SKIP_ERROR Procedure on page 86-29</td>
<td>Specifies rules regarding what action to take upon encountering errors</td>
</tr>
</tbody>
</table>
### Summary of DBMS_LOGSTDBY Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>SKIP_TRANSACTION Procedure</strong> on page 86-33</td>
<td>Specifies transactions that should not be applied on the logical standby database. Be careful in using this procedure, because not applying specific transactions may cause data corruption at the logical standby database.</td>
</tr>
<tr>
<td><strong>UNSKIP Procedure</strong> on page 86-35</td>
<td>Deletes rules specified by the SKIP procedure</td>
</tr>
<tr>
<td><strong>UNSKIP_ERROR Procedure</strong> on page 86-37</td>
<td>Deletes rules specified by the SKIP_ERROR procedure</td>
</tr>
<tr>
<td><strong>UNSKIP_TRANSACTION Procedure</strong> on page 86-39</td>
<td>Deletes rules specified by the SKIP_TRANSACTION procedure</td>
</tr>
</tbody>
</table>
**APPLY_SET Procedure**

Use this procedure to set values of parameters that configure and manage SQL Apply in a logical standby database environment. All parameters, except for `PRESERVE_COMMIT_ORDER`, can be changed without having to stop SQL Apply.

**Syntax**

```sql
DBMS_LOGSTDBY.APPLY_SET (
    inname             IN VARCHAR,
    value              IN VARCHAR);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPLY_SERVERS</td>
<td>Controls the number of APPLIER processes used to apply changes. The maximum number allowed is 1024, provided the <code>MAX_SERVERS</code> parameter is set to accommodate this.</td>
</tr>
<tr>
<td>EVENT_LOG_DEST</td>
<td>Controls where SQL Apply records the occurrence of an interesting event. It takes the following values:</td>
</tr>
<tr>
<td></td>
<td><strong>DEST_ALL</strong> - All events will be recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view and in the alert log.</td>
</tr>
<tr>
<td></td>
<td><strong>DEST_EVENTS_TABLE</strong> - All events that contain information about user data will be recorded only in the <code>DBA_LOGSTDBY_EVENTS</code> view. This is the default value.</td>
</tr>
<tr>
<td></td>
<td>For example, if SQL Apply receives an ORA-1403 error, the whole event is recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view. Whereafter, the alert log records only that SQL Apply stopped because of ORA-1403. No information regarding the user table or offending statement is logged in the alert log. Whereas, if you stop the SQL Apply engine, it gets recorded in both the <code>DBA_LOGSTDBY_EVENTS</code> view and in the alert log.</td>
</tr>
<tr>
<td></td>
<td>Note that this parameter affects the behavior of the following parameters: RECORD_APPLIED_DDL, RECORD_SKIP_DDL, RECORD_SKIP_ERRORS, and RECORD_UNSUPPORTED_OPERATIONS. For example, if RECORD_APPLIED_DDL is set to TRUE, but EVENT_LOG_DEST is set to DEST_EVENTS_TABLE, then the applied DDL string will only be recorded in the <code>DBA_LOGSTDBY_EVENTS</code> view.</td>
</tr>
<tr>
<td>LOG_AUTO_DEL_RETENTION_TARGET</td>
<td>This parameter setting is only meaningful if LOG_AUTO_DELETE has been set to TRUE. The value you supply for this parameter controls how long (in minutes) a remote archived log that is received from the primary database will be retained at the logical standby database once all redo records contained in the log have been applied at the logical standby database. The default value is 1440 minutes.</td>
</tr>
<tr>
<td>LOG_AUTO_DELETE</td>
<td>Automatically deletes foreign archived redo log files as soon as they have been applied on the logical standby database. By default, a foreign archived redo log file is not deleted until 24 hours (the default value of LOG_AUTO_DEL_RETENTION_TARGET parameter) after it has been applied at the logical standby database. Set to TRUE to enable automatic deletion of archived redo log files. Set to FALSE to disable automatic deletion. The default value is TRUE.</td>
</tr>
</tbody>
</table>
### APPLY_SET Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAX_EVENTS.Recorded</td>
<td>Number of recent events that will be visible through the <code>DBA_LOGSTDBY EVENTS</code> view. To record all events encountered by SQL Apply, use the <code>DBMS_LOGSTDBY.MAX_EVENTS</code> constant as the number value. The default value is 10,000.</td>
</tr>
<tr>
<td>MAX_SERVERS</td>
<td>Number of processes that SQL Apply uses to read and apply redo. The default value is 9. The maximum number allowed is 2048.</td>
</tr>
<tr>
<td>MAX_SGA</td>
<td>Number of megabytes from shared pool in System Global Area (SGA) that SQL Apply will use. The default value is 30 megabytes or one quarter of the value set for <code>SHARED_POOL_SIZE</code>, whichever is lower. The maximum size allowed is 4095 megabytes.</td>
</tr>
<tr>
<td>PREPARE_SERVERS</td>
<td>Controls the number of PREPARER processes used to prepare changes. The maximum number allowed is 1024, provided the <code>MAX_SERVERS</code> parameter is set to accommodate this.</td>
</tr>
</tbody>
</table>
| PRESERVE_COMMIT_ORDER      | TRUE: Transactions are applied to the logical standby database in the exact order in which they were committed on the primary database. This is the default parameter setting.  
FALSE: Transactions containing non-overlapping sets of rows may be committed in a different order than they were committed on the primary database.  
Regardless of the level chosen, modifications done to the same row are always applied in the same order as they happened on the primary database.  
You cannot modify this parameter while SQL Apply is running. |
| RECORD_APPLIED DDL         | Controls whether DDL statements that have been applied to the logical standby database are recorded in the location specified by the `EVENT_LOG_DEST` parameter. Specify one of the following values:  
TRUE: Indicates that DDL statements applied to the logical standby database are recorded in the `DBA_LOGSTDBY EVENTS` table and the alert log.  
FALSE: Indicates that applied DDL statements are not recorded. This is the default parameter setting. |
| RECORD_SKIP DDL            | Controls whether skipped DDL statements are recorded in the location specified by the `EVENT_LOG_DEST` parameter. Specify one of the following values:  
TRUE: Skipped DDL statements are recorded in the `DBA_LOGSTDBY_EVENTS` table and the alert log. This is the default parameter setting.  
FALSE: Skipped DDL statements are not recorded in the `DBA_LOGSTDBY_EVENTS` table and the alert log. |
Summary of DBMS_LOGSTDBY Subprograms

If a parameter is changed while SQL Apply is running, the change will take effect at some point in the future. In such a case, an informational row is inserted into the `DBA_LOGSTDBY_EVENTS` view at the time the parameter change takes effect.

Additionally, if you are modifying a parameter while SQL Apply is running on an Oracle RAC configuration, you must be connected to the same instance where SQL Apply is running.

### Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
<tr>
<td>ORA-16236</td>
<td>Logical Standby metadata operation in progress</td>
</tr>
</tbody>
</table>

### Usage Notes

- Use the `APPLY_UNSET` procedure to restore the default settings of a parameter.
- See Oracle Data Guard Concepts and Administration for help with tuning SQL Apply and for information about setting appropriate values for different parameters.

### Examples

To record DDLs in the `DBA_LOGSTDBY_EVENTS` view and in the alert log, issue the following statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_SET('RECORD_APPLIED_DDL', TRUE);
```
APPLY_UNSET Procedure

Use the APPLY_UNSET procedure to restore the default values of the parameters that you changed with the APPLY_SET procedure.

Syntax

```sql
DBMS_LOGSTDBY.APPLY_UNSET (
    inname          IN VARCHAR);
```

Parameters

The parameter information for the APPLY_UNSET procedure is the same as that described for the APPLY_SET procedure. See Table 86–2 for complete parameter information.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
<tr>
<td>ORA-16236</td>
<td>Logical Standby metadata operation in progress</td>
</tr>
</tbody>
</table>

Usage Notes

- Use the APPLY_SET procedure to specify a nondefault value for a parameter.

Examples

If you previously specified that applied DDLs show up in the DBA_LOGSTDBY_EVENTS view and the alert log, you can restore the default behavior of SQL Apply regarding applied DDL statements with the following statement:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.APPLY_UNSET('RECORD_APPLIED_DDL');
```
**BUILD Procedure**

Use this procedure on the primary database to record relevant metadata (LogMiner dictionary) information in the redo log, which will subsequently be used by SQL Apply. This procedure will enable database-wide primary- and unique-key supplemental logging, if necessary.

---

**Note:** In databases created using Oracle Database 11g release 2 (11.2) or later, supplemental logging information is automatically propagated to any existing physical standby databases. However, for databases in earlier releases, or if the database was created using an earlier release and then upgraded to 11.2, you must check whether supplemental logging is enabled at the physical standby(s) if it is also enabled at the primary database. If it is not enabled at the physical standby(s), then before performing a switchover or failover, you must enable supplemental logging on all existing physical standby databases. To do so, issue the following SQL command on each physical standby:

```
SQL> ALTER DATABASE ADD SUPPLEMENTAL LOG DATA (PRIMARY KEY, UNIQUE INDEX) COLUMNS;
```

If you do not do this, then any logical standby that is also in the same Data Guard configuration will be unusable if a switchover or failover is performed to one of the physical standby databases. If a switchover or failover has already occurred and supplemental logging was not enabled, then you must recreate all logical standby databases.

---

**Syntax**

```
DBMS_LOGSTDBY.BUILD;
```

**Usage Notes**

- Supplemental log information includes extra information in the redo logs that uniquely identifies a modified row in the logical standby database, and also includes information that helps efficient application of changes to the logical standby database.
- LogMiner dictionary information allows SQL Apply to interpret data in the redo logs.
- `DBMS_LOGSTDBY.BUILD` should be run only once for each logical standby database you want to create. You do not need to use `DBMS_LOGSTDBY.BUILD` for each Oracle RAC instance.
- `DBMS_LOGSTDBY.BUILD` waits for all transactions (including distributed transactions) that are active at the time of the procedure invocation to complete before returning. See Oracle *Database Administrator’s Guide* for information about how to handle in-doubt transactions.

**Examples**

To build the LogMiner dictionary in the redo stream of the primary database and to record additional information so that a logical standby database can be instantiated, issue the following SQL statement at the primary database:

```
SQL> EXECUTE DBMS_LOGSTDBY.BUILD;
```
INSTANTIATE_TABLE Procedure

This procedure creates and populates a table in the standby database from a corresponding table in the primary database. The table requires the name of the database link (dblink) as an input parameter. If the table already exists in the logical standby database, it will be dropped and re-created based on the table definition at the primary database. This procedure only brings over the data associated with the table, and not the associated indexes and constraints.

Use the INSTANTIATE_TABLE procedure to:

- Add a table to a standby database.
- Re-create a table in a standby database.

Syntax

DBMS_LOGSTDBY.INSTANTIATE_TABLE (schema_name IN VARCHAR2, table_name IN VARCHAR2, dblink IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the table to be created or re-created in the standby database</td>
</tr>
<tr>
<td>dblink</td>
<td>Name of the database link account that has privileges to read and lock the table in the primary database, as well as the SELECT_CATALOG_ROLE on the primary database</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16236</td>
<td>Logical Standby metadata operation in progress</td>
</tr>
<tr>
<td>ORA-16276</td>
<td>Specified database link does not correspond to primary database</td>
</tr>
<tr>
<td>ORA-16277</td>
<td>Specified table is not supported by logical standby database</td>
</tr>
<tr>
<td>ORA-16278</td>
<td>Specified table has a multi-object skip rule defined</td>
</tr>
</tbody>
</table>

Usage Notes

- Use this procedure to create and populate a table in a way that keeps the data on the standby database transactionally consistent with the primary database.
- This table will not be synchronized with the rest of the tables being maintained by SQL Apply and SQL Apply will not start to maintain it until SQL Apply encounters redo that occurred after the table was instantiated from the primary. The SCN at which the table was instantiated from the primary database is available in the DBA_LOGSTDBY_EVENTS view.
- The specified table must be a table that is supported by logical standby (that is, it does not appear in the `DBA_LOGSTDBY_UNSUPPORTED_TABLES` view on the primary database).

- If there are any skip rules that specifically name this table (without any wildcards), those skip rules will be dropped as part of `INSTANTIATE_TABLE`, so that the table will be properly maintained by SQL Apply in the future. If there are skip rules that indirectly reference this table (match a skip rule with a wildcard in the `schema_name` or `table_name`, and have a TABLE, DML, or SCHEMA_DDL statement type), `INSTANTIATE_TABLE` will fail with an ORA-16278 error. Any multiobject skip rules that pertain to the table must be dropped or changed before re-attempting the `INSTANTIATE_TABLE` call.

**Examples**

```sql
SQL> EXECUTE DBMS_LOGSTDBY.INSTANTIATE_TABLE (
  2    SCHEMA_NAME => 'HR', TABLE_NAME => 'EMPLOYEES', 
  3    DBLINK => 'INSTANTIATE_TBL_LINK');
```
IS_APPLY_SERVER Function

This function returns TRUE if it is executed from PL/SQL in the context of a logical standby apply server process. This function is used in conjunction with triggers that have the fire_once parameter in the DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY subprogram set to FALSE (the default is TRUE). Such triggers are executed when the relevant target is updated by an apply process. This function can be used within the body of the trigger to ensure that the trigger takes different (or no) actions on the primary or on the standby.

See Also: Oracle Database PL/SQL Packages and Types Reference for more information about the DBMS_DDL.SET_TRIGGER_FIRING_PROPERTY subprogram.

Syntax

DBMS_LOGSTDBY.IS_APPLY_SERVER
RETURN BOOLEAN;

Parameters

None
MAP_PRIMARY_SCN Function

Returns an SCN on the standby that predates the supplied SCN from the primary database by at least 5 minutes. This function can be used to determine a safe SCN to use in a compensating flashback database operation at the logical standby database, following a flashback database operation or a point-in-time recovery operation at the primary database.

Syntax

```
DBMS_LOGSTDBY.MAP_PRIMARY_SCN(primary_scn NUMBER) RETURN NUMBER;
```

Exceptions

Table 86–7 MAP_PRIMARY_SCN Function Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-20001</td>
<td>Primary SCN is before mapped range</td>
</tr>
<tr>
<td>ORA-20002</td>
<td>SCN mapping requires PRESERVE_COMMIT_ORDER to be TRUE</td>
</tr>
</tbody>
</table>

Usage Notes

Use this function to get a conservative SCN at the logical standby database that corresponds to an SCN at the primary database. This function is useful in the context of doing compensating flashback database operations at the logical standby following a flashback database or a point-in-time recovery operation done at the primary database.
PREPARE_FOR_NEW_PRIMARY Procedure

The PREPARE_FOR_NEW_PRIMARY procedure must be invoked at a logical standby database following a failover if that standby database was not the target of the failover operation. Such a standby database must process the exact same set of redo logs processed at the new primary database. This routine ensures that the local logical standby database has not processed more redo than the new primary database and reports the set of archive logs that must be replaced to ensure consistency. The set of replacement logs will be reported in the alert.log. These logs must be copied to the logical standby and registered using the ALTER DATABASE REGISTER LOGICAL LOGFILE statement.

Syntax

```sql
DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY (
    FORMER_STANDBY_TYPE         IN VARCHAR2,
    DBLINK                      IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORMER_STANDBY_TYPE</td>
<td>The type of standby database that was the target of the failover operation to become the new primary database. Valid values are 'PHYSICAL' if the new primary was formerly a physical standby, and 'LOGICAL' if the new primary database was formerly a logical standby database.</td>
</tr>
<tr>
<td>DBLINK</td>
<td>The name of a database link to the new primary database</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-16104</td>
<td>Invalid Logical Standby option.</td>
</tr>
<tr>
<td>ORA-16109</td>
<td>Failed to apply log data from previous primary.</td>
</tr>
</tbody>
</table>

Usage Notes

- This routine is intended only for logical standby systems.
- This routine will fail if the new primary database was formerly a logical standby database and the LogMiner dictionary build has not completed successfully.
- Log files displayed in the alert log will be referred to as terminal logs. Users should keep in mind that file paths are relative to the new primary database and may not resolve locally.
- Upon manual registration of the terminal logs, users should complete the process by calling either START LOGICAL STANDBY APPLY if the new primary database was formerly a physical standby database or START LOGICAL STANDBY APPLY NEW PRIMARY if the new primary database was formerly a logical standby database.
- See the alert log for more details regarding the reasons for any exception.
Examples

```
SQL> EXECUTE DBMS_LOGSTDBY.PREPARE_FOR_NEW_PRIMARY (  -
    FORMER_STANDBY_TYPE => 'LOGICAL',  -
    DBLINK => 'dblink_to_newprimary');
```
PURGE_SESSION Procedure

Identifies all archived redo log files that have been applied to the logical standby database and are no longer needed by SQL Apply. Once identified, you can issue operating system commands to delete some or all of the unnecessary archived redo log files.

Syntax

```
DBMS_LOGSTDBY.PURGE_SESSION;
```

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01309</td>
<td>Invalid session</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure does not delete the archived redo log files. You must issue operating system commands to delete unneeded files.
- This procedure updates the DBA_LOGMNR_PURGED_LOG view that displays the archived redo log files that have been applied to the logical standby database.
- In Oracle Database 10g Release 2, metadata related to the archived redo log files (and the actual archived redo log files) are purged automatically based on the default setting of the LOG_AUTO_DELETE parameter described in the DBMS_LOGSTDBY.APPLY_SET procedure described on page 86-7.

Example

To identify and remove unnecessary files:

1. Enter the following statement on the logical standby database:

   ```sql
   SQL> EXECUTE DBMS_LOGSTDBY.PURGE_SESSION;
   ```

2. Query the DBA_LOGMNR_PURGED_LOG view to list the archived redo log files that can be removed:

   ```sql
   SQL> SELECT * FROM DBA_LOGMNR_PURGED_LOG;
   ```

<table>
<thead>
<tr>
<th>FILE_NAME</th>
</tr>
</thead>
<tbody>
<tr>
<td>/boston/arc_dest/arc_1_40_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_41_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_42_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_43_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_44_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_45_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_46_509538672.log</td>
</tr>
<tr>
<td>/boston/arc_dest/arc_1_47_509538672.log</td>
</tr>
</tbody>
</table>

3. Use operating system-specific commands to delete archived redo log files from the file system.
REBUILD Procedure

This procedure is used if a database that has recently changed its role to a primary database following a failover operation fails to record relevant metadata (including the LogMiner dictionary) in the redo stream required for other logical standby databases.

Syntax

DBMS_LOGSTDBY.REBUILD;

Usage Notes

- LogMiner dictionary information is logged in the redo log files.
- The standby redo log files (if present) are archived.

Examples

SQL> EXECUTE DBMS_LOGSTDBY.REBUILD;
SET_TABLESPACE Procedure

Moves metadata tables required by SQL Apply to the user-specified tablespace. By default, the metadata tables are created in the SYSAUX tablespace. SQL Apply cannot be running when you invoke this procedure.

Syntax

```sql
DBMS_LOGSTDBY.SET_TABLESPACE(
    NEW_TABLESPACE IN VARCHAR2)
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NEW_TABLESPACE</td>
<td>Name of the new tablespace where metadata tables will reside.</td>
</tr>
</tbody>
</table>

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16236</td>
<td>Logical Standby metadata operation in progress</td>
</tr>
</tbody>
</table>

Examples

To move metadata tables to a new tablespace named LOGSTDBY_TBS, issue the following statement:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.SET_TABLESPACE (new_tablespace => 'LOGSTDBY_TBS');
```
SKIP Procedure

The SKIP procedure can be used to define rules that will be used by SQL Apply to skip the application of certain changes to the logical standby database. For example, the SKIP procedure can be used to skip changes to a subset of tables in the logical standby database. It can also be used to specify DDL statements that should not be applied at the logical standby database or should be modified before they are applied in the logical standby database. One reason why a DDL statement may need to be modified is to accommodate a different directory structure on the logical standby database.

Syntax

```sql
DBMS_LOGSTDBY.SKIP ( stmt                      IN VARCHAR2,
    schema_name               IN VARCHAR2 DEFAULT NULL,
    object_name               IN VARCHAR2 DEFAULT NULL,
    proc_name                 IN VARCHAR2 DEFAULT NULL,
    use_like                  IN BOOLEAN DEFAULT TRUE,
    esc                       IN CHAR1 DEFAULT NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stmt</td>
<td>Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration since keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. Table 86-14 shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter. The keyword PL/SQL is used for the execution of Oracle-supplied packages which are supported for replication. See Oracle Data Guard Concepts and Administration for information about supported packages.</td>
</tr>
<tr>
<td>schema_name</td>
<td>The name of one or more schemas (wildcards are permitted) associated with the SQL statements identified by the stmt parameter. If not applicable, this value must be set to NULL.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of one or more objects (wildcards are permitted) associated with the SQL statements identified by the stmt. If not applicable, this value must be set to NULL.</td>
</tr>
</tbody>
</table>
SKIP Procedure

Name of a stored procedure to call when SQL Apply determines that a particular statement matches the filter defined by the stmt, schema_name, and object_name parameters. Specify the procedure in the following format:

'schema.package.procedure'

This procedure returns a value that directs SQL Apply to perform one of the following: execute the statement, skip the statement, or execute a replacement statement.

For DDLs, SQL Apply calls the stored procedure with the following call signature:

- IN STATEMENT VARCHAR2 -- The SQL statement that matches the filter
- IN STATEMENT_TYPE VARCHAR2 -- The stmt of the filter
- IN SCHEMA VARCHAR2 -- The schema_name of the filter, if applicable
- IN NAME VARCHAR2 -- The object_name of the filter, if applicable
- IN XIDUSN NUMBER -- Transaction ID part 1
- IN XIDSLT NUMBER -- Transaction ID part 2
- IN XIDSQN NUMBER -- Transaction ID part 3
- OUT SKIP_ACTION NUMBER -- Action to be taken by SQL Apply upon completion of this routine. Valid values are:
  - SKIP_ACTION_APPLY -- Execute the statement
  - SKIP_ACTION_SKIP -- Skip the statement
  - SKIP_ACTION_ERROR -- Halt apply so the DBA can take appropriate steps (for example, take compensating action)
  - SKIP_ACTION_REPLACE -- Execute the replacement statement supplied in the NEW_STATEMENT output parameter

For PL/SQL, SQL Apply calls the stored procedure with the following call signature:

- IN STATEMENT VARCHAR2 -- The SQL statement that matches the filter
- IN PACKAGE_SCHEMA VARCHAR2 -- The schema of the package being skipped (for example, SYS or XDB)
- IN PACKAGE_NAME VARCHAR2 -- The name of the package being skipped (for example, DBMS_RLS)
- IN PROCEDURE_NAME VARCHAR2 -- The name of the procedure being skipped (for example, ADD_POLICY)
- IN CURRENT_SCHEMA VARCHAR2 -- The name of the current schema in which the PL/SQL was executed on the primary
- IN XIDUSN NUMBER -- Transaction ID part 1
- IN XIDSLT NUMBER -- Transaction ID part 2
- IN XIDSQN NUMBER -- Transaction ID part 3
- IN EXIT_STATUS -- 0 (Zero) if the PL/SQL succeeded on the primary, or 1

### Table 86–13 (Cont.) SKIP Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| proc_name     | Name of a stored procedure to call when SQL Apply determines that a particular statement matches the filter defined by the stmt, schema_name, and object_name parameters. Specify the procedure in the following format: 'schema.package.procedure'. This procedure returns a value that directs SQL Apply to perform one of the following: execute the statement, skip the statement, or execute a replacement statement. For DDLs, SQL Apply calls the stored procedure with the following call signature:  
- IN STATEMENT VARCHAR2 -- The SQL statement that matches the filter  
- IN STATEMENT_TYPE VARCHAR2 -- The stmt of the filter  
- IN SCHEMA VARCHAR2 -- The schema_name of the filter, if applicable  
- IN NAME VARCHAR2 -- The object_name of the filter, if applicable  
- IN XIDUSN NUMBER -- Transaction ID part 1  
- IN XIDSLT NUMBER -- Transaction ID part 2  
- IN XIDSQN NUMBER -- Transaction ID part 3  
- OUT SKIP_ACTION NUMBER -- Action to be taken by SQL Apply upon completion of this routine. Valid values are:  
  - SKIP_ACTION_APPLY -- Execute the statement  
  - SKIP_ACTION_SKIP -- Skip the statement  
  - SKIP_ACTION_ERROR -- Halt apply so the DBA can take appropriate steps (for example, take compensating action)  
  - SKIP_ACTION_REPLACE -- Execute the replacement statement supplied in the NEW_STATEMENT output parameter  

For PL/SQL, SQL Apply calls the stored procedure with the following call signature:

- IN XIDSQN NUMBER -- Transaction ID part 3  
- IN EXIT_STATUS -- 0 (Zero) if the PL/SQL succeeded on the primary, or 1 |
### Summary of DBMS_LOGSTDBY Subprograms

**Table 86–13 (Cont.) SKIP Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| proc_name (cont.) | - OUT SKIP_ACTION NUMBER -- Action to be taken by SQL Apply upon completion of this routine. Valid return values are:  
|                 |  
|                 |   SKIP_ACTION_APPLY -- Execute the statement  
|                 |   SKIP_ACTION_APPLY -- Execute the statement  
|                 |   SKIP_ACTION_ERROR -- Raise an error which halts apply so that the DBA can take appropriate steps  
|                 | **Note 1:** SKIP_ACTION_REPLACE is not supported for PL/SQL.  
|                 | **Note 2:** SQL Apply calls the skip handler when the procedure's exit is processed.  
|                 | **Note 3:** The use_like parameter must be set to FALSE for PL/SQL since wildcarding PL/SQL is not supported.  
|                 | The following example shows how to have a conditional skip rule on DBMS_RLS.DROP_POLICY:  
|                 | Create or replace procedure sec_mgr.skip_drop_policy (  
|                 |   statement     in varchar2,  
|                 |   pkgown         in varchar2,  
|                 |   pkgname        in varchar2,  
|                 |   procnm         in varchar2,  
|                 |   cuser          in varchar2,  
|                 |   xidusn         in number,  
|                 |   xidslt         in number,  
|                 |   xidsqn         in number,  
|                 |   exstatus       in number,  
|                 |   skip_action    out number) Is  
|                 |   Begin  
|                 |   If 0 = exstatus Then  
|                 |       Insert Into sec_mgr.logit Values  
|                 |           ('Success: '.'||pkgown||'.'||pkgname||'.'||procnm||' '  
|                 |           by ' '||cuser);  
|                 |       If cuser != 'TESTSCHEMA' Then  
|                 |           skip_action := DBMS_LOGSTDBY.SKIP_ACTION_APPLY;  
|                 |       Else  
|                 |           skip_action := DBMS_LOGSTDBY.SKIP_ACTION_SKIP;  
|                 |       End If;  
|                 |   End If;  
|                 | End skip_drop_policy;  
|                 | EXECUTE DBMS_LOGSTDBY.SKIP(  
|                 |   stmt => 'PL/SQL',  
|                 |   schema_name => 'SYS',  
|                 |   object_name => 'DBMS_RLS.DROP_POLICY',  
|                 |   proc_name => 'SEC_MGR.SKIP_DROP_POLICY' -  
|                 |   use_like=> FALSE);  
| use_like | Allows pattern matching to isolate the tables that you want to skip on the logical standby database. The use_like parameter matches a portion of one character value to another by searching the first value for the pattern specified by the second, and calculates strings using characters as defined by the input character set. This parameter follows the same rules for pattern matching described in the Oracle Database SQL Language Reference. |
Usage Notes

- This procedure requires DBA privileges to execute.
- You cannot associate a stored procedure to be invoked in the context of a DML statement. For example, the following statement returns the ORA-16104: invalid Logical Standby option requested error:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
    stmt => 'DML', -
    schema_name => 'HR', -
    object_name => 'EMPLOYEES', -
    proc_name => 'DML_HANDLER');
```

Also, if an event matches multiple rules either because of the use of wildcards while specifying the rule or because of a specification of overlapping rules. For example, if you specify a rule for the SCHEMA_DDL event for the HR.EMPLOYEES table, and a rule for the ALTER TABLE event for the HR.EMPLOYEES table, only one of the matching procedures will be invoked (alphabetically, by procedure). In the following code example, consider the following rules:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
    stmt => 'SCHEMA DDL', -
    schema_name => 'HR', -
    object_name => 'EMPLOYEES', -
    proc_name => 'SCHEMA_DDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
    stmt => 'ALTER TABLE', -
    schema_name => 'HR', -
    object_name => 'EMPLOYEES', -
    proc_name => 'TABLE_ALTER_HANDLER');
```

On encountering an ALTER TABLE statement, the schema_ddl_handler procedure will be invoked because its name will be at the top of an alphabetically sorted list of procedures that are relevant to the statement.

Collisions on a rule set because of a specification containing wildcard entries are resolved in a similar fashion. For example, the rules in the following example will result in the empddl_handler procedure being invoked upon encountering the ALTER TABLE HR.EMPLOYEES ADD COLUMN RATING NUMBER statement:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
    stmt => 'ALTER TABLE', -
    schema_name => 'HR', -
    object_name => 'EMP%', -
    proc_name => 'EMPDDL_HANDLER');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP(-
    stmt => 'ALTER TABLE', -
    schema_name => 'HR', -
    object_name => 'EMPLOYEES', -
    proc_name => 'EMPLOYEE_DDL_HANDLER');
```

---

**Table 86–13 (Cont.) SKIP Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>esc</td>
<td>Identifies an escape character (such as the character “/”) that you can use for pattern matching. If the escape character appears in the pattern before the character “%” or “_” then Oracle interprets this character literally in the pattern, rather than as a special pattern matching character. See Oracle Database SQL Language Reference for more information about pattern matching.</td>
</tr>
</tbody>
</table>
Use the **SKIP** procedure with caution, particularly when skipping DDL statements. If a **CREATE TABLE** statement is skipped, for example, you must also specify other DDL statements that refer to that table in the **SKIP** procedure. Otherwise, the statements will fail and cause an exception. When this happens, SQL Apply stops running.

Before calling the **SKIP** procedure, SQL Apply must be halted. Do this by issuing an **ALTER DATABASE STOP LOGICAL STANDBY APPLY** statement. Once all desired filters have been specified, issue an **ALTER DATABASE START LOGICAL STANDBY APPLY IMMEDIATE** statement to start SQL Apply using the new filter settings.

See the **UNSKIP** procedure on page 86-35 for information about reversing (undoing) the settings of the **SKIP** procedure.

For **USER** statements, the **SCHEMA_NAME** parameter will be the user and specify '%/ for the **OBJECT_NAME** parameter.

If the **PROC_NAME** parameter is supplied, it must already exist in **DBA_PROCEDURES** and it must execute with **DEFINER** rights. If the procedure is declared with **INVOKER** rights, the **ORA-1031: insufficient privileges** message will be returned.

If the procedure returns a **REPLACEMENT** statement, the **REPLACEMENT** statement will be executed using the **SYSTEM** and **OBJECT** privileges of the owner of the procedure.

The PL/SQL block of a **SKIP** procedure cannot contain transaction control statements (for example, **COMMIT**, **ROLLBACK**, **SAVEPOINT**, and **SET CONSTRAINT**) unless the block is declared to be an autonomous transaction.

**Skip Statement Options**

Table 86–14 lists the supported values for the **stmt** parameter of the **SKIP** procedure. The left column of the table lists the keywords that may be used to identify the set of SQL statements to the right of the keyword. In addition, any of the SQL statements listed in the **sys.audit_actions** table (shown in the right column of Table 86–14) are also valid values. Note that keywords are generally defined by database object.

1 All directory objects are owned by SYS, but for the purpose of filtering them with a skip directive the schema should be specified as ‘%’.

2 See Oracle Data Guard Concepts and Administration for information about supported packages.

3 Java schema objects (sources, classes, and resources) are considered the same as procedure for purposes of skipping (ignoring) SQL statements.

Exceptions

</tr>
<tr>
<td>ORA-16236</td>
<td>Logical standby metadata operation in progress.</td>
</tr>
</tbody>
</table>
Examples

Example 1  Skipping all DML and DDL changes made to a schema
The following example shows how to specify rules so that SQL Apply will skip both DDL and DML statements made to the HR schema.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'SCHEMA DDL', -
          schema_name => 'HR', -
          object_name => '%', -
          proc_name => null);
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML', -
          schema_name => 'HR', -
          object_name => '%', -
          proc_name => null);
```

Example 2  Creating a procedure to handle different file system organization
For example, if the file system organization in the logical standby database is different than that in the primary database, you can write a skip procedure to handle DDL statements with file specifications transparently.

The following procedure can handle DDL statements as long as you follow a specific naming convention for the file specification string.

1. Create the skip procedure to handle tablespace DDL statements:

```
CREATE OR REPLACE PROCEDURE sys.handle_tbs_ddl (old_stmt  IN  VARCHAR2,
                                                stmt_typ  IN  VARCHAR2,
                                                schema    IN  VARCHAR2,
                                                name      IN  VARCHAR2,
                                                xidusn    IN  NUMBER,
                                                xidslt    IN  NUMBER,
                                                xidsqn    IN  NUMBER,
                                                action    OUT NUMBER,
                                                new_stmt  OUT VARCHAR2) AS
BEGIN
  -- All primary file specification that contains a directory
  -- /usr/orcl/primary/dbs
  -- should go to /usr/orcl/stdby directory specification

  new_stmt = replace(old_stmt,
                      '/usr/orcl/primary/dbs',
                      '/usr/orcl/stdby');

  action := DBMS_LOGSTDBY.SKIP_ACTION_REPLACE;
EXCEPTION
  WHEN OTHERS THEN
    action := DBMS_LOGSTDBY.SKIP_ACTION_ERROR;
    new_stmt := NULL;
END handle_tbs_ddl;
```

2. Register the skip procedure with SQL Apply:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (stmt => 'TABLESPACE', -
                                 proc_name => 'SYS.HANDLE_TBS_DDL');
```
SKIP_ERROR Procedure

Upon encountering an error, the logical standby database uses the criteria contained in this procedure to determine a course of action. The default action when a match is found is to skip the error and continue with applying changes. However, if a procedure is supplied, then SKIP_ERROR can take other actions depending on the situation. It can do nothing, which causes SQL Apply to stop, or it can change the error message text and stop SQL Apply, or it can actually skip the error.

Syntax

```
DBMS_LOGSTDBY.SKIP_ERROR (  
    stmt                      IN VARCHAR2,  
    schema_name               IN VARCHAR2 DEFAULT NULL,  
    object_name               IN VARCHAR2 DEFAULT NULL,  
    proc_name                 IN VARCHAR2 DEFAULT NULL,  
    use_like                  IN BOOLEAN  DEFAULT NULL,  
    esc                       IN CHAR1    DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stmt</td>
<td>Either a keyword that identifies a set of SQL statements or a specific SQL statement. The use of keywords simplifies configuration because keywords, generally defined by the database object, identify all SQL statements that operate on the specified object. Table 86–14 shows a list of keywords and the equivalent SQL statements, either of which is a valid value for this parameter.</td>
</tr>
<tr>
<td>schema_name</td>
<td>The name of one or more schemas (wildcards are permitted) associated with the SQL statements identified by the stmt parameter. If not applicable, this value must be set to NULL.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of one or more objects (wildcards are permitted) associated with the SQL statements identified by the stmt. If not applicable, this value must be set to NULL.</td>
</tr>
</tbody>
</table>
A stored procedure provided to the SKIP_ERROR procedure is called when SQL Apply encounters an error that could shut down the application of redo logs to the standby database.

Running this stored procedure affects the error being written in the STATUS column of the DBA_LOGSTDBY_EVENTS table. The STATUS_CODE column remains unchanged. If the stored procedure is to have no effect, that is, apply will be stopped, then the NEW_ERROR is written to the events table. To truly have no effect, set NEW_ERROR to ERROR in the procedure.
If the stored procedure requires that a shutdown be avoided, then you must set `NEW_ERROR` to `NULL`.

This procedure requires `DBA` privileges to execute.

For `USER` statements, the `SCHEMA_NAME` parameter will be the user and you should specify '%' for the `OBJECT_NAME` parameter.

If the `PROC_NAME` parameter is specified, it must already exist in `DBA_PROCEDURES` and it must execute with `DEFINERS` rights. If the procedure is declared with `INVOKERS` rights, the `ORA-1031: insufficient privileges` message will be returned.

The PL/SQL block of a `SKIP_ERROR` procedure cannot contain transaction control statements (for example: `COMMIT`, `ROLLBACK`, `SAVEPOINT`, and `SET CONSTRAINT`) unless the block is declared to be an autonomous transaction using the following syntax:

```
PRAGMA AUTONOMOUS_TRANSACTION
```

### Exceptions

**Table 86–17 SKIP_ERROR Procedure Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01031</td>
<td>Insufficient privileges:</td>
</tr>
<tr>
<td></td>
<td>- Procedure used <code>INVOKER</code> rights</td>
</tr>
<tr>
<td></td>
<td>- Procedure needs <code>DBA</code> privileges</td>
</tr>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
<tr>
<td>ORA-16236</td>
<td>Logical Standby metadata operation in progress</td>
</tr>
</tbody>
</table>

### Example 1

The following example shows how to specify rules so that SQL Apply will skip any error raised from any `GRANT DDL` command.

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR('GRANT')
```

### Example 2

To skip errors on `GRANT` statements on `SYS` or `HR` schemas, define a procedure `handle_error_ddl` and register it. In the following example, assume that `handle_error_ddl` is a free-standing procedure in the `SYS` schema.

1. Create the error-handler procedure:

   ```sql
   CREATE OR REPLACE PROCEDURE sys.handle_error_ddl (
   old_stmt IN VARCHAR2,
   stmt_type IN VARCHAR2,
   schema IN VARCHAR2,
   name IN VARCHAR2,
   xidusn IN NUMBER,
   xidslt IN NUMBER,
   xidsqn IN NUMBER,
   error IN VARCHAR2,
   new_error OUT VARCHAR2
   ) AS
   BEGIN
   ```
```
-- Default to what we already have
new_error := error;
-- Ignore any GRANT errors on SYS or HR schemas
IF INSTR(UPPER(old_stmt), 'GRANT') > 0 THEN
  IF schema IS NULL
    OR (schema IS NOT NULL AND
        (UPPER(schema) = 'SYS' OR UPPER(schema) = 'HR'))
  THEN
    new_error := NULL;
  END IF;
END IF;
END handle_error_ddl;
/

2. Register the error handler with SQL Apply:

   SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR ( -
        statement => 'NON_SCHEMA_DDL', -
        schema_name => NULL, -
        object_name => NULL, -
        proc_name => 'SYS.HANDLE_ERROR_DDL');
```
SKIP_TRANSACTION Procedure

This procedure provides a way to skip (ignore) applying transactions to the logical standby database. You can skip specific transactions by specifying transaction identification information.

Syntax

```
DBMS_LOGSTDBY.SKIP_TRANSACTION (
   xidusn   IN NUMBER,
   xidslt   IN NUMBER,
   xidsqn   IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XIDUSN</td>
<td>NUMBER</td>
</tr>
<tr>
<td>XIDSLT</td>
<td>NUMBER</td>
</tr>
<tr>
<td>XIDSQN</td>
<td>NUMBER</td>
</tr>
</tbody>
</table>

Usage Notes

If SQL Apply stops due to a particular transaction (for example, a DDL transaction), you can specify that transaction ID and then continue to apply. You can call this procedure multiple times for as many transactions as you want SQL Apply to ignore.

---

**CAUTION:** SKIP_TRANSACTION is an inherently dangerous operation. Do not invoke this procedure unless you have examined the transaction in question through the V$LOGMNR_CONTENTS view and have taken compensating actions at the logical standby database. SKIP_TRANSACTION is not the appropriate procedure to invoke to skip DML changes to a table.

To skip a DML failure, use a SKIP procedure, such as SKIP('DML', 'MySchema', 'MyFailed Table'). Using the SKIP_TRANSACTION procedure for DML transactions may skip changes for other tables, thus logically corrupting them.

---

- This procedure requires DBA privileges to execute.
- Use the DBA_LOGSTDBY_SKIP_TRANSACTION view to list the transactions that are going to be skipped by SQL Apply.
- Also, see the ALTER DATABASE START LOGICAL STANDBY SKIP FAILED TRANSACTION statement in Oracle Database SQL Language Reference.
Exceptions

Table 86–19 SKIP_TRANSACTION Procedure Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01031</td>
<td>Need DBA privileges</td>
</tr>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
</tbody>
</table>

Examples

To skip a DDL transaction with (XIDUSN, XIDSLT, XIDSQN) of (1.13.1726) you can register a rule as shown in the following example:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_TRANSACTION (-
                XIDUSN => 1, XIDSLT => 13, XIDSQN => 1726);
```
UNSKIP Procedure

Use the UNSKIP procedure to delete rules specified earlier with the SKIP procedure. The parameters specified in the UNSKIP procedure must match exactly for it to delete an already-specified rule.

Syntax

```
DBMS_LOGSTDBY.UNSKIP (
  stmt                      IN VARCHAR2,
  schema_name               IN VARCHAR2 DEFAULT NULL,
  object_name               IN VARCHAR2 DEFAULT NULL);
```

Parameters

The parameter information for the UNSKIP procedure is the same as that described for the SKIP procedure. See Table 86–13 on page 86-21 for complete parameter information.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01031</td>
<td>need DBA privileges to execute this procedure</td>
</tr>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure requires DBA privileges to execute.
- Wildcards passed in the schema_name or the object_name parameter are not expanded. The wildcard character is matched at the character level. Thus, you can delete only one specified rule by invoking the UNSKIP procedure, and you will need a distinct UNSKIP procedure call to delete each rule that was previously specified.

For example, assume you have specified the following two rules to skip applying DML statements to the HR.EMPLOYEE and HR.EMPTEMP tables:

```
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPLOYEE', -
    PROC_NAME => null);
SQL> EXECUTE DBMS_LOGSTDBY.SKIP (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPTEMP', -
    PROC_NAME => null);
```
In the following example, the wildcard in the `TABLE_NAME` parameter cannot be used to delete the rules that were specified:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP (STMT => 'DML', -
   2   SCHEMA_NAME => 'HR', -
   3   OBJECT_NAME => 'EMP%');
```

In fact, this `UNSKIP` procedure matches neither of the rules, because the wildcard character in the `TABLE_NAME` parameter is not expanded. Instead, the wildcard character will be used in an exact match to find the corresponding `SKIP` rule.
UNSKIP_ERROR Procedure

Use the UNSKIP_ERROR procedure to delete rules specified earlier with the SKIP_ERROR procedure. The parameters specified in the UNSKIP_ERROR procedure must match exactly for the procedure to delete an already-specified rule.

Syntax

```sql
DBMS_LOGSTDBY.UNSKIP_ERROR (
    stmt                      IN VARCHAR2,
    schema_name               IN VARCHAR2 DEFAULT NULL,
    object_name               IN VARCHAR2 DEFAULT NULL);
```

Parameters

The parameter information for the UNSKIP_ERROR procedure is the same as that described for the SKIP_ERROR procedure. See Table 86–16 for complete parameter information.

Exceptions

### Table 86–21 UNSKIP_ERROR Procedure Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01031</td>
<td>Need DBA privileges</td>
</tr>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure requires DBA privileges to execute.
- Wildcards passed in the schema_name or the object_name parameters are not expanded. Instead, the wildcard character is treated as any other character and an exact match is made. Thus, you can delete only one specified rule by invoking the UNSKIP_ERROR procedure, and you need a distinct UNSKIP_ERROR procedure call to delete each rule that you previously specified.

For example, assume you have specified the following two rules to handle the HR.EMPLOYEE and HR.EMPTEMP tables:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPLOYEE', -
    PROC_NAME => 'hr_employee_handler');
SQL> EXECUTE DBMS_LOGSTDBY.SKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMPTEMP', -
    PROC_NAME => 'hr_tempemp_handler');
```

In this case, the following UNSKIP procedure cannot be used to delete the rules that you have specified:

```sql
SQL> EXECUTE DBMS_LOGSTDBY.UNSKIP_ERROR (STMT => 'DML',-
    SCHEMA_NAME => 'HR', -
    OBJECT_NAME => 'EMP%');
```
In fact, the `UNSKIP` procedure will match neither of the rules, because the wildcard character in the `OBJECT_NAME` parameter will not be expanded.

**Example**

To remove a handler that was previously registered with SQL Apply from getting called on encountering an error, you can issue the following statement:

```sql
DBMS_LOGSTDBY.UNSKIP_ERROR ( -
    statement => 'NON_SCHEMA_DDL', -
    schema_name => NULL, -
    object_name => NULL);
```
**UNSKIP_TRANSACTION Procedure**

Use the **UNSKIP_TRANSACTION** procedure to delete rules specified earlier with the **SKIP_TRANSACTION** procedure. The parameters specified in the **UNSKIP_TRANSACTION** procedure must match exactly for the procedure to delete an already-specified rule.

**Syntax**

```sql
DBMS_LOGSTDBY.UNSKIP_TRANSACTION (          xidusn_p         IN NUMBER,  
                                          xidslt_p         IN NUMBER,  
                                          xidsqn_p         IN NUMBER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XIDUSN</td>
<td>Transaction ID undo segment number of the transaction being skipped</td>
</tr>
<tr>
<td>XIDSLT</td>
<td>Transaction ID slot number of the transaction being skipped</td>
</tr>
<tr>
<td>XIDSQN</td>
<td>Transaction ID sequence number of the transaction being skipped</td>
</tr>
</tbody>
</table>

**Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-01031</td>
<td>need DBA privileges to execute this procedure</td>
</tr>
<tr>
<td>ORA-16103</td>
<td>Logical Standby apply must be stopped to allow this operation</td>
</tr>
<tr>
<td>ORA-16104</td>
<td>invalid Logical Standby option requested</td>
</tr>
</tbody>
</table>

**Usage Notes**

- This procedure requires DBA privileges to execute.
- Query the **DBA_LOGSTDBY_SKIP_TRANSACTION** view to list the transactions that are going to be skipped by SQL Apply.

**Examples**

To remove a rule that was originally specified to skip the application of a transaction with (XIDUSN, XIDSLT, XIDSQN) of (1.13.1726) issue the following statement:

```sql
SQL> DBMS_LOGSTDBY.UNSKIP_TRANSACTION (XIDUSN => 1, XIDSLT => 13, XIDSQN => 1726);
```
The DBMS_METADATA package provides a way for you to retrieve metadata from the database dictionary as XML or creation DDL and to submit the XML to re-create the object.

See Also: Oracle Database Utilities for more information and for examples of using the Metadata API

This chapter contains the following topics:

- **Using DBMS_METADATA**
  - Overview
  - Security Model
  - Rules and Limits
- **Data Structures - Object and Table Types**
- **Subprogram Groupings**
  - Subprograms for Retrieving Multiple Objects From the Database
  - Subprograms for Submitting XML to the Database
- **Summary of All DBMS_METADATA Subprograms**
Using DBMS_METADATA

This section contains topics which relate to using the DBMS_METADATA package.

- Overview
- Security Model
- Rules and Limits
Overview

You can use the `DBMS_METADATA` package to retrieve metadata and also to submit XML, as described in the following sections.

- Retrieving Metadata
- Submitting XML

Retrieving Metadata

If you are retrieving metadata, you can specify:

- The kind of object to be retrieved. This can be either a particular object type (such as a table, index, or procedure) or a heterogeneous collection of object types that form a logical unit (such as a database export or schema export).
- Optional selection criteria, such as owner or name.
- Parse items (attributes of the returned objects to be parsed and returned separately).
- Optional transformations on the output, implemented by XSLT (Extensible Stylesheet Language Transformation) scripts. By default the output is represented in XML, but you can specify transformations (into SQL DDL, for example), which are implemented by XSLT stylesheets stored in the database or externally.

`DBMS_METADATA` provides the following retrieval interfaces:

- For programmatic use: `OPEN`, `SET_FILTER`, `SET_COUNT`, `GET_QUERY`, `SET_PARSE_ITEM`, `ADD_TRANSFORM`, `SET_TRANSFORM_PARAM`, `SET_REMAP_PARAM`, `FETCH_xxx`, and `CLOSE` retrieve multiple objects.
- For use in SQL queries and for browsing: `GET_XML`, `GET_DDL` and `GET_SXML` return metadata for a single named object. The `GET_DEPENDENT_XML`, `GET_DEPENDENT_DDL`, `GET_GRANTED_XML`, and `GET_GRANTED_DDL` interfaces return metadata for one or more dependent or granted objects. These procedures do not support heterogeneous object types.

Submitting XML

If you are submitting XML, you specify:

- The type of object
- Optional transform parameters to modify the object (for example, changing the object's owner)
- Parse items (attributes of the submitted objects to be parsed and submitted separately)
- Whether to execute the operation or simply return the generated DDL

`DBMS_METADATA` provides a programmatic interface for submission of XML. It is comprised of the following procedures: `OPENW`, `ADD_TRANSFORM`, `SET_TRANSFORM_PARAM`, `SET_REMAP_PARAM`, `SET_PARSE_ITEM`, `CONVERT`, `PUT`, and `CLOSE`. 
Security Model

The **DBMS_METADATA** package considers a privileged user to be one who is connected as user **SYS** or who has the **SELECT_CATALOG_ROLE** role. The object views of the Oracle metadata model implement security as follows:

- Nonprivileged users can see the metadata of only their own objects.
- Nonprivileged users can also retrieve public synonyms, system privileges granted to them, and object privileges granted to them or by them to others. This also includes privileges granted to **PUBLIC**.
- If callers request objects they are not privileged to retrieve, no exception is raised; the object is simply not retrieved.
- If nonprivileged users are granted some form of access to an object in someone else’s schema, they will be able to retrieve the grant specification through the Metadata API, but not the object’s actual metadata.
- In stored procedures, functions, and definers-rights packages, roles (such as **SELECT_CATALOG_ROLE**) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker’s possession of **SELECT_CATALOG_ROLE**), you must make the program invokers-rights.
- For all objects that have passwords (for example, db links, users, and roles), the following rules apply:
  - A user who has the **SELECT_CATALOG_ROLE** can see all metadata for an object except the passwords for that object.
  - The SYS user, users who have the **EXP_FULL_DATABASE** role, and users who own an object can see all metadata for that object, including passwords.
Rules and Limits

In an Oracle Shared Server (OSS) environment, the DBMS_METADATA package must disable session migration and connection pooling. This results in any shared server process that is serving a session running the package to effectively become a default, dedicated server for the life of the session. You should ensure that sufficient shared servers are configured when the package is used and that the number of servers is not artificially limited by too small a value for the MAX_SHARED_SERVERS initialization parameter.
The DBMS_METADATA package defines, in the SYS schema, the following OBJECT and TABLE types.

CREATE TYPE sys.ku$_parsed_item AS OBJECT {
    item         VARCHAR2(30),
    value        VARCHAR2(4000),
    object_row   NUMBER
}/

CREATE PUBLIC SYNONYM ku$_parsed_item FOR sys.ku$_parsed_item;

CREATE TYPE sys.ku$_parsed_items IS TABLE OF sys.ku$_parsed_item /

CREATE PUBLIC SYNONYM ku$_parsed_items FOR sys.ku$_parsed_items;

CREATE TYPE sys.ku$_ddl AS OBJECT {
    ddlText     CLOB,
    parsedItem  sys.ku$_parsed_items
}/

CREATE PUBLIC SYNONYM ku$_ddl FOR sys.ku$_ddl;

CREATE TYPE sys.ku$_ddls IS TABLE OF sys.ku$_ddl /

CREATE PUBLIC SYNONYM ku$_ddls FOR sys.ku$_ddls;

CREATE TYPE sys.ku$_multi_ddl AS OBJECT {
    object_row  NUMBER,
    ddls        sys.ku$_ddls
}/

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddl FOR sys.ku$_multi_ddl;

CREATE TYPE sys.ku$_multi_ddls IS TABLE OF sys.ku$_multi_ddl /

CREATE OR REPLACE PUBLIC SYNONYM ku$_multi_ddls FOR sys.ku$_multi_ddls;

CREATE TYPE sys.ku$_ErrorLine IS OBJECT {
    errorNumber    NUMBER,
    errorText      VARCHAR2(2000)
}/

CREATE PUBLIC SYNONYM ku$_ErrorLine FOR sys.ku$_ErrorLine;

CREATE TYPE sys.ku$_ErrorLines IS TABLE OF sys.ku$_ErrorLine /

CREATE PUBLIC SYNONYM ku$ErrorLines FOR sys.ku$ErrorLines;

CREATE TYPE sys.ku$_SubmitResult AS OBJECT {
    ddl          sys.ku$_ddl,
    errorLines   sys.ku$_ErrorLines
};
CREATE TYPE sys.ku$_SubmitResults IS TABLE OF sys.ku$_SubmitResult
/
CREATE PUBLIC SYNONYM ku$_SubmitResults FOR sys.ku$_SubmitResults;
Subprogram Groupings

The `DBMS_METADATA` subprograms are used to retrieve objects from, and submit XML to, a database. Some subprograms are used for both activities, while others are used only for retrieval or only for submission.

- Table 87–1 provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to retrieve multiple objects from a database.
- Table 87–2 provides a summary, in alphabetical order, of `DBMS_METADATA` subprograms used to submit XML metadata to a database.
Subprograms for Retrieving Multiple Objects From the Database

Table 87–1 lists the subprograms used for retrieving multiple objects from the database.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD_TRANSFORM Function</td>
<td>Specifies a transform that FETCH_xxx applies to the XML representation of the retrieved objects</td>
</tr>
<tr>
<td>CLOSE Procedure</td>
<td>Invalidates the handle returned by OPEN and cleans up the associated state</td>
</tr>
<tr>
<td>FETCH_xxx Functions and Procedures</td>
<td>Returns metadata for objects meeting the criteria established by OPEN, SET_FILTER, SET_COUNT, ADD_TRANSFORM, and so on</td>
</tr>
<tr>
<td>GET_QUERY Function</td>
<td>Returns the text of the queries that are used by FETCH_xxx</td>
</tr>
<tr>
<td>GET_xxx Functions</td>
<td>Fetches the metadata for a specified object as XML, SXML, or DDL, using only a single call</td>
</tr>
<tr>
<td>OPEN Function</td>
<td>Specifies the type of object to be retrieved, the version of its metadata, and the object model</td>
</tr>
<tr>
<td>SET_COUNT Procedure</td>
<td>Specifies the maximum number of objects to be retrieved in a single FETCH_xxx call</td>
</tr>
<tr>
<td>SET_FILTER Procedure</td>
<td>Specifies restrictions on the objects to be retrieved, for example, the object name or schema</td>
</tr>
<tr>
<td>SET_PARSE_ITEM Procedure</td>
<td>Enables output parsing by specifying an object attribute to be parsed and returned</td>
</tr>
<tr>
<td>SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures</td>
<td>Specifies parameters to the XSLT stylesheets identified by transform_handle</td>
</tr>
</tbody>
</table>
Subprograms for Submitting XML to the Database

Table 87–2 lists the subprograms used for submitting XML to the database.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD_TRANSFORM Function on page 87-12</td>
<td>Specifies a transform for the XML documents</td>
</tr>
<tr>

<td>Specifies parameters to the XSLT stylesheets identified by transform_handle</td>
</tr>
</tbody>
</table>
ADD_TRANSFORM Function

This function is used for both retrieval and submission:

- When this procedure is used to retrieve objects, it specifies a transform that `FETCH_` or `xxx` applies to the XML representation of the retrieved objects.
- When used to submit objects, it specifies a transform that `CONVERT` or `PUT` applies to the XML representation of the submitted objects. It is possible to add more than one transform.

**See Also:** For more information about related subprograms:

- Subprograms for Retrieving Multiple Objects From the Database on page 87-9
- Subprograms for Submitting XML to the Database on page 87-10

**Syntax**

```sql
DBMS_METADATA.ADD_TRANSFORM (  
  handle       IN NUMBER,  
  name         IN VARCHAR2,  
  encoding     IN VARCHAR2 DEFAULT NULL,  
  object_type  IN VARCHAR2 DEFAULT NULL)  
RETURN NUMBER;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from <code>OPEN</code> when this transform is used to retrieve objects. Or the handle returned from <code>OPENW</code> when this transform is used in the submission of XML metadata.</td>
</tr>
</tbody>
</table>
The name of the transform. If name contains a period, colon, or forward slash, it is interpreted as the URL of a user-supplied XSLT script. See Oracle XML DB Developer’s Guide. Otherwise, name designates a transform implemented by DBMS_METADATA. The following transforms are defined:

- **ALTERDDL** - The document is converted from ALTER_XML format to SQL DDL.
- **ALTERXML** - The document is converted from SXML difference format to ALTER_XML format. See the DBMS_METADATA_DIFF PL/SQL package for more information about SXML difference format.
- **DDL** - The document is transformed to DDL that creates the object. The output of this transform is not an XML document.
- **MODIFY** - The document is modified as directed by transform and remap parameters. The output of this transform is an XML document. If no transform or remap parameters are specified, the document is unchanged.
- **MODIFYSXML** - The SXML format document is modified as directed by transform and remap parameters. The output of this transform is an XML document. If no transform or remap parameters are specified, the document is unchanged.
- **SXML** - The document is converted to SXML format. This transform is only valid for a subset of object types. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW.
- **SXMLDDL** - The SXML format document is transformed to DDL that creates the object.

The name of the Globalization Support character set in which the stylesheet pointed to by name is encoded. This is only valid if name is a URL. If left NULL and the URL is external to the database, UTF-8 encoding is assumed. If left NULL and the URL is internal to the database (that is, it begins with /oradb/), then the encoding is assumed to be the database character set.
The opaque handle that is returned is used as input to \texttt{SET\_TRANSFORM\_PARAM} and \texttt{SET\_REMAP\_PARAM}. Note that this handle is different from the handle returned by \texttt{OPEN} or \texttt{OPENW}; it refers to the transform, not the set of objects to be retrieved.

### Usage Notes

- With no transforms added, objects are returned by default as XML documents. You call \texttt{ADD\_TRANSFORM} to specify the XSLT stylesheets to be used to transform the returned XML documents.

- You can call \texttt{ADD\_TRANSFORM} more than once to apply multiple transforms to XML documents. Transforms are applied in the order in which they were specified, the output of the first transform being used as input to the second, and so on.

- The output of a DDL transform is \textit{not} an XML document. Therefore, no transform should be added after the DDL transform.

- Each transform expects a certain format XML document as input. If the input document is unspecified, metadata XML format is assumed.
Exceptions

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- **INVALID_OPERATION.** `ADD_TRANSFORM` was called after the first call to `FETCH_xxx` for the `OPEN` context. After the first call to `FETCH_xxx` is made, no further calls to `ADD_TRANSFORM` for the current `OPEN` context are permitted.

- **INCONSISTENT_ARGS.** The arguments are inconsistent. Possible inconsistencies include the following:
  - `encoding` is specified even though `name` is not a `URL`.
  - `object_type` is not part of the collection designated by `handle`
CLOSE Procedure

This procedure is used for both retrieval and submission. This procedure invalidates the handle returned by OPEN (or OPENW) and cleans up the associated state.

See Also: For more information about related subprograms:
- Subprograms for Retrieving Multiple Objects From the Database on page 87-9
- Subprograms for Submitting XML to the Database on page 87-10

Syntax

DBMS_METADATA.CLOSE
(handle IN NUMBER);

Parameters

Table 87–5 CLOSE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN (or OPENW).</td>
</tr>
</tbody>
</table>

Usage Notes

Note: The following notes apply only to object retrieval

You can prematurely terminate the stream of objects established by OPEN or (OPENW).
- If a call to FETCH_xxx returns NULL, indicating no more objects, a call to CLOSE is made transparently. In this case, you can still call CLOSE on the handle and not get an exception. (The call to CLOSE is not required.)
- If you know that only one specific object will be returned, you should explicitly call CLOSE after the single FETCH_xxx call to free resources held by the handle.

Exceptions

- INVALID_ARGVAL. The value for the handle parameter is NULL or invalid.
CONVERT Functions and Procedures

The CONVERT functions and procedures transform input XML documents. The CONVERT functions return creation DDL. The CONVERT procedures return either XML or DDL, depending on the specified transforms.

**See Also:** For more information about related subprograms:
- Subprograms for Submitting XML to the Database on page 87-10

**Syntax**

The CONVERT functions are as follows:

```sql
DBMS_METADATA.CONVERT (  
    handle   IN NUMBER,  
    document IN sys.XMLType)  
RETURN sys.ku$_multi_ddls;

DBMS_METADATA.CONVERT (  
    handle   IN NUMBER,  
    document IN CLOB)  
RETURN sys.ku$_multi_ddls;
```

The CONVERT procedures are as follows:

```sql
DBMS_METADATA.CONVERT (  
    handle   IN NUMBER,  
    document IN sys.XMLType,  
    result   IN OUT NOCOPY CLOB);  

DBMS_METADATA.CONVERT (  
    handle   IN NUMBER,  
    document IN CLOB,  
    result   IN OUT NOCOPY CLOB);  
```

**Parameters**

**Table 87–6 CONVERT Subprogram Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPENW.</td>
</tr>
<tr>
<td>document</td>
<td>The XML document containing object metadata of the type of the OPENW handle.</td>
</tr>
<tr>
<td>result</td>
<td>The converted document.</td>
</tr>
</tbody>
</table>

**Return Values**

Either XML or DDL, depending on the specified transforms.

**Usage Notes**

You can think of CONVERT as the second half of FETCH_xxx, either FETCH_DDL (for the function variants) or FETCH_CLOB (for the procedure variants). There are two differences:
■ **FETCH_xxx** gets its XML document from the database, but **CONVERT** gets its XML document from the caller

■ **FETCH_DDL** returns its results in a `sys.ku$_ddls` nested table, but **CONVERT** returns a `sys.ku$_multi_ddls` nested table

The transforms specified with **ADD_TRANSFORM** are applied in turn, and the result is returned to the caller. For the function variants, the DDL transform must be specified. If parse items were specified, they are returned in the `parsedItems` column. Parse items are ignored by the procedure variants.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in `OPENW`.

### Exceptions

■ **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

■ **INCONSISTENT_OPERATION.** No transform was specified. The DDL transform was not specified (function variants only).

■ **INCOMPATIBLE_DOCUMENT.** The version of the XML document is not compatible with this version of the software.
FETCH_xxx Functions and Procedures

These functions and procedures return metadata for objects meeting the criteria established by OPEN, SET_FILTER, SET_COUNT, ADD_TRANSFORM, and so on. See "Usage Notes" on page 87-20 for the variants.

**See Also:** For more information about related subprograms:
- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

### Syntax

The FETCH functions are as follows:

```sql
DBMS_METADATA.FETCH_XML (handle  IN NUMBER)
RETURN sys.XMLType;
```

**See Also:** Oracle XML DB Developer's Guide for a description of XMLType

```sql
DBMS_METADATA.FETCH_DDL (handle  IN NUMBER)
RETURN sys.ku$_ddls;
```

```sql
DBMS_METADATA.FETCH_CLOB (handle  IN NUMBER,
cache_lob    IN BOOLEAN DEFAULT TRUE,
lob_duration IN PLS INTEGER DEFAULT DBMS_LOB.SESSION)
RETURN CLOB;
```

The FETCH procedures are as follows:

```sql
DBMS_METADATA.FETCH_CLOB (handle  IN NUMBER,
doc     IN OUT NOCOPY CLOB);
```

```sql
DBMS_METADATA.FETCH_XML_CLOB (handle  IN NUMBER,
doc     IN OUT NOCOPY CLOB,
parsed_items OUT sys.ku$_parsed_items,
object_type_path OUT VARCHAR2);
```

### Parameters

**Table 87–7  FETCH_xxx Function Parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN.</td>
</tr>
<tr>
<td>cache_lob</td>
<td>TRUE=read LOB into buffer cache</td>
</tr>
<tr>
<td>lob_duration</td>
<td>The duration for the temporary LOB created by FETCH_CLOB, either DBMS_LOB.SESSION (the default) or DBMS_LOB.CALL.</td>
</tr>
<tr>
<td>doc</td>
<td>The metadata for the objects, or NULL if all objects have been returned.</td>
</tr>
<tr>
<td>parsed_items</td>
<td>A nested table containing the items specified by SET_PARSE_ITEM. If SET_PARSE_ITEM was not called, a NULL is returned.</td>
</tr>
</tbody>
</table>
Return Values

The metadata for the objects or NULL if all objects have been returned.

Usage Notes

These functions and procedures return metadata for objects meeting the criteria established by the call to `OPEN` that returned the handle, and subsequent calls to `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, and so on. Each call to `FETCH_xxx` returns the number of objects specified by `SET_COUNT` (or less, if fewer objects remain in the underlying cursor) until all objects have been returned. After the last object is returned, subsequent calls to `FETCH_xxx` return NULL and cause the stream created by `OPEN` to be transparently closed.

There are several different `FETCH_xxx` functions and procedures:

- The `FETCH_XML` function returns the XML metadata for an object as an `XMLType`. It assumes that if any transform has been specified, that transform will produce an XML document. In particular, it assumes that the DDL transform has not been specified.

- The `FETCH_DDL` function returns the DDL (to create the object) in a `sys.ku$_ddls` nested table. It assumes that the DDL transform has been specified. Each row of the `sys.ku$_ddls` nested table contains a single DDL statement in the `ddlText` column; if requested, parsed items for the DDL statement will be returned in the `parsedItems` column. Multiple DDL statements may be returned under the following circumstances:
  - When you call `SET_COUNT` to specify a count greater than 1
  - When an object is transformed into multiple DDL statements. For example, A `TYPE` object that has a DDL transform applied to it can be transformed into both `CREATE TYPE` and `CREATE TYPE BODY` statements. A `TABLE` object can be transformed into a `CREATE TABLE`, and one or more `ALTER TABLE` statements

- The `FETCH_CLOB` function simply returns the object, transformed or not, as a CLOB. By default, the CLOB is read into the buffer cache and has session duration, but these defaults can be overridden with the `cache_lob` and `lob_duration` parameters.

- The `FETCH_CLOB` procedure returns the objects by reference in an `IN OUT NOCOPY` parameter. This is faster than the function variant, which returns LOBs by value, a practice that involves an expensive LOB copy.

- The `FETCH_XML_CLOB` procedure returns the XML metadata for the objects as a CLOB in an `IN OUT NOCOPY` parameter. This helps to avoid LOB copies, which can consume a lot of resources. It also returns a nested table of parse items and the full path name of the object type of the returned objects.

- All LOBs returned by `FETCH_xxx` are temporary LOBs. You must free the LOB. If the LOB is supplied as an `IN OUT NOCOPY` parameter, you must also create the LOB.
If **SET_PARSE_ITEM** was called, **FETCH_DDL** and **FETCH_XML_CLOB** return attributes of the object's metadata (or the DDL statement) in a **sys.ku$_parsed_items** nested table. For **FETCH_XML_CLOB**, the nested table is an OUT parameter. For **FETCH_DDL**, it is a column in the returned **sys.ku$_ddls** nested table. Each row of the nested table corresponds to an item specified by **SET_PARSE_ITEM** and contains the following columns:

- **item**—the name of the attribute as specified in the name parameter to **SET_PARSE_ITEM**.
- **value**—the attribute value, or **NULL** if the attribute is not present in the DDL statement.
- **object-row**—a positive integer indicating the object to which the parse item applies. If multiple objects are returned by **FETCH_xxx**, (because **SET_COUNT** specified a count greater than 1) then **object_row=1** for all items for the first object, 2 for the second, and so on.

The rows of the **sys.ku$_parsed_items** nested table are ordered by ascending **object_row**, but otherwise the row order is undetermined. To find a particular parse item within an object row the caller must search the table for a match on **item**.

In general there is no guarantee that a requested parse item will be returned. For example, the parse item may not apply to the object type or to the particular line of DDL, or the item's value may be **NULL**.

If **SET_PARSE_ITEM** was not called, **NULL** is returned as the value of the parsed items nested table.

It is expected that the same variant of **FETCH_xxx** will be called for all objects selected by **OPEN**. That is, programs will not intermix calls to **FETCH_XML**, **FETCH_DDL**, **FETCH_CLOB**, and so on using the same **OPEN** handle. The effect of calling different variants is undefined; it might do what you expect, but there are no guarantees.

Every object fetched will be internally consistent with respect to on-going DDL (and the subsequent recursive DML) operations against the dictionary. In some cases, multiple queries may be issued, either because the object type is heterogeneous or for performance reasons (for example, one query for heap tables, one for index-organized tables). Consequently the **FETCH_xxx** calls may in fact be fetches from different underlying cursors (meaning that read consistency is not guaranteed).

**Exceptions**

Most exceptions raised during execution of the query are propagated to the caller. Also, the following exceptions may be raised:

- **INVALID_ARGVAL**. A **NULL** or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- **INCONSISTENT_OPERATION**. Either **FETCH_XML** was called when the DDL transform had been specified, or **FETCH_DDL** was called when the DDL transform had **not** been specified.
GET_xxx Functions

The following GET_xxx functions let you fetch metadata for objects with a single call:

- GET_XML
- GET_DDL
- GET_SXML
- GET_DEPENDENT_XML
- GET_DEPENDENT_DDL
- GET_GRANTED_XML
- GET_GRANTED_DDL

See Also: For more information about related subprograms:

- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

Syntax

```sql
DBMS_METADATA.GET_XML (  
object_type    IN VARCHAR2,  
name           IN VARCHAR2,  
schema         IN VARCHAR2 DEFAULT NULL,  
version        IN VARCHAR2 DEFAULT 'COMPATIBLE',  
model          IN VARCHAR2 DEFAULT 'ORACLE',  
transform      IN VARCHAR2 DEFAULT NULL)  
RETURN CLOB;

DBMS_METADATA.GET_DDL (  
object_type    IN VARCHAR2,  
name           IN VARCHAR2,  
schema         IN VARCHAR2 DEFAULT NULL,  
version        IN VARCHAR2 DEFAULT 'COMPATIBLE',  
model          IN VARCHAR2 DEFAULT 'ORACLE',  
transform      IN VARCHAR2 DEFAULT 'DDL')  
RETURN CLOB;

DBMS_METADATA.GET_SXML (  
object_type    IN VARCHAR2,  
name           IN VARCHAR2 DEFAULT NULL,  
schema         IN VARCHAR2 DEFAULT NULL,  
version        IN VARCHAR2 DEFAULT 'COMPATIBLE',  
model          IN VARCHAR2 DEFAULT 'ORACLE',  
transform      IN VARCHAR2 DEFAULT 'SXML')  
RETURN CLOB;

DBMS_METADATA.GET_DEPENDENT_XML (  
object_type    IN VARCHAR2,  
base_object_name IN VARCHAR2,  
base_object_schema IN VARCHAR2 DEFAULT NULL,  
version        IN VARCHAR2 DEFAULT 'COMPATIBLE',  
model          IN VARCHAR2 DEFAULT 'ORACLE',  
transform      IN VARCHAR2 DEFAULT NULL,  
object_count   IN NUMBER DEFAULT 10000)  
RETURN CLOB;
```
Parameters

Table 87–8  GET_xxx Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>The type of object to be retrieved. This parameter takes the same values as the OPEN object_type parameter, except that it cannot be a heterogeneous object type. The attributes of the object type must be appropriate to the function. That is, for GET_xxx it must be a named object.</td>
</tr>
<tr>
<td>name</td>
<td>The object name. It is used internally in a NAME filter. (If the name is longer than 30 characters, it will be used in a LONGNAME filter.) If this parameter is NULL, then no NAME or LONGNAME filter is specified. See Table 87–17 for a list of filters.</td>
</tr>
<tr>
<td>schema</td>
<td>The object schema. It is used internally in a SCHEMA filter. The default is the current user.</td>
</tr>
<tr>
<td>version</td>
<td>The version of metadata to be extracted. This parameter takes the same values as the OPEN version parameter.</td>
</tr>
<tr>
<td>model</td>
<td>The object model to use. This parameter takes the same values as the OPEN model parameter.</td>
</tr>
<tr>
<td>transform</td>
<td>The name of a transformation on the output. This parameter takes the same values as the ADD_TRANSFORM name parameter. For GET_XML, this must not be DDL.</td>
</tr>
<tr>
<td>base_object_name</td>
<td>The base object name. It is used internally in a BASE_OBJECT_NAME filter.</td>
</tr>
<tr>
<td>base_object_schema</td>
<td>The base object schema. It is used internally in a BASE_OBJECT_SCHEMA filter. The default is the current user.</td>
</tr>
</tbody>
</table>
GET_xxx Functions

Return Values

The metadata for the specified object as XML or DDL.

Usage Notes

- These functions allow you to fetch metadata for objects with a single call. They encapsulate calls to OPEN, SET_FILTER, and so on. The function you use depends on the characteristics of the object type and on whether you want XML, SXML, or DDL.
  - GET_xxx is used to fetch named objects, especially schema objects (tables, views).
  - GET_DEPENDENT_xxx is used to fetch dependent objects (audits, object grants).
  - GET_GRANTED_xxx is used to fetch granted objects (system grants, role grants).
- For some object types you can use more than one function. For example, you can use GET_xxx to fetch an index by name, or GET_DEPENDENT_xxx to fetch the same index by specifying the table on which it is defined.
- GET_xxx only returns a single named object.
- For GET_DEPENDENT_xxx and GET_GRANTED_xxx, an arbitrary number of dependent or granted objects can match the input criteria. You can specify an object count when fetching these objects. (The default count of 10000 should be adequate in most cases.)
- If the DDL transform is specified, session-level transform parameters are inherited.
- If you invoke these functions from SQL*Plus, you should set the PAGESIZE to 0 and set LONG to some large number to get complete, uninterrupted output.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- OBJECT_NOT_FOUND. The specified object was not found in the database.

Examples

Example: Fetch the XML Representation of SCOTT.EMP

To generate complete, uninterrupted output, set the PAGESIZE to 0 and set LONG to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
SELECT DBMS_METADATA.GET_XML('TABLE', 'EMP', 'SCOTT')
FROM DUAL;
```
Example: Fetch the DDL for all Complete Tables in the Current Schema, Filter Out Nested Tables and Overflow Segments

This example fetches the DDL for all "complete" tables in the current schema, filtering out nested tables and overflow segments. The example uses `DBMS_METADATA.SET_TRANSFORM_PARAM` (with the handle value = `DBMS_METADATA.SESSION_TRANSFORM` meaning "for the current session") to specify that storage clauses are not to be returned in the SQL DDL. Afterwards, the example resets the session-level parameters to their defaults.

To generate complete, uninterrupted output, set the `PAGESIZE` to 0 and set `LONG` to some large number, as shown, before executing your query.

```
SET LONG 2000000
SET PAGESIZE 0
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'STORAGE',false);
SELECT DBMS_METADATA.GET_DDL('TABLE',u.table_name)
  FROM USER_ALL_TABLES u
  WHERE u.nested='NO'
  AND (u.iot_type is null or u.iot_type='IOT');
EXECUTE DBMS_METADATA.SET_TRANSFORM_PARAM(DBMS_METADATA.SESSION_TRANSFORM,'DEFAULT');
```

Example: Fetch the DDL For All Object Grants On HR.EMPLOYEES

```
SELECT DBMS_METADATA.GET_DEPENDENT_DDL('OBJECT_GRANT','EMPLOYEES','HR') FROM DUAL;
```

Example: Fetch the DDL For All System Grants Granted To SCOTT

```
SELECT DBMS_METADATA.GET_GRANTED_DDL('SYSTEM_GRANT','SCOTT') FROM DUAL;
```
GET_QUERY Function

This function returns the text of the queries that are used by FETCH_xxx. This function assists in debugging.

See Also: For more information about related subprograms:
- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

Syntax

```
DBMS_METADATA.GET_QUERY (  
    handle   IN NUMBER)  
RETURN VARCHAR2;
```

Parameters

Table 87–9  GET_QUERY Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN. It cannot be the handle for a heterogeneous object type.</td>
</tr>
</tbody>
</table>

Return Values

The text of the queries that will be used by FETCH_xxx.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for the handle parameter.
OPEN Function

This function specifies the type of object to be retrieved, the version of its metadata, and the object model. The return value is an opaque context handle for the set of objects to be used in subsequent calls.

See Also: For more information about related subprograms:
- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

Syntax

```sql
DBMS_METADATA.OPEN (  
    object_type  IN VARCHAR2,
    version      IN VARCHAR2 DEFAULT 'COMPATIBLE',
    model        IN VARCHAR2 DEFAULT 'ORACLE',
    network_link IN VARCHAR2 DEFAULT NULL)  
RETURN NUMBER;
```

Parameters

**Table 87–10  Open Function Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| object_type | The type of object to be retrieved. Table 87–11 lists the valid type names and their meanings. These object types will be supported for the ORACLE model of metadata (see model in this table).  
The Attributes column in Table 87–11 specifies some object type attributes:  
- Schema objects, such as tables, belong to schemas.  
- Named objects have unique names (if they are schema objects, the name is unique to the schema).  
- Dependent objects, such as indexes, are defined with reference to a base schema object.  
- Granted objects are granted or assigned to a user or role and therefore have a named grantee.  
- Heterogeneous object types denote a collection of related objects of different types. See Table 87–12 for a listing of object types returned for the heterogeneous object type.  
These attributes are relevant when choosing object selection criteria. See "SET_FILTER Procedure" on page 87-37 for more information. |
| version | The version of metadata to be extracted. Database objects or attributes that are incompatible with the version will not be extracted. Legal values for this parameter are as follows:  
COMPATIBLE (default)—the version of the metadata corresponds to the database compatibility level.  
LATEST—the version of the metadata corresponds to the database version.  
A specific database version. The value cannot be lower than 9.2.0. |
Table 87–11 provides the name, meaning, attributes, and notes for the DBMS_METADATA package object types. In the attributes column, $S$ represents a schema object, $N$ represents a named object, $D$ represents a dependent object, $G$ represents a granted object, and $H$ represents a heterogeneous object.

Return Values

An opaque handle to the class of objects. This handle is used as input to `SET_FILTER`, `SET_COUNT`, `ADD_TRANSFORM`, `GET_QUERY`, `SET_PARSE_ITEM`, `FETCH_xxx`, and `CLOSE`.

Exceptions

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- **INVALID_OBJECT_PARAM.** The version or model parameter was not valid for the object_type.
OPENW Function

This function specifies the type of object to be submitted and the object model. The return value is an opaque context handle.

See Also: For more information about related subprograms:
- Subprograms for Submitting XML to the Database on page 87-10

Syntax

```
DBMS_METADATA.OPENW
(object_type  IN VARCHAR2,
version       IN VARCHAR2 DEFAULT 'COMPATIBLE',
model         IN VARCHAR2 DEFAULT 'ORACLE')
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>The type of object to be submitted. Valid types names and their meanings are listed in Table 87–11. The type cannot be a heterogeneous object type.</td>
</tr>
<tr>
<td>version</td>
<td>The version of DDL to be generated by the CONVERT function. DDL clauses that are incompatible with the version will not be generated. The legal values for this parameter are as follows:</td>
</tr>
<tr>
<td></td>
<td>- COMPATIBLE - This is the default. The version of the DDL corresponds to the database compatibility level. Database compatibility must be set to 9.2.0 or higher.</td>
</tr>
<tr>
<td></td>
<td>- LATEST - The version of the DDL corresponds to the database version.</td>
</tr>
<tr>
<td></td>
<td>- A specific database version. The value cannot be lower than 9.2.0.</td>
</tr>
<tr>
<td>model</td>
<td>Specifies which view to use. Only the Oracle proprietary (ORACLE) view is supported by DBMS_METADATA.</td>
</tr>
</tbody>
</table>

Return Values

An opaque handle to write context. This handle is used as input to the ADD_TRANSFORM, CONVERT, PUT, and CLOSE procedures.

Exceptions

- INVALID_ARGVAL. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- INVALID_OBJECT_PARAM. The model parameter was not valid for the object_type.
PUT Function

This function submits an XML document containing object metadata to the database to create the object.

**See Also:** For more information about related subprograms:
- [Subprograms for Submitting XML to the Database on page 87-10](#)

**Syntax**

```sql
DBMS_METADATA.PUT (  
    handle IN             NUMBER,
    document IN             sys.XMLType,
    flags IN             NUMBER,
    results IN OUT NOCOPY  sys.ku$_SubmitResults)  
RETURN BOOLEAN;

DBMS_METADATA.PUT (  
    handle IN             NUMBER,
    document IN             CLOB,
    flags IN             NUMBER,
    results IN OUT NOCOPY  sys.ku$_SubmitResults)  
RETURN BOOLEAN;
```

**Parameters**

**Table 87–14 PUT Function Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPENW.</td>
</tr>
<tr>
<td>document</td>
<td>The XML document containing object metadata for the type of the OPENW handle.</td>
</tr>
<tr>
<td>flags</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>results</td>
<td>Detailed results of the operation.</td>
</tr>
</tbody>
</table>

**Return Values**

TRUE if all SQL operations succeeded; FALSE if there were any errors.

**Usage Notes**

The PUT function converts the XML document to DDL just as CONVERT does (applying the specified transforms in turn) and then submits each resultant DDL statement to the database. As with CONVERT, the DDL transform must be specified. The DDL statements and associated parse items are returned in the sys.ku$ SubmitResults nested table. With each DDL statement is a nested table of error lines containing any errors or exceptions raised by the statement.

The encoding of the XML document is embedded in its CLOB or XMLType representation. The version of the metadata is embedded in the XML. The generated DDL is valid for the database version specified in OPENW.
Exceptions

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- **INCONSISTENT_OPERATION.** The DDL transform was not specified.
- **INCOMPATIBLE_DOCUMENT.** The version of the XML document is not compatible with this version of the software.
**SET_COUNT Procedure**

This procedure specifies the maximum number of objects to be retrieved in a single FETCH_xxx call. By default, each call to FETCH_xxx returns one object. You can use the SET_COUNT procedure to override this default. If FETCH_xxx is called from a client, specifying a count value greater than 1 can result in fewer server round trips and, therefore, improved performance.

For heterogeneous object types, a single FETCH_xxx operation only returns objects of a single object type.

**See Also:** For more information about related subprograms:

- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

**Syntax**

```sql
DBMS_METADATA.SET_COUNT (  
    handle           IN NUMBER,  
    value            IN NUMBER,  
    object_type_path IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN.</td>
</tr>
<tr>
<td>value</td>
<td>The maximum number of objects to retrieve.</td>
</tr>
<tr>
<td>object_type_path</td>
<td>A path name designating the object types to which the count value applies.</td>
</tr>
<tr>
<td></td>
<td>By default, the count value applies to the object type of the OPEN handle.</td>
</tr>
<tr>
<td></td>
<td>When the OPEN handle designates a heterogeneous object type, behavior can</td>
</tr>
<tr>
<td></td>
<td>be either of the following:</td>
</tr>
<tr>
<td></td>
<td>- if object_type_path is omitted, the count applies to all object types</td>
</tr>
<tr>
<td></td>
<td>within the heterogeneous collection</td>
</tr>
<tr>
<td></td>
<td>- if object_type_path is specified, the count only applies to the specific</td>
</tr>
<tr>
<td></td>
<td>node (or set of nodes) within the tree of object types forming the</td>
</tr>
<tr>
<td></td>
<td>heterogeneous collection</td>
</tr>
</tbody>
</table>

**Exceptions**

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- **INVALID_OPERATION.** SET_COUNT was called after the first call to FETCH_xxx for the OPEN context. After the first call to FETCH_xxx is made, no further calls to SET_COUNT for the current OPEN context are permitted.

- **INCONSISTENT_ARGS.** object_type parameter is not consistent with handle.
SET_FILTER Procedure

This procedure specifies restrictions on the objects to be retrieved, for example, the object name or schema.

**See Also:** For more information about related subprograms:
- Subprograms for Retrieving Multiple Objects From the Database on page 87-9

**Syntax**

```sql
DBMS_METADATA.SET_FILTER (  
    handle           IN NUMBER,  
    name             IN VARCHAR2,  
    value            IN VARCHAR2,  
    object_type_path IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_FILTER (  
    handle            IN NUMBER,  
    name              IN VARCHAR2,  
    value             IN BOOLEAN DEFAULT TRUE,  
    object_type_path  IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_FILTER (  
    handle            IN NUMBER,  
    name              IN VARCHAR2,  
    value             IN NUMBER,  
    object_type_path  IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN.</td>
</tr>
</tbody>
</table>
| name        | The name of the filter. For each filter, Table 87–17 lists the object_type it applies to, its name, its datatype (text or Boolean) and its meaning or effect (including its default value, if any). The Datatype column of Table 87–17 also indicates whether a text filter is an expression filter. An expression filter is the right-hand side of a SQL comparison (that is, a SQL comparison operator (=, !=, and so on.)) and the value compared against. The value must contain parentheses and quotation marks where appropriate. Note that in PL/SQL and SQL*Plus, two single quotes (not a double quote) are needed to represent an apostrophe. For example, an example of a NAME_EXPR filter in PL/SQL is as follows:

```sql
'IN (''DEPT'', 'EMP'')'
```

The filter value is combined with a particular object attribute to produce a WHERE condition in the query that fetches the objects. In the preceding example, the filter is combined with the attribute corresponding to an object name; objects named 'DEPT' and 'EMP' are selected. |
| value       | The value of the filter. Text, Boolean, and Numeric filters are supported. |
Table 87–17 describes the object type, name, datatype, and meaning of the filters available with the **SET_FILTER** procedure.

<td>The filter value is either: combined with the attribute corresponding to a schema name to produce a WHERE condition in the query that fetches the tables, combined with the attribute corresponding to a base schema name to produce a WHERE condition in the query that fetches the tables’ dependent objects. By default the current user’s objects are selected.</td>
</tr>
</tbody>
</table>
Each call to `SET_FILTER` causes a `WHERE` condition to be added to the underlying query that fetches the set of objects. The `WHERE` conditions are ANDed together, so you can use multiple `SET_FILTER` calls to refine the set of objects to be returned. For example to specify that you want the object named EMP in schema SCOTT, do the following:

```sql
SET_FILTER(handle, 'SCHEMA', 'SCOTT');
SET_FILTER(handle, 'NAME', 'EMP');
```

You can use the same text expression filter multiple times with different values. All the filter conditions will be applied to the query. For example, to get objects with names between Felix and Oscar, do the following:

```sql
SET_FILTER(handle, 'NAME_EXPR','>=''FELIX''');
SET_FILTER(handle, 'NAME_EXPR','<=''OSCAR''');
```
With SET_FILTER, you can specify the schema of objects to be retrieved, but security considerations may override this specification. If the caller is SYS or has SELECT_CATALOG_ROLE, then any object can be retrieved; otherwise, only the following can be retrieved:

- Schema objects owned by the current user
- Public synonyms
- System privileges granted to the current user or to PUBLIC
- Grants on objects for which the current user is owner, grantor, or grantee (either explicitly or as PUBLIC).
- SCHEMA_EXPORT where the name is the current user
- TABLEEXPORT where SCHEMA is the current user

If you request objects that you are not privileged to retrieve, no exception is raised; the object is not retrieved, as if it did not exist.

In stored procedures, functions, and definers-rights packages, roles (such as SELECT_CATALOG_ROLE) are disabled. Therefore, such a PL/SQL program can only fetch metadata for objects in its own schema. If you want to write a PL/SQL program that fetches metadata for objects in a different schema (based on the invoker’s possession of SELECT_CATALOG_ROLE), you must make the program invokers-rights.

For heterogeneous object types, the BEGIN_WITH and BEGIN_AFTER filters allow restart on an object type boundary. Appropriate filter values are returned by the FETCH_XML_CLOB procedure.

Filters on heterogeneous objects provide default values for filters on object types within the collection. You can override this default for a particular object type by specifying the appropriate filter for the specific object type path. For example, for SCHEMA_EXPORT the NAME filter specifies the schema to be fetched including all the tables in the schema, but you can further restrict this set of tables by supplying a NAME_EXPR filter explicitly for the TABLE object type path. Table 87–18 lists valid object type path names for the major heterogeneous object types along with an explanation of the scope of each path name. (The same information is available in the following catalog views: DATABASE_EXPORT_OBJECTS, SCHEMA_EXPORT_OBJECTS, and TABLE_EXPORT_OBJECTS.) See Table 87–17 for filters defined for each path name. These path names are valid in the INCLUDE_PATH_EXPR and EXCLUDE_PATH_EXPR filters. Path names marked with an asterisk (*) are only valid in those filters; they cannot be used as values of the SET_FILTER object_type_path parameter.

### Exceptions

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- **INVALID_OPERATION.** SET_FILTER was called after the first call to FETCH_xxx for the OPEN context. After the first call to FETCH_xxx is made, no further calls to SET_FILTER are permitted.

- **INCONSISTENT_ARGS.** The arguments are inconsistent. Possible inconsistencies include the following:
  - filter name not valid for the object type associated with the OPEN context
  - filter name not valid for the object_type_path
  - object_type_path not part of the collection designated by handle
  - filter value is the wrong datatype

---

**SET_PARSE_ITEM Procedure**

This procedure is used for both retrieval and submission. This procedure enables output parsing and specifies an object attribute to be parsed and returned.

**See Also:** For more information about related subprograms:

- Subprograms for Retrieving Multiple Objects From the Database on page 87-9
- Subprograms for Submitting XML to the Database on page 87-10

**Syntax**

The following syntax applies when SET_PARSE_ITEM is used for object retrieval:

```sql
DBMS_METADATA.SET_PARSE_ITEM (
    handle IN NUMBER,
    name IN VARCHAR2,
    object_type IN VARCHAR2 DEFAULT NULL);
```

The following syntax applies when SET_PARSE_ITEM is used for XML submission:

```sql
DBMS_METADATA.SET_PARSE_ITEM (
    handle IN NUMBER,
    name IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPEN (or OPENW).</td>
</tr>
<tr>
<td>name</td>
<td>The name of the object attribute to be parsed and returned. See Table 87–20 for the attribute object type, name, and meaning.</td>
</tr>
</tbody>
</table>
| object_type | Designates the object type to which the parse item applies (this is an object type name, not a path name). By default, the parse item applies to the object type of the OPEN handle. When the OPEN handle designates a heterogeneous object type, behavior can be either of the following:
  - if object_type is omitted, the parse item applies to all object types within the heterogeneous collection
  - if object_type is specified, the parse item only applies to that specific object type within the collection
  This parameter only applies when SET_PARSE_ITEM is used for object retrieval. |

Table 87–20 describes the object type, name, and meaning of the items available in the SET_PARSE_ITEM procedure.
### SET_PARSE_ITEM Procedure

#### Table 87–20  SET_PARSE_ITEM: Parse Items

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Name</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>All objects</td>
<td>VERB</td>
<td>If FETCH_XML_CLOB is called, no value is returned. If FETCH_DDL is called, then for every row in the sys.ku$_ddl nested table returned by FETCH_DDL the verb in the corresponding ddlText is returned. If the ddlText is a SQL DDL statement, then the SQL verb (for example, CREATE, GRANT, AUDIT) is returned. If the ddlText is a procedure call (for example, DBMS_AQADM.CREATE_QUEUE_TABLE()) then the package.procedure-name is returned.</td>
</tr>
<tr>
<td>All objects</td>
<td>OBJECT_TYPE</td>
<td>If FETCH_XML_CLOB is called, an object type name from Table 87–11 is returned. If FETCH_DDL is called and the ddlText is a SQL DDL statement whose verb is CREATE or ALTER, the object type as used in the DDL statement is returned (for example, TABLE, PACKAGE_BODY, and so on). Otherwise, an object type name from Table 87–11 is returned.</td>
</tr>
<tr>
<td>Schema objects</td>
<td>SCHEMA</td>
<td>The object schema is returned. If the object is not a schema object, no value is returned.</td>
</tr>
<tr>
<td>Named objects</td>
<td>NAME</td>
<td>The object name is returned. If the object is not a named object, no value is returned.</td>
</tr>
<tr>
<td>TABLE, TABLE_DATA, INDEX</td>
<td>TABLESPACE</td>
<td>The name of the object's tablespace or, if the object is a partitioned table, the default tablespace is returned. For a TABLE_DATA object, this is always the tablespace where the rows are stored.</td>
</tr>
<tr>
<td>TRIGGER</td>
<td>ENABLE</td>
<td>If the trigger is enabled, ENABLE is returned. If the trigger is disabled, DISABLE is returned.</td>
</tr>
<tr>
<td>OBJECT_GRANT, TABLESPACE_, QUOTA</td>
<td>GRANTOR</td>
<td>The grantor is returned.</td>
</tr>
<tr>
<td>Dependent objects (including domain index secondary tables)</td>
<td>BASE_OBJECT_NAME</td>
<td>The name of the base object is returned. If the object is not a dependent object, no value is returned.</td>
</tr>
<tr>
<td>Dependent objects (including domain index secondary tables)</td>
<td>BASE_OBJECT_SCHEMA</td>
<td>The schema of the base object is returned. If the object is not a dependent object, no value is returned.</td>
</tr>
<tr>
<td>Dependent objects (including domain index secondary tables)</td>
<td>BASE_OBJECT_TYPE</td>
<td>The object type of the base object is returned. If the object is not a dependent object, no value is returned.</td>
</tr>
<tr>
<td>Granted objects</td>
<td>GRANTEE</td>
<td>The grantee is returned. If the object is not a granted object, no value is returned.</td>
</tr>
</tbody>
</table>

#### Usage Notes

These notes apply when using SET_PARSE_ITEM to retrieve objects.

By default, the FETCH_XXX routines return an object's metadata as XML or creation DDL. By calling SET_PARSE_ITEM you can request that individual attributes of the object be returned as well.
You can call \texttt{SET\_PARSE\_ITEM} multiple times to ask for multiple items to be parsed and returned. Parsed items are returned in the \texttt{sys.ku$_\$parsed\_items} nested table.

For \texttt{TABLE\_DATA} objects, the following parse item return values are of interest:

<table>
<thead>
<tr>
<th>If Object Is</th>
<th>NAME, SCHEMA</th>
<th>BASE_OBJECT_NAME, BASE_OBJECT_SCHEMA</th>
</tr>
</thead>
<tbody>
<tr>
<td>nonpartitioned table</td>
<td>table name, schema</td>
<td>table name, schema</td>
</tr>
<tr>
<td>table partition</td>
<td>partition name, schema</td>
<td>table name, schema</td>
</tr>
<tr>
<td>nested table</td>
<td>storage table name, schema</td>
<td>name and schema of top-level table (\textit{not} the parent nested table)</td>
</tr>
</tbody>
</table>

Tables are not usually thought of as dependent objects. However, secondary tables for domain indexes are dependent on the domain indexes. Consequently, the \texttt{BASE\_OBJECT\_NAME}, \texttt{BASE\_OBJECT\_SCHEMA} and \texttt{BASE\_OBJECT\_TYPE} parse items for secondary \texttt{TABLE} objects return the name, schema, and type of the domain index.

\textbf{See Also:}

- "\texttt{FETCH\_xxx Functions and Procedures}" on page 87-19
- \textit{Oracle Database Utilities} for information about using the Metadata API

By default, the \texttt{CONVERT} and \texttt{PUT} procedures simply transform an object's XML metadata to DDL. By calling \texttt{SET\_PARSE\_ITEM} you can request that individual attributes of the object be returned as well.

\textbf{Exceptions}

- \texttt{INVALID\_ARGVAL}. A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- \texttt{INVALID\_OPERATION}. \texttt{SET\_PARSE\_ITEM} was called after the first call to \texttt{FETCH\_xxx} for the \texttt{OPEN} context. After the first call to \texttt{FETCH\_xxx} is made, no further calls to \texttt{SET\_PARSE\_ITEM} are permitted.

- \texttt{INCONSISTENT\_ARGS}. The attribute name is not valid for the object type associated with the \texttt{OPEN} context.
SET_TRANSFORM_PARAM and SET_REMAP_PARAM Procedures

These procedures are used for both retrieval and submission. SET_TRANSFORM_PARAM and SET_REMAP_PARAM specify parameters to the XSLT stylesheet identified by transform_handle. Use them to modify or customize the output of the transform.

See Also: For more information about related subprograms:

- Subprograms for Retrieving Multiple Objects From the Database on page 87-9
- Subprograms for Submitting XML to the Database on page 87-10

Syntax

```sql
DBMS_METADATA.SET_TRANSFORM_PARAM (  
  transform_handle   IN NUMBER,  
  name               IN VARCHAR2,  
  value              IN VARCHAR2,  
  object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_TRANSFORM_PARAM (  
  transform_handle   IN NUMBER,  
  name               IN VARCHAR2,  
  value              IN BOOLEAN DEFAULT TRUE,  
  object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_TRANSFORM_PARAM (  
  transform_handle   IN NUMBER,  
  name               IN VARCHAR2,  
  value              IN NUMBER,  
  object_type        IN VARCHAR2 DEFAULT NULL);

DBMS_METADATA.SET_REMAP_PARAM (  
  transform_handle   IN NUMBER,  
  name               IN VARCHAR2,  
  old_value          IN VARCHAR2,  
  new_value          IN VARCHAR2,  
  object_type        IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 87–21 describes the parameters for the SET_TRANSFORM_PARAM and SET_REMAP_PARAM procedures.

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>transform_handle</td>
<td>Either (1) the handle returned from ADD_TRANSFORM, or (2) the enumerated constant SESSION_TRANSFORM that designates the DDL transform for the whole session. Note that the handle returned by OPEN is not a valid transform handle. For SET_REMAP_PARAM, the transform handle must designate the MODIFY transform.</td>
</tr>
</tbody>
</table>
Table 87–22 describes the object type, name, datatype, and meaning of the parameters for the DDL transform in the SET_TRANSFORM_PARAM procedure.

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Name</th>
<th>Datatype</th>
<th>Meaning</th>
</tr>
</thead>

<td>INSERT</td>
<td>BOOLEAN</td>
<td>If TRUE, include the INSERT statements into the OL$ dictionary tables that will create the outline and its hints. If FALSE, omit a CREATE OUTLINE statement. Defaults to FALSE. Note: This object type is being deprecated.</td>
</tr>
</tbody>
</table>
Table 87–23 describes the object type, name, datatype, and meaning of the parameters for the MODIFY transform in the set_transform_param procedure.

### Table 87–23  
**set_transform_param: Transform Parameters for the MODIFY Transform**

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Name</th>
<th>Datatype</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>All objects</td>
<td>DEFAULT</td>
<td>BOOLEAN</td>
<td>Calling set_transform_param with this parameter set to TRUE has the effect of resetting all parameters for the transform to their default values. Setting this FALSE has no effect. There is no default.</td>
</tr>
<tr>
<td>All objects</td>
<td>INHERIT</td>
<td>BOOLEAN</td>
<td>If TRUE, inherits session-level parameters. Defaults to FALSE. If an application calls add_transform to add the DDL transform, then by default the only transform parameters that apply are those explicitly set for that transform handle. This has no effect if the transform handle is the session transform handle.</td>
</tr>
<tr>
<td>ROLE</td>
<td>REVOKE_FROM</td>
<td>Text</td>
<td>The name of a user from whom the role must be revoked. If this is a non-null string and if the CREATE ROLE statement grants you the role, a REVOKE statement is included in the DDL after the CREATE ROLE statement. Note: When you issue a CREATE ROLE statement, Oracle may grant you the role. You can use this transform parameter to undo the grant. Defaults to null string.</td>
</tr>
<tr>
<td>TABLESPACE</td>
<td>REUSE</td>
<td>BOOLEAN</td>
<td>If TRUE, include the REUSE parameter for datafiles in a tablespace to indicate that existing files can be reused. If FALSE, omit the REUSE parameter. Defaults to FALSE.</td>
</tr>

By default, names are not remapped. (Use REMAP_TABLESPACE to remap the name of a TABLESPACE object.)</td>
</tr>
</tbody>
</table>

**Exceptions**

- **INVALID_ARGVAL.** A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
- **INVALID_OPERATION.** Either **SET_TRANSFORM_PARAM** or **SET_REMAP_PARAM** was called after the first call to **FETCH_xxx** for the OPEN context. After the first call to **FETCH_xxx** is made, no further calls to **SET_TRANSFORM_PARAM** or **SET_REMAP_PARAM** are permitted.
INCONSISTENT_ARGS. The arguments are inconsistent. This can mean the following:

- The transform parameter name is not valid for the object type associated with the OPEN context or for the transform associated with the transform handle.
- The transform applies to all object types in a heterogeneous collection, but object_type is not part of the collection.

Usage Notes

XSLT allows parameters to be passed to stylesheets. You call SET_TRANSFORM_PARAM or SET_REMAP_PARAM to specify the value of a parameter to be passed to the stylesheet identified by transform_handle.

Normally, if you call SET_TRANSFORM_PARAMETER multiple times for the same parameter name, each call overrides the prior call. For example, the following sequence simply sets the STORAGE transform parameter to TRUE.

SET_TRANSFORM_PARAM(tr_handle,'STORAGE',false);
SET_TRANSFORM_PARAM(tr_handle,'STORAGE',true);

However, some transform parameters are additive which means that all specified parameter values are applied to the document, not just the last one. For example, the OBJECT_ROW parameter to the MODIFY transform is additive. If you specify the following, then both specified rows are copied to the output document.

SET_TRANSFORM_PARAM(tr_handle,'OBJECT_ROW',5);
SET_TRANSFORM_PARAM(tr_handle,'OBJECT_ROW',8);

The REMAP_TABLESPACE parameter is also additive. If you specify the following, then tablespaces TBS1 and TBS3 are changed to TBS2 and TBS4, respectively.

SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS1','TBS2');
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS3','TBS4');

The order in which the transformations are performed is undefined. For example, if you specify the following, the result is undefined.

SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS1','TBS2');
SET_REMAP_PARAM(tr_handle,'REMAP_TABLESPACE','TBS2','TBS3');

---

Note: The number of remap parameters that can be specified for a MODIFY transform is limited to ten. That is, you can specify up to ten REMAP_DATAFILE parameters, up to ten REMAP_SCHEMA parameters and so on. Additional instances are ignored. To work around this, you can perform another DBMS_METADATA.ADD_TRANSFORM and specify additional remap parameters.

The GET_DDL, GET_DEPENDENT_DDL, and GET_GRANTED_DDL functions allow the casual browser to extract the creation DDL for an object. So that you can specify transform parameters, this package defines an enumerated constant SESSION_TRANSFORM as the handle of the DDL transform at the session level. You can call SET_TRANSFORM_PARAM using DBMS_METADATA.SESSION_TRANSFORM as the transform handle to set transform parameters for the whole session. GET_DDL, GET_DEPENDENT_DDL, and GET_GRANTED_DDL inherit these parameters when they invoke the DDL transform.

---

Note: The enumerated constant must be prefixed with the package name DBMS_METADATA.SESSION_TRANSFORM.
The DBMS_METADATA_DIFF package contains the interfaces for comparing two metadata documents in SXML format.

See Also: Oracle Database Utilities for more information and for examples of using the Metadata API

This chapter contains the following topics:

- Using DBMS_METADATA_DIFF
  - Overview
  - Security Model
- Browsing APIs for Fetching and Comparing Objects
- Summary of DBMS_METADATA_DIFF Subprograms
Using DBMS_METADATA_DIFF

This section contains topics which relate to using the DBMS_METADATA_DIFF package.

- Overview
- Security Model
Overview

You can use the interfaces contained in the `DBMS_METADATA_DIFF` package to compare two metadata documents in SXML format. The result of the comparison is an SXML difference document. This document can be converted to other formats using the `DBMS_METADATA` submit interface and the `CONVERT API`. 
Security Model

The browsing interface of the DBMS_METADATA_DIFF package actually uses the DBMS_METADATA package to fetch the metadata to be compared. Therefore, the security model used for DBMS_METADATA also applies to DBMS_METADATA_DIFF. (Note, however, that DBMS_METADATA_DIFF does not support all object types.)

See Also:  DBMS_METADATA for information about the DBMS_METADATA security model
Browsing APIs for Fetching and Comparing Objects

These functions allow you to compare the metadata for two objects with a single call.

Syntax

```
DBMS_METADATA_DIFF.COMPARE_SXML(
  object_type   IN VARCHAR2,
  name1         IN VARCHAR2,
  name2         IN VARCHAR2,
  schema1       IN VARCHAR2 DEFAULT NULL,
  schema2       IN VARCHAR2 DEFAULT NULL,
  network_link1 IN VARCHAR2 DEFAULT NULL,
  network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

```
DBMS_METADATA_DIFF.COMPARE_ALTER(
  object_type   IN VARCHAR2,
  name1         IN VARCHAR2,
  name2         IN VARCHAR2,
  schema1       IN VARCHAR2 DEFAULT NULL,
  schema2       IN VARCHAR2 DEFAULT NULL,
  network_link1 IN VARCHAR2 DEFAULT NULL,
  network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

```
DBMS_METADATA_DIFF.COMPARE_ALTER_XML(
  object_type   IN VARCHAR2,
  name1         IN VARCHAR2,
  name2         IN VARCHAR2,
  schema1       IN VARCHAR2 DEFAULT NULL,
  schema2       IN VARCHAR2 DEFAULT NULL,
  network_link1 IN VARCHAR2 DEFAULT NULL,
  network_link2 IN VARCHAR2 DEFAULT NULL)
RETURN CLOB;
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object_type</code></td>
<td>The type of object to be compared. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW.</td>
</tr>
<tr>
<td><code>name1</code></td>
<td>The name of the first object in the comparison.</td>
</tr>
<tr>
<td><code>name2</code></td>
<td>The name of the second object in the comparison.</td>
</tr>
<tr>
<td><code>schema1</code></td>
<td>The schema of the first object in the comparison. The default is the current user.</td>
</tr>
<tr>
<td><code>schema2</code></td>
<td>The schema of the second object in the comparison. The default is the value of <code>schema1</code>.</td>
</tr>
</tbody>
</table>
Return Values

`DBMS_METADATA_DIFF.COMpare_XXX` returns the differences between two objects.

Exceptions

- **INVALID_ARGVAL**
  
  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.

- **OBJECT_NOT_FOUND**
  
  The specified object was not found in the database.

Usage Notes

These functions encapsulate calls to both `DBMS_METADATA` and `DBMS_METADATA_DIFF` functions and procedures to fetch the metadata for each of the two objects and compare them.

Which function you use depends on the comparison format you want:

- **COMPARE_SXML** returns an SXML difference document.
- **COMPARE_ALTER** returns a set of `ALTER` statements for making the first object like the second object.
- **COMPARE_ALTER_XML** returns an `ALTER_XML` document.

### Table 88-1 (Cont.) COMPARE_xxx Function Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>network_link1</td>
<td>The name of a database link to the database on which the first object resides. If NULL (the default), then the object is assumed to be in the database on which the caller is running.</td>
</tr>
<tr>
<td>network_link2</td>
<td>The name of a database link to the database on which the second object resides. The default is the value of <code>network_link1</code>.</td>
</tr>
</tbody>
</table>
Summary of DBMS_METADATA_DIFF Subprograms

The DBMS_METADATA_DIFF subprograms are used to:

- Specify the type of objects to be compared
- Specify the SXML documents to be compared
- Show the differences between the compared documents
- Clean up after the comparison

Table 88–2 provides a summary of DBMS_METADATA_DIFF subprograms.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPENC Function on page 88-8</td>
<td>Specifies the type of objects to be compared</td>
</tr>
<tr>
<td>ADD_DOCUMENT Procedure on page 88-9</td>
<td>Specifies an SXML document to be compared</td>
</tr>
<tr>
<td>FETCH_CLOB Functions and Procedures on page 88-10</td>
<td>Returns a CLOB showing the differences between the two documents specified by ADD_DOCUMENT</td>
</tr>
<tr>
<td>CLOSE Procedure on page 88-11</td>
<td>Invalidates the handle returned by OPENC and cleans up associated state</td>
</tr>
</tbody>
</table>
OPENC Function

This function specifies the type of objects to be compared. The return value is an opaque context handle.

Syntax

```sql
DBMS_METADATA_DIFF.OPENC (
object_type IN VARCHAR2
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>The type of object to be compared. Valid type names are CLUSTER, CONTEXT, DB_LINK, FGA_POLICY, INDEX, MATERIALIZED_VIEW, MATERIALIZED_VIEW_LOG, QUEUE, QUEUE_TABLE, RLS_CONTEXT, RLS_GROUP, RLS_POLICY, ROLE, SEQUENCE, SYNONYM, TABLE, TABLESPACE, TRIGGER, TYPE, TYPE_SPEC, TYPE_BODY, USER, and VIEW.</td>
</tr>
</tbody>
</table>

Return Values

The opaque handle that is returned is used as input to ADD_DOCUMENT, FETCH_xxx and CLOSE.

Exceptions

- **INVALID_ARGVAL**

  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
ADD_DOCUMENT Procedure

This procedure specifies an SXML document to be compared.

Syntax

DBMS_METADATA_DIFF.ADD_DOCUMENT(
handle IN NUMBER, document IN sys.XMLType);

DBMS_METADATA_DIFF.ADD_DOCUMENT(
handle IN NUMBER, document IN CLOB);

Parameters

Table 88–4 CLOSE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPENC</td>
</tr>
<tr>
<td>document</td>
<td>A document to be compared. The document must be of the type specified in OPENC.</td>
</tr>
</tbody>
</table>

Usage Notes

Because the comparison interface allows you to compare exactly two SXML documents, a program must call ADD_DOCUMENT exactly twice for each OPENC handle. In the comparison result, the document specified by the first call is document 1, and the document specified by the second call is document 2.

Exceptions

- INVALID_ARGVAL
  
  A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
FETCH_CLOB Functions and Procedures

The FETCH_CLOB functions and procedures return a CLOB showing the differences between the two documents specified by ADD_DOCUMENT.

Syntax

DBMS_METADATA_DIFF.FETCH_CLOB(
  handle IN NUMBER)
RETURN CLOB;

DBMS_METADATA_DIFF.FETCH_CLOB(
  handle IN NUMBER,
  doc    IN  OUT NOCOPY CLOB);

DBMS_METADATA_DIFF.FETCH_CLOB(
  handle IN NUMBER,
  doc    IN  OUT NOCOPY CLOB
  diffs  OUT BOOLEAN);

Parameters

Table 88–5 CONVERT Subprogram Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPENC.</td>
</tr>
<tr>
<td>doc</td>
<td>A CLOB containing the differences between documents 1 and 2.</td>
</tr>
<tr>
<td>diffs</td>
<td>TRUE if the documents are different or FALSE if they are identical.</td>
</tr>
</tbody>
</table>

Return Values

The differences between documents 1 and 2.

Exceptions

- INVALID_ARGVAL

A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
CLOSE Procedure

This procedure invalidates the handle returned by OPENC and cleans up associated state.

Syntax

```sql
DBMS_METADATA_DIFF.CLOSE(
handle IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handle</td>
<td>The handle returned from OPENC</td>
</tr>
</tbody>
</table>

Exceptions

- INVALID_ARGVAL

A NULL or invalid value was supplied for an input parameter. The error message text identifies the parameter.
The `DBMS_MGD_ID_UTL` package contains various functions and procedures that comprise the following utility subprograms:

- A logging utility that sets and gets Java and PL/SQL logging levels.
- A proxy utility consisting of two procedures used to set and unset the host and port of the proxy server.
- A metadata utility consisting of functions and procedures used for managing metadata.

**See Also:** *Oracle Database Advanced Application Developer’s Guide* for more information.

This chapter describes each of these utility subprograms and contains the following topics:

- Using `DBMS_MGD_ID_UTL`
  - Security Model
  - Constants
  - Exceptions
- Summary of `DBMS_MGD_ID_UTL` Subprograms

The examples in this chapter assume that the user has run the following set of commands before running the contents of each script:

```sql
SQL> connect / as sysdba;
Connected.
SQL> create user mgduser identified by password;
SQL> grant connect, resource to mgduser;
SQL> connect mgduser
Enter password: mgduserpassword
Connected.
SQL> set serveroutput on;
```
Using DBMS_MGD_ID_UTL

- Security Model
- Constants
- Exceptions
Security Model

You must run the catmgd.sql script to load the DBMS_MGD_ID_UTL package and Identity Code Package schema objects in the MGDSYS schema.

DBMS_MGD_ID_UTL is a MGDSYS-owned package. Any DBMS_MGD_ID_UTL subprogram called from an anonymous PL/SQL block is run using the privileges of the current user.

A user must be granted connect and resource roles to use the DBMS_MGD_ID_UTL package and its subprograms.

EXECUTE privilege is granted to PUBLIC for these ADTs: MGD_ID, MGD_ID_COMPONENT, MGD_ID_COMPONENT_VARRAY, and for this package DBMS_MGD_ID_UTL.

SELECT privilege is granted to PUBLIC for these read-only views: MGD_ID_CATEGORY and MGD_ID_SCHEME and for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME, and for table MGD_ID_XML_VALIDATOR, and for sequence MGD$SEQUENCECategoryId.

INSERT, UPDATE and DELETE privilege is granted to PUBLIC for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME.

Public synonyms, by the same name, are created for these ADTs: MGD_ID, MGD_ID_COMPONENT, MGD_ID_COMPONENT_VARRAY and for this package DBMS_MGD_ID_UTL, as well as for these read-only views: MGD_ID_CATEGORY and MGD_ID_SCHEME and for these metadata views: USER_MGD_ID_CATEGORY and USER_MGD_ID_SCHEME, and for table MGD_ID_XML_VALIDATOR.
DBMS_MGD_ID_UTL uses the constants shown in Table 89–1.

**Table 89–1  DBMS_MGD_ID_UTL Constants**

</tbody>
</table>
ADD_SCHEME Procedure

This procedure adds a tag data translation scheme to an existing category.

Syntax

```
DBMS_MGD_ID_UTL.ADD_SCHEME (
    category_id IN  VARCHAR2,
    tdt_xml     IN  CLOB);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>tdt_xml</td>
<td>Tag data translation XML</td>
</tr>
</tbody>
</table>

Examples

This example performs the following actions:

1. Creates a category.
2. Adds a contractor scheme and an employee scheme to the `MGD_SAMPLE_CATEGORY` category.
3. Validates the `MGD_SAMPLE_CATEGORY` scheme.
4. Tests the tag translation of the contractor scheme and the employee scheme.
5. Removes the contractor scheme.
6. Tests the tag translation of the contractor scheme and this returns the expected exception for the removed contractor scheme.
7. Tests the tag translation of the employee scheme and this returns the expected values.
8. Removes the `MGD_SAMPLECATEGORY` category.

```sql
--contents of add_scheme2.sql
SET LINESIZE 160
---------------------------------------------------------------------
---CREATE CATEGORY, ADD_SCHEME, REMOVE_SCHEME, REMOVE_CATEGORY-------
---------------------------------------------------------------------
DECLARE
    amt          NUMBER;
    buf          VARCHAR2(32767);
    pos          NUMBER;
    tdt_xml      CLOB;
    validate_tdtxml VARCHAR2(1042);
    category_id  VARCHAR2(256);
BEGIN
    -- remove the testing category if already existed
    DBMS_MGD_ID_UTL.remove_category('MGD_SAMPLE_CATEGORY', '1.0');
    -- Step 1. Create the testing category 'MGD_SAMPLECATEGORY', version 1.0.
    category_id := DBMS_MGD_ID_UTL.CREATE_CATEGORY('MGD_SAMPLE_CATEGORY', '1.0', 'Oracle',
    'http://www.oracle.com/mgd/sample');
    -- Step 2. Add contractor scheme to the category.
    --contents of add_scheme2.sql
```
ADD_SCHEME Procedure

```sql
DBMS_LOB.CREATETEMPORARY(tdt_xml, true);
DBMS_LOB.OPEN(tdt_xml, DBMS_LOB.LOB_READWRITE);

buf := '<?xml version="1.0" encoding="UTF-8"?>

CREATE CATEGORY Function

This function creates a new category or a new version of a category.

Syntax

```sql
DBMS_MGD_ID_UTL.CREATE_CATEGORY (
    category_name    IN  VARCHAR2,
    category_version IN  VARCHAR2,
    agency           IN  VARCHAR2,
    URI              IN  VARCHAR2)
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_name</td>
<td>Name of category</td>
</tr>
<tr>
<td>category_version</td>
<td>Category version</td>
</tr>
<tr>
<td>agency</td>
<td>Organization that owns the category. For example, EPCglobal owns the category EPC.</td>
</tr>
<tr>
<td>URI</td>
<td>URI that provides additional information about the category</td>
</tr>
</tbody>
</table>

Usage Notes

The return value is the category ID.

Examples

See the ADD_SCHEME Procedure for an example of creating the MGD_SAMPLECATEGORY category.
EPC_TO_ORACLE_SCHEME Function

This function converts the EPCglobal tag data translation (TDT) XML to Oracle Database tag data translation XML.

Syntax

```
DBMS_MGD_ID_UTL.EPC_TO_ORACLE_SCHEME (
   xml_scheme IN CLOB)
RETURN CLOB;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_scheme</td>
<td>Name of EPC tag scheme to be converted</td>
</tr>
</tbody>
</table>

Usage Notes

The return value is the contents of the `CLOB` containing the Oracle Database tag data translation XML.

Examples

The following example converts standard EPCglobal Tag Data Translation (TDT) files into Oracle Database TDT files:

```
--Contents of MGD_ID_DOC2.sql
----------------------------
-- EPC_TO_ORACLE_SCHEME --
----------------------------
call DBMS_MGD_ID_UTL.set_proxy('www-proxy.us.oracle.com', '80');
BEGIN
DBMS_JAVA.set_output(1000000);
DBMS_OUTPUT.ENABLE(1000000);
DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_SEVERE);
END;
/
DECLARE
epcScheme                 CLOB;

**GET_CATEGORY_ID Function**

This function returns the category ID for a given category name and category version.

**Syntax**

```sql
DBMS_MGD_ID_UTL.GET_CATEGORY_ID(
  category_name  IN  VARCHAR2,
  category_version  IN  VARCHAR2)
RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_name</td>
<td>Name of category</td>
</tr>
<tr>
<td>category_version</td>
<td>Category version</td>
</tr>
</tbody>
</table>

**Usage Notes**

- If the value of `category_version` is NULL, then the ID of the latest version of the specified category is returned.
- The return value is the category ID for the specified category name.

**Examples**

The following example returns a category ID given a category name and its version:

```sql
-- Contents of get_category1.sql file
SELECT DBMS_MGD_ID_UTL.get_category_id('EPC', NULL) FROM DUAL;

SQL> @get_category1.sql
.
.
.
DBMS_MGD_ID_UTL.GET_CATEGORY_ID('EPC',NULL)
--------------------------------------------------------------------------------
1
.
.
.
```
GET_COMPONENTS Function

This function returns all relevant separated component names separated by semicolon (;) for the specified scheme.

Syntax

```sql
DBMS_MGD_ID_UTL.GET_COMPONENTS (  
category_id IN VARCHAR2,  
scheme_name IN VARCHAR2)  
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>scheme_name</td>
<td>Name of scheme</td>
</tr>
</tbody>
</table>

Usage Notes

The return value contains the component names separated by a semicolon (;) for the specified scheme.

Examples

The following example gets the components:

```sql
--Contents of get_components.sql
DECLARE
  id             mgd_id;
  getcomps       VARCHAR2(1000);
  getencodings   VARCHAR2(1000);
  getschemenames VARCHAR2(1000);
BEGIN
  DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
  DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));
  getcomps := DBMS_MGD_ID_UTL.get_components(1,'SGTIN-64');
  dbms_output.put_line('Component names are: ' || getcomps);
  getencodings := DBMS_MGD_ID_UTL.get_encodings(1,'SGTIN-64');
  dbms_output.put_line('Encodings are: ' || getencodings);
  getschemenames := DBMS_MGD_ID_UTL.get_scheme_names(1);
  dbms_output.put_line('Scheme names are: ' || getschemenames);
END;
/  
SHOW ERRORS;
```

Component names are:
- filter, gtin, companyprefixlength, companyprefix, companyprefixindex, itemref, serial

Encodings are:
- ONS_HOSTNAME, LEGACY, TAG_ENCODING, PURE.IDENTITY, BINARY

Scheme names are:
- GIAI-64, GIAI-96, GID-96, GRAI-64, GRAI-96, SGLN-64, SGLN-96, SGTIN-64, SGTIN-96, SSCC-64, SSCC-96, USDDOD-64, USDDOD-96
PL/SQL procedure successfully completed.

.  .  .
GET_ENCODINGS Function

This function returns a list of semicolon (;) separated encodings (formats) for the specified scheme.

Syntax

```sql
DBMS_MGD_ID_U TL.GET_ENCODINGS (
    category_id IN VARCHAR2,
    scheme_name IN VARCHAR2)
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>scheme_name</td>
<td>Name of scheme</td>
</tr>
</tbody>
</table>

Usage Notes

The return value contains the encodings separated by a semicolon (;) for the specified scheme.

Examples

See the GET_COMPONENTS Function for an example.
GET_JAVA_LOGGING_LEVEL Function

This function returns an integer representing the current trace logging level.

Syntax

```sql
DBMS_MGD_ID_UTL.GET_JAVA_LOGGING_LEVEL
RETURN INTEGER;
```

Parameters

None.

Usage Notes

The return value is the integer value denoting the current Java logging level.

Examples

The following example gets the Java logging level.

```sql
--Contents of getjavalogginglevel.sql
DECLARE
    loglevel   NUMBER;
BEGIN
    DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
    loglevel := DBMS_MGD_ID_UTL.get_java_logging_level();
    dbms_output.put_line('Java logging level = ' ||loglevel);
END;
/
SHOW ERRORS;

SQL> @getjavalogginglevel.sql
.
.
.
Java logging level = 0
PL/SQL procedure successfully completed.
.
.
```
GET_PLSQL_LOGGING_LEVEL Function

This function returns an integer representing the current PL/SQL trace logging level.

Syntax

```
DBMS_MGD_ID_UTL.GET_PLSQL_LOGGING_LEVEL
RETURN INTEGER;
```

PRAGMA restrict_references(get_plsql_logging_level, WNDS);

Parameters

None.

Usage Notes

The return value is the integer value denoting the current PL/SQL logging level.

Examples

The following example gets the PL/SQL logging level.

```
--Contents of getplsqllogginglevel.sql
DECLARE
    loglevel   NUMBER;
BEGIN
    DBMS_MGD_ID_UTL.set_plsql_logging_level(0);
    loglevel := DBMS_MGD_ID_UTL.get_plsql_logging_level();
    dbms_output.put_line('PL/SQL logging level = ' ||loglevel);
END;
/
SHOW ERRORS;
```

```
SQL> @getplsqllogginglevel.sql
.
.
.
PL/SQL logging level = 0
PL/SQL procedure successfully completed.
.
.
.
```
GET_SCHEME_NAMES Function

This function returns a list of semicolon (;) separated scheme names for the specified category.

Syntax

```sql
DBMS_MGD_ID_UTL.GET_SCHEME_NAMES (  
    category_id IN VARCHAR2)  
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
</tbody>
</table>

Usage Notes

The return value contains the scheme names for the specified category ID.

Examples

See the GET_COMPONENTS Function for an example.
GET_TDT_XML Function

This function returns the Oracle Database tag data translation XML for the specified scheme.

Syntax

DBMS_MGD_ID_UTL.GET_TDT_XML (  
category_id  IN VARCHAR2,  
scheme_name  IN VARCHAR2)  
RETURN CLOB;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>scheme_name</td>
<td>Name of scheme</td>
</tr>
</tbody>
</table>

Usage Notes

The return value contains the Oracle Database tag data translation XML for the specified scheme.

Examples

The following example gets the Oracle Database TDT XML for the specified scheme:

```sql
--Contents of get_tdtxml.sql  
DECLARE  
gettdtxml CLOB;  
BEGIN  
gettdtxml := DBMS_MGD_ID_UTL.get_tdt_xml(1,'SGTIN-64');  
dbms_output.put_line('Length of tdt XML is '||DBMS_LOB.GETLENGTH(gettdtxml));  
dbms_output.put_line(DBMS_LOB.SUBSTR(gettdtxml, DBMS_LOB.GETLENGTH(gettdtxml), 1));  
END;  
/

."
GET_VALIDATOR Function

This function returns the Oracle Database tag data translation schema.

Syntax

```sql
DBMS_MGD_ID_UTL.GET_VALIDATOR
RETURN CLOB;
```

Usage Notes

The return value contains the Oracle Database tag data translation schema.

Examples

This example returns the Oracle Database TDT schema.

```sql

Summary of DBMS_MGD_ID_UTL Subprograms
REFRESH_CATEGORY Function

This function refreshes the metadata information on the Java stack for the specified category. This function must be called before using MGD_ID functions.

Syntax

DBMS_MGD_ID_UTL.REFRESH_CATEGORY (  
    category_id  IN VARCHAR2);

Parameters

Table 89–12  REFRESH_CATEGORY Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
</tbody>
</table>

Examples

The following example refreshes the metadata information for the EPC category ID.

```sql
-- Contents of tostring3.sql
call DBMS_MGD_ID_UTL.set_proxy('www-proxy.us.oracle.com', '80');
DECLARE
    id          MGD_ID;
BEGIN
    DBMS_MGD_ID_UTL.set_java_logging_level(DBMS_MGD_ID_UTL.LOGGING_LEVEL_OFF);
    DBMS_MGD_ID_UTL.refresh_category(DBMS_MGD_ID_UTL.get_category_id('EPC', NULL));
    dbms_output.put_line('..Testing to_string');
        ’scheme=GID-96’);
    DBMS_OUTPUT.PUT_LINE(’mgd_id object as a string’);
    DBMS_OUTPUT.PUT_LINE(id.to_string);
END;
/
SHOW ERRORS;
call DBMS_MGD_ID_UTL.remove_proxy();

SQL> @tostring3.sql
..Testing to_string
test to_string
mgd_id object as a string
 category_id =1; schemes = GID-96; objectclass = 30241; generalmanager = 0037000; scheme = GID-96;1 = 1; serial = 1041970

PL/SQL procedure successfully completed.
```
REMOVE_CATEGORY Procedure

This procedure removes a category including all the related TDT XML. This procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Removes a category based on the specified category ID.

DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
    category_id       IN VARCHAR2);

Removes a category based on the specified category name and category version.

DBMS_MGD_ID_UTL.REMOVE_CATEGORY (
    category_name     IN VARCHAR2,
    category_version  IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>category_name</td>
<td>Name of category</td>
</tr>
<tr>
<td>category_version</td>
<td>Category version</td>
</tr>
</tbody>
</table>

Usage Notes

If the value of category_version is NULL, all versions for the specified category will be removed.

Examples

See the ADD_SCHEME Procedure for an example of removing a category.
REMOVE_PROXY Procedure

This procedure unsets the host and port of the proxy server.

Syntax

DBMS_MGD_ID_UTL.REMOVE_PROXY;

Examples

See the REFRESH_CATEGORY Function for an example.
**REMOVE_SCHEME Procedure**

This procedure removes a tag data translation scheme from a category.

**Syntax**

```sql
DBMS_MGD_ID_UTL.REMOVE_SCHEME (  
    category_id  IN  VARCHAR2,  
    scheme_name  IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category_id</td>
<td>Category ID</td>
</tr>
<tr>
<td>scheme_name</td>
<td>Name of scheme</td>
</tr>
</tbody>
</table>

**Examples**

See the ADD_SCHEME Procedure for an example of removing a scheme.
SET_JAVA_LOGGING_LEVEL Procedure

This procedure sets the Java trace logging level.

Syntax

```sql
DBMS_MGD_ID_UTL.SET_JAVA_LOGGING_LEVEL {
    logginglevel IN  INTEGER};
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logginglevel</td>
<td>Logging level. The Java logging level can be one of the following values in descending order:</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_OFF CONSTANT INTEGER := 0</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_INFO CONSTANT INTEGER := 3</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_FINE CONSTANT INTEGER := 4</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_FINER CONSTANT INTEGER := 5</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6</td>
</tr>
<tr>
<td></td>
<td>- LOGGING_LEVEL_ALL CONSTANT INTEGER := 7</td>
</tr>
</tbody>
</table>

Examples

See the `GET_JAVA_LOGGING_LEVEL` Function for an example.
SET_PLSQL_LOGGING_LEVEL Procedure

This procedure sets the PL/SQL trace logging level.

Syntax

```sql
DBMS_MGD_ID_UTL.SET_PLSQL_LOGGING_LEVEL (
  level IN INTEGER);
```

PRAGMA restrict_references(set_plsql_logging_level, WNDS);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>level</td>
<td>Logging level. The PL/SQL logging level can be one of the following values in descending order:</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_OFF  CONSTANT INTEGER := 0</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_SEVERE CONSTANT INTEGER := 1</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_WARNING CONSTANT INTEGER := 2</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_INFO CONSTANT INTEGER := 3</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_FINE CONSTANT INTEGER := 4</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_FINER CONSTANT INTEGER := 5</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_FINEST CONSTANT INTEGER := 6</td>
</tr>
<tr>
<td></td>
<td>LOGGING_LEVEL_ALL CONSTANT INTEGER := 7</td>
</tr>
</tbody>
</table>

Examples

See the GET_PLSQL_LOGGING_LEVEL Function for an example.
SET_PROXY Procedure

This procedure sets the host and port of the proxy server for Internet access. This procedure must be called if the database server accesses the Internet using a proxy server. Internet access is necessary because some rules need to look up the Object Naming Service (ONS) table to get the company prefix index.

You do not need to call this procedure does if you are only using schemes that do not contain any rules requiring Internet access.

Syntax

```sql
DBMS_MGD_ID_UTL.SET_PROXY (
    proxt_host   IN  VARCHAR2,
    proxy_port   IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>proxt_host</td>
<td>Name of host</td>
</tr>
<tr>
<td>proxy_port</td>
<td>Host port number</td>
</tr>
</tbody>
</table>

Examples

See the REFRESHCATEGORY Function for an example.
VALIDATE_SCHEME Function

This function validates the input tag data translation XML against the Oracle Database tag data translation schema.

Syntax

```sql
DBMS_MGD_ID_UTL.VALIDATE_SCHEME ( xml_scheme IN CLOB) RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>xml_scheme</td>
<td>Scheme to be validated.</td>
</tr>
</tbody>
</table>

Usage Notes

The return value contains the components names for the specified scheme.

Examples

See the ADD_SCHEME Procedure or the EPC_TO_ORACLE_SCHEME Function for an example.
DBMS_MGWADM defines the Messaging Gateway administrative interface. The package and object types are owned by SYS.

**Note:** You must run the `catmgw.sql` script to load the Messaging Gateway packages and types into the database.

**See Also:** Oracle Streams Advanced Queuing User's Guide contains information on loading database objects and using DBMS_MGWADM

This chapter contains the following topics:

- Using DBMS_MGWADM
  - Constants
  - Deprecated Subprograms
- Data Structures
- Summary of DBMS_MGWADM Subprograms
Using DBMS_MGWADM

- Deprecated Subprograms
- Constants
Deprecated Subprograms

Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with Oracle Database 11g Release 1 having been superseded by improved technology:

- **ADD_SUBSCRIBER Procedure** - use instead **CREATE_JOB Procedure**
- **ALTER_PROPAGATION_SCHEDULE Procedure** - use instead **ALTER_JOB Procedure**
- **ALTER_SUBSCRIBER Procedure** - use instead **ALTER_JOB Procedure**
- **DB_CONNECT_INFO Procedure** - use instead **ALTER_AGENT Procedures**
- **DISABLE_PROPAGATION_SCHEDULE Procedure** - use instead **DISABLE_JOB Procedure**
- **ENABLE_PROPAGATION_SCHEDULE Procedure** - use instead **ENABLE_JOB Procedure**
- **REMOVE_SUBSCRIBER Procedure** - use instead **REMOVE_JOB Procedure**
- **RESET_SUBSCRIBER Procedure** - use instead **RESET_JOB Procedure**
- **SCHEDULE_PROPAGATION Procedure** - use instead **CREATE_JOB Procedure**
- **UNSCHEDULE_PROPAGATION Procedure** - use instead **REMOVE_JOB Procedure**

<td>CONSTANT BINARY_INTEGER</td>
<td>The greatest information written to the log file</td>
</tr>
<tr>
<td>TRACE_HIGH_LOGGING</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>The third level of detail of logging information written to the log file</td>
</tr>
<tr>
<td>TRACE_LITE_LOGGING</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>The second level detail of logging information written to the log file</td>
</tr>
</tbody>
</table>

### Table 90–4 DBMS_MGWADM Constants—Named Property Constants

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MGWPROP_PREFIX</td>
<td>CONSTANT VARCHAR2</td>
<td>A constant (MGWPROP$_) for the reserved property name prefix</td>
</tr>
<tr>
<td>MGWPROP_REMOVE</td>
<td>CONSTANT VARCHAR2</td>
<td>A constant (MGWPROP$_REMOVE) for the reserved property name used to remove an existing property</td>
</tr>
<tr>
<td>MGWPROP_REMOVE_ALL</td>
<td>CONSTANT VARCHAR2</td>
<td>A constant (MGWPROP$_REMOVE_ALL) for the reserved property name used to remove all properties</td>
</tr>
</tbody>
</table>

### Table 90–5 DBMS_MGWADM Constants—Other Constants

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JMS_CONNECTION</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Used to indicate that JMS connections will be used to access JMS destinations in a domain-independent manner that supports a unified messaging model</td>
</tr>
<tr>
<td>JMS_QUEUE_CONNECTION</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Used to indicate that JMS queue connections will be used to access JMS destinations</td>
</tr>
<tr>
<td>JMS_TOPIC_CONNECTION</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Used to indicate that JMS topic connections will be used to access JMS destinations</td>
</tr>
<tr>
<td>NO_CHANGE</td>
<td>CONSTANT VARCHAR2</td>
<td>Indicates that an existing value should be preserved (not changed). This is used for certain APIs where the desire is to change one or more parameters but leave others unchanged.</td>
</tr>
<tr>
<td>DEFAULT_AGENT</td>
<td>CONSTANT VARCHAR2</td>
<td>Name of the Messaging Gateway default agent</td>
</tr>
</tbody>
</table>
### DBMS_MGWADM Constants—Propagation Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INBOUND_PROPAGATION</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents the propagation type for non-Oracle to Oracle Streams AQ propagation. The propagation source is a queue in a foreign (non-Oracle) messaging system and the destination is a local Oracle Streams AQ queue.</td>
</tr>
<tr>
<td>OUTBOUND_PROPAGATION</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents the propagation type for Oracle Streams AQ to non-Oracle propagation. The propagation source is a local Oracle Streams AQ queue and the destination is a queue in a foreign (non-Oracle) messaging system.</td>
</tr>
</tbody>
</table>

### DBMS_MGWADM Constants—Queue Domain Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMAIN_QUEUE</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents a queue destination. A JMS queue (point-to-point model) is classified as a queue.</td>
</tr>
<tr>
<td>DOMAIN_TOPIC</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents a topic destination. A JMS topic (publish-subscribe model) is classified as a topic.</td>
</tr>
</tbody>
</table>

### DBMS_MGWADM Constants—Shutdown Modes

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SHUTDOWN_IMMEDIATE</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents the immediate shutdown mode</td>
</tr>
<tr>
<td>SHUTDOWN_NORMAL</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents the normal shutdown mode</td>
</tr>
</tbody>
</table>

### DBMS_MGWADM Constants—WebSphere MQ Interface Types

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MQSERIES_BASE_JAVA_INTERFACE</td>
<td>CONSTANT BINARY_INTEGER</td>
<td>Represents the Base Java interface for the WebSphere MQ messaging system</td>
</tr>
</tbody>
</table>

### DBMS_MGWADM Constants—target_type Argument of SET_OPTION and REMOVE_OPTION Procedures

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGENT_JAVA_PROP</td>
<td>CONSTANT PLS_INTEGER</td>
<td>Used for an agent option used to set a Java System property</td>
</tr>
<tr>
<td>MSGLINK_OPTION</td>
<td>CONSTANT PLS_INTEGER</td>
<td>Used for a messaging system link option</td>
</tr>
<tr>
<td>JOB_OPTION</td>
<td>CONSTANT PLS_INTEGER</td>
<td>Used for a propagation job option</td>
</tr>
</tbody>
</table>

### DBMS_MGWADM Constants—conntype Argument of CREATE_AGENT and ALTER_AGENT Procedures

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JDBC_OCI</td>
<td>CONSTANT VARCHAR2</td>
<td>Used to specify the JDBC OCI driver</td>
</tr>
<tr>
<td>JDBC_THIN</td>
<td>CONSTANT VARCHAR2</td>
<td>Used to specify the JDBC Thin driver</td>
</tr>
</tbody>
</table>
Data Structures

The **DBMS_MGWADM** package defines the following **OBJECT** types.

**Object Types**

- SYS.MGW_MQSERIES_PROPERTIES Object Type
- SYS.MGW_PROPERTIES Object Type
- SYS.MGWPROPERTY Object Type
- SYS.MGW_TIBRV_PROPERTIES Object Type
SYS.MGW_MQSERIES_PROPERTIES Object Type

This type specifies basic properties for a WebSphere MQ messaging system link.

Syntax

```plsql
TYPE SYS.MGW_MQSERIES_PROPERTIES IS OBJECT (
  queue_manager VARCHAR2(64),
  hostname VARCHAR2(64),
  port INTEGER,
  channel VARCHAR2(64),
  interface_type INTEGER,
  max_connections INTEGER,
  username VARCHAR2(64),
  password VARCHAR2(64),
  inbound_log_queue VARCHAR2(64),
  outbound_log_queue VARCHAR2(64),

  -- Methods
  STATIC FUNCTION construct
    RETURN SYS.MGW_MQSERIES_PROPERTIES,
  STATIC FUNCTION alter_construct
    RETURN SYS.MGW_MQSERIES_PROPERTIES
);
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>queue_manager</td>
<td>The name of the WebSphere MQ queue manager</td>
</tr>
<tr>
<td>hostname</td>
<td>The host on which the WebSphere MQ messaging system resides. If hostname is NULL, then a WebSphere MQ bindings connection is used. If not NULL, then a client connection is used and requires that a port and channel be specified.</td>
</tr>
<tr>
<td>port</td>
<td>The port number. This is used only for client connections; that is, when hostname is not NULL.</td>
</tr>
<tr>
<td>channel</td>
<td>The channel used when establishing a connection to the queue manager. This is used only for client connections; that is, when hostname is not NULL.</td>
</tr>
<tr>
<td>interface_type</td>
<td>The type of messaging interface to use. Values:</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.MQSERIES_BASE_JAVA_INTERFACE if the WebSphere MQ Base Java interface should be used.</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.JMS_CONNECTION if the link is to be used to access JMS destinations in a unified, domain-independent manner.</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.JMS_QUEUE_CONNECTION if the link is to be used for accessing JMS queues</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.JMS_TOPIC_CONNECTION if the link is to be used for accessing JMS topics.</td>
</tr>
<tr>
<td>max_connections</td>
<td>The maximum number of messaging connections to the WebSphere MQ messaging system</td>
</tr>
<tr>
<td>username</td>
<td>The username used for authentication to the WebSphere MQ messaging system</td>
</tr>
</tbody>
</table>
Methods

Table 90–13  SYS.MGW_MQSERIES_PROPERTIES Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>construct</td>
<td>Constructs a new SYS.MGW_MQSERIES_PROPERTIES instance. All attributes are assigned a value of NULL.</td>
</tr>
<tr>
<td>alter_construct</td>
<td>Constructs a new SYS.MGW_MQSERIES_PROPERTIES instance for altering the properties of an existing messaging link. All attributes having a VARCHAR2 data type are assigned a value of DBMS_MGWADM.NO_CHANGE. Attributes of other data types are assigned a value of NULL.</td>
</tr>
</tbody>
</table>
SYS.MGW_PROPERTIES Object Type

This type specifies an array of properties.

Syntax

```sql
TYPE SYS.MGW_PROPERTIES AS VARRAY (2000) OF SYS.MGW_PROPERTY;
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Property name</td>
</tr>
<tr>
<td>value</td>
<td>Property value</td>
</tr>
</tbody>
</table>

Usage Notes

Unless noted otherwise, Messaging Gateway uses named properties as follows:

- Names with the `MGWPROP$_` prefix are reserved. They are used for special purposes and are invalid when used as a normal property name.
- A property name can exist only once in a property list; that is, a list can contain only one value for a given name. The name is case-insensitive.
- In general, a property list is order-independent, and the property names may appear in any order. An alter property list is an exception.
- You can use a new property list to alter an existing property list. Each new property modifies the original list in one of the following ways: adds a new property, modifies a property, removes a property, or removes all properties.

The alter list is processed in order, from the first element to the last element. Thus the order in which the elements appear in the alter list is meaningful, especially when the alter list is used to remove properties from an existing list.

The property name and value are used to determine how that element affects the original list. The following rules apply:

- Add or modify property

  ```sql
  MGW_PROPERTY.NAME = property_name
  MGW_PROPERTY.VALUE = property_value
  ```

  If a property of the given name already exists, then the current value is replaced with the new value; otherwise the new property is added to the end of the list.

- Remove property

  ```sql
  MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE'
  MGW_PROPERTY.VALUE = name_of_property_to_remove
  ```

  No action is taken if the property name does not exist in the original list.

- Remove all properties

  ```sql
  MGW_PROPERTY.NAME = 'MGWPROP$_REMOVE_ALL'
  MGW_PROPERTY.VALUE = not used
  ```
See Also: "The DBMS_MGWADM package defines constants to represent the reserved property names on Table 90-4, DBMS_MGWADM Constants—Named Property Constants"
SYS.MGW_PROPERTY Object Type

This type specifies a named property which is used to specify optional properties for messaging links, foreign queues, and subscribers.

Syntax

```sql
TYPE SYS.MGW_PROPERTY IS OBJECT(
  name VARCHAR2(500),
  value VARCHAR2(4000),

-- Methods
STATIC FUNCTION construct   --- (1)
RETURN SYS.MGW_PROPERTY,

STATIC FUNCTION construct(   --- (2)
  p_name   IN VARCHAR2,
  p_value  IN VARCHAR2)
RETURN SYS.MGW_PROPERTY );
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Property name</td>
</tr>
<tr>
<td>value</td>
<td>Property value</td>
</tr>
</tbody>
</table>

Methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>construct --- (1)</td>
<td>Constructs a new MGW_PROPERTY instance. All attributes are assigned a value of NULL</td>
</tr>
<tr>
<td>construct --- (2)</td>
<td>Constructs a new MGW_PROPERTY instance initialized using the given parameters</td>
</tr>
</tbody>
</table>
SYS.MGW_TIBRV_PROPERTIES Object Type

A type that specifies basic properties for a TIB/Rendezvous messaging system link. The Messaging Gateway agent creates a TIB/Rendezvous transport of type `TibrvRvdTransport` for each Messaging Gateway link.

Syntax

```sql
TYPE SYS.MGW_TIBRV_PROPERTIES IS OBJECT(
    service   VARCHAR2(128),
    daemon    VARCHAR2(128),
    network   VARCHAR2(256),
    cm_name   VARCHAR2(256),
    cm_ledger VARCHAR2(256),

    -- Methods
    STATIC FUNCTION construct

ADD_SUBSCRIBER Procedure

This procedure adds a subscriber used to consume messages from a source queue for propagation to a destination.

---

**Note:** This subprogram has been deprecated as a result of improved technology (see CREATE_JOB Procedure on page 90-34), and is retained only for reasons of backward compatibility.

---

**Syntax**

```
DBMS_MGWADM.ADD_SUBSCRIBER(
    subscriber_id     IN VARCHAR2,
    propagation_type  IN BINARY_INTEGER,
    queue_name        IN VARCHAR2,
    destination       IN VARCHAR2,
    rule              IN VARCHAR2 DEFAULT NULL,
    transformation    IN VARCHAR2 DEFAULT NULL,
    exception_queue   IN VARCHAR2 DEFAULT NULL,
    options           IN SYS.MGW_PROPERTIES DEFAULT NULL);
```  

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_id</td>
<td>Specifies a user-defined name that identifies this subscriber</td>
</tr>
<tr>
<td>propagation_type</td>
<td>Specifies the type of message propagation. <strong>DBMS_MGWADM.OUTBOUND_PROPAGATION</strong> is for Oracle Streams AQ to non-Oracle propagation. <strong>DBMS_MGWADM.INBOUND_PROPAGATION</strong> is for non-Oracle to Oracle Streams AQ propagation</td>
</tr>
<tr>
<td>queue_name</td>
<td>Specifies the source queue to which this subscriber is being added. The syntax and interpretation of this parameter depend on the value specified for propagation_type.</td>
</tr>
<tr>
<td>destination</td>
<td>Specifies the destination queue to which messages consumed by this subscriber are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.</td>
</tr>
<tr>
<td>rule</td>
<td>Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. This is <strong>NULL</strong> if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for propagation_type.</td>
</tr>
<tr>
<td>transformation</td>
<td>Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for propagation_type.</td>
</tr>
</tbody>
</table>

If **NULL**, then the Oracle Streams AQ payload type must be supported by Messaging Gateway.
If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be NULL.

- "WebSphere MQ System Properties" in Oracle Streams Advanced Queuing User’s Guide
- "TIB/Rendezvous System Properties" in Oracle Streams Advanced Queuing User’s Guide

OUTBOUND_PROPAGATION Subscribers
The parameters for a subscriber used for outbound propagation are interpreted as follows:
- queue_name specifies the local Oracle Streams AQ queue that is the propagation source. This must have a syntax of schema.queue.
- destination specifies the foreign queue to which messages are propagated. This must have a syntax of registered_queue@message_link.
- rule specifies an optional Oracle Streams AQ subscriber rule if the native Oracle Streams AQ interface is used, or a JMS selector if the Oracle JMS interface is used. If NULL, then no rule or selector is used.
- transformation specifies the transformation used to convert the Oracle Streams AQ payload to an ADT defined by Messaging Gateway.

Messaging Gateway propagation dequeues messages from the Oracle Streams AQ queue using the transformation to convert the Oracle Streams AQ payload to a
known ADT defined by Messaging Gateway. The message is then enqueued in the
foreign messaging system based on the Messaging Gateway ADT.

- `exception_queue` specifies the name of a local Oracle Streams AQ queue to which
messages are moved if an exception occurs. This must have a syntax of
  `schema.queue`.

If the native Oracle Streams AQ interface is used, then a subscriber will be added to
the Oracle Streams AQ queue when this procedure is called, whether or not Messaging
Gateway is running. The local subscriber will be of the form `sys.aq$_agent('MGW_
subscriber_id', NULL, NULL)`.

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a
JMS durable subscriber with the name of `MGW_subscriber_id`. If the agent is not
running when this procedure is called, then the durable subscriber will be created the
next time the agent starts.

The exception queue has the following caveats:

- The user is responsible for creating the Oracle Streams AQ queue to be used as the
  exception queue.
- The payload type of the source and exception queue must match.
- The exception queue must be created as a queue type of `DBMS_AQADM.NORMAL_
  QUEUE` rather than `DBMS_AQADM.EXCEPTION_QUEUE`. Enqueue restrictions prevent
  Messaging Gateway propagation from using an Oracle Streams AQ queue of type
  `EXCEPTION_QUEUE` as a Messaging Gateway exception queue.

**INBOUND_PROPAGATION Subscribers**

The parameters for a subscriber used for inbound propagation are interpreted as
follows:

- `queue_name` specifies the foreign queue that is the propagation source. This must
  have a syntax of `registered_queue@message_link`.
- `destination` specifies the local Oracle Streams AQ queue to which messages are
  propagated. This must have a syntax of `schema.queue`.
- `rule` specifies an optional subscriber rule that is valid for the foreign messaging
  system. This is `NULL` if no rule is needed.
- `transformation` specifies the transformation used to convert an ADT defined by
  Messaging Gateway to the Oracle Streams AQ payload type.

Messaging Gateway propagation dequeues messages from the foreign messaging
system and converts the message body to a known ADT defined by Messaging
Gateway. The transformation is used to convert the Messaging Gateway ADT to
an Oracle Streams AQ payload type when the message is enqueued to the Oracle
Streams AQ queue.

- `exception_queue` specifies the name of a foreign queue to which messages are
  moved if an exception occurs. This must have a syntax of `registered_
  queue@message_link`.

Whether or not a subscriber is needed depends on the requirements of the non-Oracle
messaging system. If a durable subscriber is necessary, then it will be created by the
Messaging Gateway agent. If the agent is not running at the time this procedure is
called, then the creation of the subscriber on the non-Oracle messaging system will
occur when the agent next starts.

The exception queue has the following caveats:
- The exception queue must be a registered non-Oracle queue.
- The source and exception queues must use the same messaging system link.
ALTER_AGENT Procedures

This procedure configures Messaging Gateway agent parameters.

Syntax

```
DBMS_MGWADM.ALTER_AGENT (  
  max_connections IN BINARY_INTEGER DEFAULT NULL,
  max_memory       IN BINARY_INTEGER DEFAULT NULL,
  max_threads      IN BINARY_INTEGER DEFAULT NULL,
  service          IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

```
DBMS_MGWADM.ALTER_AGENT (  
  agent_name      IN   VARCHAR2,
  username        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  password        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  database        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  conntype        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  max_memory      IN   PLS_INTEGER DEFAULT NULL,
  max_threads     IN   PLS_INTEGER DEFAULT NULL,
  service         IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  initfile        IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,
  comment         IN   VARCHAR2  DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>max_connections</td>
<td>The maximum number of messaging connections to Oracle Database used by the Messaging Gateway agent. If it is NULL, then the current value is unchanged.</td>
</tr>
<tr>
<td></td>
<td><strong>Caution:</strong> This parameter has been deprecated.</td>
</tr>
<tr>
<td>max_memory</td>
<td>The maximum heap size, in MB, used by the Messaging Gateway agent. If it is NULL, then the current value is unchanged.</td>
</tr>
<tr>
<td>max_threads</td>
<td>The number of messaging threads that the Messaging Gateway agent creates. If it is NULL, then the current value is unchanged.</td>
</tr>
<tr>
<td>service</td>
<td>Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means</td>
</tr>
<tr>
<td></td>
<td>that the Messaging Gateway agent will run on only those database instances that are assigned to the service. If NULL, the job class used by this agent</td>
</tr>
<tr>
<td></td>
<td>will be altered to belong to the default service which is mapped to every instance. If DBMS_MGWADM.NO_CHANGE, the current value is unchanged.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
<tr>
<td>username</td>
<td>Specifies the username used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is</td>
</tr>
<tr>
<td></td>
<td>unchanged. If a username is specified then a password must also be specified.</td>
</tr>
<tr>
<td>password</td>
<td>Specifies the password used for connections to the Oracle Database. NULL is not allowed. If DBMS_MGWADM.NO_CHANGE, then the current value is</td>
</tr>
<tr>
<td></td>
<td>unchanged. A password must be specified if a username is specified.</td>
</tr>
</tbody>
</table>
Summary of DBMS_MGWADM Subprograms

Usage Notes

- Default values for these configuration parameters are set when the Messaging Gateway agent is installed.

- Changes to the `max_memory` and `max_threads` parameters take effect the next time the Messaging Gateway agent is active. If the Messaging Gateway agent is currently active, then it must be shut down and restarted for the changes to take effect.

- The `service` parameter is used to set an Oracle Scheduler job class attribute. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is NULL, the job class will belong to an internal service that is mapped to all instances.

- The `max_connections` parameter is being deprecated as of the Oracle RDBMS 11g release. The number of messaging connections used by the Messaging Gateway Agent is based on the value of the `max_threads` parameter.

- The `username`, `password`, and `database` parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the user and grant it the role `MGW_AGENT_ROLE`.

### Table 90–21 (Cont.) ALTER_AGENT Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database</td>
<td>Specifies the database connect string used for connections to the Oracle Database. NULL indicates that a local connection should be used. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. Oracle strongly recommends that a connect string, rather than NULL, be specified. Usually it will be a net service name from tnsnames.ora.</td>
</tr>
<tr>
<td>conntype</td>
<td>Specifies the type of connection to the Oracle Database, DBMS_MGWADM.JDBC_OCI or DBMS_MGWADM.JDBC_THIN. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
<tr>
<td>initfile</td>
<td>Specifies a Messaging Gateway initialization file used by this agent. NULL indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
<tr>
<td>comment</td>
<td>Optional comments for this agent. NULL if a comment is not desired. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
</tbody>
</table>

**Note:** The `max_connections` parameter included in previous versions of this subprogram has been deprecated and is non-operational.
ALTER_JOB Procedure

This procedure alters the properties of a propagation job.

Syntax

```sql
DBMS_MGWADM.ALTER_JOB (  
  job_name          IN   VARCHAR2,  
  rule              IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  transformation    IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  exception_queue   IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE,  
  poll_interval     IN   PLS_INTEGER DEFAULT 0,  
  options           IN   SYS.MGW_PROPERTIES DEFAULT NULL,  
  comments          IN   VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Identifies the propagation job</td>
</tr>
<tr>
<td>rule</td>
<td>Specifies an optional subscription rule used to dequeue messages from the propagation source. The syntax and interpretation of this parameter depend on the propagation type. A NULL value indicates that no subscription rule is needed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
<tr>
<td>transformation</td>
<td>Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for propagation_type. A NULL value indicates that no transformation is needed. If DBMS_MGWADM.NO_CHANGE, the current value is unchanged.</td>
</tr>
<tr>
<td>exception_queue</td>
<td>Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. In cases in which no exception queue is associated with the job, propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the propagation type. A NULL value indicates that no exception queue is used. If DBMS_MGWADM.NO_CHANGE, the current value is unchanged.</td>
</tr>
<tr>
<td>poll_interval</td>
<td>Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL, 0, or value &gt; 0:</td>
</tr>
<tr>
<td></td>
<td>■ If zero (default), the current value will not be changed.</td>
</tr>
<tr>
<td></td>
<td>■ If NULL, the current value will be reset and the Messaging Gateway default polling interval will be used. The default polling interval is 5 seconds and can be overridden by the Messaging Gateway initialization file.</td>
</tr>
</tbody>
</table>
### Usage Notes

- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

- The subscriber rule cannot be altered when propagating from a JMS source. Instead, the propagation job must be dropped and re-created with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.

- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be `DBMS_MGWADM.NO_CHANGE` (the default value).

- The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner; add a new property, replace an existing property, remove an existing property or remove all properties.

### See Also:

- **SYS.MGW_PROPERTY Object Type** on page 90-12 for more information about the options parameter

- **OUTBOUND_PROPAGATION Jobs** on page 90-35 for outbound propagation parameter interpretation

- **INBOUND_PROPAGATION Jobs** on page 90-36 for inbound propagation parameter interpretation
ALTER_MSGSYSTEM_LINK Procedure for TIB/Rendezvous

Alters the properties of a TIB/Rendezvous messaging system link.

Syntax

```sql
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (  
    linkname      IN  VARCHAR2,  
    properties    IN  SYS.MGW_TIBRV_PROPERTIES,  
    options       IN  SYS.MGW_PROPERTIES DEFAULT NULL,  
    comment       IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE );
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkname</td>
<td>The messaging system link name</td>
</tr>
<tr>
<td>properties</td>
<td>Basic properties for a TIB/Rendezvous messaging system link. If NULL, then no link properties will be changed.</td>
</tr>
<tr>
<td>options</td>
<td>Optional link properties. If NULL, then no options will be changed. If not NULL, then the properties specified in this list are combined with the current options properties to form a new set of link options.</td>
</tr>
<tr>
<td>comment</td>
<td>A user-specified description, or NULL if one is not desired. If DBMS_MGWADM.NO_CHANGE, then the current value will not be changed.</td>
</tr>
</tbody>
</table>

Usage Notes

To retain an existing value for a messaging link property with a VARCHAR2 data type, specify DBMS_MGWADM.NO_CHANGE for that particular property. To preserve an existing value for a property of another data type, specify NULL for that property.

The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

See Also: SYS.MGW_PROPERTIES Object Type on page 90-10

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

See Also: "TIB/Rendezvous System Properties" in Oracle Streams Advanced Queuing User's Guide for more information about the messaging system properties and options
ALTER_MSGSYSTEM_LINK Procedure for WebSphere MQ

This procedure alters the properties of a WebSphere MQ messaging system link.

Syntax

```
DBMS_MGWADM.ALTER_MSGSYSTEM_LINK (
    linkname   IN  VARCHAR2,
    properties IN  SYS.MGW_MQSERIES_PROPERTIES,
    options    IN  SYS.MGW_PROPERTIES DEFAULT NULL,
    comment    IN  VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkname</td>
<td>The messaging system link name</td>
</tr>
<tr>
<td>properties</td>
<td>Basic properties for a WebSphere MQ messaging system link. If it is NULL, then no link properties are changed.</td>
</tr>
<tr>
<td>options</td>
<td>Optional link properties. NULL if no options are changed. If not NULL, then the properties specified in this list are combined with the current options properties to form a new set of link options.</td>
</tr>
<tr>
<td>comment</td>
<td>An optional description or NULL if not desired. If DBMS_MGWADM.NO_CHANGE is specified, then the current value is not changed.</td>
</tr>
</tbody>
</table>

Usage Notes

To retain an existing value for a messaging link property with a VARCHAR2 data type, specify DBMS_MGWADM.NO_CHANGE for that particular property. To preserve an existing value for a property of another data type, specify NULL for that property.

The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

See Also: SYS.MGW_PROPERTIES Object Type on page 90-10

Some properties cannot be modified, and this procedure will fail if an attempt is made to alter such a property. For properties and options that can be changed, a few are dynamic, and Messaging Gateway uses the new values immediately. Others require the Messaging Gateway agent to be shut down and restarted before they take effect.

See Also: "WebSphere MQ System Properties" in Oracle Streams Advanced Queuing User’s Guide for more information about the messaging system properties and options
**ALTER_PROPAGATION_SCHEDULE Procedure**

This procedure alters a propagation schedule.

---

**Note:** This subprogram has been deprecated as a result of improved technology (see [ALTER_JOB Procedure on page 90-22](#)), and is retained only for reasons of backward compatibility.

**Syntax**

```sql
DBMS_MGWADM.ALTER_PROPAGATION_SCHEDULE (  
schedule_id IN VARCHAR2,  
duration IN NUMBER DEFAULT NULL,  
next_time IN VARCHAR2 DEFAULT NULL,  
latency IN NUMBER DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_id</td>
<td>Identifies the propagation schedule to be altered</td>
</tr>
<tr>
<td>duration</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>next_time</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>latency</td>
<td>Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL or value &gt; 0. If latency is NULL, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds, but it can be overridden by the Messaging Gateway initialization file.</td>
</tr>
</tbody>
</table>

**Usage Notes**

This procedure always overwrites the existing value for each parameter. If a given parameter is not specified, then the existing values are overwritten with the default value.
ALTER_SUBSCRIBER Procedure

This procedure alters the parameters of a subscriber used to consume messages from a source queue for propagation to a destination.

---

**Note:** This subprogram has been deprecated as a result of improved technology (see ALTER_JOB Procedure on page 90-22), and is retained only for reasons of backward compatibility.

---

**Syntax**

```sql
DBMS_MGWADM.ALTER_SUBSCRIBER ( 
    subscriber_id    IN VARCHAR2, 
    rule             IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE, 
    transformation   IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE, 
    exception_queue  IN VARCHAR2 DEFAULT DBMS_MGWADM.NO_CHANGE, 
    options          IN SYS.MGW_PROPERTIES DEFAULT NULL );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_id</td>
<td>Identifies the subscriber to be altered</td>
</tr>
<tr>
<td>rule</td>
<td>Specifies an optional subscription rule used by the subscriber to dequeue messages from the source queue. The syntax and interpretation of this parameter depend on the subscriber propagation type. A NULL value indicates that no subscription rule is needed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
<tr>
<td>transformation</td>
<td>Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the subscriber propagation type. A NULL value indicates that no transformation is needed. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged.</td>
</tr>
<tr>
<td>exception_queue</td>
<td>Specifies a queue used for exception message logging. This queue must be on the same messaging system as the propagation source. If no exception queue is associated with the subscriber, then propagation stops if a problem occurs. The syntax and interpretation of this parameter depend on the subscriber propagation type. A NULL value indicates that no exception queue is used. If DBMS_MGWADM.NO_CHANGE, then the current value is unchanged. The source queue and exception queue cannot be the same queue.</td>
</tr>
<tr>
<td>options</td>
<td>Optional subscriber properties. If NULL, no options will be changed. If not NULL, then the properties specified in this list are combined with the current optional properties to form a new set of subscriber options.</td>
</tr>
</tbody>
</table>
Usage Notes

If the non-Oracle messaging link being accessed for the subscriber uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

When propagating from a JMS source, the subscriber rule cannot be altered. Instead, the subscriber must be removed and added with the new rule. For JMS, changing the message selector on a durable subscription is equivalent to deleting and re-creating the subscription.

Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be DBMS_MGWADM.NO_CHANGE (the default value).

The options parameter specifies a set of properties used to alter the current optional properties. Each property affects the current property list in a particular manner: add a new property, replace an existing property, remove an existing property, or remove all properties.

- "INBOUND_PROPAGATION Subscribers" on page 90-18 for inbound propagation parameter interpretation
CLEANUP_GATEWAY Procedures

This procedure cleans up Messaging Gateway. The procedure performs cleanup or recovery actions that may be needed when Messaging Gateway is left in some abnormal or unexpected condition. The MGW_GATEWAY view lists Messaging Gateway status and configuration information that pertains to the cleanup actions.

Syntax

```
DBMS_MGWADM.CLEANUP_GATEWAY(
    action       IN   BINARY_INTEGER,
    sarg         IN   VARCHAR2 DEFAULT NULL);
```

```
DBMS_MGWADM.CLEANUP_GATEWAY(
    agent_name   IN   VARCHAR2,
    action       IN   BINARY_INTEGER,
    sarg         IN   VARCHAR2 DEFAULT NULL);
```

Parameters

Table 90–27 CLEANUP_GATEWAY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>action</td>
<td>The cleanup action to be performed. Values:</td>
</tr>
<tr>
<td></td>
<td>■ DBMS_MGWADM.CLEAN_STARTUP_STATE for Messaging Gateway start up state recovery</td>
</tr>
<tr>
<td></td>
<td>■ DBMS_MGWADM.CLEAN_LOG_QUEUES for log queue cleanup</td>
</tr>
<tr>
<td></td>
<td>■ DBMS_MGWADM.RESET_SUB_MISSING_LOG_REC for propagation job recovery due to missing log record</td>
</tr>
<tr>
<td></td>
<td>■ DBMS_MGWADM.RESET_SUB_MISSING_MESSAGE for propagation job recovery due to missing message</td>
</tr>
<tr>
<td>sarg</td>
<td>Optional argument whose meaning depends on the value specified for action. This should be NULL if it is not used for the specified action.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

Usage Notes

CLEAN_STARTUP_STATE

sarg is not used and must be NULL.

The CLEAN_STARTUP_STATE action recovers Messaging Gateway to a known state when the Messaging Gateway agent has crashed or some other abnormal event occurs, and Messaging Gateway cannot be restarted. This should be done only when the Messaging Gateway agent has been started but appears to have crashed or has been nonresponsive for an extended period of time.

The CLEAN_STARTUP_STATE action may be needed when the MGW_GATEWAY view shows that the AGENT_STATUS value is something other than NOT_STARTED or START_SCHEDULED, and the AGENT_PING value is UNREACHABLE for an extended period of time.

If the AGENT_STATUS value is BROKEN, then the Messaging Gateway agent cannot be started until the problem has been resolved and the CLEAN_STARTUP_STATE action used to reset the agent status. A BROKEN status can indicate that the Messaging Gateway
start job detected a Messaging Gateway agent already running. This condition that should never occur under normal use.

Cleanup tasks include:

- Removing the Scheduler job used to start the external Messaging Gateway agent process.
- Setting certain configuration information to a known state. For example, setting the agent status to \texttt{NOT\_STARTED}.

Execution of this command fails if:

- The agent status is \texttt{NOT\_STARTED} or \texttt{START\_SCHEDULED}.
- No shutdown attempt has been made prior to calling this procedure, except if the agent status is \texttt{STARTING}.
- The Messaging Gateway agent is successfully contacted.

The assumption is that the agent is active, and this procedure fails. If the agent does not respond after several attempts have been made, then the cleanup tasks are performed. This procedure takes at least several seconds and possibly up to one minute. This is expected behavior under conditions where this particular cleanup action is appropriate and necessary.

\begin{note}
Terminate any Messaging Gateway agent process that may still be running after a \texttt{CLEAN\_STARTUP\_STATE} action has been successfully performed. This should be done before calling \texttt{DBMS\_MGWADM.STARTUP} to start Messaging Gateway. The process is usually named \texttt{extprocmgwextproc}.
\end{note}

\section*{CLEAN\_LOG\_QUEUES}
\texttt{sarg} is not used and must be \texttt{NULL}.

The Messaging Gateway agent will clean log queues for all configured messaging system links. The agent will temporarily stop all propagation activity and then remove all obsolete and bad log records from the log queues for all links. The procedure will fail if the Messaging Gateway agent is not running.

This cleanup action is automatically performed each time the Messaging Gateway agent is started.

\begin{note}
The \texttt{CLEAN\_LOG\_QUEUES} action is performed only on agent startup. If this procedure is called when the agent is running, then the Messaging Gateway agent ignores it.
\end{note}

\section*{RESET\_SUB\_MISSING\_LOG\_REC}
\texttt{sarg} specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be \texttt{NULL}.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing log record. The agent will reset the source and destination log records. The procedure will fail if the Messaging Gateway agent is not running.
Caution: If the messages in the source queue had already been propagated to the destination queue, then this action may result in duplicate messages.

RESET_SUB_MISSING_MESSAGE

sarg specifies a Messaging Gateway job name (or subscriber ID) to be reset. It must not be NULL.

The Messaging Gateway agent recovers a Messaging Gateway propagation job that has failed due to a missing persistent source message. The agent will treat the message as a non-persistent message and continue processing that propagation job. The procedure will fail if the Messaging Gateway agent is not running.
CREATE_AGENT Procedure

This procedure creates a Messaging Gateway agent that will be used to process propagation jobs.

Syntax

```sql
DBMS_MGWADM.CREATE_AGENT (  
  agent_name     IN   VARCHAR2,  
  username       IN   VARCHAR2 DEFAULT NULL,  
  password       IN   VARCHAR2 DEFAULT NULL,  
  database       IN   VARCHAR2 DEFAULT NULL,  
  conntype       IN   VARCHAR2 DEFAULT DBMS_MGWADM.JDBC_OCI,  
  max_memory     IN   PLS_INTEGER DEFAULT 64,  
  max_threads    IN   PLS_INTEGER DEFAULT 1,  
  service        IN   VARCHAR2 DEFAULT NULL,  
  initfile       IN   VARCHAR2 DEFAULT NULL,  
  comment        IN   VARCHAR2  DEFAULT NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_name</td>
<td>A name used to identify the agent</td>
</tr>
<tr>
<td>username</td>
<td>Specifies the username used for connections to the Oracle Database</td>
</tr>
<tr>
<td>password</td>
<td>Specifies the password used for connections to the Oracle Database. A password must be specified if a username is specified.</td>
</tr>
<tr>
<td>database</td>
<td>Specifies the database connect string used for connections to the Oracle Database. NULL indicates that a local connection should be used. A value can be specified only if username is specified. Oracle strongly recommends that a connect string, rather than NULL be specified. Usually it will be a net service name from tnsnames.ora.</td>
</tr>
<tr>
<td>conntype</td>
<td>Specifies the type of connection to the Oracle Database. Values: DBMS_MGWADM.JDBC_OCI, DBMS_MGWADM.JDBC_THIN</td>
</tr>
<tr>
<td>max_memory</td>
<td>Specifies the maximum heap size, in MB, used by the Messaging Gateway agent</td>
</tr>
<tr>
<td>max_threads</td>
<td>Specifies the number of messaging threads that the Messaging Gateway agent creates. This determines the number of propagation jobs that the agent can concurrently process.</td>
</tr>
<tr>
<td>service</td>
<td>Specifies the database service that the Oracle Scheduler job class used by this agent will have affinity to. In an Oracle RAC environment, this means that the Messaging Gateway agent will only run on those database instances that are assigned to the service. If NULL, then the job class will belong to the default service which is mapped to every instance.</td>
</tr>
<tr>
<td>initfile</td>
<td>Specifies a Messaging Gateway initialization file used by this agent. NULL indicates that the default initialization file is used. If a value is specified, it should be the full path name of the file.</td>
</tr>
<tr>
<td>comment</td>
<td>An optional comment for this agent. NULL if one is not desired.</td>
</tr>
</tbody>
</table>
Usage Notes

- The Messaging Gateway automatically configures a default agent when Messaging Gateway is installed. The name of the default agent is `DEFAULT_AGENT`. This procedure can be used to create additional agents.

- The `username`, `password`, and `database` parameters specify connection information used by the Messaging Gateway agent for connections to the Oracle Database. An Oracle administrator should create the database user and grant it the role `MGW_AGENT_ROLE`. It is not mandatory that the connection information be specified when this procedure is called but it must be set before the agent can be started.

- The `service` parameter is used to create an Oracle Scheduler job class. The job class is used to create a Scheduler job that starts the Messaging Gateway agent. An Oracle administrator must create the database service. If the value is `NULL`, the job class will belong to an internal service that is mapped to all instances.
CREATE_JOB Procedure

This procedure creates a job used to propagate message from a source to a destination.

Syntax

```sql
DBMS_MGWADM.CREATE_JOB (  
    job_name           IN   VARCHAR2,  
    propagation_type   IN   PLS_INTEGER,  
    source             IN   VARCHAR2,  
    destination        IN   VARCHAR2,  
    rule               IN   VARCHAR2 DEFAULT NULL,  
    transformation     IN   VARCHAR2 DEFAULT NULL,  
    exception_queue    IN   VARCHAR2 DEFAULT NULL,  
    poll_interval      IN   PLS_INTEGER DEFAULT NULL,  
    options            IN   SYS.MGW_PROPERTIES DEFAULT NULL,  
    enabled            IN   BOOLEAN DEFAULT TRUE,  
    comments           IN   VARCHAR2 DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>A user defined name to identify the propagation job</td>
</tr>
<tr>
<td>propagation_type</td>
<td>Specifies the type of message propagation.</td>
</tr>
<tr>
<td>source</td>
<td>Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code>.</td>
</tr>
<tr>
<td>destination</td>
<td>Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code>.</td>
</tr>
<tr>
<td>rule</td>
<td>Specifies an optional subscription rule used to dequeue messages from the source queue. This should be NULL if no rule is needed. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code>.</td>
</tr>
<tr>
<td>transformation</td>
<td>Specifies the transformation needed to convert between the Oracle Streams AQ payload and an ADT defined by Messaging Gateway. The type of transformation needed depends on the value specified for <code>propagation_type</code>. If no transformation is specified the Oracle Streams AQ payload type must be supported by Messaging Gateway.</td>
</tr>
<tr>
<td>exception_queue</td>
<td>Specifies a queue used for exception message logging purposes. This queue must be on the same messaging system as the propagation source. If NULL, an exception queue will not be used and propagation will stop if a problem occurs. The syntax and interpretation of this parameter depend on the value specified for <code>propagation_type</code>. The source queue and exception queue cannot be the same queue.</td>
</tr>
</tbody>
</table>
Usage Notes

- The job must be enabled and Messaging Gateway agent started in order for messages to be propagated.

- If the non-Oracle messaging link being accessed for the propagation job uses a JMS interface, then the Messaging Gateway agent will use the Oracle JMS interface to access the Oracle Streams AQ queues. Otherwise the native Oracle Streams AQ interface will be used. Parameters are interpreted differently when the Messaging Gateway agent uses Oracle JMS for JMS connections.

- Transformations are not currently supported if the Oracle JMS interface is used for propagation. The transformation parameter must be NULL.

OUTBOUND_PROPAGATION Jobs

The parameters for an outbound propagation job are interpreted as follows:

- **source** specifies the local Oracle Streams AQ queue that is the propagation source. This must have syntax of schema.queue. This can be either a multiple consumer queue or a single consumer queue.

- **destination** specifies the non-Oracle queue to which messages are propagated. This must have syntax of registered_queue@message_link.

- **rule** specifies an optional Oracle Streams AQ subscriber rule if the native Oracle Stream AQ interface is used, or a JMS selector if the Oracle JMS interface is used. If NULL, then no rule or selector is used. This parameter must be NULL if the native Oracle Stream AQ interface is used and the propagation source is a single consumer queue.

- **transformation** specifies the transformation used to convert the Oracle Streams AQ payload to an ADT defined by Messaging Gateway. The full transformation name (schema.name) should be used if one is specified.
Messaging Gateway propagation dequeues messages from the Oracle Streams AQ queue using the transformation to convert the Oracle Streams AQ payload to a known ADT defined by Messaging Gateway. The message is then enqueued in the non-Oracle messaging system based on the Messaging Gateway ADT.

- exception_queue specifies the name of a local Oracle Streams AQ queue to which messages are moved if an exception occurs. The syntax must be schema.queue.

If the native Oracle Streams AQ interface is used and the source is a multiple consumer queue, then a subscriber will be added to the Oracle Streams AQ queue when this procedure is called, whether or not the Messaging Gateway agent is running. The local subscriber will be of the form sys.aq$_agent('MGW_job_name', NULL, NULL).

If the Oracle JMS interface is used, then the Messaging Gateway agent will create a JMS durable subscriber with the name of MGW_job_name. If the agent is not running when this procedure is called, then the durable subscriber will be created the next time the agent starts.

The exception queue has the following conditions:

- The user is responsible for creating the Oracle Streams AQ queue to be used as the exception queue.
- The payload type of the source queue and exception queue must match.
- The exception queue must be created as a queue type of DBMS_AQADM.NORMAL_QUEUE. Enqueue restrictions prevent Messaging Gateway from using an Oracle Streams AQ queue of type DBMS_AQADM.EXCEPTION_QUEUE as a Messaging Gateway exception queue.

**INBOUND_PROPAGATION Jobs**

The parameters for an inbound propagation job are interpreted as follows:

- source specifies the non-Oracle queue that is the propagation source. The syntax must be registered_queue@message_link.
- destination specifies the local Oracle Streams AQ queue to which messages are propagated. The syntax must be schema.queue.
- rule specifies an optional subscriber rule that is valid for the non-Oracle messaging system. This should be NULL if no rule is needed.
- transformation specifies the transformation used to convert an ADT defined by Messaging Gateway to the Oracle Streams AQ payload type. The full transformation name (schema.name) should be used if one is specified.

Messaging Gateway propagation dequeues messages from the non-Oracle messaging system and converts the message body to a known ADT defined by Messaging Gateway. The transformation is used to convert the Messaging Gateway ADT to an Oracle Streams AQ payload type when the message is enqueued to the Oracle Streams AQ queue.

- exception_queue specifies the name of a registered non-Oracle queue to which messages are moved if an exception occurs. The syntax must be registered_queue@message_link.

Whether or not a subscriber is needed for the source queue depends on the requirements of the non-Oracle messaging system. If a durable subscriber is necessary, then the Messaging Gateway agent will create it. If the agent is not running when this procedure is called, then the subscriber will be created on the non-Oracle messaging system the next time the agent starts.
The exception queue has the following conditions:

- The exception queue must be a registered non-Oracle queue.
- The source queue and exception queue must use the same messaging system link.
CREATE_MSGSYSTEM_LINK Procedures for TIB/Rendezvous

Creates a link to a TIB/Rendezvous messaging system.

Syntax

```sql
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (
  linkname     IN  VARCHAR2,
  properties   IN  SYS.MGW_TIBRV_PROPERTIES,
  options      IN  SYS.MGW_PROPERTIES DEFAULT NULL,
  comment      IN  VARCHAR2 DEFAULT NULL );
```

```sql
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK (
  linkname     IN  VARCHAR2,
  agent_name   IN  VARCHAR2,
  properties   IN  SYS.MGW_TIBRV_PROPERTIES,
  options      IN  SYS.MGW_PROPERTIES DEFAULT NULL,
  comment      IN  VARCHAR2 DEFAULT NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkname</td>
<td>A user-defined name to identify this messaging system link</td>
</tr>
<tr>
<td>properties</td>
<td>Basic properties of a TIB/Rendezvous messaging system link.</td>
</tr>
<tr>
<td>options</td>
<td>Optional link properties. NULL if there are none. These are less frequently used configuration properties supported by the messaging system.</td>
</tr>
<tr>
<td>comment</td>
<td>A user-specified description. NULL if one is not desired.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

See Also: "TIB/Rendezvous System Properties" in Oracle Streams Advanced Queuing User’s Guide for more information about the messaging system properties and options.
CREATE_MSGSYSTEM_LINK Procedures for WebSphere MQ

This procedure creates a messaging system link to a WebSphere MQ messaging system.

Syntax

```sql
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(
    linkname    IN VARCHAR2,
    properties  IN SYS.MGW_MQSERIES_PROPERTIES,
    options     IN SYS.MGW_PROPERTIES DEFAULT NULL,
    comment     IN VARCHAR2 DEFAULT NULL);
```

```sql
DBMS_MGWADM.CREATE_MSGSYSTEM_LINK(
    linkname    IN VARCHAR2,
    agent_name  IN VARCHAR2,
    properties  IN SYS.MGW_MQSERIES_PROPERTIES,
    options     IN SYS.MGW_PROPERTIES DEFAULT NULL,
    comment     IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkname</td>
<td>A user-defined name to identify the messaging system link</td>
</tr>
<tr>
<td>properties</td>
<td>Basic properties of a WebSphere MQ messaging system link</td>
</tr>
<tr>
<td>options</td>
<td>Optional link properties. NULL if there are none. These are less frequently used configuration properties supported by the messaging system.</td>
</tr>
<tr>
<td>comment</td>
<td>A user-specified description. NULL if one is not desired</td>
</tr>
<tr>
<td>agent_name</td>
<td>Specifies the Messaging Gateway agent that will be used to process all propagation jobs associated with this link. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

Usage Notes

The Messaging Gateway default agent will process the propagation jobs associated with this link if an agent name is not specified.

See Also: "WebSphere MQ System Properties" in Oracle Streams Advanced Queuing User's Guide for more information about the messaging system properties and options.
DB_CONNECT_INFO Procedure

This procedure configures connection information used by the Messaging Gateway default agent for connections to Oracle Database.

Note: This subprogram has been deprecated as a result of improved technology (see ALTER_AGENT Procedures on page 90-20), and is retained only for reasons of backward compatibility.

Syntax

```sql
DBMS_MGWADM.DB_CONNECT_INFO (  
username      IN VARCHAR2,  
password      IN VARCHAR2,  
database      IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>username</td>
<td>The username used for connections to Oracle Database. NULL is not allowed</td>
</tr>
<tr>
<td>password</td>
<td>The password used for connections to Oracle Database. NULL is not allowed</td>
</tr>
<tr>
<td>database</td>
<td>The database connect string used by the Messaging Gateway agent. NULL indicates that a local connection should be used. Oracle strongly recommends that a not NULL value be specified. Usually it will be a net service name from tnsnames.ora.</td>
</tr>
</tbody>
</table>

Usage Notes

The Messaging Gateway agent connects to Oracle Database as the user configured by this procedure. An Oracle administrator should create the user, grant it the role MGW_AGENT_ROLE, and then call this procedure to configure Messaging Gateway. Role MGW_AGENT_ROLE is used to grant this user special privileges needed to access Messaging Gateway configuration information stored in the database, enqueue or dequeue messages to and from Oracle Streams AQ queues, and perform certain Oracle Streams AQ administration tasks.
DISABLE_JOB Procedure

This procedure disables a propagation job.

Syntax

```
DBMS_MGWADM.DISABLE_JOB (
    job_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Identifies the propagation job</td>
</tr>
</tbody>
</table>
DISABLE_PROPAGATION_SCHEDULE Procedure

This procedure disables a propagation schedule.

**Note:** This subprogram has been deprecated as a result of improved technology (see DISABLE_JOB Procedure on page 90-41), and is retained only for reasons of backward compatibility.

**Syntax**

```sql
DBMS_MGWADM.DISABLE_PROPAGATION_SCHEDULE (
    schedule_id  IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_id</td>
<td>Identifies the propagation schedule to be disabled</td>
</tr>
</tbody>
</table>
**ENABLE_JOB Procedure**

This procedure enables a propagation job.

**Syntax**

```sql
DBMS_MGWADM.ENABLE_JOB (
    job_name IN VARCHAR2
);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Identifies the propagation job</td>
</tr>
</tbody>
</table>
ENABLE_PROPAGATION_SCHEDULE Procedure

This procedure enables a propagation schedule.

**Note:** This subprogram has been deprecated as a result of improved technology (see ENABLE_JOB Procedure on page 90-43), and is retained only for reasons of backward compatibility.

**Syntax**

```sql
DBMS_MGWADM.ENABLE_PROPAGATION_SCHEDULE (  
    schedule_id  IN VARCHAR2 );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_id</td>
<td>Identifies the propagation schedule to be enabled</td>
</tr>
</tbody>
</table>
REGISTER_FOREIGN_QUEUE Procedure

This procedure registers a non-Oracle queue entity in Messaging Gateway.

Syntax

```sql
DBMS_MGWADM.REGISTER_FOREIGN_QUEUE(
    name            IN VARCHAR2,
    linkname        IN VARCHAR2,
    provider_queue  IN VARCHAR2 DEFAULT NULL,
    domain          IN INTEGER DEFAULT NULL,
    options         IN SYS.MGW_PROPERTIES DEFAULT NULL,
    comment         IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The registered queue name. This name identifies the foreign queue within Messaging Gateway and need not match the name of the queue in the foreign messaging system.</td>
</tr>
<tr>
<td>linkname</td>
<td>The link name for the messaging system on which this queue exists</td>
</tr>
<tr>
<td>provider_queue</td>
<td>The message provider (native) queue name. If NULL, then the value provided for the name parameter is used as the provider queue name.</td>
</tr>
<tr>
<td>domain</td>
<td>The domain type of the queue. NULL means the domain type is automatically determined based on the messaging system of the queue. DBMS_MGWADM.DOMAIN_QUEUE is for a queue (point-to-point model). DBMS_MGWADM.DOMAIN_TOPIC is for a topic (publish-subscribe model).</td>
</tr>
<tr>
<td>options</td>
<td>Optional queue properties</td>
</tr>
<tr>
<td>comment</td>
<td>A user-specified description. Can be NULL.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure does not create the physical queue in the non-Oracle messaging system. The non-Oracle queue must be created using the administration tools for that messaging system.

See Also: For more information when registering queues for the WebSphere MQ messaging system or the TIB/Rendezvous messaging system, specifically "Optional Foreign Queue Configuration Properties" in Oracle Streams Advanced Queuing User’s Guide.
REMOVE_AGENT Procedure

This procedure removes a Messaging Gateway agent.

Syntax

```
DBMS_MGWADM.REMOVE_AGENT(
    agent_name   IN   VARCHAR2 );
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent</td>
</tr>
</tbody>
</table>

Usage Notes

All messaging system links associated with this Messaging Gateway agent must be removed and the agent must be stopped before it can be removed. The Messaging Gateway default agent cannot be removed.
REMOVE_JOB Procedure

This procedure removes a propagation job.

Syntax

DBMS_MGWADM.REMOVE_JOB(
    job_name   IN   VARCHAR2,
    force      IN   PLS_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE);

Parameters

Table 90–39 REMOVE_JOB Procedure Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Identifies the propagation job</td>
</tr>
<tr>
<td>force</td>
<td>Specifies whether the procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this propagation job. Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE</td>
</tr>
<tr>
<td></td>
<td>NO_FORCE (default) means the job is not removed if Messaging Gateway is unable to clean up successfully</td>
</tr>
<tr>
<td></td>
<td>FORCE means the job is removed even though all cleanup actions may not be done</td>
</tr>
</tbody>
</table>

Usage Notes

- The Messaging Gateway agent uses various resources of the Oracle Database and the non-Oracle messaging system for its propagation work. These resources need to be released when the job is removed. For example, Messaging Gateway may create a durable subscriber on the source queue that should be removed when the job is removed. Therefore, this procedure should normally be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this job.
- For outbound propagation, a local subscriber is removed from the Oracle Streams AQ queue when the propagation source is a multiple consumer queue.
**REMOVE_MSGSYSTEM_LINK Procedure**

This procedure removes a messaging system link for a non-Oracle messaging system.

**Syntax**

```sql
DBMS_MGWADM.REMOVE_MSGSYSTEM_LINK(
    linkname IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>linkname</td>
<td>The messaging system link name</td>
</tr>
</tbody>
</table>

**Usage Notes**

All registered queues associated with this link must be removed before the messaging system link can be removed. This procedure fails if there is a registered foreign (non-Oracle) queue that references this link.
**REMOVE_OPTION Procedure**

This procedure removes a Messaging Gateway configuration option. It can be used to remove an agent option, a messaging link option, or a propagation job option.

**Syntax**

```sql
DBMS_MGWADM.REMOVE_OPTION (  
    target_type   IN   PLS_INTEGER,  
    target_name   IN   VARCHAR2,  
    option_name   IN   VARCHAR2);
```

**Parameters**

**Table 90–41 REMOVE_OPTION Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target_type</td>
<td>Specifies the target type of the Messaging Gateway entity:</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.AGENT_JAVA_PROP to remove a Java System property for a Messaging Gateway agent</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.MSGLINK_OPTION to remove a messaging link option</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.JOB_OPTION to remove a propagation job option</td>
</tr>
<tr>
<td>target_name</td>
<td>Name or identifier of the target. The value for this parameter depends on the value specified for target_type parameter. This must not be NULL.</td>
</tr>
<tr>
<td>option_name</td>
<td>Option name. This must not be NULL.</td>
</tr>
</tbody>
</table>

**Usage Notes**

**DBMS_MGWADM.AGENT_JAVA_PROP Target**

The procedure removes an agent option used to set a Java System property when the Messaging Gateway agent is started. The agent must be restarted for the change to take effect.

The parameters are interpreted as follows:

- `target_name` specifies the name of the Messaging Gateway agent. `DBMS_MGWADM.DEFAULT_AGENT` can be used for the default agent.
- `option_name` specifies the Java System property
- `encrypted` can be either TRUE or FALSE

**DBMS_MGWADM.MSGLINK_OPTION Target**

The procedure removes a single option for a Messaging Gateway messaging system link. This is equivalent to calling `DBMS_MGWADM.ALTER_MSGSYSTEM_LINK` and using the options parameter to remove an option.
The parameters are interpreted as follows:
- target_name specifies the name of the message system link
- option_name specifies the option to set
- encrypted must be FALSE

**DBMS_MGWADM.JOB_OPTION Target**
The procedure removes a single option for a Messaging Gateway propagation job. This is equivalent to calling `DBMS_MGWADM.ALTER_JOB` and using the options parameter to remove an option.

The parameters are interpreted as follows:
- target_name specifies the name of the propagation job
- option_name specifies the option to set
- encrypted must be FALSE
REMOVE_SUBSCRIBER Procedure

This procedure removes a subscriber used to consume messages from a source queue for propagation to a destination.

---

**Note:** This subprogram has been deprecated as a result of improved technology (see REMOVE_JOB Procedure on page 90-47), and is retained only for reasons of backward compatibility.

---

**Syntax**

```
DBMS_MGWADM.REMOVE_SUBSCRIBER (  
    subscriber_id  IN VARCHAR2,  
    force          IN BINARY_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_id</td>
<td>Identifies the subscriber to be removed</td>
</tr>
<tr>
<td>force</td>
<td>Specifies whether this procedure should succeed even if Messaging Gateway is not able to perform all cleanup actions pertaining to this subscriber.</td>
</tr>
<tr>
<td>Values: DBMS_MGWADM.NO_FORCE, DBMS_MGWADM.FORCE</td>
<td></td>
</tr>
<tr>
<td>NO_FORCE means the subscriber is not removed if Messaging Gateway is unable to clean up successfully (default)</td>
<td></td>
</tr>
<tr>
<td>FORCE means the subscriber is removed even though all cleanup actions may not be done</td>
<td></td>
</tr>
</tbody>
</table>

**Usage Notes**

- The Messaging Gateway agent uses various resources of Oracle Database and the non-Oracle messaging system for its propagation work. These resources are typically associated with each subscriber and need to be released when the subscriber is no longer needed. Therefore, this procedure should only be called when the Messaging Gateway agent is running and able to access the non-Oracle messaging system associated with this subscriber.

- For outbound propagation, a local subscriber is removed from the Oracle Streams AQ queue.
RESET_JOB Procedure

This procedure resets the propagation error state for a propagation job.

Syntax

```
DBMS_MGWADM.RESET_JOB (
    job_name   IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Identifies the propagation job</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure can be used to reset a propagation job that has been set to a failed state and propagation activities have been stopped. The administrator should correct the problem and then call this procedure to allow the agent to retry the propagation job. The STATUS field of the MGW_JOBS view indicates the job status.
RESET_SUBSCRIBER Procedure

This procedure resets the propagation error state for a subscriber.

---

**Note:** This subprogram has been deprecated as a result of improved technology (see RESET_JOB Procedure on page 90-52), and is retained only for reasons of backward compatibility.

---

Syntax

```sql
DBMS_MGWADM.RESET_SUBSCRIBER (
    subscriber_id IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_id</td>
<td>Identifies the subscriber</td>
</tr>
</tbody>
</table>
SCHEDULE_PROPAGATION Procedure

This procedure schedules message propagation from a source to a destination. The schedule must be enabled and Messaging Gateway started in order for messages to be propagated.

**Note:** This subprogram has been deprecated as a result of improved technology (see CREATE_JOB Procedure on page 90-34), and is retained only for reasons of backward compatibility.

### Syntax

```sql
DBMS_MGWADM.SCHEDULE_PROPAGATION (
    schedule_id       IN VARCHAR2,
    propagation_type  IN BINARY_INTEGER,
    source            IN VARCHAR2,
    destination       IN VARCHAR2,
    start_time        IN DATE DEFAULT SYSDATE,
    duration          IN NUMBER DEFAULT NULL,
    next_time         IN VARCHAR2 DEFAULT NULL,
    latency           IN NUMBER DEFAULT NULL);
```

### Parameters

**Table 90–45  SCHEDULE_PROPAGATION Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_id</td>
<td>Specifies a user-defined name that identifies the schedule</td>
</tr>
<tr>
<td>propagation_type</td>
<td>Specifies the type of message propagation. DBMS_MGWADM.OUTBOUND_PROPAGATION is for Oracle Streams AQ to non-Oracle propagation. DBMS_MGWADM.INBOUND_PROPAGATION is for non-Oracle to Oracle Streams AQ propagation.</td>
</tr>
<tr>
<td>source</td>
<td>Specifies the source queue whose messages are to be propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.</td>
</tr>
<tr>
<td>destination</td>
<td>Specifies the destination queue to which messages are propagated. The syntax and interpretation of this parameter depend on the value specified for propagation_type.</td>
</tr>
<tr>
<td>start_time</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>duration</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>next_time</td>
<td>Reserved for future use</td>
</tr>
<tr>
<td>latency</td>
<td>Specifies the polling interval, in seconds, used by the Messaging Gateway agent when checking for messages in the source queue. If no messages are available in the source queue, then the agent will not poll again until the polling interval has passed. Once the agent detects a message it will continue propagating messages as long as any are available. Values: NULL or value &gt; 0. If latency is NULL, then the Messaging Gateway agent default polling interval will be used. The default polling interval is 5 seconds but it can be overridden by the Messaging Gateway initialization file.</td>
</tr>
</tbody>
</table>
Usage Notes

For outbound propagation, parameters are interpreted as follows:

- **source** specifies the local Oracle Streams AQ queue from which messages are propagated. This must have a syntax of `schema.queue`.
- **destination** specifies the foreign queue to which messages are propagated. This must have a syntax of `registered_queue@message_link`.

For inbound propagation, parameters are interpreted as follows:

- **source** specifies the foreign queue from which messages are propagated. This must have a syntax of `registered_queue@message_link`.
- **destination** specifies the local Oracle Streams AQ queue to which messages are propagated. This must have a syntax of `schema.queue`.

The schedule is set to an enabled state when it is created.
SET_LOG_LEVEL Procedures

This procedure dynamically alters the Messaging Gateway agent logging level. The Messaging Gateway agent must be running.

Syntax

```sql
DBMS_MGWADM.SET_LOG_LEVEL (log_level IN BINARY_INTEGER);

DBMS_MGWADM.SET_LOG_LEVEL (agent_name IN VARCHAR2, log_level IN BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_level</td>
<td>Level at which the Messaging Gateway agent logs information. DBMS_MGWADM.BASIC_LOGGING generates the least information while DBMS_MGWADM.TRACE_DEBUG_LOGGING generates the most information.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

See Also: Table 90-3, "DBMS_MGWADM Constants—Logging Levels" on page 90-4 for details on the log_level parameter
SET_OPTION Procedure

This procedure sets a Messaging Gateway configuration option. It can be used to set an agent option, a messaging link option, or a propagation job option.

Syntax

```
DBMS_MGWADM.SET_OPTION (
    target_type   IN   PLS_INTEGER,
    target_name   IN   VARCHAR2,
    option_name   IN   VARCHAR2,
    option_value  IN   VARCHAR2,
    encrypted     IN   BOOLEAN DEFAULT FALSE );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>target_type</td>
<td>Specifies the target type of the Messaging Gateway entity:</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.AGENT_JAVA_PROP to set a Java System property for a Messaging Gateway agent</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.MSGLINK_OPTION to set a messaging link option</td>
</tr>
<tr>
<td></td>
<td>- DBMS_MGWADM.JOB_OPTION to set a propagation job option</td>
</tr>
<tr>
<td>target_name</td>
<td>Name or identifier of the target. The value for this parameter depends on the value specified for target_type parameter. This must not be NULL.</td>
</tr>
<tr>
<td>option_name</td>
<td>Option name. This must not be NULL.</td>
</tr>
<tr>
<td>option_value</td>
<td>Option value</td>
</tr>
<tr>
<td>encrypted</td>
<td>Indicates whether the value should be stored as encrypted:</td>
</tr>
<tr>
<td></td>
<td>- TRUE if the value should be stored in an encrypted form</td>
</tr>
<tr>
<td></td>
<td>- FALSE if the value should be stored in a cleartext form</td>
</tr>
</tbody>
</table>

Usage Notes

**DBMS_MGWADM.AGENT_JAVA_PROP Target**

The procedure will store an agent option used to set a Java System property when the Messaging Gateway agent is started. The agent must be restarted for the change to take effect.

The parameters are interpreted as follows:

- target_name specifies the name of the Messaging Gateway agent. `DBMS_MGWADM.DEFAULT_AGENT` can be used for the default agent.
- option_name specifies the Java System property
- encrypted can be either TRUE or FALSE

**DBMS_MGWADM.MSGLINK_OPTION Target**
The procedure will set or alter a single option for a Messaging Gateway messaging system link. This is equivalent to calling `DBMS_MGWADM.ALTER_MSGSYSTEM_LINK` and using the options parameter to set an option.

The parameters are interpreted as follows:
- target_name specifies the name of the message system link
- option_name specifies the option to set
- encrypted must be FALSE

**DBMS_MGWADM.JOB_OPTION Target**
The procedure will set or alter a single option for a Messaging Gateway propagation job. This is equivalent to calling `DBMS_MGWADM.ALTER_JOB` and using the options parameter to set an option.

The parameters are interpreted as follows:
- target_name specifies the name of the propagation job
- option_name specifies the option to set
- encrypted must be FALSE
SHUTDOWN Procedures

This procedure shuts down the Messaging Gateway agent. No propagation activity occurs until Messaging Gateway is restarted.

Syntax

DBMS_MGWADM.SHUTDOWN (
    sdmode      IN BINARY_INTEGER DEFAULT DBMS_MGWADM.SHUTDOWN_NORMAL);

DBMS_MGWADM.SHUTDOWN (
    agent_name  IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>sdmode</td>
<td>The shutdown mode. The only value currently supported is DBMS_MGWADM.SHUTDOWN_NORMAL for normal shutdown. The Messaging Gateway agent may attempt to complete any propagation work currently in progress.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

Usage Notes

The Messaging Gateway default agent is shut down if no agent name is specified.
STARTUP Procedures

This procedure starts the Messaging Gateway agent. It must be called before any propagation activity can take place.

Syntax

```
DBMS_MGWADM.STARTUP(
    instance       IN  BINARY_INTEGER DEFAULT 0,
    force          IN  BINARY_INTEGER DEFAULT DBMS_MGWADM.NO_FORCE);
```

```
DBMS_MGWADM.STARTUP(
    agent_name     IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance</td>
<td>Specifies which instance can run the job queue job used to start the Messaging Gateway agent. If this is zero, then the job can be run by any instance.</td>
</tr>
<tr>
<td></td>
<td>Caution: This parameter has been deprecated.</td>
</tr>
<tr>
<td>force</td>
<td>If this is DBMS_MGWADM.FORCE, then any positive integer is acceptable as the job instance. If this is DBMS_MGWADM.NO_FORCE (the default), then the specified instance must be running; otherwise the routine raises an exception.</td>
</tr>
<tr>
<td></td>
<td>Caution: This parameter has been deprecated.</td>
</tr>
<tr>
<td>agent_name</td>
<td>Identifies the Messaging Gateway agent. DBMS_MGWADM.DEFAULT_AGENT specifies the default agent.</td>
</tr>
</tbody>
</table>

Usage Notes

- The Messaging Gateway default agent will be started if an agent name is not specified.
- The `force` and `instance` parameters are no longer used and will be ignored. If the `instance` affinity parameters were being used to start the default agent on a specific instance, the administrator will need to create a database service and then assign that service to the default agent using the `DBMS_MGWADM.ALTER_AGENT` procedure.
- The Messaging Gateway agent cannot be started until an agent user has been configured by the `DBMS_MGWADM.CREATE_AGENT` or `DBMS_MGWADM.ALTER_AGENT` subprograms.
UNREGISTER_FOREIGN_QUEUE Procedure

This procedure removes a non-Oracle queue entity in Messaging Gateway.

Syntax

```
DBMS_MGWADM.UNREGISTER_FOREIGN_QUEUE(
    name         IN VARCHAR2,
    linkname     IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The queue name</td>
</tr>
<tr>
<td>linkname</td>
<td>The link name for the messaging system on which the queue exists</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure does not remove the physical queue in the non-Oracle messaging system.
- All propagation jobs, subscribers and schedules referencing this queue must be removed before it can be unregistered. This procedure fails if a propagation job, subscriber, or propagation schedule references the non-Oracle queue.
UNSCHEDULE_PROPAGATION Procedure

This procedure removes a propagation schedule.

**Note:** This subprogram has been deprecated as a result of improved technology (see REMOVE_JOB Procedure on page 90-52), and is retained only for reasons of backward compatibility.

**Syntax**

```sql
DBMS_MGWADM.UNSCHEDULE_PROPAGATION (  
    schedule_id IN VARCHAR2 );
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_id</td>
<td>Identifies the propagation schedule to be removed</td>
</tr>
</tbody>
</table>
DBMS_MGWMSG provides:

- Object types used by the canonical message types to convert message bodies.
- Methods, constants, and subprograms for working with Messaging Gateway message types.

**See Also:** Chapter 90, "DBMS_MGWADM" which describes the Messaging Gateway administrative interface, DBMS_MGWADM

This chapter contains the following topics:

- **Using DBMS_MGWMSG**
  - Security Model
  - Constants
  - Types
- **Summary of DBMS_MGWMSG Subprograms**
Using DBMS_MGWMSG

- Security Model
- Constants
- Types
Security Model

The EXECUTE privilege is granted to PUBLIC on all types defined in the DBMS_MGWMSG package as well as the canonical types. The DBMS_MGWMSG packages and object types are owned by SYS.

---

**Note:** You must run the `catmgw.sql` script to load the Messaging Gateway packages and object types into the database. Refer to the *Oracle Streams Advanced Queuing User’s Guide* for information on loading database objects and using DBMS_MGWMSG.
### Constants

#### Table 91–1  DBMS_MGWMSG Constants: Value Types and Constants Representing the Type of Value for a SYS.MGW_NAME_VALUE_T Object

<table>
<thead>
<tr>
<th>Value</th>
<th>Constant</th>
</tr>
</thead>
<tbody>
<tr>
<td>TEXT_VALUE</td>

</tr>
</tbody>
</table>
SYS.MGW_NAME_VALUE_T Type

This type specifies a named value. The name attribute, type attribute, and one of the <>_value attributes are typically not NULL.

Syntax

```
TYPE SYS.MGW_NAME_VALUE_T IS OBJECT(
    name               VARCHAR2(250),
    type               INTEGER,
    integer_value      INTEGER,
    number_value       NUMBER,
    text_value         VARCHAR2(4000),
    raw_value          RAW(2000),
    date_value         DATE,

    -- Methods
    STATIC FUNCTION CONSTRUCT
    RETURN SYS.MGW_NAME_VALUE_T,

    STATIC FUNCTION CONSTRUCT_BOOLEAN
    (name   IN VARCHAR2,
     value  IN INTEGER)
    RETURN SYS.MGW_NAME_VALUE_T,

    STATIC FUNCTION CONSTRUCT_BYTE
    (name   IN VARCHAR2,
     value  IN INTEGER)
    RETURN SYS.MGW_NAME_VALUE_T,

    STATIC FUNCTION CONSTRUCT_SHORT
    (name   IN VARCHAR2,
     value  IN INTEGER)
    RETURN SYS.MGW_NAME_VALUE_T,

    STATIC FUNCTION CONSTRUCT_INTEGER
    (name   IN VARCHAR2,
     value  IN INTEGER)
    RETURN SYS.MGW_NAME_VALUE_T,

    STATIC FUNCTION CONSTRUCT_LONG
    (name   IN VARCHAR2,
     value  IN INTEGER)
    RETURN SYS.MGW_NAME_VALUE_T,

```
value IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_FLOAT (  
   name IN VARCHAR2,
   value IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_DOUBLE (  
   name IN VARCHAR2,
   value IN NUMBER )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_TEXT (  
   name IN VARCHAR2,
   value IN VARCHAR2 )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_RAW (  
   name IN VARCHAR2,
   value IN RAW )
RETURN SYS.MGW_NAME_VALUE_T,

STATIC FUNCTION CONSTRUCT_DATE (  
   name IN VARCHAR2,
   value IN DATE )
RETURN SYS.MGW_NAME_VALUE_T );

Attributes

Table 91–5 SYS.MGW_NAME_VALUE_T Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name associated with the value</td>
</tr>
<tr>
<td>type</td>
<td>Value type. Refer to the DBMS_MGWMSG.&lt;&gt;_VALUE constants in Table 91–1. This indicates which Java datatype and class are associated with the value. It also indicates which attribute stores the value.</td>
</tr>
<tr>
<td>integer_value</td>
<td>Stores a numeric integer value</td>
</tr>
<tr>
<td>number_value</td>
<td>Stores a numeric float or large integer value</td>
</tr>
<tr>
<td>text_value</td>
<td>Stores a text value</td>
</tr>
<tr>
<td>raw_value</td>
<td>Stores a RAW (bytes) value</td>
</tr>
<tr>
<td>date_value</td>
<td>Stores a date value</td>
</tr>
</tbody>
</table>

SYS.MGW_NAME_VALUE_T Type-Attribute Mapping

Table 91–6 shows the mapping between the value type and the attribute used to store the value.

Table 91–6 SYS.MGW_NAME_VALUE_T Type Attribute Mapping

<table>
<thead>
<tr>
<th>Type</th>
<th>Value Stored in Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBMS_MGWMSG.TEXT_VALUE</td>
<td>text_value</td>
</tr>
<tr>
<td>DBMS_MGWMSG.RAW_VALUE</td>
<td>raw_value</td>
</tr>
</tbody>
</table>
### CONSTRUCT Method

This method constructs a new `SYS.MGW_NAME_VALUE_T` instance. All attributes are assigned a value of `NULL`.

**Syntax**

```sql
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_NAME_VALUE_T;
```

### CONSTRUCT_TYPE Methods

These methods construct a new `SYS.MGW_NAME_VALUE_T` instance initialized with the value of a specific type. Each method sets the `name` and `type` attributes and one of the `<>_value` attributes, as shown in the mappings in Table 91–6.

**Syntax**

```sql
STATIC FUNCTION CONSTRUCT_<>
{
  name   IN VARCHAR2,
  value  IN datatype
}
RETURN SYS.MGW_NAME_VALUE_T;
```

**Usage Notes**

The `construct_boolean` method sets the value to either `DBMS_MGWMSG.BOOLEAN_TRUE` or `DBMS_MGWMSG.BOOLEAN_FALSE`.

### SYS.MGW_NAME_TYPE_ARRAY_T Type

This type specifies an array of name-value pairs. An object of `SYS.MGW_NAME_VALUE_ARRAY_T` type can have up to 1024 elements.

**Syntax**

```sql
TYPE SYS.MGW_NAME_VALUE_ARRAY_T
AS VARRAY (1024) OF SYS.MGW_NAME_VALUE_T;
```

### SYS.MGW_TEXT_VALUE_T Type

This type specifies a `TEXT` value. It can store a large value as a `CLOB` or a smaller value (size <= 4000) as `VARCHAR2`. Only one of the `<>_value` attributes should be set.

---

<table>
<thead>
<tr>
<th>Type</th>
<th>Value Stored in Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>DBMS_MGWMSG.BOOLEAN_VALUE</code></td>
<td>integer_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.BYTE_VALUE</code></td>
<td>integer_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.SHORT_VALUE</code></td>
<td>integer_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.INTEGER_VALUE</code></td>
<td>integer_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.LONG_VALUE</code></td>
<td>number_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.FLOAT_VALUE</code></td>
<td>number_value</td>
</tr>
<tr>

<td>number_value</td>
</tr>
<tr>
<td><code>DBMS_MGWMSG.DATE_VALUE</code></td>
<td>date_value</td>
</tr>
</tbody>
</table>
Using DBMS_MGWMSG

Syntax

TYPE SYS.MGW_TEXT_VALUE_T IS OBJECT(
    small_value VARCHAR2(4000),
    large_value CLOB,

-- Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_TEXT_VALUE_T);

Attributes

Table 91–7  SYS.MGW_TEXT_VALUE_T Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>small_value</td>
<td>Small TEXT value. Used for values &lt;= 4000.</td>
</tr>
<tr>
<td>large_value</td>
<td>Large TEXT value. Used when the value is too large for the small_value attribute.</td>
</tr>
</tbody>
</table>

CONSTRUCT Method

This method constructs a new SYS.MGW_TEXT_VALUE_T instance. All attributes are assigned a value of NULL.

Syntax

STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_TEXT_VALUE_T;

SYS.MGW_RAW_VALUE_T Type

This type specifies a RAW value. This type can store a large value as a BLOB or a smaller value (size <= 2000) as RAW. You must set no more than one of the < >_value attributes.

Syntax

TYPE SYS.MGW_RAW_VALUE_T IS OBJECT(
    small_value RAW(2000),
    large_value BLOB,

-- Methods
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_RAW_VALUE_T);

Attributes

Table 91–8  SYS.MGW_RAW_VALUE_T Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>small_value</td>
<td>Small RAW (bytes) value &lt;= 2000</td>
</tr>
<tr>
<td>large_value</td>
<td>Large RAW value. Used when the value is too large for the small_value attribute.</td>
</tr>
</tbody>
</table>

CONSTRUCT Method

This method constructs a new SYS.MGW_RAW_VALUE_T instance. All attributes are assigned a value of NULL.
### SYS.MGW_BASIC_MSG_T Type

This is a canonical type for a basic TEXT or RAW message. Only a single TEXT or RAW value is typically set. An object of this type must not have both TEXT and RAW set to a non-NULL value at the same time.

**Syntax**

```
TYPE SYS.MGW_BASIC_MSG_T IS OBJECT(
    header      SYS.MGW_NAME_VALUE_ARRAY_T,
    text_body   SYS.MGW_TEXT_VALUE_T,
    raw_body    SYS.MGW_RAW_VALUE_T,

    --Methods
    STATIC FUNCTION CONSTRUCT
    RETURN SYS.MGW_BASIC_MSG_T);
```

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>header</td>
<td>Message header information as an array of name-value pairs</td>
</tr>
<tr>
<td>text_body</td>
<td>Message body for a TEXT message</td>
</tr>
<tr>
<td>raw_body</td>
<td>Message body for a RAW (bytes) message</td>
</tr>
</tbody>
</table>

**CONSTRUCT Method**

This method constructs a new SYS.MGW_BASIC_MSG_T instance. All attributes are assigned a value of NULL.

**Syntax**

```
STATIC FUNCTION CONSTRUCT
RETURN SYS.MGW_BASIC_MSG_T;
```

### SYS.MGW_NUMBER_ARRAY_T Type

A type that specifies an array of numbers.

**Syntax**

```
TYPE SYS.MGW_NUMBER_ARRAY_T AS VARRAY(1024) OF NUMBER;
```

### SYS.MGW_TIBRV_FIELD_T Type

A type representing a TIB/Rendezvous message field, typically used in a read-only fashion to retrieve field information from a SYS.MGW_TIBRV_MSG_T instance.

**Syntax**

```
TYPE SYS.MGW_TIBRV_FIELD_T IS OBJECT(
    field_name  VARCHAR2(256),
    field_id    INTEGER,
```

---

91-10 Oracle Database PL/SQL Packages and Types Reference
field_type INTEGER,
number_value NUMBER,
number_array_value SYS.MGW_NUMBER_ARRAY_T,
text_value VARCHAR2(4000),
raw_value RAW(2000),
date_value DATE,
clob_value CLOB,
blob_value BLOB);

Attributes

**SYS.MGW_TIBRV_MSG_T Type**

A type representing a TIB/Rendezvous message. You must never directly reference the attributes of this type. Instead use the type methods.

**Syntax**

```sql
TYPE SYS.MGW_TIBRV_MSG_T IS OBJECT(
    send_subject    VARCHAR2(256),
    reply_subject   VARCHAR2(256),
    cm_time_limit   NUMBER,
    cm_sender_name  VARCHAR2(256),
    cm_sequence_num NUMBER,
    fields          SYS.MGW_TIBRV_IFIELDS_T,
    clob_data1      CLOB,
    clob_data2      CLOB,
    clob_data3      CLOB,
    blob_data1      BLOB,
    blob_data2      BLOB,
    blob_data3      BLOB,

    STATIC FUNCTION construct
    RETURN SYS.MGW_TIBRV_MSG_T,

Construct Method

Constructs a new SYS.MGW_TIBRV_MSG_T instance. All attributes are set to NULL.
Syntax
STATIC FUNCTION construct
RETURN SYS.MGW_TIBRV_MSG_T;

**ADD_< > Methods**

Adds a new field to the message.

**Syntax**
MEMBER PROCEDURE ADD_< > {
  name IN VARCHAR2,
  id IN INTEGER,
  value IN datatype 
};

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Field name</td>
</tr>
<tr>
<td>id</td>
<td>Field identifier</td>
</tr>
<tr>
<td>value</td>
<td>Field data</td>
</tr>
</tbody>
</table>

Table 91-13 shows, for each add method, the field type that will be assigned and valid values for the field data.

</tbody>
</table>
**SET_<> Methods**

Accessor methods to set an instance attribute to a specific value.

**Syntax**

```plaintext
MEMBER PROCEDURE SET_<>

value IN datatype;
```

**Parameters**

**Table 91–14 (Cont.) MGW_TIBRV_MSG_T Add Method Field Types**

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Field Type Assigned</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>add_opaque</td>
<td>TIBRVMSG_OPAQUE</td>
<td>Value stored as RAW if size &lt; 2000; otherwise value stored in BLOB</td>
</tr>
<tr>
<td>add_string</td>
<td>TIBRVMSG_STRING</td>
<td>Value stored as VARCHAR2 if size &lt; 4000; otherwise value stored in CLOB</td>
</tr>
<tr>
<td>add_xml</td>
<td>TIBRVMSG_XML</td>
<td>Value stored as RAW if size &lt; 2000; otherwise value stored in BLOB</td>
</tr>
</tbody>
</table>

**GET_<> Methods**

Accessor methods to retrieve the value for an instance attribute.

**Syntax**

```plaintext
MEMBER PROCEDURE GET_<>

RETURN datatype;
```

**Parameters**

None

**Return Values**

Returns the attribute value.

**GET_FIELD_COUNT Function**

Gets the number of message fields.

**Syntax**

```plaintext
MEMBER PROCEDURE get_field_count

RETURN INTEGER;
```

**Parameters**

None

**Return Values**

Returns the number of fields, or zero (0) if there are none.
GET_FIELD Function

Retrieves field information for the field having a given field collection index. This method should only be called if the GET_FIELD_COUNT Function returns a nonzero value and idx must specify a valid collection index; that is, $1 \leq idx \leq \text{get_field_count}()$.

Syntax

```plsql
MEMBER PROCEDURE get_field (
    idx    IN    INTEGER )
RETURN SYS.MGW_TIBRV_FIELD_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>idx</td>
<td>Specifies the 1-based field collection index of the field to retrieve</td>
</tr>
</tbody>
</table>

**Note:** A 1-based index begins at one (1) instead of zero (0).

Return Values

Returns the field information.

GET_FIELD_BY_NAME Function

Retrieves field information for the first field that has a given field name. The name comparison is case-sensitive.

Syntax

```plsql
MEMBER PROCEDURE get_field_by_name (
    name  IN   VARCHAR2 )
RETURN SYS.MGW_TIBRV_FIELD_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the field name to search for. This can be NULL to find the first field that does not have a field name.</td>
</tr>
</tbody>
</table>

Return Values

Returns the field information, or NULL if no match was found.

GET_FIELD_BY_ID Function

Retrieves field information for the first field that has a given field identifier.

A field can have either a unique identifier or no identifier. If the field identifier value is zero (0) or NULL, then the field is considered to have no identifier. Otherwise, the identifier is a nonzero value that is unique for all the fields of this message.
Syntax

MEMBER PROCEDURE get_field_by_id ( id IN INTEGER )
RETURN SYS.MGW_TIBRV_FIELD_T;

Parameters

Table 91–18  SYS.MGW_TIBRV_MSG_T GET_FIELD_BY_ID Function Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Specifies the field identifier to search for. This can be zero (0) or NULL to find the first field that does not have an identifier.</td>
</tr>
</tbody>
</table>

Return Values

Returns the field information, or NULL if no match was found.

FIND_FIELD_NAME Function

Searches for a field with a given field name, starting from a given index of the field collection. It returns the index of that field. The name comparison is case-sensitive. This function is useful for finding all the fields that have the same name.

Syntax

MEMBER PROCEDURE find_field_name ( name IN VARCHAR2, start_idx IN INTEGER )
RETURN INTEGER;

Parameters

Table 91–19  SYS.MGW_TIBRV_MSG_T FIND_FIELD_NAME Function Parameters
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the field name to search for. This can be NULL to search for a field that does not have a field name.</td>
</tr>
<tr>
<td>start_idx</td>
<td>Specifies the 1-based field collection index from which the search should start.</td>
</tr>
</tbody>
</table>

Return Values

Returns the field index (> 0) if a match was found, or zero (0) if no match was found.

FIND_FIELD_ID Function

Searches for a field with a given field identifier, starting from a given index of the field collection. It returns the index of that field.

Syntax

MEMBER PROCEDURE find_field_id ( id IN INTEGER, start_idx IN INTEGER )
RETURN INTEGER;
Parameters

Table 91–20  SYS.MGW_TIBRV_MSG_T FIND_FIELD_ID Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Specifies the field identifier to search for. This can be zero (0) or NULL</td>
</tr>
<tr>
<td></td>
<td>to find a field that does not have an identifier.</td>
</tr>
<tr>
<td>start_idx</td>
<td>Specifies the 1-based field collection index from which the search should</td>
</tr>
<tr>
<td></td>
<td>start.</td>
</tr>
</tbody>
</table>

Return Values

Returns the field index (> 0) if a match was found, or zero (0) if no match was found.
### Summary of DBMS_MGWMSG Subprograms

<td>Gets the value of the name-value array element that you specify in <code>p_name</code> and with the TEXT_VALUE value type</td>
</tr>
<tr>
<td><strong>XML_TO_LCR Function</strong></td>
<td>Converts a SYS.XMLTYPE object to a SYS.AnyData object encapsulating a row LCR (LCR$_ROW_RECORD) or a DDL LCR (LCR$_DDL_RECORD)</td>
</tr>
</tbody>
</table>
LCR_TO_XML Function

This function converts a SYS.ANYDATA object encapsulating a row LCR (Logical Change Record, in this case a LCR$_ROW_RECORD) or a DDL LCR (LCR$_DDL_RECORD) to a SYS.XMLTYPE object.

See Also: XML_TO_LCR Function on page 91-37

Syntax

```sql
DBMS_MGWMSG.LCR_TO_XML (  
  p_anydata IN SYS.ANYDATA  )
RETURN SYS.XMLTYPE;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_anydata</td>
<td>An ANYDATA object to be converted</td>
</tr>
</tbody>
</table>

Return Values

Returns a SYS.XMLTYPE object.

Usage Notes

An exception is raised if the encapsulated type p_anydata is not an LCR.
NVARRAY_ADD Procedure

This procedure appends a name-value element to the end of a name-value array.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_ADD ( 
    p_array  IN OUT SYS.MGW_NAME_VALUE_ARRAY_T, 
    p_value  IN     SYS.MGW_NAME_VALUE_T );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>On input, the name-value array instance to modify. If NULL, then a new array is created. On output, the modified name-value array instance.</td>
</tr>
<tr>
<td>p_value</td>
<td>The value to add. If NULL, then p_array is not changed.</td>
</tr>
</tbody>
</table>
NVARRAY_FIND_NAME Function

This function searches a name-value array for the element with the name you specify in `p_name`.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_FIND_NAME (  
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,  
    p_name     IN VARCHAR2,  
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )  
RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_array</code></td>
<td>The name-value array to search</td>
</tr>
<tr>
<td><code>p_name</code></td>
<td>The name to find</td>
</tr>
<tr>
<td><code>p_compare</code></td>
<td>Name comparison method. Values are <code>CASE_SENSITIVE</code> and <code>CASE_INSENSITIVE</code>.</td>
</tr>
</tbody>
</table>

Return Values

Returns a positive integer that is the array index of the matching element or zero (0) if the specified name is not found.
NVARRAY_FIND_NAME_TYPE Function

This function searches a name-value array for an element with the name and value type you specify.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_FIND_NAME_TYPE (
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
    p_name     IN VARCHAR2,
    p_type     IN BINARY_INTEGER
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE
) RETURN BINARY_INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array to search</td>
</tr>
<tr>
<td>p_name</td>
<td>The name to find</td>
</tr>
<tr>
<td>p_type</td>
<td>The value type. Refer to the value type constants in Table 91–1 on page 91-4.</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns a positive integer that is the array index of the matching element, zero (0) if the specified name is not found, or negative one (-1) if the specified name is found but a type mismatch exists.
NVARRAY_GET Function

This function gets the name-value element of the name you specify in `p_name` from a name-value array.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET (  
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,  
    p_name     IN VARCHAR2,  
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )  
RETURN SYS.MGW_NAME_VALUE_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the matching element, or `NULL` if the specified name is not found.
NVARRAY_GET_BOOLEAN Function

This function gets the value of the name-value array element that you specify in `p_name` and with the BOOLEAN_VALUE value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_BOOLEAN (
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
    p_name     IN VARCHAR2,
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_BYTE Function

This function gets the value of the name-value array element that you specify in p_name and with the BYTE_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_BYTE (
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
    p_name     IN VARCHAR2,
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_DATE Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `DATE_VALUE` value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_DATE ( 
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T, 
    p_name     IN VARCHAR2, 
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE ) 
RETURN DATE;
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_array</code></td>
<td>The name-value array</td>
</tr>
<tr>
<td><code>p_name</code></td>
<td>The value name</td>
</tr>
<tr>
<td><code>p_compare</code></td>
<td>Name comparison method. Values are <code>CASE_SENSITIVE</code> and <code>CASE_INSENSITIVE</code>.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_DOUBLE Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `DOUBLE_VALUE` value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_DOUBLE ( 
  p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T, 
  p_name     IN VARCHAR2, 
  p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE ) 
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_FLOAT Function

This function gets the value of the name-value array element that you specify in p_name and with the FLOAT_VALUE value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_FLOAT (  
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,  
    p_name     IN VARCHAR2,  
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE  
)  
RETURN NUMBER;  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_INTEGER Function

This function gets the value of the name-value array element that you specify in p_name and with the INTEGER_VALUE value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_INTEGER (  
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,  
    p_name     IN VARCHAR2,  
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )  
RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_LONG Function

This function gets the value of the name-value array element that you specify in p_name and with the LONG_VALUE value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_LONG (  
  p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
  p_name     IN VARCHAR2,
  p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are CASESENSITIVE and CASEINSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or NULL if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_RAW Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `RAW_VALUE` value type.

Syntax

```
DBMS_MGWMSG.NVARRAY_GET_RAW (  
  p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,  
  p_name     IN VARCHAR2,  
  p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )  
RETURN RAW;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_array</code></td>
<td>The name-value array</td>
</tr>
<tr>
<td><code>p_name</code></td>
<td>The value name</td>
</tr>
<tr>
<td><code>p_compare</code></td>
<td>Name comparison method. Values are <code>CASE_SENSITIVE</code> and <code>CASE_INSENSITIVE</code>.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_SHORT Function

This function gets the value of the name-value array element that you specify in `p_name` and with the SHORT_VALUE value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_SHORT (
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
    p_name     IN VARCHAR2,
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN INTEGER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>p_array</code></td>
<td>The name-value array</td>
</tr>
<tr>
<td><code>p_name</code></td>
<td>The value name</td>
</tr>
<tr>
<td><code>p_compare</code></td>
<td>Name comparison method. Values are CASE_SENSITIVE and CASE_INSENSITIVE.</td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.
NVARRAY_GET_TEXT Function

This function gets the value of the name-value array element that you specify in `p_name` and with the `TEXT_VALUE` value type.

Syntax

```sql
DBMS_MGWMSG.NVARRAY_GET_TEXT ( 
    p_array    IN SYS.MGW_NAME_VALUE_ARRAY_T,
    p_name     IN VARCHAR2,
    p_compare  IN BINARY_INTEGER DEFAULT CASE_SENSITIVE )
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_array</td>
<td>The name-value array</td>
</tr>
<tr>
<td>p_name</td>
<td>The value name</td>
</tr>
<tr>
<td>p_compare</td>
<td>Name comparison method. Values are <code>CASE_SENSITIVE</code> and <code>CASE_INSENSITIVE</code></td>
</tr>
</tbody>
</table>

Return Values

Returns the value, or `NULL` if either the specified name is not found or a type mismatch exists.
XML_TO_LCR Function

This function converts a SYS.XMLTYPE object to a SYS.ANYDATA object encapsulating a row LCR (LCR$_ROW_RECORD) or a DDL LCR (LCR$_DDL_RECORD).

See Also:  LCR_TO_XML Function on page 91-22

Syntax

```sql
DBMS_MGWMSG.XML_TO_LCR (  
    p_xmldata IN SYS.XMLTYPE  
) RETURN SYS.ANYDATA;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>p_xmldata</td>
<td>An XMLTYPE object representing an LCR</td>
</tr>
</tbody>
</table>

Return Values

Returns a SYS.ANYDATA object.

Usage Notes

An exception is raised if p_xmldata cannot be converted to an LCR.
The DBMS_MONITOR package let you use PL/SQL for controlling additional tracing and statistics gathering.

<tr>
<td>SESSION_TRACE_ENABLE</td>
<td>Enables the trace for a given database session identifier (SID) on the local instance</td>
</tr>
<tr>
<td>Procedure on page 92-16</td>
<td></td>
</tr>
</tbody>
</table>
CLIENT_ID_STAT_DISABLE Procedure

This procedure will disable statistics accumulation for all instances and remove the accumulated results from V$CLIENT_STATS view enabled by the CLIENT_ID_STAT_ENABLE Procedure.

Syntax

```
DBMS_MONITOR.CLIENT_ID_STAT_DISABLE(
    client_id            IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_id</td>
<td>Client Identifier for which statistic aggregation is disabled</td>
</tr>
</tbody>
</table>

Examples

To disable accumulation:

```
EXECUTE DBMS_MONITOR.CLIENT_ID_STAT_DISABLE('janedoe');
```
CLIENT_ID_STAT_ENABLE Procedure

This procedure enables statistic gathering for a given Client Identifier. Statistics gathering is global for the database and persistent across instance starts and restarts. That is, statistics are enabled for all instances of the same database, including restarts. Statistics are viewable through V$CLIENT_STATS views.

Syntax

DBMS_MONITOR.CLIENT_ID_STAT_ENABLE(
    client_id IN VARCHAR2);

Parameters

Table 92–3 CLIENT_ID_STAT_ENABLE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_id</td>
<td>Client Identifier for which statistic aggregation is enabled</td>
</tr>
</tbody>
</table>

Examples

To enable statistic accumulation for a client with a given client ID:

EXECUTE DBMS_MONITOR.CLIENT_ID_STAT_ENABLE('janedoe');
CLIENT_ID_TRACE_DISABLE Procedure

This procedure will disable tracing enabled by the CLIENT_ID_TRACE_ENABLE Procedure.

Syntax

```sql
DBMS_MONITOR.CLIENT_ID_TRACE_DISABLE(
    client_id    IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_id</td>
<td>Client Identifier for which SQL tracing is disabled</td>
</tr>
</tbody>
</table>

Examples

```sql
EXECUTE DBMS_MONITOR.CLIENT_ID_TRACE_DISABLE ('janedoe');
```
CLIENT_ID_TRACE_ENABLE Procedure

This procedure will enable the trace for a given client identifier globally for the database.

Syntax

```
DBMS_MONITOR.CLIENT_ID_TRACE_ENABLE(
    client_id    IN  VARCHAR2,
    waits        IN  BOOLEAN DEFAULT TRUE,
    binds        IN  BOOLEAN DEFAULT FALSE,
    plan_stat    IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>client_id</td>
<td>Database Session Identifier for which SQL tracing is enabled</td>
</tr>
<tr>
<td>waits</td>
<td>If TRUE, wait information is present in the trace</td>
</tr>
<tr>
<td>binds</td>
<td>If TRUE, bind information is present in the trace</td>
</tr>
<tr>
<td>plan_stat</td>
<td>Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.</td>
</tr>
</tbody>
</table>

Usage Notes

- The trace will be written to multiple trace files because more than one Oracle shadow process can work on behalf of a given client identifier.
- The tracing is enabled for all instances and persistent across restarts.

Examples

```
EXECUTE DBMS_MONITOR.CLIENT_ID_TRACE_ENABLE('janedoe', TRUE, FALSE);
```
**DATABASE_TRACE_DISABLE Procedure**

This procedure disables SQL trace for the whole database or a specific instance.

**Syntax**

```sql
DBMS_MONITOR.DATABASE_TRACE_DISABLE(
    instance_name  IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>instance_name</td>
<td>Disables tracing for the named instance</td>
</tr>
</tbody>
</table>
DATABASE_TRACE_ENABLE Procedure

This procedure enables SQL trace for the whole database or a specific instance.

Syntax

```sql
DBMS_MONITOR.DATABASE_TRACE_ENABLE(
  waits IN BOOLEAN DEFAULT TRUE,
  binds IN BOOLEAN DEFAULT FALSE,
  instance_name IN VARCHAR2 DEFAULT NULL,
  plan_stat IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>waits</td>
<td>If TRUE, wait information will be present in the trace</td>
</tr>
<tr>
<td>binds</td>
<td>If TRUE, bind information will be present in the trace</td>
</tr>
<tr>
<td>instance_name</td>
<td>If set, restricts tracing to the named instance</td>
</tr>
<tr>
<td>plan_stat</td>
<td>Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.</td>
</tr>
</tbody>
</table>
SERV_MOD_ACT_STAT_DISABLE Procedure

This procedure will disable statistics accumulation and remove the accumulated results from V$SERV_MOD_ACT_STATS view. Statistics disabling is persistent for the database. That is, service statistics are disabled for instances of the same database (plus dblinks that have been activated as a result of the enable).

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_STAT_DISABLE(
    service_name    IN VARCHAR2,
    module_name     IN VARCHAR2,
    action_name     IN VARCHAR2 DEFAULT ALL_ACTIONS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_name</td>
<td>Name of the service for which statistic aggregation is disabled</td>
</tr>
<tr>
<td>module_name</td>
<td>Name of the MODULE. An additional qualifier for the service. It is a required parameter.</td>
</tr>
<tr>
<td>action_name</td>
<td>Name of the ACTION. An additional qualifier for the Service and MODULE name. Omitting the parameter (or supplying ALL_ACTIONS constant) means enabling aggregation for all Actions for a given Service/MODULE combination. In this case, statistics are aggregated on the module level.</td>
</tr>
</tbody>
</table>

Usage Notes

Regarding statistics gathering, when you change the module or action, the change takes effect when the next user call is executed in the session. For example, if a module is set to ‘module 1’ in a session, and the module is reset to ‘module 2’ in a user call in the session, then the module remains ‘module 1’ during this user call. The module is changed to ‘module 2’ in the next user call in the session.
SERV_MOD_ACT_STAT_ENABLE Procedure

This procedure enables statistic gathering for a given combination of Service Name, MODULE and ACTION. Calling this procedure enables statistic gathering for a hierarchical combination of Service name, MODULE name, and ACTION name on all instances for the same database. Statistics are accessible by means of the V$SERV_MOD_ACT_STATS view.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE(
    service_name    IN VARCHAR2,
    module_name     IN VARCHAR2,
    action_name     IN VARCHAR2 DEFAULT ALL_ACTIONS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_name</td>
<td>Name of the service for which statistic aggregation is enabled</td>
</tr>
<tr>
<td>module_name</td>
<td>Name of the MODULE. An additional qualifier for the service. It is a required parameter.</td>
</tr>
<tr>
<td>action_name</td>
<td>Name of the ACTION. An additional qualifier for the Service and MODULE name. Omitting the parameter (or supplying ALL_ACTIONS constant) means enabling aggregation for all Actions for a given Service/MODULE combination. In this case, statistics are aggregated on the module level.</td>
</tr>
</tbody>
</table>

Usage Notes

Enabling statistic aggregation for the given combination of Service/Module/Action names is slightly complicated by the fact that the Module/Action values can be empty strings which are indistinguishable from NULLs. For this reason, we adopt the following conventions:

A special constant (unlikely to be a real action names) is defined:

```
ALL_ACTIONS constant VARCHAR2 := '###ALL_ACTIONS';
```

Using ALL_ACTIONS for an action specification means that aggregation is enabled for all actions with a given module name, while using NULL (or empty string) means that aggregation is enabled for an action whose name is an empty string.

Regarding statistics gathering, when you change the module or action, the change takes effect when the next user call is executed in the session. For example, if a module is set to 'module 1' in a session, and the module is reset to 'module 2' in a user call in the session, then the module remains 'module 1' during this user call. The module is changed to 'module 2' in the next user call in the session.

Examples

To enable statistic accumulation for a given combination of Service name and MODULE:

```
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE( 'APPS1', 'PAYROLL');
```

To enable statistic accumulation for a given combination of Service name, MODULE and ACTION:

```
EXECUTE
DBMS_MONITOR.SERV_MOD_ACT_STAT_ENABLE('APPS1','GLEDGER','DEBIT_ENTRY');

If both of the preceding commands are issued, statistics are accumulated as follows:

- For the APPS1 service, because accumulation for each Service Name is the default.
- For all actions in the PAYROLL Module.
- For the DEBIT_ENTRY Action within the GLEDGER Module.
SERV_MOD_ACT_TRACE_DISABLE Procedure

This procedure will disable the trace at all enabled instances for a given combination of Service Name, MODULE, and ACTION name globally.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE(
    service_name    IN  VARCHAR2,
    module_name     IN  VARCHAR2,
    action_name     IN  VARCHAR2 DEFAULT ALL_ACTIONS,
    instance_name   IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_name</td>
<td>Name of the service for which tracing is disabled.</td>
</tr>
<tr>
<td>module_name</td>
<td>Name of the MODULE. An additional qualifier for the service</td>
</tr>
<tr>
<td>action_name</td>
<td>Name of the ACTION. An additional qualifier for the Service and MODULE name.</td>
</tr>
<tr>
<td>instance_name</td>
<td>If set, this restricts tracing to the named instance_name</td>
</tr>
</tbody>
</table>

Usage Notes

Specifying NULL for the module_name parameter means that statistics will no longer be accumulated for the sessions which do not set the MODULE attribute.

Examples

To enable tracing for a Service named APPS1:

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1',
    DBMS_MONITOR.ALL_MODULES, DBMS_MONITOR.ALL_ACTIONS, TRUE,
    FALSE, NULL);
```

To disable tracing specified in the previous step:

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE('APPS1');
```

To enable tracing for a given combination of Service and MODULE (all ACTIONS):

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1', 'PAYROLL',
    DBMS_MONITOR.ALL_ACTIONS, TRUE, FALSE, NULL);
```

To disable tracing specified in the previous step:

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_DISABLE('APPS1', 'PAYROLL');
```
SERV_MOD_ACT_TRACE_ENABLE Procedure

This procedure will enable SQL tracing for a given combination of Service Name, MODULE and ACTION globally unless an instance_name is specified.

Syntax

```
DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE(
  service_name    IN VARCHAR2,
  module_name     IN VARCHAR2 DEFAULT ANY_MODULE,
  action_name     IN VARCHAR2 DEFAULT ANY_ACTION,
  waits           IN BOOLEAN DEFAULT TRUE,
  binds           IN BOOLEAN DEFAULT FALSE,
  instance_name   IN VARCHAR2 DEFAULT NULL,
  plan_stat       IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service_name</td>
<td>Name of the service for which SQL trace is enabled</td>
</tr>
<tr>
<td>module_name</td>
<td>Name of the MODULE for which SQL trace is enabled. An optional additional qualifier for the service. If omitted, SQL trace is enabled or all modules and actions in a given service.</td>
</tr>
<tr>
<td>action_name</td>
<td>Name of the ACTION for which SQL trace is enabled. An optional additional qualifier for the Service and MODULE name. If omitted, SQL trace is enabled for all actions in a given module.</td>
</tr>
<tr>
<td>waits</td>
<td>If TRUE, wait information is present in the trace</td>
</tr>
<tr>
<td>binds</td>
<td>If TRUE, bind information is present in the trace</td>
</tr>
<tr>
<td>instance_name</td>
<td>If set, this restricts tracing to the named instance_name</td>
</tr>
<tr>
<td>plan_stat</td>
<td>Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.</td>
</tr>
</tbody>
</table>

Usage Notes

- The procedure enables a trace for a given combination of Service, MODULE and ACTION name. The specification is strictly hierarchical: Service Name or Service Name/MODULE, or Service Name, MODULE, and ACTION name must be specified. Omitting a qualifier behaves like a wild-card, so that not specifying an ACTION means all ACTIONS. Using the ALL_ACTIONS constant achieves the same purpose.
- This tracing is useful when an application MODULE and optionally known ACTION is experiencing poor service levels.
- By default, tracing is enabled globally for the database. The instance_name parameter is provided to restrict tracing to named instances that are known, for example, to exhibit poor service levels.
- Tracing information is present in multiple trace files and you must use the trcsess tool to collect it into a single file.
- Specifying NULL for the module_name parameter means that statistics will be accumulated for the sessions which do not set the MODULE attribute.
Examples

To enable tracing for a Service named `APPS1`:

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1',
    DBMS_MONITOR.ALL_MODULES, DBMS_MONITOR.ALL_ACTIONS, TRUE,
    FALSE, NULL);
```

To enable tracing for a given combination of Service and `MODULE` (all `ACTIONS`):

```sql
EXECUTE DBMS_MONITOR.SERV_MOD_ACT_TRACE_ENABLE('APPS1', 'PAYROLL',
    DBMS_MONITOR.ALL_ACTIONS, TRUE, FALSE, NULL);
```
SESSION_TRACE_DISABLE Procedure

This procedure will disable the trace for a given database session at the local instance.

Syntax

```
DBMS_MONITOR.SESSION_TRACE_DISABLE(
    session_id IN     BINARY_INTEGER DEFAULT NULL,
    serial_num IN     BINARY_INTEGER DEFAULT NULL);
```

Parameters

Table 92–12 SESSION_TRACE_DISABLE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>Database Session Identifier for which SQL trace is disabled</td>
</tr>
<tr>
<td>serial_num</td>
<td>Serial number for this session</td>
</tr>
</tbody>
</table>

Usage Notes

If `serial_num` is NULL but `session_id` is specified, a session with a given `session_id` is no longer traced irrespective of its serial number. If both `session_id` and `serial_num` are NULL, the current user session is no longer traced. It is illegal to specify NULL `session_id` and non-NULL `serial_num`. In addition, the NULL values are default and can be omitted.

Examples

To enable tracing for a client with a given client session ID:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(7, 4634, TRUE, FALSE);
```

To disable tracing specified in the previous step:

```
EXECUTE DBMS_MONITOR.SESSION_TRACE_DISABLE(7, 4634);
```
SESSION_TRACE_ENABLE Procedure

This procedure enables a SQL trace for the given Session ID on the local instance.

Syntax

```sql
DBMS_MONITOR.SESSION_TRACE_ENABLE(
    session_id   IN  BINARY_INTEGER DEFAULT NULL,
    serial_num   IN  BINARY_INTEGER DEFAULT NULL,
    waits        IN  BOOLEAN DEFAULT TRUE,
    binds        IN  BOOLEAN DEFAULT FALSE,
    plan_stat    IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>Client Identifier for which SQL trace is enabled. If omitted (or NULL), the user's own session is assumed.</td>
</tr>
<tr>
<td>serial_num</td>
<td>Serial number for this session. If omitted (or NULL), only the session ID is used to determine a session.</td>
</tr>
<tr>
<td>waits</td>
<td>If TRUE, wait information is present in the trace</td>
</tr>
<tr>
<td>binds</td>
<td>If TRUE, bind information is present in the trace</td>
</tr>
<tr>
<td>plan_stat</td>
<td>Frequency at which we dump row source statistics. Value should be 'NEVER', 'FIRST_EXECUTION' (equivalent to NULL) or 'ALL_EXECUTIONS'.</td>
</tr>
</tbody>
</table>

Usage Notes

The procedure enables a trace for a given database session, and is still useful for client/server applications. The trace is enabled only on the instance to which the caller is connected, since database sessions do not span instances. This tracing is strictly local to an instance.

If `serial_num` is NULL but `session_id` is specified, a session with a given `session_id` is traced irrespective of its serial number. If both `session_id` and `serial_num` are NULL, the current user session is traced. It is illegal to specify NULL `session_id` and non-NUL` serial_num`. In addition, the NULL values are default and can be omitted.

Examples

To enable tracing for a client with a given client session ID:

```sql
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(7, 4634, TRUE, FALSE);
```

To disable tracing specified in the previous step:

```sql
EXECUTE DBMS_MONITOR.SESSION_TRACE_DISABLE(7, 4634);
```

Either

```sql
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(5);
```

or

```sql
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(5, NULL);
```
traces the session with session ID of 5, while either
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE();

or
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(NULL, NULL);

traces the current user session. Also,
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(NULL, NULL, TRUE, TRUE);

traces the current user session including waits and binds. The same can be also expressed using keyword syntax:
EXECUTE DBMS_MONITOR.SESSION_TRACE_ENABLE(binds=>TRUE);
DBMS_MVIEW enables you to understand capabilities for materialized views and potential materialized views, including their rewrite availability. It also enables you to refresh materialized views that are not part of the same refresh group and purge logs.

Note: DBMS_MVIEW is a synonym for DBMS_SNAPSHOT.

Using DBMS_MVIEW

This section contains topics which relate to using the DBMS_MVIEW package.

- Operational Notes
- Security Model
- Rules and Limits
Operational Notes

If a query is less than 256 characters long, you can invoke EXPLAIN_REWRITE using the EXECUTE command from SQL*Plus. Otherwise, the recommended method is to use a PL/SQL BEGIN..END block, as shown in the examples in /rdbms/demo/smxrw.sql.
Security Model

The `DBMS_MVIEW` package consists of a number of materialized view-related subprograms, each of which has different functionality and privilege requirements. The privilege model is generally based on the invoker's right. Each package subprogram is executed by first checking the privileges against the invoker. If all the required privileges are met, the subprogram will be executed. Otherwise, an insufficient privileges error will be thrown.
Rules and Limits

The `EXPLAIN_REWRITE` procedure cannot accept queries longer than 32627 characters. These restrictions also apply when passing the defining query of a materialized view to the `EXPLAIN_MVIEW` procedure.
### Summary of DBMS_MVIEW Subprograms

#### Table 93–1  DBMS_MVIEW Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BEGIN_TABLE_REORGANIZATION</td>
<td>Performs a process to preserve materialized view data needed for refresh</td>
</tr>
<tr>
<td>END_TABLE_REORGANIZATION</td>
<td>Ensures that the materialized view data for the master table is valid and that the master table is in the proper state</td>
</tr>
<tr>
<td>ESTIMATE_MVIEW_SIZE</td>
<td>Estimates the size of a materialized view that you might create, in bytes and rows</td>
</tr>
<tr>
<td>EXPLAIN_MVIEW Procedure</td>
<td>Explains what is possible with a materialized view or potential materialized view</td>
</tr>
<tr>
<td>EXPLAIN_REWRITE Procedure</td>
<td>Explains why a query failed to rewrite or why the optimizer chose to rewrite a query with a particular materialized view or materialized views</td>
</tr>
<tr>
<td>I_AM_A_REFRESH Function on page 93-13</td>
<td>Returns the value of the I_AM_REFRESH package state</td>
</tr>
<tr>
<td>PMARKER Function on page 93-14</td>
<td>Returns a partition marker from a rowid, and is used for Partition Change Tracking (PCT)</td>
</tr>

<td>PURGE_DIRECT_LOAD_LOG Procedure on page 93-15</td>
<td>Purges rows from the direct loader log after they are no longer needed by any materialized views (used with data warehousing)</td>
</tr>
<tr>
<td>PURGE_LOG Procedure on page 93-16</td>
<td>Purges rows from the materialized view log</td>
</tr>
<tr>
<td>PURGE_MVIEW_FROM_LOG Procedure on page 93-17</td>
<td>Purges rows from the materialized view log</td>
</tr>
<tr>
<td>REFRESH Procedures on page 93-18</td>
<td>Refreshes one or more materialized views that are not members of the same refresh group</td>
</tr>
<tr>
<td>REFRESH_ALL_MVIEWS Procedure on page 93-20</td>
<td>Refreshes all materialized views that do not reflect changes to their master table or master materialized view</td>
</tr>
<tr>
<td>REFRESH_DEPENDENT Procedures on page 93-21</td>
<td>Refreshes all table-based materialized views that depend on a specified master table or master materialized view, or list of master tables or master materialized views</td>
</tr>
<tr>
<td>REGISTER_MVIEW Procedure on page 93-23</td>
<td>Enables the administration of individual materialized views</td>
</tr>
<tr>
<td>UNREGISTER_MVIEW Procedure on page 93-25</td>
<td>Enables the administration of individual materialized views once invoked at a master site or master materialized view site to unregister a materialized view</td>
</tr>
</tbody>
</table>
BEGIN_TABLE_REORGANIZATION Procedure

This procedure performs a process to preserve materialized view data needed for refresh. It must be called before a master table is reorganized.

Syntax

```
DBMS_MVIEW.BEGIN_TABLE_REORGANIZATION (
    tabowner    IN   VARCHAR2,
    tabname     IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tabowner</td>
<td>Owner of the table being reorganized</td>
</tr>
<tr>
<td>tabname</td>
<td>Name of the table being reorganized</td>
</tr>
</tbody>
</table>
END_TABLE_REORGANIZATION Procedure

This procedure ensures that the materialized view data for the master table is valid and that the master table is in the proper state. It must be called after a master table is reorganized.

Syntax

```sql
DBMS_MVIEW.END_TABLE_REORGANIZATION (
    tabowner IN VARCHAR2,
    tabname  IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tabowner</td>
<td>Owner of the table being reorganized</td>
</tr>
<tr>
<td>tabname</td>
<td>Name of the table being reorganized</td>
</tr>
</tbody>
</table>
ESTIMATE_MVIEW_SIZE Procedure

This procedure estimates the size of a materialized view that you might create, in bytes and number of rows.

Syntax

```sql
DBMS_MVIEW.ESTIMATE_MVIEW_SIZE (
    stmt_id       IN  VARCHAR2,
    select_clause IN  VARCHAR2,
    num_rows      OUT NUMBER,
    num_bytes     OUT NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>stmt_id</td>
<td>Arbitrary string used to identify the statement in an EXPLAIN PLAN</td>
</tr>
<tr>
<td>select_clause</td>
<td>The SELECT statement to be analyzed</td>
</tr>
<tr>
<td>num_rows</td>
<td>Estimated cardinality</td>
</tr>
<tr>
<td>num_bytes</td>
<td>Estimated number of bytes</td>
</tr>
</tbody>
</table>
EXPLAIN_MVIEW Procedure

This procedure enables you to learn what is possible with a materialized view or potential materialized view. For example, you can determine if a materialized view is fast refreshable and what types of query rewrite you can perform with a particular materialized view.

Using this procedure is straightforward. You simply call `DBMS_MVIEW.EXPLAIN_MVIEW`, passing in as parameters the schema and materialized view name for an existing materialized view. Alternatively, you can specify the `SELECT` string or `CREATE MATERIALIZED VIEW` statement for a potential materialized view. The materialized view or potential materialized view is then analyzed and the results are written into either a table called `MV_CAPABILITIES_TABLE`, which is the default, or to an array called `MSG_ARRAY`.

The procedure is overloaded:

- The first version is for explaining an existing or potential materialized view with output to `MV_CAPABILITIES_TABLE`.
- The second version is for explaining an existing or potential materialized view with output to a VARRAY.

**Syntax**

```sql
DBMS_MVIEW.EXPLAIN_MVIEW (
  mv            IN VARCHAR2,
  statement_id  IN VARCHAR2:= NULL);

DBMS_MVIEW.EXPLAIN_MVIEW (
  mv          IN VARCHAR2,
  msg_array   OUT SYS.ExplainMVArrayType);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mv</td>
<td>The name of an existing materialized view (optionally qualified with the owner name separated by a &quot;.&quot;) or a <code>SELECT</code> statement or a <code>CREATE MATERIALIZED VIEW</code> statement for a potential materialized view.</td>
</tr>
<tr>
<td>statement_id</td>
<td>A client-supplied unique identifier to associate output rows with specific invocations of <code>EXPLAIN_MVIEW</code></td>
</tr>
<tr>
<td>msg_array</td>
<td>The PL/SQL VARRAY that receives the output. Use this parameter to direct <code>EXPLAIN_MVIEW</code>'s output to a PL/SQL VARRAY rather than <code>MV_CAPABILITIES_TABLE</code>.</td>
</tr>
</tbody>
</table>

**Usage Notes**

You must run the `utlxmv.sql` script to create `MV_CAPABILITIES_TABLE` in the current schema prior to calling `EXPLAIN_MVIEW` except when you direct output to a VARRAY. The script is found in the `ADMIN` directory.
EXPLAIN_REWRITE Procedure

This procedure enables you to learn why a query failed to rewrite, or, if it rewrites, which materialized views will be used. Using the results from the procedure, you can take the appropriate action needed to make a query rewrite if at all possible. The query specified in the EXPLAIN_REWRITE statement is never actually executed.

A demo file, xrwutl.sql, is available to help format the output from EXPLAIN_REWRITE.

Syntax

You can obtain the output from DBMS_MVIEW.EXPLAIN_REWRITE in two ways. The first is to use a table, while the second is to create a VARRAY. The following shows the basic syntax for using an output table:

```sql
DBMS_MVIEW.EXPLAIN_REWRITE (query VARCHAR2,
                               mv VARCHAR2(30),
                               statement_id VARCHAR2(30));
```

You can create an output table called REWRITE_TABLE by executing the utlxrw.sql script.

The query parameter is a text string representing the SQL query. The parameter, mv, is a fully qualified materialized view name in the form of schema.mv. This is an optional parameter. When it is not specified, EXPLAIN_REWRITE returns any relevant messages regarding all the materialized views considered for rewriting the given query. When schema is omitted and only mv is specified, EXPLAIN_REWRITE looks for the materialized view in the current schema.

If you want to direct the output of EXPLAIN_REWRITE to a VARRAY instead of a table, you should call the procedure as follows:

```sql
DBMS_MVIEW.EXPLAIN_REWRITE (query VARCHAR2 | CLOB,
                               mv VARCHAR2(30),
                               output_array SYS.RewriteArrayType);
```

Note that if the query is less than 256 characters long, EXPLAIN_REWRITE can be easily invoked with the EXECUTE command from SQL*Plus. Otherwise, the recommended method is to use a PL/SQL BEGIN... END block, as shown in the examples in /rdbms/demo/smxrw*.

You can also use EXPLAIN_REWRITE with multiple materialized views, in which case the syntax will be the same as with a single materialized view, except that the materialized views are specified by a comma-delimited string. For example, to find out whether a given set of materialized views mv1, mv2, and mv3 could be used to rewrite the query, query_txt, and, if not, why not, use EXPLAIN_REWRITE as follows:

```sql
DBMS_MVIEW.EXPLAIN_REWRITE(query_txt, 'mv1, mv2, mv3')
```

See Oracle Database Data Warehousing Guide for more information on using the EXPLAIN_REWRITE procedure.
Parameters

**Table 93–6  EXPLAIN_REWRITE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>query</td>
<td>SQL SELECT statement to be explained</td>
</tr>
<tr>
<td>mv</td>
<td>The fully qualified name of an existing materialized view in the form of <code>SCHEMA.MV</code>. For multiple materialized views, you can provide a comma-delimited list of names.</td>
</tr>
<tr>
<td>statement_id</td>
<td>A client-supplied unique identifier to distinguish output messages</td>
</tr>
<tr>
<td>msg_array</td>
<td>The PL/SQL <code>VARRAY</code> that receives the output. Use this parameter to direct <code>EXPLAIN_REWRITE</code>'s output to a PL/SQL <code>VARRAY</code>.</td>
</tr>
</tbody>
</table>

Usage Notes

To obtain the output into a table, you must run the `utlxrw.sql` script before calling `EXPLAIN_REWRITE`. This script creates a table named `REWRITE_TABLE` in the current schema.
I_AM_A_REFRESH Function

This function returns the value of the I_AM_REFRESH package state.

Syntax

```
DBMS_MVIEW.I_AM_A_REFRESH
    RETURN BOOLEAN;
```

Return Values

A return value of `true` indicates that all local replication triggers for materialized views are effectively disabled in this session because each replication trigger first checks this state. A return value of `false` indicates that these triggers are enabled.
PMARKER Function

This function returns a partition marker from a rowid. It is used for Partition Change Tracking (PCT).

Syntax

```sql
DBMS_MVIEW.PMARKER(
    rid IN ROWID)
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rid</td>
<td>The rowid of a row entry in a master table</td>
</tr>
</tbody>
</table>
**PURGE_DIRECT_LOAD_LOG Procedure**

This procedure removes entries from the direct loader log after they are no longer needed for any known materialized view. This procedure usually is used in environments using Oracle's data warehousing technology.

*See Also:* Oracle Database Data Warehousing Guide for more information

**Syntax**

```
DBMS_MVIEW.PURGE_DIRECT_LOAD_LOG();
```
PURGE_LOG Procedure

This procedure purges rows from the materialized view log.

Syntax

```
DBMS_MVIEW.PURGE_LOG (  
  master   IN   VARCHAR2,
  num      IN   BINARY_INTEGER := 1,
  flag     IN   VARCHAR2       := 'NOP');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>master</td>
<td>Name of the master table or master materialized view.</td>
</tr>
<tr>
<td>num</td>
<td>Number of least recently refreshed materialized views whose rows you want to remove from materialized view log. For example, the following statement deletes rows needed to refresh the two least recently refreshed materialized views:</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.PURGE_LOG('master_table', 2);</code></td>
</tr>
<tr>
<td></td>
<td>To delete all rows in the materialized view log, indicate a high number of materialized views to disregard, as in this example:</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.PURGE_LOG('master_table', 9999);</code></td>
</tr>
<tr>
<td></td>
<td>This statement completely purges the materialized view log that corresponds to <code>master_table</code> if fewer than 9999 materialized views are based on <code>master_table</code>. A simple materialized view whose rows have been purged from the materialized view log must be completely refreshed the next time it is refreshed.</td>
</tr>
<tr>
<td>flag</td>
<td>Specify <code>delete</code> to guarantee that rows are deleted from the materialized view log for at least one materialized view. This parameter can override the setting for the parameter <code>num</code>. For example, the following statement deletes rows from the materialized view log that has dependency rows in the least recently refreshed materialized view:</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.PURGE_LOG('master_table',1,'delete');</code></td>
</tr>
</tbody>
</table>
PURGE_MVIEW_FROM_LOG Procedure

This procedure is called on the master site or master materialized view site to delete the rows in materialized view refresh related data dictionary tables maintained at the master for the specified materialized view identified by its mview_id or the combination of the mviewowner, mviewname, and the mviewsite. If the materialized view specified is the oldest materialized view to have refreshed from any of the master tables or master materialized views, then the materialized view log is also purged. This procedure does not unregister the materialized view.

Syntax

```
DBMS_MVIEW.PURGE_MVIEW_FROM_LOG (  
  mview_id       IN   BINARY_INTEGER  |  
  mviewowner     IN   VARCHAR2,  
  mviewname      IN   VARCHAR2,  
  mviewsite      IN   VARCHAR2);  
```

**Note:** This procedure is overloaded. The mview_id parameter is mutually exclusive with the three remaining parameters: mviewowner, mviewname, and mviewsite.

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mview_id</td>
<td>If you want to execute this procedure based on the identification of the target materialized view, specify the materialized view identification using the mview_id parameter. Query the DBA_BASE_TABLE_MVIEWS view at the materialized view log site for a listing of materialized view IDs. Executing this procedure based on the materialized view identification is useful if the target materialized view is not listed in the list of registered materialized views (DBA_REGISTERED_MVIEWS).</td>
</tr>
<tr>
<td>mviewowner</td>
<td>If you do not specify an mview_id, enter the owner of the target materialized view using the mviewowner parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view owners.</td>
</tr>
<tr>
<td>mviewname</td>
<td>If you do not specify an mview_id, enter the name of the target materialized view using the mviewname parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view names.</td>
</tr>
<tr>
<td>mviewsite</td>
<td>If you do not specify an mview_id, enter the site of the target materialized view using the mviewsite parameter. Query the DBA_REGISTERED_MVIEWS view at the materialized view log site to view the materialized view sites.</td>
</tr>
</tbody>
</table>

Usage Notes

If there is an error while purging one of the materialized view logs, the successful purge operations of the previous materialized view logs are not rolled back. This is to minimize the size of the materialized view logs. In case of an error, this procedure can be invoked again until all the materialized view logs are purged.
REFRESH Procedures

This procedure refreshes a list of materialized views.

Syntax

```sql
DBMS_MVIEW.REFRESH (  
    { list IN VARCHAR2,  
    | tab IN DBMS_UTILITY.UNCL_ARRAY,}  
method IN VARCHAR2 := NULL,  
rollback_seg IN VARCHAR2 := NULL,  
push_deferred_rpc IN BOOLEAN := true,  
refresh_after_errors IN BOOLEAN := false,  
purge_option IN BINARY_INTEGER := 1,  
parallelism IN BINARY_INTEGER := 0,  
heap_size IN BINARY_INTEGER := 0,  
atomic_refresh IN BOOLEAN := true,  
nested IN BOOLEAN := false);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>list</td>
<td>tab</td>
</tr>
<tr>
<td>method</td>
<td>A string of refresh methods indicating how to refresh the listed materialized views. An f indicates fast refresh, ? indicates force refresh, C or c indicates complete refresh, and A or a indicates always refresh. A and C are equivalent. P or p refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables. If a materialized view does not have a corresponding refresh method (that is, if more materialized views are specified than refresh methods), then that materialized view is refreshed according to its default refresh method. For example, consider the following <code>EXECUTE</code> statement within SQL*Plus:</td>
</tr>
<tr>
<td>rollback_seg</td>
<td>Name of the materialized view site rollback segment to use while refreshing materialized views</td>
</tr>
</tbody>
</table>
### Table 93–10  (Cont.) REFRESH Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>push_deferred_rpc</td>
<td>Used by updatable materialized views only. Set this parameter to <code>true</code> if you want to push changes from the materialized view to its associated master tables or master materialized views before refreshing the materialized view. Otherwise, these changes may appear to be temporarily lost.</td>
</tr>
<tr>
<td>refresh_after_errors</td>
<td>If this parameter is <code>true</code>, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the <code>DEFERROR</code> view for the materialized view's master table or master materialized view. If this parameter is <code>true</code> and <code>atomic_refresh</code> is <code>false</code>, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.</td>
</tr>
<tr>
<td>purge_option</td>
<td>If you are using the parallel propagation mechanism (in other words, parallelism is set to 1 or greater), 0 means do not purge, 1 means lazy purge, and 2 means aggressive purge. In most cases, lazy purge is the optimal setting. Set purge to aggressive to trim the queue if multiple master replication groups are pushed to different target sites, and updates to one or more replication groups are infrequent and infrequently pushed. If all replication groups are infrequently updated and pushed, then set this parameter to 0 and occasionally execute \texttt{PUSH} with this parameter set to 2 to reduce the queue.</td>
</tr>
</tbody>
</table>
| parallelism             | 0 specifies serial propagation.  
|                         | \( n > 1 \) specifies parallel propagation with \( n \) parallel processes.  
|                         | 1 specifies parallel propagation using only one parallel process.  |
| heap_size               | Maximum number of transactions to be examined simultaneously for parallel propagation scheduling. Oracle automatically calculates the default setting for optimal performance.  
|                         | Note: Do not set this parameter unless directed to do so by Oracle Support Services.  |
| atomic_refresh          | If this parameter is set to `true`, then the list of materialized views is refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated.  
|                         | If this parameter is set to `false`, then each of the materialized views is refreshed in a separate transaction.  
|                         | As part of complete refresh, if truncate is used (non-atomic refresh), unique index rebuild is executed. `INDEX REBUILD` automatically computes statistics. Thus, statistics are updated for truncated tables.  |
| nested                  | If `true`, then perform nested refresh operations for the specified set of materialized views. Nested refresh operations refresh all the depending materialized views and the specified set of materialized views based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables. |
REFRESH_ALL_MVIEWS Procedure

This procedure refreshes all materialized views that have the following properties:

- The materialized view has not been refreshed since the most recent change to a master table or master materialized view on which it depends.
- The materialized view and all of the master tables or master materialized views on which it depends are local.
- The materialized view is in the view DBA_MVIEWS.

This procedure is intended for use with data warehouses.

Syntax

```sql
DBMS_MVIEW.REFRESH_ALL_MVIEWS (  
    number_of_failures   OUT   BINARY_INTEGER,  
    method               IN    VARCHAR2         := NULL,  
    rollback_seg         IN    VARCHAR2         := NULL,  
    refresh_after_errors IN    BOOLEAN          := false,  
    atomic_refresh       IN    BOOLEAN          := true);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number_of_failures</td>
<td>Returns the number of failures that occurred during processing</td>
</tr>
<tr>
<td>method</td>
<td>A single refresh method indicating the type of refresh to perform for each materialized view that is refreshed. P or f indicates fast refresh, f indicates force refresh, C or c indicates complete refresh, and A or a indicates always refresh. A and C are equivalent. If no method is specified, a materialized view is refreshed according to its default refresh method. P or p refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables.</td>
</tr>
<tr>
<td>rollback_seg</td>
<td>Name of the materialized view site rollback segment to use while refreshing materialized views</td>
</tr>
<tr>
<td>refresh_after_errors</td>
<td>If this parameter is true, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the DEFERROR view for the materialized view’s master table or master materialized view. If this parameter is true and atomic_refresh is false, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.</td>
</tr>
<tr>
<td>atomic_refresh</td>
<td>If this parameter is set to true, then the refreshed materialized views are refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated. If this parameter is set to false, then each of the refreshed materialized views is refreshed in a separate transaction.</td>
</tr>
</tbody>
</table>
REFRESH_DEPENDENT Procedures

This procedure refreshes all materialized views that have the following properties:

- The materialized view depends on a master table or master materialized view in the list of specified masters.
- The materialized view has not been refreshed since the most recent change to a master table or master materialized view on which it depends.
- The materialized view and all of the master tables or master materialized views on which it depends are local.
- The materialized view is in the view DBA_MVIEWS.

This procedure is intended for use with data warehouses.

Syntax

```sql
DBMS_MVIEW.REFRESH_DEPENDENT (
    number_of_failures     OUT    BINARY_INTEGER,
    { list                 IN     VARCHAR2,
      | tab                  IN     DBMS_UTILITY.UNCL_ARRAY,}
    method                 IN     VARCHAR2    := NULL,
    rollback_seg           IN     VARCHAR2    := NULL,
    refresh_after_errors   IN     BOOLEAN     := false,
    atomic_refresh         IN     BOOLEAN     := true,
    nested                 IN     BOOLEAN     := false);
```

Note: This procedure is overloaded. The list and tab parameters are mutually exclusive.

Parameters

**Table 93–12 REFRESH_DEPENDENT Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number_of_failures</td>
<td>Returns the number of failures that occurred during processing</td>
</tr>
<tr>
<td>list</td>
<td>Comma-delimited list of master tables or master materialized views on which materialized views can depend. (Synonyms are not supported.) These tables and the materialized views that depend on them can be located in different schemas. However, all of the tables and materialized views must be in your local database. Alternatively, you may pass in a PL/SQL index-by table of type DBMS_UTILITY.UNCL_ARRAY, where each element is the name of a table.</td>
</tr>
</tbody>
</table>
A string of refresh methods indicating how to refresh the dependent materialized views. All of the materialized views that depend on a particular table are refreshed according to the refresh method associated with that table. F or f indicates fast refresh, ? indicates force refresh, C or c indicates complete refresh, and A or a indicates always refresh. A and C are equivalent. P or p refreshes by recomputing the rows in the materialized view affected by changed partitions in the detail tables.

If a table does not have a corresponding refresh method (that is, if more tables are specified than refresh methods), then any materialized view that depends on that table is refreshed according to its default refresh method. For example, the following EXECUTE statement within SQL*Plus:

```sql
DBMS_MVIEW.REFRESH_DEPENDENT
    ('employees,departments,hr.regions','cf');
```

performs a complete refresh of the materialized views that depend on the `employees` table, a fast refresh of the materialized views that depend on the `departments` table, and a default refresh of the materialized views that depend on the `hr.regions` table.

**rollback_seg**
Name of the materialized view site rollback segment to use while refreshing materialized views

**refresh_after_errors**
If this parameter is true, an updatable materialized view continues to refresh even if there are outstanding conflicts logged in the DEFERROR view for the materialized view’s master table or master materialized view. If this parameter is true and atomic_refresh is false, this procedure continues to refresh other materialized views if it fails while refreshing a materialized view.

**atomic_refresh**
If this parameter is set to true, then the refreshed materialized views are refreshed in a single transaction. All of the refreshed materialized views are updated to a single point in time. If the refresh fails for any of the materialized views, none of the materialized views are updated.

If this parameter is set to false, then each of the refreshed materialized views is refreshed in a separate transaction.

**nested**
If true, then perform nested refresh operations for the specified set of tables. Nested refresh operations refresh all the depending materialized views of the specified set of tables based on a dependency order to ensure the nested materialized views are truly fresh with respect to the underlying base tables.
**REGISTER_MVIEW Procedure**

This procedure enables the administration of individual materialized views. It is invoked at a master site or master materialized view site to register a materialized view.

Note that, typically, a materialized view is registered automatically during materialized view creation. You should only run this procedure to manually register a materialized view if the automatic registration failed or if the registration information was deleted.

**Syntax**

```sql
DBMS_MVIEW.REGISTER_MVIEW (  
    mviewowner IN VARCHAR2,  
    mviewname IN VARCHAR2,  
    mviewsite IN VARCHAR2,  
    mview_id IN DATE | BINARY_INTEGER,  
    flag IN BINARY_INTEGER,  
    qry_txt IN VARCHAR2,  
    rep_type IN BINARY_INTEGER := DBMS_MVIEW.REG_UNKNOWN);  
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mviewowner</td>
<td>Owner of the materialized view.</td>
</tr>
<tr>
<td>mviewname</td>
<td>Name of the materialized view.</td>
</tr>
<tr>
<td>mviewsite</td>
<td>Name of the materialized view site for a materialized view registering at an Oracle database version 8.x and higher master site or master materialized view site. This name should not contain any double quotes.</td>
</tr>
<tr>
<td>mview_id</td>
<td>The identification number of the materialized view. Specify an Oracle database version 8.x and higher materialized view as a BINARY_INTEGER. Specify an Oracle database version 7 materialized view registering at an Oracle database version 8.x and higher master sites or master materialized view sites as a DATE.</td>
</tr>
<tr>
<td>flag</td>
<td>A constant that describes the properties of the materialized view being registered. Valid constants that can be assigned include the following: DBMS_MVIEW.REG_ROWID_MVIEW for a rowid materialized view DBMS_MVIEW.REG_PRIMARY_KEY_MVIEW for a primary key materialized view DBMS_MVIEW.REG_OBJECT_ID_MVIEW for an object id materialized view DBMS_MVIEW.REG_FAST_REFRESHABLE_MVIEW for a materialized view that can be fast refreshed DBMS_MVIEW.REG_UPDATABLE_MVIEW for a materialized view that is updatable A materialized view can have more than one of these properties. In this case, use the plus sign (+) to specify more than one property. For example, if a primary key materialized view can be fast refreshed, you can enter the following for this parameter: DBMS_MVIEW.REG_PRIMARY_KEY_MVIEW + DBMS_MVIEW.REG_FAST_REFRESHABLE_MVIEW You can determine the properties of a materialized view by querying the ALL_MVIEWS data dictionary view.</td>
</tr>
<tr>
<td>qry_txt</td>
<td>The first 32,000 bytes of the materialized view definition query.</td>
</tr>
</tbody>
</table>
**Usage Notes**

This procedure is invoked at the master site or master materialized view site by a remote materialized view site using a remote procedure call. If `REGISTER_MVIEW` is called multiple times with the same `mviewowner`, `mviewname`, and `mviewsite`, then the most recent values for `mview_id`, `flag`, and `qry_txt` are stored. If a query exceeds the maximum `VARCHAR2` size, then `qry_txt` contains the first 32000 characters of the query and the remainder is truncated. When invoked manually, the value of `mview_id` must be looked up in the materialized view data dictionary views by the person who calls the procedure.

---

### Table 93–13 (Cont.) REGISTER_MVIEW Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rep_type</td>
<td>Version of the materialized view. Valid constants that can be assigned include the following:</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.REG_V7_SNAPSHOT</code> if the materialized view is at an Oracle database version 7 site</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.REG_V8_SNAPSHOT</code> if the materialized view is at an Oracle database version 8.x or higher site</td>
</tr>
<tr>
<td></td>
<td><code>DBMS_MVIEW.REG_UNKNOWN</code> (the default) if you do not know whether the materialized view is at an Oracle database version 7 site or an Oracle database version 8.x (or higher) site</td>
</tr>
<tr>
<td>reg_repapi_snapshot</td>
<td>if the materialized view is at an Oracle database version 8.x or higher site</td>
</tr>
</tbody>
</table>

---
UNREGISTER_MVIEW Procedure

This procedure enables the administration of individual materialized views. It is invoked at a master site or master materialized view site to unregister a materialized view.

Syntax

```
DBMS_MVIEW.UNREGISTER_MVIEW (
    mviewowner  IN   VARCHAR2,
    mviewname   IN   VARCHAR2,
    mviewsite   IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mviewowner</td>
<td>Owner of the materialized view</td>
</tr>
<tr>
<td>mviewname</td>
<td>Name of the materialized view</td>
</tr>
<tr>
<td>mviewsite</td>
<td>Name of the materialized view site</td>
</tr>
</tbody>
</table>
The `DBMS_NETWORK_ACL_ADMIN` package provides the interface to administer the network Access Control List (ACL).

**See Also:** For more information, see "Managing Fine-grained Access to External Network Services" in Oracle Database Security Guide

The chapter contains the following topics:

- Using `DBMS_NETWORK_ACL_ADMIN`
  - Examples
- Summary of `DBMS_NETWORK_ACL_ADMIN` Subprograms
Using DBMS_NETWORK_ACL_ADMIN

- Examples
Examples

Example 1
Grant the connect and resolve privileges for host www.us.oracle.com to SCOTT.

BEGIN
DBMS_NETWORK_ACL_ADMIN.CREATE_ACL(acl => 'www.xml',
    description => 'WWW ACL',
    principal => 'SCOTT',
    is_grant => true,
    privilege => 'connect');

DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(acl => 'www.xml',
    principal => 'SCOTT',
    is_grant => true,
    privilege => 'resolve');

DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL(acl => 'www.xml',
    host => 'www.us.oracle.com');
END;
/
COMMIT;

Example 2
Grant the resolve privilege for www.us.oracle.com to ADAMS. Since an ACL for www.us.oracle.com exists already, just add the privilege for ADAMS.

BEGIN
DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(acl => 'www.xml',
    principal => 'ADAMS',
    is_grant => true,
    privilege => 'resolve');
END;
/
COMMIT;

Example 3
Assign the ACL www.xml to www-proxy.us.oracle.com so that SCOTT and ADAMS can access www-proxy.us.oracle.com also.

BEGIN
DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL(acl => 'www.xml',
    host => 'www-proxy.us.oracle.com');
END;
/
COMMIT;

Example 4
Unassign the ACL from www.us.oracle.com so that no access to www.us.oracle.com is allowed.

BEGIN
DBMS_NETWORK_ACL_ADMIN.UNASSIGN_ACL(host => 'www.us.oracle.com');
END;
/
COMMIT;
### Example 5

The **DOMAINS Function** in the DBMS_NETWORK_ACL_UTILITY package returns all the domains to which a host belongs. It can be used in conjunction with the **CHECK_PRIVILEGE_ACLID Function** in this package to determine the privilege assignments affecting a user's permission to access a network host. The function **DOMAIN_LEVEL Function** in the DBMS_NETWORK_ACL_UTILITY package returns the level of each domain and can be used to order the ACL assignments by their precedence.

For example, for SCOTT’s permission to connect to www.us.oracle.com:

```sql
SELECT host, lower_port, upper_port, acl,
       DECODE(
           DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'connect'),
           1, 'GRANTED', 0, 'DENIED', NULL) privilege
FROM dba_network_acls
WHERE host IN
    (SELECT * FROM TABLE(DBMS_NETWORK_ACL_UTILITY.DOMAINS('www.us.oracle.com')))
ORDER BY DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL(host) desc, lower_port, upper_port;
```

<table>
<thead>
<tr>
<th>Host</th>
<th>Lower_Port</th>
<th>Upper_Port</th>
<th>ACL</th>
<th>Privilege</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.us.oracle.com">www.us.oracle.com</a></td>
<td>80</td>
<td>80</td>
<td>/sys/acls/www.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td><a href="http://www.us.oracle.com">www.us.oracle.com</a></td>
<td>3000</td>
<td>3999</td>
<td>/sys/acls/www.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td><a href="http://www.us.oracle.com">www.us.oracle.com</a></td>
<td></td>
<td></td>
<td>/sys/acls/www.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td>*.oracle.com</td>
<td></td>
<td></td>
<td>/sys/acls/all.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td>*</td>
<td></td>
<td></td>
<td>/sys/acls/all.xml</td>
<td>GRANTED</td>
</tr>
</tbody>
</table>

### Example 6

For example, for SCOTT’s permission to do domain name resolution for www.us.oracle.com:

```sql
SELECT host, acl,
       DECODE(
           DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'resolve'),
           1, 'GRANTED', 0, 'DENIED', NULL) privilege
FROM dba_network_acls
WHERE host IN
    (SELECT * FROM TABLE(DBMS_NETWORK_ACL_UTILITY.DOMAINS('www.us.oracle.com'))) and
        lower_port IS NULL AND upper_port IS NULL
ORDER BY DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL(host) desc;
```

<table>
<thead>
<tr>
<th>Host</th>
<th>ACL</th>
<th>Privilege</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.us.oracle.com">www.us.oracle.com</a></td>
<td>/sys/acls/www.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td>*.oracle.com</td>
<td>/sys/acls/all.xml</td>
<td>GRANTED</td>
</tr>
<tr>
<td>*</td>
<td>/sys/acls/all.xml</td>
<td>GRANTED</td>
</tr>
</tbody>
</table>

Note that the 'resolve' privilege takes effect only in ACLs assigned without any port range (when `lower_port` and `upper_port` are NULL). For this reason, the example does not include `lower_port` and `upper_port` columns in the query.
## Summary of DBMS_NETWORK_ACL_ADMIN Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ADD_PRIVILEGE Procedure</strong> on page 94-6</td>
<td>Adds a privilege to grant or deny the network access to the user in an access control list (ACL)</td>
</tr>
<tr>
<td><strong>ASSIGN_ACL Procedure</strong> on page 94-7</td>
<td>Assigns an access control list (ACL) to a network host, and optionally specific to a TCP port range</td>
</tr>
<tr>
<td><strong>ASSIGN_WALLET_ACL Procedure</strong> on page 94-9</td>
<td>Assigns an access control list (ACL) to a wallet</td>
</tr>
<tr>
<td><strong>CHECK_PRIVILEGE Function</strong> on page 94-10</td>
<td>Checks if a privilege is granted to or denied from the user in an access control list (ACL)</td>
</tr>
<tr>
<td><strong>CHECK_PRIVILEGE_ACLID Function</strong> on page 94-11</td>
<td>Checks if a privilege is granted to or denied from the user in an ACL by specifying the object ID of the access control list</td>
</tr>
<tr>
<td><strong>CREATE_ACL Procedure</strong> on page 94-12</td>
<td>Creates an access control list (ACL) with an initial privilege setting</td>
</tr>
<tr>
<td><strong>DELETE_PRIVILEGE Procedure</strong> on page 94-13</td>
<td>Deletes a privilege in an access control list (ACL)</td>
</tr>
<tr>
<td><strong>DROP_ACL Procedure</strong> on page 94-14</td>
<td>Drops an access control list (ACL)</td>
</tr>
<tr>
<td><strong>UNASSIGN_ACL Procedure</strong> on page 94-15</td>
<td>Unassigns the access control list (ACL) currently assigned to a network host</td>
</tr>
<tr>
<td><strong>UNASSIGN_WALLET_ACL Procedure</strong> on page 94-16</td>
<td>Unassigns the access control list (ACL) currently assigned to a wallet</td>
</tr>
</tbody>
</table>
ADD_PRIVILEGE Procedure

This procedure adds a privilege to grant or deny the network access to the user. The access control entry (ACE) is created if it does not exist.

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE (  
  acl             IN VARCHAR2,  
  principal       IN VARCHAR2,  
  is_grant        IN BOOLEAN,  
  privilege       IN VARCHAR2,  
  position        IN PLS_INTEGER DEFAULT NULL,  
  start_date      IN TIMESTAMP WITH TIMESTAMP DEFAULT NULL,  
  end_date        IN TIMESTAMP WITH TIMESTAMP DEFAULT NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;</td>
</tr>
<tr>
<td>principal</td>
<td>Principal (database user or role) to whom the privilege is granted or denied. Case sensitive.</td>
</tr>
<tr>
<td>is_grant</td>
<td>Privilege is granted or denied.</td>
</tr>
<tr>
<td>privilege</td>
<td>Network privilege to be granted or denied</td>
</tr>
<tr>
<td>position</td>
<td>Position (1-based) of the ACE. If a non-NULL value is given, the privilege will be added in a new ACE at the given position and there should not be another ACE for the principal with the same is_grant (grant or deny). If a NULL value is given, the privilege will be added to the ACE matching the principal and the is_grant if one exists, or to the end of the ACL if the matching ACE does not exist.</td>
</tr>
<tr>
<td>start_date</td>
<td>Start date of the access control entry (ACE). When specified, the ACE will be valid only on and after the specified date. The start_date will be ignored if the privilege is added to an existing ACE.</td>
</tr>
<tr>
<td>end_date</td>
<td>End date of the access control entry (ACE). When specified, the ACE expires after the specified date. The end_date must be greater than or equal to the start_date. The end_date will be ignored if the privilege is added to an existing ACE.</td>
</tr>
</tbody>
</table>

Usage Notes

To remove the permission, use the DELETE_PRIVILEGE Procedure.

Examples

```sql
BEGIN
  DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(
    acl        => 'us-oracle-com-permissions.xml',
    principal  => 'ST_USERS',
    is_grant   => TRUE,
    privilege  => 'connect'
  )
END;
```
ASSIGN_ACL Procedure

This procedure assigns an access control list (ACL) to a host computer, domain, or IP subnet, and if specified, the TCP port range.

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL (    acl         IN VARCHAR2,    host        IN VARCHAR2,    lower_port  IN PLS_INTEGER DEFAULT NULL,    upper_port  IN PLS_INTEGER DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;.</td>
</tr>
<tr>
<td>host</td>
<td>Host to which the ACL is to be assigned. The host can be the name or the IP address of the host. A wildcard can be used to specify a domain or a IP subnet. The host or domain name is case-insensitive.</td>
</tr>
<tr>
<td>lower_port</td>
<td>Lower bound of a TCP port range if not NULL</td>
</tr>
<tr>
<td>upper_port</td>
<td>Upper bound of a TCP port range. If NULL, lower_port is assumed.</td>
</tr>
</tbody>
</table>

Usage Notes

- Only one ACL can be assigned to any host computer, domain, or IP subnet, and if specified, the TCP port range. When you assign a new access control list to a network target, Oracle Database unassigns the previous access control list that was assigned to the same target. However, Oracle Database does not drop the access control list. You can drop the access control list by using the DROP_ACL Procedure. To remove an access control list assignment, use the UNASSIGN_ACL Procedure.

- The ACL assigned to a domain takes a lower precedence than the other ACLs assigned sub-domains, which take a lower precedence than the ACLs assigned to the individual hosts. So for a given host, for example, "www.us.oracle.com", the following domains are listed in decreasing precedences:
  - www.us.oracle.com
  - *.us.oracle.com
  - *.oracle.com
  - *.com
  - *

  In the same way, the ACL assigned to an subnet takes a lower precedence than the other ACLs assigned smaller subnets, which take a lower precedence than the ACLs assigned to the individual IP addresses. So for a given IP address, for example, "192.168.0.100", the following subnets are listed in decreasing precedences:
ASSIGN_ACL Procedure

- 192.168.0.100
- 192.168.0.*
- 192.168.*
- 192.*
- *

- The port range is applicable only to the "connect" privilege assignments in the ACL. The "resolve" privilege assignments in an ACL have effects only when the ACL is assigned to a host without a port range.

For the "connect" privilege assignments, an ACL assigned to the host without a port range takes a lower precedence than other ACLs assigned to the same host with a port range.

- When specifying a TCP port range, both lower_port and upper_port must not be NULL and upper_port must be greater than or equal to lower_port. The port range must not overlap with any other port ranges for the same host assigned already.

- To remove the assignment, use UNASSIGN_ACL Procedure.

Examples

BEGIN
  DBMS_NETWORK_ACL_ADMIN.ASSIGN_ACL(
    acl => 'us-oracle-com-permissions.xml',
    host => '*.us.oracle.com',
    lower_port => 80);
END;
ASSIGN_WALLET_ACL Procedure

This procedure assigns an access control list (ACL) to a wallet.

Syntax

```sql
UTL_HTTP.ASSIGN_WALLET_ACL (  
    acl          IN  VARCHAR2,  
    wallet_path  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;</td>
</tr>
<tr>
<td>wallet_path</td>
<td>Directory path of the wallet to which the ACL is to be assigned. The path is case-sensitive and of the format <code>file:directory-path</code></td>
</tr>
</tbody>
</table>

Usage Notes

To remove the assignment, use the UNASSIGN_WALLET_ACL Procedure.

Examples

```sql
BEGIN
  DBMS_NETWORK_ACL_ADMIN.CREATE_ACL(
    acl => 'wallet-acl.xml',
    description => 'Wallet ACL',
    principal => 'SCOTT',
    is_grant => TRUE,
    privilege => 'use-client-certificates');

  DBMS_NETWORK_ACL_ADMIN.ADD_PRIVILEGE(
    acl => 'wallet-acl.xml',
    principal => 'SCOTT',
    is_grant => TRUE,
    privilege => 'use-passwords');

  DBMS_NETWORK_ACL_ADMIN.ASSIGN_WALLET_ACL(
    acl => 'wallet-acl.xml',
    wallet_path => 'file:/oracle/wallets/test_wallet');
END;
```
CHECK_PRIVILEGE Function

This function checks if a privilege is granted to or denied from the user in an ACL.

Syntax

DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE (  
  acl               IN VARCHAR2,  
  user             IN VARCHAR2,  
  privilege       IN VARCHAR2)  
RETURN NUMBER;

Parameters

Table 94–5  CHECK_PRIVILEGE Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;.</td>
</tr>
<tr>
<td>user</td>
<td>User to check against. If the user is NULL, the invoker is assumed. The username is case-sensitive as in the USERNAME column of the ALL_USERS view.</td>
</tr>
<tr>
<td>privilege</td>
<td>Network privilege to check</td>
</tr>
</tbody>
</table>

Return Values

Returns 1 when the privilege is granted; 0 when the privilege is denied; NULL when the privilege is neither granted or denied.

Examples

SELECT DECODE(  
  DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE(  
    'us-oracle-com-permissions.xml', 'SCOTT', 'resolve'),  
  1, 'GRANTED', 0, 'DENIED', NULL) PRIVILEGE  
FROM DUAL;
CHECK_PRIVILEGE_ACLID Function

This function checks if a privilege is granted to or denied from the user in an ACL by specifying the object ID of the access control list.

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID (    aclid IN RAW,    user IN VARCHAR2 DEFAULT NULL)    privilege IN VARCHAR2, RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>aclid</td>
<td>Object ID of the ACL</td>
</tr>
<tr>
<td>user</td>
<td>User to check against. If the user is NULL, the invoker is assumed. The username is case-sensitive as in the USERNAME column of the ALL_USERS view.</td>
</tr>
<tr>
<td>privilege</td>
<td>Network privilege to check</td>
</tr>
</tbody>
</table>

Return Values

Returns 1 when the privilege is granted; 0 when the privilege is denied; NULL when the privilege is neither granted or denied.
CREATE_ACL Procedure

This procedure creates an access control list (ACL) with an initial privilege setting. An ACL must have at least one privilege setting. The ACL has no access control effect unless it is assigned to the network target.

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.CREATE_ACL (
    acl             IN VARCHAR2,
    description     IN VARCHAR2,
    principal       IN VARCHAR2,
    is_grant        IN BOOLEAN,
    privilege       IN VARCHAR2,
    start_date      IN TIMESTAMP WITH TIMEZONE DEFAULT NULL,
    end_date        IN TIMESTAMP WITH TIMEZONE DEFAULT NULL );
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;.</td>
</tr>
<tr>
<td>description</td>
<td>Description attribute in the ACL</td>
</tr>
<tr>
<td>principal</td>
<td>Principal (database user or role) to whom the privilege is granted or denied. Case sensitive.</td>
</tr>
<tr>
<td>is_grant</td>
<td>Privilege is granted or not (denied)</td>
</tr>
<tr>
<td>privilege</td>
<td>Network privilege to be granted or denied - 'connect</td>
</tr>
<tr>
<td>start_date</td>
<td>Start date of the access control entry (ACE). When specified, the ACE is valid only on and after the specified date.</td>
</tr>
<tr>
<td>end_date</td>
<td>End date of the access control entry (ACE). When specified, the ACE expires after the specified date. The end_date must be greater than or equal to the start_date.</td>
</tr>
</tbody>
</table>

Usage Notes

To drop the access control list, use the DROP_ACL Procedure.

Examples

```sql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.CREATE_ACL(
        acl => 'us-oracle-com-permissions.xml',
        description => 'Network permissions for *.us.oracle.com',
        principal => 'SCOTT',
        is_grant => TRUE,
        privilege => 'connect');
END;
```
DELETE_PRIVILEGE Procedure

This procedure deletes a privilege in an access control list.

Syntax

```
DBMS_NETWORK_ACL_ADMIN.DELETE_PRIVILEGE (
    acl           IN VARCHAR2,
    principal     IN VARCHAR2,
    is_grant      IN BOOLEAN DEFAULT NULL,
    privilege     IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;.</td>
</tr>
<tr>
<td>principal</td>
<td>Principal (database user or role) for whom all the ACE will be deleted</td>
</tr>
<tr>
<td>is_grant</td>
<td>Privilege is granted or not (denied). If a NULL value is given, the deletion is applicable to both granted or denied privileges.</td>
</tr>
<tr>
<td>privilege</td>
<td>Network privilege to be deleted. If a NULL value is given, the deletion is applicable to all privileges.</td>
</tr>
</tbody>
</table>

Examples

```
BEGIN
    DBMS_NETWORK_ACL_ADMIN.DELETE_PRIVILEGE(
        acl => 'us-oracle-com-permissions.xml',
        principal => 'ST_USERS')
END;
```
DROP_ACL Procedure

This procedure drops an access control list (ACL).

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.DROP_ACL (  
    acl IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;.</td>
</tr>
</tbody>
</table>

Examples

```sql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.DROP_ACL(
        acl => 'us-oracle-com-permissions.xml');
END;
```
UNASSIGN_ACL Procedure

This procedure unassigns the access control list (ACL) currently assigned to a network host.

Syntax

```sql
DBMS_NETWORK_ACL_ADMIN.UNASSIGN_ACL (    
acl IN VARCHAR2 DEFAULT NULL,    
host IN VARCHAR2 DEFAULT NULL,    
lower_port IN PLS_INTEGER DEFAULT NULL,    
upper_port IN PLS_INTEGER DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>acl</td>
<td>Name of the ACL. Relative path will be relative to &quot;/sys/acls&quot;. If ACL is NULL, any ACL assigned to the host is unassigned.</td>
</tr>
<tr>
<td>host</td>
<td>Host from which the ACL is to be removed. The host can be the name or the IP address of the host. A wildcard can be used to specify a domain or a IP subnet. The host or domain name is case-insensitive. If host is NULL, the ACL will be unassigned from any host. If both host and acl are NULL, all ACLs assigned to any hosts are unassigned.</td>
</tr>
<tr>
<td>lower_port</td>
<td>Lower bound of a TCP port range if not NULL</td>
</tr>
<tr>
<td>upper_port</td>
<td>Upper bound of a TCP port range. If NULL, lower_port is assumed.</td>
</tr>
</tbody>
</table>

Examples

```sql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.UNASSIGN_ACL(
        host => '*.us.oracle.com',
        lower_port => 80);
END;
```
UNASSIGN_WALLET_ACL Procedure

This procedure unassigns the access control list (ACL) currently assigned to a wallet.

Syntax

```plsql
UTL_HTTP.UNASSIGN_WALLET_ACL (
    acl          IN  VARCHAR2 DEFAULT NULL,
    wallet_path  IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| acl         | Name of the ACL. Relative path will be relative to 
"/sys/acls". If acl is NULL, any ACL assigned to the wallet is unassigned. |
| wallet_path | Directory path of the wallet to which the ACL is assigned. The path is case-sensitive and of the format file:directory-path. If both acl and wallet_path are NULL, all ACLs assigned to any wallets are unassigned. |

Examples

```plsql
BEGIN
    DBMS_NETWORK_ACL_ADMIN.UNASSIGN_WALLET_ACL(
        acl => 'wallet-acl.xml',
        wallet_path => 'file:/oracle/wallets/test_wallet');
END;
```
The `DBMS_NETWORK_ACL_UTIL` package provides the utility functions to facilitate the evaluation of access control list (ACL) assignments governing TCP connections to network hosts.

**See Also:** For more information, see "Managing Fine-grained Access to External Network Services" in Oracle Database Security Guide

The chapter contains the following topics:

  - Examples
- **Summary of DBMS_NETWORK_ACL_UTIL Subprograms**
Using DBMS_NETWORK_ACLUTILITY

- Examples
Examples

The \texttt{CONTAINS\_HOST} Function in this package indicates if a domain or subnet contains a given host or IP address. It can be used in conjunction with the \texttt{CHECK\_PRIVILEGE\_ACLID} Function in the \texttt{DBMS\_NETWORK\_ACL\_ADMIN} package to determine the privilege assignments affecting a user's permission to access a network host. The return value of the \texttt{CONTAINS\_HOST} Function in can also be used to order the ACL assignments by their precedence.

Example 1
For example, for SCOTT's permission to connect to www.hr.example.com:

\begin{verbatim}
SELECT host, lower_port, upper_port, acl,
   DECODE(
      DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'connect'),
         1, 'GRANTED', 0, 'DENIED', NULL) privilege
FROM (SELECT host, acl, aclid, lower_port, upper_port,
      DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.hr.example.com', host)
      precedence
      FROM dba_network_acls)
WHERE precedence > 0
ORDER BY precedence DESC, lower_port nulls LAST;
\end{verbatim}

\begin{tabular}{lcccr}
\hline
HOST & LOWER_PORT & UPPER_PORT & ACL & PRIVILEGE \\
\hline
www.hr.example.com & 80 & 80 & /sys/acls/www.xml & GRANTED \\
www.hr.example.com & 3000 & 3999 & /sys/acls/www.xml & GRANTED \\
www.hr.example.com & & & /sys/acls/www.xml & GRANTED \\
*.hr.example.com & & & /sys/acls/all.xml & \\
*.example.com & & & /sys/acls/all.xml & \\
\hline
\end{tabular}

Example 2
For example, for SCOTT's permission to do domain name resolution for www.hr.example.com:

\begin{verbatim}
SELECT host, acl,
   DECODE(
      DBMS_NETWORK_ACL_ADMIN.CHECK_PRIVILEGE_ACLID(aclid, 'SCOTT', 'resolve'),
         1, 'GRANTED', 0, 'DENIED', null) privilege
FROM (SELECT host, acl, aclid,
      DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('www.hr.example.com', host)
      precedence
      FROM dba_network_acls
      WHERE lower_port IS NULL AND upper_port IS NULL)
WHERE precedence > 0
ORDER BY precedence DESC;
\end{verbatim}

\begin{tabular}{lcc}
\hline
HOST & ACL & PRIVILEGE \\
\hline
www.hr.example.com & /sys/acls/hr-www.xml & GRANTED \\
*.hr.example.com & /sys/acls/hr-domain.xml & \\
*.example.com & /sys/acls/corp-domain.xml & \\
\hline
\end{tabular}

Note that the "resolve" privilege takes effect only in ACLs assigned without any port range (when \texttt{lower_port} and \texttt{upper_port} are \texttt{NULL}). For this reason, the example does not include \texttt{lower_port} and \texttt{upper_port} columns in the query.
Summary of DBMS_NETWORK_ACL_UTILITY Subprograms

Table 95–1  DBMS_NETWORK_ACL_UTILITY Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONTAINS_HOST Function on page 95-5</td>
<td>Determines if the given host is equal to or contained in the given host, domain, or subnet</td>
</tr>
<tr>
<td>DOMAIN_LEVEL Function on page 95-6</td>
<td>Returns the domain level of the given host name, domain, or subnet</td>
</tr>
<tr>
<td>DOMAINS Function on page 95-7</td>
<td>For a given host, this function returns the domains whose ACL assigned is used to determine if a user has the privilege to access the given host or not.</td>
</tr>
<tr>
<td>EQUALS_HOST Function on page 95-8</td>
<td>Determines if the two given hosts, domains, or subnets are equal</td>
</tr>
</tbody>
</table>
CONTAINS_HOST Function

This function determines if the given host is equal to or contained in the given host, domain, or subnet. It handles different representation of the same IP address or subnet. For example, an IPv4-mapped IPv6 address is considered equal to the IPv4-native address it represents. It does not perform domain name resolution when evaluating the host or domain.

Syntax

```sql
DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST (host IN VARCHAR2, domain IN VARCHAR2) RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Network host</td>
</tr>
<tr>
<td>domain</td>
<td>Network host, domain, or subnet</td>
</tr>
</tbody>
</table>

Return Values

Returns a non-NULL value if the given host is equal to or contained in the related host, domain, or subnet:

- If `domain` is a hostname, returns the level of its domain + 1
- If `domain` is a domain name, returns the domain level
- If `domain` is an IP address or subnet, return the number of significant address bits of the IP address or subnet
- If `domain` is the wildcard "*", returns 0

The non-NULL value returned indicates the precedence of the domain or subnet for ACL assignment. The higher the value, the higher is the precedence. NULL will be returned if the host is not equal to or contained in the given host, domain or subnet.

Examples

```sql
SELECT host, acl, precedence
FROM (select host, acl,
       DBMS_NETWORK_ACL_UTILITY.CONTAINS_HOST('192.0.2.3', host)
       precedence
       FROM dba_network_acls)
WHERE precedence > 0
ORDER BY precedence DESC;
```

<table>
<thead>
<tr>
<th>HOST</th>
<th>ACL</th>
<th>PRECEDENCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.0.2.3</td>
<td>/sys/acls/hr-www.xml</td>
<td>32</td>
</tr>
<tr>
<td>::ffff:192.0.2.0/120</td>
<td>/sys/acls/hr-domain.xml</td>
<td>24</td>
</tr>
<tr>
<td>::ffff:192.0.0.0/104</td>
<td>/sys/acls/corp-domain.xml</td>
<td>8</td>
</tr>
</tbody>
</table>
DOMAIN_LEVEL Function

This function returns the domain level of the given host name, domain, or subnet.

Syntax

```sql
DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL (host  IN VARCHAR2)
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Network host, domain, or subnet</td>
</tr>
</tbody>
</table>

Return Values

The domain level of the given host, domain, or subnet.

Usage Notes

Note that this function cannot handle IPv6 addresses and subnets, and subnets in CIDR notation.

Examples

```sql
SELECT host, acl, domain_level
FROM (select host, acl,
       DBMS_NETWORK_ACL_UTILITY.DOMAIN_LEVEL(host) domain_level
FROM dba_network_acls)
order by domain_level desc;
```

<table>
<thead>
<tr>
<th>HOST</th>
<th>ACL</th>
<th>DOMAIN_LEVEL</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.hr.example.com">www.hr.example.com</a></td>
<td>/sys/acls/hr-www.xml</td>
<td>4</td>
</tr>
<tr>
<td>*.hr.example.com</td>
<td>/sys/acls/hr-domain.xml</td>
<td>3</td>
</tr>
<tr>
<td>*.example.com</td>
<td>/sys/acls/corp-domain.xml</td>
<td>2</td>
</tr>
</tbody>
</table>
**DOMAINS Function**

For a given host, this function returns the domains whose ACL assigned determines if a user has the privilege to access the given host or not. When the IP address of the host is given, return the subnets instead.

**Syntax**

```sql
DBMS_NETWORK_ACL_UTILITY.DOMAINS (
    host  IN VARCHAR2)
RETURN DOMAIN_TABLE PIPELINED;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host</td>
<td>Network host</td>
</tr>
</tbody>
</table>

**Return Values**

The domains or subnets for the given host.

**Usage Notes**

Note that this function cannot handle IPv6 addresses. Nor can it generate subnets of arbitrary number of prefix bits for an IPv4 address.

**Examples**

```sql
select * from table(dbms_network_acl_utility.domains('www.hr.example.com'));
```

```sql
DOMAINS
---------
www.hr.example.com
*.hr.example.com
*.example.com
*.com
*
```
EQUALS_HOST Function

This function determines if the two given hosts, domains, or subnets are equal. It handles different representation of the same IP address or subnet. For example, an IPv4-mapped IPv6 address is considered equal to the IPv4-native address it represents. It does not perform domain name resolution when comparing the two hosts or domains.

Syntax

```sql
DBMS_NETWORK_ACL_UTILITY.EQUALS_HOST (
    host1    IN    VARCHAR2,
    host2    IN    VARCHAR2)
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>host1</td>
<td>Network host, domain, or subnet to compare</td>
</tr>
<tr>
<td>host2</td>
<td>Network host, domain, or subnet to compare</td>
</tr>
</tbody>
</table>

Return Values

1 if the two hosts, domains, or subnets are equal. 0 otherwise.

Examples

```sql
SELECT host, acl
FROM dba_network_acls
WHERE DBMS_NETWORK_ACL_UTILITY.EQUALS_HOST('192.0.2.*', host) = 1;
```

```
HOST          ACL
------------- -----------------------------
::ffff:192.0.2.0/120  /sys/acls/hr-domain.xml
```
DBMS_OBFUSCATION_TOOLKIT enables an application to encrypt data using either the Data Encryption Standard (DES) or the Triple DES algorithms.

---

**Note:** DBMS_OBFUSCATION_TOOLKIT is deprecated. DBMS_CRYPTO is intended to replace the DBMS_OBFUSCATION_TOOLKIT, providing greater ease of use and support for a range of algorithms to accommodate new and existing systems. See Chapter 39, "DBMS_CRYPTO" for more information.

  - Security Model
  - Operational Notes

- **Summary of DBMS_OBFUSCATION Subprograms**
Using DBMS_OBFUSCATION_TOOLKIT

- Overview
- Security Model
- Operational Notes
Overview

The Data Encryption Standard (DES), also known as the Data Encryption Algorithm (DEA) by the American National Standards Institute (ANSI) and DEA-1 by the International Standards Organization (ISO), has been a worldwide encryption standard for over 20 years. The banking industry has also adopted DES-based standards for transactions between private financial institutions, and between financial institutions and private individuals. DES will eventually be replaced by a new Advanced Encryption Standard (AES).

DES is a symmetric key cipher; that is, the same key is used to encrypt data as well as decrypt data. DES encrypts data in 64-bit blocks using a 56-bit key. The DES algorithm ignores 8 bits of the 64-bit key that is supplied; however, you must supply a 64-bit key to the algorithm.

Triple DES (3DES) is a far stronger cipher than DES; the resulting ciphertext (encrypted data) is much harder to break using an exhaustive search: $2^{112}$ or $2^{168}$ attempts instead of $2^{56}$ attempts. Triple DES is also not as vulnerable to certain types of cryptanalysis as is DES.
Oracle installs this package in the SYS schema. You can then grant package access to existing users and roles as needed. The package also grants access to the PUBLIC role so no explicit grant needs to be done.
Operational Notes

Key Management

Key management, including both generation and secure storage of cryptographic keys, is one of the most important aspects of encryption. If keys are poorly chosen or stored improperly, then it is far easier for a malefactor to break the encryption. Rather than using an exhaustive key search attack (that is, cycling through all the possible keys in hopes of finding the correct decryption key), cryptanalysts typically seek weaknesses in the choice of keys, or the way in which keys are stored.

Key generation is an important aspect of encryption. Typically, keys are generated automatically through a random-number generator. Provided that the random number generation is cryptographically secure, this can be an acceptable form of key generation. However, if random numbers are not cryptographically secure, but have elements of predictability, the security of the encryption may be easily compromised.

The DBMS_OBFUSCATION_TOOLKIT package includes tools for generating random material that can be used for encryption keys, but it does not provide a mechanism for maintaining them. Care must be taken by the application developer to ensure the secure generation and storage of encryption keys used with this package.

Furthermore, the encryption and decryption done by the DBMS_OBFUSCATION_TOOLKIT takes place on the server, not the client. If the key is passed over the connection between the client and the server, the connection must be protected by using network encryption. Otherwise, the key is vulnerable to capture over the wire. See Oracle Database Advanced Security Administrator’s Guide for information about configuring and using network encryption for Oracle Net.

Key storage is one of the most important, yet difficult aspects of encryption and one of the hardest to manage properly. To recover data encrypted with a symmetric key, the key must be accessible to the application or user seeking to decrypt data. The key needs to be easy enough to retrieve that users can access encrypted data when they need to without significant performance degradation. The key also needs to be secure enough that it is not easily recoverable by unauthorized users trying to access encrypted data that they are not supposed to see.

The three options available are:

- Store the key in the database
- Store the key in the operating system
- Have the user manage the key

Storing the Key in the Database

Storing the keys in the database cannot always provide bullet-proof security if you are trying to protect data against the DBA accessing encrypted data (since an all-privileged DBA can access tables containing encryption keys), but it can provide
security against the casual snooper, or against someone compromising the database files on the operating system. Furthermore, the security you can obtain by storing keys in the database does not have to be bullet-proof in order to be extremely useful.

For example, suppose you want to encrypt an employee's social security number, one of the columns in table EMP. You could encrypt each employee's SSN using a key which is stored in a separate column in EMP. However, anyone with SELECT access on the EMP table could retrieve the encryption key and decrypt the matching social security number. Alternatively, you could store the encryption keys in another table, and use a package to retrieve the correct key for the encrypted data item, based on a primary key-foreign key relationship between the tables.

You can envelope both the DBMS_OBFUSCATION_TOOLKIT package and the procedure to retrieve the encryption keys supplied to the package. Furthermore, the encryption key itself could be transformed in some way (for example, XORed with the foreign key to the EMP table) so that the key itself is not stored in easily recoverable form.

Oracle recommends using the wrap utility of PL/SQL to obfuscate the code within a PL/SQL package itself that does the encryption. That prevents people from breaking the encryption by looking at the PL/SQL code that handles keys, calls encrypting routines, and so on. In other words, use the wrap utility to obfuscate the PL/SQL packages themselves. This scheme is secure enough to prevent users with SELECT access to EMP from reading unencrypted sensitive data, and a DBA from easily retrieving encryption keys and using them to decrypt data in the EMP table. It can be made more secure by changing encryption keys regularly, or having a better key storage algorithm (so the keys themselves are encrypted, for example).

Storing the Key in the Operating System

Storing keys in a flat file in the operating system is another option. You can make callouts from PL/SQL, which you can use to retrieve encryption keys. If you store keys in a file and make callouts to retrieve the keys, the security of your encrypted data is only as secure as the protection of the key file on the operating system. Of course, a user retrieving keys from the operating system would have to be able to either access the Oracle database files (to decrypt encrypted data), or be able to gain access to the table in which the encrypted data is stored as a legitimate user.

User-Supplied Keys

If you ask a user to supply the key, it is crucial that you use network encryption, such as that provided by Oracle Advanced Security, so the key is not passed from client to server in the clear. The user must remember the key, or your data is not recoverable.
## Summary of DBMS_OBFUSCATION Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DES3DECrypt Procedures and Functions on page 96-8</td>
<td>Generates the decrypted form of the input data</td>
</tr>
<tr>
<td>DES3ENCRYPT Procedures and Functions on page 96-10</td>
<td>Generates the encrypted form of the input data by passing it through the Triple DES encryption algorithm</td>
</tr>
<tr>
<td>DES3GETKEY Procedures and Functions on page 96-8</td>
<td>Takes a random value and uses it to generate an encryption key, using Triple DES</td>
</tr>
<tr>
<td>DESDECRYPT Procedures and Functions on page 96-13</td>
<td>Generates the decrypted form of the input data</td>
</tr>
<tr>
<td>DESENCRYPT Procedures and Functions on page 96-15</td>
<td>Generates the encrypted form of the input data</td>
</tr>
<tr>
<td>DESGETKEY Procedures and Functions on page 96-17</td>
<td>Takes a random value and uses it to generate an encryption key</td>
</tr>
<tr>
<td>MD5 Procedures and Functions on page 96-18</td>
<td>Generates MD5 hashes of data</td>
</tr>
</tbody>
</table>
These subprograms generate the decrypted form of the input data.

For a discussion of the initialization vector that you can use with this procedure, see the section, "DES3ENCRYPT Procedures and Functions" on page 96-10.

**Syntax**

```
DBMS_OBFUSCATION_TOOLKIT.DES3DECRYPT(
    input             IN   RAW,
    key               IN   RAW,
    decrypted_data    OUT  RAW,
    which             IN   PLS_INTEGER  DEFAULT TwoKeyMode
    iv                IN   RAW          DEFAULT NULL);

DBMS_OBFUSCATION_TOOLKIT.DES3DECRYPT(
    input_string      IN   VARCHAR2,
    key_string        IN   VARCHAR2,
    decrypted_string  OUT  VARCHAR2,
    which             IN   PLS_INTEGER  DEFAULT TwoKeyMode
    iv_string         IN   VARCHAR2     DEFAULT NULL);

DBMS_OBFUSCATION_TOOLKIT.DES3DECRYPT(
    input         IN  RAW,
    key           IN  RAW,
    which         IN  PLS_INTEGER DEFAULT TwoKeyMode
    iv            IN  RAW         DEFAULT NULL)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DES3DECRYPT(
    input_string  IN  VARCHAR2,
    key_string    IN  VARCHAR2,
    which         IN  PLS_INTEGER DEFAULT TwoKeyMode
    iv_string     IN  VARCHAR2    DEFAULT NULL)
RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Data to be decrypted</td>
</tr>
<tr>
<td>key</td>
<td>Decryption key</td>
</tr>
<tr>

<td>Decrypted string</td>
</tr>
<tr>
<td>iv_string</td>
<td>Initialization vector</td>
</tr>
</tbody>
</table>
Usage Notes

If the input data or key given to the `DES3DECRYPT` procedure is empty, then the procedure raises the error ORA-28231 "Invalid input to Obfuscation toolkit."

If the input data given to the `DES3DECRYPT` procedure is not a multiple of 8 bytes, the procedure raises the error ORA-28232 "Invalid input size for Obfuscation toolkit." ORA-28233 is NOT applicable for the `DES3DECRYPT` function.

If the key length is missing or is less than 8 bytes, then the procedure raises the error ORA-28234 "Key length too short." Note that if larger keys are used, extra bytes are ignored. So a 9-byte key will not generate an exception.

If an incorrect value is specified for the `WHICH` parameter, ORA-28236 "Invalid Triple DES mode" is generated. Only the values 0 (TwoKeyMode) and 1 (ThreeKeyMode) are valid.

Restrictions

You must supply a single key of either 128 bits for a 2-key implementation (of which only 112 are used), or a single key of 192 bits for a 3-key implementation (of which 168 bits are used). Oracle automatically truncates the supplied key into 56-bit lengths for decryption. This key length is fixed and cannot be altered.

**Note:** Both the key length limitation and the prevention of multiple encryption passes are requirements of U.S. regulations governing the export of cryptographic products.
These subprograms generate the encrypted form of the input data by passing it through the Triple DES (3DES) encryption algorithm.

Oracle’s implementation of 3DES supports either a 2-key or 3-key implementation, in outer cipher-block-chaining (CBC) mode.

**Syntax**

```sql
DBMS_OBFUSCATION_TOOLKIT.DES3Encrypt(
    input           IN     RAW,
    key             IN     RAW,
    encrypted_data  OUT    RAW,
    which           IN     PLS_INTEGER  DEFAULT TwoKeyMode
    iv              IN     RAW          DEFAULT NULL);

DBMS_OBFUSCATION_TOOLKIT.DES3Encrypt(
    input_string      IN     VARCHAR2,
    key_string        IN     VARCHAR2,
    encrypted_string  OUT    VARCHAR2,
    which             IN     PLS_INTEGER  DEFAULT TwoKeyMode
    iv_string         IN     VARCHAR2     DEFAULT NULL);

DBMS_OBFUSCATION_TOOLKIT.DES3Encrypt(
    input        IN RAW,
    key          IN RAW,
    which        IN PLS_INTEGER DEFAULT TwoKeyMode
    iv           IN RAW         DEFAULT NULL)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DES3Encrypt(
    input_string  IN VARCHAR2,
    key_string    IN VARCHAR2,
    which         IN PLS_INTEGER DEFAULT TwoKeyMode
    iv_string     IN VARCHAR2    DEFAULT NULL)
RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>

<td>encrypted_string</td>
<td>Encrypted string.</td>
</tr>
<tr>
<td>iv_string</td>
<td>Initialization vector.</td>
</tr>
</tbody>
</table>
Usage Notes

If you are using Oracle's 3DES interface with a 2-key implementation, you must supply a single key of 128 bits as an argument to the \texttt{DES3ENCRYPT} procedure. With a 3-key implementation, you must supply a single key of 192 bits. Oracle then breaks the supplied key into two 64-bit keys. As with DES, the 3DES algorithm throws away 8 bits of each derived key. However, you must supply a single 128-bit key for the 2-key 3DES implementation or a single 192-bit key for the 3-key 3DES implementation; otherwise the package will raise an error. The \texttt{DES3ENCRYPT} procedure uses the 2-key implementation by default.

You also have the option of providing an \textit{initialization vector} (IV) with the \texttt{DES3ENCRYPT} procedure. An IV is a block of random data prepended to the data you intend to encrypt. The IV has no meaning. It is there to make each message unique. Prepending an IV to your input data avoids starting encrypted blocks of data with common header information, which may give cryptanalysts information they can use to decrypt your data.

If the input data or key given to the PL/SQL \texttt{DES3ENCRYPT} procedure is empty, then the procedure raises the error \texttt{ORA-28231} "Invalid input to Obfuscation toolkit."

If the input data given to the \texttt{DES3ENCRYPT} procedure is not a multiple of 8 bytes, the procedure raises the error \texttt{ORA-28232} "Invalid input size for Obfuscation toolkit."

If you try to double encrypt data using the \texttt{DES3ENCRYPT} procedure, then the procedure raises the error \texttt{ORA-28233} "Double encryption not supported."

If the key length is missing or is less than 8 bytes, then the procedure raises the error \texttt{ORA-28234} "Key length too short." Note that if larger keys are used, extra bytes are ignored. So a 9-byte key will not generate an exception.

If an incorrect value is specified for the \texttt{which} parameter, \texttt{ORA-28236} "Invalid Triple DES mode" is generated. Only the values 0 (\texttt{TwoKeyMode}) and 1 (\texttt{ThreeKeyMode}) are valid.

Restrictions

The \texttt{DES3ENCRYPT} procedure has two restrictions. The first is that the DES key length for encryption is fixed at 128 bits (for 2-key DES) or 192 bits (for 3-key DES); you cannot alter these key lengths.

The second is that you cannot execute multiple passes of encryption using 3DES. (Note: the 3DES algorithm itself encrypts data multiple times; however, you cannot call the \texttt{DES3ENCRYPT} function itself more than once to encrypt the same data using 3DES.)

\textbf{Note:} Both the key length limitation and the prevention of multiple encryption passes are requirements of U.S. regulations governing the export of cryptographic products.
**DES3GETKEY Procedures and Functions**

These subprograms take a random value and uses it to generate an encryption key. For Triple DES, you specify the mode so that the returned key has the proper length.

**Syntax**

```sql
DBMS_OBFUSCATION_TOOLKIT.DES3GetKey(
    which        IN   PLS_INTEGER DEFAULT TwoKeyMode,
    seed         IN   RAW,
    key          OUT  RAW);

DBMS_OBFUSCATION_TOOLKIT.DES3GetKey(
    which        IN   PLS_INTEGER DEFAULT TwoKeyMode,
    seed_string  IN   VARCHAR2,
    key          OUT  VARCHAR2);

DBMS_OBFUSCATION_TOOLKIT.DES3GetKey(
    which  IN  PLS_INTEGER DEFAULT TwoKeyMode,
    seed   IN  RAW)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DES3GetKey(
    which        IN  PLS_INTEGER DEFAULT TwoKeyMode,
    seed_string  IN  VARCHAR2)
RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>which</td>
<td>If = 0, (default), then TwoKeyMode is used. If = 1, then ThreeKeyMode is used.</td>
</tr>
<tr>
<td>seed</td>
<td>A value at least 80 characters long.</td>
</tr>
<tr>
<td>key</td>
<td>Encryption key.</td>
</tr>
<tr>
<td>seed_string</td>
<td>A value at least 80 characters long.</td>
</tr>
<tr>
<td>key</td>
<td>Encryption key.</td>
</tr>
</tbody>
</table>
## DESDECRYPT Procedures and Functions

These subprograms generate the decrypted form of the input data.

### Syntax

```sql
DBMS_OBFUSCATION_TOOLKIT.DESDecrypt(
    input             IN   RAW,
    key               IN   RAW,
    decrypted_data    OUT  RAW);

DBMS_OBFUSCATION_TOOLKIT.DESDecrypt(
    input_string      IN   VARCHAR2,
    key_string        IN   VARCHAR2,
    decrypted_string  OUT  VARCHAR2);

DBMS_OBFUSCATION_TOOLKIT.DESDecrypt(
    input            IN  RAW,
    key              IN  RAW)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DESDecrypt(
    input_string     IN  VARCHAR2,
    key_string       IN  VARCHAR2)
RETURN VARCHAR2;
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Data to be decrypted.</td>
</tr>
<tr>
<td>key</td>
<td>Decryption key.</td>
</tr>
<tr>
<td>decrypted_data</td>
<td>Decrypted data.</td>
</tr>
<tr>
<td>input_string</td>
<td>String to be decrypted.</td>
</tr>
<tr>
<td>key_string</td>
<td>Decryption key string.</td>
</tr>
<tr>
<td>decrypted_string</td>
<td>Decrypted string.</td>
</tr>
</tbody>
</table>

### Usage Notes

If the input data or key given to the PL/SQL DESDECRYPT function is empty, then Oracle raises ORA error 28231 "Invalid input to Obfuscation toolkit."

If the input data given to the DESDECRYPT function is not a multiple of 8 bytes, Oracle raises ORA error 28232 "Invalid input size for Obfuscation toolkit."

If the key length is missing or is less than 8 bytes, then the procedure raises the error ORA-28234 "Key length too short." Note that if larger keys are used, extra bytes are ignored. So a 9-byte key will not generate an exception.

**Note:** ORA-28233 is not applicable to the DESDECRYPT function.
Restrictions

The DES key length for encryption is fixed at 64 bits (of which 56 bits are used); you cannot alter this key length.

---

**Note:** The key length limitation is a requirement of U.S. regulations governing the export of cryptographic products.
DESENCRYPT Procedures and Functions

These subprograms generate the encrypted form of the input data.

Syntax

```sql
DBMS_OBFUSCATION_TOOLKIT.DESEncrypt(
    input            IN    RAW,
    key              IN    RAW,
    encrypted_data   OUT   RAW);

DBMS_OBFUSCATION_TOOLKIT.DESEncrypt(
    input_string     IN    VARCHAR2,
    key_string       IN    VARCHAR2,
    encrypted_string OUT   VARCHAR2);

DBMS_OBFUSCATION_TOOLKIT.DESEncrypt(
    input         IN  RAW,
    key           IN  RAW)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DESEncrypt(
    input_string  IN  VARCHAR2,
    key_string    IN  VARCHAR2)
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Data to be encrypted.</td>
</tr>
<tr>
<td>key</td>
<td>Encryption key.</td>
</tr>
<tr>
<td>encrypted_data</td>
<td>Encrypted data.</td>
</tr>
<tr>
<td>input_string</td>
<td>String to be encrypted.</td>
</tr>
<tr>
<td>key_string</td>
<td>Encryption key string.</td>
</tr>
<tr>
<td>encrypted_string</td>
<td>Encrypted string.</td>
</tr>
</tbody>
</table>

Usage Notes

The DES algorithm encrypts data in 64-bit blocks using a 56-bit key. The DES algorithm throws away 8 bits of the supplied key (the particular bits which are thrown away is beyond the scope of this documentation). However, when using the algorithm, you must supply a 64-bit key or the package will raise an error.

If the input data or key given to the PL/SQL DESEncrypt procedure is empty, then the procedure raises the error ORA-28231 "Invalid input to Obfuscation toolkit".

If the input data given to the DESENCRYPT procedure is not a multiple of 8 bytes, the procedure raises the error ORA-28232 "Invalid input size for Obfuscation toolkit."

If you try to double-encrypt data using the DESENCRYPT procedure, then the procedure raises the error ORA-28233 "Double encryption not supported."
If the key length is missing or is less than 8 bytes, then the procedure raises the error ORA-28234 "Key length too short." Note that if larger keys are used, extra bytes are ignored. So a 9-byte key will not generate an exception.

Restrictions

The DESENCRYPT procedure has the following restrictions:

- The DES key length for encryption is fixed at 56 bits; you cannot alter this key length.
- You cannot execute multiple passes of encryption. That is, you cannot re-encrypt previously encrypted data by calling the function twice.

**Note:** Both the key length limitation and the prevention of multiple encryption passes are requirements of U.S. regulations governing the export of cryptographic products.
**DESGETKEY Procedures and Functions**

These subprograms take a random value and use it to generate an encryption key.

**Syntax**

```sql
DBMS_OBFUSCATION_TOOLKIT.DESGetKey(
    seed         IN   RAW,
    key          OUT  RAW);

DBMS_OBFUSCATION_TOOLKIT.DESGetKey(
    seed_string  IN   VARCHAR2,
    key          OUT  VARCHAR2);

DBMS_OBFUSCATION_TOOLKIT.DESGetKey(
    seed IN RAW)
RETURN RAW;

DBMS_OBFUSCATION_TOOLKIT.DESGetKey(
    seed_string IN VARCHAR2)
RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>seed</td>
<td>A value at least 80 characters long.</td>
</tr>
<tr>
<td>key</td>
<td>Encryption key.</td>
</tr>
<tr>
<td>seed_string</td>
<td>A value at least 80 characters long.</td>
</tr>
<tr>
<td>key</td>
<td>Encryption key.</td>
</tr>
</tbody>
</table>
MD5 Procedures and Functions

These subprograms generate MD5 hashes of data. The MD5 algorithm ensures data integrity by generating a 128-bit cryptographic message digest value from given data.

Syntax

```sql
DBMS_OBFUSCATION_TOOLKIT.MD5(
    input            IN   RAW,
    checksum         OUT  raw_checksum);

DBMS_OBFUSCATION_TOOLKIT.MD5(
    input_string     IN   VARCHAR2,
    checksum_string  OUT  varchar2_checksum);

DBMS_OBFUSCATION_TOOLKIT.MD5(
    input         IN  RAW)
RETURN raw_checksum;

DBMS_OBFUSCATION_TOOLKIT.MD5(
    input_string  IN  VARCHAR2)
RETURN varchar2_checksum;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Data to be hashed</td>
</tr>
<tr>
<td>checksum</td>
<td>128-bit cryptographic message digest</td>
</tr>
<tr>
<td>input_string</td>
<td>String to be hashed</td>
</tr>
<tr>
<td>checksum_string</td>
<td>128-bit cryptographic message digest</td>
</tr>
</tbody>
</table>
DBMS_ODCI package contains a single user function related to the use of Data Cartridges.

Summary of DBMS_ODCI Subprograms

Table 97–1  DBMS_ODCI Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESTIMATE_CPU_UNITS</td>
<td>Returns the approximate number of CPU instructions (in thousands) corresponding to a specified time interval (in seconds)</td>
</tr>
</tbody>
</table>

*Oracle Database PL/SQL Packages and Types Reference*
**ESTIMATE_CPU_UNITS Function**

This function returns the approximate number of CPU instructions (in thousands) corresponding to a specified time interval (in seconds). This information can be used to associate the CPU cost with a user-defined function for the extensible optimizer.

The function takes as input the elapsed time of the user function, measures CPU units by multiplying the elapsed time by the processor speed of the machine, and returns the approximate number of CPU instructions that should be associated with the user function. For a multiprocessor machine, `ESTIMATE_CPU_UNITS` considers the speed of a single processor.

**Syntax**

```
DBMS_ODCI.ESTIMATE_CPU_UNITS(
    elapsed_time   NUMBER)
RETURN NUMBER;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>elapsed_time</td>
<td>The elapsed time in seconds that it takes to execute a function.</td>
</tr>
</tbody>
</table>

**Usage Notes**

When associating CPU cost with a user-defined function, use the full number of CPU units rather than the number of *thousands* of CPU units returned by `ESTIMATE_CPU_UNITS`; multiply the number returned by `ESTIMATE_CPU_UNITS` by 1,000.
The DBMS_OFFLINE_OG package contains the public interface for offline instantiation of master groups.

This chapter contains the following topics:

- Documentation of DBMS_OFFLINE_OG
Documentation of DBMS_OFFLINE_OG

For a complete description of this package within the context of Replication, see DBMS_OFFLINE_OG in the Oracle Database Advanced Replication Management API Reference.
The DBMS_OUTLN package, synonymous with OUTLN_PKG, contains the functional interface for subprograms associated with the management of stored outlines.

See Also: For more information about using the DBMS_OUTLN package, see "Using Plan Stability" in Oracle Database Performance Tuning Guide.

Note: Stored outlines will be desupported in a future release in favor of SQL plan management. In Oracle Database 11g Release 1 (11.1), stored outlines continue to function as in past releases. However, Oracle strongly recommends that you use SQL plan management for new applications. SQL plan management creates SQL plan baselines, which offer superior SQL performance and stability compared with stored outlines.

If you have existing stored outlines, please consider migrating them to SQL plan baselines by using the LOAD_PLANS_FROM_CURSOR_CACHE Functions or LOAD_PLANS_FROM_SQLSET Function of the DBMS_SPM package. When the migration is complete, you should disable or remove the stored outlines.

This chapter contains the following topics:

- Using DBMS_OUTLN
  - Overview
  - Security Model
- Summary of DBMS_OUTLN Subprograms
Using DBMS_OUTLN

- Overview
- Security Model
Overview

A stored outline is the stored data that pertains to an execution plan for a given SQL statement. It enables the optimizer to repeatedly re-create execution plans that are equivalent to the plan originally generated along with the outline. The data stored in an outline consists, in part, of a set of hints that are used to achieve plan stability.

Stored outlines will be de-supported in a future release in favor of SQL plan management. As of 11g R1, stored outlines continue to function as in past releases, but Oracle strongly recommends that you use SQL plan management for new applications. SQL plan management creates SQL plan baselines, which offer superior SQL performance and stability compared with stored outlines.

If you have existing stored outlines, please consider migrating them to SQL plan baselines by using the LOAD_PLANS_FROM_CURSOR_CACHE Functions or the LOAD_PLANS_FROM_SQLSET Function of the DBMS_SPM package. When the migration is complete, you should disable or remove the stored outlines.
Security Model

DBMS_OUTLN contains management procedures that should be available to appropriate users only. EXECUTE privilege is not extended to the general user community unless the DBA explicitly does so.

PL/SQL functions that are available for outline management purposes can be executed only by users with EXECUTE privilege on the procedure (or package).
Summary of DBMS_OUTLN Subprograms

Table 99–1  DBMS_OUTLN Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLEAR_USED Procedure on page 99-6</td>
<td>Clears the outline 'used' flag</td>
</tr>
<tr>
<td>CREATE_OUTLINE Procedure on page 99-7</td>
<td>Generates outlines from the shared cursor identified by hash value and child number</td>
</tr>
<tr>
<td>DROP_BY_CAT Procedure on page 99-8</td>
<td>Drops outlines that belong to a specified category</td>
</tr>
<tr>
<td>DROP_UNUSED Procedure on page 99-9</td>
<td>Drops outlines that have never been applied in the compilation of a SQL statement</td>
</tr>
<tr>
<td>EXACT_TEXT_SIGNATURES Procedure on page 99-10</td>
<td>Updates outline signatures to those that compute based on exact text matching</td>
</tr>
<tr>
<td>UPDATE_BY_CAT Procedure on page 99-11</td>
<td>Changes the category of outlines in one category to a new category</td>
</tr>
<tr>
<td>UPDATE_SIGNATURES Procedure on page 99-12</td>
<td>Updates outline signatures to the current version's signature</td>
</tr>
</tbody>
</table>
CLEAR_USED Procedure

This procedure clears the outline 'used' flag.

Syntax

DBMS_OUTLN.CLEAR_USED (name IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Name of the outline.</td>
</tr>
</tbody>
</table>
CREATE_OUTLINE Procedure

This procedure generates an outline by reparsing the SQL statement from the shared cursor identified by hash value and child number.

Syntax

```
DBMS_OUTLN.CREATE_OUTLINE (
    hash_value    IN NUMBER,
    child_number  IN NUMBER,
    category      IN VARCHAR2 DEFAULT 'DEFAULT');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hash_value</td>
<td>Hash value identifying the target shared cursor.</td>
</tr>
<tr>
<td>child_number</td>
<td>Child number of the target shared cursor.</td>
</tr>
<tr>
<td>category</td>
<td>Category in which to create outline (optional).</td>
</tr>
</tbody>
</table>
DROP_BY_CAT Procedure

This procedure drops outlines that belong to a particular category. While outlines are put into the DEFAULT category unless otherwise specified, users have the option of grouping their outlines into groups called categories.

Syntax

```sql
DBMS_OUTLN.DROP_BY_CAT (  
cat VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cat</td>
<td>Category of outlines to drop.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure purges a category of outlines in a single call.

Examples

This example drops all outlines in the DEFAULT category:

```sql
DBMS_OUTLN.DROP_BY_CAT('DEFAULT');
```
**DROP_UNUSED Procedure**

This procedure drops outlines that have never been applied in the compilation of a SQL statement.

**Syntax**

```
DBMS_OUTLN.DROP_UNUSED;
```

**Usage Notes**

You can use DROP_UNUSED for outlines generated by an application for one-time use SQL statements created as a result of dynamic SQL. These outlines are never used and take up valuable disk space.
EXACT_TEXT_SIGNATURES Procedure

This procedure updates outline signatures to those that compute based on exact text matching.

Syntax

DBMS_OUTLN.EXACT_TEXT_SIGNATURES;

Usage Notes

This procedure is relevant only for downgrading an outline to 8.1.6 or earlier.
UPDATE_BY_CAT Procedure

This procedure changes the category of all outlines in one category to a new category.

Syntax

```sql
DBMS_OUTLN.UPDATE_BY_CAT (   
   oldcat VARCHAR2 default 'DEFAULT',   
   newcat VARCHAR2 default 'DEFAULT');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>oldcat</td>
<td>The current category of outlines.</td>
</tr>
<tr>
<td>newcat</td>
<td>The new category of outlines.</td>
</tr>
</tbody>
</table>
UPDATE_SIGNATURES Procedure

This procedure updates outline signatures to the current version's signature.

Syntax

DBMS_OUTLN.UPDATE_SIGNATURES;

Usage Notes

You should execute this procedure if you have imported outlines generated in an earlier release to ensure that the signatures are compatible with the current release's computation algorithm.
The `DBMS_OUTPUT` package enables you to send messages from stored procedures, packages, and triggers. The package is especially useful for displaying PL/SQL debugging information.

This chapter contains the following topics:

- **Using DBMS_OUTPUT**
  - Overview
  - Security Model
  - Operational Notes
  - Exceptions
  - Rules and Limits
  - Examples

- **Data Structures**
  - TABLE Types
  - OBJECT Types

- **Summary of DBMS_OUTPUT Subprograms**
Using DBMS_OUTPUT

This section contains topics which relate to using the DBMS_OUTPUT package.

- Overview
- Security Model
- Operational Notes
- Exceptions
- Rules and Limits
- Examples
Overview

The package is typically used for debugging, or for displaying messages and reports to SQL*DBA or SQL*Plus (such as are produced by applying the SQL command `DESCRIBE` to procedures).

The `PUT Procedure` and `PUT_LINE Procedure` in this package enable you to place information in a buffer that can be read by another trigger, procedure, or package. In a separate PL/SQL procedure or anonymous block, you can display the buffered information by calling the `GET_LINE Procedure` and `GET_LINES Procedure`.

If the package is disabled, all calls to subprograms are ignored. In this way, you can design your application so that subprograms are available only when a client is able to process the information.
The `dbmsotpt.sql` script must be run as user `SYS`. This creates the public synonym `DBMS_OUTPUT`, and `EXECUTE` permission on this package is granted to `public`. 
Operational Notes

- If you do not call GET_LINE, or if you do not display the messages on your screen in SQL*Plus, the buffered messages are ignored.

- SQL*Plus calls GET_LINES after issuing a SQL statement or anonymous PL/SQL calls.

- Typing SET SERVEROUTPUT ON in SQL*Plus has the effect of invoking
  \[ DBMS_OUTPUT.ENABLE (buffer_size => NULL); \]

  with no limit on the output.

- You should generally avoid having application code invoke either the DISABLE Procedure or ENABLE Procedure because this could subvert the attempt of an external tool like SQL*Plus to control whether or not to display output.

---

**Note:** Messages sent using DBMS_OUTPUT are not actually sent until the sending subprogram or trigger completes. There is no mechanism to flush output during the execution of a procedure.
Exceptions

DBMS_OUTPUT subprograms raise the application error ORA-20000, and the output procedures can return the following errors:

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORU-10027:</td>
<td>Buffer overflow</td>
</tr>
<tr>
<td>ORU-10028:</td>
<td>Line length overflow</td>
</tr>
</tbody>
</table>
Rules and Limits

- The maximum line size is 32767 bytes.
- The default buffer size is 20000 bytes. The minimum size is 2000 bytes and the maximum is unlimited.
Example 1: Using a Trigger to Produce Output

You can use a trigger to print out some output from the debugging process. For example, you could code the trigger to invoke:

```sql
DBMS_OUTPUT.PUT_LINE('I got here:'||:new.col||' is the new value');
```

If you have enabled the `DBMS_OUTPUT` package, then the text produced by this `PUT_LINE` would be buffered, and you could, after executing the statement (presumably some `INSERT`, `DELETE`, or `UPDATE` that caused the trigger to fire), retrieve the line of information. For example:

```sql
BEGIN
    DBMS_OUTPUT.GET_LINE(:buffer, :status);
END;
```

You could then optionally display the buffer on the screen. You repeat calls to `GET_LINE` until `status` comes back as nonzero. For better performance, you should use calls to `GET_LINES Procedure` which can return an array of lines.

Example 2: Debugging Stored Procedures and Triggers

The `DBMS_OUTPUT` package is commonly used to debug stored procedures and triggers. This package can also be used to enable you to retrieve information about an object and format this output, as shown in "Example 3: Retrieving Information About an Object" on page 100-9.

This function queries the employee table and returns the total salary for a specified department. The function includes several calls to the `PUT_LINE` procedure:

```sql
CREATE FUNCTION dept_salary (dnum NUMBER) RETURN NUMBER IS
    CURSOR emp_cursor IS
        SELECT sal, comm FROM emp WHERE deptno = dnum;
    total_wages    NUMBER(11, 2) := 0;
    counter        NUMBER(10) := 1;
    BEGIN
        FOR emp_record IN emp_cursor LOOP
            emp_record.comm := NVL(emp_record.comm, 0);
            total_wages := total_wages + emp_record.sal
            + emp_record.comm;
            DBMS_OUTPUT.PUT_LINE('Loop number = ' || counter ||
                '; Wages = '|| TO_CHAR(total_wages)); /* Debug line */
            counter := counter + 1; /* Increment debug counter */
        END LOOP;
        /* Debug line */
        DBMS_OUTPUT.PUT_LINE('Total wages = ' ||
            TO_CHAR(total_wages));
        RETURN total_wages;
    END dept_salary;
```

Assume the `EMP` table contains the following rows:

<table>
<thead>
<tr>
<th>EMPNO</th>
<th>SAL</th>
<th>COMM</th>
<th>DEPT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1002</td>
<td>1500</td>
<td>500</td>
<td>20</td>
</tr>
<tr>
<td>1203</td>
<td>1000</td>
<td></td>
<td>30</td>
</tr>
<tr>
<td>1289</td>
<td>1000</td>
<td>10</td>
<td></td>
</tr>
</tbody>
</table>
Assume the user executes the following statements in SQL*Plus:

```
SET SERVEROUTPUT ON
VARIABLE salary NUMBER;
EXECUTE :salary := dept_salary(20);
```

The user would then see the following information displayed in the output pane:

Loop number = 1; Wages = 2000
Loop number = 2; Wages = 3250
Total wages = 3250

PL/SQL procedure successfully executed.

### Example 3: Retrieving Information About an Object

In this example, the user has used the `EXPLAIN PLAN` command to retrieve information about the execution plan for a statement and has stored it in `PLAN_TABLE`. The user has also assigned a statement ID to this statement. The example `EXPLAIN_OUT` procedure retrieves the information from this table and formats the output in a nested manner that more closely depicts the order of steps undergone in processing the SQL statement.

```sql
CREATE OR REPLACE PROCEDURE explain_out
    (statement_id IN VARCHAR2) AS

    -- Retrieve information from PLAN_TABLE into cursor EXPLAIN_ROWS.
    CURSOR explain_rows IS
        SELECT level, id, position, operation, options, object_name
        FROM plan_table
        WHERE statement_id = explain_out.statement_id
        CONNECT BY PRIOR id = parent_id
        AND statement_id = explain_out.statement_id
        START WITH id = 0
        ORDER BY id;

    BEGIN

    -- Loop through information retrieved from PLAN_TABLE:
    FOR line IN explain_rows LOOP

        -- At start of output, include heading with estimated cost.
        IF line.id = 0 THEN
            DBMS_OUTPUT.PUT_LINE ('Plan for statement ' || statement_id || ', estimated cost = ' || line.position);
        END IF;

        -- Output formatted information. LEVEL determines indentation level.
        DBMS_OUTPUT.PUT_LINE (lpad(' ',2*(line.level-1)) ||
```

```
line.operation || ' ' || line.options || ' ' ||
line.object_name);
END LOOP;

END;

See Also:  Chapter 224, "UTL_FILE"
Data Structures

The `DBMS_OUTPUT` package declares 2 collection types for use with the `GET_LINES Procedure`.

**TABLE Types**

- CHARARR Table Type

**OBJECT Types**

- DBMSOUTPUT_LINESARRAY Object Type
CHARARR Table Type

This package type is to be used with the GET_LINES Procedure to obtain text submitted through the PUT Procedure and PUT_LINE Procedure.

Syntax

```sql
TYPE CHARARR IS TABLE OF VARCHAR2(32767) INDEX BY BINARY_INTEGER;
```
DBMSOUTPUT_LINESARRAY Object Type

This package type is to be used with the GET_LINES Procedure to obtain text submitted through the PUT Procedure and PUT_LINE Procedure.

Syntax

```
TYPE DBMSOUTPUT_LINESARRAY IS
  VARRAY(2147483647) OF VARCHAR2(32767);
```
### Summary of DBMS_OUTPUT Subprograms

#### Table 100–2  DBMS_OUTPUT Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DISABLE Procedure on page 100-15</td>
<td>Disables message output</td>
</tr>
<tr>
<td>ENABLE Procedure on page 100-16</td>
<td>Enables message output</td>
</tr>
<tr>
<td>GET_LINE Procedure on page 100-17</td>
<td>Retrieves one line from buffer</td>
</tr>
<tr>
<td>GET_LINES Procedure on page 100-18</td>
<td>Retrieves an array of lines from buffer</td>
</tr>
<tr>
<td>NEW_LINE Procedure on page 100-19</td>
<td>Terminates a line created with PUT</td>
</tr>
<tr>
<td>PUT Procedure on page 100-20</td>
<td>Places a partial line in the buffer</td>
</tr>
<tr>
<td>PUT_LINE Procedure on page 100-21</td>
<td>Places line in buffer</td>
</tr>
</tbody>
</table>

**Note:** The PUT Procedure that take a number are obsolete and, while currently supported, are included in this release for legacy reasons only.
DISABLE Procedure

This procedure disables calls to PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES, and purges the buffer of any remaining information.

As with the ENABLE Procedure, you do not need to call this procedure if you are using the SERVEROUTPUT option of SQL*Plus.

Syntax

DBMS_OUTPUT.DISABLE;

Pragmas

pragma restrict_references(disable,WNDS,RNDS);
ENABLE Procedure

This procedure enables calls to PUT, PUT_LINE, NEW_LINE, GET_LINE, and GET_LINES. Calls to these procedures are ignored if the DBMS_OUTPUT package is not activated.

Syntax

```sql
DBMS_OUTPUT.ENABLE (
    buffer_size IN INTEGER DEFAULT 20000);
```

Pragmas

```sql
pragma restrict_references(enable,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>buffer_size</td>
<td>Upper limit, in bytes, the amount of buffered information. Setting buffer_size to NULL specifies that there should be no limit.</td>
</tr>
</tbody>
</table>

Usage Notes

- It is not necessary to call this procedure when you use the SET SERVEROUTPUT option of SQL*Plus.
- If there are multiple calls to ENABLE, then buffer_size is the last of the values specified. The maximum size is 1,000,000, and the minimum is 2,000 when the user specifies buffer_size (NOT NULL).
- NULL is expected to be the usual choice. The default is 20,000 for backwards compatibility with earlier database versions that did not support unlimited buffering.
**GET_LINE Procedure**

This procedure retrieves a single line of buffered information.

**Syntax**

```
DBMS_OUTPUT.GET_LINE (    
  line    OUT VARCHAR2,     
  status  OUT INTEGER); 
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>line</td>
<td>Returns a single line of buffered information, excluding a final newline character. You should declare the actual for this parameter as VARCHAR2 (32767) to avoid the risk of 'ORA-06502: PL/SQL: numeric or value error: character string buffer too small'.</td>
</tr>
<tr>
<td>status</td>
<td>If the call completes successfully, then the status returns as 0. If there are no more lines in the buffer, then the status is 1.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- You can choose to retrieve from the buffer a single line or an array of lines. Call the GET_LINE procedure to retrieve a single line of buffered information. To reduce the number of calls to the server, call the GET_LINES procedure to retrieve an array of lines from the buffer.
- You can choose to automatically display this information if you are using SQL*Plus by using the special SET SERVEROUTPUT ON command.
- After calling GET_LINE or GET_LINES, any lines not retrieved before the next call to PUT, PUT_LINE, or NEW_LINE are discarded to avoid confusing them with the next message.
GET_LINES Procedure

This procedure retrieves an array of lines from the buffer.

Syntax

```sql
DBMS_OUTPUT.GET_LINES (  
  lines      OUT   CHARARR,  
  numlines   IN OUT  INTEGER);

DBMS_OUTPUT.GET_LINES (  
  lines      OUT   DBMSOUTPUT_LINESARRAY,  
  numlines   IN OUT  INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>lines</td>
<td>Returns an array of lines of buffered information. The maximum length of each line in the array is 32767 bytes. It is recommended that you use the VARARRAY overload version in a 3GL host program to execute the procedure from a PL/SQL anonymous block.</td>
</tr>
<tr>
<td>numlines</td>
<td>Number of lines you want to retrieve from the buffer. After retrieving the specified number of lines, the procedure returns the number of lines actually retrieved. If this number is less than the number of lines requested, then there are no more lines in the buffer.</td>
</tr>
</tbody>
</table>

Usage Notes

- You can choose to retrieve from the buffer a single line or an array of lines. Call the GET_LINE procedure to retrieve a single line of buffered information. To reduce the number of calls to the server, call the GET_LINES procedure to retrieve an array of lines from the buffer.
- You can choose to automatically display this information if you are using SQL*Plus by using the special SET SERVEROUTPUT ON command.
- After calling GET_LINE or GET_LINES, any lines not retrieved before the next call to PUT, PUT_LINE, or NEW_LINE are discarded to avoid confusing them with the next message.
NEW_LINE Procedure

This procedure puts an end-of-line marker. The GET_LINE Procedure and the GET_LINES Procedure return "lines" as delimited by "newlines". Every call to the PUT_LINE Procedure or NEW_LINE Procedure generates a line that is returned by GET_LINE(S).

Syntax

DBMS_OUTPUT.NEW_LINE;
PUT Procedure

This procedure places a partial line in the buffer.

---

**Note:** The **PUT** procedure that takes a **NUMBER** is obsolete and, while currently supported, is included in this release for legacy reasons only.

---

**Syntax**

```sql
DBMS_OUTPUT.PUT (
    item IN VARCHAR2);
```

**Parameters**

**Table 100–6 PUT Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>Item to buffer.</td>
</tr>
</tbody>
</table>

**Exceptions**

**Table 100–7 PUT Procedure Exceptions**

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-20000, ORU-10027</td>
<td>Buffer overflow, limit of &lt;buf_limit&gt; bytes.</td>
</tr>
<tr>
<td>ORA-20000, ORU-10028</td>
<td>Line length overflow, limit of 32767 bytes for each line.</td>
</tr>
</tbody>
</table>

**Usage Notes**

- You can build a line of information piece by piece by making multiple calls to **PUT**, or place an entire line of information into the buffer by calling **PUT_LINE**.
- When you call **PUT_LINE** the item you specify is automatically followed by an end-of-line marker. If you make calls to **PUT** to build a line, then you must add your own end-of-line marker by calling **NEW_LINE**. **GET_LINE** and **GET_LINES** do not return lines that have not been terminated with a newline character.
- If your lines exceed the line limit, you receive an error message.
- Output that you create using **PUT** or **PUT_LINE** is buffered. The output cannot be retrieved until the PL/SQL program unit from which it was buffered returns to its caller.

For example, SQL*Plus does not display **DBMS_OUTPUT** messages until the PL/SQL program completes. There is no mechanism for flushing the **DBMS_OUTPUT** buffers within the PL/SQL program.

```sql
SQL> SET SERVEROUTPUT ON
SQL> BEGIN
  2  DBMS_OUTPUT.PUT_LINE ('hello');
  3  DBMS_LOCK.SLEEP (10);
  4  END;
```
PUT_LINE Procedure

This procedure places a line in the buffer.

---

Note: The PUT_LINE procedure that takes a NUMBER is obsolete and, while currently supported, is included in this release for legacy reasons only.

---

Syntax

DBMS_OUTPUT.PUT_LINE (
    item IN VARCHAR2);

Parameters

Table 100–8 PUT_LINE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>Item to buffer.</td>
</tr>
</tbody>
</table>

Exceptions

Table 100–9 PUT_LINE Procedure Exceptions

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-20000,</td>
<td>Buffer overflow, limit of &lt;buf_limit&gt; bytes.</td>
</tr>
<tr>
<td>ORU-10027:</td>
<td></td>
</tr>
<tr>
<td>ORA-20000,</td>
<td>Line length overflow, limit of 32767 bytes for each line.</td>
</tr>
<tr>
<td>ORU-10028:</td>
<td></td>
</tr>
</tbody>
</table>

Usage Notes

- You can build a line of information piece by piece by making multiple calls to PUT, or place an entire line of information into the buffer by calling PUT_LINE.
- When you call PUT_LINE the item you specify is automatically followed by an end-of-line marker. If you make calls to PUT to build a line, then you must add your own end-of-line marker by calling NEW_LINE. GET_LINE and GET_LINES do not return lines that have not been terminated with a newline character.
- If your lines exceeds the line limit, you receive an error message.
- Output that you create using PUT or PUT_LINE is buffered. The output cannot be retrieved until the PL/SQL program unit from which it was buffered returns to its caller.

For example, SQL*Plus does not display DBMS_OUTPUT messages until the PL/SQL program completes. There is no mechanism for flushing the DBMS_OUTPUT buffers within the PL/SQL program. For example:

SQL> SET SERVEROUTPUT ON
SQL> BEGIN
  2  DBMS_OUTPUT.PUT_LINE ('hello');
  3  DBMS_LOCK.SLEEP (10);
  4 END;
The DBMS_PARALLEL_EXECUTE package enables the user to incrementally update table data in parallel.

Using DBMS_PARALLEL_EXECUTE

- Overview
- Security Model
- Constants
- Views
- Exceptions
- Examples
Overview

This package enables the user to incrementally update table data in parallel, in two high level steps:

1. Group sets of rows in the table into smaller sized chunks.
2. Run a user specified statement on these chunks in parallel, and commit when finished processing each chunk.

This package introduces the notion of parallel execution task. This task groups the various steps associated with the parallel execution of a PL/SQL block, which is typically updating table data.

All of the package subroutines (except the GENERATE_TASK_NAME Function and the TASK_STATUS Procedure) perform a commit.
Security Model

`DBMS_PARALLEL_EXECUTE` is a SYS-owned package which is granted to PUBLIC. Any user can create or operate his own parallel execution tasks and access the USER view.

Users who have the `ADM_PARALLEL_EXECUTE_TASK` role can perform administrative routines (qualified by the prefix `ADM_`) and access the DBA view.

Apart from the administrative routines, all the subprograms refer to tasks owned by the current user.

To execute chunks in parallel, the user must have CREATE JOB system privilege.

The `CHUNK_BY_SQL`, `RUN_TASK`, and `RESUME_TASK` subprograms require a query, and are executed using `DBMS_SQL`. Invokers of the `DBMS_SQL` interface must ensure that none of the queries passed-in contains SQL injection.
Constants

The DBMS_PARALLEL_EXECUTE package uses the constants shown in following tables:

- Table 101–1, "DBMS_PARALLEL_EXECUTE Constants - Chunk Status Value"
- Table 101–2, "DBMS_PARALLEL_EXECUTE Constants - Task Status Value"

### Table 101–1 DBMS_PARALLEL_EXECUTE Constants - Chunk Status Value

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASSIGNED NUMBER</td>
<td>NUMBER</td>
<td>1</td>
<td>Chunk has been assigned for processing</td>
</tr>
<tr>
<td>PROCESSED NUMBER</td>
<td>NUMBER</td>
<td>2</td>
<td>Chunk has been processed successfully</td>
</tr>
<tr>
<td>PROCESSED_ WITH_ERROR NUMBER</td>
<td>NUMBER</td>
<td>3</td>
<td>Chunk has been processed, but an error occurred during processing</td>
</tr>
<tr>
<td>UNASSIGNED NUMBER</td>
<td>NUMBER</td>
<td>0</td>
<td>Chunk is unassigned</td>
</tr>
</tbody>
</table>

### Table 101–2 DBMS_PARALLEL_EXECUTE Constants - Task Status Value

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHUNKED NUMBER</td>
<td>NUMBER</td>
<td>4</td>
<td>Table associated with the task has been chunked, but none of the chunk has been assigned for processing</td>
</tr>
<tr>
<td>CHUNKING NUMBER</td>
<td>NUMBER</td>
<td>2</td>
<td>Table associated with the task is being chunked</td>
</tr>
<tr>
<td>CHUNKING_ FAILED</td>
<td>NUMBER</td>
<td>3</td>
<td>Chunking failed</td>
</tr>
<tr>
<td>CRASHED NUMBER</td>
<td>NUMBER</td>
<td>8</td>
<td>Only applicable if parallel execution is used, this occurs if a job slave crashes or if the database crashes during EXECUTE, leaving a chunk in ASSIGNED or UNASSIGNED state.</td>
</tr>
<tr>
<td>CREATED NUMBER</td>
<td>NUMBER</td>
<td>1</td>
<td>The task has been created by the CREATE_TASK Procedure</td>
</tr>
<tr>
<td>FINISHED NUMBER</td>
<td>NUMBER</td>
<td>6</td>
<td>All chunks processed without error</td>
</tr>
<tr>
<td>FINISHED_WITH_ERROR NUMBER</td>
<td>NUMBER</td>
<td>7</td>
<td>All chunks processed, but with errors in some cases</td>
</tr>
<tr>
<td>PROCESSING NUMBER</td>
<td>NUMBER</td>
<td>5</td>
<td>Part of the chunk assigned for processing, or which has been processed</td>
</tr>
</tbody>
</table>
Views

The `DBMS_PARALLEL_EXECUTE` package uses views listed in the Oracle Database Reference:

- `DBA_PARALLEL_EXECUTE_CHUNKS`
- `DBA_PARALLEL_EXECUTE_TASKS`
- `USER_PARALLEL_EXECUTE_CHUNKS`
- `USER_PARALLEL_EXECUTE_TASKS`
Exceptions

The following table lists the exceptions raised by DBMS_PARALLEL_EXECUTE.

<table>
<thead>
<tr>
<th>Exception</th>
<th>Error Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CHUNK_NOT_FOUND</td>
<td>29499</td>
<td>Specified chunk does not exist</td>
</tr>
<tr>
<td>DUPLICATE_TASK_NAME</td>
<td>29497</td>
<td>Same task name has been used by an existing task</td>
</tr>
<tr>
<td>INVALID_STATE_FOR_CHUNK</td>
<td>29492</td>
<td>Attempts to chunk a table that is not in CREATED or CHUNKING_FAILED state</td>
</tr>
<tr>
<td>INVALID_STATE_FOR_RESUME</td>
<td>29495</td>
<td>Attempts to resume execution, but the task is not in FINISHED_WITH_ERROR or CRASHED state</td>
</tr>
<tr>
<td>INVALID_STATE_FOR_RUN</td>
<td>29494</td>
<td>Attempts to execute the task that is not in CHUNKED state</td>
</tr>
<tr>
<td>INVALID_STATUS</td>
<td>29493</td>
<td>Attempts to set an invalid value to the chunk status</td>
</tr>
<tr>
<td>INVALID_TABLE</td>
<td>29491</td>
<td>Attempts to chunk a table by rowid in cases in which the table is not a physical table, or the table is an IOT</td>
</tr>
<tr>
<td>MISSING_ROLE</td>
<td>29490</td>
<td>User does not have the necessary ADM_PARALLEL_EXECUTE role</td>
</tr>
<tr>
<td>TASK_NOT_FOUND</td>
<td>29498</td>
<td>Specified task_name does not exist</td>
</tr>
</tbody>
</table>
Examples

The following examples run on the Human Resources (HR) schema of the Oracle Database Sample Schemas. It requires that the HR schema be created with the JOB SYSTEM privilege.

**Chunk by ROWID**

This example shows the most common usage of this package. After calling the RUN_TASK Procedure, it checks for errors and re-runs in the case of error.

```sql
DECLARE
  l_sql_stmt VARCHAR2(1000);
  l_try NUMBER;
  l_status NUMBER;
BEGIN
  -- Create the TASK
  DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');

  -- Chunk the table by ROWID
  DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID('mytask', 'HR', 'EMPLOYEES', true, 100);

  -- Execute the DML in parallel
  l_sql_stmt := 'update /*+ ROWID (dda) */ EMPLOYEES e
  set e.salary = e.salary + 10
  where rowid between :start_id and :end_id';
  DBMS_PARALLEL_EXECUTE.RUN_TASK('mytask', l_sql_stmt, DBMS_SQL.NATIVE,
                                  parallel_level => 10);

  -- If there is an error, RESUME it for at most 2 times.
  l_try := 0;
  l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  WHILE(l_try < 2 and l_status != DBMS_PARALLEL_EXECUTE.FINISHED)
  LOOP
    l_try := l_try + 1;
    DBMS_PARALLEL_EXECUTE.RESUME_TASK('mytask');
    l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  END LOOP;

  -- Done with processing; drop the task
  DBMS_PARALLEL_EXECUTE.DROP_TASK('mytask');
END;
/
```

**Chunk by User-Provided SQL**

A user can specify their own chunk algorithm by using the CREATE_CHUNKS_BY_SQL Procedure. This example shows that rows with the same manager_id are grouped together and processed in one chunk.

```sql
DECLARE
  l_chunk_sql VARCHAR2(1000);
  l_sql_stmt VARCHAR2(1000);
  l_try NUMBER;
  l_status NUMBER;
BEGIN
  -- Create the TASK
  DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');

  -- Chunk the table by SQL
  l_chunk_sql := 'select e.manager_id, e.salary
  from EMPLOYEES e
  where e.manager_id = :manager_id';
  DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_SQL('mytask', l_chunk_sql,
                                             parallel_level => 100);

  -- Execute the DML in parallel
  l_sql_stmt := 'update /*+ SQL (dda) */ EMPLOYEES e
  set e.salary = e.salary + 10
  where rowid between :start_id and :end_id';
  DBMS_PARALLEL_EXECUTE.RUN_TASK('mytask', l_sql_stmt, DBMS_SQL.NATIVE,
                                  parallel_level => 10);

  -- If there is an error, RESUME it for at most 2 times.
  l_try := 0;
  l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  WHILE(l_try < 2 and l_status != DBMS_PARALLEL_EXECUTE.FINISHED)
  LOOP
    l_try := l_try + 1;
    DBMS_PARALLEL_EXECUTE.RESUME_TASK('mytask');
    l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
  END LOOP;

  -- Done with processing; drop the task
  DBMS_PARALLEL_EXECUTE.DROP_TASK('mytask');
END;
/
```
-- Create the TASK
DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');

-- Chunk the table by MANAGER_ID
l_chunk_sql := 'SELECT distinct manager_id, manager_id FROM employees';
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_SQL('mytask', l_chunk_sql, false);

-- Execute the DML in parallel
-- the WHERE clause contain a condition on manager_id, which is the chunk
-- column. In this case, grouping rows is by manager_id.
l_sql_stmt := 'update /*+ ROWID (dda) */ EMPLOYEES e
   SET e.salary = e.salary + 10
   WHERE manager_id between :start_id and :end_id';
DBMS_PARALLEL_EXECUTE.RUN_TASK('mytask', l_sql_stmt, DBMS_SQL.NATIVE,
   parallel_level => 10);

-- If there is error, RESUME it for at most 2 times.
l_try := 0;
l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
WHILE (l_try < 2 and l_status != DBMS_PARALLEL_EXECUTE.FINISHED)
   Loop
      l_try := l_try + 1;
      DBMS_PARALLEL_EXECUTE.RESUME_TASK('mytask');
      l_status := DBMS_PARALLEL_EXECUTE.TASK_STATUS('mytask');
   END LOOP;

-- Done with processing; drop the task
DBMS_PARALLEL_EXECUTE.DROP_TASK('mytask');
end;
/

Executing Chunks in an User-defined Framework
The user can execute chunks in his own defined framework without using the RUN_TASK Procedure. This example shows how to use GET_ROWID_CHUNK Procedure, EXECUTE IMMEDIATE, SET_CHUNK_STATUS Procedure to execute the chunks.

DECLARE
   l_sql_stmt varchar2(1000);
l_try number;
l_status number;
l_chunk_id number;
l_start_rowid rowid;
l_end_rowid rowid;
l_any_rows boolean;
CURSOR c1 IS SELECT chunk_id
   FROM user_parallel_execute_chunks
   WHERE task_name = 'mytask'
   AND STATUS IN (DBMS_PARALLEL_EXECUTE.PROCESSED_WITH_ERROR,
                   DBMS_PARALLEL_EXECUTE.ASSIGNED);
BEGIN
   -- Create the Objects, task, and chunk by ROWID
   DBMS_PARALLEL_EXECUTE.CREATE_TASK ('mytask');
   DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID('mytask', 'HR', 'EMPLOYEES', true, 100);
   l_sql_stmt := 'update /*+ ROWID (dda) */ EMPLOYEES e
      SET e.salary = e.salary + 10
      WHERE rowid BETWEEN :start_id AND :end_id';

-- Execute the DML in his own framework
--
-- Process each chunk and commit.
-- After processing one chunk, repeat this process until
-- all the chunks are processed.
--
<<main_processing>>
LOOP
    --
    -- Get a chunk to process; if there is nothing to process, then exit the
    -- loop;
    --
    DBMS_PARALLEL_EXECUTE.GET_ROWID_CHUNK('mytask',
        l_chunk_id,
        l_start_rowid,
        l_end_rowid,
        l_any_rows);

    IF (l_any_rows = false) THEN EXIT; END IF;
    --
    -- The chunk is specified by start_id and end_id.
    -- Bind the start_id and end_id and then execute it
    --
    -- If no error occured, set the chunk status to PROCESSED.
    --
    -- Catch any exception. If an exception occured, store the error num/msg
    -- into the chunk table and then continue to process the next chunk.
    --
    BEGIN
        EXECUTE IMMEDIATE l_sql_stmt using l_start_rowid, l_end_rowid;
        DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS('mytask', l_chunk_id,
            DBMS_PARALLEL_EXECUTE.PROCESSED);
        EXCEPTION WHEN OTHERS THEN
            DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS('mytask', l_chunk_id,
                DBMS_PARALLEL_EXECUTE.PROCESSED_WITH_ERROR, SQLCODE, SQLERRM);
        END;
    --
    -- Finished processing one chunk; Commit here
    --
    COMMIT;
END LOOP;
### Summary of DBMS_PARALLEL_EXECUTE Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>

</tbody>
</table>
**ADM_DROP_CHUNKS Procedure**

This procedure drops all chunks of the specified task owned by the specified owner.

**Syntax**

```sql
DBMS_PARALLEL_EXECUTE.ADM_DROP_CHUNKS (
    task_owner IN VARCHAR2,
    task_name  IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_owner</td>
<td>Owner of the task</td>
</tr>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
ADM_DROP_TASK Procedure

This procedure drops the task of the specified user and all related chunks.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.ADM_DROP_TASK (
    task_owner IN VARCHAR2,
    task_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_owner</td>
<td>Owner of the task</td>
</tr>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
ADM_TASK_STATUS Procedure

This function returns the task status.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.ADM_TASK_STATUS  (
    task_owner      IN  VARCHAR2,
    task_name       IN  VARCHAR2)
RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_owner</td>
<td>Owner of the task</td>
</tr>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
ADM_STOP_TASK Procedure

This procedure stops the task of the specified owner and related job slaves.

Syntax

```
DBMS_PARALLEL_EXECUTE.ADM_STOP_TASK (
    task_owner   IN  VARCHAR2,
    task_name   IN  VARCHAR2);
```

Parameters

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_owner</td>
<td>Owner of the task</td>
</tr>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
```
CREATE_TASK Procedure

This procedure creates a task for the current user. The pairing of `task_name` and `current_user` must be unique.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.CREATE_TASK (
    task_name IN VARCHAR2,
    comment IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task. The task_name can be any string in which related length must be less than or equal to 128 bytes.</td>
</tr>
<tr>
<td>comment</td>
<td>Comment field. The comment must be less than 4000 bytes.</td>
</tr>
</tbody>
</table>
CREATE_CHUNKS_BY_NUMBER_COL Procedure

This procedure chunks the table (associated with the specified task) by the specified column. The specified column must be a NUMBER column. This procedure takes the MIN and MAX value of the column, and then divide the range evenly according to chunk_size. The chunks are:

<table>
<thead>
<tr>
<th>START_ID</th>
<th>END_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>min_id_val</td>
<td>min_id_val+1*chunk_size-1</td>
</tr>
<tr>
<td>min_id_val+1*chunk_size</td>
<td>min_id_val+2*chunk_size-1</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>min_id_val+i*chunk_size</td>
<td>max_id_val</td>
</tr>
</tbody>
</table>

Syntax

```
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_NUMBER_COL (
    task_name       IN  VARCHAR2,
    table_owner     IN  VARCHAR2,
    table_name      IN  VARCHAR2,
    table_column    IN  VARCHAR2,
    chunk_size      IN  NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>table_owner</td>
<td>Owner of the table</td>
</tr>
<tr>
<td>table_name</td>
<td>Name of the table</td>
</tr>
<tr>
<td>table_column</td>
<td>Name of the NUMBER column</td>
</tr>
<tr>
<td>chunk_size</td>
<td>Range of each chunk</td>
</tr>
</tbody>
</table>
CREATE_CHUNKS_BY_ROWID Procedure

This procedure chunks the table (associated with the specified task) by ROWID. num_row and num_block are approximate guidance for the size of each chunk. The table to be chunked must be a physical table with physical ROWID having views and table functions. Index Organized Tables are not allowed.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_ROWID (  
    task_name       IN  VARCHAR2,  
    table_owner     IN  VARCHAR2,  
    table_name      IN  VARCHAR2,  
    by_row          IN  BOOLEAN,  
    chunk_size      IN  NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>

</tbody>
</table>
CREATE_CHUNKS_BY_SQL Procedure

This procedure chunks the table (associated with the specified task) by means of a user-provided SELECT statement. The select statement which returns the range of each chunk must have two columns: start_id and end_id. If task is to chunk by ROWID, then the two columns must be of ROWID type. If the task is to chunk the table by NUMBER column, then the two columns must be of NUMBER type. The procedure provides the flexibility to users who want to deploy user-defined chunk algorithms.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.CREATE_CHUNKS_BY_SQL (    task_name       IN  VARCHAR2,
    sql_statement   IN  CLOB,
    by_rowid        IN  BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>sql_statement</td>
<td>SQL which returns the chunk ranges</td>
</tr>
<tr>
<td>by_rowid</td>
<td>TRUE if the table is chunked by rowids</td>
</tr>
</tbody>
</table>
DROP_TASK Procedure

This procedure drops the task and all related chunks.

Syntax

```
DBMS_PARALLEL_EXECUTE.DROP_TASK (  
  task_name       IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
DROP_CHUNKS Procedure

This procedure drops the task's chunks.

Syntax

DBMS_PARALLEL_EXECUTE.DROP_CHUNKS {
    task_name       IN VARCHAR2);

Parameters

Table 101–14 DROP_CHUNKS Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
GENERATE_TASK_NAME Function

This function returns a unique name for a task. The name is of the form prefixN where N is a number from a sequence. If no prefix is specified, the generated name is, by default, be TASK$_1$, TASK$_2$, TASK$_3$, and so on. If 'SCOTT' is specified as the prefix, the name is SCOTT1, SCOTT2, and so on.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.GENERATE_TASK_NAME (  
    prefix      IN      VARCHAR2 DEFAULT 'TASK$_')
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>The prefix to use when generating the task name</td>
</tr>
</tbody>
</table>
GET_NUMBER_COL_CHUNK Procedure

This procedure picks an unassigned NUMBER chunk and changes it to ASSIGNED. If there are no more chunks to assign, any_rows is set to FALSE. Otherwise, the chunk_id, start and end_id of the chunk is returned as OUT parameters. The chunk info in DBMS_PARALLEL_EXECUTE_CHUNKS$ is updated as follows: STATUS becomes ASSIGNED; START_TIMESTAMP records the current time; END_TIMESTAMP is cleared.

See Also: Views on page 101-6

Syntax

DBMS_PARALLEL_EXECUTE.GET_NUMBER_COL_CHUNK ( 
  task_name       IN VARCHAR2,
  chunk_id        OUT NUMBER,
  start_rowid     OUT ROWID,
  end_id          OUT ROWID,
  any_rows        OUT BOOLEAN);

Parameters

Table 101–16  GET_NUMBER_COL_CHUNK Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>chunk_id</td>
<td>Chunk_id of the chunk</td>
</tr>
<tr>
<td>start_rowid</td>
<td>Start rowid in the returned range</td>
</tr>
<tr>
<td>end_id</td>
<td>End rowid in the returned range</td>
</tr>
<tr>
<td>any_rows</td>
<td>Indicating if there could be any rows to process in the range</td>
</tr>
</tbody>
</table>

Usage Notes

If the task is chunked by ROWID, then get_rowid_range should be used. If the task is chunked by NUMBER column, then get_number_col_range should be used. If the user makes the wrong function call, the returning chunk_id and any_rows has a valid value but start/end(row)id is NULL.
GET_ROWID_CHUNK Procedure

This procedure picks an unassigned ROWID chunk and changes it to ASSIGNED. If there are no more chunks to assign, any_rows is set to FALSE. Otherwise, the chunk_id, start and end_id of the chunk is returned as OUT parameters. The chunk info in DBMS_PARALLEL_EXECUTE_CHUNKS$ is updated as follows: STATUS becomes ASSIGNED; START_TIMESTAMP records the current time; END_TIMESTAMP is cleared.

See Also: Views on page 101-6

Syntax

```sql
DBMS_PARALLEL_EXECUTE.GET_ROWID_CHUNK (  
  task_name       IN VARCHAR2,  
  chunk_id        OUT NUMBER,  
  start_rowid     OUT ROWID,  
  end_id          OUT ROWID,  
  any_rows        OUT BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>chunk_id</td>
<td>Chunk_id of the chunk</td>
</tr>
<tr>
<td>start_rowid</td>
<td>Start rowid in the returned range</td>
</tr>
<tr>
<td>end_id</td>
<td>End rowid in the returned range</td>
</tr>
<tr>
<td>any_rows</td>
<td>Indicating if there could be any rows to process in the range</td>
</tr>
</tbody>
</table>

Usage Notes

If the task is chunked by ROWID, then get_rowid_range should be used. If the task is chunked by NUMBER column, then get_number_col_range should be used. If the user makes the wrong function call, the returning chunk_id and any_rows still have valid value but start/end_rowid is NULL.
PURGE_PROCESSED_CHUNKS Procedure

This procedure deletes all the processed chunks whose status is PROCESSED or PROCESSED_WITH_ERROR.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.PURGE_PROCESSED_CHUNKS (
    task_name       IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
This procedure retries the specified task if the RUN_TASK Procedure finished with error, or resumes the task if a crash has occurred.

The user can only invoke this procedure if the task is in a CRASHED or FINISHED_WITH_ERROR state. For a crashed serial execution, the state remains in processing. The FORCE option allows user to resume any task in PROCESSING state. However, it is the user’s responsibility to determine that a crash has occurred.

The procedure resumes processing the chunks which have not been processed. Also, chunks which are in PROCESSED_WITH_ERROR or ASSIGNED (due to crash) state are processed because those chunks did not commit.

This procedure takes the same argument as the RUN_TASK Procedure.

The overload which takes task_name as the only input argument re-uses the arguments provided in the previous invoking of the RUN_TASK Procedure or RESUME_TASK Procedures.

See Also: Table 101–2, "DBMS_PARALLEL_EXECUTE Constants - Task Status Value" on page 101-5

Syntax

```
DBMS_PARALLEL_EXECUTE.RESUME_TASK (    
    task_name                     IN  VARCHAR2,    
    sql_stmt                      IN  CLOB,    
    language_flag                 IN  NUMBER,    
    edition                       IN  VARCHAR2  DEFAULT NULL,    
    apply_crossedition_trigger    IN  VARCHAR2  DEFAULT NULL,    
    fire_apply_trigger            IN  BOOLEAN   DEFAULT TRUE,    
    parallel_level                IN  NUMBER    DEFAULT 0,    
    job_class                     IN  VARCHAR2  DEFAULT 'DEFAULT_JOB_CLASS',    
    force                         IN  BOOLEAN   DEFAULT FALSE);
```

```
DBMS_PARALLEL_EXECUTE.RESUME_TASK (    
    task_name                     IN  VARCHAR2,    
    force                         IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>sql_stmt</td>
<td>SQL statement; must have :start_id and :end_id placeholder</td>
</tr>
<tr>
<td>language_flag</td>
<td>Determines how Oracle handles the SQL statement. The following options are recognized:</td>
</tr>
<tr>
<td></td>
<td>■ V6 (or 0) specifies version 6 behavior</td>
</tr>
<tr>
<td></td>
<td>■ NATIVE (or 1) specifies normal behavior for the database to which the program is connected</td>
</tr>
<tr>
<td></td>
<td>■ V7 (or 2) specifies Oracle database version 7 behavior</td>
</tr>
<tr>
<td>edition</td>
<td>Specifies the edition to run the statement in. Default is the current edition.</td>
</tr>
</tbody>
</table>
Table 101–19 (Cont.) RESUME_TASK Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>apply_crossedition_trigger</td>
<td>Specifies the unqualified name of a forward crossedition trigger that is to be applied to the specified SQL. The name is resolved using the edition and current_schema setting in which the statement is to be executed. The trigger must be owned by the user who executes the statement.</td>
</tr>
<tr>
<td>fire_apply_trigger</td>
<td>Indicates whether the specified apply_crossedition_trigger is itself to be executed, or should only be a guide used in selecting other triggers</td>
</tr>
<tr>
<td>parallel_level</td>
<td>Number of parallel jobs; zero if run in serial; NULL uses the default parallelism</td>
</tr>
<tr>
<td>job_class</td>
<td>If running in parallel, the jobs all belong to the specified job class</td>
</tr>
<tr>
<td>force</td>
<td>If TRUE, do not raise an error if the status is PROCESSING.</td>
</tr>
</tbody>
</table>

Examples

Suppose the chunk table contains the following chunk ranges:

<table>
<thead>
<tr>
<th>START_ID</th>
<th>END_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>11</td>
<td>20</td>
</tr>
<tr>
<td>21</td>
<td>30</td>
</tr>
</tbody>
</table>

And the specified SQL statement is:

```
UPDATE employees
SET salary = salary + 10
WHERE e.employee_id BETWEEN :start_id AND :end_id
```

This procedure executes the following statements in parallel:

```
UPDATE employees
SET salary = salary + 10
WHERE employee_id BETWEEN 1 and 10;
COMMIT;

UPDATE employees
SET salary = salary + 10
WHERE employee_id between 11 and 20;
COMMIT;

UPDATE employees
SET salary = salary + 10
WHERE employee_id between 21 and 30;
COMMIT;
```
RUN_TASK Procedure

This procedure executes the specified statement (sql_stmt) on the chunks in parallel. It commits after processing each chunk. The specified statement must have two placeholders called start_id and end_id respectively, which represent the range of the chunk to be processed. The types of the placeholder must be rowid where ROWID based chunking was used, or NUMBER where number based chunking was used. The specified statement should not commit unless it is idempotent.

The SQL statement is executed as the current user.

If apply_crossedition_trigger is specified, DBMS_CROSSEDITION_TRIGGER.IS_APPLYING returns true for the sessions executing the SQL. Therefore, for parallel execution, DBMS_CROSSEDITION_TRIGGER.IS_APPLYING returns true in the Job slaves session.

Chunks can be executed in parallel by DBMS_SCHEDULER Job slaves. Therefore, parallel execution requires CREATE JOB system privilege. The Job slaves is created under the current user. The default number of Job slaves is computed as the product of Oracle parameters cpu_count and parallel_threads_per_cpu. On a Real Application Clusters installation, the number of Job slaves is the sum of individual settings on each node in the cluster. This procedure returns only when all the chunks are processed. In parallel cases, this procedure returns only when all the Job slaves finished.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.RUN_TASK (
    task_name                     IN  VARCHAR2,
    sql_stmt                      IN  CLOB,
    language_flag                 IN  NUMBER,
    edition                       IN  VARCHAR2  DEFAULT NULL,
    apply_crossedition_trigger    IN  VARCHAR2  DEFAULT NULL,
    fire_apply_trigger            IN  BOOLEAN   DEFAULT TRUE,
    parallel_level                IN  NUMBER    DEFAULT 0,
    job_class                     IN  VARCHAR2  DEFAULT 'DEFAULT_JOB_CLASS');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
<tr>
<td>sql_stmt</td>
<td>SQL statement; must have :start_id and :end_id placeholder</td>
</tr>
<tr>
<td>language_flag</td>
<td>Determines how Oracle handles the SQL statement. The following options are recognized:</td>
</tr>
<tr>
<td>edition</td>
<td>Specifies the edition to run the statement in. Default is the current edition.</td>
</tr>
<tr>
<td>apply_crossedition_trigger</td>
<td></td>
</tr>
<tr>
<td>fire_apply_trigger</td>
<td></td>
</tr>
<tr>
<td>parallel_level</td>
<td></td>
</tr>
<tr>
<td>job_class</td>
<td></td>
</tr>
</tbody>
</table>
### Examples

Suppose the chunk table contains the following chunk ranges:

<table>
<thead>
<tr>
<th>START_ID</th>
<th>END_ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
<tr>
<td>11</td>
<td>20</td>
</tr>
<tr>
<td>21</td>
<td>30</td>
</tr>
</tbody>
</table>

And the specified SQL statement is:

```sql
UPDATE employees
SET salary = salary + 10
WHERE e.employee_id BETWEEN :start_id AND :end_id
```

This procedure executes the following statements in parallel:

```sql
UPDATE employees
SET salary = salary + 10 WHERE employee_id BETWEEN 1 and 10;
COMMIT;

UPDATE employees
SET salary = salary + 10 WHERE employee_id between 11 and 20;
COMMIT;

UPDATE employees
SET salary = salary + 10 WHERE employee_id between 21 and 30;
COMMIT;
```
SET_CHUNK_STATUS Procedure

This procedure sets the status of the chunk. The \texttt{START\_TIMESTAMP} and \texttt{END\_TIMESTAMP} of the chunk is updated according to the new status:

<table>
<thead>
<tr>
<th>Value of the new Status</th>
<th>Side Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>UNASSIGNED</td>
<td>\texttt{START_TIMESTAMP} and \texttt{END_TIMESTAMP} will be cleared</td>
</tr>
<tr>
<td>ASSIGNED</td>
<td>\texttt{START_TIMESTAMP} will be the current time and \texttt{END_TIMESTAMP} will be cleared.</td>
</tr>
<tr>
<td>PROCESSED or PROCESSED_WITH_ERROR</td>
<td>The current time will be recorded in \texttt{END_TIMESTAMP}</td>
</tr>
</tbody>
</table>

\textbf{See Also:} \texttt{Views} on page 101-6

\textbf{Syntax}

\begin{verbatim}
DBMS_PARALLEL_EXECUTE.SET_CHUNK_STATUS (  
    task_name       IN VARCHAR2,  
    chunk_id        OUT NUMBER,  
    status          IN  NUMBER,  
    err_num         IN  NUMBER DEFAULT NULL,  
    err_msg         IN  VARCHAR2 DEFAULT NULL);  
\end{verbatim}

\textbf{Parameters}

\begin{table}[h]
\centering
\caption{SET_CHUNK_STATUS Procedure Parameters}
\begin{tabular}{|c|p{12cm}|}
\hline
\textbf{Parameter} & \textbf{Description} \\
\hline
\texttt{task\_name} & Name of the task \\
\texttt{chunk\_id} & Chunk\_id of the chunk \\
\texttt{status} & Status of the chunk: UNASSIGNED, ASSIGNED, PROCESSED, PROCESSED\_WITH\_ERROR \\
\texttt{err\_num} & Error code returned during the processing of the chunk \\
\texttt{err\_msg} & Error message returned during the processing of the chunk \\
\hline
\end{tabular}
\end{table}
STOP_TASK Procedure

This procedure stops the task and related job slaves.

Syntax

```sql
DBMS_PARALLEL_EXECUTE.STOP_TASK (
    task_name    IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
**TASK_STATUS Procedure**

This function returns the task status.

**Syntax**

```sql
DBMS_PARALLEL_EXECUTE.TASK_STATUS (task_name IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>task_name</td>
<td>Name of the task</td>
</tr>
</tbody>
</table>
The DBMS_PCLXUTIL package provides intra-partition parallelism for creating partition-wise local indexes. DBMS_PCLXUTIL circumvents the limitation that, for local index creation, the degree of parallelism is restricted to the number of partitions as only one slave process for each partition is used.

See Also: There are several rules concerning partitions and indexes. For more information, see Oracle Database Concepts and Oracle Database Administrator’s Guide.

This chapter contains the following topics:

- Using DBMS_PCLXUTIL
  - Overview
  - Security Model
  - Operational Notes
  - Rules and Limits

- Summary of DBMS_PCLXUTIL Subprograms
Using DBMS_PCLXUTIL

- Overview
- Security Model
- Operational Notes
- Rules and Limits
Overview

**DBMS_PCLXUTIL** uses the **DBMS_JOB** package to provide a greater degree of parallelism for creating a local index for a partitioned table. This is achieved by asynchronous inter-partition parallelism using the background processes (with **DBMS_JOB**), in combination with intra-partition parallelism using the parallel query slave processes.

**DBMS_PCLXUTIL** works with both range and range-hash composite partitioning.

The **DBMS_PCLXUTIL** package can be used during the following DBA tasks:

1. **Local index creation**
   
The procedure **BUILD_PART_INDEX** assumes that the dictionary information for the local index already exists. This can be done by issuing the create index SQL command with the **UNUSABLE** option.
   
   ```sql
   CREATE INDEX <idx_name> on <tab_name>(...) local(...) unusable;
   ```

   This causes the dictionary entries to be created without "building" the index itself, the time consuming part of creating an index. Now, invoking the procedure **BUILD_PART_INDEX** causes a concurrent build of local indexes with the specified degree of parallelism.
   
   ```sql
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,FALSE);
   ```

   For composite partitions, the procedure automatically builds local indexes for all subpartitions of the composite table.

2. **Local index maintenance**
   
   By marking desired partitions usable or unusable, the **BUILD_PART_INDEX** procedure also enables selective rebuilding of local indexes. The **force_opt** parameter provides a way to override this and build local indexes for all partitions.
   
   ```sql
   ALTER INDEX <idx_name> local(...) usable;
   ```

   Rebuild only the desired (sub)partitions (that are marked unusable):
   
   ```sql
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,FALSE);
   ```

   Rebuild all (sub)partitions using **force_opt** = **TRUE**:
   
   ```sql
   EXECUTE dbms_pclxutil.build_part_index(4,4,<tab_name>,<idx_name>,TRUE);
   ```

   A progress report is produced, and the output appears on screen when the program is ended (because the **DBMS_OUTPUT** package writes messages to a buffer first, and flushes the buffer to the screen only upon termination of the program).
Security Model

This utility can be run only as table owner, and not as any other user.
Operational Notes

DBMS_PCLXUTIL submits a job for each partition. It is the responsibility of the user/dba to control the number of concurrent jobs by setting the INIT.ORA parameter JOB_QUEUE PROCESSES correctly. There is minimal error checking for correct syntax. Any errors are reported in the job queue process trace files.
Rules and Limits

**Note:** For range partitioning, the minimum compatibility mode is 8.0; for range-hash composite partitioning, the minimum compatibility mode is 8i.

Because `DBMS_PCLXUTIL` uses the `DBMS_JOB` package, you must be aware of the following limitations pertaining to `DBMS_JOB`:

- You must decide appropriate values for the `job_queue_processes` initialization parameter. Clearly, if the job processes are not started before calling `BUILD_PART_INDEX()`, then the package will not function properly. The background processes are specified by the following `init.ora` parameters:
  
  ```
  job_queue_processes=n  #the number of background processes = n
  ```

- Failure conditions are reported only in the trace files (a `DBMS_JOB` limitation), making it impossible to give interactive feedback to the user. This package prints a failure message, removes unfinished jobs from the queue, and requests the user to take a look at the `j*.trc` trace files.
### Summary of DBMS_PCLXUTIL Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BUILD_PART_INDEX</td>
<td>Provides intra-partition parallelism for creating partition-wise local indexes</td>
</tr>
</tbody>
</table>

Table 102–1  DBMS_PCLXUTIL Package Subprograms
BUILD_PART_INDEX Procedure

This procedure provides intra-partition parallelism for creating partition-wise local indexes.

Syntax

```
DBMS_PCLXUTIL.BUILD_PART_INDEX (    
   jobs_per_batch  IN NUMBER   DEFAULT 1,    
   procs_per_job   IN NUMBER   DEFAULT 1,    
   tab_name        IN VARCHAR2 DEFAULT NULL,    
   idx_name        IN VARCHAR2 DEFAULT NULL,    
   force_opt       IN BOOLEAN  DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobs_per_batch</td>
<td>The number of concurrent partition-wise &quot;local index builds&quot;.</td>
</tr>
<tr>
<td>procs_per_job</td>
<td>The number of parallel query slaves to be utilized for each local index build (1 &lt;= procs_per_job &lt;= max_slaves).</td>
</tr>
<tr>
<td>tab_name</td>
<td>The name of the partitioned table (an exception is raised if the table does not exist or not partitioned).</td>
</tr>
<tr>
<td>idx_name</td>
<td>The name given to the local index (an exception is raised if a local index is not created on the table tab_name).</td>
</tr>
<tr>
<td>force_opt</td>
<td>If TRUE, then force rebuild of all partitioned indexes; otherwise, rebuild only the partitions marked 'UNUSABLE'.</td>
</tr>
</tbody>
</table>

Usage Notes

This utility can be run only as table owner, and not as any other user.

Examples

Suppose a table PROJECT is created with two partitions PROJ001 and PROJ002, along with a local index IDX.

A call to the procedure BUILD_PART_INDEX(2,4,'PROJECT','IDX',TRUE) produces the following output:

```
SQLPLUS> EXECUTE dbms_pclxutil.build_part_index(2,4,'PROJECT','IDX',TRUE);
Statement processed.
INFO: Job #21 created for partition PROJ001 with 4 slaves
INFO: Job #22 created for partition PROJ002 with 4 slaves
```
The DBMS_PIPE package lets two or more sessions in the same instance communicate. Oracle pipes are similar in concept to the pipes used in UNIX, but Oracle pipes are not implemented using the operating system pipe mechanisms.

This chapter contains the following topics:

- Using DBMS_PIPE
  - Overview
  - Security Model

- Summary of DBMS_PIPE Subprograms
Using DBMS_PIPE

- Overview
- Security Model
- Constants
- Operational Notes
- Exceptions
- Examples
Overview

Pipe functionality has several potential applications:

- **External service interface:** You can communicate with user-written services that are external to the RDBMS. This can be done effectively in a shared server process, so that several instances of the service are executing simultaneously. Additionally, the services are available asynchronously. The requestor of the service does not need to block a waiting reply. The requestor can check (with or without time out) at a later time. The service can be written in any of the 3GL languages that Oracle supports.

- **Independent transactions:** The pipe can communicate to a separate session which can perform an operation in an independent transaction (such as logging an attempted security violation detected by a trigger).

- **Alerters (non-transactional):** You can post another process without requiring the waiting process to poll. If an "after-row" or "after-statement" trigger were to alert an application, then the application would treat this alert as an indication that the data probably changed. The application would then read the data to get the current value. Because this is an "after" trigger, the application would want to do a "SELECT FOR UPDATE" to make sure it read the correct data.

- **Debugging:** Triggers and stored procedures can send debugging information to a pipe. Another session can keep reading out of the pipe and display it on the screen or write it to a file.

- **Concentrator:** This is useful for multiplexing large numbers of users over a fewer number of network connections, or improving performance by concentrating several user-transactions into one DBMS transaction.
Security Model

Security can be achieved by use of GRANT EXECUTE on the DBMS_PIPE package by creating a pipe using the private parameter in the CREATE_PIPE function and by writing cover packages that only expose particular features or pipenames to particular users or roles.

Depending upon your security requirements, you may choose to use either Public Pipes or Private Pipes.
Constants

maxwait  constant integer := 86400000; /* 1000 days */

This is the maximum time to wait attempting to send or receive a message.
Operational Notes

Information sent through Oracle pipes is buffered in the system global area (SGA). All information in pipes is lost when the instance is shut down.

Caution: Pipes are independent of transactions. Be careful using pipes when transaction control can be affected.

The operation of DBMSPIPE is considered with regard to the following topics:

- Public Pipes
- Writing and Reading Pipes
- Private Pipes

Public Pipes

You may create a public pipe either implicitly or explicitly. For implicit public pipes, the pipe is automatically created when it is referenced for the first time, and it disappears when it no longer contains data. Because the pipe descriptor is stored in the SGA, there is some space usage overhead until the empty pipe is aged out of the cache.

You create an explicit public pipe by calling the CREATE_PIPE function with the private flag set to FALSE. You must deallocate explicitly-created pipes by calling the REMOVE_PIPE function.

The domain of a public pipe is the schema in which it was created, either explicitly or implicitly.

Writing and Reading Pipes

Each public pipe works asynchronously. Any number of schema users can write to a public pipe, as long as they have EXECUTE permission on the DBMS_PIPE package, and they know the name of the public pipe. However, once buffered information is read by one user, it is emptied from the buffer, and is not available for other readers of the same pipe.

The sending session builds a message using one or more calls to the PACK_MESSAGE procedure. This procedure adds the message to the session’s local message buffer. The information in this buffer is sent by calling the SEND_MESSAGE function, designating the pipe name to be used to send the message. When SEND_MESSAGE is called, all messages that have been stacked in the local buffer are sent.

A process that wants to receive a message calls the RECEIVE_MESSAGE function, designating the pipe name from which to receive the message. The process then calls the UNPACK_MESSAGE procedure to access each of the items in the message.

Private Pipes

You explicitly create a private pipe by calling the CREATE_PIPE function. Once created, the private pipe persists in shared memory until you explicitly deallocate it by calling the REMOVE_PIPE function. A private pipe is also deallocated when the database instance is shut down.
You cannot create a private pipe if an implicit pipe exists in memory and has the same name as the private pipe you are trying to create. In this case, CREATE_PIPE returns an error.

Access to a private pipe is restricted to:

- Sessions running under the same userid as the creator of the pipe
- Stored subprograms executing in the same userid privilege domain as the pipe creator
- Users connected as SYSDBA

An attempt by any other user to send or receive messages on the pipe, or to remove the pipe, results in an immediate error. Any attempt by another user to create a pipe with the same name also causes an error.

As with public pipes, you must first build your message using calls to PACK_MESSAGE before calling SEND_MESSAGE. Similarly, you must call RECEIVE_MESSAGE to retrieve the message before accessing the items in the message by calling UNPACK_MESSAGE.
Exceptions

DBMSPIPE package subprograms can return the following errors:

Table 103–1  DBMSPIPE Errors

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-23321</td>
<td>Pipename may not be null. This can be returned by the CREATEPIPE function, or any subprogram that takes a pipe name as a parameter.</td>
</tr>
<tr>
<td>ORA-23322</td>
<td>Insufficient privilege to access pipe. This can be returned by any subprogram that references a private pipe in its parameter list.</td>
</tr>
</tbody>
</table>
Examples

- Example 1: Debugging - PL/SQL
- Example 3: Execute System Commands
- Example 4: External Service Interface

Example 1: Debugging - PL/SQL

This example shows the procedure that a PL/SQL program can call to place debugging information in a pipe.

```sql
CREATE OR REPLACE PROCEDURE debug (msg VARCHAR2) AS
  status  NUMBER;
BEGIN
  DBMS_PIPE.PACK_MESSAGE(LENGTH(msg));
  DBMS_PIPE.PACK_MESSAGE(msg);
  status := DBMS_PIPE.SEND_MESSAGE('plsql_debug');
  IF status != 0 THEN
    raise_application_error(-20099, 'Debug error');
  END IF;
END debug;
```

Example 2: Debugging - Pro*C

The following Pro*C code receives messages from the PLSQL_DEBUG pipe in the previous example, and displays the messages. If the Pro*C session is run in a separate window, then it can be used to display any messages that are sent to the debug procedure from a PL/SQL program executing in a separate session.

```c
#include <stdio.h>
#include <string.h>

EXEC SQL BEGIN DECLARE SECTION;
  VARCHAR username[20];
  int     status;
  int     msg_length;
  char    retval[2000];
EXEC SQL END DECLARE SECTION;

EXEC SQL INCLUDE SQLCA;

void sql_error();

main()
{
  -- Prepare username:
  strcpy(username.arr, "SCOTT/TIGER");
  username.len = strlen(username.arr);

  EXEC SQL WHENEVER SQLERROR DO sql_error();
  EXEC SQL CONNECT :username;
  printf("connected\n");

  -- Start an endless loop to look for and print messages on the pipe:
  FOR (;;) {
    (}
```
Example 3: Execute System Commands

This example shows PL/SQL and Pro*C code let a PL/SQL stored procedure (or anonymous block) call PL/SQL procedures to send commands over a pipe to a Pro*C program that is listening for them.

The Pro*C program sleeps and waits for a message to arrive on the named pipe. When a message arrives, the Pro*C program processes it, carrying out the required action, such as executing a UNIX command through the `system()` call or executing a SQL command using embedded SQL.

`DAEMON.SQL` is the source code for the PL/SQL package. This package contains procedures that use the `DBMS_PIPE` package to send and receive message to and from the Pro*C daemon. Note that full handshaking is used. The daemon always sends a message back to the package (except in the case of the `STOP` command). This is valuable, because it allows the PL/SQL procedures to be sure that the Pro*C daemon is running.

You can call the `DAEMON` packaged procedures from an anonymous PL/SQL block using SQL*Plus or Enterprise Manager. For example:
Using DBMS_PIPE

SQLPLUS> variable rv number
SQLPLUS> execute :rv := DAEMON.EXECUTE_SYSTEM('ls -la');

On a UNIX system, this causes the Pro*C daemon to execute the command `ls -la`.

Remember that the daemon needs to be running first. You might want to run it in the background, or in another window beside the SQL*Plus or Enterprise Manager session from which you call it.

The DAEMON.SQL also uses the DBMS_OUTPUT package to display the results. For this example to work, you must have execute privileges on this package.

DAEMON.SQL Example. This is the code for the PL/SQL DAEMON package:

```sql
CREATE OR REPLACE PACKAGE daemon AS
  FUNCTION execute_sql(command VARCHAR2, timeout NUMBER DEFAULT 10) RETURN NUMBER;
  FUNCTION execute_system(command VARCHAR2, timeout NUMBER DEFAULT 10) RETURN NUMBER;
  PROCEDURE stop(timeout NUMBER DEFAULT 10);
END daemon;
/
CREATE OR REPLACE PACKAGE BODY daemon AS
  FUNCTION execute_system(command VARCHAR2, timeout NUMBER DEFAULT 10) RETURN NUMBER IS
    status NUMBER;
    result VARCHAR2(20);
    command_code NUMBER;
    pipe_name VARCHAR2(30);
    BEGIN
      pipe_name := DBMS_PIPE.UNIQUE_SESSION_NAME;
      DBMS_PIPE.PACK_MESSAGE('SYSTEM');
      DBMS_PIPE.PACK_MESSAGE(pipe_name);
      DBMS_PIPE.PACK_MESSAGE(command);
      status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
      IF status <> 0 THEN
        RAISE_APPLICATION_ERROR(-20010, 'Execute_system: Error while sending. Status = ' || status);
      END IF;
      status := DBMS_PIPE.RECEIVE_MESSAGE(pipe_name, timeout);
      IF status <> 0 THEN
        RAISE_APPLICATION_ERROR(-20011, 'Execute_system: Error while receiving. Status = ' || status);
      END IF;
      DBMS_PIPE.UNPACK_MESSAGE(result);
      IF result <> 'done' THEN
        RAISE_APPLICATION_ERROR(-20012, 'Execute_system: Done not received.');
      END IF;
    END execute_system;
  END daemon;
```

DBMS_PIPE 103-11
END IF;

DBMS_PIPE.UNPACK_MESSAGE(command_code);
DBMS_OUTPUT.PUT_LINE('System command executed. result = ' ||
                        command_code);
RETURN command_code;
END execute_system;

FUNCTION execute_sql(command VARCHAR2,
                        timeout NUMBER DEFAULT 10)
RETURN NUMBER IS
    status       NUMBER;
    result       VARCHAR2(20);
    command_code NUMBER;
    pipe_name    VARCHAR2(30);
BEGIN
    pipe_name := DBMS_PIPE.UNIQUE_SESSION_NAME;

    DBMS_PIPE.PACK_MESSAGE('SQL');
    DBMS_PIPE.PACK_MESSAGE(pipe_name);
    DBMS_PIPE.PACK_MESSAGE(command);
    status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
    IF status <> 0 THEN
        RAISE_APPLICATION_ERROR(-20020,
            'Execute_sql: Error while sending. Status = ' || status);
    END IF;

    status := DBMS_PIPE.RECEIVE_MESSAGE(pipe_name, timeout);
    IF status <> 0 THEN
        RAISE_APPLICATION_ERROR(-20021,
            'execute_sql: Error while receiving. Status = ' || status);
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(result);
    IF result <> 'done' THEN
        RAISE_APPLICATION_ERROR(-20022,
            'execute_sql: done not received.');
    END IF;

    DBMS_PIPE.UNPACK_MESSAGE(command_code);
    DBMS_OUTPUT.PUT_LINE
        ('SQL command executed. sqlcode = ' || command_code);
    RETURN command_code;
END execute_sql;

PROCEDURE stop(timeout NUMBER DEFAULT 10) IS
    status NUMBER;
BEGIN
    DBMS_PIPE.PACK_MESSAGE('STOP');
    status := DBMS_PIPE.SEND_MESSAGE('daemon', timeout);
    IF status <> 0 THEN
        RAISE_APPLICATION_ERROR(-20030,
            'stop: error while sending. status = ' || status);
    END IF;
    END stop;
END daemon;
daemon.pc Example. This is the code for the Pro*C daemon. You must precompile this using the Pro*C Precompiler, Version 1.5.x or later. You must also specify the USERID and SQLCHECK options, as the example contains embedded PL/SQL code.

Note: To use a VARCHAR output host variable in a PL/SQL block, you must initialize the length component before entering the block.

#include <stdio.h>
#include <string.h>
EXEC SQL INCLUDE SQLCA;
EXEC SQL BEGIN DECLARE SECTION;
char *uid = "scott/tiger";
int status;
VARCHAR command[20];
VARCHAR value[2000];
VARCHAR return_name[30];
EXEC SQL END DECLARE SECTION;

void connect_error()
{
    char msg_buffer[512];
    int msg_length;
    int buffer_size = 512;

    EXEC SQL WHENEVER SQLERROR CONTINUE;
    sqlglm(msg_buffer, &buffer_size, &msg_length);
    printf("Daemon error while connecting:\n");
    printf("%.9s\n", msg_length, msg_buffer);
    printf("Daemon quitting.\n");
    exit(1);
}

void sql_error()
{
    char msg_buffer[512];
    int msg_length;
    int buffer_size = 512;

    EXEC SQL WHENEVER SQLERROR CONTINUE;
    sqlglm(msg_buffer, &buffer_size, &msg_length);
    printf("Daemon error while executing:\n");
    printf("%.9s\n", msg_length, msg_buffer);
    printf("Daemon continuing.\n");
}
main()
{
    command.len = 20; /*initialize length components*/
    value.len = 2000;
    return_name.len = 30;
EXEC SQL WHENEVER SQLERROR DO connect_error();
EXEC SQL CONNECT :uid;
printf("Daemon connected.\n");

EXEC SQL WHENEVER SQLERROR DO sql_error();
printf("Daemon waiting...\n");
while (1) {
    EXEC SQL EXECUTE
    BEGIN
        :status := DBMS_PIPE.RECEIVE_MESSAGE('daemon');
        IF :status = 0 THEN
            DBMS_PIPE.UNPACK_MESSAGE(:command);
        END IF;
    END;
END-EXEC;
    IF (status == 0)
    {
        command.arr[command.len] = '\0';
        IF (!strcmp((char *) command.arr, "STOP"))
        {
            printf("Daemon exiting.\n");
            break;
        }
    }
    ELSE IF (!strcmp((char *) command.arr, "SYSTEM"))
    {
        EXEC SQL EXECUTE
        BEGIN
            DBMS_PIPE.UNPACK_MESSAGE(:return_name);
            DBMS_PIPE.UNPACK_MESSAGE(:value);
        END;
        END-EXEC;
        value.arr[value.len] = '\0';
        printf("Will execute system command '%s'\n", value.arr);
        status = system(value.arr);
        EXEC SQL EXECUTE
        BEGIN
            DBMS_PIPE.PACK_MESSAGE('done');
            DBMS_PIPE.PACK_MESSAGE(:status);
            :status := DBMS_PIPE.SEND_MESSAGE(:return_name);
        END;
        END-EXEC;
    }
    IF (status)
    {
        printf("Daemon error while responding to system command.\n");
        printf(" status: %d\n", status);
    }
    }
ELSE IF (!strcmp((char *) command.arr, "SQL"))
{
    EXEC SQL EXECUTE
    BEGIN
        DBMSPIPE.UNPACK_MESSAGE(:return_name);
        DBMS_PIPE.UNPACK_MESSAGE(:value);
    END;
    END-EXEC;
    value.arr[value.len] = '\0';
    printf("Will execute sql command '%s'\n", value.arr);
EXEC SQL WHENEVER SQLERROR CONTINUE;
EXEC SQL EXECUTE IMMEDIATE :value;
status = sqlca.sqlcode;

EXEC SQL WHENEVER SQLERROR DO sql_error();
EXEC SQL EXECUTE
BEGIN
  DBMS_PIPE.PACK_MESSAGE('done');
  DBMS_PIPE.PACK_MESSAGE(:status);
  :status := DBMS_PIPE.SEND_MESSAGE(:return_name);
END;
END-EXEC;

IF (status)
{
  printf("Daemon error while responding to sql command.");
  printf(" status: \%d\n", status);
}
ELSE
{
  printf("Daemon error: invalid command \'\%s\' received.\n", command.arr);
}
ELSE
{
  printf("Daemon error while waiting for signal.");
  printf(" status = \%d\n", status);
}

EXEC SQL COMMIT WORK RELEASE;
exit(0);

Example 4: External Service Interface

Put the user-written 3GL code into an OCI or Precompiler program. The program connects to the database and executes PL/SQL code to read its request from the pipe, computes the result, and then executes PL/SQL code to send the result on a pipe back to the requestor.

Below is an example of a stock service request. The recommended sequence for the arguments to pass on the pipe for all service requests is:

protocol_version   VARCHAR2   - '1', 10 bytes or less
returnpipe         VARCHAR2   - 30 bytes or less
service            VARCHAR2   - 30 bytes or less
arg1               VARCHAR2/NUMBER/DATE
...                
argn               VARCHAR2/NUMBER/DATE

The recommended format for returning the result is:

success            VARCHAR2   - 'SUCCESS' if OK,
                    otherwise error message
arg1               VARCHAR2/NUMBER/DATE
...                
argn               VARCHAR2/NUMBER/DATE
The "stock price request server" would do, using OCI or PRO* (in pseudo-code):

```plaintext
<loop forever>
  BEGIN dbms_stock_server.get_request(:stocksymbol); END;
  <figure out price based on stocksymbol (probably from some radio
  signal), set error if can't find such a stock>
  BEGIN dbms_stock_server.return_price(:error, :price); END;
</loop forever>
```

A client would do:

```plaintext
BEGIN :price := stock_request('YOURCOMPANY'); end;
```

The stored procedure, `dbms_stock_server`, which is called by the preceding "stock price request server" is:

```plaintext
CREATE OR REPLACE PACKAGE dbms_stock_server IS
  PROCEDURE get_request(symbol OUT VARCHAR2);
  PROCEDURE return_price(errormsg IN VARCHAR2, price IN VARCHAR2);
END;
```

```plaintext
CREATE OR REPLACE PACKAGE BODY dbms_stock_server IS
  returnpipe VARCHAR2(30);

  PROCEDURE returnerror(reason VARCHAR2) IS
    s INTEGER;
    BEGIN
      dbms_pipe.pack_message(reason);
      s := dbms_pipe.send_message(returnpipe);
      IF s <> 0 THEN
        raise_application_error(-20000, 'Error:' || to_char(s) || ' sending on pipe');
      END IF;
    END;

  PROCEDURE get_request(symbol OUT VARCHAR2) IS
    protocol_version VARCHAR2(10);
    s INTEGER;
    service VARCHAR2(30);
    BEGIN
      s := dbms_pipe.receive_message('stock_service');
      IF s <> 0 THEN
        raise_application_error(-20000, 'Error:' || to_char(s) || ' reading pipe');
      END IF;
      dbms_pipe.unpack_message(protocol_version);
      IF protocol_version <> '1' THEN
        raise_application_error(-20000, 'Bad protocol: ' || protocol_version);
      END IF;
      dbms_pipe.unpack_message(returnpipe);
      dbms_pipe.unpack_message(service);
      IF service != 'getprice' THEN
        returnerror('Service ' || service || ' not supported');
      END IF;
      dbms_pipe.unpack_message(symbol);
    END;

  PROCEDURE return_price(errormsg in VARCHAR2, price in VARCHAR2) IS
    s INTEGER;
    BEGIN
      IF errormsg is NULL THEN
```
dbms_pipe.pack_message('SUCCESS');
dbms_pipe.pack_message(price);
ELSE
  dbms_pipe.pack_message(errormsg);
END IF;
s := dbms_pipe.send_message(returnpipe);
IF s <> 0 THEN
  raise_application_error(-20000, 'Error:'||to_char(s)||
    ' sending on pipe');
END IF;
END;
END;

The procedure called by the client is:

CREATE OR REPLACE FUNCTION stock_request (symbol VARCHAR2)
RETURN VARCHAR2 IS
  s        INTEGER;
  price    VARCHAR2(20);
  errormsg VARCHAR2(512);
BEGIN
  dbms_pipe.pack_message('1');  -- protocol version
  dbms_pipe.pack_message(dbms_pipe.unique_session_name); -- return pipe
  dbms_pipe.pack_message('getprice');
  dbms_pipe.pack_message(symbol);
  s := dbms_pipe.send_message('stock_service');
  IF s <> 0 THEN
    raise_application_error(-20000, 'Error:'||to_char(s)||
      ' sending on pipe');
  END IF;
  s := dbms_pipe.receive_message(dbms_pipe.unique_session_name);
  IF s <> 0 THEN
    raise_application_error(-20000, 'Error:'||to_char(s)||
      ' receiving on pipe');
  END IF;
  dbms_pipe.unpack_message(errormsg);
  IF errormsg <> 'SUCCESS' THEN
    raise_application_error(-20000, errormsg);
  END IF;
  dbms_pipe.unpack_message(price);
  RETURN price;
END;

You would typically only GRANT EXECUTE on DBMS_STOCK_SERVICE to the stock service application server, and would only GRANT EXECUTE on stock_request to those users allowed to use the service.

<tr>
<td>UNIQUE_SESSION_NAME Function on page 103-31</td>
<td>Returns unique session name</td>
</tr>
<tr>
<td>UNPACK_MESSAGE Procedures on page 103-32</td>
<td>Accesses next item in buffer</td>
</tr>
</tbody>
</table>
**CREATE_PIPE Function**

This function explicitly creates a public or private pipe. If the private flag is TRUE, then the pipe creator is assigned as the owner of the private pipe.

Explicitly-created pipes can only be removed by calling REMOVE_PIPE, or by shutting down the instance.

**Syntax**

```sql
DBMS_PIPE.CREATE_PIPE (
    pipename     IN VARCHAR2,
    maxpipesize  IN INTEGER DEFAULT 8192,
    private      IN BOOLEAN DEFAULT TRUE)
RETURN INTEGER;
```

**Pragmas**

`pragma restrict_references(create_pipe,WNDS,RNDS);`

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipename</td>
<td>Name of the pipe you are creating. You must use this name when you call SEND_MESSAGE and RECEIVE_MESSAGE. This name must be unique across the instance. Caution: Do not use pipe names beginning with ORA$. These are reserved for use by procedures provided by Oracle. Pipename should not be longer than 128 bytes, and is case insensitive. At this time, the name cannot contain Globalization Support characters.</td>
</tr>
<tr>
<td>maxpipesize</td>
<td>The maximum size allowed for the pipe, in bytes. The total size of all of the messages on the pipe cannot exceed this amount. The message is blocked if it exceeds this maximum. The default maxpipesize is 8192 bytes. The maxpipesize for a pipe becomes a part of the characteristics of the pipe and persists for the life of the pipe. Callers of SEND_MESSAGE with larger values cause the maxpipesize to be increased. Callers with a smaller value use the existing, larger value.</td>
</tr>
<tr>
<td>private</td>
<td>Uses the default, TRUE, to create a private pipe. Public pipes can be implicitly created when you call SEND_MESSAGE.</td>
</tr>
</tbody>
</table>
Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0      | Successful.

If the pipe already exists and the user attempting to create it is authorized to use it, then Oracle returns 0, indicating success, and any data already in the pipe remains.

If a user connected as **SYSDBA/SYSOPER** re-creates a pipe, then Oracle returns status 0, but the ownership of the pipe remains unchanged.

| ORA-23322 | Failure due to naming conflict. |

If a pipe with the same name exists and was created by a different user, then Oracle signals error **ORA-23322**, indicating the naming conflict.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null pipe name</td>
<td>Permission error: Pipe with the same name already exists, and you are not allowed to use it.</td>
</tr>
</tbody>
</table>
**NEXT_ITEM_TYPE Function**

This function determines the datatype of the next item in the local message buffer. After you have called `RECEIVE_MESSAGE` to place pipe information in a local buffer, call `NEXT_ITEM_TYPE`.

**Syntax**

```sql
DBMS_PIPE.NEXT_ITEM_TYPE
RETURN INTEGER;
```

**Pragmas**

```sql
pragma restrict_references(next_item_type,WNDS,RNDS);
```

**Return Values**

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>No more items</td>
</tr>
<tr>
<td>6</td>
<td>NUMBER</td>
</tr>
<tr>
<td>9</td>
<td>VARCHAR2</td>
</tr>
<tr>
<td>11</td>
<td>ROWID</td>
</tr>
<tr>
<td>12</td>
<td>DATE</td>
</tr>
<tr>
<td>23</td>
<td>RAW</td>
</tr>
</tbody>
</table>
PACK_MESSAGE Procedures

This procedure builds your message in the local message buffer. To send a message, first make one or more calls to PACK_MESSAGE. Then, call SEND_MESSAGE to send the message in the local buffer on the named pipe.

The procedure is overloaded to accept items of type VARCHAR2, NCHAR, NUMBER, DATE, RAW and ROWID items. In addition to the data bytes, each item in the buffer requires one byte to indicate its type, and two bytes to store its length. One additional byte is needed to terminate the message. The overhead for all types other than VARCHAR is 4 bytes.

Syntax

```sql
DBMS_PIPE.PACK_MESSAGE (
  item  IN  VARCHAR2);

DBMS_PIPE.PACK_MESSAGE (
  item  IN  NCHAR);

DBMS_PIPE.PACK_MESSAGE (
  item  IN  NUMBER);

DBMS_PIPE.PACK_MESSAGE (
  item  IN  DATE);

DBMS_PIPE.PACK_MESSAGE_RAW (
  item  IN  RAW);

DBMS_PIPE.PACK_MESSAGE_ROWID (
  item  IN  ROWID);
```

Pragmas

```sql
pragma restrict_references(pack_message,WNDS,RNDS);
pragma restrict_references(pack_message_raw,WNDS,RNDS);
pragma restrict_references(pack_message_rowid,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>Item to pack into the local message buffer.</td>
</tr>
</tbody>
</table>

Usage Notes

In Oracle database version 8.x, the char-set-id (2 bytes) and the char-set-form (1 byte) are stored with each data item. Therefore, the overhead when using Oracle database version 8.x is 7 bytes.

When you call SEND_MESSAGE to send this message, you must indicate the name of the pipe on which you want to send the message. If this pipe already exists, then you must have sufficient privileges to access this pipe. If the pipe does not already exist, then it is created automatically.
Exceptions

ORA-06558 is raised if the message buffer overflows (currently 4096 bytes). Each item in the buffer takes one byte for the type, two bytes for the length, plus the actual data. There is also one byte needed to terminate the message.
PURGE Procedure

This procedure empties the contents of the named pipe. An empty implicitly-created pipe is aged out of the shared global area according to the least-recently-used algorithm. Thus, calling PURGE lets you free the memory associated with an implicitly-created pipe.

Syntax

```sql
DBMS_PIPE.PURGE (
    pipename  IN  VARCHAR2);
```

Pragmas

```
pragma restrict_references(purge,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipename</td>
<td>Name of pipe from which to remove all messages. The local buffer may be overwritten with messages as they are discarded. Pipename should not be longer than 128 bytes, and is case-insensitive.</td>
</tr>
</tbody>
</table>

Usage Notes

Because PURGE calls RECEIVE_MESSAGE, the local buffer might be overwritten with messages as they are purged from the pipe. Also, you can receive an ORA-23322 (insufficient privileges) error if you attempt to purge a pipe with which you have insufficient access rights.

Exceptions

Permission error if pipe belongs to another user.
RECEIVE_MESSAGE Function

This function copies the message into the local message buffer.

Syntax

```sql
DBMS_PIPE.RECEIVE_MESSAGE (    pipename     IN VARCHAR2,    timeout      IN INTEGER      DEFAULT maxwait) RETURN INTEGER;
```

Pragmas

```sql
pragma restrict_references(receive_message,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipename</td>
<td>Name of the pipe on which you want to receive a message. Names beginning with ORA$ are reserved for use by Oracle.</td>
</tr>
<tr>
<td>timeout</td>
<td>Time to wait for a message, in seconds. The default value is the constant MAXWAIT, which is defined as 86400000 (1000 days). A timeout of 0 lets you read without blocking.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
<tr>
<td>1</td>
<td>Timed out. If the pipe was implicitly-created and is empty, then it is removed.</td>
</tr>
<tr>
<td>2</td>
<td>Record in the pipe is too large for the buffer. (This should not happen.)</td>
</tr>
<tr>
<td>3</td>
<td>An interrupt occurred.</td>
</tr>
<tr>
<td>ORA-23322</td>
<td>User has insufficient privileges to read from the pipe.</td>
</tr>
</tbody>
</table>

Usage Notes

To receive a message from a pipe, first call RECEIVE_MESSAGE. When you receive a message, it is removed from the pipe; hence, a message can only be received once. For implicitly-created pipes, the pipe is removed after the last record is removed from the pipe.

If the pipe that you specify when you call RECEIVE_MESSAGE does not already exist, then Oracle implicitly creates the pipe and waits to receive the message. If the message does not arrive within a designated timeout interval, then the call returns and the pipe is removed.

After receiving the message, you must make one or more calls to UNPACK_MESSAGE to access the individual items in the message. The UNPACK_MESSAGE procedure is
overloaded to unpack items of type DATE, NUMBER, VARCHAR2, and there are two additional procedures to unpack RAW and ROWID items. If you do not know the type of data that you are attempting to unpack, then call NEXT_ITEM_TYPE to determine the type of the next item in the buffer.

Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null pipe name</td>
<td>Permission error. Insufficient privilege to remove the record from the pipe. The pipe is owned by someone else.</td>
</tr>
</tbody>
</table>
RESET_BUFFER Procedure

This procedure resets the PACK_MESSAGE and UNPACK_MESSAGE positioning indicators to 0.

Because all pipes share a single buffer, you may find it useful to reset the buffer before using a new pipe. This ensures that the first time you attempt to send a message to your pipe, you do not inadvertently send an expired message remaining in the buffer.

Syntax

```
DBMS_PIPE.RESET_BUFFER;
```

Pragmas

```
pragma restrict_references(reset_buffer,WNDS,RNDS);
```
**REMOVE_PIPE Function**

This function removes explicitly-created pipes.

Pipes created implicitly by `SEND_MESSAGE` are automatically removed when empty. However, pipes created explicitly by `CREATE_PIPE` are removed only by calling `REMOVE_PIPE`, or by shutting down the instance. All unconsumed records in the pipe are removed before the pipe is deleted.

This is similar to calling `PURGE` on an implicitly-created pipe.

**Syntax**

```sql
DBMS_PIPE.REMOVE_PIPE (pipename  IN  VARCHAR2) RETURN INTEGER;
```

**Pragmas**

```sql
pragma restrict_references(remove_pipe,WNDS,RNDS);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipename</td>
<td>Name of pipe that you want to remove.</td>
</tr>
</tbody>
</table>

**Return Values**

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success</td>
</tr>
</tbody>
</table>

If the pipe does not exist, or if the pipe already exists and the user attempting to remove it is authorized to do so, then Oracle returns 0, indicating success, and any data remaining in the pipe is removed.

| ORA-23322 | Insufficient privileges. |

If the pipe exists, but the user is not authorized to access the pipe, then Oracle signals error ORA-23322, indicating insufficient privileges.

**Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null pipe name</td>
<td>Permission error: Insufficient privilege to remove pipe. The pipe was created and is owned by someone else.</td>
</tr>
</tbody>
</table>
SEND_MESSAGE Function

This function sends a message on the named pipe.

The message is contained in the local message buffer, which was filled with calls to PACK_MESSAGE. You can create a pipe explicitly using CREATE_PIPE, otherwise, it is created implicitly.

Syntax

```
DBMS_PIPE SEND_MESSAGE (
    pipename     IN VARCHAR2,
    timeout      IN INTEGER DEFAULT MAXWAIT,
    maxpipesize  IN INTEGER DEFAULT 8192)
RETURN INTEGER;
```

Pragmas

```
pragma restrict_references(send_message,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pipename</td>
<td>Name of the pipe on which you want to place the message. If you are using an explicit pipe, then this is the name that you specified when you called CREATE_PIPE. Caution: Do not use pipe names beginning with 'ORA$. These names are reserved for use by procedures provided by Oracle. Pipename should not be longer than 128 bytes, and is case-insensitive. At this time, the name cannot contain Globalization Support characters.</td>
</tr>
<tr>
<td>timeout</td>
<td>Time to wait while attempting to place a message on a pipe, in seconds. The default value is the constant MAXWAIT, which is defined as 86400000 (1000 days).</td>
</tr>
<tr>
<td>maxpipesize</td>
<td>Maximum size allowed for the pipe, in bytes. The total size of all the messages on the pipe cannot exceed this amount. The message is blocked if it exceeds this maximum. The default is 8192 bytes. The maxpipesize for a pipe becomes a part of the characteristics of the pipe and persists for the life of the pipe. Callers of SEND_MESSAGE with larger values cause the maxpipesize to be increased. Callers with a smaller value simply use the existing, larger value. Specifying maxpipesize as part of the SEND_MESSAGE procedure eliminates the need for a separate call to open the pipe. If you created the pipe explicitly, then you can use the optional maxpipesize parameter to override the creation pipe size specifications.</td>
</tr>
</tbody>
</table>
Return Values

Table 103–16 SEND_MESSAGE Function Return Values

<table>
<thead>
<tr>
<th>Return</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Success. If the pipe already exists and the user attempting to create it is authorized to use it, then Oracle returns 0, indicating success, and any data already in the pipe remains. If a user connected as SYSDBS/SYSOPER re-creates a pipe, then Oracle returns status 0, but the ownership of the pipe remains unchanged.</td>
</tr>
<tr>
<td>1</td>
<td>Timed out. This procedure can timeout either because it cannot get a lock on the pipe, or because the pipe remains too full to be used. If the pipe was implicitly-created and is empty, then it is removed.</td>
</tr>
<tr>
<td>3</td>
<td>An interrupt occurred. If the pipe was implicitly created and is empty, then it is removed.</td>
</tr>
<tr>
<td>ORA-23322</td>
<td>Insufficient privileges. If a pipe with the same name exists and was created by a different user, then Oracle signals error ORA-23322, indicating the naming conflict.</td>
</tr>
</tbody>
</table>

Exceptions

Table 103–17 SEND_MESSAGE Function Exception

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Null pipe name</td>
<td>Permission error. Insufficient privilege to write to the pipe. The pipe is private and owned by someone else.</td>
</tr>
</tbody>
</table>
UNIQUE_SESSION_NAME Function

This function receives a name that is unique among all of the sessions that are currently connected to a database.

Multiple calls to this function from the same session always return the same value. You might find it useful to use this function to supply the PIPENAME parameter for your SEND_MESSAGE and RECEIVE_MESSAGE calls.

Syntax

```
DBMS_PIPE.UNIQUE_SESSION_NAME
    RETURN VARCHAR2;
```

Pragmas

```
pragma restrict_references(unique_session_name,WNDS,RNDS,WNPS);
```

Return Values

This function returns a unique name. The returned name can be up to 30 bytes.
UNPACK_MESSAGE Procedures

This procedure retrieves items from the buffer. After you have called RECEIVE_MESSAGE to place pipe information in a local buffer, call UNPACK_MESSAGE.

Note: The UNPACK_MESSAGE procedure is overloaded to return items of type VARCHAR2, NCHAR, NUMBER, or DATE. There are two additional procedures to unpack RAW and ROWID items.

Syntax

```
DBMS_PIPE.UNPACK_MESSAGE (
  item  OUT VARCHAR2);

DBMS_PIPE.UNPACK_MESSAGE (
  item  OUT NCHAR);

DBMS_PIPE.UNPACK_MESSAGE (
  item  OUT NUMBER);

DBMS_PIPE.UNPACK_MESSAGE (
  item  OUT DATE);

DBMS_PIPE.UNPACK_MESSAGE_RAW (
  item  OUT RAW);

DBMS_PIPE.UNPACK_MESSAGE_ROWID (
  item  OUT ROWID);
```

Pragmas

```
pragma restrict_references(unpack_message,WNDS,RNDS);
pragma restrict_references(unpack_message_raw,WNDS,RNDS);
pragma restrict_references(unpack_message_rowid,WNDS,RNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>item</td>
<td>Argument to receive the next unpacked item from the local message buffer.</td>
</tr>
</tbody>
</table>

Exceptions

ORA-06556 or 06559 are generated if the buffer contains no more items, or if the item is not of the same type as that requested.
Data mining can discover useful information buried in vast amounts of data. However, it is often the case that both the programming interfaces and the data mining expertise required to obtain these results are too complex for use by the wide audiences that can obtain benefits from using Oracle Data Mining.

The DBMS_PREDICTIVE_ANALYTICS package addresses both of these complexities by automating the entire data mining process from data preprocessing through model building to scoring new data. This package provides an important tool that makes data mining possible for a broad audience of users, in particular, business analysts.

See Also: Oracle Data Mining Concepts for an overview of Oracle predictive analytics, including information about the Oracle Spreadsheet Add-In for Predictive Analytics.

This chapter contains the following topics:

- Using DBMS_PREDICTIVE_ANALYTICS
  - Overview
  - Security Model
- Summary of DBMS_PREDICTIVE_ANALYTICS Subprograms
Using DBMS_PREDICTIVE_ANALYTICS

This section contains topics that relate to using the DBMS_PREDICTIVE_ANALYTICS package.

- Overview
- Security Model
Overview

Data mining, according to a commonly used process model, requires the following steps:

1. Understand the business problem.
2. Understand the data.
3. Prepare the data for mining.
4. Create models using the prepared data.
5. Evaluate the models.
6. Deploy and use the model to score new data.

DBMS_PREDICTIVE_ANALYTICS automates parts of step 3 — 5 of this process.

Predictive analytics procedures analyze and prepare the input data, create and test mining models using the input data, and then use the input data for scoring. The results of scoring are returned to the user. The models and supporting objects are not preserved after the operation completes.
Security Model

The DBMS_PREDICTIVE_ANALYTICS package is owned by user SYS and is installed as part of database installation. Execution privilege on the package is granted to public. The routines in the package are run with invokers’ rights (run with the privileges of the current user).

The DBMS_PREDICTIVE_ANALYTICS package exposes APIs which are leveraged by the Oracle Data Mining option. Users who wish to invoke procedures in this package require the CREATE_MINING_MODEL system privilege (as well as the CREATE_TABLE and CREATE_VIEW system privilege).
### Summary of DBMS_PREDICTIVE_ANALYTICS Subprograms

**Table 104–1  DBMS_PREDICTIVE_ANALYTICS Package Subprograms**

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>EXPLAIN Procedure</td>
<td>Ranks attributes in order of influence in explaining a target column.</td>
</tr>
<tr>
<td>on page 104-6</td>
<td></td>
</tr>
<tr>
<td>PREDICT Procedure</td>
<td>Predicts the value of a target column based on values in the input data.</td>
</tr>
<tr>
<td>on page 104-8</td>
<td></td>
</tr>
<tr>
<td>PROFILE Procedure</td>
<td>Generates rules that identify the records that have the same target value.</td>
</tr>
<tr>
<td>on page 104-10</td>
<td></td>
</tr>
</tbody>
</table>
The **EXPLAIN** procedure identifies the attributes that are important in explaining the variation in values of a target column.

The input data must contain some records where the target value is known (not NULL). These records are used by the procedure to train a model that calculates the attribute importance.

---

**Note:** EXPLAIN supports DATE and TIMESTAMP data types in addition to the numeric, character, and nested data types supported by Oracle Data Mining models.

Data requirements for Oracle Data Mining are described in *Oracle Data Mining Application Developer’s Guide*.

---

The **EXPLAIN** procedure creates a result table that lists the attributes in order of their explanatory power. The result table is described in the Usage Notes.

**Syntax**

```sql
DBMS_PREDICTIVE_ANALYTICS.EXPLAIN (  
data_table_name     IN VARCHAR2,
    explain_column_name IN VARCHAR2,
    result_table_name   IN VARCHAR2,
    data_schema_name    IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_table_name</td>
<td>Name of input table or view</td>
</tr>
<tr>
<td>explain_column_name</td>
<td>Name of the column to be explained</td>
</tr>
<tr>
<td>result_table_name</td>
<td>Name of the table where results are saved</td>
</tr>
<tr>
<td>data_schema_name</td>
<td>Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.</td>
</tr>
</tbody>
</table>

**Usage Notes**

The **EXPLAIN** procedure creates a result table with the columns described in Table 104–3.
Example

The following example performs an EXPLAIN operation on the SUPPLEMENTARY_DEMOGRAPHICS table of Sales History.

```sql
-- Perform EXPLAIN operation
BEGIN
    DBMS_PREDICTIVE_ANALYTICS.EXPLAIN(
        data_table_name      => 'supplementary_demographics',
        explain_column_name  => 'home_theater_package',
        result_table_name    => 'demographics_explain_result');
END;
/
-- Display results
SELECT * FROM demographics_explain_result;
```

<table>
<thead>
<tr>
<th>ATTRIBUTE_NAME</th>
<th>EXPLANATORY_VALUE</th>
<th>RANK</th>
</tr>
</thead>
<tbody>
<tr>
<td>Y_BOX_GAMES</td>
<td>.524311073</td>
<td>1</td>
</tr>
<tr>
<td>YRS_RESIDENCE</td>
<td>.495987246</td>
<td>2</td>
</tr>
<tr>
<td>HOUSEHOLD_SIZE</td>
<td>.146208506</td>
<td>3</td>
</tr>
<tr>
<td>AFFINITY_CARD</td>
<td>.0598227</td>
<td>4</td>
</tr>
<tr>
<td>EDUCATION</td>
<td>.018462703</td>
<td>5</td>
</tr>
<tr>
<td>OCCUPATION</td>
<td>.009721543</td>
<td>6</td>
</tr>
<tr>
<td>FLAT_PANEL_MONITOR</td>
<td>.00013733</td>
<td>7</td>
</tr>
<tr>
<td>PRINTER_SUPPLIES</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>OS_DOC_SET_KANJI</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>BULK_PACK_DISKETTES</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>BOOKKEEPING_APPLICATION</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>COMMENTS</td>
<td>0</td>
<td>8</td>
</tr>
<tr>
<td>CUST_ID</td>
<td>0</td>
<td>8</td>
</tr>
</tbody>
</table>

The results show that Y_BOX_GAMES, YRS_RESIDENCE, and HOUSEHOLD_SIZE are the best predictors of HOME_THEATER_PACKAGE.
The PREDICT procedure predicts the values of a target column. The input data must contain some records where the target value is known (not NULL). These records are used by the procedure to train and test a model that makes the predictions.

**Note:** PREDICT supports DATE and TIMESTAMP data types in addition to the numeric, character, and nested data types supported by Oracle Data Mining models.

Data requirements for Oracle Data Mining are described in *Oracle Data Mining Application Developer's Guide*.

The PREDICT procedure creates a result table with the columns described in Table 104–5.

Data requirements for Oracle Data Mining are described in *Oracle Data Mining Application Developer's Guide*.

### Syntax

```sql
DBMS_PREDICTIVE_ANALYTICS.PREDICT (
    accuracy                  OUT NUMBER,
    data_table_name           IN VARCHAR2,
    case_id_column_name       IN VARCHAR2,
    target_column_name        IN VARCHAR2,
    result_table_name         IN VARCHAR2,
    data_schema_name          IN VARCHAR2 DEFAULT NULL);
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>accuracy</td>
<td>Output parameter that returns the predictive confidence, a measure of the accuracy of the predicted values. The predictive confidence for a categorical target is the most common target value; the predictive confidence for a numerical target is the mean.</td>
</tr>
<tr>
<td>data_table_name</td>
<td>Name of the input table or view.</td>
</tr>
<tr>
<td>case_id_column_name</td>
<td>Name of the column that uniquely identifies each case (record) in the input data.</td>
</tr>
<tr>
<td>target_column_name</td>
<td>Name of the column to predict.</td>
</tr>
<tr>
<td>result_table_name</td>
<td>Name of the table where results will be saved.</td>
</tr>
<tr>
<td>data_schema_name</td>
<td>Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.</td>
</tr>
</tbody>
</table>

### Usage Notes

The PREDICT procedure creates a result table with the columns described in Table 104–5.
Predictions are returned for all cases whether or not they contained target values in
the input.

Predicted values for known cases may be interesting in some situations. For example,
you could perform deviation analysis to compare predicted values and actual values.

**Example**

The following example performs a `PREDICT` operation and displays the first 10
predictions. The results show an accuracy of 79% in predicting whether each customer
has an affinity card.

```sql
--Perform PREDICT operation
DECLARE
  v_accuracy NUMBER(10,9);
BEGIN
  DBMS_PREDICTIVE_ANALYTICS.PREDICT(
    accuracy => v_accuracy,
    data_table_name => 'supplementary_demographics',
    case_id_column_name => 'cust_id',
    target_column_name => 'affinity_card',
    result_table_name => 'pa_demographics_predict_result');
  DBMS_OUTPUT.PUT_LINE('Accuracy = ' || v_accuracy);
END;
/

Accuracy = .788696903

--Display results
SELECT * FROM pa_demographics_predict_result WHERE rownum < 10;
```

<table>
<thead>
<tr>
<th>CUST_ID</th>
<th>PREDICTION</th>
<th>PROBABILITY</th>
</tr>
</thead>
<tbody>
<tr>
<td>101501</td>
<td>1</td>
<td>.834069848</td>
</tr>
<tr>
<td>101502</td>
<td>0</td>
<td>.991269965</td>
</tr>
<tr>
<td>101503</td>
<td>0</td>
<td>.999783111</td>
</tr>
<tr>
<td>101504</td>
<td>1</td>
<td>.971643388</td>
</tr>
<tr>
<td>101505</td>
<td>1</td>
<td>.541754127</td>
</tr>
<tr>
<td>101506</td>
<td>0</td>
<td>.803719133</td>
</tr>
<tr>
<td>101507</td>
<td>0</td>
<td>.999999303</td>
</tr>
<tr>
<td>101508</td>
<td>0</td>
<td>.999999987</td>
</tr>
<tr>
<td>101509</td>
<td>0</td>
<td>.999999374</td>
</tr>
</tbody>
</table>

**Table 104–5 PREDICT Procedure Result Table**

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Case ID column name</td>
<td>VARCHAR2 or NUMBER</td>
<td>The name of the case ID column in the input data.</td>
</tr>
<tr>
<td>PREDICTION</td>
<td>VARCHAR2 or NUMBER</td>
<td>The predicted value of the target column for the given case.</td>
</tr>
<tr>
<td>PROBABILITY</td>
<td>NUMBER</td>
<td>For classification (categorical target), the probability of the prediction. For regression problems (numerical target), this column contains NULL.</td>
</tr>
</tbody>
</table>

**Note:** Make sure that the name of the case ID column is not 'PREDICTION' or 'PROBABILITY'.

PROFILE Procedure

The PROFILE procedure generates rules that describe the cases (records) from the input data. For example, if a target column `CHURN` has values 'Yes' and 'No', PROFILE generates a set of rules describing the expected outcomes. Each profile includes a rule, record count, and a score distribution.

The input data must contain some cases where the target value is known (not NULL). These cases are used by the procedure to build a model that calculates the rules.

---

**Note:** PROFILE does not support nested types or dates.

Data requirements for Oracle Data Mining are described in *Oracle Data Mining Application Developer’s Guide*.

---

The PROFILE procedure creates a result table that specifies rules (profiles) and their corresponding target values. The result table is described in the Usage Notes.

**Syntax**

```sql
DBMS_PREDICTIVE_ANALYTICS.PROFILE (
  data_table_name           IN VARCHAR2,
  target_column_name        IN VARCHAR2,
  result_table_name         IN VARCHAR2,
  data_schema_name          IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>data_table_name</td>
<td>Name of the table containing the data to be analyzed.</td>
</tr>
<tr>
<td>target_column_name</td>
<td>Name of the target column.</td>
</tr>
<tr>
<td>result_table_name</td>
<td>Name of the table where the results will be saved.</td>
</tr>
<tr>
<td>data_schema_name</td>
<td>Name of the schema where the input table or view resides and where the result table is created. Default: the current schema.</td>
</tr>
</tbody>
</table>

**Usage Notes**

The PROFILE procedure creates a result table with the columns described in Table 104–7.

<table>
<thead>
<tr>
<th>Column Name</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROFILE_ID</td>
<td>NUMBER</td>
<td>A unique identifier for this profile (rule).</td>
</tr>
<tr>
<td>RECORD_COUNT</td>
<td>NUMBER</td>
<td>The number of records described by the profile.</td>
</tr>
<tr>
<td>DESCRIPTION</td>
<td>SYS.XMLTYPE</td>
<td>The profile rule. See &quot;XML Schema for Profile Rules&quot;.</td>
</tr>
</tbody>
</table>

**XML Schema for Profile Rules**

The DESCRIPTION column of the result table contains XML that conforms to the following XSD:

---
Example

This example generates a rule describing customers who are likely to use an affinity card (target value is 1) and a set of rules describing customers who are not likely to use an affinity card (target value is 0). The rules are based on only two predictors: education and occupation.

```
SET serveroutput ON
SET trimspool ON
SET pages 10000
SET long 10000
SET pagesize 10000
SET linesize 150
CREATE VIEW cust_edu_occ_view AS
    SELECT cust_id, education, occupation, affinity_card
    FROM sh.supplementary_demographics;
BEGIN
    DBMS_PREDICTIVE_ANALYTICS.PROFILE(
        DATA_TABLE_NAME    => 'cust_edu_occ_view',
        TARGET_COLUMN_NAME => 'affinity_card',
        RESULT_TABLE_NAME  => 'profile_result');
END;
/
```

This example generates eight rules in the result table `profile_result`. Seven of the rules suggest a target value of 0; one rule suggests a target value of 1. The `score` attribute on a rule identifies the target value.

This `SELECT` statement returns all the rules in the result table.

```
SELECT a.profile_id, a.record_count, a.description.getstringval()
FROM profile_result a;
```

This `SELECT` statement returns the rules for a target value of 0.

```
SELECT *
FROM profile_result t
WHERE extractvalue(t.description, '/SimpleRule/@score') = 0;
```

To obtain more readable output, you can cut and paste the XML for a rule into a text file, save it with the .xml extension, and view the rule in a browser. The eight rules generated by this example are displayed as follows.

```
<SimpleRule id='1' score='0' recordCount='443'>
    <CompoundPredicate booleanOperator='and'>
        <SimpleSetPredicate field='OCCUPATION' booleanOperator='isIn'>
            <Array type='string'>"Armed-F" "Exec." "Prof." "Protec."</Array>
        </SimpleSetPredicate>
    </CompoundPredicate>
</SimpleRule>
```
<SimpleSetPredicate field="EDUCATION" booleanOperator="isIn">

The DBMS_PREPROCESSOR package provides an interface to print or retrieve the source text of a PL/SQL unit in its post-processed form.

This package contains the following topics

- Using DBMS_PREPROCESSOR
  - Overview
  - Operating Notes
- Data Structures
  - Table Types
- Summary of DBMS_PREPROCESSOR Subprograms
Using DBMS_PREPROCESSOR

- Overview
- Operating Notes
Overview

There are three styles of subprograms.

1. Subprograms that take a schema name, a unit type name, and the unit name.
2. Subprograms that take a VARCHAR2 string which contains the source text of an arbitrary PL/SQL compilation unit.
3. Subprograms that take a VARCHAR2 index-by table which contains the segmented source text of an arbitrary PL/SQL compilation unit.

Subprograms of the first style are used to print or retrieve the post-processed source text of a stored PL/SQL unit. The user must have the privileges necessary to view the original source text of this unit. The user must also specify the schema in which the unit is defined, the type of the unit, and the name of the unit. If the schema is null, then the current user schema is used. If the status of the stored unit is VALID and the user has the required privilege, then the post-processed source text is guaranteed to be the same as that of the unit the last time it was compiled.

Subprograms of the second or third style are used to generate post-processed source text in the current user schema. The source text is passed in as a single VARCHAR2 string in the second style, or as a VARCHAR2 index-by table in the third style. The source text can represent an arbitrary PL/SQL compilation unit. A typical usage is to pass the source text of an anonymous block and generate its post-processed source text in the current user schema. The third style can be useful when the source text exceeds the VARCHAR2 length limit.
Operating Notes

- For subprograms of the first style, the status of the stored PL/SQL unit does not need to be VALID. Likewise, the source text passed in as a VARCHAR2 string or a VARCHAR2 index-by table may contain compile time errors. If errors are found when generating the post-processed source, the error message text will also appear at the end of the post-processed source text. In some cases, the preprocessing can be aborted because of errors. When this happens, the post-processed source text will appear to be incomplete and the associated error message can help to indicate that an error has occurred during preprocessing.

- For subprograms of the second or third style, the source text can represent any arbitrary PL/SQL compilation unit. However, the source text of a valid PL/SQL compilation unit cannot include commonly used prefixes such as CREATE OR REPLACE. In general, the input source should be syntactically prepared in a way as if it were obtained from the ALL_SOURCE view. The following list gives some examples of valid initial syntax for some PL/SQL compilation units.

```
anonymous block   (BEGIN | DECLARE) ...
package           PACKAGE <name> ...
package body      PACKAGE BODY <name> ...
procedure         PROCEDURE <name> ...
function          FUNCTION <name> ...
type              TYPE <name> ...
type body         TYPE BODY <name> ...
trigger           (BEGIN | DECLARE) ...
```

If the source text represents a named PL/SQL unit that is valid, that unit will not be created after its post-processed source text is generated.

- If the text of a wrapped PL/SQL unit is obtained from the ALL_SOURCE view, the keyword WRAPPED always immediately follows the name of the unit, as in this example:

```
PROCEDURE "some proc" WRAPPED
a000000
b2
...
```

If such source text is presented to one of the GET_POST_PROCESSED_SOURCE Functions or to one of the PRINT_POST_PROCESSED_SOURCE Procedures, the exception DBMS_PREPROCESSOR.WRAPPED_INPUT is raised.
Data Structures

The DBMS_PREPROCESSOR package defines a TABLE type.

Table Types

SOURCE_LINES_T Table Type
SOURCE_LINES_T Table Type

This table type stores lines of post-processed source text. It is used to hold PL/SQL source text both before and after it is processed. It is especially useful in cases in which the amount of text exceeds 32K.

Syntax

```sql
TYPE source_lines_t IS
  TABLE OF VARCHAR2(32767) INDEX BY BINARY_INTEGER;
```
### Summary of DBMS_PREPROCESSOR Subprograms

**Table 105–1  DBMS_PREPROCESSOR Package Subprograms**

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GET_POST_PROCESSED_SOURCE Functions on page 105-8</td>
<td>Returns the post-processed source text</td>
</tr>
<tr>
<td>PRINT_POST_PROCESSED_SOURCE Procedures on page 105-10</td>
<td>Prints post-processed source text</td>
</tr>
</tbody>
</table>
GET_POST_PROCESSED_SOURCE Functions

This overloaded function returns the post-processed source text. The different functionality of each form of syntax is presented along with the definition.

Syntax

Returns post-processed source text of a stored PL/SQL unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
    object_type    IN VARCHAR2,
    schema_name    IN VARCHAR2,
    object_name    IN VARCHAR2)
RETURN source_lines_t;
```

Returns post-processed source text of a compilation unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
    source        IN VARCHAR2)
RETURN source_lines_t;
```

Returns post-processed source text of an INDEX-BY table containing the source text of the compilation unit:

```
DBMS_PREPROCESSOR.GET_POST_PROCESSED_SOURCE (
    source        IN source_lines_t)
RETURN source_lines_t;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>Must be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, BODY or TRIGGER. Case sensitive.</td>
</tr>
<tr>
<td>schema_name</td>
<td>The schema name. Case insensitive unless a quoted identifier is used. If NULL, use current schema.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object. The object_type is always case insensitive. Case insensitive unless a quoted identifier is used.</td>
</tr>
<tr>
<td>source</td>
<td>The source text of the compilation unit</td>
</tr>
<tr>
<td>source_lines_t</td>
<td>INDEX-BY table containing the source text of the compilation unit. The source text is a concatenation of all the non-NULL INDEX-BY table elements in ascending index order.</td>
</tr>
</tbody>
</table>

Return Values

The function returns an INDEX-BY table containing the lines of the post-processed source text starting from index 1.

Usage Notes

- Newline characters are not removed.
- Each line in the post-processed source text is mapped to a row in the INDEX-BY table.
- In the post-processed source, unselected text will have blank lines.
## Exceptions

### Table 105–3  GET_POST_PROCESSED_SOURCE Function Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-24234</td>
<td>Insufficient privileges or object does not exist</td>
</tr>
<tr>
<td>ORA-24235</td>
<td>Bad value for object type. Should be one of PACKAGE, PACKAGE BODY, PROCEDURE, FUNCTION, TYPE, BODY or TRIGGER.</td>
</tr>
<tr>
<td>ORA-24236</td>
<td>The source text is empty</td>
</tr>
<tr>
<td>ORA-00931</td>
<td>Missing identifier. The object_name should not be NULL.</td>
</tr>
<tr>
<td>ORA-06502</td>
<td>Numeric or value error:</td>
</tr>
<tr>
<td></td>
<td>- Character string buffer too small</td>
</tr>
<tr>
<td></td>
<td>- A line is too long (&gt; 32767 bytes)</td>
</tr>
</tbody>
</table>
This overloaded procedure calls `DBMS_OUTPUT.PUT_LINE` to let you view post-processed source text. The different functionality of each form of syntax is presented along with the definition.

**Syntax**

Prints post-processed source text of a stored PL/SQL unit:

```sql
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (object_type    IN VARCHAR2,
                                                    schema_name    IN VARCHAR2,
                                                    object_name    IN VARCHAR2);
```

Prints post-processed source text of a compilation unit:

```sql
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (source        IN VARCHAR2);
```

Prints post-processed source text of an `INDEX-BY` table containing the source text of the compilation unit:

```sql
DBMS_PREPROCESSOR.PRINT_POST_PROCESSED_SOURCE (source        IN source_lines_t);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>object_type</code></td>
<td>Must be one of <code>PACKAGE</code>, <code>PACKAGE BODY</code>, <code>PROCEDURE</code>, <code>FUNCTION</code>, <code>TYPE</code>, <code>TYPE</code>, <code>BODY</code> or <code>TRIGGER</code>. Case sensitive.</td>
</tr>
<tr>
<td><code>schema_name</code></td>
<td>The schema name. Case insensitive unless a quoted identifier is used. If NULL, use current schema.</td>
</tr>
<tr>
<td><code>object_name</code></td>
<td>The name of the object. The <code>object_type</code> is always case insensitive. Case insensitive unless a quoted identifier is used.</td>
</tr>
<tr>
<td><code>source</code></td>
<td>The source text of the compilation unit</td>
</tr>
<tr>
<td><code>source_lines_t</code></td>
<td><code>INDEX-BY</code> table containing the source text of the compilation unit. The source text is a concatenation of all the non-NULL <code>INDEX-BY</code> table elements in ascending index order.</td>
</tr>
</tbody>
</table>

**Exceptions**

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ORA-24234</td>
<td>Insufficient privileges or object does not exist</td>
</tr>
<tr>
<td>ORA-24235</td>
<td>Bad value for object type. Should be one of <code>PACKAGE</code>, <code>PACKAGE BODY</code>, <code>PROCEDURE</code>, <code>FUNCTION</code>, <code>TYPE</code>, <code>TYPE</code>, <code>BODY</code> or <code>TRIGGER</code>.</td>
</tr>
<tr>
<td>ORA-24236</td>
<td>The source text is empty</td>
</tr>
<tr>
<td>ORA-00931</td>
<td>Missing identifier. The <code>object_name</code> should not be NULL.</td>
</tr>
</tbody>
</table>
Usage Notes

The index-by table may contain holes. NULL elements are ignored when doing the concatenation.

</tbody>
</table>
The **DBMS_PROFILER** package provides an interface to profile existing PL/SQL applications and identify performance bottlenecks. You can then collect and persistently store the PL/SQL profiler data.

This chapter contains the following topics:

- **Using DBMS_PROFILER**
  - Overview
  - Security Model
  - Operational Notes
  - Exceptions
- **Summary of DBMS_PROFILER Subprograms**
Using DBMS_PROFILER

- Overview
- Security Model
- Operational Notes
- Exceptions
Overview

This package enables the collection of profiler (performance) data for performance improvement or for determining code coverage for PL/SQL applications. Application developers can use code coverage data to focus their incremental testing efforts.

With this interface, you can generate profiling information for all named library units that are executed in a session. The profiler gathers information at the PL/SQL virtual machine level. This information includes the total number of times each line has been executed, the total amount of time that has been spent executing that line, and the minimum and maximum times that have been spent on a particular execution of that line.

---

**Note:** It is possible to infer the code coverage figures for PL/SQL units for which data has been collected.

---

The profiling information is stored in database tables. This enables querying on the data: you can build customizable reports (summary reports, hottest lines, code coverage data, and so on. And you can analyze the data.

The PROFTAB.SQL script creates tables with the columns, datatypes, and definitions as shown in Table 106–1, Table 106–2, and Table 106–3.

**Table 106–1  Columns in Table PLSQL_PROFILER_RUNS**

<table>
<thead>

Security Model

The profiler only gathers data for units for which a user has CREATE privilege; you cannot use the package to profile units for which EXECUTE ONLY access has been granted. In general, if a user can debug a unit, the same user can profile it. However, a unit can be profiled whether or not it has been compiled DEBUG. Oracle advises that modules that are being profiled should be compiled DEBUG, since this provides additional information about the unit in the database.

Note: DBMS_PROFILER treats any program unit that is compiled in NATIVE mode as if you do not have CREATE privilege, that is, you will not get any output.
**Operational Notes**

- **Typical Run**
- **Two Methods of Exception Generation**

**Typical Run**

Improving application performance is an iterative process. Each iteration involves the following steps:

1. Running the application with one or more benchmark tests with profiler data collection enabled.
2. Analyzing the profiler data and identifying performance problems.
3. Fixing the problems.

The PL/SQL profiler supports this process using the concept of a "run". A run involves running the application through benchmark tests with profiler data collection enabled. You can control the beginning and the ending of a run by calling the `START_PROFILER` and `STOP_PROFILER` functions.

The user must first create database tables in the profiler user's schema to collect the data. The `PROFTAB.SQL` script creates the tables and other data structures required for persistently storing the profiler data.

Note that running `PROFTAB.SQL` drops the current tables. The `PROFTAB.SQL` script is in the `RDBMS/ADMIN` directory. Some PL/SQL operations, such as the first execution of a PL/SQL unit, may involve I/O to catalog tables to load the byte code for the PL/SQL unit being executed. Also, it may take some time executing package initialization code the first time a package procedure or function is called.

To avoid timing this overhead, "warm up" the database before collecting profile data. To do this, run the application once without gathering profiler data.

You can allow profiling across all users of a system, for example, to profile all users of a package, independent of who is using it. In such cases, the `SYSADMIN` should use a modified `PROFTAB.SQL` script which:

- Creates the profiler tables and sequence
- Grants `SELECT/INSERT/UPDATE` on those tables and sequence to all users
- Defines public synonyms for the tables and sequence

**Note:** Do not alter the actual fields of the tables.

A typical run then involves:

- Starting profiler data collection in the run.
- Executing PL/SQL code for which profiler and code coverage data is required.
- Stopping profiler data collection, which writes the collected data for the run into database tables.
As the application executes, profiler data is collected in memory data structures that last for the duration of the run. You can call the `FLUSH_DATA` function at intermediate points during the run to get incremental data and to free memory for allocated profiler data structures. Flushing the collected data involves storing collected data in the database tables created earlier.

**See Also:** "FLUSH_DATA Function and Procedure" on page 106-10.

### Two Methods of Exception Generation

Each routine in this package has two versions that allow you to determine how errors are reported.

- A function that returns success/failure as a status value and will never raise an exception
- A procedure that returns normally if it succeeds and raises an exception if it fails

In each case, the parameters of the function and procedure are identical. Only the method by which errors are reported differs. If there is an error, there is a correspondence between the error codes that the functions return, and the exceptions that the procedures raise.

To avoid redundancy, the following section only provides details about the functional form.

---

**Note:** The collected profiler data is not automatically stored when the user disconnects. You must issue an explicit call to the `FLUSH_DATA` or the `STOP_PROFILER` function to store the data at the end of the session. Stopping data collection stores the collected data.
A 0 return value from any function denotes successful completion; a nonzero return value denotes an error condition. The possible errors are as follows:

- 'A subprogram was called with an incorrect parameter.'
  
  ```plsql
  error_param constant binary_integer := 1;
  ```

- 'Data flush operation failed. Check whether the profiler tables have been created, are accessible, and that there is adequate space.'
  
  ```plsql
  error_io constant binary_integer := 2;
  ```

- There is a mismatch between package and database implementation. Oracle returns this error if an incorrect version of the DBMS_PROFILER package is installed, and if the version of the profiler package cannot work with this database version. The only recovery is to install the correct version of the package.
  
  ```plsql
  error_version constant binary_integer := -1;
  ```

### Table 106–4  DBMS_PROFI LER Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>

</tr>
<tr>
<td><strong>STOP_PROFILER Function and Procedure</strong> on page 106-16</td>
<td>Stops profiler data collection in the user's session</td>
</tr>
</tbody>
</table>
**FLUSH_DATA Function and Procedure**

This function flushes profiler data collected in the user's session. The data is flushed to database tables, which are expected to preexist.

**Note:** Use the PROFTAB.SQL script to create the tables and other data structures required for persistently storing the profiler data.

**Syntax**

```sql
DBMS_PROFILER.FLUSH_DATA
RETURN BINARY_INTEGER;
```

```sql
DBMS_PROFILER.FLUSH_DATA;
```
**GET_VERSION Procedure**

This procedure gets the version of this API.

**Syntax**

```sql
DBMS_PROFILER.GET_VERSION (
    major  OUT BINARY_INTEGER,
    minor  OUT BINARY_INTEGER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>major</td>
<td>Major version of DBMS_PROFILER.</td>
</tr>
<tr>
<td>minor</td>
<td>Minor version of DBMS_PROFILER.</td>
</tr>
</tbody>
</table>
INTERNAL_VERSION_CHECK Function

This function verifies that this version of the DBMS_PROFILER package can work with the implementation in the database.

Syntax

DBMS_PROFILER.INTERNAL_VERSION_CHECK
RETURN BINARY_INTEGER;
PAUSE_PROFILER Function and Procedure

This function pauses profiler data collection.

Syntax

```sql
DBMS_PROFILER.PAUSE_PROFILER
RETURN BINARY_INTEGER;

DBMS_PROFILER.PAUSE_PROFILER;
```
RESUME_PROFILER Function and Procedure

This function resumes profiler data collection.

Syntax

```
DBMS_PROFILER.RESUME_PROFILER
RETURN BINARY_INTEGER;

DBMS_PROFILER.RESUME_PROFILER;
```
START_PROFILER Functions and Procedures

This function starts profiler data collection in the user's session.

There are two overloaded forms of the `START_PROFILER` function; one returns the run number of the started run, as well as the result of the call. The other does not return the run number. The first form is intended for use with GUI-based tools controlling the profiler.

**Syntax**

```sql
DBMS_PROFILER.START_PROFILER(
    run_comment   IN VARCHAR2 := sysdate,
    run_comment1  IN VARCHAR2 := '','
    run_number    OUT BINARY_INTEGER)
RETURN BINARY_INTEGER;

DBMS_PROFILER.START_PROFILER(
    run_comment IN VARCHAR2 := sysdate,
    run_comment1 IN VARCHAR2 := ')
RETURN BINARY_INTEGER;

DBMS_PROFILER.START_PROFILER(
    run_comment   IN VARCHAR2 := sysdate,
    run_comment1  IN VARCHAR2 := ','
    run_number    OUT BINARY_INTEGER);

DBMS_PROFILER.START_PROFILER(
    run_comment IN VARCHAR2 := sysdate,
    run_comment1 IN VARCHAR2 := ');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>run_comment</td>
<td>Each profiler run can be associated with a comment. For example, the comment could provide the name and version of the benchmark test that was used to collect data.</td>
</tr>
<tr>
<td>run_number</td>
<td>Stores the number of the run so you can store and later recall the run's data.</td>
</tr>
<tr>
<td>run_comment1</td>
<td>Allows you to make interesting comments about the run.</td>
</tr>
</tbody>
</table>
STOP_PROFILER Function and Procedure

This function stops profiler data collection in the user's session.
This function has the side effect of flushing data collected so far in the session, and it signals the end of a run.

Syntax

```
DBMS_PROFILER.STOP_PROFILER
RETURN BINARY_INTEGER;

DBMS_PROFILER.STOP_PROFILER;
```
The DBMS_PROPAGATION_ADM package, one of a set of Oracle Streams packages, provides administrative interfaces for configuring a propagation from a source queue to a destination queue.

- **Using DBMS_PROPAGATION_ADM**
  - Overview
  - Security Model
- **Summary of DBMS_PROPAGATION_ADM Subprograms**
Using DBMS_PROPAGATION_ADM

This section contains topics which relate to using the DBMS_CAPTURE_ADM package.

■ Overview
■ Security Model
Overview

This package provides interfaces to start, stop, and configure a propagation.

See Also: Oracle Streams Concepts and Administration and Oracle Streams Replication Administrator’s Guide for more information about this package and propagations
Security Model

Security on this package can be controlled in either of the following ways:

- Granting `EXECUTE` on this package to selected users or roles.
- Granting `EXECUTE_CATALOG_ROLE` to selected users or roles.

If subprograms in the package are run from within a stored procedure, then the user who runs the subprograms must be granted `EXECUTE` privilege on the package directly. It cannot be granted through a role.

When the `DBMS_PROPAGATION_ADM` package is used to manage an Oracle Streams configuration, it requires that the user is granted the privileges of an Oracle Streams administrator.

**See Also:** *Oracle Streams Concepts and Administration* for information about configuring an Oracle Streams administrator.
Summary of DBMS_PROPAGATION_ADM Subprograms

Table 107–1  DBMS_PROPAGATION_ADM Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALTER_PROPAGATION Procedure on page 107-6</td>
<td>Adds, alters, or removes a rule set for a propagation</td>
</tr>
<tr>
<td>CREATE_PROPAGATION Procedure on page 107-8</td>
<td>Creates a propagation and specifies the source queue, destination queue, and rule set for the propagation</td>
</tr>
<tr>
<td>DROP_PROPAGATION Procedure on page 107-11</td>
<td>Drops a propagation</td>
</tr>
<tr>
<td>START_PROPAGATION Procedure on page 107-13</td>
<td>Starts a propagation</td>
</tr>
<tr>
<td>STOP_PROPAGATION Procedure on page 107-14</td>
<td>Stops a propagation</td>
</tr>
</tbody>
</table>

**Note:** All subprograms commit unless specified otherwise.
ALTER_PROPAGATION Procedure

This procedure adds, alters, or removes a rule set for a propagation.

See Also: Oracle Streams Concepts and Administration and Chapter 128, "DBMS_RULE_ADM" for more information about rules and rule sets

Syntax

DBMS_PROPAGATION_ADM.ALTER_PROPAGATION(
  propagation_name          IN  VARCHAR2,
  rule_set_name             IN  VARCHAR2  DEFAULT NULL,
  remove_rule_set           IN  BOOLEAN   DEFAULT FALSE,
  negative_rule_set_name    IN  VARCHAR2  DEFAULT NULL,
  remove_negative_rule_set  IN  BOOLEAN   DEFAULT FALSE);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propagation_name</td>
<td>The name of the propagation you are altering. You must specify an existing propagation name. Do not specify an owner.</td>
</tr>
<tr>
<td>rule_set_name</td>
<td>The name of the positive rule set for the propagation. The positive rule set contains the rules that instruct the propagation to propagate messages.</td>
</tr>
<tr>
<td>remove_rule_set</td>
<td>If TRUE, then the procedure removes the positive rule set for the specified propagation. If you remove a positive rule set for a propagation, and the propagation does not have a negative rule set, then the propagation propagates all messages. If you remove a positive rule set for a propagation, and a negative rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the negative rule set. If FALSE, then the procedure retains the positive rule set for the specified propagation.</td>
</tr>
<tr>
<td>negative_rule_set_name</td>
<td>An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.</td>
</tr>
<tr>
<td>remove_negative_rule_set</td>
<td>If you specify NULL and the remove_rule_set parameter is set to FALSE, then the procedure retains any existing positive rule set. If you specify NULL and the remove_rule_set parameter is set to TRUE, then the procedure removes any existing positive rule set.</td>
</tr>
</tbody>
</table>

Table 107–2 ALTER_PROPAGATION Procedure Parameters
### Table 107–2 (Cont.) ALTER_PROPAGATION Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>negative_rule_set_name</td>
<td>The name of the negative rule set for the propagation. The negative rule set contains the rules that instruct the propagation to discard messages.</td>
</tr>
<tr>
<td></td>
<td>If you want to use a negative rule set for the propagation, then you must specify an existing rule set in the form [schema_name.]rule_set_name. For example, to specify a negative rule set in the hr schema named neg_rules, enter hr.neg_rules. If the schema is not specified, then the current user is the default. A negative rule set name is required. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.</td>
</tr>
<tr>
<td>remove_negative_rule_set</td>
<td>If TRUE, then the procedure removes the negative rule set for the specified propagation. If you remove a negative rule set for a propagation, and the propagation does not have a positive rule set, then the propagation propagates all messages. If you remove a negative rule set for a propagation, and a positive rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the positive rule set. If FALSE, then the procedure retains the negative rule set for the specified propagation. If the negative_rule_set_name parameter is non-NULL, then this parameter should be set to FALSE.</td>
</tr>
</tbody>
</table>
CREATE_PROPAGATION Procedure

This procedure creates a propagation and specifies the source queue, destination queue, and any rule set for the propagation. A propagation propagates messages in a local source queue to a destination queue. The destination queue might or might not be in the same database as the source queue.

Syntax

DBMS_PROPAGATION_ADM.CREATE_PROPAGATION(
    propagation_name           IN  VARCHAR2,
    source_queue               IN  VARCHAR2,
    destination_queue          IN  VARCHAR2,
    destination_dblink         IN  VARCHAR2  DEFAULT NULL,
    rule_set_name              IN  VARCHAR2  DEFAULT NULL,
    negative_rule_set_name     IN  VARCHAR2  DEFAULT NULL,
    queue_to_queue             IN  BOOLEAN   DEFAULT NULL,
    original_propagation_name  IN  VARCHAR2  DEFAULT NULL,
    auto_merge_threshold       IN  NUMBER    DEFAULT NULL);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propagation_name</td>
<td>The name of the propagation you are creating. A NULL setting is not allowed. Do not specify an owner.</td>
</tr>
<tr>
<td></td>
<td><strong>Note:</strong> The propagation_name setting cannot be altered after the propagation is created.</td>
</tr>
<tr>
<td>source_queue</td>
<td>The name of the source queue, specified as [schema_name.]queue_name. The current database must contain the source queue. For example, to specify a source queue named streams_queue in the strmadmin schema, enter strmadmin.streams_queue for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>destination_queue</td>
<td>The name of the destination queue, specified as [schema_name.]queue_name. For example, to specify a destination queue named streams_queue in the strmadmin schema, enter strmadmin.streams_queue for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
</tbody>
</table>
| destination_dblink     | The name of the database link that will be used by the propagation. The database link is from the database that contains the source queue to the database that contains the destination queue. If NULL, then the source queue and destination queue must be in the same database. **Note:** Connection qualifiers are not allowed.
Summary of DBMS_PROPAGATION_ADM Subprograms

**rule_set_name**
The name of the positive rule set for the propagation. The positive rule set contains the rules that instruct the propagation to propagate messages.

If you want to use a positive rule set for the propagation, then you must specify an existing rule set in the form `[schema_name.]rule_set_name`. For example, to specify a positive rule set in the `hr` schema named `prop_rules`, enter `hr.prop_rules`. If the schema is not specified, then the current user is the default.

An error is returned if the specified rule set does not exist.
You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.

If you specify `NULL`, and no negative rule set exists for the propagation, then the propagation propagates all messages in its queue.

If you specify `NULL`, and a negative rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the negative rule set.

**negative_rule_set_name**
The name of the negative rule set for the propagation. The negative rule set contains the rules that instruct the propagation to discard messages.

If you want to use a negative rule set for the propagation, then you must specify an existing rule set in the form `[schema_name.]rule_set_name`. For example, to specify a negative rule set in the `hr` schema named `neg_rules`, enter `hr.neg_rules`. If the schema is not specified, then the current user is the default.

An error is returned if the specified rule set does not exist.
You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.

If you specify `NULL`, and no positive rule set exists for the propagation, then the propagation propagates all messages in its queue.

If you specify `NULL`, and a positive rule set exists for the propagation, then the propagation propagates all messages in its queue that are not discarded by the positive rule set.

If you specify both a positive and a negative rule set for a propagation, then the negative rule set is always evaluated first.

**queue_to_queue**
If `TRUE` or `NULL`, then the propagation is a queue to queue propagation. A queue-to-queue propagation always has its own propagation job and uses a service for automatic failover when the destination queue is a buffered queue in an Oracle Real Application Clusters (Oracle RAC) database.

If `FALSE`, then the propagation is a queue-to-dblink propagation. A queue-to-dblink propagation can share a propagation job with other propagations that use the same database link and does not support automatic failover in an Oracle RAC environment.

**See Also:** Oracle Streams Concepts and Administration for more information about queue-to-queue propagations

---

**Table 107–3 (Cont.) CREATE_PROPAGATION Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_set_name</td>
<td>The name of the positive rule set for the propagation. The positive rule set contains the rules that instruct the propagation to propagate messages. If you want to use a positive rule set for the propagation, then you must specify an existing rule set in the form <code>[schema_name.]rule_set_name</code>. For example, to specify a positive rule set in the <code>hr</code> schema named <code>prop_rules</code>, enter <code>hr.prop_rules</code>. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.</td>
</tr>
<tr>
<td>negative_rule_set_name</td>
<td>The name of the negative rule set for the propagation. The negative rule set contains the rules that instruct the propagation to discard messages. If you want to use a negative rule set for the propagation, then you must specify an existing rule set in the form <code>[schema_name.]rule_set_name</code>. For example, to specify a negative rule set in the <code>hr</code> schema named <code>neg_rules</code>, enter <code>hr.neg_rules</code>. If the schema is not specified, then the current user is the default. An error is returned if the specified rule set does not exist. You can create a rule set and add rules to it using the DBMS_STREAMS_ADM package or the DBMS_RULE_ADM package.</td>
</tr>
<tr>
<td>queue_to_queue</td>
<td>If <code>TRUE</code> or <code>NULL</code>, then the propagation is a queue to queue propagation. A queue-to-queue propagation always has its own propagation job and uses a service for automatic failover when the destination queue is a buffered queue in an Oracle Real Application Clusters (Oracle RAC) database. If <code>FALSE</code>, then the propagation is a queue-to-dblink propagation. A queue-to-dblink propagation can share a propagation job with other propagations that use the same database link and does not support automatic failover in an Oracle RAC environment. See Also: Oracle Streams Concepts and Administration for more information about queue-to-queue propagations</td>
</tr>
</tbody>
</table>
CREATE_PROPAGATION Procedure

Usage Notes

This procedure starts propagation and might create a propagation job. If this procedure creates a propagation job, then it establishes a default schedule for the propagation job. Each propagation job is an Oracle Scheduler job. You can adjust the schedule of a propagation job using Oracle Scheduler.

The user who owns the source queue is the user who propagates messages. This user must have the necessary privileges to propagate messages.

See Also:

- Chapter 128, "DBMS_RULE_ADM"
- Oracle Streams Concepts and Administration for more information about propagations, the privileges required to propagate messages, propagation jobs, and propagation schedules
DROP_PROPAGATION Procedure

This procedure drops a propagation and deletes all messages for the destination queue in the source queue. This procedure also removes the schedule for propagation from the source queue to the destination queue.

Syntax

```sql
DBMS_PROPAGATION_ADM.DROP_PROPAGATION(
    propagation_name       IN  VARCHAR2,
    drop_unused_rule_sets  IN  BOOLEAN  DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propagation_name</td>
<td>The name of the propagation you are dropping. You must specify an existing propagation name. Do not specify an owner.</td>
</tr>
<tr>
<td>drop_unused_rule_sets</td>
<td>If TRUE, then the procedure drops any rule sets, positive and negative, used by the specified propagation if these rule sets are not used by any other Oracle Streams client, which includes capture processes, propagations, apply processes, and messaging clients. If this procedure drops a rule set, then this procedure also drops any rules in the rule set that are not in another rule set. If FALSE, then the procedure does not drop the rule sets used by the specified propagation, and the rule sets retain their rules.</td>
</tr>
</tbody>
</table>

Usage Notes

When you use this procedure to drop a propagation, information about rules created for the propagation using the DBMS_STREAMS_ADM package is removed from the data dictionary views for Oracle Streams rules. Information about such a rule is removed even if the rule is not in either rule set for the propagation.

See Also: Oracle Streams Concepts and Administration for more information about Oracle Streams data dictionary views

The following are the data dictionary views for Oracle Streams rules:

- ALL_STREAMS_GLOBAL_RULES
- DBA_STREAMS_GLOBAL_RULES
- ALL_STREAMS_MESSAGE_RULES
- DBA_STREAMS_MESSAGE_RULES
- ALL_STREAMS_SCHEMA_RULES
- DBA_STREAMS_SCHEMA_RULES
- ALL_STREAMS_TABLE_RULES
- DBA_STREAMS_TABLE_RULES
Note: When you drop a propagation, the propagation job used by the propagation is dropped automatically, if no other propagations are using the propagation job.
START_PROPAGATION Procedure

This procedure starts a propagation.

Syntax

DBMS_PROPAGATION_ADM.START_PROPAGATION(
    propagation_name  IN  VARCHAR2);

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propagation_name</td>
<td>The name of the propagation you are starting. You must specify an existing propagation name. Do not specify an owner.</td>
</tr>
</tbody>
</table>

Usage Notes

The propagation status is persistently recorded. Hence, if the status is ENABLED, then the propagation is started upon database instance startup.
STOP_PROPAGATION Procedure

This procedure stops a propagation.

Syntax

```sql
DBMS_PROPAGATION_ADM.STOP_PROPAGATION(
    propagation_name  IN  VARCHAR2,
    force             IN  BOOLEAN  DEFAULT FALSE);
```

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>propagation_name</td>
<td>The name of the propagation you are stopping. You must specify an existing propagation name. Do not specify an owner.</td>
</tr>
<tr>
<td>force</td>
<td>If <code>TRUE</code>, then the procedure stops the propagation and clears the statistics for the propagation. If <code>FALSE</code>, then the procedure stops the propagation without clearing the statistics for the propagation.</td>
</tr>
</tbody>
</table>

Usage Notes

The propagation status is persistently recorded. Hence, if the status is `DISABLED` or `ABORTED`, then the propagation is not started upon database instance startup.
The DBMS_RANDOM package provides a built-in random number generator. DBMS_RANDOM is not intended for cryptography.

This chapter contains the following topics:

- **Using DBMS_RANDOM**
  - Deprecated Subprograms
  - Security Model
  - Operational Notes
- **Summary of DBMS_RANDOM Subprograms**
Using DBMS_RANDOM

- Deprecated Subprograms
- Security Model
- Operational Notes
Deprecated Subprograms

**Note:** Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with Oracle Database 11g:

- INITIALIZE Procedure
- RANDOM Procedure
- TERMINATE Procedure
Security Model

This package should be installed as SYS. By default, the package is initialized with the current user name, current time down to the second, and the current session. Oracle recommends that users who need to execute this package should be given EXECUTE privilege explicitly and should not rely on PUBLIC EXECUTE privilege.
Operational Notes

- **DBMS_RANDOM.RANDOM** produces integers in \([-2^{31}, 2^{31})\).
- **DBMS_RANDOM.VALUE** produces numbers in \([0,1)\) with 38 digits of precision.

**DBMS_RANDOM** can be explicitly initialized, but does not need to be initialized before calling the random number generator. It will automatically initialize with the date, user ID, and process ID if no explicit initialization is performed.

If this package is seeded twice with the same seed, then accessed in the same way, it will produce the same results in both cases.

In some cases, such as when testing, you may want the sequence of random numbers to be the same on every run. In that case, you seed the generator with a constant value by calling one of the overloads of **DBMS_RANDOM.SEED**. To produce different output for every run, simply to omit the call to "Seed" and the system will choose a suitable seed for you.
### Summary of DBMS_RANDOM Subprograms

**Table 108–1  DBMS_RANDOM Package Subprograms**

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>INITIALIZE Procedure on page 108-7</td>
<td>Initializes the package with a seed value</td>
</tr>
<tr>
<td>NORMAL Function on page 108-8</td>
<td>Returns random numbers in a normal distribution</td>
</tr>
<tr>
<td>RANDOM Procedure on page 108-9</td>
<td>Generates a random number</td>
</tr>
<tr>
<td>SEED Procedures on page 108-10</td>
<td>Resets the seed</td>
</tr>
<tr>
<td>STRING Function on page 108-11</td>
<td>Gets a random string</td>
</tr>
<tr>
<td>TERMINATE Procedure on page 108-12</td>
<td>Terminates package</td>
</tr>
<tr>
<td>VALUE Functions on page 108-13</td>
<td>Gets a random number, greater than or equal to 0 and less than 1, with 38 digits to the right of the decimal (38-digit precision), while the overloaded function gets a random Oracle number x, where x is greater than or equal to low and less than high</td>
</tr>
</tbody>
</table>
INITIALIZE Procedure

This procedure initializes the generator.

---

**Note:** This procedure is deprecated with Release 11gR1 and, although currently supported, it should not be used.

---

Syntax

```sql
DBMS_RANDOM.INITIALIZE (
    val IN BINARY_INTEGER);
```

Pragmas

```sql
PRAGMA restrict_references (initialize, WNDS);
```

Parameters

**Table 108–2**  INITIALIZE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Seed number used to generate a random number</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure is obsolete as it simply calls the SEED Procedures on page 108-10.
NORMAL Function

This function returns random numbers in a standard normal distribution.

Syntax

```sql
DBMS_RANDOM.NORMAL
RETURN NUMBER;
```

Pragmas

```sql
PRAGMA restrict_references (normal, WNDS);
```

Return Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number</td>
<td>Returns a random number</td>
</tr>
</tbody>
</table>
RANDOM Procedure

This procedure generates a random number.

---

**Note:** This procedure is deprecated with Release 11gR1 and, although currently supported, it should not be used.

---

Syntax

DBMS_RANDOM.RANDOM

RETURN binary_integer;

Pragmas

PRAGMA restrict_references (random, WNDS);

Return Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>binary_integer</td>
<td>Returns a random integer greater or equal to ( -\text{power}(2^{31}) ) and less than ( \text{power}(2^{31}) )</td>
</tr>
</tbody>
</table>
SEED Procedures

This procedure resets the seed.

Syntax

DBMS_RANDOM.SEED {
  val  IN  BINARY_INTEGER};

DBMS_RANDOM.SEED {
  val  IN  VARCHAR2};

Pragmas

PRAGMA restrict_references (seed, WNDS);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>val</td>
<td>Seed number or string used to generate a random number</td>
</tr>
</tbody>
</table>

Usage Notes

The seed can be a string up to length 2000.
STRING Function

This function gets a random string.

Syntax

```sql
DBMS_RANDOM.STRING
    opt  IN  CHAR,
    len  IN  NUMBER)
RETURN VARCHAR2;
```

Pragmas

```
PRAGMA restrict_references (string, WNDS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>opt</td>
<td>Specifies what the returning string looks like:</td>
</tr>
<tr>
<td></td>
<td>• 'u', 'U' - returning string in uppercase alpha characters</td>
</tr>
<tr>
<td></td>
<td>• 't', 'T' - returning string in lowercase alpha characters</td>
</tr>
<tr>
<td></td>
<td>• 'a', 'A' - returning string in mixed case alpha characters</td>
</tr>
<tr>
<td></td>
<td>• 'x', 'X' - returning string in uppercase alpha-numeric characters</td>
</tr>
<tr>
<td></td>
<td>• 'p', 'P' - returning string in any printable characters. Otherwise the returning string is in uppercase alpha characters.</td>
</tr>
<tr>
<td>len</td>
<td>Length of the returning string</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>VARCHAR2</td>
<td>Returns a VARCHAR2</td>
</tr>
</tbody>
</table>
TERMİNATE Procedure

When you are finished with the package, call the TERMİNATE procedure.

Note: This procedure is deprecated with Release 11gR1 and, although currently supported, it should not be used.

Syntax

DBMS_RANDOM.TERMİNATE;
VALUE Functions

The basic function gets a random number, greater than or equal to 0 and less than 1, with 38 digits to the right of the decimal (38-digit precision). Alternatively, you can get a random Oracle number x, where x is greater than or equal to low and less than high.

Syntax

```
DBMS_RANDOM.VALUE
RETURN NUMBER;

DBMS_RANDOM.VALUE(
  low  IN  NUMBER,
  high IN  NUMBER)
RETURN NUMBER;
```

Parameters

**Table 108–8 VALUE Function Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>low</td>
<td>Lowest number in a range from which to generate a random number. The number generated may be equal to low</td>
</tr>
<tr>
<td>high</td>
<td>Highest number below which to generate a random number. The number generated will be less than high</td>
</tr>
</tbody>
</table>

Return Values

**Table 108–9 VALUE Function Return Values**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER</td>
<td>Returns an Oracle Number</td>
</tr>
</tbody>
</table>
The DBMS_RECTIFIER_DIFF package provides an interface used to detect and resolve data inconsistencies between two replicated sites.

- Documentation of DBMS_RECTIFIER_DIFF
For a complete description of this package within the context of Replication, see DBMS_RECTIFIER_DIFF in the Oracle Database Advanced Replication Management API Reference.
The DBMS_REDEFINITION package provides an interface to perform an online redefinition of tables.

See Also: Oracle Database Administrator’s Guide for more information about online redefinition of tables

This chapter contains the following topics:

- Using DBMS_REDEFINITION
  - Overview
  - Security Model
  - Constants
  - Operational Notes
- Summary of DBMS_REDEFINITION Subprograms
Using DBMS_REDEFINITION

- Overview
- Security Model
- Constants
- Operational Notes
Overview

To achieve online redefinition, incrementally maintainable local materialized views are used. These logs keep track of the changes to the master tables and are used by the materialized views during refresh synchronization.
Subprograms in the DBMS_REDEFINTION package are run with invokers’ rights (with the privileges of the current user). There are two modes:

- In USER mode, the user who has the CREATE TABLE and CREATE MVIEW privileges may redefine a table residing in his own schema.

- In FULL mode, the user who has the ANY privilege may redefine tables in any schema.
Constants

The DBMS_REDEFINITION package uses the constants shown in Table 110–1, “DBMS_REDEFINITION Constants”:

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CONS_CONSTRAINT</td>
<td>PLS_INTEGER</td>
<td>3</td>
<td>Used to specify that dependent object type is a constraint</td>
</tr>
<tr>
<td>CONS_INDEX</td>
<td>PLS_INTEGER</td>
<td>2</td>
<td>Used to specify that dependent object type is a index</td>
</tr>
<tr>
<td>CONS_MVLOG</td>
<td>PLS_INTEGER</td>
<td>10</td>
<td>Used to (un)register a materialized view log, as a dependent object of the table, through the REGISTER_DEPENDENT_OBJECT Procedure and the UNREGISTER_DEPENDENT_OBJECT Procedure.</td>
</tr>
<tr>
<td>CONS_ORIG_PARAMS</td>
<td>PLS_INTEGER</td>
<td>1</td>
<td>Used to specify that indexes should be cloned with their original storage parameters</td>
</tr>
<tr>
<td>CONS_TRIGGER</td>
<td>PLS_INTEGER</td>
<td>4</td>
<td>Used to specify that dependent object type is a trigger</td>
</tr>
<tr>
<td>CONS_USE_PK</td>
<td>BINARYINTEGER</td>
<td>1</td>
<td>Used to indicate that the redefinition should be done using primary keys or pseudo-primary keys (unique keys with all component columns having not-NUL constraints)</td>
</tr>
<tr>
<td>CONS_USE_ROWID</td>
<td>BINARYINTEGER</td>
<td>2</td>
<td>Used to indicate that the redefinition should be done using rowids</td>
</tr>
</tbody>
</table>
Operational Notes

- CONS_USE_PK and CONS_USE_ROWID are constants used as input to the "options_flag" parameter in both the START_REDEF_TABLE Procedure and CAN_REDEF_TABLE Procedure. CONS_USE_ROWID is used to indicate that the redefinition should be done using rowids while CONS_USE_PK implies that the redefinition should be done using primary keys or pseudo-primary keys (which are unique keys with all component columns having NOT NULL constraints).

- CONS_INDEX, CONS_MVLOG, CONS_TRIGGER and CONS_CONSTRAINT are used to specify the type of the dependent object being (un)registered in REGISTER_DEPENDENT_OBJECT Procedure and UNREGISTER_DEPENDENT_OBJECT Procedure (parameter "dep_type").
  
  - CONS_INDEX ==> dependent object is of type INDEX
  - CONS_TRIGGER ==> dependent object is of type TRIGGER
  - CONS_CONSTRAINT ==> dependent object type is of type CONSTRAINT
  - CONS_MVLOG ==> dependent object is of type MATERIALIZED VIEW LOG

- CONS_ORIG_PARAMS as used as input to the "copy_indexes" parameter in COPY_TABLE_DEPENDENTS Procedure. Using this parameter implies that the indexes on the original table be copied onto the interim table using the same storage parameters as that of the original index.
Rules and Limits

For information about various rules and limits that apply to implementation of this package, see the *Oracle Database Administrator’s Guide*. 
## Summary of DBMS_REDEFINITION Subprograms

Table 110–2  DBMS_REDEFINITION Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT_REDEF_TABLE Procedure</td>
<td>Cleans up errors that occur during the redefinition process and removes all temporary objects created by the reorganization process</td>
</tr>
<tr>
<td>CAN_REDEF_TABLE Procedure</td>
<td>Determines if a given table can be redefined online</td>
</tr>
<tr>
<td>COPY_TABLE_DEPENDENTS Procedure</td>
<td>Copies the dependent objects of the original table onto the interim table</td>
</tr>
<tr>
<td>FINISH_REDEF_TABLE Procedure</td>
<td>Completes the redefinition process.</td>
</tr>
<tr>
<td>REGISTER_DEPENDENT_OBJECT Procedure</td>
<td>Registers a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table</td>
</tr>
<tr>
<td>START_REDEF_TABLE Procedure</td>
<td>Initiates the redefinition process</td>
</tr>
<tr>
<td>SYNC_INTERIM_TABLE Procedure</td>
<td>Keeps the interim table synchronized with the original table</td>
</tr>
<tr>
<td>UNREGISTER_DEPENDENT_OBJECT Procedure</td>
<td>Unregisters a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table</td>
</tr>
</tbody>
</table>
ABORT_REDEF_TABLE Procedure

This procedure cleans up errors that occur during the redefinition process. This procedure can also be used to terminate the redefinition process any time after the START_REDEF_TABLE Procedure has been called and before the FINISH_REDEF_TABLE Procedure is called. This process will remove the temporary objects that are created by the redefinition process such as materialized view logs.

Syntax

```
DBMS_REDEFINITION.ABORT_REDEF_TABLE (
    uname       IN VARCHAR2,
    orig_table  IN VARCHAR2,
    int_table   IN VARCHAR2,
    part_name   IN  VARCHAR2 := NULL);
```

Parameters

```
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>part_name</td>
<td>Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined.</td>
</tr>
</tbody>
</table>
```
CAN_REDEF_TABLE Procedure

This procedure determines if a given table can be redefined online. This is the first step of the online redefinition process. If the table is not a candidate for online redefinition, an error message is raised.

Syntax

DBMS_REDEFINITION.CAN_REDEF_TABLE (  
  uname IN VARCHAR2,  
  tname IN VARCHAR2,  
  options_flag IN PLS_INTEGER := 1,  
  part_name IN VARCHAR2 := NULL);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the table</td>
</tr>
<tr>
<td>tname</td>
<td>Name of the table to be re-organized</td>
</tr>
<tr>
<td>options_flag</td>
<td>Indicates the type of redefinition method to use.</td>
</tr>
<tr>
<td></td>
<td>■ If dbms_redefinition.cons_use_pk, the redefinition is done using primary</td>
</tr>
<tr>
<td></td>
<td>keys or pseudo-primary keys (unique keys with all component columns</td>
</tr>
<tr>
<td></td>
<td>having NOT NULL constraints). The default method of redefinition is</td>
</tr>
<tr>
<td></td>
<td>using primary keys.</td>
</tr>
<tr>
<td></td>
<td>■ If dbms_redefinition.cons_use_rowid, the redefinition is done using</td>
</tr>
<tr>
<td></td>
<td>rowids.</td>
</tr>
<tr>
<td>part_name</td>
<td>Name of the partition being redefined. If redefining only a single partition</td>
</tr>
<tr>
<td></td>
<td>of a table, specify the partition name in this parameter. NULL implies the</td>
</tr>
<tr>
<td></td>
<td>entire table is being redefined.</td>
</tr>
</tbody>
</table>

Exceptions

If the table is not a candidate for online redefinition, an error message is raised.
COPY_TABLE_DEPENDENTS Procedure

This procedure clones the dependent objects of the table being redefined onto the interim table and registers the dependent objects. This procedure does not clone the already registered dependent objects.

This subprogram is used to clone the dependent objects like grants, triggers, constraints and privileges from the table being redefined to the interim table (which represents the post-redefinition table).

Syntax

```
DBMS_REDEFINITION.COPY_TABLE_DEPENDENTS(
    uname                    IN  VARCHAR2,
    orig_table               IN  VARCHAR2,
    int_table                IN  VARCHAR2,
    copy_indexes             IN  PLS_INTEGER := 1,
    copy_triggers            IN  BOOLEAN     := TRUE,
    copy_constraints         IN  BOOLEAN     := TRUE,
    copy_privileges          IN  BOOLEAN     := TRUE,
    ignore_errors            IN  BOOLEAN     := FALSE,
    num_errors               OUT PLS_INTEGER,
    copy_statistics          IN  BOOLEAN     := FALSE,
    copy_mvlog               IN  BOOLEAN     := FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table being redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>copy_indexes</td>
<td>Flag indicating whether to copy the indexes</td>
</tr>
<tr>
<td></td>
<td>■ 0 - do not copy any index</td>
</tr>
<tr>
<td></td>
<td>■ dbms_redefinition.cons_orig_params = copy the indexes using the physical parameters of the source indexes</td>
</tr>
<tr>
<td>copy_triggers</td>
<td>TRUE = clone triggers, FALSE = do nothing</td>
</tr>
<tr>
<td>copy_constraints</td>
<td>TRUE = clone constraints, FALSE = do nothing. If compatibility setting is 10.2 or higher, then clone CHECK and NOT NULL constraints</td>
</tr>
<tr>
<td>copy_privileges</td>
<td>TRUE = clone privileges, FALSE = do nothing</td>
</tr>
<tr>
<td>ignore_errors</td>
<td>TRUE = if an error occurs while cloning a particular dependent object, then skip that object and continue cloning other dependent objects. FALSE = that the cloning process should stop upon encountering an error.</td>
</tr>
<tr>
<td>num_errors</td>
<td>Number of errors that occurred while cloning dependent objects</td>
</tr>
<tr>
<td>copy_statistics</td>
<td>TRUE = copy statistics, FALSE = do nothing</td>
</tr>
<tr>
<td>copy_mvlog</td>
<td>TRUE = copy materialized view log, FALSE = do nothing</td>
</tr>
</tbody>
</table>
Usage Notes

- The user must check the column `num_errors` before proceeding to ensure that no errors occurred during the cloning of the objects.

- In case of an error, the user should fix the cause of the error and call the `COPY_TABLE_DEPENDENTS Procedure` again to clone the dependent object. Alternatively the user can manually clone the dependent object and then register the manually cloned dependent object using the `REGISTER_DEPENDENT_OBJECT Procedure`.

- All cloned referential constraints involving the interim tables will be created disabled (they will be automatically enabled after the redefinition) and all triggers on interim tables will not fire till the redefinition is completed. After the redefinition is complete, the cloned objects will be renamed to the corresponding pre-redefinition names of the objects (from which they were cloned from).

- It is the user’s responsibility that the cloned dependent objects are unaffected by the redefinition. All the triggers will be cloned and it is the user’s responsibility that the cloned triggers are unaffected by the redefinition.
**FINISH_REDEF_TABLE Procedure**

This procedure completes the redefinition process. Before this step, you can create new indexes, triggers, grants, and constraints on the interim table. The referential constraints involving the interim table must be disabled. After completing this step, the original table is redefined with the attributes and data of the interim table. The original table is locked briefly during this procedure.

**Syntax**

```sql
DBMS_REDEFINITION.FINISH_REDEF_TABLE (
    uname       IN VARCHAR2,
    orig_table  IN VARCHAR2,
    int_table   IN VARCHAR2,
    part_name   IN  VARCHAR2 := NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>part_name</td>
<td>Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined.</td>
</tr>
</tbody>
</table>
REGISTER_DEPENDENT_OBJECT Procedure

This procedure registers a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table.

This can be used to have the same object on each table but with different attributes. For example: for an index, the storage and tablespace attributes could be different but the columns indexed remain the same

Syntax

```
DBMS_REDEFINITION.REGISTER_DEPENDENT_OBJECT(
    uname             IN VARCHAR2,
    orig_table        IN VARCHAR2,
    int_table         IN VARCHAR2,
    dep_type          IN  PLS_INTEGER,
    dep_owner         IN VARCHAR2,
    dep_orig_name     IN VARCHAR2,
    dep_int_name      IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>dep_type</td>
<td>Type of the dependent object (see Constants on page 110-5 and Operational Notes on page 110-6)</td>
</tr>
<tr>
<td>dep_owner</td>
<td>Owner of the dependent object</td>
</tr>
<tr>
<td>dep_orig_name</td>
<td>Name of the original dependent object</td>
</tr>
<tr>
<td>dep_int_name</td>
<td>Name of the interim dependent object</td>
</tr>
</tbody>
</table>

Usage Notes

- Attempting to register an already registered object will raise an error.
- Registering a dependent object will automatically remove that object from DBA_REDEFINITION_ERRORS if an entry exists for that object.
START_REDEF_TABLE Procedure

Prior to calling this procedure, you must manually create an empty interim table (in the same schema as the table to be redefined) with the desired attributes of the post-redefinition table, and then call this procedure to initiate the redefinition.

Syntax

```sql
DBMS_REDEFINITION.START_REDEF_TABLE (    
  uname        IN VARCHAR2,    
  orig_table   IN VARCHAR2,    
  int_table    IN VARCHAR2,    
  col_mapping  IN VARCHAR2 := NULL,    
  options_flag IN BINARY_INTEGER := 1,    
  orderby_cols IN VARCHAR2 := NULL,    
  part_name    IN VARCHAR2 := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>col_mapping</td>
<td>Mapping information from the columns in the original table to</td>
</tr>
<tr>
<td></td>
<td>the columns in the interim table. (This is similar to the column list on</td>
</tr>
<tr>
<td></td>
<td>the SELECT clause of a query.) If NULL, all the columns in the original</td>
</tr>
<tr>
<td></td>
<td>table are selected and have the same name after redefinition.</td>
</tr>
<tr>
<td>options_flag</td>
<td>Indicates the type of redefinition method to use:</td>
</tr>
<tr>
<td></td>
<td>- If dbms_redefinition.cons_use_pk, the redefinition is done using primary</td>
</tr>
<tr>
<td></td>
<td>keys or pseudo-primary keys (unique keys with all component columns having</td>
</tr>
<tr>
<td></td>
<td>NOT NULL constraints). The default method of redefinition is using</td>
</tr>
<tr>
<td></td>
<td>primary keys.</td>
</tr>
<tr>
<td></td>
<td>- If dbms_redefinition.cons_use_rowid, the redefinition is done using</td>
</tr>
<tr>
<td></td>
<td>rowids.</td>
</tr>
<tr>
<td>orderby_cols</td>
<td>This optional parameter accepts the list of columns (along with the</td>
</tr>
<tr>
<td></td>
<td>optional keyword(s) ascending/descending) with which to order by the rows</td>
</tr>
<tr>
<td></td>
<td>during the initial instantiation of the interim table (the order by is</td>
</tr>
<tr>
<td></td>
<td>only done for the initial instantiation and not for subsequent</td>
</tr>
<tr>
<td></td>
<td>synchronizations)</td>
</tr>
<tr>
<td>part_name</td>
<td>Name of the partition being redefined. If redefining only a single partition</td>
</tr>
<tr>
<td></td>
<td>of a table, specify the partition name in this parameter. NULL implies</td>
</tr>
<tr>
<td></td>
<td>the entire table is being redefined.</td>
</tr>
</tbody>
</table>
SYNC_INTERIM_TABLE Procedure

This procedure keeps the interim table synchronized with the original table.

Syntax

```sql
DBMS_REDEFINITION.SYNC_INTERIM_TABLE (
    uname          IN  VARCHAR2,
    orig_table     IN  VARCHAR2,
    int_table      IN  VARCHAR2,
    part_name      IN  VARCHAR2 := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the table</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>part_name</td>
<td>Name of the partition being redefined. If redefining only a single partition of a table, specify the partition name in this parameter. NULL implies the entire table is being redefined.</td>
</tr>
</tbody>
</table>

Usage Notes

- This step is useful in minimizing the amount of synchronization needed to be done by the FINISH_REDEF_TABLE Procedure before completing the online redefinition.
- This procedure can be called between long running operations (such as CREATE INDEX) on the interim table to sync it up with the data in the original table and speed up subsequent operations.
UNREGISTER_DEPENDENT_OBJECT Procedure

This procedure unregisters a dependent object (index, trigger, constraint or materialized view log) on the table being redefined and the corresponding dependent object on the interim table.

Syntax

```
DBMS_REDEFINITION.UNREGISTER_DEPENDENT_OBJECT(
    uname              IN VARCHAR2,
    orig_table        IN VARCHAR2,
    int_table         IN VARCHAR2,
    dep_type          IN PLS_INTEGER,
    dep_owner         IN VARCHAR2,
    dep_orig_name     IN VARCHAR2,
    dep_int_name      IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uname</td>
<td>Schema name of the tables</td>
</tr>
<tr>
<td>orig_table</td>
<td>Name of the table to be redefined</td>
</tr>
<tr>
<td>int_table</td>
<td>Name of the interim table</td>
</tr>
<tr>
<td>dep_type</td>
<td>Type of the dependent object</td>
</tr>
<tr>
<td>dep_owner</td>
<td>Owner of the dependent object</td>
</tr>
<tr>
<td>dep_orig_name</td>
<td>Name of the original dependent object</td>
</tr>
<tr>
<td>dep_int_name</td>
<td>Name of the interim dependent object</td>
</tr>
</tbody>
</table>
The `DBMS_REDACT` package provides an interface to Oracle Data Redaction, which enables you to mask (redact) data that is returned from queries issued by low-privileged users or an application.

Using DBMS_REDACT

- Overview
- Security Model
- Constants
- Operating Procedures
Overview

Data Redaction provides a way to define masking policies for an application. Oracle Data Redaction provides functionality to mask (redact) data that is returned from user SELECT queries. The masking takes place in real time. The Data Redaction policy applies to the querying user, depending on this user's SYS_CONTEXT values. This redaction process does not require that the queried data be static or unchanging, or for the entire data set to be redacted at one time in an off-line manner. Oracle Database redacts only the data for the rows specified by the user's query, not the data for the entire column. The redaction takes place immediately before the data is returned to the querying user or application.
Security Model

If the querying user has the `EXEMPT REDACTION POLICY` system privilege, redaction will not be performed. If the user does not have the `EXEMPT REDACTION POLICY` system privilege, the policy expression will be evaluated in the current user's environment. If the policy expression evaluates to `TRUE`, then redaction will be performed, otherwise no redaction will be performed.

You need the `EXECUTE` privilege on the `DBMS_REDACT` package in order to execute its subprograms. Procedures in the interface are executed with privileges of the current user.
Constants

The DBMS_REDACT package uses the constants shown in the following tables:

**Table 111–1  Values for function_type Parameter of DBMS_REDACT.ADD_POLICY**

<table>
<thead>
<tr>
<th>Constant</th>
<th>Value</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>0</td>
<td>BINARY_INTEGER</td>
<td>No redaction</td>
</tr>
<tr>
<td>FULL</td>
<td>1</td>
<td>BINARY_INTEGER</td>
<td>Redact to fixed values</td>
</tr>
<tr>
<td>PARTIAL</td>
<td>2</td>
<td>BINARY_INTEGER</td>
<td>Partial redaction, redact a portion of the column data</td>
</tr>
<tr>
<td>RANDOM</td>
<td>4</td>
<td>BINARY_INTEGER</td>
<td>Random redaction, each query results in a different random value</td>
</tr>
<tr>
<td>REGEXP</td>
<td>5</td>
<td>BINARY_INTEGER</td>
<td>Regular expression based redaction</td>
</tr>
</tbody>
</table>

**Table 111–2  Values for action Parameter of DBMS_REDACT.ALTER_POLICY**

<table>
<thead>
<tr>
<th>Constant</th>
<th>Value</th>
<th>Type</th>

</tr>
</thead>
<tbody>
<tr>
<td>ADD_COLUMN</td>
<td>1</td>
<td>BINARY_INTEGER</td>
<td>Add a column to the redaction policy</td>
</tr>
<tr>
<td>DROP_COLUMN</td>
<td>2</td>
<td>BINARY_INTEGER</td>
<td>Drop a column from the redaction policy</td>
</tr>
<tr>
<td>MODIFY_EXPRESSION</td>
<td>3</td>
<td>BINARY_INTEGER</td>
<td>Modify the expression of a redaction policy (the expression evaluates to a BOOLEAN value: if TRUE then redaction is applied, otherwise not)</td>
</tr>
<tr>
<td>MODIFY_COLUMN</td>
<td>4</td>
<td>BINARY_INTEGER</td>
<td>Modify a column in the redaction policy to change the redaction function_type or the function_parameters</td>
</tr>
<tr>
<td>SET_POLICY_DESCRIPTION</td>
<td>5</td>
<td>BINARY_INTEGER</td>
<td>Set a description for the redaction policy</td>
</tr>
<tr>
<td>SET_COLUMN_DESCRIPTION</td>
<td>6</td>
<td>BINARY_INTEGER</td>
<td>Set a description for the redaction performed on the column</td>
</tr>
</tbody>
</table>
The following table presents the relationship between the type of redaction function and its parameters, based on the datatype of the column being redacted. Examples of the various format strings are provided, showing how to perform some commonplace redaction for a string datatype (in this case, a Social Security Number (SSN)), a DATE datatype, and various examples of redaction for the number datatype.

<table>
<thead>
<tr>
<th>function_type</th>
<th>function_parameters</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBMS_REDACT.NONE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DBMS_REDACT.FULL</td>
<td></td>
<td></td>
</tr>
<tr>
<td>DBMS_REDACT.PARTIAL</td>
<td>A comma-separated list, containing the following five fields (with no spaces after the commas delimiting the fields):</td>
<td>‘VVVFVVFVVVV, VVV-VVV-VVVV, X, 1, 5’ for masking the first 5 digits of SSN strings like 123-45-6789, adding dashes back to format it, resulting in strings like XXX-XX-6789</td>
</tr>
<tr>
<td></td>
<td>• REDACT_PARTIAL_INPUT_FORMAT</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REDACT_PARTIAL_OUTPUT_FORMAT</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REDACT_PARTIAL_MASKCHAR</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• REDACT_PARTIAL_MASKFROM</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>See Table 111–4, &quot;Format Descriptors with Component Field Names and Delimiters&quot;.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>REDACT_PARTIAL_INPUT_FORMAT - the input format: V for value to be possibly redacted, P for formatting character to be ignored</td>
<td>The REDACT_PARTIAL_INPUT_FORMAT field value VVVFVVFVVVV for matching SSN strings like 123-45-6789</td>
<td></td>
</tr>
<tr>
<td>REDACT_PARTIAL_OUTPUT_FORMAT - the output format: V for output of redaction. Any other character will be treated as a formatting character and output literally.</td>
<td>The REDACT_PARTIAL_OUTPUT_FORMAT field value VVV-VV-VVVV can be used to redact SSN strings into XXX-XX-6789 (X comes from REDACT_PARTIAL_MASKCHAR field).</td>
<td></td>
</tr>
<tr>
<td>REDACT_PARTIAL_MASKCHAR - the character used to redact the input</td>
<td>The value X for redacting SSN strings into XXX-XX-6789.</td>
<td></td>
</tr>
<tr>
<td>REDACT_PARTIAL_MASKFROM - specifies which V within the REDACT_PARTIAL_INPUT_FORMAT from which to start the redaction (see explanation following the next entry, REDACT_PARTIAL_MASKTO)</td>
<td>The value 1 for redacting SSN strings starting at the first V of REDACT_PARTIAL_INPUT_FORMAT of VVVFVVFVVVV into strings like XXX-XX-6789.</td>
<td></td>
</tr>
</tbody>
</table>
Using DBMS_REDACT

The `REDACT_PARTIALMASKTO` field specifies which V within the `REDACT_PARTIAL_INPUT_FORMAT` at which to end the redaction. The value 5 for redacting SSN strings up to and including the fifth V within `REDACT_PARTIAL_INPUT_FORMAT` of `VVVFVFVVVV` into strings like `XXX-XX-6789`. Note how the format character '-' (corresponding to the first F within `REDACT_PARTIAL_INPUT_FORMAT`) is ignored as far as redaction is concerned, so the value here is 5 as opposed to 6.

The `REDACT_PARTIAL_MASKFROM` and `REDACT_PARTIAL_MASKTO` field values are specified as counts of the number of V characters in the `REDACT_PARTIAL_INPUT_FORMAT` field, up to and including the intended position, starting from the leftmost V. This way, `REDACT_PARTIAL_MASKFROM` and `REDACT_PARTIAL_MASKTO` are independent of the specific formatting of the data. For example, in the common use case of masking an SSN to show only the last four digits, data like `123456789` (with `REDACT_PARTIAL_INPUT_FORMAT` of `VVVVVVVVV`) and data like `123-45-6789` (with `REDACT_PARTIAL_INPUT_FORMAT` of `VVVFVFVVVV`), would both use `REDACT_PARTIAL_MASKFROM` of 1 and `REDACT_PARTIAL_MASKTO` of 5.

**DBMS_REDACT.PARTIAL** (for number types)

A comma-separated list, containing the following three fields (with no spaces after the commas delimiting the fields):

- `REDACT_PARTIAL_MASKCHAR`
- `REDACT_PARTIAL_MASKFROM`
- `REDACT_PARTIAL_MASKTO`

See Table 111–4, "Format Descriptors with Component Field Names and Delimiters".

ADD_POLICY Procedure

This procedure defines a Data Redaction policy for a table or view.

Syntax

DBMS_REDACT.ADD_POLICY ( object_schema                IN    VARCHAR2 := NULL,
object_name                  IN    VARCHAR2,
policy_name                  IN    VARCHAR2,
column_name                  IN    VARCHAR2 := NULL,
function_type                IN    BINARY_INTEGER := DBMS_REDACT.FULL,
function_parameters          IN    VARCHAR2 := NULL,
expression                   IN    VARCHAR2,
enable                       IN    BOOLEAN := TRUE,
regexp_pattern               IN    VARCHAR2 := NULL,
regexp_replace_string        IN    VARCHAR2 := NULL,
regexp_position              IN    BINARY_INTEGER := 1,
regexp_occurrence            IN    BINARY_INTEGER := 0,
regexp_match_parameter       IN    VARCHAR2 := NULL,
policy_description           IN    VARCHAR2 := NULL,
column_description           IN    VARCHAR2 := NULL);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema owning the table, current user if NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table or view to which to add a Data Redaction policy</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy</td>
</tr>
<tr>
<td>column_name</td>
<td>[Optional] Name of one column to which the redaction policy applies. If you must redact more than one column, use the ALTER_POLICY Procedure to add the additional columns.</td>
</tr>
<tr>
<td>function_type</td>
<td>Type of redaction function to use. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>- DBMS_REDACT.NONE</td>
</tr>
<tr>
<td></td>
<td>- DBMS_REDACT.FULL (default)</td>
</tr>
<tr>
<td></td>
<td>- DBMS_REDACT.PARTIAL</td>
</tr>
<tr>
<td></td>
<td>- DBMS_REDACT.RANDOM</td>
</tr>
<tr>
<td></td>
<td>- DBMS_REDACT.REGEXP</td>
</tr>
<tr>
<td></td>
<td>If the function_type is DBMS_REDACT.REGEXP, then the function_parameters parameter must be omitted completely, and the regexp_* parameters must be used to define the Data Redaction policy.</td>
</tr>
<tr>
<td></td>
<td>See Table 111–1, &quot;Values for function_type Parameter of DBMS_REDACT.ADD_POLICY&quot; for an overview of the meanings of these values, and for some examples of their use.</td>
</tr>
</tbody>
</table>
function_parameters

Parameters to the redaction function. The possible values depend on the value of the function_type provided.

If the function_type is DBMS_REDACT.REGEXP, then the function_parameters parameter must be omitted completely, and the regexp_* parameters must be used to define the Data Redaction policy.

- DBMS_REDACT.NONE: Can be omitted entirely and defaults to NULL
- DBMS_REDACT.FULL: Can be omitted entirely and defaults to NULL

- Masking parameters for partial character masking. For character datatypes, a comma-separated list containing these fields:
  - Input format: ‘V’ for value to be possibly masked, ‘F’ for formatting character to be ignored
  - Output format: ‘V’ for output of masking, any other characters will be treated as formatting characters.
  - Mask character: a character that will be used to replace the actual values. Examples are ‘*’ and ‘x’.
  - Starting digit position: specifies the starting (character) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include formatting characters.
  - Ending digit position: specifies the ending (character) position to end masking. An example is ‘VVVFVVVVV,VVV,VVV,TX,VV-VVV,1,5’ for masking the first 5 digits of SSN string 123-45-6789, and adding dashes back to format it like an SSN, resulting in XXX-XX-6789.

For number datatypes, a comma-separated list containing these fields:
  - Mask character: this is a character between ‘0’ to ‘9’ that will be used to replace the actual values.
  - Starting digit position: specifies the starting (digit) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include the decimal point.
  - Ending digit position: this specifies the ending digit position to end masking. An example is ‘9,1,5’ for masking the first 5 digits of a Social Security number number 123456789, resulting in 999996789.
For datetime datatypes, the format is a packed string (no spaces or commas) containing the following sequence of fields. Please note that each field can consist of one or more characters, and the field length depends on whether masking is required. The one-character fields are used to specify that no redaction of that component of the datetime value is to take place. The longer fields indicate a specific time or date to use as the redacted value of that component of the datetime value.

- Month: ‘M’ (no masking of month) or ‘m#’ (mask month to a specific month, if possible), where # (the month specified by its number) is between 1 and 12.
- Day: ‘D’ (no masking of date) or ‘d#’ (mask day to #, if possible), # between 1 and 31.
- Year: ‘Y’ (no masking of year) or ‘y#’ (mask year to #, if possible), # between 1 and 9999.
- Hour: ‘H’ (no masking of hour) or ‘h#’ (mask hour to #, if possible), # between 0 and 23.
- Minute: ‘M’ (no masking of minute) or ‘m#’ (mask minute to #, if possible), # between 0 and 59.
- Second: ‘S’ (no masking of second) or ‘s#’ (mask second to #, if possible), # between 0 and 59.

An example is ‘m12DYHMS’, which changes 01-May-01 01:01:01 to 01-Dec-01 01:01:01.

For partial character and number-masking shortcuts, see Oracle Database Advanced Security Administrator’s Guide.

**Table 111–6 (Cont.) ADD_POLICY Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>Boolean expression for the table or view, using either the SYS_CONTEXT function or 1=1. Redaction takes place only if this policy expression evaluates to TRUE.</td>
</tr>
<tr>
<td>enable</td>
<td>Boolean value that determines whether the Data Redaction policy is enabled on creation. The default value is TRUE, which means that the policy is automatically enabled upon creation. If the enable parameter is set to FALSE, the policy takes effect only when it is subsequently enabled by calling the DBMS_REDACT.ENABLE_POLICY procedure.</td>
</tr>
<tr>
<td>regexp_pattern</td>
<td>Regular expression pattern up to 512 bytes. Use only if the function_type parameter is DBMS_REDACT.REGEXP. Also, do not specify the function_parameters parameter when function_type is DBMS_REDACT.REGEXP. See Oracle Database SQL Language Reference for more information and examples on using regular expression patterns.</td>
</tr>
<tr>
<td>regexp_replace_string</td>
<td>Replacement string (up to 4000 characters in length) with up to 500 back-references to subexpressions in the form \n, where n is a number between 1 and 9. Use only if the function_type parameter is DBMS_REDACT.REGEXP.</td>
</tr>
<tr>
<td>regexp_position</td>
<td>Integer counting from 1, specifies the position where the search must begin. Use only if the function_type parameter is DBMS_REDACT.REGEXP.</td>
</tr>
</tbody>
</table>
Exceptions

- ORA-28060 - A Data Redaction policy already exists on this column.
- ORA-28061 - This object cannot have a Data Redaction policy defined on it.
- ORA-28062 - The policy expression is too long.
- ORA-28063 - The policy expression is empty.
- ORA-28064 - The type of redaction function is not valid.
- ORA-28066 - Invalid column column
- ORA-28069 - A Data Redaction policy already exists on this object.
- ORA-28073 - The column column_name has an unsupported datatype.
- ORA-28074 - The field field_name of the masking parameters is not valid

The field can be any of the following:
- REDACT_PARTIAL_INPUT_FORMAT
- REDACT_PARTIAL_OUTPUT_FORMAT
- REDACT_PARTIAL_MASKCHAR
- REDACT_PARTIAL_MASKFROM
- REDACT_PARTIAL_MASKTO
- REDACT_PARTIAL_DATE_MONTH
- REDACT_PARTIAL_DATE_DAY
- REDACT_PARTIAL_DATE_YEAR
- REDACT_PARTIAL_DATE_HOUR
- REDACT_PARTIAL_DATE_MINUTE
- REDACT_PARTIAL_DATE_SECOND

See Table 111–3 and Table 111–4 for examples of the field contents and field ordering.
Summary of DBMS_REDACT Subprograms

- ORA-28075 - The policy expression has unsupported functions
- ORA-28076 - An attribute was not specified for SYS_SESSION_ROLES
- ORA-28077 - The attribute specified (attribute) exceeds the maximum length
- ORA-28078 - A regular expression parameter is missing or invalid
- ORA-28082 - The parameter parameter is invalid (where the possible values are function_parameters, column_description, policy_name and policy_description)
- ORA-28085 - The input and output lengths of the redaction do not match.

Usage Notes

See Operating Procedures for more information regarding function types and function parameters with related examples.

Example

Partial redaction policy:

BEGIN
    DBMS_REDACT.ADD_POLICY(
        object_schema    => 'hr',
        object_name      => 'employees',
        column_name      => 'employee_id',
        policy_name      => 'mask_emp_id_nums',
        function_type    => DBMS_REDACT.PARTIAL,
        function_parameters => '7,1,5',
        expression       => '1=1');
END;

Full redaction policy:

BEGIN
    DBMS_REDACT.ADD_POLICY(
        object_schema    => 'hr',
        object_name      => 'employees',
        column_name      => 'employee_id',
        policy_name      => 'mask_emp_ids',
        function_type    => DBMS_REDACT.FULL,
        expression       => 'SYS_CONTEXT(''SYS_SESSION_ROLES'',''CLERK'')
                           = ''FALSE'');
END;
ALTER_POLICY Procedure

This procedure alters an existing Data Redaction policy for a table or view in one or more of the following ways:

- By changing the policy expression
- By changing the type of redaction for a specified column
- By changing the parameters to the redaction function for a specified column
- By adding a column to the redaction policy (the redaction type and any parameters must be specified).
- By removing a column from the redaction policy

Syntax

```
DBMS_REDACT.ALTER_POLICY ( 
    object_schema    IN    VARCHAR2 := NULL,
    object_name      IN    VARCHAR2,
    policy_name      IN    VARCHAR2,
    action           IN    BINARY_INTEGER := DBMS_REDACT.ADD_COLUMN,
    column_name      IN    VARCHAR2 := NULL,
    function_type    IN    BINARY_INTEGER := DBMS_REDACT.FULL,
    function_parameters IN   VARCHAR2 := NULL,
    expression       IN    VARCHAR2,
    regexp_pattern   IN    VARCHAR2 := NULL,
    regexp_replace_string IN   VARCHAR2 := NULL,
    regexp_position  IN    BINARY_INTEGER := 1,
    regexp_occurrence IN    BINARY_INTEGER := 0,
    regexp_match_parameter IN   VARCHAR2 := NULL,
    policy_description IN   VARCHAR2 := NULL,
    column_description IN   VARCHAR2 := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema owning the table, current user if NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table or view to which to alter a Data Redaction policy</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy limited to 30 bytes</td>
</tr>
<tr>
<td>action</td>
<td>Action to take. For more information see Table 111–2, &quot;Values for action Parameter of DBMS_REDACT.ALTER_POLICY&quot;.</td>
</tr>
<tr>
<td>column_name</td>
<td>[Optional] Name of one column to which the redaction policy applies.</td>
</tr>
</tbody>
</table>
If the `function_type` is `DBMS_REDACT.REGEXP`, then the `function_parameters` parameter must be omitted completely, and the `regexp_pattern`, `regexp_replace_string`, `regexp_position`, `regexp_occurrence`, and `regexp_match_parameter` must be used to define the Data Redaction policy.

See Table 111–1, "Values for function_type Parameter of DBMS_REDACT.ADD_POLICY" for an overview of the meanings of these values, and for some examples of their use.
ALTER_POLICY Procedure

function_parameters

Parameters to the redaction function. The possible values depend on the value of the function_type provided.

- If the function_type is DBMS_REDACT.REEXP, then the function_parameters parameter must be omitted completely, and the regexp_pattern, regexp_replace_string, regexp_position, regexp_occurrence, and regexp_match parameter must be used to define the Data Redaction policy.

- If the function_type is DBMS_REDACT.NONE, the function_parameters parameter can be omitted entirely and defaults to NULL.

- If the function_type is DBMS_REDACT.FULL, the function_parameters parameter can be omitted entirely and defaults to NULL.

- If the function_type is DBMS_REDACT.PARTIAL, the function_parameters parameter represents the masking parameters for partial masking.

  - Input format: ‘V’ for value to be possibly masked, ‘F’ for formatting character to be ignored.
  - Output format: ‘V’ for output of masking, any other characters will be treated as formatting characters.
  - Mask character: a character that will be used to replace the actual values. Examples are ‘*’ and ‘x’.
  - Starting digit position: specifies the starting (character) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include formatting characters.
  - Ending digit position: specifies the ending (digit) position to end masking. An example is ‘VVVFVVVVVV, VV-VVVV-VVVV, X, 1, 5’ for masking the first 5 digits of SSN string 123-45-6789, and adding dashes back to format it like an SSN, resulting in XXX-XX-6789.

For number datatypes, a comma-separated list containing these fields:

  - Mask character: this is a character between ‘0’ to ‘9’ that will be used to replace the actual values.
  - Starting digit position: specifies the starting (digit) position to begin replacing actual values with the masking character. The beginning of the string is position 1. Positions do not include the decimal point.
  - Ending digit position: this specifies the ending digit position to end masking. An example is ‘9,1,5’ for masking the first 5 digits of a Social Security number number 123456789, resulting in 999996789.

Table 111–7 (Cont.) ALTER_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>function_parameters</td>
<td>Parameters to the redaction function. The possible values depend on the value of the function_type provided.</td>
</tr>
</tbody>
</table>
For datetime datatypes, the format is a packed string (no spaces or commas) containing the following sequence of fields. Please note that each field can consist of one or more characters, and the field length depends on whether masking is required. The one-character fields are used to specify that no redaction of that component of the datetime value is to take place. The longer fields indicate a specific time or date to use as the redacted value of that component of the datetime value.

- **Month**: ‘M’ (no masking of month) or ‘m#’ (mask month to a specific month, if possible), where # (the month specified by its number) is between 1 and 12
- **Day**: ‘D’ (no masking of date) or ‘d#’ (mask day to #, if possible), # between 1 and 31
- **Year**: ‘Y’ (no masking of year) or ‘y#’ (mask year to #, if possible), # between 1 and 9999
- **Hour**: ‘H’ (no masking of hour) or ‘h#’ (mask hour to #, if possible), # between 0 and 23
- **Minute**: ‘M’ (no masking of minute) or ‘m#’ (mask minute to #, if possible), # between 0 and 59
- **Second**: ‘S’ (no masking of second) or ‘s#’ (mask second to #, if possible), # between 0 and 59

An example is ‘m12DYHMS’, which changes 01-May-01 01:01:01 to 01-Dec-01 01:01:01

For partial character and number-masking shortcuts, see Oracle Database Advanced Security Administrator’s Guide.

### Table 111–7 (Cont.) ALTER_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>expression</td>
<td>Boolean expression for the table or view, using either the SYS_CONTEXT function or 1=1. Redaction takes place only if this policy expression evaluates to TRUE.</td>
</tr>
<tr>
<td>regexp_pattern</td>
<td>Regular expression pattern up to 512 bytes. Use only if the function_type parameter is DBMS_REDACT.REGEXP. Also, do not specify the function_parameters parameter when function_type is DBMS_REDACT.REGEXP. See Oracle Database SQL Language Reference for more information and examples on using regular expression patterns</td>
</tr>
<tr>
<td>regexp_replace_string</td>
<td>Replacement string (up to 4000 characters in length) with up to 500 back-references to subexpressions in the form \n, where n is a number between 1 and 9. Use only if the function_type parameter is DBMS_REDACT.REGEXP</td>
</tr>
<tr>
<td>regexp_position</td>
<td>Integer counting from 1, specifies the position where the search must begin. Use only if the function_type parameter is DBMS_REDACT.REGEXP</td>
</tr>
<tr>
<td>regexp_occurrence</td>
<td>Use 0 to replace all occurrences of the match. Use positive integer n to replace the n-th occurrence of the match. Use only if the function_type parameter is DBMS_REDACT.REGEXP</td>
</tr>
</tbody>
</table>
ALTER_POLICY Procedure

Table 111–7 (Cont.) ALTER_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>regexp_match_parameter</td>
<td>Changes the default matching behavior, possible values are a combination of 'i', 'c', 'n', 'm', 'x'</td>
</tr>
<tr>
<td></td>
<td>Use only if the function_type parameter is DBMS_REDACT.REGPEXP</td>
</tr>
<tr>
<td></td>
<td>See Oracle Database SQL Language Reference for more information and examples on using regular expression match parameters.</td>
</tr>
<tr>
<td>policy_description</td>
<td>Description of redaction policy</td>
</tr>
<tr>
<td>column_description</td>
<td>Description of the column being redacted</td>
</tr>
</tbody>
</table>

Exceptions

- ORA-28062 - The policy expression is too long.
- ORA-28063 - The policy expression is empty.
- ORA-28064 - The type of redaction function is not valid.
- ORA-28066 - Invalid column column
- ORA-28067 - Missing or invalid column name
- ORA-28068 - The object object does not have a Data Redaction policy.
- ORA-28070 - The column column does not have a Data Redaction policy.
- ORA-28071 - The action is not valid.
- ORA-28072 - The specified policy name is incorrect.
- ORA-28073 - The column column_name has an unsupported datatype.
- ORA-28074 - The field field_name of the masking parameters is not valid

The field can be any of the following:
- REDACT_PARTIAL_INPUT_FORMAT
- REDACT_PARTIAL_OUTPUT_FORMAT
- REDACT_PARTIAL_MASKCHAR
- REDACT_PARTIAL_MASKFROM
- REDACT_PARTIAL_MASKTO
- REDACT_PARTIAL_DATE_MONTH
- REDACT_PARTIAL_DATE_DAY
- REDACT_PARTIAL_DATE_YEAR
- REDACT_PARTIAL_DATE_HOUR
- REDACT_PARTIAL_DATE_MINUTE
- REDACT_PARTIAL_DATE_SECOND

See Table 111–3 and Table 111–4 for examples of the field contents and field ordering.

- ORA-28075 - The policy expression has unsupported functions.
- ORA-28076 - An attribute was not specified for SYS_SESSION_ROLES.
■ ORA-28077 - The attribute specified (attribute) exceeds the maximum length.
■ ORA-28078 - A regular expression parameter is missing or invalid.
■ ORA-28082 - The parameter parameter is invalid (where the possible values are function_parameters, column_description, policy_name and policy_description)
■ ORA-28085 - The input and output lengths of the redaction do not match.

Usage Notes

See Operating Procedures for more information regarding Function Types and Function Parameters with related examples.

Examples

BEGIN
    DBMS_REDACT.ALTER_POLICY(
        object_schema => 'hr',
        object_name => 'employees',
        policy_name => 'mask_emp_id_nums',
        action => DBMS_REDACT.ADD_COLUMN,
    )
END;
DISABLE_POLICY Procedure

This procedure disables a Data Redaction policy.

Syntax

```plsql
DBMS_REDACT.DISABLE_POLICY (  
    object_schema    IN    VARCHAR2 := NULL,  
    object_name      IN    VARCHAR2,  
    policy_name      IN    VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema owning the table or view, current user if NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table or view for which to disable a Data Redaction policy</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be disabled</td>
</tr>
</tbody>
</table>

Exceptions

- ORA-28068 - The object object does not have a Data Redaction policy.
- ORA-28072 - The specified policy name is incorrect.
- ORA-28080 - The policy was already disabled.

Examples

```plsql
BEGIN
    DBMS_REDACT.DISABLE_POLICY (  
        object_schema    => 'hr',  
        object_name      => 'employees',  
        policy_name      => 'mask_emp_ids');
END;
```
DROP_POLICY Procedure

This procedure drops a Data Redaction policy by removing a masking policy from the table or view.

Syntax

DBMS_REDACT.DROP_POLICY (  
  object_schema                IN    VARCHAR2 := NULL,  
  object_name                  IN    VARCHAR2,  
  policy_name                  IN    VARCHAR2);  

Parameters

Table 111–9 DROP_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema owning the table or view, current user if NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table or view from which to drop a Data Redaction policy</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be dropped</td>
</tr>
</tbody>
</table>

Exceptions

- ORA-28068 - The object object does not have a Data Redaction policy.
- ORA-28072 - The specified policy name is incorrect.

Examples

BEGIN  
  DBMS_REDACT.DROP_POLICY (  
    object_schema => 'hr',  
    object_name   => 'employees',  
    policy_name   => 'mask_emp_ids');  
END;
ENABLE_POLICY Procedure

This procedure re-enables a Data Redaction policy.

Syntax

```sql
DBMS_REDACT.ENABLE_POLICY (  
  object_schema                IN    VARCHAR2 := NULL,  
  object_name                  IN    VARCHAR2,  
  policy_name                  IN    VARCHAR2);  
```

Parameters

Table 111–10 ENABLE_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema owning the table or view, current user if NULL</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table or view to which to enable a Data Redaction policy</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be enabled</td>
</tr>
</tbody>
</table>

Exceptions

- ORA-28068 - The object `object` does not have a Data Redaction policy.
- ORA-28071 - The action is not valid.
- ORA-28072 - The specified policy name is incorrect.
- ORA-28079 - The policy was already enabled.

Examples

```sql
BEGIN  
  DBMS_REDACT.ENABLE_POLICY (  
    object_schema => 'hr',  
    object_name   => 'employees',  
    policy_name   => 'mask_emp_ids');  
END;  
```
UPDATE_FULL_REDACTION_VALUES Procedure

This procedure modifies the default displayed values for a Data Redaction policy for full redaction.

Syntax

DBMS_REDACT.UPDATE_FULL_REDACTION_VALUES ( 
  number_val       IN NUMBER                    :=  NULL,
  binfloat_val     IN BINARY_FLOAT              :=  NULL,
  bindouble_val    IN BINARY_DOUBLE             :=  NULL,
  char_val         IN CHAR                      :=  NULL,
  varchar_val      IN VARCHAR2                  :=  NULL,
  nchar_val        IN NCHAR                     :=  NULL,
  nvarchar_val     IN NVARCHAR2                 :=  NULL,
  date_val         IN DATE                      :=  NULL,
  ts_val           IN TIMESTAMP                 :=  NULL,
  tswtz_val        IN TIMESTAMP WITH TIME ZONE  :=  NULL); 

Parameters

Table 111–11 UPDATE_FULL_REDACTION_VALUES Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>number_val</td>
<td>Modifies the default value for columns of the NUMBER datatype</td>
</tr>
<tr>
<td>binfloat_val</td>
<td>Modifies the default value for columns of the BINARY_FLOAT datatype</td>
</tr>
<tr>
<td>bindouble_val</td>
<td>Modifies the default value for columns of the BINARY_DOUBLE datatype</td>
</tr>
<tr>
<td>char_val</td>
<td>Modifies the default value for columns of the CHAR datatype</td>
</tr>
<tr>
<td>varchar_val</td>
<td>Modifies the default value for columns of the VARCHAR2 datatype</td>
</tr>
<tr>
<td>nchar_val</td>
<td>Modifies the default value for columns of the NCHAR datatype</td>
</tr>
<tr>
<td>nvarchar_val</td>
<td>Modifies the default value for columns of the NVARCHAR2 datatype</td>
</tr>
<tr>
<td>date_val</td>
<td>Modifies the default value for columns of the DATE datatype</td>
</tr>
<tr>
<td>ts_val</td>
<td>Modifies the default value for columns of the TIMESTAMP datatype</td>
</tr>
<tr>
<td>tswtz_val</td>
<td>Modifies the default value for columns of the TIMESTAMP WITH TIME ZONE datatype</td>
</tr>
</tbody>
</table>

Exceptions

ORA-28082 - The parameter parameter is invalid (where the possible values are char_val, nchar_val, varchar_val and nvarchar_val)

Usage Note

LOB data types are supported for Oracle Database 11 Release 2 (11.2.0.4) by means of an update script. For more information see ”Altering the Default Full Data Redaction Value for LOB Data Type Columns” in Oracle Database Advanced Security Administrator’s Guide.
The DBMS_REFRESH package enables you to create groups of materialized views that can be refreshed together to a transactionally consistent point in time.

- Documentation of DBMS_REFRESH
For a complete description of this package within the context of Replication, see DBMS_REFRESH in the Oracle Database Advanced Replication Management API Reference.
The DBMS_REPAIR package contains data corruption repair procedures that enable you to detect and repair corrupt blocks in tables and indexes. You can address corruptions where possible and continue to use objects while you attempt to rebuild or repair them.

See Also: For detailed information about using the DBMS_REPAIR package, see Oracle Database Administrator’s Guide.

Overview

Note: The DBMS_REPAIR package is intended for use by database administrators only. It is not intended for use by application developers.
Security Model

The package is owned by SYS. Execution privilege is not granted to other users.
Constants

The DBMS_REPAIR package defines several enumerated constants that should be used for specifying parameter values. Enumerated constants must be prefixed with the package name. For example, DBMS_REPAIR.TABLE_OBJECT.

Table 113–1 lists the parameters and the enumerated constants.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Option</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_type</td>
<td>TABLE_OBJECT</td>
<td>BINARY_INTEGER</td>
<td></td>
</tr>
<tr>
<td></td>
<td>INDEX_OBJECT</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>CLUSTER_OBJECT</td>
<td></td>
<td></td>
</tr>
<tr>
<td>action</td>
<td>CREATE_ACTION</td>
<td>BINARY_INTEGER</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DROP_ACTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>PURGE_ACTION</td>
<td></td>
<td></td>
</tr>
<tr>
<td>table_type</td>
<td>REPAIR_TABLE</td>
<td>BINARY_INTEGER</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ORPHAN_TABLE</td>
<td></td>
<td></td>
</tr>
<tr>
<td>flags</td>

<td>LOCK_WAIT := 1</td>
<td>BINARY_INTEGER</td>
<td>Specifies whether to try getting DML locks</td>
</tr>
<tr>
<td></td>
<td>LOCK_NOWAIT := 0</td>
<td></td>
<td>on underlying table [[sub]partition] object</td>
</tr>
</tbody>
</table>

Note: The default table_name will be REPAIR_TABLE when table_type is REPAIR_TABLE, and will be ORPHAN_KEY_TABLE when table_type is ORPHAN_TABLE.
Operating Notes

The procedure to create the **ORPHAN_KEYS_TABLE** is similar to the one used to create the **REPAIR_TABLE**.

```sql
CONNECT / AS SYSDBA;
EXEC DBMS_REPAIR.ADMIN_TABLES('ORPHAN_KEYS_TABLE', DBMS_REPAIR.ORPHAN_TABLE,
                                 DBMS_REPAIR.CREATE_ACTION);
EXEC DBMS_REPAIR.ADMIN_TABLES('REPAIR_TABLE', DBMS_REPAIR.REPAIR_TABLE,
                                 DBMS_REPAIR.CREATE_ACTION);

DESCRIBE ORPHAN_KEYS_TABLE;
DESCRIBE REPAIR_TABLE;
SELECT * FROM ORPHAN_KEYS_TABLE;
SELECT * FROM REPAIR_TABLE;
```

The DBA would create the repair and orphan keys tables once. Subsequent executions of the **CHECK_OBJECT Procedure** would add rows into the appropriate table indicating the types of errors found.

The name of the repair and orphan keys tables can be chosen by the user, with the following restriction: the name of the repair table must begin with the 'REPAIR_' prefix, and the name of the orphan keys table must begin with the 'ORPHAN_' prefix. The following code is also legal:

```sql
CONNECT / AS SYSDBA;
EXEC DBMS_REPAIR.ADMIN_TABLES('ORPHAN_FOOBAR', DBMS_REPAIR.ORPHAN_TABLE,
                                 DBMS_REPAIR.CREATE_ACTION);
EXEC DBMS_REPAIR.ADMIN_TABLES('REPAIR_ABCD', DBMS_REPAIR.REPAIR_TABLE,
                                 DBMS_REPAIR.CREATE_ACTION);

DESCRIBE ORPHAN_FOOBAR;
DESCRIBE REPAIR_ABCD;
SELECT * FROM ORPHAN_FOOBAR;
SELECT * FROM REPAIR_ABCD;
```

When invoking the **CHECK_OBJECT Procedure** the name of the repair and orphan keys tables that were created should be specified correctly, especially if the default values were not used in the **ADMIN_TABLES Procedure** or **CREATE_ACTION**.

Other actions in the **ADMIN_TABLES Procedure** can be used to purge/delete the **REPAIR_TABLE** and the **ORPHAN_KEYS_TABLE**.
## Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>942</td>
<td>Reported by DBMS_REPAIR.ADMIN_TABLES during a DROP_ACTION when the specified table doesn’t exist.</td>
<td>-</td>
</tr>
<tr>
<td>955</td>
<td>Reported by DBMS_REPAIR.CREATE_ACTION when the specified table already exists.</td>
<td>-</td>
</tr>
<tr>
<td>24120</td>
<td>An invalid parameter was passed to the specified DBMS_REPAIR procedure.</td>
<td>Specify a valid parameter value or use the parameter’s default.</td>
</tr>
<tr>
<td>24122</td>
<td>An incorrect block range was specified.</td>
<td>Specify correct values for the BLOCK_START and BLOCK_END parameters.</td>
</tr>
<tr>
<td>24123</td>
<td>An attempt was made to use the specified feature, but the feature is not yet implemented.</td>
<td>Do not attempt to use the feature.</td>
</tr>
<tr>
<td>24124</td>
<td>An invalid ACTION parameter was specified.</td>
<td>Specify CREATE_ACTION, PURGE_ACTION or DROP_ACTION for the ACTION parameter.</td>
</tr>
<tr>
<td>24125</td>
<td>An attempt was made to fix corrupt blocks on an object that has been dropped or truncated since DBMS_REPAIR.CHECK_OBJECT was run.</td>
<td>Use DBMS_REPAIR.ADMIN_TABLES to purge the repair table and run DBMS_REPAIR.CHECK_OBJECT to determine whether there are any corrupt blocks to be fixed.</td>
</tr>
<tr>
<td>24127</td>
<td>TABLESPACE parameter specified with an ACTION other than CREATE_ACTION.</td>
<td>Do not specify TABLESPACE when performing actions other than CREATE_ACTION.</td>
</tr>
<tr>
<td>24128</td>
<td>A partition name was specified for an object that is not partitioned.</td>
<td>Specify a partition name only if the object is partitioned.</td>
</tr>
<tr>
<td>24129</td>
<td>An attempt was made to pass a table name parameter without the specified prefix.</td>
<td>Pass a valid table name parameter.</td>
</tr>
<tr>
<td>24130</td>
<td>An attempt was made to specify a repair or orphan table that does not exist.</td>
<td>Specify a valid table name parameter.</td>
</tr>
<tr>
<td>24131</td>
<td>An attempt was made to specify a repair or orphan table that does not have a correct definition.</td>
<td>Specify a table name that refers to a properly created table.</td>
</tr>
<tr>
<td>24132</td>
<td>An attempt was made to specify a table name is greater than 30 characters long.</td>
<td>Specify a valid table name parameter.</td>
</tr>
</tbody>
</table>
Examples

/* Fix the bitmap status for all the blocks in table mytab in schema sys */
EXECUTE DBMS_REPAIR.SEGMENT_FIX_STATUS('SYS', 'MYTAB');

/* Mark block number 45, filenumber 1 for table mytab in sys schema as FULL. */
EXECUTE DBMS_REPAIR.SEGMENT_FIX_STATUS('SYS', 'MYTAB', TABLE_OBJECT, 1, 45, 1);
### Table 113–3  DBMS_REPAIR Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADMIN_TABLES Procedure</td>
<td>Provides administrative functions for the DBMS_REPAIR package repair and orphan key tables, including create, purge, and drop functions</td>
</tr>
<tr>
<td>CHECK_OBJECT Procedure</td>
<td>Detects and reports corruptions in a table or index</td>
</tr>
<tr>
<td>DUMP_ORPHAN_KEYS Procedure</td>
<td>Reports on index entries that point to rows in corrupt data blocks</td>
</tr>
<tr>
<td>FIX_CORRUPT_BLOCKS Procedure</td>
<td>Marks blocks software corrupt that have been previously detected as corrupt by CHECK_OBJECT</td>
</tr>
<tr>
<td>ONLINE_INDEX_CLEAN Function</td>
<td>Performs a manual cleanup of failed or interrupted online index builds or rebuilds</td>
</tr>
<tr>
<td>REBUILD_FREELISTS Procedure</td>
<td>Rebuilds an object's freelists</td>
</tr>
<tr>
<td>SEGMENT_FIX_STATUS Procedure</td>
<td>Fixes the corrupted state of a bitmap entry</td>
</tr>
<tr>
<td>SKIP_CORRUPT_BLOCKS Procedure</td>
<td>Sets whether to ignore blocks marked corrupt during table and index scans or to report ora-1578 when blocks marked corrupt are encountered</td>
</tr>
</tbody>
</table>
ADMIN_TABLES Procedure

This procedure provides administrative functions for the DBMS_REPAIR package repair and orphan key tables.

Syntax

```plsql
DBMS_REPAIR.ADMIN_TABLES (
    table_name  IN   VARCHAR2,
    table_type  IN   BINARY_INTEGER,
    action      IN   BINARY_INTEGER,
    tablespace  IN   VARCHAR2  DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>table_name</td>
<td>Name of the table to be processed. Defaults to ORPHAN_KEY_TABLE or REPAIR_TABLE based on the specified table_type. When specified, the table name must have the appropriate prefix: ORPHAN_ or REPAIR_.</td>
</tr>
<tr>
<td>table_type</td>
<td>Type of table; must be either ORPHAN_TABLE or REPAIR_TABLE. See &quot;Constants&quot; on page 113-5.</td>
</tr>
<tr>
<td>action</td>
<td>Indicates what administrative action to perform. Must be either CREATE_ACTION, PURGE_ACTION, or DROP_ACTION. If the table already exists, and if CREATE_ACTION is specified, then an error is returned. PURGE_ACTION indicates to delete all rows in the table that are associated with non-existent objects. If the table does not exist, and if DROP_ACTION is specified, then an error is returned. When CREATE_ACTION and DROP_ACTION are specified, an associated view named DBA_&lt;table_name&gt; is created and dropped respectively. The view is defined so that rows associated with non-existent objects are eliminated. Created in the SYS schema. See &quot;Constants&quot; on page 113-5.</td>
</tr>
<tr>
<td>tablespace</td>
<td>Indicates the tablespace to use when creating a table. By default, the SYS default tablespace is used. An error is returned if the tablespace is specified and if the action is not CREATE_ACTION.</td>
</tr>
</tbody>
</table>
CHECK_OBJECT Procedure

This procedure checks the specified objects and populates the repair table with information about corruptions and repair directives.

Validation consists of block checking all blocks in the object.

Syntax

```
DBMS_REPAIR.CHECK_OBJECT (  
    schema_name       IN  VARCHAR2,  
    object_name       IN  VARCHAR2,  
    partition_name    IN  VARCHAR2       DEFAULT NULL,  
    object_type       IN  BINARY_INTEGER DEFAULT TABLE_OBJECT,  
    repair_table_name IN  VARCHAR2       DEFAULT 'REPAIR_TABLE',  
    flags             IN  BINARY_INTEGER DEFAULT NULL,  
    relative_fno      IN  BINARY_INTEGER DEFAULT NULL,  
    block_start       IN  BINARY_INTEGER DEFAULT NULL,  
    block_end         IN  BINARY_INTEGER DEFAULT NULL,  
    corrupt_count     OUT BINARY_INTEGER);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Schema name of the object to be checked.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the table or index to be checked.</td>
</tr>
<tr>
<td>partition_name</td>
<td>Partition or subpartition name to be checked.</td>
</tr>
<tr>
<td></td>
<td>If this is a partitioned object, and if partition_name is not specified,</td>
</tr>
<tr>
<td></td>
<td>then all partitions and subpartitions are checked.</td>
</tr>
<tr>
<td></td>
<td>If this is a partitioned object, and if the specified partition contains</td>
</tr>
<tr>
<td></td>
<td>subpartitions, then all subpartitions are checked.</td>
</tr>
<tr>
<td>object_type</td>
<td>Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT.</td>
</tr>
<tr>
<td></td>
<td>See &quot;Constants&quot; on page 113-5.</td>
</tr>
<tr>
<td>repair_table_name</td>
<td>Name of the repair table to be populated.</td>
</tr>
<tr>
<td></td>
<td>The table must exist in the SYS schema. Use the ADMIN_TABLES Procedure to</td>
</tr>
<tr>
<td></td>
<td>create a repair table. The default name is REPAIR_TABLE.</td>
</tr>
<tr>
<td>flags</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>relative_fno</td>
<td>Relative file number: Used when specifying a block range.</td>
</tr>
<tr>
<td>block_start</td>
<td>First block to process if specifying a block range. May be specified only</td>
</tr>
<tr>
<td></td>
<td>if the object is a single table, partition, or subpartition.</td>
</tr>
<tr>
<td>block_end</td>
<td>Last block to process if specifying a block range. May be specified only</td>
</tr>
<tr>
<td></td>
<td>if the object is a single table, partition, or subpartition. If only one of</td>
</tr>
<tr>
<td></td>
<td>block_start or block_end is specified, then the other defaults to the first</td>
</tr>
<tr>
<td></td>
<td>or last block in the file respectively.</td>
</tr>
<tr>
<td>corrupt_count</td>
<td>Number of corruptions reported.</td>
</tr>
</tbody>
</table>
Usage Notes

You may optionally specify a DBA range, partition name, or subpartition name when you want to check a portion of an object.
DUMP_ORPHAN_KEYS Procedure

This procedure reports on index entries that point to rows in corrupt data blocks. For each such index entry encountered, a row is inserted into the specified orphan table.

If the repair table is specified, then any corrupt blocks associated with the base table are handled in addition to all data blocks that are marked software corrupt. Otherwise, only blocks that are marked corrupt are handled.

This information may be useful for rebuilding lost rows in the table and for diagnostic purposes.

Syntax

```sql
DBMS_REPAIR.DUMP_ORPHAN_KEYS (  
  schema_name       IN  VARCHAR2,  
  object_name       IN  VARCHAR2,  
  partition_name    IN  VARCHAR2  DEFAULT NULL,  
  object_type       IN  BINARY_INTEGER DEFAULT INDEX_OBJECT,  
  repair_table_name IN  VARCHAR2  DEFAULT 'REPAIR_TABLE',  
  orphan_table_name IN  VARCHAR2  DEFAULT 'ORPHAN_KEYS_TABLE',  
  flags             IN  BINARY_INTEGER DEFAULT NULL,  
  key_count         OUT BINARY_INTEGER);
```

Parameters

**Table 113–6  DUMP_ORPHAN_KEYS Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Schema name.</td>
</tr>
<tr>
<td>object_name</td>
<td>Object name.</td>
</tr>
<tr>
<td>partition_name</td>
<td>Partition or subpartition name to be processed.</td>
</tr>
<tr>
<td></td>
<td>If this is a partitioned object, and if partition_name is not specified, then all partitions and subpartitions are processed. If this is a partitioned object, and if the specified partition contains subpartitions, then all subpartitions are processed.</td>
</tr>
</tbody>
</table>
| object_type       | Type of the object to be processed. The default is INDEX_OBJECT  
|                   | See "Constants" on page 113-5.                        |
| repair_table_name | Name of the repair table that has information regarding corrupt blocks in the base table.  
|                   | The specified table must exist in the SYS schema. The ADMIN_TABLES Procedure is used to create the table. |
| orphan_table_name | Name of the orphan key table to populate with information regarding each index entry that refers to a row in a corrupt data block.  
|                   | The specified table must exist in the SYS schema. The ADMIN_TABLES Procedure is used to create the table. |
| flags             | Reserved for future use.                             |
| key_count         | Number of index entries processed.                   |
This procedure fixes the corrupt blocks in specified objects based on information in the repair table that was previously generated by the CHECK_OBJECT Procedure.

Prior to effecting any change to a block, the block is checked to ensure the block is still corrupt. Corrupt blocks are repaired by marking the block software corrupt. When a repair is effected, the associated row in the repair table is updated with a fix timestamp.

**Syntax**

```sql
DBMS_REPAIR.FIX_CORRUPT_BLOCKS (
    schema_name       IN  VARCHAR2,
    object_name       IN  VARCHAR2,
    partition_name    IN  VARCHAR2       DEFAULT NULL,
    object_type       IN  BINARY_INTEGER DEFAULT TABLE_OBJECT,
    repair_table_name IN  VARCHAR2       DEFAULT 'REPAIR_TABLE',
    flags             IN  BINARY_INTEGER DEFAULT NULL,
    fix_count         OUT BINARY_INTEGER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Schema name.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the object with corrupt blocks to be fixed.</td>
</tr>
<tr>
<td>partition_name</td>
<td>Partition or subpartition name to be processed.</td>
</tr>
<tr>
<td>object_type</td>
<td>Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT.</td>
</tr>
<tr>
<td>repair_table_name</td>
<td>Name of the repair table with the repair directives.</td>
</tr>
<tr>
<td>flags</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>fix_count</td>
<td>Number of blocks fixed.</td>
</tr>
</tbody>
</table>

See "Constants" on page 113-5.
ONLINE_INDEX_CLEAN Function

This function performs a manual cleanup of failed or interrupted online index builds or rebuilds. This action is also performed periodically by SMON, regardless of user-initiated cleanup.

This function returns TRUE if all indexes specified were cleaned up and FALSE if one or more indexes could not be cleaned up.

Syntax

```sql
DBMS_REPAIR.ONLINE_INDEX_CLEAN (    object_id IN BINARY_INTEGER DEFAULT ALL_INDEX_ID,    wait_for_lock IN BINARY_INTEGER DEFAULT LOCK_WAIT)    RETURN BOOLEAN;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_id</td>
<td>Object id of index to be cleaned up. The default cleans up all object ids that qualify.</td>
</tr>
<tr>
<td>wait_for_lock</td>
<td>This parameter specifies whether to try getting DML locks on underlying table ([sub]partition) object. The default retries up to an internal retry limit, after which the lock get will give up. If LOCK_NOWAIT is specified, then the lock get does not retry.</td>
</tr>
</tbody>
</table>
REBUILD_FREELISTS Procedure

This procedure rebuilds the freelists for the specified object. All free blocks are placed on the master freelist. All other freelists are zeroed.

If the object has multiple freelist groups, then the free blocks are distributed among all freelists, allocating to the different groups in round-robin fashion.

Syntax

```sql
DBMS_REPAIR.REBUILD_FREELISTS (
    schema_name    IN VARCHAR2,
    object_name    IN  VARCHAR2,
    partition_name IN VARCHAR2 DEFAULT NULL,
    object_type    IN BINARY_INTEGER DEFAULT TABLE_OBJECT);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Schema name.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the object whose freelists are to be rebuilt.</td>
</tr>
<tr>
<td>partition_name</td>
<td>Partition or subpartition name whose freelists are to be rebuilt.</td>
</tr>
<tr>
<td></td>
<td>If this is a partitioned object, and partition_name is not specified, then all partitions and subpartitions are processed. If this is a partitioned object, and the specified partition contains subpartitions, then all subpartitions are processed.</td>
</tr>
<tr>
<td>object_type</td>
<td>Type of the object to be processed. This must be either TABLE_OBJECT (default) or INDEX_OBJECT.</td>
</tr>
</tbody>
</table>

See “Constants” on page 113-5.
SEGMENT_FIX_STATUS Procedure

With this procedure you can fix the corrupted state of a bitmap entry. The procedure either recalculates the state based on the current contents of the corresponding block or sets the state to a specific value.

Syntax

```sql
DBMS_REPAIR.SEGMENT_FIX_STATUS (
    segment_owner   IN VARCHAR2,
    segment_name    IN VARCHAR2,
    segment_type    IN BINARY_INTEGER DEFAULT TABLE_OBJECT,
    file_number     IN BINARY_INTEGER DEFAULT NULL,
    block_number    IN BINARY_INTEGER DEFAULT NULL,
    status_value    IN BINARY_INTEGER DEFAULT NULL,
    partition_name  IN VARCHAR2 DEFAULT NULL,);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_owner</td>
<td>Schema name of the segment.</td>
</tr>
<tr>
<td>segment_name</td>
<td>Segment name.</td>
</tr>
<tr>
<td>partition_name</td>
<td>Optional. Name of an individual partition. NULL for nonpartitioned objects. Default is NULL.</td>
</tr>
<tr>
<td>segment_type</td>
<td>Optional Type of the segment (for example, TABLE_OBJECT or INDEX_OBJECT). Default is NULL.</td>
</tr>
<tr>
<td>file_number</td>
<td>(optional) The tablespace-relative file number of the data block whose status has to be fixed. If omitted, all the blocks in the segment will be checked for state correctness and fixed.</td>
</tr>
<tr>
<td>block_number</td>
<td>(optional) The file-relative block number of the data block whose status has to be fixed. If omitted, all the blocks in the segment will be checked for state correctness and fixed.</td>
</tr>
<tr>
<td>status_value</td>
<td>(optional) The value to which the block status described by the file_number and block_number will be set. If omitted, the status will be set based on the current state of the block. This is almost always the case, but if there is a bug in the calculation algorithm, the value can be set manually. Status values:</td>
</tr>
<tr>
<td></td>
<td>■ 1 = block is full</td>
</tr>
<tr>
<td></td>
<td>■ 2 = block is 0-25% free</td>
</tr>
<tr>
<td></td>
<td>■ 3 = block is 25-50% free</td>
</tr>
<tr>
<td></td>
<td>■ 4 = block is 50-75% free</td>
</tr>
<tr>
<td></td>
<td>■ 5 = block is 75-100% free</td>
</tr>
<tr>
<td></td>
<td>The status for bitmap blocks, segment headers, and extent map blocks cannot be altered. The status for blocks in a fixed hash area cannot be altered. For index blocks, there are only two possible states: 1 = block is full and 3 = block has free space.</td>
</tr>
</tbody>
</table>
SKIP_CORRUPT_BLOCKS Procedure

This procedure enables or disables the skipping of corrupt blocks during index and table scans of the specified object.

When the object is a table, skip applies to the table and its indexes. When the object is a cluster, it applies to all of the tables in the cluster, and their respective indexes.

---

**Note:** When Oracle performs an index range scan on a corrupt index after DBMS_REPAIR.SKIP_CORRUPT_BLOCKS has been set for the base table, corrupt branch blocks and root blocks are not skipped. Only corrupt non-root leaf blocks are skipped.

---

Syntax

```sql
DBMS_REPAIR.SKIP_CORRUPT_BLOCKS (
    schema_name  IN VARCHAR2,
    object_name  IN VARCHAR2,
    object_type  IN BINARY_INTEGER DEFAULT TABLE_OBJECT,
    flags        IN BINARY_INTEGER DEFAULT SKIP_FLAG);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schema_name</td>
<td>Schema name of the object to be processed.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the object.</td>
</tr>
<tr>
<td>object_type</td>
<td>Type of the object to be processed. This must be either TABLE_OBJECT (default) or CLUSTER_OBJECT. See &quot;Constants&quot; on page 113-5.</td>
</tr>
<tr>
<td>flags</td>
<td>If SKIP_FLAG is specified, then it turns on the skip of software corrupt blocks for the object during index and table scans. If NOSKIP_FLAG is specified, then scans that encounter software corrupt blocks return an ORA-1578. See &quot;Constants&quot; on page 113-5.</td>
</tr>
</tbody>

The `DBMS_REPCAT` package provides routines to administer and update the replication catalog and environment.

- Documentation of `DBMS_REPCAT`
For a complete description of this package within the context of Replication, see DBMS_REPCAT in the Oracle Database Advanced Replication Management API Reference.
The DBMS_REPCAT_ADMIN package enables you to create users with the privileges needed by the symmetric replication facility.

- Documentation of DBMS_REPCAT_ADMIN
For a complete description of this package within the context of Replication, see DBMS_REPCAT_ADMIN in the Oracle Database Advanced Replication Management API Reference.
The DBMS_REPCAT_INSTANTIATE package instantiates deployment templates.

- Documentation of DBMS_REPCAT_INSTANTIATE
Documentation of DBMS_REPCAT_INSTANTIATE

For a complete description of this package within the context of Replication, see DBMS_REPCAT_INSTANTIATE in the Oracle Database Advanced Replication Management API Reference.
The DBMS_REPCAT_RGT package controls the maintenance and definition of refresh group templates.

- Documentation of DBMS_REPCAT_RGT
Documentation of DBMS_REPCAT_RGT

For a complete description of this package within the context of Replication, see DBMS_REPCAT_RGT in the Oracle Database Advanced Replication Management API Reference.
The `DBMS_REPUTIL` package contains subprograms to generate shadow tables, triggers, and packages for table replication, as well as subprograms to generate wrappers for replication of standalone procedure invocations and packaged procedure invocations. This package is referenced only by the generated code.

- Documentation of DBMS_REPUTIL
Documentation of DBMS_REPUTIL

For a complete description of this package within the context of Replication, see DBMS_REPUTIL in the Oracle Database Advanced Replication Management API Reference.
The `DBMS_RESCONFIG` package provides an interface to operate on the resource configuration list, and to retrieve listener information for a resource.

**See Also:** *Oracle XML DB Developer’s Guide* for more information about "Resource Configuration".

This chapter contains the following topics:

- **Using DBMS_RESCONFIG**
  - Overview

- **Summary of DBMS_RESCONFIG Subprograms**
Using DBMS_RESCONFIG

- Overview
Overview

The `DBMS_RESCONFIG` package contains functions and procedures to manage the resource configuration lists of individual resources and the repository.
Summary of DBMS_RESCONFIG Subprograms

This table lists the package subprograms in alphabetical order.

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADDREPOSITORYRESCONFIG Procedure on page 119-5</td>
<td>Inserts the resource configuration specified by absolute path at the given position of the repository’s configuration list</td>
</tr>

</tbody>
</table>
ADDREPOSITORYRESCONFIG Procedure

This procedure inserts the resource configuration specified by absolute path of the resource configuration at the specified position of the repository's configuration list. It shifts the element currently at that position (if any) and any subsequent elements to the right.

Syntax

```
DBMS_RESCONFIG.ADDREPOSITORYRESCONFIG(
   rcpath     IN   VARCHAR2,
   pos        IN   PLS_INTEGER := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rcpath</td>
<td>Absolute path of the resource configuration to be inserted. An exception is raised if rcpath already exists in the target's configuration list.</td>
</tr>
<tr>
<td>pos</td>
<td>Index at which the new configuration is to be inserted. If this parameter is not specified then the new configuration is appended to the end of the list. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt; the size of the target resource's configuration list).</td>
</tr>
</tbody>
</table>

Usage Notes

- An error is raised if the document referenced by rcpath is not based on XDBResConfig.xsd schema.
- Users must have XDBADMIN role and READ privilege on the resource configuration to be inserted; otherwise, an error is returned.
ADDRESCONFIG Procedure

This procedure inserts the resource configuration specified by the absolute path of the resource configuration at the given position in the target resource's configuration list. It shifts the element currently at that position (if any) and any subsequent elements to the right.

Syntax

```
DBMS_RESCONFIG.ADDRESCONFIG(
    respath    IN   VARCHAR2,
    rcpath     IN   VARCHAR2,
    pos        IN   PLS_INTEGER := NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>respath</td>
<td>Absolute path of the target resource</td>
</tr>
<tr>
<td>rcpath</td>
<td>Absolute path of the resource configuration to be inserted. An exception is raised if rcpath already exists in the target's configuration list.</td>
</tr>
<tr>
<td>pos</td>
<td>Index at which the new configuration is to be inserted. If this parameter is not specified then the new configuration is appended to the end of the list. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt; the size of the target resource's configuration list).</td>
</tr>
</tbody>
</table>

Usage Notes

- An error is raised if the document referenced by rcpath is not based on XDBResConfig.xsd schema.
- Users must have WRITE-CONFIG privilege on the target resource and read privilege on the resource configuration to be inserted; otherwise, an error is returned.
APPENDRESCONFIG Procedure

This procedure appends the resource configuration specified by rcpath to the target resource's configuration list if it is not already included in the list.

Syntax

```sql
DBMS_RESCONFIG.ADDRESCONFIG(
    respath       IN   VARCHAR2,
    rcpath        IN   VARCHAR2,
    appendOption  IN   PLS_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>respath</td>
<td>Absolute path of the target resource</td>
</tr>
<tr>
<td>rcpath</td>
<td>Absolute path of the resource configuration to be appended at the end of the target's configuration list. If rcpath already exists in the list then nothing is appended.</td>
</tr>
<tr>
<td>appendOption</td>
<td>Either APPEND_RESOURCE or APPEND_RECURSIVE. If APPEND_RESOURCE is specified then only the target resource is affected. If APPEND_RECURSIVE is specified then the target resource and all its descendents will be affected.</td>
</tr>
</tbody>
</table>

Usage Notes

- An error is raised if the document referenced by rcpath is not based on XDBResConfig.xsd schema.
- Users must have WRITE-CONFIG privilege on all affected resources and required read privilege on the resource configuration to be inserted; otherwise, an error is returned.
DELETEREPOSITORYRESCONFIG Procedure

This procedure removes the configuration at the given position in the repository’s configuration list. It shifts any subsequent elements to the left.

Syntax

```
DBMS_RESCONFIG.DELETEREPOSITORYRESCONFIG(
   pos           IN   PLS_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pos</td>
<td>The index of the configuration to be removed. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt;= the size of the target resource’s configuration list).</td>
</tr>
</tbody>
</table>

Usage Notes

- Users must have XDBADMIN role to execute this.
- This statement is treated as if it is a DDL statement. This means the system will implicitly commit before and after this statement.
DELETERESCONFIG Procedures

This procedure removes the configuration at the given position in the target resource’s configuration list. It shifts any subsequent elements to the left. Users can use the overloaded for recursive deletion.

Syntax

DBMS_RESCONFIG.DELETERESCONFIG(
    respath       IN   VARCHAR2,
    pos           IN   PLS_INTEGER);

DBMS_RESCONFIG.DELETERESCONFIG(
    respath        IN  VARCHAR2,
    rcpath         IN  VARCHAR2,
    deleteOption   IN  PLS_INTEGER);

Parameters

Table 119–6 DELETERESCONFIG Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>respath</td>
<td>Absolute path of the target resource</td>
</tr>
<tr>
<td>pos</td>
<td>The index of the configuration to be removed. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt;= the size of the target resource’s configuration list).</td>
</tr>
<tr>
<td>rcpath</td>
<td>Absolute path of the resource configuration to be deleted if found in list.</td>
</tr>
<tr>
<td>deleteOption</td>
<td>Either DELETE_RESOURCE or DELETE_RECURSIVE. If DELETE_RESOURCE is specified then only the configuration list of the target resource is affected. If DELETE_RECURSIVE is specified then the configuration list of the target resource and all its descendents will be affected.</td>
</tr>
</tbody>
</table>

Usage Notes

Users must have WRITE-CONFIG privilege on the target resource to execute this.
GETLISTENERS Function

This function returns the list of listeners applicable for a given resource.

The value returned by this function is an XML document containing the `<event-listeners>` element of the XDBResconfig.xsd schema. It contains all the listeners applicable to the target resource, including repository-level listeners. From the returned XML document users can use the EXTRACT operator to retrieve the listeners defined for a specific event.

Syntax

```
DBMS_RESCONFIG.GETLISTENERS(
    path    IN   VARCHAR2)
RETURN XMLTYPE;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>Absolute path of the target resource</td>
</tr>
</tbody>
</table>

Usage Notes

Users must have the required access privilege on all resource configurations referenced by the repository and the target resource; otherwise, an error is returned.
GETREPOSITORYRESCONFIG Function

This function returns the resource configuration at the specified position of the repository’s configuration list.

Syntax

DBMS_RESCONFIG.GETREPOSITORYRESCONFIG(
    pos IN PLS_INTEGER)
RETURN XMLTYPE;

Parameters

Table 119–8  GETREPOSITORYRESCONFIG Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pos</td>
<td>Index of element to return. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt;= the size of the repository’s configuration list).</td>
</tr>
</tbody>
</table>

Usage Notes

Users must have the required read privilege on the requested resource configuration; otherwise, an error is returned.
GETREPOSITORYRESCONFIGPATHS Function

This function returns a list of resource configuration paths defined for the repository.

Syntax

DBMS_RESCONFIG.GETREPOSITORYRESCONFIGPATHS
RETURN XDB$STRING_LIST_T;

Usage Notes

Users must be able to access all the referenced resource configurations; otherwise, an error is returned.
**GETRESCONFIG Function**

This function returns the resource configuration at the specified position of the target resource's configuration list.

**Syntax**

```sql
DBMS_RESCONFIG.GETRESCONFIG(
    respath IN VARCHAR2,
    pos IN PLS_INTEGER)
RETURN XMLTYPE;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>respath</code></td>
<td>Absolute path of the target resource</td>
</tr>
<tr>
<td><code>pos</code></td>
<td>Index of element to return. An exception is raised if the index is out of range (pos &lt; 0 or pos &gt;= the size of the target resource's configuration list).</td>
</tr>
</tbody>
</table>

**Usage Notes**

Users must have the required read privilege on the requested resource configuration; otherwise, an error is returned.
GETRESCONFIGPATHS Function

This function returns a list of resource configuration paths defined in the target resource's configuration list.

Syntax

```sql
DBMS_RESCONFIG.GETRESCONFIGPATHS(
    respath IN VARCHAR2)
RETURN XDB$STRING_LIST_T;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>respath</td>
<td>Absolute path of the target resource</td>
</tr>
</tbody>
</table>

Usage Notes

Users must be able to access all the referenced resource configurations; otherwise, an error is returned.
PATCHREPOSITORYRESCONFIGLIST Procedure

Under normal circumstances, deletion of a resource configuration resource cannot be performed if it is part of the repository resource configuration list. If, for some reason, the deletion of a resource configuration resource that is part of the repository resource configuration list succeeds, then any repository operation results in a 'dangling reference' error. This procedure removes invalid references from the repository resource configuration list, and makes the repository available. This procedure must be run as SYS.

Syntax

DBMS_RESCONFIG.PATCHREPOSITORYRESCONFIGLIST;
The DBMS_RESOURCE_MANAGER package maintains plans, consumer groups, and plan directives. It also provides semantics so that you may group together changes to the plan schema.

**See Also:** For more information on using the Database Resource Manager, see *Oracle Database Administrator’s Guide*.

This chapter contains the following topics:

- Using DBMS_RESOURCE_MANAGER
  - Deprecated Subprograms
  - Security Model
  - Constants
- Summary of DBMS_RESOURCE_MANAGER Subprograms
Using DBMS RESOURCE MANAGER

- Deprecated Subprograms
- Security Model
- Constants
 Deprecated Subprograms

**Note:** Oracle recommends that you do not use deprecated procedures in new applications. Support for deprecated features is for backward compatibility only.

The following subprograms are deprecated with Oracle Database 11g:

- SET_INITIAL_CONSUMER_GROUP Procedure
Security Model

The invoker must have the ADMINISTER_RESOURCE_MANAGER system privilege to execute these procedures. The procedures to grant and revoke this privilege are in the package Chapter 121, "DBMS_RESOURCE_MANAGER_PRIVS".
Constants

Table 120–1  DBMS_RESOURCE_MANAGER Constants

<table>
<thead>
<tr>
<th>Constant</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLIENT_MACHINE</td>
<td>VARCHAR2 (30)</td>
<td>CLIENT_MACHINE</td>
<td>Name of the computer from which the client is making the connection</td>
</tr>
<tr>
<td>CLIENT_OS_USER</td>
<td>VARCHAR2 (30)</td>
<td>CLIENT_OS_USER</td>
<td>Operating system user name of the client that is logging in</td>
</tr>
<tr>
<td>CLIENT_PROGRAM</td>
<td>VARCHAR2 (30)</td>
<td>CLIENT_PROGRAM</td>
<td>Name of the client program used to log in to the server</td>
</tr>
<tr>
<td>MODULE_NAME</td>
<td>VARCHAR2 (30)</td>
<td>MODULE_NAME</td>
<td>Module name in the currently running application as set by the SET_MODULE Procedure in the DBMS_APPLICATION_INFO package, or the equivalent OCI attribute setting</td>
</tr>
<tr>
<td>MODULE_NAME_ACTION</td>
<td>VARCHAR2 (30)</td>
<td>MODULE_NAME_ACTION</td>
<td>A combination of the current module and the action being performed as set by either of the following procedures in the DBMS_APPLICATION_INFO package, or their equivalent OCI attribute setting:</td>

<td>Validates pending changes for the resource manager</td>
</tr>
</tbody>
</table>
BEGIN_SQL_BLOCK Procedure

This procedure, to be used with parallel statement queuing, indicates the start of a block of SQL statements that should be treated as a group by resource manager.

Note: This functionality is available starting with Oracle Database 11g Release 2 (11.2.0.2).

Syntax

DBMS_RESOURCE_MANAGER.BEGIN_SQL_BLOCK;

Usage Notes

For more information, see "Parallel Statement Queuing" and "Managing Parallel Statement Queuing with Resource Manager" in Oracle Database VLDB and Partitioning Guide.
CALIBRATE_IO Procedure

This procedure calibrates the I/O capabilities of storage. Calibration status is available from the `V$IO_CALIBRATION_STATUS` view and results for a successful calibration run are located in `DBA_RSRC_IO_CALIBRATE` table.

Syntax

```sql
DBMS_RESOURCE_MANAGER.CALIBRATE_IO (
  num_physical_disks      IN  PLS_INTEGER DEFAULT 1,
  max_latency             IN  PLS_INTEGER DEFAULT 20,
  max_iops                OUT PLS_INTEGER,
  max_mbps                OUT PLS_INTEGER,
  actual_latency          OUT PLS_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>num_physical_disks</td>
<td>Approximate number of physical disks in the database storage</td>
</tr>
<tr>
<td>max_latency</td>
<td>Maximum tolerable latency in milliseconds for database-block-sized I/O requests</td>
</tr>
<tr>
<td>max_iops</td>
<td>Maximum number of I/O requests per second that can be sustained. The I/O requests are randomly-distributed, database-block-sized reads.</td>
</tr>
<tr>
<td>max_mbps</td>
<td>Maximum throughput of I/O that can be sustained, expressed in megabytes per second. The I/O requests are randomly-distributed, 1 megabyte reads.</td>
</tr>
<tr>
<td>actual_latency</td>
<td>Average latency of database-block-sized I/O requests at max_iops rate, expressed in milliseconds</td>
</tr>
</tbody>
</table>

Usage Notes

- Only users with the SYSDBA privilege can run this procedure. Qualified users must also turn on `timed_statistics`, and ensure `asynch_io` is enabled for datafiles. This can be achieved by setting `filesystemio_options` to either `ASYNCH` or `SETALL`. One can also query the `asynch_io` status by means of the following SQL statement:

  ```sql
col name format a50
  SELECT name, asynch_io FROM v$datafile f, v$iostat_file i
  WHERE f.file# = i.file_no
  AND   filetype_name = 'Data File'
  / 
```

- Only one calibration can be run at a time. If another calibration is initiated at the same time, it will fail.

- For an Oracle Real Application Clusters (Oracle RAC) database, the workload is simultaneously generated from all instances.

See Also: Oracle Database Performance Tuning Guide for more information about calibration
Examples

Example of using I/O Calibration procedure

```sql
SET SERVEROUTPUT ON
DECLARE
  lat INTEGER;
  iops INTEGER;
  mbps INTEGER;
BEGIN
  -- DBMS_RESOURCE_MANAGER.CALIBRATE_IO (<DISKS>, <MAX_LATENCY>, iops, mbps, lat);
  DBMS_RESOURCE_MANAGER.CALIBRATE_IO (2, 10, iops, mbps, lat);
  DBMS_OUTPUT.PUT_LINE ('max_iops = ' || iops);
  DBMS_OUTPUT.PUT_LINE ('latency  = ' || lat);
  DBMS_OUTPUT.PUT_LINE ('max_mbps = ' || mbps);
END;
/
```

View for I/O calibration results

```sql
SQL> desc V$IO_CALIBRATION_STATUS
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
STATUS                                             VARCHAR2(13)
CALIBRATION_TIME                                   TIMESTAMP(3)

SQL> desc gv$io_calibration_status
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
INST_ID                                            NUMBER
STATUS                                             VARCHAR2(13)
CALIBRATION_TIME                                   TIMESTAMP(3)

Column explanation:
-------------------
STATUS:
IN PROGRESS   : Calibration in Progress (Results from previous calibration run displayed, if available)
READY         : Results ready and available from earlier run
NOT AVAILABLE : Calibration results not available.

CALIBRATION_TIME: End time of the last calibration run

DBA table that stores I/O Calibration results

```sql
SQL> desc DBA_RSRC_IO_CALIBRATE
Name                                      Null?    Type
----------------------------------------- -------- ----------------------------
START_TIME                                         TIMESTAMP(6)
END_TIME                                           TIMESTAMP(6)
MAX_IOPS                                           NUMBER
MAX_MBPSC                                          NUMBER
MAX_PMBPS                                          NUMBER
LATENCY                                            NUMBER
NUM_PHYSICAL_DISKS                                 NUMBER
```

comment on table DBA_RSRC_IO_CALIBRATE is
'Results of the most recent I/O calibration'
/
comment on column DBA_RSRC_IO_CALIBRATE.START_TIME is
'start time of the most recent I/O calibration'
/
comment on column DBA_RSRC_IO_CALIBRATE.END_TIME is
'end time of the most recent I/O calibration'
/
comment on column DBA_RSRC_IO_CALIBRATE.MAX_IOPS is
'maximum number of data-block read requests that can be sustained per second'
/
comment on column DBA_RSRC_IO_CALIBRATE.MAX_MBPS is
'maximum megabytes per second of maximum-sized read requests that can be sustained'
/
comment on column DBA_RSRC_IO_CALIBRATE.MAX_PMBPS is
'maximum megabytes per second of large I/O requests that can be sustained by a single process'
/
comment on column DBA_RSRC_IO_CALIBRATE.LATENCY is
'latency for data-block read requests'
/
comment on column DBA_RSRC_IO_CALIBRATE.NUM_PHYSICAL_DISKS is
'number of physical disks in the storage subsystem (as specified by user)'
/
CLEAR_PENDING_AREA Procedure

This procedure clears pending changes for the resource manager.

Syntax

DBMS_RESOURCE_MANAGER.CLEAR_PENDING_AREA;
CREATE_CATEGORY Procedure

This procedure creates a new consumer group category. The primary purpose of this attribute is to support Exadata I/O Resource Manager category plans. The view DBA_RSRC_CATEGORIES defines the currently defined categories. The ADMINISTRATIVE, INTERACTIVE, BATCH, MAINTENANCE, and OTHER categories are available.

Syntax

```
DBMS_RESOURCE_MANAGER.CREATE_CATEGORY (category IN VARCHAR2, comment IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Name of consumer group category</td>
</tr>
<tr>
<td>comment</td>
<td>User's comment</td>
</tr>
</tbody>
</table>
CREATE_CONSUMER_GROUP Procedure

This procedure creates entries which define resource consumer groups.

Syntax

```sql
DBMS_RESOURCE_MANAGER.CREATE_CONSUMER_GROUP (
    consumer_group  IN VARCHAR2,
    comment         IN VARCHAR2,
    cpu_mth         IN VARCHAR2 DEFAULT NULL,
    mgmt_mth        IN VARCHAR2 DEFAULT 'ROUND-ROBIN',
    category        IN VARCHAR2 DEFAULT 'OTHER');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>consumer_group</td>
<td>Name of the consumer group</td>
</tr>
<tr>
<td>comment</td>
<td>User's comment</td>
</tr>
<tr>
<td>cpu_mth</td>
<td>Name of CPU resource allocation method (deprecated)</td>
</tr>
<tr>
<td>mgmt_mth</td>
<td>Name of CPU resource allocation method</td>
</tr>
<tr>
<td>category</td>
<td>Describes the category of the consumer group. The primary purpose of this attribute is to support Exadata I/O Resource Manager category plans. The view <code>DBA_RSRC_CATEGORIES</code> defines the currently defined categories. Categories can be modified, using the <code>CREATE_CATEGORY Procedure</code>, <code>UPDATE_CATEGORY Procedure</code>, and <code>DELETE_CATEGORY Procedure</code>.</td>
</tr>
</tbody>
</table>
CREATE_PENDING_AREA Procedure

This procedure makes changes to resource manager objects.

All changes to the plan schema must be done within a pending area. The pending area can be thought of as a "scratch" area for plan schema changes. The administrator creates this pending area, makes changes as necessary, possibly validates these changes, and only when the submit is completed do these changes become active.

**Syntax**

```
DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA;
```

**Usage Notes**

You may, at any time while the pending area is active, view the current plan schema with your changes by selecting from the appropriate user views.

At any time, you may clear the pending area if you want to stop the current changes. You may also call the `VALIDATE` procedure to confirm whether the changes you have made are valid. You do not have to perform your changes in a given order to maintain a consistent group of entries. These checks are also implicitly done when the pending area is submitted.

---

**Note:** Oracle allows “orphan” consumer groups (in other words, consumer groups that have no plan directives that refer to them). This is in anticipation that an administrator may want to create a consumer group that is not currently being used, but will be used in the future.

---

The following rules must be adhered to, and they are checked whenever the validate or submit procedures are executed:

- No plan schema may contain any loops.
- All plans and consumer groups referred to by plan directives must exist.
- All plans must have plan directives that refer to either plans or consumer groups.
- All percentages in any given level must not add up to greater than 100 for the emphasis resource allocation method.
- No plan may be deleted that is currently being used as a top plan by an active instance.
- The plan directive parameter, `parallel_degree_limit_pl`, may only appear in plan directives that refer to consumer groups (that is, not at subplans).
- There cannot be more than 28 plan directives coming from any given plan (that is, no plan can have more than 28 children).
- There cannot be more than 28 consumer groups in any active plan schema.
- Plans and consumer groups use the same namespace; therefore, no plan can have the same name as any consumer group.
- There must be a plan directive for `OTHER_GROUPS` somewhere in any active plan schema. This ensures that a session not covered by the currently active plan is allocated resources as specified by the `OTHER_GROUPS` directive.
If any of the preceding rules are broken when checked by the **VALIDATE** or **SUBMIT** procedures, then an informative error message is returned. You may then make changes to fix one or more problems and reissue the validate or submit procedures.
CREATE_PLAN Procedure

This procedure creates entries which define resource plans.

Syntax

```sql
DBMS_RESOURCE_MANAGER.CREATE_PLAN (  
  plan           IN   VARCHAR2,  
  comment        IN   VARCHAR2,  
  cpu_mth        IN   VARCHAR2 DEFAULT NULL, -- deprecated  
  active_sess_pool_mth IN   VARCHAR2 DEFAULT 'ACTIVE_SESS_POOL_ABSOLUTE',  
  parallel_degree_limit_mth IN   VARCHAR2 DEFAULT 'PARALLEL_DEGREE_LIMIT_ABSOLUTE',  
  queueing_mth   IN   VARCHAR2 DEFAULT 'FIFO_TIMEOUT',  
  mgmt_mth       IN   VARCHAR2 DEFAULT 'EMPHASIS',  
  sub_plan       IN   BOOLEAN DEFAULT FALSE,  
  max_iops       IN   NUMBER DEFAULT NULL,  
  max_mbps       IN   NUMBER DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of the resource plan</td>
</tr>
<tr>
<td>comment</td>
<td>User's comment</td>
</tr>
<tr>
<td>cpu_mth</td>
<td>Allocation method for CPU resources (deprecated)</td>
</tr>
<tr>
<td>active_sess_pool_mth</td>
<td>Active session pool resource allocation method. Limits the number of active sessions. All other sessions are inactive and wait in a queue to be activated. ACTIVE_SESS_POOL_ABSOLUTE is the default and only method available.</td>
</tr>
<tr>
<td>parallel_degree_limit_mth</td>
<td>Resource allocation method for specifying a limit on the degree of parallelism of any operation. PARALLEL_DEGREE_LIMIT_ABSOLUTE is the default and only method available.</td>
</tr>
<tr>
<td>queueing_mth</td>
<td>Queuing resource allocation method. Controls order in which queued inactive sessions will execute. FIFO_TIMEOUT is the default and only method available.</td>
</tr>
<tr>
<td>mgmt_mth</td>
<td>Resource allocation method for specifying how much resources (for example, CPU or I/O) each consumer group or sub-plan gets</td>
</tr>
<tr>
<td>sub_plan</td>
<td>If TRUE, indicates that this plan is only intended for use as a sub-plan. Sub-plans are not required to have an OTHER_GROUPS directive. Default is FALSE.</td>
</tr>
<tr>
<td>max_iops</td>
<td>Nonoperative</td>
</tr>
<tr>
<td>max_mbps</td>
<td>Nonoperative</td>
</tr>
</tbody>
</table>
Usage Notes

If you want to use any default resource allocation method, then you do not need to specify it when creating or updating a plan.
CREATE_PLAN_DIRECTIVE Procedure

This procedure creates resource plan directives.

---

**Note:** The functionality associated with the `parallel_target_percentage` and `parallel_queue_timeout` parameters is available starting with Oracle Database 11g Release 2 (11.2.0.2).

### Syntax

```sql
DBMS_RESOURCE_MANAGER.CREATE_PLAN_DIRECTIVE (  
  plan                      IN VARCHAR2,  
  group_or_subplan          IN VARCHAR2,  
  comment                   IN VARCHAR2,  
  cpu_p1                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p2                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p3                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p4                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p5                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p6                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p7                    IN NUMBER   DEFAULT NULL, -- deprecated  
  cpu_p8                    IN NUMBER   DEFAULT NULL, -- deprecated  
  active_sess_pool_p1       IN NUMBER   DEFAULT NULL,  
  queueing_pl               IN NUMBER   DEFAULT NULL,  
  parallel_degree_limit_p1  IN NUMBER   DEFAULT NULL,  
  switch_group              IN VARCHAR2 DEFAULT NULL,  
  switch_time               IN NUMBER   DEFAULT NULL,  
  switch_estimate           IN BOOLEAN  DEFAULT FALSE,  
  max_est_exec_time         IN NUMBER   DEFAULT NULL,  
  undo_pool                 IN NUMBER   DEFAULT NULL,  
  max_idle_time             IN NUMBER   DEFAULT NULL,  
  max_idle_blocker_time     IN NUMBER   DEFAULT NULL,  
  switch_time_in_call       IN NUMBER   DEFAULT NULL, -- deprecated  
  mgmt_p1                   IN NUMBER   DEFAULT NULL,  
  mgmt_p2                   IN NUMBER   DEFAULT NULL,  
  mgmt_p3                   IN NUMBER   DEFAULT NULL,  
  mgmt_p4                   IN NUMBER   DEFAULT NULL,  
  mgmt_p5                   IN NUMBER   DEFAULT NULL,  
  mgmt_p6                   IN NUMBER   DEFAULT NULL,  
  mgmt_p7                   IN NUMBER   DEFAULT NULL,  
  mgmt_p8                   IN NUMBER   DEFAULT NULL,  
  switch_io_megabytes       IN NUMBER   DEFAULT NULL,  
  switch_io_reqs            IN NUMBER   DEFAULT NULL,  
  switch_for_call           IN BOOLEAN  DEFAULT NULL,  
  max utilizarization_limit IN NUMBER   DEFAULT NULL,  
  parallel_target_percentage IN NUMBER   DEFAULT NULL,  
  parallel_queue_timeout    IN NUMBER   DEFAULT NULL);
```

<tr>
<td>mgmt_p8</td>
<td>Resource allocation value for level 8 (replaces cpu_p8)</td>
</tr>
<tr>
<td></td>
<td>- EMPHASIS - specifies the resource percentage at the eighth level \</td>
</tr>
<tr>
<td></td>
<td>- RATIO - non-applicable</td>
</tr>
<tr>
<td>switch_io_megabytes</td>
<td>Specifies the amount of I/O (in MB) that a session can issue before an action is taken. Default is NULL, which means unlimited. \</td>
</tr>
<tr>
<td>switch_io_reqs</td>
<td>Specifies the number of I/O requests that a session can issue before an action is taken. Default is NULL, which means unlimited. \</td>
</tr>
<tr>
<td>switch_for_call</td>
<td>Specifies that if an action is taken because of the switch_time, switch_io_megabytes, or switch_io_reqs parameters, the consumer group is restored to its original consumer group at the end of the top call. Default is FALSE, which means that the original consumer group is not restored at the end of the top call.</td>
</tr>
<tr>
<td>max_utilization_limit</td>
<td>Specifies the maximum percentage of CPU that this Consumer Group or Sub-Plan can utilize. Valid values are 0% to 100%. NULL implies that there is no limit, or equivalently 100%. You can specify this attribute and leave mgmt_p1 through mgmt_p8 NULL.</td>
</tr>
</tbody>
</table>
Usage Notes

- All parameters default to NULL. However, for the EMPHASIS CPU resource allocation method, this case would severely limit resources to all the users.

- For max_idle_time and max_idle_blocker_time, PMON will check these limits once a minute. If it finds a session that has exceeded one of the limits, it will forcibly kill the session and clean up all its state.

- The parameter switch_time_in_call is mostly useful for three-tier applications where the mid-tier server is implementing session pooling. By using switch_time_in_call, the resource usage of one client will not affect a future client that happens to be executed on the same session.
CREATE_SIMPLE_PLAN Procedure

This procedure creates a single-level resource plan containing up to eight consumer groups in one step. You do not need to create a pending area manually before creating a resource plan, or use the CREATE_CONSUMER_GROUP and CREATE_RESOURCE_PLAN_DIRECTIVES procedures separately.

Syntax

```sql
DBMS_RESOURCE_MANAGER.CREATE_SIMPLE_PLAN (  
  simple_plan      IN  VARCHAR2  DEFAULT NULL,  
  consumer_group1  IN  VARCHAR2  DEFAULT NULL,  
  group1_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group2  IN  VARCHAR2  DEFAULT NULL,  
  group2_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group3  IN  VARCHAR2  DEFAULT NULL,  
  group3_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group4  IN  VARCHAR2  DEFAULT NULL,  
  group4_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group5  IN  VARCHAR2  DEFAULT NULL,  
  group5_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group6  IN  VARCHAR2  DEFAULT NULL,  
  group6_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group7  IN  VARCHAR2  DEFAULT NULL,  
  group7_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group8  IN  VARCHAR2  DEFAULT NULL,  
  group8_cpu       IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group1  IN  VARCHAR2  DEFAULT NULL,  
  group1_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group2  IN  VARCHAR2  DEFAULT NULL,  
  group2_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group3  IN  VARCHAR2  DEFAULT NULL,  
  group3_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group4  IN  VARCHAR2  DEFAULT NULL,  
  group4_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group5  IN  VARCHAR2  DEFAULT NULL,  
  group5_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group6  IN  VARCHAR2  DEFAULT NULL,  
  group6_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group7  IN  VARCHAR2  DEFAULT NULL,  
  group7_percent   IN  NUMBER    DEFAULT NULL,   -- deprecated  
  consumer_group8  IN  VARCHAR2  DEFAULT NULL,  
  group8_percent   IN  NUMBER    DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>

<td>Percentage of resources allocated for this consumer group</td>
</tr>
<tr>
<td>group8_percent</td>
<td>Percentage of resources allocated for this consumer group</td>
</tr>
</tbody>
</table>
DELETE_CATEGORY Procedure

This procedure deletes an existing resource consumer group category.

Syntax

```sql
DBMS_RESOURCE_MANAGER.DELETE_CATEGORY (
    category        IN    VARCHAR2,
    new_comment     IN    VARCHAR2  DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Name of consumer group category</td>
</tr>
</tbody>
</table>
DELETE_CONSUMER_GROUP Procedure

This procedure deletes entries which define resource consumer groups.

Syntax

```sql
DBMS_RESOURCE_MANAGER.DELETE_CONSUMER_GROUP (consumer_group IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>consumer_group</td>
<td>Name of the consumer group to be deleted</td>
</tr>
</tbody>
</table>
DELETE_PLAN Procedure

This procedure deletes the specified plan as well as all the plan directives to which it refers.

Syntax

```sql
DBMS_RESOURCE_MANAGER.DELETE_PLAN (
    plan IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of the resource plan to delete</td>
</tr>
</tbody>
</table>
DELETE_PLAN_CASCADE Procedure

This procedure deletes the specified plan and all of its descendants (plan directives, subplans, consumer groups). Mandatory objects and directives are not deleted.

Syntax

```
DBMS_RESOURCE_MANAGER.DELETE_PLAN_CASCADE (plan IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of the plan</td>
</tr>
</tbody>
</table>

Usage Notes

If DELETE_PLAN_CASCADE encounters any error, then it rolls back the operation, and nothing is deleted.
DELETE_PLAN_DIRECTIVE Procedure

This procedure deletes resource plan directives.

Syntax

```sql
DBMS_RESOURCE_MANAGER.DELETE_PLAN_DIRECTIVE (
    plan              IN VARCHAR2,
    group_or_subplan  IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of the resource plan</td>
</tr>
<tr>
<td>group_or_subplan</td>
<td>Name of the group or subplan</td>
</tr>
</tbody>
</table>
END_SQL_BLOCK Procedure

This procedure, to be used with parallel statement queuing, indicates the end of a block of SQL statements that should be treated as a group by resource manager.

---

**Note:** This functionality is available starting with Oracle Database 11g Release 2 (11.2.0.2).

---

**Syntax**

```sql
DBMS_RESOURCE_MANAGER.END_SQL_BLOCK;
```

**Usage Notes**

For more information, see "Parallel Statement Queuing" and "Managing Parallel Statement Queuing with Resource Manager" in *Oracle Database VLDB and Partitioning Guide*. 
SET_CONSUMER_GROUP_MAPPING Procedure

This procedure adds, deletes, or modifies entries that map sessions to consumer groups, based on the session’s login and runtime attributes.

Syntax

```
DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING(
    attribute  IN VARCHAR2,
    value      IN VARCHAR2,
    consumer_group  IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>Mapping attribute to add or modify. It can be one of the <code>Constants</code> listed.</td>
</tr>
<tr>
<td>value</td>
<td>Attribute value to match. This includes both absolute mapping and regular expressions.</td>
</tr>
<tr>
<td>consumer_group</td>
<td>Name of the mapped consumer group, or <code>NULL</code> to delete a mapping</td>
</tr>
</tbody>
</table>

Usage Notes

- If no mapping exists for the given attribute and value, a mapping to the given consumer group will be created. If a mapping already exists for the given attribute and value, the mapped consumer group will be updated to the one given. If the `consumer_group` argument is `NULL`, then any mapping from the given attribute and value will be deleted.

- The subprogram supports simple regex expressions for the `value` parameter. It implements the same semantics as the SQL `LIKE` operator. Specifically, it uses `%' as a multicharacter wildcard and `_` as a single character wildcard. The `\` character can be used to escape the wildcards. Note that wildcards can only be used if the attribute is one of the following:
  - `CLIENT_OS_USER`
  - `CLIENT_PROGRAM`
  - `CLIENT_MACHINE`
  - `MODULE_NAME`
  - `MODULE_NAME_ACTION`
  - `SERVICE_MODULE`
  - `SERVICE_MODULE_ACTION`

- Consumer group mapping comparisons for `DBMS_RESOURCE_MANAGER.CLIENT_PROGRAM` are performed by stripping the `@` sign and following characters from `V$SESSION.PROGRAM` before comparing it to the `CLIENT_PROGRAM` value supplied.
SET_CONSUMER_GROUP_MAPPING_PRI Procedure

Multiple attributes of a session can be used to map the session to a consumer group. This procedure prioritizes the attribute mappings.

Syntax

```
DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING_PRI(
    explicit               IN NUMBER,
    oracle_user            IN NUMBER,
    service_name           IN NUMBER,
    client_os_user         IN NUMBER,
    client_program         IN NUMBER,
    client_machine         IN NUMBER,
    module_name            IN NUMBER,
    module_name_action     IN NUMBER,
    service_module         IN NUMBER,
    service_module_action  IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>explicit</td>
<td>Priority of the explicit mapping</td>
</tr>
<tr>
<td>oracle_user</td>
<td>Priority of the Oracle user name mapping</td>
</tr>
<tr>
<td>service_name</td>
<td>Priority of the client service name mapping</td>
</tr>
<tr>
<td>client_os_user</td>
<td>Priority of the client operating system user name mapping</td>
</tr>
<tr>
<td>client_program</td>
<td>Priority of the client program mapping</td>
</tr>
<tr>
<td>client_machine</td>
<td>Priority of the client machine mapping</td>
</tr>
<tr>
<td>module_name</td>
<td>Priority of the application module name mapping</td>
</tr>
<tr>
<td>module_name_action</td>
<td>Priority of the application module name and action mapping</td>
</tr>
<tr>
<td>service_module</td>
<td>Priority of the service name and application module name</td>
</tr>
<tr>
<td>module_name_action</td>
<td>Priority of the service name, application module name, and</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure requires that you include the pseudo-attribute `explicit` as an argument. It must be set to 1. It indicates that explicit consumer group switches have the highest priority. You explicitly switch consumer groups with these package procedures:
  - `DBMS_SESSION.SWITCH_CURRENT_CONSUMER_GROUP`
  - `DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESSION`
  - `DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER`
- Each priority value must be a unique integer from 1 to 10. Together, they establish an ordering where 1 is the highest priority and 10 is the lowest.
SET_INITIAL_CONSUMER_GROUP Procedure

Note: This procedure is deprecated in Release 11gR1. While the procedure remains available in the package, Initial Consumer Group is set by the session-to-consumer group mapping rules.

The initial consumer group of a user is the consumer group to which any session created by that user initially belongs. This procedure sets the initial resource consumer group for a user.

Syntax

\[
\text{DBMS\_RESOURCE\_MANAGER\_SET\_INITIAL\_CONSUMER\_GROUP}\{\ \\
\text{user IN VARCHAR2,} \ \\
\text{consumer\_group IN VARCHAR2}\};
\]

Parameters

<table>
<thead>
<tr>
<th>Parameters</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>Name of the user</td>
</tr>
<tr>
<td>consumer_group</td>
<td>User's initial consumer group</td>
</tr>
</tbody>
</table>

Usage Notes

- The ADMINISTER\_RESOURCE\_MANAGER or the ALTER USER system privilege are required to be able to execute this procedure. The user, or PUBLIC, must be directly granted switch privilege to a consumer group before it can be set to be the user's initial consumer group. Switch privilege for the initial consumer group cannot come from a role granted to that user.

  Note: These semantics are similar to those for ALTER USER DEFAULT ROLE.

- If the initial consumer group for a user has never been set, then the user's initial consumer group is automatically the consumer group: DEFAULT_CONSUMER_GROUP.

- DEFAULT_CONSUMER_GROUP has switch privileges granted to PUBLIC; therefore, all users are automatically granted switch privilege for this consumer group. Upon deletion of a consumer group, all users having the deleted group as their initial consumer group now have DEFAULT_CONSUMER_GROUP as their initial consumer group. All currently active sessions belonging to a deleted consumer group are switched to DEFAULT_CONSUMER_GROUP.
**SUBMIT_PENDING_AREA Procedure**

This procedure submits pending changes for the resource manager. It clears the pending area after validating and committing the changes (if valid).

---

**Note:** A call to `SUBMIT_PENDING_AREA` may fail even if `VALIDATE_PENDING_AREA` succeeds. This may happen if a plan being deleted is loaded by an instance after a call to `VALIDATE_PENDING_AREA`, but before a call to `SUBMIT_PENDING_AREA`.

---

**Syntax**

```sql
DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA;
```
SWITCH_CONSUMER_GROUP_FOR_SESS Procedure

This procedure changes the resource consumer group of a specific session. It also changes the consumer group of any (PQ) slave sessions that are related to the top user session.

Syntax

```sql
DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_SESS (  
    session_id      IN NUMBER,
    session_serial  IN NUMBER,
    consumer_group  IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>SID column from the view V$SESSION</td>
</tr>
<tr>
<td>session_serial</td>
<td>SERIAL# column from view V$SESSION</td>
</tr>
<tr>
<td>consumer_group</td>
<td>Name of the consumer group to which to switch</td>
</tr>
</tbody>
</table>
**SWITCH_CONSUMER_GROUP_FOR_USER Procedure**

This procedure changes the resource consumer group for all sessions with a given user ID. It also changes the consumer group of any (PQ) slave sessions that are related to the top user session.

**Syntax**

```sql
DBMS_RESOURCE_MANAGER.SWITCH_CONSUMER_GROUP_FOR_USER (
    user            IN VARCHAR2,
    consumer_group  IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>user</td>
<td>Name of the user</td>
</tr>
<tr>
<td>consumer_group</td>
<td>Name of the consumer group to which to switch</td>
</tr>
</tbody>
</table>

**Usage Notes**

- The **SWITCH_CONSUMER_GROUP_FOR_SESS Procedure** and the **SWITCH_CONSUMER_GROUP_FOR_USER** procedures let you raise or lower the allocation of CPU resources of certain sessions or users. This provides a functionality similar to the **nice** command on UNIX.
- These procedures cause the session to be moved into the newly specified consumer group immediately.
SWITCH_PLAN Procedure

This procedure sets the current resource manager plan.

Syntax

```sql
DBMS_RESOURCE_MANAGER.SWITCH_PLAN(
    plan_name                     IN   VARCHAR2,
    sid                           IN   VARCHAR2 DEFAULT '*',
    allow_scheduler_plan_switches IN   BOOLEAN DEFAULT TRUE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan_name</td>
<td>Name of the plan to which to switch. Passing in an empty string (&quot;&quot;) for the plan_name, disables the resource manager</td>
</tr>
<tr>
<td>sid</td>
<td>The sid parameter is relevant only in an Oracle Real Application Clusters environment. This parameter lets you change the plan for a particular instance. Specify the sid of the instance where you want to change the plan. Or specify &quot;*&quot; if you want Oracle to change the plan for all instances.</td>
</tr>
<tr>
<td>allow_scheduler_plan_switches</td>
<td>FALSE - disables automated plan switches by the job scheduler at window boundaries. To reenable automated plan switches, switch_plan must be called again by the administrator with allow_scheduler_plan_switches set to TRUE. By default automated plan switches by the job scheduler are enabled.</td>
</tr>
</tbody>
</table>
UPDATE_CATEGORY Procedure

This procedure updates an existing resource consumer group category.

Syntax

```sql
DBMS_RESOURCE_MANAGER.UPDATE_CATEGORY (  
category        IN    VARCHAR2,  
new_comment     IN    VARCHAR2  DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>Name of consumer group category</td>
</tr>
<tr>
<td>new_comment</td>
<td>User's comment</td>
</tr>
</tbody>
</table>
UPDATE_CONSUMER_GROUP Procedure

This procedure updates entries which define resource consumer groups.

Syntax

```sql
DBMS_RESOURCE_MANAGER.UPDATE_CONSUMER_GROUP (
    consumer_group  IN VARCHAR2,
    new_comment     IN VARCHAR2 DEFAULT NULL,
    new_cpu_mth     IN VARCHAR2 DEFAULT NULL,
    new_mgmt_mth    IN VARCHAR2 DEFAULT NULL,
    new_category    IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>consumer_group</td>
<td>Name of consumer group</td>
</tr>
<tr>
<td>new_comment</td>
<td>New user's comment</td>
</tr>
<tr>
<td>new_cpu_mth</td>
<td>Name of new method for CPU resource allocation (deprecated)</td>
</tr>
<tr>
<td>new_mgmt_mth</td>
<td>Name of new method for CPU resource allocation</td>
</tr>
<tr>
<td>new_category</td>
<td>New consumer group category</td>
</tr>
</tbody>
</table>

Usage Notes

If the parameters to the UPDATE_CONSUMER_GROUP procedure are not specified, then they remain unchanged in the data dictionary.
UPDATE_PLAN Procedure

This procedure updates entries which define resource plans.

Syntax

```
DBMS_RESOURCE_MANAGER.UPDATE_PLAN (
    plan                               IN VARCHAR2,
    new_comment                        IN VARCHAR2 DEFAULT NULL,
    new_cpu_mth                        IN VARCHAR2 DEFAULT NULL, -- deprecated
    new_active_sess_pool_mth           IN VARCHAR2 DEFAULT NULL,
    new_parallel_degree_limit_mth      IN VARCHAR2 DEFAULT NULL,
    new_queueing_mth                   IN VARCHAR2 DEFAULT NULL,
    new_mgmt_mth                       IN VARCHAR2 DEFAULT NULL,
    new_sub_plan                       IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of resource plan</td>
</tr>
<tr>
<td>new_comment</td>
<td>New user's comment</td>
</tr>
<tr>
<td>new_cpu_mth</td>
<td>Name of new allocation method for CPU resources (deprecated)</td>
</tr>
<tr>
<td>new_active_sess_pool_mth</td>
<td>Name of new method for maximum active sessions</td>
</tr>
<tr>
<td>new_parallel_degree_limit_mth</td>
<td>Name of new method for degree of parallelism</td>
</tr>
<tr>
<td>new_queueing_mth</td>
<td>Specifies type of queuing policy to use with active session pool feature</td>
</tr>
<tr>
<td>new_mgmt_mth</td>
<td>Resource allocation method for specifying how much resources (for example, CPU or I/O) each consumer group or sub-plan gets</td>
</tr>
<tr>
<td>■ EMPHASIS - for multilevel plans that use percentages to specify how I/O resources are distributed among consumer groups.</td>
<td></td>
</tr>
<tr>
<td>■ RATIO - for single-level plans that use ratios to specify how I/O resources are distributed.</td>
<td></td>
</tr>
<tr>
<td>new_sub_plan</td>
<td>New setting for whether the plan is only intended for use as a sub-plan</td>
</tr>
</tbody>
</table>

Usage Notes

- If the parameters to UPDATE_PLAN Procedure are not specified, then they remain unchanged in the data dictionary.
- If you want to use any default resource allocation method, then you do not need to specify it when creating or updating a plan.
UPDATE_PLAN_DIRECTIVE Procedure

This procedure updates resource plan directives.

---

**Note:** The functionality associated with the `new_parallel_target_percentage` and `new_parallel_queue_timeout` parameters is available starting with Oracle Database 11g Release 2 (11.2.0.2).

---

**Syntax**

```sql
DBMS_RESOURCE_MANAGER.UPDATE_PLAN_DIRECTIVE (plan IN VARCHAR2,
group_or_subplan IN VARCHAR2,
new_comment IN VARCHAR2 DEFAULT NULL,
new_cpu_p1 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p2 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p3 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p4 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p5 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p6 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p7 IN NUMBER DEFAULT NULL, -- deprecated
new_cpu_p8 IN NUMBER DEFAULT NULL, -- deprecated
new_active_sess_pool_p1 IN NUMBER DEFAULT NULL,
new_queueing_p1 IN NUMBER DEFAULT NULL,
new_parallel_degree_limit_p1 IN NUMBER DEFAULT NULL,
new_switch_group IN VARCHAR2 DEFAULT NULL,
new_switch_time IN NUMBER DEFAULT NULL,
new_switch_estimate IN BOOLEAN DEFAULT FALSE,
new_max_est_exec_time IN NUMBER DEFAULT NULL,
new_undo_pool IN NUMBER DEFAULT NULL,
new_max_idle_time IN NUMBER DEFAULT NULL,
new_max_idle_blocker_time IN NUMBER DEFAULT NULL,
switch_time_in_call IN NUMBER DEFAULT NULL, -- deprecated
new_mgmt_p1 IN NUMBER DEFAULT NULL,
new_mgmt_p2 IN NUMBER DEFAULT NULL,
new_mgmt_p3 IN NUMBER DEFAULT NULL,
new_mgmt_p4 IN NUMBER DEFAULT NULL,
new_mgmt_p5 IN NUMBER DEFAULT NULL,
new_mgmt_p6 IN NUMBER DEFAULT NULL,
new_mgmt_p7 IN NUMBER DEFAULT NULL,
new_mgmt_p8 IN NUMBER DEFAULT NULL,
new_switch_io_megabytes IN NUMBER DEFAULT NULL,
new_switch_io_reqs IN NUMBER DEFAULT NULL,
new_switch_for_call IN BOOLEAN DEFAULT NULL,
new_max_utilization_limit IN NUMBER DEFAULT NULL,
new_parallel_target_percentage IN NUMBER DEFAULT NULL,
new_parallel_queue_timeout IN NUMBER DEFAULT NULL);
```

---

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>plan</td>
<td>Name of the resource plan</td>
</tr>
<tr>
<td>group_or_subplan</td>
<td>Name of the consumer group or subplan</td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td>(deprecated - use new_mgmt_p7 instead)</td>
</tr>
<tr>
<td>new_cpu_p8</td>
<td>Parameter for the CPU resources allocation method</td>
</tr>
<tr>
<td></td>
<td>(deprecated - use new_mgmt_p8 instead)</td>
</tr>
<tr>
<td>new_active_sess_pool_p1</td>
<td>Specifies maximum number of concurrently active sessions for a consumer group. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_queueing_p1</td>
<td>Specified time (in seconds) after which a job in the inactive session queue (waiting for execution) will time out. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_parallel_degree_limit_p1</td>
<td>Specifies a limit on the degree of parallelism for any operation. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_switch_group</td>
<td>Specifies consumer group to which this session is switched if other switch criteria are met. Default is NULL. If the group name is 'CANCEL_SQL', the current call will be canceled when other switch criteria are met. If the group name is 'KILL_SESSION', the session will be killed when other switch criteria are met.</td>
</tr>
<tr>
<td>new_switch_time</td>
<td>Specifies time (in CPU seconds) that a session can execute before an action is taken. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_switch_estimate</td>
<td>If TRUE, tells Oracle to use its execution time estimate to automatically switch the consumer group of an operation before beginning its execution. Default is FALSE.</td>
</tr>
<tr>
<td>new_max_est_exec_time</td>
<td>Specifies the maximum execution time (in CPU seconds) allowed for a session. If the optimizer estimates that an operation will take longer than MAX_EST_EXEC_TIME, the operation is not started and ORA-07455 is issued. If the optimizer does not provide an estimate, this directive has no effect. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_undo_pool</td>
<td>Limits the size in kilobytes of the undo records corresponding to uncommitted transactions by this consumer group</td>
</tr>
<tr>
<td>new_max_idle_time</td>
<td>Indicates the maximum session idle time. Default is NULL, which means unlimited.</td>
</tr>
<tr>
<td>new_max_idle_blocker_time</td>
<td>Maximum amount of time in seconds that a session can be idle while blocking another session's acquisition of a resource</td>
</tr>
</tbody>
</table>
### Table 120–23 (Cont.) UPDATE_PLAN_DIRECTIVE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>new_switch_time_in_call</td>
<td>Deprecated. If this parameter is specified, new_switch_time will be effectively set to new_switch_time_in_call and new_switch_for_call will be effectively set to TRUE.</td>
</tr>
</tbody>
</table>
| new_mgmt_p1                   | Resource allocation value for level 1 (replaces new_cpu_p1):  
|                               | - EMPHASIS - specifies the resource percentage at the first level  
|                               | - RATIO - specifies the weight of resource usage  |
| new_mgmt_p2                   | Resource allocation value for level 2 (replaces new_cpu_p2)  
|                               | - EMPHASIS - specifies the resource percentage at the second level  |
| new_mgmt_p3                   | Resource allocation value for level 3 (replaces new_cpu_p3)  
|                               | - EMPHASIS - specifies the resource percentage at the third level  
|                               | - RATIO - non-applicable  |
| new_mgmt_p4                   | Resource allocation value for level 4 (replaces new_cpu_p4)  
|                               | - EMPHASIS - specifies the resource percentage at the fourth level  
|                               | - RATIO - non-applicable  |
| new_mgmt_p5                   | Resource allocation value for level 5 (replaces new_cpu_p5)  
|                               | - EMPHASIS - specifies the resource percentage at the fifth level  
|                               | - RATIO - non-applicable  |
| new_mgmt_p6                   | Resource allocation value for level 6 (replaces new_cpu_p6)  
|                               | - EMPHASIS - specifies the resource percentage at the sixth level  
|                               | - RATIO - non-applicable  |
| new_mgmt_p7                   | Resource allocation value for level 7 (replaces new_cpu_p7)  
|                               | - EMPHASIS - specifies the resource percentage at the seventh level  
|                               | - RATIO - non-applicable  |
| new_mgmt_p8                   | Resource allocation value for level 8 (replaces new_cpu_p8)  
|                               | - EMPHASIS - specifies the resource percentage at the eighth level  
|                               | - RATIO - non-applicable  |
| new_switch_io_megabytes       | Specifies the amount of I/O (in MB) that a session can issue before an action is taken. Default is NULL, which means unlimited. |
| new_switch_io_reqs            | Specifies the number of I/O requests that a session can issue before an action is taken. Default is NULL, which means unlimited. |
| new_switch_for_call           | Specifies that if an action is taken because of the new_switch_time, new_switch_io_megabytes, or new_switch_io_reqs parameters, the consumer group is restored to its original consumer group at the end of the top call. Default is FALSE, which means that the original consumer group is not restored at the end of the top call. |
### Usage Notes

- If the parameters for `UPDATE_PLAN_DIRECTIVE` are left unspecified, then they remain unchanged in the data dictionary.

- For `new_max_idle_time` and `new_max_idle_blocker_time`, PMON will check these limits once a minute. If it finds a session that has exceeded one of the limits, it will forcibly kill the session and clean up all its state.

- The parameter `new_switch_time_in_call` is mostly useful for three-tier applications where the mid-tier server is implementing session pooling. By turning on `new_switch_time_in_call`, the resource usage of one client will not affect the consumer group of a future client that happens to be executed on the same session.

- To clear (zero or nullify) any numeric parameter in a resource plan directive, set it to `-1` using the `UPDATE_PLAN_DIRECTIVE` Procedure.

---

### Table 120–23 (Cont.)  `UPDATE_PLAN_DIRECTIVE` Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>new_max_utilization_limit</code></td>
<td>Specifies the maximum percentage of CPU that this Consumer Group or Sub-Plan can utilize. Valid values are 0% to 100%. To unset the limit, use <code>-1</code>.</td>
</tr>
<tr>
<td><code>new_parallel_target_percentage</code></td>
<td>Specifies the maximum percentage of the target number of parallel servers in an Oracle RAC environment a consumer group can use. Any additional parallel statements that are launched from this consumer group will be queued. The default is <code>NULL</code>, which means that the limit is 100% of the target number. Valid values for queuing are in the range of 0 to 100 (%). For updates to the plan directive, the value of <code>-1</code> will reset the value to <code>NULL</code>.</td>
</tr>
<tr>
<td></td>
<td>If a consumer group does not have any parallel statements running within an Oracle RAC database, the first parallel statement is allowed to exceed this limit.</td>
</tr>
<tr>
<td></td>
<td>The target number of parallel servers in an Oracle RAC environment is the sum of the parameter <code>parallel_servers_target</code> across all instances.</td>
</tr>
<tr>
<td><code>new_parallel_queue_timeout</code></td>
<td>Specifies the time (in seconds) that a query may remain in its Consumer Group’s parallel statement queue before it is removed and terminated with an error (ORA-07454).</td>
</tr>
</tbody>
</table>
VALIDATE_PENDING_AREA Procedure

This procedure validates pending changes for the resource manager.

Syntax

```
DBMS_RESOURCE_MANAGER.VALIDATE_PENDING_AREA;
```
The `DBMS_RESOURCE_MANAGER_PRIVS` package maintains privileges associated with the Resource Manager.

See Also: For more information on using the Database Resource Manager, see *Oracle Database Administrator’s Guide*.

This chapter contains the following topics:
- Summary of `DBMS_RESOURCE_MANAGER_PRIVS` Subprograms
### Summary of DBMSRESOURCE_MANAGER_PRIVS Subprograms

**Table 121–1 DBMSRESOURCE_MANAGER_PRIVS Package Subprograms**

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>GRANT_SWITCH_CONSUMER_GROUP Procedure</td>
<td>Grants the privilege to switch to resource consumer groups</td>
</tr>
<tr>
<td>GRANT_SYSTEM_PRIVILEGE Procedure on page 121-4</td>
<td>Performs a grant of a system privilege</td>
</tr>
<tr>
<td>REVOKE_SWITCH_CONSUMER_GROUP Procedure</td>
<td>Revokes the privilege to switch to resource consumer groups.</td>
</tr>
<tr>
<td>REVOKE_SYSTEM_PRIVILEGE Procedure on page 121-6</td>
<td>Performs a revoke of a system privilege</td>
</tr>
</tbody>
</table>
GRANT_SWITCH_CONSUMER_GROUP Procedure

This procedure grants the privilege to switch to a resource consumer group.

Syntax

```sql
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SWITCH_CONSUMER_GROUP (  
grantee_name   IN VARCHAR2,  
consumer_group IN VARCHAR2,  
grant_option   IN BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantee_name</td>
<td>Name of the user or role to whom privilege is to be granted.</td>
</tr>
<tr>
<td>consumer_group</td>
<td>Name of consumer group.</td>
</tr>
<tr>
<td>grant_option</td>
<td>TRUE if grantee should be allowed to grant access, FALSE otherwise.</td>
</tr>
</tbody>
</table>

Usage Notes

If you grant permission to switch to a particular consumer group to a user, then that user can immediately switch their current consumer group to the new consumer group.

If you grant permission to switch to a particular consumer group to a role, then any users who have been granted that role and have enabled that role can immediately switch their current consumer group to the new consumer group.

If you grant permission to switch to a particular consumer group to PUBLIC, then any user can switch to that consumer group.

If the `grant_option` parameter is TRUE, then users granted switch privilege for the consumer group may also grant switch privileges for that consumer group to others.

In order to set the initial consumer group of a user, you must grant the switch privilege for that group to the user.

See Also: Chapter 120, "DBMS_RESOURCE_MANAGER"

Examples

```sql
BEGIN
  DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SWITCH_CONSUMER_GROUP (  
    'scott', 'mail_maintenance_group', true);
  DBMS_RESOURCE_MANAGER.CREATE_PENDING_AREA();
  DBMS_RESOURCE_MANAGER.set_consumer_group_mapping(
    dbms_resource_manager.oracle_user, 'scott', 'mail_maintenance_group');
  DBMS_RESOURCE_MANAGER.SUBMIT_PENDING_AREA();
END;
/```
GRANT_SYSTEM_PRIVILEGE Procedure

This procedure performs a grant of a system privilege to a user or role.

Syntax

```sql
DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SYSTEM_PRIVILEGE (    
grantee_name    IN VARCHAR2,
    privilege_name  IN VARCHAR2 DEFAULT 'ADMINISTER_RESOURCE_MANAGER',
    admin_option    IN BOOLEAN);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>grantee_name</td>
<td>Name of the user or role to whom privilege is to be granted.</td>
</tr>
<tr>
<td>privilege_name</td>
<td>Name of the privilege to be granted.</td>
</tr>
<tr>
<td>admin_option</td>
<td>TRUE if the grant is with admin_option, FALSE otherwise.</td>
</tr>
</tbody>
</table>

Usage Notes

Currently, Oracle provides only one system privilege for the Resource Manager: ADMINISTER_RESOURCE_MANAGER. Database administrators have this system privilege with the ADMIN option. The grantee and the revokee can either be a user or a role. Users that have been granted the system privilege with the ADMIN option can also grant this privilege to others.

Examples

The following call grants this privilege to a user called scott without the ADMIN option:

```sql
BEGIN
    DBMS_RESOURCE_MANAGER_PRIVS.GRANT_SYSTEM_PRIVILEGE (    
        grantee_name => 'scott',
        privilege_name => 'ADMINISTER_RESOURCE_MANAGER',
        admin_option => FALSE);
END;
/
REVOKE_SWITCH_CONSUMER_GROUP Procedure

This procedure revokes the privilege to switch to a resource consumer group.

Syntax

DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SWITCH_CONSUMER_GROUP (  
    revokee_name   IN VARCHAR2,  
    consumer_group IN VARCHAR2);  

Parameters

Table 121–4  REVOKE_SWITCH_CONSUMER_GROUP Procedure Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>revokee_name</td>
<td>Name of user/role from which to revoke access.</td>
</tr>
<tr>
<td>consumer_group</td>
<td>Name of consumer group.</td>
</tr>
</tbody>
</table>

Usage Notes

If you revoke a user's switch privilege for a particular consumer group, then any subsequent attempts by that user to switch to that consumer group will fail.

If you revoke the initial consumer group from a user, then that user will automatically be part of the DEFAULT_CONSUMER_GROUP consumer group when logging in.

If you revoke the switch privilege for a consumer group from a role, then any users who only had switch privilege for the consumer group through that role will not be able to switch to that consumer group.

If you revoke the switch privilege for a consumer group from PUBLIC, then any users who could previously only use the consumer group through PUBLIC will not be able to switch to that consumer group.

Examples

The following example revokes the privileges to switch to mail_maintenance_group from Scott:

BEGIN  
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SWITCH_CONSUMER_GROUP (  
    'scott', 'mail_maintenance_group');  
END;  
/
This procedure performs a revoke of a system privilege from a user or role.

Syntax

```sql
DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SYSTEM_PRIVILEGE (  
  revokee_name   IN VARCHAR2,  
  privilege_name IN VARCHAR2 DEFAULT 'ADMINISTER_Resource_MANAGER');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>revokee_name</td>
<td>Name of the user or role from whom privilege is to be revoked.</td>
</tr>
<tr>
<td>privilege_name</td>
<td>Name of the privilege to be revoked.</td>
</tr>
</tbody>
</table>

Examples

The following call revokes the `ADMINISTER_Resource_MANAGER` from user scott:

```sql
BEGIN
  DBMS_RESOURCE_MANAGER_PRIVS.REVOKE_SYSTEM_PRIVILEGE ('scott');
END;
/
The **DBMS_RESULT_CACHE** package provides an interface to allow the DBA to administer that part of the shared pool that is used by the SQL result cache and the PL/SQL function result cache. Both these caches use the same infrastructure. Therefore, for example, **DBMS_RESULT_CACHE.BYPASS** determines whether both caches are bypassed or both caches are used, and **DBMS_RESULT_CACHE.FLUSH** flushes both all the cached results for SQL queries and all the cached results for PL/SQL functions.

**See Also:**

- *Oracle Database PL/SQL Language Reference* for more information about "Using the Cross-Session PL/SQL Function Result Cache"

</tr>
</tbody>
</table>
BYPASS Procedure

This procedure sets the bypass mode for the Result Cache:

- When bypass mode is turned on, it implies that cached results are no longer used and that no new results are saved in the cache.
- When bypass mode is turned off, the cache resumes normal operation.

Syntax

```
DBMS_RESULT_CACHE.BYPASS (  
  bypass_mode    IN   BOOLEAN,  
  session        IN   BOOLEAN); 
```

Parameters

Table 122–3  BYPASS Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| bypass_mode | ■ TRUE => Result Cache usage is bypassed  
               ■ FALSE => Result Cache usage is turned on |
| session    | ■ TRUE => Applies to current session  
               ■ FALSE (default) => Applies to all sessions |

Usage Notes

This operation is database instance specific.

Examples

This operation can be used when there is a need to hot patch PL/SQL code in a running system. If a code-patch is applied to a PL/SQL module on which a result cached function directly or transitively depends, then the cached results associated with the result cache function are not automatically flushed (if the instance is not restarted/bounced). This must be manually achieved.

To ensure correctness during the patching process follow these steps:

1. Place the result cache in bypass mode, and flush existing result.

   ```
   BEGIN  
   DBMS_RESULT_CACHE.BYPASS(TRUE);  
   DBMS_RESULT_CACHE.FLUSH;  
   END;  
   /
   ```

   This step must be performed on each instance if in a Oracle Real Application Clusters environment.

2. Apply the PL/SQL code patches.

3. Resume use of the result cache, by turning off the cache bypass mode.

   ```
   BEGIN  
   DBMS_RESULT_CACHE.BYPASS(FALSE);  
   END;  
   /
   ```
This step must be performed on each instance if in an Oracle Real Application Clusters environment.
FLUSH Function & Procedure

This function and procedure attempts to remove all the objects from the Result Cache, and depending on the arguments retains or releases the memory and retains or clears the statistics.

Syntax

```sql
DBMS_RESULT_CACHE.FLUSH (  
    retainMem  IN  BOOLEAN DEFAULT FALSE,  
    retainSta  IN  BOOLEAN DEFAULT FALSE)  
RETURN BOOLEAN;
```

Table 122–4 FLUSH Function & Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>retainMem</td>
<td></td>
</tr>
</tbody>
</table>
  ■ TRUE => retains the free memory in the cache  
  ■ FALSE (default) => releases the free memory to the system |
| retainSta |  
  ■ TRUE => retains the existing cache statistics  
  ■ FALSE (default) => clears the existing cache statistics |

Return Values

TRUE if successful in removing all the objects.
INVALIDATE Functions & Procedures

This function and procedure invalidates all the result-set objects that dependent upon the specified dependency object.

Syntax

```
DBMS_RESULT_CACHE.INVALIDATE (
    owner        IN  VARCHAR2,
    name         IN  VARCHAR2)
RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE (
    owner       IN  VARCHAR2,
    name        IN  VARCHAR2);

DBMS_RESULT_CACHE.INVALIDATE (
    object_id    IN BINARY_INTEGER)
RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE (
    object_id    IN BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>Schema name</td>
</tr>
<tr>
<td>name</td>
<td>Object name</td>
</tr>
<tr>
<td>object_id</td>
<td>Dictionary object number</td>
</tr>
</tbody>
</table>

Return Values

The number of objects invalidated.
INVALIDATE_OBJECT Functions & Procedures

This function and procedure invalidates the specified result-set object(s).

Syntax

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (  
id          IN  BINARY_INTEGER)  
RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (  
id          IN  BINARY_INTEGER);

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (  
cache_id   IN  VARCHAR2)  
RETURN NUMBER;

DBMS_RESULT_CACHE.INVALIDATE_OBJECT (  
cache_id   IN  VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Address of the cache object in the Result Cache</td>
</tr>
<tr>
<td>cache_id</td>
<td>Cache-id</td>
</tr>
</tbody>
</table>

Return Values

The number of objects invalidated.
MEMORY_REPORT Procedure

This procedure produces the memory usage report for the Result Cache.

Syntax

```sql
DBMS_RESULT_CACHE.MEMORY_REPORT (   
  detailed IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| detailed  | TRUE => produces a more detailed report  
            | FALSE (default) => produces the standard report |

Usage Notes

Invoking this procedure from SQL*Plus requires that the serveroutput be turned on.
STATUS Function

This function checks the status of the Result Cache.

Syntax

```
DBMS_RESULT_CACHE.STATUS
RETURN VARCHAR2;
```

Return Values

One of the following values:

- STATUS_DISA - Cache is not available
- STATUS_ENAB - Cache is available
- STATUS_BYP - Cache has been made temporarily unavailable.
- STATUS_SYNC - Cache is available, but synchronizing with Oracle RAC nodes
With the `DBMS_RESUMABLE` package, you can suspend large operations that run out of space or reach space limits after executing for a long time, fix the problem, and make the statement resume execution. In this way you can write applications without worrying about running into space-related errors.

This chapter contains the following topics:

- **Using DBMS_RESUMABLE**
  - Operational Notes
- **Summary of DBMS_RESUMABLE Subprograms**
Using DBMS_RESUMABLE

- Operational Notes
**Operational Notes**

When you suspend a statement, you should log the suspension in the alert log. You should also register a procedure to be executed when the statement is suspended. Using a view, you can monitor the progress of the statement and indicate whether the statement is currently executing or suspended.

Suspending a statement automatically results in suspending the transaction. Thus all transactional resources are held during a statement suspend and resume. When the error condition disappears, the suspended statement automatically resumes execution. A resumable space allocation can be suspended and resumed multiple times during execution.

A suspension timeout interval is associated with resumable space allocations. A resumable space allocation that is suspended for the timeout interval (the default is two hours) wakes up and returns an exception to the user. A suspended statement may be forced to throw an exception using the `DBMS_RESUMABLE.ABORT()` procedure.
## Summary of DBMS_RESUMABLE Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABORT Procedure on page 123-5</td>
<td>Aborts a suspended resumable space allocation</td>
</tr>
<tr>
<td>GET_SESSION_TIMEOUT Function on page 123-6</td>
<td>Returns the current timeout value of the resumable space allocations for a session with session_id</td>
</tr>
<tr>
<td>GET_TIMEOUT Function on page 123-7</td>
<td>Returns the current timeout value of resumable space allocations for the current session</td>
</tr>
<tr>
<td>SET_SESSION_TIMEOUT Procedure on page 123-8</td>
<td>Sets the timeout of resumable space allocations for a session with session_id</td>
</tr>
<tr>
<td>SET_TIMEOUT Procedure on page 123-9</td>
<td>Sets the timeout of resumable space allocations for the current session</td>
</tr>
<tr>
<td>SPACE_ERROR_INFO Function on page 123-10</td>
<td>Looks for space-related errors in the error stack, otherwise returning FALSE</td>
</tr>
</tbody>
</table>
ABORT Procedure

This procedure aborts a suspended resumable space allocation. The parameter `session_id` is the session ID in which the statement is executed. For a parallel DML/DDL, `session_id` is any session ID that participates in the parallel DML/DDL. This operation is guaranteed to succeed. The procedure can be called either inside or outside of the `AFTER SUSPEND` trigger.

Syntax

```
DBMS_RESUMABLE.ABORT (
    session_id IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>The session identifier of the resumable space allocation.</td>
</tr>
</tbody>
</table>

Usage Notes

To call an `ABORT` procedure, you must be the owner of the session with `session_id`, have `ALTER SYSTEM` privileges, or be a DBA.
GET_SESSION_TIMEOUT Function

This function returns the current timeout value of resumable space allocations for a session with session_id.

Syntax

```plsql
DBMS_RESUMABLE.GET_SESSION_TIMEOUT (session_id  IN NUMBER) RETURN NUMBER;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>The session identifier of the resumable space allocation.</td>
</tr>
</tbody>
</table>

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER</td>
<td>The current timeout value of resumable space allocations for a session with session_id. The timeout is returned in seconds.</td>
</tr>
</tbody>
</table>

Usage Notes

If session_id does not exist, the GET_SESSION_TIMEOUT function returns -1.
GET_TIMEOUT Function

This function returns the current timeout value of resumable space allocations for the current session.

Syntax

```sql
DBMS_RESUMABLE.GET_TIMEOUT
RETURN NUMBER;
```

Return Values

<table>
<thead>
<tr>
<th>Return Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NUMBER</td>
<td>The current timeout value of resumable space allocations for the current session. The returned value is in seconds.</td>
</tr>
</tbody>
</table>

Usage Notes

If the current session is not resumable enabled, the `GET_TIMEOUT` function returns -1.
SET_SESSION_TIMEOUT Procedure

This procedure sets the timeout of resumable space allocations for a session with session_id. The new timeout setting applies to the session immediately. If session_id does not exist, no operation occurs.

Syntax

```sql
DBMS_RESUMABLE.SET_SESSION_TIMEOUT(
    session_id  IN NUMBER,
    timeout     IN NUMBER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>session_id</td>
<td>The session identifier of the resumable space allocation.</td>
</tr>
<tr>
<td>timeout</td>
<td>The timeout of the resumable space allocation.</td>
</tr>
</tbody>
</table>
**SET_TIMEOUT Procedure**

This procedure sets the timeout of resumable space allocations for the current session. The new timeout setting applies to the session immediately.

**Syntax**

```sql
DBMS_RESUMABLE.SET_TIMEOUT (  
    timeout IN NUMBER);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>timeout</td>
<td>The timeout of the resumable space allocation.</td>
</tr>
</tbody>
</table>
SPACE_ERROR_INFO Function

This function looks for space-related errors in the error stack. If it cannot find a space related error, it will return FALSE. Otherwise, TRUE is returned and information about the particular object that causes the space error is returned.

Syntax

```sql
DBMS_RESUMABLE.SPACE_ERROR_INFO
error_type OUT VARCHAR2,
object_type OUT VARCHAR2,
object_owner OUT VARCHAR2,
table_space_name OUT VARCHAR2,
object_name OUT VARCHAR2,
sub_object_name OUT VARCHAR2)
RETURN BOOLEAN;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>error_type</td>
<td>The space error type. It will be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- NO MORE SPACE</td>
</tr>
<tr>
<td></td>
<td>- MAX EXTENTS REACHED</td>
</tr>
<tr>
<td></td>
<td>- SPACE QUOTA EXCEEDED</td>
</tr>
<tr>
<td>object_type</td>
<td>The object type. It will be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- TABLE</td>
</tr>
<tr>
<td></td>
<td>- INDEX</td>
</tr>
<tr>
<td></td>
<td>- CLUSTER</td>
</tr>
<tr>
<td></td>
<td>- TABLE SPACE</td>
</tr>
<tr>
<td></td>
<td>- ROLLBACK SEGMENT</td>
</tr>
<tr>
<td></td>
<td>- UNDO SEGMENT</td>
</tr>
<tr>
<td></td>
<td>- LOB SEGMENT</td>
</tr>
<tr>
<td></td>
<td>- TEMP SEGMENT</td>
</tr>
<tr>
<td></td>
<td>- INDEX PARTITION</td>
</tr>
<tr>
<td></td>
<td>- TABLE PARTITION</td>
</tr>
<tr>
<td></td>
<td>- LOB PARTITION</td>
</tr>
<tr>
<td></td>
<td>- TABLE SUBPARTITION</td>
</tr>
<tr>
<td></td>
<td>- INDEX SUBPARTITION</td>
</tr>
<tr>
<td></td>
<td>- LOB SUBPARTITION</td>
</tr>
<tr>
<td></td>
<td>The type can also be NULL if it does not apply.</td>
</tr>
<tr>
<td>object_owner</td>
<td>The owner of the object. NULL if it cannot be determined.</td>
</tr>
<tr>
<td>table_space_name</td>
<td>The table space where the object resides. NULL if it cannot be determined.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of rollback segment, temp segment, table, index, or cluster.</td>
</tr>
<tr>
<td>sub_object_name</td>
<td>The partition name or sub-partition name of LOB, TABLE, or INDEX. NULL if it cannot be determined.</td>
</tr>
</tbody>
</table>
The `DBMS_RLMGR` package contains various procedures to create and manage rules and rule sessions by the Rules Manager.

**Note:** This functionality is deprecated with Oracle Database Release 11.2 and obsoleted with Release 12.1. For details regarding obsolescence, see My Oracle Support Note ID 1244535.1

See Also: Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information.

This chapter contains the following topic:

- Using `DBMS_RLMGR`
- Summary of Rules Manager Subprograms
Using DBMS_RLMGR

This section contains topics that relate to using the Rules Manager DBMS_RLMGR package.

- Security Model
Security Model

The Oracle Database installation runs the catrul.sql script to load the DBMS_RLMGR package and create the required Rules Manager schema objects in the EXFSYS Schema.

DBMS_RLMGR is an EXFSYS-owned package compiled with AUTHID CURRENT_USER. Any DBMS_RLMGR subprogram called from an anonymous PL/SQL block is run using the privileges of the current user.

A user must be granted CONNECT and RESOURCE roles, EXECUTE privilege on DBMS_LOCK, and CREATE VIEW privilege to use this package.

For successful creation of a rule class, you must have sufficient privileges to create views, object types, tables, packages, and procedures.

The owner of the rule class always has privileges to drop a rule class, process rules in a rule class, add rules and delete rules from a rules class. Only the owner of the rule class can drop a rule class and this privilege cannot be granted to another user. Rule class privileges cannot be revoked from the owner of the rule class.

A user who is not the owner of the rule class must be granted appropriate types of privileges to perform certain tasks. The types of privileges that can be granted are:

- **PROCESS RULES**: A user with PROCESS RULES privilege on a rule class can process the rules in the rule class using the PROCESS_RULES procedure or the ADD_EVENT procedure. Also, the user with this privilege can select from the corresponding rule class results view.

- **ADD RULE**: A user with ADD RULE privilege on a rule class can add rules to a rule class. Alternatively, the owner of the rule class can grant the INSERT privilege on one rule class table to other users.

- **DELETE RULE**: A user with DELETE RULE privilege on a rule class can delete rules from a rule class. Alternatively, the owner of the rule class can grant the DELETE privilege on one rule class table to other users.

- **ALL**: Granting the ALL privilege on a rule class is equivalent to granting all the above privileges on the rule class to the user.

A user must have the EXECUTE privilege on the primitive event types associated with a rule class before that user can make use of the corresponding rule class results view.

The owner of the rule class can add the rules using SQL INSERT statement on the rule class table (that shares the same name as the rule class). Note that the owner of the rule class can also grant direct DML privileges on the rule class table to other users. When you use the schema extended name for the rule class, the user must have the ADD RULE privilege on the rule class to add a rule to the rule class.

The owner of the rule class can use an SQL DELETE statement on one rule class table to delete a rule. When you use the schema extended name for the rule class, the user must have the DELETE RULE privilege on the rule class.

When the schema extended name is used for the rule class, the user must have PROCESS RULES privilege on the rule class.

A user must have EXECUTE privilege on the CTX_DDL package for successful synchronization of the text indexes using the DBMS_RLMGR.SYNC_TEXT_INDEXES procedure.

The USER_RLMGR_PRIVILEGES view lists privileges of the current user for the rule classes.
Summary of Rules Manager Subprograms

Table 124–1 describes the subprograms in the **DBMS_RLMGR** package.

All the values and names passed to the procedures defined in the **DBMS_RLMGR** package are case insensitive unless otherwise mentioned. To preserve the case, enclose the values with double quotation marks.

**Table 124–1  DBMS_RLMGR Package Subprograms**

ADD_ELEMENTARY_ATTRIBUTE Procedures

This procedure adds the specified attribute to an event structure, which is also the Expression Filter attribute set. The procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Adds the specified elementary attribute to the attribute set:

```sql
DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE (  
    event_struct   IN   VARCHAR2,
    attr_name      IN   VARCHAR2,
    attr_type      IN   VARCHAR2,
    attr_defvl     IN   VARCHAR2 default NULL);
```

Identifies the elementary attributes that are table aliases and adds them to the event structure:

```sql
DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE (  
    event_struct   IN   VARCHAR2,
    attr_name      IN   VARCHAR2,
    tab_alias      IN   rlm$table_alias);
```

Allows addition of text attributes to the attribute set:

```sql
DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE (  
    event_struct   IN   VARCHAR2,
    attr_name      IN   VARCHAR2,
    attr_type      IN   VARCHAR2,
    text_pref      IN   EXF$TEXT);
```

Parameters

| Table 124–2  ADD_ELEMENTARY_ATTRIBUTE Procedure Parameters |
|--------------|----------------------------------------------------------|
| Parameter    | Description                                                                 |
| event_struct | Name of the event structure or attribute set to which this attribute is added |
| attr_name    | Name of the elementary attribute to be added. No two attributes in a set can have the same name. |
| attr_type    | Datatype of the attribute. This argument accepts any standard SQL datatype or the name of an object type that is accessible to the current user. |
| tab_alias    | The type that identifies the database table to which the attribute is aliased |
| attr_defvl   | Default value for the elementary attribute |
| text_pref    | Text preferences such as LEXER and WORDLIST specification |

Usage Notes

- This procedure adds an elementary attribute to an event structure. The event structure is internally managed as the Expression Filter attribute set. If the event structure was originally created from an existing object type, then additional attributes cannot be added.
Elementary attributes cannot be added to an attribute set that is already assigned to a column storing expressions, which is equivalent to an event structure that is used for a rule class.

- One or more, or all elementary attributes in an attribute set can be table aliases. If an elementary attribute is a table alias, then the value assigned to the elementary attribute is a ROWID from the corresponding table. An attribute set with one or more table alias attributes cannot be created from an existing object type. For more information about table aliases, see Oracle Database Rules Manager and Expression Filter Developer’s Guide.

- You cannot add elementary attributes to an attribute set that is already assigned to a column storing expressions.

- See the section on defining attribute sets in Oracle Database Rules Manager and Expression Filter Developer’s Guide for more information about adding elementary attributes.

- Related views: USER_EXPFIL_ATTRIBUTE_SETS and USER_EXPFIL_ATTRIBUTES.

- This procedure with a text preference bound to the text_pref argument creates a text attribute in the attribute set. The data type for such an attribute should be a VARCHAR2 or a CLOB. The preferences specified for a text attribute are used to process the predicates involving CONTAINS operator on the attributes. The valid preferences are those that are valid in the PARAMETERS clause of CXTRULE index creation. See Oracle Text Application Developer’s Guide for the syntax.

Examples

The following command adds two elementary attributes to an attribute set:

```sql
BEGIN
    DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE (
        EVENT_STRUCT => 'HRAttrSet',
        ATTR_NAME => 'HRREP',
        attr_type => 'VARCHAR2');
    DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE (
        EVENT_STRUCT => 'HRAttrSet',
        ATTR_NAME => 'DEPT',
        TAB_ALIAS => RLM$TABLE_ALIAS('DEPT'));
END;
```

The following commands create an attribute set with each hotel reservation including some additional information, described as the AddlInfo attribute of CLOB data type. Rule conditions specified for this event structure can include text predicates on this attribute.

```sql
BEGIN
    DBMS_RLMGR.CREATE_EVENT_STRUCT (EVENT_STRUCT => 'AddFlight');
    DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE {
        EVENT_STRUCT => 'AddHotel',
        ATTR_NAME => 'CustId',
        ATTR_TYPE => 'NUMBER'};
    DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE {
        EVENT_STRUCT => 'AddHotel',
        ATTR_NAME => 'Type',
        ATTR_TYPE => 'VARCHAR2(20)'};
    DBMS_RLMGR.ADD_ELEMENTARY_ATTRIBUTE { 
        EVENT_STRUCT => 'AddHotel',
        ATTR_NAME => 'AddlInfo',
    }
END;
```
ATTR_TYPE => 'CLOB',
TEXT_PREF => EXP$TEXT('LEXER hotelreserv_lexer')));
END;
ADD_EVENT Procedure

This procedure adds a primitive event to a rule class in an active rule session. The procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Adds a string representation of the primitive event instance to a rule class:

```sql
DBMS_RLMGR.ADD_EVENT (    rule_class      IN VARCHAR2,    event_inst      IN VARCHAR2,    event_type      IN VARCHAR2 default null);
```

Adds an AnyData representation of the primitive event instance to a rule class:

```sql
DBMS_RLMGR.ADD_EVENT (    rule_class      IN VARCHAR2,    event_inst      IN sys.AnyData);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>event_inst</td>
<td>String or AnyData representation of the event instance being added to the rule class</td>
</tr>
<tr>
<td>event_type</td>
<td>Type of event instance assigned to the event_inst argument when the string representation of the event instance is used for a rule class configured for composite events</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure is used to add a primitive or a simple event to a rule class within an active rule session. By default, a rule session is the same as the database session. Optionally, multiple (sequential) rule sessions can be started within a database session by using the `RESET_SESSION` or `PROCESS_RULES` procedures.

- When the rule class is configured for simple events (consisting of only one primitive event structure), the `event_type` argument for the ADD_EVENT procedure can be ignored. Also, when the AnyData format of the event instance is passed, the event type information is embedded in the AnyData instance. In all other cases, the name of the primitive event structure being added to the rule class should be assigned to the `event_type` argument.

- For a valid event instance, the ADD_EVENT procedure processes the rules in the rule class and captures the results in the rule class results view (configured at the time of rule class creation). These results are preserved until the end of the rule session.

- When schema extended name is used for the rule class, you should have `PROCESS RULES` privilege on the rule class. See the GRANT_PRIVILEGE Procedure for additional information. The value specified for the `event_type` argument is always resolved in the rule class owner's schema and should not use schema extended names. When a composite event structure is configured with a table alias primitive
event type, the name of the corresponding table should be assigned to the `event_type` argument.

**Examples**

The following commands add two events to the `CompTravelPromo` rule class that is configured for two types of primitive events (`AddFlight` and `AddRentalCar`).

```sql
BEGIN
    DBMS_RLMGR.ADD_EVENT(rule_class => 'CompTravelPromo',
                          event_inst =>
                          AddFlight.getVarchar(987, 'Abcair', 'Boston',
                                              'Orlando', '01-APR-2003', '08-APR-2003'),
                          event_type => 'AddFlight');

    DBMS_RLMGR.ADD_EVENT(rule_class => 'Scott.CompteTravelPromo',
                          event_inst =>
                          AnyData.convertObject(
                          AddRentalCar(987, 'Luxury', '03-APR-2003',
                                       '08-APR-2003', NULL)));
END;
/```
Summary of Rules Manager Subprograms

ADD_FUNCTIONS Procedure
This procedure adds a user-defined function, package, or type representing a set of
functions to the event structure, which is also the Expression Filter attribute set.

Syntax
124

DBMS_RLMGR.ADD_FUNCTIONS (
event_struct
IN
VARCHAR2,
funcs_name
IN
VARCHAR2);

Parameters
124

Table 124–4

ADD_FUNCTIONS Procedure Parameters

Parameter

Description

event_struct

Name of the event structure to which the functions are added

funcs_name

Name of a function, package, or type (representing a function set) or its
synonyms

Usage Notes
124

■

■

■

■

■

By default, an attribute set implicitly allows references to all Oracle
Database-supplied SQL functions for use in the rule conditions. If the expression
set refers to a user-defined function, the expression set must be explicitly added to
the attribute set.
The ADD_FUNCTIONS procedure adds a user-defined function or a package (or type)
representing a set of functions to the attribute set. Any new or modified
expressions are validated using this list.
You can specify the function or the package name with a schema extension. If you
specify a function name without a schema extension, only such references in the
rule condition are considered valid. You can restrict the conditional expression to
use a synonym to a function or a package by adding the corresponding synonym
to the attribute set. This preserves the portability of the expression set to other
schemas.
See the section on defining attribute sets in Oracle Database Rules Manager and
Expression Filter Developer's Guide for more information about adding functions to
an attribute set.
Related views: USER_EXPFIL_ATTRIBUTE_SETS and USER_EXPFIL_ASET_FUNCTIONS

Examples
124

The following command adds two functions to the attribute set:
BEGIN
DBMS_RLMGR.ADD_FUNCTIONS (attr_set
=> 'Car4Sale',
funcs_name => 'HorsePower');
DBMS_RLMGR.ADD_FUNCTIONS (attr_set
=> 'Car4Sale',
funcs_name => 'Scott.CrashTestRating');
END;
/

DBMS_RLMGR 124-11


ADD_RULE Procedure

This procedure adds new rules to a rule class.

Syntax

```sql
DBMS_RLMGR.ADD_RULE (
  rule_class      IN  VARCHAR2,
  rule_id         IN  VARCHAR2,
  rule_cond       IN  VARCHAR2,
  actprf_nml      IN  VARCHAR2 DEFAULT NULL,
  actprf_vall     IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>rule_id</td>
<td>Unique identifier for the rule within the rule class</td>
</tr>
<tr>
<td>rule_cond</td>
<td>The condition for the rule. The condition uses the variables defined in the rule class's event structure.</td>
</tr>
<tr>
<td>actprf_nml</td>
<td>The list of action preference names for which values will be assigned through the actprf_vall argument</td>
</tr>
<tr>
<td>actprf_vall</td>
<td>The list of action preference values for the names list assigned to the actprf_nml argument</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure is used to add new rules to the rule class. The rule condition passed to the ADD_RULE procedure is validated using the event structure associated with the rule class. The action preferences names list is a subset of action preference categories configured during rule class creation.
- When schema extended name is used for the rule class, you should have ADD RULE privilege on the rule class. See the GRANT_PRIVILEGE Procedure for more information.
- Alternately, the owner of the rule class can add the rules using SQL INSERT statement on the rule class table (that shares the same name as the rule class). Note that the owner of the rule class can also grant direct DML privileges on the rule class table to other users.

**Note:** The AUTOCOMMIT property of the rule class is ignored if the new rules are added using the SQL INSERT statement instead of the ADD_RULE procedure.

- See the CREATE_RULE_CLASS Procedure procedure for the structure of the rule class table.

Examples

The following command adds a rule to the rule class.
BEGIN
DBMS_RLMGR.ADD_RULE {
  rule_class => 'CompTravelPromo',
  rule_id => 'AB_AV_FL',
  rule_cond =>
    '<condition>
      <and join="Flt.CustId = Car.CustId">
        <object name="Flt">
          Airline='Abcair' and ToCity='Orlando'
        </object>
        <object name="Car">
          CarType = 'Luxury'
        </object>
      </and>
    </condition>',
  actprf_nml => 'PromoType, OfferedBy',
  actprf_vall => '''RentalCar'', ''Acar''');
END;

With proper privileges, the following SQL INSERT statement can be used to add the rule to the rule class.

INSERT INTO CompTravelPromo (rlm$ruleid, rlm$rulecond, PromoType, OfferedBy)
VALUES ('AB_AV_FL',
  '<condition>
    <and join="Flt.CustId = Car.CustId">
      <object name="Flt">
        Airline='Abcair' and ToCity='Orlando'
      </object>
      <object name="Car">
        CarType = 'Luxury'
      </object>
    </and>
  </condition>',
  'RentalCar', 'Acar');
CONDITION_REF Function

This function retrieves the primitive rule condition reference from a rule condition for composite events.

Syntax

```sql
DBMS_RLMGR.CONDITION_REF (  
    rule_cond IN   VARCHAR2,  
    eventnm   IN   VARCHAR2)  
RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_cond</td>
<td>Rule condition in XML format</td>
</tr>
<tr>
<td>eventnm</td>
<td>Name of the event for which the reference should be retrieved</td>
</tr>
</tbody>
</table>

Usage Notes

- For a rule condition in XML format, with a root `<condition>` element, this function retrieves the reference to a shared conditional expression on a particular primitive event.
- Use this function in a query operating on the rule class table to find all the references to a given primitive rule condition. To speed-up such queries, one or more functional indexes are defined on the `rlm$rulecond` column of the rule class table using this function signature. In order to make use of the index for a lookup query, the value assigned to the `eventnm` argument should be case sensitive.

Examples

The following command joins the rule class table with the primitive conditions table to identify all the rule conditions that have references to the shareable primitive conditions (the query uses a functional index defined on the `rlm$rulecond` column). This query identifies all the rule conditions that refer to any shared conditions stored in the `FlightConditions` table.

```sql
select ctp.rlm$ruleid from CompTravelPromo ctp, FlightConditions fc  
where dbms_rlmgr.condition_ref(ctp.rlm$rulecond, 'FLT') = fc.rlm$condid;
```
**CONSUME_EVENT Function**

This function consumes an event and prepares the corresponding rule for action execution. This is required only when the action (or rule execution) is carried by the user's application and not in the callback.

**Syntax**

```sql
DBMS_RLMGR.CONSUME_EVENT (  
  rule_class       IN VARCHAR2,  
  event_ident      IN VARCHAR2)  
RETURN NUMBER;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>event_ident</td>
<td>Event identifier obtained from the corresponding rule class results view (or arguments of the action callback procedure in the case of rule class configured for RULE based consumption policy)</td>
</tr>
</tbody>
</table>

**Returns**

The function returns:

- 1 -- If the event is successfully consumed.
- 0 -- If the event is expired (owing to duration policy) or consumed by another session prior to this call.

**Usage Notes**

- When an EXCLUSIVE consumption policy is set for the events in a rule class, an event must be deleted from the system immediately after the rule it matched is executed (action is executed). When the rule action is carried in the rule class callback procedure by calling the PROCESS_RULES procedure, the rule manager automatically handles the consumption of the events. However, when you request the results from matching events with rules in a rule class results view using the ADD_EVENT procedure, you should take appropriate action to indicate the exact rule-event combination that is to be used for rule execution. The CONSUME_EVENT function performs the required housekeeping services when the unique identifier for the event used in a rule execution is passed in.

- Because there could be a time lag between fetching the rule class matching results and the execution of the user initiated action, the application must execute the action only if the CONSUME_EVENT call succeeds in consuming the event. This avoids any race condition with parallel sessions trying to consume the same events. When the event is successfully consumed, this call returns 1. In all other cases, it returns 0. A return value of 0 implies that the event is already consumed by another session and hence it is not available for this session.

- The CONSUME_EVENT function deletes the events configured with EXCLUSIVE consumption policy and does nothing for events configured for 4 consumption policy.
Unlike the EXCLUSIVE and SHARED consumption policies, which are determined at the rule class level, you use a RULE consumption policy to determine the consumption of an event on a rule by rule basis. That is a subset of the rules in a rule class may be configured such that when they are matched, the event is deleted from the system. At the same time the other set of rules could leave the event in the system even after executing the corresponding action. In this scenario, the action callback procedure implemented by the application developer can call CONSUME_EVENT function (with appropriate arguments) to conditionally consume the event for certain rules. Also see the use of CONSUME_PRIM_EVENTS Function for rule classes configured for RULE consumption policy.

Examples

The following commands identify an event that is used for a rule execution and consumes it using its identifier.

```sql
var eventid VARCHAR(40);
var evtcnsmd NUMBER;
BEGIN
    SELECT rlm$eventid INTO :eventid FROM MatchingPromos WHERE rownum < 2;

    -- carry the required action for a rule matched by the above event --
    :evtcnsmd := DBMS_RLMGR.CONSUME_EVENT(rule_class => 'TravelPromotion',
                                          event_ident => :eventid);
END;
```
CONSUME_PRIM_EVENTS Function

This function consumes a set of primitive events with all or nothing semantics in the case of a rule class configured with RULE based consumption policy.

Syntax

```sql
DBMS_RLMGR.CONSUME_PRIM_EVENTS (  
    rule_class       IN VARCHAR2,  
    event_idents     IN RLM$EVENTIDS)  
RETURN NUMBER;
```

Parameters

Table 124–8   CONSUME_PRIM_EVENTS Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>event_ident</td>
<td>Event identifiers obtained from the corresponding rule class results view or the arguments of the action callback procedure</td>
</tr>
</tbody>
</table>

Returns

The function returns:

- **1**  -- If all the events, the identifiers for which are passed in, are successfully consumed.
- **0**  -- If one or more primitive event could not be consumed.

Usage Notes

- When you configure the rule class for RULE based consumption policy, it uses the CONSUME_PRIM_EVENTS function to consume one or more primitive events that constitute a composite event. This operation succeeds only when all the events passed in are still valid and are available for consumption. Any user initiated action must be implemented after checking the return value of the CONSUME_PRIM_EVENTS call.

Examples

The following commands show the body of the action callback procedure for a rule class configured for RULE consumption policy. This demonstrates the use of CONSUME_PRIM_EVENTS function to consume the events before executing the action for the matched rules.

```sql
create or replace procedure PromoAction (  
    Flt        AddFlight,  
    Flt_EvtId  ROWID,    --- rowid for the flight primitive event  
    Car        AddRentalCar,  
    Car_EvtId  ROWID,  
    rlm$rule   TravelPromotions%ROWTYPE) is  
    evtcnsmd   NUMBER;
BEGIN  
    evtcnsmd := DBMS_RLMGR.CONSUME_PRIM_EVENTS(  
        rule_class    => 'TravelPromotions',  
        event_idents => RLM$EVENTIDS(Flt_EvtId, Car_EvtId));
```

if (evtcnsmd = 1) then
    -- consume operation was successful; perform the action ---
    OfferPromotion (Flt.CustId, rlm$rule.PromoType, rlm$rule.OfferedBy);
end if;
END;
/
CREATE_CONDITIONS_TABLE Procedure

This procedure creates a conditions table, which is a repository for the primitive rule conditions that can be shared by multiple rules from the same or different rule classes. The procedure is overloaded. The different functionality of each form of syntax is presented along with the definitions.

Syntax

Creates a conditions table to store shareable primitive conditions defined for a primitive event.

```
DBMS_RLMGR.CREATE_CONDITIONS_TABLE (    
    cond_table    IN  VARCHAR2,    
    pevent_struct IN  VARCHAR2,    
    stg_clause    IN  VARCHAR2 DEFAULT NULL);
```

Creates a conditions table to store shareable primitive conditions defined for a relational table identified through table aliases.

```
DBMS_RLMGR.CREATE_CONDITIONS_TABLE (    
    cond_table    IN  VARCHAR2,    
    tab_alias     IN  rlm$table_alias,    
    stg_clause    IN  VARCHAR2 DEFAULT NULL);
```

Parameters

Table 124–9  CREATE_CONDITIONS_TABLE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pevent_struct</td>
<td>Primitive event structure for which the shareable primitive rule conditions are defined</td>
</tr>
<tr>
<td>cond_table</td>
<td>Name of the table storing the primitive rule conditions</td>
</tr>
<tr>
<td>stg_clause</td>
<td>Storage clause for the conditions table</td>
</tr>
<tr>
<td>tab_alias</td>
<td>Type that identifies the database table for which the shareable primitive rule conditions are defined</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure creates a relational table to store the primitive rule conditions that can be shared by multiple rules. It creates the table with the user specified name and it has a VARCHAR2 column to store the unique identifier for each primitive rule condition (rlm$condid), an expression data type column to store the conditional expressions (rlm$condition), and a VARCHAR2 column to store the descriptions for the primitive rule conditions in plain text (rlm$conddesc).

- Once it creates the table, the primitive rule condition can be added or modified using standard DML operations on the conditions table. The conditions table is configured to validate the primitive rule conditions (in the rlm$condition column) using the primitive event structure specified for the pevent_struct argument.

- A rule class configured with a primitive event structure can include some rule conditions that refer to rows in the conditions table using corresponding identifiers.
Examples

The following command creates a conditions table that can store shareable primitive rule conditions for the AddRentalCar event structure:

```sql
BEGIN
    DBMS_RLMGR.CREATE_CONDITIONS_TABLE (
        cond_table => 'FlightConditions',
        pevent_struct => 'AddFlight',
        stg_clause => 'TABLESPACE TBS_1');
END;
/
```
**CREATE_EVENT_STRUCT Procedure**

This procedure creates an event structure.

**Syntax**

```sql
DBMS_RLMGR.CREATE_EVENT_STRUCT  (  
   event_struct  IN  VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event_struct</td>
<td>Name of the event structure to be created in the current schema</td>
</tr>
</tbody>
</table>

**Usage Notes**

- This procedure creates a dummy event structure in the current schema. One or more attributes can be added to this event structure using the `ADD_ELEMENTARY_ATTRIBUTE` procedure.

**Examples**

The following command creates the event structure.

```sql
BEGIN
   DBMS_RLMGR.CREATE_EVENT_STRUCT(event struct => 'AddFlight');
END;
```
CREATE_EXPFIL_INDEXES Procedure

This procedure creates expression filter indexes for the rule class if the default indexes have been dropped. If a representative set of rules is stored in the rule class table, the indexes can be tuned for these expressions by collecting statistics.

Syntax

```
DBMS_RLMGR.CREATE_EXPFIL_INDEXES  (
    rule_class  IN  VARCHAR2,
    coll_stats  IN  VARCHAR2 default 'NO');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class</td>
</tr>
<tr>
<td>coll_stats</td>
<td>To collect expression statistics for building the indexes</td>
</tr>
</tbody>
</table>

Usage Notes

- Expression filter indexes are used to identify the rule conditions in a rule class for appropriate events. The default indexes created at the time of rule class creation assume that all types of predicates (equality, inequality, and so forth) involving scalar attributes in an event structure are equally likely. The performance of a rule class can be improved by tuning the expression filter indexes for a specific workload. This is achieved either by collecting statistics on a representative workload or by identifying the most common predicate constructs with some domain knowledge.

- The default expression filter indexes created for the rule class can be dropped using the `DBMS_RLMGR.DROP_EXPFIL_INDEXES` procedure. Once the indexes are dropped, they can be recreated using the `DBMS_RLMGR.CREATE_EXPFIL_INDEXES` procedure. When the `coll_stats` argument of the `CREATE_EXPFIL_INDEXES` procedure is set to `YES`, rule condition statistics are collected for the most common predicate constructs and the indexes are created using these statistics. Alternately, a domain expert can manually set the index parameters by identifying the most common and discriminating predicate constructs and then create the indexes with these parameters. Note that the index parameters can be set for each of the primitive event structures associated with the rule class. The index parameters can be assigned to the event structure (which is also the Expression Filter attribute set) using the `DBMS_EXPRFIL.DEFAULT_INDEX_PARAMETERS` procedure. When the `coll_stats` argument of the `CREATE_EXPFIL_INDEXES` procedure is set to `NO`, the expression filter indexes created for the rule class make use of the default index parameters associated with each primitive event structure. (See the chapter on indexing expressions in Oracle Database Rules Manager and Expression Filter Developer’s Guide for additional information on tuning the Expression Filter indexes for better performance).

- Related view: `USER_EXPRFIL_DEF_INDEX_PARAMS`
Examples

The following commands collect the statistics for the rules defined in the CompTravelPromo rule class and create the expression filter indexes that are based on the most common predicates in the set.

```
BEGIN
DBMS_RLMGR.CREATE_EXPFIL_INDEXES (rule_class => 'CompTravelPromo',
  coll_stats => 'yes');
END;
/
```

This is an Expression Filter tuning example where the domain knowledge is used to assign specific index parameters. The following commands associate specific index parameters to the AddFlight event structure such that the expression filter index created for corresponding expressions are optimized accordingly. The subsequent CREATE_EXPFIL_INDEXES step makes use of these index parameters.

```
BEGIN
  DBMS_EXPFIL.DEFAULT_INDEX_PARAMETERS('AddFlight',
    exf$attribute_list {
      exf$attribute {attr_name => 'Airline',
        attr_oper => exf$indexoper('='),
        attr_indexed => 'TRUE'),
      exf$attribute {attr_name => 'ToCity',
        attr_oper => exf$indexoper('='),
        attr_indexed => 'TRUE'),
      exf$attribute {attr_name => 'Depart',
        attr_oper => exf$indexoper('','<','('>','<','<='),
        attr_indexed => 'FALSE')
    };
  -- create the indexes after assigning the index parameters --
  DBMS_RLMGR.CREATE_EXPFIL_INDEXES (rule_class => 'CompTravelPromo');
END;
/```
CREATE_INTERFACE Procedure

This procedure creates a rule class interface package that can be used to directly operate on the rule class for efficiency and ease of use.

Syntax

```sql
DBMS_RLMGR.CREATE_INTERFACE  (
    rule_class   IN  VARCHAR2,
    interface_nm IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class for which the interface package is created</td>
</tr>
<tr>
<td>interface_nm</td>
<td>Name of the PL/SQL package that acts as the interface to the rule application</td>
</tr>
</tbody>
</table>

Usage Notes

- The common set of DBMS_RLMGR procedures used for runtime operations such as processing the rules for some events, consuming the events and resetting the session make use of the rule class name passed in as one of the arguments and associate them to the corresponding operations on the rule class. You can cut the overhead involved in this step by creating a rule class interface package that is used to directly operate on the rule class.

- The rule class interface package is a PL/SQL package that has procedures or functions to process rules (PROCESS_RULES), add event (ADD_EVENT), consume events (CONSUME_EVENT, CONSUME_PRIM_EVENTS) and reset rule session (RESET_SESSION). The operational characteristics of these procedures and functions are the same as those of DBMS_RLMGR procedures and functions with matching names with two exceptions. Since the rule class interface package is created for a specific rule class, the rule class name is implicit and it need not be passed in as an argument to the procedures and functions of the rule class interface package. Additionally, the rule class interface package has separate PROCESS_RULES and ADD_EVENT procedures to accept each primitive event type configured with the rule class. This is in contrast to the same procedures in the DBMS_RLMGR package, which are generalized to accept the event instances only as a VARCHAR or an AnyData instance.

Examples

The following commands create the rule class interface package for the CompTravelPromo rule class.

```sql
BEGIN
    DBMS_RLMGR.CREATE_INTERFACE  (rule_class => 'CompTravelPromo',
                                   interface_nm => 'TravelPromoRules');
END;
```

The following commands make use of the interface created in previous step to process the rules for an instance of AddFlight event.

```sql
BEGIN
    TravelPromoRules.process_rules (event_inst =>
```
AddFlight(987, 'Abcair', 'Boston', 'Orlando',
    '01-APR-2009', '08-APR-2009');

END;
CREATE_RULE_CLASS Procedure

This procedure creates a rule class.

Syntax

```sql
DBMS_RLMGR.CREATE_RULE_CLASS  (  
  rule_class      IN  VARCHAR2,
  event_struct    IN  VARCHAR2,
  action_cbk      IN  VARCHAR2,
  actprf_spec     IN  VARCHAR2  default null,
  rslt_viewnm     IN  VARCHAR2  default null,
  rlcls_prop      IN  VARCHAR2  default <simple/>);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class to be created in the current schema</td>
</tr>
<tr>
<td>event_struct</td>
<td>Name of the object type or an Expression Filter attribute set in the current schema that represents the event structure for the rule class</td>
</tr>
<tr>
<td>action_cbk</td>
<td>Name of the action callback procedure to be created for the rule class</td>
</tr>
<tr>
<td>actprf_spec</td>
<td>Specification (name and SQL datatype pairs) for the action preferences associated with the rule class</td>
</tr>
<tr>
<td>rlst_viewnm</td>
<td>Name of rule class results view that lists the matching events and rules within a session. A view with this name is created in the current schema.</td>
</tr>
<tr>
<td>rlcls_prop</td>
<td>XML document for setting the rule class properties. By default, the rule class created is for simple events (non-composite).</td>
</tr>
</tbody>
</table>

Usage Notes

- For successful creation of a rule class, you must have sufficient privileges to create views, object types, tables, packages, and procedures.
- This command creates the rule class and its dependent objects in the user’s schema. For this operation to succeed the name specified for the event structure must refer to an existing object type or an Expression Filter attribute set in the user’s schema. When an object type is used for an event structure, the CREATE_RULE_CLASS procedure implicitly creates an attribute set for the object type. In the case of a rule class configured for composite events, the previous procedure also creates attribute sets for the object types that are directly embedded in the event structure’s object type (or the attribute set). A maximum of 32 embedded objects (and or or table aliases) can be specified with an event structure that is used for a composite rule class. The types of dependent objects created with this procedure and their structure depend on the properties of the rule class and its event structure. The minimum set of dependent objects created for a rule class is as follows:
  - Rule class table – A rule class table that shares the name of the rule class is created in the user’s schema to store the rule definitions (rule identifiers, rule conditions, rule descriptions, and action preferences). This table implicitly has four columns, rlm$ruleid, rlm$rulecond, rlm$enabled, and rlm$ruledesc to store the rule identifiers, rule conditions, rule states, and rule descriptions respectively. In addition to these four columns, the rule class table has few columns for storing rule definitions.
columns according to the action preference specification for the rule class. For example, if a TravelPromotion rule class uses 'PromoType VARCHAR(20), OfferedBy VARCHAR(20)' as its action preference specification (assigned to actpref_spec argument), the rule class table is created with the following structure.

```
TABLE TravelPromotion (
  rlm$ruleid VARCHAR(100),  -- rule identifier column --
  PromoType VARCHAR(20),     -- action preference 1 --
  OfferedBy VARCHAR(20),     -- action preference 2 --
  rlm$rulecond VARCHAR(4000), -- rule condition --
  rlm$ruledesc VARCHAR(1000), -- rule description --
  rlm$enabled CHAR(1));      -- rule status --
```

The rule class table structure varies from one rule class to another based on the exact list of action preference categories specified for the rule class.

- **Action Callback Procedure** — You create the skeleton for the action callback procedure with the given name in the user's schema and it is associated with the rule class. During rule evaluation, the callback procedure is called for each matching rule and event. You must implement the body of the action callback procedure to perform the appropriate action for each rule. The exact action for a rule can be determined based on the event that matched the rule and rule definition along with its action preferences. This information is passed to the action callback procedure through its arguments. Hence, the argument list for the action callback procedure depends on the event structure associated with the rule class and the rule class itself.

In the case of a rule class configured for simple events (`<simple/>` assigned to the properties of the rule class), the event that matches a rule is passed through a rlm$event argument that is declared to be of the same type as the event structure. Additionally, the rule definitions are passed to the action callback procedure using an rlm$rule argument that is declared as ROWTYPE of the corresponding rule class table. For example, the structure of the PromoAction action callback procedure created for a TravelPromotion rule class configured for a simple (non-composite) AddFlight event structure is as follows:

```
PROCEDURE PromoAction (rlm$event AddFlight,
                        rlm$rule TravlePromotion%ROWTYPE);
```

In the case of a rule class created for composite events (`<composite/>` assigned to the properties of the rule class), the action callback procedure is created to pass each primitive event as a separate argument. For example, the CompPromoAction action callback procedure created for a rule class CompTravelPromo configured for a composite event with AddFlight and AddRentalCar primitive events are shown as follows:

```
-- composite event structure --
TYPE TSCompEvent (Flt AddFlight,
                  Car AddRentalCar);
-- corresponding action callback procedure --
PROCEDURE PromoAction (Flt AddFlight,
                        Car AddRentalCar,
                        rlm$rule CompTravelPromo%ROWTYPE)
```

The action callback procedure includes additional arguments when the rule class is configured for the RULE consumption policy or when the rule class is enabled for one or more collection events. The arguments in these cases...
include the identifiers for the events (ROWID data type) in addition to the event instances. You can use these event identifiers to further operate on the matched rules. For example, in the case of the rule class configured for rule consumption, the event identifiers are used to consume the events with DBMS_RLMGR.CONSUME_PRIM_EVENTS function. In the case of rule class enabled for collection events, the same identifiers for the collection events can be used to fetch specific aggregate values with the DBMS_RLMGR.GET_AGGREGATE_VALUE function.

- Rule class results view – A view to display the results from matching some events with rules is created in the same schema as the rule class. By default, this view is created with a system-generated name. Optionally, the rule class creator can specify a name for this view with the rlst_viewnm argument of the CREATE_RULE_CLASS procedure. When the events are added to the rule manager within a rule session using the ADD_EVENT procedure, the list of matching events and rules are displayed in the rule class results view.

The structure of the view defined for the rule class results depends on the event structure and the action preferences configured with the rule class. Minimally, the view has three columns to display the system generated event identifier (rlm$eventid), the identifier of the rule it matches (rlm$ruleid), and the rule condition (rlm$rulecond). Additionally, it has columns to display the event information and the rule action preferences.

In the case of a rule class configured for simple events, the event information is displayed as rlm$event that is declared to be of the event structure type. So, a MatchingPromos view created for the TravelPromotion rule class configured for a simple AddFlight event structure is as follows:

```sql
VIEW MatchingPromos (
    rlm$eventid ROWID,
    rlm$event AddFlight,
    rlm$ruleid VARCHAR(100),
    PromoType VARCHAR(30),   -- action preference 1 --
    OffredBy VARCHAR(30),    -- action preference 2 --
    rlm$rulecond VARCHAR(4000),
    rlm$ruledesc VARCHAR(1000)
);
```

In the case of a rule class configured for composite events, the primitive events matching a rule are displayed separately using corresponding columns. For the above CompTravelPromo rule class, a MatchingCompPromos view is created with the following structure.

```sql
VIEW MatchingCompPromos (
    rlm$eventid ROWID,
    Flt AddFlight,
    Car AddRentalCar,
    rlm$ruleid VARCHAR(100),
    PromoType VARCHAR(30),   -- action preference 1 --
    OffredBy VARCHAR(30),    -- action preference 2 --
    rlm$rulecond VARCHAR(4000),
    rlm$ruledesc VARCHAR(1000)
);
```

The values from the rlm$eventid column are used to enforce rule class consumption policies when the corresponding rule is executed. See the CONSUME_EVENT Function for more information.
Examples

The following commands create a rule class for simple events (of AddFlight type).

```sql
CREATE or REPLACE TYPE AddFlight AS OBJECT {
    CustId NUMBER,
    Airline VARCHAR(20),
    FromCity VARCHAR(30),
    ToCity VARCHAR(30),
    Depart DATE,
    Return DATE);
BEGIN
    DBMS_RLMGR.CREATE_RULE_CLASS {
        rule_class => 'TravelPromotion', -- rule class name --
        event_struct => 'AddFlight', -- event struct name --
        action_cbk => 'PromoAction', -- callback proc name --
        rslt_viewnm => 'MatchingPromos', -- results view --
        actprf_spec => 'PromoType VARCHAR(20), OfferedBy VARCHAR(20)');
    END;
```

The following commands create a rule class for composite events consisting of two primitive events (AddFlight and AddRentalCar).

```sql
CREATE or REPLACE TYPE TSCompEvent (Flt AddFlight,
                                      Car AddRentalCar);
BEGIN
    DBMS_RLMGR.CREATE_RULE_CLASS {
        rule_class => 'CompTravelPromo', -- rule class name --
        event_struct => 'TSCompEvent', -- event struct name --
        action_cbk => 'CompPromoAction', -- callback proc name --
        rslt_viewnm => 'MatchingCompPromos', -- results view --
        actprf_spec => 'PromoType VARCHAR(20),
                       OfferedBy VARCHAR(20)');
    properties => '<composite/>');
    END;
```
DELETE_RULE Procedure

This procedure deletes a rule from a rule class.

Syntax

DBMS_RLMGR.DELETE_RULE (
    rule_class IN VARCHAR2,
    rule_id IN VARCHAR2);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>rule_id</td>
<td>Identifier for the rule to be deleted</td>
</tr>
</tbody>
</table>

Usage Notes

- Use this procedure to delete a rule from the rule class. The identifier for the rule to be deleted can be obtained by querying the rule class table (that shares the same name as the rule class). Alternately, the owner of the rule class can use a SQL DELETE statement on one rule class table to delete a rule.

- When you use the schema extended name for the rule class, you must have the DELETE RULE privilege on the rule class. See the GRANT_PRIVILEGE Procedure for more information.

  **Note:** AUTOCOMMIT property of the rule class is ignored if the rules are deleted with the SQL DELETE statement instead of the DELETE_RULE procedure.

- See the CREATE_RULE_CLASS Procedure for the structure of the rule class table.

Examples

The following command deletes a rule from the rule class.

BEGIN
    DBMS_RLMGR.DELETE_RULE (
        rule_class => 'CompTravelPromo',
        rule_id => 'AB_AV_FL');
END;

Alternately, you can issue the following SQL DELETE statement to delete the above rule from the rule class.

DELETE FROM CompTravelPromo WHERE rlm$ruleid = 'AB_AV_FL';
DROP_CONDITIONS_TABLE Procedure

This procedure drops the conditions table.

Syntax

```
DBMS_RLMGR.DROP_CONDITIONS_TABLE (
    cond_table IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cond_table</td>
<td>Name of conditions table in the user schema</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure drops the table that stores the shareable conditional expressions. If one of the conditional expressions in this table is used to form a rule condition in a rule class, the drop operation fails with an appropriate error.

Examples

The following command drops the conditions table:

```
BEGIN
    DBMS_RLMGR.DROP_CONDITIONS_TABLE (cond_table => 'FlightConditions');
END;
/```
DROP_EVENT_STRUCT Procedure

This procedure drops an event structure.

Syntax

```
DBMS_RLMGR.DROP_EVENT_STRUCT  (  
   event_struct  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>event_struct</code></td>
<td>Name of event structure in the current schema</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure drops the event structure from the current schema. This drops all the dependent objects created to manage the event structure.

Examples

The following command drops the event structure.

```
BEGIN  
   DBMS_RLMGR.DROP_EVENT_STRUCT(event_struct => 'AddFlight');  
END;
```
**DROP_EXPFIL_INDEXES Procedure**

This procedure drops the expression filter indexes created for a rule class.

**Syntax**

```sql
DBMS_RLMGR.DROP_EXPFIL_INDEXES (rule_class IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class</td>
</tr>
</tbody>
</table>

**Usage Notes**

This procedure drops all the expression filter indexes associated with a rule class. You can recreate the indexes using the `DBMS_RLMGR.CREATE_EXPFIL_INDEXES` call.

**Examples**

The following command drops the expression filter indexes created for the `CompTravelPromo` rule class.

```sql
BEGIN
   DBMS_RLMGR.DROP_EXPFIL_INDEXES (rule_class => 'CompTravelPromo');
   END;
/
```
DROP_INTERFACE Procedure

This procedure drops the rule class interface package created for a rules application.

Syntax

```sql
DBMS_RLMGR.DROP_INTERFACE  (
    interface_nm  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>interface_nm</td>
<td>Name of the PL/SQL package that acts as the interface to the rule application</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure drops the rule class interface package created with the `DBMS_RLMGR.CREATE_INTERFACE` call.

Examples

The following command drops the rule class interface package `TravelPromoRules`.

```sql
BEGIN
    DBMS_RLMGR.DROP_INTERFACE (interface_nm => 'TravelPromoRules'
END;
```
**DROP_RULE_CLASS Procedure**

This procedure drops a rule class.

**Syntax**

```sql
DBMS_RLMGR.DROP_RULE_CLASS (rule_class IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of rule class in the current schema</td>
</tr>
</tbody>
</table>

**Usage Notes**

- This procedure drops the rule class from the current schema. This drops all the dependent objects created to manage the rule class. Because an event structure in a user's schema can be shared across multiple rule classes, the event structure is not dropped with this command. You must use the `DROP_EVENT_STRUCTURE` procedure for the composite event as well as the individual primitive events to cleanup unused event structures.

**Examples**

The following command drops the rule class.

```sql
BEGIN
    DBMS_RLMGR.DROP_RULE_CLASS(rule_class => 'CompTravelPromo');
END;
```
EXTEND_EVENT_STRUCT Procedure

This is used to extend the primitive event structure used by one or more rule classes by adding a new attribute.

Syntax

```
DBMS_RLMGR.EXTEND_EVENT_STRUCT (
  event_struct    IN   VARCHAR2,
  attr_name       IN   VARCHAR2,
  attr_type       IN   VARCHAR2,
  attr_defvl      IN   VARCHAR2 default NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event_struct</td>
<td>Name of the event structure to which this attribute is added</td>
</tr>
<tr>
<td>attr_name</td>
<td>Name of the elementary attribute to be added. No two attributes in a set can have the same name.</td>
</tr>
<tr>
<td>attr_type</td>
<td>Data type of the attribute. This argument accepts any standard SQL data type or the name of an object type that is accessible to the current user.</td>
</tr>
<tr>
<td>attr_defvl</td>
<td>Default value for the elementary attribute</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure extends a primitive event structure already associated with a rule class to include a new attribute. You can use this procedure mostly to migrate a fully developed rules application to use extended event structures and you should not use it in the place of the ADD_ELEMENTARY_ATTRIBUTE call. Unlike the ADD_ELEMENTARY_ATTRIBUTE call, which builds an event structure one attribute at a time, the EXTEND_EVENT_STRUCT call evolves the object type associated with the event structure to include the new attributes and performs some maintenance operations on the dependent objects.

- The usage of the EXTEND_EVENT_STRUCT call is similar to that of the ADD_ELEMENTARY_ATTRIBUTE call with the same set of arguments. Table alias attributes and attributes of text and spatial data types cannot be added to the event structure using the EXTEND_EVENT_STRUCT call.

Examples

The following commands add an attribute to the AddRentalCar event structure that is used by the CompTravelPromo rule class.

```
BEGIN
  DBMS_RLMGR.EXTEND_EVENT_STRUCT (
    event_struct    => 'AddRentalCar',
    attr_name       => 'PrefMemberId',
    attr_type       => 'VARCHAR2(30)');
END;
```
GET_AGGREGATE_VALUE Function

This function retrieves the aggregate value computed for a collection event.

Syntax

```sql
DBMS_RLMGR.GRANT_PRIVILEGE  {
  rule_class      IN  VARCHAR2,
  event_ident     IN  VARCHAR2,
  aggr_func       IN  VARCHAR2) RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class for the collection event</td>
</tr>
<tr>
<td>event_ident</td>
<td>System-generated identifier for the collection event</td>
</tr>
<tr>
<td>aggr_func</td>
<td>Signature for the aggregate value to be retrieved</td>
</tr>
</tbody>
</table>

Usage Notes

- When a rule condition with collection construct matches a set of events, an instance representing the collection event and a system-generated identifier for the collection event are passed into the action callback procedure. This event identifier can be used to fetch any aggregate values that are computed as part of the collection event evaluation.

- Within a collection construct in a rule condition, the aggregate functions can be included in the HAVING clause or in the COMPUTE clause. For example, the following rule condition computes three aggregate values for \( \text{sum(amount)} \), \( \text{count(*)} \), and \( \text{max(amount)} \). At the time of action execution, these values can be obtained using the identifier for the collection event that represents all the instances of BankTransaction with the same subjectId (the attribute on which the events are grouped).

```xml
<condition>
  <collection name="bank" groupby="subjectId"
    having="\text{sum(amount)} > 10000"
    compute="\text{max(amount)}, \text{count(*)}"/>
</condition>
```

- The signature for the aggregate function is bound to the `aggr_func` argument of the GET_AGGREGATE_VALUE function to fetch the specific aggregate value. If the value is a NUMBER or a DATE data type, it returns the equivalent VARCHAR representation. It returns a NULL value if an attempt was made to fetch an aggregate value that is never computed as part of the collection event.

Examples

The following example shows a sample implementation of the action callback procedure that prints the computed aggregate values as part of action execution. In this particular case, the BankTransaction primitive event is enabled for collections.

```sql
CREATE OR REPLACE PROCEDURE LAWENFORCEMENTCBK  {
  bank                 banktransaction,
```
GET_AGGREGATE_VALUE Function

```sql
bankcollid rowid,
transport transportation,
fldrpt fieldreport,
rlm$rule LawEnforcementRC%ROWTYPE) IS
aggrval VARCHAR(30);
begin
  dbms_output.put_line('Matching Rule :'||rlm$rule.rlm$ruleid||chr(10));
  if (bank is not null) then
    dbms_output.put_line('-->Bank Transactions by ('||bank.subjectId||')'||chr(10);
    aggrval := dbms_rlmgr.get_aggregate_value(rule_class  =>'LawEnforcementRC',
                                          event_ident => bankcollid,
                                          aggr_func   => 'sum(amount)');
    if (aggrval is not null) then
      dbms_output.put_line('---> Sum of the amounts is :'||aggrval||chr(10));
    end if;
  end if;
  end;
```

124-38  Oracle Database PL/SQL Packages and Types Reference
GRANT_PRIVILEGE Procedure

This procedure grants privileges on a rule class to another user.

Syntax

```
DBMS_RLMGR.GRANT_PRIVILEGE  (
    rule_class      IN  VARCHAR2,
    priv_type       IN  VARCHAR2,
    to_user         IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class in the current schema</td>
</tr>
<tr>
<td>priv_type</td>
<td>Type of rule class privilege to be granted</td>
</tr>
<tr>
<td>to_user</td>
<td>User to whom the privilege is to be granted</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure grants appropriate privileges to a user who is not the owner of the rule class. The types of privileges that can be granted to a user are:
  - **PROCESS RULES**: A user with **PROCESS RULES** privilege on a rule class can process the rules in the rule class using the **PROCESS_RULES** procedure or the **ADD_EVENT** procedure. Also, the user with this privilege can select from the corresponding rule class results view.
  - **ADD RULE**: A user with **ADD RULE** privilege on a rule class can add rules to a rule class. Alternatively, the owner of the rule class can grant the **INSERT** privilege on one rule class table to other users.
  - **DELETE RULE**: A user with **DELETE RULE** privilege on a rule class can delete rules from a rule class. Alternatively, the owner of the rule class can grant the **DELETE** privilege on one rule class table to other users.
  - **ALL**: Granting the **ALL** privilege on a rule class is equivalent to granting all the above privileges on the rule class to the user.
- The owner of the rule class always has privileges to drop a rule class, process rules in a rule class, add rules and delete rules from a rules class. Only the owner of the rule class can drop a rule class and this privilege cannot be granted to another user.
- You must have the **EXECUTE** privilege on the primitive event types associated with a rule class before you make use of the corresponding rule class results view.

Examples

The following command grants **PROCESS RULES** privilege on TravelPromo rule class to the user SCOTT.

```
BEGIN
    DBMS_RLMGR.GRANT_PRIVILEGE(
        rule_class => 'TravelPromo',
        priv_type => 'PROCESS RULES',
        to_user => 'SCOTT');
END;
```
E. N. D.
processes the rules for a given event. The procedure is overloaded. The
different functionality of each form of syntax is presented along with the definitions.

### Syntax

Processes the rules for a string representation of the event instance being added to the
rule class:

```sql
DBMS_RLMGR.PROCESS_RULES (  
    rule_class    IN  VARCHAR2,
    event_inst    IN  VARCHAR2,
    event_type    IN  VARCHAR2 default null);
```

Processes the rules for an AnyData representation of the event instance being added to
the rule class:

```sql
DBMS_RLMGR.PROCESS_RULES (  
    rule_class    IN  VARCHAR2,
    event_inst    IN  sys.AnyData);
```

### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
<tr>
<td>event_inst</td>
<td>String or AnyData representation of the event instance being added to the rule class.</td>
</tr>
<tr>
<td>event_type</td>
<td>Type of event instance assigned to the event_inst argument when the string representation of the event instance is used for a rule class configured for composite events</td>
</tr>
</tbody>
</table>

### Usage Notes

- This procedure is used to process the rules in a rule class for an event instance assigned to the event_inst argument.

- In the case of a rule class configured for simple events (non-composite), the event instance is an instantiation of the corresponding event structure. The rules are evaluated (conclusively) for this event and the corresponding action callback procedure is called for each matching rule. If the event does not match any rule, no further action is performed. If the event matches two or more rules, the ordering clause configured for the rule class is used to order them accordingly to invoke the action callback procedure. If the rule class is configured for EXCLUSIVE consumption policy, once the first rule in this order is executed (and the corresponding action callback procedure is called), the rest of the rules that matched the event are ignored.

- In the case of a rule class configured for composite events, the event instance assigned to the event_inst argument is an instantiation of one of the primitive type within the composite event. When the instance is represented as a string, the corresponding type name should be assigned to the event_type argument. The PROCESS_RULES call on a rule class configured for composite events performs
various actions depending on the state of the rule class and the kind of rules in the rule class. Note the following.

- The rules operating only on the primitive event passed in are evaluated conclusively and the action callback procedure is called for the matching rules, as described in previous paragraph.

- In the case of a rule operating on more than one primitive event, the event instance passed through `PROCESS_RULES` procedure could match only a part of the rule.

* If there are other primitive event instances that matches the rest of the rule, the current event instance is combined with the other instances to form a complete composite event that matches a rule in the rule class. So, the event instance assigned to the `event_inst` argument of the `PROCESS_RULES` procedure could be combined with various other primitive events (previously processed) to evaluate one or more rules conclusively. The action callback procedure for the rule class is called for each such combination of primitive events (composite event) and the rule. The ordering clause for the rule class and the consumption policy for the primitive events in taken into account while invoking the action callback procedure.

* If there is no other primitive event that matches the rest of the rule, the current event instance and its (incremental) evaluation results are recorded in the database. These results are preserved until either the event is consumed or deleted from the system owing to the duration policy used for the rule class.

Examples

The following command processes the rules in the `TravelPromotion` rule class for the given events.

```sql
BEGIN
DBMS_RLMGR.PROCESS_RULES (
  rule_class => 'TravelPromotion',
  event_inst =>
    AddFlight.getVarchar(987, 'Abcair', 'Boston', 'Orlando',
    '01-APR-2003', '08-APR-2003'));
END;
```

The following commands process the rules in the `CompTravelPromo` rule class for the two primitive events shown.

```sql
BEGIN
DBMS_RLMGR.PROCESS_RULES (  
  rule_class => 'CompTravelPromo',
  event_inst =>
    AddFlight.getVarchar(987, 'Abcair', 'Boston', 'Orlando',
    '01-APR-2003', '08-APR-2003'),
  event_type => 'AddFlight');
DBMS_RLMGR.PROCESS_RULES (  
  rule_class => 'Scott.CompTravelPromo',
  event_inst =>
    AnyData.convertObject(AddRentalCar(987, 'Luxury', '03-APR-2003',
    '08-APR-2003', NULL)));
END;
```
PURGE_EVENTS Procedure

This procedure resets the incremental state maintained by the rule class by removing all the events associated with the rule class and purging any state information pertaining to rules matching some events.

Syntax

```sql
DBMS_RLMGR.PURGE_EVENTS (
    rule_class IN  VARCHAR2);
```

Parameters

Table 124–24  PURGE_EVENTS Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of rule class in the current schema</td>
</tr>
</tbody>
</table>

Usage Notes

- Use this procedure while developing rules applications using Rules Manager. You can test the rules defined in the rule class with hypothetical events and then remove all these events by issuing this procedure call. This call cleans up all the events in the events repository and purges any partial state information associated with the matching rules.

Examples

The following command removes the events associated with the CompTravelPromo rule class:

```sql
BEGIN
    DBMS_RLMGR.PURGE_EVENTS (rule_class => 'CompTravelPromo');
END;
/
RESET_SESSION Procedure

This procedure starts a new session and thus discards the results in the rule class results view.

Syntax

```
DBMS_RLMGR.RESET_SESSION  (
    rule_class  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of rule class. A schema extended rule class name can be used to refer to a rule class that does not belong to the current schema.</td>
</tr>
</tbody>
</table>

Usage Notes

- When you use the ADD_EVENT procedure to add events to the rule class, the results from matching rules with events are recorded in the rule class results view. By default, these results are reset at the end of the database session. Alternately, you can use the RESET_SESSION Procedure to reset and start a new rule session within a database session.
- This procedure is only applicable while using ADD_EVENT Procedure to evaluate the rules.

Examples

The following command resets a rule class session.

```
BEGIN
    DBMS_RLMGR.RESET_SESSION(
        rule_class => 'CompTravelPromo');
END;
```
REVOKE_PRIVILEGE Procedure

This procedure revokes privileges on a rule class from another user.

Syntax

```
DBMS_RLMGR.REVOKE_PRIVILEGE  (
    rule_class      IN  VARCHAR2,
    priv_type       IN  VARCHAR2,
    from_user       IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class in the current schema</td>
</tr>
<tr>
<td>priv_type</td>
<td>Type of rule class privilege to be revoked</td>
</tr>
<tr>
<td>from_user</td>
<td>User from whom the privilege is to be revoked</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure revokes appropriate privileges from a user. The types of privileges that can be revoked are the same as the types listed in the description of the GRANT_PRIVILEGE Procedure. Rule class privileges cannot be revoked from the owner of the rule class.

Examples

The following command revokes PROCESS RULES privilege on TravelPromo rule class from the user SCOTT.

```
BEGIN
    DBMS_RLMGR.REVOKE_PRIVILEGE(
        rule_class  => 'TravelPromo',
        priv_type   => 'PROCESS RULES',
        from_user   => 'SCOTT');
END;
```
SYNC_TEXT_INDEXES Procedure

This procedure synchronizes the indexes defined to process the predicates involving the CONTAINS operator in rule conditions.

Syntax

```sql
DBMS_RLMGR.SYNC_TEXT_INDEXES (
    rule_class IN   VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_class</td>
<td>Name of the rule class in the current schema</td>
</tr>
</tbody>
</table>

Usage Notes

- When a rule class is configured for events with one or more text attributes, the text predicates in the corresponding rule conditions are processed using CTXRULE indexes. Unlike other types of indexes (bitmap for scalar and XML predicates or spatial for spatial predicates) used to process other types of predicates in the rule conditions, the CTXRULE indexes are not transactional in nature. That is, if the text predicates in a rule condition are modified in a database transaction, the new predicates are not automatically reflected in the corresponding CTXRULE index. This could result in inconsistent results while matching events with the rule conditions. All the CTXRULE indexes associated with a rule class can be synchronized with the latest rule conditions using this procedure.

  You must have EXECUTE privilege on the CTX_DDL package for successful synchronization of the text indexes.

Examples

The following command synchronizes any text indexes associated with the CompTravelPromo rule class:

```sql
BEGIN
    DBMS_RLMGR.SYNC_TEXT_INDEXES (rule_class => 'CompTravelPromo');
END;
/
```
The DBMS_RLS package contains the fine-grained access control administrative interface, which is used to implement Virtual Private Database (VPD). DBMS_RLS is available with the Enterprise Edition only.

See Also: Oracle Database Security Guide for usage information on DBMS_RLS.

This chapter contains the following topics:

- **Using DBMS_RLS**

  - Security Model
  - Operational Notes

- **Summary of DBMS_RLS Subprograms**
Using DBMS_RLS

- Overview
- Security Model
- Operational Notes
Overview

The functionality to support fine-grained access control is based on dynamic predicates, where security rules are not embedded in views, but are acquired at the statement parse time, when the base table or view is referenced in a DML statement.

A dynamic predicate for a table, view, or synonym is generated by a PL/SQL function, which is associated with a security policy through a PL/SQL interface. For example:

```plsql
DBMS_RLS.ADD_POLICY (    'hr', 'employees', 'emp_policy', 'hr', 'emp_sec', 'select');
```

Whenever the `employees` table, under the HR schema, is referenced in a query or subquery (SELECT), the server calls the `EMP_SEC` function (under the HR schema). This function returns a predicate specific to the current user for the `emp_policy` policy. The policy function may generate the predicates based on the session environment variables available during the function call. These variables usually appear in the form of application contexts. The policy can specify any combination of security-relevant columns and of these statement types: INDEX, SELECT, INSERT, UPDATE, or DELETE.

The server then produces a transient view with the text:

```sql
SELECT * FROM hr.employees WHERE P1
```

Here, `P1` (for example, where `SAL > 10000`, or even a subquery) is the predicate returned from the `EMP_SEC` function. The server treats the `employees` table as a view and does the view expansion just like the ordinary view, except that the view text is taken from the transient view instead of the data dictionary.

If the predicate contains subqueries, then the owner (definer) of the policy function is used to resolve objects within the subqueries and checks security for those objects. In other words, users who have access privilege to the policy-protected objects do not need to know anything about the policy. They do not need to be granted object privileges for any underlying security policy. Furthermore, the users do not require `EXECUTE` privilege on the policy function, because the server makes the call with the function definer’s right.

---

**Note:** The transient view can preserve the updatability of the parent object because it is derived from a single table or view with predicate only; that is, no JOIN, ORDER BY, GROUP BY, and so on.

---

DBMS_RLS also provides the interface to drop or enable security policies. For example, you can drop or enable the `EMP_POLICY` with the following PL/SQL statements:

```plsql
DBMS_RLS.DROP_POLICY('hr', 'employees', 'emp_policy');
DBMS_RLS.ENABLE_POLICY('hr', 'employees', 'emp_policy', TRUE);
```
A security check is performed when the transient view is created with a subquery. The schema owning the policy function, which generates the dynamic predicate, is the transient view’s definer for security check and object lookup.
Operational Notes

The DBMS_RLS procedures cause current DML transactions, if any, to commit before the operation. However, the procedures do not cause a commit first if they are inside a DDL event trigger. With DDL transactions, the DBMS_RLS procedures are part of the DDL transaction.

For example, you may create a trigger for CREATE TABLE. Inside the trigger, you may add a column through ALTER TABLE, and you can add a policy through DBMS_RLS. All these operations are in the same transaction as CREATE TABLE, even though each one is a DDL statement. The CREATE TABLE succeeds only if the trigger is completed successfully.

Views of current cursors and corresponding predicates are available from v$vpd_policies.

A synonym can reference only a view or a table.

ADD_GROUPED_POLICY Procedure

This procedure adds a policy associated with a policy group.

Syntax

```sql
DBMS_RLS.ADD_GROUPED_POLICY(
    object_schema         IN VARCHAR2 NULL,
    object_name           IN VARCHAR2,
    policy_group          IN VARCHAR2 'SYS_DEFAULT',
    policy_name           IN VARCHAR2,
    function_schema       IN VARCHAR2 NULL,
    policy_function       IN VARCHAR2,
    statement_types       IN VARCHAR2 NULL,
    update_check          IN BOOLEAN FALSE,
    enable                IN BOOLEAN TRUE,
    static_policy         IN BOOLEAN FALSE,
    policy_type           IN BINARY_INTEGER NULL,
    long_predicate           BOOLEAN FALSE,
    sec_relevant_cols     IN VARCHAR2,
    sec_relevant_cols_opt IN BINARY_INTEGER NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym. The default is NULL, which means that the current user schema is used as the object_schema.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym to which the policy is added.</td>
</tr>
<tr>
<td>policy_group</td>
<td>The name of the policy group that the policy belongs to.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The name of the policy; must be unique for the same table or view.</td>
</tr>
<tr>
<td>function_schema</td>
<td>The schema owning the policy function. The default is NULL, which means that the current user schema is used as the function_schema.</td>
</tr>
<tr>
<td>policy_function</td>
<td>The name of the function that generates a predicate for the policy. If the function is defined within a package, the name of the package must be present.</td>
</tr>
<tr>
<td>statement_types</td>
<td>Statement types to which the policy applies. It can be any combination of INDEX, SELECT, INSERT, UPDATE, or DELETE. The default is to apply to all of these types except INDEX.</td>
</tr>
<tr>
<td>update_check</td>
<td>For INSERT and UPDATE statements only, setting update_check to TRUE causes the server to check the policy against the value after INSERT or UPDATE.</td>
</tr>
<tr>
<td>enable</td>
<td>Indicates if the policy is enable when it is added. The default is TRUE.</td>
</tr>
<tr>
<td>static_policy</td>
<td>The default is FALSE. If it is set to TRUE, the server assumes that the policy function for the static policy produces the same predicate string for anyone accessing the object, except for SYS or the privilege user who has the EXEMPT_ACCESS POLICY privilege.</td>
</tr>
</tbody>
</table>
## ADD_GROUPED_POLICY Procedure

### Usage Notes

- This procedure adds a policy to the specified table, view, or synonym and associates the policy with the specified policy group.
- The policy group must have been created by using the `CREATE_POLICY_GROUP Procedure` on page 125-14.
- The policy name must be unique within a policy group for a specific object.
- Policies from the default policy group, SYS_DEFAULT, are always executed regardless of the active policy group; however, fine-grained access control policies do not apply to users with EXEMPT ACCESS POLICY system privilege.
- If no `object_schema` is specified, the current user's schema is assumed.
- If no `function_schema` is specified, the current user's schema is assumed.

### Table 125–2 (Cont.) ADD_GROUPED_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>policy_type</td>
<td>Default is NULL, which means policy_type is decided by the value of static_policy. The available policy types are listed in Table 125–4. Specifying any of these policy types overrides the value of static_policy.</td>
</tr>
<tr>
<td>long_predicate</td>
<td>Default is FALSE, which means the policy function can return a predicate with a length of up to 4000 bytes. TRUE means the predicate text string length can be up to 32K bytes. Policies existing prior to the availability of this parameter retain a 32K limit.</td>
</tr>
<tr>
<td>sec_relevant_cors</td>
<td>Enables column-level Virtual Private Database (VPD), which enforces security policies when a column containing sensitive information is referenced in a query. Applies to tables and views, but not to synonyms. Specify a list of comma- or space-separated valid column names of the policy-protected object. The policy is enforced only if a specified column is referenced (or, for an abstract datatype column, its attributes are referenced) in the user SQL statement or its underlying view definition. Default is all the user-defined columns for the object.</td>
</tr>
<tr>
<td>sec_relevant_cors_opt</td>
<td>Use with <code>sec_relevant_cors</code> to display all rows for column-level VPD filtered queries (SELECT only), but where sensitive columns appear as NULL. Default is set to NULL, which allows the filtering defined with <code>sec_relevant_cors</code> to take effect. Set to <code>dbms_rls.ALL_ROWS</code> to display all rows, but with sensitive column values, which are filtered by <code>sec_relevant_cors</code>, displayed as NULL. See &quot;Usage Notes&quot; on page 125-11 for restrictions and additional information about this option.</td>
</tr>
</tbody>
</table>
ADD_Policy Procedure

This procedure adds a fine-grained access control policy to a table, view, or synonym. The procedure causes the current transaction, if any, to commit before the operation is carried out. However, this does not cause a commit first if it is inside a DDL event trigger.

See Also: Operational Notes on page 125-5

A COMMIT is also performed at the end of the operation.

Syntax

```sql
DBMS_RLS.ADD_POLICY ( 
object_schema            IN VARCHAR2 NULL, 
object_name              IN VARCHAR2, 
policy_name              IN VARCHAR2, 
function_schema          IN VARCHAR2 NULL, 
policy_function          IN VARCHAR2, 
statement_types          IN VARCHAR2 NULL, 
update_check             IN BOOLEAN  FALSE, 
enable                   IN BOOLEAN  TRUE, 
static_policy            IN BOOLEAN  FALSE, 
policy_type              IN BINARY_INTEGER NULL, 
long_predicate           IN BOOLEAN  FALSE, 
sec_relevant_cols        IN VARCHAR2 NULL, 
sec_relevant_cols_opt    IN BINARY_INTEGER NULL);
```

Parameters

### Table 125-3  ADD_Policy Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema containing the table, view, or synonym. If no object_schema is specified, the current user’s schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table, view, or synonym to which the policy is added.</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be added. It must be unique for the same table or view.</td>
</tr>
<tr>
<td>function_schema</td>
<td>Schema of the policy function (current default schema, if NULL). If no function_schema is specified, the current user’s schema is assumed.</td>
</tr>
<tr>
<td>policy_function</td>
<td>Name of a function which generates a predicate for the policy. If the function is defined within a package, then the name of the package must be present.</td>
</tr>
<tr>
<td>statement_types</td>
<td>Statement types to which the policy applies. It can be any combination of INDEX, SELECT, INSERT, UPDATE, or DELETE. The default is to apply to all of these types except INDEX.</td>
</tr>
<tr>
<td>update_check</td>
<td>Optional argument for INSERT or UPDATE statement types. The default is FALSE. Setting update_check to TRUE causes the server to also check the policy against the value after insert or update.</td>
</tr>
<tr>
<td>enable</td>
<td>Indicates if the policy is enabled when it is added. The default is TRUE.</td>
</tr>
</tbody>
</table>
ADD_POLICY Procedure

The default is FALSE. If it is set to TRUE, the server assumes that the policy function for the static policy produces the same predicate string for anyone accessing the object, except for SYS or the privileged user who has the EXEMPT ACCESS POLICY privilege.

Default is NULL, which means policy_type is decided by the value of static_policy. The available policy types are listed in Table 125–4. Specifying any of these policy types overrides the value of static_policy.

Default is FALSE, which means the policy function can return a predicate with a length of up to 4000 bytes. TRUE means the predicate text string length can be up to 32K bytes. Policies existing prior to the availability of this parameter retain a 32K limit.

Enables column-level Virtual Private Database (VPD), which enforces security policies when a column containing sensitive information is referenced in a query. Applies to tables and views, but not to synonyms. Specify a list of comma- or space-separated valid column names of the policy-protected object. The policy is enforced only if a specified column is referenced (or, for an abstract datatype column, its attributes are referenced) in the user SQL statement or its underlying view definition. Default is all the user-defined columns for the object.

Use with sec_relevant_cols to display all rows for column-level VPD filtered queries (SELECT only), but where sensitive columns appear as NULL. Default is set to NULL, which allows the filtering defined with sec_relevant_cols to take effect. Set to dbms_rls.ALL_ROWS to display all rows, but with sensitive column values, which are filtered by sec_relevant_cols, displayed as NULL. See "Usage Notes" on page 125-11 for restrictions and additional information about this option.

<table>
<thead>
<tr>
<th>Policy Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>STATIC</td>
<td>Predicate is assumed to be the same regardless of the runtime environment. Static policy functions are executed once and then cached in SGA. Statements accessing the same object do not reexecute the policy function. However, each execution of the same cursor could produce a different row set even for the same predicate because the predicate may filter the data differently based on attributes such as SYS_CONTEXT or SYSDATE. Applies to only one object.</td>
</tr>
<tr>
<td>SHARED_STATIC</td>
<td>Same as STATIC except that the server first looks for a cached predicate generated by the same policy function of the same policy type. Shared across multiple objects.</td>

<td>The default policy type. Server assumes the predicate may be affected by any system or session environment at any time, and so always reexecutes the policy function upon each statement parsing and execution. Applies to only one object.</td>
</tr>
</tbody>
</table>
Usage Notes

- SYS is free of any security policy.
- If no object_schema is specified, the current user’s schema is assumed.
- If no function_schema is specified, the current user’s schema is assumed.
- The policy functions are called by the server. Following is the interface for the function:

  ```
  FUNCTION policy_function (object_schema IN VARCHAR2, object_name VARCHAR2) 
  RETURN VARCHAR2 
  
  --- object_schema is the schema owning the table or view.
  --- object_name is the name of table, view, or synonym to which the policy applies.
  ```

- The policy functions must have the purity level of WNDS (write no database state).

  **See Also:** The Oracle Database Advanced Application Developer’s Guide has more details about the RESTRICT_REFERENCES pragma.

- Predicates generated from different VPD policies for the same object have the combined effect of a conjunction (anded) of all the predicates.
- The security check and object lookup are performed against the owner of the policy function for objects in the subqueries of the dynamic predicates.
- If the function returns a zero length predicate, then it is interpreted as no restriction being applied to the current user for the policy.
- When a table alias is required (for example, parent object is a type table) in the predicate, the name of the table or view itself must be used as the name of the alias. The server constructs the transient view as something like

  ```
  *select c1, c2, ... from tab tab where <predicate>*
  ```

- Validity of the function is checked at runtime for ease of installation and other dependency issues during import and export.
- Column-level VPD column masking behavior (specified with sec_relevant_cols_opt => dbms_rls.ALL_ROWS) is fundamentally different from all other VPD policies, which return only a subset of rows. Instead the column masking behavior returns all rows specified by the user’s query, but the sensitive column values display as NULL. The restrictions for this option are as follows:
  - Only applies to SELECT statements
  - Unlike regular VPD predicates, the masking condition that is generated by the policy function must be a simple boolean expression.
  - If your application performs calculations, or does not expect NULL values, then you should use the default behavior of column-level VPD, which is specified with the sec_relevant_cols parameter.
  - If you use UPDATE AS SELECT with this option, then only the values in the columns you are allowed to see will be updated.
  - This option may prevent some rows from displaying. For example:

    ```
    select * from employees
    where salary = 10
    ```
This query may not return rows if the salary column returns a NULL value because the column masking option has been set.

- When you add a VPD policy to a synonym, it causes all the dependent objects of the synonym, including policy functions that reference the synonym, to be marked INVALID.

Examples

As the first of two examples, the following creates a policy that applies to the hr.employee table. This is a column-level VPD policy that will be enforced only if a SELECT or an INDEX statement refers to the salary, birthdate, or SSN columns of the table explicitly, or implicitly through a view. It is also a CONTEXT_SENSITIVE policy, so the server will invoke the policy function hr.hrfun at parse time. During execution, it will only invoke the function if there has been any session private context change since the last use of the statement cursor. The predicate generated by the policy function must not exceed 4000 bytes, the default length limit, since the long_predicate parameter is omitted from the call.

```sql
BEGIN
  dbms_rls.add_policy(object_schema => 'hr',
                       object_name => 'employee',
                       policy_name => 'hr_policy',
                       function_schema => 'hr',
                       policy_function => 'hrfun',
                       statement_types => 'select,index',
                       policy_type => dbms_rls.CONTEXT_SENSITIVE,
                       sec_relevant_cols => 'salary,birthdate,ssn');
END;
/
```

As the second example, the following command creates another policy that applies to the same object for hosting, so users can access only data based on their subscriber ID. Since it is defined as a SHARED_STATIC policy type, the server will first try to find the predicate in the SGA cache. The server will only invoke the policy function, subfun, if that search fails.

```sql
BEGIN
  dbms_rls.add_policy(object_schema => 'hr',
                       object_name => 'employee',
                       policy_name => 'hosting_policy',
                       function_schema => 'hr',
                       policy_function => 'subfun',
                       policy_type => dbms_rls.SHARED_STATIC);
END;
/
```
ADD_POLICY_CONTEXT Procedure

This procedure adds the context for the active application.

Syntax

```
DBMS_RLS.ADD_POLICY_CONTEXT (  
  object_schema   IN VARCHAR2 NULL,  
  object_name     IN VARCHAR2,  
  namespace       IN VARCHAR2,  
  attribute       IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym to which the policy is added.</td>
</tr>
<tr>
<td>namespace</td>
<td>The namespace of the driving context</td>
</tr>
<tr>
<td>attribute</td>
<td>The attribute of the driving context</td>
</tr>
</tbody>
</table>

Usage Notes

Note the following:

- This procedure indicates the application context that drives the enforcement of policies; this is the context that determines which application is running.
- If no object_schema is specified, the current user's schema is assumed.
- The driving context can be session or global.
- At execution time, the server retrieves the name of the active policy group from the value of this context.
- There must be at least one driving context defined for each object that has fine-grained access control policies; otherwise, all policies for the object will be executed.
- Adding multiple context to the same object will cause policies from multiple policy groups to be enforced.
- If the driving context is NULL, policies from all policy groups are used.
- If the driving context is a policy group with policies, all enabled policies from that policy group will be applied, along with all policies from the SYS_DEFAULT policy group.
- To add a policy to table hr.employees in group access_control_group, the following command is issued:

```
DBMS_RLS.ADD_GROUPED_POLICY('hr','employees','access_control_group','policy1','SYS', 'HR.ACCESS');
```
CREATE_POLICY_GROUP Procedure

This procedure creates a policy group.

Syntax

```sql
DBMS_RLS.CREATE_POLICY_GROUP (
    object_schema   IN VARCHAR2 NULL,
    object_name     IN VARCHAR2,
    policy_group    IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema containing the table, view, or synonym.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the table, view, or synonym to which the policy is added.</td>
</tr>
<tr>
<td>policy_group</td>
<td>Name of the policy group that the policy belongs to.</td>
</tr>
</tbody>
</table>

Usage Notes

The group must be unique for each table or view.
DELETE_POLICY_GROUP Procedure

This procedure deletes a policy group.

Syntax

```sql
DBMS_RLS.DELETE_POLICY_GROUP ( 
    object_schema   IN VARCHAR2 NULL,
    object_name     IN VARCHAR2,
    policy_group    IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym to which the policy is added.</td>
</tr>
<tr>
<td>policy_group</td>
<td>The name of the policy group that the policy belongs to.</td>
</tr>
</tbody>
</table>

Usage Notes

Note the following:

- This procedure deletes a policy group for the specified table, view, or synonym.
- No policy can be in the policy group.
DISABLEGROUPED_POLICY Procedure

This procedure disables a row-level group security policy.

Syntax

```sql
DBMS_RLS.DISABLE_GROUPED_POLICY (object_schema IN VARCHAR2 NULL,
object_name IN VARCHAR2,
group_name IN VARCHAR2,
policy_name IN VARCHAR2);
```

Parameters

**Table 125–8 ENABLE_GROUPED_POLICY Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym with which the policy is associated.</td>
</tr>
<tr>
<td>group_name</td>
<td>The name of the group of the policy.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The name of the policy to be enabled or disabled.</td>
</tr>
</tbody>
</table>

Usage Notes

- The procedure causes the current transaction, if any, to commit before the operation is carried out.
- A commit is performed at the end of the operation.
- A policy is disabled when this procedure is executed or when the ENABLE_GROUPED_POLICY procedure is executed with “enable” set to FALSE.
DROP_GROUPED_POLICY Procedure

This procedure drops a policy associated with a policy group.

Syntax

```sql
DBMS_RLS.DROP_GROUPED_POLICY (  
    object_schema   IN VARCHAR2 NULL,  
    object_name     IN VARCHAR2,  
    policy_group    IN VARCHAR2 'SYS_DEFAULT',  
    policy_name     IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym to which the policy is dropped.</td>
</tr>
<tr>
<td>policy_group</td>
<td>The name of the policy group that the policy belongs to.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The name of the policy.</td>
</tr>
</tbody>
</table>
DROP_POLICY Procedure

This procedure drops a fine-grained access control policy from a table, view, or synonym.

The procedure causes the current transaction, if any, to commit before the operation is carried out. However, this does not cause a commit first if it is inside a DDL event trigger.

See Also: Operational Notes on page 125-5

A COMMIT is also performed at the end of the operation.

Syntax

```sql
DBMS_RLS.DROP_POLICY (  
    object_schema   IN VARCHAR2 NULL,  
    object_name     IN VARCHAR2,  
    policy_name     IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema containing the table, view or synonym. If no object_schema is specified, or NULL is provided, then the current user's schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the table, view, or synonym for which the policy is dropped.</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be dropped from table, view, or synonym.</td>
</tr>
</tbody>
</table>

Usage Notes

- When you drop a VPD policy from a synonym, it causes all the dependent objects of the synonym, including policy functions that reference the synonym, to be marked INVALID.
DROP_POLICY_CONTEXT Procedure

This procedure drops a driving context from the object so that it will have one less driving context.

Syntax

```sql
DBMS_RLS.DROP_POLICY_CONTEXT (  
    object_schema   IN VARCHAR2 NULL,  
    object_name     IN VARCHAR2,  
    namespace       IN VARCHAR2,  
    attribute       IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym. If no object_schema is specified, or NULL is provided, then the current user's schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym to which the policy is dropped.</td>
</tr>
<tr>
<td>namespace</td>
<td>The namespace of the driving context.</td>
</tr>
<tr>
<td>attribute</td>
<td>The attribute of the driving context.</td>
</tr>
</tbody>
</table>
ENABLE_GROUPED_POLICY Procedure

This procedure enables or disables a row-level group security policy.

Syntax

```sql
DBMS_RLS.ENABLE_GROUPED_POLICY (  
    object_schema   IN VARCHAR2 NULL,
    object_name     IN VARCHAR2,
    group_name      IN VARCHAR2,
    policy_name     IN VARCHAR2,
    enable          IN BOOLEAN TRUE);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym. If no object_schema is specified, or NULL is provided, then the current user's schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym with which the policy is associated.</td>
</tr>
<tr>
<td>group_name</td>
<td>The name of the group of the policy.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The name of the policy to be enabled or disabled.</td>
</tr>
<tr>
<td>enable</td>
<td>TRUE enables the policy; FALSE disables the policy.</td>
</tr>
</tbody>
</table>

Usage Notes

- The procedure causes the current transaction, if any, to commit before the operation is carried out.
- A commit is performed at the end of the operation.
- A policy is enabled when it is created.
**ENABLE_POLICY Procedure**

This procedure enables or disables a fine-grained access control policy. A policy is enabled when it is created.

The procedure causes the current transaction, if any, to commit before the operation is carried out. However, this does not cause a commit first if it is inside a DDL event trigger.

**See Also:** Operational Notes on page 125-5

A COMMIT is also performed at the end of the operation.

**Syntax**

```
DBMS_RLS.ENABLE_POLICY (  
    object_schema IN VARCHAR2 NULL,  
    object_name   IN VARCHAR2,  
    policy_name   IN VARCHAR2,  
    enable        IN BOOLEAN TRUE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema containing table, view, or synonym. If no object_schema is specified, or NULL is provided, then the current user's schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table, view, or synonym with which the policy is associated.</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be enabled or disabled.</td>
</tr>
<tr>
<td>enable</td>
<td>TRUE to enable the policy, FALSE to disable the policy.</td>
</tr>
</tbody>
</table>
REFRESH_GROUPED_POLICY Procedure

This procedure reparses the SQL statements associated with a refreshed policy.

Syntax

```sql
DBMS_RLS.REFRESH_GROUPED_POLICY (
    object_schema   IN VARCHAR2 NULL,
    object_name     IN VARCHAR2 NULL,
    group_name      IN VARCHAR2 NULL,
    policy_name     IN VARCHAR2 NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>The schema containing the table, view, or synonym. If no object_schema is specified, or NULL is provided, then the current user's schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the table, view, or synonym with which the policy is associated.</td>
</tr>
<tr>
<td>group_name</td>
<td>The name of the group of the policy.</td>
</tr>
<tr>
<td>policy_name</td>
<td>The name of the policy.</td>
</tr>
</tbody>
</table>

Usage Notes

- This procedure causes all the cached statements associated with the policy to be reparsed. This guarantees that the latest change to the policy has immediate effect after the procedure is executed.
- The procedure causes the current transaction, if any, to commit before the operation is carried out.
- A commit is performed at the end of the operation.
- The procedure returns an error if it tries to refresh a disabled policy.
REFRESH_POLICY Procedure

This procedure causes all the cached statements associated with the policy to be reparsed. This guarantees that the latest change to this policy will have immediate effect after the procedure is executed.

The procedure causes the current transaction, if any, to commit before the operation is carried out. However, this does not cause a commit first if it is inside a DDL event trigger.

See Also: Operational Notes on page 125-5

A COMMIT is also performed at the end of the operation.

Syntax

DBMS_RLS.REFRESH_POLICY (object_schema IN VARCHAR2 NULL, object_name   IN VARCHAR2 NULL, policy_name   IN VARCHAR2 NULL);

Parameters

Table 125–15  REFRESH_POLICY Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>object_schema</td>
<td>Schema containing the table, view, or synonym. If no object_schema is specified, or NULL is provided, then the current user’s schema is assumed.</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of table, view, or synonym with which the policy is associated.</td>
</tr>
<tr>
<td>policy_name</td>
<td>Name of policy to be refreshed.</td>
</tr>
</tbody>
</table>

Usage Notes

The procedure returns an error if it tries to refresh a disabled policy.
REFRESH_POLICY Procedure
The DBMS_ROWID package lets you create ROWIDs and obtain information about ROWIDs from PL/SQL programs and SQL statements. You can find the data block number, the object number, and other ROWID components without writing code to interpret the base-64 character external ROWID. DBMS_ROWID is intended for upgrading from Oracle database version 7 to Oracle database version 8.X.

**Note:** DBMS_ROWID is not to be used with universal ROWIDs (UROWIDs).

This chapter contains the following topics:

- Using DBMS_ROWID
  - Security Model
  - Types
  - Exceptions
  - Operational Notes
  - Examples
- Summary of DBMS_ROWID Subprograms
Using DBMS_ROWID

- Security Model
- Types
- Exceptions
- Operational Notes
- Examples
Security Model

This package runs with the privileges of calling user, rather than the package owner SYST.
Types

- Extension and Restriction Types
- Verification Types
- Object Types
- Conversion Types

Extension and Restriction Types

The types are as follows:

- RESTRICTED—restricted ROWID
- EXTENDED—extended ROWID

For example:

```sql
rowid_type_restricted constant integer := 0;
rowid_type_extended   constant integer := 1;
```

Note: Extended ROWIDs are only used in Oracle database version 8.Xi and higher.

Verification Types

<table>
<thead>
<tr>
<th>Table 126–1 Verification Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result</td>
</tr>
<tr>
<td>VALID</td>
</tr>
<tr>
<td>INVALID</td>
</tr>
</tbody>
</table>

For example:

```sql
rowid_is_valid   constant integer := 0;
rowid_is_invalid constant integer := 1;
```

Object Types

<table>
<thead>
<tr>
<th>Table 126–2 Object Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result</td>
</tr>
<tr>
<td>UNDEFINED</td>
</tr>
</tbody>
</table>

For example:

```sql
rowid_object_undefined constant integer := 0;
```

Conversion Types

<table>
<thead>
<tr>
<th>Table 126–3 Conversion Types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Result</td>
</tr>
<tr>
<td>INTERNAL</td>
</tr>
<tr>
<td>EXTERNAL</td>
</tr>
</tbody>
</table>
For example:

rowid_convert_internal constant integer := 0;
rowid_convert_external constant integer := 1;
Exceptions

<table>
<thead>
<tr>
<th>Exception</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWID_INVALID</td>
<td>Invalid rowid format</td>
</tr>
<tr>
<td>ROWID_BAD_BLOCK</td>
<td>Block is beyond end of file</td>
</tr>
</tbody>
</table>

For example:

```sql
ROWID_INVALID exception;
    pragma exception_init(ROWID_INVALID, -1410);

ROWID_BAD_BLOCK exception;
    pragma exception_init(ROWID_BAD_BLOCK, -28516);
```
Operational Notes

- Some of the functions in this package take a single parameter, such as a ROWID. This can be a character or a PL/SLQ ROWID, either restricted or extended, as required.
- You can call the DBMS_ROWID functions and procedures from PL/SQL code, and you can also use the functions in SQL statements.

Note: ROWID_INFO is a procedure. It can only be used in PL/SQL code.

- You can use functions from the DBMS_ROWID package just like built-in SQL functions; in other words, you can use them wherever you can use an expression. In this example, the ROWID_BLOCK_NUMBER function is used to return just the block number of a single row in the EMP table:

  ```sql
  SELECT DBMS_ROWID.ROWID_BLOCK_NUMBER(rowid)
  FROM emp
  WHERE ename = 'KING';
  ```

- If Oracle returns the error "ORA:452, 0, 'Subprogram '%s' violates its associated pragma' for pragma restrict_references," it could mean the violation is due to:
  - A problem with the current procedure or function
  - Calling a procedure or function without a pragma or due to calling one with a less restrictive pragma
  - Calling a package procedure or function that touches the initialization code in a package or that sets the default values
Examples

This example returns the \texttt{ROWID} for a row in the \texttt{EMP} table, extracts the data object number from the \texttt{ROWID}, using the \texttt{ROWID\_OBJECT} function in the \texttt{DBMS\_ROWID} package, then displays the object number:

\begin{verbatim}
DECLARE
    object_no   INTEGER;
    row_id      ROWID;
    ...
BEGIN
    SELECT ROWID INTO row_id FROM emp
        WHERE empno = 7499;
    object_no := DBMS\_ROWID\_OBJECT(row_id);
    DBMS\_OUTPUT\_PUT\_LINE('The obj. # is '|| object_no);
    ...
\end{verbatim}
## Summary of DBMS_ROWID Subprograms

### Table 126–5  
DBMS_ROWID Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ROWID_BLOCK_NUMBER Function</td>
<td>Returns the block number of a ROWID</td>
</tr>
<tr>
<td>ROWID_CREATE Function</td>
<td>Creates a ROWID, for testing only</td>
</tr>
<tr>
<td>ROWID_INFO Procedure</td>
<td>Returns the type and components of a ROWID</td>
</tr>
<tr>
<td>ROWID_OBJECT Function</td>
<td>Returns the object number of the extended ROWID</td>
</tr>
<tr>
<td>ROWID_RELATIVE_FNO Function</td>
<td>Returns the file number of a ROWID</td>
</tr>
<tr>
<td>ROWID_ROW_NUMBER Function</td>
<td>Returns the row number</td>
</tr>
<tr>
<td>ROWID_TO_ABSOLUTE_FNO Function</td>
<td>Returns the absolute file number associated with the ROWID for a row in a specific table</td>
</tr>
<tr>
<td>ROWID_TO_EXTENDED Function</td>
<td>Converts a ROWID from restricted format to extended</td>
</tr>
<tr>
<td>ROWID_TO_RESTRICTED Function</td>
<td>Converts an extended ROWID to restricted format</td>
</tr>
<tr>
<td>ROWID_TYPE Function</td>
<td>Returns the ROWID type: 0 is restricted, 1 is extended</td>
</tr>
<tr>
<td>ROWID_VERIFY Function</td>
<td>Checks if a ROWID can be correctly extended by the ROWID_TO_EXTENDED function</td>
</tr>
</tbody>
</table>
ROWID_BLOCK_NUMBER Function

This function returns the database block number for the input ROWID.

Syntax

```sql
DBMS_ROWID.ROWID_BLOCK_NUMBER (
    row_id      IN   ROWID,
    ts_type_in  IN   VARCHAR2 DEFAULT 'SMALLFILE')
RETURN NUMBER;
```

Pragmas

```sql
pragma RESTRICT_REFERENCES(rowid_block_number,WNDS,RNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id</td>
<td>ROWID to be interpreted</td>
</tr>
<tr>
<td>ts_type_in</td>
<td>The type of the tablespace (bigfile/smallfile) to which the row belongs</td>
</tr>
</tbody>
</table>

Examples

The example SQL statement selects the block number from a ROWID and inserts it into another table:

```sql
INSERT INTO T2 (SELECT dbms_rowid.rowid_block_number(ROWID, 'BIGFILE')
FROM some_table
WHERE key_value = 42);
```
ROWID_CREATE Function

This function lets you create a ROWID, given the component parts as parameters. This is useful for testing ROWID operations, because only the Oracle Server can create a valid ROWID that points to data in a database.

Syntax

```sql
DBMS_ROWID.ROWID_CREATE (  
    rowid_type    IN NUMBER,  
    object_number IN NUMBER,  
    relative_fno  IN NUMBER,  
    block_number  IN NUMBER,  
    row_number    IN NUMBER)  
RETURN ROWID;
```

Pragmas

```
pragma RESTRICT_REFERENCES(rowid_create,WNDS,RNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowid_type</td>
<td>Type (restricted or extended)</td>
</tr>
<tr>
<td></td>
<td>Set the rowid_type parameter to 0 for a restricted ROWID. Set it to 1 to</td>
</tr>
<tr>
<td></td>
<td>create an extended ROWID.</td>
</tr>
<tr>
<td></td>
<td>If you specify rowid_type as 0, then the required object_number parameter</td>
</tr>
<tr>
<td></td>
<td>is ignored, and ROWID_CREATE returns a restricted ROWID.</td>
</tr>
<tr>
<td>object_number</td>
<td>Data object number (rowid_object_undefined for restricted)</td>
</tr>
<tr>
<td>relative_fno</td>
<td>Relative file number</td>
</tr>
<tr>
<td>block_number</td>
<td>Block number in this file</td>
</tr>
<tr>
<td>row_number</td>
<td>Returns row number in this block</td>
</tr>
</tbody>
</table>

Examples

Create a dummy extended ROWID:

```sql
my_rowid := DBMS_ROWID.ROWID_CREATE(1, 9999, 12, 1000, 13);
```

Find out what the rowid_object function returns:

```sql
obj_number := DBMS_ROWID.ROWID_OBJECT(my_rowid);
```

The variable obj_number now contains 9999.
ROWID_INFO Procedure

This procedure returns information about a ROWID, including its type (restricted or extended), and the components of the ROWID. This is a procedure, and it cannot be used in a SQL statement.

Syntax

DBMS_ROWID.ROWID_INFO (rowid_in IN ROWID,
                           rowid_type OUT NUMBER,
                           object_number OUT NUMBER,
                           relative_fno OUT NUMBER,
                           block_number OUT NUMBER,
                           row_number OUT NUMBER);

Pragmas

pragma RESTRICT_REFERENCES(rowid_info,WNDS,RNDS,WNPS,RNPS);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowid_in</td>
<td>ROWID to be interpreted. This determines if the ROWID is a restricted (0) or extended (1) ROWID.</td>
</tr>
<tr>
<td>rowid_type</td>
<td>Returns type (restricted/extended)</td>
</tr>
<tr>
<td>object_number</td>
<td>Returns data object number (rowid_object_undefined for restricted)</td>
</tr>
<tr>
<td>relative_fno</td>
<td>Returns relative file number</td>
</tr>
<tr>
<td>block_number</td>
<td>Returns block number in this file</td>
</tr>
<tr>
<td>row_number</td>
<td>Returns row number in this block</td>
</tr>
</tbody>
</table>

See Also: "ROWID_TYPE Function" on page 126-20

Examples

This example reads back the values for the ROWID that you created in the ROWID CREATE:

DBMS_ROWID.ROWID_INFO (my_rowid, rid_type, obj_num, file_num, block_num, row_num, 'BIGFILE');
ROWID_OBJECT Function

This function returns the data object number for an extended ROWID. The function returns zero if the input ROWID is a restricted ROWID.

Syntax

```sql
DBMS_ROWID.ROWID_OBJECT (  
    rowid_id IN ROWID)  
RETURN NUMBER;
```

Pragmas

```sql
pragma RESTRICT_REFERENCES(rowid_object,WNDS,RNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id</td>
<td>ROWID to be interpreted</td>
</tr>
</tbody>
</table>

**Note:** The ROWID_OBJECT_UNDEFINED constant is returned for restricted ROWIDs.

Examples

```sql
SELECT dbms_rowid.rowid_object(ROWID)  
    FROM emp  
    WHERE empno = 7499;
```
ROWID_RELATIVE_FNO Function

This function returns the relative file number of the ROWID specified as the IN parameter. (The file number is relative to the tablespace.)

Syntax

```
DBMS_ROWID.ROWID_RELATIVE_FNO (rowid_id IN ROWID, ts_type_in IN VARCHAR2 DEFAULT 'SMALLFILE') RETURN NUMBER;
```

Pragmas

```
pragma RESTRICT_REFERENCES(rowid_relative_fno,WNDS,RNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id ROWID</td>
<td>ROWID to be interpreted</td>
</tr>
<tr>
<td>ts_type_in VARCHAR2 DEFAULT 'SMALLFILE'</td>
<td>Type of the tablespace (bigfile/smallfile) to which the row belongs</td>
</tr>
</tbody>
</table>

Examples

The example PL/SQL code fragment returns the relative file number:

```
DECLARE
    file_number    INTEGER;
    rowid_val      ROWID;
BEGIN
    SELECT ROWID INTO rowid_val
    FROM dept
    WHERE loc = 'Boston';
    file_number :=
        dbms_rowid.rowid_relative_fno(rowid_val, 'SMALLFILE');
...
```
ROWID_ROW_NUMBER Function

This function extracts the row number from the ROWID IN parameter.

Syntax

DBMS_ROWID.ROWID_ROW_NUMBER (row_id IN ROWID)
RETURN NUMBER;

Pragmas

PRAGMA RESTRICT_REFERENCES(rowid_row_number,WNDS,RNDS,WNPS,RNPS);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id</td>
<td>ROWID to be interpreted.</td>
</tr>
</tbody>
</table>

Examples

Select a row number:

SELECT dbms_rowid.rowid_row_number(ROWID)
FROM emp
WHERE ename = 'ALLEN';
ROWID_TO_ABSOLUTE_FNO Function

This function extracts the absolute file number from a ROWID, where the file number is absolute for a row in a given schema and table. The schema name and the name of the schema object (such as a table name) are provided as IN parameters for this function.

Syntax

```sql
DBMS_ROWID.ROWID_TO_ABSOLUTE_FNO (
    row_id      IN ROWID,
    schema_name IN VARCHAR2,
    object_name IN VARCHAR2)
RETURN NUMBER;
```

Pragmas

```sql
pragma RESTRICT_REFERENCES(rowid_to_absolute_fno,WNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id</td>
<td>ROWID to be interpreted</td>
</tr>
<tr>
<td>schema_name</td>
<td>Name of the schema which contains the table</td>
</tr>
<tr>
<td>object_name</td>
<td>Table name</td>
</tr>
</tbody>
</table>

Examples

```sql
DECLARE
    abs_fno        INTEGER;
    rowid_val      CHAR(18);
    object_name    VARCHAR2(20) := 'EMP';
BEGIN
    SELECT ROWID INTO rowid_val
    FROM emp
    WHERE empno = 9999;
    abs_fno := dbms_rowid.rowid_to_absolute_fno(
        rowid_val, 'SCOTT', object_name);
END;
```

Note: For partitioned objects, the name must be a table name, not a partition or a sub/partition name.
**ROWID_TO_EXTENDED Function**

This function translates a restricted ROWID that addresses a row in a schema and table that you specify to the extended ROWID format. Later, it may be removed from this package into a different place.

**Syntax**

```sql
DBMS_ROWID.ROWID_TO_EXTENDED (
    old_rowid       IN ROWID,
    schema_name     IN VARCHAR2,
    object_name     IN VARCHAR2,
    conversion_type IN INTEGER)
RETURN ROWID;
```

**Pragmas**

```sql
pragma RESTRICT_REFERENCES(rowid_to_extended,WNDS,WNPS,RNPS);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>old_rowid</td>
<td>ROWID to be converted</td>
</tr>
<tr>
<td>schema_name</td>
<td>Name of the schema which contains the table (optional)</td>
</tr>
<tr>
<td>object_name</td>
<td>Table name (optional).</td>
</tr>
<tr>
<td>conversion_type</td>
<td>The following constants are defined:</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_INTERNAL (:=0)</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_EXTERNAL (:=1)</td>
</tr>
</tbody>
</table>

**Return Values**

ROWID_TO_EXTENDED returns the ROWID in the extended character format. If the input ROWID is NULL, then the function returns NULL. If a zero-valued ROWID is supplied (00000000.0000.0000), then a zero-valued restricted ROWID is returned.

**Examples**

Assume that there is a table called RIDS in the schema SCOTT, and that the table contains a column ROWID_COL that holds ROWIDs (restricted), and a column TABLE_COL that point to other tables in the SCOTT schema. You can convert the ROWIDs to extended format with the statement:

```sql
UPDATE SCOTT.RIDS
SET rowid_col =
    dbms_rowid.rowid_to_extended (
        rowid_col, 'SCOTT', TABLE_COL, 0);
```

**Usage Notes**

- If the schema and object names are provided as IN parameters, then this function verifies SELECT authority on the table named, and converts the restricted ROWID provided to an extended ROWID, using the data object number of the table. That ROWID_TO_EXTENDED returns a value, however, does not guarantee that the
converted ROWID actually references a valid row in the table, either at the time that the function is called, or when the extended ROWID is actually used.

- If the schema and object name are not provided (are passed as NULL), then this function attempts to fetch the page specified by the restricted ROWID provided. It treats the file number stored in this ROWID as the absolute file number. This can cause problems if the file has been dropped, and its number has been reused prior to the migration. If the fetched page belongs to a valid table, then the data object number of this table is used in converting to an extended ROWID value. This is very inefficient, and Oracle recommends doing this only as a last resort, when the target table is not known. The user must still know the correct table name at the time of using the converted value.

- If an extended ROWID value is supplied, the data object number in the input extended ROWID is verified against the data object number computed from the table name parameter. If the two numbers do not match, the INVALID_ROWID exception is raised. If they do match, the input ROWID is returned.

- ROWID_TO_EXTENDED cannot be used with partition tables.

**See Also:** The ROWID_VERIFY Function has a method to determine if a given ROWID can be converted to the extended format.
ROWID_TO_RESTRICTED Function

This function converts an extended ROWID into restricted ROWID format.

Syntax

```sql
DBMS_ROWID.ROWID_TO_RESTRICTED (
    old_rowid       IN ROWID,
    conversion_type IN INTEGER)
RETURN ROWID;
```

Pragmas

```sql
pragma RESTRICT_REFERENCES(rowid_to_restricted,WNDS,RNDS,WNPS,RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>old_rowid</td>
<td>ROWID to be converted</td>
</tr>
<tr>
<td>conversion_type</td>
<td>The following constants are defined:</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_INTERNAL (:=0)</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_EXTERNAL (:=1)</td>
</tr>
</tbody>
</table>
ROWID_TYPE Function

This function returns 0 if the ROWID is a restricted ROWID, and 1 if it is extended.

Syntax

```sql
DBMS_ROWID.ROWID_TYPE (rowid_id IN ROWID)
RETURN NUMBER;
```

Pragmas

```sql
pragma RESTRICT_REFERENCES(rowid_type, WNDS, RNDS, WNPS, RNPS);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_id</td>
<td>ROWID to be interpreted</td>
</tr>
</tbody>
</table>

Examples

```sql
IF DBMS_ROWID.ROWID_TYPE(my_rowid) = 1 THEN
    my_obj_num := DBMS_ROWID.ROWID_OBJECT(my_rowid);
```
ROWID_VERIFY Function

This function verifies the ROWID. It returns 0 if the input restricted ROWID can be converted to extended format, given the input schema name and table name, and it returns 1 if the conversion is not possible.

---

**Note:** You can use this function in a WHERE clause of a SQL statement, as shown in the example.

---

**Syntax**

```sql
DBMS_ROWID.ROWID_VERIFY (  
    rowid_in        IN ROWID,  
    schema_name     IN VARCHAR2,  
    object_name     IN VARCHAR2,  
    conversion_type IN INTEGER  
RETURN NUMBER;
```

**Pragmas**

```sql
pragma RESTRICT_REFERENCES(rowid_verify,WNDS,WNPS,RNPS);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rowid_in</td>
<td>ROWID to be verified</td>
</tr>
<tr>
<td>schema_name</td>
<td>Name of the schema which contains the table</td>
</tr>
<tr>
<td>object_name</td>
<td>Table name</td>
</tr>
<tr>
<td>conversion_type</td>
<td>The following constants are defined:</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_INTERNAL (:=0)</td>
</tr>
<tr>
<td></td>
<td>ROWID_CONVERT_EXTERNAL (:=1)</td>
</tr>
</tbody>
</table>

**Examples**

Considering the schema in the example for the ROWID_TO_EXTENDED function, you can use the following statement to find bad ROWIDs prior to conversion. This enables you to fix them beforehand.

```sql
SELECT ROWID, rowid_col  
FROM SCOTT.RIDS  
WHERE dbms_rowid.rowid_verify(rowid_col, NULL, NULL, 0) =1;
```

Summary of DBMS_RULE Subprograms

### Table 127–1  DBMS_RULE Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
</table>
| CLOSE_ITERATOR  
Procedure on page 127-6 | Closes an open iterator |
| EVALUATE Procedures on page 127-7 | Evaluates the rules in the specified rule set that use the evaluation context specified |
| GET_NEXT_HIT Function on page 127-11 | Returns the next rule that evaluated to `TRUE` from a true rules iterator, or returns the next rule that evaluated to `MAYBE` from a maybe rules iterator; returns `NULL` if there are no more rules that evaluated to `TRUE` or `MAYBE`. |
CLOSE_ITERATOR Procedure

This procedure closes an open iterator.

Syntax

```sql
DBMS_RULE.CLOSE_ITERATOR(
    iterator IN BINARY_INTEGER);
```

Parameter

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iterator</td>
<td>The iterator to be closed</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure requires an open iterator that was returned by an earlier call to `DBMS_RULE.EVALUATE` in the same session. The user who runs this procedure does not require any privileges on the rule set being evaluated.

Closing an iterator frees resources, such as memory, associated with the iterator. Therefore, Oracle recommends that you close an iterator when it is no longer needed.

See Also: EVALUATE Procedures on page 127-7
EVALUATE Procedures

This procedure evaluates the rules in the specified rule set that use the evaluation context specified for a specified event.

This procedure is overloaded. The `true_rules` and `maybe_rules` parameters are mutually exclusive with the `true_rules_iterator` and `maybe_rules_iterator` parameters. In addition, the procedure with the `true_rules` and `maybe_rules` parameters includes the `stop_on_first_hit` parameter, but the other procedure does not.

Syntax

```
DBMS_RULE.EVALUATE(
    rule_set_name   IN   VARCHAR2,
    evaluation_context   IN   VARCHAR2,
    event_context        IN   SYS.RE$NV_LIST               DEFAULT NULL,
    table_values   IN   SYS.RE$TABLE_VALUE_LIST      DEFAULT NULL,
    column_values   IN   SYS.RE$COLUMN_VALUE_LIST     DEFAULT NULL,
    variable_values   IN   SYS.RE$VARIABLE_VALUE_LIST   DEFAULT NULL,
    attribute_values   IN   SYS.RE$ATTRIBUTE_VALUE_LIST  DEFAULT NULL,
    stop_on_first_hit   IN   BOOLEAN                      DEFAULT FALSE,
    simple_rules_only   IN   BOOLEAN                      DEFAULT FALSE,
    true_rules   OUT  SYS.RE$RULE_HIT_LIST,
    maybe_rules   OUT  SYS.RE$RULE_HIT_LIST);
```

```
DBMS_RULE.EVALUATE(
    rule_set_name   IN   VARCHAR2,
    evaluation_context   IN   VARCHAR2,
    event_context        IN   SYS.RE$NV_LIST               DEFAULT NULL,
    table_values   IN   SYS.RE$TABLE_VALUE_LIST      DEFAULT NULL,
    column_values   IN   SYS.RE$COLUMN_VALUE_LIST     DEFAULT NULL,
    variable_values   IN   SYS.RE$VARIABLE_VALUE_LIST   DEFAULT NULL,
    attribute_values   IN   SYS.RE$ATTRIBUTE_VALUE_LIST  DEFAULT NULL,
    simple_rules_only   IN   BOOLEAN                      DEFAULT FALSE,
    true_rules_iterator   OUT  BINARY_INTEGER,
    maybe_rules_iterator  OUT  BINARY_INTEGER);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_set_name</td>
<td>Name of the rule set in the form [schema_name.]rule_set_name. For example, to evaluate all of the rules in a rule set named hr_rules in the hr schema, enter hr.hr_rules for this parameter. If the schema is not specified, then the schema of the current user is used.</td>
</tr>
<tr>
<td>evaluation_context</td>
<td>An evaluation context name in the form [schema_name.]evaluation_context_name. If the schema is not specified, then the name of the current user is used. Only rules that use the specified evaluation context are evaluated.</td>
</tr>
<tr>
<td>event_context</td>
<td>A list of name-value pairs that identify events that cause evaluation</td>
</tr>
<tr>
<td>Parameter</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>table_values</td>
<td>Contains the data for table rows using the table aliases specified when the evaluation context was created. Each table alias in the list must be unique.</td>
</tr>
<tr>
<td>column_values</td>
<td>Contains the partial data for table rows. It must not contain column values for tables, whose values are already specified in table_values.</td>
</tr>
<tr>
<td>variable_values</td>
<td>A list containing the data for variables. The only way for an explicit variable value to be known is to specify its value in this list.</td>
</tr>
<tr>
<td></td>
<td>If an implicit variable value is not specified in the list, then the function used to obtain the value of the implicit variable is invoked. If an implicit variable value is specified in the list, then this value is used and the function is not invoked.</td>
</tr>
<tr>
<td>attribute_values</td>
<td>Contains the partial data for variables. It must not contain attribute values for variables whose values are already specified in variable_values.</td>
</tr>
<tr>
<td>stop_on_first_hit</td>
<td>If TRUE, then the rules engine stops evaluation as soon as it finds a TRUE rule.</td>
</tr>
<tr>
<td></td>
<td>If TRUE and there are no TRUE rules, then the rules engine stops evaluation as soon as it finds a rule that may evaluate to TRUE given more data.</td>
</tr>
<tr>
<td></td>
<td>If FALSE, then the rules engine continues to evaluate rules even after it finds a TRUE rule.</td>
</tr>
<tr>
<td>simple_rules_only</td>
<td>If TRUE, then only those rules that are simple enough to be evaluated fast (without issuing SQL) are considered for evaluation.</td>
</tr>
<tr>
<td></td>
<td>If FALSE, then evaluates all rules.</td>
</tr>
<tr>
<td>true_rules</td>
<td>Receives the output of the evaluate procedure into a varray of $RULE_HIT_LIST$ type.</td>
</tr>
<tr>
<td></td>
<td>If no rules evaluate to TRUE, then true_rules is empty.</td>
</tr>
<tr>
<td></td>
<td>If at least one rule evaluates to TRUE and stop_on_first_hit is TRUE, then true_rules contains one rule that evaluates to TRUE.</td>
</tr>
<tr>
<td></td>
<td>If stop_on_first_hit is FALSE, then true_rules contains all rules that evaluate to TRUE.</td>
</tr>
<tr>
<td>maybe_rules</td>
<td>If all rules can be evaluated completely, without requiring any additional data, then maybe_rules is empty.</td>
</tr>
<tr>
<td></td>
<td>If stop_on_first_hit is TRUE, then if there is at least one rule that may evaluate to TRUE given more data, and no rules evaluate to TRUE, then maybe_rules contains one rule that may evaluate to TRUE.</td>
</tr>
<tr>
<td></td>
<td>If stop_on_first_hit is FALSE, then maybe_rules contains all rules that may evaluate to TRUE given more data.</td>
</tr>
<tr>
<td>true_rules_iterator</td>
<td>Contains the iterator for accessing rules that are TRUE</td>
</tr>
<tr>
<td>maybe_rules_iterator</td>
<td>Contains the iterator for accessing rules that may be TRUE given additional data or the ability to issue SQL.</td>
</tr>
</tbody>
</table>
Usage Notes

**Note:** Rules in the rule set that use an evaluation context different from the one specified are not considered for evaluation.

The rules in the rule set are evaluated using the data specified for `table_values`, `column_values`, `variable_values`, and `attribute_values`. These values must refer to tables and variables in the specified evaluation context. Otherwise, an error is raised.

The caller may specify, using `stop_on_first_hit`, if evaluation must stop as soon as the first `TRUE` rule or the first `MAYBE` rule (if there are no `TRUE` rules) is found.

The caller may also specify, using `simple_rules_only`, if only rules that are simple enough to be evaluated fast (which means without SQL) should be considered for evaluation. This makes evaluation faster, but causes rules that cannot be evaluated without SQL to be returned as `MAYBE` rules.

Partial evaluation is supported. The `EVALUATE` procedure can be called with data for only some of the tables, columns, variables, or attributes. In such a case, rules that cannot be evaluated because of a lack of data are returned as `MAYBE` rules, unless they can be determined to be `TRUE` or `FALSE` based on the values of one or more simple expressions within the rule. For example, given a value of 1 for attribute "a.b" of variable "x", a rule with the following rule condition can be returned as `TRUE`, without a value for table "tab":

\[(x.a.b = 1) \lor (tab.c > 10)\]

The results of an evaluation are the following:

- **TRUE** rules, which is the list of rules that evaluate to `TRUE` based on the given data. These rules are returned either in the `OUT` parameter `true_rules`, which returns all of the rules that evaluate to `TRUE`, or in the `OUT` parameter `true_rules_iterator`, which returns each rule that evaluates to `TRUE` one at a time.

- **MAYBE** rules, which is the list of rules that could not be evaluated for one of the following reasons:
  - The rule refers to data that was unavailable. For example, a variable attribute "x.a.b" is specified, but no value is specified for the variable "x", the attribute "a", or the attribute "a.b".
  - The rule is not simple enough to be evaluated fast (without SQL) and `simple_rules_only` is specified as `TRUE`, or partial data is available.

  Maybe rules are returned either in the `OUT` parameter `maybe_rules`, which returns all of the rules that evaluate to `MAYBE`, or in the `OUT` parameter `maybe_rules_iterator`, which returns each rule that evaluates to `MAYBE` one at a time.

The caller may specify whether the procedure returns all of the rules that evaluate to `TRUE` and `MAYBE` for the event or an iterator for rules that evaluate to `TRUE` and `MAYBE`. A true rules iterator enables the client to fetch each rule that evaluates to `TRUE` one at a time, and a maybe rules iterator enables the client to fetch each rule that evaluates to `MAYBE` one at a time.

If you use an iterator, then you use the `GET_NEXT_HIT` function in the `DBMS_RULE` package to retrieve the next rule that evaluates to `TRUE` or `MAYBE` from an iterator. Oracle recommends that you close an iterator if it is no longer needed to free resources, such as memory, used by the iterator. An iterator can be closed in the following ways:
The `CLOSE_ITERATOR` procedure in the `DBMS_RULE` package is run with the iterator specified.

- The iterator returns `NULL` because no more rules evaluate to `TRUE` or `MAYBE`.
- The session in which the iterator is running ends.

To run the `DBMS_RULE.EVALUATE` procedure, a user must meet at least one of the following requirements:

- Have `EXECUTE_ON_RULE_SET` privilege on the rule set
- Have `EXECUTE_ANY_RULE_SET` system privilege
- Be the rule set owner

---

**Note:** The rules engine does not invoke any actions. An action context can be returned with each returned rule, but the client of the rules engine must invoke any necessary actions.

---

**See Also:**

- Chapter 257, "Rule TYPEs" for more information about the types used with the `DBMS_RULE` package
- `GET_NEXT_HIT Function` on page 127-11
- `CLOSE_ITERATOR Procedure` on page 127-6
GET_NEXT_HIT Function

This function returns the next rule that evaluated to TRUE from a true rules iterator, or returns the next rule that evaluated to MAYBE from a maybe rules iterator. The function returns NULL if there are no more rules that evaluated to TRUE or MAYBE.

Syntax

```
DBMS_RULE.GET_NEXT_HIT(
    iterator IN  BINARY_INTEGER)
RETURN SYS.RE$RULE_HIT;
```

Parameter

**Table 127–4 GET_NEXT_HIT Function Parameter**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>iterator</td>
<td>The iterator from which the rule that evaluated to TRUE or MAYBE is retrieved</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure requires an open iterator that was returned by an earlier call to `DBMS_RULE.EVALUATE` in the same session. The user who runs this procedure does not require any privileges on the rule set being evaluated.

When an iterator returns NULL, it is closed automatically. If an open iterator is no longer needed, then use the `CLOSE_ITERATOR` procedure in the `DBMS_RULE` package to close it.

**Note:** This function raises an error if the rule set being evaluated was modified after the call to the `DBMS_RULE.EVALUATE` procedure that returned the iterator. Modifications to a rule set include added rules to the rule set, changing existing rules in the rule set, dropping rules from the rule set, and dropping the rule set.

<tr>
<td>REVOKE_SYSTEM_PRIVILEGE Procedure on page 128-28</td>
<td>Revokes the specified system privilege from the specified user or role</td>
</tr>
</tbody>
</table>

**Note:** All subprograms commit unless specified otherwise.
ADD_RULE Procedure

This procedure adds the specified rule to the specified rule set.

Syntax

```
DBMS_RULE_ADM.ADD_RULE(
    rule_name       IN  VARCHAR2,
    rule_set_name       IN  VARCHAR2,
    evaluation_context  IN  VARCHAR2   DEFAULT NULL,
    rule_comment        IN  VARCHAR2   DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>The name of the rule you are adding to the rule set, specified as [schema_name.]rule_name. For example, to add a rule named all_a in the hr schema, enter hr.all_a for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>rule_set_name</td>
<td>The name of the rule set to which you are adding the rule, specified as [schema_name.]rule_set_name. For example, to add the rule to a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>evaluation_context</td>
<td>An evaluation context name in the form [schema_name.]evaluation_context_name. If the schema is not specified, then the current user is the default. Only specify an evaluation context if the rule itself does not have an evaluation context and you do not want to use the rule set's evaluation context for the rule.</td>
</tr>
<tr>
<td>rule_comment</td>
<td>Optional description, which can contain the reason for adding the rule to the rule set</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Have ALTER_ON_RULE_SET privilege on the rule set
- Have ALTER_ANY_RULE_SET system privilege
- Be the owner of the rule set

Also, the rule set owner must meet at least one of the following requirements:

- Have EXECUTE_ON_RULE privilege on the rule
- Have EXECUTE_ANY_RULE system privilege
- Be the rule owner

If the rule has no evaluation context and no evaluation context is specified when you run this procedure, then the rule uses the evaluation context associated with the rule set. In such a case, the rule owner must have the necessary privileges on all the base objects accessed by the rule using the evaluation context.

If an evaluation context is specified, then the rule set owner must meet at least one of the following requirements:
- Have `EXECUTE_ON_EVALUATIONCONTEXT` privilege on the evaluation context
- Have `EXECUTE_ANY_EVALUATIONCONTEXT` system privilege, and the owner of the evaluation context must not be `SYS`
- Be the evaluation context owner

Also, the rule owner must have the necessary privileges on all the base objects accessed by the rule using the evaluation context.
ALTER_EVALUATION_CONTEXT Procedure

This procedure alters a rule evaluation context. A rule evaluation context defines external data that can be referenced in rule conditions. The external data can either exist as variables or as table data.

Syntax

```sql
DBMS_RULE_ADM.ALTER_EVALUATION_CONTEXT(
    evaluation_context_name  IN  VARCHAR2,
    table_aliases IN  SYS.RE$TABLE_ALIAS_LIST    DEFAULT NULL,
    remove_table_aliases IN  BOOLEAN                    DEFAULT FALSE,
    variable_types IN  SYS.RE$VARIABLE_TYPE_LIST  DEFAULT NULL,
    remove_variable_types IN  BOOLEAN                    DEFAULT FALSE,
    evaluation_function IN  VARCHAR2                   DEFAULT NULL,
    remove_evaluation_function IN  BOOLEAN                    DEFAULT FALSE,
    evaluation_context_comment   IN  VARCHAR2                   DEFAULT NULL,
    remove_eval_context_comment IN  BOOLEAN                    DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluation_context_name</td>
<td>The name of the evaluation context you are altering, specified as <code>[schema_name.]evaluation_context_name</code>.</td>
</tr>
<tr>
<td></td>
<td>For example, to alter an evaluation context named <code>dept_eval_context</code> in the <code>hr</code> schema, enter <code>hr.dept_eval_context</code> for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>table_aliases</td>
<td>If NULL and remove_table_aliases is FALSE, then the procedure retains the existing table aliases. If NULL and remove_table_aliases is TRUE, then the procedure removes the existing table aliases.</td>
</tr>
<tr>
<td></td>
<td>If non-NULL, then the procedure replaces the existing table aliases for the evaluation context with the specified table aliases.</td>
</tr>
<tr>
<td></td>
<td>Table aliases specify the tables in an evaluation context. The table aliases can be used to reference tables in rule conditions.</td>
</tr>
<tr>
<td>remove_table_aliases</td>
<td>If TRUE and table_aliases is NULL, then the procedure removes the existing table aliases for the evaluation context. If TRUE and table_aliases is non-NULL, then the procedure raises an error.</td>
</tr>
<tr>
<td></td>
<td>If FALSE, then the procedure does not remove table aliases.</td>
</tr>
<tr>
<td>variable_types</td>
<td>If NULL and remove_variable_types is FALSE, then the procedure retains the variable types. If NULL and remove_variable_types is TRUE, then the procedure removes the existing variable types.</td>
</tr>
<tr>
<td></td>
<td>If non-NULL, then the procedure replaces the existing variable types for the evaluation context with the specified variable types.</td>
</tr>
</tbody>
</table>
To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the evaluation context being altered
- Have `ALL_ON_EVALUATION_CONTEXT` or `ALTER_ON_EVALUATION_CONTEXT` object privilege on an evaluation context owned by another user
- Have `ALTER_ANY_EVALUATION_CONTEXT` system privilege
See Also: Chapter 257, "Rule TYPES" for more information about the types used with the DBMS_RULE_ADM package
ALTER_RULE Procedure

This procedure changes one or more aspects of the specified rule.

Syntax

```sql
DBMS_RULE_ADM.ALTER_RULE(
  rule_name IN VARCHAR2,
  condition IN VARCHAR2 DEFAULT NULL,
  evaluation_context IN VARCHAR2 DEFAULT NULL,
  remove_evaluation_context IN BOOLEAN DEFAULT FALSE,
  action_context IN SYS.RE$NV_LIST DEFAULT NULL,
  remove_action_context IN BOOLEAN DEFAULT FALSE,
  rule_comment IN VARCHAR2 DEFAULT NULL,
  remove_rule_comment IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>rule_name</code></td>
<td>The name of the rule you are altering, specified as <code>{schema_name.}rule_name</code>. For example, to alter a rule named <code>all_a</code> in the <code>hr</code> schema, enter <code>hr.all_a</code> for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td><code>condition</code></td>
<td>The condition to be associated with the rule. If non-NULL, then the procedure replaces the existing condition of the rule with the specified condition.</td>
</tr>
<tr>
<td><code>evaluation_context</code></td>
<td>An evaluation context name in the form <code>{schema_name.}evaluation_context_name</code>. If the schema is not specified, then the current user is the default. If non-NULL, then the procedure replaces the existing evaluation context of the rule with the specified evaluation context.</td>
</tr>
<tr>
<td><code>remove_evaluation_context</code></td>
<td>If TRUE, then the procedure sets the evaluation context for the rule to NULL, which effectively removes the evaluation context from the rule. If FALSE, then the procedure retains any evaluation context for the specified rule.</td>
</tr>
<tr>
<td><code>action_context</code></td>
<td>If non-NULL, then the procedure changes the action context associated with the rule. A rule action context is information associated with a rule that is interpreted by the client of the rules engine when the rule is evaluated.</td>
</tr>
<tr>
<td><code>remove_action_context</code></td>
<td>If TRUE, then the procedure sets the action context for the rule to NULL, which effectively removes the action context from the rule. If FALSE, then the procedure retains any action context for the specified rule.</td>
</tr>
</tbody>
</table>

If the `evaluation_context` parameter is non-NULL, then this parameter should be set to FALSE.
Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Have `ALTER_ON_RULE` privilege on the rule
- Have `ALTER_ANY_RULE` system privilege
- Be the owner of the rule being altered

If an evaluation context is specified, then the rule owner must meet at least one of the following requirements:

- Have `EXECUTE_ON_EVALUATION_CONTEXT` privilege on the evaluation context
- Have `EXECUTE_ANY_EVALUATION_CONTEXT` system privilege, and the owner of the evaluation context must not be `SYS`
- Be the evaluation context owner

Also, the rule owner must have the necessary privileges on all the base objects accessed by the rule using the evaluation context.

See Also: Chapter 257, "Rule TYPES" for more information about the types used with the DBMS_RULE_ADM package
CREATE_EVALUATION_CONTEXT Procedure

This procedure creates a rule evaluation context. A rule evaluation context defines external data that can be referenced in rule conditions. The external data can either exist as variables or as table data.

Syntax

```
DBMS_RULE_ADM.CREATE_EVALUATION_CONTEXT(
    evaluation_context_name  IN  VARCHAR2,
    table_aliases IN  SYS.RE$TABLE_ALIAS_LIST    DEFAULT NULL,
    variable_types IN  SYS.RE$VARIABLE_TYPE_LIST  DEFAULT NULL,
    evaluation_function IN  VARCHAR2                   DEFAULT NULL,
    evaluation_context_comment   IN  VARCHAR2                   DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluation_context_name</td>
<td>The name of the evaluation context you are creating, specified as [schema_name.]evaluation_context_name. For example, to create an evaluation context named dept_eval_context in the hr schema, enter hr.dept_eval_context for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>table_aliases</td>
<td>Table aliases that specify the tables in an evaluation context. The table aliases can be used to reference tables in rule conditions.</td>
</tr>
<tr>
<td>variable_types</td>
<td>A list of variables for the evaluation context</td>
</tr>
<tr>
<td>evaluation_function</td>
<td>An optional function that will be called to evaluate rules using the evaluation context. It must have the same form as the DBMS_RULE.EVALUATE procedure. If the schema is not specified, then the current user is the default. See &quot;Usage Notes&quot; for more information about the evaluation function.</td>
</tr>
<tr>
<td>evaluation_context_comment</td>
<td>An optional description of the rule evaluation context.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the evaluation context being created and have CREATE_EVALUATION_CONTEXT_OBJ system privilege
- Have CREATE_ANY_EVALUATION_CONTEXT system privilege

See Also: Chapter 257, "Rule TYPES" for more information about the types used with the DBMS_RULE_ADM package

The evaluation function must have the following signature:

```
FUNCTION evaluation_function_name(
    rule_set_name       IN   VARCHAR2,
    evaluation_context  IN   VARCHAR2,
```
CREATE_EVALUATION_CONTEXT Procedure

```
event_context       IN   SYS.RE$NV_LIST               DEFAULT NULL,
table_values        IN   SYS.RE$TABLE_VALUE_LIST      DEFAULT NULL,
column_values       IN   SYS.RE$COLUMN_VALUE_LIST     DEFAULT NULL,
variable_values     IN   SYS.RE$VARIABLE_VALUE_LIST   DEFAULT NULL,
attribute_values    IN   SYS.RE$ATTRIBUTE_VALUE_LIST  DEFAULT NULL,
stop_on_first_hit   IN   BOOLEAN                      DEFAULT FALSE,
simple_rules_only   IN   BOOLEAN                      DEFAULT FALSE,
true_rules          OUT  SYS.RE$RULE_HIT_LIST,
maybe_rules         OUT  SYS.RE$RULE_HIT_LIST);
RETURN BINARY_INTEGER;
```

**Note:** Each parameter is required and must have the specified data type. However, you can change the names of the parameters.

The return value of the function must be one of the following:

- **DBMS_RULE_ADM.EVALUATION_SUCCESS**: The user specified evaluation function completed the rule set evaluation successfully. The rules engine returns the results of the evaluation obtained by the evaluation function to the rules engine client using the DBMS_RULE.EVALUATE procedure.

- **DBMS_RULE_ADM.EVALUATION_CONTINUE**: The rules engine evaluates the rule set as if there were no evaluation function. The evaluation function is not used, and any results returned by the evaluation function are ignored.

- **DBMS_RULE_ADM.EVALUATION_FAILURE**: The user specified evaluation function failed. Rule set evaluation stops, and an error is raised.
CREATE_RULE Procedure

This procedure creates a rule.

Syntax

```sql
DBMS_RULE_ADM.CREATE_RULE(
    rule_name  IN  VARCHAR2,
    condition  IN  VARCHAR2,
    evaluation_context IN  VARCHAR2 DEFAULT NULL,
    action_context IN  SYS.RE$NV_LIST DEFAULT NULL,
    rule_comment IN  VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>The name of the rule you are creating, specified as [schema_name.]rule_name. For example, to create a rule named all_a in the hr schema, enter hr.all_a for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>condition</td>
<td>The condition to be associated with the rule. A condition evaluates to TRUE or FALSE and can be any condition allowed in the WHERE clause of a SELECT statement. For example, the following is a valid rule condition: department_id = 30. Ensure that the proper case is used for text in rule conditions. Note: Do not include the word &quot;WHERE&quot; in the condition.</td>
</tr>
<tr>
<td>evaluation_context</td>
<td>An optional evaluation context name in the form [schema_name.]evaluation_context_name, which is associated with the rule. If the schema is not specified, then the current user is the default. If evaluation_context is not specified, then the rule inherits the evaluation context from its rule set.</td>
</tr>
<tr>
<td>action_context</td>
<td>The action context associated with the rule. A rule action context is information associated with a rule that is interpreted by the client of the rules engine when the rule is evaluated.</td>
</tr>
<tr>
<td>rule_comment</td>
<td>An optional description of the rule</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:
- Be the owner of the rule being created and have the CREATE_RULE_OBJ system privilege
- Have CREATE_ANY_RULE system privilege

If an evaluation context is specified, then the rule owner must meet at least one of the following requirements:
- Have EXECUTE_ON_EVALUATION_CONTEXT privilege on the evaluation context
- Have EXECUTE_ANY_EVALUATION_CONTEXT system privilege, and the owner of the evaluation context must not be SYS.
CREATE_RULE Procedure

- Be the evaluation context owner

Also, the rule owner must have the necessary privileges on all the base objects accessed by the rule using the evaluation context.

**See Also:** Chapter 257, "Rule TYPES" for more information about the types used with the DBMS_RULE_ADM package
CREATE_RULE_SET Procedure

This procedure creates a rule set.

Syntax

DBMS_RULE_ADM.CREATE_RULE_SET(
    rule_set_name  IN  VARCHAR2,
    evaluation_context  IN  VARCHAR2  DEFAULT NULL,
    rule_set_comment   IN  VARCHAR2  DEFAULT NULL);

Parameters

Table 128–7 CREATE_RULE_SET Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_set_name</td>
<td>The name of the rule set you are creating, specified as [schema_name.]rule_set_name. For example, to create a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>evaluation_context</td>
<td>An optional evaluation context name in the form [schema_name.]evaluation_context_name, which applies to all rules in the rule set that are not associated with an evaluation context explicitly. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>rule_set_comment</td>
<td>An optional description of the rule set</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the rule set being created and have CREATE_RULE_SET_OBJ system privilege
- Have CREATE_ANY_RULE_SET system privilege

If an evaluation context is specified, then the rule set owner must meet at least one of the following requirements:

- Have EXECUTE_ON_EVALUATION_CONTEXT privilege on the evaluation context
- Have EXECUTE_ANY_EVALUATION_CONTEXT system privilege, and the owner of the evaluation context must not be SYS
- Be the evaluation context owner
DROP_EVALUATION_CONTEXT Procedure

This procedure drops a rule evaluation context.

Syntax

```sql
DBMS_RULE_ADM.DROP_EVALUATION_CONTEXT(
    evaluation_context_name  IN  VARCHAR2,
    force   IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>evaluation_context_name</td>
<td>The name of the evaluation context you are dropping, specified as [schema_name.]evaluation_context_name.</td>
</tr>
<tr>
<td></td>
<td>For example, to drop an evaluation context named dept_eval_context in the hr schema, enter hr.dept_eval_context for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>force</td>
<td>If TRUE, then the procedure removes the rule evaluation context from all rules and rule sets that use it.</td>
</tr>
<tr>
<td></td>
<td>If FALSE and no rules or rule sets use the rule evaluation context, then the procedure drops the rule evaluation context.</td>
</tr>
<tr>
<td></td>
<td>If FALSE and one or more rules or rule sets use the rule evaluation context, then the procedure raises an exception.</td>
</tr>
<tr>
<td></td>
<td><strong>Caution:</strong> Setting <code>force</code> to TRUE can result in rules and rule sets that do not have an evaluation context. If neither a rule nor the rule set it is in has an evaluation context, and no evaluation context was specified for the rule by the <code>ADD_RULE</code> procedure, then the rule cannot be evaluated.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the evaluation context
- Have DROP_ANY_EVALUATION_CONTEXT system privilege
DROP_RULE Procedure

This procedure drops a rule.

Syntax

```sql
DBMS_RULE_ADM.DROP_RULE(
    rule_name  IN  VARCHAR2,
    force   IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>The name of the rule you are dropping, specified as [schema_name.]rule_name. For example, to drop a rule named all_a in the hr schema, enter hr.all_a for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>force</td>
<td>If TRUE, then the procedure removes the rule from all rule sets that contain it. If FALSE and no rule sets contain the rule, then the procedure drops the rule. If FALSE and one or more rule sets contain the rule, then the procedure raises an exception.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the rule
- Have DROP_ANYRULE system privilege

Note:

- To remove a rule from a rule set without dropping the rule from the database, use the REMOVE_RULE procedure.
- The rule evaluation context associated with the rule, if any, is not dropped when you run this procedure.
DROP_RULE_SET Procedure

This procedure drops a rule set.

Syntax

```
DBMS_RULE_ADM.DROP_RULE_SET(
    rule_set_name  IN  VARCHAR2,
    delete_rules IN  BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_set_name</td>
<td>The name of the rule set you are dropping, specified as [schema_name.]rule_set_name. For example, to drop a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>delete_rules</td>
<td>If TRUE, then the procedure drops any rules that are in the rule set. If any of the rules in the rule set are also in another rule set, then these rules are not dropped. If FALSE, then the procedure does not drop the rules in the rule set.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Have DROP_ANY_RULE_SET system privilege
- Be the owner of the rule set

**Note:** The rule evaluation context associated with the rule set, if any, is not dropped when you run this procedure.
GRANT_OBJECT_PRIVILEGE Procedure

This procedure grants the specified object privilege on the specified object to the specified user or role. If a user owns the object, then the user automatically is granted all privileges on the object, with grant option.

Syntax

```
DBMS_RULE_ADM.GRANT_OBJECT_PRIVILEGE(
    privilege    IN  BINARY_INTEGER,
    object_name IN  VARCHAR2,
    grantee   IN  VARCHAR2,
    grant_option  IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The name of the object privilege to grant to the grantee on the object. See &quot;Usage Notes&quot; on page 128-21 for the available object privileges.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object for which you are granting the privilege to the grantee, specified as [schema_name.]object_name. For example, to grant the privilege on a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default. The object must be an existing rule, rule set, or evaluation context.</td>
</tr>
<tr>
<td>grantee</td>
<td>The name of the user or role for which the privilege is granted. The specified user cannot be the owner of the object.</td>
</tr>
<tr>
<td>grant_option</td>
<td>If TRUE, then the specified user or users granted the specified privilege can grant this privilege to others. If FALSE, then the specified user or users granted the specified privilege cannot grant this privilege to others.</td>
</tr>
</tbody>
</table>

Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Be the owner of the object on which the privilege is granted
- Have the same privilege as the privilege being granted with the grant option

In addition, if the object is a rule set, then the user must have EXECUTE privilege on all the rules in the rule set with grant option or must own the rules in the rule set.

Table 128–12 lists the object privileges.
For example, to grant the HR user the privilege to alter a rule named hr_dml in the strmadmin schema, enter the following:

```sql
BEGIN
    DBMS_RULE_ADM.GRANT_OBJECT_PRIVILEGE(
        privilege    => SYS.DBMS_RULE_ADM.ALTER_ON_RULE,
        object_name  => 'strmadmin.hr_dml',
        grantee      => 'hr',
        grant_option => FALSE);
END;
/
```
**GRANT_SYSTEM_PRIVILEGE Procedure**

This procedure grants the specified system privilege to the specified user or role.

**Syntax**

```sql
DBMS_RULE_ADM.GRANT_SYSTEM_PRIVILEGE(
  privilege    IN  BINARY_INTEGER,
  grantee   IN  VARCHAR2,
  grant_option  IN  BOOLEAN   DEFAULT FALSE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The name of the system privilege to grant to the grantee.</td>
</tr>
<tr>
<td>grantee</td>
<td>The name of the user or role for which the privilege is granted.</td>
</tr>
<tr>
<td>grant_option</td>
<td>If TRUE, then the specified user or users granted the specified privilege can grant the system privilege to others. If FALSE, then the specified user or users granted the specified privilege cannot grant the system privilege to others.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Table 128–14 lists the system privileges.

<table>
<thead>
<tr>
<th>Privilege</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYS.DBMS_RULE_ADM.ALTER_ANY_EVALUATION_CONTEXT</td>
<td>Alter any evaluation context owned by any user</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.ALTER_ANY_RULE</td>
<td>Alter any rule owned by any user</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.ALTER_ANY_RULE_SET</td>
<td>Alter any rule set owned by any user</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_ANY_EVALUATION_CONTEXT</td>
<td>Create a new evaluation context in any schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_EVALUATION_CONTEXT_OBJ</td>
<td>Create a new evaluation context in the grantee's schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_ANY_RULE</td>
<td>Create a new rule in any schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_RULE_OBJ</td>
<td>Create a new rule in the grantee's schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_ANY_RULE_SET</td>
<td>Create a new rule set in any schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.CREATE_RULE_SET_OBJ</td>
<td>Create a new rule set in the grantee's schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.DROP_ANY_EVALUATION_CONTEXT</td>
<td>Drop any evaluation context in any schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.DROP_ANY_RULE</td>
<td>Drop any rule in any schema</td>
</tr>
<tr>
<td>SYS.DBMS_RULE_ADM.DROP_ANY_RULE_SET</td>
<td>Drop any rule set in any schema</td>
</tr>
</tbody>
</table>
For example, to grant the strmadmin user the privilege to create a rule set in any schema, enter the following:

```sql
BEGIN
    DBMS_RULE_ADM.GRANT_SYSTEM_PRIVILEGE(
        privilege => SYS.DBMS_RULE_ADM.CREATE_ANY_RULE_SET,
        grantee   => 'strmadmin',
        grant_option => FALSE);
END;
/
```

**Note:** When you grant a privilege on "ANY" object (for example, ALTER_ANY_RULE), and the initialization parameter O7_DICTIONARY_ACCESSIBILITY is set to FALSE, you give the user access to that type of object in all schemas except the SYS schema. By default, the initialization parameter O7_DICTIONARY_ACCESSIBILITY is set to FALSE.

If you want to grant access to an object in the SYS schema, then you can grant object privileges explicitly on the object. Alternatively, you can set the O7_DICTIONARY_ACCESSIBILITY initialization parameter to TRUE. Then privileges granted on "ANY" object allows access to any schema, including SYS.
REMOVE_RULE Procedure

This procedure removes the specified rule from the specified rule set.

Syntax

```
DBMS_RULE_ADM.REMOVE_RULE(
    rule_name            IN  VARCHAR2,
    rule_set_name            IN  VARCHAR2,
    evaluation_context       IN  VARCHAR2  DEFAULT NULL,
    all_evaluation_contexts  IN  BOOLEAN   DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_name</td>
<td>The name of the rule you are removing from the rule set, specified as [schema_name.]rule_name. For example, to remove a rule named all_a in the hr schema, enter hr.all_a for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>rule_set_name</td>
<td>The name of the rule set from which you are removing the rule, specified as [schema_name.]rule_set_name. For example, to remove the rule from a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>evaluation_context_name</td>
<td>The name of the evaluation context associated with the rule you are removing, specified as [schema_name.]evaluation_context_name. For example, to specify an evaluation context named dept_eval_context in the hr schema, enter hr.dept_eval_context for this parameter. If the schema is not specified, then the current user is the default.</td>
</tr>
<tr>
<td>all_evaluation_contexts</td>
<td>If TRUE, then the procedure removes the rule from the rule set with all of its associated evaluation contexts. If FALSE, then the procedure only removes the rule with the specified evaluation context. This parameter is relevant only if the same rule is added more than once to the rule set with different evaluation contexts.</td>
</tr>
</tbody>
</table>
Usage Notes

To run this procedure, a user must meet at least one of the following requirements:

- Have `ALTER_ON_RULE_SET` privilege on the rule set
- Have `ALTER_ANY_RULE_SET` system privilege
- Be the owner of the rule set

**Note:** This procedure does not drop a rule from the database. To drop a rule from the database, use the `DROP_RULE` procedure.
REVOKE_OBJECT_PRIVILEGE Procedure

This procedure revokes the specified object privilege on the specified object from the specified user or role.

Syntax

```sql
DBMS_RULE_ADM.REVOKE_OBJECT_PRIVILEGE(
    privilege   IN  BINARY_INTEGER,
    object_name IN  VARCHAR2,
    revokee  IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The name of the object privilege on the object to revoke from the revokee. See GRANT_OBJECT_PRIVILEGE Procedure on page 128-21 for a list of the object privileges.</td>
</tr>
<tr>
<td>object_name</td>
<td>The name of the object for which you are revoking the privilege from the revokee, specified as [schema_name.]object_name. For example, to revoke an object privilege on a rule set named apply_rules in the hr schema, enter hr.apply_rules for this parameter. If the schema is not specified, then the current user is the default. The object must be an existing rule, rule set, or evaluation context.</td>
</tr>
<tr>
<td>revokee</td>
<td>The name of the user or role from which the privilege is revoked. The user who owns the object cannot be specified.</td>
</tr>
</tbody>
</table>
REVOKE_SYSTEM_PRIVILEGE Procedure

This procedure revokes the specified system privilege from the specified user or role.

Syntax

```plsql
DBMS_RULE_ADM.REVOKE_SYSTEM_PRIVILEGE(
   privilege  IN  BINARY_INTEGER,
   revokee    IN  VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>privilege</td>
<td>The name of the system privilege to revoke from the revokee. See GRANT_SYSTEM_PRIVILEGE Procedure on page 128-23 for a list of the system privileges.</td>
</tr>
<tr>
<td>revokee</td>
<td>The name of the user or role from which the privilege is revoked</td>
</tr>
</tbody>
</table>
The `DBMS_SCHEDULER` package provides a collection of scheduling functions and procedures that can be called from any PL/SQL program.

See Also: *Oracle Database Administrator’s Guide* for more information regarding how to use `DBMS_SCHEDULER`.

This chapter contains the following topics:

- Data Structures
- Using `DBMS_SCHEDULER`
  - Security Model
  - Rules and Limits
  - Operational Notes
- Summary of `DBMS_SCHEDULER` Subprograms
Data Structures

The DBMS_SCHEDULER package defines OBJECT types and TABLE types.

**OBJECT Types**
- JOBARG Object Type
- JOB Object Type
- JOB_DEFINITION Object Type
- JOBATTR Object Type
- SCHEDULER$_STEP_TYPE Object Type
- SCHEDULER$_EVENT_INFO Object Type
- SCHEDULER_FILEWATCHER_RESULT Object Type
- SCHEDULER_FILEWATCHER_REQUEST Object Type

**TABLE Types**
- JOBARG_ARRAY Table Type
- JOB_ARRAY Table Type
- JOB_DEFINITION_ARRAY Table Type
- JOBATTR_ARRAY Table Type
- SCHEDULER$_STEP_TYPE_LIST Table Type
**JOBARG Object Type**

This type is used by the JOB and JOBATTR object types. It represents a job argument in a batch of job arguments.

**Syntax**

```sql
TYPE jobarg IS OBJECT {
    arg_position    NUMBER,
    arg_text_value  VARCHAR2(4000),
    arg_anydata_value ANYDATA,
    arg_operation   VARCHAR2(5));
```

**Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg_position</td>
<td>Position of the argument</td>
</tr>
<tr>
<td>arg_text_value</td>
<td>Value of the argument if the type is VARCHAR2</td>
</tr>
<tr>
<td>arg_anydata_value</td>
<td>Value of the argument if the type is AnyData</td>
</tr>
<tr>
<td>arg_operation</td>
<td>Type of the operation:</td>
</tr>
<tr>
<td></td>
<td>■ SET</td>
</tr>
<tr>
<td></td>
<td>■ RESET</td>
</tr>
</tbody>
</table>

**JOBARG Constructor Function**

This constructor function constructs a job argument. It is overloaded to construct job arguments with different types of values.

**Syntax**

- Constructs a job argument with a text value.
  ```sql
  constructor function jobarg (
    arg_position    IN POSITIVEN,
    arg_value       IN VARCHAR2)
  RETURN SELF AS RESULT;
  ```

- Constructs a job argument with an AnyData value.
  ```sql
  constructor function jobarg (
    arg_position    IN POSITIVEN,
    arg_value       IN ANYDATA)
  RETURN SELF AS RESULT;
  ```

- Constructs a job argument with a NULL value.
  ```sql
  constructor function jobarg (
    arg_position    IN POSITIVEN,
    arg_reset       IN BOOLEAN DEFAULT FALSE)
  RETURN SELF AS RESULT;
  ```
Parameters

Table 129–2  JOBARG Constructor Function Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>arg_position</td>
<td>Position of the argument</td>
</tr>
<tr>
<td>arg_value</td>
<td>Value of the argument</td>
</tr>
<tr>
<td>arg_reset</td>
<td>If arg_reset is TRUE, then the argument at that position is reset. Setting arg_reset to FALSE (which is the default) will create an argument with a NULL value.</td>
</tr>
</tbody>
</table>

JOBARG_ARRAY Table Type

Syntax

```plsql
TYPE jobarg_array IS TABLE OF jobarg;
```
**JOB Object Type**

**** Deprecated. Use the JOB_DEFINITION object type instead.

**JOB_ARRAY Table Type**

*** Deprecated. Use the JOB_DEFINITION_ARRAY table type instead.
JOB_DEFINITION Object Type

This type is used by the CREATE_JOBS procedure and represents a job in a batch of jobs.

Syntax

```sql
TYPE job_definition IS OBJECT (  
  job_name               VARCHAR2(100),  
  job_class              VARCHAR2(32),  
  job_style              VARCHAR2(11),  
  program_name           VARCHAR2(100),  
  job_action             VARCHAR2(4000),  
  job_type               VARCHAR2(20),  
  schedule_name          VARCHAR2(65),  
  repeat_interval        VARCHAR2(4000),  
  schedule_limit         INTERVAL DAY TO SECOND,  
  start_date             TIMESTAMP WITH TIME ZONE,  
  end_date               TIMESTAMP WITH TIME ZONE,  
  event_condition        VARCHAR2(4000),  
  queue_spec             VARCHAR2(100),  
  number_of_arguments    NUMBER,  
  arguments              SYS.JOBARG_ARRAY,  
  job_priority           NUMBER,  
  job_weight             NUMBER,

  allow_runs_in_restricted_mode VARCHAR2(5));
```

Object Attributes

Table 129-3 provides brief descriptions of the attributes of the JOB_DEFINITION object type. For more complete information about these attributes, see the "CREATE_JOB Procedure" on page 129-55 and the "SET_ATTRIBUTE Procedure" on page 129-127.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Name of the job</td>
</tr>
<tr>
<td>job_class</td>
<td>Name of the job class</td>
</tr>
<tr>
<td>job_style</td>
<td>Style of the job:</td>
</tr>
<tr>
<td></td>
<td>• REGULAR</td>
</tr>
<tr>
<td></td>
<td>• LIGHTWEIGHT</td>
</tr>
</tbody>
</table>
### Table 129–3 (Cont.) JOB_DEFINITION Object Type Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>Name of the program that the job runs</td>
</tr>
<tr>
<td>job_action</td>
<td>Inline action of the job. This is either the code for an anonymous PL/SQL block or the name of a stored procedure, external executable, or chain.</td>
</tr>
<tr>
<td>job_type</td>
<td>Job action type ('PLSQL_BLOCK', 'STORED_PROCEDURE', 'EXECUTABLE', or 'CHAIN')</td>
</tr>
<tr>
<td>schedule_name</td>
<td>Name of the schedule that specifies when the job has to execute</td>
</tr>
<tr>
<td>repeat_interval</td>
<td>Inline time-based schedule</td>
</tr>
<tr>
<td>schedule_limit</td>
<td>Maximum delay time between scheduled and actual job start before a job run is canceled</td>
</tr>
<tr>
<td>start_date</td>
<td>Start date and time of the job</td>
</tr>
<tr>
<td>end_date</td>
<td>End date and time of the job</td>
</tr>
<tr>
<td>event_condition</td>
<td>Event condition for event-based jobs</td>
</tr>
<tr>
<td>queue_spec</td>
<td>File watcher name or queue specification for event-based jobs</td>
</tr>
<tr>

<td>Number of job arguments</td>
</tr>
<tr>
<td>arguments</td>
<td>Array of job arguments</td>
</tr>
<tr>
<td>job_priority</td>
<td>Job priority</td>
</tr>
<tr>
<td>job_weight</td>
<td>*** Deprecated in Oracle Database 11g Release 2 (11.2). Do not change the value of this attribute from the default, which is 1. Weight of the job for parallel execution.</td>
</tr>
<tr>
<td>max_run_duration</td>
<td>Maximum run duration of the job</td>
</tr>
<tr>
<td>max_runs</td>
<td>Maximum number of runs before the job is marked as completed</td>
</tr>
<tr>
<td>max_failures</td>
<td>Maximum number of failures tolerated before the job is marked as broken</td>
</tr>
<tr>
<td>logging_level</td>
<td>Job logging level</td>
</tr>
<tr>
<td>restartable</td>
<td>Indicates whether the job is restartable (TRUE) or not (FALSE)</td>
</tr>
<tr>
<td>stop_on_window_exit</td>
<td>Indicates whether the job is stopped when the window that it runs in ends (TRUE) or not (FALSE). Equivalent to the stop_on_window_close job attribute described in the SET_ATTRIBUTE Procedure.</td>
</tr>
<tr>
<td>raise_events</td>
<td>State changes that raise events</td>
</tr>
<tr>
<td>comments</td>
<td>Comments on the job</td>
</tr>
<tr>
<td>auto_drop</td>
<td>If TRUE (the default), indicates that the job should be dropped once completed</td>
</tr>
<tr>
<td>enabled</td>
<td>Indicates whether the job should be enabled immediately after creating it (TRUE) or not (FALSE)</td>
</tr>
<tr>
<td>follow_default_timezone</td>
<td>If TRUE and if the job start_date is null, then when the default_timezone scheduler attribute is changed, the Scheduler recomputes the next run date and time for this job so that it is in accordance with the new time zone.</td>
</tr>
</tbody>
</table>
### JOB_DEFINITION Constructor Function

This constructor function constructs a job_definition object.

#### Syntax

```sql
constructor function job_definition ( 
    job_name                   IN     VARCHAR2, 
    job_style                  IN     VARCHAR2 DEFAULT 'REGULAR', 
    program_name               IN     VARCHAR2 DEFAULT NULL, 
    job_action                 IN     VARCHAR2 DEFAULT NULL, 
    job_type                   IN     VARCHAR2 DEFAULT NULL, 
    schedule_name              IN     VARCHAR2 DEFAULT NULL, 
    repeat_interval            IN     VARCHAR2 DEFAULT NULL, 
    event_condition            IN     VARCHAR2 DEFAULT NULL, 
    queue_spec                 IN     VARCHAR2 DEFAULT NULL, 
    start_date                 IN     TIMESTAMP WITH TIME ZONE DEFAULT NULL, 
    end_date                   IN     TIMESTAMP WITH TIME ZONE DEFAULT NULL, 
    number_of_arguments        IN     NATURAL DEFAULT NULL, 
    arguments                  IN     SYS.JOBARG_ARRAY DEFAULT NULL, 
    job_class                  IN     VARCHAR2 DEFAULT 'DEFAULT_JOB_CLASS', 
    schedule_limit             IN     INTERVAL DAY TO SECOND DEFAULT NULL, 
    job_priority               IN     NATURAL DEFAULT NULL, 
    job_weight                 IN     NATURAL DEFAULT NULL, 
    max_run_duration           IN     INTERVAL DAY TO SECOND DEFAULT NULL, 
    max_runs                   IN     NATURAL DEFAULT NULL, 
    max_failures               IN     NATURAL DEFAULT NULL, 
    logging_level              IN     NATURAL DEFAULT 64, 
    restartable                IN     BOOLEAN DEFAULT FALSE, 
    stop_on_window_close       IN     BOOLEAN DEFAULT FALSE, 
    raise_events               IN     VARCHAR2 DEFAULT NULL, 
    comments                   IN     VARCHAR2 DEFAULT NULL, 
    enabled                    IN     BOOLEAN DEFAULT TRUE, 
    auto_drop                   IN     BOOLEAN DEFAULT FALSE, 
    follow_default_timezone    IN     BOOLEAN DEFAULT FALSE, 
    parallel_instances         FOR event-based jobs only. 
                                If TRUE, on the arrival of the specified event, the Scheduler 
                                creates a new lightweight job to handle that event, so multiple 
                                instances of the same event-based job can run in parallel. 
                                If FALSE, then an event is discarded if it is raised while the job 
                                that handles it is already running, 
    instance_id                The instance ID of the instance that the job must run on 
    credential_name            The credential to use for a single destination or the default 
                                credential for a group of destinations 
    destination                The name of a single external destination or database 
                                destination, or a group name of type external destination or 
                                database destination 
    database_role              In an Oracle Data Guard environment, the database role 
                                (‘PRIMARY’ or ‘LOGICAL STANDBY’) for which the job runs 
    allow_runs_in_restricted_mode If TRUE, the job is permitted to run when the database is in 
                                   restricted mode, provided that the job owner is permitted to log 
                                   in during this mode 
) 
```

**JOB_DEFINITION_ARRAY** Table Type

**Syntax**

```
TYPE job_definition_array IS TABLE OF job_definition;
```
JOBATTR Object Type

This type is used by the `SET_JOB_ATTRIBUTES` procedure and represents a job attribute in a batch of job attributes.

Syntax

```sql
TYPE jobattr IS OBJECT (
    job_name             VARCHAR2(100),
    attr_name            VARCHAR2(30),
    char_value           VARCHAR2(4000),
    char_value2          VARCHAR2(4000),
    args_value           JOBARG_ARRAY,
    num_value            NUMBER,
    timestamp_value      TIMESTAMP(6) WITH TIME ZONE,
    interval_value       INTERVAL DAY(2) TO SECOND(6));
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Name of the job</td>
</tr>
<tr>
<td>attr_name</td>
<td>Name of the attribute</td>
</tr>
<tr>
<td>char_value</td>
<td>Value of the argument if the type is VARCHAR2</td>
</tr>
<tr>
<td>char_value2</td>
<td>Second VARCHAR2 attribute value</td>
</tr>
<tr>
<td>args_value</td>
<td>Value of the argument if the type is a JOBARG array</td>
</tr>
<tr>
<td>num_value</td>
<td>Value of the argument if the type is NUMBER</td>
</tr>
<tr>
<td>timestamp_value</td>
<td>Value of the argument if the type is TIMESTAMP WITH TIME ZONE</td>
</tr>
<tr>
<td>interval_value</td>
<td>Value of the argument if the type is INTERVAL DAY TO SECOND</td>
</tr>
</tbody>
</table>

JOBATTR Constructor Function

This constructor function constructs a job attribute. It is overloaded to create attribute values of the following types: VARCHAR2, NUMBER, TIMESTAMP WITH TIME ZONE, INTERVAL DAY TO SECOND, and an array of JOBARG types.

Syntax

```sql
constructor function jobattr (
    job_name    IN VARCHAR2,
    attr_name   IN VARCHAR2,
    attr_value  IN VARCHAR2,
    attr_value2 IN VARCHAR2 DEFAULT NULL)
RETURN SELF AS RESULT;

constructor function jobattr (
    job_name    IN VARCHAR2,
    attr_name   IN VARCHAR2,
    attr_value  IN [NUMBER, BOOLEAN,
                    TIMESTAMP WITH TIME ZONE,
                    INTERVAL DAY TO SECOND, JOBARG_ARRAY])
RETURN SELF AS RESULT;
```
constructor function jobattr (
    job_name            IN VARCHAR2,
    attr_name           IN VARCHAR2)
RETURN SELF AS RESULT;

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Name of the job</td>
</tr>
<tr>
<td>attr_name</td>
<td>Name of the argument</td>
</tr>
<tr>
<td>attr_value</td>
<td>Value of the argument</td>
</tr>
<tr>
<td>attr_value2</td>
<td>Most attributes have only one value associated with them, but some can have two. The attr_value2 argument is for this optional second value.</td>
</tr>
</tbody>
</table>

JOBATTR_ARRAY Table Type

Syntax

```
TYPE jobattr_array IS TABLE OF jobattr;
```
SCHEDULER$_STEP_TYPE Object Type

This type is used by RUN_CHAIN to return a list of chain steps with an initial state.

Syntax

```
TYPE scheduler$_step_type IS OBJECT {
    step_name  VARCHAR2(32),
    step_type  VARCHAR2(32));
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>step_name</td>
<td>Name of the step</td>
</tr>
<tr>
<td>step_type</td>
<td>State of the step</td>
</tr>
</tbody>
</table>

SCHEDULER$_STEP_TYPE_LIST Table Type

Syntax

```
TYPE scheduler$_step_type_list IS TABLE OF scheduler$_step_type;
```
SCHEDULER$EVENT_INFO Object Type

This the data type of the Scheduler event queue SYS.SCHEDULER$EVENT_QUEUE, from which your application consumes job state events raised by the Scheduler. It is a secure queue owned by SYS.

Syntax

```sql
TYPE SCHEDULER$EVENT_INFO IS OBJECT (
    event_type         VARCHAR2(4000),
    object_owner       VARCHAR2(4000),
    object_name        VARCHAR2(4000),
    event_timestamp    TIMESTAMP WITH TIME ZONE,
    error_code         NUMBER,
    error_msg          VARCHAR2(4000),
    event_status       NUMBER,
    log_id             NUMBER,
    run_count          NUMBER,
    failure_count      NUMBER,
    retry_count        NUMBER,
    spare1             NUMBER,
    spare2             NUMBER,
    spare3             VARCHAR2(4000),
    spare4             VARCHAR2(4000),
    spare5             TIMESTAMP WITH TIME ZONE,
    spare6             TIMESTAMP WITH TIME ZONE,
    spare7             RAW(2000),
    spare8             RAW(2000));
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event_type</td>
<td>One of &quot;JOB_STARTED&quot;, &quot;JOB_SUCCEEDED&quot;, &quot;JOB_FAILED&quot;, &quot;JOB_BROKEN&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;JOB_COMPLETED&quot;, &quot;JOB_STOPPED&quot;, &quot;JOB_SCH_LIM_REACHED&quot;, &quot;JOB_DISABLED&quot;,</td>
</tr>
<tr>
<td></td>
<td>&quot;JOB_CHAIN_STALLED&quot;, &quot;JOB_OVER_MAX_DUR&quot;.</td>
</tr>
<tr>
<td></td>
<td>For descriptions of these event types, see Table 129-82, &quot;Event Types</td>
</tr>
<tr>
<td></td>
<td>Raised by the Scheduler&quot; on page 129-134.</td>
</tr>
<tr>
<td>object_owner</td>
<td>Owner of the job that raised the event</td>
</tr>
<tr>
<td>object_name</td>
<td>Name of the job that raised the event</td>
</tr>
<tr>
<td>event_timestamp</td>
<td>Time at which the event occurred</td>
</tr>
<tr>
<td>error_code</td>
<td>Applicable only when an error is thrown during job execution. Contains</td>
</tr>
<tr>
<td></td>
<td>the top-level error code.</td>
</tr>
<tr>
<td>error_msg</td>
<td>Applicable only when an error is thrown during job execution. Contains</td>
</tr>
<tr>
<td></td>
<td>the entire error stack.</td>
</tr>
</tbody>
</table>
SCHEDULER$_EVENT_INFO Object Type

Table 129–7 (Cont.) SCHEDULER_EVENT_INFO Object Type Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>event_status</td>
<td>Adds further qualification to the event type. If <code>event_type</code> is &quot;JOB_STARTED,&quot; status 1 indicates that it is a normal start, and status 2 indicates that it is a retry. If <code>event_type</code> is &quot;JOB_FAILED,&quot; status 4 indicates that it was a failure due to an error that was thrown during job execution, and status 8 indicates that it was an abnormal termination of some kind. If <code>event_type</code> is &quot;JOB_STOPPED,&quot; status 16 indicates that it was a normal stop, and status 32 indicates that it was a stop with the FORCE option set to TRUE.</td>
</tr>
<tr>
<td>log_id</td>
<td>Points to the ID in the scheduler job log from which additional information can be obtained. Note that there need not always be a log entry corresponding to an event. In such cases, <code>log_id</code> is NULL.</td>
</tr>
<tr>
<td>run_count</td>
<td>Run count for the job when the event was raised.</td>
</tr>
<tr>
<td>failure_count</td>
<td>Failure count for the job when the event was raised.</td>
</tr>
<tr>
<td>retry_count</td>
<td>Retry count for the job when the event was raised.</td>
</tr>
<tr>
<td>spare1–spare8</td>
<td>Not currently in use.</td>
</tr>
</tbody>
</table>
SCHEDULER_FILEWATCHER_RESULT Object Type

This is the data type of a file arrival event message. You access the event message as a parameter of an event-based job (or a parameter of a program referenced by an event-based job). The message contains information needed to locate and process a file that arrived on a local or remote system.

Syntax

```sql
TYPE scheduler_filewatcher_result IS OBJECT (
    destination VARCHAR2(4000),
    directory_path VARCHAR2(4000),
    actual_file_name VARCHAR2(4000),
    file_size NUMBER,
    file_timestamp TIMESTAMP WITH TIME ZONE,
    ts_ms_from_epoch NUMBER,
    matching_requests SYS.SCHEDULER_FILEWATCHER_REQ_LIST);
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination</td>
<td>Destination at which the file was found, expressed as a host name or IP address.</td>
</tr>
<tr>
<td>directory_path</td>
<td>Absolute path of directory in which the file was found.</td>
</tr>
<tr>
<td>actual_file_name</td>
<td>Actual name of the file that was found. If the file name specified in the file watcher did not contain wildcards, then this is the same as the name specified in the file watcher.</td>
</tr>
<tr>
<td>file_size</td>
<td>Size of the file that was found, in bytes.</td>
</tr>
<tr>
<td>file_timestamp</td>
<td>Timestamp assigned to the file when the file watcher considered the file found, based on the minimum file size and steady state duration attributes.</td>
</tr>
<tr>
<td>ts_ms_from_epoch</td>
<td>For internal use only.</td>
</tr>
<tr>
<td>matching_requests</td>
<td>List of matching requests. This is a TABLE of type objects SCHEDULER_FILEWATCHER_REQUEST. Each matching request corresponds to a file watcher whose destination, directory_path, and file_name attributes matched the arrived file. See “SCHEDULER_FILEWATCHER_REQUEST Object Type” on page 129-16.</td>
</tr>
</tbody>
</table>
SCHEDULER_FILEWATCHER_REQUEST Object Type

This type is returned in the matching_requests attribute of the SCHEDULER_FILEWATCHER_RESULT Object Type. Its attributes are similar to the attributes of a file watcher.

Syntax

```sql
TYPE scheduler_filewatcher_request IS OBJECT {
  owner                 VARCHAR2(4000),
  name                  VARCHAR2(4000),
  requested_path_name   VARCHAR2(4000),
  requested_file_name   VARCHAR2(4000),
  credential_owner      VARCHAR2(4000),
  credential_name       VARCHAR2(4000),
  min_file_size         NUMBER,
  steady_state_dur      NUMBER};
```

Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner</td>
<td>Owner of the matched file watcher.</td>
</tr>
<tr>
<td>name</td>
<td>Name of the matched file watcher.</td>
</tr>
<tr>
<td>requested_path_name</td>
<td>Value of the directory_path attribute of the matched file watcher.</td>
</tr>
<tr>
<td>requested_file_name</td>
<td>Value of the file_name attribute of the matched file watcher.</td>
</tr>
<tr>
<td>credential_owner</td>
<td>Owner of the credential referenced by the matched file watcher.</td>
</tr>
<tr>
<td>credential_name</td>
<td>Name of the credential referenced by the matched file watcher.</td>
</tr>
<tr>
<td>min_file_size</td>
<td>Value of the min_file_size attribute of the matched file watcher.</td>
</tr>
<tr>
<td>steady_state_dur</td>
<td>Value of the steady_state_duration attribute of the matched file watcher.</td>
</tr>
</tbody>
</table>
Using DBMS_SCHEDULER

This section contains:

- Security Model
- Rules and Limits
- Operational Notes
Security Model

The DBMS_SCHEDULER package ignores privileges granted on scheduler objects, such as jobs or chains, through roles. Object privileges must be granted directly to the user.
Rules and Limits

The following rules apply when using the DBMS_SCHEDULER package:

- Only SYS can perform actions on objects in the SYS schema.
- Several of the procedures accept comma-delimited lists of object names. If you provide a list of names, then the Scheduler stops executing the list at the first object that returns an error. Therefore, the Scheduler does not perform the tasks needed for the remaining objects on the list.

For example, consider the statement `DBMS_SCHEDULER.STOP_JOB ('job1, job2, job3, sys.jobclass1, sys.jobclass2, sys.jobclass3');`

If job3 cannot be stopped, then the jobs that follow it, jobclass1, jobclass2, and jobclass3 cannot be stopped. The jobs that preceded job3, job1 and job2, are stopped.

- Performing an action on an object that does not exist returns a PL/SQL exception stating that the object does not exist.
Operational Notes

The Scheduler uses a rich calendaring syntax to enable you to define repeating schedules, such as "every Tuesday and Friday at 4:00 p.m." or "the second Wednesday of every month." This calendaring syntax is used in calendaring expressions in the repeat_interval argument of a number of package subprograms. Evaluating a calendaring expression results in a set of discrete timestamps.

See Oracle Database Administrator's Guide for examples of the calendaring syntax.

Calendaring Syntax

This section starts with the calendaring syntax. It is followed by descriptions of various parts of the syntax.

In the calendaring syntax, * means 0 or more.

repeat_interval = regular_schedule | combined_schedule

regular_schedule = frequency_clause
[""," interval_clause"] | ";" bymonth_clause] [""," byweekno_clause]
[""," byyearday_clause] [""," bydate_clause] [""," bymonthday_clause]
[""," byday_clause] [""," byhour_clause] [""," byminute_clause]
[""," bysecond_clause] [""," bysetpos_clause] [""," include_clause]
["", exclude_clause] | ";" intersect_clause] ["", periods_clause]
["", byperiod_clause]

combined_schedule = schedule_list

frequency_clause = "FREQ" '=' ( predefined_frequency | user_defined_frequency )
predefined_frequency = "YEARLY" | "MONTHLY" | "WEEKLY" | "DAILY" |
"HOURLY" | "MINUTELY" | "SECONDLY"
user_defined_frequency = named_schedule

interval_clause = "INTERVAL" '=' intervalnum
intervalnum = 1 through 99

bymonth_clause = "BOfMonth" '=' monthlist
monthlist = month ( "," month)*
month = numeric_month | char_month
numeric_month = 1 | 2 | 3 ... 12
char_month = "JAN" | "FEB" | "MAR" | "APR" | "MAY" | "JUN" |
"JUL" | "AUG" | "SEP" | "OCT" | "NOV" | "DEC"

byweekno_clause = "BYWEEKNO" '=' weeknumber_list
weeknumber_list = weeknumber ( "," weeknumber)*
weeknumber = [minus] weekno
weekno = 1 through 53

byyearday_clause = "BYYEARDAY" '=' yearday_list
yearday_list = yearday ( "," yearday)*

<tr>
<td></td>
<td>HOURLY, MINUTELY, and SECONDLY. Alternatively, specifies an existing schedule</td>
</tr>
<tr>
<td></td>
<td>to use as a user-defined frequency.</td>
</tr>
<tr>
<td>INTERVAL</td>
<td>This specifies a positive integer representing how often the recurrence</td>
</tr>
<tr>
<td></td>
<td>repeats. The default is 1, which means every second for secondly, every</td>
</tr>
<tr>
<td></td>
<td>day for daily, and so on. The maximum value is 99.</td>
</tr>
<tr>
<td>BYMONTH</td>
<td>This specifies which month or months you want the job to execute in. You</td>
</tr>
<tr>
<td></td>
<td>can use numbers such as 1 for January and 3 for March, as well as three-letter</td>
</tr>
<tr>
<td></td>
<td>abbreviations such as FEB for February and JUL for July.</td>
</tr>
</tbody>
</table>
This specifies the week of the year as a number. It follows ISO-8601, which defines the week as starting with Monday and ending with Sunday; and the first week of a year as the first week, which is mostly within the Gregorian year. The first week is equivalent to the following two variants: the week that contains the first Thursday of the Gregorian year; and the week containing January 4th.

The ISO-8601 week numbers are integers from 1 to 52 or 53; parts of week 1 may be in the previous calendar year; parts of week 52 may be in the following calendar year; and if a year has a week 53, parts of it must be in the following calendar year.

BYWEEKNO is only valid for YEARLY.

Examples of invalid specifications are 

```
FREQ=YEARLY; BYWEEKNO=1; BYMONTH=12

FREQ=YEARLY; BYWEEKNO=53; BYMONTH=1
```

This specifies the day of the year as a number. Valid values are 1 to 366. An example is 69, which is March 10 (31 for January, 28 for February, and 10 for March). 69 evaluates to March 10 for non-leap years and March 9 in leap years. -2 will always evaluate to December 30th independent of whether it is a leap year.

BYYEARDAY

This specifies a list of dates, where each date is of the form [YYYY]MMDD. A list of consecutive dates can be generated by using the SPAN modifier, and a date can be adjusted with the OFFSET modifier. An example of a simple BYDATE clause follows:

```
BYDATE=0115,0315,0615,0915,1215,20060115
```

The following SPAN example is equivalent to

```
BYDATE=0110,0111,0112,0113,0114
```

The plus sign in front of the SPAN keyword indicates a span starting at the supplied date. The minus sign indicates a span ending at the supplied date, and the "^" sign indicates a span of n days or weeks centered around the supplied date. If n is an even number, it is adjusted up to the next odd number.

Offsets adjust the supplied date by adding or subtracting n days or weeks.

```
BYDATE=0205-OFFSET:2W is equivalent to BYDATE=0205-14D (the OFFSET: keyword is optional), which is also equivalent to BYDATE=0122.
```

This specifies the day of the month as a number. Valid values are 1 to 31. An example is 10, which means the 10th day of the selected month. You can use the minus sign (-) to count backward from the last day, so, for example, BYMONTHDAY=-1 means the last day of the month and BYMONTHDAY=-2 means the next to last day of the month.

BYHOUR

This specifies the hour on which the job is to run. Valid values are 0 to 23. As an example, 10 means 10 a.m.

BYMINUTE

This specifies the minute on which the job is to run. Valid values are 0 to 59. As an example, 45 means 45 minutes past the chosen hour.
This specifies the second on which the job is to run. Valid values are 0 to 59. As an example, 30 means 30 seconds past the chosen minute.

This selects one or more items, by position, in the list of timestamps that result after the whole calendaring expression is evaluated. It is useful for requirements such as running a job on the last workday of the month. Rather than attempting to express this with the other BY clauses, you can code the calendaring expression to evaluate to a list of every workday of the month, and then add the BYSETPOS clause to select only the last item of that list. Assuming that workdays are Monday through Friday, the syntax would then be:

```
FREQ=MONTHLY; BYDAY=MON,TUE,WED,THU,FRI; BYSETPOS=-1
```

Valid values are 1 through 9999. A negative number selects an item from the end of the list (-1 is the last item, -2 is the next to last item, and so on) and a positive number selects from the front of the list. The BYSETPOS clause is always evaluated last. BYSETPOS is only supported with the MONTHLY and YEARLY frequencies.

The BYSETPOS clause is applied to the list of timestamps once per frequency period. For example, when the frequency is defined as MONTHLY, the Scheduler determines all valid timestamps for the month, orders that list, and then applies the BYSETPOS clause. The Scheduler then moves on to the next month and repeats the procedure. Assuming a start date of Jun 10, 2004, the example evaluates to: Jun 30, Jul 30, Aug 31, Sep 30, Oct 29, and so on.

This includes one or more named schedules in the calendaring expression. That is, the set of timestamps defined by each included named schedule is added to the results of the calendaring expression. If an identical timestamp is contributed by both an included schedule and the calendaring expression, it is included in the resulting set of timestamps only once. The named schedules must have been defined with the CREATE_SCHEDULE procedure.

This excludes one or more named schedules from the calendaring expression. That is, the set of timestamps defined by each excluded named schedule is removed from the results of the calendaring expression. The named schedules must have been defined with the CREATE_SCHEDULE procedure.

This specifies an intersection between the calendaring expression results and the set of timestamps defined by one or more named schedules. Only the timestamps that appear both in the calendaring expression and in one of the named schedules are included in the resulting set of timestamps.

For example, assume that the named schedule last_sat indicates the last Saturday in every month, and that for the year 2005, the only months where the last day of the month is also a Saturday are April and December. Assume also that the named schedule end_qtr indicates the last day of each quarter in 2005:

```
```

These calendaring expressions result in the dates that follow:

```
```

```
FREQ=MONTHLY; BYMONTHDAY=-1; INTERSECT=last_sat,end_qtr
```

In this example, the terms FREQ=MONTHLY; BYMONTHDAY=-1 indicate the last day of each month.
Combining Schedules

There are two ways to combine schedules:

- **Using a combined schedule expression**, which is a list of individual schedules
  
  For example, to create a schedule for all company holidays, you provide a list of individual schedules, where each schedule in the list defines a single holiday. The Scheduler evaluates each individual schedule, and then returns a union of the timestamps returned by each individual schedule.

- **Embedding other schedules into the main schedule using `include`, `exclude`, and `intersect` clauses**
  
  With this method, the embedded schedules inherit certain attributes from the main schedule.
  
  - Timestamps generated by the `INCLUDE` clause that fall into periods that are skipped by the main schedule are ignored. This is the case when the main schedule skips periods due to the `INTERVAL` clause, the `BYPERIOD` clause, or the `BYMOMTH` clause for `freq=monthly`.
  
  - Days that are added by the `INCLUDE` clause follow the hourly/ minutely/ secondly execution pattern of the main schedule.
  
  - When the `INCLUDE` clause is present, no date-specific defaults are retrieved from the start date (but time-specific defaults can be). (See “Start Dates and Repeat Intervals”, later in this section.) For example, a `repeat_interval` of `FREQ=MONTHLY;INCLUDE=HOLIDAY` executes only on holidays and not on the month/day defaults retrieved from the start date.

The following is an example:

```sql
BEGIN
  dbms_scheduler.create_schedule('embed_sched', repeat_interval =>
    'FREQ=YEARLY;BYDATE=0301,0601,0901,1201;PERIODS=4');
  dbms_scheduler.create_schedule('main_sched', repeat_interval =>
    'FREQ=MONTHLY;INTERVAL=2;BYMONTHDAY=15;BYHOUR=9,17;INCLUDE=embed_sched');
END;
/
```

In this example, the dates 1/30, 2/20, and 7/25 are added to the main schedule. However, the Scheduler does not include dates that fall in months that are skipped by the `INTERVAL` clause. If the start date of the main schedule is 1/1/2005, then 2/20 is not added. On the dates that are added, the embedded schedule follows the execution pattern of the main schedule: jobs are executed at 9:00 a.m. and 5:00 p.m. on 1/30 and 7/25. If the embedded schedule does not itself have a start date, it inherits the start date from the main schedule.
**User-Defined Frequencies**  Instead of using predefined frequencies like DAILY, WEEKLY, MONTHLY, and so on, you can create your own frequencies by creating a schedule that returns the start date of each period. For example, the following repeat_interval expression is used in a schedule named `fiscal_year` that defines the start of each quarter in a fiscal year:

```
FREQ=YEARLY;BYDATE=0301,0601,0901,1201;PERIODS=4
```

To return the last Wednesday of every quarter, you create a schedule (the "main schedule") that uses the `fiscal_year` schedule as a user-defined frequency:

```
FREQ=fiscal_year;BYDAY=-1WED
```

Periods in a user-defined frequency do not have to be equal in length. In the main schedule, the `BYSETPOS` clause and numbered weekdays are recalculated based on the size of each period. To select dates in specific periods, you must use the `BYPERIOD` clause in the main schedule. To enable this, the schedule that is used as the user-defined frequency must include a `PERIODS` clause, and it must set its start date appropriately. The first date returned by this schedule is used as the starting point of period 1.

As another example, assuming work days are Monday through Friday, to get the last work day of the 2nd and 4th quarters of the fiscal year, the repeat_interval clause in the main schedule is the following:

```
FREQ=fiscal_year;BYDAY=MON,TUE,WED,THU,FRI;BYPERIOD=2,4;BYSETPOS=-1
```

**Start Dates and Repeat Intervals**  The Scheduler retrieves the date and time from the job or schedule start date and incorporates them as defaults into the repeat_interval. For example, if the specified frequency is yearly and there is no `BYMTH` or `BMDY` clause in the repeat interval, then the month and day that the job runs on are retrieved from the start date. Similarly, if frequency is monthly but there is no `BMDY` clause in the repeat interval, then the day of the month that the job runs on is retrieved from the start date. If present, `BHR`, `BRMIN`, and `BSEC` defaults are also retrieved from the start date, and used if those clauses are not specified. Note that if the `INCLUDE`, `EXCLUDE`, or `INTERSECT` clauses are present, no date-related defaults are retrieved from the start date, but time-related defaults are.

The following are some examples:

```
start_date: 4/15/05 9:00:00
repeat_interval: freq=yearly
```

is expanded internally to:

```
freq=yearly;bymonth=4;bymonthday=15;byhour=9;byminute=0;bysecond=0
```

The preceding schedule executes on 04/15/05 9:00:00, 04/15/06 9:00:00, 04/15/07 9:00:00, and so on.

For the next example, assume that schedule `S1` has a repeat_interval of `FREQ=YEARLY;BYDATE=0701`.

```
start_date: 01/20/05 9:00:00
repeat_interval: freq=yearly;include=S1
```

is expanded internally to:

```
freq=yearly;byhour=9;byminute=0;bysecond=0;include=S1
```
Because an `INCLUDE` clause is present, date-related information is not retrieved from the start date. However, time-specific information is, so the preceding schedule executes on 07/01/05 9:00:00, 07/01/06 9:00:00, 07/01/08 9:00:00, and so on.

**General Rules** When using a calendaring expression, consider the following rules:

- For a regular schedule (as opposed to a combined schedule), the calendar string must start with the frequency clause. All other clauses are optional and can be put in any order.
- All clauses are separated by a semicolon, and each clause can be present at most once, with the exception of the `include`, `exclude`, and `intersect` clauses.
- Spaces are allowed between syntax elements and the strings are case-insensitive.
- The list of values for a specific `BY` clause do not need to be ordered.
- When not enough `BY` clauses are present to determine what the next date is, this information is retrieved from the start date. For example, "FREQ=YEARLY" with a start date of 02/15/2003 becomes "FREQ=YEARLY;BYMONTH=FEB; BYMONTHDAY=15", which means every year on the 15th of February.
  
  "FREQ=YEARLY;BYMONTH=JAN, JUL" with start date 01/21/2003 becomes "FREQ=YEARLY;BYMONTH=JAN, JUL;BYMONTHDAY=21", which means every year on January 21 and July 21.
- The `byweekno` clause is only allowed if the frequency is `YEARLY`. It cannot be used with other frequencies. When it is present, it will return all days in that week number. If you want to limit it to specific days within the week, you have to add a `BYDAY` clause. For example, "FREQ=YEARLY;BYWEEKNO=2" with a start date of 01/01/2003 will return:
  
  01/06/2003, 01/07/2003, 01/08/2003, 01/09/2003, 01/10/2003, 01/11/2003, 01/12/2003, 01/05/2004, 01/06/2004, 01/07/2004, .... and so on.

Note that when the `byweekno` clause is used, it is possible that the dates returned are from a year other than the current year. For example, if returning dates for the year 2004 and the calendar string is "FREQ=YEARLY;BYWEEKNO=1,53" for the specified week numbers in 2004, it will return the dates:

12/29/03, 12/30/03, 12/31/03, 01/01/04, 01/02/04, 01/03/04, 01/04/04, 12/27/04, 12/28/04, 12/29/04, 12/30/04, 12/31/04, 01/01/05, 01/02/05

- For those `BY` clauses that do not have a consistent range of values, you can count backward by putting a "-" in front of the numeric value. For example, specifying `BMONTHDAY=31` will not give you the last day of every month, because not every month has 31 days. Instead, `BMONTHDAY=-1` will give you the last day of the month.

This is not supported for `BY` clauses that are fixed in size. In other words, `BMONTH`, `BYHOUR`, `BMINUTE`, and `BSECOND` are not supported.

- The basic values for the `BYDAY` clause are the days of the week. When the frequency is `YEARLY`, or `MONTHLY`, you are allowed to specify a positive or negative number in front of each day of the week. In the case of `YEARLY`, `BYDAY=40MON`, indicates the 40th Monday of the year. In the case of `MONTHLY`, `BYDAY=-2SAT`, indicates the second to last Saturday of the month.

Note that positive or negative numbers in front of the weekdays are not supported for other frequencies and that in the case of yearly, the number ranges from -53 ... -1, 1 ... 53, whereas for the monthly frequency it is limited to -5 ... -1, 1 ... 5.
If no number is present in front of the weekday it specifies, every occurrence of that weekday in the specified frequency.

- The first day of the week is Monday.

- Repeating jobs with frequencies smaller than daily follow their frequencies exactly across daylight savings adjustments. For example, suppose that a job is scheduled to repeat every 3 hours, the clock is moved forward from 1:00 a.m. to 2:00 a.m., and the last time the job ran was midnight. Its next scheduled time will be 4:00 a.m. Thus, the 3 hour period between subsequent job runs is retained. The same applies when the clock is moved back. This behavior is not the case for repeating jobs that have frequencies of daily or larger. For example, if a repeating job is supposed to be executed on a daily basis at midnight, it will continue to run at midnight if the clock is moved forward or backward. When the execution time of such a daily (or larger frequency) job happens to fall inside a window where the clock is moved forward, the job executes at the end of the window.

- The calendaring syntax does not allow you to specify a time zone. Instead the Scheduler retrieves the time zone from the start_date argument. If jobs must follow daylight savings adjustments, then you must specify a region name for the time zone of the start_date. For example specifying the start_date time zone as 'US/Eastern' in New York ensures that daylight saving adjustments are automatically applied. If instead, the time zone of the start_date is set to an absolute offset, such as '-5:00', then daylight savings adjustments are not followed and your job execution is off by an hour for half the year.

- When start_date is NULL, the Scheduler determines the time zone for the repeat interval as follows:
  1. It checks whether or not the session time zone is a region name. The session time zone can be set by either:
     - Issuing an ALTER SESSION statement, for example:
       ```sql
       SQL> ALTER SESSION SET time_zone = 'Asia/Shanghai';
       ```
     - Setting the ORA_SDTZ environment variable.
  2. If the session time zone is an absolute offset instead of a region name, the Scheduler uses the value of the DEFAULT_TIMEZONE Scheduler attribute. For more information, see the SET_SCHEDULER_ATTRIBUTE Procedure.
  3. If the DEFAULT_TIMEZONE attribute is NULL, the Scheduler uses the time zone of systimestamp when the job or window is enabled.

**BYSETPOS Clause Rules**  The following are rules for the BYSETPOS clause.

- The BYSETPOS clause is the last clause to be evaluated. It is processed after all other BY clauses and the INCLUDE, EXCLUDE and INTERSECT clauses have been evaluated.

- The INTERVAL clause does not change the size of the period to which the BYSETPOS clause is applied. For example, when the frequency is set to monthly and interval is set to 3, the list of timestamps to which BYSETPOS is applied is generated from a month, not a quarter. The only impact of the INTERVAL clause is to cause months to be skipped. However, you can still select the second to last workday of the quarter like this:

  ```sql
  FREQ=MONTHLY;INTERVAL=3;BYDAY=MON,TUE,WED,THU,FRI;BYSETPOS=-2
  ```

  provided that you set the start date in the right month. This example returns the next to last workday of a month, and repeats once a quarter.
To get consistent results, the set to which BYSETPOS is applied is determined from the beginning of the frequency period independently of when the evaluation occurs. Whether the Scheduler evaluates

\[
\text{FREQ=MONTHLY; BYDAY=MON, TUE, FRI; BYSETPOS=1, 3}
\]

on 01/01/2004 or 01/15/2004, in both cases the expression evaluates to Friday 01/02/2004, and Tuesday 01/06/2004. The only difference is that when the expression is evaluated on 01/15/2004, the Scheduler determines that there are no matches in January because the timestamps found are in the past, and it moves on to the matches in the next month, February.

**BYDATE Clause Rules**  The following are rules for the BYDATE clause.

- If dates in the BYDATE clause do not have their optional year component, the job runs on those dates every year.
- The job execution times on the included dates are derived from the BY clauses in the calendaring expression. For example, if repeat_interval is defined as

\[
\text{freq=daily; byhour=8,13,18; byminute=0; bysecond=0; bydate=0502,0922}
\]

then the execution times on 05/02 and 09/22 are 8:00 a.m., 1:00 p.m., and 6:00 p.m.

**EXCLUDE Clause Rules**  Excluded dates without a time component are 24 hour periods. All timestamps that fall on an excluded date are removed. In the following example, jan_fifteen is a named schedule that resolves to the single date of 01/15:

\[
\text{freq=monthly; bymonthday=15,30; byhour=8,13,18; byminute=0; bysecond=0; exclude=jan_fifteenth}
\]

In this case, all three instances of the job are removed for 01/15.

**OFFSET Rules**  You can adjust the dates of individual named schedules by adding positive offsets to them. For example, to execute JOB2 exactly 15 days after every occurrence of JOB1, add +OFFSET:15D to the schedule of JOB1, as follows:

\[
\begin{align*}
\text{BEGIN} \\
\text{dbms_scheduler.create_schedule('job2_schedule', repeat_interval =>} \\
\text{'job1_schedule+OFFSET:15D');} \\
\text{END;}
\end{align*}
\]

Note that negative offsets to named schedules are not supported.

**Example 129–1 Putting It All Together**

This example demonstrates the use of user-defined frequencies, spans, offsets, and the BYSETPOS and INCLUDE clauses. (Note that the OFFSET: keyword is optional in an offset clause.)

Many companies in the retail industry share the same fiscal year. The fiscal year starts on the Sunday closest to February 1st, and subsequent quarters start exactly 13 weeks later. The fiscal year schedule for the retail industry can be defined as the following:

\[
\begin{align*}
\text{begin} \\
\text{dbms_scheduler.create_schedule('year_start', repeat_interval=>} \\
\text{'FREQ=YEARLY; BYDATE=0201^SPAN:1W; BYDAY=SUN');} \\
\text{dbms_scheduler.create_schedule('retail_fiscal_year',} \\
\text{to_timestamp_tz('15-JAN-2005 12:00:00','DD-MON-YYYY HH24:MI:SS'),} \\
\text{'year_start,year_start+13w,year_start+26w,year_start+39w;periods=4');}
\end{align*}
\]
end;
/

The following schedule can be used to execute a job on the 5th day off in the 2nd and
the 4th quarters of the retail industry. This assumes that Saturday and Sunday are off
days as well as the days in the existing holiday schedule.

begin
  dbms_scheduler.create_schedule('fifth_day_off', repeat_interval=>
  'FREQ=retail_fiscal_year;BYDAY=SAT,SUN;INCLUDE=holiday;
    BYPERIOD=2,4;BYSETPOS=5');
end;
/
### Summary of DBMS_SCHEDULER Subprograms

#### Table 129–11  DBMS_SCHEDULER Package Subprograms

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADD_EVENT_QUEUE_SUBSCRIBER Procedure on page 129-34</td>
<td>Adds a user as a subscriber to the Scheduler event queue \texttt{SYS.SCHEDULER$_EVENT_QUEUE}</td>
</tr>
<tr>
<td>ADD_GROUP_MEMBER Procedure on page 129-35</td>
<td>Adds one or more members to an existing group</td>
</tr>
<tr>
<td>ADD_JOB_EMAIL_NOTIFICATION Procedure on page 129-36</td>
<td>Adds e-mail notifications for a job for a list of recipients and a list of job state events</td>
</tr>
<tr>
<td>ADD_WINDOW_GROUP_MEMBER Procedure on page 129-38</td>
<td>***Deprecated. Use \texttt{CREATE_GROUP} and \texttt{ADD_GROUP_MEMBER} instead</td>
</tr>
<tr>
<td>ALTER_CHAIN Procedure on page 129-39</td>
<td>Alters specified steps of a chain</td>

**Table 129–11 (Cont.) DBMS_SCHEDULER Package Subprograms**

<table>
<thead>
<tr>
<th>Subprogram</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLE Procedure on page 129-100</td>
<td>Enables a program, job, chain, window, database destination, external destination, file watcher, or group</td>
</tr>
<tr>
<td>END_DETACHED_JOB_RUN Procedure on page 129-102</td>
<td>Ends a running detached job</td>
</tr>
<tr>
<td>EVALUATE_CALENDAR_STRING Procedure on page 129-103</td>
<td>Evaluates the calendar string and tells you what the next execution date of a job or window will be</td>
</tr>
<tr>
<td>EVALUATE_RUNNING_CHAIN Procedure on page 129-105</td>
<td>Forces reevaluation of the rules of a running chain to trigger any rules for conditions that have been satisfied</td>
</tr>
<tr>
<td>GENERATE_JOB_NAME Function on page 129-106</td>
<td>Generates a unique name for a job. This enables you to identify jobs by adding a prefix, so, for example, Sally's jobs would be named sally1, sally2, and so on</td>
</tr>
<tr>
<td>&quot;GET_AGENT_INFO Function&quot; on page 129-107</td>
<td>Returns job information specific to an agent, such as how many are running and so on, depending on the attribute selected</td>
</tr>
<tr>
<td>&quot;GET_AGENT_VERSION Function&quot; on page 129-108</td>
<td>Returns the version string of a Scheduler agent that is registered with the database and is currently running</td>
</tr>
<tr>
<td>GET_ATTRIBUTE Procedure on page 129-109</td>
<td>Retrieves the value of an attribute of an object</td>
</tr>
<tr>
<td>GET_FILE Procedure on page 129-110</td>
<td>Retrieves a file from a host</td>
</tr>
<tr>
<td>GET_SCHEDULER_ATTRIBUTE Procedure on page 129-112</td>
<td>Retrieves the value of a Scheduler attribute</td>
</tr>
<tr>
<td>OPEN_WINDOW Procedure on page 129-113</td>
<td>Opens a window prematurely. The window is opened immediately for the duration</td>
</tr>
<tr>
<td>PURGE_LOG Procedure on page 129-115</td>
<td>Purges specific rows from the job and window logs</td>
</tr>
<tr>
<td>PUT_FILE Procedure on page 129-116</td>
<td>Saves a file to one or more hosts</td>

<td>Sets the value of a job argument encapsulated in an AnyData object</td>
</tr>
<tr>
<td>SET_JOB_ARGUMENT_VALUE Procedure on page 129-143</td>
<td>Sets the value of a job argument</td>
</tr>
<tr>
<td>SET_JOB_ATTRIBUTES Procedure on page 129-145</td>
<td>Sets the value of a job attribute</td>
</tr>
<tr>
<td>SET_SCHEDULER_ATTRIBUTE Procedure on page 129-146</td>
<td>Sets the value of a Scheduler attribute</td>
</tr>
<tr>
<td>STOP_JOB Procedure on page 129-148</td>
<td>Stops a currently running job or all jobs in a job class</td>
</tr>
</tbody>
</table>
ADD_EVENT_QUEUE_SUBSCRIBER Procedure

This procedure adds a user as a subscriber to the Scheduler event queue SYS.SCHEDULER$_EVENT_QUEUE, and grants the user permission to dequeue from this queue using the designated agent.

Syntax

```
DBMS_SCHEDULER.ADD_EVENT_QUEUE_SUBSCRIBER (
    subscriber_name IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_name</td>
<td>Name of the Oracle Streams Advanced Queuing (AQ) agent to be used to subscribe to the Scheduler event queue. If NULL, an agent is created and assigned the user name of the calling user.</td>
</tr>
</tbody>
</table>

Usage Notes

The subscription is rule-based. The rule permits the user to see only events raised by jobs that the user owns, and filters out all other messages. If an AQ agent with the same name already exists, an error is raised.
ADD_GROUP_MEMBER Procedure

This procedure adds one or more members to an existing group.

Syntax

```sql
DBMS_SCHEDULER.ADD_GROUP_MEMBER (  
    group_name  IN VARCHAR2,  
    member      IN VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name of the group.</td>
</tr>
<tr>
<td>member</td>
<td>A comma-separated list of members to add to the group. Members must match the group type. A group of the same type can be a member. The Scheduler immediately expands the included group name into its list of members. An error is returned if any of the members do not exist. A member that is already in the group is skipped, and no error is generated. The keyword LOCAL can be included as a member for database destination or external destination groups. See the &quot;CREATE_GROUP Procedure&quot; on page 53 for information about this keyword.</td>
</tr>
</tbody>
</table>

Usage Notes

The following users may add members to a group:

- The group owner
- A user that has been granted the ALTER object privilege on the group
- A user with the CREATE ANY JOB system privilege

You must have the MANAGE SCHEDULER privilege to add a member to a group of type WINDOW.

See Also:  "CREATE_GROUP Procedure" on page 129-53
ADD_JOB_EMAIL_NOTIFICATION Procedure

This procedure adds e-mail notifications for a job. E-mails are then sent to the specified list of recipients whenever any of the specified job state events is raised.

Syntax

```sql
DBMS_SCHEDULER.ADD_JOB_EMAIL_NOTIFICATION (  
  job_name             IN VARCHAR2,  
  recipients           IN VARCHAR2,  
  sender               IN VARCHAR2 DEFAULT NULL,  
  subject              IN VARCHAR2 DEFAULT DBMS_SCHEDULER.DEFAULT_NOTIFICATION_SUBJECT,  
  body                 IN VARCHAR2 DEFAULT DBMS_SCHEDULER.DEFAULT_NOTIFICATION_BODY,  
  events               IN VARCHAR2 DEFAULT 'JOB_FAILED,JOB_BROKEN,JOB_SCH_LIM_REACHED, JOB_CHAIN_STALLED,JOB_OVER_MAX_DUR',  
  filter_condition     IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Name of the job that e-mail notifications are added for. Cannot be NULL.</td>
</tr>
<tr>
<td>recipients</td>
<td>Comma-separated list of e-mail addresses to send notifications to. E-mail notifications for all listed events are sent to all recipients. Cannot be NULL.</td>
</tr>
<tr>
<td>sender</td>
<td>e-mail address to use as the sender address (the From: address) in the e-mail header. If NULL or omitted, the e-mail address specified in the Scheduler attribute email_sender is used. See Oracle Database Administrator’s Guide for more information on this Scheduler attribute.</td>
</tr>
</tbody>
</table>
| subject   | The subject to use in the e-mail header. Table 129–15 describes the variables that you can include within this parameter. The Scheduler assigns values to these variables before sending the notification. If subject is omitted, the default subject is used. The default subject is the following text, where text enclosed in the '%’ character represents a variable:

  'Oracle Scheduler Job Notification - %job_owner%.%job_name%.%job_subname% %event_type' |
| body      | The body of the e-mail message. Table 129–15 describes the variables that you can include within this parameter. The Scheduler assigns values to these variables before sending the notification. If body is omitted, the default body is used. The default body is the following text, where text enclosed in the '%’ character represents a variable:

  'Job: %job_owner%.%job_name%.%job_subname%  
  Event: %event_type%  
  Date: %event_timestamp%  
  Log id: %log_id%  
  Job class: %job_class_name%  
  Run count: %run_count%  
  Failure count: %failure_count%  
  Retry count: %retry_count%  
  Error code: %error_code%  
  Error message: %error_message%' |

Table 129–15  ADD_JOB_EMAIL_NOTIFICATION Procedure Parameters
Table 129–15 lists the variables that you can use in the subject and body arguments.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>%job_owner%</td>
<td>Schema in which job was created</td>
</tr>
<tr>
<td>%job_name%</td>
<td>Name of the job that e-mail notifications are added for</td>
</tr>
<tr>
<td>%job_subname%</td>
<td>Present for event-based jobs with the parallel_instances attribute set and for chain steps</td>
</tr>
<tr>
<td>%event_type%</td>
<td>Valid values are listed in Table 129–82 on page 129-134</td>
</tr>
<tr>
<td>%event_timestamp%</td>
<td>Time at which the event occurred</td>
</tr>
<tr>
<td>%log_id%</td>
<td>Refers to the LOG_ID column in views *_SCHEDULER_JOB_LOG and *_SCHEDULER_JOB_RUN_DETAILS</td>
</tr>
<tr>
<td>%error_code%</td>
<td>Number of the error code.</td>
</tr>
<tr>
<td>%error_message%</td>
<td>The text of the error message</td>
</tr>
<tr>
<td>%run_count%</td>
<td>Run count for the job when the event was raised</td>
</tr>
<tr>
<td>%failure_count%</td>
<td>Failure count for the job when the event was raised</td>
</tr>
<tr>
<td>%retry_count%</td>
<td>Retry count for the job when the event was raised</td>
</tr>
</tbody>
</table>

Usage Notes

You can call ADD_JOB_EMAIL_NOTIFICATION once for each different set of notifications that you want to configure for a particular job. For example, you may want to send notifications for the JOB_FAILED, JOB_BROKEN, JOB_SCH_LIM_REACHED, and JOB_CHAIN_STALLED events to the principle DBA and all senior DBAs, but send a notification for the JOB_OVER_MAX_DUR event only to the principle DBA.

This procedure succeeds only if the Scheduler attribute email_server is set to a valid SMTP server. See Oracle Database Administrator’s Guide for more information.

To call this procedure, you must be the job owner or have the CREATE ANY JOB system privilege or have the ALTER object privilege on the job.
ADD_WINDOW_GROUP_MEMBER Procedure

*** Deprecated in Oracle Database 11g Release 2 (11.2). Use ADD_GROUP_MEMBER instead.

This procedure adds one or more windows to an existing window group.

Syntax

```sql
DBMS_SCHEDULER.ADD_WINDOW_GROUP_MEMBER (
    group_name              IN VARCHAR2,
    window_list             IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name of the window group</td>
</tr>
<tr>
<td>window_list</td>
<td>The name of the window or windows</td>
</tr>
</tbody>
</table>

Usage Notes

If an already open window is added to a window group, the Scheduler will not pick up jobs that point to this window group until the next window in the window group opens.

Adding a window to a group requires the MANAGE_SCHEDULER privilege.

Note that a window group cannot be a member of another window group.
**ALTER_CHAIN Procedure**

This procedure alters an attribute of the specified steps of a chain. This affects all future runs of the specified steps, both in the currently running chain job and in future runs of the same chain job or other chain jobs that point to the chain.

**Syntax**

Alters the value of a boolean attribute of one or more steps:

```sql
DBMS_SCHEDULER.ALTER_CHAIN (  
    chain_name   IN VARCHAR2,  
    step_name    IN VARCHAR2,  
    attribute    IN VARCHAR2,  
    value        IN BOOLEAN);
```

Alters the value of a character attribute of one or more steps:

```sql
DBMS_SCHEDULER.ALTER_CHAIN (  
    chain_name   IN VARCHAR2,  
    step_name    IN VARCHAR2,  
    attribute    IN VARCHAR2,  
    char_value   IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to alter</td>
</tr>
<tr>
<td>step_name</td>
<td>The name of the step or a comma-separated list of steps to alter. This cannot be NULL.</td>
</tr>
</tbody>
</table>
ALTER_CHAIN Procedure

The attribute of the steps to change. Must be one of the following:

- **‘PAUSE’**
  
  If set to TRUE for a step, after the step has run, its state changes to PAUSED (and the completed attribute remains FALSE).

  If PAUSE is reset to FALSE for a paused chain step (using ALTER_RUNNING_CHAIN), the state is set to its completion state (SUCCEEDED, FAILED, or STOPPED) and the completed attribute is set to TRUE.

  Setting PAUSE has no effect on steps that have already run. This allows execution of a chain to be suspended after the execution of certain steps.

- **‘PAUSED_BEFORE’**
  
  If set to TRUE for a step and if any of the rule conditions that start the step are true, then its state changes to PAUSED and the step does not run.

  If PAUSE_BEFORE is reset to FALSE for a chain step that has paused before starting (using ALTER_RUNNING_CHAIN), then the step starts running if any of the rule conditions that start the step are true.

  Setting PAUSE_BEFORE has no effect on steps that are running or have already run. This allows execution of a chain to be suspended before the execution of certain steps.

- **‘SKIP’**
  
  If set to TRUE for a step, when the step condition is met, instead of being run, the step is treated as if it has immediately succeeded.

  Setting SKIP to TRUE has no effect for a step that is running, scheduled to run after a delay, or has already run. If SKIP is set TRUE for a step that PAUSE is also set for, when the step condition is met, the step immediately changes to state PAUSED.

- **‘RESTART_ON_FAILURE’**
  
  If set to TRUE for a step and the step fails due to an application error, then the step is retried using the normal Scheduler retry mechanism (after 1 second, after 10 seconds, after 100 seconds, and so on, up to a maximum of 6 times). If all 6 retries fail (after about 30 hours), then the chain step is marked FAILED.

  If set to FALSE (the default), a failed chain step is immediately marked FAILED.

- **‘RESTART_ON_RECOVERY’**
  
  If set to TRUE for a step and the step is stopped by a database shutdown, then the step is restarted when the database is recovered.

  If set to FALSE, and the step is stopped by a database shutdown, then the step is marked as stopped when the database is recovered and the chain continues.

- **‘DESTINATION_NAME’**
  
  The name of an existing database destination or external destination. You can view external destination names in the view ALL_SCHEDULER_EXTERNAL_DESTS, and database destination names in the views *_SCHEDULER_DB_DESTS. You cannot specify a destination group for this attribute. This parameter is NULL by default.

- **‘CREDENTIAL_NAME’**
  
  The credential to use when running this step. NULL by default.

Table 129–17 (Cont.) ALTER_CHAIN Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>The attribute of the steps to change. Must be one of the following:</td>
</tr>
<tr>
<td>value</td>
<td>The value to set for the attribute (for a boolean attribute).</td>
</tr>
</tbody>
</table>
Table 129–17  (Cont.) ALTER_CHAIN Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>char_value</td>
<td>The value to set for the attribute (for a character attribute).</td>
</tr>
</tbody>
</table>

**Usage Notes**

Altering a chain requires ALTER privileges on the chain either by being the owner of the chain, or by having the ALTER object privilege on the chain or by having the CREATE ANY JOB system privilege.
ALTER_RUNNING_CHAIN Procedure

This procedure alters an attribute of the specified steps of a chain. This affects only steps of the instance of the chain for the specified running chain job.

Syntax

```
DBMS_SCHEDULER.ALTER_RUNNING_CHAIN (
    job_name                IN VARCHAR2,
    step_name               IN VARCHAR2,
    attribute               IN VARCHAR2,
    value                   IN {BOOLEAN|VARCHAR2});
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the job that is running the chain</td>
</tr>
<tr>
<td>step_name</td>
<td>The name of the step or a comma-separated list of steps to alter. If this is set to NULL and attribute is PAUSE or SKIP, then all steps of the running chain are altered.</td>
</tr>
<tr>
<td>attribute</td>
<td>The attribute of the steps to change. Valid values are:</td>
</tr>
<tr>
<td></td>
<td>'PAUSE'</td>
</tr>
<tr>
<td></td>
<td>If the PAUSE attribute is set TRUE for a step, then after the step runs, its state changes to PAUSED (and the completed attribute remains false).</td>
</tr>
<tr>
<td></td>
<td>If PAUSE is reset to FALSE for a paused chain step (using ALTER_RUNNING_CHAIN), the state is set to completion (SUCCEEDED, FAILED, or STOPPED) and the completed attribute is set to TRUE. Setting PAUSE has no effect on steps that have already run. This allows execution of a chain to be suspended after the execution of certain steps. If step_name is set to NULL, PAUSE is set to TRUE for all steps of this running chain.</td>
</tr>
<tr>
<td></td>
<td>'PAUSE_BEFORE'</td>
</tr>
<tr>
<td></td>
<td>If set to TRUE for a step that has not yet run and if any of the rule conditions that start the step are true, then its state changes to PAUSED and the step does not run.</td>
</tr>
<tr>
<td></td>
<td>If PAUSE_BEFORE is reset to FALSE for a chain step that has paused before starting, then the step starts running if any of the rule conditions that start the step are true. Setting PAUSE_BEFORE has no effect on steps that are running or have already run. This allows execution of a chain to be suspended before the execution of certain steps.</td>
</tr>
<tr>
<td></td>
<td>If step_name is set to NULL, then PAUSE_BEFORE is set to the specified value for all steps of this running chain.</td>
</tr>
</tbody>
</table>
Altering a running chain requires you to have alter privileges on the job that is running (either as the owner, or as a user with ALTER privileges on the job or the CREATE ANY JOB system privilege).

Usage Notes

If the SKIP attribute is set to TRUE for a step, when the step condition is met, instead of being run, the step is treated as if it has immediately succeeded. Setting SKIP to TRUE has no effect for a step that is running, scheduled to run after a delay, or has already run.

If step_name is set to NULL, SKIP is set TRUE for all steps of this running chain. If SKIP is set TRUE for a step that PAUSE is also set for, when the step condition is met the step immediately changes to state PAUSED.

If SKIP is set to TRUE for a step and the step fails due to an application error, then the step is retried using the normal Scheduler retry mechanism (after 1 second, after 10 seconds, after 100 seconds, and so on, up to a maximum of 6 times). If all 6 retries fail (after about 30 hours), then the chain step is marked FAILED.

If set to FALSE (the default), a failed chain step is immediately marked FAILED.

If the RESTART_ON_RECOVERY attribute is set to TRUE for a step, then if the step is stopped by a database shutdown, it is restarted when the database is recovered.

If set to FALSE, then if the step is stopped by a database shutdown, the step is marked as stopped when the database is recovered and the chain continues.

This changes the state of the steps. The state can only be changed if the step is not running. The state can only be changed to one of the following:

- 'NOT_STARTED'
- 'SUCCEEDED'
- 'FAILED error_code'

If the state is being changed to FAILED, an error code must be included (this must be a positive integer).

The value to set for the attribute. Valid values are: TRUE, FALSE, 'NOT_STARTED', 'SUCCEEDED', or 'FAILED error_code'.
CLOSE_WINDOW Procedure

This procedure closes an open window prematurely. A closed window means that it is no longer in effect. When a window is closed, the Scheduler switches the resource plan to the one that is in effect outside the window, or in the case of overlapping windows, to another window.

Syntax

```sql
DBMS_SCHEDULER.CLOSE_WINDOW (window_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>window_name</td>
<td>The name of the window</td>
</tr>
</tbody>
</table>

Usage Notes

If you try to close a window that does not exist or is not open, an error is generated.

A job that is running does not stop when the window it is running in closes, unless the attribute `stop_on_window_close` is set to `TRUE` for the job. However, the resources allocated to the job can change if the resource plan changes.

When a running job has a group of type `WINDOW` as its schedule, the job is not stopped when its window is closed if another window in the same window group becomes active. This is the case even if the job has the attribute `stop_on_window_close` set to `TRUE`.

Closing a window requires the `MANAGE_SCHEDULER` privilege.
COPY_JOB Procedure

This procedure copies all attributes of an existing job to a new job. The new job is created disabled, while the state of the existing job is unaltered.

Syntax

```sql
DBMS_SCHEDULER.COPY_JOB (  
    old_job    IN VARCHAR2,  
    new_job    IN VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>old_job</td>
<td>The name of the existing job</td>
</tr>
<tr>
<td>new_job</td>
<td>The name of the new job</td>
</tr>
</tbody>
</table>

Usage Notes

To copy a job, you must have privileges to create a job in the schema of the new job (the CREATE JOB system privilege if it is in your own schema, otherwise, the CREATE ANY JOB system privilege). If the old job is not in your own schema, then you must also have ALTER privileges on the old job or the CREATE ANY JOB system privilege.
CREATE_CHAIN Procedure

This procedure creates a new chain. The chain name can be optionally qualified with a schema name (for example, myschema.myname).

A chain is always created as disabled and must be enabled with the ENABLE Procedure before it can be used.

Syntax

```sql
DBMS_SCHEDULER.CREATE_CHAIN (  
  chain_name              IN VARCHAR2,  
  rule_set_name           IN VARCHAR2 DEFAULT NULL,  
  evaluation_interval     IN INTERVAL DAY TO SECOND DEFAULT NULL,  
  comments                IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name to assign to the new chain, which can optionally be qualified with a schema. This must be unique in the SQL namespace, therefore, there cannot already be a table or other object with this name and schema.</td>
</tr>
<tr>
<td>rule_set_name</td>
<td>In the normal case, no rule set should be passed in. The Scheduler automatically creates a rule set and associated empty evaluation context. You then use DEFINE_CHAIN_RULE to add rules and DROP_CHAIN_RULE to remove them. Advanced users can create a rule set that describes their chain dependencies and pass it in here. This allows greater flexibility in defining rules. For example, conditions can refer to external variables, and tables can be exposed through the evaluation context. If you pass in a rule set, you must ensure that it is in the format of a chain rule set. (For example, all steps must be listed as variables in the evaluation context). If no rule set is passed in, the rule set created is of the form SCHED_RULESETS(N) and the evaluation context created is of the form SCHED_EVCTXS(N). See Oracle Streams Concepts and Administration for information on rules and rule sets.</td>
</tr>
<tr>
<td>evaluation_interval</td>
<td>If this is NULL, reevaluation of the rules of a running chain are performed only when the job starts and when a step completes. A non-NULL value causes rule evaluations to also occur periodically at the specified interval. Because evaluation may be CPU-intensive, this should be conservatively set to the highest possible value or left at NULL if possible. evaluation_interval cannot be less than a minute or greater than a day.</td>
</tr>
<tr>
<td>comments</td>
<td>An optional comment describing the purpose of the chain</td>
</tr>
</tbody>
</table>

Usage Notes

To create a chain in your own schema, you must have the CREATE JOB system privilege. To create a chain in a different schema you must have the CREATE ANY JOB system privilege. If you do not provide a rule_set_name, a rule set and evaluation context is created in the schema that the chain is being created in, so you must have the privileges required to create these objects. See the DBMS_RULE_ADM.CREATE_RULE_SET and DBMS_RULE_ADM.CREATE_EVALUATIONCONTEXT procedures for more information.
**CREATE_CREDENTIAL Procedure**

This procedure creates a stored username/password pair. Credentials are assigned to jobs so that they can authenticate with a local or remote host operating system or a remote Oracle database.

**Syntax**

```sql
DBMS_SCHEDULER.CREATE_CREDENTIAL (  
    credential_name     IN VARCHAR2,  
    username            IN VARCHAR2,  
    password            IN VARCHAR2,  
    database_role       IN VARCHAR2 DEFAULT NULL,  
    windows_domain      IN VARCHAR2 DEFAULT NULL,  
    comments            IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credential_name</td>
<td>The name to assign to the credential. It can optionally be prefixed with a schema name. It cannot be set to NULL. It is converted to uppercase unless enclosed in double-quotes.</td>
</tr>
<tr>
<td>username</td>
<td>The user name for logging into the host operating system or remote Oracle database. This cannot be set to NULL and is case-sensitive. It cannot contain double quotes or spaces. Maximum length is 64.</td>
</tr>
<tr>
<td>password</td>
<td>The password for the user name. This cannot be set to NULL and is case sensitive. The password is stored obfuscated and is not displayed in the Scheduler dictionary views. Maximum length is 128.</td>
</tr>
<tr>
<td>database_role</td>
<td>The value of the database_role attribute is used as the system privilege for logging into a remote database to run a remote database job. Valid values are: SYSDBA and SYSOPER</td>
</tr>
<tr>
<td>windows_domain</td>
<td>For a Windows remote executable target, this is the domain that the specified user belongs to. The domain is converted to uppercase automatically. Maximum length is 64.</td>
</tr>
<tr>
<td>comments</td>
<td>A text string that can be used to describe the credential. Scheduler does not use this parameter. Maximum length is 240.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Credentials reside in a particular schema and can be created by any user with the CREATE_JOB system privilege. To create a credential in a schema other than your own, you must have the CREATE ANY JOB privilege.
CREATE_DATABASE_DESTINATION Procedure

This procedure creates a database destination. A database destination represents an Oracle database on which remote database jobs run.

The host that the remote database resides on must have a running Scheduler agent that is registered with the database that this procedure is called from.

Syntax

```
DBMS_SCHEDULER.CREATE_DATABASE_DESTINATION (  
  destination_name        IN VARCHAR2,  
  agent                   IN VARCHAR2,  
  tns_name                IN VARCHAR2,  
  comments                IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination_name</td>
<td>The name to assign to the database destination. It can optionally be prefixed with a schema name. Cannot be NULL. It is converted to uppercase unless enclosed in double-quotes.</td>
</tr>
<tr>
<td>agent</td>
<td>The external destination name of the Scheduler agent to connect. Equivalent to an agent name. The external destination must already exist. The external destination representing an agent is created automatically on a database instance when the agent registers with that instance. An agent's name is specified in its agent configuration file. If it is not specified, it defaults to the first part (before the first period) of the name of the host it resides on.</td>
</tr>
<tr>
<td>tns_name</td>
<td>An Oracle Net connect identifier that is resolved to the Oracle database instance being connected to. The exact syntax depends on the Oracle Net configuration. The connect identifier can be a complete Oracle Net connect descriptor (network address and database service name) or a net service name, which is an alias for a connect descriptor. The alias must be resolved in the tnsnames.ora file on the local computer. The maximum size for tns_name is 2000 characters. If tns_name is NULL, the agent connects to the default Oracle database on its host. You specify the default database by assigning values to the ORACLE_HOME and ORACLE_SID parameters in the agent configuration file, schagent.conf, located in the agent home directory. See Oracle Database Net Services Administrator’s Guide for more information on connect identifiers.</td>
</tr>
<tr>
<td>comments</td>
<td>A text string that describes the database destination. Scheduler does not use this argument.</td>
</tr>
</tbody>
</table>

Usage Notes

Database destinations reside in a particular schema and can be created by any user with the CREATE JOB system privilege. To create a database destination in a schema other than your own, you must have the CREATE ANY JOB privilege.
CREAITE_EVENT_SCHEDULE Procedure

This procedure creates an event schedule, which is used to start a job when a particular event is raised.

Syntax

```
DBMS_SCHEDULER.CREATE_EVENT_SCHEDULE (  
  schedule_name           IN VARCHAR2,  
  start_date              IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  event_condition         IN VARCHAR2 DEFAULT NULL,  
  queue_spec              IN VARCHAR2,  
  end_date                IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  comments                IN VARCHAR2 DEFAULT NULL);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_name</td>
<td>The name to assign to the schedule. The name must be unique in the SQL namespace. For example, a schedule cannot have the same name as a table in a schema. If no name is specified, then an error occurs.</td>
</tr>
<tr>
<td>start_date</td>
<td>This attribute specifies the date and time that this schedule becomes valid. Occurrences of the event before this date and time are ignored in the context of this schedule.</td>
</tr>
<tr>
<td>event_condition</td>
<td>This is a conditional expression based on the columns of the event source queue table. The expression must have the syntax of an Advanced Queuing rule. Accordingly, you can include user data properties in the expression, provided that the message payload is an object type, and that you prefix object attributes in the expression with tab.user_data. For more information on rules, see the DBMS_AQADM.ADD_SUBSCRIBER procedure.</td>
</tr>
<tr>
<td>queue_spec</td>
<td>This argument specifies either a file watcher name or the queue into which events that start this particular job are enqueued (the source queue). If the source queue is a secure queue, the queue_spec argument is a string containing a pair of values of the form queue_name, agent name. For non-secure queues, only the queue name need be provided. If a fully qualified queue name is not provided, the queue is assumed to be in the job owner's schema. In the case of secure queues, the agent name provided should belong to a valid agent that is currently subscribed to the queue.</td>
</tr>
<tr>
<td>end_date</td>
<td>The date and time after which jobs do not run and windows do not open. An event schedule that has no end_date is valid forever. end_date must be after the start_date. If it is not, then an error is generated when the schedule is created.</td>
</tr>
<tr>
<td>comments</td>
<td>This attribute specifies an optional comment about the schedule. By default, this attribute is NULL.</td>
</tr>
</tbody>
</table>

Usage Notes

You must have the CREATE JOB privilege to create a schedule in your own schema or the CREATE ANY JOB privilege to create a schedule in someone else's schema by specifying schema.schedule_name. Once a schedule has been created, it can be used by
other users. The schedule is created with access to PUBLIC. Therefore, there is no need to explicitly grant access to the schedule.

See Also:  "CREATE_FILE_WATCHER Procedure" on page 129-51
CREATE_FILE_WATCHER Procedure

This procedure creates a file watcher, which is a Scheduler object that defines the location, name, and other properties of a file whose arrival on a system causes the Scheduler to start a job. After you create a file watcher, you reference it in an event-based job or event schedule.

Syntax

```
DBMS_SCHEDULER.CREATE_FILE_WATCHER (  
    file_watcher_name    IN VARCHAR2,  
    directory_path      IN VARCHAR2,  
    file_name           IN VARCHAR2,  
    credential_name     IN VARCHAR2,  
    destination         IN VARCHAR2 DEFAULT NULL,  
    min_file_size       IN PLS_INTEGER DEFAULT 0,  
    steady_state_duration IN INTERVAL DAY TO SECOND DEFAULT NULL,  
    comments            IN VARCHAR2 DEFAULT NULL,  
    enabled             IN BOOLEAN DEFAULT TRUE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_watcher_name</td>
<td>The name to assign to the file watcher. The name must be unique in the SQL namespace. For example, a file watcher cannot have the same name as a table in a schema. This can optionally be prefixed with a schema name. Cannot be NULL.</td>
</tr>
<tr>
<td>directory_path</td>
<td>Directory in which the file is expected to arrive. The single wildcard '?' at the beginning of the path denotes the Oracle home path. For example, '?/rdbms/log' denotes the rdbms/log subdirectory of the Oracle home directory.</td>
</tr>
<tr>
<td>file_name</td>
<td>Name of the file to look for. Two wildcards are permitted anywhere in the file name: '?' denotes any single character, and '*' denotes zero or more characters. This attribute cannot be NULL.</td>
</tr>
<tr>
<td>credential_name</td>
<td>Name of a valid Scheduler credential object. The file watcher uses the credential to authenticate itself with the host operating system to access the watched-for file. The file watcher owner must have EXECUTE privileges on the credential. Cannot be NULL.</td>
</tr>
<tr>
<td>destination</td>
<td>Name of an external destination. You create an external destination by registering a remote Scheduler agent with the database. See the view ALL_SCHEDULER_EXTERNAL_DESTS for valid external destination names. If this parameter is NULL, the file watcher is created on the local host.</td>
</tr>
<tr>
<td>min_file_size</td>
<td>Minimum size in bytes that the file must be before the file watcher considers the file found. Default is 0.</td>
</tr>
<tr>
<td>steady_state_duration</td>
<td>Minimum time interval that the file must remain unchanged before the file watcher considers the file found. Cannot exceed one hour. If NULL, an internal value is used.</td>
</tr>
<tr>
<td>comments</td>
<td>Optional comment.</td>
</tr>
<tr>
<td>enabled</td>
<td>If TRUE (the default), the file watcher is enabled.</td>
</tr>
</tbody>
</table>
Usage Notes

You must have the `CREATE JOB` system privilege to create a file watcher in your own schema. You require the `CREATE ANY JOB` system privilege to create a file watcher in a schema different from your own (except the `SYS` schema, which is disallowed).
CREATE_GROUP Procedure

This procedure creates a group. Groups contain members, which you can specify when you create the group or at a later time. There are three types of groups: window groups, database destination groups, and external destination groups.

You can use a group name in other DBMS_SCHEDULER package procedures to specify a list of objects. For example, to specify multiple destinations for a remote database job, you provide a group name for the DESTINATION_NAME parameter of the job.

Syntax

```sql
DBMS_SCHEDULER.CREATE_GROUP (  
group_name           IN VARCHAR2,  
group_type           IN VARCHAR2,  
member               IN VARCHAR2 DEFAULT NULL,  
comments             IN VARCHAR2 DEFAULT NULL);
```

Parameters

Table 129–26 CREATE_GROUP Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name to assign to the group. It can optionally be prefixed with a schema name. It cannot be NULL. It is converted to uppercase unless enclosed in double-quotes.</td>
</tr>
<tr>
<td>group_type</td>
<td>The type of members in the group. All members must be of the same type. Possible types are:</td>
</tr>
<tr>
<td></td>
<td>'DB_DEST'</td>
</tr>
<tr>
<td></td>
<td>Database destination: Members are database destinations, for running remote database jobs.</td>
</tr>
<tr>
<td></td>
<td>'EXTERNAL_DEST'</td>
</tr>
<tr>
<td></td>
<td>External destination: Members are external destinations, for running remote external jobs.</td>
</tr>
<tr>
<td></td>
<td>'WINDOW'</td>
</tr>
<tr>
<td></td>
<td>Members are Scheduler windows. You must have the MANAGE SCHEDULER privilege to create a group of this type.</td>
</tr>
</tbody>
</table>

Members in database destination and external destination groups have the following format:

```
[[schema.]credential@]schema.]destination
```

where:

- `credential` is the name of an existing credential.
- `destination` is the name of an existing database destination or external destination.

The credential portion of a destination member is optional. If omitted, the job using this destination member uses its default credential.

Members in window groups are window names. Because all Scheduler windows reside in the SYS schema, you do not specify a schema name for windows.
**Usage Notes**

Groups reside in a particular schema and can be created by any user with the `CREATE JOB` system privilege. To create a group in a schema other than your own, you must have the `CREATE ANY JOB` privilege. The group name must be unique among all Scheduler objects.

You can grant the `SELECT` privilege on a group so that other users can reference the group when creating jobs or schedules. To enable other users to modify a group, you can grant the `ALTER` privilege on the group.

Each group member must be unique within the group. For destination groups, the credential/destination name pairs must be unique within the group. An error is generated if any of the group members do not exist. For destination groups, both the credential and destination portions of a member must exist.

Another group of the same type can be a group member. The Scheduler immediately expands the included group name into its list of members.

Groups are created enabled, but you can disable them.

This procedure supersedes the procedure `CREATE_WINDOW_GROUP`, which is deprecated in Oracle Database 11g Release 2 (11.2).

**Example**

The following PL/SQL block creates a group named `production_dest1`, whose members are database destinations for a collection of production databases.

```plsql
BEGIN
  DBMS_SCHEDULER.CREATE_GROUP(
    GROUP_NAME => 'production_dest1',
    GROUP_TYPE => 'DB_DEST',
    MEMBER => 'LOCAL, oracle_cred@prodhost1, prodhost2',
    COMMENTS => 'All sector1 production machines');
END;
```

---

**Table 129–26 (Cont.) CREATE_GROUP Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| member    | Optional comma-separated list of group members. The default is NULL. If NULL, use the `ADD_GROUP_MEMBER` procedure to add members. You can also use `ADD_GROUP_MEMBER` to add additional members at a later time. The keyword `LOCAL` can be used as a member in database destination groups and external destination groups.  
  - In database destination groups, `LOCAL` represents the source database on which the job is created. It cannot be preceded with a credential.  
  - In external destination groups, `LOCAL` represents the host on which the source database resides. It can be optionally preceded with a credential name. If no credential is provided, jobs that use this group as their destination must have a default credential. |
| comments  | A text string that describes the group. Scheduler does not use this argument. |
CREATE_JOB Procedure

This procedure creates a single job (regular or lightweight). If you create the job as enabled by setting the enabled attribute to TRUE, the Scheduler automatically runs the job according to its schedule. If you create the job disabled, the job does not run until you enable it with the SET_ATTRIBUTE Procedure.

The procedure is overloaded. The different functionality of each form of syntax is presented along with the syntax declaration.

Syntax

Creates a job in a single call without using an existing program or schedule:

```sql
DBMS_SCHEDULER.CREATE_JOB (  
  job_name             IN VARCHAR2,  
  job_type             IN VARCHAR2,  
  job_action           IN VARCHAR2,  
  number_of_arguments  IN PLS_INTEGER DEFAULT 0,  
  start_date           IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  repeat_interval      IN VARCHAR2 DEFAULT NULL,  
  end_date             IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  job_class            IN VARCHAR2 DEFAULT 'DEFAULT_JOB_CLASS',  
  enabled              IN BOOLEAN DEFAULT FALSE,  
  auto_drop            IN BOOLEAN DEFAULT TRUE,  
  comments             IN VARCHAR2 DEFAULT NULL,  
  credential_name      IN VARCHAR2 DEFAULT NULL,  
  destination_name     IN VARCHAR2 DEFAULT NULL);
```

Creates a job using a named schedule object and a named program object:

```sql
DBMS_SCHEDULER.CREATE_JOB (  
  job_name                IN VARCHAR2,  
  program_name            IN VARCHAR2,  
  schedule_name           IN VARCHAR2,  
  job_class               IN VARCHAR2 DEFAULT 'DEFAULT_JOB_CLASS',  
  enabled                 IN BOOLEAN DEFAULT FALSE,  
  auto_drop               IN BOOLEAN DEFAULT TRUE,  
  comments                IN VARCHAR2 DEFAULT NULL,  
  job_style               IN VARCHAR2 DEFAULT 'REGULAR',  
  credential_name         IN VARCHAR2 DEFAULT NULL,  
  destination_name        IN VARCHAR2 DEFAULT NULL);
```

Creates a job using a named program object and an inlined schedule:

```sql
DBMS_SCHEDULER.CREATE_JOB (  
  job_name             IN VARCHAR2,  
  program_name         IN VARCHAR2,  
  start_date           IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  repeat_interval      IN VARCHAR2 DEFAULT NULL,  
  end_date             IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  job_class            IN VARCHAR2 DEFAULT 'DEFAULT_JOB_CLASS',  
  enabled              IN BOOLEAN DEFAULT FALSE,  
  auto_drop            IN BOOLEAN DEFAULT TRUE,  
  comments             IN VARCHAR2 DEFAULT NULL,  
  job_style            IN VARCHAR2 DEFAULT 'REGULAR',  
  credential_name      IN VARCHAR2 DEFAULT NULL,  
  destination_name     IN VARCHAR2 DEFAULT NULL);
```

Creates a job using a named schedule object and an inlined program:
CREATE_JOB Procedure

DBMS_SCHEDULER.CREATE_JOB(
    job_name               IN VARCHAR2,
    schedule_name         IN VARCHAR2,
    job_type               IN VARCHAR2,
    job_action            IN VARCHAR2,
    number_of_arguments   IN PLS_INTEGER       DEFAULT 0,
    job_class               IN VARCHAR2          DEFAULT 'DEFAULT_JOB_CLASS',
    enabled                 IN BOOLEAN           DEFAULT FALSE,
    auto_drop               IN BOOLEAN           DEFAULT TRUE,
    comments                IN VARCHAR2          DEFAULT NULL,
    credential_name         IN VARCHAR2          DEFAULT NULL,
    destination_name        IN VARCHAR2          DEFAULT NULL);

Creates a job using an inlined program and an event:

DBMS_SCHEDULER.CREATE_JOB(
    job_name                IN VARCHAR2,
    job_type               IN VARCHAR2,
    job_action            IN VARCHAR2,
    number_of_arguments   IN PLS_INTEGER       DEFAULT 0,
    start_date             IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
    event_condition        IN VARCHAR2          DEFAULT NULL,
    queue_spec             IN VARCHAR2,
    end_date               IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
    job_class               IN VARCHAR2          DEFAULT 'DEFAULT_JOB_CLASS',
    enabled                 IN BOOLEAN           DEFAULT FALSE,
    auto_drop               IN BOOLEAN           DEFAULT TRUE,
    comments                IN VARCHAR2          DEFAULT NULL,
    credential_name         IN VARCHAR2          DEFAULT NULL,
    destination_name        IN VARCHAR2          DEFAULT NULL);

Creates a job using a named program object and an event:

DBMS_SCHEDULER.CREATE_JOB(
    job_name                IN VARCHAR2,
    program_name            IN VARCHAR2,
    start_date             IN TIMESTAMP WITH TIME ZONE,
    event_condition        IN VARCHAR2,
    queue_spec             IN VARCHAR2,
    end_date               IN TIMESTAMP WITH TIME ZONE,
    job_class               IN VARCHAR2          DEFAULT 'DEFAULT_JOB_CLASS',
    enabled                 IN BOOLEAN           DEFAULT FALSE,
    auto_drop               IN BOOLEAN           DEFAULT TRUE,
    comments                IN VARCHAR2          DEFAULT NULL,
    job_style               IN VARCHAR2          DEFAULT 'REGULAR',
    credential_name         IN VARCHAR2          DEFAULT NULL,
    destination_name        IN VARCHAR2          DEFAULT NULL);
Parameters

Table 129–27  CREATE_JOB Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name to assign to the job. The name must be unique in the SQL namespace. For example, a job cannot have the same name as a table in a schema. If the job being created will reside in another schema, it must be qualified with the schema name. If job_name is not specified, an error is generated. If you want to have a name generated by the Scheduler, you can use the GENERATE_JOB_NAME procedure to generate a name and then use the output in the CREATE_JOB procedure. The GENERATE_JOB_NAME procedure generates a number from a sequence, which is the job name. You can prefix the number with a string. The job name will then be the string with the number from the sequence appended to it. See &quot;GENERATE_JOB_NAME Function&quot; on page 129-106 for more information.</td>
</tr>
</tbody>
</table>
| job_type   | This attribute specifies the type of job that you are creating. If it is not specified, an error is generated. The supported values are:  
- 'PLSQL_BLOCK'  
  This specifies that the job is an anonymous PL/SQL block. Job or program arguments are not supported when the job or program type is PLSQL_BLOCK. In this case, the number of arguments must be 0.  
- 'STORED_PROCEDURE'  
  This specifies that the job is a PL/SQL or Java stored procedure, or an external C subprogram. Only procedures, not functions with return values, are supported.  
- 'EXECUTABLE'  
  This specifies that the job is external to the database. External jobs are anything that can be executed from the command line of the operating system. Any data arguments are not supported with a job or program type of EXECUTABLE. The job owner must have the CREATE EXTERNAL JOB system privilege before the job can be enabled or run.  
- 'CHAIN'  
  This specifies that the job is a chain. Arguments are not supported for a chain, so number_of_arguments must be 0. |
job_action

This attribute specifies the action of the job. If job_action is not specified for an inline program, then an error is generated when creating the job.

The following actions are possible:

- For a PL/SQL block:

  The action is to execute PL/SQL code. These blocks must end with a semicolon. For example, my_proc(); or BEGIN my_proc(); END; or DECLARE arg pls_integer:= 10; BEGIN my_proc2(arg); END;.

  Note that the Scheduler wraps job_action in its own block and passes the following to PL/SQL for execution: DECLARE ... BEGIN job_action END; This is done to declare some internal Scheduler variables. You can include any Scheduler metadata attribute except event_message in your PL/SQL code. You use the attribute name as you use any other PL/SQL identifier, and the Scheduler assigns it a value. See Table 129–39 on page 129-78 for details on available metadata attributes.

- For a stored procedure:

  The action is the name of the stored procedure. You have to specify the schema if the procedure resides in another schema than the job. If case sensitivity is needed, enclose the schema name and the stored procedure name in double quotes. For example, job_action=>"Schema"."Procedure".

  PL/SQL procedures with INOUT or OUT arguments are not supported as job_action when the job or program type is STORED_PROCEDURE.

- For an executable:

  The action is the name of the external executable, including the full path name, but excluding any command-line arguments. If the action starts with a single question mark ('?'), the question mark is replaced by the path to the Oracle home directory for a local job or to the Scheduler agent home for a remote job. If the action contains an at-sign (@) and the job is local, the at-sign is replaced with the SID of the current Oracle instance.

- For a chain:

  The action is the name of a Scheduler chain object. You must specify the schema of the chain if it resides in a different schema than the job.

number_of_arguments

This attribute specifies the number of arguments that the job expects. The range is 0-255, with the default being 0.

program_name

The name of the program associated with this job. If the program is of type EXECUTABLE, the job owner must have the CREATE_EXTERNAL_JOB system privilege before the job can be enabled or run.

start_date

This attribute specifies the first date and time on which this job is scheduled to start. If start_date and repeat_interval are left null, then the job is scheduled to run as soon as the job is enabled.

For repeating jobs that use a calendaring expression to specify the repeat interval, start_date is used as a reference date. The first time the job runs is the first match of the calendaring expression that is on or after the current date and time.

The Scheduler cannot guarantee that a job executes on an exact time because the system may be overloaded and thus resources unavailable.
event_condition

This is a conditional expression based on the columns of the event source queue table. The expression must have the syntax of an Advanced Queuing rule. Accordingly, you can include user data properties in the expression provided that the message payload is an object type, and that you prefix object attributes in the expression with tab.user_data. For more information on rules, see the DBMS_AQADM.ADD_SUBSCRIBER procedure.

queue_spec

This argument specifies either of the following:

- The source queue where events that start this particular job are enqueued. If it is secure, then the queue_spec argument is a pair of values of the form queue_name, agent name. If it is not secure, then only the queue name need be provided. If a fully qualified queue name is not provided, the queue is assumed to be in the job owner’s schema. In the case of secure queues, the agent name provided should belong to a valid agent that is currently subscribed to the queue.

- A file watcher name. For more information on this option, see Oracle Database Administrator’s Guide.

repeat_interval

This attribute specifies how often the job repeats. You can specify the repeat interval by using calendaring or PL/SQL expressions.

The expression specified is evaluated to determine the next time the job should run. If repeat_interval is not specified, the job runs only once at the specified start date. See “Calendaring Syntax” on page 129-20 for further information.

schedule_name

The name of the schedule, window, or window group associated with this job.

job_class

The class this job is associated with.

end_date

This attribute specifies the date and time after which the job expires and is no longer run. After the end_date, if auto_drop is TRUE, the job is dropped. If auto_drop is FALSE, the job is disabled and the state of the job is set to COMPLETED.

If no value for end_date is specified, the job repeats forever unless max_runs or max_failures is set, in which case the job stops when either value is reached.

The value for end_date must be after the value for start_date. If it is not, an error is generated when the job is enabled.

comments

This attribute specifies a comment about the job. By default, this attribute is NULL.

job_style

Style of the job being created. This argument can have one of the following values:

- 'REGULAR' creates a regular job. This is the default.
- 'LIGHTWEIGHT' creates a lightweight job. This value is permitted only when the job references a program object. Use lightweight jobs when you have many short-duration jobs that run frequently. Under certain circumstances, using lightweight jobs can deliver a small performance gain.

credential_name

The default credential to use with the job. Applicable only to remote database jobs, remote external jobs, local external jobs, and event-based jobs that process file arrival events. The credential must exist.

For local database jobs, it must be NULL.

For local external jobs only, if this attribute is NULL (the default), then a preferred (default) credential is selected. See Oracle Database Administrator’s Guide for information about preferred credentials for local external jobs.

See also: "CREATE_CREDENTIAL Procedure" on page 129-47
The database destination or external destination for the job. Use for remote database jobs and remote external jobs only. Must be NULL for jobs running on the local database or for local external jobs (executables).

This attribute can be a single destination name or the name of a group of type 'EXTERNAL_DEST' or 'DB_DEST'. The single destination or group must already exist.

The following applies to this attribute:

- If it is a database destination, it must have been created by the CREATE_DATABASE_DESTINATION Procedure.
- If it is an external destination, it must have been implicitly created by registering a remote Scheduler agent with the local database.
- If it is a group, each member of the group must exist, and the job must run on all destinations named in the group. See "CREATE_GROUP Procedure" on page 129-53.

destination_name cannot reference a destination group when:

- The job type is 'CHAIN'
- The job style is 'LIGHTWEIGHT'

If the credential_name argument of CREATE_JOB is NULL, each destination must be preceded by a credential, in the following format:

credential.destination

The credential must already exist. If the credential_name argument is provided, then it serves as the default credential for every destination that is not preceded by a credential.

You can query the views *_SCHEDULER_DB_DESTS and ALL_SCHEDULER_EXTERNAL_DESTS for existing destinations and *_SCHEDULER_GROUP_MEMBERS for existing groups and their members.

***destination_name supersedes the destination job attribute, which is deprecated in Oracle Database 11g Release 2 (11.2).

destination_name

enabled

This attribute specifies whether the job is created enabled or not. The possible settings are TRUE or FALSE. By default, this attribute is set to FALSE and, therefore, the job is created as disabled. A disabled job means that the metadata about the job has been captured, and the job exists as a database object. However, the Scheduler ignores the job and the job coordinator does not pick it for processing. In order for the job coordinator to process the job, the job must be enabled. You can enable a job by setting this argument to TRUE or by using the ENABLE procedure.

auto_drop

This flag, if TRUE, causes a job to be automatically dropped after it has completed or has been automatically disabled. A job is considered completed if:

- Its end date (or the end date of the job schedule) has passed.
- It has run max_runs number of times. max_runs must be set with SET_ATTRIBUTE.
- It is not a repeating job and has run once.

A job is disabled when it has failed max_failures times. max_failures is also set with SET_ATTRIBUTE.

If this flag is set to FALSE, the jobs are not dropped and their metadata is kept until the job is explicitly dropped with the DROP_JOB procedure.

By default, jobs are created with auto_drop set to TRUE.
Usage Notes

Jobs are created as disabled by default. You must explicitly enable them so that they will become active and scheduled. Before enabling a job, ensure that all program arguments, if any, are defined, either by defining default values in the program object or by supplying values with the job.

The JOB_QUEUE_PROCESSES initialization parameter specifies the maximum number of processes that can be created for the execution of jobs. Beginning with Oracle Database 11g Release 2 (11.2), JOB_QUEUE_PROCESSES applies to DBMS_SCHEDULER jobs. Setting this parameter to 0 disables DBMS_SCHEDULER jobs.

To create a job in your own schema, you need to have the CREATE JOB privilege. A user with the CREATE ANY JOB privilege can create a job in any schema. If the job being created will reside in another schema, the job name must be qualified with the schema name. For a job of type EXECUTABLE (or for a job that points to a program of type EXECUTABLE), the job owner must have the CREATE_EXTERNAL_JOB system privilege before the job can be enabled or run.

Associating a job with a particular class or program requires EXECUTE privileges for that class or program.

Not all possible job attributes can be set with CREATE_JOB. Some must be set after the job is created. For example, job arguments must be set with the SET_JOB_ARGUMENT_VALUE Procedure or the SET_JOB_ANYDATA_VALUE Procedure. Other job attributes, such as job_priority and max_runs, are set with the SET_ATTRIBUTE Procedure.

To create multiple jobs efficiently, use the CREATE_JOBS procedure.

---

**Note:** The Scheduler runs event-based jobs for each occurrence of an event that matches the event condition of the job. However, events that occur while the job is already running are ignored; the event gets consumed, but does not trigger another run of the job.
CREATE_JOB_CLASS Procedure

This procedure creates a job class. Job classes are created in the SYS schema.

Syntax

```sql
DBMS_SCHEDULER.CREATE_JOB_CLASS (    
job_class_name            IN VARCHAR2,  
resource_consumer_group   IN VARCHAR2 DEFAULT NULL,  
service                   IN VARCHAR2 DEFAULT NULL,  
logging_level             IN PLS_INTEGER DEFAULT DBMS_SCHEDULER.LOGGING_RUNS,  
log_history               IN PLS_INTEGER DEFAULT NULL,  
comments                  IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_class_name</td>
<td>The name to assign to the job class. Job classes can only be created in the SYS schema. This attribute specifies the name of the job class and uniquely identifies the job class. The name must be unique in the SQL namespace. For example, a job class cannot have the same name as a table in a schema.</td>
</tr>
<tr>
<td>resource_consumer_group</td>
<td>This attribute specifies the resource consumer group that his class is associated with. A resource consumer group is a set of synchronous or asynchronous sessions that are grouped together based on their processing needs. A job class has a many-to-one relationship with a resource consumer group. The resource consumer group that the job class associates with determines the resources that are allocated to the job class. If a resource consumer group is dropped, job classes associated with it are then associated with the default resource consumer group. If no resource consumer group is specified, job classes are associated with the default resource consumer group. If the specified resource consumer group does not exist when creating the job class, an error occurs.</td>
</tr>
<tr>
<td>service</td>
<td>This attribute specifies the database service that the jobs in this class have affinity to. In an Oracle RAC environment, this means that the jobs in this class only run on those database instances that are assigned to the specific service. Note that a service can be mapped to a resource consumer group, so you can also control resources allocated to jobs by specifying a service. See DBMS_RESOURCE_MANAGER.SET_CONSUMER_GROUP_MAPPING for details. If both the resource_consumer_group and service attributes are specified, and if the service is mapped to a resource consumer group, the resource_consumer_group attribute takes precedence. If no service is specified, the job class belongs to the default service, which means it has no service affinity and any one of the database instances within the cluster might run the job. If the service that a job class belongs to is dropped, the job class will then belong to the default service. If the specified service does not exist when creating the job class, then an error occurs.</td>
</tr>
</tbody>
</table>
Usage Notes

For users to create jobs that belong to a job class, the job owner must have EXECUTE privileges on the job class. Therefore, after the job class has been created, EXECUTE privileges must be granted on the job class so that users create jobs belonging to that class. You can also grant the EXECUTE privilege to a role.

Creating a job class requires the MANAGE_SCHEDULER system privilege.
CREATE_JOBS Procedure

This procedure creates multiple jobs (regular or lightweight) and sets the values of their arguments in a single call.

Syntax

```sql
DBMS_SCHEDULER.CREATE_JOBS (
    jobdef_array      IN SYS.JOB_DEFINITION_ARRAY,
    commit_semantics  IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobdef_array</td>
<td>The array of job definitions. See “Data Structures” on page 129-2 for a description of the JOB_DEFINITION_ARRAY and JOB_DEFINITION data types.</td>
</tr>
<tr>
<td>commit_semantics</td>
<td>The commit semantics. The following types are supported:</td>
</tr>
<tr>
<td></td>
<td>STOP_ON_FIRST_ERROR returns on the first error. Previous successfully created jobs are committed to disk. This is the default.</td>
</tr>
<tr>
<td></td>
<td>TRANSACTIONAL returns on the first error and everything that happened before that error is rolled back.</td>
</tr>
<tr>
<td></td>
<td>ABSORB_ERRORS tries to absorb any errors and attempts to create the rest of the jobs on the list. It commits all successfully created jobs. If errors occur, you can query the view SCHEDULER_BATCH_ERRORS for details.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure creates many jobs in the context of a single transaction. To realize the desired performance gains, the jobs being created must be grouped in batches of sufficient size. Calling CREATE_JOBS with a small array size may not be much faster than calling CREATE_JOB once for each job.

You cannot use this procedure to create multiple-destination jobs. That is, the destination attribute of the job_definition object cannot reference a destination group.

Examples

See Oracle Database Administrator’s Guide.
CREATE_PROGRAM Procedure

This procedure creates a program.

Syntax

```sql
DBMS_SCHEDULER.CREATE_PROGRAM (
    program_name IN VARCHAR2,
    program_type IN VARCHAR2,
    program_action IN VARCHAR2,
    number_of_arguments IN PLS_INTEGER DEFAULT 0,
    enabled IN BOOLEAN DEFAULT FALSE,
    comments IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>The name to assign to the program. The name must be unique in the SQL namespace. For example, a program cannot have the same name as a table in a schema. If no name is specified, then an error occurs.</td>
</tr>
<tr>
<td>program_type</td>
<td>This attribute specifies the type of program you are creating. If it is not specified then you get an error. There are three supported values for program_type:</td>
</tr>
<tr>
<td></td>
<td>'PLSQL_BLOCK'</td>
</tr>
<tr>
<td></td>
<td>This specifies that the program is a PL/SQL block. Job or program arguments are not supported when the job or program type is PLSQL_BLOCK. In this case, the number of arguments must be 0.</td>
</tr>
<tr>
<td></td>
<td>'STORED_PROCEDURE'</td>
</tr>
<tr>
<td></td>
<td>This specifies that the program is a PL/SQL or Java stored procedure, or an external C subprogram. Only procedures, not functions with return values, are supported. PL/SQL procedures with INOUT or OUT arguments are not supported.</td>
</tr>
<tr>
<td></td>
<td>'EXECUTABLE'</td>
</tr>
<tr>
<td></td>
<td>This specifies that the program is external to the database. External programs imply anything that can be executed from the operating system command line. AnyData arguments are not supported with job or program type EXECUTABLE.</td>
</tr>
</tbody>
</table>
To create a program in their own schema, users need the CREATE JOB privilege. A user with the CREATE ANY JOB privilege can create a program in any schema. A program is created in a disabled state by default (unless the enabled parameter is set to TRUE). It cannot be executed by a job until it is enabled.

To use your programs, other users must have EXECUTE privileges, therefore once a program has been created, you have to grant EXECUTE privileges on it.

Usage Notes
See Also: "DEFINE_PROGRAM_ARGUMENT Procedure" on page 129-80
CREATE_SCHEDULE Procedure

This procedure creates a schedule.

Syntax

```sql
DBMS_SCHEDULER.CREATE_SCHEDULE (
    schedule_name          IN VARCHAR2,
    start_date             IN TIMESTAMP WITH TIMEZONE DEFAULT NULL,
    repeat_interval        IN VARCHAR2,
    end_date               IN TIMESTAMP WITH TIMEZONE DEFAULT NULL,
    comments               IN VARCHAR2 DEFAULT NULL);
```

Parameters

**Table 129–31 CREATE_SCHEDULE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_name</td>
<td>The name to assign to the schedule. The name must be unique in the SQL namespace. For example, a schedule cannot have the same name as a table in a schema. If no name is specified, then an error occurs.</td>
</tr>
<tr>
<td>start_date</td>
<td>This attribute specifies the first date and time on which this schedule becomes valid. For a repeating schedule, the value for start_date is a reference date. In this case, the start of the schedule is not the start_date; it depends on the repeat interval specified. start_date is used to determine the first instance of the schedule. If start_date is specified in the past and no value for repeat_interval is specified, the schedule is invalid. For a repeating job or window, start_date can be derived from the repeat_interval if it is not specified. If start_date is null, then the date that the job or window is enabled is used. start_date and repeat_interval cannot both be null.</td>
</tr>
<tr>
<td>repeat_interval</td>
<td>This attribute specifies how often the schedule repeats. It is expressed using calendaring syntax. See “Calendaring Syntax” on page 129-20 for further information. PL/SQL expressions are not allowed as repeat intervals for named schedules.</td>
</tr>
<tr>
<td>end_date</td>
<td>The date and time after which jobs will not run and windows will not open. A non-repeating schedule that has no end_date is valid forever. end_date has to be after the start_date. If this is not the case, then an error is generated when the schedule is created.</td>
</tr>
<tr>
<td>comments</td>
<td>This attribute specifies an optional comment about the schedule. By default, this attribute is NULL.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure requires the CREATE JOB privilege to create a schedule in your own schema or the CREATE ANY JOB privilege to create a schedule in someone else’s schema by specifying schema.schedule_name. Once a schedule has been created, it can be used by other users. The schedule is created with access to PUBLIC. Therefore, there is no need to explicitly grant access to the schedule.
**CREATE_WINDOW Procedure**

This procedure creates a recurring time window and associates it with a resource plan. You can then use the window to schedule jobs that run under the associated resource plan. Windows are created in the `SYS` schema.

The procedure is overloaded.

**Syntax**

Creates a window using a named schedule object:

```sql
DBMS_SCHEDULER.CREATE_WINDOW (
    window_name             IN VARCHAR2,
    resource_plan           IN VARCHAR2,
    schedule_name           IN VARCHAR2,
    duration                IN INTERVAL DAY TO SECOND,
    window_priority         IN VARCHAR2 DEFAULT 'LOW',
    comments                IN VARCHAR2 DEFAULT NULL);
```

Creates a window using an inlined schedule:

```sql
DBMS_SCHEDULER.CREATE_WINDOW (
    window_name             IN VARCHAR2,
    resource_plan           IN VARCHAR2,
    start_date              IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
    repeat_interval         IN VARCHAR2,
    end_date                IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,
    duration                IN INTERVAL DAY TO SECOND,
    window_priority         IN VARCHAR2 DEFAULT 'LOW',
    comments                IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>window_name</td>
<td>The name to assign to the window. The name must be unique in the SQL namespace. All windows are in the <code>SYS</code> schema, so the preface 'SYS' is optional.</td>
</tr>
<tr>
<td>resource_plan</td>
<td>This attribute specifies the resource plan that automatically activates when the window opens. When the window closes, the system switches to the appropriate resource plan, which is usually the plan that was in effect before the window opened, but can also be the plan of a different window. Only one resource plan can be associated with a window. It may be <code>NULL</code> or the empty string (&quot;&quot;&quot;). When it is <code>NULL</code>, the resource plan in effect when the window opens stays in effect for the duration of the window. When it is the empty string, the resource manager is disabled for the duration of the window. If the window is open and the resource plan is dropped, then the resource allocation for the duration of the window is not affected.</td>
</tr>
</tbody>
</table>
Creating a window requires the MANAGE SCHEDULER privilege.

Scheduler windows are the principal mechanism used to automatically switch resource plans according to a schedule. You can also manually activate a resource plan by using the ALTER SYSTEM SET RESOURCE_MANAGER_PLAN statement or the DBMS_RESOURCE_MANAGER.SWITCH_PLAN package procedure. Note that either of these manual methods can also disable resource plan switching by Scheduler windows. For more information, see Oracle Database Administrator’s Guide and "SWITCH_PLAN Procedure" on page 120-38.
CREATE_WINDOW_GROUP Procedure

*** Deprecated in Oracle Database 11g Release 2 (11.2). Use CREATE_GROUP instead.

This procedure creates a new window group. A window group is defined by a list of Scheduler windows. You can assign a window group as a job schedule. The job then runs when any of the windows in the group become active.

Window groups are created in the SYS schema.

Syntax

DBMS_SCHEDULER.CREATE_WINDOW_GROUP (  
group_name            IN VARCHAR2,  
window_list           IN VARCHAR2 DEFAULT NULL,  
comments              IN VARCHAR2 DEFAULT NULL);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name to assign to the window group</td>
</tr>
<tr>
<td>window_list</td>
<td>A list of the windows assigned to the window group. If a window that does not exist is specified, an error is generated and the window group is not created. Windows can also be added using the ADD_WINDOW_GROUP_MEMBER procedure. A window group cannot be a member of another window group. Can be NULL.</td>
</tr>
<tr>
<td>comments</td>
<td>A comment about the window group</td>
</tr>
</tbody>
</table>

Usage Notes

Creating a window group requires the MANAGE_SCHEDULER privilege. Window groups, like windows, are created with access to PUBLIC, therefore, no privileges are required to access window groups.

A window group cannot contain another window group.
DEFINE_ANYDATA_ARGUMENT Procedure

This procedure defines a name or default value for a program argument that is of a complex type and must be encapsulated within an ANYDATA object. A job that references the program can override the default value.

Syntax

```sql
DBMS_SCHEDULER.DEFINE_ANYDATA_ARGUMENT (
    program_name            IN VARCHAR2,
    argument_position       IN PLS_INTEGER,
    argument_name           IN VARCHAR2 DEFAULT NULL,
    argument_type           IN VARCHAR2,
    default_value           IN SYS.ANYDATA,
    out_argument            IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>The name of the program to be altered. A program with this name must exist.</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the argument as it is passed to the executable. Argument numbers go from one to the <code>number_of_arguments</code> specified for the program. This must be unique, so it can replace any argument already defined at this position.</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name to assign to the argument. It is optional, but must be unique for the program if it is specified. If you assign a name, the name can then be used by other package procedures, including the <code>SET_JOB_ANYDATA_VALUE Procedure</code>.</td>
</tr>
<tr>
<td>argument_type</td>
<td>The data type of the argument being defined. This is not verified or used by the Scheduler. It is only used by the user of the program when deciding what value to assign to the argument.</td>
</tr>
<tr>
<td>default_value</td>
<td>The default value to be assigned to the argument encapsulated within an AnyData object. This is optional.</td>
</tr>
<tr>
<td>out_argument</td>
<td>This parameter is reserved for future use. It must be set to FALSE.</td>
</tr>
</tbody>
</table>

Usage Notes

All program arguments from one to the `number_of_arguments` value must be defined before a program can be enabled. If a default value for an argument is not defined with this procedure, a value must be defined in the job.

Defining a program argument requires that you be the owner of the program or have ALTER privileges on that program. You can also define a program argument if you have the CREATE ANY JOB privilege.

See Also:

- "DEFINE_PROGRAM_ARGUMENT Procedure" on page 129-80
- "SET_JOB_ANYDATA_VALUE Procedure" on page 129-142
DEFINE_CHAIN_EVENT_STEP Procedure

This procedure adds or replaces a chain step and associates it with an event schedule or an inline event. Once started in a running chain, this step does not complete until the specified event has occurred. Every step in a chain must be defined before the chain can be enabled and used. Defining a step gives it a name and specifies what happens during the step. If a step already exists with this name, the new step replaces the old one.

Syntax

```
DBMS_SCHEDULER.DEFINE_CHAIN_EVENT_STEP (  
  chain_name              IN VARCHAR2,  
  step_name               IN VARCHAR2,  
  event_schedule_name     IN VARCHAR2,  
  timeout                 IN INTERVAL DAY TO SECOND DEFAULT NULL);
```

```
DBMS_SCHEDULER.DEFINE_CHAIN_EVENT_STEP (  
  chain_name              IN VARCHAR2,  
  step_name               IN VARCHAR2,  
  event_condition         IN VARCHAR2,  
  queue_spec              IN VARCHAR2,  
  timeout                 IN INTERVAL DAY TO SECOND DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain that the step is in</td>
</tr>
<tr>
<td>step_name</td>
<td>The name of the step</td>
</tr>
<tr>
<td>event_schedule_name</td>
<td>The name of the event schedule that the step waits for</td>
</tr>
<tr>
<td>timeout</td>
<td>This parameter is reserved for future use</td>
</tr>
<tr>
<td>event_condition</td>
<td>See the CREATE_EVENT_SCHEDULE Procedure</td>
</tr>
<tr>
<td>queue_spec</td>
<td>See the CREATE_EVENT_SCHEDULE Procedure</td>
</tr>
</tbody>
</table>

Usage Notes

Defining a chain step requires ALTER privileges on the chain either as the owner of the chain, or as a user with the ALTER object privilege on the chain or the CREATE ANY JOB system privilege.

You can base a chain step on a file watcher as well. To do this, provide the file watcher name directly in the queue_spec parameter, or use a file watcher schedule for the event_schedule_name parameter.

See Also: "DEFINE_CHAIN_STEP Procedure" on page 129-77
DEFINE_CHAIN_RULE Procedure

This procedure adds a new rule to an existing chain, specified as a condition-action pair. The condition is expressed using either SQL or the Scheduler chain condition syntax and indicates the prerequisites for the action to occur. The action is a result of the condition being met.

An actual rule object is created to store the rule in the schema where the chain resides. If a rule name is given, this name is used for the rule object. If an existing rule name in the schema of the chain is given, the existing rule is altered. (A schema different than the schema of the chain cannot be specified). If no rule name is given, one is generated in the form SCHED_RULE$(N)$.

Syntax

```sql
DBMS_SCHEDULER.DEFINE_CHAIN_RULE (  
    chain_name              IN VARCHAR2,
    condition               IN VARCHAR2,
    action                  IN VARCHAR2,
    rule_name               IN VARCHAR2 DEFAULT NULL,
    comments                IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to alter</td>
</tr>
<tr>
<td>condition</td>
<td>A boolean expression which must evaluate to TRUE for the action to be performed. Every chain must have a rule that evaluates to TRUE to start the chain. For this purpose, you can use a rule that has 'TRUE' as its condition if you are using Scheduler chain condition syntax, or '1=1' as its condition if you are using SQL syntax.</td>
</tr>
</tbody>
</table>

- **Scheduler Chain Condition Syntax**
  
  See "Scheduler Chain Condition Syntax" on page 129-75 for details

- **SQL WHERE Clause Syntax**

  Conditions expressed with SQL must use the syntax of a SELECT statement WHERE clause.

  You can refer to chain step attributes by using the chain step name as a bind variable.

  The bind variable syntax is :step_name.attribute.(step_name refers to a typed object.) Possible attributes are: completed, state, start_date, end_date, error_code, and duration.

  Possible values for the state attribute include: 'NOT_STARTED', 'SCHEDULED', 'RUNNING', 'PAUSED', 'STALLED', 'SUCCEEDED', 'FAILED', and 'STOPPED'. If a step is in the state 'SUCCEEDED', 'FAILED', or 'STOPPED', its completed attribute is set to 'TRUE', otherwise completed is 'FALSE'.
Scheduler Chain Condition Syntax

The Scheduler chain condition syntax provides an easy way to construct a condition using the states and error codes of steps in the current chain. The following are the available constructs, which are all boolean expressions:

- TRUE
- FALSE
- stepname [NOT] SUCCEEDED
- stepname [NOT] FAILED
- stepname [NOT] STOPPED
- stepname [NOT] COMPLETED
- stepname ERROR_CODE IN (integer, integer, integer ...)
- stepname ERROR_CODE NOT IN (integer, integer, integer ...)
- stepname ERROR_CODE = integer
- stepname ERROR_CODE != integer
- stepname ERROR_CODE <> integer
- stepname ERROR_CODE > integer
- stepname ERROR_CODE >= integer
- stepname ERROR_CODE < integer
- stepname ERROR_CODE <= integer

These boolean operators are available to create more complex conditions:

- expression AND expression
- expression OR expression
- NOT (expression)

integer can be positive or negative. Parentheses may be used for clarity or to enforce ordering. You must use parentheses with the NOT operator.

PL/SQL code that runs as part of a step can set the value of ERROR_CODE for that step with the RAISE_APPLICATION_ERROR statement.

---

**Table 129-36 (Cont.) DEFINE_CHAIN_RULE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
</table>
| action    | The action to be performed when the rule evaluates to TRUE. The action must consist of at least one keyword with an optional value and an optional delay clause. Possible actions include:  
  - [AFTER delay_interval] START step_1[,step_2 ...]  
  - STOP step_1[,step_2 ...]  
  - END [[end_value] step_name.error_code]  
At the beginning of the START action, a delay clause can specify a delay interval before performing the action. delay_interval is a formatted datetime interval of the form HH:MM:SS.  
The END action ends the chain with an error code equal to either the supplied end_value or the error code that step_name completes with. The default error code is 0, indicating a successful chain run. |
| rule_name | The name of the rule being created. If no rule_name is given, one is generated in the form SCHED_RULE$_{N}$. |
| comments  | An optional comment describing the rule. This is stored in the rule object created. |
Usage Notes

Defining a chain rule requires ALTER privileges on the chain (either as the owner, or as a user with ALTER privileges on the chain or the CREATE ANY JOB system privilege).

You must define at least one rule that starts the chain and at least one that ends it. See the section "Adding Rules to a Chain" in Oracle Database Administrator’s Guide for more information.

Examples

The following are examples of using rule conditions and rule actions.

Rule Conditions Using Scheduler Chain Condition Syntax

```plaintext
'step1 completed'
-- satisfied when step step1 has completed. (step1 completed is also TRUE when any
-- of the following are TRUE: step1 succeeded, step1 failed, step1 stopped.)

'step1 succeeded and step2 succeeded'
-- satisfied when steps step1 and step2 have both succeeded

'step1 error_code > 100'
-- satisfied when step step1 has failed with an error_code greater than 100

'step1 error_code IN (1, 3, 5, 7)'
-- satisfied when step step1 has failed with an error_code of 1, 3, 5, or 7
```

Rule Conditions Using SQL Syntax

```plaintext
':step1.completed = ''TRUE'' AND :step1.end_date >SYSDATE-1/24'
--satisfied when step step1 completed less than an hour ago

':step1.duration > interval ''5'' minute'
-- satisfied when step step1 has completed and took longer than 5 minutes to complete
```

Rule Actions

```plaintext
'AFTER 01:00:00 START step1, step2'
--After an hour start steps step1 and step2

'STOP step1'
--Stop step step1

END step4.error_code
--End the chain with the error code that step step4 finished with. If step4 has not completed, the chain will be ended unsuccessfullly with error code 27435.

'END' or 'END 0'
--End the chain successfully (with error_code 0)

'END 100'
--End the chain unsuccessfullly with error code 100.
```
**DEFINE_CHAIN_STEP Procedure**

This procedure adds or replaces a chain step and associates it with a program or a nested chain. When the chain step is started, the specified program or chain is run. If a step already exists with the name supplied in the `chain_name` argument, the new step replaces the old one.

The chain owner must have EXECUTE privileges on the program or chain associated with the step. Only one program or chain can run during a step.

You cannot set all possible step attributes with this procedure. Use the ALTER_CHAIN procedure to set additional chain step attributes, such as credential_name and destination_name.

**Syntax**

```sql
DBMS_SCHEDULER.DEFINE_CHAIN_STEP (    
    chain_name              IN VARCHAR2,  
    step_name               IN VARCHAR2,  
    program_name            IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to alter.</td>
</tr>
<tr>
<td>step_name</td>
<td>The name of the step being defined. If a step already exists with this name, the new step replaces the old one.</td>
</tr>
<tr>
<td>program_name</td>
<td>The name of a program or chain to run during this step. The chain owner must have EXECUTE privileges on this program or chain.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Defining a chain step requires ALTER privileges on the chain (either as the owner, or a user with ALTER privileges on the chain or the CREATE ANY JOB system privilege).

See Also:

- "ALTER_CHAIN Procedure" on page 129-39
- "DEFINE_CHAIN_EVENT_STEP Procedure" on page 129-73
DEFINE_METADATA_ARGUMENT Procedure

This procedure defines a special metadata argument for the program. The Scheduler can pass Scheduler metadata through this argument to your stored procedure or other executable. You cannot set values for jobs using this argument.

Syntax

```sql
DBMS_SCHEDULER.DEFINE_METADATA_ARGUMENT (
    program_name            IN VARCHAR2,
    metadata_attribute      IN VARCHAR2,
    argument_position       IN PLS_INTEGER,
    argument_name           IN VARCHAR2 DEFAULT NULL);
```

Parameters

- `program_name`: The name of the program to be altered
- `metadata_attribute`: The metadata to be passed. Valid metadata attributes are: 'job_name', 'job_subname', 'job_owner', 'job_start', 'window_start', 'window_end', and 'event_message'. Table 129–39 describes these attributes in detail.
- `argument_position`: The position of the argument as it is passed to the executable. The position cannot be greater than the number_of_arguments specified for the program. It must be unique, so it replaces any argument already defined at this position.
- `argument_name`: The name to assign to the argument. It is optional, but must be unique for the program if it is specified. If you assign a name, the name can then be used by other package procedures.

Table 129–39 Metadata Attributes

<table>
<thead>
<tr>
<th>Metadata Attribute</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>VARCHAR2</td>
<td>Name of the currently running job</td>
</tr>
<tr>
<td>job_subname</td>
<td>VARCHAR2</td>
<td>Subname of the currently running job. The name + subname form a unique identifier for a job that is running a chain step. NULL if the job is not part of a chain.</td>
</tr>
<tr>
<td>job_owner</td>
<td>VARCHAR2</td>
<td>Owner of the currently running job</td>
</tr>
<tr>
<td>job_scheduled_start</td>
<td>TIMESTAMP WITH TIME ZONE</td>
<td>When the currently running job was scheduled to start</td>
</tr>
<tr>
<td>job_start</td>
<td>TIMESTAMP WITH TIME ZONE</td>
<td>When the currently running job started</td>
</tr>
</tbody>
</table>
**Table 129–39  (Cont.) Metadata Attributes**

<table>
<thead>
<tr>
<th>Metadata Attribute</th>
<th>Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>window_start</td>
<td>TIMESTAMP WITH TIME ZONE</td>
<td>If the job was started by a window, the time that the window opened</td>
</tr>
<tr>
<td>window_end</td>
<td>TIMESTAMP WITH TIME ZONE</td>
<td>If the job was started by a window, the time that the window is scheduled to close</td>
</tr>
<tr>
<td>event_message</td>
<td>(See Description)</td>
<td>For an event-based job, the message content of the event that started the job. The data type of this attribute depends on the queue used for the event. It has the same type as the USER_DATA column of the queue table. In the case of a file arrival event, event_message is of type SYS.SCHEDULER_FILEWATCHER_RESULT. See &quot;SCHEDULER_FILEWATCHER_RESULT Object Type&quot; on page 15.</td>
</tr>
</tbody>
</table>

**Usage Notes**

Defining a program argument requires that you be the owner of the program or have ALTER privileges on that program. You can also define a program argument if you have the CREATE ANY JOB privilege.

All metadata attributes except event_message can be used in PL/SQL blocks that you enter into the job_action or program_action attributes of jobs or programs, respectively. You use the attribute name as you use any other PL/SQL identifier, and the Scheduler assigns it a value.
DEFINE_PROGRAM_ARGUMENT Procedure

This procedure defines a name or default value for a program argument. If no default value is defined for a program argument, the job that references the program must supply an argument value. (The job can also override a default value.)

This procedure is overloaded.

Syntax

Defines a program argument without a default value:

```sql
PROCEDURE define_program_argument(
    program_name            IN VARCHAR2,
    argument_position       IN PLS_INTEGER,
    argument_name           IN VARCHAR2 DEFAULT NULL,
    argument_type           IN VARCHAR2,
    out_argument            IN BOOLEAN DEFAULT FALSE);
```

Defines a program argument with a default value:

```sql
PROCEDURE define_program_argument(
    program_name            IN VARCHAR2,
    argument_position       IN PLS_INTEGER,
    argument_name           IN VARCHAR2 DEFAULT NULL,
    argument_type           IN VARCHAR2,
    default_value           IN VARCHAR2,
    out_argument            IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>The name of the program to be altered. A program with this name must exist.</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the argument as it is passed to the executable. Argument numbers go from one to the number_of_arguments specified for the program. This must be unique so it replaces any argument already defined at this position.</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name to assign to the argument. It is optional, but must be unique for the program if specified. If you assign a name, the name can then be used by other package procedures, including the SET_JOB_ARGUMENT_VALUE Procedure.</td>
</tr>
<tr>
<td>argument_type</td>
<td>The data type of the argument being defined. This is not verified or used by the Scheduler. The program user uses argument_type when deciding what value to assign to the argument. Any valid SQL data type is allowed.</td>
</tr>
<tr>
<td>default_value</td>
<td>The default value to be assigned to the argument if none is specified by the job.</td>
</tr>
<tr>
<td>out_argument</td>
<td>This parameter is reserved for future use. It must be set to FALSE.</td>
</tr>
</tbody>
</table>

Usage Notes

All program arguments from 1 to the number_of_arguments value must be defined before a program can be enabled. If a default value for an argument is not defined with this procedure, a value must be defined in the job.
Defining a program argument requires that you be the owner of the program or have ALTER privileges on that program. You can also define a program argument if you have the CREATE ANY JOB privilege.

DEFINE_PROGRAM_ARGUMENT only supports arguments of SQL type. Therefore, argument values that are not of SQL type, such as booleans, are not supported as program or job arguments.

See Also:
- "DEFINE_ANYDATA_ARGUMENT Procedure" on page 129-72
- "SET_JOB_ARGUMENT_VALUE Procedure" on page 129-143
DISABLE Procedure

This procedure disables a program, job, chain, window, database destination, external destination, file watcher, or group. When an object is disabled, its enabled attribute is set to FALSE.

Syntax

```
DBMS_SCHEDULER.DISABLE (
    name              IN VARCHAR2,
    force             IN BOOLEAN DEFAULT FALSE,
    commit_semantics  IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

Parameters

**Table 129–41 DISABLE Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the object being disabled. Can be a comma-delimited list.</td>
</tr>
<tr>
<td></td>
<td>If a job class name is specified, then all the jobs in the job class are disabled. The job class is not disabled.</td>
</tr>
<tr>
<td></td>
<td>If a group name is specified, then the group is disabled, but the enabled state of the group members is unaffected.</td>
</tr>
<tr>
<td>force</td>
<td>If TRUE, objects are disabled even if other objects depend on them.</td>
</tr>
<tr>
<td></td>
<td>See the usage notes for more information.</td>
</tr>
<tr>
<td>commit_semantics</td>
<td>The commit semantics. The following types are supported:</td>
</tr>
<tr>
<td></td>
<td><strong>STOP_ON_FIRST_ERROR</strong>: The procedure returns on the first error and the previous disable operations that were successful are committed to disk.</td>
</tr>
<tr>
<td></td>
<td>This is the default.</td>
</tr>
<tr>
<td></td>
<td><strong>TRANSACTIONAL</strong>: The procedure returns on the first error and everything that happened before that error is rolled back.</td>
</tr>
<tr>
<td></td>
<td>This type is only supported when disabling a job or a list of jobs. In addition, this type is not supported when force is set to TRUE.</td>
</tr>
<tr>
<td></td>
<td><strong>ABSORB_ERRORS</strong>: The procedure tries to absorb any errors and disable the rest of the jobs and commits all the disable operations that were successful. If errors occur, you can query the view SCHEDULER_BATCH_ERRORS for details.</td>
</tr>
<tr>
<td></td>
<td>This type is only supported when disabling a job or a list of jobs.</td>
</tr>
</tbody>
</table>

Usage Notes

Windows must be preceded by SYS.

Disabling an object that is already disabled does not generate an error.

The purpose of the force option is to point out dependencies. No dependent objects are altered.

To run DISABLE for a window or a group of type WINDOW, you must have the MANAGE SCHEDULER privilege.
You can use `DISABLE` with any schema except the `SYS` schema.

**Jobs**
Disabling a job means that, although the metadata of the job is there, it should not run and the job coordinator will not pick up these jobs for processing. When a job is disabled, its state in the job queue is changed to disabled.

If `force` is set to `FALSE` and the job is currently running, an error is returned.

If `force` is set to `TRUE`, the job is disabled, but the currently running instance is allowed to finish.

For jobs with multiple destinations, you cannot disable a child job at a specific destination. Instead, you can disable the destination.

**Programs**
When a program is disabled, the status is changed to disabled. A disabled program implies that, although the metadata is still there, jobs that point to this program cannot run.

If `force` is set to `FALSE`, the program must not be referenced by any job, otherwise an error will occur.

If `force` is set to `TRUE`, those jobs that point to the program will not be disabled, however, they will fail at runtime because their program will not be valid.

Running jobs that point to the program are not affected by the `DISABLE` call and are allowed to continue

No arguments that pertain to the program are affected when the program is disabled.

**File Watchers**
If `force` is set to `FALSE`, the file watcher must not be referenced by any job, otherwise an error will occur. If you force disabling a file watcher, jobs that depend on it become disabled.

**Windows**
This means that the window will not open, however, the metadata of the window is still there, so it can be reenabled.

If `force` is set to `FALSE`, the window must not be open or referenced by any job otherwise an error occurs.

If `force` is set to `TRUE`, disabling a window that is open will succeed but the window will not be closed. It will prevent the window from opening in the future until it is reenabled.

When the window is disabled, those jobs that have the window as their schedule will not be disabled.

**Window Groups**
When a group of type `WINDOW` is disabled, jobs (other than a running job) that have the window group as their schedule will not run when the member windows open. However, a job that has one of the window group members as its schedule still runs.

The metadata of the window group is still there, so it can be reenabled. Note that the members of the window group will still open.

If `force` is set to `FALSE`, the window group must not have any members that are open or referenced by any job, otherwise an error will occur.
If `force` is set to `TRUE`:

- The window group is disabled and the open window will be not closed or disabled. It will be allowed to continue to its end.
- The window group is disabled but those jobs that have the window group as their schedule will not be disabled.

**Job Chains**

When a chain is disabled, the metadata for the chain is still there, but jobs that point to it will not be able to be run. This allows changes to the chain to be made safely without the risk of having an incompletely specified chain run.

If `force` is set to `FALSE`, the chain must not be referenced by any job, otherwise an error will occur.

If `force` is set to `TRUE`, those jobs that point to the chain will not be disabled, however, they will fail at runtime.

Running jobs that point to this chain are not affected by the `DISABLE` call and are allowed to complete.

**Database Destinations**

When you disable a database destination:

- The destination is skipped when a multiple destination job runs.
- If all destinations are disabled for a job, the Scheduler generates an error when it attempts to run the job.
- The `REFS_ENABLED` column in `*_SCHEDULER_JOB_DESTS` is set to `FALSE` for all jobs that reference the database destination.

**External Destinations**

When you disable an external destination:

- Dependent database destinations remain enabled, but the Scheduler generates an error when it attempts to run a job with a database destination that depends on the external destination.
- The `REFS_ENABLED` column in `*_SCHEDULER_JOB_DESTS` is set to `FALSE` for all external jobs that reference the external destination and for all database jobs with a database destination that depends on the external destination.

**Groups**

If you disable an external destination group or database destination group, the Scheduler generates an error when it attempts to run a job that names the group as its destination.
DROP_AGENT_DESTINATION Procedure

This procedure drops one or more external destinations, also known as agent destinations. It should be used only when the preferred method of dropping an external destination—using the schagent utility to unregister a Scheduler agent with a database—is unavailable due to failures.

This procedure can be called only by the SYS user or a user with the MANAGE SCHEDULER privilege.

---

**Note:** External destinations are created on a source database only implicitly by registering an agent with the database. There is no user-callable CREATE_AGENT_DESTINATION procedure.

### Syntax

```
DBMS_SCHEDULER.DROP_AGENT_DESTINATION (destination_name IN VARCHAR2);
```

### Parameters

**Table 129–42  DROP_AGENT_DESTINATION Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination_name</td>
<td>A comma-separated list of external destinations to drop. Because user SYS owns all external destinations, do not prefix them with a schema name. The procedure stops processing if it encounters an external destination that does not exist. All external destinations processed before the error are dropped. Cannot be NULL.</td>
</tr>
</tbody>
</table>

### Usage Notes

When an external destination is dropped:

- All database destinations that refer to the external destination are disabled and their agent attribute is set to NULL.
- Members of external destination groups that refer to the destination are removed from the group.
- All job instances in the *_SCHEDULER_JOB_DESTS views that refer to the external destination are also dropped.
- Jobs running against the destination are stopped.
DROP_CHAIN Procedure

This procedure drops an existing chain.

Syntax

```sql
DBMS_SCHEDULER.DROP_CHAIN (  
    chain_name         IN VARCHAR2,
    force              IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to drop. Can also be a comma-delimited list of chains.</td>
</tr>
</tbody>
</table>
| force      | If `force` is set to `FALSE`, the chain must not be referenced by any job, otherwise an error will occur.  
If `force` is set to `TRUE`, all jobs pointing to the chain are disabled before the chain is dropped.  
Running jobs that point to this chain are stopped before the chain is dropped. |

Usage Notes

Dropping a chain requires alter privileges on the chain (either as the owner, or a user with `ALTER` privileges on the chain or the `CREATE ANY JOB` system privilege).

All steps associated with the chain are dropped. If no rule set was specified when the chain was created, then the automatically created rule set and evaluation context associated with the chain are also dropped, so the user must have the privileges required to do this. See the `DBMS_RULE_ADM.DROP_RULE_SET` and `DBMS_RULE_ADM.DROP_EVALUATION_CONTEXT` procedures for more information.

If `force` is `FALSE`, no jobs may be using this chain. If `force` is `TRUE`, any jobs that use this chain are disabled before the chain is dropped (and any of these jobs that are running will be stopped).
DROP_CHAIN_RULE Procedure

This procedure removes a rule from an existing chain. The rule object corresponding to this rule will also be dropped. The chain will not be disabled. If dropping this rule makes the chain invalid, the user should first disable the chain to ensure that it does not run.

Syntax

```
DBMS_SCHEDULER.DROP_CHAIN_RULE (  
    chain_name              IN VARCHAR2,  
    rule_name               IN VARCHAR2,  
    force                   IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to alter</td>
</tr>
<tr>
<td>rule_name</td>
<td>The name of the rule to drop</td>
</tr>
<tr>
<td>force</td>
<td>If force is set to TRUE, the drop operation proceeds even if the chain is currently running. The running chain is not stopped or interrupted. If force is set to FALSE and the chain is running, an error is generated.</td>
</tr>
</tbody>
</table>

Usage Notes

Dropping a chain rule requires alter privileges on the chain (either as the owner or as a user with ALTER privileges on the chain or the CREATE ANY JOB system privilege).

Dropping a chain rule also drops the underlying rule database object so you must have the privileges to drop this rule object. See the DBMS_RULE_ADM.DROP_RULE procedure for more information.
DROP_CHAIN_STEP Procedure

This procedure drops a chain step. If this chain step is still used in the chain rules, the chain will be disabled.

Syntax

```
DBMS_SCHEDULER.DROP_CHAIN_STEP (  
    chain_name              IN VARCHAR2,  
    step_name               IN VARCHAR2,  
    force                   IN BOOLEAN DEFAULT FALSE);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to alter</td>
</tr>
<tr>
<td>step_name</td>
<td>The name of the step being dropped. Can be a comma-separated list.</td>
</tr>
<tr>
<td>force</td>
<td>If force is set to TRUE, this succeeds even if this chain is currently running. The running chain will not be stopped or interrupted. If force is set to FALSE and this chain is currently running, an error is thrown.</td>
</tr>
</tbody>
</table>

Usage Notes

Dropping a chain step requires ALTER privileges on the chain (either as the owner or as a user with ALTER privileges on the chain or the CREATE ANY JOB system privilege).
DROP_CREDENTIAL Procedure

This procedure drops a credential.

Syntax

```sql
DBMS_SCHEDULER.DROP_CREDENTIAL (
    credential_name         IN VARCHAR2,
    force                   IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>credential_name</td>
<td>The name of the credential being dropped. This can optionally be prefixed with a schema name. This cannot be set to NULL.</td>
</tr>
<tr>
<td>force</td>
<td>If set to FALSE, the credential must not be referenced by any job, or an error will occur. If set to TRUE, the credential is dropped whether or not there are jobs referencing it. Jobs that reference the credential will continue to point to a nonexistent credential and throw an error at runtime.</td>
</tr>
</tbody>
</table>

Usage Notes

Only the owner of a credential or a user with the CREATE ANY JOB system privilege may drop the credential.

Running jobs that point to the credential are not affected by this procedure and are allowed to continue.

See Also:  "CREATE_CREDENTIAL Procedure" on page 129-47
DROP_DATABASE_DESTINATION Procedure

This procedure drops one or more database destinations.

Syntax

```sql
DBMS_SCHEDULER.DROP_DATABASE_DESTINATION ( destination_name IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination_name</td>
<td>The name of the destination to drop. Can be a comma-separated list of database destinations to drop. Each database destination can optionally be prefixed with a schema name. The procedure stops processing if it encounters a database destination that does not exist. All database destinations processed before the error are dropped. Cannot be NULL.</td>
</tr>
</tbody>
</table>

Usage Notes

Only the owner or a user with the CREATE ANY JOB system privilege may drop the database destination.

When a database destination is dropped:

- All job instances that refer to the destination in the *_SCHEDULER_JOB_DESTS views are also dropped.
- Jobs running against the destination are stopped.
- Members of database destination groups that refer to the destination are removed from the group.

See Also: CREATE_DATABASE_DESTINATION Procedure on page 129-48
DROP_FILE_WATCHER Procedure

This procedure drops one or more file watchers.

Syntax

```
DBMS_SCHEDULER.DROP_FILE_WATCHER (  
  file_watcher_name       IN VARCHAR2,  
  force                   IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_watcher_name</td>
<td>The file watcher to drop. Can be a comma-separated list of file watchers. Each file watcher name can optionally be prefixed with a schema name. Cannot be NULL.</td>
</tr>
<tr>
<td>force</td>
<td>If set to FALSE, the file watcher must not be referenced by any job, or an error occurs. If set to TRUE, the file watcher is dropped whether or not there are jobs referencing it. In this case, jobs that reference the dropped file watcher are disabled.</td>
</tr>
</tbody>
</table>

Usage Notes

Only the owner of a file watcher or a user with the CREATE ANY JOB system privilege may drop the file watcher.

Running jobs that point to the file watcher are not affected by this procedure and are allowed to continue.

See Also: "CREATE_FILE_WATCHER Procedure" on page 129-51
DROP_GROUP Procedure

This procedure drops one or more groups.

Syntax

```sql
DBMS_SCHEDULER.DROP_GROUP (  
group_name       IN VARCHAR2,  
force            IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>A group to drop. Can be a comma-separated list of group names. Each group name can optionally be prefixed with a schema name. The procedure stops processing if it encounters a group that does not exist. All groups processed before the error are dropped. Cannot be NULL.</td>
</tr>
<tr>
<td>force</td>
<td>If FALSE, the group must not be referenced by any job, otherwise an error occurs. If TRUE, the group is dropped whether or not there are jobs referencing it. In this case, all jobs referencing the group are disabled and all job instances that reference the group are removed from the *_SCHEDULER_JOB_DESTS views.</td>
</tr>
</tbody>
</table>

Usage Notes

Only the owner or a user with the CREATE ANY JOB system privilege may drop a group. You must have the MANAGE SCHEDULER privilege to drop a group of type WINDOW.

See Also: "CREATE_FILE_WATCHER Procedure" on page 129-51
DROP_JOB Procedure

This procedure drops one or more jobs or all jobs in one or more job classes. Dropping a job also drops all argument values set for that job.

**Syntax**

```sql
DBMS_SCHEDULER.DROP_JOB (  
  job_name                IN VARCHAR2,  
  force                   IN BOOLEAN DEFAULT FALSE,  
  defer                   IN BOOLEAN DEFAULT FALSE,  
  commit_semantics        IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

**Parameters**

*Table 129–50  DROP_JOB Procedure Parameters*

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of a job or job class. Can be a comma-delimited list. For a job class, the SYS schema should be specified. If the name of a job class is specified, the jobs that belong to that job class are dropped, but the job class itself is not dropped.</td>
</tr>
<tr>
<td>force</td>
<td>If force is set to TRUE, the Scheduler first attempts to stop the running job instances (by issuing the STOP_JOB call with the force flag set to false), and then drops the jobs.</td>
</tr>
<tr>
<td>defer</td>
<td>If defer is set to TRUE, the Scheduler allows the running jobs to complete and then drops the jobs.</td>
</tr>
<tr>
<td>commit_semantics</td>
<td>The commit semantics. The following types are supported:</td>
</tr>
<tr>
<td></td>
<td>■ STOP_ON_FIRST_ERROR returns on the first error and previous successful drop operations are committed to disk. This is the default.</td>
</tr>
<tr>
<td></td>
<td>■ TRANSACTIONAL returns on the first error. Everything that happened before that error is rolled back. This type is not supported when force is set to TRUE.</td>
</tr>
<tr>
<td></td>
<td>■ ABSORB_ERRORS tries to absorb any errors and drop the rest of the jobs, and commits all the successful drops. If errors occur, you can query the view SCHEDULER_BATCH_ERRORS for details.</td>
</tr>
</tbody>
</table>

Only STOP_ON_FIRST_ERROR is permitted when job classes are included in the job_name list.

**Usage Notes**

If both force and defer are set to FALSE and a job is running at the time of the call, the attempt to drop that job fails. The entire call to DROP_JOB may then fail, depending on the setting of commit_semantics.

Setting both force and defer to TRUE results in an error.

Dropping a job requires ALTER privileges on the job either as the owner of the job or as a user with the ALTER object privilege on the job or the CREATE ANY JOB system privilege.
DROP_JOB_CLASS Procedure

This procedure drops a job class. Dropping a job class means that all the metadata about the job class is removed from the database.

Syntax

```sql
DBMS_SCHEDULER.DROP_JOB_CLASS (
    job_class_name  IN VARCHAR2,
    force           IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_class_name</td>
<td>The name of the job class. Can be a comma-delimited list.</td>
</tr>
<tr>
<td>force</td>
<td>If force is set to FALSE, a class being dropped must not be referenced by any jobs, otherwise an error occurs.</td>
</tr>
<tr>
<td></td>
<td>If force is set to TRUE, jobs belonging to the class are disabled and their class is set to the default class. Only if this is successful is the class dropped.</td>
</tr>
<tr>
<td></td>
<td>Running jobs that belong to the job class are not affected.</td>
</tr>
</tbody>
</table>

Usage Notes

Dropping a job class requires the MANAGE SCHEDULER system privilege.
### DROP_PROGRAM Procedure

This procedure drops a program. Any arguments that pertain to the program are also dropped when the program is dropped.

#### Syntax

```sql
DBMS_SCHEDULER.DROP_PROGRAM (  
    program_name            IN VARCHAR2,  
    force                   IN BOOLEAN DEFAULT FALSE);
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>The name of the program to be dropped. Can be a comma-delimited list.</td>
</tr>
<tr>
<td>force</td>
<td>If <code>force</code> is set to <code>FALSE</code>, the program must not be referenced by any job, otherwise an error occurs.</td>
</tr>
<tr>
<td></td>
<td>If <code>force</code> is set to <code>TRUE</code>, all jobs referencing the program are disabled before the program is dropped.</td>
</tr>
<tr>
<td></td>
<td>Running jobs that point to the program are not affected by the <code>DROP_PROGRAM</code> call and are allowed to continue.</td>
</tr>
</tbody>
</table>

#### Usage Notes

Dropping a program requires that you be the owner of the program or have `ALTER` privileges on that program. You can also drop a program if you have the `CREATE ANY JOB` privilege.
DROP_PROGRAM_ARGUMENT Procedure

This procedure drops a program argument. An argument can be specified by either name (if one has been given) or position.

The procedure is overloaded.

Syntax

Drops a program argument by position:

```sql
DBMS_SCHEDULER.DROP_PROGRAM_ARGUMENT (  
    program_name            IN VARCHAR2,  
    argument_position       IN PLS_INTEGER);
```

Drops a program argument by name:

```sql
DBMS_SCHEDULER.DROP_PROGRAM_ARGUMENT (  
    program_name            IN VARCHAR2,  
    argument_name           IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>program_name</td>
<td>The name of the program to be altered. A program with this name must exist.</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name of the argument being dropped</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the argument to be dropped</td>
</tr>
</tbody>
</table>

Usage Notes

Dropping a program argument requires that you be the owner of the program or have ALTER privileges on that program. You can also drop a program argument if you have the CREATE ANY JOB privilege.
**DROP_SCHEDULE Procedure**

This procedure drops a schedule.

**Syntax**

```sql
DBMS_SCHEDULER.DROP_SCHEDULE (  
    schedule_name    IN VARCHAR2,  
    force            IN BOOLEAN DEFAULT FALSE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_name</td>
<td>The name of the schedule. Can be a comma-delimited list.</td>
</tr>
<tr>
<td>force</td>
<td>If <code>force</code> is set to <code>FALSE</code>, the schedule must not be referenced by any job or window, otherwise an error will occur.</td>
</tr>
<tr>
<td></td>
<td>If <code>force</code> is set to <code>TRUE</code>, any jobs or windows that use this schedule are disabled before the schedule is dropped.</td>
</tr>
<tr>
<td></td>
<td>Running jobs and open windows that point to the schedule are not affected.</td>
</tr>
</tbody>
</table>

**Usage Notes**

You must be the owner of the schedule being dropped or have *ALTER* privileges for the schedule or the *CREATE ANY JOB* privilege.
DROP_WINDOW Procedure

This procedure drops a window. All metadata about the window is removed from the database. The window is removed from any groups that reference it.

Syntax

```
DBMS_SCHEDULER.DROP_WINDOW (  
    window_name             IN VARCHAR2,  
    force                   IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>window_name</td>
<td>The name of the window. Can be a comma-delimited list.</td>
</tr>
<tr>
<td>force</td>
<td>If <code>force</code> is set to <code>FALSE</code>, the window must not be open or referenced by any job, otherwise an error occurs.</td>
</tr>
</tbody>
</table>

If `force` is set to `TRUE`, the window is dropped and those jobs that have the window as their schedule are disabled. However, jobs that have a window group, of which the dropped window is a member, as their schedule, are not disabled. If the window is open then, the Scheduler attempts to first close the window and then drop it. When the window is closed, normal close window rules apply.

Running jobs that have the window as their schedule is allowed to continue, unless the `stop_on_window_close` flag is set to `TRUE` for the job. If this is the case, the job is stopped when the window is dropped.

Usage Notes

Dropping a window requires the `MANAGE_SCHEDULER` privilege.
**DROP_WINDOW_GROUP Procedure**

*** Deprecated in Oracle Database 11g Release 2 (11.2). Use DROP_GROUP instead.***

This procedure drops a window group but not the windows that are members of this window group.

**Syntax**

```sql
DBMS_SCHEDULER.DROP_WINDOW_GROUP (
    group_name              IN VARCHAR2
    force                   IN BOOLEAN DEFAULT FALSE);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name of the window group</td>
</tr>
<tr>
<td>force</td>
<td>If <code>force</code> is set to <code>FALSE</code>, the window group must not be referenced by any job otherwise an error will occur. If <code>force</code> is set to <code>TRUE</code>, the window group is dropped and those jobs that have the window group as their schedule are disabled. Running jobs that have the window group as their schedule are allowed to continue, even if the <code>stop_on_window_close</code> flag was set to <code>TRUE</code> when for the job. If a member of the window group that is being dropped is open, the window group can still be dropped.</td>
</tr>
</tbody>
</table>

**Usage Notes**

If you want to drop all the windows that are members of this group but not the window group itself, you can use the DROP_WINDOW procedure and provide the name of the window group to the call.

To drop a window group, you must have the MANAGE_SCHEDULER privilege.
ENABLE Procedure

This procedure enables a program, job, chain, window, database destination, external destination, file watcher, or group. When an object is enabled, its enabled attribute is set to TRUE. By default, jobs, chains, and programs are created disabled and database destinations, external destinations, file watchers, windows, and groups are created enabled.

If a job was disabled and you enable it, the Scheduler begins to automatically run the job according to its schedule. Enabling a disabled job also resets the job RUN_COUNT, FAILURE_COUNT and RETRY_COUNT columns in the *_SCHEDULER_JOBS data dictionary views.

Validity checks are performed before enabling an object. If the check fails, the object is not enabled, and an appropriate error is returned. This procedure does not return an error if the object was already enabled.

Syntax

```sql
DBMS_SCHEDULER.ENABLE (
    name              IN VARCHAR2,
    commit_semantics  IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the Scheduler object being enabled. Can be a comma-delimited list of names.</td>
</tr>
<tr>
<td></td>
<td>If a job class name is specified, then all the jobs in the job class are enabled.</td>
</tr>
<tr>
<td></td>
<td>If a group name is specified, then the group is enabled, but the enabled state of the group members is unaffected.</td>
</tr>
<tr>
<td>commit_semantics</td>
<td>The commit semantics. The following types are supported:</td>
</tr>
<tr>
<td></td>
<td>- STOP_ON_FIRST_ERROR - The procedure returns on the first error and previous successful enable operations are committed to disk. This is the default.</td>
</tr>
<tr>
<td></td>
<td>- TRANSACTIONAL - The procedure returns on the first error and everything that happened before that error is rolled back. This type is only supported when enabling a job or a list of jobs.</td>
</tr>
<tr>
<td></td>
<td>- ABSORB_ERRORS - The procedure tries to absorb any errors and enable the rest of the jobs. It commits all the enable operations that were successful. If errors occur, you can query the view SCHEDULER_BATCH_ERRORS for details. This type is only supported when enabling a job or a list of jobs.</td>
</tr>
</tbody>
</table>

Usage Notes

Window names must be preceded by SYS.

To run ENABLE for a window or group of type WINDOW, you must have the MANAGE SCHEDULER privilege. For a job of type EXECUTABLE (or for a job that points to a program of type EXECUTABLE), the job owner must have the CREATE EXTERNAL JOB system privilege before the job can be enabled or run.
To enable a file watcher, the file watcher owner must have the `EXECUTE` privilege on the designated credential.

You can use `ENABLE` with any schema except the `SYS` schema.
END_DETACHED_JOB_RUN Procedure

This procedure ends a detached job run. A detached job points to a detached program, which is a program with the detached attribute set to TRUE. A detached job run does not end until this procedure or the STOP_JOB Procedure is called.

Syntax

```sql
DBMS_SCHEDULER.END_DETACHED_JOB_RUN (  
    job_name    IN VARCHAR2,  
    error_number IN PLS_INTEGER DEFAULT 0,  
    additional_info IN VARCHAR2 DEFAULT NULL);
```

Parameters

**Table 129–58 END_DETACHED_JOB_RUN Procedure Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the job to end. Must be a detached job that is running.</td>
</tr>
<tr>
<td>error_number</td>
<td>If zero, then the job run is logged as succeeded. If -1013, then the job run is logged as stopped. If non-zero, then the job run is logged as failed with this error number.</td>
</tr>
</tbody>
</table>
| additional_info | This text is stored in the additional_info column of the *

_scheduler_*

_job_run_details views for this job run. |

Usage Notes

This procedure requires that you either own the job or have ALTER privileges on it. You can also end any detached job run if you have the CREATE ANY JOB privilege.

**See Also:** Oracle Database Administrator’s Guide for information about detached jobs.
EVALUATECALENDAR_STRING Procedure

You can define repeat intervals of jobs, windows or schedules using the Scheduler calendaring syntax. This procedure evaluates the calendar expression and tells you the next execution date and time of a job or window. This is very useful for testing the correct definition of the calendar string without actually scheduling the job or window.

This procedure can also get multiple steps of the repeat interval by passing the next_run_date returned by one invocation as the return_date_after argument of the next invocation.

See the calendaring syntax described in "Operational Notes" on page 129-20.

Syntax

```
DBMS_SCHEDULER.EVALUATECALENDAR_STRING (
    calendar_string IN VARCHAR2,
    start_date IN TIMESTAMP WITH TIME ZONE,
    return_date_after IN TIMESTAMP WITH TIME ZONE,
    next_run_date OUT TIMESTAMP WITH TIME ZONE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>calendar_string</td>
<td>The calendar expression to be evaluated. The string must be in the calendaring syntax described in &quot;Operational Notes&quot; on page 129-20.</td>
</tr>
<tr>
<td>start_date</td>
<td>The date and time after which the repeat interval becomes valid. It can also be used to fill in specific items that are missing from the calendar string. Can optionally be NULL.</td>
</tr>
<tr>
<td>return_date_after</td>
<td>The return_date_after argument helps the Scheduler determine which one of all possible matches (all valid execution dates) to return from those determined by the start_date and the calendar string. When a NULL value is passed for this argument, the Scheduler automatically fills in systimestamp as its value.</td>
</tr>
<tr>
<td>next_run_date</td>
<td>The first timestamp that matches the calendar string and start date that occur after the value passed in for the return_date_after argument.</td>
</tr>
</tbody>
</table>

Examples

The following code fragment can be used to determine the next five dates a job will run given a specific calendar string.

```
SET SERVEROUTPUT ON;
ALTER SESSION set NLS_DATE_FORMAT = 'DD-MON-YYYY HH24:MI:SS';
Session altered.

DECLARE
    start_date       TIMESTAMP;
    return_date_after TIMESTAMP;
    next_run_date    TIMESTAMP;
BEGIN
    start_date :=
        to_timestamp_tz('01-JAN-2003 10:00:00','DD-MON-YYYY HH24:MI:SS');
    return_date_after := start_date;
```
FOR i IN 1..5 LOOP
    DBMS_SCHEDULER.EVALUATE_CALENDAR_STRING(
        'FREQ=DAILY;BYHOUR=9;BYMINUTE=30;BYDAY=MON,TUE,WED,THU,FRI',
        start_date, return_date_after, next_run_date);
    DBMS_OUTPUT.PUT_LINE('next_run_date: ' || next_run_date);
    return_date_after := next_run_date;
END LOOP;
END;
/

next_run_date: 02-JAN-03 09.30.00.000000 AM
next_run_date: 03-JAN-03 09.30.00.000000 AM
next_run_date: 06-JAN-03 09.30.00.000000 AM
next_run_date: 07-JAN-03 09.30.00.000000 AM
next_run_date: 08-JAN-03 09.30.00.000000 AM

PL/SQL procedure successfully completed.

Usage Notes

No specific Scheduler privileges are required.
**EVALUATE_RUNNING_CHAIN Procedure**

This procedure forces reevaluation of the rules of a running chain to trigger any rules for which the conditions have been satisfied. The job passed as an argument must point to a chain and must be running. If the job is not running, an error is thrown. (`RUN_JOB` can be used to start the job.)

If any of the steps of the chain are themselves running chains, another `EVALUATE_RUNNING_CHAIN` is performed on each of the nested running chains.

**Syntax**

```sql
DBMS_SCHEDULER.EVALUATE_RUNNING_CHAIN (  
    job_name      IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the running job (pointing to a chain) to reevaluate the rules for</td>
</tr>
</tbody>
</table>

**Usage Notes**

Running `EVALUATE_RUNNING_CHAIN` on a job requires alter privileges on the job (either as the owner, or as a user with `ALTER` privileges on the job or the `CREATE ANY JOB` system privilege).

---

**Note:** The Scheduler automatically evaluates a chain:

- At the start of the chain job
- When a chain step completes
- When an event occurs that is associated with an event step in the chain

For most chains, this is sufficient. `EVALUATE_RUNNING_CHAIN` should be used only under the following circumstances:

- After manual intervention of a running chain with the `ALTER_RUNNING_CHAIN` procedure
- When chain rules use SQL syntax and the rule conditions contain elements that are not under the control of the Scheduler.

In these cases, `EVALUATE_RUNNING_CHAIN` may not be needed if you set the `evaluation_interval` attribute when you created the chain.
GENERATE_JOB_NAME Function

This function returns a unique name for a job. The name will be of the form \( \text{prefix}N \) where \( N \) is a number from a sequence. If no prefix is specified, the generated name will, by default, be \texttt{JOB$_1$}, \texttt{JOB$_2$}, \texttt{JOB$_3$}, and so on. If 'SCOTT' is specified as the prefix, the name will be \texttt{SCOTT1}, \texttt{SCOTT2}, and so on.

**Syntax**

```sql
DBMS_SCHEDULER.GENERATE_JOB_NAME (prefix IN VARCHAR2 DEFAULT 'JOB$_') RETURN VARCHAR2;
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>prefix</td>
<td>The prefix to use when generating the job name</td>
</tr>
</tbody>
</table>

**Usage Notes**

If the prefix is explicitly set to \texttt{NULL}, the name is just the sequence number. In order to successfully use such numeric names, they must be surrounded by double quotes throughout the \texttt{DBMS_SCHEDULER} calls. A prefix cannot be longer than 18 characters and cannot end with a digit.

Note that, even though the \texttt{GENERATE_JOB_NAME} function never returns the same job name twice, there is a small chance that the returned name matches an already existing database object.

No specific Scheduler privileges are required to use this function.
GET_AGENT_INFO Function

This function can return job information specific to an agent, such as how many are running and so on, depending on the attribute selected.

Syntax

```
DBMS_SCHEDULER.GET_AGENT_INFO (
    agent_name        IN VARCHAR2,
    attribute         IN VARCHAR2) RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_name</td>
<td>The name of an external destination where the agent is running</td>
</tr>
<tr>
<td>attribute</td>
<td>Possible Attributes values</td>
</tr>
<tr>
<td></td>
<td>■ VERSION: Returns the agent version number. Requires the CREATE JOB system privilege.</td>
</tr>
<tr>
<td></td>
<td>■ UPTIME: Returns the time the agent has been up and running. Requires the CREATE JOB system privilege.</td>
</tr>
<tr>
<td></td>
<td>■ NUMBER_OF_RUNNING_JOBS: Returns the number of jobs that the agent is currently running. Requires the CREATE JOB system privilege.</td>
</tr>
<tr>
<td></td>
<td>■ TOTAL_JOBS_RUN: Returns the number of jobs run by the agent since it was started. Requires the CREATE JOB system privilege.</td>
</tr>
<tr>
<td></td>
<td>■ RUNNING_JOBS: Returns a comma-separated list of the names of the jobs running currently. Requires the MANAGE SCHEDULER system privilege.</td>
</tr>
<tr>
<td></td>
<td>■ ALL: Returns all the information the previous options return. It requires the MANAGE SCHEDULER system privilege.</td>
</tr>
</tbody>
</table>

Usage Notes

This function returns the same information as the schagent utility status option.
GET_AGENT_VERSION Function

This function returns the version string of a Scheduler agent that is registered with the database and is currently running. GET_AGENT_VERSION throws an error if the agent is not registered with the database or if the agent is not currently running.

Syntax

```sql
DBMS_SCHEDULER.GET_AGENT_VERSION (agent_host IN VARCHAR2) RETURN VARCHAR2;
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent_host</td>
<td>Either the hostname and port on which the agent is running in the form hostname:port or the name of the agent as shown in the destination_name column of the ALL_SCHEDULER_EXTERNAL_DESTS view which lists all Scheduler agents registered with the database.</td>
</tr>
</tbody>
</table>

Usage Notes

This function requires the CREATE EXTERNAL JOB system privilege.
GET_ATTRIBUTE Procedure

This procedure retrieves the value of an attribute of a Scheduler object. It is overloaded to retrieve values of various types.

Syntax

```
DBMS_SCHEDULER.GET_ATTRIBUTE (  
    name           IN VARCHAR2,  
    attribute      IN VARCHAR2,  
    value          OUT {VARCHAR2|PLS_INTEGER|BOOLEAN|DATE|TIMESTAMP|  
                    TIMESTAMP WITH TIME ZONE|TIMESTAMP WITH LOCAL TIME ZONE|  
                    INTERVAL DAY TO SECOND});
```

```
DBMS_SCHEDULER.GET_ATTRIBUTE (  
    name           IN VARCHAR2,  
    attribute      IN VARCHAR2,  
    value          OUT VARCHAR2,  
    value2         OUT VARCHAR2);  
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the object</td>
</tr>
<tr>
<td>attribute</td>
<td>The attribute being retrieved. See the SET_ATTRIBUTE Procedure on page 129-127 for tables of attribute values.</td>
</tr>
<tr>
<td>value</td>
<td>The existing value of the attribute</td>
</tr>
<tr>
<td>value2</td>
<td>The value2 argument is for an optional second value. Most attributes have only one value associated with them, but some can have two.</td>
</tr>
</tbody>
</table>

Usage Notes

To run GET_ATTRIBUTE for a job class, you must have the MANAGE SCHEDULER privilege or have EXECUTE privileges on the class. For a schedule, window, or group, no privileges are necessary. Otherwise, you must be the owner of the object or have ALTER or EXECUTE privileges on that object or have the CREATE ANY JOB privilege.

See the SET_ATTRIBUTE Procedure on page 129-127 for tables of attribute values that you can retrieve for the various Scheduler object types.
GET_FILE Procedure

This procedure retrieves a file from the operating system file system of a specified host. The file is copied to a destination, or its contents are returned in a procedure output parameter.

You can also use this procedure to retrieve the standard output or error text for a run of an external job that has an associated credential.

This procedures differs from the equivalent UTL_FILE procedure in that it uses a credential and can retrieve files from remote hosts that have only a Scheduler agent (and not an Oracle database) installed.

Syntax

```sql
DBMS_SCHEDULER.GET_FILE (  
    source_file                  IN VARCHAR2,  
    source_host                  IN VARCHAR2,  
    credential_name              IN VARCHAR2,  
    file_contents                IN OUT NOCOPY {BLOB|CLOB});

DBMS_SCHEDULER.GET_FILE (  
    source_file                  IN VARCHAR2,  
    source_host                  IN VARCHAR2,  
    credential_name              IN VARCHAR2,  
    destination_file_name        IN VARCHAR2,  
    destination_directory_object IN VARCHAR2,  
    destination_permissions      IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_file</td>
<td>Fully qualified path name of the file to retrieve from the operating system. The file name is case-sensitive and is not converted to uppercase. If the file name starts with a question mark (&quot;&quot;), the question mark is replaced by the path to the Oracle home if getting a file from the local host, or to the Scheduler agent home if getting a file from a remote host. If the format of this parameter is <code>external_log_id_stdout</code>, then the stdout from the designated external job run is returned. If the format of this parameter is <code>external_log_id_stderr</code>, the error text from the designated external job run is returned. You obtain the value of <code>external_log_id</code> from the ADDITIONAL_INFO column of the <code>*_SCHEDULER_JOB_RUN_DETAILS</code> views. This column contains a set of name/value pairs in an indeterminate order, so you must parse this column for the <code>external_log_id</code> name/value pair, and then append either &quot;_stdout&quot; or &quot;_stderr&quot; to its value. The external job must have an associated credential. The <code>credential_name</code> parameter of GET_FILE must name the same credential that is used by the job, and the <code>source_host</code> parameter must be the same as the <code>destination</code> attribute of the job.</td>
</tr>
</tbody>
</table>
### Table 129–65 (Cont.) GET_FILE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>source_host</td>
<td>If the file is to be retrieved from a remote host, then this parameter must be a valid an external destination name. (An external destination is created when you register a remote Scheduler agent with the database. You can view external destination names in the views <em>SCHEDULER_EXTERNAL_DESTS.</em>)&lt;br&gt;&lt;br&gt;    If source_host is NULL or set to 'localhost', then the file is retrieved from the file system of the local host. To determine the port number of a Scheduler agent, view the schagent.conf file, which is located in the Scheduler agent home directory on the remote host.</td>
</tr>
<tr>
<td>credential_name</td>
<td>The name of the credential to use for accessing the file system.</td>
</tr>
<tr>
<td>file_contents</td>
<td>The variable from which the file contents is read.</td>
</tr>
<tr>
<td>destination_file_name</td>
<td>The file to which the file contents is written.</td>
</tr>
<tr>
<td>destination_directory_object</td>
<td>The directory object that specifies the path to the destination file, when destination_file_name is used. The caller must have the necessary privileges on the directory object.</td>
</tr>
<tr>
<td>destination_permissions</td>
<td>Reserved for future use</td>
</tr>
</tbody>
</table>

### Usage Notes

The caller must have the CREATE EXTERNAL JOB system privilege and have EXECUTE privileges on the credential.
GET_SCHEDULER_ATTRIBUTE Procedure

This procedure retrieves the value of a Scheduler attribute.

Syntax

```sql
DBMS_SCHEDULER.GET_SCHEDULER_ATTRIBUTE (  
  attribute      IN VARCHAR2,  
  value          OUT VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>The name of the attribute</td>
</tr>
<tr>
<td>value</td>
<td>The existing value of the attribute</td>
</tr>
</tbody>
</table>

Usage Notes

To run GET_SCHEDULER_ATTRIBUTE, you must have the MANAGE SCHEDULER privilege.

Table 129–67 lists the Scheduler attributes that you can retrieve. For more detail on these attributes, see Table 129–97 on page 129-147 and the section "Configuring the Scheduler" in Oracle Database Administrator's Guide.

<table>
<thead>
<tr>
<th>Scheduler Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>current_open_window</td>
<td>Name of the currently open window</td>
</tr>
<tr>
<td>default_timezone</td>
<td>Default time zone used by the Scheduler for repeat intervals and windows</td>
</tr>
<tr>
<td>email_sender</td>
<td>The default e-mail address of the sender for job state e-mail notifications</td>
</tr>
<tr>
<td>email_server</td>
<td>The SMTP server address that the Scheduler uses to send e-mail notifications for job state events. E-mail notifications cannot be sent if this attribute is NULL.</td>
</tr>
<tr>
<td>event_expiry_time</td>
<td>Time in seconds before an event generated by the Scheduler and enqueued onto the Scheduler event queue expires. May be NULL.</td>
</tr>
<tr>
<td>log_history</td>
<td>Retention period in days for job and window logs. The range of valid values is 0 through 1000000.</td>
</tr>
<tr>
<td>max_job_slave_processes</td>
<td>This Scheduler attribute is not used.</td>
</tr>
</tbody>
</table>
OPEN_WINDOW Procedure

This procedure opens a window independent of its schedule. This window opens and the resource plan associated with it takes effect immediately for the duration specified or for the normal duration of the window if no duration is given. Only an enabled window can be manually opened.

Syntax

```
DBMS_SCHEDULER.OPEN_WINDOW (
    window_name             IN VARCHAR2,
    duration                IN INTERVAL DAY TO SECOND,
    force                   IN BOOLEAN DEFAULT FALSE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>window_name</td>
<td>The name of the window</td>
</tr>
<tr>
<td>duration</td>
<td>The duration of the window. It is of type interval day to second. If it is NULL, then the window opens for the regular duration as specified in the window metadata.</td>
</tr>
</tbody>
</table>
| force | If force is set to FALSE, then opening an already open window generates an error. If force is set to TRUE:

  - You can open a window that is already open. The window stays open for the duration specified in the call, from the time the OPEN_WINDOW command was issued.
  - For example: window1 was created with a duration of four hours. It has how been open for two hours. If, at this point, you reopen window1 using the OPEN_WINDOW call and do not specify a duration, then window1 stays open for four hours because it was created with that duration. If you specified a duration of 30 minutes, the window will close in 30 minutes.
  - The Scheduler automatically closes any window that is open at that time, even if it has a higher priority. For the duration of this manually opened window, the Scheduler does not open any other scheduled windows even if they have a higher priority. |

Usage Notes

Opening a window manually has no impact on regular scheduled runs of the window. The next open time of the window is not updated and is determined by the regular scheduled opening.

When a window that was manually opened closes, the rules about overlapping windows are applied to determine which other window should be opened at that time if any at all.

If there are jobs running when the window opens, the resources allocated to them might change if there is a switch in resource plan.

If a window fails to switch resource plans because the designated resource plan no longer exists or because resource plan switching by windows is disabled (for example, by using the ALTER SYSTEM statement with the force option), the failure to switch resource plans is recorded in the window log.
Opening a window requires the MANAGE SCHEDULER privilege.
PURGE_LOG Procedure

By default, the Scheduler automatically purges all rows in the job log and window log that are older than 30 days. The PURGE_LOG procedure is used to purge additional rows from the job and window log.

Rows in the job log table pertaining to the steps of a chain are purged only when the entry for the main chain job is purged (either manually or automatically).

Syntax

```sql
DBMS_SCHEDULER.PURGE_LOG(
    log_history             IN PLS_INTEGER  DEFAULT 0,
    which_log               IN VARCHAR2     DEFAULT 'JOB_AND_WINDOW_LOG',
    job_name                IN VARCHAR2     DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>log_history</td>
<td>This specifies how much history (in days) to keep. The valid range is 0 - 1000000. If set to 0, no history is kept.</td>
</tr>
<tr>
<td>which_log</td>
<td>This specifies the log type. Valid values are: job_log, window_log, and job_and_window_log.</td>
</tr>
<tr>
<td>job_name</td>
<td>This specifies which job-specific entries must be purged from the job log. This can be a comma-delimited list of job names and job classes. Whenever job_name has a value other than NULL, the which_log argument implicitly includes the job log.</td>
</tr>
</tbody>
</table>

Usage Notes

This procedure requires the MANAGE_SCHEDULER privilege.

Examples

The following completely purges all rows from both the job log and the window log:

```sql
DBMS_SCHEDULER.PURGE_LOG();
```

The following purges all rows from the window log that are older than 5 days:

```sql
DBMS_SCHEDULER.PURGE_LOG(5, 'window_log');
```

The following purges all rows from the window log that are older than 1 day and all rows from the job log that are related to jobs in jobclass1 and older than 1 day:

```sql
DBMS_SCHEDULER.PURGE_LOG(1, 'job_and_window_log', 'sys.jobclass1');
```
PUT_FILE Procedure

This procedure saves a file to the operating system file system of a specified remote host or of the local computer. It differs from the equivalent UTL_FILE procedure in that it uses a credential and can save files to a remote host that has only a Scheduler agent (and not an Oracle Database) installed.

Syntax

```sql
DBMS_SCHEDULER.PUT_FILE (.destination_file IN VARCHAR2, destination_host IN VARCHAR2, credential_name IN VARCHAR2, file_contents IN {BLOB|CLOB}, destination_permissions IN VARCHAR2 DEFAULT NULL);

DBMS_SCHEDULER.PUT_FILE (destination_file IN VARCHAR2, destination_host IN VARCHAR2, credential_name IN VARCHAR2, source_file_name IN VARCHAR2, source_directory_object IN VARCHAR2, destination_permissions IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination_file</td>
<td>Fully qualified path name of the file to save to the operating system file system. The file name is case-sensitive. If the file name starts with a question mark ('?'), the question mark is replaced by the path to the Oracle home if saving to the local host, or to the Scheduler agent home if saving to a remote host.</td>
</tr>
<tr>
<td>destination_host</td>
<td>If NULL or set to 'localhost', the file is saved to the file system of the local computer. To save to a remote host, this parameter must be a valid external destination name. (An external destination is created when you register a remote Scheduler agent with the database. You can view external destination names in the views <code>*_SCHEDULER_EXTERNAL_DESTS</code>.)</td>
</tr>
<tr>
<td>credential_name</td>
<td>The name of the credential to use for accessing the destination file system.</td>
</tr>
<tr>
<td>file_contents</td>
<td>The variable from which the file contents is read.</td>
</tr>
<tr>
<td>source_file_name</td>
<td>The file from which the file contents is written.</td>
</tr>
<tr>
<td>source_directory_object</td>
<td>The directory object that specifies the path to the source file, when source_file_name is used. The caller must have the necessary privileges on the directory object.</td>
</tr>
<tr>
<td>destination_permissions</td>
<td>Reserved for future use</td>
</tr>
</tbody>
</table>

Usage Notes

The caller must have the CREATE EXTERNAL JOB system privilege and have EXECUTE privileges on the credential.
REMOVED_EVENT_QUEUE_SUBSCRIBER Procedure

This procedure unsubscribes a user from the Scheduler event queue SYS.SCHEDULER$_EVENT_QUEUE.

Syntax

```sql
DBMS_SCHEDULER.REMOVE_EVENT_QUEUE_SUBSCRIBER ( subscriber_name IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>subscriber_name</td>
<td>Name of the Oracle Streams Advanced Queuing (AQ) agent to remove the subscription from. If NULL, the user name of the calling user is used.</td>
</tr>
</tbody>
</table>

Usage Notes

After the agent is unsubscribed, it is deleted. If the agent does not exist or is not currently subscribed to the Scheduler event queue, an error is raised.
REMOVE_GROUP_MEMBER Procedure

This procedure removes one or more members from an existing group.

Syntax

```sql
DBMS_SCHEDULER.REMOVE_GROUP_MEMBER (  
group_name              IN VARCHAR2,  
member                  IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name of the group.</td>
</tr>
<tr>
<td>member_name</td>
<td>The name of the member to remove from group. Comma-separated list of members to remove. An error is returned if any of the members is not part of the group. A group of the same type can be named as a member. The Scheduler immediately expands the included group name into its list of members. If the member is a destination, any job instances that run on this destination are removed from the *_SCHEDULER_JOB_DESTS views.</td>
</tr>
</tbody>
</table>

Usage Notes

The following users may remove members from a group:

- The group owner
- A user that has been granted the ALTER object privilege on the group
- A user with the CREATE ANY JOB system privilege

You must have the MANAGE SCHEDULER privilege to remove a member from a group of type WINDOW.

See Also: "CREATE_GROUP Procedure" on page 129-53
**REMOVE_JOB_EMAIL_NOTIFICATION Procedure**

This procedure removes e-mail notifications for a job. You can remove all e-mail notifications or remove notifications only for specified recipients or specified events.

**Syntax**

```
DBMS_SCHEDULER.REMOVE_JOB_EMAIL_NOTIFICATION (  
    job_name             IN VARCHAR2,  
    recipients           IN VARCHAR2 DEFAULT NULL,  
    events               IN VARCHAR2 DEFAULT NULL);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>Name of the job to remove e-mail notifications for. Cannot be NULL.</td>
</tr>
<tr>
<td>recipients</td>
<td>E-mail address to remove e-mail notification for. Comma-separated list of e-mail addresses.</td>
</tr>
<tr>
<td>events</td>
<td>Job state event to remove e-mail notification for. Comma-separated list of job state events.</td>
</tr>
</tbody>
</table>

**Usage Notes**

When you specify multiple recipients and multiple events, the notification for each specified event is removed for each specified recipient. The procedure ignores any recipients or events that are specified but that were not previously added.

If `recipients` is NULL, e-mail notifications for the specified events are removed for all existing recipients. If `events` is NULL, notifications for all events are removed for the specified recipients. If both `recipients` and `events` are NULL, all e-mail notifications are removed for the job.

For example, if `recipients` is `'jsmith@example.com,rjones@example.com'` and `events` is `'JOB_FAILED,JOB_BROKEN'`, then notifications for both the `JOB_FAILED` and `JOB_BROKEN` events are removed for both jsmith and rjones. If `recipients` is NULL, then notifications for both the `JOB_FAILED` and `JOB_BROKEN` events are removed for jsmith, rjones, and any other previously defined recipients for these events.

To call this procedure, you must be the job owner or a user with the `CREATE ANY JOB` system privilege or `ALTER` object privilege on the job.

**See Also:** "ADD_JOB_EMAIL_NOTIFICATION Procedure" on page 129-36
REMOVE_WINDOW_GROUP_MEMBER Procedure

*** Deprecated in Oracle Database 11g Release 2 (11.2). Use REMOVE_GROUP_MEMBER instead.

This procedure removes one or more windows from an existing window group.

Syntax

```sql
DBMS_SCHEDULER.REMOVE_WINDOW_GROUP_MEMBER (
  group_name              IN VARCHAR2,
  window_list             IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_name</td>
<td>The name of the window group.</td>
</tr>
<tr>
<td>window_list</td>
<td>The name of the window or windows.</td>
</tr>
</tbody>
</table>

Usage Notes

If any of the windows specified is invalid, does not exist, or is not a member of the given group, the call fails. Removing a window from a group requires the MANAGE SCHEDULER privilege.

Dropping an open window from a window group has no impact on any running jobs that has the window as its schedule because the jobs only stop when a window closes.
RESET_JOB_ARGUMENT_VALUE Procedure

This procedure resets (clears) the value previously set to an argument for a job. 
RESET_JOB_ARGUMENT_VALUE is overloaded.

Syntax

Clears a previously set job argument value by argument position:

```sql
DBMS_SCHEDULER.RESET_JOB_ARGUMENT_VALUE (
    job_name                IN VARCHAR2,
    argument_position       IN PLS_INTEGER);
```

Clears a previously set job argument value by argument name:

```sql
DBMS_SCHEDULER.RESET_JOB_ARGUMENT_VALUE (
    job_name                IN VARCHAR2,
    argument_name           IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the job being altered</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the program argument being reset</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name of the program argument being reset</td>
</tr>
</tbody>
</table>

Usage Notes

If the corresponding program argument has no default value, the job is disabled. Resetting a program argument of a job belonging to another user requires ALTER privileges on that job. Arguments can be specified by position or by name.

RESET_JOB_ARGUMENT_VALUE requires that you be the owner of the job or have ALTER privileges on that job. You can also reset a job argument value if you have the CREATE ANY JOB privilege.

RESET_JOB_ARGUMENT_VALUE only supports arguments of SQL type. Therefore, argument values that are not of SQL type, such as booleans, are not supported as program or job arguments.
RUN_CHAIN Procedure

This procedure immediately runs a chain or part of a chain by creating a run-once job with the job name given. If no job_name is given, one is generated of the form RUN_CHAIN$_chainnameN, where chainname is the first 8 characters of the chain name and N is an integer.

If a list of start steps is given, only those steps are started when the chain begins running. Steps not in the list that would normally have started are skipped and paused (so that they or the steps after them do not run). If start_steps is NULL, then the chain starts normally—that is, it performs an initial evaluation to see which steps to start running.

If a list of initial step states is given, the newly created chain job sets every listed step to the state specified for that step before evaluating the chain rules to see which steps to start. (Steps in the list are not started.)

Syntax

Runs a chain, with a list of start steps.

```sql
DBMS_SCHEDULER.RUN_CHAIN (  
  chain_name                IN VARCHAR2,  
  start_steps               IN VARCHAR2,  
  job_name                  IN VARCHAR2 DEFAULT NULL);
```

Runs a chain, with a list of initial step states.

```sql
DBMS_SCHEDULER.RUN_CHAIN (  
  chain_name               IN VARCHAR2,  
  step_state_list          IN SYS.SCHEDULER$_STEP_TYPE_LIST,  
  job_name                 IN VARCHAR2 DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chain_name</td>
<td>The name of the chain to run</td>
</tr>
<tr>
<td>job_name</td>
<td>The name of the job to create to run the chain</td>
</tr>
<tr>
<td>start_steps</td>
<td>Comma-separated list of the steps to start when the chain starts running</td>
</tr>
</tbody>
</table>
| step_state_list| List of chain steps with an initial state (SUCCEEDED or FAILED) to set for each. Set the attributes of sys.scheduler$$_step_type as follows:  
  - step_name: The name of the step  
  - step_type: ‘SUCCEEDED’ or ‘FAILED’ error_number’  
    where error_number is a positive or negative integer. |

Usage Notes

Running a chain requires CREATE JOB if the job is being created in the user's schema, or CREATE ANY JOB otherwise. In addition, the owner of the job being created needs execute privileges on the chain (as the owner of the chain, or as a user with the EXECUTE privilege on the chain or the EXECUTE ANY PROGRAM system privilege).
Examples

The following example illustrates how to start a chain in the middle by providing the initial state of some chain steps.

```sql
declare
    initial_step_states sys.scheduler$_.step_type_list;
begin
    initial_step_states := sys.scheduler$_.step_type_list(
        sys.scheduler$_.step_type('step1', 'SUCCEEDED'),
        sys.scheduler$_.step_type('step2', 'FAILED 27486'),
        sys.scheduler$_.step_type('step3', 'SUCCEEDED'),
        sys.scheduler$_.step_type('step5', 'SUCCEEDED'));
    dbms_scheduler.run_chain('my_chain', initial_step_states);
end;
/
```
RUN_JOB Procedure

This procedure runs a job immediately.

If a job is enabled, the Scheduler runs it automatically. It is not necessary to call RUN_JOB to run a job according to its schedule. Use RUN_JOB to run a job outside of its normal schedule.

Syntax

```sql
DBMS_SCHEDULER.RUN_JOB (  
    job_name                IN VARCHAR2,  
    use_current_session     IN BOOLEAN DEFAULT TRUE);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>A job name or a comma-separate list of entries, where each is the name of an existing job, optionally preceded by a schema name and dot separator.</td>
</tr>
<tr>
<td></td>
<td>If you specify a multiple-destination job, the job runs on all destinations. In this case, the use_current_session argument must be FALSE.</td>
</tr>
<tr>
<td>use_current_session</td>
<td>This specifies whether or not the job run should occur in the same session that the procedure was invoked from.</td>
</tr>
<tr>
<td></td>
<td>When use_current_session is set to TRUE:</td>
</tr>
<tr>
<td></td>
<td>- The job runs as the user who called RUN_JOB, or in the case of a local external job with a credential, the user named in the credential.</td>
</tr>
<tr>
<td></td>
<td>- You can test a job and see any possible errors on the command line.</td>
</tr>
<tr>
<td></td>
<td>- run_count, last_start_date, last_run_duration, and failure_count are not updated.</td>
</tr>
<tr>
<td></td>
<td>- RUN_JOB can be run in parallel with a regularly scheduled job run.</td>
</tr>
<tr>
<td></td>
<td>When use_current_session is set to FALSE:</td>
</tr>
<tr>
<td></td>
<td>- The job runs as the user who is the job owner.</td>
</tr>
<tr>
<td></td>
<td>- You need to check the job log to find error information.</td>
</tr>
<tr>
<td></td>
<td>- run_count, last_start_date, last_run_duration, and failure_count are updated.</td>
</tr>
<tr>
<td></td>
<td>- RUN_JOB fails if a regularly scheduled job is running.</td>
</tr>
</tbody>
</table>

Usage Notes

The job does not have to be enabled. If the job is disabled, the following validity checks are performed before running it:

- The job points to a valid job class.
- The job owner has EXECUTE privileges on the job class.
- If a program or chain is referenced, the program/chain exists.
- If a program or chain is referenced, the job owner has privileges to execute the program/chain.
- All argument values have been set (or have defaults).
- The job owner has the CREATE EXTERNAL JOB privilege if this is an external job.

A TRUE value for use_current_session is not permitted for the following types of jobs:
- Jobs that specify a destination or destination group in the destination_name attribute
- Jobs that point to chains (chain jobs)
- Jobs that make use of detached programs (detached jobs).

When use_current_session is TRUE, the call to RUN_JOB blocks until the job completes. Any errors that occur during the execution of the job are returned as errors to the RUN_JOB procedure. When use_current_session is FALSE, RUN_JOB returns immediately and the job is picked up by the job coordinator and passed on to a job slave for execution. The Scheduler views and logs must be queried for the outcome of the job.

Multiple user sessions can use RUN_JOB in their sessions simultaneously when use_current_session is set to TRUE.

RUN_JOB requires that you own the job or have ALTER privileges on that job. You can also run a job if you have the CREATE ANY JOB privilege.

**Example**

The following is an example of using RUN_JOB.

```sql
BEGIN
    DBMS_SCHEDULER.RUN_JOB(
        JOB_NAME => 'EODJOB, DSS.ETLJOB',
        USE_CURRENT_SESSION => FALSE);
END;
```
SET_AGENT_REGISTRATION_PASS Procedure

This procedure sets the agent registration password for a database. A Scheduler agent must register with the database before the database can submit jobs to the agent. The agent must provide this password when registering.

Syntax

```sql
DBMS_SCHEDULER.SET_AGENT_REGISTRATION_PASS (  
  registration_password   IN VARCHAR2,  
  expiration_date         IN TIMESTAMP WITH TIME ZONE DEFAULT NULL,  
  max_uses                IN NUMBER DEFAULT NULL);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>registration_password</td>
<td>This is the password that remote agents must specify in order to successfully register with the database. If this is NULL, then no agents will be able to register with the database.</td>
</tr>
<tr>
<td>expiration_date</td>
<td>If this is set to a non-NULL value, then the registration_password is not valid after this date. After this date, no agents can register with the database. This cannot be set to a date in the past.</td>
</tr>
<tr>
<td>max_uses</td>
<td>This is the maximum number of successful registrations that can be performed with this password. After the number of successful registrations has been performed with this password, then no agents can register with the database. This cannot be set to 0 or a negative value. If this is set to NULL, then there will be no limit on the number of successful registrations.</td>
</tr>
</tbody>
</table>

Usage Notes

To prevent abuse, this password can be set to expire after a given date or a maximum number of successful registrations. This procedure will overwrite any password already set. This requires the MANAGE SCHEDULER system privilege.

By default, max_uses is set to NULL, which means that there is no limit to the number of successful registrations.

Oracle recommends that an agent registration password be reset after every agent registration or every known set of agent registrations. Furthermore, Oracle recommends that this password be set to NULL if no new agents are being registered.
SET_ATTRIBUTE Procedure

This procedure modifies an attribute of a Scheduler object. It is overloaded to accept values of various types. To set an attribute to NULL, use the SET_ATTRIBUTE_NULL procedure. The attributes that can be set depend on the object being altered. All object attributes can be changed, except the object name.

Syntax

DBMS_SCHEDULER.SET_ATTRIBUTE (  
  name           IN VARCHAR2,  
  attribute      IN VARCHAR2,  
  value          IN {BOOLEAN|DATE|TIMESTAMP|TIMESTAMP WITH TIME ZONE|TIMESTAMP WITH LOCAL TIME ZONE|INTERVAL DAY TO SECOND});

DBMS_SCHEDULER.SET_ATTRIBUTE (  
  name           IN VARCHAR2,  
  attribute      IN VARCHAR2,  
  value          IN VARCHAR2,  
  value2         IN VARCHAR2 DEFAULT NULL);

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the object</td>
</tr>
<tr>
<td>attribute</td>
<td>See Table 129–81 through Table 129–91.</td>
</tr>
<tr>
<td>value</td>
<td>The new value being set for the attribute. This cannot be NULL. To set an attribute value to NULL, use the SET_ATTRIBUTE_NULL procedure.</td>
</tr>
<tr>
<td>value2</td>
<td>The value2 argument is for an optional second value. Most attributes have only one value associated with them, but some can have two.</td>
</tr>
</tbody>
</table>

Table 129–79 is a directory of Scheduler object types and tables of attributes for the object types.

These object types can be viewed with Scheduler Data Dictionary Views, listed in Oracle Database Administrator’s Guide.

</tr>
<tr>
<td>Database Destination</td>
<td>Table 129–89 on page 129-139</td>
</tr>
</tbody>
</table>
Usage Notes

If an object is altered and it was in the enabled state, the Scheduler first disables it, then makes the change and reenables it. If any errors are encountered during the enable process, the object is not reenabled and an error is generated.

If an object is altered and it was in the disabled state, it remains disabled after it is altered.

To run SET_ATTRIBUTE for a window, a group of type WINDOW, or job class, you must have the MANAGE SCHEDULER privilege. Otherwise, you must be the owner of the object being altered or have ALTER privileges on that object or have the CREATE ANY JOB privilege.

Job

If there is a running instance of the job when the SET_ATTRIBUTE call is made, it is not affected by the call. The change is only affects future runs of the job.

If any of the schedule attributes of a job are altered while the job is running, the time of the next job run is scheduled using the new schedule attributes. Schedule attributes of a job include schedule_name, start_date, end_date, and repeat_interval.

If any of the program attributes of a job are altered while the job is running, the new program attributes take effect the next time the job runs. Program attributes of a job include program_name, job_action, job_type, and number_of_arguments.

If any job argument values are altered while the job is running, the new values take effect the next time the job runs.

Granting the ALTER privilege on a job lets a user alter all attributes of that job except its program attributes (program_name, job_type, job_action, program_action, and number_of_arguments) and does not allow a user to use a PL/SQL expression to specify the schedule for a job.

Oracle recommends that you not alter a job that was automatically created for you by the database. Jobs that were created by the database have the column SYSTEM set to TRUE in job views.

Program

If any currently running jobs use the program that was altered, they continue to run with the program definition prior to the alter. The job runs with the new program definition the next time the job executes.

Schedule

If a schedule is altered, the change does not affect running jobs and open windows that use this schedule. The change only goes into effect the next time the jobs runs or the window opens.
File Watcher
If a file watcher is altered, any currently running event-based jobs started by the file arrival event are not affected. On the local system, the new file watcher attributes take effect the next time that the file watcher checks for the arrival of the file (every ten minutes by default). On remote systems, there may be an additional delay before the new file watcher attributes take effect.

Job Class
With the exception of the default job class, all job classes can be altered. To alter a job class, you must have the MANAGE_SCHEDULER privilege.

When a job class is altered, running jobs that belong to the class are not affected. The change only takes effect for jobs that have not started running yet.

Window
When a window is altered, it does not affect an active window. The changes only take effect the next time the window opens.

If there is no current resource plan, when a window with a designated resource plan opens, the Resource Manager activates with that plan.

Job Attribute Values
Table 129–81 lists attribute values for jobs.

Note: See the CREATE_JOB procedure and the CREATE_JOBS procedure for more complete descriptions of the attributes in this table.

Table 129–81 Job Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allow_runs_in_restricted_mode</td>
<td>If TRUE, the job is permitted to run when the database is in restricted mode, provided that the job owner is permitted to log in during this mode. FALSE by default.</td>
</tr>
<tr>
<td>auto_drop</td>
<td>This attribute, if TRUE, causes a job to be automatically dropped after it completes or is automatically disabled. A job is considered completed if:</td>
</tr>
<tr>
<td></td>
<td>• Its end date (or the end date of the schedule) has passed.</td>
</tr>
<tr>
<td></td>
<td>• It has run max_runs number of times. max_runs must be set with SET_ATTRIBUTE.</td>
</tr>
<tr>
<td></td>
<td>• It is not a repeating job and has run once.</td>
</tr>
<tr>
<td></td>
<td>A job is automatically disabled when it has failed max_failures times. max_failures is also set with SET_ATTRIBUTE.</td>
</tr>
<tr>
<td></td>
<td>If this attribute is set to FALSE, the jobs are not dropped and their metadata is kept until the job is explicitly dropped with the DROP_JOB procedure.</td>
</tr>
<tr>
<td></td>
<td>By default, jobs are created with auto_drop set to TRUE.</td>
</tr>
<tr>
<td>comments</td>
<td>An optional comment.</td>
</tr>
<tr>
<td>credential_name</td>
<td>This attribute specifies the name of the Scheduler credential object (credential) to use for a remote database job, a remote external job, a local external job, or an event-based job that processes a file arrival event. For local external jobs only, if this attribute is NULL (the default), then a preferred (default) credential is selected. See Oracle Database Administrator’s Guide for information about preferred credentials for local external jobs.</td>
</tr>
</tbody>
</table>
|                           | See also: “CREATE_CREDENTIAL Procedure” on page 129-47
This attribute applies when the database participates in an Oracle Data Guard environment. If this attribute is set to 'PRIMARY', the job runs only when the database is in the role of the primary database. If set to 'LOGICAL STANDBY', the job runs only when the database is in the role of a logical standby. The default is 'PRIMARY' when the database is the primary database, and 'LOGICAL STANDBY' when the database is a logical standby.

Note: If you want a job to run for all database roles on a particular host, you must create two copies of the job on that host: one with a database_role of 'PRIMARY', and the other with a database_role of 'LOGICAL STANDBY'.

### destination

*** Deprecated in Oracle Database 11g Release 2 (11.2). Use destination_name instead.***

This attribute specifies a host on which to run a remote external job. It must be set to the host name or IP address of the destination host. It can optionally be followed by a port number, in the following format:

```
hostname:port
```

This attribute is set to NULL by default.

### destination_name

The database destination or external destination for the job. Use for remote database jobs and remote external jobs only. For jobs running on the local database or for local external jobs (executables), must be NULL. See Table 129–27 on page 129-57 for details about this attribute.

### end_date

Specifies the date and time after which the job expires and is no longer run. After the end_date, if auto_drop is TRUE, the job is dropped. If auto_drop is FALSE, the job is disabled and the STATE of the job is set to COMPLETED.

If no value for end_date is specified, the job repeats forever unless max_runs or max_failures is set, in which case the job stops when either value is reached.

The value for end_date must be after the value for start_date. If it is not, an error is generated when the job is enabled.

### event_spec

This attribute takes two values: the value argument specifies the event condition and the value2 argument specifies the queue specification. For more details, see the descriptions for the event_condition and queue_spec arguments in the "CREATE_JOB Procedure" on page 129-55.

### follow_default_timezone

If TRUE and if the job start_date is null, then when the default_timezone scheduler attribute is changed, the Scheduler recomputes the next run date and time for this job so that it is in accordance with the new time zone.

For example, if the job was set to run at 02:00 in the previous time zone, it will run at 02:00 in the new time zone.

If the job start_date is not null, then the time zone for the run date and time for the job is always specified by the time zone of the start_date.

If FALSE, the next start date and time for the job is not recomputed when the default_timezone scheduler attribute is changed. In this case, if the old time zone is three hours earlier than the new time zone, then a job scheduled to run at 02:00 in the old time zone runs at 05:00 in the new time zone.

Summer and winter transitions do not change the default time zone name.

### instance_id

Valid only in an Oracle Real Application Clusters environment. Indicates the instance on which the job is to be run.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>database_role</td>
<td>This attribute applies when the database participates in an Oracle Data Guard environment. If this attribute is set to 'PRIMARY', the job runs only when the database is in the role of the primary database. If set to 'LOGICAL STANDBY', the job runs only when the database is in the role of a logical standby. The default is 'PRIMARY' when the database is the primary database, and 'LOGICAL STANDBY' when the database is a logical standby. Note: If you want a job to run for all database roles on a particular host, you must create two copies of the job on that host: one with a database_role of 'PRIMARY', and the other with a database_role of 'LOGICAL STANDBY'.</td>
</tr>
<tr>
<td>destination</td>
<td>*** Deprecated in Oracle Database 11g Release 2 (11.2). Use destination_name instead. This attribute specifies a host on which to run a remote external job. It must be set to the host name or IP address of the destination host. It can optionally be followed by a port number, in the following format: hostname:port This attribute is set to NULL by default.</td>
</tr>
<tr>
<td>destination_name</td>
<td>The database destination or external destination for the job. Use for remote database jobs and remote external jobs only. For jobs running on the local database or for local external jobs (executables), must be NULL. See Table 129–27 on page 129-57 for details about this attribute.</td>
</tr>
<tr>
<td>end_date</td>
<td>Specifies the date and time after which the job expires and is no longer run. After the end_date, if auto_drop is TRUE, the job is dropped. If auto_drop is FALSE, the job is disabled and the STATE of the job is set to COMPLETED. If no value for end_date is specified, the job repeats forever unless max_runs or max_failures is set, in which case the job stops when either value is reached. The value for end_date must be after the value for start_date. If it is not, an error is generated when the job is enabled.</td>
</tr>
<tr>
<td>event_spec</td>
<td>This attribute takes two values: the value argument specifies the event condition and the value2 argument specifies the queue specification. For more details, see the descriptions for the event_condition and queue_spec arguments in the &quot;CREATE_JOB Procedure&quot; on page 129-55.</td>
</tr>
<tr>
<td>follow_default_timezone</td>
<td>If TRUE and if the job start_date is null, then when the default_timezone scheduler attribute is changed, the Scheduler recomputes the next run date and time for this job so that it is in accordance with the new time zone. If the job start_date is not null, then the time zone for the run date and time for the job is always specified by the time zone of the start_date. If FALSE, the next start date and time for the job is not recomputed when the default_timezone scheduler attribute is changed. In this case, if the old time zone is three hours earlier than the new time zone, then a job scheduled to run at 02:00 in the old time zone runs at 05:00 in the new time zone. Summer and winter transitions do not change the default time zone name.</td>
</tr>
<tr>
<td>instance_id</td>
<td>Valid only in an Oracle Real Application Clusters environment. Indicates the instance on which the job is to be run.</td>
</tr>
</tbody>
</table>
instance_stickiness

This attribute should only be used for a database running in an Oracle Real Application Clusters (Oracle RAC) environment. By default, it is set to TRUE. If you set instance_stickiness to TRUE, jobs start running on the instance with the lightest load and the Scheduler thereafter attempts to run on the instance that it last ran on. If that instance is either down or so overloaded that it does not start new jobs for a significant period of time, another instance runs the job. If the interval between runs is large, instance_stickiness is ignored and the job is handled as if it were a non-sticky job.

If instance_stickiness is set to FALSE, each instance of the job runs on the first instance available.

For environments other than Oracle RAC, this attribute is not useful because there is only one instance.

job_action

The action that the job performs, depending on the job_type attribute. For example, if job_type is 'STORED_PROCEDURE', job_action contains the name of the stored procedure.

job_class

The class this job is associated with.

job_priority

This attribute specifies the priority of this job relative to other jobs in the same class as this job. If multiple jobs within a class are scheduled to be executed at the same time, the job priority determines the order in which jobs from that class are picked up for execution by the job coordinator. It can be a value from 1 through 5, with 1 being the first to be picked up for job execution.

If no job priority is specified when creating a job, the default priority of 3 is assigned to it.

job_type

The type of this job. Valid values are: 'PLSQL_BLOCK', 'STORED_PROCEDURE', 'EXECUTABLE', and 'CHAIN'.

If this is set, program_name must be NULL.

job_weight

*** Deprecated in Oracle Database 11g Release 2 (11.2). Do not change the value of this attribute from the default, which is 1.

Weight of the job for parallel execution.

logging_level

This attribute specifies how much information is logged. The possible options are:

DBMS_SCHEDULER.LOGGING_OFF

(The default) No logging is performed for this job. However, the logging level of the job class takes precedence and job logging may occur.

DBMS_SCHEDULER.LOGGING_FAILED_RUNS

The Scheduler logs only jobs that failed, with the reason for failure. If the job class has a higher logging level, then the higher logging level takes precedence.

DBMS_SCHEDULER.LOGGING_RUNS

The Scheduler writes detailed information to the job log for all runs of each job in this class. If the job class has a higher logging level, then the higher logging level takes precedence.

DBMS_SCHEDULER.LOGGING_FULL

In addition to recording every run of a job, the Scheduler records all operations performed on the job, including create, enable, disable, alter (with SET_ATTRIBUTE), stop, and so on.
max_failures

This attribute specifies the number of times a job can fail on consecutive scheduled runs before it is automatically disabled. Once a job is disabled, it is no longer executed and its STATE is set to BROKEN in the *_SCHEDULER_JOB views.

max_failures can be an integer between 1 to 1,000,000. By default, it is set to NULL, which indicates that new instances of the job are started regardless of how many previous instances have failed.

max_run_duration

This attribute specifies the maximum amount of time that the job should be allowed to run. Its data type is INTERVAL DAY TO SECOND. If this attribute is set to a non-zero and non-NULL value, and job duration exceeds this value, the Scheduler raises an event of type JOB_OVER_MAX_DUR. It is then up to your event handler to decide whether or not to allow the job to continue.

max_runs

This attribute specifies the maximum number of consecutive scheduled runs of the job. Once max_runs is reached, the job is disabled and its state is changed to COMPLETED.

max_runs can be an integer between 1 and 1,000,000. By default, it is set to NULL, which means that it repeats forever or until end_date or max_failures is reached.

number_of_arguments

The number of arguments if the program is inlined. If this is set, program_name should be NULL.

parallel_instances

This is a boolean attribute that can be set only for event-based jobs.

If FALSE (the default), then if an event is raised and the event-based job that processes that event is already running, the new event is ignored.

If TRUE, then an instance of the job is started for every instance of the event, and each job instance is a lightweight job so multiple instances of the same event-based job can run in parallel. Each lightweight job takes its attributes (such as action, maximum run duration, and so on) from the definition of the event-based job (its parent job). After the lightweight job completes, it is dropped. There is no explicit limit to the number of lightweight jobs that can run simultaneously to process multiple instances of the event. However, limitations may be imposed by available system resources.

The lightweight jobs are not visible in any of the *_SCHEDULER_JOBS views. However, they are visible in the *_SCHEDULER_RUNNING_JOBS views. The name of each lightweight job is the same as that of the parent job, and a subname is automatically generated to distinguish each lightweight job from its parent and from its siblings.

program_name

The name of a program object to use with this job. If this is set, job_action, job_type and number_of_arguments should be NULL.

---

</table>
Summary of DBMS_SCHEDULER Subprograms

**raise_events**

This attribute tells the Scheduler at what stages of the job execution to raise events. It is a bit vector in which zero or more of the following bits can be set. Each bit has a package constant corresponding to it.

- `job_started` CONSTANT PLS_INTEGER := 1
- `job_succeeded` CONSTANT PLS_INTEGER := 2
- `job_failed` CONSTANT PLS_INTEGER := 4
- `job_broken` CONSTANT PLS_INTEGER := 8
- `job_completed` CONSTANT PLS_INTEGER := 16
- `job_stopped` CONSTANT PLS_INTEGER := 32
- `job_sch_lim_reached` CONSTANT PLS_INTEGER := 64
- `job_disabled` CONSTANT PLS_INTEGER := 128
- `job_chain_stalled` CONSTANT PLS_INTEGER := 256
- `job_all_events` CONSTANT PLS_INTEGER := 511
- `job_run_completed` CONSTANT PLS_INTEGER := `job_succeeded` + `job_failed` + `job_stopped`

Table 129–82 describes these event types in detail.

**repeat_interval**

Either a PL/SQL function returning the next date and time on which to run, or calendaring syntax expression. If this is set, schedule_name should be NULL. See "Calendaring Syntax" on page 129-20 for more information.

**restartable**

This attribute specifies whether or not a job can be restarted in case of failure. By default, jobs are not restartable and this attribute is set to FALSE. Setting this to TRUE means that if a job fails while running, it is restarted from the beginning point of the job.

In the case of a chain job, if this attribute is TRUE, the chain is restarted from the beginning after an application failure. If this attribute is FALSE, or if there has been a database failure, the chain is restarted at the last running step. The restart_on_recovery attribute of that step then determines if the step is restarted or marked as stopped. (If marked as stopped, the chain evaluates rules and continues.)

Note that setting this attribute to TRUE might lead to data inconsistencies in some situations, for example, if data is committed within a job.

Retries on errors are not counted as regular runs. The run count or failure count is not incremented until the job succeeds or has failed all its six retries.

The restartable attribute is used by the Scheduler to determine whether to retry the job not only on regular application errors, but after a database malfunction as well. The Scheduler retries the job a maximum of six times. The first time, it waits for one second and multiplies this wait time with a factor of 10 each time thereafter.

Both the run count and failure count are incremented by 1 if the job has failed all its six retries. If the job immediately succeeds, or it succeeds on one of its retries, run count is incremented by 1.

The Scheduler stops retrying a job when:

- One of the retries succeeds.
- All of its six retries have failed.
- The next retry would occur after the next regularly scheduled run of the job.

The Scheduler no longer retries the job if the next scheduled retry is past the next regularly scheduled run for repeating jobs.
The following event types are valid values for the raise_events attribute in Table 129–81, “Job Attribute Values”.

### Table 129–82  Event Types Raised by the Scheduler

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_all_events</td>
<td>Not an event, but a constant that provides an easy way for you to enable all events</td>
</tr>
<tr>
<td>job_broken</td>
<td>The job has been disabled and has changed to the BROKEN state because it exceeded the number of failures defined by the max_failures job attribute</td>
</tr>
<tr>
<td>job_chain_stalled</td>
<td>A job running a chain is in the CHAIN_STALLED state. A running chain becomes stalled if there are no steps running or scheduled to run and the chain evaluation_interval is set to NULL. No progress is made in the chain unless there is manual intervention.</td>
</tr>
<tr>
<td>job_completed</td>
<td>The job completed because it reached its max_runs or end_date</td>
</tr>
<tr>
<td>job_disabled</td>
<td>The job was disabled by the Scheduler or by a call to SET_ATTRIBUTE</td>
</tr>
<tr>
<td>job_failed</td>
<td>The job failed, either due to an error or an abnormal termination.</td>
</tr>
<tr>
<td>job_over_max_dur</td>
<td>The job exceeded the maximum run duration specified by its max_run_duration attribute. (Note: you do not need to enable this event with the raise_events job attribute; it is always enabled.)</td>
</tr>
<tr>
<td>job_run_completed</td>
<td>A job run either failed, succeeded, or was stopped</td>
</tr>
</tbody>
</table>
Table 129–82  (Cont.) Event Types Raised by the Scheduler

<table>
<thead>
<tr>
<th>Event Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_sch_lim_reached</td>
<td>The schedule limit of the job was reached. The job was not started because</td>
</tr>
<tr>
<td></td>
<td>the delay in starting the job exceeded the value of the schedule_limit job</td>
</tr>
<tr>
<td></td>
<td>attribute.</td>
</tr>
<tr>
<td>job_started</td>
<td>The job started.</td>
</tr>
<tr>
<td>job_stopped</td>
<td>The job was stopped by a call to STOP_JOB</td>
</tr>
<tr>
<td>job_succeeded</td>
<td>The job completed successfully</td>
</tr>
</tbody>
</table>

Program Attribute Values

Table 129–83 lists program attribute values.

Note: See the CREATE_PROGRAM procedure for more complete descriptions of the attributes in this table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>An optional comment. This can describe what the program does or give usage</td>
</tr>
<tr>
<td></td>
<td>details.</td>
</tr>
<tr>
<td>detached</td>
<td>If TRUE, the program is a detached program. See Oracle Database Administrator's Guide for information about detached jobs and detached programs.</td>
</tr>
<tr>
<td>number_of_arguments</td>
<td>The number of arguments required by the stored procedure or other executable that the program invokes</td>
</tr>
<tr>
<td>program_action</td>
<td>The action that the program performs, indicated by the program_type attribute. For example, if program_type is 'STORED_PROCEDURE', program_action contains the name of the stored procedure.</td>
</tr>
<tr>
<td>program_type</td>
<td>The type of program. This must be one of these supported program types: 'PLSQL_BLOCK', 'STORED_PROCEDURE', and 'EXECUTABLE'.</td>
</tr>
</tbody>
</table>

Schedule Attribute Values

Table 129–84 lists schedule attribute values.

Note: See the CREATE_SCHEDULE and CREATECALENDAR_SCHEDULE procedures for more complete descriptions of the attributes in this table.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>An optional comment.</td>
</tr>
<tr>
<td>end_date</td>
<td>The cutoff date and time after which the schedule does not specify any dates.</td>
</tr>
<tr>
<td>event_spec</td>
<td>This attribute takes two values: the value argument should contain the event condition and the value2 argument should contain the queue specification. For more details, see the descriptions for the event_condition and queue_spec arguments to the &quot;CREATE JOB Procedure&quot; on page 129-55.</td>
</tr>
</tbody>
</table>
File Watcher Attribute Values

Table 129–85 lists file watcher attribute values.

Table 129–85  File Watcher Attribute Values

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination</td>
<td>Remote host name or IP address where the file is expected to arrive. If NULL, destination is the local host.</td>
</tr>
<tr>
<td>directory_path</td>
<td>Directory in which the file is expected to arrive. The single wildcard '?' at the beginning of the path denotes the Oracle home path. For example, '?/rdbms/log' denotes the rdbms/log subdirectory of the Oracle home directory.</td>
</tr>
<tr>
<td>file_name</td>
<td>Name of the file being looked for. Two wildcards are permitted anywhere in the file name: '?' denotes any single character, and '?' denotes zero or more characters. This attribute cannot be NULL.</td>
</tr>
<tr>
<td>credential_name</td>
<td>Name of a valid Scheduler credential object. The file watcher uses the credential to authenticate itself with the host operating system to access the watched-for file. The file watcher owner must have the EXECUTE privilege on the credential. Cannot be NULL.</td>
</tr>
<tr>
<td>min_file_size</td>
<td>Minimum file size in bytes before the file watcher considers the file found. Default is 0.</td>
</tr>
<tr>
<td>steady_state_duration</td>
<td>Minimum time interval that the file must remain unchanged before the file watcher considers the file found. If NULL, an internal value is used.</td>
</tr>
<tr>
<td>comments</td>
<td>Optional comment.</td>
</tr>
</tbody>
</table>

Job Class Attribute Values

Table 129–86 lists job class attribute values.

Note: See the CREATE_JOB_CLASS procedure for more complete descriptions of the attributes in this table.

Table 129–86  Job Class Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>An optional comment about the class.</td>
</tr>
<tr>
<td>log_history</td>
<td>This attribute controls the number of days that job log entries for jobs in this class are retained. It helps prevent the job log from growing indiscriminately.</td>
</tr>
</tbody>
</table>

The range of valid values is 0 through 1000000. If set to 0, no history is kept. If NULL, retention days are set by the log_history Scheduler attribute (set with SET_SCHEDULER_ATTRIBUTE).
**Window Attribute Values**

Table 129–87 lists window attribute values.

**Note:** See the `CREATE_WINDOW` procedure for more complete descriptions of the attributes in this table.

### Table 129–87 Window Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>comments</td>
<td>An optional comment about the window.</td>
</tr>
<tr>
<td>duration</td>
<td>The duration of the window.</td>
</tr>
<tr>
<td>end_date</td>
<td>The date after which the window no longer opens. If this is set, <code>schedule_name</code> must be NULL.</td>
</tr>
<tr>
<td>repeat_interval</td>
<td>An attribute specifying how often the schedule should repeat, using the calendaring syntax. PL/SQL date functions are not allowed. If this is set, <code>schedule_name</code> must be NULL. See “Calendaring Syntax” on page 129-20 for more information.</td>
</tr>
<tr>
<td>resource_plan</td>
<td>The resource plan to be associated with a window. When the window opens, the system switches to this resource plan. When the window closes, the original resource plan is restored. If a resource plan has been made active with the <code>force</code> option, no resource plan switch occurs. Only one resource plan can be associated with a window. It may be NULL or the empty string (&quot;&quot;). When it is NULL, the resource plan that is in effect when the window opens stays in effect for the duration of the window. When it is the empty string, the resource manager is disabled for the duration of the window.</td>
</tr>
</tbody>
</table>
Table 129–88 (Cont.) Window Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>schedule_name</td>
<td>The name of a schedule to use with this window. If this is set, start_date,</td>
</tr>
<tr>
<td></td>
<td>end_date, and repeat_interval must all be NULL.</td>
</tr>
<tr>
<td>start_date</td>
<td>The next date and time on which this window is scheduled to open.</td>
</tr>
<tr>
<td></td>
<td>If this is set, schedule_name must be NULL.</td>
</tr>
<tr>
<td>window_priority</td>
<td>The priority of the window. Must be either 'LOW' (default) or 'HIGH'.</td>
</tr>
</tbody>
</table>

Chain Attribute Values

Table 129–88 lists chain attribute values.

Note: See the CREATE_CHAIN procedure for more complete descriptions of the attributes in this table.

Table 129–88 Chain Attribute Values

<table>

</table>

Database Destination Attribute Values

Table 129–89 lists database destination attribute values.

Note: See the CREATE_DATABASE_DESTINATION procedure for more complete descriptions of the attributes in this table.
### Table 129–89  Database Destination Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>agent</td>
<td>The name of the external destination (also known as agent destination) that is used to connect to the remote database. You can obtain valid external destination names from the view ALL_SCHEDULER_EXTERNAL_DESTS.</td>
</tr>
<tr>
<td>connect_info</td>
<td>The TNS connect descriptor that identifies the remote database to connect to, or the net service name (alias) in tnsnames.ora that resolves to the connect descriptor. Note: This corresponds to the tns_name argument of CREATE_DATABASE_DESTINATION.</td>
</tr>
<tr>
<td>enabled</td>
<td>If TRUE, the database destination is enabled.</td>
</tr>
<tr>
<td>comments</td>
<td>An optional comment about the database destination.</td>
</tr>
</tbody>
</table>

### External Destination Attribute Values

Table 129–90 lists external destination attribute values.

**Note:** External destinations are created only implicitly by registering a remote Scheduler agent with the local database.

### Table 129–90  External Destination Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hostname</td>
<td>(GET_ATTRIBUTE only) The fully qualified host name (including domain) or IP address of the computer on which the Scheduler agent resides.</td>
</tr>
<tr>
<td>port</td>
<td>(GET_ATTRIBUTE only) The TCP port number on which the agent listens.</td>
</tr>
<tr>
<td>ip_address</td>
<td>(GET_ATTRIBUTE only) The IP address of the host on which the agent resides.</td>
</tr>
<tr>
<td>enabled</td>
<td>If TRUE, the external destination is enabled.</td>
</tr>
<tr>
<td>comments</td>
<td>An optional comment about the external destination.</td>
</tr>
</tbody>
</table>

### Group Attribute Values

Table 129–91 lists group attribute values.

**Note:** See the CREATE_GROUP procedure for more complete descriptions of the attributes in this table.

### Table 129–91  Group Attribute Values

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>group_type</td>
<td>(GET_ATTRIBUTE only) The group type (either WINDOW, DB_DEST, or EXTERNAL_DEST).</td>
</tr>
<tr>
<td>member_name</td>
<td>Comma-separated list of members. Replaces the existing list of members. To add one or more members to the existing list, use ADD_GROUP_MEMBER. Note: this attribute corresponds to the member argument of CREATE_GROUP.</td>
</tr>
<tr>
<td>enabled</td>
<td>If TRUE, the group is enabled.</td>
</tr>
</tbody>
</table>
Credential Attribute Values

Table 129–92 lists credential attribute values.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>username</td>
<td>The user name for logging into the host operating system or remote Oracle database. Maximum length is 64.</td>
</tr>
<tr>
<td>password</td>
<td>The password for the user name. Maximum length is 128.</td>
</tr>
<tr>
<td>comments</td>
<td>A description of the credential. Maximum length is 240.</td>
</tr>
<tr>
<td>windows_domain</td>
<td>For a Windows remote executable target, this is the domain that the specified user belongs to. Maximum length is 64.</td>
</tr>
<tr>
<td>database_role</td>
<td>The value of the database_role attribute is used as the system privilege for logging into a remote database to run a remote database job.</td>
</tr>
<tr>
<td></td>
<td>Valid values are: SYSDBA and SYSOPER.</td>
</tr>
</tbody>
</table>
**SET_ATTRIBUTE_NULL Procedure**

This procedure sets an attribute of an object to **NULL**. The attributes that can be set depend on the object being altered. If the object is enabled, it is disabled before being altered and reenabled afterward. If the object cannot be reenabled, an error is generated and the object is left in a disabled state.

**Syntax**

```sql
DBMS_SCHEDULER.SET_ATTRIBUTE_NULL (
    name              IN VARCHAR2,
    attribute         IN VARCHAR2);
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the object</td>
</tr>
<tr>
<td>attribute</td>
<td>The attribute being changed</td>
</tr>
</tbody>
</table>

**Usage Notes**

To run **SET_ATTRIBUTE_NULL** for a window, group of type **WINDOW**, or job class, you must have the **MANAGE SCHEDULER** privilege. Otherwise, you must be the owner of the object being altered or have **ALTER** privileges on that object or have the **CREATE ANY JOB** privilege.
SET_JOB_ANYDATA_VALUE Procedure

This procedure sets the value for an argument of the associated program for a job, encapsulated in an AnyData object. It overrides any default value set for the program argument. NULL is a valid assignment for a program argument. The argument can be specified by position or by name. You can specify by name only when:

- The job points to a saved program object
- The argument was assigned a name with the DEFINE_ANYDATA_ARGUMENT Procedure

Scheduler does no type checking of the argument at any time.

SET_JOB_ANYDATA_VALUE is overloaded.

Syntax

Sets a program argument by its position.

```
DBMS_SCHEDULER.SET_JOB_ANYDATA_VALUE (
    job_name                IN VARCHAR2,
    argument_position       IN PLS_INTEGER,
    argument_value          IN SYS.ANYDATA);
```

Sets a program argument by its name.

```
DBMS_SCHEDULER.SET_JOB_ANYDATA_VALUE (
    job_name                IN VARCHAR2,
    argument_name           IN VARCHAR2,
    argument_value          IN SYS.ANYDATA);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the job to be altered</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name of the program argument being set</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the program argument being set</td>
</tr>
<tr>
<td>argument_value</td>
<td>The new value to be assigned to the program argument, encapsulated in an AnyData object</td>
</tr>
</tbody>
</table>

Usage Notes

SET_JOB_ANYDATA_VALUE requires that you own the job or have ALTER privileges on that job. You can also set a job argument value if you have the CREATE ANY JOB privilege.

SET_JOB_ANYDATA_VALUE does not apply to lightweight jobs because lightweight jobs cannot take AnyData arguments.

See Also:

- "SET_JOB_ARGUMENT_VALUE Procedure" on page 129-143
- "DEFINE_ANYDATA_ARGUMENT Procedure" on page 129-72
SET_JOB_ARGUMENT_VALUE Procedure

This procedure sets the value of an argument in a program associated with a job. It overrides any default value set for the program argument. NULL is a valid assignment for a program argument. The argument can be specified by position or by name. You can specify by name only when:

- The job points to a saved program object
- The argument was assigned a name with the DEFINE_PROGRAM_ARGUMENT Procedure or the DEFINE_METADATA_ARGUMENT Procedure

Scheduler does no type checking of the argument at any time.

SET_JOB_ARGUMENT_VALUE is overloaded.

Syntax

Sets an argument value by position:

```sql
DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE (  
    job_name                IN VARCHAR2,  
    argument_position       IN PLS_INTEGER,  
    argument_value          IN VARCHAR2);
```

Sets an argument value by name:

```sql
DBMS_SCHEDULER.SET_JOB_ARGUMENT_VALUE (  
    job_name                IN VARCHAR2,  
    argument_name           IN VARCHAR2,  
    argument_value          IN VARCHAR2);
```

Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>job_name</td>
<td>The name of the job to be altered</td>
</tr>
<tr>
<td>argument_name</td>
<td>The name of the program argument being set</td>
</tr>
<tr>
<td>argument_position</td>
<td>The position of the program argument being set</td>
</tr>
<tr>
<td>argument_value</td>
<td>The new value to be set for the program argument. To set a non-VARCHAR value, use the SET_JOB_ANYDATA_VALUE procedure.</td>
</tr>
</tbody>
</table>

Usage Notes

SET_JOB_ARGUMENT_VALUE requires that you be the owner of the job or have ALTER privileges on that job. You can also set a job argument value if you have the CREATE ANY JOB privilege.

SET_JOB_ARGUMENT_VALUE only supports arguments of SQL type. Therefore, argument values that are not of SQL type, such as booleans, are not supported as program or job arguments.

SET_JOB_ARGUMENT_VALUE can be used to set arguments of lightweight jobs but only if the argument is of type VARCHAR2.

- "SETJOB_ANYDATA_VALUE Procedure" on page 129-142
- "DEFINE_PROGRAM_ARGUMENT Procedure" on page 129-80
### SET_JOB_ATTRIBUTES Procedure

This procedure changes an attribute of a job.

#### Syntax

```sql
DBMS_SCHEDULER.SET_JOB_ATTRIBUTES (
  jobattr_array     IN JOBATTR_ARRAY,
  commit_semantics  IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

#### Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jobattr_array</td>
<td>The array of job attribute changes.</td>
</tr>
<tr>
<td>commit_semantics</td>
<td>The commit semantics. The following types are supported:</td>
</tr>
<tr>
<td></td>
<td>■ STOP_ON_FIRST_ERROR returns on the first error and commits</td>
</tr>
<tr>
<td></td>
<td>previous successful attribute changes to disk. This is the</td>
</tr>
<tr>
<td></td>
<td>default.</td>
</tr>
<tr>
<td></td>
<td>■ TRANSACTIONAL returns on the first error and rolls back</td>
</tr>
<tr>
<td></td>
<td>everything that happened before that error.</td>
</tr>
<tr>
<td></td>
<td>■ ABSORB_ERRORS tries to absorb any errors and complete the</td>
</tr>
<tr>
<td></td>
<td>rest of the job attribute changes on the list. It commits</td>
</tr>
<tr>
<td></td>
<td>all the successful changes. If errors occur, you can</td>
</tr>
<tr>
<td></td>
<td>query the view SCHEDULER_BATCH_ERRORS for details.</td>
</tr>
</tbody>
</table>

#### Usage Notes

Calling `SET_ATTRIBUTE` on an enabled job disables the job, changes the attribute value, and reenables the job. `SET_JOB_ATTRIBUTES` changes the attribute values in the context of a single transaction.
SET_SCHEDULER_ATTRIBUTE Procedure

This procedure sets the value of a Scheduler attribute. This takes effect immediately but the resulting changes may not be seen immediately.

Table 129–97 provides short attribute descriptions for the SET_SCHEDULER_ATTRIBUTE procedure. For complete descriptions, see section "Setting Scheduler Preferences" in Oracle Database Administrator’s Guide.

Syntax

```
DBMS_SCHEDULER.SET_SCHEDULER_ATTRIBUTE (
    attribute   IN VARCHAR2,
    value       IN VARCHAR2);
```
Parameters

Table 129–97  SET_SCHEDULER_ATTRIBUTE Procedure Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>attribute</td>
<td>The name of the Scheduler attribute. Possible values are:</td>
</tr>
<tr>
<td></td>
<td>■ 'default_timezone': Repeating jobs and windows that use the calendaring syntax retrieve the time zone from this attribute when start_date is not specified. See &quot;Calendaring Syntax&quot; on page 129-20 for more information.</td>
</tr>
<tr>
<td></td>
<td>■ 'email_server': The SMTP server address that the Scheduler uses to send e-mail notifications for job state events. E-mail notifications cannot be sent if this attribute is NULL.</td>
</tr>
<tr>
<td></td>
<td>■ 'email_sender': The default e-mail address of the sender of job state e-mail notifications.</td>
</tr>
<tr>
<td></td>
<td>■ 'email_server_credential': The schema and name of an existing credential object that SYS has execute object privileges on. Default is NULL. The username and password stored in this credential are used to authenticate with the e-mail server when sending e-mail notifications. This functionality is available with Oracle Database 11g Release 2 (11.2.0.2).</td>
</tr>
<tr>
<td></td>
<td>■ 'email_server_encryption': This attribute indicates whether or not encryption is enabled for this email server connection, and if so, at what point encryption starts, and with which protocol. Values are:</td>
</tr>
<tr>
<td></td>
<td>– NONE: the default, indicating no encryption used</td>
</tr>
<tr>
<td></td>
<td>– SSL_TLS: indicating that either SSL or TLS are used, from the beginning of the connection</td>
</tr>
<tr>
<td></td>
<td>– STARTTLS: indicating that the connection starts unencrypted, but the command STARTTLS is sent to the e-mail server and starts encryption</td>
</tr>
<tr>
<td></td>
<td>This functionality is available starting with Oracle Database 11g Release 2 (11.2.0.2).</td>
</tr>
<tr>
<td></td>
<td>■ 'event_expiry_time': The time, in seconds, before a job state event generated by the Scheduler expires from the Scheduler event queue. If NULL, job state events expire after 24 hours.</td>
</tr>
<tr>
<td></td>
<td>■ 'log_history': The number of days that log entries for both the job log and the window log are retained. Default is 30 and the range of valid values is 0 through 100000.</td>
</tr>
<tr>
<td></td>
<td>■ 'max_job_slave_processes': This Scheduler attribute is not used.</td>
</tr>
<tr>
<td>value</td>
<td>The new value of the attribute</td>
</tr>
</tbody>
</table>

Usage Notes

To run SET_SCHEDULER_ATTRIBUTE, you must have the MANAGE SCHEDULER privilege.

See Also:  Oracle Database Administrator’s Guide for more detailed descriptions of Scheduler attributes
**STOP_JOB Procedure**

This procedure stops currently running jobs or all jobs in a job class. After stopping the job, the state of a one-time job is set to STOPPED, whereas the state of a repeating job is set to SCHEDULED or COMPLETED, depending on whether the next run of the job is scheduled.

If a job pointing to a chain is stopped, all running steps of the running chain are stopped.

If a job has multiple destinations, the database attempts to stop the job at all destinations.

For external jobs, **STOP_JOB** stops only the external process that was directly started by the job action. It does not stop child processes of external jobs.

**Syntax**

```sql
DBMS_SCHEDULER.STOP_JOB (
    job_name         IN VARCHAR2
  , force            IN BOOLEAN DEFAULT FALSE
  , commit_semantics IN VARCHAR2 DEFAULT 'STOP_ON_FIRST_ERROR');
```

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>job_name</strong></td>
<td>Name of a job to stop. Can be a comma-separate list of jobs, where each entry can be one of the following:</td>
</tr>
<tr>
<td></td>
<td>- Job name: the name of an existing job, optionally preceded by a schema name and dot separator.</td>
</tr>
<tr>
<td></td>
<td>- Job destination ID: a number, obtained from the JOB_DEST_ID column of the *_SCHEDULER_JOB_DESTS views, that represents the unique combination of a job, a credential, and a destination.</td>
</tr>
<tr>
<td></td>
<td>- Job class: the name of a job class. Must be preceded by the SYS schema name and a dot separator.</td>
</tr>
<tr>
<td></td>
<td>If you specify a job class, all jobs that belong to that job class are stopped. If you specify a job that was created with a destination group as its destination_name attribute, all job instances on all destinations are stopped.</td>
</tr>
<tr>
<td><strong>force</strong></td>
<td>If force is set to FALSE, the Scheduler tries to gracefully stop the job using an interrupt mechanism. This method gives control back to the slave process, which can update the status of the job in the job queue to stopped. If this fails, an error is returned.</td>
</tr>
<tr>
<td></td>
<td>If force is set to TRUE, the Scheduler immediately terminates the job slave. Oracle recommends that <strong>STOP_JOB</strong> with force set to TRUE be used only after a <strong>STOP_JOB</strong> with force set to FALSE has failed.</td>
</tr>
<tr>
<td></td>
<td>Use of the force option requires the MANAGE SCHEDULER system privilege.</td>
</tr>
</tbody>
</table>
STOP_JOB without the force option requires that you be the owner of the job or have ALTER privileges on that job. You can also stop a job if you have the CREATE ANY JOB or MANAGE SCHEDULER privilege.

STOP_JOB with the force option requires that you have the MANAGE SCHEDULER privilege.

Example

The following is an example of using STOP_JOB.

```
BEGIN
    DBMS_SCHEDULER.STOP_JOB('DSS.ETLJOB, 984, 1223, SYS.ETL_JOBCLASS');
END;
```
The `DBMS_SERVER_ALERT` package enables you to configure the Oracle Database server to issue an alert when a threshold for a specified server metric has been violated. You can configure both warning and critical thresholds for a large number of predefined metrics.

If a warning threshold is reached, the server generates a severity level 5 alert. If a critical threshold is reached, the server generates a severity level 1 alert.

The chapter contains the following topics:

- **Using DBMS_SERVER_ALERT**
  - Security Model
  - Object Types
  - Relational Operators
  - Supported Metrics
- **Summary of DBMS_SERVER_ALERT Subprograms**
Using DBMS_SERVER_ALERT

This section contains topics which relate to using the DBMS_SERVER_ALERT package. The following topics define constants used in package procedures.

- Security Model
- Object Types
- Relational Operators
- Supported Metrics
Security Model

The user needs DBA or IMP_FULL_DATABASE roles to use the DBMS_SERVER_ALERT package.
Object Types

You qualify the metric by an individual object for the following object types.

<table>
<thead>
<tr>
<th>Table 130–1 Object Types Defined as Constants</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Constant</strong></td>
</tr>
<tr>
<td>OBJEKT_TYPE_SYSTEM</td>
</tr>
<tr>
<td>OBJEKT_TYPE_FILE</td>
</tr>
<tr>
<td>OBJEKT_TYPE_SERVICE</td>
</tr>
<tr>
<td>OBJEKT_TYPE_TABLESPACE</td>
</tr>
<tr>
<td>OBJEKT_TYPE_EVENT_CLASS</td>
</tr>
<tr>
<td>OBJEKT_TYPE_SESSION</td>
</tr>
<tr>
<td>OBJEKT_TYPE_WRCLIENT</td>
</tr>
</tbody>
</table>
Relational Operators

You can specify a relational comparison operator to determine whether or not a given metric's value violates the threshold setting. The server supports the following operators.

Table 130–2  Relational Operators Defined as Constants

<table>
<thead>
<tr>
<th>Constant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OPERATOR_CONTAINS</td>
<td>A metric value matching an entry in a list of threshold values is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_DO_NOT_CHECK</td>
<td>The metric value is not compared to the threshold value, and no alerts are generated. Use this operator to disable alerts for a metric.</td>
</tr>
<tr>
<td>OPERATOR_EQ</td>
<td>A metric value equal to the threshold value is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_GE</td>
<td>A metric value greater than or equal to the threshold value is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_GT</td>
<td>A metric value greater than the threshold value is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_LE</td>
<td>A metric value less than or equal to the threshold value is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_LT</td>
<td>A metric value less than the threshold value is considered a violation.</td>
</tr>
<tr>
<td>OPERATOR_NE</td>
<td>A metric value not equal to the threshold value is considered a violation.</td>
</tr>
</tbody>
</table>
# Supported Metrics

The following metrics are supported. All internal metric names are supplied as package constants.

## Table 130–3  List of Supported Metrics

<table>
<thead>
<tr>
<th>Metric Name (Internal)</th>
<th>Metric Name (External)</th>
<th>Units</th>
</tr>
</thead>
<tbody>
<tr>
<td>AVG_FILE_READ_TIME</td>
<td>Average File Read Time</td>
<td>Microseconds</td>
</tr>
<tr>
<td>AVG_FILE_WRITE_TIME</td>
<td>Average File Write Time</td>
<td>Microseconds</td>
</tr>
<tr>
<td>AVG_USERS_WAITING</td>
<td>Average Number of Users Waiting on a Class of Wait Events</td>
<td>Count of sessions</td>
</tr>
<tr>
<td>BLOCKED_USERS</td>
<td>Number of Users blocked by some Session</td>
<td>Number of Users</td>
