This preface describes the document accessibility features and conventions used in this
guide—Programming JSP Tag Extensions for Oracle WebLogic Server

Documentation Accessibility

Our goal is to make Oracle products, services, and supporting documentation accessible to all users, including users that are disabled. To that end, our documentation includes features that make information available to users of assistive technology. This documentation is available in HTML format, and contains markup to facilitate access by the disabled community. Accessibility standards will continue to evolve over time, and Oracle is actively engaged with other market-leading technology vendors to address technical obstacles so that our documentation can be accessible to all of our customers. For more information, visit the Oracle Accessibility Program Web site at http://www.oracle.com/accessibility/.

Accessibility of Code Examples in Documentation

Screen readers may not always correctly read the code examples in this document. The conventions for writing code require that closing braces should appear on an otherwise empty line; however, some screen readers may not always read a line of text that consists solely of a bracket or brace.

Accessibility of Links to External Web Sites in Documentation

This documentation may contain links to Web sites of other companies or organizations that Oracle does not own or control. Oracle neither evaluates nor makes any representations regarding the accessibility of these Web sites.

Deaf/Hard of Hearing Access to Oracle Support Services

To reach Oracle Support Services, use a telecommunications relay service (TRS) to call Oracle Support at 1.800.223.1711. An Oracle Support Services engineer will handle technical issues and provide customer support according to the Oracle service request process. Information about TRS is available at http://www.fcc.gov/cgb/consumerfacts/trs.html, and a list of phone numbers is available at http://www.fcc.gov/cgb/dro/trsphonebk.html.

Conventions

The following text conventions are used in this document:
<table>
<thead>
<tr>
<th>Convention</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface</strong></td>
<td>Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.</td>
</tr>
<tr>
<td><em>italic</em></td>
<td>Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.</td>
</tr>
<tr>
<td><strong>monospace</strong></td>
<td>Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.</td>
</tr>
</tbody>
</table>
This section describes the contents and organization of this guide—*Programming WebLogic JSP Tag Extensions*:

- Section 1.1, "Document Scope and Audience"
- Section 1.2, "Guide to this Document"
- Section 1.3, "Related Documentation"
- Section 1.4, "New and Changed JSP Features In This Release"

**1.1 Document Scope and Audience**

The JSP 2.1 specification enables you to create and use custom tags in Java Server Pages (JSPs). Custom tags are an excellent way to abstract the complexity of business logic from the presentation of Web pages in a way that is easy for the Web author to use and control. You can use custom JSP tag extensions in JSP pages to generate dynamic content, and you can use a variety of Web development tools to create the presentation.

This document is a resource for software developers who want to create and use custom tags in JavaServer Pages (JSPs). It is also a resource for Web authors who want to use custom tags in JSPs.

This document does not address production phase administration, monitoring, or performance tuning topics. For links to WebLogic Server documentation and resources for these topics, see Section 1.3, "Related Documentation."

It is assumed that the reader is familiar with Java EE platform and JSP concepts.

**1.2 Guide to this Document**

- This chapter, Chapter 1, "Introduction and Roadmap," introduces the organization of this guide.

- Chapter 2, "Understanding and Creating Custom JSP Tags," provides an overview of custom JSP tag functionality, format, and components, as well as procedures for creating and configuring a tag library.

- Chapter 3, "Creating a Tag Library Descriptor," describes how to create a tag library descriptor (TLD) file.
Chapter 4, "Implementing the Tag Handler," describes how to write Java classes that implement the functionality of an extended tag.

Chapter 5, "Administration and Configuration," provides an overview of administration and configuration tasks for using JSP tag extensions.

1.3 Related Documentation

This document contains JSP extension-specific design and development information. For comprehensive guidelines for developing, deploying, and monitoring WebLogic Server applications, see the following documents:

- Oracle Fusion Middleware Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server is a guide to developing WebLogic Server applications.
- Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server is a guide to developing WebLogic Server applications.
- Oracle Fusion Middleware Deploying Applications to Oracle WebLogic Server is the primary source of information about deploying WebLogic Server applications.
- JavaServer Pages (JSP) product overview from Sun Microsystems at http://www.java.sun.com/products/jsp

1.4 New and Changed JSP Features In This Release

For a comprehensive listing of the new WebLogic Server features introduced in this release, see Oracle Fusion Middleware What’s New in Oracle WebLogic Server.
The following sections provide an overview of custom JSP tag functionality, format, and components, as well as procedures for creating and configuring a tag library:

- Section 2.1, "Tag Handler API and Implementation"
- Section 2.2, "Custom Tag Library"
- Section 2.3, "Custom Tag Format"
- Section 2.4, "What Can You Do with Custom Tags?"
- Section 2.5, "Creating and Configuring a JSP Tag Library: Example Procedures"

### 2.1 Tag Handler API and Implementation

You write a custom JSP tag by writing a Java class called a tag handler.

The JSP 2.1 API defines a set of classes and interfaces that you use to write custom tag handlers, as described in the JSP 2.1 Specification at http://java.sun.com/products/jsp/reference/api/index.html.

Your tag handler must be one of the following two types:

- **Classic Tag Handlers** (SimpleTag interface):
  - Tag—Implement the javax.servlet.jsp.tagext.Tag interface if you are creating a custom tag that does not need access to its interface. The API also provides a convenience class TagSupport that implements the Tag interface and provides default empty methods for the methods defined in the interface.
  - BodyTag—Implement the javax.servlet.jsp.tagext.BodyTag interface if your custom tag needs to use a body. The API also provides a convenience class BodyTagSupport that implements the BodyTag interface and provides default empty methods for the methods defined in the interface. Because BodyTag extends Tag it is a super set of the interface methods.
  - IterationTag—Implement the javax.servlet.jsp.tagext.IterationTag interface to extend Tag by defining an additional method doAfterBody() that controls the reevaluation of the body.

- **Simple Tag Handlers** (SimpleTag interface):
Implement the `javax.servlet.jsp.tagext.SimpleTag` interface if you wish to use a much simpler invocation protocol. The `SimpleTag` interface does not extend the `javax.servlet.jsp.tagext.Tag` interface as does the `BodyTag` interface. Therefore, instead of supporting the `doStartTag()` and `doEndTag()` methods, the `SimpleTag` interface provides a simple `doTag()` method, which is called once and only once for each tag invocation.

You write the tag handler class by doing one of the following:

- Implement one of three interfaces, `SimpleTag`, `Tag`, or `BodyTag`, which define methods that are invoked during the life cycle of the tag.
- Extend an abstract base class that implements the `SimpleTag`, `Tag`, or `BodyTag` interfaces.

Extending an abstract base class relieves the tag handler class from having to implement all methods in the interfaces and also provides other convenient functionality. The `SimpleTagSupport`, `TagSupport`, and `BodyTagSupport` classes implement the `SimpleTag`, `Tag` or `BodyTag` interfaces and are included in the API.

You can include one or more custom JSP tags in a tag library. You define a tag library by a tag library descriptor (.tld) file. The TLD describes the syntax for each tag and ties it to the Java classes that execute its functionality.

### 2.2 Custom Tag Library

JSP tag libraries include one or more custom JSP tags and are defined in a tag library descriptor (.tld) file. To use a custom tag library from a JSP page, reference its tag library descriptor with a `<%@ taglib %>` directive. For example:

```jsp
<%@ taglib uri="myTLD" prefix="mytaglib" %>
```

- **uri**
  
The JSP engine attempts to find the tag library descriptor by matching the `uri` attribute to a `uri` that is defined in the Web Application deployment descriptor (`web.xml`) with the `<taglib-uri>` element.

---

**Note:** You do not need to mention the `<taglib>` tag in the `web.xml` if the value of `uri` in `<%@ taglib uri='myTLD' prefix='mytaglib' %>` is the same as the `uri` specified in the .tld file, provided the .tld file is in the default location (`/WEB-INF/` or `/WEB-INF/tags/`). For more information, see the JSP 2.1 specification.

For example, `myTLD` in the above the `taglib` directive would reference its tag library descriptor (`library.tld`) in the Web Application deployment descriptor like this:

```xml
<taglib>
  <taglib-uri>myTLD</taglib-uri>
  <taglib-location>library.tld</taglib-location>
</taglib>
```

- **prefix**
  
The `prefix` attribute assigns a label to the tag library. You use this label to reference its associated tag library when writing your pages using custom JSP tags.
For example, if the library (called mytaglib) from the example above defines a new tag called newtag, you would use the tag in your JSP page like this:

```html
<mytaglib:newtag>
</mytaglib:newtag>
```

For more information, see Chapter 3, "Creating a Tag Library Descriptor."

### 2.3 Custom Tag Format

A custom tag format can be empty, called an empty tag, or can contain a body, called a body tag. Both types of tags can accept a number of attributes that are passed to the Java class that implements the tag. For more details, see Section 4.6, "Handling Exceptions within a Tag Body."

An empty tag takes the following form:

```html
<mytaglib:newtag attr1="aaa" attr2="bbb" ... />
```

A body tag takes the following form:

```html
<mytaglib:newtag attr1="aaa" attr2="bbb" ... >
  body
</mytaglib:newtag>
```

A tag body can include more JSP syntax, and even other custom JSP tags that also have nested bodies. Tags can be nested within each other to any level. For example:

```html
<mytaglib:tagA>
  <h2>This is the body of tagA</h2>
  You have seen this text <mytaglib:counter /> times!
  <p>
  <mytaglib:repeater repeat=4>
    <p>Hello World!</p>
  </mytaglib:repeater>
</mytaglib:tagA>
```

The preceding example uses three custom tags to illustrate the ability to nest tags within a body tag. The tags function like this:

- The body tag `<mytaglib:tagA>` only sees the HTML output from its evaluated body. That is, the nested JSP tags `<mytaglib:counter>` and `<mytaglib:repeater>` are first evaluated and their output becomes part of the evaluated body of the `<mytaglib:tagA>` tag.

- The body of a body tag is first evaluated as JSP and all tags that it contains are translated, including nested body tags, whose bodies are recursively evaluated. The result of an evaluated body can then be used directly as the output of a body tag, or the body tag can determine its output based on the content of the evaluated body.

- The output generated from the JSP of a body tag is treated as plain HTML. That is, the output is not further interpreted as JSP.

### 2.4 What Can You Do with Custom Tags?

Custom tags can perform the following tasks:

- Produce output. The output of the tag is sent to the surrounding scope. The scope can be one of the following:
Creating and Configuring a JSP Tag Library: Example Procedures

- If the tag is included directly in the JSP page, then the surrounding scope is the JSP page output.
- If the tag is nested within another parent tag, then the output becomes part of the evaluated body of its parent tag.

- Define new objects that can be referenced and used as scripting variables in the JSP page. A tag can introduce fixed-named scripting variables, or can define a dynamically named scripting variable with the `id` attribute.

- Iterate over body content of the tags until a certain condition is met. Use iteration to create repetitive output, or to repeatedly invoke a server side action.

- Determine whether the rest of the JSP page should be processed as part of the request, or skipped.

- An empty tag can perform server-side work based on the tag's attributes. The action that the tag performs can determine whether the rest of the page is interpreted or some other action is taken, such as a redirect. This function is useful for checking that users are logged in before accessing a page, and redirecting them to a login page if necessary.

- An empty tag can insert content into a page based on its attributes. You can use such a tag to implement a simple page-hits counter or another template-based insertion.

- An empty tag can define a server-side object that is available in the rest of the page, based on its attributes. You can use this tag to create a reference to an EJB, which is queried for data elsewhere in the JSP page.

- A body tag has the option to process its output before the output becomes part of the HTML page sent to the browser, evaluate that output, and then determine the resulting HTML that is sent to the browser. This functionality could be used to produce 'quoted HTML," reformatted content, or used as a parameter that you pass to another function, such as an SQL query, where the output of the tag is a formatted result set.

- A body tag can repeatedly process its body until a particular condition is met.

2.5 Creating and Configuring a JSP Tag Library: Example Procedures

Perform the following steps to create and use custom JSP tags:

1. Write a tag handler class. When you use a custom tag in your JSP, this class executes the functionality of the tag. A tag handler class implements one of three interfaces:

   `javax.servlet.jsp.tagext.BodyTag`
   `javax.servlet.jsp.tagext.Tag`
   `javax.servlet.jsp.tagext.SimpleTag`

   Your tag handler class is implemented as part of a `tag library`. For more information, see Chapter 4, "Implementing the Tag Handler."

2. Reference the tag library in your JSP source using the JSP `<taglib>` directive. A tag library is a collection of JSP tags. Include this directive at the top of your JSP source. For more information, see Section 5.1, "Configuring JSP Tag Libraries."

3. Write the tag library descriptor (TLD). The TLD defines the tag library and provides additional information about each tag, such as the name of the tag handler class, attributes, and other information about the tags. For more information, see Chapter 3, "Creating a Tag Library Descriptor."
4. Reference the TLD in the Web application deployment descriptor (web.xml).

5. Use your custom tag in your JSP. For more information, see Section 5.1, "Configuring JSP Tag Libraries."
The following sections describe how to create a tag library descriptor (TLD):

- Section 3.1, "Overview of Tag Library Descriptors"
- Section 3.2, "Writing the Tag Library Descriptor"
- Section 3.3, "Sample Tag Library Descriptor"
- Section 3.4, "The DynamicAttributes Interface"
- Section 3.5, "Tag Handler Support of Dynamic Attributes"

### 3.1 Overview of Tag Library Descriptors

A tag library allows a developer to group together tags with related functionality. A tag library uses a tag library descriptor (TLD) file that describes the tag extensions and relates them to their Java classes. WebLogic Server and some authoring tools use the TLD to get information about the extensions. TLD files have the file extension .tld and are written in XML notation.

### 3.2 Writing the Tag Library Descriptor

Order the elements in the tag library descriptor file as they are defined in the XSD. This ordering is used in the following procedure. The XML parser throws an exception if you incorrectly order the TLD elements.

The body of the TLD contains additional nested elements inside of the `<taglib>` ... `</taglib>` element. These nested elements are also described in the steps below. For display in this document, nested elements are indented from their parent elements, but indenting is not required in the TLD.

The example in Section 3.3, "Sample Tag Library Descriptor" declares a new tag called code. The functionality of this tag is implemented by the Java class `weblogic.taglib.quote.CodeTag`.

To create a TLD:

1. Create a text file with an appropriate name and the extension .tld, and save it in the WEB-INF directory of the Web application containing your JSP(s). Content beneath the WEB-INF directory is non-public and is not served over HTTP by WebLogic Server.

2. Include the following header:

```xml
<taglib version="2.0" xmlns="http://java.sun.com/xml/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-jsptaglibrary_2_0.xsd">
```
3. Add the contents of the TLD, embedded in a `<taglib>` element, as indicated in steps 4-7. The contents include elements containing information about the tag library and elements that define each tag. For example:

```xml
<taglib>
  ... body of taglib descriptor ...
</taglib>
```

4. Identify the tag library:

```xml
<lib-version>version_number</lib-version>
```
(Required) The version number of the tag library.

```xml
<jsp-version>version_number</jsp-version>
```
(Required) Describes the JSP specification version (number) this tag library requires in order to function. The default is 2.0.

```xml
<short-name>TagLibraryName</short-name>
```
(Required) Assigns a short name to this tag library. This element is not used by WebLogic Server.

```xml
<uri>unique_string</uri>
```
(Required) Defines a public URI that uniquely identifies this version of the tag library.

```xml
<display-name>display_name</display-name>
```
(Optional) Contains a short name that is intended to be displayed by tools.

```xml
<icon>
  <small-icon>icon.jpg</small-icon>
  <large-icon>icon.jpg</large-icon>
</icon>
```
(Optional) Contains the name of a file containing a small (16 x 16) icon image. The file name is a relative path within the tag library. The image must be either in the JPEG or GIF format, and the file name must end with the suffix ".jpg" or ".gif" respectively. The icon can be used by tools.

```xml
<description>...text...</description>
```
(Required) Defines an arbitrary text string describing the tag library.

```xml
<validator>unique_string</validator>
```
(Optional) Provides information on the scripting variables defined by this tag. A translation-time error occurs if a tag that has one or more variable subelements has a TagExtraInfo class that returns a non-null object.

```xml
<listener>unique_string</listener>
```
(Optional) Defines an optional event listener object to be instantiated and registered automatically.

5. Define a tag library validator (Optional).

   <validator>
   
   Top level element for a validator.
   
   <validator-class>my.validator</validator-class>
   
   (Required) The Java class that performs the validation.
   
   <init-param>
   
   (Optional) Defines initialization parameters for the validator class.
   
   <param-name>param</param-name>
   
   Defines the name of this parameter.
   
   <param-value>value</param-value>
   
   Defines the name of this parameter.

   Use a separate <tag> element to define each new tag in the tag library. The <tag> element takes the following nested tags:

   <name>tag_name</name>
   
   (Required) Defines the name of the tag. This is used when referencing the tag in a JSP file, after the ":" symbol. For example:

   <mytaglib:tag_name>

   For more information, see Section 1.4, "New and Changed JSP Features In This Release."

   <tag-class>package.class.name</tag-class>

   (Required) Declares the tag handler class that implements the functionality of this tag. Specify the fully qualified package name of the class.

   Locate the class file under the WEB-INF/classes directory, in a directory structure reflecting the package name. You can also package the classes in a tag library jar file; for more information, see Section 5.2, "Packaging a JSP Tag Library as JAR File."

   <tei-class>package.class.name</tei-class>

   (Optional) Declares the subclass of TagExtraInfo that describes the scripting variables introduced by this tag. If your tag does not define new scripting variables, it does not use this element. Specify the fully qualified package name of the class. You can perform validation of the tag’s attributes in this class.

   Place the class files under the WEB-INF/classes directory of your Web application, under a directory structure reflecting the package name. You can also package the classes in a tag library jar file; for more information, see Section 5.2, "Packaging a JSP Tag Library as JAR File."

   <body-content>empty | JSP | scriptless | tagdependent</body-content>
(Optional) Defines the content of the tag body.
empty means that you use the tag in the empty tag format in the JSP page. For example:
<taglib:tagname/>

JSP means that the contents of the tag can be interpreted as a JSP and that you must use the tag in the body tag format. For example:
<taglib:tagname>...</taglib:tagname>

scriptless means that the contents of the tag do not contain any scripts or scripting elements.
tagdependent means that your tag will interpret the contents of the body as a non-JSP (for example, an SQL statement).

(attribute)

(Optional) Defines the name of the attribute as it appears in the tag element in the JSP page. For example:
<taglib:mytag myAttribute="myAttributeValue">

Use a separate <attribute> element to define each attribute that the tag can take. Tag attributes allow the JSP author to alter the behavior of your tags.

<name>myAttribute</name>
<required>true | false</required>

(Optional) Defines whether this attribute has optional use in the JSP page. If not defined here, the default is false — that is, the attribute is optional by default. If true is specified, and the attribute is not used in a JSP page, a translation-time error occurs.

<rtexprvalue>true | false</rtexprvalue>

(Optional) Defines whether this attribute can take a scriptlet expression as a value, allowing it to be dynamically calculated at request time. If this element is not specified, the value is presumed to be false.

</attribute>

7. Define scripting variables (optional).
Within the <tag> element, you can define scripting variables.

<variable>
Top level element for declaring a variable.

<name-given>someName</name-given>

Defines the name of the variable, or you can define the name from an attribute using:

<name-from-attribute>attrName</name-from-attribute>

Names the variable with the value of attrName.

<variable-class>some.java.type</variable-class>
The DynamicAttributes Interface

Creating a Tag Library Descriptor

3.3 Sample Tag Library Descriptor

The following is a sample listing of a tag library descriptor.

Example 3–1 Sample Tag Library Descriptor (tld)

```xml
<taglib version="2.0" xmlns="http://java.sun.com/xml/j2ee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee/web-jsptaglibrary_2_0.xsd">
  <taglib>
    <tlib-version>2.0</tlib-version>
    <jsp-version>2.0</jsp-version>
    <short-name>quote</short-name>
    <uri>tag lib version id</uri>
    <description>
      This tag library contains several tag extensions useful for formatting content for HTML.
    </description>
    <tag>
      <name>code</name>
      <tag-class>weblogic.taglib.quote.CodeTag</tag-class>
      <body-content>tagdependent</body-content>
      <attribute>
        <name>fontAttributes</name>
      </attribute>
      <attribute>
        <name>commentColor</name>
      </attribute>
      <attribute>
        <name>quoteColor</name>
      </attribute>
    </tag>
  </taglib>
</taglib>
```

3.4 The DynamicAttributes Interface

The DynamicAttributes interface, supported by the JSP 2.0 container, allows you to use tags with values that are treated in a consistent manner but with names that are not necessarily known at development time. For example, if you want to customize the width portion of the `<table>` HTML tag by determining its value at runtime, you could make use of the DynamicAttributes interface to customize only the portion of the tag you want to change, without needing to specify anything about the other
portions of the <table> tag (border, cellspacing, and so on). Without the DynamicAttributes interface, you would have needed to write a Tag Handler or other complicated code to accomplish the task of determining the value of width dynamically at runtime.

3.5 Tag Handler Support of Dynamic Attributes

The TLD is what ultimately determines whether a tag handler accepts dynamic attributes or not. If a tag handler declares that it supports dynamic attributes in the TLD but it does not implement the DynamicAttributes interface, the tag handler must be considered invalid by the container.

If the dynamic-attributes element (a child element to the tag element for the tag library being authored) for a tag being invoked contains the value true, the following requirements apply:

■ For each attribute specified in the tag invocation that does not have a corresponding attribute element in the TLD for this tag, a call must be made to setDynamicAttribute(), passing in the namespace of the attribute (or null if the attribute does not have a namespace or prefix), the name of the attribute without the namespace prefix, and the final value of the attribute.

■ Dynamic attributes must be considered to accept request-time expression values.

■ Dynamic attributes must be treated as though they were of type java.lang.Object.

■ The JSP container must recognize dynamic attributes that are passed to the tag handler using the <jsp:attribute> standard action.

■ If the setDynamicAttribute() method throws JspException, the doStartTag() or doTag() method is not invoked for this tag, and the exception must be treated in the same manner as if it came from a regular attribute setter method.

■ For a JSP document in either standard or XML syntax, if a dynamic attribute has a prefix that does not map to a namespace, a translation error must occur. In standard syntax, only namespaces defined using taglib directives are recognized.

3.6 Dynamic Attributes Example

In the following example, assume attributes a and b are declared using the attribute element in the TLD, attributes d1 and d2 are not declared, and the dynamic-attributes element is set to true. You set the attributes using the calls:

■ setA( "1" ),

■ setDynamicAttribute( null, "d1", "2" ),

■ setDynamicAttribute( "http://www.foo.com/jsp/taglib/mytag.tld", "d2", "3" ),

■ setB( "4" ),

■ setDynamicAttribute( null, "d3", "5" ), and

**Example 3–2 Dynamic Attribute Example**

<jsp:root xmlns:mytag="http://www.foo.com/jsp/taglib/mytag.tld" version="2.0">
3.6.1 Dynamic Attributes Syntax

For a tag to declare that it accepts dynamic attributes, it must implement the DynamicAttributes interface. The syntax is as follows:

```java
public interface DynamicAttributes
```

You must also configure an entry for the tag in the TLD to indicate dynamic attributes are accepted. For any attribute that is not declared in the TLD for this tag, instead of getting an error at translation time, the `setDynamicAttribute()` method is called, with the name and value of the attribute. You configure the tag to remember the names and values of the dynamic attributes.

The `setDynamicAttribute()` method is called when a tag declared to accept dynamic attributes passes an attribute that is not declared in the TLD. The syntax is as follows:

```java
public void setDynamicAttribute(java.lang.String uri, java.lang.String localName, java.lang.Object value)
```

The parameter values are as follows:

- **uri** - the namespace of the attribute, or null if in the default namespace.
- **localName** - the name of the attribute being set.
- **value** - the value of the attribute.

A `JspException` is thrown if the tag handler signals that it does not accept the given attribute. The container must not call `doStartTag()` or `doTag()` for this tag.

Implementing the Tag Handler

The following sections describe how to write Java classes that implement the functionality of an extended tag:

- Section 4.1, "Simple Tag Handler Life Cycle (SimpleTag Interface)"
- Section 4.2, "Events in the Simple Tag Handler Life Cycle"
- Section 4.3, "JSP Fragments"
- Section 4.4, "Tag Handler Life Cycle (Tag and BodyTag Interfaces)"

4.1 Simple Tag Handler Life Cycle (SimpleTag Interface)

Simple tag handlers present a much simpler invocation protocol than do classic tag handlers. The tag library descriptor maps tag library declarations to their physical underlying implementations. A simple tag handler is represented in Java by a class that implements the SimpleTag interface.

The life cycle of a simple tag handler is straightforward and is not complicated by caching semantics. Once a simple tag handler is instantiated by the container, it is executed and then discarded. The same instance must not be cached and reused. Initial performance metrics show that caching a tag handler instance does not necessarily lead to greater performance. To accommodate such caching makes writing portable tag handlers difficult and makes the tag handler prone to error.

In addition to being simpler to work with, simple tag extensions do not rely directly on any servlet APIs, which allows for potential future integration with other technologies. This capability is facilitated by the JspContext class, which PageContext extends. JspContext provides generic services such as storing the JspWriter and keeping track of scoped attributes, whereas PageContext has functionality specific to serving JSPs in the context of servlets. Whereas the Tag interface relies on PageContext, SimpleTag only relies on JspContext. The body
of SimpleTag, if present, is translated into a JSP fragment and passed to the 
setJspBody method. The tag can then execute the fragment as many times as 
needed. See Section 4.3, "JSP Fragments."

Unlike classic tag handlers, the SimpleTag interface does not extend Tag. Instead of 
supporting doStartTag() and doEndTag(), the SimpleTag interface provides a 
simple doTag() method, which is called once and only once for any given tag 
invocation. All tag logic, iteration, body evaluations, and so on are performed in this 
single method. Thus, simple tag handlers have the equivalent power of BodyTag, but 
with a much simpler life cycle and interface.

To support body content, the setJspBody() method is provided. The container 
invokes the setJspBody() method with a JspFragment object encapsulating the 
body of the tag. The tag handler implementation can call invoke() on that fragment 
to evaluate the body. The SimpleTagSupport convenience class provides 
getJspBody() and other useful methods to make this even easier.

4.2 Events in the Simple Tag Handler Life Cycle

The following describes the life cycle of simple tag handlers, from creation to 
invocation. When a simple tag handler is invoked, the following events occur (in 
order):

1. Simple tag handlers are created initially using a zero argument constructor on the 
corresponding implementation class. Unlike classic tag handlers, a simple tag 
handler instance must never be pooled by the container. A new instance must be 
created for each tag invocation.

2. The setJspContext() and setParent() methods are invoked on the tag 
handler. The setParent() method need not be called if the value being passed 
in is null. In the case of tag files, a JspContext wrapper is created so that the 
tag file can appear to have its own page scope. Calling getJspContext() must 
return the wrapped JspContext.

3. The attributes specified as XML element attributes (if any) are evaluated next, in 
the order in which they are declared, according to the following rules (referred to 
as "evaluating an XML element attribute" below). The appropriate bean property 
setter is invoked for each. If no setter is defined for the specified attribute but the 
tag accepts dynamic attributes, the setDynamicAttribute() method is 
invoked as the setter.

   If the attribute is a scripting expression (for example, "&lt;%= 1+1 %&gt;" in JSP 
syntax, or "%= 1+1 %" in XML syntax), the expression is evaluated, and the 
result is converted and passed to the setter.

   Otherwise, if the attribute contains any expression language expressions (for 
example, "Hello ${name}"), the expression is evaluated, and the result is 
converted and passed to the setter.

   Otherwise, the attribute value is taken verbatim, converted, and passed to the 
setter.

4. The value for each <jsp:attribute> element is evaluated, and the 
corresponding bean property setter methods are invoked for each, in the order in 
which they appear in the body of the tag. If no setter is defined for the specified 
attribute but the tag accepts dynamic attributes, the setDynamicAttribute() 
method is invoked as the setter.

   Otherwise, if the attribute is not of type JspFragment, the container evaluates the 
body of the <jsp:attribute> element. This evaluation can be done in a
container-specific manner. Container implementors should note that in the process of evaluating this body, other custom actions may be invoked.

Otherwise, if the attribute is of type JspFragment, an instance of a Jsp-Fragment object is created and passed in.

5. The value for the body of the tag is determined, and if a body exists the setJsp-Body() method is called on the tag handler.

   If the tag is declared to have a body-content of empty or no body or an empty body is passed for this invocation, then setJspBody() is not called.

   Otherwise, the body of the tag is either the body of the <jsp:body> element, or the body of the custom action invocation if no <jsp:body> or <jsp:attribute> elements are present. In this case, an instance of a Jsp-Fragment object is created and it is passed to the setter. If the tag is declared to have a body-content of tagdependent, the JspFragment must echo the body's contents verbatim.

   Otherwise, if the tag is declared to have a body-content of type scriptless, the JspFragment must evaluate the body's contents as a JSP scriptless body.

6. The doTag() method is invoked.

7. The implementation of doTag() performs its function, potentially calling other tag handlers (if the tag handler is implemented as a tag file) and invoking fragments.

8. The doTag() method returns, and the tag handler instance is discarded. If Skip-PageException is thrown, the rest of the page is not evaluated and the request is completed. If this request was forwarded or included from another page (or servlet), only the current page evaluation stops.

9. For each tag scripting variable declared with scopes AT_BEGIN or AT_END, the appropriate scripting variables and scoped attributes are declared, as with classic tag handlers.

### 4.3 JSP Fragments

A JSP fragment is a portion of JSP code passed to a tag handler that can be invoked as many times as needed. You can think of a fragment as a template that is used by a tag handler to produce customized content. Thus, unlike simple attributes which are evaluated by the container, fragment attributes are evaluated by tag handlers during tag invocation.

JSP fragments can be parameterized using the JSP expression language (JSP EL) variables in the JSP code that composes the fragment. The JSP EL variables are set by the tag handler, thus allowing the handler to customize the fragment each time it is invoked. For more information on the JSP expression language, see "WebLogic JSP Reference" in Oracle Fusion Middleware Developing Web Applications, Servlets, and JSPs for Oracle WebLogic Server.

During the simple tag handler life cycle, the body of a SimpleTag, if present, is translated into a JSP fragment and passed to the setJspBody method. During the translation phase, various sections of the page are translated into implementations of the javax.servlet.jsp.tagext.JspFragment abstract class, before being passed to a tag handler. This is done automatically for any JSP code in the body of a named attribute (one that is defined by <jsp:attribute>) that is declared to be a fragment, or of type JspFragment, in the tag library descriptor (TLD). This is also automatically done for the body of any tag handled by a simple tag handler. Once
passed in, the tag handler can then evaluate and re-evaluate the fragment as many
times as needed, or even pass it along to other tag handlers, in the case of tag files.

A JSP fragment can be parameterized by a tag handler by setting page-scoped
attributes in the JspContext associated with the fragment. These attributes can then
be accessed by way of the expression language.

A translation error must occur if a piece of JSP code that is to be translated into a JSP
fragment contains scriptlets or scriptlet expressions.

4.4 Tag Handler Life Cycle (Tag and BodyTag Interfaces)

The methods inherited from the Tag or BodyTag interfaces and implemented by the
tag handler class are invoked by the JSP engine at specific points during the processing
of the JSP page. These methods signify points in the life cycle of a tag and are executed
in the following sequence:

1. When the JSP engine encounters a tag in a JSP page, a new tag handler is
initialized. The setPageContext() and setParent() methods of the
javax.servlet.jsp.tagext.Tag interface are invoked to set up the
environment context for the tag handler. As a tag developer, you need not
implement these methods if you extend the TagSupport or BodyTagSupport
base classes.

2. The setXXX() JavaBean-like methods for each tag attribute are invoked. For
more details, see Section 4.6, "Handling Exceptions within a Tag Body."

3. The doStartTag() method is invoked. You can define this method in your tag
handler class to initialize your tag handler or open connections to any resources it
needs, such as a database.

   At the end of the doStartTag() method, you can determine whether the tag
   body should be evaluated by returning one of the following value constants from
   your tag handler class:

   SKIP_BODY—Directs the JSP engine to skip the body of the tag. Return this value
   if the tag is an empty-body tag. The body-related parts of the tag’s life cycle are
   skipped, and the next method invoked is doEndTag().

   EVAL_BODY_INCLUDE—Directs the JSP engine to evaluate and include the
   content of the tag body. The body-related parts of the tag’s life cycle are skipped,
   and the next method invoked is doEndTag().

   You can only return this value for tags that implement the Tag interface. This
   allows you to write a tag that can determine whether its body is included, but is
   not concerned with the contents of the body. You cannot return this value if your
   tag implements the BodyTag interface (extends the BodyTagSupport class).

   EVAL_BODY_TAG—Instructs the JSP engine to evaluate the tag body, then invokes
   the doInitBody() method. You can only return this value if your tag
   implements the BodyTag interface (extends the BodyTagSupport class).

4. The setBodyContent() method is invoked. At this point, any output from the
tag is diverted into a special JspWriter called BodyContent, and is not sent to
the client. All content from evaluating the body is appended to the BodyContent
buffer. This method allows the tag handler to store a reference to the
BodyContent buffer so it is available to the doAfterBody() method for
post-evaluation processing.

   If the tag is passing output to the JSP page (or the surrounding tag scope if it is
   nested), the tag must explicitly write its output to the parent-scoped JspWriter
Tag Handler Life Cycle (Tag and BodyTag Interfaces)

Implementing the Tag Handler

between this point in the tag life cycle and the end of the doEndTag() method. The tag handler can gain access to the enclosing output using the getEnclosingWriter() method.

You do not need to implement this method if you are using the BodyTagSupport convenience class, because the tag keeps a reference to the BodyContent and makes the reference available through the getBodyContent() method.

5. The doInitBody() method is invoked. This method allows you to perform some work immediately before the tag body is evaluated for the first time. You might use this opportunity to set up some scripting variables, or to push some content into the BodyContent before the tag body. The content you prepend here will not be evaluated as JSP—unlike the tag body content from the JSP page.

The significant difference between performing work in this method and performing work at the end of the doStartTag() method (once you know you are going to return EVAL_BODY_TAG) is that with this method, the scope of the tag's output is nested and does not go directly to the JSP page (or parent tag). All output is now buffered in a special type of JspWriter called BodyContent.

6. The doAfterBody() method is invoked. This method is called after the body of the tag is evaluated and appended to the BodyContent buffer. Your tag handler should implement this method to perform some work based on the evaluated tag body. If your handler extends the convenience class BodyTagSupport, you can use the getBodyContent() method to access the evaluated body. If you are simply implementing the BodyTag interface, you should have defined the setBodyContent() method where you stored a reference to the BodyContent instance.

At the end of the doAfterBody() method, you can determine the life cycle of the tag again by returning one of the following value constants:

- SKIP_BODY—Directs the JSP engine to continue, not evaluating the body again. The life cycle of the tag skips to the doEndTag() method.
- EVAL_BODY_TAG—Directs the JSP engine to evaluate the body again. The evaluated body is appended to the BodyContent and the doAfterBody() method is invoked again.

At this point, you may want your tag handler to write output to the surrounding scope. Obtain a writer to the enclosing scope using the BodyTagSupport.getPreviousOut() method or the BodyContent.getEnclosingWriter() method. Either method obtains the same enclosing writer.

Your tag handler can write the contents of the evaluated body to the surrounding scope, or can further process the evaluated body and write some other output. Because the BodyContent is appended to the existing BodyContent upon each iteration through the body, you should only write out the entire iterated body content once you decide you are going to return SKIP_BODY. Otherwise, you will see the content of each subsequent iteration repeated in the output.

7. The out writer in the pageContext is restored to the parent JspWriter. This object is actually a stack that is manipulated by the JSP engine on the pageContext using the pushBody() and popBody() methods. Do not, however, attempt to manipulate the stack using these methods in your tag handler.

8. The doEndTag() method is invoked. Your tag handler can implement this method to perform post-tag, server side work, write output to the parent scope JspWriter, or close resources such as database connections.
Your tag handler writes output directly to the surrounding scope using the JspWriter obtained from pageContext.getOut() in the doEndTag() method. The previous step restored pageContext.out to the enclosing writer when popBody() was invoked on the pageContext.

You can control the flow for evaluation of the rest of the JSP page by returning one of the following values from the doEndTag() method:

- EVAL_PAGE—Directs the JSP engine to continue processing the rest of the JSP page.
- SKIP_PAGE—Directs the JSP engine to skip the rest of the JSP page.

9. The release() method is invoked. This occurs just before the tag handler instance is de-referenced and made available for garbage collection.

### 4.5 Iteration Over a Body Tag (IterationTag Interface)

A tag that implements the javax.servlet.jsp.tagext.IterationTag interface has a method available called doAfterBody() that allows you to conditionally re-evaluate the body of the tag. If doAfterBody() returns IterationTag.EVAL_BODY_AGAIN the body is re-evaluated, if doAfterBody() returns Tag.SKIP_BODY, the body is skipped and the doEndTag() method is called. For more information, see the Java EE Javadocs for this interface. (You can download the Javadocs from Sun Microsystems at http://java.sun.com/products/jsp/index.jsp)

### 4.6 Handling Exceptions within a Tag Body

You can catch exceptions thrown from within a tag by implementing the doCatch() and doFinally() methods of the javax.servlet.jsp.tagext.TryCatchFinally interface. For more information, see the J2EE Javadocs for this interface. (You can download the Javadocs from Sun Microsystems at http://java.sun.com/products/jsp/index.jsp)

### 4.7 Using Tag Attributes

Your custom tags can define any number of attributes that can be specified from the JSP page. You can use these attributes to pass information to the tag handler and customize its behavior.

You declare each attribute name in the TLD, in the <attribute> element. This declares the name of the attribute and other attribute properties.

Your tag handler must implement setter and getter methods based on the attribute name, similar to the JavaBean convention. For example, if you declare an attribute named foo, your tag handler must define the following public methods:

```java
public void setFoo(String f);
public String getFoo();
```

Note that the first letter of the attribute name is capitalized after the set/get prefix.

The JSP engine invokes the setter methods for each attribute appropriately after the tag handler is initialized and before the doStartTag() method is called. Generally, you should implement the setter methods to store the attribute value in a member variable that is accessible to the other methods of the tag handler.
4.8 Defining New Scripting Variables

Your tag handler can introduce new scripting variables that can be referenced by the JSP page at various scopes. Scripting variables can be used like implicit objects within their defined scope.

Define a new scripting variable by using the <tei-class> element to identify a Java class that extends javax.servlet.jsp.tagext.TagExtraInfo. For example:

```<tei-class>weblogic.taglib.session.ListTagExtraInfo</tei-class>```

Then write the TagExtraInfo class. For example:

```java
package weblogic.taglib.session;
import javax.servlet.jsp.tagext.*;
public class ListTagExtraInfo extends TagExtraInfo {

    public VariableInfo[] getVariableInfo(TagData data) {
        return new VariableInfo[] {
            new VariableInfo("username",
                'String',
                true,
                VariableInfo.NESTED),
            new VariableInfo("dob",
                'java.util.Date',
                true,
                VariableInfo.NESTED)
        };
    }
}
```

The example above defines a single method, getVariableInfo(), which returns an array of VariableInfo elements. Each element defines a new scripting variable. The example shown above defines two scripting variables called username and dob, which are of type java.lang.String and java.util.Date, respectively.

The constructor for VariableInfo() takes four arguments.

- A String that defines the name of the new variable.
- A String that defines the Java type of the variable. Give the full package name for types in packages other than the java.lang package.
- A boolean that declares whether the variable must be instantiated before use. Set this argument to "true" unless your tag handler is written in a language other than Java.
- An int declaring the scope of the variable. Use a static field from VariableInfo shown here:

```java
VariableInfo.NESTED—Available only within the start and end tags of the tag.
VariableInfo.AT_BEGIN—Available from the start tag until the end of the page.
VariableInfo.AT_END—Available from the end tag until the end of the page.
```

Configure your tag handler to initialize the value of the scripting variables via the page context. For example, the following Java source could be used in the doStartTag() method to initialize the values of the scripting variables defined above:

```java
pageContext.setAttribute("name", nameStr);
pageContext.setAttribute("dob", bday);
```
Where the first parameter names the scripting variable, and the second parameter is the value assigned. Here, the Java variable `nameStr` is of type `String` and `bday` is of type `java.util.Date`.

You can also access variables created with the `TagExtraInfo` class by referencing it the same way you access a JavaBean that was created with `useBean`.

### 4.9 Dynamically Named Scripting Variables

It is possible to define the name of a new scripting variable from a tag attribute. This definition allows you to use multiple instances of a tag that define a scripting variable at the same scope, without the scripting variables of the tag clashing. In order to achieve this from your class that extends `TagExtraInfo`, you must get the name of the scripting variable from the `TagData` that is passed into the `getVariableInfo()` method.

From `TagData`, you can retrieve the value of the attribute that names the scripting variable using the `getAttributeString()` method. There is also the `getId()` method that returns the value of the `id` attribute, which is often used to name a new implicit object from JSP tag.

### 4.10 Defining Variables in the Tag Library Descriptor

You can define variables in the TLD. For more information, see Section 7, "Define scripting variables (optional).”

### 4.11 Writing Cooperative Nested Tags

You can design your tags to implicitly use properties from tags they are nested within. For example, in the code example called SQL Query (see the samples/examples/jsp/tagext/sql directory of your WebLogic Server installation) a `<sql:query>` tag is nested within a `<sql:connection>` tag. The query tag searches for a parent scope connection tag and uses the JDBC connection established by the parent scope.

To locate a parent scope tag, your nested tag uses the static `findAncestorWithClass()` method of the `TagSupport` class. The following is an example taken from the `QueryTag` example.

```java
try {
    ConnectionTag connTag = (ConnectionTag)
        findAncestorWithClass(this,
            Class.forName("weblogic.taglib.sql.ConnectionTag"));
} catch(ClassNotFoundException cnfe) {
    throw new JspException("Query tag connection +
        "attribute not nested +
        "within connection tag");
}
```

This example returns the closest parent tag class whose tag handler class matched the class given. If the direct parent tag is not of this type, then it is parent is checked and so on until a matching tag is found, or a `ClassNotFoundException` is thrown.

Using this feature in your custom tags can simplify the syntax and usage of tags in the JSP page.
4.12 Using a Tag Library Validator

A Tag Library Validator is a user-written Java class that you can use to perform
validation of the XML view of a JSP page. validate(String, String,
PageData) on the validator class is invoked by the JSP compiler at translation time
(when the JSP is converted to a servlet) and returns a null string if the page is
validated or a string containing error information if the validation fails.

To implement a Tag Library Validator:

1. Write the validator class. A validator class extends the
javax.servlet.jsp.tagext.TagLibraryValidator class.

2. Reference the validator in the tag library descriptor. For example:

```xml
<validator>
  <validator-class>
    myapp.tools.MyValidator
  </validator-class>
</validator>
```

3. (Optional) Define initialization parameters. Your validator class can get and use
initialization parameters. For example:

```xml
<validator>
  <validator-class>
    myapp.tools.MyValidator
  </validator-class>
  <init-param>
    <param-name>myInitParam</param-name>
    <param-value>foo</param-value>
  </init-param>
</validator>
```

4. Package the validator class in the WEB-INF/classes directory of a Web
application. You can also package the classes in a tag library jar file; for more
information, see Section 5.2, "Packaging a JSP Tag Library as JAR File."
The following sections provide an overview of administration and configuration tasks for using JSP tag extensions:

- Section 5.1, "Configuring JSP Tag Libraries"
- Section 5.2, "Packaging a JSP Tag Library as JAR File"

### 5.1 Configuring JSP Tag Libraries

The following steps describe how to configure a JSP tag library. You can also package a tag library as a jar file (see Section 5.2, "Packaging a JSP Tag Library as JAR File").

1. Create a tag library descriptor (TLD).
   For more information, see Chapter 3, "Creating a Tag Library Descriptor."

2. Reference this TLD in the Web Application deployment descriptor, web.xml. For example:
   ```xml
   <taglib>
     <taglib-uri>myTLD</taglib-uri>
     <taglib-location>WEB-INF/library.tld</taglib-location>
   </taglib>
   ```
   In this example the tag library descriptor is a file called library.tld. Always specify the location of the tld relative to the root of the Web application.

3. Place the tag library descriptor file in the WEB-INF directory of the Web application.

4. Reference the tag library in the JSP page.
   In your JSP, reference the tag library with a JSP directive. For example:
   ```jsp
   <%@ taglib uri="myTLD" prefix="mytaglib" %>
   ```

5. Place the tag handler Java class files for your tags in the WEB-INF/classes directory of your Web application.

6. Deploy the Web application on WebLogic Server. For more information, see "Deploying and Packaging from a Split Development Directory" in Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server.

### 5.2 Packaging a JSP Tag Library as JAR File

In addition to the procedure described in the previous section Section 5.1, "Configuring JSP Tag Libraries" you can also package a JSP tag library as a jar file:
1. Create a TLD (tag library descriptor) file named taglib.tld.
   For more information, see Chapter 3, "Creating a Tag Library Descriptor."
2. Create a directory containing the compiled Java tag handler class files used in your
   tag library.
3. Create a subdirectory of the directory you created in step 2 and call it META-INF.
4. Copy the taglib.tld file you created in step 1 into the META-INF directory you
   created in step 3.
5. Archive your compiled Java class files into a jar file by executing the following
   command from the directory you created in step 2.
   
   ```
   jar cvf myTagLibrary.jar
   ```
   (where myTagLibrary.jar is a name you provide)
6. Copy the jar file into the WEB-INF/lib directory of the Web application that uses
   your tag library.
7. Reference this tag library descriptor in the Web application deployment descriptor,
   web.xml. For example:
   
   ```
   <taglib>
     <taglib-uri>myjar.tld</taglib-uri>
     <taglib-location>
       /WEB-INF/lib/myTagLibrary.jar
     </taglib-location>
   </taglib>
   ```
8. Reference the tag library in your JSP. For example:
   
   ```
   <%@ taglib uri="myjar.tld" prefix="wl" %>
   ```
