# Message-Level Security

This chapter explains how to configure message-level security between .NET 2.0 and AquaLogic Service Bus. The chapter contains the following topics:

- [Message-Level Security Between .NET 2.0 and AquaLogic Service Bus](#)
- [What is .NET?](#)
- [Message-Level Security Configuration in .NET For AquaLogic Service Bus Interoperability](#)
- [AquaLogic Service Bus Configuration for Message-Level Security with .NET](#)

## Message-Level Security Between .NET 2.0 and AquaLogic Service Bus

You can set up Message-level security between the Microsoft .NET 2.0 framework and AquaLogic Service Bus 2.6. Message-level security applies security checks to a SOAP message after a Web services client establishes a connection with an AquaLogic Service Bus proxy service or business service and before the proxy service or business service processes the message.

## What is .NET?

The .NET framework is a software component that you can add to the Microsoft Windows operating system. It provides pre-coded solutions to common program requirements, and manages the execution of programs written specifically for the framework.

# Message-Level Security Configuration in .NET For AquaLogic Service Bus Interoperability

This section provides the steps that you need to perform for .NET 2.0 and for AquaLogic Service Bus to configure message-level security.

**WARNING:** Before you perform these steps, you must follow the steps in [Configuring Message-Level Security for Web Services](#) in the *Security Guide* to configure inbound and outbound messaging for AquaLogic Service Bus.

To configure message-level security between .NET and AquaLogic Service Bus:

1. Verify that you completed the steps to configure inbound and outbound messaging for AquaLogic Service Bus. See the Warning above for instructions.
2. Download Web Service Enhancements (WSE) 3.0 from [Microsoft](#) and install it. WSE 3.0 is a SOAP extension managed API (`Microsoft.Web.Services3.dll`) that is compatible with the .NET 2.0 framework.
3. After you install WSE 3.0, you must enable the WSE features for your web application and enable WSE Soap Protocol Factory support. You can enable both these features using wizards in Visual Studio. See <http://msdn.microsoft.com/library/default.asp?url=/library/en-us/wse3.0/html/5a8f03b1-16ac-4c5c-9d9e-132a9c0b628a.asp> for details.

After you enable WSE 3.0, you will notice the following restrictions:

- WSE 3.0 no longer supports WS-Policy and therefore, WS-SecurityPolicy for configuration purposes, as it did in .NET 1.1 and WSE 2.0. WSE 3.0 supports only a proprietary policy configuration using the `wse3policyCache.config` file (or equivalent .NET code) that provides similar features to those in WSE 2.0. One consequence of this is that the WSDLs for the .NET web service no longer contain WS-Policy statements. On the other hand, AquaLogic Service Bus supports a WebLogic Server-proprietary format that is based on the assertions described in the December 18, 2002 version of the Web Services Security Policy Language (WS-SecurityPolicy) specification. In order to consume .NET WSDLs in AquaLogic Service Bus, you must incorporate the equivalent AquaLogic Service Bus proprietary version of WS-Policy in the WSDL.

The WSDL code sample in [Listing 1-1 on page 6](#) shows how to configure WS-Policy for message-level identity propagation, confidentiality, and integrity in AquaLogic Service Bus.

- WSE 3.0 provides policy configuration for a few Turnkey Security Assertions in the `wse3policyCache.config` file, which can be selected with a wizard in Visual Studio. The certificate that maps to providing message-level security (encryption and signing, for example) is `MutualCertificate10`, which is compatible with the WS-Security 1.0 specification that ALSB currently supports. For details on configuring the `MutualCertificate10` Security Assertion, see <http://msdn2.microsoft.com/en-us/library/aa480581.aspx>.
- The WSE Soap Protocol Factory does not support security with SOAP 1.2. The generated client stubs using the Web Reference option in Visual Studio contain the security-enabled operations only if you select SOAP 1.1. Message-level security interoperability works only with SOAP 1.1.
- As with .NET 1.1 and WSE 2.0, you must disable automatic signing of WS-Addressing headers and timestamps that are configured by default. You must change some of the properties in the `wse3policyCache.config` file, as shown in the following example:

Default Config

```
<protection>
  <request signatureOptions="IncludeAddressing, IncludeTimestamp,
    IncludeSoapBody" encryptBody="true" />
  <response signatureOptions="IncludeAddressing, IncludeTimestamp,
    IncludeSoapBody" encryptBody="true" />
  <fault signatureOptions="IncludeAddressing, IncludeTimestamp,
    IncludeSoapBody" encryptBody="false" />
</protection>
```

Required Config

```
<protection>
  <request signatureOptions="IncludeSoapBody" encryptBody="true" />
  <response signatureOptions="IncludeSoapBody" encryptBody="true"
    />
  <fault signatureOptions="IncludeSoapBody" encryptBody="false" />
</protection>
```

- By default, WSE 3.0 expects the key wrapping algorithm to be OAEP. However, ALSB uses the RSA15 algorithm. If the configuration remains as OAEP, the following exception appears: `Microsoft.Web.Services3.Security.SecurityFault: An unsupported signature or encryption algorithm was used`  
`System.Exception: WSE3002: The receiver is expecting the key wrapping algorithm to be http://www.w3.org/2001/04/xmlenc#rsa-oaep-mgf1p, but the incoming message used http://www.w3.org/2001/04/xmlenc#rsa-1_5.` You can change the key wrapping algorithm by configuring the security token manager.

To avoid this error, add the following configuration to the `web.config` file (on the .NET web service) and the `app.config` file (on the .NET client side) under the `<microsoft.web.services3>` `<security>` elements:

```
<binarySecurityTokenManager>
  <add valueType="http://docs.oasis-open.org/wss/2004/01/
    oasis-200401-wss-x509-token-profile-1.0#X509v3" ;>
    <keyAlgorithm name="RSA15" />
  </add>
</binarySecurityTokenManager>
```

This configuration forces WSE to use RSA15 instead of OAEP.

- For Username Token Authentication, .NET provides a `usernameForCertificateSecurity` turnkey assertion that secures the communication channel between the client and the service at the message layer using the service's X.509 certificate. However, this certificate depends on the ability to reference `<EncryptedKey>` elements as security tokens, and enables the option for signature confirmation to correlate a response message with the request that prompted it. Both of these features are available only in WS-Security 1.1. Consequently, this turnkey assertion cannot be used with AquaLogic Service Bus because it supports only WS-Security 1.0.

An alternative for Username Token Authentication is the `.NET usernameOverTransportSecurity` turnkey assertion, which assumes that communication between the client and service will be secured at the transport layer. This approach is WS-Security 1.0 compatible and supports message-level authentication over SSL. If you want to combine the `usernameOverTransportSecurity` turnkey assertion with other message-level security mechanisms, such as encryption and signing, you must write custom code in .NET.

## AquaLogic Service Bus Configuration for Message-Level Security with .NET

Before you configure AquaLogic Service Bus, the following conditions must exist:

- A .NET client invokes an AquaLogic Service Bus proxy with a plain text message (for example, message-level security does not exist between the .NET client and the AquaLogic Service Bus proxy).
- AquaLogic Service Bus enforces outbound message-level security on the SOAP request.

**Note:** For cases where the .NET client has message-level security enabled, you can use AquaLogic Service Bus as a pass-through proxy.

To configure AquaLogic Service Bus for message-level security with .NET:

1. The .NET web service expects the WS-Addressing `<wsa:To>` element to contain its own URL. As the .NET client first invokes the AquaLogic Service Bus proxy, the `<wsa:To>` element is originally set to the AquaLogic Service Bus proxy URL. Change this URL to the URL of the .NET web service in the AquaLogic Service Bus proxy message flow, using a `Replace` action as shown in the following example:

Original URL

```
<wsa:To wsu:Id="To_1mbmRK4w0bo2Dz1z"
xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-
wssecurity-utility-1.0.xsd">http://localhost:7001/SecurityALSBProxy</
wsa:To>
```

URL after Replace Action

```
<wsa:To wsu:Id="To_1mbmRK4w0bo2Dz1z"
xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-
wssecurity-utility-1.0.xsd">http://localhost/SimpleSecurity/
SecurityService.asmx</wsa:To>
```

If you do not change this URL, the following error appears:

```
Microsoft.Web.Services3.Addressing.AddressingFault: Destination
Unreachable System.Exception: WSE846: The header must match the actor
URI value of the web service. The actor URI value can be explicitly
specified using SoapActorAttribute on the ASMX class. In the absence
of the attribute, the actor URI is assumed to be equal to the HTTP
Request Url of the incoming message. The header received contained
"http://localhost:7001/SecurityALSBProxy"; while the receiver is
expecting "http://localhost/SimpleSecurity/SecurityService.asmx";
```

2. The .NET client includes its own Timestamp elements to the SOAP header. AquaLogic Service Bus adds an additional Timestamp header that results in the following error:

```
Microsoft.Web.Services3.Security.SecurityFault: An error was discovered
processing the header Microsoft.Web.Services3.Security.Security
FormatException: WSE001: The input was not a valid Security element
because it contains more than one Timestamp child element.
```

To solve this issue, use a `Delete` action to remove the original Timestamp elements that the .NET client adds in the message flow.

## Sample WSDL File

The sample WSDL in [Listing 1-1](#) shows how to configure `WS-Policy` for message-level identity propagation, confidentiality, and integrity in ALSB.
