Service Bus ™

JMX Monitoring API
Programming Guide

Contents: JMX Monitoring API

1. Introduction

2. Concepts

3. API Usage Example

Introduction

Purpose of JMX Monitoring API

In previous releases of AquaLogic Service Bus, run-time service-monitoring data was only available through the Monitoring Dashboard of the AquaLogic Service Bus console. It was not possible for clients to programmatically access and consume monitoring data.

The JMX Monitoring API in AquaLogic Service Bus provides external access to monitoring data. Java Management Extensions (JMX) technology was used for the implementation, as it is a public standard that meets the implementation requirements.

The primary purpose of the JMX Monitoring API is to provide efficient, lower-level APIs supporting bulk operations. It does this using JMX as a transport. This API is not a high-level API compatible with JMX-based tools. However, if you are developing client software, you may want to develop high-level JMX APIs that support JMX-based tooling.

Description

The JMX monitoring API makes use of JMX as a transport only.

It exposes a public MBean to provide all the required operations to get monitoring data (statistical information) for any monitored service and its components.

It also exposes a set of public POJO objects required to carry out operations provided by the MBean.

There is no need for third-party client software to know the intricacies of the hierarchy inherent in the statistical information stored in the AquaLogic Service Bus monitoring system.

Using these APIs, customers can integrate their monitoring/management systems with AquaLogic Service Bus to do the following:

- Identify services enabled for monitoring.

- Get detailed statistical information for a specific service, for its components, or for both.

- Reset statistics accumulated since the last reset.

More Information

For more information about AquaLogic Service Bus 3.0, see BEA AquaLogic Service Bus 3.0.

For basic concepts and terminology, see AquaLogic Service Bus Concepts and Architecture.

Concepts

The public JMX APIs are modeled by a single instance of `ServiceDomainMBean`, which has operations to check for monitored services and retrieve data from them.

A public set of POJOs provide additional objects and methods that, along with `ServiceDomainMbean`, provide a complete API for monitoring statistics.

The following sections provide brief descriptions of the POJOs and MBean. The Javadoc provides detailed descriptions. There is also a detailed description of statistics that are reported for resources.

Please be sure to read the important notes at the end of this chapter.

Public POJO Objects

The following POJO objects are exposed as part this API.

ResourceType

ServiceResourceStatistic

ResourceStatistic

StatisticValue

StatisticType

ResourceType

This object represents all types of resources that are enabled for service monitoring. There are four `enum` constants representing types: `SERVICE`, `FLOW_COMPONENT`, `URI`, and `WEBSERVICE_OPERATION`.

See `com.bea.wli.monitoring.ResourceType` in the javadoc at:

`http://edocs.bea.com/alsb/docs30/javadoc/`

ServiceResourceStatistic

This object represents all business and proxy service resource types and the statistics associated with them. There are methods to get statistics for all resources or for a specified one.

See `com.bea.wli.monitoring.ServiceResourceStatistic` in the javadoc at:

`http://edocs.bea.com/alsb/docs30/javadoc/`

ResourceStatistic

This object represents a resource for which statistics collection is supported. There are methods to get the name of the resource, the type, and the statistics.

See `com.bea.wli.monitoring.ResourceStatistic` in the javadoc at:

`http://edocs.bea.com/alsb/docs30/javadoc/`

StatisticValue

This object represents a statistic value for a resource. The monitoring system currently supports the following types of statistic values, both nested classes:

- `CountStatistic`
- `IntervalStatistic`
- `StatusStatistic`

`StatisticValue` is an abstract class so that concrete objects representing count and interval statistic values can be derived from it. It includes `getName()` and `getType()` methods.

See `com.bea.wli.monitoring.StatisticValue` in the javadoc at:

`http://edocs.bea.com/alsb/docs30/javadoc/`

StatisticType

This object represents predefined types of statistics. There are three enum types: STATUS, COUNT, and INTERVAL.

See com.bea.wli.monitoring.StatisticValue in the javadoc at:

http://edocs.bea.com/alsb/docs30/javadoc/

ServiceDomainMBean

This is the only MBean exposed as part of the public JMX API. It provides methods to find monitored service and get and reset statistics.

See com.bea.wli.monitoring.ServiceDomainMBean in the javadoc at:

http://edocs.bea.com/alsb/docs30/javadoc/

Statistics Details

The following sections provide detailed information about statistics reported for each resource type.

Statistics details for Resource Type - SERVICE

A service is an inbound or outbound endpoint that is configured within AquaLogic Service Bus. It may have an associated WSDL, security settings, etc.

The following statistics are reported for this resource type.

Table 2-1 SERVICE Statistics

Statistic Name	Type
message-count	count
error-count	count
failover-count	count
wss-error	count
response-time	interval
validation-errors	count

Table 2-1 SERVICE Statistics

Statistic Name	Type
failure-rate	count
success-rate	count
sla-severity-warning	count
sla-severity-major	count
sla-severity-minor	count
sla-severity-normal	count
sla-severity-fatal	count
sla-severity-critical	count
sla-severity-all	count
pipeline-severity-warning	count
pipeline-severity-major	count
pipeline-severity-minor	count
pipeline-severity-normal	count
pipeline-severity-fatal	count
pipeline-severity-critical	count
pipeline-severity-all	count
throttling-time	interval
uri-offline-count	count

The statistics `sla-severity-warning`, `sla-severity-major`, `sla-severity-minor`, `sla-severity-normal`, `sla-severity-fatal`, `sla-severity-critical`, and `sla-severity-all` are collected for both proxy services and business services.

The statistics `pipeline-severity-warning`, `pipeline-severity-major`, `pipeline-severity-minor`, `pipeline-severity-normal`, `pipeline-severity-fatal`,

`pipeline-severity-critical`, and `pipeline-severity-all` are collected only for proxy services.

Notes:

- Statistic "wss-error" provides Web Service security violations counts. It is applicable to both business and proxy services.

- Statistic "validation errors" is only applicable to proxy service; it is not returned for a business service.

- Statistic "failover-count" is only applicable to business service; it is not returned for a proxy service.

- When the statistics of a managed server are retrieved from a cluster domain using the ServiceDomainMBean the statistics for proxy services will not contain `sla-severity-normal`, `sla-severity-minor`, `sla-severity-major`, `sla-severity-warning`, `sla-severity-critical`, `sla-severity-fatal`, `sla-severity-all`.

Statistics details for Resource Type–FLOW_COMPONENT

Statistics are collected for the following two types of components that can be present in the flow definition of a proxy service.

- Pipeline-pair node

- Route node

Pipelines are one-way processing paths consisting of stages that are executed sequentially against the current message. Stages are used to perform activities such as transformation, logging and publishing.

There are three categories of pipelines: request, response, and error.

The pipeline-pair node ties together a single request and a single response pipeline into one top-level element.

A routing node consists of a set of routes. A route identifies a target service and includes some additional configuration options that determines how the message will be packaged and sent to that service. A routing node will result in at most one route being selected as part of request processing.

The following statistics are reported for this resource type.

Table 2-2 FLOW_COMPONENT Statistics

Statistic Name	Type
elapse-time	interval
message-count	count
error-count	count

Notes:

1. Statistics for pipeline and route nodes are returned as statistics for flow components. enum value ResourceType.FLOW_COMPONENT represents both pipeline and route nodes.

2. Thus there is no way for a client to check if the returned flow component is a pipeline or route node. The name of the flow component, however, may suggest the type.

Statistics details for Resource Type – WEBSERVICE_OPERATION

This resource type provides statistical information pertaining to WSDL operations. Statistics are reported for each defined operation.

The following statistics are reported.

Table 2-3 WEBSERVICE_OPERATION Statistics

Statistic Name	Type
elapsed-time	interval
message-count	count
error-count	count

Statistics details for Resource Type –URI

This resource type provides statistical information pertaining to endpoint URI for a business service. Statistics are reported for each defined Endpoint URI. The following statistics are reported.

Table 2-4 Statistics for Endpoint URI

Statistic Name	Type
message-count	count
error-count	count
response-time	interval
status	status

Caveats

Please be aware of the following:

- A client program will not know about newly added services that have monitoring turned on, or services modified to turn on monitoring, unless it periodically checks for such changes.

- Reset operations should not be performed too frequently. BEA recommends that reset intervals be greater than 15 minutes.

- BEA strongly discourages using this API in a concurrent manner with more than one thread or process. This is because a reset performed in one thread or process is not visible to another threads or processes. This caveat also applies to resets performed from the Monitoring Dashboard of the AquaLogic Service Bus Console, as such resets are not visible to this API.

Performance

Performance should be better than or equivalent to that observed in the Monitoring Dashboard of the AquaLogic Service Bus Console.

Concepts

API Usage Example

The sample program in this section demonstrates how to use the JMX Monitoring API.

The following steps describe how statistics can be retrieved for a proxy service that is enabled for monitoring.

1. Get `ServiceDomainMBean` from the MBean Server.

2. Get the references for monitored proxy services using the `getMonitoredProxyServiceRefs` operation of the `ServiceDomainMBean`.

3. Identify the references of the desired proxy service from the retrieved references.

4. Get `ServiceResourceStatistics` using the `getProxyServiceStatistics` operation of the `ServiceDomainMBean` of the desired proxy service.

5. Get all `ResourceStatistic` objects using the operations of `ServiceResourceStatistic`.

6. For each retrieved `ResourceStatistic` object, get `StatisticValue` objects using the `getStatistics` operation and print statistical information.

7. Repeat process as necessary.

Sample Program

The following sample program explains how to:

1. Find by type services enabled for monitoring.

2. Set a resource-type filter.

3. Retrieve by type statistics for one or more services.

4. Extract statistics from the `ServiceResourceStatistics` object.

5. Save retrieved statistics in the proper format.

6. Reset statistics for one or more services.

To run this program, include the following JAR files in the classpath:

1. `weblogic.jar`

2. `sb-kernel-api.jar`

3. `com.bea.common.configfwk_1.1.0.0.jar` (found in the `ALSBInstallHome/modules` directory)

You may need to reset the default values for `SERVER_NAME`, `HOSTNAME`, `PORT`, `USERNAME`, and/or `PASSWORD` in the code below for your environment.

Note: If you need to get the Status statistics for each end point of a business service, set the `SERVER_NAME` attribute in a cluster environment. If you are running on a single node, Status statistics are returned even if you do not set this property.

For performance reasons, avoid extracting and resetting statistics for a large number of services too often. See "Caveats" on page 2-7. See Listing 3-1 for a sample program.
