About This Document

This document describes how to use the BEA WebLogic Adapter for RDBMS. This document is organized as follows:

- **Chapter 1, “Introducing the BEA WebLogic Adapter for RDBMS,”** describes the adapter, how it relates to both RDBMS business objects and WebLogic Integration.

- **Chapter 2, “Defining Application Views for RDBMS,”** describes application views and how to use them to configure events and services.

- **Appendix A, “Service and Event Examples,”** contains sample XML documents based the request and response schemas for services and the event schemas for events.

- **Appendix B, “Supported Data Types,”** lists the data types for which the Adapter for RDBMS has been tested.

- **Appendix C, “Supported Drivers,”** lists the commonly used drivers with which the Adapter for RDBMS has been tested.

- **Appendix D, “Error Messages and Troubleshooting,”** explains the various error messages you might encounter while using the Adapter for RDBMS, and how you can troubleshoot them.

**Who Should Read This Documentation**

This document is intended for the following members of an integration team:

- **Integration Specialists**—Lead the integration design effort. Integration specialists have expertise in defining the business and technical requirements of integration projects, and in
designing integration solutions that implement specific features of WebLogic Integration. The skills of integration specialists include business and technical analysis, architecture design, project management, and WebLogic Integration product knowledge.

- **Technical Analysts**—Provide expertise in an organization’s information technology infrastructure, including telecommunications, operating systems, applications, data repositories, future technologies, and IT organizations. The skills of technical analysts include technical analysis, application design, and information systems knowledge.

- **Enterprise Information System (EIS) Specialists**—Provide domain expertise in the systems that are being integrated using WebLogic adapters. The skills of EIS specialists include technical analysis and application integration design.

- **System Administrators**—Provide in-depth technical and operational knowledge about databases and applications deployed in an organization. The skills of system administrators include capacity and load analysis, performance analysis and tuning, deployment topologies, and support planning.

### Additional Information

To learn more about the software components associated with the adapter, see the following documents:

- **BEA WebLogic Adapter for RDBMS Release Notes**
  

- **BEA WebLogic Adapter for RDBMS Installation and Configuration Guide**
  

- **Introduction to the BEA WebLogic Adapters**
  

- **BEA WebLogic Adapters 8.1 Dev2Dev Product Documentation**
  
  [http://dev2dev.bea.com/products/wladapters/index.jsp](http://dev2dev.bea.com/products/wladapters/index.jsp)

- **Application Integration documentation**
  

- **BEA Application Explorer Installation and Configuration Guide**
  
How to Use This Document

This document is designed to be used in conjunction with *Using the Application Integration Design Console*, available at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

*Using the Application Integration Design Console* describes, in detail, the process of defining an application view, which is a key part of making an adapter available to process designers and other users. What *Using the Application Integration Design Console* does not cover is the specific information about Adapter for RDBMS that you need to supply to complete the application view definition. You will find that information in this document.

At each point in *Using the Application Integration Design Console* where you need to refer to this document, you will see a note that directs you to a section in your adapter user guide, with a link to the edocs page for adapters. The following roadmap illustration shows where you need to refer from *Using the Application Integration Design Console* to this document.

Figure 1  Information Interlock with *Using the Application Integration Design Console*

Contact Us!

Your feedback on the BEA WebLogic Adapter for RDBMS documentation is important to us. Send us e-mail at docsupport@bea.com if you have questions or comments. Your comments
will be reviewed directly by the BEA professionals who create and update the BEA WebLogic Adapter for RDBMS documentation.

In your e-mail message, please indicate that you are using the documentation for BEA WebLogic Adapter for RDBMS and the version of the documentation.

If you have any questions about this version of BEA WebLogic Adapter for RDBMS, or if you have problems using the BEA WebLogic Adapter for RDBMS, contact BEA Customer Support through BEA WebSUPPORT at www.bea.com. You can also contact Customer Support by using the contact information provided on the Customer Support Card which is included in the product package.

When contacting Customer Support, be prepared to provide the following information:

- Your name, e-mail address, phone number, and fax number
- Your company name and company address
- Your machine type and authorization codes
- The name and version of the product you are using
- A description of the problem and the content of pertinent error messages

**Documentation Conventions**

The following documentation conventions are used throughout this document.

<table>
<thead>
<tr>
<th>Convention</th>
<th>Item</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boldface text</strong></td>
<td>Indicates terms defined in the glossary.</td>
</tr>
<tr>
<td>Ctrl+Tab</td>
<td>Indicates that you must press two or more keys simultaneously.</td>
</tr>
<tr>
<td><em>italics</em></td>
<td>Indicates emphasis or book titles.</td>
</tr>
<tr>
<td>Convention</td>
<td>Item</td>
</tr>
<tr>
<td>------------</td>
<td>------</td>
</tr>
</tbody>
</table>
| monospace text | Indicates code samples, commands and their options, data structures and their members, data types, directories, and file names and their extensions. Monospace text also indicates text that you must enter from the keyboard.  
Examples:  
#include <iostream.h> void main ( ) the pointer psz  
chmod u+w *  
\tux\data\ap  
(doc  
tux.doc  
BITMAP  
float |
| monospace boldface text | Identifies significant words in code.  
Example:  
void commit ( ) |
| monospace italic text | Identifies variables in code.  
Example:  
String expr |
| UPPERCASE TEXT | Indicates device names, environment variables, and logical operators.  
Examples:  
LPT1  
SIGNON  
OR |
| { } | Indicates a set of choices in a syntax line. The braces themselves should never be typed. |
| [ ] | Indicates optional items in a syntax line. The brackets themselves should never be typed.  
Example:  
buildobjcclient [-v] [-o name ] [-f file-list]...  
[=l file-list]... |
| | Separates mutually exclusive choices in a syntax line. The symbol itself should never be typed. |
Indicates one of the following in a command line:

- That an argument can be repeated several times in a command line
- That the statement omits additional optional arguments
- That you can enter additional parameters, values, or other information

The ellipsis itself should never be typed.

*Example:*

```bash
buildobjclient [-v] [-o name ] [-f file-list]... [-l file-list]...
```

 Indicates the omission of items from a code example or from a syntax line.

- The vertical ellipsis itself should never be typed.
Introducing the BEA WebLogic Adapter for RDBMS

This section introduces the BEA WebLogic Adapter for RDBMS and describes how the adapter enables integration with RDBMS business objects and WebLogic Integration.

It includes the following topics:

- About Adapters and BEA WebLogic Integration
- Key Components of Integration Solutions
- About the BEA WebLogic Adapter for RDBMS
- Getting Started With the Adapter for RDBMS
About Adapters and BEA WebLogic Integration

The BEA application integration solution uses adapters and application views to help you integrate applications in your enterprise. At its most fundamental level, an adapter is software that connects an enterprise information system (EIS) and an integration server. This bi-directional connection consists of services—interactions that originate in the adapter (and may require a response from the EIS)—and events, interactions that originate in the EIS.

Most EIS systems make selected information and functions available to other applications by way of specialized integration APIs. An adapter connects to the EIS through its integration API, or through database or system calls, and exposes the available functions from the EIS. However, rather than exposing the intricacies of APIs to users, WebLogic Integration incorporates application views—business-oriented interfaces that provide a layer of abstraction between an adapter and the EIS capabilities the adapter exposes.

Application views contain definitions for the services and events used by business processes to communicate with an EIS. They also contain connection information and XML schema that define inputs and outputs for services and events. After an adapter is deployed, you can use its Web-based interface to define as many application views as you need, and other WebLogic Integration components and applications can use that adapter to access data on the EIS.

To learn more about BEA WebLogic Integration in the BEA WebLogic Workshop environment, see the WebLogic Integration site at the following URL:

http://edocs.bea.com/wladapters/docs81/index.html

To learn more about the role of adapters in application integration architecture, see “Key Components of Integration Solutions” on page 1-3.

To learn more about adapters in general, see the Introduction to the BEA WebLogic Adapters at the following URL:

http://edocs.bea.com/wladapters/docs81/index.html
Key Components of Integration Solutions

This section describes some of the key concepts you need to be familiar with before you work with an adapter.

- **Basic WebLogic Integration Architecture**
- **Enterprise Information Systems**
- **Resource Adapters**
- **Application Views**
- **Service Clients and Event Consumers**
- **Schema**

**Basic WebLogic Integration Architecture**

Adapters are used in conjunction with the Application Integration component of BEA WebLogic Integration. This component provides a systematic, standards-based architecture for hosting business-oriented interfaces to enterprise applications.

**Figure 1-2 Adapters in the Application Integration Architecture**

<table>
<thead>

For general information about Application Integration, see the following documents:

- *Introducing Application Integration* at the following URL:
  
  http://edocs.bea.com/wli/docs81/aiover/index.html

- *Using the Application Integration Design Console* at the following URL:
  
  http://edocs.bea.com/wli/docs81/aiuser/index.html

### Enterprise Information Systems

An *enterprise information system* (EIS) is software that provides the information infrastructure for an enterprise. An EIS offers a set of services to its clients, which are made available to clients via local and/or remote interfaces. An integration solution involves integration with one or more EISs.

### Resource Adapters

A *resource adapter* (or simply *adapter*) is a BEA software component that acts as a connector between an EIS and a J2EE application server (such as BEA WebLogic Server). Each adapter provides bi-directional, request-response integration with a specific application or technology.

Adapters handle two general types of operations:

- **Services** are request/response communications with the EIS. Client applications submit service requests to the EIS via the adapter, and the adapter returns the EIS response back to the client. For example, a business process might invoke a service to execute a SELECT statement on an RDBMS. Responses are either synchronous or asynchronous.

  **Figure 1-3 Service Invocations**

  ![Service Invocations Diagram](image)

- **Events** are asynchronous, one-way messages received from an EIS. For example, the adapter can receive data from an RDBMS in response to an event triggered. The adapter routes the EIS message to the appropriate software component via the WebLogic Integration Message Broker and the Application Integration JMS infrastructure.
In effect, a service is a request for some work to be done and an event is a notification that some work has been done.

For more information about the specific services and events supported by Adapter for RDBMS, see “About the BEA WebLogic Adapter for RDBMS” on page 1-9.

To learn more about the WebLogic Integration Message Broker and the Application Integration JMS infrastructure, see “Introducing Application Integration” at the following URL:
http://edocs.bea.com/wli/docs81/aiover/index.html

**Application Views**

An application view is a business oriented interface to objects and operations within an EIS. Application views include the information needed to communicate with the EIS as well as configurations for services and events.

To learn more about using application views in business processes, see “WebLogic Workshop Development Environment” at the following URL:

You typically define an application view for a specific business process. Therefore, you might have multiple application views defined for a single adapter, each designed to meet a specific requirement.

An application view defines:

- **Communication with the EIS**, including connection settings, login credentials, and so on.

- **Service invocations**, including the information that the EIS requires for the request, as well as any service request and response schemas associated with the service.

- **Event notifications**, including the information that the EIS publishes and the event schemas for inbound messages.
You create application views in either of two ways:

- Using the Application View Console. For detailed information about application views, see “What Are Application Views?” in “Understanding Application Integration” in *Using the Application Integration Design Console* at the following URL:
  
  http://edocs.bea.com/wli/docs81/aiover/2intfra.html

- Writing custom code. For more information, see “Using Application Views by Writing Custom Code” in *Using the Application Integration Design Console* at the following URL:

  http://edocs.bea.com/wli/docs81/aiuser/4usrcust.html

An application view for Adapter for RDBMS provides these features:

- Standards-based data representation. All events, requests, and responses are represented as standards-based XML.

- Abstraction from the details of the EIS. Application views offer a level of abstraction from the details of the underlying EIS, freeing the developers to concentrate on the business processes and data and not on the configuration and details of that system.

To learn more about application views, see Chapter 2, “Defining Application Views for RDBMS.”

Service Clients and Event Consumers

In an integration solution, there are clients that invoke services, and consumers for event notifications.

Service Clients

A variety of clients can invoke services on an EIS via an application view. They include BEA WebLogic Workshop business processes, web services, and portals; queries and BEA Liquid Data; and custom Java applications.

For more information, see the following topics in the BEA WebLogic Workshop Help System:

- “Building Integration Applications”
- “Building Web Services”
- “Building Portal Applications”

at the following URL:

In addition, see “Using Application Views With Business Processes” in *Using the Application Integration Design Console* at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/3usruse.html

**Event Consumers**

Adapters deliver events using the WebLogic Integration Message Broker, which provides business processes with a channels-based publish and subscribe communication mechanism. Consumers can include BEA WebLogic Workshop business processes, web services, and portals, as well as custom Java applications.

For more information, see the following topics in the BEA WebLogic Workshop Help System:

- “Message Broker Subscription Control” in “Message Broker Controls”
- “Integrating Enterprise Applications”

at the following URL:

In addition, see “Receiving Events” in “Using Applications With Business Processes” in *Using the Application Integration Design Console* at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/3usruse.html
Schema

At run-time, the EIS and the adapter exchange service requests, service responses, and events via XML documents. The adapter handles the data translation between XML documents and the EIS format, using schemas that map the data between XML and the EIS format. The Adapter for RDBMS automatically generates the schema when you add services and events to an application view.

- For service requests, the request arrives at the adapter in the form of an XML document. The adapter uses the request schema associated with the service to translate the request to the format that the EIS expects. Similarly, when the adapter receives the response back from the EIS, it uses the response schema associated with the service to translate the response to an XML document that the requesting application handles.

Figure 1-5 Adapter Translation for Service Invocations

- For event notifications, the message arrives at the adapter in the format that the EIS uses to publish the event. The adapter uses the event schema associated with the event to translate the response to an XML document that the subscribed application handles.
About the BEA WebLogic Adapter for RDBMS

The BEA WebLogic Adapter for RDBMS connects to your RDBMS system so that you can easily use your RDBMS data and functions within your business processes. The adapter provides scalable, reliable, and secure access to your RDBMS system.

This section includes the following topics:

- Supported Versions
- Supported RDBMS Operations for Application Integration
- Supported Services
- Supported Events
- Benefits of the Adapter for RDBMS

**Supported Versions**

The Adapter for RDBMS supports the following RDBMS versions:

- Oracle 8i and 9i
- SQL Server 2000
- DB2 UDB V7.2

For details on the drivers with which the Adapter for RDBMS has been tested, see Appendix C, “Supported Drivers.”
For a list of the data types that the adapter supports for each database, see Appendix B, “Supported Data Types.”

Note: The Adapter for RDBMS will soon support more databases and versions. Please check with BEA Customer Support for the latest information on supported RDBMS versions. For details on how to contact Customer Support, see section “Contact Us!” on page -ix.

Supported RDBMS Operations for Application Integration

The Adapter for RDBMS enables integration with RDBMS by providing bi-directional access to a database. Services and events act, therefore, as plugable components that can be used in business processes to interact with the database.

The input and output of a query or stored procedure invocation are expressed in XML. This provides a convenient and simple method for integrating databases with enterprise applications using WebLogic Integration.

The Adapter for RDBMS supports the following operations:

- Asynchronous, bi-directional message interactions between applications and databases, including Oracle, Microsoft SQL Server, and IBM DB2 UDB
- Integration of requests and table event (outbound) operations in processes
- JDBC 2.1 standard SQL operations (DELETE, INSERT, SELECT, and UPDATE)
- Execution of stored procedures

Supported Services

The Adapter for RDBMS supports the following service types:

- Standard SQL, which invokes a standard static SQL statement without any parameters for the statement defined at design time
- Parametrized SQL, which invokes a parametrized SQL statement for the statement defined at design time
- Stored Procedure, which invokes a stored procedure defined in the RDBMS
- Arbitrary SQL, which invokes an SQL statement without any parameters for the statement defined at run time
Supported Events

Events are asynchronous, one-way messages received from an RDBMS. Events post an XML response document from an RDBMS whenever a specific event of interest is triggered. The event could contain data about a Select, Insert, Update or Delete operation that has occurred on a table in the RDBMS.

An event:

1. Polls the RDBMS for an event of interest.

2. Transforms the data of interest (response) from the RDBMS data format to an XML document that conforms to the response XML schema for the event, which is based on metadata in the RDBMS.

The Adapter for RDBMS supports the following event types:

- Trigger, which notifies that an Insert, Update, or Delete event has occurred in a database table
- Select By Timestamp, which notifies an Insert or Update event in a database table with the corresponding timestamp columns
- Select Then Delete, which notifies records of interest based on a Select query on a database table

Benefits of the Adapter for RDBMS

The combination of the adapter and WebLogic Integration supplies everything you need to integrate your business processes and enterprise applications with your RDBMS system. The Adapter for RDBMS provides these benefits:

- Integration can be achieved without custom coding.
- Business processes can be started by events generated by RDBMS.
- Business processes can request and receive data from your RDBMS system using services.

- Adapter events and services are standards-based. The adapter services and events provide extensions to the J2EE Connector Architecture (JCA) version 1.0 from Sun Microsystems, Inc. For more information, see the Sun JCA page at the following URL:

  http://java.sun.com/j2ee/connector/
The adapter and WebLogic Integration solution is scalable. The BEA WebLogic Platform provides clustering, load balancing, and resource pooling for a scalable solution. For more information about scalability, see the following URL:
http://e-docs.bea.com/wls/docs81/cluster/index.html

The adapter and WebLogic Integration solution benefits from the fault-tolerant features of the BEA WebLogic Platform. For more information about high availability, see the following URL:
http://edocs.bea.com/wli/docs81/deploy/index.html

The adapter and WebLogic Integration solution is secure, using the security features of the BEA WebLogic Platform and the security of your RDBMS system. For more information about security, see the following URL:
http://edocs.bea.com/wls/docs81/secintro/index.html

Getting Started With the Adapter for RDBMS

This section gives an overview of how to get started using the BEA WebLogic Adapter for RDBMS within the context of an application integration solution. Integration with RDBMS involves the following tasks:

- **Step 1: Design the Application Integration Solution**
- **Step 2: Determine the Required RDBMS Functions**
- **Step 3: Define Application Views and Configure Services and Events**
- **Step 4: Integrate with Other BEA Software Components**
- **Step 5: Deploy the Solution to the Production Environment**

**Step 1: Design the Application Integration Solution**

The first step is to design an application integration solution, which includes (but is not limited to) such tasks as:

- Defining the overall scope of application integration.
- Determining the business process(es) to integrate.
- Determining which WebLogic Platform components will be involved in the integration, such as business processes or portals built in the BEA WebLogic Workshop environment.
• Determining which external systems and technologies will be involved in the integration, such as RDBMS systems and other EISs.

• Determining which BEA WebLogic Adapters will be required, such as the BEA WebLogic Adapter for RDBMS. An application integration solution can involve multiple adapters.

This step involves the expertise of business analysts, system integrators, and EIS specialists (including RDBMS specialists). Note that an application integration solution can be part of a larger integration solution.

To learn more about designing an application integration solution, see *Designing WebLogic Integration Solutions* at the following URL:

http://edocs.bea.com/wli/docs81/design/index.html

**Step 2: Determine the Required RDBMS Functions**

Within the larger context of an application integration project, you must determine which specific RDBMS tables and stored procedures you need to access.

Factors to consider include (but are not limited to):

• Access requirements for your RDBMS

• RDBMS transactions involved in business processes

• RDBMS operations you need to perform

• Whether operations are, from the adapter point of view:
  – services, which notify the RDBMS with a request for action, and, in addition, whether such services should be processed synchronously or asynchronously
  – events, which are notifications from the RDBMS system that trigger business processes.

This step involves the expertise of RDBMS specialists, including analysts and administrators.

**Step 3: Define Application Views and Configure Services and Events**

You create an application view that provides an XML-based interface between WebLogic Integration and a particular RDBMS system within your enterprise. If you are accessing multiple RDBMS systems, you define a separate application view for each RDBMS system you want to
access. To provide different levels of security access (such as “guest” and “administrator”), define a separate application view for each security level.

Once you define an application view, you can configure events and services in that application view that employ the XML schemas that the adapter automatically generates for you.

To learn more about defining application views, see Chapter 2, “Defining Application Views for RDBMS” in conjunction with Using the Application Integration Design Console, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

Step 4: Integrate with Other BEA Software Components

Once you have configured and published one or more application views for RDBMS integration, you can integrate these application views into other BEA software components, such as business processes or portals built in the BEA WebLogic Workshop environment.

For more information, see Using the Application Integration Design Console, particularly “Using Application Views with Business Processes,” at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

Step 5: Deploy the Solution to the Production Environment

After you have designed, built, and tested your application integration solution, you can deploy it into a production environment. The following list describes some of the tasks involved in deploying an application integration:

- Design the deployment.
- Deploy the required components of the BEA WebLogic Platform.
- Install and deploy the BEA WebLogic Adapter for RDBMS as described in BEA WebLogic Adapter for RDBMS Installation and Configuration Guide.
- Deploy your application views and schemas for RDBMS integration.
- Verify business processes in the production environment.
- Monitor and tune the deployment.

To learn more about deploying your application integration solution, see Deploying WebLogic Integration Solutions at the following URL:
http://edocs.bea.com/wls/docs81/deploy/index.html
Defining Application Views for RDBMS

An application view is a business-oriented interface to objects and operations within an EIS. This section presents the following topics:

- How to Use This Document
- Before You Begin
- About Application Views
- About Defining Application Views
- Defining Service Connection Parameters
- Setting Service Properties
- Setting Event Properties
- Defining Event Connection Parameters
- Testing Services
- Testing Events Using a Service
- Testing Events Manually
- Handling Null Values
How to Use This Document

This document is designed to be used in conjunction with *Using the Application Integration Design Console*, available at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

*Using the Application Integration Design Console* describes, in detail, the process of defining an application view, which is a key part of making an adapter available to process designers and other users. What *Using the Application Integration Design Console* does not cover is the specific information—about connections to your RDBMS, as well as supported services and events—that you must supply as part of the application view definition. You will find that information in this section.

At each point in *Using the Application Integration Design Console* where you need to refer to this document, you will see a note that directs you to a section in your adapter user guide, with a link to the edocs page for adapters. The following road map illustration shows where you need to refer to this document from *Using the Application Integration Design Console*.

**Figure 2-1  Information Interlock with Using the Application Integration Design Console**

Before You Begin

Before you define an application view, make sure you have:

- Installed and deployed the adapter according to the instructions in *BEA WebLogic Adapter for RDBMS Installation and Configuration Guide*.

- Determined which business processes need to be supported by the application view. The required business processes determine the types of services and events you include in your application views. Therefore, you must gather information about the application’s business requirements from the business analyst. Once you determine the necessary business
processes, you can define and test the appropriate services and events. For more information, see “Getting Started With the Adapter for RDBMS” on page 1-12.

- Gathered the connection information for your RDBMS system.

## About Application Views

An application view defines:

- Connection information for the EIS, including login information, connection settings, and so on.
- Service invocations, including the information the EIS requires for this request, as well as the request and response schemas associated with the service.
- Event notifications, including the information the EIS publishes and the event schema for inbound messages.

Typically, an application view is configured for a single business purpose and contains only the services and events required for that purpose. An EIS might have multiple application views, each defined for a different purpose.

## About Defining Application Views

Defining an application view is a multi-step process described in *Using the Application Integration Design Console*, available at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

The information you enter depends on the requirements of your business process and your EIS system configuration. Figure 2-2 summarizes the procedure for defining and configuring an application view.
To define an application view:

1. Log on to the WebLogic Integration Application View Console.

2. Define the application context by selecting an existing application or specifying a new application name and root directory.
   This application will be using the events and services you define in your application view. The application view works within the context of this application.

3. Add folders as required to help you organize application views.

4. Define a new application view for your adapter.

**Note:** The Adapter for RDBMS supports the following transaction levels: No Transaction, Local Transaction, and XA Transaction. Each transaction level exposes a connector. When you define an application view, you must choose a connector (RAR file). The file you choose depends on your integration requirements. You must then select an appropriate driver to connect to the RDBMS.
For details on how to choose connectors, see the following table.

### Table 2-1 Choosing Connectors Based on the Required Transaction Support Level

<table>
<thead>
<tr>
<th>Transaction Support Level</th>
<th>Description</th>
<th>Choose the Connector…</th>
<th>Choose Appropriate Driver…</th>
</tr>
</thead>
<tbody>

</table>

5. Add a new connection service or select an existing one.
   If you are adding a new connection service, see “Defining Service Connection Parameters” on page 2-6 for details about RDBMS requirements.

6. Add the events and services for this application view.
   See the following sections for details about RDBMS requirements:
   – “Setting Service Properties” on page 2-7
   – “Setting Event Properties” on page 2-11

7. Perform final configuration tasks.
   If you are adding an event connection, see “Defining Event Connection Parameters” on page 2-16 for details about RDBMS requirements.
8. Test all services and events to make sure they can properly interact with the target RDBMS system.

   See the following sections for details about RDBMS requirements:
   - “Testing Services” on page 2-18
   - “Testing Events Using a Service” on page 2-19
   - “Testing Events Manually” on page 2-20

9. Publish the application view to the target WebLogic Workshop application.

   This is the application you specified in step 2. Publishing the application view allows business process developers within the target application to interact with the newly published application view using an Application View control.

**Defining Service Connection Parameters**

This information applies to “Step 5A, Create a New Browsing Connection” in *Using the Application Integration Design Console*, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

After you enter a connection name and description, you use the Configure Connection Parameters page to specify connection parameters for a connection factory.

To configure connection parameters:

1. In the Create New Browsing Connection page, enter a connection name and description as described in *Using the Application Integration Design Console*.

2. Click Define.

   The Configure Connection Parameters page appears, to allow you to configure the newly created connection factory within the new adapter instance.
Setting Service Properties

On this page, you supply parameters to connect to your DBMS:

- **Database User Name**
- **Database Password**

Create a Connection Using a Driver

- **JDBC URL**
- **Driver Name**
- **Driver Supports XA**: Yes/No

Note: A red asterisk (*) indicates that a field is required.

3. Enter your database user name and password.

4. Enter the JDBC URL and the driver name. Select the appropriate Driver Supports XA setting. Click Continue.

You return to the Create New Browsing Connections, where you can specify connection pool parameters and logging levels. For more information, see Using the Application Integration Design Console at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

Setting Service Properties

This information applies to “Step 6A, Add a Service to an Application View” in Using the Application Integration Design Console, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

The Adapter for RDBMS uses services to make requests of the RDBMS system. A service consists of both a request and a response.

The Adapter for RDBMS supports the following services:

- Standard SQL: This service invokes a static standard SQL statement without any parameters. You give the SQL statement, without parameters, at design time. The SQL executed can be either a Data Manipulation Language (DML) - SELECT, INSERT, UPDATE, or DELETE statement or a Data Definition Language (DDL) - CREATE, ALTER, or DROP statement. The list of resultant records is converted into a response XML document, based on the XML schema formed during design time.
This service type does not support Insert/Update statements containing Character Large Objects (CLOB) or Binary Large Objects (BLOB) data types.

- **Parametrized SQL**: This service invokes a parametrized SQL. You give the SQL statement, with parameters, at design time. The SQL executed can only be a DML (SELECT, INSERT, UPDATE, or DELETE) statement. This service type receives an XML document that gives the values for the parameters specified. Based on the data type of the input provided, the adapter binds the parameter values. The prepared SQL statement is executed, and the list of resultant records is converted into a response XML document, based on the XML schema formed during design time.

  This service type supports statements containing CLOB/BLOB data type. Such parameters should be base64 encoded. The adapter decodes the input and binds it to the statement before execution. The output from a table with a column of the type CLOB/BLOB will be encoded to base64 before forming the output XML document.

- **Stored Procedure**: This service invokes a stored procedure defined in an RDBMS. The stored procedure executed can have IN, IN-OUT, and OUT parameters and a RETURN value. This service type receives an XML document giving the input values for the parameters of the type IN and IN-OUT. Based on the data type of the input provided, the adapter binds the parameter values. The stored procedure is executed and the list of resultant records is converted into a response XML document, based on the XML schema formed during design time.

  **Note:**
  
  - Because DBMS manufacturers produce JDBC agents with varying degrees of functionality, stored procedures can be executed in several different ways within the service adapter.
  
  - Oracle subprograms (stored procedures) can be called whether they reside as functions, stored procedures, or stored procedures located within packages.

  - For this service type, Oracle JDBC drivers do not support boolean data type.

- **Arbitrary SQL**: This service invokes an SQL statement. You give the SQL statement, with parameters, at run time. The SQL executed can either be a DML (SELECT, INSERT, UPDATE, or DELETE) or a DDL (CREATE, ALTER, or DROP) statement. The list of resultant records is converted into the response XML document, based on the type of statement executed.

  **Note:** In Standard SQL, the statement is given at design time, whereas in Arbitrary SQL, it is given at run time. Otherwise, the same rules apply.
To configure a service:

1. Enter a unique service name that describes the function the service performs and a description.

   The service name must be unique to its application view. Valid characters include a-z, A-Z, 0-9, and the _ (underscore) character.

   On this page, you add services to your Application View:

   - **Unique Service Name**: * 
   - **Description**:  

   **Service Details**

   - **Service Type**: * 
   - **Isolation Level**:  

   Enter SQL Statement (If you have chosen the Service Type For Parameterized Query & Standard Query)

   SQL Statement:  

   Syntax Help: 1. Use fully qualified table name (i.e. catalog.schema.table). 2. to get a user into, brackets the column name and type as follows: [ColumnName:ColumnType], next browse to cut & paste ColumnName and ColumnType into your sql.

   *Browse Tables and Views*

   Parameters created in SQL only support JDBC types. To view the supported types follow the link: JDBC Types

   Enter the Stored Procedure Name (If You have chosen the Service Type as Stored Procedure)

   Stored Procedure Name:  

   (This field is mandatory for service type is 'Stored Procedure')

   **Note**: A red asterisk ( * ) indicates that a field is required.

2. Select the Service Type from the Service Type list. You can select one of the following:

   - Standard SQL, which invokes a static standard SQL statement without any parameters for the statement defined at design time
   - Parametrized SQL, which invokes a parametrized SQL statement for the statement defined at design time
   - Stored Procedure, which invokes a stored procedure defined in the RDBMS
– Arbitrary SQL, which invokes an SQL statement for the statement defined at run time

3. Select the Isolation Level.

<table>
<thead>
<tr>
<th>Isolation Level</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>Does not specifically set an isolation level for the connection. If you select None, the default setting for the driver is taken.</td>
</tr>
<tr>
<td>Read Committed</td>
<td>Limits a transaction to reading only data that has already been committed by other transactions. Prohibits a transaction from reading a row with uncommitted changes in it.</td>
</tr>
<tr>
<td>Read Uncommitted</td>
<td>Permits a transaction to read data that has been updated but not yet committed by other transactions. Does not prevent read violations.</td>
</tr>
<tr>
<td>Repeatable Read</td>
<td>Permits a transaction to read only data that has been committed by another transaction. Multiple reads of the same data yield the same committed result within a transaction. Uncommitted data is not read.</td>
</tr>
<tr>
<td>Serializable</td>
<td>Requires transactions to be run serially to achieve maximum data integrity. Yields the slowest performance and least concurrency.</td>
</tr>
</tbody>
</table>

**Note:** The transaction isolation levels should be same for all the services participating in a transaction.

4. Enter the SQL statement for Standard SQL or Parametrized SQL services.

For both service types, the table name should be fully qualified with the SCHEMA/CATALOG name as the database requires. The table name is case sensitive—use upper case. For example, in Oracle, it should be `SCHEMA.TABLENAME`.

To gather user input for Parametrized SQL, enter the column name and column type within brackets. For example, `[ParamName ColumnType]`. The `ParamName` is used to define an element in the input schema. This name should be unique in the parametrized SQL statement. The `ColumnType` should be a JDBC data type. To see the list of supported types, click the JDBC Types link. To see the list of data types tested and supported by this adapter on various RDBMS, see Appendix B, “Supported Data Types.”

Examples of SQL statements:

– **Standard SQL**: `SELECT * FROM BEAUSER.BONUS`
5. Enter the Stored Procedure Name for Stored Procedures service.

The stored procedure name should be in the format `ProcedureName(?, ?, ...)`. For example, `BEAUSER.RaiseSAL(?, ?)`

The ?s indicate the number of IN, IN-OUT, and OUT parameters. The ProcedureName must be qualified with the catalog and/or schema name as per the requirement of the database.

<table>
<thead>
<tr>
<th>RDBMS</th>
<th>Stored Procedure Name Format</th>
</tr>
</thead>
</table>
| Oracle         | For a packaged procedure, `SchemaName.PackageName.ProcedureName(?, ?, ...)`  
                | For a non-packaged procedure, `SchemaName.ProcedureName(?, ?, ...)` |
| SQL Server     | `CatalogName.SchemaName.ProcedureName(?, ?, ...)` |
| DB2 UDB        | `SchemaName.ProcedureName(?, ?, ...)` |

**Note:** Click the Browse DBMS to view Tables, Views, and Stored Procedures link to select the stored procedure name. You can click the option button next to the stored procedure name to fill it in the field.

6. When finished, click Add. The service is added to the list.

For examples of design-time and run-time input values for services, see Appendix A, “Service and Event Examples.”

**Setting Event Properties**

This information applies to “Step 6B, Add an Event to an Application View” in *Using the Application Integration Design Console*, at the following URL:
An event defines how your application responds to events generated by the RDBMS. The Adapter for RDBMS supports the following event types:

- **Trigger**: This event type notifies an Insert, Update, or Delete event occurring in a database table using the trigger mechanism.

- **Select By Timestamp**: This event type notifies an Insert and Update event occurring in a database table. The table of interest should have columns that represent Created Timestamp and Updated Timestamp. You can configure Insert event only if Created Timestamp is maintained as a part of the table, and Update event only if Updated Timestamp is maintained as a part of the table.

  **Note**: Ensure that the system time of the machine running the EIS is in sync with the system time of the machine running the WebLogic Server, so that the events do not time out.

- **Select Then Delete**: This event type notifies records of interest based on a select query given on a database table. The event polling mechanism looks for records based on the select query, packages the result into one or more rows, and creates an XML document representing the records of interest. You can choose to either delete or retain the selected records after the events are processed.

The following table shows the events that each of the event types supports.

**Table 2-4  Supported Events for Event Types**

<table>
<thead>
<tr>
<th></th>
<th>Insert</th>
<th>Update</th>
<th>Delete</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trigger</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>Select By Timestamp</td>
<td>Yes</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Select Then Delete</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

The application view publishes the event as an XML document during the specified occurrence, acting as a broker between the target application and the client.

Before you configure an event, ensure the following tables are created:

- **EventPollingMetadataTable**: This table stores the last polled timestamp for the application view and the event. The last polled timestamp is used to construct the next event payload for a Select By Timestamp event type.
For example: If you specify a polling interval of 4 seconds, and the last polled timestamp is T1, the event generator scans the target table for any row whose timestamp column T satisfies the following condition: T1 < T <= T1 + 4.

- Trigger Tables: These tables are used when you configure a Trigger event. When an Insert/Update/Delete takes place in the target table, a trigger is invoked. This trigger creates entries in the event and event data tables, which contain event and event data respectively. The event generator then scans these tables for rows that indicate event occurrences. After the event is successfully invoked, the respective rows are deleted from the event and event data tables.

For details on how to set up and run the EventPollingMetadataTable and Trigger Tables, see the BEA WebLogic Adapter for RDBMS Installation and Configuration Guide at the following URL:
http://edocs.bea.com/wladapters/docs81/index.html
To configure an event:

1. Enter a unique event name that describes the function the event performs and a description.

   Each event name must be unique to its application view. Valid characters include a-z, A-Z, 0-9, and the _ (underscore) character.

   
   On this page, you add events to your application view.

   unique event name:*  
   Description:

   Event Details
   Maximum Event Records:*  
   Table Name:*  
   
   [Select help: ORACLE: SCHEMA.TABLENAME, MS SQLSERVER: catalog.schema.tablename, DB2: schema.tablename]

   
   ○ Trigger
   please select the type of event to create:  
   ○ Insert Event  
   ○ Update Event  
   ○ Delete Event

   ○ Select_By_TimeStamp
   please select the type of event to create:  
   ○ Insert Event  
   ○ Update Event

   Updated TimeStamp Column  
   Created TimeStamp Column

   ○ Select_Then_Delete
   Enter SQL Query

   Delete Required  
   ○ Yes  
   ○ No

   
   Note:  A red asterisk (*) indicates that a field is required.

2. Enter the maximum number of data records to be processed as an event.

   For example, if there are 10 records of interest, and the Maximum Event Records is 3, there will be 3 events with 3 records each, and an event with the remaining record. If there
are 2 records of interest, and the Maximum Event Records is 3, there will still be an event with 2 records.

3. Enter the name of the database table.
   Use the corresponding syntax for the following databases:

<table>
<thead>
<tr>
<th>Database</th>
<th>Syntax for Table Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle</td>
<td>SCHEMA . TABLENAME</td>
</tr>
<tr>
<td>SQL Server</td>
<td>catalog . schema . tablename</td>
</tr>
<tr>
<td>DB2 UDB</td>
<td>SCHEMA . TABLENAME</td>
</tr>
</tbody>
</table>

**Note:** Click the Browse DBMS link to see the schemas and table names. You can click the option button next to the table name, and then click Fill Table Name for the selected table.

4. Select the option button for the type of event to add:
   - Trigger, which notifies an Insert, Update, or Delete event occurring in a database table
   - Select_By_Timestamp, which notifies an Insert or Update event in a database table with the corresponding timestamp columns
   - Select_Then_Delete, which notifies records of interest based on a select query given on a database table

5. Do one of the following, based on the type of event:
   a. For a Trigger event, select one of the following actions: Insert Event, Update Event, Delete Event.
   b. For a Select_By_Timestamp event, select Insert Event or Update Event. For Insert Event, enter the Created Timestamp Column name. For Update Event, enter the Updated Timestamp Column name.
      **Note:** Click the Browse Columns link to see the column names. You can click the option button next to the column name, and then click Fill Column Name to fill in the field.
   c. For a Select_Then_Delete event, enter the SQL Query. Select the Delete Required Yes option button to delete the selected records after the event is triggered.
6. When finished, click Add. The event is added to the list.

<table>
<thead>
<tr>
<th>Events</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Events</strong></td>
</tr>
<tr>
<td><strong>Add</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Services</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Services</strong></td>
</tr>
<tr>
<td><strong>Add</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>StdRDBMS</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>StdRDBMS</strong></td>
</tr>
<tr>
<td><strong>Add</strong></td>
</tr>
</tbody>
</table>

---

### Defining Event Connection Parameters

This information applies to “Step 7, Perform Final Configuration Tasks” in *Using the Application Integration Design Console*, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

Once you have finished adding services and events and have saved your application view, you must perform some final configuration tasks, including configuring event-delivery connections, before testing the services and events. Perform these configuration tasks from the Final Configuration and Testing page.

To define event connection parameters:

1. In the Connections area on the Application View Administration page, click Select/Edit.

2. In the Event Connection area, click the Select Existing link, then click Event in the Event Connection page to edit the default event connection.

   The following page appears.

   On this page you configure the connection properties, log level of your event connection.

   **Connection Parameters:**

   **Connection Name:** 
   Description: 

   **Log Configuration**
   Set the log verbosity level for this Connection Factory.
   - Log warnings, errors, and audit messages

3. Click Define to enter the event-delivery parameters.
The parameters you enter on this page enable connection to your RDBMS and are used when generating events. The parameters are specific to the associated adapter and are defined in the `weblogic-ra.xml` file within the base adapter.

On this page, you supply parameters to configure event delivery for this application/view.

**Event Connection Details**
- JDBC URL: connection property to the RDBMS
- Driver Name: JDBC Driver Name
- Username: JDBC URL username
- Password: JDBC URL password
- Default Datasource: JNDI name of the Datasource for the WL Integration domain (your Domain Repository)

**Other Details**
- Sleepcount (in milliseconds): Polling interval for Events
- DB Access Flag: If true the trigger is generated on the DB, else if false it is written to a file `AppViewNameEventName_trigger.sql` (located under your DOMAIN_HOME directory)

4. Enter the JDBC URL and Driver Name required to connect to the database.

5. Enter the Username and Password required to connect to the database.

6. Enter the Default Datasource, the JNDI name of the Weblogic Integration domain datasource.

   This is the datasource that contains the EventPollingMetadata table created while you installed the adapter. The default is `WLAI_DataSource`.

7. Enter the Sleepcount, the number of seconds the adapter will wait between polling for events.

   The default is 4000 milliseconds, which means that the database is polled every four seconds for new events.

8. For Trigger event, enter True for the DB Access Flag if you have access to your customer’s database. Otherwise, enter False.

   If true, the trigger is created on the database. If false, it is written to the file `DOMAIN_HOME\AppViewNameEventName_trigger.sql`. The default is True.

9. Click Continue to return to the Edit Event Connection page, and then click OK to return to the Final Configuration and Testing page.
The Edit Event Connection page allows you to define event parameters and configure the information that will be logged for the connection factory. Select one of the following settings for the log:

- Log errors and audit messages (recommended)
- Log warnings, errors, and audit messages
- Log informational, warning, error, and audit messages
- Log all messages

The table that follows describes the type of information that each logging message contains.

<table>
<thead>
<tr>
<th>This type of message</th>
<th>Contains</th>
</tr>
</thead>
<tbody>
<tr>
<td>Audit</td>
<td>Extremely important information related to the business processing performed by an adapter.</td>
</tr>
<tr>
<td>Error</td>
<td>Information about an error that has occurred in the adapter, which may affect system stability.</td>
</tr>
<tr>
<td>Warning</td>
<td>Information about a suspicious situation that has occurred. Although this is not an error, it could have an impact on adapter operation.</td>
</tr>
<tr>
<td>Information</td>
<td>Information about normal adapter operations.</td>
</tr>
</tbody>
</table>

Testing Services

This information applies to “Step 8A, Test an Application View’s Services” in Using the Application Integration Design Console, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

The purpose of testing an application view service is to evaluate whether that service interacts properly with the target RDBMS. When you test a service, you supply any inputs required to start the service. For the Adapter for RDBMS, the input is in the form of a valid SQL statement that acts as input for the service.

**Note:** You can test an application view only if it is in Test mode and only if it contains at least one event or service.
To test a service:

1. In the Application View Administration page, click the Test link beside the service to be tested.
   
   The Test Services page appears.

2. In the Test Service window, enter the appropriate SQL statement to execute the service.

3. Click Test.
   
   The results appear in the Test Results window.

### Testing Events Using a Service

This information applies to “Step 8B, Test an Application View’s Events” in *Using the Application Integration Design Console*, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

The purpose of testing an application view event is to make sure that the adapter correctly handles events generated by the RDBMS. When you test an event, you can trigger the event using a service or manually.

**Note:** You can test an application view only if it is in Test mode and only if it contains at least one event or service.

To test an event:

1. In the Application View Administration page, click the Test link beside the event to be tested.
   
   The Test Events page appears.

2. Click Service and select a service that triggers the event you are testing.

3. In the Time field, enter a reasonable period of time to wait, specified in milliseconds, before the test times out (One second = 1000 milliseconds. One minute = 60,000 milliseconds.).

4. Click Test and enter the SQL statement needed to trigger the service.
   
   The service is executed.
   
   - If the test succeeds, the Test Result page displays the event document, the service input document, and the service output document.
– If the event is not available within the specified time limit, the Test Result page displays only a Timed Out message.

Testing Events Manually

This information applies to “Step 8B, Test an Application View’s Events” in Using the Application Integration Design Console, at the following URL:

http://edocs.bea.com/wli/docs81/aiuser/index.html

To test an event manually:

1. In the Time field, enter a reasonable period of time to wait, specified in milliseconds, before the test times out (One second = 1000 milliseconds. One minute = 60,000 milliseconds.).

2. Click Test. The test waits for an event to trigger it.

3. Using the triggering RDBMS application, perform an action that executes the service that, in turn, tests the application view event.
   – If the test succeeds, the Test Result page displays the event document from the application.
   – If the test fails or takes too long, the Test Result page shows a Timed Out message.

Handling Null Values

RDBMS support null values in a data field. In services, you should properly set null values when performing an insert or update through a parametrized query or giving input to a stored procedure. In events, you may need to ascertain whether a field in the output contains a null value, or is simply an empty string.

Null Values in Services

The BEA WebLogic Adapter for RDBMS propagates null values into SQL through the following code.

```xml
<?xml version="1.0"?>
<ns:Input xmlns:ns="wlai/Test_Parametrized_request">
  <ns:INPUT_VALUE isNull="true"></ns:INPUT_VALUE>
</ns:Input>
```
Here, the application view has a service that is defined with Target_Nodes set to /INPUT_VALUE/ and SQL set to INSERT INTO ANOTHER_TABLE VALUES([INPUT_VALUE VARCHAR])

The resulting SQL is sent to the RDBMS is INSERT INTO ANOTHER_TABLE VALUES(NULL)

Null Values in Events

The BEA WebLogic Adapter for RDBMS handles null values for events as shown in the following table.

**Table 2-7 Handling Null Values in Events**

<table>
<thead>
<tr>
<th>Database Value</th>
<th>Database Nullable</th>
<th>XML Value</th>
<th>XML Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spaces</td>
<td>Yes</td>
<td>Spaces</td>
<td>isNull='false'</td>
</tr>
<tr>
<td>Spaces</td>
<td>No</td>
<td>Spaces</td>
<td>N/A</td>
</tr>
<tr>
<td>Null</td>
<td>Yes</td>
<td>None</td>
<td>isNull='true'</td>
</tr>
<tr>
<td>Null</td>
<td>No</td>
<td>N/A</td>
<td>N/A</td>
</tr>
<tr>
<td>Text</td>
<td>Yes</td>
<td>Text</td>
<td>isNull='false'</td>
</tr>
<tr>
<td>Text</td>
<td>No</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

For the Field and Column formats, the attribute isNull is set to 'true' to indicate a nullable field containing a null value. The following is an example of XML, in the Field format, containing fields representing the valid combinations from the above table.

```xml
<?xml version="1.0"?>
<Rows xmlns="wlai/Test_BASE" xmlns:ns="wlai/Test_BASE">
  <ns:Row>
    <ns:COMM isNull="false">88</ns:COMM>
    <ns:ENAME isNull="false">name</ns:ENAME>
    <ns:JOB isNull="false"> </ns:JOB>
    <ns:SAL isNull="false">9000</ns:SAL>
  </ns:Row>
  <ns:Row>
    <ns:COMM isNull="false">44</ns:COMM>
    <ns:ENAME> </ns:ENAME>
    <ns:JOB> </ns:JOB>
    <ns:SAL> </ns:SAL>
  </ns:Row>
</Rows>
```
<ns:JOB isNull="false">program</ns:JOB>
<ns:SAL isNull="true"></ns:SAL>
</ns:Row>
</ns:Rows>
At run-time, the EIS and the adapter exchange service requests, service responses, and events via XML documents. The adapter handles the data translation between XML documents and the EIS format, using schemas that map the data between XML and the EIS format. The Adapter for RDBMS automatically generates the schema when you add services and events to an application view. You can click the corresponding link on the Application View Administration page to view the automatically generated schemas.

This section gives examples of input values, input XML, and/or output XML for the services and events that the adapter offers.

The examples given assume the EIS to be MS SQL 2000 with the following schema:

```sql
CREATE TABLE adaptertesting.dbo.base ( 
   CHAR1 CHAR (10), 
   VARCHAR1 VARCHAR (10), 
   NUMERIC1 NUMERIC(6, 0), 
   INTEGER1 INT, 
   SMALLINT1 SMALLINT, 
   REAL1 REAL, 
   FLOAT1 FLOAT, 
   DOUBLE1 DOUBLE PRECISION, 
   DECIMAL1 DECIMAL(8, 2), 
   CREATEDT DATETIME, 
   MODDT DATETIME 
)
```
where adaptertesting is the catalog name, dbo is the schema name, and base is the table name.

The stored procedure used is:

```
CREATE PROCEDURE PROCCHAR (@X CHAR(10),@Y char(10) output, @Z char(10) output) as BEGIN
  INSERT INTO base (CHAR1) VALUES (@X);
  SET @Y = 'THIS IS Y';
  SET @Z = 'THIS IS @Z';
END
```

## Services

### Standard SQL

The following section gives sample input values and input and output XML for the Standard SQL service.

#### Design-Time Input

Standard SQL Statement:

```
SELECT * FROM adaptertesting.dbo.base
```

#### Run-Time Input

None

#### Input XML

```
<?xml version="1.0" encoding="UTF-8"?>
<ns:Input xmlns:ns="wlai/Test_Standard_request"/>
```

#### Output XML

```
<?xml version="1.0" encoding="UTF-8"?>
<ns0:Output xmlns:ns0="wlai/Test_Standard_response">
  <ns0:Rows>
    <ns0:Row>
      <ns0:Char1 isNull="false">A</ns0:Char1>
      <ns0:CreateDt isNull="false">2003-02-02T00:00:00+05:30</ns0:CreateDt>
      <ns0:Decimal1 isNull="false">1.00</ns0:Decimal1>
      <ns0:Double1 isNull="false">1.0</ns0:Double1>
      <ns0:Float1 isNull="false">1.0</ns0:Float1>
      <ns0:Integer1 isNull="false">1</ns0:Integer1>
    </ns0:Row>
  </ns0:Rows>
</ns0:Output>
```
Parametrized SQL

The following section gives sample input values and input and output XML for the Parametrized SQL service. It also explains why CLOB/BLOB datatypes require base64 encoding.

Design-Time Input

Parametrized SQL Statement:

```
SELECT * FROM adaptertesting.dbo.base WHERE 
CHAR1=[CHAR1 CHAR] 
AND VARCHAR1=[VARCHAR1 VARCHAR]

Run-Time Input

Parameter Values: A , A , 1 , 1 , 1 , 1.0 , 1.0 , 1.0 , 1.0 , 1.0 , 2003-02-02 , 1998-10-22

Input XML

```
<?xml version="1.0"?>
<ns:Input xmlns:ns="wlai/Test_Parametrized_request">
```
Why Use Base64 Encoding for CLOB/BLOB Datatypes?

Base64 encoding is most commonly used to encode binary and text data that may contain non-ASCII characters, or characters that are considered special or reserved characters, so that this information can be safely transmitted across the Internet. All binary representations, including 0x00 - 0xFF, can be encoded in

Output XML

```xml
<?xml version="1.0"?>
<ns0:Output xmlns:ns0="wlai/Test_Parametrized_response">
  <ns0:Rows>
    <ns0:Row>
      <ns0:Char1 isNull="false">A</ns0:Char1>
      <ns0:CreateDt isNull="false">2003-02-02T00:00:00+05:30</ns0:CreateDt>
      <ns0:Decimal1 isNull="false">1.00</ns0:Decimal1>
      <ns0:Double1 isNull="false">1.0</ns0:Double1>
      <ns0:Float1 isNull="false">1.0</ns0:Float1>
      <ns0:Integer1 isNull="false">1</ns0:Integer1>
      <ns0:ModDt isNull="false">1998-10-22T00:00:00+05:30</ns0:ModDt>
      <ns0:Numeric1 isNull="false">1</ns0:Numeric1>
      <ns0:Real1 isNull="false">1.0</ns0:Real1>
      <ns0:Smallint1 isNull="false">1</ns0:Smallint1>
      <ns0:Varchar1 isNull="false">A</ns0:Varchar1>
    </ns0:Row>
  </ns0:Rows>
</ns0:Output>

Why Use Base64 Encoding for CLOB/BLOB Datatypes?

Base64 encoding is most commonly used to encode binary and text data that may contain non-ASCII characters, or characters that are considered special or reserved characters, so that this information can be safely transmitted across the Internet. All binary representations, including 0x00 - 0xFF, can be encoded in
Base64. It is particularly useful to users of XML, because the information one wishes to encode within these documents may contain reserved or special characters.

**CLOB Datatype: Sample Code Snippet to Encode to Base64**

```java
String str = new String("Sample String");
byte[] bytes = str.getBytes();
String strToSendInXml = new sun.misc.BASE64Encoder().encode(bytes);
```

**CLOB Datatype: Sample Code Snippet to Decode from Base64**

```java
bytes = new sun.misc.BASE64Decoder().decodeBuffer(stringFromXml);
String decodedStr = new String(bytes);
```

where //stringFromXml is the Base64 encoded string obtained from the response document.

**BLOB Datatype: Sample Code Snippet to Encode to Base64**

```java
Integer intToSend = new Integer(95);
ByteArrayOutputStream bos = new ByteArrayOutputStream();
ObjectOutputStream os = new ObjectOutputStream(bos);
os.writeObject(intToSend);
os.flush();
String sendThisInXml = new 
sun.misc.BASE64Encoder().encode(bos.toByteArray());
```

where //intToSend is the Integer object to be sent to the RDBMS as a BLOB datatype.

**BLOB Datatype: Sample Code Snippet to Decode from Base64**

```java
byte[] fromXml=new sun.misc.BASE64Decoder().decodeBuffer(stringFromXml);
ByteArrayInputStream bytestream = new ByteArrayInputStream(fromXml);
ObjectInputStream is = new ObjectInputStream(bytestream);
Integer originalInt = (Integer)is.readObject();
```

where //stringFromXml is the Base64 encoded string obtained from the response document.
Stored Procedure

The following section gives sample input values and input and output XML for the Stored Procedure service.

Design-Time Input

Procedure Name: AdapterTesting.dbo.PROCCHAR(?, ?, ?)

where the ?s represent the IN, IN-OUT, and OUT parameters respectively.

Run-Time Input

STRING1, STRING2, AND STRING3

Input XML

```xml
<?xml version="1.0"?>
<ns:Input xmlns:ns="wlai/Test_StoredProcedure_request">
    <ns:X isNull="false">String1</ns:X>
    <ns:Y isNull="false">String2</ns:Y>
    <ns:Z isNull="false">String3</ns:Z>
</ns:Input>
```

Output XML

```xml
<?xml version="1.0"?>
<ns0:Output xmlns:ns0="wlai/Test_StoredProcedure_response">
    <ns0:ReturnValue>0</ns0:ReturnValue>
    <ns0:Params>
        <ns0:Y isNull="false">THIS IS Y </ns0:Y>
        <ns0:Z isNull="false">THIS IS @Z</ns0:Z>
    </ns0:Params>
</ns0:Output>
```
Arbitrary SQL

The following section gives sample input values and input and output XML for the Arbitrary SQL service.

**Design-Time Input**

None

**Run-Time Input**

SQL Statement: `SELECT * FROM adaptertesting.dbo.base`

**Input XML**

```xml
<?xml version="1.0"?>
<ns:Input xmlns:ns="wlai/Test_Arbitrary_request">
  <ns:Sql>SELECT * FROM adaptertesting.dbo.base</ns:Sql>
</ns:Input>
```

**Output XML**

```xml
<?xml version="1.0"?>
<ns0:Output xmlns:ns0="wlai/Test_Arbitrary_response">
  <ns0:Rows>
    <ns0:Row>
      <ns0:Char1 isNull="false">A</ns0:Char1>
      <ns0:Varchar1 isNull="false">A</ns0:Varchar1>
      <ns0:Numeric1 isNull="false">1</ns0:Numeric1>
      <ns0:Integer1 isNull="false">1</ns0:Integer1>
      <ns0:Smallint1 isNull="false">1</ns0:Smallint1>
      <ns0:Real1 isNull="false">1.0</ns0:Real1>
      <ns0:Float1 isNull="false">1.0</ns0:Float1>
      <ns0:Double1 isNull="false">1.0</ns0:Double1>
      <ns0:Decimal1 isNull="false">1.00</ns0:Decimal1>
      <ns0:CreateDt isNull="false">2003-02-02T00:00:00+05:30</ns0:CreateDt>
      <ns0:ModDt isNull="false">1998-10-22T00:00:00+05:30</ns0:ModDt>
    </ns0:Row>
  </ns0:Rows>
</ns0:Output>
```
Events

Trigger Insert

The following section gives sample input values and output XML for the Trigger Insert event.

Design-Time Input

Maximum Event Records: 5

Table Name: adaptertesting.dbo.base

Event: Insert

Run-Time Input

Time (in milliseconds): 20000

Trigger method: Manual or through a service

Output XML

```xml
<?xml version="1.0"?>
<Rows xmlns="wlai/TriggerInsert_BASE_insert"
     xmlns:ns="wlai/TriggerInsert_BASE_insert">
   <ns:Row>
     <ns:Char1 isNull="false">STRING1</ns:Char1>
     <ns:CreateDt isNull="false">2003-07-16T15:21:02+05:30</ns:CreateDt>
     <ns:Decimal1 isNull="false">1</ns:Decimal1>
     <ns:Double1 isNull="false">1</ns:Double1>
     <ns:Float1 isNull="false">1</ns:Float1>
     <ns:Integer1 isNull="false">1</ns:Integer1>
     <ns:ModDt isNull="false">2003-07-16T15:21:02+05:30</ns:ModDt>
     <ns:Numeric1 isNull="false">1</ns:Numeric1>
     <ns:Real1 isNull="false">1</ns:Real1>
     <ns:Smallint1 isNull="false">1</ns:Smallint1>
     <ns:Varchar1 isNull="false">STRING2</ns:Varchar1>
   </ns:Row>
</Rows>
```
Trigger Update
The following section gives sample input values and output XML for the Trigger Update event.

**Design-Time Input**
- Maximum Event Records: 5
- Table Name: adaptertesting dbo base
- Event: Update

**Run-Time Input**
- Time (in milliseconds): 20000
- Trigger method: Manual or through a service

**Output XML**
```xml
<?xml version="1.0"?>
<Rows xmlns="wlai/TriggerUpdate_BASE_update"
xmlns:ns="wlai/TriggerUpdate_BASE_update">
  <ns:Row>
    <ns:Old>
      <ns:Char1 isNull="false">A</ns:Char1>
      <ns:CreateDt isNull="false">2003-02-02T00:00:00+05:30</ns:CreateDt>
      <ns:Decimal1 isNull="false">1</ns:Decimal1>
      <ns:Double1 isNull="false">1</ns:Double1>
      <ns:Float1 isNull="false">1</ns:Float1>
      <ns:Integer1 isNull="false">1</ns:Integer1>
      <ns:ModDt isNull="false">1998-10-22T00:00:00+05:30</ns:ModDt>
      <ns:Numeric1 isNull="false">1</ns:Numeric1>
      <ns:Real1 isNull="false">1</ns:Real1>
      <ns:Smallint1 isNull="false">1</ns:Smallint1>
      <ns:Varchar1 isNull="false">A</ns:Varchar1>
    </ns:Old>
    <ns:New>
      <ns:Char1 isNull="false">STRING1 </ns:Char1>
      <ns:CreateDt isNull="false">2003-02-02T00:00:00+05:30</ns:CreateDt>
      <ns:Decimal1 isNull="false">1</ns:Decimal1>
    </ns:New>
  </ns:Row>
</Rows>
```
Trigger Delete

The following section gives sample input values and output XML for the Trigger Delete event.

**Design-Time Input**
- Maximum Event Records: 5
- Table Name: `adaptertesting.dbo.base`
- Event: Delete

**Run-Time Input**
- Time (in milliseconds): 20000
- Trigger method: Manual or through a service

**Output XML**

```xml
<Rows xmlns="wlai/TriggerDelete_BASE_delete" xmlns:ns="wlai/TriggerDelete_BASE_delete">
<ns:Row>
<ns:Char1 isNull="false">STRING1</ns:Char1>
<ns:CreateDt isNull="false">2003-07-15T15:02+05:30</ns:CreateDt>
<ns:Decimal1 isNull="false">1</ns:Decimal1>
<ns:Double1 isNull="false">1</ns:Double1>
<ns:Float1 isNull="false">1</ns:Float1>
<ns:Integer1 isNull="false">1</ns:Integer1>
<ns:ModDt isNull="false">1998-10-22T00:00:00+05:30</ns:ModDt>
<ns:Numeric1 isNull="false">1</ns:Numeric1>
<ns:Real1 isNull="false">1</ns:Real1>
<ns:Smallint1 isNull="false">1</ns:Smallint1>
<ns:Varchar1 isNull="false">A</ns:Varchar1>
</ns:Row>
</Rows>
```
Select By Insert Timestamp

The following section gives sample input values and output XML for the Select By Insert Timestamp event.

**Design-Time Input**

Maximum Event Records: 5

Table Name: adaptertesting.dbo.base

Event: Insert

Created Timestamp: A column of type TIMESTAMP or TIME

**Run-Time Input**

Time (in milliseconds): 20000

Trigger method: Manual or through a service

If the trigger is manual, insert CURRENT TIME for the column of type TIMESTAMP or TIME.

**Output XML**

```xml
<?xml version="1.0"?>
<Rows xmlns="wlai/TimeStampInsert_BASE"
     xmlns:ns="wlai/TimeStampInsert_BASE">
  <ns:Row>
    <ns:Char1 isNull="false">STRING1</ns:Char1>
    <ns:CreateDt isNull="false">2003-07-16T15:34:46.827+05:30</ns:CreateDt>
    <ns:Decimal1 isNull="false">1.00</ns:Decimal1>
  </ns:Row>
</Rows>
```
Select By Update Timestamp

The following section gives sample input values and output XML for the Select By Update Timestamp event.

**Design-Time Input**

Maximum Event Records: 5

Table Name: AdapterTesting.dbo.BASE

Event: Update

Updated Timestamp: A column of type `TIMESTAMP` or `TIME`

**Run-Time Input**

Time (in milliseconds): 20000

Trigger method: Manual or through a service

If the trigger is manual, update `CURRENT TIME` for the column of type `TIMESTAMP` or `TIME`.

**Output XML**

```xml
<Rows xmlns="wlai/TimeStampUpdate_BASE"
 xmlns:ns="wlai/TimeStampUpdate_BASE">
 <ns:Row>
  <ns:Char1 isNull="false">STRING1</ns:Char1>
  <ns:CreateDt
```
The following section gives sample input values and output XML for the Select Then Delete event.

**Design-Time Input**

Maximum Event Records: 5  
Table Name: adaptertesting.dbo.base  
Delete Required: Yes/No

```xml
<Rows>
  <Row>
    <ns:Char1 isNull="false">STRING1</ns:Char1>

Supported Data Types
Supported Drivers

This section lists the drivers that the BEA WebLogic Adapter for RDBMS supports on the following operating systems:

- Windows 2000 Professional
- Sun Solaris 8 and 9
- HP-UX 11i

It also lists the driver class names and JDBC URLs corresponding to the drivers.

**Note:** The BEA WebLogic Adapter for RDBMS should be used in conjunction with a JDBC 2.1 compliant driver.

**Oracle Thin Driver**

You can download the Oracle9i 9.2.0.3 Thin Driver file, `classes12.zip`, from the following URL:

http://download.oracle.com/otn/utilities_drivers/jdbc/9203/classes12.zip

<table>
<thead>

http://edocs.bea.com/wladapters/docs81/index.html
## Description
Events may start timing out. It could be due to either of the following reasons:
- The WebLogic Server might have been shut down abnormally without undeploying the application views.
- The system time of the machine running the EIS is not in sync with the system time of the machine running the WebLogic Server.

## Action
1. Restart the WebLogic Integration Server.
2. Redeploy the application views with events.

If the events time out without giving correct results, ensure that the system time of the machine running the EIS is in sync with the system time of the machine running the WebLogic Server.
